`scipy.linalg.lapack.dsytrf(a[, lower, lwork, overwrite_a]) = <fortran object>`

Wrapper for `dsytrf`.

**Parameters**

- `a` [input rank-2 array('d') with bounds (n,n)]

**Returns**

- `ldu` [rank-2 array('d') with bounds (n,n) and a storage]
- `ipiv` [rank-1 array('i') with bounds (n)]
- `info` [int]

**Other Parameters**

- `lower` [input int, optional] Default: 0
- `overwrite_a` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: max(n,1)
scipy.linalg.lapack.csytrf

scipy.linalg.lapack.csytrf(a[, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for csytrf.

Parameters
    a          [input rank-2 array('F') with bounds (n,n)]

Returns
    ldu        [rank-2 array('F') with bounds (n,n) and a storage]
    ipiv       [rank-1 array('i') with bounds (n)]
    info       [int]

Other Parameters
    lower      [input int, optional] Default: 0
    overwrite_a [input int, optional] Default: 0
    lwork      [input int, optional] Default: max(n,1)

scipy.linalg.lapack.zsytrf

scipy.linalg.lapack.zsytrf(a[, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for zsytrf.

Parameters
    a          [input rank-2 array('D') with bounds (n,n)]

Returns
    ldu        [rank-2 array('D') with bounds (n,n) and a storage]
    ipiv       [rank-1 array('i') with bounds (n)]
    info       [int]

Other Parameters
    lower      [input int, optional] Default: 0
    overwrite_a [input int, optional] Default: 0
    lwork      [input int, optional] Default: max(n,1)

scipy.linalg.lapack.ssyrf_lwork

scipy.linalg.lapack.ssyrf_lwork(n[, lower]) = <fortran object>
Wrapper for ssyrf_lwork.

Parameters
    n          [input int]

Returns
    work       [float]
    info       [int]

Other Parameters
    lower      [input int, optional] Default: 0
scipy.linalg.lapack.dsytrf_lwork

scipy.linalg.lapack.dsytrf_lwork(n[, lower]) = <fortran object>
Wrapper for dsytrf_lwork.

Parameters
   n  [input int]

Returns
   work [float]
   info [int]

Other Parameters
   lower [input int, optional] Default: 0

scipy.linalg.lapack.csytrf_lwork

scipy.linalg.lapack.csytrf_lwork(n[, lower]) = <fortran object>
Wrapper for csytrf_lwork.

Parameters
   n  [input int]

Returns
   work [complex]
   info [int]

Other Parameters
   lower [input int, optional] Default: 0

scipy.linalg.lapack.zsytrf_lwork

scipy.linalg.lapack.zsytrf_lwork(n[, lower]) = <fortran object>
Wrapper for zsytrf_lwork.

Parameters
   n  [input int]

Returns
   work [complex]
   info [int]

Other Parameters
   lower [input int, optional] Default: 0
scipy.linalg.lapack.stfsm

\[
\text{scipy.linalg.lapack.stfsm}(\alpha, a, b[, transr, side, uplo, trans, diag, overwrite_b]) = \text{<fortran object>}
\]

Wrapper for stfsm.

**Parameters**

- \(\alpha\) [input float]
- \(a\) [input rank-1 array(‘f’) with bounds (nt)]
- \(b\) [input rank-2 array(‘f’) with bounds (m,n)]

**Returns**

- \(x\) [rank-2 array(‘f’) with bounds (m,n) and b storage]

**Other Parameters**

- \(\text{transr}\) [input string(len=1), optional] Default: ‘N’
- \(\text{side}\) [input string(len=1), optional] Default: ‘L’
- \(\text{uplo}\) [input string(len=1), optional] Default: ‘U’
- \(\text{trans}\) [input string(len=1), optional] Default: ‘N’
- \(\text{diag}\) [input string(len=1), optional] Default: ‘N’
- \(\text{overwrite}_b\) [input int, optional] Default: 0

scipy.linalg.lapack.dtfsm

\[
\text{scipy.linalg.lapack.dtfsm}(\alpha, a, b[, transr, side, uplo, trans, diag, overwrite_b]) = \text{<fortran object>}
\]

Wrapper for dtfsm.

**Parameters**

- \(\alpha\) [input float]
- \(a\) [input rank-1 array(‘d’) with bounds (nt)]
- \(b\) [input rank-2 array(‘d’) with bounds (m,n)]

**Returns**

- \(x\) [rank-2 array(‘d’) with bounds (m,n) and b storage]

**Other Parameters**

- \(\text{transr}\) [input string(len=1), optional] Default: ‘N’
- \(\text{side}\) [input string(len=1), optional] Default: ‘L’
- \(\text{uplo}\) [input string(len=1), optional] Default: ‘U’
- \(\text{trans}\) [input string(len=1), optional] Default: ‘N’
- \(\text{diag}\) [input string(len=1), optional] Default: ‘N’
- \(\text{overwrite}_b\) [input int, optional] Default: 0

scipy.linalg.lapack.ctfsm

\[
\text{scipy.linalg.lapack.ctfsm}(\alpha, a, b[, transr, side, uplo, trans, diag, overwrite_b]) = \text{<fortran object>}
\]

Wrapper for ctfsm.

**Parameters**
**scipy.linalg.lapack.ztfsm**

```python
scipy.linalg.lapack.ztfsm(alpha, a, b[, transr, side, uplo, trans, diag, overwrite_b]) = <fortran object>
```

Wrapper for `ztfsm`.

**Parameters**

- **alpha**  [input complex]
- **a**  [input rank-1 array('F') with bounds (nt)]
- **b**  [input rank-2 array('F') with bounds (m,n)]

**Returns**

- **x**  [rank-2 array('F') with bounds (m,n) and b storage]

**Other Parameters**

- **transr**  [input string(len=1), optional] Default: ‘N’
- **side**  [input string(len=1), optional] Default: ‘L’
- **uplo**  [input string(len=1), optional] Default: ‘U’
- **trans**  [input string(len=1), optional] Default: ‘N’
- **diag**  [input string(len=1), optional] Default: ‘N’
- **overwrite_b**  [input int, optional] Default: 0

**scipy.linalg.lapack.stfttp**

```python
scipy.linalg.lapack.stfttp(n, arf[, transr, uplo]) = <fortran object>
```

Wrapper for `stfttp`.

**Parameters**

- **n**  [input int]
- **arf**  [input rank-1 array('f') with bounds (nt)]

**Returns**

- **ap**  [rank-1 array('f') with bounds (nt)]
- **info**  [int]

**Other Parameters**

transr  [input string(len=1), optional] Default: ‘N’
uplo    [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.dtfttp

scipy.linalg.lapack.dtfttp(n, arf[, transr, uplo]) = <fortran object>
Wrapper for dtfttp.

Parameters
   n       [input int]
   arf     [input rank-1 array('d') with bounds (nt)]

Returns
   ap      [rank-1 array('d') with bounds (nt)]
   info    [int]

Other Parameters
   transr  [input string(len=1), optional] Default: ‘N’
   uplo    [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.ctfttp

scipy.linalg.lapack.ctfttp(n, arf[, transr, uplo]) = <fortran object>
Wrapper for ctfttp.

Parameters
   n       [input int]
   arf     [input rank-1 array('F') with bounds (nt)]

Returns
   ap      [rank-1 array('F') with bounds (nt)]
   info    [int]

Other Parameters
   transr  [input string(len=1), optional] Default: ‘N’
   uplo    [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.ztfttp

scipy.linalg.lapack.ztfttp(n, arf[, transr, uplo]) = <fortran object>
Wrapper for ztfttp.

Parameters
   n       [input int]
   arf     [input rank-1 array('D') with bounds (nt)]

Returns
   ap      [rank-1 array('D') with bounds (nt)]
   info    [int]

Other Parameters
transr  [input string(len=1), optional] Default: ‘N’
uplo  [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.stfttr

scipy.linalg.lapack.stfttr \( (n, arf[, transr, uplo]) \) = <fortran object>
Wrapper for stfttr.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>[input int]</td>
</tr>
<tr>
<td>arf</td>
<td>[input rank-1 array('f') with bounds (nt)]</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>[rank-2 array('f') with bounds (lda,n)]</td>
</tr>
<tr>
<td>info</td>
<td>[int]</td>
</tr>
</tbody>
</table>

Other Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>transr</td>
<td>[input string(len=1), optional] Default: ‘N’</td>
</tr>
<tr>
<td>uplo</td>
<td>[input string(len=1), optional] Default: ‘U’</td>
</tr>
</tbody>
</table>

scipy.linalg.lapack.dtfttr

scipy.linalg.lapack.dtfttr \( (n, arf[, transr, uplo]) \) = <fortran object>
Wrapper for dtfttr.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>[input int]</td>
</tr>
<tr>
<td>arf</td>
<td>[input rank-1 array('d') with bounds (nt)]</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>[rank-2 array('d') with bounds (lda,n)]</td>
</tr>
<tr>
<td>info</td>
<td>[int]</td>
</tr>
</tbody>
</table>

Other Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>transr</td>
<td>[input string(len=1), optional] Default: ‘N’</td>
</tr>
<tr>
<td>uplo</td>
<td>[input string(len=1), optional] Default: ‘U’</td>
</tr>
</tbody>
</table>

scipy.linalg.lapack.ctfttr

scipy.linalg.lapack.ctfttr \( (n, arf[, transr, uplo]) \) = <fortran object>
Wrapper for ctfttr.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>[input int]</td>
</tr>
<tr>
<td>arf</td>
<td>[input rank-1 array('F') with bounds (nt)]</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>[rank-2 array('F') with bounds (lda,n)]</td>
</tr>
<tr>
<td>info</td>
<td>[int]</td>
</tr>
</tbody>
</table>

Other Parameters
transr  [input string(len=1), optional] Default: ‘N’
uplo   [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.ztfttr

scipy.linalg.lapack.ztfttr(n, arf[, transr, uplo]) = <fortran object>
Wrapper for ztfttr.

Parameters

n  [input int]
arf [input rank-1 array('D') with bounds (nt)]

Returns

a  [rank-2 array('D') with bounds (lda,n)]
info [int]

Other Parameters

transr  [input string(len=1), optional] Default: ‘N’
uplo   [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.stgsen

scipy.linalg.lapack.stgsen(select, a, b, q[, lwork, liwork, overwrite_a, overwrite_b, overwrite_q, overwrite_z]) = <fortran object>
Wrapper for stgsen.

Parameters

select  [input rank-1 array('i') with bounds (n)]
a  [input rank-2 array('f') with bounds (lda,n)]
b  [input rank-2 array('f') with bounds (ldb,n)]
q  [input rank-2 array('f') with bounds (ldq,n)]
z  [input rank-2 array('f') with bounds (ldz,n)]

Returns

a  [rank-2 array('f') with bounds (lda,n)]
b  [rank-2 array('f') with bounds (ldb,n)]
alphar [rank-1 array('f') with bounds (n)]
alphai [rank-1 array('f') with bounds (n)]
beta  [rank-1 array('f') with bounds (n)]
q  [rank-2 array('f') with bounds (ldq,n)]
z  [rank-2 array('f') with bounds (ldz,n)]
m  [int]
pl  [float]
pr  [float]
dif  [rank-1 array('f') with bounds (2)]
work [rank-1 array('f') with bounds (MAX(lwork,1))]
iwork [rank-1 array('i') with bounds (MAX(1,liwork))]
info  [int]

Other Parameters

overwrite_a  [input int, optional] Default: 0
over写_b
  [input int, optional] Default: 0
over写_q
  [input int, optional] Default: 0
over写_z
  [input int, optional] Default: 0
lwork
  [input int, optional] Default: max(MAX(4*n+16,2*m*(n-m)),1)
liwork
  [input int, optional] Default: n+6

scipy.linalg.lapack.dtgsen

scipy.linalg.lapack.dtgsen (select, a, b, q, z[, lwork, liwork, overwrite_a, overwrite_b, overwrite_q,
  overwrite_z]) = <fortran object>

Wrapper for dtgsen.

Parameters

select [input rank-1 array('i') with bounds (n)]
a [input rank-2 array('d') with bounds (lda,n)]
b [input rank-2 array('d') with bounds (ldb,n)]
q [input rank-2 array('d') with bounds (ldq,n)]
z [input rank-2 array('d') with bounds (ldz,n)]

Returns

a [rank-2 array('d') with bounds (lda,n)]
b [rank-2 array('d') with bounds (ldb,n)]
alphar [rank-1 array('d') with bounds (n)]
alphai [rank-1 array('d') with bounds (n)]
beta [rank-1 array('d') with bounds (n)]
q [rank-2 array('d') with bounds (ldq,n)]
z [rank-2 array('d') with bounds (ldz,n)]
m [int]
pl [float]
pr [float]
dif [rank-1 array('d') with bounds (2)]
work [rank-1 array('d') with bounds (MAX(lwork,1))] iwork [rank-1 array('i') with bounds (MAX(1,liwork))]
info [int]

Other Parameters

overwrite_a
  [input int, optional] Default: 0
overwrite_b
  [input int, optional] Default: 0
overwrite_q
  [input int, optional] Default: 0
overwrite_z
  [input int, optional] Default: 0
lwork
  [input int, optional] Default: max(MAX(4*n+16,2*m*(n-m)),1)
liwork
  [input int, optional] Default: n+6
scipy.linalg.lapack.ctgsen

Wrapper for ctgsen.

Parameters

- **select**: [input rank-1 array('i') with bounds (n)]
- **a**: [input rank-2 array('F') with bounds (lda,n)]
- **b**: [input rank-2 array('F') with bounds (ldb,n)]
- **q**: [input rank-2 array('F') with bounds (ldq,n)]
- **z**: [input rank-2 array('F') with bounds (ldz,n)]

Returns

- **a**: [rank-2 array('F') with bounds (lda,n)]
- **b**: [rank-2 array('F') with bounds (ldb,n)]
- **alpha**: [rank-1 array('F') with bounds (n)]
- **beta**: [rank-1 array('F') with bounds (n)]
- **q**: [rank-2 array('F') with bounds (ldq,n)]
- **z**: [rank-2 array('F') with bounds (ldz,n)]
- **m**: [int]
- **pl**: [float]
- **pr**: [float]
- **dif**: [rank-1 array('F') with bounds (2)]
- **work**: [rank-1 array('F') with bounds (MAX(1,lwork))]
- **iwork**: [rank-1 array('i') with bounds (MAX(1,liwork))]
- **info**: [int]

Other Parameters

- **overwrite_a**: [input int, optional] Default: 0
- **overwrite_b**: [input int, optional] Default: 0
- **overwrite_q**: [input int, optional] Default: 0
- **overwrite_z**: [input int, optional] Default: 0
- **lwork**: [input int, optional] Default: max(2*m*(n-m),1)
- **liwork**: [input int, optional] Default: n+2

scipy.linalg.lapack.ztgsen

Wrapper for ztgsen.

Parameters

- **select**: [input rank-1 array('i') with bounds (n)]
- **a**: [input rank-2 array('D') with bounds (lda,n)]
- **b**: [input rank-2 array('D') with bounds (ldb,n)]
- **q**: [input rank-2 array('D') with bounds (ldq,n)]
- **z**: [input rank-2 array('D') with bounds (ldz,n)]

Returns

6.11. Low-level LAPACK functions (scipy.linalg.lapack)
SciPy Reference Guide, Release 1.3.2

a  [rank-2 array('D') with bounds (lda,n)]
b  [rank-2 array('D') with bounds (ldb,n)]
alpha  [rank-1 array('D') with bounds (n)]
beta  [rank-1 array('D') with bounds (n)]
q  [rank-2 array('D') with bounds (ldq,n)]
z  [rank-2 array('D') with bounds (ldz,n)]
m  [int]
pl  [float]
pr  [float]
dif  [rank-1 array('d') with bounds (2)]
work  [rank-1 array('D') with bounds (MAX(lwork,1))]
iwork  [rank-1 array('i') with bounds (MAX(1,liwork))]
info  [int]

Other Parameters
overwrite_a  [input int, optional] Default: 0
overwrite_b  [input int, optional] Default: 0
overwrite_q  [input int, optional] Default: 0
overwrite_z  [input int, optional] Default: 0
lwork  [input int, optional] Default: max(2*m*(n-m),1)
liwork  [input int, optional] Default: n+2

scipy.linalg.lapack.stpttf

scipy.linalg.lapack.stpttf(n, ap[, transr, uplo]) = <fortran object>
Wrapper for stpttf.

Parameters
n  [input int]
ap  [input rank-1 array('f') with bounds (nt)]

Returns
arf  [rank-1 array('f') with bounds (nt)]
info  [int]

Other Parameters
transr  [input string(len=1), optional] Default: ‘N’
uplo  [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.dtpttf

scipy.linalg.lapack.dtpttf(n, ap[, transr, uplo]) = <fortran object>
Wrapper for dtpttf.

Parameters
n  [input int]
ap  [input rank-1 array('d') with bounds (nt)]
Returns

arf     [rank-1 array('d') with bounds (nt)]
info    [int]

Other Parameters

transr  [input string(len=1), optional] Default: ‘N’
uplo    [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.ctpttf

scipy.linalg.lapack.ctpttf(n, ap[, transr, uplo]) = <fortran object>

Parameters

n       [input int]
ap      [input rank-1 array('F') with bounds (nt)]

Returns

arf     [rank-1 array('F') with bounds (nt)]
info    [int]

Other Parameters

transr  [input string(len=1), optional] Default: ‘N’
uplo    [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.ztpttf

scipy.linalg.lapack.ztpttf(n, ap[, transr, uplo]) = <fortran object>

Parameters

n       [input int]
ap      [input rank-1 array('D') with bounds (nt)]

Returns

arf     [rank-1 array('D') with bounds (nt)]
info    [int]

Other Parameters

transr  [input string(len=1), optional] Default: ‘N’
uplo    [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.stpttr

scipy.linalg.lapack.stpttr(n, ap[, uplo]) = <fortran object>

Parameters

n       [input int]
ap      [input rank-1 array('f') with bounds (nt)]
Returns

a  [rank-2 array('f') with bounds (n,n)]
info [int]

Other Parameters

uplo [input string(len=1), optional] Default: 'U'

scipy.linalg.lapack.dtpttr

scipy.linalg.lapack.dtpttr(n, ap[, uplo]) = <fortran object>
Wrapper for dtpttr.

Parameters

n  [input int]
ap  [input rank-1 array('d') with bounds (nt)]

Returns

a  [rank-2 array('d') with bounds (n,n)]
info [int]

Other Parameters

uplo  [input string(len=1), optional] Default: 'U'

scipy.linalg.lapack.ctpttr

scipy.linalg.lapack.ctpttr(n, ap[, uplo]) = <fortran object>
Wrapper for ctpttr.

Parameters

n  [input int]
ap  [input rank-1 array('F') with bounds (nt)]

Returns

a  [rank-2 array('F') with bounds (n,n)]
info [int]

Other Parameters

uplo  [input string(len=1), optional] Default: 'U'

scipy.linalg.lapack.ztpttr

scipy.linalg.lapack.ztpttr(n, ap[, uplo]) = <fortran object>
Wrapper for ztpttr.

Parameters

n  [input int]
ap  [input rank-1 array('D') with bounds (nt)]

Returns

a  [rank-2 array('D') with bounds (n,n)]
info [int]
Other Parameters

uplo      [input string(len=1), optional] Default: 'U'

scipy.linalg.lapack.strsyl

scipy.linalg.lapack.strsyl(a, b, c[, trana, tranb, isgn, overwrite_c]) = <fortran object>
Wrapper for strsyl.

Parameters

a         [input rank-2 array('f') with bounds (m,m)]
b         [input rank-2 array('f') with bounds (n,n)]
c         [input rank-2 array('f') with bounds (m,n)]

Returns

x         [rank-2 array('f') with bounds (m,n) and c storage]
scale     [float]
info      [int]

Other Parameters

trana     [input string(len=1), optional] Default: 'N'
tranb     [input string(len=1), optional] Default: 'N'
isgn      [input int, optional] Default: 1
overwrite_c      [input int, optional] Default: 0

scipy.linalg.lapack.dtrsyl

scipy.linalg.lapack.dtrsyl(a, b, c[, trana, tranb, isgn, overwrite_c]) = <fortran object>
Wrapper for dtrsyl.

Parameters

a         [input rank-2 array('d') with bounds (m,m)]
b         [input rank-2 array('d') with bounds (n,n)]
c         [input rank-2 array('d') with bounds (m,n)]

Returns

x         [rank-2 array('d') with bounds (m,n) and c storage]
scale     [float]
info      [int]

Other Parameters

trana     [input string(len=1), optional] Default: 'N'
tranb     [input string(len=1), optional] Default: 'N'
isgn      [input int, optional] Default: 1
overwrite_c      [input int, optional] Default: 0
scipy.linalg.lapack.ctrsyl

scipy.linalg.lapack.ctrsyl(a, b, c, trana, tranb, isgn, overwrite_c) = <fortran object>

Wrapper for ctrsyl.

Parameters

a [input rank-2 array('F') with bounds (m,m)]
b [input rank-2 array('F') with bounds (n,n)]
c [input rank-2 array('F') with bounds (m,n)]

Returns

x [rank-2 array('F') with bounds (m,n) and c storage]
scale [float]
info [int]

Other Parameters

trana [input string(len=1), optional] Default: 'N'
tranb [input string(len=1), optional] Default: 'N'
isgn [input int, optional] Default: 1
overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.ztrtrs

scipy.linalg.lapack.ztrtrs(a, b, c, trana, tranb, isgn, overwrite_c) = <fortran object>

Wrapper for ztrtrs.

Parameters

a [input rank-2 array('D') with bounds (m,m)]
b [input rank-2 array('D') with bounds (n,n)]
c [input rank-2 array('D') with bounds (m,n)]

Returns

x [rank-2 array('D') with bounds (m,n) and c storage]
scale [float]
info [int]

Other Parameters

trana [input string(len=1), optional] Default: 'N'
tranb [input string(len=1), optional] Default: 'N'
isgn [input int, optional] Default: 1
overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.strtri

scipy.linalg.lapack.strtri(c, lower, unitdiag, overwrite_c) = <fortran object>

Wrapper for strtri.

Parameters

c [input rank-2 array('f') with bounds (n,n)]
Returns

- `inv_c`  [rank-2 array('f') with bounds (n,n) and c storage]
- `info`   [int]

Other Parameters

- `overwrite_c`  [input int, optional] Default: 0
- `lower`  [input int, optional] Default: 0
- `unitdiag`  [input int, optional] Default: 0

**scipy.linalg.lapack.dtrtri**

```python
scipy.linalg.lapack.dtrtri(c[, lower, unitdiag, overwrite_c]) = <fortran object>
```

Wrapper for dtrtri.

Parameters

- `c`  [input rank-2 array('d') with bounds (n,n)]

Returns

- `inv_c`  [rank-2 array('d') with bounds (n,n) and c storage]
- `info`   [int]

Other Parameters

- `overwrite_c`  [input int, optional] Default: 0
- `lower`  [input int, optional] Default: 0
- `unitdiag`  [input int, optional] Default: 0

**scipy.linalg.lapack.ctrtri**

```python
scipy.linalg.lapack.ctrtri(c[, lower, unitdiag, overwrite_c]) = <fortran object>
```

Wrapper for ctrtri.

Parameters

- `c`  [input rank-2 array('F') with bounds (n,n)]

Returns

- `inv_c`  [rank-2 array('F') with bounds (n,n) and c storage]
- `info`   [int]

Other Parameters

- `overwrite_c`  [input int, optional] Default: 0
- `lower`  [input int, optional] Default: 0
- `unitdiag`  [input int, optional] Default: 0
**scipy.linalg.lapack.ztrtri**

```python
scipy.linalg.lapack.ztrtri(c[, lower, unitdiag, overwrite_c]) = <fortran object>
```

Wrapper for ztrtri.

**Parameters**
- `c` [input rank-2 array('D') with bounds (n,n)]

**Returns**
- `inv_c` [rank-2 array('D') with bounds (n,n) and c storage]
- `info` [int]

**Other Parameters**
- `overwrite_c` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
- `unitdiag` [input int, optional] Default: 0

**scipy.linalg.lapack.strtrs**

```python
scipy.linalg.lapack.strtrs(a, b[, lower, trans, unitdiag, lda, overwrite_b]) = <fortran object>
```

Wrapper for strtrs.

**Parameters**
- `a` [input rank-2 array('f') with bounds (lda,n)]
- `b` [input rank-2 array('f') with bounds (ldb,nrhs)]

**Returns**
- `x` [rank-2 array('f') with bounds (ldb,nrhs) and b storage]
- `info` [int]

**Other Parameters**
- `lower` [input int, optional] Default: 0
- `trans` [input int, optional] Default: 0
- `unitdiag` [input int, optional] Default: 0
- `lda` [input int, optional] Default: shape(a,0)
- `overwrite_b` [input int, optional] Default: 0

**scipy.linalg.lapack.dtrtrs**

```python
scipy.linalg.lapack.dtrtrs(a, b[, lower, trans, unitdiag, lda, overwrite_b]) = <fortran object>
```

Wrapper for dtrtrs.

**Parameters**
- `a` [input rank-2 array('d') with bounds (lda,n)]
- `b` [input rank-2 array('d') with bounds (ldb,nrhs)]

**Returns**
- `x` [rank-2 array('d') with bounds (ldb,nrhs) and b storage]
info  [int]

**Other Parameters**

- **lower**  [input int, optional] Default: 0
- **trans**  [input int, optional] Default: 0
- **unitdiag**  [input int, optional] Default: 0
- **lda**  [input int, optional] Default: shape(a,0)
- **overwrite_b**  [input int, optional] Default: 0

**scipy.linalg.lapack.ctrtrs**

scipy.linalg.lapack.ctrtrs(a, b[, lower, trans, unitdiag, lda, overwrite_b]) = <fortran object>

Wrapper for ctrtrs.

**Parameters**

- **a**  [input rank-2 array('F') with bounds (lda,n)]
- **b**  [input rank-2 array('F') with bounds (ldb,nrhs)]

**Returns**

- **x**  [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
- **info**  [int]

**Other Parameters**

- **lower**  [input int, optional] Default: 0
- **trans**  [input int, optional] Default: 0
- **unitdiag**  [input int, optional] Default: 0
- **lda**  [input int, optional] Default: shape(a,0)
- **overwrite_b**  [input int, optional] Default: 0

**scipy.linalg.lapack.ztrtrs**

scipy.linalg.lapack.ztrtrs(a, b[, lower, trans, unitdiag, lda, overwrite_b]) = <fortran object>

Wrapper for ztrtrs.

**Parameters**

- **a**  [input rank-2 array('D') with bounds (lda,n)]
- **b**  [input rank-2 array('D') with bounds (ldb,nrhs)]

**Returns**

- **x**  [rank-2 array('D') with bounds (ldb,nrhs) and b storage]
- **info**  [int]

**Other Parameters**

- **lower**  [input int, optional] Default: 0
- **trans**  [input int, optional] Default: 0
- **unitdiag**  [input int, optional] Default: 0
- **lda**  [input int, optional] Default: shape(a,0)

6.11. Low-level LAPACK functions (scipy.linalg.lapack)
overwrite_b
   [input int, optional] Default: 0

scipy.linalg.lapack.strttf

scipy.linalg.lapack.strttf(a[, transr, uplo]) = <fortran object>
Wrapper for strttf.

Parameters
a        [input rank-2 array('f') with bounds (lda,n)]

Returns
arf      [rank-1 array('f') with bounds (n*(n+1)/2)]
info     [int]

Other Parameters
transr   [input string(len=1), optional] Default: ‘N’
uplo     [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.dtrttf

scipy.linalg.lapack.dtrttf(a[, transr, uplo]) = <fortran object>
Wrapper for dtrttf.

Parameters
a        [input rank-2 array('d') with bounds (lda,n)]

Returns
arf      [rank-1 array('d') with bounds (n*(n+1)/2)]
info     [int]

Other Parameters
transr   [input string(len=1), optional] Default: ‘N’
uplo     [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.ctrttf

scipy.linalg.lapack.ctrttf(a[, transr, uplo]) = <fortran object>
Wrapper for ctrttf.

Parameters
a        [input rank-2 array('F') with bounds (lda,n)]

Returns
arf      [rank-1 array('F') with bounds (n*(n+1)/2)]
info     [int]

Other Parameters
transr   [input string(len=1), optional] Default: ‘N’
uplo     [input string(len=1), optional] Default: ‘U’
scipy.linalg.lapack.ztrttf

scipy.linalg.lapack.ztrttf(a[, transr, uplo]) = <fortran object>

Wrapper for ztrttf.

Parameters

- a [input rank-2 array('D') with bounds (lda,n)]

Returns

- arf [rank-1 array('D') with bounds (n*(n+1)/2)]
- info [int]

Other Parameters

- transr [input string(len=1), optional] Default: ‘N’
- uplo [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.strttp

scipy.linalg.lapack.strttp(a[, uplo]) = <fortran object>

Wrapper for strttp.

Parameters

- a [input rank-2 array('f') with bounds (lda,n)]

Returns

- ap [rank-1 array('f') with bounds (n*(n+1)/2)]
- info [int]

Other Parameters

- uplo [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.dtrttp

scipy.linalg.lapack.dtrttp(a[, uplo]) = <fortran object>

Wrapper for dtrttp.

Parameters

- a [input rank-2 array('d') with bounds (lda,n)]

Returns

- ap [rank-1 array('d') with bounds (n*(n+1)/2)]
- info [int]

Other Parameters

- uplo [input string(len=1), optional] Default: ‘U’
scipy.linalg.lapack.ctrttp

scipy.linalg.lapack.ctrttp(a[, uplo]) = <fortran object>

Wrapper for ctrttp.

Parameters
a
   [input rank-2 array('F') with bounds (lda,n)]

Returns
ap
   [rank-1 array('F') with bounds (n*(n+1)/2)]
info
   [int]

Other Parameters
uplo
   [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.ztrttp

scipy.linalg.lapack.ztrttp(a[, uplo]) = <fortran object>

Wrapper for ztrttp.

Parameters
a
   [input rank-2 array('D') with bounds (lda,n)]

Returns
ap
   [rank-1 array('D') with bounds (n*(n+1)/2)]
info
   [int]

Other Parameters
uplo
   [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.stzrzf

scipy.linalg.lapack.stzrzf(a[, lwork, overwrite_a]) = <fortran object>

Wrapper for stzrzf.

Parameters
a
   [input rank-2 array('f') with bounds (m,n)]

Returns
rz
   [rank-2 array('f') with bounds (m,n) and a storage]
tau
   [rank-1 array('f') with bounds (m)]
info
   [int]

Other Parameters
overwrite_a
   [input int, optional] Default: 0
lwork
   [input int, optional] Default: MAX(m,1)
scipy.linalg.lapack.dtzrzf

scipy.linalg.lapack.dtzrzf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for dtzrzf.

Parameters
   a [input rank-2 array('d') with bounds (m,n)]

Returns
   rz [rank-2 array('d') with bounds (m,n) and a storage]
   tau [rank-1 array('d') with bounds (m)]
   info [int]

Other Parameters
   overwrite_a [input int, optional] Default: 0
   lwork [input int, optional] Default: MAX(m,1)

scipy.linalg.lapack.ctzrzf

scipy.linalg.lapack.ctzrzf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for ctzrzf.

Parameters
   a [input rank-2 array('F') with bounds (m,n)]

Returns
   rz [rank-2 array('F') with bounds (m,n) and a storage]
   tau [rank-1 array('F') with bounds (m)]
   info [int]

Other Parameters
   overwrite_a [input int, optional] Default: 0
   lwork [input int, optional] Default: MAX(m,1)

scipy.linalg.lapack.ztzrzf

scipy.linalg.lapack.ztzrzf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for ztzrzf.

Parameters
   a [input rank-2 array('D') with bounds (m,n)]

Returns
   rz [rank-2 array('D') with bounds (m,n) and a storage]
   tau [rank-1 array('D') with bounds (m)]
   info [int]

Other Parameters
   overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: MAX(m,1)

scipy.linalg.lapack.stzrzf_lwork

scipy.linalg.lapack.stzrzf_lwork(m, n) = <fortran object>
Wrapper for stzrzf_lwork.

Parameters
  m [input int]
  n [input int]

Returns
  work [float]
  info [int]

scipy.linalg.lapack.dtzrzf_lwork

scipy.linalg.lapack.dtzrzf_lwork(m, n) = <fortran object>
Wrapper for dtzrzf_lwork.

Parameters
  m [input int]
  n [input int]

Returns
  work [float]
  info [int]

scipy.linalg.lapack.ctzrzf_lwork

scipy.linalg.lapack.ctzrzf_lwork(m, n) = <fortran object>
Wrapper for ctzrzf_lwork.

Parameters
  m [input int]
  n [input int]

Returns
  work [complex]
  info [int]

scipy.linalg.lapack.ztzrzf_lwork

scipy.linalg.lapack.ztzrzf_lwork(m, n) = <fortran object>
Wrapper for ztzrzf_lwork.

Parameters
  m [input int]
  n [input int]

Returns
work [complex]
info [int]

**scipy.linalg.lapack.cunghr**

scipy.linalg.lapack.cunghr(a, tau[, lo, hi, lwork, overwrite_a]) = <fortran object>

Wrapper for cunghr.

**Parameters**

- a [input rank-2 array('F') with bounds (n,n)]
- tau [input rank-1 array('F') with bounds (n - 1)]

**Returns**

- ht [rank-2 array('F') with bounds (n,n) and a storage]
- info [int]

**Other Parameters**

- lo [input int, optional] Default: 0
- hi [input int, optional] Default: n-1
- overwrite_a [input int, optional] Default: 0
- lwork [input int, optional] Default: max(hi-lo,1)

**scipy.linalg.lapack.zunghr**

scipy.linalg.lapack.zunghr(a, tau[, lo, hi, lwork, overwrite_a]) = <fortran object>

Wrapper for zunghr.

**Parameters**

- a [input rank-2 array('D') with bounds (n,n)]
- tau [input rank-1 array('D') with bounds (n - 1)]

**Returns**

- ht [rank-2 array('D') with bounds (n,n) and a storage]
- info [int]

**Other Parameters**

- lo [input int, optional] Default: 0
- hi [input int, optional] Default: n-1
- overwrite_a [input int, optional] Default: 0
- lwork [input int, optional] Default: max(hi-lo,1)

**scipy.linalg.lapack.cunghr_lwork**

scipy.linalg.lapack.cunghr_lwork(n[, lo, hi]) = <fortran object>

Wrapper for cunghr_lwork.

**Parameters**

- n [input int]

**Returns**
work [complex]
info [int]

Other Parameters
lo [input int, optional] Default: 0
hi [input int, optional] Default: n-1

scipy.linalg.lapack.zunghr_lwork

scipy.linalg.lapack.zunghr_lwork(\([n, lo, hi]\)) = <fortran object>
Wrapper for zunghr_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

Other Parameters
lo [input int, optional] Default: 0
hi [input int, optional] Default: n-1

scipy.linalg.lapack.cungqr

scipy.linalg.lapack.cungqr(\([a, \tau, lwork, overwrite_a]\)) = <fortran object>
Wrapper for cungqr.

Parameters
a [input rank-2 array('F') with bounds (m,n)]
\tau [input rank-1 array('F') with bounds (k)]

Returns
q [rank-2 array('F') with bounds (m,n) and a storage]
work [rank-1 array('F') with bounds (MAX(lwork,1))]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.zungqr

scipy.linalg.lapack.zungqr(\([a, \tau, lwork, overwrite_a]\)) = <fortran object>
Wrapper for zungqr.

Parameters
a [input rank-2 array('D') with bounds (m,n)]
\tau [input rank-1 array('D') with bounds (k)]

Returns
SciPy Reference Guide, Release 1.3.2

```python
q [rank-2 array('D') with bounds (m,n) and a storage]
work [rank-1 array('D') with bounds (MAX(lwork,1))]
info [int]

Other Parameters
overwrite_a
    [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.cungrq

scipy.linalg.lapack.cungrq(a, tau[, lwork, overwrite_a]) = <fortran object>
Wrapper for cungrq.

Parameters
a [input rank-2 array('F') with bounds (m,n)]
tau [input rank-1 array('F') with bounds (k)]

Returns
q [rank-2 array('F') with bounds (m,n) and a storage]
work [rank-1 array('F') with bounds (MAX(lwork,1))]
info [int]

Other Parameters
overwrite_a
    [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*m,1)

scipy.linalg.lapack.zungrq

scipy.linalg.lapack.zungrq(a, tau[, lwork, overwrite_a]) = <fortran object>
Wrapper for zungrq.

Parameters
a [input rank-2 array('D') with bounds (m,n)]
tau [input rank-1 array('D') with bounds (k)]

Returns
q [rank-2 array('D') with bounds (m,n) and a storage]
work [rank-1 array('D') with bounds (MAX(lwork,1))]
info [int]

Other Parameters
overwrite_a
    [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*m,1)
```

6.11. Low-level LAPACK functions (scipy.linalg.lapack)
scipy.linalg.lapack.cunmqr

scipy.linalg.lapack.cunmqr (side, trans, a, tau, lwork[, overwrite_c]) = <fortran object>
Wrapper for cunmqr.

Parameters

side [input string(len=1)]
trans [input string(len=1)]
a [input rank-2 array('F') with bounds (lda,k)]
tau [input rank-1 array('F') with bounds (k)]
c [input rank-2 array('F') with bounds (ldc,n)]
lwork [input int]

Returns

cq [rank-2 array('F') with bounds (ldc,n) and c storage]
work [rank-1 array('F') with bounds (MAX(lwork,1))]
info [int]

Other Parameters

overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.zunmqr

scipy.linalg.lapack.zunmqr (side, trans, a, tau, lwork[, overwrite_c]) = <fortran object>
Wrapper for zunmqr.

Parameters

side [input string(len=1)]
trans [input string(len=1)]
a [input rank-2 array('D') with bounds (lda,k)]
tau [input rank-1 array('D') with bounds (k)]
c [input rank-2 array('D') with bounds (ldc,n)]
lwork [input int]

Returns

cq [rank-2 array('D') with bounds (ldc,n) and c storage]
work [rank-1 array('D') with bounds (MAX(lwork,1))]
info [int]

Other Parameters

overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.cunmrz

scipy.linalg.lapack.cunmrz (a, tau, c[, side, trans, lwork, overwrite_c]) = <fortran object>
Wrapper for cunmrz.

Parameters

a [input rank-2 array('F') with bounds (k,nt)]
tau [input rank-1 array('F') with bounds (k)]
c [input rank-2 array('F') with bounds (m,n)]

Returns

cq [rank-2 array('F') with bounds (m,n) and c storage]
info [int]

Other Parameters

side [input string(len=1), optional] Default: ‘L’
trans [input string(len=1), optional] Default: ‘N’
overwrite_c [input int, optional] Default: 0
lwork [input int, optional] Default: MAX((side[0]=='L'?n:m),1)

**scipy.linalg.lapack.zunmrz**

scipy.linalg.lapack.zunmrz (a, tau, c[, side, trans, lwork, overwrite_c]) = <fortran object>

Wrapper for zunmrz.

Parameters

a [input rank-2 array('D') with bounds (k,nt)]
tau [input rank-1 array('D') with bounds (k)]
c [input rank-2 array('D') with bounds (m,n)]

Returns

cq [rank-2 array('D') with bounds (m,n) and c storage]
info [int]

Other Parameters

side [input string(len=1), optional] Default: ‘L’
trans [input string(len=1), optional] Default: ‘N’
overwrite_c [input int, optional] Default: 0
lwork [input int, optional] Default: MAX((side[0]=='L'?n:m),1)

**scipy.linalg.lapack.cunmrz_lwork**

scipy.linalg.lapack.cunmrz_lwork (m, n[, side, trans]) = <fortran object>

Wrapper for cunmrz_lwork.

Parameters

m [input int]
n [input int]

Returns

work [complex]
info [int]

Other Parameters

side [input string(len=1), optional] Default: ‘L’
trans [input string(len=1), optional] Default: ‘N’
scipy.linalg.lapack.zunmrz_lwork

scipy.linalg.lapack.zunmrz_lwork (m, n[, side, trans]) = <fortran object>

Wrapper for zunmrz_lwork.

Parameters

m [input int]
n [input int]

Returns

work [complex]
info [int]

Other Parameters

side [input string(len=1), optional] Default: ‘L’
trans [input string(len=1), optional] Default: ‘N’

scipy.linalg.lapack.ilaver

scipy.linalg.lapack.ilaver = <fortran object>

Wrapper for ilaver.

Returns

major [int]
minor [int]
patch [int]

6.12 BLAS Functions for Cython

Usable from Cython via:

```python
cimport scipy.linalg.cython_blas
```

These wrappers do not check for alignment of arrays. Alignment should be checked before these wrappers are used.

Raw function pointers (Fortran-style pointer arguments):

- caxpy
- ccopy
- cdotc
- cdotu
- cgbmv
- cgemm
- cgemv
- cgerc
- cgeru
- chbmv

6.13 LAPACK functions for Cython

Usable from Cython via:

```python
cimport scipy.linalg.cython_lapack
```
This module provides Cython-level wrappers for all primary routines included in LAPACK 3.4.0 except for \texttt{zcgesv} since its interface is not consistent from LAPACK 3.4.0 to 3.6.0. It also provides some of the fixed-api auxiliary routines.

These wrappers do not check for alignment of arrays. Alignment should be checked before these wrappers are used.

Raw function pointers (Fortran-style pointer arguments):

- \texttt{cbbcsd}
- \texttt{cbdsqr}
- \texttt{cgbbrd}

6.14 Interpolative matrix decomposition (scipy.linalg.interpolative)

New in version 0.13.

An interpolative decomposition (ID) of a matrix $A \in \mathbb{C}^{m \times n}$ of rank $k \leq \min\{m, n\}$ is a factorization

$$A\Pi = \begin{bmatrix} A\Pi_1 & A\Pi_2 \end{bmatrix} = A\Pi_1 \begin{bmatrix} I & T \end{bmatrix},$$

where $\Pi = [\Pi_1, \Pi_2]$ is a permutation matrix with $\Pi_1 \in \{0, 1\}^{n \times k}$, i.e., $A\Pi_2 = A\Pi_1 T$. This can equivalently be written as $A = BP$, where $B = A\Pi_1$ and $P = [I, T]\Pi^T$ are the skeleton and interpolation matrices, respectively.

If $A$ does not have exact rank $k$, then there exists an approximation in the form of an ID such that $A = BP + E$, where $\|E\| \sim \sigma_{k+1}$ is on the order of the $(k + 1)$-th largest singular value of $A$. Note that $\sigma_{k+1}$ is the best possible error for a rank-$k$ approximation and, in fact, is achieved by the singular value decomposition (SVD) $A \approx USV^*$, where $U \in \mathbb{C}^{m \times k}$ and $V \in \mathbb{C}^{n \times k}$ have orthonormal columns and $S = \text{diag}(\sigma_i) \in \mathbb{C}^{k \times k}$ is diagonal with nonnegative entries.

The principal advantages of using an ID over an SVD are that:
• it is cheaper to construct;
• it preserves the structure of $A$; and
• it is more efficient to compute with in light of the identity submatrix of $P$.

6.14.1 Routines

Main functionality:

**scipy.linalg.interpolative.interp_decomp**

*scipy.linalg.interpolative.* interp_decomp(A, eps_or_k, rand=True)

Compute ID of a matrix.

An ID of a matrix $A$ is a factorization defined by a rank $k$, a column index array $idx$, and interpolation coefficients $proj$ such that:

\[
\text{numpy.dot}(A[:, idx[:k]], proj) = A[:, idx[k:]]
\]

The original matrix can then be reconstructed as:

\[
\text{numpy.hstack}([[A[:,idx[:k]],
\quad \text{numpy.dot}(A[:,idx[:k]], proj)]
\quad[:,\text{numpy.argsort(idx)]
\]

or via the routine `reconstruct_matrix_from_id`. This can equivalently be written as:

\[
\text{numpy.dot}(A[:,idx[:k]],
\quad \text{numpy.hstack}([[\text{numpy.eye(k)}, proj)])
\quad[:,\text{numpy.argsort(id)]}
\]

in terms of the skeleton and interpolation matrices:

\[
B = A[:,idx[:k]]
\]

and:

\[
P = \text{numpy.hstack}([[\text{numpy.eye(k)}, proj])[:,\text{numpy.argsort(idx)]}
\]

respectively. See also `reconstruct_interp_matrix` and `reconstruct_skel_matrix`.

The ID can be computed to any relative precision or rank (depending on the value of \( \text{eps}_\text{or}_k \)). If a precision is specified (\( \text{eps}_\text{or}_k < 1 \)), then this function has the output signature:

\[
k, \text{idx}, \text{proj} = \text{interp_decomp}(A, \text{eps}_\text{or}_k)
\]

Otherwise, if a rank is specified (\( \text{eps}_\text{or}_k \geq 1 \)), then the output signature is:

\[
\text{idx}, \text{proj} = \text{interp_decomp}(A, \text{eps}_\text{or}_k)
\]

**Parameters**

- **A**
  - [numpy.ndarray or scipy.sparse.linalg.LinearOperator with \( \text{rmatvec} \)]
  - Matrix to be factored
- **eps_or_k**
  - [float or int]
  - Relative error (if \( \text{eps}_\text{or}_k < 1 \)) or rank (if \( \text{eps}_\text{or}_k \geq 1 \)) of approximation.
- **rand**
  - [bool, optional]
  - Whether to use random sampling if \( A \) is of type numpy.ndarray (randomized algorithms are always used if \( \text{eps}_\text{or}_k \) is of type scipy.sparse.linalg.LinearOperator).

**Returns**

- **k**
  - [int]
  - Rank required to achieve specified relative precision if \( \text{eps}_\text{or}_k < 1 \).
- **idx**
  - [numpy.ndarray]
  - Column index array.
- **proj**
  - [numpy.ndarray]
  - Interpolation coefficients.

### scipy.linalg.interpolative.reconstruct_matrix_from_id

**scipy.linalg.interpolative.reconstruct_matrix_from_id**

\( \text{reconstruct_matrix_from_id}(B, \text{idx}, \text{proj}) \)

Reconstruct matrix from its ID.

A matrix \( A \) with skeleton matrix \( B \) and ID indices and coefficients \( \text{idx} \) and \( \text{proj} \), respectively, can be reconstructed as:

\[
\text{numpy.hstack}([B, \text{numpy.dot}(B, \text{proj})])[:, \text{numpy.argsort} \text{(idx)}]
\]

See also **reconstruct_interp_matrix** and **reconstruct_skel_matrix**.

**Parameters**

- **B**
  - [numpy.ndarray]
  - Skeleton matrix.
- **idx**
  - [numpy.ndarray]
  - Column index array.
- **proj**
  - [numpy.ndarray]
  - Interpolation coefficients.

**Returns**

- **numpy.ndarray**
  - Reconstructed matrix.

### scipy.linalg.interpolative.reconstruct_interp_matrix

**scipy.linalg.interpolative.reconstruct_interp_matrix**

\( \text{reconstruct_interp_matrix}(\text{idx}, \text{proj}) \)

Reconstruct interpolation matrix from ID.

The interpolation matrix can be reconstructed from the ID indices and coefficients \( \text{idx} \) and \( \text{proj} \), respectively, as:

\[
\text{P} = \text{numpy.hstack}([\text{numpy.eye} \text{(proj.shape[0])}, \text{proj}])[:, \text{numpy.argsort} \text{(idx)}]
\]

The original matrix can then be reconstructed from its skeleton matrix \( B \) via:
```python
numpy.dot(B, P)
```

See also `reconstruct_matrix_from_id` and `reconstruct_skel_matrix`.

**Parameters**

- `idx` : [numpy.ndarray] Column index array.
- `proj` : [numpy.ndarray] Interpolation coefficients.

**Returns**

- `numpy.ndarray` Interpolation matrix.

---

### scipy.linalg.interpolative.reconstruct_skel_matrix

```python
scipy.linalg.interpolative.reconstruct_skel_matrix(A, k, idx)
```

Reconstruct skeleton matrix from ID.

The skeleton matrix can be reconstructed from the original matrix `A` and its ID rank and indices `k` and `idx`, respectively, as:

```plaintext
B = A[:, idx[:k]]
```

The original matrix can then be reconstructed via:

```python
numpy.hstack([B, numpy.dot(B, proj)])[:, numpy.argsort(idx)]
```

See also `reconstruct_matrix_from_id` and `reconstruct_interp_matrix`.

**Parameters**

- `k` : [int] Rank of ID.
- `idx` : [numpy.ndarray] Column index array.

**Returns**

- `numpy.ndarray` Skeleton matrix.

---

### scipy.linalg.interpolative.id_to_svd

```python
scipy.linalg.interpolative.id_to_svd(B, idx, proj)
```

Convert ID to SVD.

The SVD reconstruction of a matrix with skeleton matrix `B` and ID indices and coefficients `idx` and `proj`, respectively, is:

```python
U, S, V = id_to_svd(B, idx, proj)
A = numpy.dot(U, numpy.dot(numpy.diag(S), V.conj().T))
```

See also `svd`.

**Parameters**

- `B` : [numpy.ndarray] Skeleton matrix.
- `idx` : [numpy.ndarray] Column index array.
SciPy Reference Guide, Release 1.3.2

`proj`  [numpy.ndarray] Interpolation coefficients.

**Returns**

- `U`  [numpy.ndarray] Left singular vectors.
- `S`  [numpy.ndarray] Singular values.
- `V`  [numpy.ndarray] Right singular vectors.

**scipy.linalg.interpolative.svd**

`scipy.linalg.interpolative.svd(A, eps_or_k, rand=True)`

Compute SVD of a matrix via an ID.

An SVD of a matrix $A$ is a factorization:

\[
A = \text{numpy.dot}(U, \text{numpy.dot}(\text{numpy.diag}(S), V^{\text{conj}}.T))
\]

where $U$ and $V$ have orthonormal columns and $S$ is nonnegative.

The SVD can be computed to any relative precision or rank (depending on the value of `eps_or_k`).

See also `interp_decomp` and `id_to_svd`.

**Parameters**

- `A`  [numpy.ndarray or scipy.sparse.linalg.LinearOperator] Matrix to be factored, given as either a `numpy.ndarray` or a `scipy.sparse.linalg.LinearOperator` with the `matvec` and `rmatvec` methods (to apply the matrix and its adjoint).
- `eps_or_k` [float or int] Relative error (if `eps_or_k < 1`) or rank (if `eps_or_k >= 1`) of approximation.
- `rand` [bool, optional] Whether to use random sampling if $A$ is of type `numpy.ndarray` (randomized algorithms are always used if $A$ is of type `scipy.sparse.linalg.LinearOperator`).

**Returns**

- `U`  [numpy.ndarray] Left singular vectors.
- `S`  [numpy.ndarray] Singular values.
- `V`  [numpy.ndarray] Right singular vectors.

**scipy.linalg.interpolative.estimate_spectral_norm**

`scipy.linalg.interpolative.estimate_spectral_norm(A, its=20)`

Estimate spectral norm of a matrix by the randomized power method.

**Parameters**

- `its` [int, optional] Number of power method iterations.

**Returns**

- `float` Spectral norm estimate.
scipy.linalg.interpolative.estimate_spectral_norm_diff

\texttt{scipy.linalg.interpolative.estimate_spectral_norm_diff (A, B, its=20)}

Estimates spectral norm of the difference of two matrices by the randomized power method.

\textbf{Parameters}

- \texttt{A} \quad [\texttt{scipy.sparse.linalg.LinearOperator}] First matrix given as a \texttt{scipy.sparse.linalg.LinearOperator} with the matvec and rmatvec methods (to apply the matrix and its adjoint).
- \texttt{B} \quad [\texttt{scipy.sparse.linalg.LinearOperator}] Second matrix given as a \texttt{scipy.sparse.linalg.LinearOperator} with the matvec and rmatvec methods (to apply the matrix and its adjoint).
- \texttt{its} \quad [\text{int, optional}] Number of power method iterations.

\textbf{Returns}

- \texttt{float} \quad Spectral norm estimate of matrix difference.

scipy.linalg.interpolative.estimate_rank

\texttt{scipy.linalg.interpolative.estimate_rank (A, eps)}

Estimates matrix rank to a specified relative precision using randomized methods.

The matrix \( A \) can be given as either a \texttt{numpy.ndarray} or a \texttt{scipy.sparse.linalg.LinearOperator}, with different algorithms used for each case. If \( A \) is of type \texttt{numpy.ndarray}, then the output rank is typically about 8 higher than the actual numerical rank.

\textbf{Parameters}

- \texttt{A} \quad [\texttt{numpy.ndarray} or \texttt{scipy.sparse.linalg.LinearOperator}] Matrix whose rank is to be estimated, given as either a \texttt{numpy.ndarray} or a \texttt{scipy.sparse.linalg.LinearOperator} with the rmatvec method (to apply the matrix adjoint).
- \texttt{eps} \quad [\text{float}] Relative error for numerical rank definition.

\textbf{Returns}

- \texttt{int} \quad Estimated matrix rank.

Support functions:

\begin{tabular}{ll}
\texttt{seed([seed])} & Seed the internal random number generator used in this ID package. \\
\texttt{rand(*shape)} & Generate standard uniform pseudorandom numbers via a very efficient lagged Fibonacci method. \\
\end{tabular}

scipy.linalg.interpolative.seed

\texttt{scipy.linalg.interpolative.seed (seed=None)}

Seed the internal random number generator used in this ID package.

The generator is a lagged Fibonacci method with 55-element internal state.

\textbf{Parameters}

- \texttt{seed} \quad [\text{int, sequence, ‘default’, optional}] If ‘default’, the random seed is reset to a default value. If \texttt{seed} is a sequence containing 55 floating-point numbers in range \([0,1]\), these are used to set the internal state of the generator.
If the value is an integer, the internal state is obtained from `numpy.random.mtrand.RandomState` (MT19937) with the integer used as the initial seed. If `seed` is omitted (None), `numpy.random.rand` is used to initialize the generator.

`scipy.linalg.interpolative.rand`

`scipy.linalg.interpolative.rand(*shape)`

Generate standard uniform pseudorandom numbers via a very efficient lagged Fibonacci method.

This routine is used for all random number generation in this package and can affect ID and SVD results.

**Parameters**

- `shape` : shape of output array

---

### 6.14.2 References

This module uses the ID software package [R5a82238cdab4-1] by Martinsson, Rokhlin, Shkolnisky, and Tygert, which is a Fortran library for computing IDs using various algorithms, including the rank-revealing QR approach of [R5a82238cdab4-2] and the more recent randomized methods described in [R5a82238cdab4-3], [R5a82238cdab4-4], and [R5a82238cdab4-5]. This module exposes its functionality in a way convenient for Python users. Note that this module does not add any functionality beyond that of organizing a simpler and more consistent interface.

We advise the user to consult also the documentation for the ID package.

---

### 6.14.3 Tutorial

#### Initializing

The first step is to import `scipy.linalg.interpolative` by issuing the command:

```python
>>> import scipy.linalg.interpolative as sli
```

Now let’s build a matrix. For this, we consider a Hilbert matrix, which is well known to have low rank:

```python
>>> from scipy.linalg import hilbert
>>> n = 1000
>>> A = hilbert(n)
```

We can also do this explicitly via:

```python
>>> import numpy as np
>>> n = 1000
>>> A = np.empty((n, n), order='F')
>>> for j in range(n):
...     for i in range(n):
...         A[i, j] = 1. / (i + j + 1)
```

Note the use of the flag `order='F'` in `numpy.empty`. This instantiates the matrix in Fortran-contiguous order and is important for avoiding data copying when passing to the backend.

We then define multiplication routines for the matrix by regarding it as a `scipy.sparse.linalg.LinearOperator`:
This automatically sets up methods describing the action of the matrix and its adjoint on a vector.

**Computing an ID**

We have several choices of algorithm to compute an ID. These fall largely according to two dichotomies:

1. how the matrix is represented, i.e., via its entries or via its action on a vector; and
2. whether to approximate it to a fixed relative precision or to a fixed rank.

We step through each choice in turn below.

In all cases, the ID is represented by three parameters:

1. a rank \( k \);
2. an index array \( \text{idx} \); and
3. interpolation coefficients \( \text{proj} \).

The ID is specified by the relation \( \text{np.dot}(A[:, \text{idx}[:k]], \text{proj}) == A[:, \text{idx}[k:]] \).

**From matrix entries**

We first consider a matrix given in terms of its entries.

To compute an ID to a fixed precision, type:

```python
>>> k, idx, proj = sli.interp_decomp(A, eps)
```

where \( \text{eps} < 1 \) is the desired precision.

To compute an ID to a fixed rank, use:

```python
>>> idx, proj = sli.interp_decomp(A, k)
```

where \( k \geq 1 \) is the desired rank.

Both algorithms use random sampling and are usually faster than the corresponding older, deterministic algorithms, which can be accessed via the commands:

```python
>>> k, idx, proj = sli.interp_decomp(A, eps, rand=False)
```

and:

```python
>>> idx, proj = sli.interp_decomp(A, k, rand=False)
```

respectively.

**From matrix action**

Now consider a matrix given in terms of its action on a vector as a `scipy.sparse.linalg.LinearOperator`.

To compute an ID to a fixed precision, type:

```python
>>> k, idx, proj = sli.interp_decomp(L, eps)
```

To compute an ID to a fixed rank, use:
These algorithms are randomized.

Reconstructing an ID

The ID routines above do not output the skeleton and interpolation matrices explicitly but instead return the relevant information in a more compact (and sometimes more useful) form. To build these matrices, write:

```python
>>> idx, proj = sli.interp_decomp(L, k)
```

for the skeleton matrix and:

```python
>>> B = sli.reconstruct_skel_matrix(A, k, idx)
```

for the interpolation matrix. The ID approximation can then be computed as:

```python
>>> C = np.dot(B, P)
```

This can also be constructed directly using:

```python
>>> C = sli.reconstruct_matrix_from_id(B, idx, proj)
```

without having to first compute \( P \).

Alternatively, this can be done explicitly as well using:

```python
>>> B = A[:,idx[:k]]
>>> P = np.hstack([np.eye(k), proj])[:,np.argsort(idx)]
>>> C = np.dot(B, P)
```

Computing an SVD

An ID can be converted to an SVD via the command:

```python
>>> U, S, V = sli.id_to_svd(B, idx, proj)
```

The SVD approximation is then:

```python
>>> C = np.dot(U, np.dot(np.diag(S), np.dot(V.conj().T)))
```

The SVD can also be computed “fresh” by combining both the ID and conversion steps into one command. Following the various ID algorithms above, there are correspondingly various SVD algorithms that one can employ.

From matrix entries

We consider first SVD algorithms for a matrix given in terms of its entries.

To compute an SVD to a fixed precision, type:

```python
>>> U, S, V = sli.svd(A, eps)
```

To compute an SVD to a fixed rank, use:
Both algorithms use random sampling; for the deterministic versions, issue the keyword `rand=False` as above.

**From matrix action**

Now consider a matrix given in terms of its action on a vector.

To compute an SVD to a fixed precision, type:

```python
>>> U, S, V = sli.svd(A, k)
```

To compute an SVD to a fixed rank, use:

```python
>>> U, S, V = sli.svd(L, k)
```

**Utility routines**

Several utility routines are also available.

To estimate the spectral norm of a matrix, use:

```python
>>> snorm = sli.estimate_spectral_norm(A)
```

This algorithm is based on the randomized power method and thus requires only matrix-vector products. The number of iterations to take can be set using the keyword `its` (default: `its=20`). The matrix is interpreted as a `scipy.sparse.linalg.LinearOperator`, but it is also valid to supply it as a `numpy.ndarray`, in which case it is trivially converted using `scipy.sparse.linalg.aslinearoperator`.

The same algorithm can also estimate the spectral norm of the difference of two matrices $A_1$ and $A_2$ as follows:

```python
>>> diff = sli.estimate_spectral_norm_diff(A1, A2)
```

This is often useful for checking the accuracy of a matrix approximation.

Some routines in `scipy.linalg.interpolative` require estimating the rank of a matrix as well. This can be done with either:

```python
>>> k = sli.estimate_rank(A, eps)
```

or:

```python
>>> k = sli.estimate_rank(L, eps)
```

depending on the representation. The parameter `eps` controls the definition of the numerical rank.

Finally, the random number generation required for all randomized routines can be controlled via `scipy.linalg.interpolative.seed`. To reset the seed values to their original values, use:

```python
>>> sli.seed('default')
```

To specify the seed values, use:

```python
>>> sli.seed(s)
```
where \( s \) must be an integer or array of 55 floats. If an integer, the array of floats is obtained by using `numpy.random.rand` with the given integer seed.

To simply generate some random numbers, type:

```python
>>> sli.rand(n)
```

where \( n \) is the number of random numbers to generate.

**Remarks**

The above functions all automatically detect the appropriate interface and work with both real and complex data types, passing input arguments to the proper backend routine.

### 6.15 Miscellaneous routines (scipy.misc)

Various utilities that don’t have another home.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ascent()</td>
<td>Get an 8-bit grayscale bit-depth, 512 x 512 derived image for easy use in demos</td>
</tr>
<tr>
<td>central_diff_weights(Np[, ndiv])</td>
<td>Return weights for an Np-point central derivative.</td>
</tr>
<tr>
<td>derivative(func, x0[, dx, n, args, order])</td>
<td>Find the n-th derivative of a function at a point.</td>
</tr>
<tr>
<td>face([gray])</td>
<td>Get a 1024 x 768, color image of a raccoon face.</td>
</tr>
<tr>
<td>electrocardiogram()</td>
<td>Load an electrocardiogram as an example for a one-dimensional signal.</td>
</tr>
</tbody>
</table>

#### 6.15.1 scipy.misc.ascent

`scipy.misc.ascent()`

Get an 8-bit grayscale bit-depth, 512 x 512 derived image for easy use in demos

**Parameters**

None

**Returns**

ascent [ndarray] convenient image to use for testing and demonstration

**Examples**

```python
>>> import scipy.misc
>>> ascent = scipy.misc.ascent()
>>> ascent.shape
(512, 512)
>>> ascent.max()
255
```
6.15.2 scipy.misc.central_diff_weights

`scipy.misc.central_diff_weights(Np, ndiv=1)`

Return weights for an Np-point central derivative. Assumes equally-spaced function points.

If weights are in the vector w, then derivative is \( w[0] \* f(x-ho*dx) + \ldots + w[-1] \* f(x+h0*dx) \)

**Parameters**

- `Np` [int] Number of points for the central derivative.
- `ndiv` [int, optional] Number of divisions. Default is 1.

**Notes**

Can be inaccurate for large number of points.

6.15.3 scipy.misc.derivative

`scipy.misc.derivative(func, x0, dx=1.0, n=1, args=(), order=3)`

Find the n-th derivative of a function at a point.

Given a function, use a central difference formula with spacing \( dx \) to compute the n-th derivative at \( x0 \).

**Parameters**

- `func` [function] Input function.
- `x0` [float] The point at which n-th derivative is found.
**dx**       [float, optional] Spacing.
**n**       [int, optional] Order of the derivative. Default is 1.
**args**       [tuple, optional] Arguments
**order**       [int, optional] Number of points to use, must be odd.

**Notes**

Decreasing the step size too small can result in round-off error.

**Examples**

```python
>>> from scipy.misc import derivative
>>> def f(x):
...     return x**3 + x**2
>>> derivative(f, 1.0, dx=1e-6)
4.9999999999217337
```

### 6.15.4 scipy.misc.face

**scipy.misc.face** *(gray=False)*

Get a 1024 x 768, color image of a raccoon face.

**Parameters**

- **gray** [bool, optional] If True return 8-bit grey-scale image, otherwise return a color image

**Returns**

- **face** [ndarray] image of a raccoon face

**Examples**

```python
>>> import scipy.misc
>>> face = scipy.misc.face()
>>> face.shape
(768, 1024, 3)
>>> face.max()
255
>>> face.dtype
dtype('uint8')

>>> import matplotlib.pyplot as plt
>>> plt.gray()
>>> plt.imshow(face)
>>> plt.show()
```
6.15.5 scipy.misc.electrocardiogram

scipy.misc.electrocardiogram()

Load an electrocardiogram as an example for a one-dimensional signal.

The returned signal is a 5 minute long electrocardiogram (ECG), a medical recording of the heart's electrical activity, sampled at 360 Hz.

Returns

cg [ndarray] The electrocardiogram in millivolt (mV) sampled at 360 Hz.

Notes

The provided signal is an excerpt (19:35 to 24:35) from the record 208 (lead MLII) provided by the MIT-BIH Arrhythmia Database [1] on PhysioNet [2]. The excerpt includes noise induced artifacts, typical heartbeats as well as pathological changes.

New in version 1.1.0.

References

[1],[2]

Examples

```python
>>> from scipy.misc import electrocardiogram
>>> ecg = electrocardiogram()
>>> ecg
array([-0.245, -0.215, -0.185, ..., -0.405, -0.395, -0.385])
>>> ecg.shape, ecg.mean(), ecg.std()
((108000,), -0.16510875, 0.5992473991177294)
```
As stated the signal features several areas with a different morphology. E.g. the first few seconds show the electrical activity of a heart in normal sinus rhythm as seen below.

```python
>>> import matplotlib.pyplot as plt
>>> fs = 360
>>> time = np.arange(ecg.size) / fs
>>> plt.plot(time, ecg)
>>> plt.xlabel("time in s")
>>> plt.ylabel("ECG in mV")
>>> plt.xlim(9, 10.2)
>>> plt.ylim(-1, 1.5)
>>> plt.show()
```

![ECG signal graph]

After second 16 however, the first premature ventricular contractions, also called extrasystoles, appear. These have a different morphology compared to typical heartbeats. The difference can easily be observed in the following plot.

```python
>>> plt.plot(time, ecg)
>>> plt.xlabel("time in s")
>>> plt.ylabel("ECG in mV")
>>> plt.xlim(46.5, 50)
>>> plt.ylim(-2, 1.5)
>>> plt.show()
```

At several points large artifacts disturb the recording, e.g.:

```python
>>> plt.plot(time, ecg)
>>> plt.xlabel("time in s")
>>> plt.ylabel("ECG in mV")
>>> plt.xlim(207, 215)
>>> plt.ylim(-2, 3.5)
>>> plt.show()
```

Finally, examining the power spectrum reveals that most of the biosignal is made up of lower frequencies. At 60 Hz the noise induced by the mains electricity can be clearly observed.
6.15. Miscellaneous routines (scipy.misc)
```python
>>> from scipy.signal import welch
>>> f, Pxx = welch(ecg, fs=fs, nperseg=2048, scaling="spectrum")
>>> plt.semilogy(f, Pxx)
>>> plt.xlabel("Frequency in Hz")
>>> plt.ylabel("Power spectrum of the ECG in mV**2")
>>> plt.xlim(f[[0, -1]])
>>> plt.show()
```

### 6.16 Multi-dimensional image processing (scipy.ndimage)

This package contains various functions for multi-dimensional image processing.

#### 6.16.1 Filters

- `convolve(input, weights[, output, mode, ...])`: Multidimensional convolution.
- `convolve1d(input, weights[, axis, output, ...])`: Calculate a one-dimensional convolution along the given axis.
- `correlate(input, weights[, output, mode, ...])`: Multi-dimensional correlation.
- `correlate1d(input, weights[, axis, output, ...])`: Calculate a one-dimensional correlation along the given axis.
- `gaussian_filter(input, sigma[, order, ...])`: Multidimensional Gaussian filter.
- `gaussian_filter1d(input, sigma[, axis, ...])`: One-dimensional Gaussian filter.
- `gaussian_gradient_magnitude(input, sigma[, ...])`: Multidimensional gradient magnitude using Gaussian derivatives.
- `gaussian_laplace(input, sigma[, order, ...])`: Multidimensional Laplace filter using gaussian second derivatives.
- `generic_filter(input, function[, size, ...])`: Calculate a multi-dimensional filter using the given function.
- `generic_filter1d(input, function, filter_size)`: Calculate a one-dimensional filter along the given axis.
Table 100 – continued from previous page

</table>

**scipy.ndimage.convolve**

`scipy.ndimage.convolve(input, weights, output=None, mode='reflect', cval=0.0, origin=0)`  
Multidimensional convolution.

The array is convolved with the given kernel.

**Parameters**

- `input`  
  [array_like] The input array.

- `weights`  
  [array_like] Array of weights, same number of dimensions as input

- `output`  
  [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

- `mode`  
  [str or sequence, optional] The `mode` parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:

  - `reflect` (d c b a \mid a b c d \mid d c b a)  
    The input is extended by reflecting about the edge of the last pixel.

  - `constant` (k k k k \mid a b c d \mid k k k k)  
    The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.

  - `nearest` (a a a a \mid a b c d \mid d d d d)  
    The input is extended by replicating the last pixel.

  - `mirror` (d c b \mid a b c d \mid c b a)  
    The input is extended by reflecting about the center of the last pixel.

  - `wrap` (a b c d \mid a b c d \mid a b c d)  
    The input is extended by wrapping around to the opposite edge.

- `cval`  
  [scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0

- `origin`  
  [int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different origins can be specified along each axis.
to the number of dimensions of the input array, different shifts can be specified along each axis.

**Returns**

result  [ndarray] The result of convolution of input with weights.

**See also:**

correlate

Correlate an image with a kernel.

**Notes**

Each value in result is $C_i = \sum_j I_{i+k-j}W_j$, where $W$ is the weights kernel, $j$ is the n-D spatial index over $W$, $I$ is the input and $k$ is the coordinate of the center of $W$, specified by origin in the input parameters.

**Examples**

Perhaps the simplest case to understand is `mode='constant', cval=0.0`, because in this case borders (i.e. where the weights kernel, centered on any one value, extends beyond an edge of input) are treated as zeros.

```python
>>> a = np.array([[1, 2, 0, 0],
                ... [5, 3, 0, 4],
                ... [0, 0, 0, 7],
                ... [9, 3, 0, 0]])
>>> k = np.array([[1,1,1],[1,1,0],[1,0,0]])
>>> ndimage.convolve(a, k, mode='constant', cval=0.0)
array([[11, 10,  7,  4],
       [10,  3, 11, 11],
       [15, 12, 14,  7],
       [12,  3,  7,  0]])
```

Setting `cval=1.0` is equivalent to padding the outer edge of input with 1.0’s (and then extracting only the original region of the result).

```python
>>> ndimage.convolve(a, k, mode='constant', cval=1.0)
array([[13,  0,  0],
       [11,  0,  0],
       [16, 12, 14, 10],
       [15,  6, 10,  5]])
```

With `mode='reflect'` (the default), outer values are reflected at the edge of input to fill in missing values.

```python
>>> b = np.array([[2, 0, 0],
                ... [1, 0, 0],
                ... [0, 0, 0]])
>>> k = np.array([[0,1,0], [0,1,0], [0,1,0]])
>>> ndimage.convolve(b, k, mode='reflect')
array([[5,  0,  0],
       [3,  0,  0],
       [1,  0,  0]])
```
This includes diagonally at the corners.

```python
>>> k = np.array([[1,0,0],[0,1,0],[0,0,1]])
>>> ndimage.convolve(b, k)
array([[4, 2, 0],
       [3, 2, 0],
       [1, 1, 0]])
```

With `mode='nearest'`, the single nearest value in to an edge in `input` is repeated as many times as needed to match the overlapping weights.

```python
>>> c = np.array([[2, 0, 1],
                 [1, 0, 0],
                 [0, 0, 0]])
>>> k = np.array([[0, 1, 0],
                 [0, 1, 0],
                 [0, 1, 0],
                 [0, 1, 0],
                 [0, 1, 0]])
>>> ndimage.convolve(c, k, mode='nearest')
array([[7, 0, 3],
       [5, 0, 2],
       [3, 0, 1]])
```

### scipy.ndimage.convolve1d

**scipy.ndimage.convolve1d** *(input, weights, axis=-1, output=None, mode='reflect', cval=0.0, origin=0)*

Calculate a one-dimensional convolution along the given axis.

The lines of the array along the given axis are convolved with the given weights.

**Parameters**

- **input** *array_like* The input array.
- **weights** *ndarray* One-dimensional sequence of numbers.
- **axis** *int, optional* The axis of `input` along which to calculate. Default is -1.
- **output** *array or dtype, optional* The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** *{‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’}, optional* The `mode` parameter determines how the input array is extended beyond its boundaries. Default is ‘reflect’. Behavior for each valid value is as follows:
  - **reflect** *(d c b a | a b c d | d c b a)*
    The input is extended by reflecting about the edge of the last pixel.
  - **constant** *(k k k k | a b c d | k k k k)*
    The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
  - **nearest** *(a a a a | a b c d | d d d d)*
    The input is extended by replicating the last pixel.
  - **mirror** *(d c b a | a b c d | c b a)*
    The input is extended by reflecting about the center of the last pixel.
  - **wrap** *(a b c d | a b c d | a b c d)*
    The input is extended by wrapping around to the opposite edge.
- **cval** *scalar, optional* Value to fill past edges of `input` if `mode` is ‘constant’. Default is 0.0.
origin  [int, optional] Controls the placement of the filter on the input array's pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right.

Returns

convolve1d  [ndarray] Convolved array with same shape as input

Examples

```python
>>> from scipy.ndimage import convolve1d
>>> convolve1d([2, 8, 0, 4, 1, 9, 9, 0], weights=[1, 3])
array([14, 24, 4, 13, 12, 36, 27, 0])
```

scipy.ndimage.correlate

scipy.ndimage.correlate  (input, weights, output=None, mode='reflect', cval=0.0, origin=0)

Multi-dimensional correlation.

The array is correlated with the given kernel.

Parameters

- **input**  [array_like] The input array.
- **weights**  [ndarray] array of weights, same number of dimensions as input
- **output**  [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode**  [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:
  - **reflect**  
    (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel.
  - **constant**  
    (k k k k | a b c d | k k k k)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the **cval** parameter.
  - **nearest**  
    (a a a a | a b c d | d d d d)
    The input is extended by replicating the last pixel.
  - **mirror**  
    (d c b | a b c d | c b a)
    The input is extended by reflecting about the center of the last pixel.
  - **wrap**  
    (a b c d | a b c d | a b c d)
    The input is extended by wrapping around to the opposite edge.
- **cval**  [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
- **origin**  [int or sequence, optional] Controls the placement of the filter on the input array's pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

See also:

- **convolve**  Convolve an image with a kernel.
scipy.ndimage.correlate1d

**scipy.ndimage.correlate1d** *(input, weights, axis=-1, output=None, mode='reflect', cval=0.0, origin=0)*

Calculate a one-dimensional correlation along the given axis.

The lines of the array along the given axis are correlated with the given weights.

**Parameters**

- **input** [array_like] The input array.
- **weights** [array] One-dimensional sequence of numbers.
- **axis** [int, optional] The axis of input along which to calculate. Default is -1.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is 'reflect'. Behavior for each valid value is as follows:
  - 'reflect' ([d c b a | a b c d | d c b a])
    The input is extended by reflecting about the edge of the last pixel.
  - 'constant' ([k k k k | a b c d | k k k k])
    The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - 'nearest' ([a a a a | a b c d | d d d d])
    The input is extended by replicating the last pixel.
  - 'mirror' ([d c b a | a b c d | c b a])
    The input is extended by reflecting about the center of the last pixel.
  - 'wrap' ([a b c d | a b c d | a b c d])
    The input is extended by wrapping around to the opposite edge.
- **cval** [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
- **origin** [int, optional] Controls the placement of the filter on the input array's pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right.

**Examples**

```python
>>> from scipy.ndimage import correlate1d
>>> correlate1d([2, 8, 0, 4, 1, 9, 9, 0], weights=[1, 3])
array([ 8, 26,  8, 12,  7, 28, 36,  9])
```

scipy.ndimage.gaussian_filter

**scipy.ndimage.gaussian_filter** *(input, sigma, order=0, output=None, mode='reflect', cval=0.0, truncate=4.0)*

Multidimensional Gaussian filter.

**Parameters**

- **input** [array_like] The input array.
- **sigma** [scalar or sequence of scalars] Standard deviation for Gaussian kernel. The standard deviations of the Gaussian filter are given for each axis as a sequence, or as a single number, in which case it is equal for all axes.
- **order** [int or sequence of ints, optional] The order of the filter along each axis is given as a sequence of integers, or as a single number. An order of 0 corresponds to convolution with a Gaussian kernel. A positive order corresponds to convolution with that derivative of a Gaussian.
output [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

mode [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:

- ‘reflect’ (d c b a | a b c d | d c b a)
  The input is extended by reflecting about the edge of the last pixel.
- ‘constant’ (k k k k | a b c d | k k k k)
  The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
- ‘nearest’ (a a a a | a b c d | d d d d)
  The input is extended by replicating the last pixel.
- ‘mirror’ (d c b | a b c d | c b a)
  The input is extended by reflecting about the center of the last pixel.
- ‘wrap’ (a b c d | a b c d | a b c d)
  The input is extended by wrapping around to the opposite edge.

cval [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

truncate [float] Truncate the filter at this many standard deviations. Default is 4.0.

Returns

gaussian_filter

[ndarray] Returned array of same shape as input.

Notes

The multidimensional filter is implemented as a sequence of one-dimensional convolution filters. The intermediate arrays are stored in the same data type as the output. Therefore, for output types with a limited precision, the results may be imprecise because intermediate results may be stored with insufficient precision.

Examples

```python
>>> from scipy.ndimage import gaussian_filter
>>> a = np.arange(50, step=2).reshape((5, 5))
>>> a
array([[ 0,  2,  4,  6,  8],
       [10, 12, 14, 16, 18],
       [20, 22, 24, 26, 28],
       [30, 32, 34, 36, 38],
       [40, 42, 44, 46, 48]])
>>> gaussian_filter(a, sigma=1)
array([[ 4,  6,  8,  9, 11],
       [10, 12, 14, 15, 17],
       [20, 22, 24, 25, 27],
       [29, 31, 33, 34, 36],
       [35, 37, 39, 40, 42]])
```

(continues on next page)
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = gaussian_filter(ascent, sigma=5)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
The input is extended by reflecting about the center of the last pixel.

'The input is extended by wrapping around to the opposite edge.

cval [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
truncat [float, optional] Truncate the filter at this many standard deviations. Default is 4.0.

Returns

gaussian_filter1d [ndarray]

Examples

```python
>>> from scipy.ndimage import gaussian_filter1d
>>> gaussian_filter1d([1.0, 2.0, 3.0, 4.0, 5.0], 1)
array([ 1.42704095, 2.06782203, 3.          , 3.93217797, 4.57295905])
>>> gaussian_filter1d([1.0, 2.0, 3.0, 4.0, 5.0], 4)
array([ 2.91948343, 2.95023502, 3.          , 3.04976498, 3.08051657])
>>> import matplotlib.pyplot as plt
>>> np.random.seed(280490)
>>> x = np.random.randn(101).cumsum()
>>> y3 = gaussian_filter1d(x, 3)
>>> y6 = gaussian_filter1d(x, 6)
>>> plt.plot(x, 'k', label='original data')
>>> plt.plot(y3, '--', label='filtered, sigma=3')
>>> plt.plot(y6, ':', label='filtered, sigma=6')
>>> plt.legend()
>>> plt.grid()
>>> plt.show()
```
scipy.ndimage.gaussian_gradient_magnitude

scipy.ndimage.gaussian_gradient_magnitude(input, sigma, output=None, mode='reflect', cval=0.0, **kwargs)

Multidimensional gradient magnitude using Gaussian derivatives.

Parameters

- **input** [array_like] The input array.
- **sigma** [scalar or sequence of scalars] The standard deviations of the Gaussian filter are given for each axis as a sequence, or as a single number, in which case it is equal for all axes.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [str or sequence, optional] The 'mode' parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:
  - 'reflect' (d c b a | a b c d | d c b a) The input is extended by reflecting about the edge of the last pixel.
  - 'constant' (k k k k | a b c d | k k k k) The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - 'nearest' (a a a a | a b c d | d d d d) The input is extended by replicating the last pixel.
  - 'mirror' (d c b | a b c d | c b a) The input is extended by reflecting about the center of the last pixel.
  - 'wrap' (a b c d | a b c d | a b c d) The input is extended by wrapping around to the opposite edge.
- **cval** [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.

Extra keyword arguments will be passed to gaussian_filter().

Returns

- **gaussian_gradient_magnitude** [ndarray] Filtered array. Has the same shape as input.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.gaussian_gradient_magnitude(ascent, sigma=5)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```

scipy.ndimage.gaussian_laplace

scipy.ndimage.gaussian_laplace(input, sigma, output=None, mode='reflect', cval=0.0, **kwargs)

Multidimensional Laplace filter using gaussian second derivatives.
Parameters

- **input** [array_like] The input array.
- **sigma** [scalar or sequence of scalars] The standard deviations of the Gaussian filter are given for each axis as a sequence, or as a single number, in which case it is equal for all axes.
- **output** [array or dtypes, optional] The array in which to place the output, or the dtypes of the returned array. By default an array of the same dtype as input will be created.
- **mode** [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:
  - 'reflect' (d c b a \ a b c d \ d c b a)
    The input is extended by reflecting about the edge of the last pixel.
  - 'constant' (k k k k \ a b c d \ k k k k)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - 'nearest' (a a a a \ a b c d \ d d d d)
    The input is extended by replicating the last pixel.
  - 'mirror' (d c b \ a b c d \ c b a)
    The input is extended by reflecting about the center of the last pixel.
  - 'wrap' (a b c d \ a b c d \ a b c d)
    The input is extended by wrapping around to the opposite edge.
- **cval** [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> ascent = misc.ascent()
```
```python
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side

>>> result = ndimage.gaussian_laplace(ascent, sigma=1)
>>> ax1.imshow(result)

>>> result = ndimage.gaussian_laplace(ascent, sigma=3)
>>> ax2.imshow(result)
>>> plt.show()
```

---

**scipy.ndimage.generic_filter**

`scipy.ndimage.generic_filter(input, function, size=None, footprint=None, output=None, mode='reflect', cval=0.0, origin=0, extra_arguments=(), extra_keywords=None)`

Calculate a multi-dimensional filter using the given function.

At each element the provided function is called. The input values within the filter footprint at that element are passed to the function as a 1D array of double values.

**Parameters**

- `input` [array_like] The input array.
- `function` [{callable, scipy.LowLevelCallable}] Function to apply at each element.
- `size` [scalar or tuple, optional] See footprint, below. Ignored if footprint is given.
- `footprint` [array, optional] Either `size` or `footprint` must be defined. `size` gives the shape that is taken from the input array, at every element position, to define the input to the filter function. `footprint` is a boolean array that specifies (implicitly) a shape, but also which of the elements within this shape will get passed to the filter function. Thus `size=(n,m)` is equivalent to `footprint=np.ones((n,m))`. We adjust `size` to the number of dimensions of the input array, so that, if the input array is shape (10,10,10), and `size` is 2, then the actual size used is (2,2,2). When `footprint` is given, `size` is ignored.
output [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

mode [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:

- ‘reflect’ (d c b a | a b c d | d c b a)
  The input is extended by reflecting about the edge of the last pixel.

- ‘constant’ (k k k k | a b c d | k k k k)
  The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.

- ‘nearest’ (a a a a | a b c d | d d d d)
  The input is extended by replicating the last pixel.

- ‘mirror’ (d c b | a b c d | c b a)
  The input is extended by reflecting about the center of the last pixel.

- ‘wrap’ (a b c d | a b c d | a b c d)
  The input is extended by wrapping around to the opposite edge.

cval [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

origin [int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

extra_arguments [sequence, optional] Sequence of extra positional arguments to pass to passed function.

extra_keywords [dict, optional] dict of extra keyword arguments to pass to passed function.

Notes

This function also accepts low-level callback functions with one of the following signatures and wrapped in scipy.

LowLevelCallable:

```c
int callback(double *buffer, npy_intp filter_size,
              double *return_value, void *user_data)
```

The calling function iterates over the elements of the input and output arrays, calling the callback function at each element. The elements within the footprint of the filter at the current element are passed through the buffer parameter, and the number of elements within the footprint through filter_size. The calculated value is returned in return_value. user_data is the data pointer provided to scipy.LowLevelCallable as-is.

The callback function must return an integer error status that is zero if something went wrong and one otherwise. If an error occurs, you should normally set the python error status with an informative message before returning, otherwise a default error message is set by the calling function.

In addition, some other low-level function pointer specifications are accepted, but these are for backward compatibility only and should not be used in new code.
**scipy.ndimage.generic_filter1d**

Calculates a one-dimensional filter along the given axis.

`generic_filter1d` iterates over the lines of the array, calling the given function at each line. The arguments of the line are the input line, and the output line. The input and output lines are 1D double arrays. The input line is extended appropriately according to the filter size and origin. The output line must be modified in-place with the result.

**Parameters**

- `input` [array_like] The input array.
- `function` [{callable, scipy.LowLevelCallable}] Function to apply along given axis.
- `filter_size` [scalar] Length of the filter.
- `axis` [int, optional] The axis of `input` along which to calculate. Default is -1.
- `output` [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- `mode` [{‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘reflect’. Behavior for each valid value is as follows:
  - ‘reflect’ (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel.
  - ‘constant’ (k k k k | a b c d | k k k k)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
  - ‘nearest’ (a a a a | a b c d | d d d d)
    The input is extended by replicating the last pixel.
  - ‘mirror’ (d c b | a b c d | c b a)
    The input is extended by reflecting about the center of the last pixel.
  - ‘wrap’ (a b c d | a b c d | a b c d)
    The input is extended by wrapping around to the opposite edge.
- `cval` [scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0.
- `origin` [int, optional] Controls the placement of the filter on the input array's pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right.
- `extra_arguments` [sequence, optional] Sequence of extra positional arguments to pass to passed function.
- `extra_keywords` [dict, optional] dict of extra keyword arguments to pass to passed function.

**Notes**

This function also accepts low-level callback functions with one of the following signatures and wrapped in `scipy.LowLevelCallable`:

```c
int function(double *input_line, npy_intp input_length,
              double *output_line, npy_intp output_length,
              void *user_data)
```

```c
int function(double *input_line, intptr_t input_length,
              double *output_line, intptr_t output_length,
              void *user_data)
```
The calling function iterates over the lines of the input and output arrays, calling the callback function at each line. The current line is extended according to the border conditions set by the calling function, and the result is copied into the array that is passed through `input_line`. The length of the input line (after extension) is passed through `input_length`. The callback function should apply the filter and store the result in the array passed through `output_line`. The length of the output line is passed through `output_length`. `user_data` is the data pointer provided to `scipy.LowLevelCallable` as-is.

The callback function must return an integer error status that is zero if something went wrong and one otherwise. If an error occurs, you should normally set the python error status with an informative message before returning, otherwise a default error message is set by the calling function.

In addition, some other low-level function pointer specifications are accepted, but these are for backward compatibility only and should not be used in new code.

### scipy.ndimage.generic_gradient_magnitude

```python
def scipy.ndimage.generic_gradient_magnitude(input, derivative, output=None, mode='reflect', cval=0.0, extra_arguments=(), extra_keywords=None)
```

Gradient magnitude using a provided gradient function.

**Parameters**

- `input` [array_like] The input array.
- `derivative` [callable] Callable with the following signature:

  ```python
def derivative(input, axis, output, mode, cval, *extra_arguments, **extra_keywords)
```

  See `extra_arguments`, `extra_keywords` below. `derivative` can assume that `input` and `output` are ndarrays. Note that the output from `derivative` is modified in place; be careful to copy important inputs before returning them.

- `output` [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- `mode` [str or sequence, optional] The `mode` parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:
  - ‘reflect’ (d c b a | a b c d | d c b a) The input is extended by reflecting about the edge of the last pixel.
  - ‘constant’ (k k k k | a b c d | k k k k) The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
  - ‘nearest’ (a a a a | a b c d | d d d d) The input is extended by replicating the last pixel.
  - ‘mirror’ (d c b | a b c d | c b a) The input is extended by reflecting about the center of the last pixel.
  - ‘wrap’ (a b c d | a b c d | a b c d) The input is extended by wrapping around to the opposite edge.
- `cval` [scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0.
- `extra_keywords` [dict, optional] dict of extra keyword arguments to pass to passed function.
- `extra_arguments` [sequence, optional] Sequence of extra positional arguments to pass to passed function.
scipy.ndimage.generic_laplace

scipy.ndimage.generic_laplace(input, derivative2, output=None, mode='reflect', cval=0.0, extra_arguments=(), extra_keywords=None)

N-dimensional Laplace filter using a provided second derivative function.

**Parameters**

- **input** [array_like] The input array.
- **derivative2** [callable] Callable with the following signature:

```
    derivative2(input, axis, output, mode, cval,
                *extra_arguments, **extra_keywords)
```

See `extra_arguments`, `extra_keywords` below.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [str or sequence, optional] The `mode` parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:
  - 'reflect' (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel.
  - 'constant' (k k k k | a b c d | k k k k)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
  - 'nearest' (a a a a | a b c d | d d d d)
    The input is extended by replicating the last pixel.
  - 'mirror' (d c b | a b c d | c b a)
    The input is extended by reflecting about the center of the last pixel.
  - 'wrap' (a b c d | a b c d | a b c d)
    The input is extended by wrapping around to the opposite edge.
- **cval** [scalar, optional] Value to fill past edges of input if `mode` is 'constant'. Default is 0.0.
- **extra_keywords** [dict, optional] dict of extra keyword arguments to pass to passed function.
- **extra_arguments** [sequence, optional] Sequence of extra positional arguments to pass to passed function.

scipy.ndimage.laplace

scipy.ndimage.laplace(input, output=None, mode='reflect', cval=0.0)

N-dimensional Laplace filter based on approximate second derivatives.

**Parameters**

- **input** [array_like] The input array.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [str or sequence, optional] The `mode` parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:
  - 'reflect' (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel.
The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.

The input is extended by replicating the last pixel.

The input is extended by reflecting about the center of the last pixel.

The input is extended by wrapping around to the opposite edge.

**cval**

[scalar, optional] Value to fill past edges of input if `mode` is 'constant'. Default is 0.0.

### Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.laplace(ascent)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```

**scipy.ndimage.maximum_filter**

`scipy.ndimage.maximum_filter` *(input, size=None, footprint=None, output=None, mode='reflect', cval=0.0, origin=0)*

Calculate a multi-dimensional maximum filter.

**Parameters**
input [array_like] The input array.
size [scalar or tuple, optional] See footprint, below. Ignored if footprint is given.
footprint [array, optional] Either size or footprint must be defined. size gives the shape that is taken from the input array, at every element position, to define the input to the filter function. footprint is a boolean array that specifies (implicitly) a shape, but also which of the elements within this shape will get passed to the filter function. Thus size=(n,m) is equivalent to footprint=np.ones((n,m)). We adjust size to the number of dimensions of the input array, so that, if the input array is shape (10,10,10), and size is 2, then the actual size used is (2,2,2). When footprint is given, size is ignored.
output [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
mode [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:
   'reflect' (d c b a | a b c d | d c b a)
       The input is extended by reflecting about the edge of the last pixel.
   'constant' (k k k k | a b c d | k k k k)
       The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
   'nearest' (a a a a | a b c d | d d d d)
       The input is extended by replicating the last pixel.
   'mirror' (d c b | a b c d | c b a)
       The input is extended by reflecting about the center of the last pixel.
   'wrap' (a b c d | a b c d | a b c d)
       The input is extended by wrapping around to the opposite edge.

cval [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
origin [int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

Returns
maximum_filter [ndarray] Filtered array. Has the same shape as input.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray() # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121) # left side
>>> ax2 = fig.add_subplot(122) # right side
>>> ascent = misc.ascent()
>>> result = ndimage.maximum_filter(ascent, size=20)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```
scipy.ndimage.maximum_filter1d

scipy.ndimage.maximum_filter1d(input, size, axis=-1, output=None, mode='reflect', cval=0.0, origin=0)

Calculate a one-dimensional maximum filter along the given axis.

The lines of the array along the given axis are filtered with a maximum filter of given size.

**Parameters**

- **input** [array_like] The input array.
- **size** [int] Length along which to calculate the 1-D maximum.
- **axis** [int, optional] The axis of input along which to calculate. Default is -1.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** ['reflect', 'constant', 'nearest', 'mirror', 'wrap'], optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is 'reflect'. Behavior for each valid value is as follows:
  - 'reflect' (d c b a | a b c d | d c b a)
    - The input is extended by reflecting about the edge of the last pixel.
  - 'constant' (k k k k | a b c d | k k k k)
    - The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - 'nearest' (a a a a | a b c d | d d d d)
    - The input is extended by replicating the last pixel.
  - 'mirror' (d c b | a b c d | c b a)
    - The input is extended by reflecting about the center of the last pixel.
  - 'wrap' (a b c d | a b c d | a b c d)
    - The input is extended by wrapping around to the opposite edge.
- **cval** [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.
- **origin** [int, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right.

**Returns**
maximum1d

[ndarray, None] Maximum-filtered array with same shape as input. None if output is not None

Notes

This function implements the MAXLIST algorithm [1], as described by Richard Harter [2], and has a guaranteed O(n) performance, n being the input length, regardless of filter size.

References

[1], [2]

Examples

```python
>>> from scipy.ndimage import maximum_filter1d
>>> maximum_filter1d([2, 8, 0, 4, 1, 9, 9, 0], size=3)
array([8, 8, 8, 4, 9, 9, 9, 9])
```

scipy.ndimage.median_filter

scipy.ndimage.median_filter(input, size=None, footprint=None, output=None, mode='reflect', cval=0.0, origin=0)

Calculate a multidimensional median filter.

Parameters

input [array_like] The input array.

size [scalar or tuple, optional] See footprint, below. Ignored if footprint is given.

footprint [array, optional] Either size or footprint must be defined. size gives the shape that is taken from the input array, at every element position, to define the input to the filter function. footprint is a boolean array that specifies (implicitly) a shape, but also which of the elements within this shape will get passed to the filter function. Thus size=(n,m) is equivalent to footprint=np.ones((n,m)). We adjust size to the number of dimensions of the input array, so that, if the input array is shape (10,10,10), and size is 2, then the actual size used is (2,2,2). When footprint is given, size is ignored.

output [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

mode [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:

‘reflect’ (d c b a | a b c d | d c b a)

The input is extended by reflecting about the edge of the last pixel.

‘constant’ (k k k k | a b c d | k k k k)

The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.

‘nearest’ (a a a a | a b c d | d d d d)

The input is extended by replicating the last pixel.

‘mirror’ (d c b | a b c | c b a)

The input is extended by reflecting about the center of the last pixel.
scipy.ndimage.minimum_filter

scipy.ndimage.minimum_filter(input, size=None, footprint=None, output=None, mode='reflect', cval=0.0, origin=0)

Calculate a multi-dimensional minimum filter.
Parameters

- **input** [array_like] The input array.
- **size** [scalar or tuple, optional] See footprint, below. Ignored if footprint is given.
- **footprint** [array, optional] Either size or footprint must be defined. size gives the shape that is taken from the input array, at every element position, to define the input to the filter function. footprint is a boolean array that specifies (implicitly) a shape, but also which of the elements within this shape will get passed to the filter function. Thus size=(n,m) is equivalent to footprint=np.ones((n,m)). We adjust size to the number of dimensions of the input array, so that, if the input array is shape (10,10,10), and size is 2, then the actual size used is (2,2,2). When footprint is given, size is ignored.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:
  - **reflect** (`d c b a | a b c d | d c b a`)
    - The input is extended by reflecting about the edge of the last pixel.
  - **constant** (`k k k k | a b c d | k k k k`)
    - The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
  - **nearest** (`a a a a | a b c d | d d d d`)
    - The input is extended by replicating the last pixel.
  - **mirror** (`d c b | a b c d | c b a`)
    - The input is extended by reflecting about the center of the last pixel.
  - **wrap** (`a b c d | a b c d | a b c d`)
    - The input is extended by wrapping around to the opposite edge.
- **cval** [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
- **origin** [int or sequence, optional] Controls the placement of the filter on the input array's pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

Returns

- **minimum_filter** [ndarray] Filtered array. Has the same shape as `input`.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.minimum_filter(ascent, size=20)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```
scipy.ndimage.minimum_filter1d

scipy.ndimage.minimum_filter1d(input, size, axis=-1, output=None, mode='reflect', cval=0.0, origin=0)

Calculate a one-dimensional minimum filter along the given axis.

The lines of the array along the given axis are filtered with a minimum filter of given size.

Parameters

**input** [array_like] The input array.

**size** [int] length along which to calculate 1D minimum

**axis** [int, optional] The axis of input along which to calculate. Default is -1.

**output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

**mode** [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is 'reflect'. Behavior for each valid value is as follows:

- **reflect** (d c b a | a b c d | d c b a)
  The input is extended by reflecting about the edge of the last pixel.

- **constant** (k k k k | a b c d | k k k k)
  The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.

- **nearest** (a a a a | a b c d | d d d d)
  The input is extended by replicating the last pixel.

- **mirror** (d c b | a b c d | b a)
  The input is extended by reflecting about the center of the last pixel.

- **wrap** (a b c d | a b c d | a b c d)
  The input is extended by wrapping around to the opposite edge.

**cval** [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.

**origin** [int, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right.
Notes

This function implements the MINLIST algorithm [1], as described by Richard Harter [2], and has a guaranteed O(n) performance, n being the input length, regardless of filter size.

References

[1], [2]

Examples

```python
>>> from scipy.ndimage import minimum_filter1d
>>> minimum_filter1d([2, 8, 0, 4, 1, 9, 9, 0], size=3)
array([2, 0, 0, 0, 1, 1, 0, 0])
```

scipy.ndimage.percentile_filter

scipy.ndimage.**percentile_filter**(*input*, *percentile*, *size=None*, *footprint=None*, *output=None*, 
*mode='reflect'*, *cval=0.0*, *origin=0*)

Calculate a multi-dimensional percentile filter.

**Parameters**

- **input**: [array_like] The input array.
- **percentile**: [scalar] The percentile parameter may be less than zero, i.e., percentile = -20 equals percentile = 80
- **size**: [scalar or tuple, optional] See footprint, below. Ignored if footprint is given.
- **footprint**: [array, optional] Either size or footprint must be defined. size gives the shape that is taken from the input array, at every element position, to define the input to the filter function. footprint is a boolean array that specifies (implicitly) a shape, but also which of the elements within this shape will get passed to the filter function. Thus size=(n,m) is equivalent to footprint=np.ones((n,m)). We adjust size to the number of dimensions of the input array, so that, if the input array is shape (10,10,10), and size is 2, then the actual size used is (2,2,2). When footprint is given, size is ignored.
- **output**: [array or dttype, optional] The array in which to place the output, or the dttype of the returned array. By default an array of the same dttype as input will be created.
- **mode**: [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:
  - ’reflect’ (*d c b a* | *a b c d* | *d c b a*)
    - The input is extended by reflecting about the edge of the last pixel.
  - ’constant’ (*k k k k* | *a b c d* | *k k k k*)
    - The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - ’nearest’ (*a a a a* | *a b c d* | *d d d d*)
    - The input is extended by replicating the last pixel.
  - ’mirror’ (*d c b a* | *a b c d* | *c b a*)
    - The input is extended by reflecting about the center of the last pixel.
  - ’wrap’ (*a b c d* | *a b c d* | *a b c d*)
    - The input is extended by wrapping around to the opposite edge.
- **cval**: [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.
origin

[int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

Returns

percentile_filter

[ndarray] Filtered array. Has the same shape as input.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.percentile_filter(ascent, percentile=20, size=20)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```

scipy.ndimage.prewitt

scipy.ndimage.prewitt (input, axis=-1, output=None, mode='reflect', cval=0.0)
Calculate a Prewitt filter.

Parameters

input [array_like] The input array.
axis [int, optional] The axis of input along which to calculate. Default is -1.
output [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

mode [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:

- **reflect** (`d c b a | a b c d | d c b a`)
  The input is extended by reflecting about the edge of the last pixel.

- **constant** (`k k k k | a b c d | k k k k`)
  The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.

- **nearest** (`a a a a | a b c d | d d d d`)
  The input is extended by replicating the last pixel.

- **mirror** (`d c b | a b c d | c b a`)
  The input is extended by reflecting about the center of the last pixel.

- **wrap** (`a b c d | a b c d | a b c d`)
  The input is extended by wrapping around to the opposite edge.

cval [scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0.

### Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.prewitt(ascent)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```

![Image](image_url)

6.16. Multi-dimensional image processing (`scipy.ndimage`)
scipy.ndimage.rank_filter

Calculate a multi-dimensional rank filter.

Parameters

- **input** ([array_like]) The input array.
- **rank** ([int]) The rank parameter may be less then zero, i.e., rank = -1 indicates the largest element.
- **size** ([scalar or tuple, optional]) See footprint, below. Ignored if footprint is given.
- **footprint** ([array, optional]) Either size or footprint must be defined. size gives the shape that is taken from the input array, at every element position, to define the input to the filter function. footprint is a boolean array that specifies (implicitly) a shape, but also which of the elements within this shape will get passed to the filter function. Thus size=(n,m) is equivalent to footprint=np.ones((n,m)). We adjust size to the number of dimensions of the input array, so that, if the input array is shape (10,10,10), and size is 2, then the actual size used is (2,2,2). When footprint is given, size is ignored.
- **output** ([array or dtype, optional]) The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** ([str or sequence, optional]) The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:
  - ‘reflect’ (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel.
  - ‘constant’ (k k k | a b c d | k k k k)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - ‘nearest’ (a a a a | a b c d | d d d d)
    The input is extended by replicating the last pixel.
  - ‘mirror’ (d c b | a b c d | c b a)
    The input is extended by reflecting about the center of the last pixel.
  - ‘wrap’ (a b c d | a b c d | a b c d)
    The input is extended by wrapping around to the opposite edge.
- **cval** ([scalar, optional]) Value to fill past edges of input if mode is ‘constant’. Default is 0.0.
- **origin** ([int or sequence, optional]) Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

Returns

- **rank_filter** ([ndarray]) Filtered array. Has the same shape as input.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
(continues on next page)```
scipy.ndimage.sobel

Calculate a Sobel filter.

**Parameters**

- **input** [array_like]: The input array.
- **axis** [int, optional]: The axis of `input` along which to calculate. Default is -1.
- **output** [array or dtype, optional]: The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [str or sequence, optional]: The `mode` parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:
  - **reflect**: The input is extended by reflecting about the edge of the last pixel.
  - **constant**: The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
  - **nearest**: The input is extended by replicating the last pixel.
  - **mirror**: The input is extended by reflecting about the center of the last pixel.
  - **wrap**: The input is extended by wrapping around to the opposite edge.
cval     [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()    # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)    # left side
>>> ax2 = fig.add_subplot(122)    # right side
>>> ascent = misc.ascent()
>>> result = ndimage.sobel(ascent)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```

scipy.ndimage.uniform_filter

`scipy.ndimage.uniform_filter(input, size=3, output=None, mode='reflect', cval=0.0, origin=0)`  
Multi-dimensional uniform filter.

**Parameters**

- **input**  [array_like] The input array.
- **size**  [int or sequence of ints, optional] The sizes of the uniform filter are given for each axis as a sequence, or as a single number, in which case the size is equal for all axes.
- **output**  [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode**  [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:
'reflect' (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel.
'constant' (k k k k | a b c d | k k k k)
    The input is extended by filling all values beyond the edge with the same constant
    value, defined by the cval parameter.
'nearest' (a a a a | a b c d | d d d d)
    The input is extended by replicating the last pixel.
'mirror' (d c b | a b c d | c b a)
    The input is extended by reflecting about the center of the last pixel.
'wrap' (a b c d | a b c d | a b c d)
    The input is extended by wrapping around to the opposite edge.

   cval
   [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
   origin
   [int or sequence, optional] Controls the placement of the filter on the input array's pixels. A
   value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter
   to the left, and negative ones to the right. By passing a sequence of origins with length equal
   to the number of dimensions of the input array, different shifts can be specified along each
   axis.

   Returns

   uniform_filter
   [ndarray] Filtered array. Has the same shape as input.

Notes

The multi-dimensional filter is implemented as a sequence of one-dimensional uniform filters. The intermediate
arrays are stored in the same data type as the output. Therefore, for output types with a limited precision, the results
may be imprecise because intermediate results may be stored with insufficient precision.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray() # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121) # left side
>>> ax2 = fig.add_subplot(122) # right side
>>> ascent = misc.ascent()
>>> result = ndimage.uniform_filter(ascent, size=20)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```

scipy.ndimage.uniform_filter1d

scipy.ndimage.uniform_filter1d(input, size=-1, axis=-1, output=None, mode='reflect', cval=0.0, origin=0)

Calculate a one-dimensional uniform filter along the given axis.

The lines of the array along the given axis are filtered with a uniform filter of given size.

Parameters
**input**  
[array_like] The input array.

**size**  
[int] length of uniform filter

**axis**  
[int, optional] The axis of input along which to calculate. Default is -1.

**output**  
[array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

**mode**  
[{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is 'reflect'. Behavior for each valid value is as follows:

- **reflect**  
  \[
  \begin{array}{cccc|cccc|cccc}
  d & c & b & a & | & a & b & c & d & | & d & c & b & a \\
  \end{array}
  \]
  
The input is extended by reflecting about the edge of the last pixel.

- **constant**  
  \[
  \begin{array}{cccc|cccc|cccc}
  k & k & k & k & | & a & b & c & d & | & k & k & k & k \\
  \end{array}
  \]
  
The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.

- **nearest**  
  \[
  \begin{array}{cccc|cccc|cccc}
  a & a & a & a & | & a & b & c & d & | & d & d & d & d \\
  \end{array}
  \]
  
The input is extended by replicating the last pixel.

- **mirror**  
  \[
  \begin{array}{cccc|cccc|cccc}
  d & c & b & | & a & b & c & d & | & c & b & a \\
  \end{array}
  \]
  
The input is extended by reflecting about the center of the last pixel.

- **wrap**  
  \[
  \begin{array}{cccc|cccc|cccc}
  a & b & c & d & | & a & b & c & d & | & a & b & c & d \\
  \end{array}
  \]
  
The input is extended by wrapping around to the opposite edge.

**cval**  
[scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.

**origin**  
[int, optional] Controls the placement of the filter on the input array's pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right.

**Examples**

```python
>>> from scipy.ndimage import uniform_filter1d
>>> uniform_filter1d([2, 8, 0, 4, 1, 9, 9, 0], size=3)
array([4, 3, 4, 1, 4, 6, 6, 3])
```
6.16.2 Fourier filters

- `fourier_ellipsoid(input, size[, n, axis, output])` Multi-dimensional ellipsoid fourier filter.
- `fourier_gaussian(input, sigma[, n, axis, output])` Multi-dimensional Gaussian fourier filter.
- `fourier_shift(input, shift[, n, axis, output])` Multi-dimensional fourier shift filter.
- `fourier_uniform(input, size[, n, axis, output])` Multi-dimensional uniform fourier filter.

**scipy.ndimage.fourier_ellipsoid**

`scipy.ndimage.fourier_ellipsoid(input, size[, n=-1, axis=-1, output=None])`

Multi-dimensional ellipsoid fourier filter.

The array is multiplied with the fourier transform of a ellipsoid of given sizes.

**Parameters**

- **input** [array_like] The input array.
- **size** [float or sequence] The size of the box used for filtering. If a float, `size` is the same for all axes. If a sequence, `size` has to contain one value for each axis.
- **n** [int, optional] If `n` is negative (default), then the input is assumed to be the result of a complex fft. If `n` is larger than or equal to zero, the input is assumed to be the result of a real fft, and `n` gives the length of the array before transformation along the real transform direction.
- **axis** [int, optional] The axis of the real transform.
- **output** [ndarray, optional] If given, the result of filtering the input is placed in this array. None is returned in this case.

**Returns**

- `fourier_ellipsoid` [ndarray] The filtered input.

**Notes**

This function is implemented for arrays of rank 1, 2, or 3.

**Examples**

```python
>>> from scipy import ndimage, misc
>>> import numpy.fft
>>> import matplotlib.pyplot as plt
>>> fig, (ax1, ax2) = plt.subplots(1, 2)
>>> plt.gray()  # show the filtered result in grayscale
>>> ascent = misc.ascent()
>>> input_ = numpy.fft.fft2(ascent)
>>> result = ndimage.fourier_ellipsoid(input_, size=20)
>>> result = numpy.fft.ifft2(result)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result.real)  # the imaginary part is an artifact
>>> plt.show()
```
scipy.ndimage.fourier_gaussian

scipy.ndimage.fourier_gaussian(input, sigma, n=-1, axis=-1, output=None)

Multi-dimensional Gaussian fourier filter.

The array is multiplied with the fourier transform of a Gaussian kernel.

Parameters

- **input** [array_like] The input array.
- **sigma** [float or sequence] The sigma of the Gaussian kernel. If a float, sigma is the same for all axes. If a sequence, sigma has to contain one value for each axis.
- **n** [int, optional] If n is negative (default), then the input is assumed to be the result of a complex fft. If n is larger than or equal to zero, the input is assumed to be the result of a real fft, and n gives the length of the array before transformation along the real transform direction.
- **axis** [int, optional] The axis of the real transform.
- **output** [ndarray, optional] If given, the result of filtering the input is placed in this array. None is returned in this case.

Returns

fourier_gaussian [ndarray] The filtered input.

Examples

```python
>>> from scipy import ndimage, misc
>>> import numpy.fft
>>> import matplotlib.pyplot as plt
>>> fig, (ax1, ax2) = plt.subplots(1, 2)
>>> plt.gray()  # show the filtered result in grayscale
>>> ascent = misc.ascent()
>>> input_ = numpy.fft.fft2(ascent)
>>> result = ndimage.fourier_gaussian(input_, sigma=4)
>>> result = numpy.fft.ifft2(result)
```
scipy.ndimage.fourier_shift

scipy.ndimage.fourier_shift(input, shift, n=-1, axis=-1, output=None)

Multi-dimensional fourier shift filter.

The array is multiplied with the fourier transform of a shift operation.

Parameters

- **input** [array_like] The input array.
- **shift** [float or sequence] The size of the box used for filtering. If a float, shift is the same for all axes. If a sequence, shift has to contain one value for each axis.
- **n** [int, optional] If n is negative (default), then the input is assumed to be the result of a complex fft. If n is larger than or equal to zero, the input is assumed to be the result of a real fft, and n gives the length of the array before transformation along the real transform direction.
- **axis** [int, optional] The axis of the real transform.
- **output** [ndarray, optional] If given, the result of shifting the input is placed in this array. None is returned in this case.

Returns

fourier_shift [ndarray] The shifted input.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> from numpy import fft
```

(continues on next page)
>>> fig, (ax1, ax2) = plt.subplots(1, 2)
>>> plt.gray()  # show the filtered result in grayscale
>>> ascent = misc.ascent()
>>> input_ = numpy.fft.fft2(ascent)
>>> result = ndimage.fourier_shift(input_, shift=200)
>>> result = numpy.fft.ifft2(result)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result.real)  # the imaginary part is an artifact
>>> plt.show()
Examples

```python
>>> from scipy import ndimage, misc
>>> import numpy.fft
>>> import matplotlib.pyplot as plt
>>> fig, (ax1, ax2) = plt.subplots(1, 2)
>>> plt.gray()  # show the filtered result in grayscale
>>> ascent = misc.ascent()
>>> input_ = numpy.fft.fft2(ascent)
>>> result = ndimage.fourier_uniform(input_, size=20)
>>> result = numpy.fft.ifft2(result)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result.real)  # the imaginary part is an artifact
>>> plt.show()
```

**scipy.ndimage.affine_transform**

*scipy.ndimage.affine_transform*(input, matrix, offset=0.0, output_shape=None, output=None, order=3, mode='constant', cval=0.0, prefilter=True)

Apply an affine transformation.

Given an output image pixel index vector o, the pixel value is determined from the input image at position `np.dot(matrix, o) + offset`.

This does ‘pull’ (or ‘backward’) resampling, transforming the output space to the input to locate data. Affine transformations are often described in the ‘push’ (or ‘forward’) direction, transforming input to output. If you have a matrix for the ‘push’ transformation, use its inverse (`numpy.linalg.inv`) in this function.

**Parameters**

- **input** [array_like] The input array.
- **matrix** [ndarray] The inverse coordinate transformation matrix, mapping output coordinates to input coordinates. If ndim is the number of dimensions of input, the given matrix must have one of the following shapes:
  - (ndim, ndim): the linear transformation matrix for each output coordinate.
  - (ndim,): assume that the 2D transformation matrix is diagonal, with the diagonal specified by the given value. A more efficient algorithm is then used that exploits the separability of the problem.
  - (ndim + 1, ndim + 1): assume that the transformation is specified using homogeneous coordinates [1]. In this case, any value passed to offset is ignored.
  - (ndim, ndim + 1): as above, but the bottom row of a homogeneous transformation matrix is always `[0, 0, ..., 1]` and may be omitted.
- **offset** [float or sequence, optional] The offset into the array where the transform is applied. If a float, offset is the same for each axis. If a sequence, offset should contain one value for each axis.
- **output_shape** [tuple of ints, optional] Shape tuple.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **order** [int, optional] The order of the spline interpolation, default is 3. The order has to be in the range 0-5.
- **mode** [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘constant’. Behavior for each valid value is as follows:
  - ‘reflect’ *(d c b a | a b c d | d c b a)*
    The input is extended by reflecting about the edge of the last pixel.
  - ‘constant’ *(k k k k | a b c d | k k k k)*
    The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - ‘nearest’ *(a a a a | a b c d | d d d d)*
    The input is extended by replicating the last pixel.
  - ‘mirror’ *(d c b | a b c d | c b a)*
    The input is extended by reflecting about the center of the last pixel.
  - ‘wrap’ *(a b c d | a b c d | a b c d)*
    The input is extended by wrapping around to the opposite edge.
- **cval** [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.
- **prefilter** [bool, optional] Determines if the input array is prefiltered with `spline_filter` before interpolation. The default is True, which will create a temporary `float64` array of filtered values if order > 1. If setting this to False, the output will be slightly blurred if order > 1, unless the input is prefiltered, i.e. it is the result of calling `spline_filter` on the original input.
Returns

affine_transform
[ndarray] The transformed input.

Notes

The given matrix and offset are used to find for each point in the output the corresponding coordinates in the input by an affine transformation. The value of the input at those coordinates is determined by spline interpolation of the requested order. Points outside the boundaries of the input are filled according to the given mode.

Changed in version 0.18.0: Previously, the exact interpretation of the affine transformation depended on whether the matrix was supplied as a one-dimensional or two-dimensional array. If a one-dimensional array was supplied to the matrix parameter, the output pixel value at index $o$ was determined from the input image at position $\text{matrix} * (o + \text{offset})$.

References

[1]

scipy.ndimage.geometric_transform

scipy.ndimage.geometric_transform(input, mapping, output_shape=None, output=None, order=3, mode='constant', cval=0.0, prefilter=True, extra_arguments=(), extra_keywords={})

Apply an arbitrary geometric transform.

The given mapping function is used to find, for each point in the output, the corresponding coordinates in the input. The value of the input at those coordinates is determined by spline interpolation of the requested order.

Parameters

input [array_like] The input array.
mapping [{callable, scipy.LowLevelCallable}] A callable object that accepts a tuple of length equal to the output array rank, and returns the corresponding input coordinates as a tuple of length equal to the input array rank.
output_shape [tuple of ints, optional] Shape tuple.
output [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
order [int, optional] The order of the spline interpolation, default is 3. The order has to be in the range 0-5.
mode [{‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘constant’. Behavior for each valid value is as follows:
   ‘reflect’ (d c b a | a b c d | d c b a)
       The input is extended by reflecting about the edge of the last pixel.
   ‘constant’ (k k k k | a b c d | k k k k)
       The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
   ‘nearest’ (a a a a | a b c d | d d d d)
       The input is extended by replicating the last pixel.
   ‘mirror’ (d c b | a b c d | c b a)
       The input is extended by reflecting about the center of the last pixel.
`'wrap' (a b c d | a b c d | a b c d)`

The input is extended by wrapping around to the opposite edge.

- `cval` [scalar, optional] Value to fill past edges of input if `mode` is 'constant'. Default is 0.0.
- `prefilter` [bool, optional] Determines if the input array is prefiltered with `spline_filter` before interpolation. The default is True, which will create a temporary `float64` array of filtered values if `order > 1`. If setting this to False, the output will be slightly blurred if `order > 1`, unless the input is prefiltered, i.e. it is the result of calling `spline_filter` on the original input.
- `extra_arguments` [tuple, optional] Extra arguments passed to `mapping`.
- `extra_keywords` [dict, optional] Extra keywords passed to `mapping`.

**Returns**

- `output` [ndarray] The filtered input.

**See also:**

`map_coordinates`, `affine_transform`, `spline_filter1d`

**Notes**

This function also accepts low-level callback functions with one the following signatures and wrapped in `scipy`.

**LowLevelCallable**:

```python
int mapping(npy_intp *output_coordinates, double *input_coordinates, int output_rank, int input_rank, void *user_data)
int mapping(intptr_t *output_coordinates, double *input_coordinates, int output_rank, int input_rank, void *user_data)
```

The calling function iterates over the elements of the output array, calling the callback function at each element. The coordinates of the current output element are passed through `output_coordinates`. The callback function must return the coordinates at which the input must be interpolated in `input_coordinates`. The rank of the input and output arrays are given by `input_rank` and `output_rank` respectively. `user_data` is the data pointer provided to `scipy.LowLevelCallable` as-is.

The callback function must return an integer error status that is zero if something went wrong and one otherwise. If an error occurs, you should normally set the python error status with an informative message before returning, otherwise a default error message is set by the calling function.

In addition, some other low-level function pointer specifications are accepted, but these are for backward compatibility only and should not be used in new code.

**Examples**

```python
>>> import numpy as np
>>> from scipy.ndimage import geometric_transform
>>> a = np.arange(12.).reshape((4, 3))
>>> def shift_func(output_coords):
...     return (output_coords[0] - 0.5, output_coords[1] - 0.5)
... >>> geometric_transform(a, shift_func)
array([[[ 0.,  0.,  0.],
        [ 0.,  0.,  0.],
        [ 0.,  0.,  0.]],
       [[ 0.,  0.,  0.],
        [ 0.,  0.,  0.],
        [ 0.,  0.,  0.]],
       [[ 0.,  0.,  0.],
        [ 0.,  0.,  0.],
        [ 0.,  0.,  0.]],
       [[ 0.,  0.,  0.],
        [ 0.,  0.,  0.],
        [ 0.,  0.,  0.]]])
```
```python
>>> b = [1, 2, 3, 4, 5]
>>> def shift_func(output_coords):
...     return (output_coords[0] - 3,)
...     
>>> geometric_transform(b, shift_func, mode='constant')
array([0, 0, 0, 1, 2])
>>> geometric_transform(b, shift_func, mode='nearest')
array([1, 1, 1, 1, 2])
>>> geometric_transform(b, shift_func, mode='reflect')
array([3, 2, 1, 1, 2])
>>> geometric_transform(b, shift_func, mode='wrap')
array([2, 3, 4, 1, 2])
```

### scipy.ndimage.map_coordinates

**scipy.ndimage.map_coordinates** *(input, coordinates, output=None, order=3, mode='constant', cval=0.0, prefilter=True)*

Map the input array to new coordinates by interpolation.

The array of coordinates is used to find, for each point in the output, the corresponding coordinates in the input. The value of the input at those coordinates is determined by spline interpolation of the requested order.

The shape of the output is derived from that of the coordinate array by dropping the first axis. The values of the array along the first axis are the coordinates in the input array at which the output value is found.

**Parameters**

- **input** [array_like] The input array.
- **coordinates** [array_like] The coordinates at which *input* is evaluated.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **order** [int, optional] The order of the spline interpolation, default is 3. The order has to be in the range 0-5.
- **mode** [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The *mode* parameter determines how the input array is extended beyond its boundaries. Default is 'constant'. Behavior for each valid value is as follows:
  - **reflect** *(d c b a | a b c d | d c b a)*
    The input is extended by reflecting about the edge of the last pixel.
  - **constant** *(k k k k | a b c d | k k k k)*
    The input is extended by filling all values beyond the edge with the same constant value, defined by the *cval* parameter.
  - **nearest** *(a a a a | a b c d | d d d d)*
    The input is extended by replicating the last pixel.
  - **mirror** *(d c b | a b c d | c b a)*
    The input is extended by reflecting about the center of the last pixel.
  - **wrap** *(a b c d | a b c d | a b c d)*
    The input is extended by wrapping around to the opposite edge.
- **cval** [scalar, optional] Value to fill past edges of input if *mode* is 'constant'. Default is 0.0.
prefilter [bool, optional] Determines if the input array is prefiltered with \texttt{spline\_filter} before interpolation. The default is True, which will create a temporary float64 array of filtered values if \texttt{order} > 1. If setting this to False, the output will be slightly blurred if \texttt{order} > 1, unless the input is prefiltered, i.e. it is the result of calling \texttt{spline\_filter} on the original input.

\textbf{Returns}

\texttt{map\_coordinates} [ndarray] The result of transforming the input. The shape of the output is derived from that of \texttt{coordinates} by dropping the first axis.

\textbf{See also:}

\texttt{spline\_filter, geometric\_transform, scipy\_interpolate}

\textbf{Examples}

```python
tfrom scipy import ndimage
da = np.arange(12.).reshape((4, 3))
da
array([[ 0.,  1.,  2.],
       [ 3.,  4.,  5.],
       [ 6.,  7.,  8.],
       [ 9., 10., 11.]])
ndimage.map_coordinates(a, [[0.5, 2], [0.5, 1]], order=1)
array([ 2.,  7.])
```

Above, the interpolated value of \texttt{a[0.5, 0.5]} gives output[0], while \texttt{a[2, 1]} is output[1].

```python
tinds = np.array([[0.5, 2], [0.5, 4]])
tndimage.map_coordinates(a, inds, order=1, cval=-33.3)
array([ 2., -33.3])
tndimage.map_coordinates(a, inds, order=1, mode='nearest')
array([ 2.,  8.])
tndimage.map_coordinates(a, inds, order=1, cval=0, output=bool)
array([ True, False])
```

\texttt{scipy.ndimage.rotate}

\texttt{scipy.ndimage.rotate(input, angle, axes=(1, 0), reshape=True, output=None, order=3, mode='constant', cval=0.0, prefilter=True)}

Rotate an array.

The array is rotated in the plane defined by the two axes given by the \texttt{axes} parameter using spline interpolation of the requested order.

\textbf{Parameters}

- \texttt{input} [array_like] The input array.
- \texttt{angle} [float] The rotation angle in degrees.
- \texttt{axes} [tuple of 2 ints, optional] The two axes that define the plane of rotation. Default is the first two axes.
- \texttt{reshape} [bool, optional] If \texttt{reshape} is true, the output shape is adapted so that the input array is contained completely in the output. Default is True.
**output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

**order** [int, optional] The order of the spline interpolation, default is 3. The order has to be in the range 0-5.

**mode** [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘constant’. Behavior for each valid value is as follows:

- **‘reflect’** (`d c b a | a b c d | d c b a`)
  The input is extended by reflecting about the edge of the last pixel.

- **‘constant’** (`k k k k | a b c d | k k k k`)
  The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.

- **‘nearest’** (`a a a a | a b c d | d d d d`)
  The input is extended by replicating the last pixel.

- **‘mirror’** (`d c b | a b c d | c b a`)
  The input is extended by reflecting about the center of the last pixel.

- **‘wrap’** (`a b c d | a b c d | a b c d`)
  The input is extended by wrapping around to the opposite edge.

**cval** [scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0.

**prefilter** [bool, optional] Determines if the input array is prefiltered with `spline_filter` before interpolation. The default is True, which will create a temporary float64 array of filtered values if `order > 1`. If setting this to False, the output will be slightly blurred if `order > 1`, unless the input is prefiltered, i.e. it is the result of calling `spline_filter` on the original input.

**Returns**

**rotate** [ndarray] The rotated input.

**Examples**

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure(figsize=(10, 3))
>>> ax1, ax2, ax3 = fig.subplots(1, 3)
>>> img = misc.ascent()
>>> img_45 = ndimage.rotate(img, 45, reshape=False)
>>> full_img_45 = ndimage.rotate(img, 45, reshape=True)
>>> ax1.imshow(img, cmap='gray')
>>> ax1.set_axis_off()
>>> ax2.imshow(img_45, cmap='gray')
>>> ax2.set_axis_off()
>>> ax3.imshow(full_img_45, cmap='gray')
>>> ax3.set_axis_off()
>>> fig.set_tight_layout(True)
>>> plt.show()
```

```python
>>> print(img.shape)
(512, 512)
>>> print(img_45.shape)
(512, 512)
>>> print(full_img_45.shape)
(724, 724)
```
scipy.ndimage.shift

scipy.ndimage.shift(input, shift, output=None, order=3, mode='constant', cval=0.0, prefilter=True)

Shift an array.

The array is shifted using spline interpolation of the requested order. Points outside the boundaries of the input are filled according to the given mode.

**Parameters**

- **input** [array_like] The input array.
- **shift** [float or sequence] The shift along the axes. If a float, *shift* is the same for each axis. If a sequence, *shift* should contain one value for each axis.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **order** [int, optional] The order of the spline interpolation, default is 3. The order has to be in the range 0-5.
- **mode** [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is 'constant'. Behavior for each valid value is as follows:
  - **reflect** (d c b a | a b c d | d c b a)
    
    The input is extended by reflecting about the edge of the last pixel.
  - **constant** (k k k k | a b c d | k k k k)
    
    The input is extended by filling all values beyond the edge with the same constant value, defined by the *cval* parameter.
  - **nearest** (a a a a | a b c d | d d d d)
    
    The input is extended by replicating the last pixel.
  - **mirror** (d c b | a b c d | c b a)
    
    The input is extended by reflecting about the center of the last pixel.
  - **wrap** (a b c d | a b c d | a b c d)
    
    The input is extended by wrapping around to the opposite edge.
- **cval** [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
- **prefilter** [bool, optional] Determines if the input array is prefiltered with `spline_filter` before interpolation. The default is True, which will create a temporary float64 array of filtered values if order > 1. If setting this to False, the output will be slightly blurred if order > 1, unless the input is prefiltered, i.e. it is the result of calling `spline_filter` on the original input.

**Returns**

- **shift** [ndarray] The shifted input.
scipy.ndimage.spline_filter

scipy.ndimage.spline_filter(input, order=3, output=<class 'numpy.float64'>, mode='mirror')

Multi-dimensional spline filter.

For more details, see spline_filter1d.

See also:

spline_filter1d

Notes

The multi-dimensional filter is implemented as a sequence of one-dimensional spline filters. The intermediate arrays are stored in the same data type as the output. Therefore, for output types with a limited precision, the results may be imprecise because intermediate results may be stored with insufficient precision.

scipy.ndimage.spline_filter1d

scipy.ndimage.spline_filter1d(input, order=3, axis=-1, output=<class 'numpy.float64'>, mode='mirror')

Calculate a one-dimensional spline filter along the given axis.

The lines of the array along the given axis are filtered by a spline filter. The order of the spline must be >= 2 and <= 5.

Parameters

input [array_like] The input array.

order [int, optional] The order of the spline, default is 3.

axis [int, optional] The axis along which the spline filter is applied. Default is the last axis.

output [ndarray or dtype, optional] The array in which to place the output, or the dtype of the returned array. Default is numpy.float64.

mode [{‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘constant’. Behavior for each valid value is as follows:

‘reflect’ (d c b a | a b c | d c b a)
The input is extended by reflecting about the edge of the last pixel.

‘constant’ (k k k k | a b c | k k k k)
The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.

‘nearest’ (a a a a | a b c d | d d d d)
The input is extended by replicating the last pixel.

‘mirror’ (d c b | a b c d | c b a)
The input is extended by reflecting about the center of the last pixel.

‘wrap’ (a b c d | a b c d | a b c)
The input is extended by wrapping around to the opposite edge.

Returns

spline_filter1d [ndarray] The filtered input.
Notes

All functions in `ndimage.interpolation` do spline interpolation of the input image. If using b-splines of `order > 1`, the input image values have to be converted to b-spline coefficients first, which is done by applying this one-dimensional filter sequentially along all axes of the input. All functions that require b-spline coefficients will automatically filter their inputs, a behavior controllable with the `prefilter` keyword argument. For functions that accept a `mode` parameter, the result will only be correct if it matches the `mode` used when filtering.

**scipy.ndimage.zoom**

```python
scipy.ndimage.zoom(input, zoom, output=None, order=3, mode='constant', cval=0.0, prefilter=True)
```

Zoom an array.

The array is zoomed using spline interpolation of the requested order.

**Parameters**

- **input** [array_like] The input array.
- **zoom** [float or sequence] The zoom factor along the axes. If a float, `zoom` is the same for each axis. If a sequence, `zoom` should contain one value for each axis.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **order** [int, optional] The order of the spline interpolation, default is 3. The order has to be in the range 0-5.
- **mode** [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The `mode` parameter determines how the input array is extended beyond its boundaries. Default is 'constant'. Behavior for each valid value is as follows:
  - ‘reflect’ (d c b a | a b c d | d c b a)
    - The input is extended by reflecting about the edge of the last pixel.
  - ‘constant’ (k k k k | a b c d | k k k k)
    - The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
  - ‘nearest’ (a a a a | a b c d | d d d d)
    - The input is extended by replicating the last pixel.
  - ‘mirror’ (d c b | a b c d | c b a)
    - The input is extended by reflecting about the center of the last pixel.
  - ‘wrap’ (a b c d | a b c d | a b c d)
    - The input is extended by wrapping around to the opposite edge.
- **cval** [scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0.
- **prefilter** [bool, optional] Determines if the input array is prefiltered with `spline_filter` before interpolation. The default is True, which will create a temporary `float64` array of filtered values if `order > 1`. If setting this to False, the output will be slightly blurred if `order > 1`, unless the input is prefiltered, i.e. it is the result of calling `spline_filter` on the original input.

**Returns**

- **zoom** [ndarray] The zoomed input.

**Examples**

```python
given the following code:

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> im = misc谠lena()
```
```python
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.zoom(ascent, 3.0)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```

```python
>>> print(ascent.shape)
(512, 512)
```

```python
>>> print(result.shape)
(1536, 1536)
```

scipy.ndimage.center_of_mass

scipy.ndimage.center_of_mass (input, labels=None, index=None)

Calculate the center of mass of the values of an array at labels.

**Parameters**

- **input** [ndarray] Data from which to calculate center-of-mass. The masses can either be positive or negative.
- **labels** [ndarray, optional] Labels for objects in input, as generated by ndimage.label. Only used with index. Dimensions must be the same as input.
- **index** [int or sequence of ints, optional] Labels for which to calculate centers-of-mass. If not specified, all labels greater than zero are used. Only used with labels.

**Returns**

- **center_of_mass** [tuple, or list of tuples] Coordinates of centers-of-mass.

**Examples**

```python
>>> a = np.array([[0, 0, 0, 0],
...                [0, 1, 1, 0],
...                [0, 1, 1, 0],
...                [0, 1, 1, 0]])
>>> from scipy import ndimage
>>> ndimage.measurements.center_of_mass(a)
(2.0, 1.5)
```

Calculation of multiple objects in an image

```python
>>> b = np.array([[0, 1, 1, 0],
...                [0, 1, 0, 0],
...                [0, 0, 0, 0],
...                [0, 0, 1, 1],
...                [0, 0, 1, 1]])
```
Negative masses are also accepted, which can occur for example when bias is removed from measured data due to random noise.

```python
>>> c = np.array(([-1, 0, 0, 0], ...
...                [0, -1, -1, 0], ...
...                [0, 1, -1, 0], ...
...                [0, 1, 1, 0]))
>>> ndimage.measurements.center_of_mass(c)
(-4.0, 1.0)
```

If there are division by zero issues, the function does not raise an error but rather issues a RuntimeWarning before returning inf and/or NaN.

```python
>>> d = np.array([-1, 1])
>>> ndimage.measurements.center_of_mass(d)
(inf,)
```

### scipy.ndimage.extrema

**scipy.ndimage.extrema** (*input, labels=None, index=None*)

Calculate the minimums and maximums of the values of an array at labels, along with their positions.

**Parameters**

- **input**: [ndarray] Nd-image data to process.
- **labels**: [ndarray, optional] Labels of features in input. If not None, must be same shape as input.
- **index**: [int or sequence of ints, optional] Labels to include in output. If None (default), all values where non-zero labels are used.

**Returns**

- **minimums, maximums**: [int or ndarray] Values of minimums and maximums in each feature.
- **min_positions, max_positions**: [tuple or list of tuples] Each tuple gives the n-D coordinates of the corresponding minimum or maximum.

**See also:**

- `maximum`, `minimum`, `maximum_position`, `minimum_position`, `center_of_mass`

**Examples**

```python
>>> a = np.array([[1, 2, 0, 0], ...
...               [5, 3, 0, 4], ...
...               [0, 0, 0, 7], ...
...               [9, 3, 0, 0]])
>>> from scipy import ndimage
```
Features to process can be specified using `labels` and `index`:

```python
>>> lb1, nlbl = ndimage.label(a)
>>> ndimage.extrema(a, lb1, index=np.arange(1, nlbl+1))
(array([1, 4, 3]),
 array([5, 7, 9]),
 [(0, 0), (1, 3), (3, 1)],
 [(1, 0), (2, 3), (3, 0)])
```

If no index is given, non-zero `labels` are processed:

```python
>>> ndimage.extrema(a, lb1)
(1, 9, (0, 0), (3, 0))
```

### scipy.ndimage.find_objects

**scipy.ndimage.find_objects** *(input, max_label=0)*

Find objects in a labeled array.

**Parameters**

- **input**  
  [ndarray of ints] Array containing objects defined by different labels. Labels with value 0 are ignored.

- **max_label**  
  [int, optional] Maximum label to be searched for in `input`. If max_label is not given, the positions of all objects are returned.

**Returns**

- **object_slices**  
  [list of tuples] A list of tuples, with each tuple containing N slices (with N the dimension of the input array). Slices correspond to the minimal parallelepiped that contains the object. If a number is missing, None is returned instead of a slice.

**See also:**

- **label, center_of_mass**

**Notes**

This function is very useful for isolating a volume of interest inside a 3-D array, that cannot be “seen through”.

**Examples**

```python
>>> from scipy import ndimage
>>> a = np.zeros((6, 6), dtype=int)
>>> a[2:4, 2:4] = 1
>>> a[4, 4] = 1
>>> a[:, 3] = 2
>>> a[0, 5] = 3
```
>>> a
array([[2, 2, 2, 0, 0, 3],
       [2, 2, 2, 0, 0, 0],
       [0, 0, 1, 1, 0, 0],
       [0, 0, 1, 1, 0, 0],
       [0, 0, 0, 0, 1, 0],
       [0, 0, 0, 0, 0, 0]])
>>> ndimage.find_objects(a)
[(slice(2, 5, None), slice(2, 5, None)), (slice(0, 2, None),
  slice(0, 3, None)), (slice(0, 1, None), slice(5, 6, None))]
>>> ndimage.find_objects(a, max_label=2)
[(slice(2, 5, None), slice(2, 5, None)), (slice(0, 2, None), slice(0, 3,
  None))]
>>> ndimage.find_objects(a == 1, max_label=2)
[(slice(2, 5, None), slice(2, 5, None)), None]

loc = ndimage.find_objects(a)[0]
>>> a[loc]
array([[1, 1, 0],
       [1, 1, 0],
       [0, 0, 1]])

scipy.ndimage.histogram

The function `scipy.ndimage.histogram` calculates the histogram of the values of an array, optionally at labels. Histogram calculates the frequency of values in an array within bins determined by `min`, `max`, and `bins`. The `labels` and `index` keywords can limit the scope of the histogram to specified sub-regions within the array.

**Parameters**
- `input` [array_like] Data for which to calculate histogram.
- `min, max` [int] Minimum and maximum values of range of histogram bins.
- `bins` [int] Number of bins.
- `labels` [array_like, optional] Labels for objects in `input`. If not None, must be same shape as `input`. (continues on next page)
With labels and no indices, non-zero elements are counted:

```python
>>> lbl, nlbl = ndimage.label(a)
>>> ndimage.measurements.histogram(a, 0, 1, 10, lbl)
array([0, 0, 2, 1, 0, 1, 1, 2, 0, 0])
```

Indices can be used to count only certain objects:

```python
>>> ndimage.measurements.histogram(a, 0, 1, 10, lbl, 2)
array([0, 0, 1, 1, 0, 0, 1, 1, 0, 0])
```

### scipy.ndimage.label

`scipy.ndimage.label (input, structure=None, output=None)`

Label features in an array.

**Parameters**

- **input** [array_like] An array-like object to be labeled. Any non-zero values in `input` are counted as features and zero values are considered the background.
- **structure** [array_like, optional] A structuring element that defines feature connections. `structure` must be centrosymmetric (see Notes). If no structuring element is provided, one is automatically generated with a squared connectivity equal to one. That is, for a 2-D `input` array, the default structuring element is:

  ```
  [[0, 1, 0],
   [1, 1, 1],
   [0, 1, 0]]
  ```

- **output** [(None, data-type, array_like), optional] If `output` is a data type, it specifies the type of the resulting labeled feature array. If `output` is an array-like object, then `output` will be updated with the labeled features from this function. This function can operate in-place, by passing `output=input`. Note that the output must be able to store the largest label, or this function will raise an Exception.

**Returns**

- **label** [ndarray or int] An integer ndarray where each unique feature in `input` has a unique label in the returned array.
- **num_features** [int] How many objects were found.

If `output` is None, this function returns a tuple of `(labeled_array, num_features)`. If `output` is a ndarray, then it will be updated with values in `labeled_array` and only `num_features` will be returned by this function.

**See also:**

- `find_objects`

  generate a list of slices for the labeled features (or objects); useful for finding features' position or dimensions
Notes

A centrosymmetric matrix is a matrix that is symmetric about the center. See [1] for more information.

The structure matrix must be centrosymmetric to ensure two-way connections. For instance, if the structure matrix is not centrosymmetric and is defined as:

\[
\begin{bmatrix}
0 & 1 & 0 \\
1 & 1 & 0 \\
0 & 0 & 0
\end{bmatrix}
\]

and the input is:

\[
\begin{bmatrix}
[1,2], \\
[0,3]
\end{bmatrix}
\]

then the structure matrix would indicate the entry 2 in the input is connected to 1, but 1 is not connected to 2.

References

[1]

Examples

Create an image with some features, then label it using the default (cross-shaped) structuring element:

```python
>>> from scipy.ndimage import label, generate_binary_structure
>>> a = np.array([[0,1,0],
...                [0,0,1,0,0],
...                [1,0,1,0,0],
...                [0,0,0,1,0],
...                [0,0,0,0,1]]

>>> labeled_array, num_features = label(a)
```

Each of the 4 features are labeled with a different integer:

```python
>>> num_features
4
>>> labeled_array
array([[0, 0, 1, 1, 0, 0],
       [0, 0, 1, 0, 0, 0],
       [2, 2, 0, 0, 3, 0],
       [0, 0, 0, 4, 0, 0]])
```

Generate a structuring element that will consider features connected even if they touch diagonally:

```python
>>> s = generate_binary_structure(2,2)
```
or,

```python
>>> s = [[1,1,1],
...       [1,1,1],
...       [1,1,1]]
```

Label the image using the new structuring element:
Show the 2 labeled features (note that features 1, 3, and 4 from above are now considered a single feature):

```python
>>> num_features
2
>>> labeled_array
array([[0, 0, 1, 1, 0, 0],
       [0, 0, 1, 0, 0],
       [2, 2, 0, 0, 1, 0],
       [0, 0, 1, 0, 0]])
```

### scipy.ndimage.labeled_comprehension

**scipy.ndimage.labeled_comprehension**

Roughly equivalent to `[func(input[labels == i]) for i in index].

Sequentially applies an arbitrary function (that works on array_like input) to subsets of an n-D image array specified by **labels** and **index**. The option exists to provide the function with positional parameters as the second argument.

**Parameters**

- `input` [array_like] Data from which to select **labels** to process.
- `labels` [array_like or None] Labels to objects in **input**. If not None, array must be same shape as **input**. If None, **func** is applied to raveled **input**.
- `index` [int, sequence of ints or None] Subset of **labels** to which to apply **func**. If a scalar, a single value is returned. If None, **func** is applied to all non-zero values of **labels**.
- `func` [callable] Python function to apply to **labels** from **input**.
- `out_dtype` [dtype] Dtype to use for result.
- `default` [int, float or None] Default return value when a element of **index** does not exist in **labels**.
- `pass_positions` [bool, optional] If True, pass linear indices to **func** as a second argument. Default is False.

**Returns**

- `result` [ndarray] Result of applying **func** to each of **labels** to **input** in **index**.

**Examples**

```python
>>> a = np.array([[1, 2, 0, 0],
...                [5, 3, 0, 4],
...                [0, 0, 0, 7],
...                [9, 3, 0, 0]])
>>> from scipy import ndimage
>>> lbl, nlbl = ndimage.label(a)
>>> lbs = np.arange(1, nlbl+1)
>>> ndimage.labeled_comprehension(a, lbl, lbs, np.mean, float, 0)
array([ 2.75,  5.5 ,  6. ])
```

Falling back to `default`: 
```python
>>> lbls = np.arange(1, nlbl+2)
>>> ndimage.labeled_comprehension(a, lbl, lbls, np.mean, float, -1)
array([ 2.75,  5.5,  6. , -1. ])
```

Passing positions:

```python
>>> def fn(val, pos):
    ...
    print("fn says: %s \n" % (val, pos))
    ...
    return (val.sum()) if (pos.sum() % 2 == 0) else (-val.sum())
...
>>> ndimage.labeled_comprehension(a, lbl, lbls, fn, float, 0, True)
fn says: [1 2 5 3] : [0 1 4 5]
fn says: [4 7] : [ 7 11]
fn says: [9 3] : [12 13]
array([ 11.,  11., -12.,  0.])
```

**scipy.ndimage.maximum**

**scipy.ndimage**.maximum(*input*, *labels=None*, *index=None*)

Calculate the maximum of the values of an array over labeled regions.

**Parameters**

- **input** [array_like] Array_like of values. For each region specified by *labels*, the maximal values of *input* over the region is computed.
- **labels** [array_like, optional] An array of integers marking different regions over which the maximum value of *input* is to be computed. *labels* must have the same shape as *input*. If *labels* is not specified, the maximum over the whole array is returned.
- **index** [array_like, optional] A list of region labels that are taken into account for computing the maxima. If *index* is None, the maximum over all elements where *labels* is non-zero is returned.

**Returns**

- **output** [float or list of floats] List of maxima of *input* over the regions determined by *labels* and whose index is in *index*. If *index* or *labels* are not specified, a float is returned: the maximal value of *input* if *labels* is None, and the maximal value of elements where *labels* is greater than zero if *index* is None.

**See also:**

- label, minimum, median, maximum_position, extrema, sum, mean, variance
- standard_deviation

**Notes**

The function returns a Python list and not a NumPy array, use `np.array` to convert the list to an array.

**Examples**
>>> a = np.arange(16).reshape((4,4))
>>> a
array([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11],
        [12, 13, 14, 15]])
>>> labels = np.zeros_like(a)
>>> labels[:2,:2] = 1
>>> labels[2:, 1:3] = 2
>>> labels
array([[1, 1, 0, 0],
        [1, 1, 0, 0],
        [0, 2, 2, 0],
        [0, 2, 2, 0]])

```python
>>> from scipy import ndimage
>>> ndimage.maximum(a)
15.0
>>> ndimage.maximum(a, labels=labels, index=[1,2])
[5.0, 14.0]
```  
```python
>>> ndimage.maximum(a, labels=labels)
14.0
```  
```python
>>> b = np.array([[1, 2, 0, 0],
                ...   [5, 3, 0, 4],
                ...   [0, 0, 0, 7],
                ...   [9, 3, 0, 0]])
>>> labels, labels_nb = ndimage.label(b)
>>> labels
array([[1, 1, 0, 0],
        [1, 1, 0, 2],
        [0, 0, 2, 0],
        [3, 3, 0, 0]])

```python
>>> ndimage.maximum(b, labels=labels, index=np.arange(1, labels_nb + 1))
[5.0, 7.0, 9.0]

**scipy.ndimage.maximum_position**

`scipy.ndimage.maximum_position(input, labels=None, index=None)`  
Find the positions of the maximums of the values of an array at labels.

For each region specified by `labels`, the position of the maximum value of `input` within the region is returned.

**Parameters**

- `input` [array_like] Array_like of values.
- `labels` [array_like, optional] An array of integers marking different regions over which the position of the maximum value of `input` is to be computed. `labels` must have the same shape as `input`. If `labels` is not specified, the location of the first maximum over the whole array is returned. The `labels` argument only works when `index` is specified.
- `index` [array_like, optional] A list of region labels that are taken into account for finding the location of the maxima. If `index` is None, the first maximum over all elements where `labels` is non-zero is returned. The `index` argument only works when `labels` is specified.
Returns

**output**

[ list of tuples of ints ] List of tuples of ints that specify the location of maxima of *input* over the regions determined by *labels* and whose index is in *index*.

If *index* or *labels* are not specified, a tuple of ints is returned specifying the location of the first maximal value of *input*.

See also:

`label`, `minimum`, `median`, `maximum_position`, `extrema`, `sum`, `mean`, `variance`, `standard_deviation`

#### scipy.ndimage.mean

**scipy.ndimage.mean**(input, labels=None, index=None)

Calculate the mean of the values of an array at labels.

**Parameters**

- **input**
  - array_like: Array on which to compute the mean of elements over distinct regions.
- **labels**
  - array_like, optional: Array of labels of same shape, or broadcastable to the same shape as *input*. All elements sharing the same label form one region over which the mean of the elements is computed.
- **index**
  - int or sequence of ints, optional: Labels of the objects over which the mean is to be computed. Default is None, in which case the mean for all values where label is greater than 0 is calculated.

**Returns**

- **out**
  - list: Sequence of same length as *index*, with the mean of the different regions labeled by the labels in *index*.

See also:

`variance`, `standard_deviation`, `minimum`, `maximum`, `sum`, `label`

**Examples**

```python
>>> from scipy import ndimage
>>> a = np.arange(25).reshape(5,5)
>>> labels = np.zeros_like(a)
>>> labels[3:5,3:5] = 1
>>> index = np.unique(labels)
>>> labels
array([[0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0],
       [0, 0, 0, 1, 1],
       [0, 0, 0, 1, 1]])
>>> index
array([0, 1])
>>> ndimage.mean(a, labels=labels, index=index)
[10.285714285714286, 21.0]
```
scipy.ndimage.median

scipy.ndimage.median(input, labels=None, index=None)

Calculate the median of the values of an array over labeled regions.

Parameters

- **input** [array_like] Array_like of values. For each region specified by labels, the median value of input over the region is computed.
- **labels** [array_like, optional] An array_like of integers marking different regions over which the median value of input is to be computed. labels must have the same shape as input. If labels is not specified, the median over the whole array is returned.
- **index** [array_like, optional] A list of region labels that are taken into account for computing the medians. If index is None, the median over all elements where labels is non-zero is returned.

Returns

- **median** [float or list of floats] List of medians of input over the regions determined by labels and whose index is in index. If index or labels are not specified, a float is returned: the median value of input if labels is None, and the median value of elements where labels is greater than zero if index is None.

See also:

- label, minimum, maximum, extrema, sum, mean, variance, standard_deviation

Notes

The function returns a Python list and not a NumPy array, use np.array to convert the list to an array.

Examples

```python
>>> from scipy import ndimage
>>> a = np.array([[1, 2, 0, 1],
...                [5, 3, 0, 4],
...                [0, 0, 0, 7],
...                [9, 3, 0, 0]])
>>> labels, labels_nb = ndimage.label(a)
>>> labels
array([[1, 1, 0, 2],
       [1, 1, 0, 2],
       [0, 0, 0, 2],
       [3, 3, 0, 0]])
>>> ndimage.median(a, labels=labels, index=np.arange(1, labels_nb + 1))
[2.5, 4.0, 6.0]
>>> ndimage.median(a)
1.0
>>> ndimage.median(a, labels=labels)
3.0
```
scipy.ndimage.minimum

scipy.ndimage.minimum(input, labels=None, index=None)

Calculate the minimum of the values of an array over labeled regions.

Parameters

*input* [array_like] Array_like of values. For each region specified by *labels*, the minimal values of *input* over the region is computed.

*labels* [array_like, optional] An array_like of integers marking different regions over which the minimum value of *input* is to be computed. *labels* must have the same shape as *input*. If *labels* is not specified, the minimum over the whole array is returned.

*index* [array_like, optional] A list of region labels that are taken into account for computing the minima. If *index* is None, the minimum over all elements where *labels* is non-zero is returned.

Returns

*minimum* [float or list of floats] List of minima of *input* over the regions determined by *labels* and whose index is in *index*. If *index* or *labels* are not specified, a float is returned: the minimal value of *input* if *labels* is None, and the minimal value of elements where *labels* is greater than zero if *index* is None.

See also:

*label*, *maximum*, *median*, *minimum_position*, *extrema*, *sum*, *mean*, *variance*, *standard_deviation*

Notes

The function returns a Python list and not a NumPy array, use *np.array* to convert the list to an array.

Examples

```python
>>> from scipy import ndimage
>>> a = np.array([[1, 2, 0, 0],
...               [5, 3, 0, 4],
...               [0, 0, 0, 7],
...               [9, 3, 0, 0]])
>>> labels, labels_nb = ndimage.label(a)
>>> labels
array([[1, 1, 0, 0],
       [1, 0, 0, 2],
       [3, 3, 0, 0]], dtype=int32)
>>> ndimage.minimum(a, labels=labels, index=np.arange(1, labels_nb + 1))[1.0, 4.0, 3.0]
>>> ndimage.minimum(a)
0.0
>>> ndimage.minimum(a, labels=labels)
1.0
```
scipy.ndimage.minimum_position

scipy.ndimage.minimum_position(input, labels=None, index=None)

Find the positions of the minimums of the values of an array at labels.

Parameters

input  [array_like] Array_like of values.
labels [array_like, optional] An array of integers marking different regions over which the position
        of the minimum value of input is to be computed. labels must have the same shape as input.
        If labels is not specified, the location of the first minimum over the whole array is returned.
        The labels argument only works when index is specified.
index  [array_like, optional] A list of region labels that are taken into account for finding the location
        of the minima. If index is None, the first minimum over all elements where labels is non-
        zero is returned. The index argument only works when labels is specified.

Returns

output [list of tuples of ints] Tuple of ints or list of tuples of ints that specify the location of minima
        of input over the regions determined by labels and whose index is in index.
        If index or labels are not specified, a tuple of ints is returned specifying the location of the
        first minimal value of input.

See also:

label, minimum, median, maximum_position, extrema, sum, mean, variance
standard_deviation

Examples

>>> a = np.array([[10, 20, 30],
                ...               [40, 80, 100],
                ...               [1, 100, 200]])
>>> b = np.array([[1, 2, 0, 1],
                ...               [5, 3, 0, 4],
                ...               [0, 0, 0, 7],
                ...               [9, 3, 0, 0]])

>>> from scipy import ndimage

>>> ndimage.minimum_position(a)
(2, 0)
>>> ndimage.minimum_position(b)
(0, 2)

Features to process can be specified using labels and index:

>>> label, pos = ndimage.label(a)
>>> ndimage.minimum_position(a, label, index=np.arange(1, pos+1))
[(2, 0)]
>>> label, pos = ndimage.label(b)
>>> ndimage.minimum_position(b, label, index=np.arange(1, pos+1))
[(0, 0), (0, 3), (3, 1)]

scipy.ndimage.standard_deviation

scipy.ndimage.standard_deviation(input, labels=None, index=None)
Calculate the standard deviation of the values of an n-D image array, optionally at specified sub-regions.

Parameters

- **input**: [array_like] Nd-image data to process.
- **labels**: [array_like, optional] Labels to identify sub-regions in input. If not None, must be same shape as input.
- **index**: [int or sequence of ints, optional] labels to include in output. If None (default), all values where labels is non-zero are used.

Returns

- **standard_deviation**: [float or ndarray] Values of standard deviation, for each sub-region if labels and index are specified.

See also:

- label, variance, maximum, minimum, extrema

Examples

```python
>>> a = np.array([[1, 2, 0, 0],
...                [5, 3, 0, 4],
...                [0, 0, 0, 7],
...                [9, 3, 0, 0]])
>>> from scipy import ndimage
>>> ndimage.standard_deviation(a)
2.7585095613392387
```

Features to process can be specified using labels and index:

```python
>>> lbl, nlbl = ndimage.label(a)
>>> ndimage.standard_deviation(a, lbl, index=np.arange(1, nlbl+1))
array([ 1.479, 1.5 , 3. ])
```

If no index is given, non-zero labels are processed:

```python
>>> ndimage.standard_deviation(a, lbl)
2.4874685927665499
```

scipy.ndimage.sum

scipy.ndimage.sum(input, labels=None, index=None)
Calculate the sum of the values of the array.
Parameters

- **input**: [array_like] Values of input inside the regions defined by labels are summed together.
- **labels**: [array_like of ints, optional] Assign labels to the values of the array. Has to have the same shape as input.
- **index**: [array_like, optional] A single label number or a sequence of label numbers of the objects to be measured.

Returns

- **sum**: [ndarray or scalar] An array of the sums of values of input inside the regions defined by labels with the same shape as index. If ‘index’ is None or scalar, a scalar is returned.

See also:

- mean, median

Examples

```python
>>> from scipy import ndimage
>>> input = [0, 1, 2, 3]
>>> labels = [1, 1, 2, 2]
>>> ndimage.sum(input, labels, index=[1, 2])
[1.0, 5.0]
>>> ndimage.sum(input, labels, index=1)
1
>>> ndimage.sum(input, labels)
6
```

### scipy.ndimage.variance

**scipy.ndimage.variance** *(input, labels=None, index=None)*

Calculate the variance of the values of an n-D image array, optionally at specified sub-regions.

Parameters

- **input**: [array_like] Nd-image data to process.
- **labels**: [array_like, optional] Labels defining sub-regions in input. If not None, must be same shape as input.
- **index**: [int or sequence of ints, optional] labels to include in output. If None (default), all values where labels is non-zero are used.

Returns

- **variance**: [float or ndarray] Values of variance, for each sub-region if labels and index are specified.

See also:

- label, standard_deviation, maximum, minimum, extrema

Examples
Features to process can be specified using *labels* and *index*:

```python
>>> lbl, nlbl = ndimage.label(a)
>>> ndimage.variance(a, lbl, index=np.arange(1, nlbl+1))
array([ 2.1875, 2.25 , 9. ])
```

If no index is given, all non-zero *labels* are processed:

```python
>>> ndimage.variance(a, lbl)
6.1875
```

**scipy.ndimage.watershed_if**

**scipy.ndimage.watershed_if** *(input, markers, structure=None, output=None)*

Apply watershed from markers using image foresting transform algorithm.

**Parameters**

- **input** *(array_like)*: Input.
- **markers** *(array_like)*: Markers are points within each watershed that form the beginning of the process. Negative markers are considered background markers which are processed after the other markers.
- **structure** *(structure element, optional)*: A structuring element defining the connectivity of the object can be provided. If None, an element is generated with a squared connectivity equal to one.
- **output** *(ndarray, optional)*: An output array can optionally be provided. The same shape as *input*.

**Returns**

- **watershed_if** *(ndarray)*: Output. Same shape as *input*.

**scipy.ndimage.binary_closing**

scipy.ndimage.binary_closing (input, structure=None, iterations=1, output=None, origin=0, mask=None, border_value=0, brute_force=False)

Multi-dimensional binary closing with the given structuring element.

The closing of an input image by a structuring element is the erosion of the dilation of the image by the structuring element.

**Parameters**

- **input** [array_like] Binary array_like to be closed. Non-zero (True) elements form the subset to be closed.
- **structure** [array_like, optional] Structuring element used for the closing. Non-zero elements are considered True. If no structuring element is provided an element is generated with a square connectivity equal to one (i.e., only nearest neighbors are connected to the center, diagonally-connected elements are not considered neighbors).
- **iterations** [int, optional] The dilation step of the closing, then the erosion step are each repeated iterations times (one, by default). If iterations is less than 1, each operations is repeated until the result does not change anymore. Only an integer of iterations is accepted.
- **output** [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.
- **origin** [int or tuple of ints, optional] Placement of the filter, by default 0.
- **mask** [array_like, optional] If a mask is given, only those elements with a True value at the corresponding mask element are modified at each iteration. New in version 1.1.0.
- **border_value** [int (cast to 0 or 1), optional] Value at the border in the output array. New in version 1.1.0.
brute_force

[boolean, optional] Memory condition: if False, only the pixels whose value was changed in the last iteration are tracked as candidates to be updated in the current iteration; if true all pixels are considered as candidates for update, regardless of what happened in the previous iteration. False by default. New in version 1.1.0.

Returns

binary_closing

[ndarray of bools] Closing of the input by the structuring element.

See also:

grey_closing, binary_opening, binary_dilation, binary_erosion

generate_binary_structure

Notes

Closing [1] is a mathematical morphology operation [2] that consists in the succession of a dilation and an erosion of the input with the same structuring element. Closing therefore fills holes smaller than the structuring element. Together with opening (binary_opening), closing can be used for noise removal.

Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((5,5), dtype=int)
>>> a[1:-1, 1:-1] = 1; a[2,2] = 0
>>> a
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 0, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
>>> # Closing removes small holes
>>> ndimage.binary_closing(a).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
>>> # Closing is the erosion of the dilation of the input
>>> ndimage.binary_dilation(a).astype(int)
array([[1, 1, 1, 1, 1],
       [1, 1, 1, 1, 1],
       [1, 1, 1, 1, 1],
       [1, 1, 1, 1, 1],
       [1, 1, 1, 1, 1]],
       dtype=int32)
```

(continues on next page)
>> ndimage.binary_erosion(ndimage.binary_dilation(a)).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])

>>> a = np.zeros((7,7), dtype=int)
>>> a[1:6, 2:5] = 1; a[1:3, 3] = 0
>>> a
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 0, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])

>>> # In addition to removing holes, closing can also
>>> # coarsen boundaries with fine hollows.
>>> ndimage.binary_closing(a).astype(int)
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])

>>> ndimage.binary_closing(a, structure=np.ones((2,2))).astype(int)
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],

scipy.ndimage.binary_dilation

scipy.ndimage.binary_dilation (input, structure=None, iterations=1, mask=None, output=None, border_value=0, origin=0, brute_force=False)

Multi-dimensional binary dilation with the given structuring element.

Parameters

- **input** [array_like] Binary array_like to be dilated. Non-zero (True) elements form the subset to be dilated.
- **structure** [array_like, optional] Structuring element used for the dilation. Non-zero elements are considered True. If no structuring element is provided an element is generated with a square connectivity equal to one.
- **iterations** [int, optional] The dilation is repeated iterations times (one, by default). If iterations is less than 1, the dilation is repeated until the result does not change anymore. Only an integer of
iterations is accepted.

**mask**  
[array_like, optional] If a mask is given, only those elements with a True value at the corresponding mask element are modified at each iteration.

**output**  
[ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.

**border_value**  
[int (cast to 0 or 1), optional] Value at the border in the output array.

**origin**  
[int or tuple of ints, optional] Placement of the filter, by default 0.

**brute_force**  
[boolean, optional] Memory condition: if False, only the pixels whose value was changed in the last iteration are tracked as candidates to be updated (dilated) in the current iteration; if True all pixels are considered as candidates for dilation, regardless of what happened in the previous iteration. False by default.

**Returns**

**binary_dilation**  
[ndarray of bools] Dilation of the input by the structuring element.

**See also:**

grey_dilation, binary_erosion, binary_closing, binary_opening

**generate_binary_structure**

**Notes**

Dilation [1] is a mathematical morphology operation [2] that uses a structuring element for expanding the shapes in an image. The binary dilation of an image by a structuring element is the locus of the points covered by the structuring element, when its center lies within the non-zero points of the image.

**Examples**

```python
>>> from scipy import ndimage
>>> a = np.zeros((5, 5))
>>> a[2, 2] = 1
>>> a
array([[ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.]])
>>> ndimage.binary_dilation(a)
array([[False, False, False, False, False],
       [False, False,  True, False, False],
       [False,  True,  True, False, False],
       [False, False,  True, False, False],
       [False, False, False, False, False]], dtype=bool)
```
```python
>>> ndimage.binary_dilation(a).astype(a.dtype)
array([[ 0., 0., 0., 0., 0.],
       [ 0., 0., 1., 0., 0.],
       [ 0., 1., 1., 1., 0.],
       [ 0., 0., 1., 0., 0.],
       [ 0., 0., 0., 0., 0.]])

>>> # 3x3 structuring element with connectivity 1, used by default
>>> struct1 = ndimage.generate_binary_structure(2, 1)
>>> struct1
array([[False,  True, False],
       [ True,  True,  True],
       [False,  True, False]], dtype=bool)

>>> # 3x3 structuring element with connectivity 2
>>> struct2 = ndimage.generate_binary_structure(2, 2)
>>> struct2
array([[ True,  True,  True],
       [ True,  True,  True],
       [ True,  True,  True]], dtype=bool)

>>> ndimage.binary_dilation(a, structure=struct1).astype(a.dtype)
array([[ 0., 0., 0., 0., 0.],
       [ 0., 0., 1., 0., 0.],
       [ 0., 1., 1., 1., 0.],
       [ 0., 0., 1., 0., 0.],
       [ 0., 0., 0., 0., 0.]])

>>> ndimage.binary_dilation(a, structure=struct2).astype(a.dtype)
array([[ 0., 0., 0., 0., 0.],
       [ 0., 1., 1., 1., 0.],
       [ 0., 1., 1., 1., 0.],
       [ 0., 0., 0., 0., 0.],
       [ 0., 0., 0., 0., 0.]])

>>> ndimage.binary_dilation(a, structure=struct1,
... iterations=2).astype(a.dtype)
array([[ 0., 0., 1., 0., 0.],
       [ 0., 1., 1., 1., 0.],
       [ 1., 1., 1., 1., 1.],
       [ 0., 1., 1., 1., 0.],
       [ 0., 0., 1., 0., 0.]]
```

### scipy.ndimage.binary_erosion

scipy.ndimage.binary_erosion(input, structure=None, iterations=1, mask=None, output=None, border_value=0, origin=0, brute_force=False)

Multi-dimensional binary erosion with a given structuring element.

Binary erosion is a mathematical morphology operation used for image processing.

**Parameters**

- **input** [array_like] Binary image to be eroded. Non-zero (True) elements form the subset to be eroded.
- **structure** [array_like, optional] Structuring element used for the erosion. Non-zero elements are considered True. If no structuring element is provided, an element is generated with a square connectivity equal to one.
iterations [int, optional] The erosion is repeated \textit{iterations} times (one, by default). If iterations is less than 1, the erosion is repeated until the result does not change anymore.

mask [array_like, optional] If a mask is given, only those elements with a True value at the corresponding mask element are modified at each iteration.

output [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.

border_value [int (cast to 0 or 1), optional] Value at the border in the output array.

origin [int or tuple of ints, optional] Placement of the filter, by default 0.

brute_force [boolean, optional] Memory condition: if False, only the pixels whose value was changed in the last iteration are tracked as candidates to be updated (eroded) in the current iteration; if True all pixels are considered as candidates for erosion, regardless of what happened in the previous iteration. False by default.

Returns

binary_erosion [ndarray of bools] Erosion of the input by the structuring element.

\texttt{grey\_erosion}, \texttt{binary\_dilation}, \texttt{binary\_closing}, \texttt{binary\_opening}

\texttt{generate\_binary\_structure}

Notes

Erosion \cite{1} is a mathematical morphology operation \cite{2} that uses a structuring element for shrinking the shapes in an image. The binary erosion of an image by a structuring element is the locus of the points where a superimposition of the structuring element centered on the point is entirely contained in the set of non-zero elements of the image.

Examples

\begin{verbatim}
>>> from scipy import ndimage
>>> a = np.zeros((7,7), dtype=int)
>>> a[1:6, 2:5] = 1
>>> a
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
>>> ndimage.binary_erosion(a).astype(a.dtype)
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]],
      dtype=int32)
\end{verbatim}
```python
>>> # Erosion removes objects smaller than the structure
>>> ndimage.binary_erosion(a, structure=np.ones((5,5))).astype(a.dtype)
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
```

SciPy Reference Guide, Release 1.3.2

scipy.ndimage.binary_fill_holes

**scipy.ndimage.binary_fill_holes** *(input, structure=None, output=None, origin=0)*

Fill the holes in binary objects.

**Parameters**

- **input** [array_like] n-dimensional binary array with holes to be filled
- **structure** [array_like, optional] Structuring element used in the computation; large-size elements make computations faster but may miss holes separated from the background by thin regions. The default element (with a square connectivity equal to one) yields the intuitive result where all holes in the input have been filled.
- **output** [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.
- **origin** [int, tuple of ints, optional] Position of the structuring element.

**Returns**

- **out** [ndarray] Transformation of the initial image *input* where holes have been filled.

**See also:**

*binary_dilation, binary_propagation, label*

**Notes**

The algorithm used in this function consists in invading the complementary of the shapes in *input* from the outer boundary of the image, using binary dilations. Holes are not connected to the boundary and are therefore not invaded. The result is the complementary subset of the invaded region.

[1]
Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((5, 5), dtype=int)
>>> a[1:4, 1:4] = 1
>>> a[2,2] = 0
>>> a
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 0, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
>>> ndimage.binary_fill_holes(a).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
```

```python
>>> # Too big structuring element
>>> ndimage.binary_fill_holes(a, structure=np.ones((5,5))).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
```

**scipy.ndimage.binary_hit_or_miss**

scipy.ndimage.binary_hit_or_miss (input, structure1=None, structure2=None, output=None, origin1=0, origin2=None)

Multi-dimensional binary hit-or-miss transform.

The hit-or-miss transform finds the locations of a given pattern inside the input image.

**Parameters**

- `input` [array_like (cast to booleans)] Binary image where a pattern is to be detected.
- `structure1` [array_like (cast to booleans), optional] Part of the structuring element to be fitted to the foreground (non-zero elements) of input. If no value is provided, a structure of square connectivity 1 is chosen.
- `structure2` [array_like (cast to booleans), optional] Second part of the structuring element that has to miss completely the foreground. If no value is provided, the complementary of structure1 is taken.
- `output` [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.
- `origin1` [int or tuple of ints, optional] Placement of the first part of the structuring element structure1, by default 0 for a centered structure.
- `origin2` [int or tuple of ints, optional] Placement of the second part of the structuring element structure2, by default 0 for a centered structure. If a value is provided for origin1 and not for origin2, then origin2 is set to origin1.

**Returns**

- `binary_hit_or_miss`
[ndarray] Hit-or-miss transform of input with the given structuring element (structure1, structure2).

```
scipy.ndimage.binary_opening

scipy.ndimage.binary_opening(input, structure=None, iterations=1, output=None, origin=0, mask=None, border_value=0, brute_force=False)

Multi-dimensional binary opening with the given structuring element.

The opening of an input image by a structuring element is the dilation of the erosion of the image by the structuring element.

**Parameters**

- **input** [array_like] Binary array_like to be opened. Non-zero (True) elements form the subset to be opened.
- **structure** [array_like, optional] Structuring element used for the opening. Non-zero elements are considered True. If no structuring element is provided an element is generated with a square connectivity equal to one (i.e., only nearest neighbors are connected to the center, diagonally-connected elements are not considered neighbors).
- **iterations** [int, optional] The erosion step of the opening, then the dilation step are each repeated iterations times (one, by default). If iterations is less than 1, each operation is repeated until the result does not change anymore. Only an integer of iterations is accepted.
- **output** [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.
- **origin** [int or tuple of ints, optional] Placement of the filter, by default 0.
- **mask** [array_like, optional] If a mask is given, only those elements with a True value at the corresponding mask element are modified at each iteration. New in version 1.1.0.
- **border_value** [int (cast to 0 or 1), optional] Value at the border in the output array. New in version 1.1.0.
- **brute_force** [boolean, optional] Memory condition: if False, only the pixels whose value was changed in the last iteration are tracked as candidates to be updated in the current iteration; if true all pixels are considered as candidates for update, regardless of what happened in the previous iteration. False by default. New in version 1.1.0.

**Returns**

- **binary_opening** [ndarray of bools] Opening of the input by the structuring element.

See also:

grey_opening, binary_closing, binary_erosion, binary_dilation
generate_binary_structure

**Notes**

*Opening* [1] is a mathematical morphology operation [2] that consists in the succession of an erosion and a dilation of the input with the same structuring element. Opening therefore removes objects smaller than the structuring element.

Together with *closing* (binary_closing), opening can be used for noise removal.

Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((5,5), dtype=int)
>>> a[1:4, 1:4] = 1; a[4, 4] = 1
>>> a
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 1]])
>>> # Opening removes small objects
>>> ndimage.binary_opening(a, structure=np.ones((3,3))).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
>>> # Opening can also smooth corners
>>> ndimage.binary_opening(a).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 1, 0, 0],
       [0, 0, 0, 0, 0]])
>>> # Opening is the dilation of the erosion of the input
>>> ndimage.binary_erosion(a).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0]])
>>> ndimage.binary_dilation(ndimage.binary_erosion(a)).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 1, 0, 0],
       [0, 0, 0, 0, 0]])
```

scipy.ndimage.binary_propagation

scipy.ndimage.binary_propagation(input, structure=None, mask=None, output=None, border_value=0, origin=0)

Multi-dimensional binary propagation with the given structuring element.

**Parameters**

- **input** [array_like] Binary image to be propagated inside *mask*.  

structure [array_like, optional] Structuring element used in the successive dilations. The output may depend on the structuring element, especially if mask has several connex components. If no structuring element is provided, an element is generated with a squared connectivity equal to one.

mask [array_like, optional] Binary mask defining the region into which input is allowed to propagate.

output [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.

border_value [int (cast to 0 or 1), optional] Value at the border in the output array.

origin [int or tuple of ints, optional] Placement of the filter, by default 0.

Returns

Notes

This function is functionally equivalent to calling binary_dilation with the number of iterations less than one: iterative dilation until the result does not change anymore.

The succession of an erosion and propagation inside the original image can be used instead of an opening for deleting small objects while keeping the contours of larger objects untouched.

Examples

```python
>>> from scipy import ndimage
>>> input = np.zeros((8, 8), dtype=int)
>>> input[2, 2] = 1
>>> mask = np.zeros((8, 8), dtype=int)
>>> input
array([[0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0]])
>>> mask
array([[0, 0, 0, 0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 0, 0, 0, 1, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0]])
(continues on next page)

```python
>>> ndimage.binary_propagation(input, mask=mask).astype(int)
array([[0, 0, 0, 0, 0, 0, 1, 1],
       [0, 0, 0, 0, 0, 0, 1, 1]])
```

```python
>>> ndimage.binary_propagation(input, mask=mask,
... structure=np.ones((3,3)).astype(int))
array([[0, 0, 0, 0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0]])
```

```python
>>> # Comparison between opening and erosion+propagation
>>> a = np.zeros((6,6), dtype=int)
>>> a[2:5, 2:5] = 1; a[0, 0] = 1; a[5, 5] = 1
>>> a
array([[1, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0],
       [0, 0, 1, 1, 1, 0],
       [0, 0, 1, 1, 1, 0],
       [0, 0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0, 1]])

scipy.ndimage.black_tophat

**scipy.ndimage.black_tophat** *(input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)*

Multi-dimensional black tophat filter.

**Parameters**

- **input** ([array_like]) Input.
- **size** ([tuple of ints, optional]) Shape of a flat and full structuring element used for the filter. Optional if `footprint` or `structure` is provided.
- **footprint** ([array of ints, optional]) Positions of non-infinite elements of a flat structuring element used for the black tophat filter.
- **structure** ([array of ints, optional]) Structuring element used for the filter. `structure` may be a non-flat structuring element.
- **output** ([array, optional]) An array used for storing the output of the filter may be provided.
- **mode** ([{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional]) The `mode` parameter determines how the array borders are handled, where `cval` is the value when mode is equal to 'constant'. Default is 'reflect'
- **cval** ([scalar, optional]) Value to fill past edges of input if `mode` is 'constant'. Default is 0.0.
- **origin** ([scalar, optional]) The `origin` parameter controls the placement of the filter. Default 0

**Returns**

- **black_tophat** ([ndarray]) Result of the filter of `input` with `structure`.

See also:

- `white_tophat`, `grey_opening`, `grey_closing`

scipy.ndimage.distance_transform_bf

**scipy.ndimage.distance_transform_bf** *(input, metric='euclidean', sampling=None, return_distances=True, return_indices=False, distances=None, indices=None)*

Distance transform function by a brute force algorithm.

This function calculates the distance transform of the `input`, by replacing each foreground (non-zero) element, with its shortest distance to the background (any zero-valued element).

In addition to the distance transform, the feature transform can be calculated. In this case the index of the closest background element is returned along the first axis of the result.

**Parameters**

- **input** ([array_like]) Input
- **metric** ([str, optional]) Three types of distance metric are supported: ‘euclidean’, ‘taxicab’ and ‘chessboard’.
**sampling**  
[[int, sequence of ints], optional] This parameter is only used in the case of the euclidean `metric` distance transform.  
The sampling along each axis can be given by the `sampling` parameter which should be a sequence of length equal to the input rank, or a single number in which the `sampling` is assumed to be equal along all axes.

**return_distances**  
[bool, optional] The `return_distances` flag can be used to indicate if the distance transform is returned.  
The default is True.

**return_indices**  
[bool, optional] The `return_indices` flags can be used to indicate if the feature transform is returned.  
The default is False.

**distances**  
[float64 ndarray, optional] Optional output array to hold distances (if `return_distances` is True).

**indices**  
[int64 ndarray, optional] Optional output array to hold indices (if `return_indices` is True).

**Returns**

**distances**  
[ndarray] Distance array if `return_distances` is True.

**indices**  
[ndarray] Indices array if `return_indices` is True.

**Notes**

This function employs a slow brute force algorithm, see also the function `distance_transform_cdt` for more efficient taxicab and chessboard algorithms.

```python
scipy.ndimage.distance_transform_cdt
```

Distance transform for chamfer type of transforms.

**Parameters**

**input**  
[array_like] Input

**metric**  
[{'chessboard', 'taxicab'}, optional] The `metric` determines the type of chamfering that is done. If the `metric` is equal to 'taxicab' a structure is generated using `generate_binary_structure` with a squared distance equal to 1. If the `metric` is equal to 'chessboard', a `metric` is generated using `generate_binary_structure` with a squared distance equal to the dimensionality of the array. These choices correspond to the common interpretations of the 'taxicab' and the 'chessboard' distance metrics in two dimensions.  
The default for `metric` is 'chessboard'.

**return_distances, return_indices**  
[bool, optional] The `return_distances` and `return_indices` flags can be used to indicate if the distance transform, the feature transform, or both must be returned.  
If the feature transform is returned (`return_indices=True`), the index of the closest background element is returned along the first axis of the result.  
The `return_distances` default is True, and the `return_indices` default is False.

**distances, indices**  
[ndarrays of int32, optional] The `distances` and `indices` arguments can be used to give optional output arrays that must be the same shape as `input`. 
scipy.ndimage.distance_transform_edt

`scipy.ndimage.distance_transform_edt` (input, sampling=None, return_distances=True, return_indices=False, distances=None, indices=None)

Exact euclidean distance transform.

In addition to the distance transform, the feature transform can be calculated. In this case the index of the closest background element is returned along the first axis of the result.

**Parameters**

- **input** [array_like] Input data to transform. Can be any type but will be converted into binary: 1 wherever input equates to True, 0 elsewhere.
- **sampling** [float or int, or sequence of same, optional] Spacing of elements along each dimension. If a sequence, must be of length equal to the input rank; if a single number, this is used for all axes. If not specified, a grid spacing of unity is implied.
- **return_distances** [bool, optional] Whether to return distance matrix. At least one of return_distances/return_indices must be True. Default is True.
- **return_indices** [bool, optional] Whether to return indices matrix. Default is False.
- **distances** [ndarray, optional] Used for output of distance array, must be of type float64.
- **indices** [ndarray, optional] Used for output of indices, must be of type int32.

**Returns**

distance_transform_edt [ndarray or list of ndarrays] Either distance matrix, index matrix, or a list of the two, depending on return_x flags and distance and indices input parameters.

**Notes**

The euclidean distance transform gives values of the euclidean distance:

\[ y_i = \sqrt{\sum_n (x[i] - b[i])^2} \]

where b[i] is the background point (value 0) with the smallest Euclidean distance to input points x[i], and n is the number of dimensions.

**Examples**

```python
>>> from scipy import ndimage
>>> a = np.array([[0,1,1,1,1],
...                [0,0,1,1,1],
...                [0,1,1,1,1],
...                [0,1,1,1,0],
...                [0,1,1,0,0]])
>>> ndimage.distance_transform_edt(a)
array([[ 0.   ,  1.0000,  1.4142,  2.2361,  3.   ],
       [ 0.00,  0.00,  1.00,  2.00,  2.00],
       [ 0.00,  1.00,  1.4142,  1.4142,  1.00],
       [ 0.00,  1.00,  1.4142,  1.00,  0.00],
       [ 0.00,  1.00,  1.00,  0.00,  0.00]])
```
With a sampling of 2 units along x, 1 along y:

```python
>>> ndimage.distance_transform_edt(a, sampling=[2,1])
array([[ 0. , 1. , 2. , 2.8284, 3.6056],
       [ 0. , 0. , 1. , 2. , 3. ],
       [ 0. , 1. , 2. , 2.2361, 2. ],
       [ 0. , 1. , 2. , 1. , 0. ],
       [ 0. , 1. , 1. , 0. , 0. ]])
```

Asking for indices as well:

```python
>>> edt, inds = ndimage.distance_transform_edt(a, return_indices=True)
>>> inds
array([[[0, 0, 1, 1, 3],
       [1, 1, 1, 1, 3],
       [2, 2, 1, 3, 3],
       [3, 3, 4, 4, 3],
       [4, 4, 4, 4, 4]],
       [[0, 0, 1, 1, 4],
       [0, 1, 1, 1, 4],
       [0, 0, 1, 4, 4],
       [0, 0, 3, 3, 4],
       [0, 0, 3, 3, 4]]])
```

With arrays provided for inplace outputs:

```python
>>> indices = np.zeros(((np.ndim(a),) + a.shape), dtype=np.int32)
>>> ndimage.distance_transform_edt(a, return_indices=True, indices=indices)
array([[ 0. , 1. , 1.4142, 2.2361, 3. ],
       [ 0. , 0. , 1. , 2. , 2. ],
       [ 0. , 1. , 1.4142, 1.4142, 1. ],
       [ 0. , 1. , 1.4142, 1. , 0. ],
       [ 0. , 1. , 1. , 0. , 0. ]])
>>> indices
array([[[0, 0, 1, 1, 3],
       [1, 1, 1, 1, 3],
       [2, 2, 1, 3, 3],
       [3, 3, 4, 4, 3],
       [4, 4, 4, 4, 4]],
       [[0, 0, 1, 1, 4],
       [0, 1, 1, 1, 4],
       [0, 0, 1, 4, 4],
       [0, 0, 3, 3, 4],
       [0, 0, 3, 3, 4]]])
```

**scipy.ndimage.generate_binary_structure**

`scipy.ndimage.generate_binary_structure(rank, connectivity)`

Generate a binary structure for binary morphological operations.

**Parameters**
**rank**  [int] Number of dimensions of the array to which the structuring element will be applied, as returned by `np.ndim`.

**connectivity**  [int] `connectivity` determines which elements of the output array belong to the structure, i.e. are considered as neighbors of the central element. Elements up to a squared distance of `connectivity` from the center are considered neighbors. `connectivity` may range from 1 (no diagonal elements are neighbors) to `rank` (all elements are neighbors).

**Returns**

**output**  [ndarray of bools] Structuring element which may be used for binary morphological operations, with `rank` dimensions and all dimensions equal to 3.

**See also:**

`iterate_structure`, `binary_dilation`, `binary_erosion`

**Notes**

generate_binary_structure can only create structuring elements with dimensions equal to 3, i.e. minimal dimensions. For larger structuring elements, that are useful e.g. for eroding large objects, one may either use `iterate_structure`, or create directly custom arrays with numpy functions such as `numpy.ones`.

**Examples**

```python
>>> from scipy import ndimage
>>> struct = ndimage.generate_binary_structure(2, 1)
>>> struct
array([[[False,  True, False],
       [ True,  True,  True],
       [False,  True, False]],
      dtype=bool)
>>> a = np.zeros((5,5))
>>> a[2, 2] = 1
>>> a
array([[ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.]]
      dtype=float64)
>>> b = ndimage.binary_dilation(a, structure=struct).astype(a.dtype)
>>> b
array([[ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.]]
      dtype=float64)
>>> ndimage.binary_dilation(b, structure=struct).astype(a.dtype)
array([[ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  1.,  1.,  1.,  0.],
       [ 0.,  0.,  1.,  1.,  1.],
       [ 0.,  1.,  1.,  1.,  0.],
       [ 0.,  0.,  1.,  0.,  0.]]
      dtype=float64)
>>> struct = ndimage.generate_binary_structure(2, 2)
(continues on next page)
```python
>>> struct = array([[ True,  True,  True],
    [ True,  True,  True],
    [ True,  True,  True]], dtype=bool)
>>> struct
array([[ True,  True,  True],
    [ True,  True,  True],
    [ True,  True,  True]], dtype=bool)
```

```python
>>> struct = ndimage.generate_binary_structure(3, 1)
>>> struct # no diagonal elements
array([[False, False, False],
    [False,  True, False],
    [False, False, False]], dtype=bool)
```

**scipy.ndimage.grey_closing**

`scipy.ndimage.grey_closing(input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)`

Multi-dimensional greyscale closing.  

A greyscale closing consists in the succession of a greyscale dilation, and a greyscale erosion.

**Parameters**

- **input** [array_like] Array over which the grayscale closing is to be computed.
- **size** [tuple of ints] Shape of a flat and full structuring element used for the grayscale closing. Optional if footprint or structure is provided. 
- **footprint** [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the grayscale closing. 
- **structure** [array of ints, optional] Structuring element used for the grayscale closing. structure may be a non-flat structuring element. 
- **output** [array, optional] An array used for storing the output of the closing may be provided. 
- **mode** [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The mode parameter determines how the array borders are handled, where cval is the value when mode is equal to ‘constant’. Default is ‘reflect’
- **cval** [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.
- **origin** [scalar, optional] The origin parameter controls the placement of the filter. Default 0

**Returns**

- **grey_closing** [ndarray] Result of the grayscale closing of input with structure.

**See also:**

- `binary_closing`, `grey_dilation`, `grey_erosion`, `grey_opening`
- `generate_binary_structure`
Notes

The action of a grayscale closing with a flat structuring element amounts to smoothen deep local minima, whereas binary closing fills small holes.

Examples

```python
>>> from scipy import ndimage
>>> a = np.arange(36).reshape((6,6))
>>> a[3,3] = 0
>>> a
array([[  0,   1,   2,   3,   4,   5],
       [  6,   7,   8,   9,  10,  11],
       [ 12,  13,  14,  15,  16,  17],
       [ 18,  19,  20,   0,  22,  23],
       [ 24,  25,  26,  27,  28,  29],
       [ 30,  31,  32,  33,  34,  35]])
>>> ndimage.grey_closing(a, size=(3,3))
array([[  7,   7,   8,   9,  10,  11],
       [  7,   7,   8,   9,  10,  11],
       [ 13,  13,  14,  15,  16,  17],
       [ 19,  19,  20,  20,  22,  23],
       [ 25,  25,  26,  27,  28,  29],
       [ 31,  31,  32,  33,  34,  35]])
>>> # Note that the local minimum a[3,3] has disappeared
```

scipy.ndimage.grey_dilation

```
scipy.ndimage.grey_dilation (input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)
```

Calculate a greyscale dilation, using either a structuring element, or a footprint corresponding to a flat structuring element.

Grayscale dilation is a mathematical morphology operation. For the simple case of a full and flat structuring element, it can be viewed as a maximum filter over a sliding window.

Parameters

- **input** [array_like] Array over which the grayscale dilation is to be computed.
- **size** [tuple of ints] Shape of a flat and full structuring element used for the grayscale dilation. Optional if footprint or structure is provided.
- **footprint** [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the grayscale dilation. Non-zero values give the set of neighbors of the center over which the maximum is chosen.
- **structure** [array of ints, optional] Structuring element used for the grayscale dilation. structure may be a non-flat structuring element.
- **output** [array, optional] An array used for storing the output of the dilation may be provided.
mode  [{‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’}, optional] The mode parameter determines how the array borders are handled, where cval is the value when mode is equal to ‘constant’. Default is ‘reflect’.

cval   [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

origin [scalar, optional] The origin parameter controls the placement of the filter. Default 0

Returns

grey_dilation  [ndarray] Grayscale dilation of input.

See also:

binary_dilation, grey_erosion, grey_closing, grey_opening
generate_binary_structure, maximum_filter

Notes

The grayscale dilation of an image input by a structuring element s defined over a domain E is given by:

\[(input+s)(x) = \max \{input(y) + s(x-y), \text{for } y \in E\}\]

In particular, for structuring elements defined as \(s(y) = 0\) for \(y \in E\), the grayscale dilation computes the maximum of the input image inside a sliding window defined by E.

Grayscale dilation [1] is a mathematical morphology operation [2].

Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((7,7), dtype=int)
>>> a[2:5, 2:5] = 1
>>> a[4, 4] = 2; a[2,3] = 3
>>> a
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 3, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 2, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
>>> ndimage.grey_dilation(a, size=(3,3))
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 1, 3, 3, 3, 1, 0],
       [0, 1, 3, 3, 3, 1, 0],
       [0, 1, 3, 3, 3, 2, 0],
       [0, 1, 1, 2, 2, 2, 0],
       [0, 1, 1, 2, 2, 2, 0],
       [0, 0, 0, 0, 0, 0, 0]])
```
scipy.ndimage.grey_erosion

scipy.ndimage.grey_erosion(input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)

Calculate a greyscale erosion, using either a structuring element, or a footprint corresponding to a flat structuring element.

Grayscale erosion is a mathematical morphology operation. For the simple case of a full and flat structuring element, it can be viewed as a minimum filter over a sliding window.

Parameters

- **input** [array_like] Array over which the grayscale erosion is to be computed.
- **size** [tuple of ints] Shape of a flat and full structuring element used for the grayscale erosion. Optional if footprint or structure is provided.
- **footprint** [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the grayscale erosion. Non-zero values give the set of neighbors of the center over which the minimum is chosen.
- **structure** [array of ints, optional] Structuring element used for the grayscale erosion. structure may be a non-flat structuring element.
- **output** [array, optional] An array used for storing the output of the erosion may be provided.
- **mode** [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The mode parameter determines how the array borders are handled, where cval is the value when mode is equal to ‘constant’.
Default is ‘reflect’

`cval` [scalar, optional] Value to fill past end of input if mode is ‘constant’. Default is 0.0.

`origin` [scalar, optional] The origin parameter controls the placement of the filter. Default 0

**Returns**

`output` [ndarray] Grayscale erosion of input.

`binary_erosion`, `grey_dilation`, `grey_opening`, `grey_closing`

`generate_binary_structure`, `minimum_filter`

**Notes**

The grayscale erosion of an image input by a structuring element s defined over a domain E is given by:

\[(\text{input} + s)(x) = \min \{\text{input}(y) - s(x-y), \text{for } y \in E\}\]

In particular, for structuring elements defined as s(y) = 0 for y in E, the grayscale erosion computes the minimum of the input image inside a sliding window defined by E.

Grayscale erosion [1] is a mathematical morphology operation [2].

**Examples**

```python
>>> from scipy import ndimage
>>> a = np.zeros((7,7), dtype=int)
>>> a[1:6, 1:6] = 3
>>> a[4,4] = 2; a[2,3] = 1
>>> a
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 3, 3, 3, 3, 3, 0],
       [0, 3, 3, 1, 3, 3, 0],
       [0, 3, 3, 3, 3, 3, 0],
       [0, 3, 3, 3, 2, 3, 0],
       [0, 3, 3, 3, 3, 3, 0],
       [0, 0, 0, 0, 0, 0, 0]])
>>> ndimage.grey_erosion(a, size=(3,3))
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 1, 1, 1, 0],
       [0, 0, 3, 2, 2, 2, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
>>> footprint = ndimage.generate_binary_structure(2, 1)
>>> footprint
array([[False, True, False],
       [True, True, True],
       [False, True, False]], dtype=bool)```

(continues on next page)
>>> # Diagonally-connected elements are not considered neighbors
>>> ndimage.grey_erosion(a, size=(3,3), footprint=footprint)
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 3, 1, 2, 0, 0],
       [0, 0, 3, 2, 2, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])

scipy.ndimage.grey_opening

scipy.ndimage.grey_opening(input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)

Multi-dimensional greyscale opening.

A greyscale opening consists in the succession of a greyscale erosion, and a greyscale dilation.

Parameters

- **input** [array_like] Array over which the greyscale opening is to be computed.
- **size** [tuple of ints] Shape of a flat and full structuring element used for the greyscale opening. Optional if footprint or structure is provided.
- **footprint** [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the greyscale opening.
- **structure** [array of ints, optional] Structuring element used for the greyscale opening. structure may be a non-flat structuring element.
- **output** [array, optional] An array used for storing the output of the opening may be provided.
- **mode** [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The mode parameter determines how the array borders are handled, where cval is the value when mode is equal to ‘constant’. Default is ‘reflect’
- **cval** [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.
- **origin** [scalar, optional] The origin parameter controls the placement of the filter. Default 0

Returns

grey_opening [ndarray] Result of the greyscale opening of input with structure.

binary_opening, grey_dilation, grey_erosion, grey_closing

generate_binary_structure

Notes

The action of a greyscale opening with a flat structuring element amounts to smoothen high local maxima, whereas binary opening erases small objects.

Examples

```python
>>> from scipy import ndimage
>>> a = np.arange(36).reshape((6,6))
>>> a[3, 3] = 50
>>> a
array([[ 0,  1,  2,  3,  4,  5],
        [ 6,  7,  8,  9, 10, 11],
        [12, 13, 14, 15, 16, 17],
        [18, 19, 20, 22, 23, 29],
        [24, 25, 26, 27, 28, 35]])
>>> ndimage.grey_opening(a, size=(3,3))
array([[ 0,  1,  2,  3,  4,  4],
        [ 6,  7,  8,  9, 10, 10],
        [12, 13, 14, 15, 16, 16],
        [18, 19, 20, 22, 22, 22],
        [24, 25, 26, 27, 28, 28],
        [24, 25, 26, 27, 28, 28]])
>>> # Note that the local maximum a[3,3] has disappeared
```

`scipy.ndimage.iterate_structure`

`scipy.ndimage.iterate_structure(structure, iterations, origin=None)`

Iterate a structure by dilating it with itself.

**Parameters**

- `structure` [array_like] Structuring element (an array of bools, for example), to be dilated with itself.
- `iterations` [int] Number of dilations performed on the structure with itself.
- `origin` [optional] If origin is None, only the iterated structure is returned. If not, a tuple of the iterated structure and the modified origin is returned.

**Returns**

- `iterate_structure` [ndarray of bools] A new structuring element obtained by dilating `structure (iterations - 1)` times with itself.

**See also:**

`generate_binary_structure`

**Examples**

```python
>>> from scipy import ndimage
>>> struct = ndimage.generate_binary_structure(2, 1)
>>> struct.astype(int)
```
array([[0, 1, 0],
       [1, 1, 1],
       [0, 1, 0]])

>>> ndimage.iterate_structure(struct, 2).astype(int)
array([[0, 0, 1, 0, 0],
       [0, 1, 1, 1, 0],
       [1, 1, 1, 1, 1],
       [0, 1, 1, 1, 0],
       [0, 0, 1, 0, 0]])

>>> ndimage.iterate_structure(struct, 3).astype(int)
array([[0, 0, 0, 1, 0, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 1, 1, 1, 1, 1, 0],
       [1, 1, 1, 1, 1, 1, 1],
       [0, 1, 1, 1, 1, 1, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 0, 1, 0, 0, 0]])

scipy.ndimage.morphological_gradient

scipy.ndimage.morphological_gradient (input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)

Multi-dimensional morphological gradient.

The morphological gradient is calculated as the difference between a dilation and an erosion of the input with a given structuring element.

**Parameters**

- **input** [array_like] Array over which to compute the morphological gradient.
- **size** [tuple of ints] Shape of a flat and full structuring element used for the mathematical morphology operations. Optional if footprint or structure is provided. A larger size yields a more blurred gradient.
- **footprint** [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the morphology operations. Larger footprints give a more blurred morphological gradient.
- **structure** [array of ints, optional] Structuring element used for the morphology operations. structure may be a non-flat structuring element.
- **output** [array, optional] An array used for storing the output of the morphological gradient may be provided.
- **mode** [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The mode parameter determines how the array borders are handled, where cval is the value when mode is equal to ‘constant’. Default is ‘reflect’
- **cval** [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.
- **origin** [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

**Returns**

- **morphological_gradient** [ndarray] Morphological gradient of input.

- grey_dilation
- grey_erosion
- gaussian_gradient_magnitude

6.16. Multi-dimensional image processing (scipy.ndimage) 1265
Notes

For a flat structuring element, the morphological gradient computed at a given point corresponds to the maximal difference between elements of the input among the elements covered by the structuring element centered on the point.

[1]

Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((7,7), dtype=int)
>>> a[2:5, 2:5] = 1
>>> ndimage.morphological_gradient(a, size=(3,3))
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 1, 1, 1, 1, 1, 0],
       [0, 1, 1, 1, 1, 1, 0],
       [0, 1, 1, 0, 1, 1, 0],
       [0, 1, 1, 1, 1, 1, 0],
       [0, 1, 1, 1, 1, 1, 0],
       [0, 0, 0, 0, 0, 0, 0]])
```

```python
>>> # The morphological gradient is computed as the difference
>>> # between a dilation and an erosion
>>> ndimage.grey_dilation(a, size=(3,3)) -
... ndimage.grey_erosion(a, size=(3,3))
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 1, 3, 3, 3, 1, 0],
       [0, 1, 3, 3, 3, 1, 0],
       [0, 1, 3, 2, 3, 2, 0],
       [0, 0, 0, 0, 0, 0, 0]])
```

```python
>>> a = np.zeros((7,7), dtype=int)
>>> a[2:5, 2:5] = 1
>>> a[4,4] = 2; a[2,3] = 3
>>> a
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 3, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 2, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
```

```python
>>> ndimage.morphological_gradient(a, size=(3,3))
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 1, 3, 3, 3, 1, 0],
       [0, 1, 3, 3, 3, 1, 0],
       [0, 1, 3, 2, 3, 2, 0],
       [0, 1, 1, 2, 2, 2, 0],
       [0, 1, 1, 1, 1, 1, 0],
       [0, 0, 0, 0, 0, 0, 0]])
```
scipy.ndimage.morphological_laplace

scipy.ndimage.morphological_laplace(input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)

Multi-dimensional morphological laplace.

**Parameters**

- **input** [array_like] Input.
- **size** [int or sequence of ints, optional] See `structure`.
- **footprint** [bool or ndarray, optional] See `structure`.
- **structure** [structure, optional] Either `size`, `footprint`, or the `structure` must be provided.
- **output** [ndarray, optional] An output array can optionally be provided.
- **mode** ['reflect', 'constant', 'nearest', 'mirror', 'wrap'], optional The mode parameter determines how the array borders are handled. For 'constant' mode, values beyond borders are set to be `cval`. Default is 'reflect'.
- **cval** [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0
- **origin** [origin, optional] The origin parameter controls the placement of the filter.

**Returns**

morphological_laplace [ndarray] Output

scipy.ndimage.white_tophat

scipy.ndimage.white_tophat(input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)

Multi-dimensional white tophat filter.

**Parameters**

- **input** [array_like] Input.
- **size** [tuple of ints] Shape of a flat and full structuring element used for the filter. Optional if `footprint` or `structure` is provided.
- **footprint** [array of ints, optional] Positions of elements of a flat structuring element used for the white tophat filter.
- **structure** [array of ints, optional] Structuring element used for the filter. `structure` may be a non-flat structuring element.
- **output** [array, optional] An array used for storing the output of the filter may be provided.
- **mode** ['reflect', 'constant', 'nearest', 'mirror', 'wrap'], optional The `mode` parameter determines how the array borders are handled, where `cval` is the value when mode is equal to 'constant'. Default is 'reflect'
- **cval** [scalar, optional] Value to fill past edges of input if `mode` is 'constant'. Default is 0.0.
- **origin** [scalar, optional] The `origin` parameter controls the placement of the filter. Default is 0.

**Returns**

output [ndarray] Result of the filter of input with structure.

</tbody>
</table>
for the i'th observation. If wd is a rank-3 array of shape (m, m, n), then wd[:,:,i] is the full specification of the covariant weighting matrix for each observation.

fix
[array_like of ints, optional] The fix argument is the same as ifixx in the class ODR. It is an array of integers with the same shape as data.x that determines which input observations are treated as fixed. One can use a sequence of length m (the dimensionality of the input observations) to fix some dimensions for all observations. A value of 0 fixes the observation, a value > 0 makes it free.

meta

Notes
Each argument is attached to the member of the instance of the same name. The structures of x and y are described in the Model class docstring. If y is an integer, then the Data instance can only be used to fit with implicit models where the dimensionality of the response is equal to the specified value of y.

The we argument weights the effect a deviation in the response variable has on the fit. The wd argument weights the effect a deviation in the input variable has on the fit. To handle multidimensional inputs and responses easily, the structure of these arguments has the n'th dimensional axis first. These arguments heavily use the structured arguments feature of ODRPACK to conveniently and flexibly support all options. See the ODRPACK User's Guide for a full explanation of how these weights are used in the algorithm. Basically, a higher value of the weight for a particular data point makes a deviation at that point more detrimental to the fit.

Methods

set_meta(self, \*\*kwds)
Update the metadata dictionary with the keywords and data provided by keywords.

scipy.odr.Data.set_meta
Data.set_meta (self, **kwds)
Update the metadata dictionary with the keywords and data provided by keywords.

 Examples

data.set_meta(lab="Ph 7; Lab 26", title="Ag110 + Ag108 Decay")

scipy.odr.RealData
class scipy.odr.RealData(x, y=None, sx=None, sy=None, covx=None, covy=None, fix=None, meta={})
The data, with weightings as actual standard deviations and/or covariances.

Parameters

x
[array_like] Observed data for the independent variable of the regression

y
[array_like, optional] If array-like, observed data for the dependent variable of the regression. A scalar input implies that the model to be used on the data is implicit.

sx
[array_like, optional] Standard deviations of x. sx are standard deviations of x and are converted to weights by dividing 1.0 by their squares.

sy
[array_like, optional] Standard deviations of y. sy are standard deviations of y and are converted to weights by dividing 1.0 by their squares.
covx  [array_like, optional] Covariance of \( x \) \( \text{cov} x \) is an array of covariance matrices of \( x \) and are converted to weights by performing a matrix inversion on each observation's covariance matrix.

covy  [array_like, optional] Covariance of \( y \) \( \text{cov} y \) is an array of covariance matrices and are converted to weights by performing a matrix inversion on each observation's covariance matrix.

fix  [array_like, optional] The argument and member \( \text{fix} \) is the same as Data.fix and ODR.ifixx: It is an array of integers with the same shape as \( x \) that determines which input observations are treated as fixed. One can use a sequence of length \( m \) (the dimensionality of the input observations) to fix some dimensions for all observations. A value of 0 fixes the observation, a value > 0 makes it free.

Notes

The weights \( w_d \) and \( w_e \) are computed from provided values as follows:

\( s_x \) and \( s_y \) are converted to weights by dividing 1.0 by their squares. For example, \( w_d = 1./\text{numpy.power}(s_x, 2) \).

\( \text{cov} x \) and \( \text{cov} y \) are arrays of covariance matrices and are converted to weights by performing a matrix inversion on each observation's covariance matrix. For example, \( w_e[i] = \text{numpy.linalg.inv(covy[i])} \).

These arguments follow the same structured argument conventions as \( w_d \) and we only restricted by their natures: \( s_x \) and \( s_y \) can't be rank-3, but \( \text{cov} x \) and \( \text{cov} y \) can be.

Only set either \( s_x \) or \( \text{cov} x \) (not both). Setting both will raise an exception. Same with \( s_y \) and \( \text{cov} y \).

Methods

```
set_meta(self, **kwds)  Update the metadata dictionary with the keywords and data provided by keywords.
```

```
scipy.odr.RealData.set_meta

RealData.set_meta(self, **kwds)

Update the metadata dictionary with the keywords and data provided by keywords.
```

Examples

```
data.set_meta(lab="Ph 7; Lab 26", title="Ag110 + Ag108 Decay")
```

scipy.odr.Model

```
class scipy.odr.Model(fcn, fjacb=None, fjacd=None, extra_args=None, estimate=None, implicit=0, meta=None)

The Model class stores information about the function you wish to fit.

It stores the function itself, at the least, and optionally stores functions which compute the Jacobians used during fitting. Also, one can provide a function that will provide reasonable starting values for the fit parameters possibly given the set of data.

Parameters
```
**fcn**  
[function] $fcn(\beta, x) \rightarrow y$

**fjacb**  
[function] Jacobian of $fcn$ wrt the fit parameters $\beta$.  
$fjacb(\beta, x) \rightarrow \partial f_i(x, B)/\partial \beta_j$

**fjacd**  
[function] Jacobian of $fcn$ wrt the (possibly multidimensional) input variable.  
$fjacd(\beta, x) \rightarrow \partial f_i(x, B)/\partial x_j$

**extra_args**  
[tuple, optional] If specified, extra_args should be a tuple of extra arguments to pass to $fcn$, $fjacb$, and $fjacd$. Each will be called by $apply(fcn, (\beta, x) + extra_args)$

**estimate**  
[array_like of rank-1] Provides estimates of the fit parameters from the data  
$estimate(data) \rightarrow \hat{\beta}$

**implicit**  
[boolean] If TRUE, specifies that the model is implicit; i.e. $fcn(\beta, x) \approx 0$ and there is no $y$ data to fit against

**meta**  
[dict, optional] freeform dictionary of metadata for the model

### Notes

Note that the $fcn$, $fjacb$, and $fjacd$ operate on NumPy arrays and return a NumPy array. The $estimate$ object takes an instance of the Data class.

Here are the rules for the shapes of the argument and return arrays of the callback functions:

- **$x$** if the input data is single-dimensional, then $x$ is rank-1 array; i.e. $x = \text{array}([1, 2, 3, \ldots])$; $x$.shape = (n,)  
  If the input data is multi-dimensional, then $x$ is a rank-2 array; i.e., $x = \text{array}([[1, 2, \ldots], [2, 4, \ldots]])$; $x$.shape = (m, n). In all cases, it has the same shape as the input data array passed to $odr$. $m$ is the dimensionality of the input data, $n$ is the number of observations.

- **$y$** if the response variable is single-dimensional, then $y$ is a rank-1 array, i.e., $y = \text{array}([2, 4, \ldots])$; $y$.shape = (n,).  
  If the response variable is multi-dimensional, then $y$ is a rank-2 array, i.e., $y = \text{array}([[2, 4, \ldots], [3, 6, \ldots]])$; $y$.shape = (q, n) where $q$ is the dimensionality of the response variable.

- **$\beta$**  
  rank-1 array of length $p$ where $p$ is the number of parameters; i.e. $\beta = \text{array}([B_1, B_2, \ldots, B_p])$

- **$fjacb$**  
  if the response variable is multi-dimensional, then the return array’s shape is $(q, p, n)$ such that $fjacb(x, \beta)[l, k, i] = d f_l(X, B)/d B_k$ evaluated at the $i$’th data point. If $q == 1$, then the return array is only rank-2 and with shape $(p, n)$.

- **$fjacd$**  
  as with $fjacb$, only the return array’s shape is $(q, m, n)$ such that $fjacd(x, \beta)[l, j, i] = d f_l(X, B)/d X_j$ at the $i$’th data point. If $q == 1$, then the return array’s shape is $(m, n)$. If $m == 1$, the shape is $(q, n)$. If $m == q == 1$, the shape is $(n,)$.

### Methods

- **$set_meta$(self, **kwds)**  
  Update the metadata dictionary with the keywords and data provided here.

- **$scipy.odr.Model.set_meta$**  
  Model.$set_meta$(self, **kwds)  
  Update the metadata dictionary with the keywords and data provided here.
Examples

```python
set_meta(name="Exponential", equation="y = a \exp(b x) + c")
```

`scipy.odr.ODR`

```python
class scipy.odr.ODR(data, model, beta0=None, delta0=None,ifixb=None, ifixx=None, job=None, iprint=None, errfile=None, rptfile=None, ndigit=None, taufac=None, sstol=None, partol=None, maxit=None, stpb=None, std=None, sclb=None, scld=None, work=None, iwork=None)
```

The ODR class gathers all information and coordinates the running of the main fitting routine.

Members of instances of the ODR class have the same names as the arguments to the initialization routine.

**Parameters**

- **data** [Data class instance] instance of the Data class
- **model** [Model class instance] instance of the Model class

**Other Parameters**

- **beta0** [array_like of rank-1] a rank-1 sequence of initial parameter values. Optional if model provides an “estimate” function to estimate these values.
- **delta0** [array_like of floats of rank-1, optional] a (double-precision) float array to hold the initial values of the errors in the input variables. Must be same shape as data.x
- **ifixb** [array_like of ints of rank-1, optional] sequence of integers with the same length as beta0 that determines which parameters are held fixed. A value of 0 fixes the parameter, a value > 0 makes the parameter free.
- **ifixx** [array_like of ints with same shape as data.x, optional] an array of integers with the same shape as data.x that determines which input observations are treated as fixed. One can use a sequence of length m (the dimensionality of the input observations) to fix some dimensions for all observations. A value of 0 fixes the observation, a value > 0 makes it free.
- **job** [int, optional] an integer telling ODRPACK what tasks to perform. See p. 31 of the ODRPACK User's Guide if you absolutely must set the value here. Use the method set_job post-initialization for a more readable interface.
- **iprint** [int, optional] an integer telling ODRPACK what to print. See pp. 33-34 of the ODRPACK User's Guide if you absolutely must set the value here. Use the method set_iprint post-initialization for a more readable interface.
- **errfile** [str, optional] string with the filename to print ODRPACK errors to. Do Not Open This File Yourself!
- **rptfile** [str, optional] string with the filename to print ODRPACK summaries to. Do Not Open This File Yourself!
- **ndigit** [int, optional] integer specifying the number of reliable digits in the computation of the function.
- **taufac** [float, optional] float specifying the initial trust region. The default value is 1. The initial trust region is equal to taufac times the length of the first computed Gauss-Newton step. taufac must be less than 1.
- **sstol** [float, optional] float specifying the tolerance for convergence based on the relative change in the sum-of-squares. The default value is eps**(1/2) where eps is the smallest value such that 1 + eps > 1 for double precision computation on the machine. sstol must be less than 1.
- **partol** [float, optional] float specifying the tolerance for convergence based on the relative change in the estimated parameters. The default value is eps**(2/3) for explicit models and eps**(1/3) for implicit models. partol must be less than 1.
- **maxit** [int, optional] integer specifying the maximum number of iterations to perform. For first runs, maxit is the total number of iterations performed and defaults to 50. For restarts, maxit is the number of additional iterations to perform and defaults to 10.
stpb  [array_like, optional] sequence (len(stpb) == len(beta0)) of relative step sizes to compute finite difference derivatives wrt the parameters.

stpd  [optional] array (stpd.shape == data.x.shape or stpd.shape == (m,)) of relative step sizes to compute finite difference derivatives wrt the input variable errors. If stpd is a rank-1 array with length m (the dimensionality of the input variable), then the values are broadcast to all observations.

sclb  [array_like, optional] sequence (len(stpb) == len(beta0)) of scaling factors for the parameters. The purpose of these scaling factors are to scale all of the parameters to around unity. Normally appropriate scaling factors are computed if this argument is not specified. Specify them yourself if the automatic procedure goes awry.

scld  [array_like, optional] array (scld.shape == data.x.shape or scld.shape == (m,)) of scaling factors for the errors in the input variables. Again, these factors are automatically computed if you do not provide them. If scld.shape == (m,), then the scaling factors are broadcast to all observations.

work  [ndarray, optional] array to hold the double-valued working data for ODRPACK. When restarting, takes the value of self.output.work.

iwork  [ndarray, optional] array to hold the integer-valued working data for ODRPACK. When restarting, takes the value of self.output.iwork.

Attributes

data  [Data] The data for this fit
model  [Model] The model used in fit
output  [Output] An instance if the Output class containing all of the returned data from an invocation of ODR.run() or ODR.restart()

Methods

restart(self[, iter])  Restarts the run with iter more iterations.

run(self)  Run the fitting routine with all of the information given and with full_output=1.

set_iprint(self[, init, so_init, iter, …])  Set the iprint parameter for the printing of computation reports.

set_job(self[, fit_type, deriv, var_calc, …])  Sets the “job” parameter is a hopefully comprehensible way.

scipy.odr.ODR.restart

ODR.restart (self, iter=None)  Restarts the run with iter more iterations.

Parameters

iter  [int, optional] ODRPACK’s default for the number of new iterations is 10.

Returns

output  [Output instance] This object is also assigned to the attribute .output .

scipy.odr.ODR.run

ODR.run (self)  Run the fitting routine with all of the information given and with full_output=1.

Returns

output  [Output instance] This object is also assigned to the attribute .output .
scipy.odr.ODR.set_iprint

**ODR.set_iprint** *(self, init=None, so_init=None, iter=None, so_iter=None, iter_step=None, final=None, so_final=None)*

Set the iprint parameter for the printing of computation reports.

If any of the arguments are specified here, then they are set in the iprint member. If iprint is not set manually or with this method, then ODRPACK defaults to no printing. If no filename is specified with the member rptfile, then ODRPACK prints to stdout. One can tell ODRPACK to print to stdout in addition to the specified filename by setting the so_* arguments to this function, but one cannot specify to print to stdout but not a file since one can do that by not specifying a rptfile filename.

There are three reports: initialization, iteration, and final reports. They are represented by the arguments init, iter, and final respectively. The permissible values are 0, 1, and 2 representing “no report”, “short report”, and “long report” respectively.

The argument iter_step (0 <= iter_step <= 9) specifies how often to make the iteration report; the report will be made for every iter_step'th iteration starting with iteration one. If iter_step == 0, then no iteration report is made, regardless of the other arguments.

If the rptfile is None, then any so_* arguments supplied will raise an exception.

scipy.odr.ODR.set_job

**ODR.set_job** *(self, fit_type=None, deriv=None, var_calc=None, del_init=None, restart=None)*

Sets the “job” parameter in a hopefully comprehensible way.

If an argument is not specified, then the value is left as is. The default value from class initialization is for all of these options set to 0.

**Parameters**

- **fit_type**
  - [(0, 1, 2) int] 0 -> explicit ODR
  - 1 -> implicit ODR
  - 2 -> ordinary least-squares

- **deriv**
  - [(0, 1, 2, 3) int] 0 -> forward finite differences
  - 1 -> central finite differences
  - 2 -> user-supplied derivatives (Jacobians) with results checked by ODRPACK
  - 3 -> user-supplied derivatives, no checking

- **var_calc**
  - [(0, 1, 2) int]
    - 0 -> calculate asymptotic covariance matrix and fit parameter uncertainties (V_B, s_B) using derivatives recomputed at the final solution
    - 1 -> calculate V_B and s_B using derivatives from last iteration
    - 2 -> do not calculate V_B and s_B

- **del_init**
  - [(0, 1) int] 0 -> initial input variable offsets set to 0
  - 1 -> initial offsets provided by user in variable “work”

- **restart**
  - [(0, 1) int] 0 -> fit is not a restart
  - 1 -> fit is a restart

**Notes**

The permissible values are different from those given on pg. 31 of the ODRPACK User’s Guide only in that one cannot specify numbers greater than the last value for each variable.
If one does not supply functions to compute the Jacobians, the fitting procedure will change deriv to 0, finite differences, as a default. To initialize the input variable offsets by yourself, set del_init to 1 and put the offsets into the “work” variable correctly.

**scipy.odr.Output**

```python
class scipy.odr.Output(output)
```

The `Output` class stores the output of an ODR run.

**Notes**

Takes one argument for initialization, the return value from the function `odr`. The attributes listed as “optional” above are only present if `odr` was run with `full_output=1`.

**Attributes**

- `beta` [ndarray] Estimated parameter values, of shape (q,).
- `sd_beta` [ndarray] Standard errors of the estimated parameters, of shape (p,).
- `cov_beta` [ndarray] Covariance matrix of the estimated parameters, of shape (p,p).
- `delta` [ndarray, optional] Array of estimated errors in input variables, of same shape as x.
- `eps` [ndarray, optional] Array of estimated errors in response variables, of same shape as y.
- `xplus` [ndarray, optional] Array of x + delta.
- `y` [ndarray, optional] Array y = fcn(x + delta).
- `res_var` [float, optional] Residual variance.
- `sum_square` [float, optional] Sum of squares error.
- `sum_square_delta` [float, optional] Sum of squares of delta error.
- `sum_square_eps` [float, optional] Sum of squares of eps error.
- `inv_condnum` [float, optional] Inverse condition number (cf. ODRPACK UG p. 77).
- `rel_error` [float, optional] Relative error in function values computed within fcn.
- `work` [ndarray, optional] Final work array.
- `work_ind` [dict, optional] Indices into work for drawing out values (cf. ODRPACK UG p. 83).
- `info` [int, optional] Reason for returning, as output by ODRPACK (cf. ODRPACK UG p. 38).
- `stopreason` [list of str, optional] `info` interpreted into English.

**Methods**

```python
scipy.odr.Output.pprint(self)
```

Pretty-print important results.
scipy.odr

scipy.odr(fcn, beta0, y, x, we=None, wd=None, fjacb=None, fjacd=None, extra_args=None, ifixx=None, ifixb=None, job=0, iprint=0, errfile=None, rptfile=None, ndigit=0, taufac=0.0, sstol=-1.0, partol=-1.0, maxit=-1, stpb=None, stpd=None, sclb=None, scld=None, work=None, iwork=None, full_output=0)

Low-level function for ODR.

Notes

This is a function performing the same operation as the ODR, Model and Data classes together. The parameters of this function are explained in the class documentation.

scipy.odr.OdrWarning

exception scipy.odr.OdrWarning

Warning indicating that the data passed into ODR will cause problems when passed into ‘odr’ that the user should be aware of.

with_traceback()
    Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

scipy.odr.OdrError

exception scipy.odr.OdrError

Exception indicating an error in fitting.

This is raised by odr if an error occurs during fitting.

with_traceback()
    Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

scipy.odr.OdrStop

exception scipy.odr.OdrStop

Exception stopping fitting.

You can raise this exception in your objective function to tell odr to stop fitting.

with_traceback()
    Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

Prebuilt models:
### 6.17.2 Usage information

**Introduction**

Why Orthogonal Distance Regression (ODR)? Sometimes one has measurement errors in the explanatory (a.k.a., “independent”) variable(s), not just the response (a.k.a., “dependent”) variable(s). Ordinary Least Squares (OLS) fitting procedures treat the data for explanatory variables as fixed, i.e., not subject to error of any kind. Furthermore, OLS procedures require that the response variables be an explicit function of the explanatory variables; sometimes making the equation explicit is impractical and/or introduces errors. ODR can handle both of these cases with ease, and can even reduce to the OLS case if that is sufficient for the problem.

ODRPACK is a FORTRAN-77 library for performing ODR with possibly non-linear fitting functions. It uses a modified trust-region Levenberg-Marquardt-type algorithm [1] to estimate the function parameters. The fitting functions are provided by Python functions operating on NumPy arrays. The required derivatives may be provided by Python functions as well, or may be estimated numerically. ODRPACK can do explicit or implicit ODR fits, or it can do OLS. Input and output variables may be multi-dimensional. Weights can be provided to account for different variances of the observations, and even covariances between dimensions of the variables.

The `scipy.odr` package offers an object-oriented interface to ODRPACK, in addition to the low-level `odr` function. Additional background information about ODRPACK can be found in the ODRPACK User's Guide, reading which is recommended.

**Basic usage**

1. Define the function you want to fit against:

   ```python
   def f(B, x):
       # 'Linear function y = m*x + b'
       # B is a vector of the parameters.
       # x is an array of the current x values.
       # x is in the same format as the x passed to Data or RealData.
       #
       # Return an array in the same format as y passed to Data or RealData.
       return B[0]*x + B[1]
   ```

2. Create a Model:

   ```python
   linear = Model(f)
   ```

3. Create a Data or RealData instance:
SciPy Reference Guide, Release 1.3.2

```python
mydata = Data(x, y, wd=1./power(sx, 2), we=1./power(sy, 2))
```

or, when the actual covariances are known:

```python
mydata = RealData(x, y, sx=sx, sy=sy)
```

4. Instantiate ODR with your data, model and initial parameter estimate:

```python
myodr = ODR(mydata, linear, beta0=[1., 2.])
```

5. Run the fit:

```python
myoutput = myodr.run()
```

6. Examine output:

```python
myoutput.pprint()
```

6.18 Optimization and Root Finding (scipy.optimize)

SciPy optimize provides functions for minimizing (or maximizing) objective functions, possibly subject to constraints. It includes solvers for nonlinear problems (with support for both local and global optimization algorithms), linear programming, constrained and nonlinear least-squares, root finding and curve fitting.

Common functions and objects, shared across different solvers, are:

```python
show_options([solver, method, disp])
```
Show documentation for additional options of optimization solvers.

```python
OptimizeResult
```
Represents the optimization result.

```python
OptimizeWarning
```

6.18.1 scipy.optimize.show_options

```python
scipy.optimize.show_options(solver=None, method=None, disp=True)
```
Show documentation for additional options of optimization solvers.

These are method-specific options that can be supplied through the options dict.

**Parameters**

- `method` [str, optional] If not given, shows all methods of the specified solver. Otherwise, show only the options for the specified method. Valid values corresponds to methods’ names of respective solver (e.g. ‘BFGS’ for ‘minimize’).
- `disp` [bool, optional] Whether to print the result rather than returning it.

**Returns**

- `text` Either None (for disp=True) or the text string (disp=False)
Notes

The solver-specific methods are:

\texttt{scipy.optimize.minimize}

- \texttt{Nelder-Mead}
- \texttt{Powell}
- \texttt{CG}
- \texttt{BFGS}
- \texttt{Newton-CG}
- \texttt{L-BFGS-B}
- \texttt{TNC}
- \texttt{COBYLA}
- \texttt{SLSQP}
- \texttt{dogleg}
- \texttt{trust-ncg}

\texttt{scipy.optimize.root}

- \texttt{hybr}
- \texttt{lm}
- \texttt{broyden1}
- \texttt{broyden2}
- \texttt{anderson}
- \texttt{linearmixing}
- \texttt{diagbroyden}
- \texttt{excitingmixing}

- \texttt{interior-point}

\texttt{6.18.2 \texttt{scipy.optimize.OptimizeResult}}

\texttt{class \texttt{scipy.optimize.OptimizeResult}}

Represents the optimization result.
Notes

There may be additional attributes not listed above depending on the specific solver. Since this class is essentially a subclass of dict with attribute accessors, one can see which attributes are available using the `keys()` method.

**Attributes**

- **x** [ndarray] The solution of the optimization.
- **success** [bool] Whether or not the optimizer exited successfully.
- **status** [int] Termination status of the optimizer. Its value depends on the underlying solver. Refer to `message` for details.
- **message** [str] Description of the cause of the termination.
- **fun, jac, hess**: [ndarray] Values of objective function, its Jacobian and its Hessian (if available). The Hessians may be approximations, see the documentation of the function in question.
- **hess_inv** [object] Inverse of the objective function's Hessian; may be an approximation. Not available for all solvers. The type of this attribute may be either np.ndarray or scipy.sparse.linalg.LinearOperator.
- **nfev, njev, nhev** [int] Number of evaluations of the objective functions and of its Jacobian and Hessian.
- **nit** [int] Number of iterations performed by the optimizer.
- **maxcv** [float] The maximum constraint violation.

**Methods**

```
__getitem__() x.__getitem__(y) <==> x[y]
__len__(self, /) Return len(self).
clear()
copy()
fromkeys(iterable[, value]) Returns a new dict with keys from iterable and values equal to value.
get()
items()
keys()
pop() If key is not found, d is returned if given, otherwise KeyError is raised
popitem() 2-tuple; but raise KeyError if D is empty.
setdefault() update() If E is present and has a .keys() method, then does: for k in E: D[k] = E[k] If E is present and lacks a .keys() method, then does: for k, v in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]
values()
```

```
scipy.optimize.OptimizeResult.__getitem__

OptimizeResult.__getitem__(y) <==> x[y]
```

1280 Chapter 6. API Reference
scipy.optimize.OptimizeResult.__len__

OptimizeResult.__len__(self, /)
    Return len(self).

scipy.optimize.OptimizeResult.clear

OptimizeResult.clear()

scipy.optimize.OptimizeResult.copy

OptimizeResult.copy()

scipy.optimize.OptimizeResult.fromkeys

OptimizeResult.fromkeys(iterable, value=None, /)
    Returns a new dict with keys from iterable and values equal to value.

scipy.optimize.OptimizeResult.get

OptimizeResult.get()

scipy.optimize.OptimizeResult.items

OptimizeResult.items()

scipy.optimize.OptimizeResult.keys

OptimizeResult.keys()

scipy.optimize.OptimizeResult.pop

OptimizeResult.pop()
    If key is not found, d is returned if given, otherwise KeyError is raised

scipy.optimize.OptimizeResult.popitem

OptimizeResult.popitem()
    2-tuple; but raise KeyError if D is empty.

scipy.optimize.OptimizeResult.setdefault

OptimizeResult.setdefault()
scipy.optimize.OptimizeResult.update

OptimizeResult.update()
If E is present and has a .keys() method, then does: for k in E: D[k] = E[k] If E is present and lacks a .keys() method, then does: for k, v in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]

scipy.optimize.OptimizeResult.values

OptimizeResult.values()

6.18.3 scipy.optimize.OptimizeWarning
exception scipy.optimize.OptimizeWarning

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

6.18.4 Optimization

Scalar Functions Optimization

minimize_scalar(fun[, bracket, bounds, ...]) Minimization of scalar function of one variable.

scipy.optimize.minimize_scalar

scipy.optimize.minimize_scalar(fun, bracket=None, bounds=None, args=(), method='brent', tol=None, options=None)
Minimization of scalar function of one variable.

Parameters

- **fun**
  [callable] Objective function. Scalar function, must return a scalar.

- **bracket**
  [sequence, optional] For methods ‘brent’ and ‘golden’, **bracket** defines the bracketing interval and can either have three items (a, b, c) so that a < b < c and fun(b) < fun(a), fun(c) or two items a and c which are assumed to be a starting interval for a downhill bracket search (see **bracket**); it doesn’t always mean that the obtained solution will satisfy a <= x <= c.

- **bounds**
  [sequence, optional] For method ‘bounded’, **bounds** is mandatory and must have two items corresponding to the optimization bounds.

- **args**
  [tuple, optional] Extra arguments passed to the objective function.

- **method**
  [str or callable, optional] Type of solver. Should be one of:
  - ‘Brent’ (see here)
  - ‘Bounded’ (see here)
  - ‘Golden’ (see here)
  - custom - a callable object (added in version 0.14.0), see below

- **tol**
  [float, optional] Tolerance for termination. For detailed control, use solver-specific options.

- **options**
  - **maxiter**
    [int] Maximum number of iterations to perform.
  - **disp**
    [bool] Set to True to print convergence messages.

See **show_options** for solver-specific options.

Returns
res       [OptimizeResult] The optimization result represented as an OptimizeResult object. Important attributes are: x the solution array, success a Boolean flag indicating if the optimizer exited successfully and message which describes the cause of the termination. See OptimizeResult for a description of other attributes.

minimize

Interface to minimization algorithms for scalar multivariate functions

show_options

Additional options accepted by the solvers

Notes

This section describes the available solvers that can be selected by the ‘method’ parameter. The default method is Brent.

Method Brent uses Brent’s algorithm to find a local minimum. The algorithm uses inverse parabolic interpolation when possible to speed up convergence of the golden section method.

Method Golden uses the golden section search technique. It uses analog of the bisection method to decrease the bracketed interval. It is usually preferable to use the Brent method.

Method Bounded can perform bounded minimization. It uses the Brent method to find a local minimum in the interval $x_1 < x_{opt} < x_2$.

Custom minimizers

It may be useful to pass a custom minimization method, for example when using some library frontend to minimize_scalar. You can simply pass a callable as the method parameter.

The callable is called as method(fun, args, **kwarsgs, **options) where kwargs corresponds to any other parameters passed to minimize (such as bracket, tol, etc.), except the options dict, which has its contents also passed as method parameters pair by pair. The method shall return an OptimizeResult object.

The provided method callable must be able to accept (and possibly ignore) arbitrary parameters; the set of parameters accepted by minimize may expand in future versions and then these parameters will be passed to the method. You can find an example in the scipy.optimize tutorial.

New in version 0.11.0.

Examples

Consider the problem of minimizing the following function.

```python
>>> def f(x):
...         return (x - 2) * x * (x + 2)**2
```

Using the Brent method, we find the local minimum as:

```python
>>> from scipy.optimize import minimize_scalar
>>> res = minimize_scalar(f)
>>> res.x
1.28077640403
```

Using the Bounded method, we find a local minimum with specified bounds as:
The `minimize_scalar` function supports the following methods:

**minimize_scalar(method='brent')**

```python
scipy.optimize.minimize_scalar (fun, args=(), method='brent', tol=None, options={'func': None, 'brack': None, 'xtol': 1.48e-08, 'maxiter': 500})
```

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize_scalar`

**Options**

- `maxiter` [int] Maximum number of iterations to perform.
- `xtol` [float] Relative error in solution $x_{opt}$ acceptable for convergence.

**Notes**

Uses inverse parabolic interpolation when possible to speed up convergence of golden section method.

**minimize_scalar(method='bounded')**

```python
scipy.optimize.minimize_scalar (fun, bounds=None, args=(), method='bounded', tol=None, options={'func': None, 'xatol': 1e-05, 'maxiter': 500, 'disp': 0})
```

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize_scalar`

**Options**

- `maxiter` [int] Maximum number of iterations to perform.
- `disp: int, optional` If non-zero, print messages. 
  - 0: no message printing. 1: non-convergence notification messages only. 2: print a message on convergence too. 3: print iteration results.
- `xatol` [float] Absolute error in solution $x_{opt}$ acceptable for convergence.

**minimize_scalar(method='golden')**

```python
scipy.optimize.minimize_scalar (fun, args=(), method='golden', tol=None, options={'func': None, 'brack': None, 'xtol': 1.4901161193847656e-08, 'maxiter': 5000})
```

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize_scalar`

**Options**

- `maxiter` [int] Maximum number of iterations to perform.
- `xtol` [float] Relative error in solution $x_{opt}$ acceptable for convergence.
Local (Multivariate) Optimization

**minimize** *(fun, x0[, args, method, jac, hess, ...])*  
Minimization of scalar function of one or more variables.

**scipy.optimize.minimize**

```python
scipy.optimize.minimize (fun, x0, args=(), method=None, jac=None, hess=None, hessp=None,
bounds=None, constraints=(), tol=None, callback=None, options=None)
```

Minimization of scalar function of one or more variables.

**Parameters**

- **fun**
  [callable] The objective function to be minimized.
  ```python
  fun(x, *args) -> float
  ```
  where `x` is an 1-D array with shape `(n,)` and `args` is a tuple of the fixed parameters needed to completely specify the function.

- **x0**
  [ndarray, shape `(n,)`] Initial guess. Array of real elements of size `(n,)`, where ‘n’ is the number of independent variables.

- **args**
  [tuple, optional] Extra arguments passed to the objective function and its derivatives (`fun`, `jac` and `hess` functions).

- **method**
  [str or callable, optional] Type of solver. Should be one of
  ```
  • 'Nelder-Mead' (see here)
  • 'Powell' (see here)
  • 'CG' (see here)
  • 'BFGS' (see here)
  • 'Newton-CG' (see here)
  • 'L-BFGS-B' (see here)
  • 'TNC' (see here)
  • 'COBYLA' (see here)
  • 'SLSQP' (see here)
  • 'trust-constr'(see here)
  • 'dogleg' (see here)
  • 'trust-ncg' (see here)
  • 'trust-exact' (see here)
  • 'trust-krylov' (see here)
  ```
  • custom - a callable object (added in version 0.14.0), see below for description.
  If not given, chosen to be one of BFGS, L-BFGS-B, SLSQP, depending if the problem has constraints or bounds.

- **jac**
  [{callable, '2-point', '3-point', 'cs', bool}, optional] Method for computing the gradient vector. Only for CG, BFGS, Newton-CG, L-BFGS-B, TNC, SLSQP, dogleg, trust-ncg, trust-krylov, trust-exact and trust-constr. If it is a callable, it should be a function that returns the gradient vector:
  ```python
  jac(x, *args) -> array_like, shape (n,)
  ```
  where `x` is an array with shape `(n,)` and `args` is a tuple with the fixed parameters. Alternatively, the keywords ['2-point', '3-point', 'cs'] select a finite difference scheme for numerical estimation of the gradient. Options '3-point' and 'cs' are available only to 'trust-constr'. If `jac` is a Boolean and is True, `fun` is assumed to return the gradient along with the objective function. If False, the gradient will be estimated using '2-point' finite difference estimation.

- **hess**
  [{callable, '2-point', '3-point', 'cs', HessianUpdateStrategy}, optional] Method for computing the Hessian matrix. Only for Newton-CG, dogleg, trust-ncg, trust-krylov, trust-exact and trust-constr. If it is a callable, it should return the Hessian matrix:
  ```python
  hess(x, *args) -> {LinearOperator, spmatrix, array}, (n, n)
  ```
where \( x \) is a \((n,)\) ndarray and \( \text{args} \) is a tuple with the fixed parameters. LinearOperator and sparse matrix returns are allowed only for ‘trust-constr’ method. Alternatively, the keywords \{'2-point', '3-point', 'cs'\} select a finite difference scheme for numerical estimation. Or, objects implementing \texttt{HessianUpdateStrategy} interface can be used to approximate the Hessian. Available quasi-Newton methods implementing this interface are:

- \texttt{BFGS};
- \texttt{SR1}.

Whenever the gradient is estimated via finite-differences, the Hessian cannot be estimated with options \{'2-point', '3-point', 'cs'\} and needs to be estimated using one of the quasi-Newton strategies. Finite-difference options \{'2-point', '3-point', 'cs'\} and \texttt{HessianUpdateStrategy} are available only for ‘trust-constr’ method.

\texttt{hessp} [callable, optional] Hessian of objective function times an arbitrary vector \( p \). Only for Newton-CG, trust-ncg, trust-krylov, trust-constr. Only one of \texttt{hessp} or \texttt{hess} needs to be given. If \texttt{hess} is provided, then \texttt{hessp} will be ignored. \texttt{hessp} must compute the Hessian times an arbitrary vector:

\[
\text{hessp}(x, p, *\text{args}) \rightarrow \text{ndarray shape (n,)}
\]

where \( x \) is a \((n,)\) ndarray, \( p \) is an arbitrary vector with dimension \((n,)\) and \text{args} is a tuple with the fixed parameters.

\texttt{bounds} [sequence or \texttt{Bounds}, optional] Bounds on variables for L-BFGS-B, TNC, SLSQP and trust-constr methods. There are two ways to specify the bounds:

1. Instance of \texttt{Bounds} class.
2. Sequence of \((\text{min}, \text{max})\) pairs for each element in \( x \). None is used to specify no bound.

\texttt{constraints} [[\texttt{Constraint}, dict] or List of \{\texttt{Constraint}, dict\}, optional] Constraints definition (only for COBYLA, SLSQP and trust-constr). Constraints for ‘trust-constr’ are defined as a single object or a list of objects specifying constraints to the optimization problem. Available constraints are:

- \texttt{LinearConstraint}
- \texttt{NonlinearConstraint}

Constraints for COBYLA, SLSQP are defined as a list of dictionaries. Each dictionary with fields:

- \texttt{fun} [callable] The function defining the constraint.
- \texttt{jac} [callable, optional] The Jacobian of \texttt{fun} (only for SLSQP).
- \texttt{args} [sequence, optional] Extra arguments to be passed to the function and Jacobian.

Equality constraint means that the constraint function result is to be zero whereas inequality means that it is to be non-negative. Note that COBYLA only supports inequality constraints.

\texttt{tol} [float, optional] Tolerance for termination. For detailed control, use solver-specific options.

\texttt{options} [dict, optional] A dictionary of solver options. All methods accept the following generic options:

- \texttt{maxiter} [int] Maximum number of iterations to perform.
- \texttt{disp} [bool] Set to True to print convergence messages.

For method-specific options, see \texttt{show_options}.

\texttt{callback} [callable, optional] Called after each iteration. For ‘trust-constr’ it is a callable with the signature:

\[
\text{callback}(xk, \text{OptimizeResult state}) \rightarrow \text{bool}
\]

where \( xk \) is the current parameter vector, and \text{state} is an \texttt{OptimizeResult} object, with the same fields as the ones from the return. If callback returns True the algorithm execution is terminated. For all the other methods, the signature is:

\[
\text{callback}(xk)
\]

where \( xk \) is the current parameter vector.

\textbf{Returns}
res [OptimizeResult] The optimization result represented as a `OptimizeResult` object. Important attributes are: `x` the solution array, `success` a Boolean flag indicating if the optimizer exited successfully and `message` which describes the cause of the termination. See `OptimizeResult` for a description of other attributes.

*show_options*

Additional options accepted by the solvers

Notes

This section describes the available solvers that can be selected by the `method` parameter. The default method is `BFGS`.

**Unconstrained minimization**

Method *Nelder-Mead* uses the Simplex algorithm [1], [2]. This algorithm is robust in many applications. However, if numerical computation of derivative can be trusted, other algorithms using the first and/or second derivatives information might be preferred for their better performance in general.

Method *Powell* is a modification of Powell’s method [3], [4] which is a conjugate direction method. It performs sequential one-dimensional minimizations along each vector of the directions set (direct field in options and info), which is updated at each iteration of the main minimization loop. The function need not be differentiable, and no derivatives are taken.

Method *CG* uses a nonlinear conjugate gradient algorithm by Polak and Ribiere, a variant of the Fletcher-Reeves method described in [5] pp. 120-122. Only the first derivatives are used.

Method *BFGS* uses the quasi-Newton method of Broyden, Fletcher, Goldfarb, and Shanno (BFGS) [5] pp. 136. It uses the first derivatives only. BFGS has proven good performance even for non-smooth optimizations. This method also returns an approximation of the Hessian inverse, stored as `hess_inv` in the `OptimizeResult` object.

Method *Newton-CG* uses a Newton-CG algorithm [5] pp. 168 (also known as the truncated Newton method). It uses a CG method to compute the search direction. See also *TNC* method for a box-constrained minimization with a similar algorithm. Suitable for large-scale problems.

Method *dogleg* uses the dog-leg trust-region algorithm [5] for unconstrained minimization. This algorithm requires the gradient and Hessian; furthermore the Hessian is required to be positive definite.

Method *trust-ncg* uses the Newton conjugate gradient trust-region algorithm [5] for unconstrained minimization. This algorithm requires the gradient and either the Hessian or a function that computes the product of the Hessian with a given vector. Suitable for large-scale problems.

Method *trust-krylov* uses the Newton GLTR trust-region algorithm [14], [15] for unconstrained minimization. This algorithm requires the gradient and either the Hessian or a function that computes the product of the Hessian with a given vector. Suitable for large-scale problems. On indefinite problems it requires usually less iterations than the *trust-ncg* method and is recommended for medium and large-scale problems.

Method *trust-exact* is a trust-region method for unconstrained minimization in which quadratic subproblems are solved almost exactly [13]. This algorithm requires the gradient and the Hessian (which is *not* required to be positive definite). It is, in many situations, the Newton method to converge in fewer iteration and the most recommended for small and medium-size problems.

**Bound-Constrained minimization**

Method \textit{TNC} uses a truncated Newton algorithm [5], [8] to minimize a function with variables subject to bounds. This algorithm uses gradient information; it is also called Newton Conjugate-Gradient. It differs from the \textit{Newton-CG} method described above as it wraps a C implementation and allows each variable to be given upper and lower bounds.

\textbf{Constrained Minimization}

Method \textit{COBYLA} uses the Constrained Optimization BY Linear Approximation (COBYLA) method [9], [10], [11]. The algorithm is based on linear approximations to the objective function and each constraint. The method wraps a FORTRAN implementation of the algorithm. The constraints functions ‘fun’ may return either a single number or an array or list of numbers.

Method \textit{SLSQP} uses Sequential Least SQuares Programming to minimize a function of several variables with any combination of bounds, equality and inequality constraints. The method wraps the SLSQP Optimization subroutine originally implemented by Dieter Kraft [12]. Note that the wrapper handles infinite values in bounds by converting them into large floating values.

Method \textit{trust-constr} is a trust-region algorithm for constrained optimization. It switches between two implementations depending on the problem definition. It is the most versatile constrained minimization algorithm implemented in SciPy and the most appropriate for large-scale problems. For equality constrained problems it is an implementation of Byrd-Omojokun Trust-Region SQP method described in [17] and in [5], p. 549. When inequality constraints are imposed as well, it switches to the trust-region interior point method described in [16]. This interior point algorithm, in turn, solves inequality constraints by introducing slack variables and solving a sequence of equality-constrained barrier problems for progressively smaller values of the barrier parameter. The previously described equality constrained SQP method is used to solve the subproblems with increasing levels of accuracy as the iterate gets closer to a solution.

\textbf{Finite-Difference Options}

For Method \textit{trust-constr} the gradient and the Hessian may be approximated using three finite-difference schemes: (‘2-point’, ‘3-point’, ‘cs’). The scheme ‘cs’ is, potentially, the most accurate but it requires the function to correctly handles complex inputs and to be differentiable in the complex plane. The scheme ‘3-point’ is more accurate than ‘2-point’ but requires twice as much operations.

\textbf{Custom minimizers}

It may be useful to pass a custom minimization method, for example when using a frontend to this method such as \textit{scipy.optimize.basinhopping} or a different library. You can simply pass a callable as the \texttt{method} parameter.

The callable is called as \texttt{method(fun, x0, args, **kwargs, **options)} where \texttt{kwargs} corresponds to any other parameters passed to \textit{minimize} (such as \texttt{callback}, \texttt{hess}, etc.), except the \texttt{options} dict, which has its contents also passed as \texttt{method} parameters pair by pair. Also, if \texttt{jac} has been passed as a bool type, \texttt{jac} and \texttt{fun} are mangled so that \texttt{fun} returns just the function values and \texttt{jac} is converted to a function returning the Jacobian. The method shall return an \texttt{OptimizeResult} object.

The provided \texttt{method} callable must be able to accept (and possibly ignore) arbitrary parameters; the set of parameters accepted by \textit{minimize} may expand in future versions and then these parameters will be passed to the method. You can find an example in the \texttt{scipy.optimize} tutorial.

New in version 0.11.0.

Examples

Let us consider the problem of minimizing the Rosenbrock function. This function (and its respective derivatives) is implemented in `rosen` (resp. `rosen_der`, `rosen_hess`) in the `scipy.optimize`.

```python
>>> from scipy.optimize import minimize, rosen, rosen_der
```

A simple application of the Nelder-Mead method is:

```python
>>> x0 = [1.3, 0.7, 0.8, 1.9, 1.2]
>>> res = minimize(rosen, x0, method='Nelder-Mead', tol=1e-6)
>>> res.x
array([ 1., 1., 1., 1., 1.])
```

Now using the BFGS algorithm, using the first derivative and a few options:

```python
>>> res = minimize(rosen, x0, method='BFGS', jac=rosen_der, ... options={'gtol': 1e-6, 'disp': True})
Optimization terminated successfully.
Current function value: 0.000000
Iterations: 26
Function evaluations: 31
Gradient evaluations: 31
```

```python
>>> res.x
array([ 1., 1., 1., 1., 1.])
>>> print(res.message)
Optimization terminated successfully.
>>> res.hess_inv
array([[ 0.00749589, 0.01255155, 0.02396251, 0.04750988, 0.09495377],
       [ 0.01255155, 0.02510441, 0.04794055, 0.09502834, 0.18996269],
       [ 0.02396251, 0.04794055, 0.09631614, 0.19092151, 0.38165151],
       [ 0.04750988, 0.09502834, 0.19092151, 0.38341252, 0.7664427 ],
       [ 0.09495377, 0.18996269, 0.38165151, 0.7664427, 1.53713523]])
```

Next, consider a minimization problem with several constraints (namely Example 16.4 from [5]). The objective function is:

```python
>>> fun = lambda x: (x[0] - 1)**2 + (x[1] - 2.5)**2
```

There are three constraints defined as:

```python
>>> cons = [{'type': 'ineq', 'fun': lambda x: x[0] - 2 * x[1] + 2}, ...
     {'type': 'ineq', 'fun': lambda x: -x[0] - 2 * x[1] + 6}, ...
     {'type': 'ineq', 'fun': lambda x: -x[0] + 2 * x[1] + 2}]
```

And variables must be positive, hence the following bounds:

```python
>>> bnds = ((0, None), (0, None))
```

The optimization problem is solved using the SLSQP method as:

```python
>>> res = minimize(fun, (2, 0), method='SLSQP', bounds=bnds, ...
    constraints=cons)
```
It should converge to the theoretical solution (1.4, 1.7).

The `minimize` function supports the following methods:

**minimize(method='Nelder-Mead')**

```python
scipy.optimize.minimize(fun, x0, args=(), method='Nelder-Mead', tol=None, callback=None, options={}
    'func': None, 'maxiter': None, 'maxfev': None, 'disp': False, 'return_all': False,
    'initial_simplex': None, 'xatol': 0.0001, 'fatol': 0.0001, 'adaptive': False)
```

Minimization of scalar function of one or more variables using the Nelder-Mead algorithm.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

**Options**

- `disp` [bool] Set to True to print convergence messages.
- `maxiter, maxfev` [int] Maximum allowed number of iterations and function evaluations. Will default to \(N \times 200\), where \(N\) is the number of variables, if neither `maxiter` or `maxfev` is set. If both `maxiter` and `maxfev` are set, minimization will stop at the first reached.
- `initial_simplex` [array_like of shape (\(N + 1, N\))] Initial simplex. If given, overrides `x0`. `initial_simplex[j,:]` should contain the coordinates of the \(j\)-th vertex of the \(N+1\) vertices in the simplex, where \(N\) is the dimension.
- `xatol` [float, optional] Absolute error in `xopt` between iterations that is acceptable for convergence.
- `fatol` [number, optional] Absolute error in `func(xopt)` between iterations that is acceptable for convergence.

**References**

[1]

**minimize(method='Powell')**

```python
scipy.optimize.minimize(fun, x0, args=(), method='Powell', tol=None, callback=None, options={}
    'func': None, 'xatol': 0.0001, 'ftol': 0.0001, 'maxiter': None, 'maxfev': None,
    'disp': False, 'direc': None, 'return_all': False)
```

Minimization of scalar function of one or more variables using the modified Powell algorithm.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

**Options**

- `disp` [bool] Set to True to print convergence messages.
- `xtol` [float] Relative error in solution `xopt` acceptable for convergence.
- `ftol` [float] Relative error in `func(xopt)` acceptable for convergence.
- `maxiter, maxfev` [int] Maximum allowed number of iterations and function evaluations. Will default to \(N \times 1000\), where \(N\) is the number of variables, if neither `maxiter` or `maxfev` is set. If both `maxiter` and `maxfev` are set, minimization will stop at the first reached.
- `direc` [ndarray] Initial set of direction vectors for the Powell method.
minimize(method='CG')

```python
scipy.optimize.minimize(fun, x0, args=(), method='CG', jac=None, tol=None, callback=None, options={'gtol': 1e-05, 'norm': 'inf', 'eps': 1.4901161193847656e-08, 'maxiter': None, 'disp': False, 'return_all': False})
```

Minimization of scalar function of one or more variables using the conjugate gradient algorithm.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

Options

- `disp` [bool] Set to True to print convergence messages.
- `maxiter` [int] Maximum number of iterations to perform.
- `gtol` [float] Gradient norm must be less than `gtol` before successful termination.
- `norm` [float] Order of norm (Inf is max, -Inf is min).
- `eps` [float or ndarray] If `jac` is approximated, use this value for the step size.

minimize(method='BFGS')

```python
scipy.optimize.minimize(fun, x0, args=(), method='BFGS', jac=None, tol=None, callback=None, options={'gtol': 1e-05, 'norm': 'inf', 'eps': 1.4901161193847656e-08, 'maxiter': None, 'disp': False, 'return_all': False})
```

Minimization of scalar function of one or more variables using the BFGS algorithm.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

Options

- `disp` [bool] Set to True to print convergence messages.
- `maxiter` [int] Maximum number of iterations to perform.
- `gtol` [float] Gradient norm must be less than `gtol` before successful termination.
- `norm` [float] Order of norm (Inf is max, -Inf is min).
- `eps` [float or ndarray] If `jac` is approximated, use this value for the step size.

minimize(method='Newton-CG')

```python
scipy.optimize.minimize(fun, x0, args=(), method='Newton-CG', jac=None, hess=None, hessp=None, tol=None, callback=None, options={'xtol': 1e-05, 'eps': 1.4901161193847656e-08, 'maxiter': None, 'disp': False, 'return_all': False})
```

Minimization of scalar function of one or more variables using the Newton-CG algorithm.

Note that the `jac` parameter (Jacobian) is required.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

Options

- `disp` [bool] Set to True to print convergence messages.
- `xtol` [float] Average relative error in solution `xopt` acceptable for convergence.
- `maxiter` [int] Maximum number of iterations to perform.
- `eps` [float or ndarray] If `jac` is approximated, use this value for the step size.
minimize(method='L-BFGS-B')

```python
scipy.optimize.minimize(fun, x0, args=(), method='L-BFGS-B', jac=None, bounds=None,
                         tol=None, callback=None, options={'disp': None, 'maxcor': 10, 'ftol':
                         2.220446049250313e-09, 'gtol': 1e-05, 'eps': 1e-08, 'maxfun': 15000,
                         'maxiter': 15000, 'iprint': -1, 'maxls': 20})
```

Minimize a scalar function of one or more variables using the L-BFGS-B algorithm.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

### Options

- **disp** [None or int] If `disp` is `None` (the default), then the supplied version of `iprint` is used. If `disp` is not `None`, then it overrides the supplied version of `iprint` with the behaviour you outlined.
- **maxcor** [int] The maximum number of variable metric corrections used to define the limited memory matrix. (The limited memory BFGS method does not store the full hessian but uses this many terms in an approximation to it.)
- **ftol** [float] The iteration stops when $\frac{f^k - f^{k+1}}{\max\{|f^k|,|f^{k+1}|,1\}} \leq \text{ftol}$. 
- **gtol** [float] The iteration will stop when $\max\{|\text{proj } g_i | i = 1, \ldots, n\} \leq \text{gtol}$ where $\text{pg}_i$ is the i-th component of the projected gradient.
- **eps** [float] Step size used for numerical approximation of the jacobian.
- **maxfun** [int] Maximum number of function evaluations.
- **maxiter** [int] Maximum number of iterations.
- **maxls** [int, optional] Maximum number of line search steps (per iteration). Default is 20.

### Notes

The option `ftol` is exposed via the `scipy.optimize.minimize` interface, but calling `scipy.optimize.fmin_l_bfgs_b` directly exposes `factr`. The relationship between the two is $\text{ftol} = \text{factr} \times \text{numpy.finfo(float).eps}$. I.e., `factr` multiplies the default machine floating-point precision to arrive at `ftol`.

minimize(method='TNC')

```python
scipy.optimize.minimize(fun, x0, args=(), method='TNC', jac=None, bounds=None, tol=None, callback=None, options={'eps': 1e-08, 'scale': None, 'offset': None, 'mesg_num': None, 'maxCGit': -1, 'maxiter': None, 'eta': -1, 'stepmx': 0, 'accuracy': 0, 'minfev': 0, 'ftol': -1, 'xtol': -1, 'gtol': -1, 'rescale': -1, 'disp': False})
```

Minimize a scalar function of one or more variables using a truncated Newton (TNC) algorithm.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

### Options

- **eps** [float] Step size used for numerical approximation of the jacobian.
- **scale** [list of floats] Scaling factors to apply to each variable. If None, the factors are up-low for interval bounded variables and $|1+x|$ for the others. Defaults to None
- **offset** [float] Value to subtract from each variable. If None, the offsets are $(up+low)/2$ for interval bounded variables and $x$ for the others.
- **disp** [bool] Set to True to print convergence messages.
- **maxCGit** [int] Maximum number of hessian*vector evaluations per main iteration. If maxCGit == 0, the direction chosen is -gradient if maxCGit < 0, maxCGit is set to max(1,min(50,n/2)). Defaults to -1.
maxiter  [int] Maximum number of function evaluation. If None, maxiter is set to max(100, 10*len(x0)). Defaults to None.

eta     [float] Severity of the line search. If < 0 or > 1, set to 0.25. Defaults to -1.

stepmx  [float] Maximum step for the line search. May be increased during call. If too small, it will be set to 10.0. Defaults to 0.

accuracy [float] Relative precision for finite difference calculations. If <= machine_precision, set to sqrt(machine_precision). Defaults to 0.

minfev  [float] Minimum function value estimate. Defaultsto 0.

ftol    [float] Precision goal for the value of f in the stopping criterion. If ftol < 0.0, ftol is set to 0.0 defaults to -1.

xtol    [float] Precision goal for the value of x in the stopping criterion (after applying x scaling factors). If xtol < 0.0, xtol is set to sqrt(machine_precision). Defaults to -1.

gtol    [float] Precision goal for the value of the projected gradient in the stopping criterion (after applying x scaling factors). If gtol < 0.0, gtol is set to 1e-2 * sqrt(accuracy). Setting it to 0.0 is not recommended. Defaults to -1.

rescale [float] Scaling factor (in log10) used to trigger f value rescaling. If 0, rescale at each iteration. If a large value, never rescale. If < 0, rescale is set to 1.3.

minimize(method='COBYLA')

scipy.optimize.minimize (fun, x0, args=(), method='COBYLA', constraints=(), tol=None, callback=None, options={'rhobeg': 1.0, 'maxiter': 1000, 'disp': False, 'catol': 0.0002})

Minimize a scalar function of one or more variables using the Constrained Optimization BY Linear Approximation (COBYLA) algorithm.

See also:

For documentation for the rest of the parameters, see scipy.optimize.minimize

Options

rhobeg  [float] Reasonable initial changes to the variables.

tol     [float] Final accuracy in the optimization (not precisely guaranteed). This is a lower bound on the size of the trust region.

disp    [bool] Set to True to print convergence messages. If False, verbosity is ignored as set to 0.

maxiter [int] Maximum number of function evaluations.

minimize(method='SLSQP')

scipy.optimize.minimize (fun, x0, args=(), method='SLSQP', jac=None, bounds=None, constraints=(), tol=None, callback=None, options={'func': None, 'maxiter': 100, 'ftol': 1e-06, 'print': 1, 'disp': False, 'eps': 1.4901161193847656e-08})

Minimize a scalar function of one or more variables using Sequential Least SQUares Programming (SLSQP).

See also:

For documentation for the rest of the parameters, see scipy.optimize.minimize

Options

ftol    [float] Precision goal for the value of f in the stopping criterion.

eps     [float] Step size used for numerical approximation of the Jacobian.

disp    [bool] Set to True to print convergence messages. If False, verbosity is ignored and set to 0.

maxiter [int] Maximum number of iterations.
Minimize a scalar function subject to constraints.

**Parameters**

- **gtol** [float, optional] Tolerance for termination by the norm of the Lagrangian gradient. The algorithm will terminate when both the infinity norm (i.e., max abs value) of the Lagrangian gradient and the constraint violation are smaller than `gtol`. Default is 1e-8.

- **xtol** [float, optional] Tolerance for termination by the change of the independent variable. The algorithm will terminate when `tr_radius < xtol`, where `tr_radius` is the radius of the trust region used in the algorithm. Default is 1e-8.

- **barrier_tol** [float, optional] Threshold on the barrier parameter for the algorithm termination. When inequality constraints are present, the algorithm will terminate only when the barrier parameter is less than `barrier_tol`. Default is 1e-8.

- **sparse_jacobian** [{bool, None}, optional] Determines how to represent Jacobians of the constraints. If bool, then Jacobians of all the constraints will be converted to the corresponding format. If None (default), then Jacobians won't be converted, but the algorithm can proceed only if they all have the same format.

- **initial_tr_radius** [float, optional] Initial trust radius. The trust radius gives the maximum distance between solution points in consecutive iterations. It reflects the trust the algorithm puts in the local approximation of the optimization problem. For an accurate local approximation, the trust-region should be large, and for an approximation valid only close to the current point, it should be a small one. The trust radius is automatically updated throughout the optimization process, with `initial_tr_radius` being its initial value. Default is 1 (recommended in [1], p. 19).

- **initial_constr_penalty** [float, optional] Initial constraints penalty parameter. The penalty parameter is used for balancing the requirements of decreasing the objective function and satisfying the constraints. It is used for defining the merit function: 

\[
\text{merit\_function}(x) = \text{func}(x) + \text{constr\_penalty} \times \text{constr\_norm\_l2}(x),
\]

where `constr\_norm\_l2` is the L2 norm of a vector containing all the constraints. The merit function is used for accepting or rejecting trial points. The penalty parameter weights the two conflicting goals of reducing objective function and constraints. The penalty is automatically updated throughout the optimization process, with `initial_constr_penalty` being its initial value. Default is 1 (recommended in [1], p. 19).

- **initial_barrier_parameter**, **initial_barrier_tolerance** [float, optional] Initial barrier parameter and initial tolerance for the barrier subproblem. Both are used only when inequality constraints are present. For dealing with optimization problems \(\min_x \text{func}(x)\) subject to inequality constraints \(c(x) <= 0\), the algorithm introduces slack variables, solving the problem \(\min_{(x,s)} \text{func}(x) + \text{barrier\_parameter}\times\sum(\ln(s))\) subject to the equality constraints \(c(x) + s = 0\) instead of the original problem. This subproblem is solved for increasing values of `barrier\_parameter` and with decreasing tolerances for the termination, starting with `initial\_barrier\_parameter` for the barrier parameter and `initial\_barrier\_tolerance` for the barrier subproblem. Default is 0.1 for both values (recommended in [1], p. 19).
factorization_method

[string or None, optional] Method to factorize the Jacobian of the constraints. Use None (default) for the auto selection or one of:

- ‘NormalEquation’ (requires scikit-sparse)
- ‘AugmentedSystem’
- ‘QRFactorization’
- ‘SVDFactorization’

The methods ‘NormalEquation’ and ‘AugmentedSystem’ can be used only with sparse constraints. The projections required by the algorithm will be computed using, respectively, the normal equation and the augmented system approaches explained in [1]. ‘NormalEquation’ computes the Cholesky factorization of $A^T A$ and ‘AugmentedSystem’ performs the LU factorization of an augmented system. They usually provide similar results. ‘AugmentedSystem’ is used by default for sparse matrices.

The methods ‘QRFactorization’ and ‘SVDFactorization’ can be used only with dense constraints. They compute the required projections using, respectively, QR and SVD factorizations. The ‘SVDFactorization’ method can cope with Jacobian matrices with deficient row rank and will be used whenever other factorization methods fail (which may imply the conversion of sparse matrices to a dense format when required). By default ‘QRFactorization’ is used for dense matrices.

finite_diff_rel_step

[None or array_like, optional] Relative step size for the finite difference approximation.

maxiter

[int, optional] Maximum number of algorithm iterations. Default is 1000.

verbose

[{0, 1, 2}, optional] Level of algorithm’s verbosity:
- 0 (default): works silently.
- 1: display a termination report.
- 2: display progress during iterations.
- 3: display progress during iterations (more complete report).

disp

[bool, optional] If True (default) then verbose will be set to 1 if it was 0.

Returns

OptimizeResult with the fields documented below. Note the following:

1. All values corresponding to the constraints are ordered as they were passed to the solver. And values corresponding to bounds constraints are put after other constraints.
2. All numbers of function, Jacobian or Hessian evaluations correspond to numbers of actual Python function calls. It means, for example, that if a Jacobian is estimated by finite differences then the number of Jacobian evaluations will be zero and the number of function evaluations will be incremented by all calls during the finite difference estimation.

x

[ndarray, shape (n,)] Solution found.

optimality

[float] Infinity norm of the Lagrangian gradient at the solution.

constr_violation

[float] Maximum constraint violation at the solution.

fun

[float] Objective function at the solution.

grad

[ndarray, shape (n,)] Gradient of the objective function at the solution.

lagrangian_grad

[ndarray, shape (n,)] Gradient of the Lagrangian function at the solution.

nit

[int] Total number of iterations.

nfev

[integer] Number of the objective function evaluations.

ngev

[integer] Number of the objective function gradient evaluations.

nhev

[integer] Number of the objective function Hessian evaluations.

cg_niter

[int] Total number of the conjugate gradient method iterations.

method

[‘equality_constrained_sqp’, ‘tr_interior_point’] Optimization method used.

constr

[list of ndarray] List of constraint values at the solution.
jac [list of {ndarray, sparse matrix}] List of the Jacobian matrices of the constraints at the solution.
v [list of ndarray] List of the Lagrange multipliers for the constraints at the solution. For an inequality constraint a positive multiplier means that the upper bound is active, a negative multiplier means that the lower bound is active and if a multiplier is zero it means the constraint is not active.

**constr_nfev**
[list of int] Number of constraint evaluations for each of the constraints.

**constr_njev**
[list of int] Number of Jacobian matrix evaluations for each of the constraints.

**constr_nhev**
[list of int] Number of Hessian evaluations for each of the constraints.

**tr_radius** [float] Radius of the trust region at the last iteration.

**constr_penalty** [float] Penalty parameter at the last iteration, see initial_constr_penalty.

**barrier_tolerance** [float] Tolerance for the barrier subproblem at the last iteration. Only for problems with inequality constraints.

**barrier_parameter** [float] Barrier parameter at the last iteration. Only for problems with inequality constraints.

**execution_time** [float] Total execution time.

**message** [str] Termination message.

**status** [0, 1, 2, 3]) Termination status:
• 0: The maximum number of function evaluations is exceeded.
• 1: gtol termination condition is satisfied.
• 2: xtol termination condition is satisfied.
• 3: callback function requested termination.

**cg_stop_cond** [int] Reason for CG subproblem termination at the last iteration:
• 0: CG subproblem not evaluated.
• 1: Iteration limit was reached.
• 2: Reached the trust-region boundary.
• 3: Negative curvature detected.
• 4: Tolerance was satisfied.

---

**References**

**minimize(method='dogleg')**

\[
\text{scipy.optimize.minimize}(\text{fun, x0, args=(), method='dogleg', jac=None, hess=None, tol=None, callback=None, options=})
\]

Minimization of scalar function of one or more variables using the dog-leg trust-region algorithm.

**See also:**

For documentation for the rest of the parameters, see \texttt{scipy.optimize.minimize}

**Options**

**initial_trust_radius** [float] Initial trust-region radius.
SciPy Reference Guide, Release 1.3.2

max_trust_radius  [float] Maximum value of the trust-region radius. No steps that are longer than this value will be proposed.
eta  [float] Trust region related acceptance stringency for proposed steps.
gtol  [float] Gradient norm must be less than gtol before successful termination.

minimize(method='trust-ncg')

scipy.optimize.minimize (fun, x0, args=(), method='trust-ncg', jac=None, hess=None, hessp=None,
tol=None, callback=None, options={})

Minimization of scalar function of one or more variables using the Newton conjugate gradient trust-region algorithm.

See also:
For documentation for the rest of the parameters, see scipy.optimize.minimize

Options

initial_trust_radius  [float] Initial trust-region radius.
max_trust_radius  [float] Maximum value of the trust-region radius. No steps that are longer than this value will be proposed.
eta  [float] Trust region related acceptance stringency for proposed steps.
gtol  [float] Gradient norm must be less than gtol before successful termination.

minimize(method='trust-krylov')

scipy.optimize.minimize (fun, x0, args=(), method='trust-krylov', jac=None, hess=None, hessp=None,
tol=None, callback=None, options={'inexact': True})

Minimization of a scalar function of one or more variables using a nearly exact trust-region algorithm that only requires matrix vector products with the hessian matrix.

New in version 1.0.0.

See also:
For documentation for the rest of the parameters, see scipy.optimize.minimize

Options

inexact  [bool, optional] Accuracy to solve subproblems. If True requires less nonlinear iterations, but more vector products.

minimize(method='trust-exact')

scipy.optimize.minimize (fun, x0, args=(), method='trust-exact', jac=None, hess=None, tol=None, callback=None, options={})

Minimization of scalar function of one or more variables using a nearly exact trust-region algorithm.

See also:
For documentation for the rest of the parameters, see scipy.optimize.minimize

Options

initial_tr_radius  [float] Initial trust-region radius.
max_tr_radius
[float] Maximum value of the trust-region radius. No steps that are longer than this value will be proposed.

eta
[float] Trust region related acceptance stringency for proposed steps.

gtol
[float] Gradient norm must be less than gtol before successful termination.

Constraints are passed to minimize function as a single object or as a list of objects from the following classes:

- **NonlinearConstraint**
  ```python
  NonlinearConstraint(fun, lb, ub[, jac, ...])
  ```
  Nonlinear constraint on the variables.

- **LinearConstraint**
  ```python
  LinearConstraint(A, lb, ub[, keep_feasible])
  ```
  Linear constraint on the variables.

```python
class scipy.optimize.NonlinearConstraint (fun, lb, ub, jac='2-point',
hess=<scipy.optimize._hessian_update_strategy.BFGS
object>, keep_feasible=False, finite_diff_rel_step=None,
finite_diff_jac_sparsity=None)
class scipy.optimize.LinearConstraint(A, lb, ub[, keep_feasible])
```

Nonlinear constraint on the variables.

The constraint has the general inequality form:

```python
lb <= fun(x) <= ub
```

Here the vector of independent variables x is passed as ndarray of shape (n,) and fun returns a vector with m components.

It is possible to use equal bounds to represent an equality constraint or infinite bounds to represent a one-sided constraint.

**Parameters**

- **fun**
  [callable] The function defining the constraint. The signature is fun(x) -> array_like, shape (m,).

- **lb, ub**
  [array_like] Lower and upper bounds on the constraint. Each array must have the shape (m,) or be a scalar, in the latter case a bound will be the same for all components of the constraint. Use np.inf with an appropriate sign to specify a one-sided constraint. Set components of lb and ub equal to represent an equality constraint. Note that you can mix constraints of different types: interval, one-sided or equality, by setting different components of lb and ub as necessary.

- **jac**
  [{callable, ‘2-point’, ‘3-point’, ‘cs’}, optional] Method of computing the Jacobian matrix (an m-by-n matrix, where element (i, j) is the partial derivative of f[i] with respect to x[j]). The keywords {‘2-point’, ‘3-point’, ‘cs’} select a finite difference scheme for the numerical estimation. A callable must have the following signature: jac(x) -> {ndarray, sparse matrix}, shape (m, n). Default is ‘2-point’.

- **hess**
  [{callable, ‘2-point’, ‘3-point’, ‘cs’, HessianUpdateStrategy, None}, optional] Method for computing the Hessian matrix. The keywords {‘2-point’, ‘3-point’, ‘cs’} select a finite difference scheme for numerical estimation. Alternatively, objects implementing HessianUpdateStrategy interface can be used to approximate the Hessian. Currently available implementations are:
  - BFGS (default option)
  - SR1

  A callable must return the Hessian matrix of dot(fun, v) and must have the following signature: hess(x, v) -> {LinearOperator, sparse matrix, array_like}, shape (n, n). Here v is ndarray with shape (m,) containing Lagrange multipliers.
**keep_feasible**
[array_like of bool, optional] Whether to keep the constraint components feasible throughout iterations. A single value set this property for all components. Default is False. Has no effect for equality constraints.

**finite_diff_rel_step**: None or array_like, optional
Relative step size for the finite difference approximation. Default is None, which will select a reasonable value automatically depending on a finite difference scheme.

**finite_diff_jac_sparsity**: {None, array_like, sparse matrix}, optional
Defines the sparsity structure of the Jacobian matrix for finite difference estimation, its shape must be (m, n). If the Jacobian has only few non-zero elements in each row, providing the sparsity structure will greatly speed up the computations. A zero entry means that a corresponding element in the Jacobian is identically zero. If provided, forces the use of ‘lsmr’ trust-region solver. If None (default) then dense differencing will be used.

**Notes**

Finite difference schemes {‘2-point’, ‘3-point’, ‘cs’} may be used for approximating either the Jacobian or the Hessian. We, however, do not allow its use for approximating both simultaneously. Hence whenever the Jacobian is estimated via finite-differences, we require the Hessian to be estimated using one of the quasi-Newton strategies.

The scheme ‘cs’ is potentially the most accurate, but requires the function to correctly handles complex inputs and be analytically continuable to the complex plane. The scheme ‘3-point’ is more accurate than ‘2-point’ but requires twice as many operations.

**scipy.optimize.LinearConstraint**

```python
class scipy.optimize.LinearConstraint (A, lb, ub, keep_feasible=False)
```

Linear constraint on the variables.

The constraint has the general inequality form:

\[ lb \leq A \cdot x \leq ub \]

Here the vector of independent variables \( x \) is passed as ndarray of shape \((n,)\) and the matrix \( A \) has shape \((m, n)\).

It is possible to use equal bounds to represent an equality constraint or infinite bounds to represent a one-sided constraint.

**Parameters**

- **A**
  [{array_like, sparse matrix}, shape (m, n)] Matrix defining the constraint.

- **lb, ub**
  [array_like] Lower and upper bounds on the constraint. Each array must have the shape \((m,)\) or be a scalar, in the latter case a bound will be the same for all components of the constraint. Use \( np.inf \) with an appropriate sign to specify a one-sided constraint. Set components of \( lb \) and \( ub \) equal to represent an equality constraint. Note that you can mix constraints of different types: interval, one-sided or equality, by setting different components of \( lb \) and \( ub \) as necessary.

- **keep_feasible**
  [array_like of bool, optional] Whether to keep the constraint components feasible throughout iterations. A single value set this property for all components. Default is False. Has no effect for equality constraints.

Simple bound constraints are handled separately and there is a special class for them:

```python
Bounds([lb, ub[, keep_feasible]])
```

Bounds constraint on the variables.
**scipy.optimize.Bounds**

```python
class scipy.optimize.Bounds(lb, ub, keep_feasible=False)
```

Bounds constraint on the variables.

The constraint has the general inequality form:

```
lb <= x <= ub
```

It is possible to use equal bounds to represent an equality constraint or infinite bounds to represent a one-sided constraint.

**Parameters**

- `lb`, `ub` : [array_like, optional] Lower and upper bounds on independent variables. Each array must have the same size as x or be a scalar, in which case a bound will be the same for all the variables. Set components of `lb` and `ub` equal to fix a variable. Use `np.inf` with an appropriate sign to disable bounds on all or some variables. Note that you can mix constraints of different types: interval, one-sided or equality, by setting different components of `lb` and `ub` as necessary.

- `keep_feasible` : [array_like of bool, optional] Whether to keep the constraint components feasible throughout iterations. A single value set this property for all components. Default is False. Has no effect for equality constraints.

Quasi-Newton strategies implementing `HessianUpdateStrategy` interface can be used to approximate the Hessian in `minimize` function (available only for the ‘trust-constr’ method). Available quasi-Newton methods implementing this interface are:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>BFGS</strong></td>
<td>Broyden-Fletcher-Goldfarb-Shanno (BFGS) Hessian update strategy.</td>
</tr>
<tr>
<td><strong>SR1</strong></td>
<td>Symmetric-rank-1 Hessian update strategy.</td>
</tr>
</tbody>
</table>

**scipy.optimize.BFGS**

```python
class scipy.optimize.BFGS(exception_strategy='skip_update', min_curvature=None, init_scale='auto')
```

Broyden-Fletcher-Goldfarb-Shanno (BFGS) Hessian update strategy.

**Parameters**

- `exception_strategy` : [{'skip_update', 'damp_update'}, optional] Define how to proceed when the curvature condition is violated. Set it to ‘skip_update’ to just skip the update. Or, alternatively, set it to ‘damp_update’ to interpolate between the actual BFGS result and the unmodified matrix. Both exceptions strategies are explained in [R099e42e82f60-1], p.536-537.

- `min_curvature` : [float] This number, scaled by a normalization factor, defines the minimum curvature `dot(delta_grad, delta_x)` allowed to go unaffected by the exception strategy. By default is equal to 1e-8 when `exception_strategy = 'skip_update'` and equal to 0.2 when `exception_strategy = 'damp_update'`.

- `init_scale` : [[float, ‘auto’]] Matrix scale at first iteration. At the first iteration the Hessian matrix or its inverse will be initialized with `init_scale*np.eye(n)`, where `n` is the problem dimension. Set it to ‘auto’ in order to use an automatic heuristic for choosing the initial scale. The heuristic is described in [R099e42e82f60-1], p.143. By default uses ‘auto’.
Notes

The update is based on the description in [R099e42e82f60-1], p.140.

<td><code>update(self, delta_x, delta_grad)</code></td>
<td>Update internal matrix.</td>
</tr>
</tbody>
</table>

**scipy.optimize.BFGS.dot**

```python
BFGS.dot(self, p)
```

Compute the product of the internal matrix with the given vector.

**Parameters**

- `p` [array_like] 1-d array representing a vector.

**Returns**

- `Hp` [array] 1-d represents the result of multiplying the approximation matrix by vector p.

**scipy.optimize.BFGS.get_matrix**

```python
BFGS.get_matrix(self)
```

Return the current internal matrix.

**Returns**

- `M` [ndarray, shape (n, n)] Dense matrix containing either the Hessian or its inverse (depending on how `approx_type` was defined).

**scipy.optimize.BFGS.initialize**

```python
BFGS.initialize(self, n, approx_type)
```

Initialize internal matrix.

Allocate internal memory for storing and updating the Hessian or its inverse.

**Parameters**

- `n` [int] Problem dimension.
- `approx_type` [['hess', 'inv_hess']] Selects either the Hessian or the inverse Hessian. When set to 'hess' the Hessian will be stored and updated. When set to 'inv_hess' its inverse will be used instead.
**scipy.optimize.BFGS.update**

**BFGS.update** *(self, delta_x, delta_grad)*

Update internal matrix.

Update Hessian matrix or its inverse (depending on how `approx_type` is defined) using information about the last evaluated points.

**Parameters**

*delta_x* [ndarray] The difference between two points the gradient function have been evaluated at: `delta_x = x2 - x1`.

*delta_grad* [ndarray] The difference between the gradients: `delta_grad = grad(x2) - grad(x1)`.

**scipy.optimize.SR1**

**class scipy.optimize.SR1**(min_denominator=1e-08, init_scale='auto')

Symmetric-rank-1 Hessian update strategy.

**Parameters**

*min_denominator* [float] This number, scaled by a normalization factor, defines the minimum denominator magnitude allowed in the update. When the condition is violated we skip the update. By default uses `1e-8`.

*init_scale* [float, 'auto', optional] Matrix scale at first iteration. At the first iteration the Hessian matrix or its inverse will be initialized with `init_scale*np.eye(n)`, where `n` is the problem dimension. Set it to 'auto' in order to use an automatic heuristic for choosing the initial scale. The heuristic is described in [Rf73631950f54-1], p.143. By default uses 'auto'.

**Notes**

The update is based on the description in [Rf73631950f54-1], p.144-146.

**scipy.optimize.SR1.dot**

**SR1.dot**(self, p)

Compute the product of the internal matrix with the given vector.
Parameters

\( p \)  
[array_like] 1-d array representing a vector.

Returns

\( H_p \)  
[array] 1-d represents the result of multiplying the approximation matrix by vector \( p \).

\texttt{scipy.optimize.SR1.get_matrix}

\texttt{SR1.get_matrix\( (\textit{self}) \)}

Return the current internal matrix.

Returns

\( M \)  
[ndarray, shape \( (n, n) \)] Dense matrix containing either the Hessian or its inverse (depending on how \texttt{approx_type} was defined).

\texttt{scipy.optimize.SR1.initialize}

\texttt{SR1.initialize\( (\textit{self, n, approx\_type}) \)}

Initialize internal matrix.

Allocate internal memory for storing and updating the Hessian or its inverse.

Parameters

\( n \)  
[int] Problem dimension.

\( \text{approx\_type} \)  
[\{'hess', 'inv\_hess'\}] Selects either the Hessian or the inverse Hessian. When set to 'hess' the Hessian will be stored and updated. When set to 'inv\_hess' its inverse will be used instead.

\texttt{scipy.optimize.SR1.update}

\texttt{SR1.update\( (\textit{self, delta\_x, delta\_grad}) \)}

Update internal matrix.

Update Hessian matrix or its inverse (depending on how 'approx\_type' is defined) using information about the last evaluated points.

Parameters

\( \text{delta\_x} \)  
[ndarray] The difference between two points the gradient function have been evaluated at: \( \text{delta\_x} = x_2 - x_1 \).

\( \text{delta\_grad} \)  
[ndarray] The difference between the gradients: \( \text{delta\_grad} = \text{grad}(x_2) - \text{grad}(x_1) \).

Global Optimization

\texttt{basinhopping(func, x0[, niter, T, stepsize, ...])}  
Find the global minimum of a function using the basin-hopping algorithm

\texttt{brute(func, ranges[, args, Ns, full_output, ...])}  
Minimize a function over a given range by brute force.

**scipy.optimize.basinhopping**

`scipy.optimize.basinhopping(func, x0, niter=100, T=1.0, stepsize=0.5, minimizer_kwargs=None, take_step=None, accept_test=None, callback=None, interval=50, disp=False, niter_success=None, seed=None)`

Find the global minimum of a function using the basin-hopping algorithm.

Basin-hopping is a two-phase method that combines a global stepping algorithm with local minimization at each step. Designed to mimic the natural process of energy minimization of clusters of atoms, it works well for similar problems with “funnel-like, but rugged” energy landscapes [5].

As the step-taking, step acceptance, and minimization methods are all customizable, this function can also be used to implement other two-phase methods.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>func</code></td>
<td>[callable f(x, *args)] Function to be optimized. <code>args</code> can be passed as an optional item in the dict <code>minimizer_kwargs</code></td>
</tr>
<tr>
<td><code>x0</code></td>
<td>[array_like] Initial guess.</td>
</tr>
<tr>
<td><code>niter</code></td>
<td>[integer, optional] The number of basin-hopping iterations</td>
</tr>
<tr>
<td><code>T</code></td>
<td>[float, optional] The “temperature” parameter for the accept or reject criterion. Higher “temperatures” mean that larger jumps in function value will be accepted. For best results <code>T</code> should be comparable to the separation (in function value) between local minima.</td>
</tr>
<tr>
<td><code>minimizer_kwargs</code></td>
<td>[dict, optional] Extra keyword arguments to be passed to the local minimizer <code>scipy.optimize.minimize()</code> Some important options could be:</td>
</tr>
<tr>
<td><code>method</code></td>
<td>[str] The minimization method (e.g. &quot;L-BFGS-B&quot;)</td>
</tr>
<tr>
<td><code>args</code></td>
<td>[tuple] Extra arguments passed to the objective function (<code>func</code>) and its derivatives (Jacobian, Hessian).</td>
</tr>
<tr>
<td><code>take_step</code></td>
<td>[callable <code>take_step(x)</code>, optional] Replace the default step-taking routine with this routine. The default step-taking routine is a random displacement of the coordinates, but other step-taking algorithms may be better for some systems. <code>take_step</code> can optionally have the attribute <code>take_step.stepsize</code>. If this attribute exists, then <code>basinhopping</code> will adjust <code>take_step.stepsize</code> in order to try to optimize the global minimum search.</td>
</tr>
<tr>
<td><code>accept_test</code></td>
<td>[callable, <code>accept_test(f_new=f_new, x_new=x_new, f_old=fold, x_old=x_old)</code>, optional] Define a test which will be used to judge whether or not to accept the step. This will be used in addition to the Metropolis test based on “temperature” <code>T</code>. The acceptable return values are True, False, or &quot;force accept&quot;. If any of the tests return False then the step is rejected. If the latter, then this will override any other tests in order to accept the step. This can be used, for example, to forcefully escape from a local minimum that <code>basinhopping</code> is trapped in.</td>
</tr>
<tr>
<td><code>callback</code></td>
<td>[callable, <code>callback(x, f, accept)</code>, optional] A callback function which will be called for all minima found. <code>x</code> and <code>f</code> are the coordinates and function value of the trial minimum, and <code>accept</code> is whether or not that minimum was accepted. This can be used, for example, to save the lowest N minima found. Also, <code>callback</code> can be used to spec-</td>
</tr>
</tbody>
</table>
ify a user defined stop criterion by optionally returning True to stop the `basinhopping`
routine.

- **interval** [integer, optional] interval for how often to update the `stepsize`
- **disp** [bool, optional] Set to True to print status messages
- **niter_success** [integer, optional] Stop the run if the global minimum candidate remains the same for this
  number of iterations.
- **seed** [int or `np.random.RandomState`, optional] If `seed` is not specified the `np.RandomState`
singleton is used. If `seed` is an int, a new `np.random.RandomState` instance is used,
seeded with seed. If `seed` is already a `np.random.RandomState` instance, then that
`np.random.RandomState` instance is used. Specify `seed` for repeatable minimizations.

The random numbers generated with this seed only affect the default Metropolis `accept_test`
and the default `take_step`. If you supply your own `take_step` and `accept_test`, and these functions
use random number generation, then those functions are responsible for the state of their
random number generator.

### Returns

- **res** [OptimizeResult] The optimization result represented as an `OptimizeResult` object. Important
  attributes are: `x` the solution array, `fun` the value of the function at the solution, and
  `message` which describes the cause of the termination. The `OptimizeResult` object
  returned by the selected minimizer at the lowest minimum is also contained within this ob-
  ject and can be accessed through the `lowest_optimization_result` attribute. See
  `OptimizeResult` for a description of other attributes.

### See also:

- **minimize**

  The local minimization function called once for each basinhopping step. `minimizer_kwargs` is passed to
  this routine.

### Notes

Basin-hopping is a stochastic algorithm which attempts to find the global minimum of a smooth scalar function
of one or more variables [1] [2] [3] [4]. The algorithm in its current form was described by David Wales
and Jonathan Doye [2] [http://www-wales.ch.cam.ac.uk/].

The algorithm is iterative with each cycle composed of the following features

1) random perturbation of the coordinates

2) local minimization

3) accept or reject the new coordinates based on the minimized function value

The acceptance test used here is the Metropolis criterion of standard Monte Carlo algorithms, although there are
many other possibilities [3].

This global minimization method has been shown to be extremely efficient for a wide variety of problems in physics
and chemistry. It is particularly useful when the function has many minima separated by large barriers. See the
Cambridge Cluster Database [http://www-wales.ch.cam.ac.uk/CCD.html] for databases of molecular systems that
have been optimized primarily using basin-hopping. This database includes minimization problems exceeding 300
degrees of freedom.

See the free software program GMIN [http://www-wales.ch.cam.ac.uk/GMIN] for a Fortran implementation of
basin-hopping. This implementation has many different variations of the procedure described above, including
more advanced step taking algorithms and alternate acceptance criterion.
For stochastic global optimization there is no way to determine if the true global minimum has actually been found. Instead, as a consistency check, the algorithm can be run from a number of different random starting points to ensure the lowest minimum found in each example has converged to the global minimum. For this reason `basinhopping` will by default simply run for the number of iterations `niter` and return the lowest minimum found. It is left to the user to ensure that this is in fact the global minimum.

**Choosing stepsize:** This is a crucial parameter in `basinhopping` and depends on the problem being solved. The step is chosen uniformly in the region from `x0-stepsize` to `x0+stepsize`, in each dimension. Ideally it should be comparable to the typical separation (in argument values) between local minima of the function being optimized. `basinhopping` will, by default, adjust `stepsize` to find an optimal value, but this may take many iterations. You will get quicker results if you set a sensible initial value for `stepsize`.

**Choosing T:** The parameter `T` is the “temperature” used in the Metropolis criterion. Basinhopping steps are always accepted if `func(xnew) < func(xold)`. Otherwise, they are accepted with probability:

$$\exp\left(-\frac{func(x_{\text{new}}) - func(x_{\text{old}})}{T}\right)$$

So, for best results, `T` should be comparable to the typical difference (in function values) between local minima. (The height of “walls” between local minima is irrelevant.)

If `T` is 0, the algorithm becomes Monotonic Basin-Hopping, in which all steps that increase energy are rejected. New in version 0.12.0.

**References**

[1], [2], [3], [4], [5]

**Examples**

The following example is a one-dimensional minimization problem, with many local minima superimposed on a parabola.

```python
>>> from scipy.optimize import basinhopping
>>> func = lambda x: np.cos(14.5 * x - 0.3) + (x + 0.2) * x
>>> x0=[1.]

Basinhopping, internally, uses a local minimization algorithm. We will use the parameter `minimizer_kwargs` to tell `basinhopping` which algorithm to use and how to set up that minimizer. This parameter will be passed to `scipy.optimize.minimize()`.

```python
>>> minimizer_kwargs = {"method": "BFGS"}
>>> ret = basinhopping(func, x0, minimizer_kwargs=minimizer_kwargs,
...                     ... niter=200)
>>> print("global minimum: x = %.4f, f(x0) = %.4f" % (ret.x, ret.fun))
global minimum: x = -0.1951, f(x0) = -1.0009
```

Next consider a two-dimensional minimization problem. Also, this time we will use gradient information to significantly speed up the search.

```python
>>> def func2d(x):
...     f = np.cos(14.5 * x[0] - 0.3) + (x[1] + 0.2) * x[1] + (x[0] + 
...     0.2) * x[0]
...     df = np.zeros(2)
... (continues on next page)```
... df[0] = -14.5 * np.sin(14.5 * x[0] - 0.3) + 2. * x[0] + 0.2
... df[1] = 2. * x[1] + 0.2
... return f, df

We'll also use a different local minimization algorithm. Also we must tell the minimizer that our function returns both energy and gradient (jacobian)

```python
>>> minimizer_kwargs = {"method":"L-BFGS-B", "jac":True}
>>> x0 = [1.0, 1.0]
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
... niter=200)
>>> print("global minimum: x = [%.4f, %.4f], f(x0) = %.4f" % (ret.x[0],
... ret.x[1],
... ret.fun))
global minimum: x = [-0.1951, -0.1000], f(x0) = -1.0109
```

Here is an example using a custom step-taking routine. Imagine you want the first coordinate to take larger steps than the rest of the coordinates. This can be implemented like so:

```python
>>> class MyTakeStep(object):
...     def __init__(self, stepsize=0.5):
...         self.stepsize = stepsize
...     def __call__(self, x):
...         s = self.stepsize
...         x[0] += np.random.uniform(-2.*s, 2.*s)
...         x[1:] += np.random.uniform(-s, s, x[1:].shape)
...         return x
```

Since MyTakeStep.stepsize exists basinhopping will adjust the magnitude of stepsize to optimize the search. We'll use the same 2-D function as before

```python
>>> mytakestep = MyTakeStep()
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
... niter=200, take_step=mymakestep)
>>> print("global minimum: x = [%.4f, %.4f], f(x0) = %.4f" % (ret.x[0],
... ret.x[1],
... ret.fun))
global minimum: x = [-0.1951, -0.1000], f(x0) = -1.0109
```

Now let's do an example using a custom callback function which prints the value of every minimum found.

```python
>>> def print_fun(x, f, accepted):
...     print("at minimum %.4f accepted %d" % (f, int(accepted)))
```

We'll run it for only 10 basinhopping steps this time.

```python
>>> np.random.seed(1)
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
... niter=10, callback=print_fun)
at minimum 0.4159 accepted 1
at minimum -0.9073 accepted 1
at minimum -0.1021 accepted 1
at minimum -0.1021 accepted 1
```
at minimum 0.9102 accepted 1
at minimum 0.9102 accepted 1
at minimum 2.2945 accepted 0
at minimum -0.1021 accepted 1
at minimum -1.0109 accepted 1
at minimum -1.0109 accepted 1

Theminimumat-1.0109isactuallytheglobalminimum,foundalreadyonthe8thiteration.

Now let's implement bounds on the problem using a custom accept_test:

```python
>>> class MyBounds(object):
...     def __init__(self, xmax=[1.1,1.1], xmin=[-1.1,-1.1]):
...         self.xmax = np.array(xmax)
...         self.xmin = np.array(xmin)
...     def __call__(self, **kwargs):
...         x = kwargs["x_new"]
...         tmax = bool(np.all(x <= self.xmax))
...         tmin = bool(np.all(x >= self.xmin))
...         return tmax and tmin
```

```python
>>> mybounds = MyBounds()
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...                     niter=10, accept_test=mybounds)
```

scipy.optimize.brute

Minimize a function over a given range by brute force.

Uses the “brute force” method, i.e. computes the function’s value at each point of a multidimensional grid of points, to find the global minimum of the function.

The function is evaluated everywhere in the range with the datatype of the first call to the function, as enforced by the vectorize NumPy function. The value and type of the function evaluation returned when full_output=True are affected in addition by the finish argument (see Notes).

The brute force approach is inefficient because the number of grid points increases exponentially - the number of grid points to evaluate is Ns ** len(x). Consequently, even with coarse grid spacing, even moderately sized problems can take a long time to run, and/or run into memory limitations.

Parameters

- **func** [callable] The objective function to be minimized. Must be in the form \( f(x, \, *\text{args}) \), where \( x \) is the argument in the form of a 1-D array and \( \text{args} \) is a tuple of any additional fixed parameters needed to completely specify the function.
- **ranges** [tuple] Each component of the ranges tuple must be either a “slice object” or a range tuple of the form \((\text{low}, \text{high})\). The program uses these to create the grid of points on which the objective function will be computed. See Note 2 for more detail.
- **args** [tuple, optional] Any additional fixed parameters needed to completely specify the function.
- **Ns** [int, optional] Number of grid points along the axes, if not otherwise specified. See Note 2.
- **full_output** [bool, optional] If True, return the evaluation grid and the objective function’s values on it.
- **finish** [callable, optional] An optimization function that is called with the result of brute force minimization as initial guess. finish should take func and the initial guess as positional arguments,
and take `args` as keyword arguments. It may additionally take `full_output` and/or `disp` as keyword arguments. Use `None` if no “polishing” function is to be used. See Notes for more details.

**disp**
[bool, optional] Set to True to print convergence messages from the `finish` callable.

**workers**
[int or map-like callable, optional] If `workers` is an int the grid is subdivided into `workers` sections and evaluated in parallel (uses `multiprocessing.Pool`). Supply `-1` to use all cores available to the Process. Alternatively supply a map-like callable, such as `multiprocessing.Pool.map` for evaluating the grid in parallel. This evaluation is carried out as `workers(func, iterable)`. Requires that `func` be pickleable.

New in version 1.3.0.

**Returns**

- **x0** [ndarray] A 1-D array containing the coordinates of a point at which the objective function had its minimum value. (See Note 1 for which point is returned.)
- **fval** [float] Function value at the point `x0`. (Returned when `full_output` is True.)
- **grid** [tuple] Representation of the evaluation grid. It has the same length as `x0`. (Returned when `full_output` is True.)
- **Jout** [ndarray] Function values at each point of the evaluation grid, i.e., `Jout = func(*grid)`. (Returned when `full_output` is True.)

**See also:**

- `basinhopping`, `differential_evolution`

**Notes**

**Note 1**: The program finds the gridpoint at which the lowest value of the objective function occurs. If `finish` is None, that is the point returned. When the global minimum occurs within (or not very far outside) the grid’s boundaries, and the grid is fine enough, that point will be in the neighborhood of the global minimum.

However, users often employ some other optimization program to “polish” the gridpoint values, i.e., to seek a more precise (local) minimum near `brute`’s best gridpoint. The `brute` function’s `finish` option provides a convenient way to do that. Any polishing program used must take `brute`’s output as its initial guess as a positional argument, and take `brute`’s input values for `args` as keyword arguments, otherwise an error will be raised. It may additionally take `full_output` and/or `disp` as keyword arguments.

`brute` assumes that the `finish` function returns either an `OptimizeResult` object or a tuple in the form: `(xmin, Jmin, ..., statuscode)`, where `xmin` is the minimizing value of the argument, `Jmin` is the minimum value of the objective function, “…” may be some other returned values (which are not used by `brute`), and `statuscode` is the status code of the `finish` program.

Note that when `finish` is not None, the values returned are those of the `finish` program, not the gridpoint ones. Consequently, while `brute` confines its search to the input grid points, the `finish` program’s results usually will not coincide with any gridpoint, and may fall outside the grid’s boundary. Thus, if a minimum only needs to be found over the provided grid points, make sure to pass in `finish=None`.

**Note 2**: The grid of points is a `numpy.mgrid` object. For `brute` the `ranges` and `Ns` inputs have the following effect. Each component of the `ranges` tuple can be either a slice object or a two-tuple giving a range of values, such as `(0, 5)`. If the component is a slice object, `brute` uses it directly. If the component is a two-tuple range, `brute` internally converts it to a slice object that interpolates `Ns` points from its low-value to its high-value, inclusive.

**Examples**

We illustrate the use of `brute` to seek the global minimum of a function of two variables that is given as the sum of a positive-definite quadratic and two deep “Gaussian-shaped” craters. Specifically, define the objective function
As the sum of three other functions, \( f = f_1 + f_2 + f_3 \). We suppose each of these has a signature \((z, *params)\), where \( z = (x, y) \), and \( params \) and the functions are as defined below.

```python
>>> params = (2, 3, 7, 8, 9, 10, 44, -1, 2, 26, 1, -2, 0.5)
>>> def f1(z, *params):
...     x, y = z
...     a, b, c, d, e, f, g, h, i, j, k, l, scale = params
...     return (a * x**2 + b * x * y + c * y**2 + d*x + e*y + f)

>>> def f2(z, *params):
...     x, y = z
...     a, b, c, d, e, f, g, h, i, j, k, l, scale = params
...     return (-g*np.exp(-(x-h)**2 + (y-i)**2) / scale))

>>> def f3(z, *params):
...     x, y = z
...     a, b, c, d, e, f, g, h, i, j, k, l, scale = params
...     return (-j*np.exp(-(x-k)**2 + (y-l)**2) / scale))

>>> def f(z, *params):
...     return f1(z, *params) + f2(z, *params) + f3(z, *params)
```

Thus, the objective function may have local minima near the minimum of each of the three functions of which it is composed. To use \( fmin \) to polish its gridpoint result, we may then continue as follows:

```python
>>> rranges = (slice(-4, 4, 0.25), slice(-4, 4, 0.25))
>>> from scipy import optimize
>>> resbrute = optimize.brute(f, rranges, args=params, full_output=True,
...     ...     finish=optimize.fmin)
>>> resbrute[0]  # global minimum
array([-1.05665192,  1.80834843])
>>> resbrute[1]  # function value at global minimum
-3.4085818767
```

Note that if \( finish \) had been set to None, we would have gotten the gridpoint \([-1.0, 1.75]\) where the rounded function value is \(-2.892\).

**scipy.optimize.differential_evolution**

```python
scipy.optimize.differential_evolution(func, bounds, args=(), strategy='best1bin', maxiter=1000, popsize=15, tol=0.01, mutation=(0.5, 1), recombination=0.7, seed=None, callback=None, disp=False, polish=True, init='latinhypercube', atol=0, updating='immediate', workers=1)
```

Finds the global minimum of a multivariate function.

Differential Evolution is stochastic in nature (does not use gradient methods) to find the minimum, and can search large areas of candidate space, but often requires larger numbers of function evaluations than conventional gradient based techniques.

The algorithm is due to Storn and Price [1].

**Parameters**

- **func**  
  [callable] The objective function to be minimized. Must be in the form \( f(x, *args) \), where \( x \) is the argument in the form of a 1-D array and \( args \) is a tuple of any additional fixed parameters needed to completely specify the function.
bounds  [sequence or Bounds, optional] Bounds for variables. There are two ways to specify the bounds: 1. Instance of Bounds class. 2. (min, max) pairs for each element in x, defining the finite lower and upper bounds for the optimizing argument of func. It is required to have len(bounds) == len(x). len(bounds) is used to determine the number of parameters in x.

args  [tuple, optional] Any additional fixed parameters needed to completely specify the objective function.

strategy  [str, optional] The differential evolution strategy to use. Should be one of:
   • ‘best1bin’
   • ‘best1exp’
   • ‘rand1exp’
   • ‘randtobest1exp’
   • ‘currenttobest1exp’
   • ‘best2exp’
   • ‘rand2exp’
   • ‘randtobest1bin’
   • ‘currenttobest1bin’
   • ‘best2bin’
   • ‘rand2bin’
   • ‘rand1bin’

   The default is ‘best1bin’.

maxiter  [int, optional] The maximum number of generations over which the entire population is evolved. The maximum number of function evaluations (with no polishing) is: \((\text{maxiter} + 1) \times \text{popsize} \times \text{len}(x)\)

popsize  [int, optional] A multiplier for setting the total population size. The population has \(\text{popsize} \times \text{len}(x)\) individuals (unless the initial population is supplied via the init keyword).

tol  [float, optional] Relative tolerance for convergence, the solving stops when \(\text{np.std(pop)} \leq \text{atol} + \text{tol} \times \text{np.abs(np.mean(population_energies))}\), where and atol and tol are the absolute and relative tolerance respectively.

mutation  [float or tuple(float, float), optional] The mutation constant. In the literature this is also known as differential weight, being denoted by F. If specified as a float it should be in the range \([0, 2]\). If specified as a tuple \((\text{min}, \text{max})\) dithering is employed. Dithering randomly changes the mutation constant on a generation by generation basis. The mutation constant for that generation is taken from \(U[\text{min}, \text{max})\). Dithering can help speed convergence significantly. Increasing the mutation constant increases the search radius, but will slow down convergence.

recombination  [float, optional] The recombination constant, should be in the range \([0, 1]\). In the literature this is also known as the crossover probability, being denoted by CR. Increasing this value allows a larger number of mutants to progress into the next generation, but at the risk of population stability.

seed  [int or np.random.RandomState, optional] If seed is not specified the np.RandomState singleton is used. If seed is an int, a new np.random.RandomState instance is used, seeded with seed. If seed is already a np.random.RandomState instance, then that np.random.RandomState instance is used. Specify seed for repeatable minimizations.

disp  [bool, optional] Display status messages

callback  [callable, callback(xk, convergence=val), optional] A function to follow the progress of the minimization. xk is the current value of x0. val represents the fractional value of the population convergence. When val is greater than one the function halts. If callback returns True, then the minimization is halted (any polishing is still carried out).

polish  [bool, optional] If True (default), then scipy.optimize.minimize with the L-BFGS-B method is used to polish the best population member at the end, which can improve the minimization slightly.
init [str or array-like, optional] Specify which type of population initialization is performed. Should be one of:
- 'latinhypercube'
- 'random'
  - array specifying the initial population. The array should have shape (M, len(x)), where len(x) is the number of parameters. init is clipped to bounds before use.
The default is 'latinhypercube'. Latin Hypercube sampling tries to maximize coverage of the available parameter space. 'random' initializes the population randomly - this has the drawback that clustering can occur, preventing the whole of parameter space being covered. Use of an array to specify a population subset could be used, for example, to create a tight bunch of initial guesses in an location where the solution is known to exist, thereby reducing time for convergence.

atol [float, optional] Absolute tolerance for convergence, the solving stops when np.std(pop) <= atol + tol * np.abs(np.mean(population_energies)), where and atol and tol are the absolute and relative tolerance respectively.

updating [{‘immediate’, ‘deferred’}, optional] If ‘immediate’, the best solution vector is continuously updated within a single generation [4]. This can lead to faster convergence as trial vectors can take advantage of continuous improvements in the best solution. With ‘deferred’, the best solution vector is updated once per generation. Only 'deferred' is compatible with parallelization, and the workers keyword can over-ride this option. New in version 1.2.0.

workers [int or map-like callable, optional] If workers is an int the population is subdivided into workers sections and evaluated in parallel (uses multiprocessing.Pool). Supply -1 to use all available CPU cores. Alternatively supply a map-like callable, such as multiprocessing.Pool.map for evaluating the population in parallel. This evaluation is carried out as workers(func, iterable). This option will override the updating keyword to updating='deferred' if workers != 1. Requires that func be pickleable. New in version 1.2.0.

Returns

res [OptimizeResult] The optimization result represented as a OptimizeResult object. Important attributes are: x the solution array, success a Boolean flag indicating if the optimizer exited successfully and message which describes the cause of the termination. See OptimizeResult for a description of other attributes. If polish was employed, and a lower minimum was obtained by the polishing, then OptimizeResult also contains the jac attribute.

Notes

Differential evolution is a stochastic population based method that is useful for global optimization problems. At each pass through the population the algorithm mutates each candidate solution by mixing with other candidate solutions to create a trial candidate. There are several strategies [2] for creating trial candidates, which suit some problems more than others. The ‘best1bin’ strategy is a good starting point for many systems. In this strategy two members of the population are randomly chosen. Their difference is used to mutate the best member (the best in best1bin), b₀, so far:

\[
b' = b_0 + \text{mutation} \ast (\text{population}[\text{rand0}] - \text{population}[\text{rand1}])
\]

A trial vector is then constructed. Starting with a randomly chosen ‘i’th parameter the trial is sequentially filled (in modulo) with parameters from b' or the original candidate. The choice of whether to use b' or the original candidate is made with a binomial distribution (the ‘bin’ in ‘best1bin’) - a random number in [0, 1) is generated. If this number is less than the recombination constant then the parameter is loaded from b', otherwise it is loaded from the original candidate. The final parameter is always loaded from b'. Once the trial candidate is built its
fitness is assessed. If the trial is better than the original candidate then it takes its place. If it is also better than the best overall candidate it also replaces that. To improve your chances of finding a global minimum use higher \texttt{popsize} values, with higher \texttt{mutation} and (dithering), but lower \texttt{recombination} values. This has the effect of widening the search radius, but slowing convergence. By default the best solution vector is updated continuously within a single iteration (\texttt{updating='immediate'}). This is a modification of the original differential evolution algorithm which can lead to faster convergence as trial vectors can immediately benefit from improved solutions. To use the original Storn and Price behaviour, updating the best solution once per iteration, set \texttt{updating='deferred'}.

New in version 0.15.0.

Examples

Let us consider the problem of minimizing the Rosenbrock function. This function is implemented in \texttt{rosen} in \texttt{scipy.optimize}.

```python
>>> from scipy.optimize import rosen, differential_evolution
>>> bounds = [(0, 2), (0, 2), (0, 2), (0, 2), (0, 2)]
>>> result = differential_evolution(rosen, bounds)
>>> result.x, result.fun
(array([1., 1., 1., 1., 1.]), 1.9216496320061384e-19)
```

Now repeat, but with parallelization.

```python
>>> bounds = [(0, 2), (0, 2), (0, 2), (0, 2), (0, 2)]
>>> result = differential_evolution(rosen, bounds, updating='deferred',
... workers=2)
>>> result.x, result.fun
(array([1., 1., 1., 1., 1.]), 1.9216496320061384e-19)
```

Next find the minimum of the Ackley function (https://en.wikipedia.org/wiki/Test_functions_for_optimization).

```python
>>> from scipy.optimize import shgo, differential_evolution
>>> import numpy as np
>>> def ackley(x):
...     arg1 = -0.2 * np.sqrt(0.5 * (x[0] ** 2 + x[1] ** 2))
...     arg2 = 0.5 * (np.cos(2 * np.pi * x[0]) + np.cos(2 * np.pi *-
...               x[1]))
...     return -20. * np.exp(arg1) - np.exp(arg2) + 20. + np.e
>>> bounds = [(-5, 5), (-5, 5)]
>>> result = differential_evolution(ackley, bounds)
>>> result.x, result.fun
(array([ 0., 0.]), 4.4408920985006262e-16)
```

\texttt{scipy.optimize.shgo}

\texttt{scipy.optimize.shgo} (func, bounds, args=(), constraints=None, n=100, iters=1, callback=None, minimizer_kwargs=None, options=None, sampling_method='simplicial')

Finds the global minimum of a function using SHG optimization.

SHGO stands for “simplicial homology global optimization”.

6.18. Optimization and Root Finding (\texttt{scipy.optimize})
Parameters

func [callable] The objective function to be minimized. Must be in the form \( f(x, \ *\text{args}) \), where \( x \) is the argument in the form of a 1-D array and \( \text{args} \) is a tuple of any additional fixed parameters needed to completely specify the function.

bounds [sequence] Bounds for variables. \((\text{min, max})\) pairs for each element in \( x \), defining the lower and upper bounds for the optimizing argument of \( \text{func} \). It is required to have \( \text{len(bounds)} == \text{len(x)} \). \( \text{len(bounds)} \) is used to determine the number of parameters in \( x \). Use \( \text{None} \) for one of min or max when there is no bound in that direction. By default bounds are \((\text{None, None})\).

args [tuple, optional] Any additional fixed parameters needed to completely specify the objective function.

constraints [dict or sequence of dict, optional] Constraints definition. Function(s) \( R^\times n \) in the form:

\[
\begin{align*}
g(x) &\leq 0 \quad \text{applied as } g : R^n \rightarrow R^m \\
h(x) &== 0 \quad \text{applied as } h : R^n \rightarrow R^p
\end{align*}
\]

Each constraint is defined in a dictionary with fields:

- **type** [str] Constraint type: 'eq' for equality, 'ineq' for inequality.
- **fun** [callable] The function defining the constraint.
- **jac** [callable, optional] The Jacobian of \( \text{fun} \) (only for SLSQP).
- **args** [sequence, optional] Extra arguments to be passed to the function and Jacobian.

Equality constraint means that the constraint function result is to be zero whereas inequality means that it is to be non-negative. Note that COBYLA only supports inequality constraints.

**Note:** Only the COBYLA and SLSQP local minimize methods currently support constraint arguments. If the constraints sequence used in the local optimization problem is not defined in \( \text{minimizer_kwargs} \) and a constrained method is used then the global constraints will be used. (Defining a constraints sequence in \( \text{minimizer_kwargs} \) means that constraints will not be added so if equality constraints and so forth need to be added then the inequality functions in \( \text{constraints} \) need to be added to \( \text{minimizer_kwargs} \) too).

n [int, optional] Number of sampling points used in the construction of the simplicial complex. Note that this argument is only used for \( \text{sobol} \) and other arbitrary \( \text{sampling_methods} \).

iters [int, optional] Number of iterations used in the construction of the simplicial complex.

callback [callable, optional] Called after each iteration, as \( \text{callback}(xk) \), where \( xk \) is the current parameter vector.

minimizer_kwargs [dict, optional] Extra keyword arguments to be passed to the minimizer \( \text{scipy.optimize.minimize} \). Some important options could be:

- **method** [str] The minimization method (e.g. SLSQP).
- **args** [tuple] Extra arguments passed to the objective function \( \text{func} \) and its derivatives (Jacobian, Hessian).
- **options** [dict, optional] Note that by default the tolerance is specified as \{\text{ftol}: 1e-12\}

options [dict, optional] A dictionary of solver options. Many of the options specified for the global routine are also passed to the \( \text{scipy.optimize.minimize} \) routine. The options that are also passed to the local routine are marked with “(L)”. Stopping criteria, the algorithm will terminate if any of the specified criteria are met. However, the default algorithm does not require any to be specified:

- **maxfev** [int \( (L) \)] Maximum number of function evaluations in the feasible domain. (Note only methods that support this option will terminate the routine at pre-
• \( f_{\text{min}} \) Specify the minimum objective function value, if it is known.
• \( f_{\text{tol}} \) [float] Precision goal for the value of \( f \) in the stopping criterion. Note that the global routine will also terminate if a sampling point in the global routine is within this tolerance.
• \( \text{maxiter} \) [int] Maximum number of iterations to perform.
• \( \text{maxev} \) [int] Maximum number of sampling evaluations to perform (includes searching in infeasible points).
• \( \text{maxtime} \) [float] Maximum processing runtime allowed.
• \( \text{minhgrd} \) [int] Minimum homology group rank differential. The homology group of the objective function is calculated (approximately) during every iteration. The rank of this group has a one-to-one correspondence with the number of locally convex subdomains in the objective function (after adequate sampling points each of these subdomains contain a unique global minimum). If the difference in the hgr is 0 between iterations for \( \text{maxhgrd} \) specified iterations the algorithm will terminate.

Objective function knowledge:
• \( \text{symmetry} \) [bool] Specify True if the objective function contains symmetric variables. The search space (and therefore performance) is decreased by \( O(n!) \).
• \( \text{jac} \) [bool or callable, optional] Jacobian (gradient) of objective function. Only for CG, BFGS, Newton-CG, L-BFGS-B, TNC, SLSQP, dogleg, trust-ncg. If \( \text{jac} \) is a boolean and is True, \( \text{fun} \) is assumed to return the gradient along with the objective function. If False, the gradient will be estimated numerically. \( \text{jac} \) can also be a callable returning the gradient of the objective. In this case, it must accept the same arguments as \( \text{fun} \). (Passed to \texttt{scipy.optimize.minimize} automatically)

• \( \text{hess}, \text{hessp} \) [callable, optional] Hessian (matrix of second-order derivatives) of objective function or Hessian of objective function times an arbitrary vector \( p \). Only for Newton-CG, dogleg, trust-ncg. Only one of \( \text{hessp} \) or \( \text{hess} \) needs to be given. If \( \text{hess} \) is provided, then \( \text{hessp} \) will be ignored. If neither \( \text{hess} \) nor \( \text{hessp} \) is provided, then the Hessian product will be approximated using finite differences on \( \text{jac} \). \( \text{hessp} \) must compute the Hessian times an arbitrary vector. (Passed to \texttt{scipy.optimize.minimize} automatically)

Algorithm settings:
• \( \text{minimize\_every\_iter} \) [bool] If True then promising global sampling points will be passed to a local minimisation routine every iteration. If False then only the final minimiser pool will be run. Defaults to False.
• \( \text{local\_iter} \) [int] Only evaluate a few of the best minimiser pool candidates every iteration. If False all potential points are passed to the local minimisation routine.
• \( \text{infty\_constraints: bool} \) If True then any sampling points generated which are outside will the feasible domain will be saved and given an objective function value of \( \text{inf} \). If False then these points will be discarded. Using this functionality could lead to higher performance with respect to function evaluations before the global minimum is found, specifying False will use less memory at the cost of a slight decrease in performance. Defaults to True.

Feedback:
• \( \text{disp} \) [bool (L)] Set to True to print convergence messages.

\( \text{sampling\_method} \) [str or function, optional] Current built in sampling method options are \texttt{sobol} and \texttt{simplicial}. The default \texttt{simplicial} uses less memory and provides the theoreti-
SciPy Reference Guide, Release 1.3.2

cal guarantee of convergence to the global minimum in finite time. The sobol method is faster in terms of sampling point generation at the cost of higher memory resources and the loss of guaranteed convergence. It is more appropriate for most “easier” problems where the convergence is relatively fast. User defined sampling functions must accept two arguments of \( n \) sampling points of dimension \( \text{dim} \) per call and output an array of sampling points with shape \( n \times \text{dim} \).

**Returns**

res [OptimizeResult] The optimization result represented as a OptimizeResult object. Important attributes are: \( x \) the solution array corresponding to the global minimum, \( \text{fun} \) the function output at the global solution, \( \text{xl} \) an ordered list of local minima solutions, \( \text{funl} \) the function output at the corresponding local solutions, \( \text{success} \) a Boolean flag indicating if the optimizer exited successfully, \( \text{message} \) which describes the cause of the termination, \( \text{nfev} \) the total number of objective function evaluations including the sampling calls, \( \text{nlfev} \) the total number of objective function evaluations culminating from all local search optimisations, \( \text{nit} \) number of iterations performed by the global routine.

**Notes**

Global optimization using simplicial homology global optimisation [1]. Appropriate for solving general purpose NLP and blackbox optimisation problems to global optimality (low dimensional problems).

In general, the optimization problems are of the form:

\[
\begin{align*}
\text{minimize } f(x) & \text{ subject to} \\
g_i(x) & \geq 0, \quad i = 1, \ldots, m \\
h_j(x) & = 0, \quad j = 1, \ldots, p
\end{align*}
\]

where \( x \) is a vector of one or more variables, \( f(x) \) is the objective function \( \mathbb{R}^n \rightarrow \mathbb{R} \), \( g_i(x) \) are the inequality constraints, and \( h_j(x) \) are the equality constraints.

Optionally, the lower and upper bounds for each element in \( x \) can also be specified using the bounds argument.

While most of the theoretical advantages of SHGO are only proven for when \( f(x) \) is a Lipschitz smooth function. The algorithm is also proven to converge to the global optimum for the more general case where \( f(x) \) is non-continuous, non-convex and non-smooth, if the default sampling method is used [1].

The local search method may be specified using the \text{minimizer_kwargs} parameter which is passed on to scipy.optimize.minimize. By default the SLSQP method is used. In general it is recommended to use the SLSQP or COBYLA local minimization if inequality constraints are defined for the problem since the other methods do not use constraints.

The sobol method points are generated using the Sobol (1967) [2] sequence. The primitive polynomials and various sets of initial direction numbers for generating Sobol sequences is provided by [3] by Frances Kuo and Stephen Joe. The original program sobol.cc (MIT) is available and described at http://web.maths.unsw.edu.au/~fkuo/sobol/ translated to Python 3 by Carl Sandrock 2016-03-31.

Examples

First consider the problem of minimizing the Rosenbrock function, \texttt{rosen}:

```python
>>> from scipy.optimize import rosen, shgo
>>> bounds = [(0,2), (0,2), (0,2), (0,2), (0,2)]
>>> result = shgo(rosen, bounds)
>>> result.x, result.fun
(array([ 1., 1., 1., 1., 1.]), 2.9203923741900809e-18)
```

Note that bounds determine the dimensionality of the objective function and is therefore a required input, however you can specify empty bounds using \texttt{None} or objects like \texttt{np.inf} which will be converted to large float numbers.

```python
>>> bounds = [(None, None), ]*4
>>> result = shgo(rosen, bounds)
>>> result.x
array([0.99999851, 0.99999704, 0.99999411, 0.99998820])
```

Next we consider the Eggholder function, a problem with several local minima and one global minimum. We will demonstrate the use of arguments and the capabilities of \texttt{shgo}. (https://en.wikipedia.org/wiki/Test_functions_for_optimization)

```python
>>> def eggholder(x):
...     return -(x[0] + 47.0)
...     * np.sin(np.sqrt(abs(x[0])/2.0 + (x[1] + 47.0)))))
...     - x[0] * np.sin(np.sqrt(abs(x[0] - (x[1] + 47.0))))
...     )
...     
>>> bounds = [(-512, 512), (-512, 512)]
```

\texttt{shgo} has two built-in low discrepancy sampling sequences. First we will input 30 initial sampling points of the Sobol sequence:

```python
>>> result = shgo(eggholder, bounds, n=30, sampling_method='sobol')
>>> result.x, result.fun
(array([ 512.0, 404.23180542]), -959.64066272085051)
```

\texttt{shgo} also has a return for any other local minima that was found, these can be called using:

```python
>>> result.xl
array([[ 512.0, 404.23180542],
       [283.07593402, 487.12566542],
       [-294.66820039, 462.01964031],
       [-105.87688985, 423.15324143],
       [-242.97923629, 274.38032063],
       [-506.25823477, 6.3131022],
       [-408.71981195, -156.10117154],
       [150.23210485, 301.31378508],
       [91.00922754, -391.28375925],
       [202.8966344, -269.38042147],
       [361.66625957, -106.96490692],
       [-219.40615102, -244.06022436],
       [151.59603137, -100.61082677]])
```
These results are useful in applications where there are many global minima and the values of other global minima are desired or where the local minima can provide insight into the system (for example morphologies in physical chemistry [5]).

If we want to find a larger number of local minima, we can increase the number of sampling points or the number of iterations. We'll increase the number of sampling points to 60 and the number of iterations from the default of 1 to 5. This gives us $60 \times 5 = 300$ initial sampling points.

```python
>>> result_2 = shgo(eggholder, bounds, n=60, iters=5, sampling_method='sobol')
>>> len(result.xl), len(result_2.xl)
(13, 39)
```

Note the difference between, e.g., $n=180$, iters=1 and $n=60$, iters=3. In the first case the promising points contained in the minimiser pool is processed only once. In the latter case it is processed every 60 sampling points for a total of 3 times.

To demonstrate solving problems with non-linear constraints consider the following example from Hock and Schittkowski problem 73 (cattle-feed) [4]:

```python
minimize: $f = 24.55x_1 + 26.75x_2 + 39x_3 + 40.50x_4$
subject to: $2.3x_1 + 5.6x_2 + 11.1x_3 + 1.3x_4 - 5 \geq 0,$
          $12x_1 + 11.9x_2 + 41.8x_3 + 52.1x_4 - 21$
          $-1.645 \sqrt{0.28x_1^2 + 0.19x_2^2 + 20.5x_3^2 + 0.62x_4^2} \geq 0,$
          $x_1 + x_2 + x_3 + x_4 - 1 = 0,$
          $1 \geq x_i \geq 0 \text{ for all } i$
```

The approximate answer given in [4] is:

```python
f([0.6355216, -0.12e-11, 0.3127019, 0.05177655]) = 29.894378
```

```python
>>> def f(x):  # (cattle-feed)
...     ...
>>> def g1(x):
...     return 2.3*x[0] + 5.6*x[1] + 11.1*x[2] + 1.3*x[3] - 5  # >=0
...     ...
>>> def g2(x):
...     return (12*x[0] + 11.9*x[1] + 41.8*x[2] + 52.1*x[3] - 21
...             - 1.645 * np.sqrt(0.28*x[0]**2 + 0.19*x[1]**2 + 20.5*x[2]**2 + 0.62*x[3]**2)
...     )  # >=0
...     ...
(continues on next page)
>>> def h1(x):
    ...

>>> cons = ({'type': 'ineq', 'fun': g1},
    ... {'type': 'ineq', 'fun': g2},
    ... {'type': 'eq', 'fun': h1})

>>> bounds = [(0, 1.0),] * 4

>>> res = shgo(f, bounds, iters=3, constraints=cons)

>>> res

scipy.optimize.dual_annealing

Find the global minimum of a function using Dual Annealing.

Parameters

- **func** [callable] The objective function to be minimized. Must be in the form \( f(x, *args) \), where \( x \) is the argument in the form of a 1-D array and \( args \) is a tuple of any additional fixed parameters needed to completely specify the function.

- **bounds** [sequence, shape (n, 2)] Bounds for variables. \((\text{min}, \text{max})\) pairs for each element in \( x \), defining bounds for the objective function parameter.

- **args** [tuple, optional] Any additional fixed parameters needed to completely specify the objective function.

- **maxiter** [int, optional] The maximum number of global search iterations. Default value is 1000.

- **local_search_options** [dict, optional] Extra keyword arguments to be passed to the local minimizer (minimize). Some important options could be: `method` for the minimizer method to use and `args` for objective function additional arguments.

- **initial_temp** [float, optional] The initial temperature, use higher values to facilitates a wider search of the energy landscape, allowing dual_annealing to escape local minima that it is trapped in. Default value is 5230. Range is (0.01, 5.e4].

- **restart_temp_ratio**
During the annealing process, temperature is decreasing, when it reaches \( \text{initial\_temp} \times \text{restart\_temp\_ratio} \), the annealing process is triggered. Default value of the ratio is \( 2e^{-5} \). Range is \((0, 1)\).

**visit**

[**float**, optional] Parameter for visiting distribution. Default value is 2.62. Higher values give the visiting distribution a heavier tail, this makes the algorithm jump to a more distant region. The value range is \((0, 3)\).

**accept**

[**float**, optional] Parameter for acceptance distribution. The lower the acceptance parameter, the smaller the probability of acceptance. Default value is \(-5.0\) with a range \((-1e4, -5)\).

**maxfun**

[**int**, optional] Soft limit for the number of objective function calls. If the algorithm is in the middle of a local search, this number will be exceeded, the algorithm will stop just after the local search is done. Default value is \(1e7\).

**seed**

[**int or RandomState instance**, optional] If **seed** is not specified the RandomState singleton is used. If **seed** is an int, a new RandomState instance is used, seeded with **seed**. If **seed** is already a RandomState instance, then that instance is used. Specify **seed** for repeatable minimizations. The random numbers generated with this seed only affect the visiting distribution function and new coordinates generation.

**no_local_search**

[**bool**, optional] If **no_local_search** is set to True, a traditional Generalized Simulated Annealing will be performed with no local search strategy applied.

**callback**

[**callable**, optional] A callback function with signature \( \text{callback}(x, f, \text{context}) \), which will be called for all minima found. \( x \) and \( f \) are the coordinates and function value of the latest minimum found, and \( \text{context} \) has value in \([0, 1, 2]\), with the following meaning:

- 0: minimum detected in the annealing process.
- 1: detection occurred in the local search process.
- 2: detection done in the dual annealing process.

If the callback implementation returns True, the algorithm will stop.

**x0**

[ndarray, shape(n,), optional] Coordinates of a single n-dimensional starting point.

**Returns**

[OptimizeResult] The optimization result represented as a OptimizeResult object. Important attributes are: \( x \) the solution array, \( \text{fun} \) the value of the function at the solution, and \( \text{message} \) which describes the cause of the termination. See OptimizeResult for a description of other attributes.

**Notes**

This function implements the Dual Annealing optimization. This stochastic approach derived from [3] combines the generalization of CSA (Classical Simulated Annealing) and FSA (Fast Simulated Annealing) [1] [2] coupled to a strategy for applying a local search on accepted locations [4]. An alternative implementation of this same algorithm is described in [5] and benchmarks are presented in [6]. This approach introduces an advanced method to refine the solution found by the generalized annealing process. This algorithm uses a distorted Cauchy-Lorentz visiting distribution, with its shape controlled by the parameter \( q_v \):

\[
g_{q_v}(\Delta x(t)) \propto \frac{\left[ T_{q_v}(t) \right]^{-\frac{D}{2-2q_v}}}{\left[ 1 + \left( q_v - 1 \right) \frac{(\Delta x(t))^2}{\left[ T_{q_v}(t) \right]^{\frac{2}{2-q_v}}} \right]^\frac{1}{2-q_v} + \frac{2^{q_v-1}}{q_v}}
\]

Where \( t \) is the artificial time. This visiting distribution is used to generate a trial jump distance \( \Delta x(t) \) of variable \( x(t) \) under artificial temperature \( T_{q_v}(t) \).
From the starting point, after calling the visiting distribution function, the acceptance probability is computed as follows:

\[ p_{qa} = \min \{ 1, [1 - (1 - qa)\beta \Delta E]^{\frac{1}{1 - qa}} \} \]

Where \( qa \) is a acceptance parameter. For \( qa < 1 \), zero acceptance probability is assigned to the cases where \n
\[ [1 - (1 - qa)\beta \Delta E] < 0 \]

The artificial temperature \( T_{qv}(t) \) is decreased according to

\[ T_{qv}(t) = T_{qv}(1) \frac{2^{q_v-1} - 1}{(1 + t)^{q_v-1} - 1} \]

Where \( q_v \) is the visiting parameter.

New in version 1.2.0.

Examples

The following example is a 10-dimensional problem, with many local minima. The function involved is called Rastrigin (https://en.wikipedia.org/wiki/Rastrigin_function)

```python
>>> from scipy.optimize import dual_annealing
>>> func = lambda x: np.sum(x*x - 10* np.cos(2*np.pi*x)) + 10*np.size(x)
>>> lw = [-5.12] * 10
>>> up = [5.12] * 10
>>> ret = dual_annealing(func, bounds=list(zip(lw, up)), seed=1234)
>>> print("global minimum: xmin = \{0\}, f(xmin) = \{1:6f\}".format(
...    ret.x, ret.fun))
global minimum: xmin = [-4.26437714e-09 -3.91699361e-09 -1.86149218e-09 -3.97165720e-09 -6.29151648e-09 -6.53145322e-09 -3.93616815e-09 -6.55623025e-09 -6.05775280e-09 -5.00668935e-09], f(xmin) = 0.000000
```

6.18.5 Least-squares and Curve Fitting

Nonlinear Least-Squares

```python
least_squares(fun, x0[, jac, bounds, ...]) Solve a nonlinear least-squares problem with bounds on the variables.
```
scipy.optimize.least_squares

scipy.optimize.least_squares(fun, x0, jac='2-point', bounds=([-inf, inf]), method='trf', ftol=1e-08, xtol=1e-08, gtol=1e-08, x_scale=1.0, loss='linear', f_scale=1.0, diff_step=None, tr_solver=None, tr_options={}, jac_sparsity=None, max_nfev=None, verbose=0, args=(), kwags={})

Solve a nonlinear least-squares problem with bounds on the variables.

Given the residuals f(x) (an m-dimensional real function of n real variables) and the loss function rho(s) (a scalar function), least_squares finds a local minimum of the cost function F(x):

\[
\text{minimize } F(x) = 0.5 \times \sum \rho(f_i(x)^2), \quad i = 0, \ldots, m - 1
\]

subject to \(lb \leq x \leq ub\)

The purpose of the loss function \(\rho(s)\) is to reduce the influence of outliers on the solution.

Parameters

- **fun** [callable] Function which computes the vector of residuals, with the signature \(\text{fun}(x, *\text{args}, **\text{kwargs})\), i.e., the minimization proceeds with respect to its first argument. The argument \(x\) passed to this function is an ndarray of shape (n,) (never a scalar, even for \(n=1\)). It must return a 1-d array_like of shape (m,) or a scalar. If the argument \(x\) is complex or the function \(\text{fun}\) returns complex residuals, it must be wrapped in a real function of real arguments, as shown at the end of the Examples section.

- **x0** [array_like with shape (n,) or float] Initial guess on independent variables. If float, it will be treated as a 1-d array with one element.

- **jac** [{'2-point', '3-point', 'cs', callable}, optional] Method of computing the Jacobian matrix (an m-by-n matrix, where element (i, j) is the partial derivative of \(f[i]\) with respect to \(x[j]\)). The keywords select a finite difference scheme for numerical estimation. The scheme '3-point' is more accurate, but requires twice as many operations as '2-point' (default). The scheme 'cs' uses complex steps, and while potentially the most accurate, it is applicable only when \(\text{fun}\) correctly handles complex inputs and can be analytically continued to the complex plane. Method 'lm' always uses the '2-point' scheme. If callable, it is used as \(\text{jac}(x, *\text{args}, **\text{kwargs})\) and should return a good approximation (or the exact value) for the Jacobian as an array_like (np.atleast_2d is applied), a sparse matrix or a scipy.sparse.linalg.LinearOperator.

- **bounds** [2-tuple of array_like, optional] Lower and upper bounds on independent variables. Defaults to no bounds. Each array must match the size of \(x0\) or be a scalar, in the latter case a bound will be the same for all variables. Use np.inf with an appropriate sign to disable bounds on all or some variables.

- **method** [{'trf', 'dogbox', 'lm'}, optional] Algorithm to perform minimization.
  - 'trf': Trust Region Reflective algorithm, particularly suitable for large sparse problems with bounds. Generally robust method.
  - 'dogbox': dogleg algorithm with rectangular trust regions, typical use case is small problems with bounds. Not recommended for problems with rank-deficient Jacobian.
  - 'lm': Levenberg-Marquardt algorithm as implemented in MINPACK. Doesn't handle bounds and sparse Jacobians. Usually the most efficient method for small unconstrained problems.

Default is 'trf'. See Notes for more information.

- **ftol** [float or None, optional] Tolerance for termination by the change of the cost function. Default is 1e-8. The optimization process is stopped when \(dF < ftol \times F\), and there was an adequate agreement between a local quadratic model and the true model in the last step. If None, the termination by this condition is disabled.

- **xtol** [float or None, optional] Tolerance for termination by the change of the independent variables. Default is 1e-8. The exact condition depends on the method used:
  - For 'trf' and 'dogbox': \(\|dx\| < xtol \times (xtol + \|x\|)\)
For ‘lm’: Delta < xtol * norm(xs), where Delta is a trust-region radius and xs is the value of x scaled according to x_scale parameter (see below).

If None, the termination by this condition is disabled.

gtol
[Float or None, optional] Tolerance for termination by the norm of the gradient. Default is 1e-8. The exact condition depends on a method used:

• For ‘trf’: norm(g_scaled, ord=np.inf) < gtol, where g_scaled is the value of the gradient scaled to account for the presence of the bounds [STIR].
• For ‘dogbox’: norm(g_free, ord=np.inf) < gtol, where g_free is the gradient with respect to the variables which are not in the optimal state on the boundary.
• For ‘lm’: the maximum absolute value of the cosine of angles between columns of the Jacobian and the residual vector is less than gtol, or the residual vector is zero.

If None, the termination by this condition is disabled.

x_scale
[array_like or ‘jac’, optional] Characteristic scale of each variable. Setting x_scale is equivalent to reformulating the problem in scaled variables xs = x / x_scale. An alternative view is that the size of a trust region along j-th dimension is proportional to x_scale[j]. Improved convergence may be achieved by setting x_scale such that a step of a given size along any of the scaled variables has a similar effect on the cost function. If set to ‘jac’, the scale is iteratively updated using the inverse norms of the columns of the Jacobian matrix (as described in [JJMore]).

loss
[str or callable, optional] Determines the loss function. The following keyword values are allowed:

• ‘linear’ (default): rho(z) = z. Gives a standard least-squares problem.
• ‘soft_l1’: rho(z) = 2 * ((1 + z)**0.5 - 1). The smooth approximation of l1 (absolute value) loss. Usually a good choice for robust least squares.
• ‘huber’: rho(z) = z if z <= 1 else 2*z**0.5 - 1. Works similarly to ‘soft_l1’.
• ‘cauchy’: rho(z) = ln(1 + z). Severely weakens outliers influence, but may cause difficulties in optimization process.
• ‘arctan’: rho(z) = arctan(z). Limits a maximum loss on a single residual, has properties similar to ‘cauchy’.

If callable, it must take a 1-d ndarray z=f**2 and return an array_like with shape (3, m) where row 0 contains function values, row 1 contains first derivatives and row 2 contains second derivatives. Method ‘lm’ supports only ‘linear’ loss.

f_scale
[float, optional] Value of soft margin between inlier and outlier residuals, default is 1.0. The loss function is evaluated as follows rho_(f**2) = C**2 * rho(f**2 / C**2), where C is f_scale, and rho is determined by loss parameter. This parameter has no effect with loss=’linear’, but for other loss values it is of crucial importance.

max_nfev
[None or int, optional] Maximum number of function evaluations before the termination. If None (default), the value is chosen automatically:

• For ‘trf’ and ‘dogbox’: 100 * n.
• For ‘lm’: 100 * n if jac is callable and 100 * n * (n + 1) otherwise (because ‘lm’ counts function calls in Jacobian estimation).

diff_step
[None or array_like, optional] Determines the relative step size for the finite difference approximation of the Jacobian. The actual step is computed as x * diff_step. If None (default), then diff_step is taken to be a conventional “optimal” power of machine epsilon for the finite difference scheme used [NR].

tr_solver

• ‘exact’ is suitable for not very large problems with dense Jacobian matrices. The computational complexity per iteration is comparable to a singular value decomposition of the Jacobian matrix.
• ‘lsmr’ is suitable for problems with sparse and large Jacobian matrices. It uses the iterative procedure scipy.sparse.linalg.lsmr for finding a solution of a linear least-squares problem and only requires matrix-vector product evaluations.
If None (default) the solver is chosen based on the type of Jacobian returned on the first iteration.

**tr_options**

[dict, optional] Keyword options passed to trust-region solver.
- `tr_solver='exact'`: tr_options are ignored.
- `tr_solver='lsmr'`: options for `scipy.sparse.linalg.lsmr`. Additionally method='trf' supports ‘regularize’ option (bool, default is True) which adds a regularization term to the normal equation, which improves convergence if the Jacobian is rank-deficient [Byrd](eq. 3.4).

**jac_sparsity**

[None, array_like, sparse matrix], optional] Defines the sparsity structure of the Jacobian matrix for finite difference estimation, its shape must be (m, n). If the Jacobian has only few non-zero elements in each row, providing the sparsity structure will greatly speed up the computations [Curtis]. A zero entry means that a corresponding element in the Jacobian is identically zero. If provided, forces the use of ‘lsmr’ trust-region solver. If None (default) then dense differencing will be used. Has no effect for ‘lm’ method.

**verbose**

[0, 1, 2], optional] Level of algorithm’s verbosity:
- 0 (default): work silently.
- 1: display a termination report.
- 2: display progress during iterations (not supported by ‘lm’ method).

**args, kwargs**

[tuple and dict, optional] Additional arguments passed to fun and jac. Both empty by default. The calling signature is fun(x, *args, **kwargs) and the same for jac.

**Returns**

`OptimizeResult` with the following fields defined:
- `x` [ndarray, shape (n,)] Solution found.
- `cost` [float] Value of the cost function at the solution.
- `fun` [ndarray, shape (m,)] Vector of residuals at the solution.
- `jac` [ndarray, sparse matrix or LinearOperator, shape (m, n)] Modified Jacobian matrix at the solution, in the sense that J^T J is a Gauss-Newton approximation of the Hessian of the cost function. The type is the same as the one used by the algorithm.
- `grad` [ndarray, shape (m,)] Gradient of the cost function at the solution.
- `optimality` [float] First-order optimality measure. In unconstrained problems, it is always the uniform norm of the gradient. In constrained problems, it is the quantity which was compared with `gtol` during iterations.
- `active_mask` [ndarray of int, shape (n,)] Each component shows whether a corresponding constraint is active (that is, whether a variable is at the bound):
  - 0: a constraint is not active.
  - -1: a lower bound is active.
  - 1: an upper bound is active.
  Might be somewhat arbitrary for ‘trf’ method as it generates a sequence of strictly feasible iterates and active_mask is determined within a tolerance threshold.
- `nfev` [int] Number of function evaluations done. Methods ‘trf’ and ‘dogbox’ do not count function calls for numerical Jacobian approximation, as opposed to ‘lm’ method.
- `njev` [int or None] Number of Jacobian evaluations done. If numerical Jacobian approximation is used in ‘lm’ method, it is set to None.
- `status` [int] The reason for algorithm termination:
  - -1: improper input parameters status returned from MINPACK.
  - 0: the maximum number of function evaluations is exceeded.
  - 1: `gtol` termination condition is satisfied.
  - 2: `ftol` termination condition is satisfied.
  - 3: `xtol` termination condition is satisfied.
  - 4: Both `ftol` and `xtol` termination conditions are satisfied.
message  [str] Verbal description of the termination reason.
success  [bool] True if one of the convergence criteria is satisfied (status > 0).

leastsq

A legacy wrapper for the MINPACK implementation of the Levenberg-Marquadt algorithm.

curve_fit

Least-squares minimization applied to a curve fitting problem.

Notes

Method ‘lm’ (Levenberg-Marquardt) calls a wrapper over least-squares algorithms implemented in MINPACK (lmder, lmdif). It runs the Levenberg-Marquardt algorithm formulated as a trust-region type algorithm. The implementation is based on paper [JJMore], it is very robust and efficient with a lot of smart tricks. It should be your first choice for unconstrained problems. Note that it doesn’t support bounds. Also it doesn’t work when m < n.

Method ‘trf’ (Trust Region Reflective) is motivated by the process of solving a system of equations, which constitute the first-order optimality condition for a bound-constrained minimization problem as formulated in [STIR]. The algorithm iteratively solves trust-region subproblems augmented by a special diagonal quadratic term and with trust-region shape determined by the distance from the bounds and the direction of the gradient. This enhancements help to avoid making steps directly into bounds and efficiently explore the whole space of variables. To further improve convergence, the algorithm considers search directions reflected from the bounds. To obey theoretical requirements, the algorithm keeps iterates strictly feasible. With dense Jacobians trust-region subproblems are solved by an exact method very similar to the one described in [JJMore] (and implemented in MINPACK). The difference from the MINPACK implementation is that a singular value decomposition of a Jacobian matrix is done once per iteration, instead of a QR decomposition and series of Givens rotation eliminations. For large sparse Jacobians a 2-d subspace approach of solving trust-region subproblems is used [STIR], [Byrd]. The subspace is spanned by a scaled gradient and an approximate Gauss-Newton solution delivered by scipy.sparse.linalg.lsmr. When no constraints are imposed the algorithm is very similar to MINPACK and has generally comparable performance. The algorithm works quite robust in unbounded and bounded problems, thus it is chosen as a default algorithm.

Method ‘dogbox’ operates in a trust-region framework, but considers rectangular trust regions as opposed to conventional ellipsoids [Voglis]. The intersection of a current trust region and initial bounds is again rectangular, so on each iteration a quadratic minimization problem subject to bound constraints is solved approximately by Powell’s dogleg method [NumOpt]. The required Gauss-Newton step can be computed exactly for dense Jacobians or approximately by scipy.sparse.linalg.lsmr for large sparse Jacobians. The algorithm is likely to exhibit slow convergence when the rank of Jacobian is less than the number of variables. The algorithm often outperforms ‘trf’ in bounded problems with a small number of variables.

Robust loss functions are implemented as described in [BA]. The idea is to modify a residual vector and a Jacobian matrix on each iteration such that computed gradient and Gauss-Newton Hessian approximation match the true gradient and Hessian approximation of the cost function. Then the algorithm proceeds in a normal way, i.e. robust loss functions are implemented as a simple wrapper over standard least-squares algorithms.

New in version 0.17.0.

References

[STIR], [NR], [Byrd], [Curtis], [JJMore], [Voglis], [NumOpt], [BA]
Examples

In this example we find a minimum of the Rosenbrock function without bounds on independent variables.

```python
>>> def fun_rosenbrock(x):
...     return np.array([10 * (x[1] - x[0])**2, (1 - x[0])])
```

Notice that we only provide the vector of the residuals. The algorithm constructs the cost function as a sum of squares of the residuals, which gives the Rosenbrock function. The exact minimum is at \( x = [1.0, 1.0] \).

```python
>>> from scipy.optimize import least_squares
>>> x0_rosenbrock = np.array([2, 2])
>>> res_1 = least_squares(fun_rosenbrock, x0_rosenbrock)
>>> res_1.x
array([ 1., 1.])
>>> res_1.cost
9.8669242910846867e-30
>>> res_1.optimality
8.8928864934219529e-14
```

We now constrain the variables, in such a way that the previous solution becomes infeasible. Specifically, we require that \( x[1] >= 1.5 \), and \( x[0] \) left unconstrained. To this end, we specify the `bounds` parameter to `least_squares` in the form `bounds=([-np.inf, 1.5], np.inf)`.

We also provide the analytic Jacobian:

```python
>>> def jac_rosenbrock(x):
...     return np.array([
...         [-20 * x[0], 10],
...         [-1, 0])
```

Putting this all together, we see that the new solution lies on the bound:

```python
>>> res_2 = least_squares(fun_rosenbrock, x0_rosenbrock, jac_rosenbrock,
...                        bounds=([-np.inf, 1.5], np.inf))
>>> res_2.x
array([ 1.22437075, 1.5])
>>> res_2.cost
0.025213093946805685
>>> res_2.optimality
1.58835401433157753e-07
```

Now we solve a system of equations (i.e., the cost function should be zero at a minimum) for a Broyden tridiagonal vector-valued function of 100000 variables:

```python
>>> def fun_broyden(x):
...     f = (3 - x) * x + 1
...     f[1:] -= x[:-1]
...     f[:-1] -= 2 * x[1:]
...     return f
```

The corresponding Jacobian matrix is sparse. We tell the algorithm to estimate it by finite differences and provide the sparsity structure of Jacobian to significantly speed up this process.
>>> from scipy.sparse import lil_matrix
>>> def sparsity_broyden(n):
...     sparsity = lil_matrix((n, n), dtype=int)
...     i = np.arange(n)
...     sparsity[i, i] = 1
...     i = np.arange(i, n)
...     sparsity[i, i - 1] = 1
...     i = np.arange(n - 1)
...     sparsity[i, i + 1] = 1
...     return sparsity
...
>>> n = 100000
>>> x0_broyden = -np.ones(n)
>>> res_3 = least_squares(fun_broyden, x0_broyden,
...     jac_sparsity=sparsity_broyden(n))
>>> res_3.cost
4.5687069299604613e-23
>>> res_3.optimality
1.1650454296851518e-11
Let’s also solve a curve fitting problem using robust loss function to take care of outliers in the data. Define the model function as $y = a + b \times \exp(c \times t)$, where $t$ is a predictor variable, $y$ is an observation and $a$, $b$, $c$ are parameters to estimate.

First, define the function which generates the data with noise and outliers, define the model parameters, and generate data:

```python
>>> def gen_data(t, a, b, c, noise=0, n_outliers=0, random_state=0):
...     y = a + b * np.exp(t * c)
...     rnd = np.random.RandomState(random_state)
...     error = noise * rnd.randn(t.size)
...     outliers = rnd.randint(0, t.size, n_outliers)
...     error[outliers] *= 10
...     return y + error
...```  
```python
>>> a = 0.5
>>> b = 2.0
>>> c = -1
>>> t_min = 0
>>> t_max = 10
>>> n_points = 15
...```  
```python
>>> t_train = np.linspace(t_min, t_max, n_points)
>>> y_train = gen_data(t_train, a, b, c, noise=0.1, n_outliers=3)
Define function for computing residuals and initial estimate of parameters.

```python
>>> def fun(x, t, y):
...     return x[0] + x[1] * np.exp(x[2] * t) - y
...```  
```python
>>> x0 = np.array([1.0, 1.0, 0.0])
```
Compute a standard least-squares solution:

```python
>>> res_lsq = least_squares(fun, x0, args=(t_train, y_train))
```

Now compute two solutions with two different robust loss functions. The parameter `f_scale` is set to 0.1, meaning that inlier residuals should not significantly exceed 0.1 (the noise level used).

```python
>>> res_soft_l1 = least_squares(fun, x0, loss='soft_l1', f_scale=0.1, args=(t_train, y_train))
>>> res_log = least_squares(fun, x0, loss='cauchy', f_scale=0.1, args=(t_train, y_train))
```

And finally plot all the curves. We see that by selecting an appropriate loss we can get estimates close to optimal even in the presence of strong outliers. But keep in mind that generally it is recommended to try 'soft_l1' or 'huber' losses first (if at all necessary) as the other two options may cause difficulties in optimization process.

```python
>>> t_test = np.linspace(t_min, t_max, n_points * 10)
>>> y_true = gen_data(t_test, a, b, c)
>>> y_lsq = gen_data(t_test, *res_lsq.x)
>>> y_soft_l1 = gen_data(t_test, *res_soft_l1.x)
>>> y_log = gen_data(t_test, *res_log.x)

>>> import matplotlib.pyplot as plt
>>> plt.plot(t_train, y_train, 'o')
>>> plt.plot(t_test, y_true, 'k', linewidth=2, label='true')
>>> plt.plot(t_test, y_lsq, label='linear loss')
>>> plt.plot(t_test, y_soft_l1, label='soft_l1 loss')
>>> plt.plot(t_test, y_log, label='cauchy loss')
>>> plt.xlabel("t")
>>> plt.ylabel("y")
>>> plt.legend()
>>> plt.show()
```

In the next example, we show how complex-valued residual functions of complex variables can be optimized with `least_squares()`. Consider the following function:
>>> def f(z):
...     return z - (0.5 + 0.5j)

We wrap it into a function of real variables that returns real residuals by simply handling the real and imaginary parts as independent variables:

>>> def f_wrap(x):
...     fx = f(x[0] + 1j*x[1])
...     return np.array([fx.real, fx.imag])

Thus, instead of the original \( m \)-dimensional complex function of \( n \) complex variables we optimize a \( 2m \)-dimensional real function of \( 2n \) real variables:

>>> from scipy.optimize import least_squares
>>> res_wrapped = least_squares(f_wrap, (0.1, 0.1), bounds=([0, 0], [1, -1]))
>>> z = res_wrapped.x[0] + res_wrapped.x[1]*1j
>>> z
(0.49999999999925893+0.49999999999925893j)

Linear Least-Squares

**nnls**

\[ \text{Solve } \arg\min_x || Ax - b ||_2 \text{ for } x\geq 0. \]

\[ \text{Solve } \arg\min_x || Ax - b ||_2 \text{ for } x\geq 0. \text{ This is a wrapper for a FORTRAN non-negative least squares solver.} \]

**Parameters**

- **A** [ndarray] Matrix \( A \) as shown above.
- **b** [ndarray] Right-hand side vector.
- **maxiter**: int, optional
  Maximum number of iterations, optional. Default is \( 3 \times A.shape[1] \).

**Returns**

- **x** [ndarray] Solution vector.
- **rnorm** [float] The residual, \( || Ax-b ||_2 \).

**Notes**

The FORTRAN code was published in the book below. The algorithm is an active set method. It solves the KKT (Karush-Kuhn-Tucker) conditions for the non-negative least squares problem.

**References**

scipy.optimize.lsq_linear

scipy.optimize.lsq_linear(A, b, bounds=(-inf, inf), method='trf', tol=1e-10, lsq_solver=None, lsmr_tol=None, max_iter=None, verbose=0)

Solve a linear least-squares problem with bounds on the variables.

Given a m-by-n design matrix A and a target vector b with m elements, lsq_linear solves the following optimization problem:

\[
\text{minimize } 0.5 \cdot ||A x - b||^2 \\
\text{subject to } lb \leq x \leq ub
\]

This optimization problem is convex, hence a found minimum (if iterations have converged) is guaranteed to be global.

**Parameters**

- **A** [array_like, sparse matrix of LinearOperator, shape (m, n)] Design matrix. Can be scipy.sparse.linalg.LinearOperator.
- **b** [array_like, shape (m,)] Target vector.
- **bounds** [2-tuple of array_like, optional] Lower and upper bounds on independent variables. Defaults to no bounds. Each array must have shape (n,) or be a scalar, in the latter case a bound will be the same for all variables. Use np.inf with an appropriate sign to disable bounds on all or some variables.
- **method** ['trf' or 'bvls', optional] Method to perform minimization.
  - 'trf': Trust Region Reflective algorithm adapted for a linear least-squares problem. This is an interior-point-like method and the required number of iterations is weakly correlated with the number of variables.
  - 'bvls': Bounded-Variable Least-Squares algorithm. This is an active set method, which requires the number of iterations comparable to the number of variables. Can't be used when A is sparse or LinearOperator.
  Default is 'trf'.
- **tol** [float, optional] Tolerance parameter. The algorithm terminates if a relative change of the cost function is less than tol on the last iteration. Additionally the first-order optimality measure is considered:
  - method='trf' terminates if the uniform norm of the gradient, scaled to account for the presence of the bounds, is less than tol.
  - method='bvls' terminates if Karush-Kuhn-Tucker conditions are satisfied within tol tolerance.
- **lsq_solver** [(None, 'exact', 'lsmr'), optional] Method of solving unbounded least-squares problems throughout iterations:
  - 'exact': Use dense QR or SVD decomposition approach. Can't be used when A is sparse or LinearOperator.
  - 'lsmr': Use scipy.sparse.linalg.lsmr iterative procedure which requires only matrix-vector product evaluations. Can't be used with method='bvls'.
  If None (default) the solver is chosen based on type of A.
- **lsmr_tol** [None, float or 'auto', optional] Tolerance parameters 'atol' and 'btol' for scipy.sparse.linalg.lsmr. If None (default), it is set to 1e-2 * tol. If 'auto', the tolerance will be adjusted based on the optimality of the current iterate, which can speed up the optimization process, but is not always reliable.
- **max_iter** [None or int, optional] Maximum number of iterations before termination. If None (default), it is set to 100 for method='trf' or to the number of variables for method='bvls' (not counting iterations for 'bvls' initialization).
- **verbose** [0, 1, 2], optional] Level of algorithm's verbosity:
  - 0: work silently (default).
  - 1: display a termination report.
• 2: display progress during iterations.

Returns

OptimizeResult with the following fields defined:

- \( x \) [ndarray, shape \((n,)\)] Solution found.
- \( \text{cost} \) [float] Value of the cost function at the solution.
- \( \text{fun} \) [ndarray, shape \((m,)\)] Vector of residuals at the solution.
- \( \text{optimality} \) [float] First-order optimality measure. The exact meaning depends on method, refer to the description of \( \text{tol} \) parameter.
- \( \text{active_mask} \) [ndarray of int, shape \((n,)\)] Each component shows whether a corresponding constraint is active (that is, whether a variable is at the bound):
  - 0: a constraint is not active.
  - -1: a lower bound is active.
  - 1: an upper bound is active.
Might be somewhat arbitrary for the trf method as it generates a sequence of strictly feasible iterates and active_mask is determined within a tolerance threshold.
- \( \text{nit} \) [int] Number of iterations. Zero if the unconstrained solution is optimal.
- \( \text{status} \) [int] Reason for algorithm termination:
  - -1: the algorithm was not able to make progress on the last iteration.
  - 0: the maximum number of iterations is exceeded.
  - 1: the first-order optimality measure is less than \( \text{tol} \).
  - 2: the relative change of the cost function is less than \( \text{tol} \).
  - 3: the unconstrained solution is optimal.
- \( \text{message} \) [str] Verbal description of the termination reason.
- \( \text{success} \) [bool] True if one of the convergence criteria is satisfied (\( \text{status} > 0 \)).

See also:

- \text{nlnls}\n
  Linear least squares with non-negativity constraint.

- \text{least_squares}\n
  Nonlinear least squares with bounds on the variables.

Notes

The algorithm first computes the unconstrained least-squares solution by \text{numpy.linalg.lstsq} or \text{scipy.sparse.linalg.lsmr} depending on \text{lsq_solver}. This solution is returned as optimal if it lies within the bounds.

Method ‘trf’ runs the adaptation of the algorithm described in [STIR] for a linear least-squares problem. The iterations are essentially the same as in the nonlinear least-squares algorithm, but as the quadratic function model is always accurate, we don’t need to track or modify the radius of a trust region. The line search (backtracking) is used as a safety net when a selected step does not decrease the cost function. Read more detailed description of the algorithm in \text{scipy.optimize.least_squares}.

Method ‘bvls’ runs a Python implementation of the algorithm described in [BVLS]. The algorithm maintains active and free sets of variables, on each iteration chooses a new variable to move from the active set to the free set and then solves the unconstrained least-squares problem on free variables. This algorithm is guaranteed to give an accurate solution eventually, but may require up to \( n \) iterations for a problem with \( n \) variables. Additionally, an ad-hoc initialization procedure is implemented, that determines which variables to set free or active initially. It takes some number of iterations before actual BVLS starts, but can significantly reduce the number of further iterations.
References

[STIR], [BVLS]

Examples

In this example a problem with a large sparse matrix and bounds on the variables is solved.

```python
>>> from scipy.sparse import rand
>>> from scipy.optimize import lsq_linear
... >>> np.random.seed(0)
... >>> m = 20000
>>> n = 10000
... >>> A = rand(m, n, density=1e-4)
>>> b = np.random.randn(m)
... >>> lb = np.random.randn(n)
>>> ub = lb + 1
... >>> res = lsq_linear(A, b, bounds=(lb, ub), lsmr_tol='auto', verbose=1)
# may vary
The relative change of the cost function is less than `tol`.
Number of iterations 16, initial cost 1.5039e+04, final cost 1.1112e+04, first-order optimality 4.66e-08.
```

Curve Fitting

```
curve_fit(f, xdata, ydata[, p0, sigma, ...]) Use non-linear least squares to fit a function, f, to data.

scipy.optimize.curve_fit

scipy.optimize.curve_fit(f, xdata, ydata, p0=None, sigma=None,
    check_finite=True, bounds=(-inf, inf), method=None, jac=None, **kwargs)
Use non-linear least squares to fit a function, f, to data.

Assumes ydata = f(xdata, *params) + eps

Parameters

f [callable] The model function, f(x, ...). It must take the independent variable as the first argument and the parameters to fit as separate remaining arguments.

xdata [array_like or object] The independent variable where the data is measured. Should usually be an M-length sequence or an (k,M)-shaped array for functions with k predictors, but can actually be any object.

ydata [array_like] The dependent data, a length M array - nominally f(xdata, ...).

p0 [array_like, optional] Initial guess for the parameters (length N). If None, then the initial values will all be 1 (if the number of parameters for the function can be determined using introspection, otherwise a ValueError is raised).
```
**sigma**

[None or M-length sequence or MxM array, optional] Determines the uncertainty in ydata. If we define residuals as \( r = ydata - f(xdata, *popt) \), then the interpretation of sigma depends on its number of dimensions:

- A 1-d sigma should contain values of standard deviations of errors in ydata. In this case, the optimized function is \( chisq = \sum(\frac{r}{\text{sigma}})^2 \).
- A 2-d sigma should contain the covariance matrix of errors in ydata. In this case, the optimized function is \( chisq = r^T \times inv(sigma) \times r \).

New in version 0.19.

None (default) is equivalent of 1-d sigma filled with ones.

**absolute_sigma**

[bool, optional] If True, sigma is used in an absolute sense and the estimated parameter covariance pcov reflects these absolute values. If False, only the relative magnitudes of the sigma values matter. The returned parameter covariance matrix pcov is based on scaling sigma by a constant factor. This constant is set by demanding that the reduced chisq for the optimal parameters popt when using the scaled sigma equals unity. In other words, sigma is scaled to match the sample variance of the residuals after the fit. Mathematically, pcov(absolute_sigma=True) * chisq(popt) / (M-N) = pcov(absolute_sigma=False) * chisq(popt) / (M-N).

New in version 0.17.

**check_finite**

[bool, optional] If True, check that the input arrays do not contain nans of infs, and raise a ValueError if they do. Setting this parameter to False may silently produce nonsensical results if the input arrays do contain nans. Default is True.

**bounds**

[2-tuple of array_like, optional] Lower and upper bounds on parameters. Defaults to no bounds. Each element of the tuple must be either an array with the length equal to the number of parameters, or a scalar (in which case the bound is taken to be the same for all parameters.) Use np.inf with an appropriate sign to disable bounds on all or some parameters.

New in version 0.17.

**method**

[{'lm', 'trf', 'dogbox'}, optional] Method to use for optimization. See least_squares for more details. Default is 'lm' for unconstrained problems and 'trf' if bounds are provided. The method 'lm' won't work when the number of observations is less than the number of variables, use 'trf' or 'dogbox' in this case.

New in version 0.17.

**jac**

[callable, string or None, optional] Function with signature jac(x, ...) which computes the Jacobian matrix of the model function with respect to parameters as a dense array_like structure. It will be scaled according to provided sigma. If None (default), the Jacobian will be estimated numerically. String keywords for ‘trf’ and ‘dogbox’ methods can be used to select a finite difference scheme, see least_squares.

New in version 0.18.

**kwargs**

Keyword arguments passed to leastsq for method='lm' or least_squares otherwise.

**Returns**

- **popt** [array] Optimal values for the parameters so that the sum of the squared residuals of \( f(xdata, *popt) - ydata \) is minimized
- **pcov** [2d array] The estimated covariance of popt. The diagonals provide the variance of the parameter estimate. To compute one standard deviation errors on the parameters use perr = np.sqrt(np.diag(pcov)). How the sigma parameter affects the estimated covariance depends on absolute_sigma argument, as described above.

If the Jacobian matrix at the solution doesn’t have a full rank, then ‘lm’ method returns a matrix filled with np.inf, on the other hand ‘trf’ and ‘dogbox’ methods use Moore-Penrose pseudoinverse to compute the covariance matrix.
Raises

ValueError
if either ydata or xdata contain NaNs, or if incompatible options are used.

RuntimeError
if the least-squares minimization fails.

OptimizeWarning
if covariance of the parameters cannot be estimated.

See also:

least_squares
Minimize the sum of squares of nonlinear functions.

scipy.stats.linregress
Calculate a linear least squares regression for two sets of measurements.

Notes

With method='lm', the algorithm uses the Levenberg-Marquardt algorithm through leastsq. Note that this algorithm can only deal with unconstrained problems.

Box constraints can be handled by methods 'trf' and 'dogbox'. Refer to the docstring of least_squares for more information.

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.optimize import curve_fit

>>> def func(x, a, b, c):
...     return a * np.exp(-b * x) + c

Define the data to be fit with some noise:

```python
>>> xdata = np.linspace(0, 4, 50)
>>> y = func(xdata, 2.5, 1.3, 0.5)
>>> np.random.seed(1729)
>>> y_noise = 0.2 * np.random.normal(size=xdata.size)
>>> ydata = y + y_noise
>>> plt.plot(xdata, ydata, 'b-', label='data')
```

Fit for the parameters a, b, c of the function func:

```python
>>> popt, pcov = curve_fit(func, xdata, ydata)
>>> popt
array([ 2.55423706, 1.35190947, 0.47450618])
>>> plt.plot(xdata, func(xdata, *popt), 'r-',
...           label='fit: a=%5.3f, b=%5.3f, c=%5.3f' % tuple(popt))
```

Constrain the optimization to the region of 0 <= a <= 3, 0 <= b <= 1 and 0 <= c <= 0.5:
6.18.6 Root finding

Scalar functions

- `root_scalar(f[, args, method, bracket, ...])` Find a root of a scalar function.
- `brentq(f, a, b[, args, xtol, rtol, maxiter, ...])` Find a root of a function in a bracketing interval using Brent's method.
- `brenth(f, a, b[, args, xtol, rtol, maxiter, ...])` Find a root of a function in a bracketing interval using Brent's method with hyperbolic extrapolation.
- `ridder(f, a, b[, args, xtol, rtol, maxiter, ...])` Find a root of a function in an interval using Ridder's method.
- `bisect(f, a, b[, args, xtol, rtol, maxiter, ...])` Find root of a function within an interval using bisection.
- `newton(func, x0[, fprime, args, tol, ...])` Find a zero of a real or complex function using the Newton-Raphson (or secant or Halley's) method.
- `toms748(f, a, b[, args, k, xtol, rtol, ...])` Find a zero using TOMS Algorithm 748 method.
- `RootResults(root, iterations, ...)` Represents the root finding result.
scipy.optimize.root_scalar

Find a root of a scalar function.

Parameters

- **f** [callable] A function to find a root of.
- **args** [tuple, optional] Extra arguments passed to the objective function and its derivative(s).
- **method** [str, optional] Type of solver. Should be one of:
  - 'bisect' (see here)
  - 'brentq' (see here)
  - 'brentq' (see here)
  - 'ridder' (see here)
  - 'toms748' (see here)
  - 'newton' (see here)
  - 'secant' (see here)
  - 'halley' (see here)
- **bracket**: A sequence of 2 floats, optional
  An interval bracketing a root. \( f(x, *args) \) must have different signs at the two endpoints.
- **x0** [float, optional] Initial guess.
- **x1** [float, optional] A second guess.
- **fprime** [bool or callable, optional] If \( fprime \) is a boolean and is True, \( f \) is assumed to return the value of the objective function and of the derivative. \( fprime \) can also be a callable returning the derivative of \( f \). In this case, it must accept the same arguments as \( f \).
- **fprime2** [bool or callable, optional] If \( fprime2 \) is a boolean and is True, \( f \) is assumed to return the value of the objective function and of the first and second derivatives. \( fprime2 \) can also be a callable returning the second derivative of \( f \). In this case, it must accept the same arguments as \( f \).
- **xtol** [float, optional] Tolerance (absolute) for termination.
- **rtol** [float, optional] Tolerance (relative) for termination.
- **maxiter** [int, optional] Maximum number of iterations.
- **options** [dict, optional] A dictionary of solver options. E.g. \( k \), see \texttt{show_options()} for details.

Returns

- **sol** [RootResults] The solution represented as a \texttt{RootResults} object. Important attributes are: \texttt{root} the solution, \texttt{converged} a boolean flag indicating if the algorithm exited successfully and \texttt{flag} which describes the cause of the termination. See \texttt{RootResults} for a description of other attributes.

See also:

- \texttt{show_options}
  Additional options accepted by the solvers
- \texttt{root}
  Find a root of a vector function.

Notes

This section describes the available solvers that can be selected by the ‘method’ parameter.
The default is to use the best method available for the situation presented. If a bracket is provided, it may use one of the bracketing methods. If a derivative and an initial value are specified, it may select one of the derivative-based methods. If no method is judged applicable, it will raise an Exception.

**Examples**

Find the root of a simple cubic

```python
>>> from scipy import optimize
>>> def f(x):
...    return (x**3 - 1)  # only one real root at x = 1
```

```python
>>> def fprime(x):
...    return 3*x**2
```

The `brentq` method takes as input a bracket

```python
>>> sol = optimize.root_scalar(f, bracket=[0, 3], method='brentq')
>>> sol.root, sol.iterations, sol.function_calls
(1.0, 10, 11)
```

The `newton` method takes as input a single point and uses the derivative(s)

```python
>>> sol = optimize.root_scalar(f, x0=0.2, fprime=fprime, method='newton')
>>> sol.root, sol.iterations, sol.function_calls
(1.0, 11, 22)
```

The function can provide the value and derivative(s) in a single call.

```python
>>> def f_p_pp(x):
...    return (x**3 - 1), 3*x**2, 6*x
```

```python
>>> sol = optimize.root_scalar(f_p_pp, x0=0.2, fprime=True, method='newton')
>>> sol.root, sol.iterations, sol.function_calls
(1.0, 11, 11)
```

```python
>>> sol = optimize.root_scalar(f_p_pp, x0=0.2, fprime=True, fprime2=True, method='halley')
>>> sol.root, sol.iterations, sol.function_calls
(1.0, 7, 8)
```

**scipy.optimize.brentq**

Find a root of a function in a bracketing interval using Brent’s method.

Uses the classic Brent’s method to find a zero of the function \( f \) on the sign changing interval \([a, b]\). Generally considered the best of the rootfinding routines here. It is a safe version of the secant method that uses inverse quadratic extrapolation. Brent’s method combines root bracketing, interval bisection, and inverse quadratic interpolation. It is sometimes known as the van Wijngaarden-Dekker-Brent method. Brent (1973) claims convergence is guaranteed for functions computable within \([a, b]\).
[Brent1973] provides the classic description of the algorithm. Another description can be found in a recent edition of Numerical Recipes, including [PressEtal1992]. A third description is at http://mathworld.wolfram.com/BrentsMethod.html. It should be easy to understand the algorithm just by reading our code. Our code diverges a bit from standard presentations: we choose a different formula for the extrapolation step.

**Parameters**

- **f** [function] Python function returning a number. The function $f$ must be continuous, and $f(a)$ and $f(b)$ must have opposite signs.
- **a** [scalar] One end of the bracketing interval $[a, b]$.
- **b** [scalar] The other end of the bracketing interval $[a, b]$.
- **xtol** [number, optional] The computed root $x_0$ will satisfy $\text{np.allclose}(x, x_0, atol=xtol, rtol=rtol)$, where $x$ is the exact root. The parameter must be nonnegative. For nice functions, Brent’s method will often satisfy the above condition with $xtol/2$ and $rtol/2$. [Brent1973]
- **rtol** [number, optional] The computed root $x_0$ will satisfy $\text{np.allclose}(x, x_0, atol=xtol, rtol=rtol)$, where $x$ is the exact root. The parameter cannot be smaller than its default value of $4*\text{np.finfo(float).eps}$. For nice functions, Brent’s method will often satisfy the above condition with $xtol/2$ and $rtol/2$. [Brent1973]
- **maxiter** [int, optional] if convergence is not achieved in $maxiter$ iterations, an error is raised. Must be $\geq 0$.
- **args** [tuple, optional] containing extra arguments for the function $f$. $f$ is called by $\text{apply}(f, (x)+args)$.
- **full_output** [bool, optional] If $full_output$ is False, the root is returned. If $full_output$ is True, the return value is $(x, r)$, where $x$ is the root, and $r$ is a $\text{RootResults}$ object.
- **disp** [bool, optional] If True, raise RuntimeError if the algorithm didn’t converge. Otherwise the convergence status is recorded in any $\text{RootResults}$ return object.

**Returns**

- **x0** [float] Zero of $f$ between $a$ and $b$.
- **r** [RootResults (present if full_output = True)] Object containing information about the convergence. In particular, $r.converged$ is True if the routine converged.

**Notes**

- $f$ must be continuous. $f(a)$ and $f(b)$ must have opposite signs.

**Examples**

```python
>>> def f(x):
...     return (x**2 - 1)
```

```python
>>> from scipy import optimize
```

```python
>>> root = optimize.brentq(f, -2, 0)
>>> root
-1.0
```

```python
>>> root = optimize.brentq(f, 0, 2)
>>> root
1.0
```

**scipy.optimize.brent**

```
scipy.optimize.brent(f, a, b, args=(), xtol=2e-12, rtol=8.881784197001252e-16, maxiter=100, full_output=False, disp=True)
```

Find a root of a function in a bracketing interval using Brent’s method with hyperbolic extrapolation.

A variation on the classic Brent routine to find a zero of the function f between the arguments a and b that uses hyperbolic extrapolation instead of inverse quadratic extrapolation. There was a paper back in the 1980’s ... f(a) and f(b) cannot have the same signs. Generally on a par with the brent routine, but not as heavily tested. It is a safe version of the secant method that uses hyperbolic extrapolation. The version here is by Chuck Harris.

**Parameters**

- **f**
  - [function] Python function returning a number. f must be continuous, and f(a) and f(b) must have opposite signs.
- **a**
  - [scalar] One end of the bracketing interval [a,b].
- **b**
  - [scalar] The other end of the bracketing interval [a,b].
- **xtol**
  - [number, optional] The computed root x0 will satisfy np.allclose(x, x0, atol=xtol, rtol=rtol), where x is the exact root. The parameter must be nonnegative. As with *brentq*, for nice functions the method will often satisfy the above condition with xtol/2 and rtol/2.
- **rtol**
  - [number, optional] The computed root x0 will satisfy np.allclose(x, x0, atol=xtol, rtol=rtol), where x is the exact root. The parameter cannot be smaller than its default value of 4*np.finfo(float).eps. As with *brentq*, for nice functions the method will often satisfy the above condition with xtol/2 and rtol/2.
SciPy Reference Guide, Release 1.3.2

**maxiter**  [int, optional] if convergence is not achieved in *maxiter* iterations, an error is raised. Must be >= 0.
**args**  [tuple, optional] containing extra arguments for the function *f*. *f* is called by *apply(f, (x)+args)*.
**full_output**  [bool, optional] If *full_output* is False, the root is returned. If *full_output* is True, the return value is (*x*, *r*), where *x* is the root, and *r* is a *RootResults* object.
**disp**  [bool, optional] If True, raise RuntimeError if the algorithm didn’t converge. Otherwise the convergence status is recorded in any *RootResults* return object.

**Returns**

- **x0**  [float] Zero of *f* between *a* and *b*.
- **r**  [RootResults (present if *full_output* = True)] Object containing information about the convergence. In particular, *r*.converged is True if the routine converged.

>>> root = optimize.brenth(f, 0, 2)
>>> root
1.0
```

**scipy.optimize.ridder**

Find a root of a function in an interval using Ridder's method.

**Parameters**

- `f` [function] Python function returning a number. `f` must be continuous, and `f(a)` and `f(b)` must have opposite signs.
- `a` [scalar] One end of the bracketing interval `[a,b]`.
- `b` [scalar] The other end of the bracketing interval `[a,b]`.
- `xtol` [number, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root. The parameter must be non-negative.
- `rtol` [number, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root. The parameter cannot be smaller than its default value of `4*np.finfo(float).eps`.
- `maxiter` [int, optional] if convergence is not achieved in `maxiter` iterations, an error is raised. Must be >= 0.
- `args` [tuple, optional] containing extra arguments for the function `f`. `f` is called by `apply(f, (x)+args)`.
- `full_output` [bool, optional] If `full_output` is False, the root is returned. If `full_output` is True, the return value is `(x, r)`, where `x` is the root, and `r` is a `RootResults` object.
- `disp` [bool, optional] If True, raise RuntimeError if the algorithm didn’t converge. Otherwise the convergence status is recorded in any `RootResults` return object.

**Returns**

- `x0` [float] Zero of `f` between `a` and `b`.
- `r` [RootResults (present if full_output = True)] Object containing information about the convergence. In particular, `r.converged` is True if the routine converged.

**See also:**

`brentq`, `brenth`, `bisect`, `newton`

one-dimensional root-finding

**fixed_point**

scalar fixed-point finder

**Notes**

Uses [Ridders1979] method to find a zero of the function `f` between the arguments `a` and `b`. Ridders’ method is faster than bisection, but not generally as fast as the Brent routines. [Ridders1979] provides the classic description and source of the algorithm. A description can also be found in any recent edition of Numerical Recipes.
The routine used here diverges slightly from standard presentations in order to be a bit more careful of tolerance.

References

[Ridders1979]

Examples

```python
>>> def f(x):
...     return (x**2 - 1)

>>> from scipy import optimize

>>> root = optimize.ridder(f, 0, 2)
>>> root
1.0

>>> root = optimize.ridder(f, -2, 0)
>>> root
-1.0
```

**scipy.optimize.bisect**

The function `scipy.optimize.bisect` is used to find a zero of the function `f` between the arguments `a` and `b`. `f(a)` and `f(b)` cannot have the same signs. Slow but sure.

**Parameters**

- `f` [function] Python function returning a number. `f` must be continuous, and `f(a)` and `f(b)` must have opposite signs.
- `a` [scalar] One end of the bracketing interval `[a,b]`.
- `b` [scalar] The other end of the bracketing interval `[a,b]`.
- `xtol` [number, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root. The parameter must be non-negative.
- `rtol` [number, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root. The parameter cannot be smaller than its default value of `4*np.finfo(float).eps`.
- `maxiter` [int, optional] if convergence is not achieved in `maxiter` iterations, an error is raised. Must be `>= 0`.
- `args` [tuple, optional] containing extra arguments for the function `f`. `f` is called by `apply(f, (x)+args)`.
- `full_output` [bool, optional] If `full_output` is False, the root is returned. If `full_output` is True, the return value is `(x, r)`, where `x` is the root, and `r` is a `RootResults` object.
- `disp` [bool, optional] If True, raise RuntimeError if the algorithm didn’t converge. Otherwise the convergence status is recorded in a `RootResults` return object.

**Returns**
SciPy Reference Guide, Release 1.3.2

x0  [float] Zero of f between a and b.

r  [RootResults (present if full_output = True)] Object containing information
   about the convergence. In particular, r.converged is True if the routine converged.

scipy.optimize.newton

`scipy.optimize.newton(func, x0, fprime=None, args=(), tol=1.48e-08, maxiter=50, fprime2=None, x1=None, rtol=0.0, full_output=False, disp=True)`

Find a zero of a real or complex function using the Newton-Raphson (or secant or Halley’s) method.

Find a zero of the function `func` given a nearby starting point `x0`. The Newton-Raphson method is used if the
derivative `fprime` of `func` is provided, otherwise the secant method is used. If the second order derivative `fprime2`
of `func` is also provided, then Halley’s method is used.

If `x0` is a sequence with more than one item, then `newton` returns an array, and `func` must be vectorized and return
a sequence or array of the same shape as its first argument. If `fprime` or `fprime2` is given then its return must also
have the same shape.

Parameters

`func`  [callable] The function whose zero is wanted. It must be a function of a single variable of
        the form `f(x, a, b, c...)`, where `a, b, c...` are extra arguments that can be passed in
        the `args` parameter.

`x0`  [float, sequence, or ndarray] An initial estimate of the zero that should be somewhere near
        the actual zero. If not scalar, then `func` must be vectorized and return a sequence or array of
        the same shape as its first argument.

`fprime`  [callable, optional] The derivative of the function when available and convenient. If it is
           None (default), then the secant method is used.

`args`  [tuple, optional] Extra arguments to be used in the function call.
tol [float, optional] The allowable error of the zero value. If func is complex-valued, a larger tol is recommended as both the real and imaginary parts of \( x \) contribute to \(|x - x_0|\).

maxiter [int, optional] Maximum number of iterations.

fprime2 [callable, optional] The second order derivative of the function when available and convenient. If it is None (default), then the normal Newton-Raphson or the secant method is used. If it is not None, then Halley’s method is used.

x1 [float, optional] Another estimate of the zero that should be somewhere near the actual zero. Used if fprime is not provided.

tol [float, optional] Tolerance (relative) for termination.

full_output [bool, optional] If full_output is False (default), the root is returned. If True and \( x_0 \) is scalar, the return value is \((x, r)\), where \( x \) is the root and \( r \) is a RootResults object. If True and \( x_0 \) is non-scalar, the return value is \((x, converged, zero_der)\) (see Returns section for details).

disp [bool, optional] If True, raise a RuntimeError if the algorithm didn’t converge, with the error message containing the number of iterations and current function value. Otherwise the convergence status is recorded in a RootResults return object. Ignored if \( x_0 \) is not scalar. Note: this has little to do with displaying, however the 'disp' keyword cannot be renamed for backwards compatibility.

Returns

root [float, sequence, or ndarray] Estimated location where function is zero.

r [RootResults, optional] Present if full_output=True and \( x_0 \) is scalar. Object containing information about the convergence. In particular, r.converged is True if the routine converged.

converged [ndarray of bool, optional] Present if full_output=True and \( x_0 \) is non-scalar. For vector functions, indicates which elements converged successfully.

zero_der [ndarray of bool, optional] Present if full_output=True and \( x_0 \) is non-scalar. For vector functions, indicates which elements had a zero derivative.

See also:
brentq, brent, ridder, bisect

fsolve

find zeros in n dimensions.

Notes

The convergence rate of the Newton-Raphson method is quadratic, the Halley method is cubic, and the secant method is sub-quadratic. This means that if the function is well behaved the actual error in the estimated zero after the n-th iteration is approximately the square (cube for Halley) of the error after the (n-1)-th step. However, the stopping criterion used here is the step size and there is no guarantee that a zero has been found. Consequently the result should be verified. Safer algorithms are brentq, brent, ridder, and bisect, but they all require that the root first be bracketed in an interval where the function changes sign. The brentq algorithm is recommended for general use in one dimensional problems when such an interval has been found.

When newton is used with arrays, it is best suited for the following types of problems:

- The initial guesses, \( x_0 \), are all relatively the same distance from the roots.
- Some or all of the extra arguments, args, are also arrays so that a class of similar problems can be solved together.
- The size of the initial guesses, \( x_0 \), is larger than O(100) elements. Otherwise, a naive loop may perform as well or better than a vector.
Examples

```python
>>> from scipy import optimize
>>> import matplotlib.pyplot as plt

>>> def f(x):
...     return (x**3 - 1)  # only one real root at x = 1

fprime is not provided, use the secant method:

```python
>>> root = optimize.newton(f, 1.5)
>>> root
1.0000000000000016
```  

Only `fprime` is provided, use the Newton-Raphson method:

```python
>>> root = optimize.newton(f, 1.5, fprime=lambda x: 6 * x)
>>> root
1.0000000000000016
```  

Both `fprime2` and `fprime` are provided, use Halley’s method:

```python
>>> root = optimize.newton(f, 1.5, fprime=lambda x: 3 * x**2,
...                         fprime2=lambda x: 6 * x)
>>> root
1.0
```  

When we want to find zeros for a set of related starting values and/or function parameters, we can provide both of those as an array of inputs:

```python
>>> f = lambda x, a: x**3 - a
>>> fder = lambda x, a: 3 * x**2
>>> np.random.seed(4321)
>>> x = np.random.randn(100)
>>> a = np.arange(-50, 50)
>>> vec_res = optimize.newton(f, x, fprime=fder, args=(a, ))

The above is the equivalent of solving for each value in (x, a) separately in a for-loop, just faster:

```python
>>> loop_res = [optimize.newton(f, x0, fprime=fder, args=(a0,))
...             for x0, a0 in zip(x, a)]
>>> np.allclose(vec_res, loop_res)
True
```

Plot the results found for all values of `a`:

```python
>>> analytical_result = np.sign(a) * np.abs(a)**(1/3)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(a, analytical_result, 'o')
>>> ax.plot(a, vec_res, '.')
```

(continues on next page)
```python
>>> ax.set_xlabel(r'$a$')
>>> ax.set_ylabel(r'$x$ where $f(x, a)=0$')
>>> plt.show()
```

![Graph showing the function $f(x, a)=0$ with roots at $x=0$ and $x=2$ for different values of $a$.](image)

**scipy.optimize.toms748**

scipy.optimize.toms748 ($f$, $a$, $b$, $args=()$, $k=1$, $xtol=2e-12$, $rtol=8.881784197001252e-16$, $maxiter=100$, $full_output=False$, $disp=True$)

Find a zero using TOMS Algorithm 748 method.

Implements the Algorithm 748 method ofAlefeld, Potro and Shi to find a zero of the function $f$ on the interval $[a, b]$, where $f(a)$ and $f(b)$ must have opposite signs.

It uses a mixture of inverse cubic interpolation and “Newton-quadratic” steps. [APS1995].

**Parameters**

- **f**  
  [function] Python function returning a scalar. The function $f$ must be continuous, and $f(a)$ and $f(b)$ have opposite signs.
- **a**  
  [scalar,] lower boundary of the search interval
- **b**  
  [scalar,] upper boundary of the search interval
- **args**  
  [tuple, optional] containing extra arguments for the function $f$. $f$ is called by $f(x, *args)$.
- **k**  
  [int, optional] The number of Newton quadratic steps to perform each iteration. $k>=1$.
- **xtol**  
  [scalar, optional] The computed root $x_0$ will satisfy np.allclose($x_0$, $x$, atol=xtol, rtol=rtol), where $x$ is the exact root. The parameter must be non-negative.
- **rtol**  
  [scalar, optional] The computed root $x_0$ will satisfy np.allclose($x_0$, $x$, atol=xtol, rtol=rtol), where $x$ is the exact root.
- **maxiter**  
  [int, optional] if convergence is not achieved in maxiter iterations, an error is raised. Must be $>=0$.
- **full_output**  
  [bool, optional] If full_output is False, the root is returned. If full_output is True, the return value is $(x, r)$, where $x$ is the root, and $r$ is a RootResults object.
- **disp**  
  [bool, optional] If True, raise RuntimeError if the algorithm didn’t converge. Otherwise the convergence status is recorded in the RootResults return object.
Returns

- **x0** [float] Approximate Zero of \( f \)
- **r** [RootResults (present if full_output = True)] Object containing information about the convergence. In particular, \( r.converged \) is True if the routine converged.

Find zeroes in \( n \) dimensions.

Notes

\( f \) must be continuous. Algorithm 748 with \( k=2 \) is asymptotically the most efficient algorithm known for finding roots of a four times continuously differentiable function. In contrast with Brent's algorithm, which may only decrease the length of the enclosing bracket on the last step, Algorithm 748 decreases it each iteration with the same asymptotic efficiency as it finds the root.

For easy statement of efficiency indices, assume that \( f \) has 4 continuous derivatives. For \( k=1 \), the convergence order is at least 2.7, and with about asymptotically 2 function evaluations per iteration, the efficiency index is approximately 1.65. For \( k=2 \), the order is about 4.6 with asymptotically 3 function evaluations per iteration, and the efficiency index 1.66. For higher values of \( k \), the efficiency index approaches the \( k \)-th root of \((3k-2)\), hence \( k=1 \) or \( k=2 \) are usually appropriate.

Examples

```python
>>> def f(x):
...     return (x**3 - 1)  # only one real root at x = 1

>>> from scipy import optimize
>>> root, results = optimize.toms748(f, 0, 2, full_output=True)
>>> root
1.0
>>> results
    converged: True
    flag: 'converged'
    function_calls: 11
    iterations: 5
    root: 1.0
```

scipy.optimize.RootResults
class scipy.optimize.RootResults(root, iterations, function_calls, flag)
Represents the root finding result.

Attributes

- **root** [float] Estimated root location.
The `root_scalar` function supports the following methods:

**root_scalar(method='brentq')**

`scipy.optimize.root_scalar(args=(), method='brentq', x0=None, options={})`

See also:
For documentation for the rest of the parameters, see `scipy.optimize.root_scalar`

**Options**
- `args`: [tuple, optional] Extra arguments passed to the objective function.
- `xtol`: [float, optional] Tolerance (absolute) for termination.
- `rtol`: [float, optional] Tolerance (relative) for termination.
- `maxiter`: [int, optional] Maximum number of iterations.
- `options`: dict, optional
  Specifies any method-specific options not covered above

**root_scalar(method='brenth')**

`scipy.optimize.root_scalar(args=(), method='brenth', x0=None, options={})`

See also:
For documentation for the rest of the parameters, see `scipy.optimize.root_scalar`

**Options**
- `args`: [tuple, optional] Extra arguments passed to the objective function.
- `xtol`: [float, optional] Tolerance (absolute) for termination.
- `rtol`: [float, optional] Tolerance (relative) for termination.
- `maxiter`: [int, optional] Maximum number of iterations.
- `options`: dict, optional
  Specifies any method-specific options not covered above

**root_scalar(method='bisect')**

`scipy.optimize.root_scalar(args=(), method='bisect', x0=None, options={})`

See also:
For documentation for the rest of the parameters, see `scipy.optimize.root_scalar`

**Options**
- `args`: [tuple, optional] Extra arguments passed to the objective function.
- `xtol`: [float, optional] Tolerance (absolute) for termination.
- `rtol`: [float, optional] Tolerance (relative) for termination.
- `maxiter`: [int, optional] Maximum number of iterations.
options: dict, optional
  Specifies any method-specific options not covered above

root_scalar(method='ridder')
scipy.optimize.root_scalar(args=(), method='ridder', x0=None, options={})

See also:
  For documentation for the rest of the parameters, see scipy.optimize.root_scalar

Options
  args [tuple, optional] Extra arguments passed to the objective function.
  xtol [float, optional] Tolerance (absolute) for termination.
  rtol [float, optional] Tolerance (relative) for termination.
  maxiter [int, optional] Maximum number of iterations.
  options: dict, optional
    Specifies any method-specific options not covered above

root_scalar(method='newton')
scipy.optimize.root_scalar(args=(), method='newton', x0=None, options={})

See also:
  For documentation for the rest of the parameters, see scipy.optimize.root_scalar

Options
  args [tuple, optional] Extra arguments passed to the objective function and its derivative.
  xtol [float, optional] Tolerance (absolute) for termination.
  rtol [float, optional] Tolerance (relative) for termination.
  maxiter [int, optional] Maximum number of iterations.
  x0 [float, required] Initial guess.
  fprime [bool or callable, optional] If fprime is a boolean and is True, f is assumed to return the value of derivative along with the objective function. fprime can also be a callable returning the derivative of f. In this case, it must accept the same arguments as f.
  options: dict, optional
    Specifies any method-specific options not covered above

root_scalar(method='toms748')
scipy.optimize.root_scalar(args=(), method='toms748', x0=None, options={})

See also:
  For documentation for the rest of the parameters, see scipy.optimize.root_scalar

Options
  args [tuple, optional] Extra arguments passed to the objective function.
  xtol [float, optional] Tolerance (absolute) for termination.
  rtol [float, optional] Tolerance (relative) for termination.
  maxiter [int, optional] Maximum number of iterations.
  options: dict, optional
    Specifies any method-specific options not covered above
**root_scalar(method='secant')**

```python
scipy.optimize.root_scalar(args=(), method='secant', x0=None, options={})
```

See also:

For documentation for the rest of the parameters, see `scipy.optimize.root_scalar`

**Options**

- **args** [tuple, optional] Extra arguments passed to the objective function.
- **xtol** [float, optional] Tolerance (absolute) for termination.
- **rtol** [float, optional] Tolerance (relative) for termination.
- **maxiter** [int, optional] Maximum number of iterations.
- **x0** [float, required] Initial guess.
- **x1** [float, required] A second guess.
- **options**: dict, optional
  Specifies any method-specific options not covered above

**root_scalar(method='halley')**

```python
scipy.optimize.root_scalar(args=(), method='halley', x0=None, options={})
```

See also:

For documentation for the rest of the parameters, see `scipy.optimize.root_scalar`

**Options**

- **args** [tuple, optional] Extra arguments passed to the objective function and its derivatives.
- **xtol** [float, optional] Tolerance (absolute) for termination.
- **rtol** [float, optional] Tolerance (relative) for termination.
- **maxiter** [int, optional] Maximum number of iterations.
- **x0** [float, required] Initial guess.
- **fprime** [bool or callable, required] If `fprime` is a boolean and is True, `f` is assumed to return the value of derivative along with the objective function. `fprime` can also be a callable returning the derivative of `f`. In this case, it must accept the same arguments as `f`.
- **fprime2** [bool or callable, required] If `fprime2` is a boolean and is True, `f` is assumed to return the value of 1st and 2nd derivatives along with the objective function. `fprime2` can also be a callable returning the 2nd derivative of `f`. In this case, it must accept the same arguments as `f`.
- **options**: dict, optional
  Specifies any method-specific options not covered above

The table below lists situations and appropriate methods, along with asymptotic convergence rates per iteration (and per function evaluation) for successful convergence to a simple root(*). Bisection is the slowest of them all, adding one bit of accuracy for each function evaluation, but is guaranteed to converge. The other bracketing methods all (eventually) increase the number of accurate bits by about 50% for every function evaluation. The derivative-based methods, all built on `newton`, can converge quite quickly if the initial value is close to the root. They can also be applied to functions defined on (a subset of) the complex plane.

s`scipy.optimize.cython_optimize` – Typed Cython versions of zeros functions

Fixed point finding:

```python
fixed_point(func, x0[, args, xtol, maxiter, ...]) Find a fixed point of the function.
```

`s`cipy.optimize.fixed_point`

`s`cipy.optimize.``fixed_point`` `(func, x0, args=(), xtol=1e-08, maxiter=500, method='del2')`

Find a fixed point of the function.

Given a function of one or more variables and a starting point, find a fixed-point of the function: i.e. where \( \text{func}(x0) \equiv x0 \).

**Parameters**

- `func` [function] Function to evaluate.
- `x0` [array_like] Fixed point of function.
- `args` [tuple, optional] Extra arguments to `func`.
- `xtol` [float, optional] Convergence tolerance, defaults to 1e-08.
- `maxiter` [int, optional] Maximum number of iterations, defaults to 500.
- `method` [[“del2”, “iteration”], optional] Method of finding the fixed-point, defaults to “del2” which uses Steffensen’s Method with Aitken’s Del^2 convergence acceleration [1]. The “iteration” method simply iterates the function until convergence is detected, without attempting to accelerate the convergence.

**References**

[1]
Examples

```python
>>> from scipy import optimize
>>> def func(x, c1, c2):
...     return np.sqrt(c1/(x+c2))
>>> c1 = np.array([10, 12.])
>>> c2 = np.array([3, 5.])
>>> optimize.fixed_point(func, [1.2, 1.3], args=(c1, c2))
array([ 1.4920333 , 1.37228132])
```

Multidimensional

```python
root(fun, x0[, args, method, jac, tol, ...])  
```
Find a root of a vector function.

**scipy.optimize.root**

`scipy.optimize.root(fun, x0, args=(), method='hybr', jac=None, tol=None, callback=None, options=None)`
Find a root of a vector function.

**Parameters**

- `fun` [callable] A vector function to find a root of.
- `x0` [ndarray] Initial guess.
- `args` [tuple, optional] Extra arguments passed to the objective function and its Jacobian.
- `method` [str, optional] Type of solver. Should be one of
  - ‘hybr’ (see here)
  - ‘lm’ (see here)
  - ‘broyden1’ (see here)
  - ‘broyden2’ (see here)
  - ‘anderson’ (see here)
  - ‘linearmixing’ (see here)
  - ‘diagbroyden’ (see here)
  - ‘excitingmixing’ (see here)
  - ‘krylov’ (see here)
  - ‘df-sane’ (see here)
- `jac` [bool or callable, optional] If `jac` is a Boolean and is True, `fun` is assumed to return the value of Jacobian along with the objective function. If False, the Jacobian will be estimated numerically. `jac` can also be a callable returning the Jacobian of `fun`. In this case, it must accept the same arguments as `fun`.
- `tol` [float, optional] Tolerance for termination. For detailed control, use solver-specific options.
- `callback` [function, optional] Optional callback function. It is called on every iteration as `callback(x, f)` where `x` is the current solution and `f` the corresponding residual. For all methods but ‘hybr’ and ‘lm’.
- `options` [dict, optional] A dictionary of solver options. E.g. `xtol` or `maxiter`, see `show_options()` for details.

**Returns**

- `sol` [OptimizeResult] The solution represented as a `OptimizeResult` object. Important attributes are: `x` the solution array, `success` a Boolean flag indicating if the algorithm exited successfully and `message` which describes the cause of the termination. See `OptimizeResult` for a description of other attributes.
See also:

```
show_options
```

Additional options accepted by the solvers

Notes

This section describes the available solvers that can be selected by the `method` parameter. The default method is `hybr`.

Method `hybr` uses a modification of the Powell hybrid method as implemented in MINPACK [1].

Method `lm` solves the system of nonlinear equations in a least squares sense using a modification of the Levenberg-Marquardt algorithm as implemented in MINPACK [1].

Method `df-sane` is a derivative-free spectral method. [3]

Methods `broyden1`, `broyden2`, `anderson`, `linearmixing`, `diagbroyden`, `excitingmixing`, `krylov` are inexact Newton methods, with backtracking or full line searches [2]. Each method corresponds to a particular Jacobian approximations. See `nonlin` for details.

- Method `broyden1` uses Broyden's first Jacobian approximation, it is known as Broyden's good method.
- Method `broyden2` uses Broyden's second Jacobian approximation, it is known as Broyden's bad method.
- Method `anderson` uses (extended) Anderson mixing.
- Method `Krylov` uses Krylov approximation for inverse Jacobian. It is suitable for large-scale problem.
- Method `diagbroyden` uses diagonal Broyden Jacobian approximation.
- Method `linearmixing` uses a scalar Jacobian approximation.
- Method `excitingmixing` uses a tuned diagonal Jacobian approximation.

```
Warning: The algorithms implemented for methods `diagbroyden`, `linearmixing` and `excitingmixing` may be useful for specific problems, but whether they will work may depend strongly on the problem.
```

New in version 0.11.0.

Examples

The following functions define a system of nonlinear equations and its jacobian.

```python
>>> def fun(x):
...     return [x[0] + 0.5 * (x[0] - x[1])**3 - 1.0,
...             0.5 * (x[1] - x[0])**3 + x[1]]
```
>>> def jac(x):
...     return np.array([[1 + 1.5 * (x[0] - x[1])**2,
...                       -1.5 * (x[0] - x[1])**2,
...                       [-1.5 * (x[1] - x[0])**2,
...                       1 + 1.5 * (x[1] - x[0])**2]])

A solution can be obtained as follows.

```python
>>> from scipy import optimize
>>> sol = optimize.root(fun, [0, 0], jac=jac, method='hybr')
>>> sol.x
array([ 0.8411639, 0.1588361])
```

The `root` function supports the following methods:

```
scipy.optimize.root (fun, x0, args=(), method='hybr', jac=None, tol=None, callback=None, options={'func': None, 'col_deriv': 0, 'xtol': 1.49012e-08, 'maxfev': 0, 'band': None, 'eps': None, 'factor': 100, 'diag': None})
```

Find the roots of a multivariate function using MINPACK’s hybrd and hybrj routines (modified Powell method).

See also:

For documentation for the rest of the parameters, see `scipy.optimize.root`

**Options**

- `col_deriv` [bool] Specify whether the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).
- `xtol` [float] The calculation will terminate if the relative error between two consecutive iterates is at most `xtol`.
- `maxfev` [int] The maximum number of calls to the function. If zero, then `100*(N+1)` is the maximum where `N` is the number of elements in `x0`.
- `band` [tuple] If set to a two-sequence containing the number of sub- and super-diagonals within the band of the Jacobi matrix, the Jacobi matrix is considered banded (only for `fprime=None`).
- `eps` [float] A suitable step length for the forward-difference approximation of the Jacobian (for `fprime=None`). If `eps` is less than the machine precision, it is assumed that the relative errors in the functions are of the order of the machine precision.
- `factor` [float] A parameter determining the initial step bound (`factor * || diag * x||`). Should be in the interval `(0.1, 100)``
- `diag` [sequence] N positive entries that serve as scale factors for the variables.

```
scipy.optimize.root (fun, x0, args=(), method='lm', jac=None, tol=None, callback=None, options={'func': None, 'col_deriv': 0, 'xtol': 1.49012e-08, 'ftol': 1.49012e-08, 'gtol': 0.0, 'maxiter': 0, 'eps': 0.0, 'factor': 100, 'diag': None})
```

Solve for least squares with Levenberg-Marquardt

**Options**

---

**Chapter 6. API Reference**

---

1354
| col_deriv | [bool] non-zero to specify that the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation). |
| ftol     | [float] Relative error desired in the sum of squares. |
| xtol     | [float] Relative error desired in the approximate solution. |
| gtol     | [float] Orthogonality desired between the function vector and the columns of the Jacobian. |
| maxiter  | [int] The maximum number of calls to the function. If zero, then 100*(N+1) is the maximum where N is the number of elements in x0. |
| epsfcn   | [float] A suitable step length for the forward-difference approximation of the Jacobian (for Dfun=None). If epsfcn is less than the machine precision, it is assumed that the relative errors in the functions are of the order of the machine precision. |
| factor   | [float] A parameter determining the initial step bound (factor * || diag * x||). Should be in interval (0.1, 100). |
| diag     | [sequence] N positive entries that serve as a scale factors for the variables. |

**root(method='broyden1')**

```python
c scipy.optimize.root (fun, x0, args=(), method='broyden1', tol=None, callback=None, options={})
```

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.root`

**Options**

- nit       [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- disp      [bool, optional] Print status to stdout on every iteration.
- maxiter   [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.
- ftol      [float, optional] Relative tolerance for the residual. If omitted, not used.
- xtol      [float, optional] Relative minimum step size. If omitted, not used.
- xatol     [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- tol_norm  [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
- line_search [[None, ‘armijo’ (default), ‘wolfe’], optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.
- jac_options [dict, optional] Options for the respective Jacobian approximation.

  - **alpha** [float, optional] Initial guess for the Jacobian is (-1/alpha).
  - **reduction_method** [str or tuple, optional] Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form `(method, param1, param2, ...)` that gives the name of the method and values for additional parameters.

  Methods available:

  - **restart** Drop all matrix columns. Has no extra parameters.
- **simple**  Drop oldest matrix column. Has no extra parameters.
- **svd**  Keep only the most significant SVD components. Extra parameters:
  - `to_retain`  Number of SVD components to retain when rank reduction is done. Default is `max_rank - 2`.

**max_rank**  [int, optional] Maximum rank for the Broyden matrix. Default is infinity (ie., no rank reduction).

`root(method='broyden2')`

`scipy.optimize.root (fun, x0, args=(), method='broyden2', tol=None, callback=None, options={})`

See also:

For documentation for the rest of the parameters, see `scipy.optimize.root`.

**Options**

- **nit**  [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- **disp**  [bool, optional] Print status to stdout on every iteration.
- **maxiter**  [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.
- **ftol**  [float, optional] Relative tolerance for the residual. If omitted, not used.
- **fatol**  [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- **xtol**  [float, optional] Relative minimum step size. If omitted, not used.
- **xatol**  [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- **tol_norm**  [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
- **line_search**  [{None, ‘armijo’ (default), ‘wolfe’}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.
- **jac_options**  [dict, optional] Options for the respective Jacobian approximation.
- **alpha**  [float, optional] Initial guess for the Jacobian is (-1/alpha).
- **reduction_method**  [str or tuple, optional] Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form (method, param1, param2, ...) that gives the name of the method and values for additional parameters. Methods available:
  - **restart**  Drop all matrix columns. Has no extra parameters.
  - **simple**  Drop oldest matrix column. Has no extra parameters.
  - **svd**  Keep only the most significant SVD components. Extra parameters:
    - `to_retain`  Number of SVD components to retain when rank reduction is done. Default is `max_rank - 2`.
**max_rank** [int, optional] Maximum rank for the Broyden matrix. Default is infinity (ie., no rank reduction).

**root(method='anderson')**

```python
scipy.optimize.root (fun, x0, args=(), method='anderson', tol=None, callback=None, options={})
```

See also:

For documentation for the rest of the parameters, see `scipy.optimize.root`

**Options**

- **nit** [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- **disp** [bool, optional] Print status to stdout on every iteration.
- **maxiter** [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.
- **ftol** [float, optional] Relative tolerance for the residual. If omitted, not used.
- **fatol** [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- **xtol** [float, optional] Relative minimum step size. If omitted, not used.
- **xatol** [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- **tol_norm** [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
- **line_search** ['armijo' (default), 'wolfe'], optional] Which type of line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.
- **jac_options** [dict, optional] Options for the respective Jacobian approximation.
- **alpha** [float, optional] Initial guess for the Jacobian is (-1/alpha).
- **M** [float, optional] Number of previous vectors to retain. Defaults to 5.
- **w0** [float, optional] Regularization parameter for numerical stability. Compared to unity, good values of the order of 0.01.

**root(method='linearmixing')**

```python
scipy.optimize.root (fun, x0, args=(), method='linearmixing', tol=None, callback=None, options={})
```

\text{Options}
\[ \text{nit} \] [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
\[ \text{disp} \] [bool, optional] Print status to stdout on every iteration.
maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.

ftol [float, optional] Relative tolerance for the residual. If omitted, not used.

fatol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

xtol [float, optional] Relative minimum step size. If omitted, not used.

xatol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search [{None, ‘armijo’ (default), ‘wolfe’}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

jac_options [dict, optional] Options for the respective Jacobian approximation.

alpha [float, optional] Initial Jacobian approximation is (-1/alpha).

alphamax [float, optional] The entries of the diagonal Jacobian are kept in the range [alpha, alphamax].

root(method=’krylov’) scipy.optimize.root (fun, x0, args=(), method=’krylov’, tol=None, callback=None, options={})

See also:

For documentation for the rest of the parameters, see `scipy.optimize.root`

Options

nit [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

disp [bool, optional] Print status to stdout on every iteration.

maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.

ftol [float, optional] Relative tolerance for the residual. If omitted, not used.

fatol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

xtol [float, optional] Relative minimum step size. If omitted, not used.

xatol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search [{None, ‘armijo’ (default), ‘wolfe’}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

jac_options [dict, optional] Options for the respective Jacobian approximation.

rdiff [float, optional] Relative step size to use in numerical differentiation.

method [{’lgmres’, ’gmres’, ’bicgstab’, ’cgs’, ’minres’} or function] Krylov method to use to approximate the Jacobian. Can be a string, or a function implementing the same interface as the iterative solvers in `scipy.sparse.linalg`. The default is `scipy.sparse.linalg.lgmres`.  

6.18. Optimization and Root Finding (scipy.optimize)
inner_M  [LinearOperator or InverseJacobian] Preconditioner for the inner Krylov iteration. Note that you can use also inverse Jacobians as (adaptive) preconditioners. For example,

```python
>>> jac = BroydenFirst()
>>> kjac = KrylovJacobian(inner_M=jac.inverse).
```

If the preconditioner has a method named ‘update’, it will be called as `update(x, f)` after each nonlinear step, with x giving the current point, and f the current function value.

inner_tol, inner_maxiter, …

Parameters to pass on to the “inner” Krylov solver. See `scipy.sparse.linalg.gmres` for details.

outer_k  [int, optional] Size of the subspace kept across LGMRES nonlinear iterations. See `scipy.sparse.linalg.lgmres` for details.

root(method='df-sane')

`scipy.optimize.root (fun, x0, args=(), method='df-sane', tol=None, callback=None, options={'func':
None, 'ftol': 1e-08, 'fatol': 1e-300, 'maxfev': 1000, 'fnorm': None, 'disp': False, 'M':
10, 'eta_strategy': None, 'sigma_eps': 1e-10, 'sigma_0': 1.0, 'line_search': 'cruz'})`

Solve nonlinear equation with the DF-SANE method

See also:

For documentation for the rest of the parameters, see `scipy.optimize.root`

**Options**

- **ftol**  [float, optional] Relative norm tolerance.
- **fatol**  [float, optional] Absolute norm tolerance. Algorithm terminates when \(||f|| < fatol + ftol \||f_0||\).
- **fnorm**  [callable, optional] Norm to use in the convergence check. If None, 2-norm is used.
- **maxfev**  [int, optional] Maximum number of function evaluations.
- **disp**  [bool, optional] Whether to print convergence process to stdout.
- **eta_strategy**  [callable, optional] Choice of the eta_k parameter, which gives slack for growth of \(||F||**2\). Called as `eta_k = eta_strategy(k, x, F)` with k the iteration number, x the current iterate and F the current residual. Should satisfy `eta_k > 0` and `\sum(eta, k=0..inf) < inf`. Default: `||F||**2 / (1 + k)**2`.
- **sigma_eps**  [float, optional] The spectral coefficient is constrained to `sigma_eps < sigma < 1/sigma_eps`. Default: 1e-10
- **sigma_0**  [float, optional] Initial spectral coefficient. Default: 1.0
- **M**  [int, optional] Number of iterates to include in the nonmonotonic line search. Default: 10
- **line_search**  [['cruz', 'cheng']] Type of line search to employ. ‘cruz’ is the original one defined in [Martinez & Raydan. Math. Comp. 75, 1429 (2006)], ‘cheng’ is a modified search defined in [Cheng & Li. IMA J. Numer. Anal. 29, 814 (2009)]. Default: ‘cruz’

6.18.7 Linear Programming

```
linprog(c[, A_ub, b_ub, A_eq, b_eq, bounds, ...])
```

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints.

```
scipy.optimize.linprog
```

```
scipy.optimize.linprog(c, A_ub=None, b_ub=None, A_eq=None, b_eq=None, bounds=None, method='interior-point', callback=None, options=None, x0=None)
```

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints.

Linear programming solves problems of the following form:

\[
\min_x c^T x \\
\text{such that } A_{ub} x \leq b_{ub}, \\
A_{eq} x = b_{eq}, \\
l \leq x \leq u,
\]

where \(x\) is a vector of decision variables; \(c, b_{ub}, b_{eq}, l,\) and \(u\) are vectors; and \(A_{ub}\) and \(A_{eq}\) are matrices.

Informally, that's:

```
minimize:
c @ x
such that:
A_ub @ x <= b_ub
A_eq @ x == b_eq
lb <= x <= ub
```

Note that by default \(lb = 0\) and \(ub = None\) unless specified with \(bounds\).

**Parameters**

- **c** : [1D array] The coefficients of the linear objective function to be minimized.
- **A_ub** : [2D array, optional] The inequality constraint matrix. Each row of \(A_{ub}\) specifies the coefficients of a linear inequality constraint on \(x\).
- **b_ub** : [1D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of \(A_{ub} @ x\).
- **A_eq** : [2D array, optional] The equality constraint matrix. Each row of \(A_{eq}\) specifies the coefficients of a linear equality constraint on \(x\).
- **b_eq** : [1D array, optional] The equality constraint vector. Each element of \(A_{eq} @ x\) must equal the corresponding element of \(b_{eq}\).
- **bounds** : [sequence, optional] A sequence of \((\text{min}, \text{max})\) pairs for each element in \(x\), defining the minimum and maximum values of that decision variable. Use None to indicate that there is no bound. By default, bounds are \((0, None)\) (all decision variables are non-negative). If a single tuple \((\text{min}, \text{max})\) is provided, then \text{min} and \text{max} will serve as bounds for all decision variables.
- **method** : [‘interior-point’, ‘revised simplex’, ‘simplex’], optional] The algorithm used to solve the standard form problem. ‘interior-point’ (default), ‘revised simplex’, and ‘simplex’ (legacy) are supported.
- **callback** : [callable, optional] If a callback function is provided, it will be called at least once per iteration of the algorithm. The callback function must accept a single `scipy.optimize.OptimizeResult` consisting of the following fields:
SciPy Reference Guide, Release 1.3.2

x [1D array] The current solution vector.

fun [float] The current value of the objective function \( c \odot x \).

success [bool] True when the algorithm has completed successfully.

slack [1D array] The (nominally positive) values of the slack variables, \( b_{ub} - A_{ub} \odot x \).

con [1D array] The (nominally zero) residuals of the equality constraints, \( b_{eq} - A_{eq} \odot x \).

phase [int] The phase of the algorithm being executed.

status [int] An integer representing the status of the algorithm.

0: Optimization proceeding nominally.
1: Iteration limit reached.
2: Problem appears to be infeasible.
3: Problem appears to be unbounded.
4: Numerical difficulties encountered.

nit [int] The current iteration number.

options [dict, optional] A dictionary of solver options. All methods accept the following options:

maxiter [int] Maximum number of iterations to perform.

disp [bool] Set to True to print convergence messages.

For method-specific options, see show_options('linprog').

x0 [1D array, optional] Guess values of the decision variables, which will be refined by the optimization algorithm. This argument is currently used only by the `revised simplex` method, and can only be used if \( x0 \) represents a basic feasible solution.

Returns

res [OptimizeResult] A `scipy.optimize.OptimizeResult` consisting of the fields:

x [1D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.

fun [float] The optimal value of the objective function \( c \odot x \).

slack [1D array] The (nominally positive) values of the slack variables, \( b_{ub} - A_{ub} \odot x \).

con [1D array] The (nominally zero) residuals of the equality constraints, \( b_{eq} - A_{eq} \odot x \).

success [bool] True when the algorithm succeeds in finding an optimal solution.

status [int] An integer representing the exit status of the algorithm.

0: Optimization terminated successfully.
1: Iteration limit reached.
2: Problem appears to be infeasible.
3: Problem appears to be unbounded.
4: Numerical difficulties encountered.

nit [int] The total number of iterations performed in all phases.

See also:

show_options

Additional options accepted by the solvers.

Notes

This section describes the available solvers that can be selected by the `method` parameter.
'interior-point' is the default as it is typically the fastest and most robust method. 'revised simplex' is more accurate for the problems it solves. 'simplex' is the legacy method and is included for backwards compatibility and educational purposes.

Method interior-point uses the primal-dual path following algorithm as outlined in [4]. This algorithm supports sparse constraint matrices and is typically faster than the simplex methods, especially for large, sparse problems. Note, however, that the solution returned may be slightly less accurate than those of the simplex methods and will not, in general, correspond with a vertex of the polytope defined by the constraints.

New in version 1.0.0.

Method revised simplex uses the revised simplex method as described in [9], except that a factorization [11] of the basis matrix, rather than its inverse, is efficiently maintained and used to solve the linear systems at each iteration of the algorithm.

New in version 1.3.0.

Method simplex uses a traditional, full-tableau implementation of Dantzig’s simplex algorithm [1], [2] (not the Nelder-Mead simplex). This algorithm is included for backwards compatibility and educational purposes.

New in version 0.15.0.

Before applying any method, a presolve procedure based on [8] attempts to identify trivial infeasibilities, trivial unboundedness, and potential problem simplifications. Specifically, it checks for:

- rows of zeros in \( A_{eq} \) or \( A_{ub} \), representing trivial constraints;
- columns of zeros in \( A_{eq} \) and \( A_{ub} \), representing unconstrained variables;
- column singletons in \( A_{eq} \), representing fixed variables; and
- column singletons in \( A_{ub} \), representing simple bounds.

If presolve reveals that the problem is unbounded (e.g. an unconstrained and unbounded variable has negative cost) or infeasible (e.g. a row of zeros in \( A_{eq} \) corresponds with a nonzero in \( b_{eq} \)), the solver terminates with the appropriate status code. Note that presolve terminates as soon as any sign of unboundedness is detected; consequently, a problem may be reported as unbounded when in reality the problem is infeasible (but infeasibility has not been detected yet). Therefore, if it is important to know whether the problem is actually infeasible, solve the problem again with option presolve=False.

If neither infeasibility nor unboundedness are detected in a single pass of the presolve, bounds are tightened where possible and fixed variables are removed from the problem. Then, linearly dependent rows of the \( A_{eq} \) matrix are removed, (unless they represent an infeasibility) to avoid numerical difficulties in the primary solve routine. Note that rows that are nearly linearly dependent (within a prescribed tolerance) may also be removed, which can change the optimal solution in rare cases. If this is a concern, eliminate redundancy from your problem formulation and run with option rr=False or presolve=False.

Several potential improvements can be made here: additional presolve checks outlined in [8] should be implemented, the presolve routine should be run multiple times (until no further simplifications can be made), and more of the efficiency improvements from [5] should be implemented in the redundancy removal routines.

After presolve, the problem is transformed to standard form by converting the (tightened) simple bounds to upper bound constraints, introducing non-negative slack variables for inequality constraints, and expressing unbounded variables as the difference between two non-negative variables. The selected algorithm solves the standard form problem, and a postprocessing routine converts this to a solution to the original problem.

References

[1], [2], [3], [4], [5], [6], [7], [8], [9], [10], [11]
Examples

Consider the following problem:

\[
\begin{align*}
\min \quad & -x_0 + 4x_1 \\
\text{such that} \quad & -3x_0 + x_1 \leq 6, \\
& -x_0 - 2x_1 \geq -4, \\
& x_1 \geq -3.
\end{align*}
\]

The problem is not presented in the form accepted by `linprog`. This is easily remedied by converting the “greater than” inequality constraint to a “less than” inequality constraint by multiplying both sides by a factor of \(-1\). Note also that the last constraint is really the simple bound \(-3 \leq x_1 \leq \infty\). Finally, since there are no bounds on \(x_0\), we must explicitly specify the bounds \(-\infty \leq x_0 \leq \infty\), as the default is for variables to be non-negative. After collecting coefficients into arrays and tuples, the input for this problem is:

```python
>>> c = [-1, 4]
>>> A = [[-3, 1], [1, 2]]
>>> b = [6, 4]
>>> x0_bounds = (None, None)
>>> x1_bounds = (-3, None)
>>> from scipy.optimize import linprog
>>> res = linprog(c, A, b, bounds=[x0_bounds, x1_bounds])
```

Note that the default method for `linprog` is ‘interior-point’, which is approximate by nature.

```python
>>> print(res)
    con: array([], dtype=float64)
    fun: -21.99999984082494 # may vary
  message: 'Optimization terminated successfully.'
    nit: 6 # may vary
    slack: array([3.89999997e+01, 8.46872439e-08]) # may vary
  status: 0
  success: True
    x: array([-9.99999989, -2.99999999]) # may vary
```

If you need greater accuracy, try ‘revised simplex’.

```python
>>> res = linprog(c, A, b, bounds=[x0_bounds, x1_bounds], method='revised simplex')
>>> print(res)
    con: array([], dtype=float64)
    fun: -22.0 # may vary
  message: 'Optimization terminated successfully.'
    nit: 1 # may vary
    slack: array([-39., 0.]) # may vary
  status: 0
  success: True
    x: array([10., -3.]) # may vary
```

The `linprog` function supports the following methods:
linprog(method='simplex')

scipy.optimize.linprog(c, method='simplex', callback=None, options={'c0': None, 'A': None, 'b': None, 'maxiter': 1000, 'disp': False, 'tol': 1e-12, 'bland': False, '_T_o': None}, x0=None)

Minimize a linear objective function subject to linear equality and non-negativity constraints using the two phase simplex method. Linear programming is intended to solve problems of the following form:

Minimize:
\[ c \mathbf{x} \]

Subject to:
\[ \mathbf{A} \mathbf{x} = \mathbf{b} \]
\[ \mathbf{x} \geq 0 \]

**Parameters**
- **c** [1D array] Coefficients of the linear objective function to be minimized.
- **c0** [float] Constant term in objective function due to fixed (and eliminated) variables. (Purely for display.)
- **A** [2D array] 2D array such that \( \mathbf{A} \mathbf{x} \), gives the values of the equality constraints at \( \mathbf{x} \).
- **b** [1D array] 1D array of values representing the right hand side of each equality constraint (row) in \( \mathbf{A} \).
- **callback** [callable, optional] If a callback function is provided, it will be called within each iteration of the algorithm. The callback function must accept a single *scipy.optimize.OptimizeResult* consisting of the following fields:
  - **x** [1D array] Current solution vector
  - **fun** [float] Current value of the objective function
  - **success** [bool] True when an algorithm has completed successfully.
  - **slack** [1D array] The values of the slack variables. Each slack variable corresponds to an inequality constraint. If the slack is zero, the corresponding constraint is active.
  - **con** [1D array] The (nominally zero) residuals of the equality constraints, that is, \( \mathbf{b} - \mathbf{A}_{eq} \mathbf{x} \)
  - **phase** [int] The phase of the algorithm being executed.
  - **status** [int] An integer representing the status of the optimization:
    - 0 : Algorithm proceeding nominally
    - 1 : Iteration limit reached
    - 2 : Problem appears to be infeasible
    - 3 : Problem appears to be unbounded
    - 4 : Serious numerical difficulties encountered
  - **nit** [int] The number of iterations performed.
  - **message** [str] A string descriptor of the exit status of the optimization.

**Returns**
- **x** [1D array] Solution vector.
- **status** [int] An integer representing the exit status of the optimization:
  - 0 : Optimization terminated successfully
  - 1 : Iteration limit reached
  - 2 : Problem appears to be infeasible

(continues on next page)
Problem appears to be unbounded
Serious numerical difficulties encountered

message: [str] A string descriptor of the exit status of the optimization.
iteration: [int] The number of iterations taken to solve the problem.

See also:
For documentation for the rest of the parameters, see scipy.optimize.linprog

Options
maxiter: [int] The maximum number of iterations to perform.
disp: [bool] If True, print exit status message to sys.stdout
tol: [float] The tolerance which determines when a solution is “close enough” to zero in Phase 1 to be considered a basic feasible solution or close enough to positive to serve as an optimal solution.
bland: [bool] If True, use Bland’s anti-cycling rule [3] to choose pivot to prevent cycling. If False, choose pivots which should lead to a converged solution more quickly. The latter method is subject to cycling (non-convergence) in rare instances.

Notes
The expected problem formulation differs between the top level linprog module and the method specific solvers. The method specific solvers expect a problem in standard form:

Minimize:
\[ \min \ c^T x \]
Subject to:
\[ A x = b \]
\[ x \geq 0 \]

Whereas the top level linprog module expects a problem of form:

Minimize:
\[ \min \ c^T x \]
Subject to:
\[ A_{ub} x \leq b_{ub} \]
\[ A_{eq} x = b_{eq} \]
\[ lb \leq x \leq ub \]

where \( lb = 0 \) and \( ub = None \) unless set in bounds.

The original problem contains equality, upper-bound and variable constraints whereas the method specific solver requires equality constraints and variable non-negativity.

linprog module converts the original problem to standard form by converting the simple bounds to upper bound constraints, introducing non-negative slack variables for inequality constraints, and expressing unbounded variables as the difference between two non-negative variables.
linprog(method='interior-point')

scipy.optimize.linprog(c, method='interior-point', callback=None, options={'c0': 0, 'A': None, 'b': None, '_T_o': [], 'alpha0': 0.999995, 'beta': 0.1, 'maxiter': 1000, 'disp': False, 'tol': 1e-08, 'sparse': False, 'lstsq': False, 'sym_pos': True, 'cholesky': None, 'pc': True, 'ip': False, 'permc_spec': 'MMD_AT_PLUS_A'}, x0=None)

Minimize a linear objective function subject to linear equality and non-negativity constraints using the interior point method of [4]. Linear programming is intended to solve problems of the following form:

Minimize:

\[ \text{Minimize: } c \odot x \]

Subject to:

\[ \text{A } \odot x = b \]
\[ x \geq 0 \]

**Parameters**

- **c** [1D array] Coefficients of the linear objective function to be minimized.
- **c0** [float] Constant term in objective function due to fixed (and eliminated) variables. (Purely for display.)
- **A** [2D array] 2D array such that \( A \odot x \), gives the values of the equality constraints at \( x \).
- **b** [1D array] 1D array of values representing the right hand side of each equality constraint (row) in \( A \).

**Returns**

- **x** [1D array] Solution vector.
- **status** [int] An integer representing the exit status of the optimization:
  - 0: Optimization terminated successfully
  - 1: Iteration limit reached
  - 2: Problem appears to be infeasible
  - 3: Problem appears to be unbounded
  - 4: Serious numerical difficulties encountered
- **message** [str] A string descriptor of the exit status of the optimization.
- **iteration** [int] The number of iterations taken to solve the problem.

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.linprog`

**Options**

- **maxiter** [int (default = 1000)] The maximum number of iterations of the algorithm.
- **disp** [bool (default = False)] Set to True if indicators of optimization status are to be printed to the console each iteration.
- **tol** [float (default = 1e-8)] Termination tolerance to be used for all termination criteria; see [4] Section 4.5.
SciPy Reference Guide, Release 1.3.2

alpha0 [float (default = 0.99995)] The maximal step size for Mehrota’s predictor-corrector search direction; see $\beta_3$ of [4] Table 8.1.

beta [float (default = 0.1)] The desired reduction of the path parameter $\mu$ (see [6]) when Mehrota’s predictor-corrector is not in use (uncommon).

sparse [bool (default = False)] Set to True if the problem is to be treated as sparse after presolve. If either $A_{eq}$ or $A_{ub}$ is a sparse matrix, this option will automatically be set True, and the problem will be treated as sparse even during presolve. If your constraint matrices contain mostly zeros and the problem is not very small (less than about 100 constraints or variables), consider setting True or providing $A_{eq}$ and $A_{ub}$ as sparse matrices.

lstsq [bool (default = False)] Set to True if the problem is expected to be very poorly conditioned. This should always be left False unless severe numerical difficulties are encountered. Leave this at the default unless you receive a warning message suggesting otherwise.

sym_pos [bool (default = True)] Leave True if the problem is expected to yield a well conditioned symmetric positive definite normal equation matrix (almost always). Leave this at the default unless you receive a warning message suggesting otherwise.

cholesky [bool (default = True)] Set to True if the normal equations are to be solved by explicit Cholesky decomposition followed by explicit forward/backward substitution. This is typically faster for problems that are numerically well-behaved.

pc [bool (default = True)] Leave True if the predictor-corrector method of Mehrota is to be used. This is almost always (if not always) beneficial.

ip [bool (default = False)] Set to True if the improved initial point suggestion due to [4] Section 4.3 is desired. Whether this is beneficial or not depends on the problem.

permc_spec [str (default = 'MMD_AT_PLUS_A')] (Has effect only with sparse = True, lstsq = False, sym_pos = True, and no SuiteSparse.) A matrix is factorized in each iteration of the algorithm. This option specifies how to permute the columns of the matrix for sparsity preservation. Acceptable values are:

- NATURAL: natural ordering.
- MMD_ATA: minimum degree ordering on the structure of $A^T A$.
- MMD_AT_PLUS_A: minimum degree ordering on the structure of $A^T + A$.
- COLAMD: approximate minimum degree column ordering.

This option can impact the convergence of the interior point algorithm; test different values to determine which performs best for your problem. For more information, refer to scipy.sparse.linalg.splu.

Notes

This method implements the algorithm outlined in [4] with ideas from [8] and a structure inspired by the simpler methods of [6].

The primal-dual path following method begins with initial ‘guesses’ of the primal and dual variables of the standard form problem and iteratively attempts to solve the (nonlinear) Karush-Kuhn-Tucker conditions for the problem with a gradually reduced logarithmic barrier term added to the objective. This particular implementation uses a homogeneous self-dual formulation, which provides certificates of infeasibility or unboundedness where applicable.

The default initial point for the primal and dual variables is that defined in [4] Section 4.4 Equation 8.22. Optionally (by setting initial point option ip=True), an alternate (potentially improved) starting point can be calculated according to the additional recommendations of [4] Section 4.4.

A search direction is calculated using the predictor-corrector method (single correction) proposed by Mehrota and detailed in [4] Section 4.1. (A potential improvement would be to implement the method of multiple corrections described in [4] Section 4.2.) In practice, this is accomplished by solving the normal equations, [4] Section 5.1 Equations 8.31 and 8.32, derived from the Newton equations [4] Section 5 Equations 8.25 (compare to [4] Section 4 Equations 8.6-8.8). The advantage of solving the normal equations rather than 8.25 directly is that the matrices...
involved are symmetric positive definite, so Cholesky decomposition can be used rather than the more expensive LU factorization.

With default options, the solver used to perform the factorization depends on third-party software availability and the conditioning of the problem.

For dense problems, solvers are tried in the following order:

1. `scipy.linalg.cho_factor`
2. `scipy.linalg.solve` with option `sym_pos=True`
3. `scipy.linalg.solve` with option `sym_pos=False`
4. `scipy.linalg.lstsq`

For sparse problems:

1. `sksparse.cholmod.cholesky` (if scikit-sparse and SuiteSparse are installed)
2. `scipy.sparse.linalg.factorized` (if scikit-umfpack and SuiteSparse are installed)
3. `scipy.sparse.linalg.splu` (which uses SuperLU distributed with SciPy)
4. `scipy.sparse.linalg.lsqr`

If the solver fails for any reason, successively more robust (but slower) solvers are attempted in the order indicated. Attempting, failing, and re-starting factorization can be time consuming, so if the problem is numerically challenging, options can be set to bypass solvers that are failing. Setting `cholesky=False` skips to solver 2, `sym_pos=False` skips to solver 3, and `lstsq=True` skips to solver 4 for both sparse and dense problems.

Potential improvements for combatting issues associated with dense columns in otherwise sparse problems are outlined in [4] Section 5.3 and [10] Section 4.1-4.2; the latter also discusses the alleviation of accuracy issues associated with the substitution approach to free variables.

After calculating the search direction, the maximum possible step size that does not activate the non-negativity constraints is calculated, and the smaller of this step size and unity is applied (as in [4] Section 4.1.) [4] Section 4.3 suggests improvements for choosing the step size.

The new point is tested according to the termination conditions of [4] Section 4.5. The same tolerance, which can be set using the `tol` option, is used for all checks. (A potential improvement would be to expose the different tolerances to be set independently.) If optimality, unboundedness, or infeasibility is detected, the solve procedure terminates; otherwise it repeats.

The expected problem formulation differs between the top level `linprog` module and the method specific solvers. The method specific solvers expect a problem in standard form:

Minimize:

```
c @ x
```

Subject to:

```
A @ x == b
  x >= 0
```

Whereas the top level `linprog` module expects a problem of form:

Minimize:

```
c @ x
```

Subject to:
\[ A_{ub} \leq x \leq b_{ub} \\
A_{eq} \times = b_{eq} \\
lb \leq x \leq ub \]

where \( lb = 0 \) and \( ub = None \) unless set in bounds.

The original problem contains equality, upper-bound and variable constraints whereas the method specific solver requires equality constraints and variable non-negativity.

`linprog` module converts the original problem to standard form by converting the simple bounds to upper bound constraints, introducing non-negative slack variables for inequality constraints, and expressing unbounded variables as the difference between two non-negative variables.

`linprog(method='revised simplex')`

```python
scipy.optimize.linprog(c, method='revised_simplex', callback=None, options={}):
```

Solve the following linear programming problem via a two-phase revised simplex algorithm:

\[
\begin{align*}
\text{minimize:} & \quad c \times \\
\text{subject to:} & \quad A \times = b \\
& \quad 0 \leq x < \infty
\end{align*}
\]

**Parameters**

- `c` [1D array] Coefficients of the linear objective function to be minimized.
- `c0` [float] Constant term in objective function due to fixed (and eliminated) variables. (Currently unused.)
- `A` [2D array] 2D array which, when matrix-multiplied by \( x \), gives the values of the equality constraints at \( x \).
- `b` [1D array] 1D array of values representing the RHS of each equality constraint (row) in \( A_{eq} \).
- `x0` [1D array, optional] Starting values of the independent variables, which will be refined by the optimization algorithm. For the revised simplex method, these must correspond with a basic feasible solution.
- `callback` [callable, optional] If a callback function is provided, it will be called within each iteration of the algorithm. The callback function must accept a single `scipy.optimize.OptimizeResult` consisting of the following fields:
  - `x` [1D array] Current solution vector.
  - `fun` [float] Current value of the objective function \( c \times \).
  - `success` [bool] True only when an algorithm has completed successfully, so this is always False as the callback function is called only while the algorithm is still iterating.
  - `slack` [1D array] The values of the slack variables. Each slack variable corresponds to an inequality constraint. If the slack is zero, the corresponding constraint is active.
con: [1D array] The (nominally zero) residuals of the equality constraints, that is, \( b - A_{eq} @ x \).

phase: [int] The phase of the algorithm being executed.

status: [int] For revised simplex, this is always 0 because if a different status is detected, the algorithm terminates.

nit: [int] The number of iterations performed.

message: [str] A string descriptor of the exit status of the optimization.

Returns:

- x: [1D array] Solution vector.
- status: [int] An integer representing the exit status of the optimization:
  
<table>
<thead>
<tr>
<th>Status Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Optimization terminated successfully</td>
</tr>
<tr>
<td>1</td>
<td>Iteration limit reached</td>
</tr>
<tr>
<td>2</td>
<td>Problem appears to be infeasible</td>
</tr>
<tr>
<td>3</td>
<td>Problem appears to be unbounded</td>
</tr>
<tr>
<td>4</td>
<td>Numerical difficulties encountered</td>
</tr>
<tr>
<td>5</td>
<td>No constraints; turn presolve on</td>
</tr>
<tr>
<td>6</td>
<td>Guess x0 cannot be converted to a basic feasible solution</td>
</tr>
</tbody>
</table>

message: [str] A string descriptor of the exit status of the optimization.

iteration: [int] The number of iterations taken to solve the problem.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.linprog`

Options:

- maxiter: [int] The maximum number of iterations to perform in either phase.
- tol: [float] The tolerance which determines when a solution is “close enough” to zero in Phase 1 to be considered a basic feasible solution or close enough to positive to serve as an optimal solution.
- maxupdate: [int] The maximum number of updates performed on the LU factorization. After this many updates is reached, the basis matrix is factorized from scratch.
- mast: [bool] Minimize Amortized Solve Time. If enabled, the average time to solve a linear system using the basis factorization is measured. Typically, the average solve time will decrease with each successive solve after initial factorization, as factorization takes much more time than the solve operation (and updates). Eventually, however, the updated factorization becomes sufficiently complex that the average solve time begins to increase. When this is detected, the basis is refactorized from scratch. Enable this option to maximize speed at the risk of nondeterministic behavior. Ignored if maxupdate is 0.
- pivot: ["mrc" or "bland"] Pivot rule: Minimum Reduced Cost (default) or Bland’s rule. Choose Bland’s rule if iteration limit is reached and cycling is suspected.
- disp: [bool] Set to True if indicators of optimization status are to be printed to the console each iteration.

The simplex method supports callback functions, such as:

```
linprog_verbose_callback(res)  # A sample callback function demonstrating the linprog callback interface.
```
**scipy.optimize.linprog_verbose_callback**

**scipy.optimize.linprog_verbose_callback**(res)

A sample callback function demonstrating the linprog callback interface. This callback produces detailed output to sys.stdout before each iteration and after the final iteration of the simplex algorithm.

**Parameters**

Assignment problems:

**linear_sum_assignment**(cost_matrix) Solve the linear sum assignment problem.

**scipy.optimize.linear_sum_assignment**

**scipy.optimize.linear_sum_assignment**(cost_matrix)

Solve the linear sum assignment problem.

The linear sum assignment problem is also known as minimum weight matching in bipartite graphs. A problem instance is described by a matrix \( C \), where each \( C[i,j] \) is the cost of matching vertex \( i \) of the first partite set (a “worker”) and vertex \( j \) of the second set (a “job”). The goal is to find a complete assignment of workers to jobs of minimal cost.

Formally, let \( X \) be a boolean matrix where \( X[i,j] = 1 \) iff row \( i \) is assigned to column \( j \). Then the optimal assignment has cost

\[
\min \sum \sum C_{i,j} X_{i,j}
\]

s.t. each row is assignment to at most one column, and each column to at most one row.

This function can also solve a generalization of the classic assignment problem where the cost matrix is rectangular. If it has more rows than columns, then not every row needs to be assigned to a column, and vice versa.

The method used is the Hungarian algorithm, also known as the Munkres or Kuhn-Munkres algorithm.
Parameters

cost_matrix
[array] The cost matrix of the bipartite graph.

Returns

row_ind, col_ind
[array] An array of row indices and one of corresponding column indices giving the optimal assignment. The cost of the assignment can be computed as cost_matrix[row_ind, col_ind].sum(). The row indices will be sorted; in the case of a square cost matrix they will be equal to numpy.arange(cost_matrix.shape[0]).

Notes

New in version 0.17.0.

References

Examples

```python
>>> cost = np.array([[4, 1, 3], [2, 0, 5], [3, 2, 2]])
>>> from scipy.optimize import linear_sum_assignment
>>> row_ind, col_ind = linear_sum_assignment(cost)
>>> col_ind
array([1, 0, 2])
>>> cost[row_ind, col_ind].sum()
5
```

6.18.8 Utilities

Finite-Difference Approximation

approx_fprime(xk, f, epsilon, *args)
Finite-difference approximation of the gradient of a scalar function.

check_grad(func, grad, x0, *args, **kwargs)
Check the correctness of a gradient function by comparing it against a (forward) finite-difference approximation of the gradient.
scipy.optimize.approx_fprime

scipy.optimize.approx_fprime(xk, f, epsilon, *args)

Finite-difference approximation of the gradient of a scalar function.

Parameters

- **xk** [array_like] The coordinate vector at which to determine the gradient of f.
- **f** [callable] The function of which to determine the gradient (partial derivatives). Should take xk as first argument, other arguments to f can be supplied in *args. Should return a scalar, the value of the function at xk.
- **epsilon** [array_like] Increment to xk to use for determining the function gradient. If a scalar, uses the same finite difference delta for all partial derivatives. If an array, should contain one value per element of xk.
- ***args** [args, optional] Any other arguments that are to be passed to f.

Returns

- **grad** [ndarray] The partial derivatives of f to xk.

See also:

check_grad

Check correctness of gradient function against approx_fprime.

Notes

The function gradient is determined by the forward finite difference formula:

\[
\frac{f(xk[i] + \text{epsilon}[i]) - f(xk[i])}{\text{epsilon}[i]}
\]

The main use of approx_fprime is in scalar function optimizers like fmin_bfgs, to determine numerically the Jacobian of a function.

Examples

```python
>>> from scipy import optimize
>>> def func(x, c0, c1):
...     "Coordinate vector 'x' should be an array of size two."
...     return c0 * x[0]**2 + c1*x[1]**2

>>> x = np.ones(2)
>>> c0, c1 = (1, 200)
>>> eps = np.sqrt(np.finfo(float).eps)
>>> optimize.approx_fprime(x, func, [eps, np.sqrt(200) * eps], c0, c1)
array([ 2., 400.00004198])
```

scipy.optimize.check_grad

scipy.optimize.check_grad(func, grad, *args, **kwargs)

Check the correctness of a gradient function by comparing it against a (forward) finite-difference approximation of the gradient.
Parameters

- `func` : [callable `func(x0, *args)`] Function whose derivative is to be checked.
- `grad` : [callable `grad(x0, *args)`] Gradient of `func`.
- `x0` : [ndarray] Points to check `grad` against forward difference approximation of `grad` using `func`.
- `args` : [tuple, optional] Extra arguments passed to `func` and `grad`.
- `epsilon` : [float, optional] Step size used for the finite difference approximation. It defaults to `sqrt(numpy.finfo(float).eps)`, which is approximately 1.49e-08.

Returns

- `err` : [float] The square root of the sum of squares (i.e. the 2-norm) of the difference between `grad(x0, *args)` and the finite difference approximation of `grad` using `func` at the points `x0`.

See also:

approx_fprime

Examples

```python
>>> def func(x):
...     return x[0]**2 - 0.5 * x[1]**3

>>> def grad(x):
...     return [2 * x[0], -1.5 * x[1]**2]

>>> from scipy.optimize import check_grad

>>> check_grad(func, grad, [1.5, -1.5])
2.9802322387695312e-08
```

Line Search

Usage:

```python
bracket(func[, xa, xb, args, grow_limit, ...])  # Bracket the minimum of the function.
```

```python
line_search(f, myfprime, xk, pk[, gfk, ...])  # Find alpha that satisfies strong Wolfe conditions.
```

scipy.optimize.bracket

scipy.optimize.bracket (func, xa=0.0, xb=1.0, args=(), grow_limit=110.0, maxiter=1000)

Bracket the minimum of the function.

Given a function and distinct initial points, search in the downhill direction (as defined by the initial points) and return new points `xa`, `xb`, `xc` that bracket the minimum of the function `f(xa) > f(xb) < f(xc)`. It doesn’t always mean that obtained solution will satisfy `xa <= x <= xb`.

Parameters

- `func` : [callable `f(x,*args)`] Objective function to minimize.
- `xa, xb` : [float, optional] Bracketing interval. Defaults `xa` to 0.0, and `xb` to 1.0.
- `args` : [tuple, optional] Additional arguments (if present), passed to `func`.
- `maxiter` : [int, optional] Maximum number of iterations to perform. Defaults to 1000.

Returns

- `xa, xb, xc` : [float] Bracket.
fa, fb, fc  [float] Objective function values in bracket.
funcalls  [int] Number of function evaluations made.

**scipy.optimize.line_search**

```python
scipy.optimize.line_search(f, myfprime, xk, pk, gfk=None, old_fval=None, old_old_fval=None, args=(), c1=0.0001, c2=0.9, amax=None, extra_condition=None, maxiter=10)
```

Find alpha that satisfies strong Wolfe conditions.

**Parameters**

- **f**  [callable f(x,*args)] Objective function.
- **myfprime**  [callable f'(x,*args)] Objective function gradient.
- **xk**  [ndarray] Starting point.
- **pk**  [ndarray] Search direction.
- **gfk**  [ndarray, optional] Gradient value for x=xk (xk being the current parameter estimate). Will be recomputed if omitted.
- **old_fval**  [float, optional] Function value for x=xk. Will be recomputed if omitted.
- **old_old_fval**  [float, optional] Function value for the point preceding x=xk.
- **args**  [tuple, optional] Additional arguments passed to objective function.
- **c1**  [float, optional] Parameter for Armijo condition rule.
- **c2**  [float, optional] Parameter for curvature condition rule.
- **amax**  [float, optional] Maximum step size.
- **extra_condition**  [callable, optional] A callable of the form `extra_condition(alpha, x, f, g)` returning a boolean. Arguments are the proposed step alpha and the corresponding x, f and g values. The line search accepts the value of alpha only if this callable returns True. If the callable returns False for the step length, the algorithm will continue with new iterates. The callable is only called for iterates satisfying the strong Wolfe conditions.
- **maxiter**  [int, optional] Maximum number of iterations to perform

**Returns**

- **alpha**  [float or None] Alpha for which x_new = x0 + alpha * pk, or None if the line search algorithm did not converge.
- **fc**  [int] Number of function evaluations made.
- **gc**  [int] Number of gradient evaluations made.
- **new_fval**  [float or None] New function value f(x_new)=f(x0+alpha*pk), or None if the line search algorithm did not converge.
- **old_fval**  [float] Old function value f(x0).
- **new_slope**  [float or None] The local slope along the search direction at the new value <myfprime(x_new), pk>, or None if the line search algorithm did not converge.

**Notes**

Uses the line search algorithm to enforce strong Wolfe conditions. See Wright and Nocedal, ‘Numerical Optimization’, 1999, pg. 59-60.

For the zoom phase it uses an algorithm by […].

**Hessian Approximation**
**LbfgsInvHessProduct**(sk, yk) Linear operator for the L-BFGS approximate inverse Hessian.

**HessianUpdateStrategy** Interface for implementing Hessian update strategies.

### scipy.optimize.LbfgsInvHessProduct

class scipy.optimize.LbfgsInvHessProduct (sk, yk)

Linear operator for the L-BFGS approximate inverse Hessian.

This operator computes the product of a vector with the approximate inverse of the Hessian of the objective function, using the L-BFGS limited memory approximation to the inverse Hessian, accumulated during the optimization.

Objects of this class implement the scipy.sparse.linalg.LinearOperator interface.

**Parameters**

- **sk** [array_like, shape=(n_corr, n)] Array of \(n_{corr}\) most recent updates to the solution vector. (See [1]).
- **yk** [array_like, shape=(n_corr, n)] Array of \(n_{corr}\) most recent updates to the gradient. (See [1]).

**References**

[Reefce8c085d0-1]

**Attributes**

- **H** Hermitian adjoint.
- **T** Transpose this linear operator.

**Methods**

- **__call__**(self, x) Call self as a function.
- **adjoint**(self) Hermitian adjoint.
- **dot**(self, x) Matrix-matrix or matrix-vector multiplication.
- **matmat**(self, X) Matrix-matrix multiplication.
- **matvec**(self, x) Matrix-vector multiplication.
- **rmatvec**(self, x) Adjoint matrix-vector multiplication.
- **todense**(self) Return a dense array representation of this operator.
- **transpose**(self) Transpose this linear operator.

### scipy.optimize.LbfgsInvHessProduct.__call__

LbfgsInvHessProduct.__call__(self, x)

Call self as a function.

### scipy.optimize.LbfgsInvHessProduct.adjoint

LbfgsInvHessProduct.adjoint(self)

Hermitian adjoint.
Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.

Can be abbreviated self.H instead of self.adjoint().

Returns

\( A_H \)  

scipy.optimize.LbfgsInvHessProduct.dot

```python
LbfgsInvHessProduct.dot(self, x)
```
Matrix-matrix or matrix-vector multiplication.

**Parameters**

- **x**  
  [array_like] 1-d or 2-d array, representing a vector or matrix.

**Returns**

- **Ax**  
  [array] 1-d or 2-d array (depending on the shape of \( x \)) that represents the result of applying this linear operator on \( x \).

scipy.optimize.LbfgsInvHessProduct.matmat

```python
LbfgsInvHessProduct.matmat(self, X)
```
Matrix-matrix multiplication.

Performs the operation \( y=A \times X \) where \( A \) is an \( M \times N \) linear operator and \( X \) dense \( N \times K \) matrix or ndarray.

**Parameters**

- **X**  
  {{matrix, ndarray}} An array with shape \( (N,K) \).

**Returns**

- **Y**  
  {{matrix, ndarray}} A matrix or ndarray with shape \( (M,K) \) depending on the type of the \( X \) argument.

**Notes**

This matmat wraps any user-specified matmat routine or overridden _matmat method to ensure that \( y \) has the correct type.

scipy.optimize.LbfgsInvHessProduct.matvec

```python
LbfgsInvHessProduct.matvec(self, x)
```
Matrix-vector multiplication.

Performs the operation \( y=A \times x \) where \( A \) is an \( M \times N \) linear operator and \( x \) is a column vector or 1-d array.

**Parameters**

- **x**  
  {{matrix, ndarray}} An array with shape \( (N,) \) or \( (N,1) \).

**Returns**

- **y**  
  {{matrix, ndarray}} A matrix or ndarray with shape \( (M,) \) or \( (M,1) \) depending on the type and shape of the \( x \) argument.
Notes

This matvec wraps the user-specified matvec routine or overridden _matvec method to ensure that y has the correct shape and type.

**scipy.optimize.LbfgsInvHessProduct.rmatvec**

$LbfgsInvHessProduct.rmatvec(self, x)$

Adjoint matrix-vector multiplication.

Performs the operation $y = A^H \ast x$ where $A$ is an MxN linear operator and $x$ is a column vector or 1-d array.

**Parameters**

- $x$ : An array with shape (M,) or (M,1).

**Returns**

- $y$ : A matrix or ndarray with shape (N,) or (N,1) depending on the type and shape of the $x$ argument.

**Notes**

This rmatvec wraps the user-specified rmatvec routine or overridden _rmatvec method to ensure that $y$ has the correct shape and type.

**scipy.optimize.LbfgsInvHessProduct.todense**

$LbfgsInvHessProduct.todense(self)$

Return a dense array representation of this operator.

**Returns**

- $arr$ : [ndarray, shape=(n, n)] An array with the same shape and containing the same data represented by this LinearOperator.

**scipy.optimize.LbfgsInvHessProduct.transpose**

$LbfgsInvHessProduct.transpose(self)$

Transpose this linear operator.

Returns a LinearOperator that represents the transpose of this one. Can be abbreviated self.T instead of self.transpose().

**scipy.optimize.HessianUpdateStrategy**

class scipy.optimize.HessianUpdateStrategy

Interface for implementing Hessian update strategies.

Many optimization methods make use of Hessian (or inverse Hessian) approximations, such as the quasi-Newton methods BFGS, SR1, L-BFGS. Some of these approximations, however, do not actually need to store the entire matrix or can compute the internal matrix product with a given vector in a very efficiently manner. This class
serves as an abstract interface between the optimization algorithm and the quasi-Newton update strategies, giving freedom of implementation to store and update the internal matrix as efficiently as possible. Different choices of initialization and update procedure will result in different quasi-Newton strategies.

Four methods should be implemented in derived classes: `initialize`, `update`, `dot` and `get_matrix`.

**Notes**

Any instance of a class that implements this interface, can be accepted by the method `minimize` and used by the compatible solvers to approximate the Hessian (or inverse Hessian) used by the optimization algorithms.

**Methods**

```
dot(self, p)                  # Compute the product of the internal matrix with the given vector.
get_matrix(self)             # Return current internal matrix.
initialize(self, n, approx_type)  # Initialize internal matrix.
update(self, delta_x, delta_grad)  # Update internal matrix.
```

### scipy.optimize.HessianUpdateStrategy.dot

#### scipy.optimize.HessianUpdateStrategy.dot (self, p)

Compute the product of the internal matrix with the given vector.

**Parameters**

- **p** [array_like] 1-d array representing a vector.

**Returns**

- **Hp** [array] 1-d represents the result of multiplying the approximation matrix by vector p.

### scipy.optimize.HessianUpdateStrategy.get_matrix

#### scipy.optimize.HessianUpdateStrategy.get_matrix (self)

Return current internal matrix.

**Returns**

- **H** [ndarray, shape (n, n)] Dense matrix containing either the Hessian or its inverse (depending on how ‘approx_type’ is defined).

### scipy.optimize.HessianUpdateStrategy.initialize

#### scipy.optimize.HessianUpdateStrategy.initialize (self, n, approx_type)

Initialize internal matrix.

Allocate internal memory for storing and updating the Hessian or its inverse.

**Parameters**

- **n** [int] Problem dimension.
approx_type

[{'hess', 'inv_hess'}] Selects either the Hessian or the inverse Hessian. When set to 'hess' the Hessian will be stored and updated. When set to 'inv_hess' its inverse will be used instead.

**scipy.optimize.HessianUpdateStrategy.update**

HessianUpdateStrategy.update(self, delta_x, delta_grad)

Update internal matrix.

Update Hessian matrix or its inverse (depending on how ‘approx_type’ is defined) using information about the last evaluated points.

**Parameters**

`delta_x` [ndarray] The difference between two points the gradient function have been evaluated at: delta_x = x2 - x1.

`delta_grad` [ndarray] The difference between the gradients: delta_grad = grad(x2) - grad(x1).

**Benchmark Problems**

**scipy.optimize.rosen**

scipy.optimize.rosen(x)

The Rosenbrock function.

The function computed is:

\[
\text{sum}(100.0 \times (x[1:] - x[:1])**2.0)**2.0 + (1 - x[:1])**2.0)
\]

**Parameters**

`x` [array_like] 1-D array of points at which the Rosenbrock function is to be computed.

**Returns**

`f` [float] The value of the Rosenbrock function.

**See also:**

rosen_der, rosen_hess, rosen_hess_prod

**Examples**
```python
>>> from scipy.optimize import rosen
>>> X = 0.1 * np.arange(10)
>>> rosen(X)
76.56
```

**scipy.optimize.rosen_der**

`scipy.optimize.rosen_der(x)`

The derivative (i.e., gradient) of the Rosenbrock function.

**Parameters**

- `x` : array_like
  1-D array of points at which the derivative is to be computed.

**Returns**

- `rosen_der` : (N,) ndarray
  The gradient of the Rosenbrock function at `x`.

**See also:**

`rosen`, `rosen_hess`, `rosen_hess_prod`

**Examples**

```python
>>> from scipy.optimize import rosen_der
>>> X = 0.1 * np.arange(9)
>>> rosen_der(X)
array([-2., 10.6, 15.6, 13.4, 6.4, -3., -12.4, -19.4, 62.])
```

**scipy.optimize.rosen_hess**

`scipy.optimize.rosen_hess(x)`

The Hessian matrix of the Rosenbrock function.

**Parameters**

- `x` : array_like
  1-D array of points at which the Hessian matrix is to be computed.

**Returns**

- `rosen_hess` : (ndarray) The Hessian matrix of the Rosenbrock function at `x`.

**See also:**

`rosen`, `rosen_der`, `rosen_hess_prod`

**Examples**

```python
>>> from scipy.optimize import rosen_hess
>>> X = 0.1 * np.arange(4)
>>> rosen_hess(X)
array([[ -38.,   0.,   0.,   0.],
       [  0., 134., -40.,   0.],
       [  0., -40., 130., -80.],
       [  0.,   0., -80., 200.]]
```
scipy.optimize.rosen_hess_prod

scipy.optimize.rosen_hess_prod(x, p)

Product of the Hessian matrix of the Rosenbrock function with a vector.

Parameters

- **x** [array_like] 1-D array of points at which the Hessian matrix is to be computed.
- **p** [array_like] 1-D array, the vector to be multiplied by the Hessian matrix.

Returns

- **rosen_hess_prod** [ndarray] The Hessian matrix of the Rosenbrock function at \( x \) multiplied by the vector \( p \).

See also:

- rosen, rosen_der, rosen_hess

Examples

```python
>>> from scipy.optimize import rosen_hess_prod
>>> X = 0.1 * np.arange(9)
>>> p = 0.5 * np.arange(9)
>>> rosen_hess_prod(X, p)
array([-0., 27., -10., -95., -192., -265., -278., -195., -180.])
```

6.18.9 Legacy Functions

The functions below are not recommended for use in new scripts; all of these methods are accessible via a newer, more consistent interfaces, provided by the interfaces above.

**Optimization**

General-purpose multivariate methods:

- `fmin(func, x0[, args, xtol, ftol, maxiter, …])` Minimize a function using the downhill simplex algorithm.
- `fmin_powell(func, x0[, args, xtol, ftol, …])` Minimize a function using modified Powell’s method.
- `fmin_cg(f, x0[, fprime, args, gtol, norm, …])` Minimize a function using a nonlinear conjugate gradient algorithm.
- `fmin_bfgs(f, x0[, fprime, args, gtol, norm, …])` Minimize a function using the BFGS algorithm.
- `fmin_ncg(f, x0[, fprime[, Thess_p, Thess, …]])` Unconstrained minimization of a function using the Newton-CG method.

scipy.optimize.fmin

scipy.optimize.fmin(func, x0[, args=(), xtol=0.0001, ftol=0.0001, maxiter=None, maxfun=None, full_output=0, disp=1, retall=0, callback=None, initial_simplex=None])

Minimize a function using the downhill simplex algorithm.

This algorithm only uses function values, not derivatives or second derivatives.

Parameters
func  [callable func(x,*args)] The objective function to be minimized.
x0   [ndarray] Initial guess.
args [tuple, optional] Extra arguments passed to func, i.e. \( f(x,*\text{args}) \).
xtol [float, optional] Absolute error in xopt between iterations that is acceptable for convergence.
ftol [number, optional] Absolute error in func(xopt) between iterations that is acceptable for convergence.
maxiter [int, optional] Maximum number of iterations to perform.
maxfun [number, optional] Maximum number of function evaluations to make.
full_output [bool, optional] Set to True if fopt and warnflag outputs are desired.
disp [bool, optional] Set to True to print convergence messages.
retall [bool, optional] Set to True to return list of solutions at each iteration.
callback [callable, optional] Called after each iteration, as callback(xk), where xk is the current parameter vector.
initial_simplex [array_like of shape (N + 1, N), optional] Initial simplex. If given, overrides x0. initial_simplex[j,:] should contain the coordinates of the j-th vertex of the N+1 vertices in the simplex, where N is the dimension.

Returns

xopt [ndarray] Parameter that minimizes function.
fopt [float] Value of function at minimum: \( fopt = func(xopt) \).
iter [int] Number of iterations performed.
funcalls [int] Number of function calls made.
warnflag [int] 1 : Maximum number of function evaluations made. 2 : Maximum number of iterations reached.
allvecs [list] Solution at each iteration.

See also:

minimize

Interface to minimization algorithms for multivariate functions. See the ‘Nelder-Mead’ method in particular.

Notes

Uses a Nelder-Mead simplex algorithm to find the minimum of function of one or more variables.

This algorithm has a long history of successful use in applications. But it will usually be slower than an algorithm that uses first or second derivative information. In practice it can have poor performance in high-dimensional problems and is not robust to minimizing complicated functions. Additionally, there currently is no complete theory describing when the algorithm will successfully converge to the minimum, or how fast it will if it does. Both the ftol and xtol criteria must be met for convergence.

[1], [2]

Examples

```python
>>> def f(x):
...     return x**2
```
```python
>>> from scipy import optimize

>>> minimum = optimize.fmin(f, 1)
Optimization terminated successfully.
    Current function value: 0.000000
    Iterations: 17
    Function evaluations: 34
>>> minimum[0]
-8.8817841970012523e-16
```

**scipy.optimize.fmin_powell**

`scipy.optimize.fmin_powell(func, x0, args=(), xtol=0.0001, ftol=0.0001, maxiter=None, maxfun=None, full_output=0, disp=1, retall=0, callback=None, direc=None)`

Minimize a function using modified Powell's method.

This method only uses function values, not derivatives.

**Parameters**

- `func [callable f(x,*args)]`: Objective function to be minimized.
- `x0 [ndarray]`: Initial guess.
- `args [tuple, optional]`: Extra arguments passed to `func`.
- `ftol [float, optional]`: Relative error in `func(xopt)` acceptable for convergence.
- `maxiter [int, optional]`: Maximum number of iterations to perform.
- `maxfun [int, optional]`: Maximum number of function evaluations to make.
- `full_output [bool, optional]`: If True, `fopt`, `xi`, `direc`, `iter`, `funcalls`, and `warnflag` are returned.
- `disp [bool, optional]`: If True, print convergence messages.
- `retall [bool, optional]`: If True, return a list of the solution at each iteration.
- `callback [callable, optional]`: An optional user-supplied function, called after each iteration. Called as `callback(xk)`, where `xk` is the current parameter vector.
- `direc [ndarray, optional]`: Initial fitting step and parameter order set as an (N, N) array, where N is the number of fitting parameters in `x0`. Defaults to step size 1.0 fitting all parameters simultaneously (np.ones((N, N))). To prevent initial consideration of values in a step or to change initial step size, set to 0 or desired step size in the Jth position in the Mth block, where J is the position in `x0` and M is the desired evaluation step, with steps being evaluated in index order. Step size and ordering will change freely as minimization proceeds.

**Returns**

- `xopt [ndarray]`: Parameter which minimizes `func`.
- `fopt [number]`: Value of function at minimum: `fopt = func(xopt)`.
- `iter [int]`: Number of iterations.
- `funcalls [int]`: Number of function calls made.
- `warnflag [int]`: Integer warning flag:
  - 1 : Maximum number of function evaluations.
  - 2 : Maximum number of iterations.
  - 3 : NaN result encountered.
- `allvecs [list]`: List of solutions at each iteration.

minimize

Interface to unconstrained minimization algorithms for multivariate functions. See the ‘Powell’ method in particular.

Notes

Uses a modification of Powell’s method to find the minimum of a function of N variables. Powell’s method is a conjugate direction method.

The algorithm has two loops. The outer loop merely iterates over the inner loop. The inner loop minimizes over each current direction in the direction set. At the end of the inner loop, if certain conditions are met, the direction that gave the largest decrease is dropped and replaced with the difference between the current estimated x and the estimated x from the beginning of the inner-loop.

The technical conditions for replacing the direction of greatest increase amount to checking that

1. No further gain can be made along the direction of greatest increase from that iteration.
2. The direction of greatest increase accounted for a large sufficient fraction of the decrease in the function value from that iteration of the inner loop.

Examples

```python
>>> def f(x):
...     return x**2

>>> from scipy import optimize

>>> minimum = optimize.fmin_powell(f, -1)
Optimization terminated successfully.
    Current function value: 0.000000
    Iterations: 2
    Function evaluations: 18
>>> minimum
array(0.0)
```

scipy.optimize.fmin_cg

scipy.optimize.fmin_cg(f, x0, fprime=None, args=(), gtol=1e-05, norm=inf, epsilon=1.4901161193847656e-08, maxiter=None, full_output=0, disp=1, retall=0, callback=None)

Minimize a function using a nonlinear conjugate gradient algorithm.

Parameters
SciPy Reference Guide, Release 1.3.2

**f**

[callable, f(x, *args)] Objective function to be minimized. Here x must be a 1-D array of the variables that are to be changed in the search for a minimum, and args are the other (fixed) parameters of f.

**x0**

[ndarray] A user-supplied initial estimate of xopt, the optimal value of x. It must be a 1-D array of values.

**fprime**

[callable, fprime(x, *args), optional] A function that returns the gradient of f at x. Here x and args are as described above for f. The returned value must be a 1-D array. Defaults to None, in which case the gradient is approximated numerically (see epsilon, below).

**args**

[tuple, optional] Parameter values passed to f and fprime. Must be supplied whenever additional fixed parameters are needed to completely specify the functions f and fprime.

**gtol**

[double, optional] Stop when the norm of the gradient is less than gtol.

**norm**

[double, optional] Order to use for the norm of the gradient (-np.inf is min, np.inf is max).

**epsilon**

[float or ndarray, optional] Step size(s) to use when fprime is approximated numerically. Can be a scalar or a 1-D array. Defaults to \sqrt{\text{eps}}$, with eps the floating point machine precision. Usually \sqrt{\text{eps}} is about 1.5e-8.

**maxiter**

[int, optional] Maximum number of iterations to perform. Default is 200 * len(x0).

**full_output**

[bool, optional] If True, return fopt, func_calls, grad_calls, and warnflag in addition to xopt. See the Returns section below for additional information on optional return values.

**disp**

[bool, optional] If True, return a convergence message, followed by xopt.

**retall**

[bool, optional] If True, add to the returned values the results of each iteration.

**callback**

[callable, optional] An optional user-supplied function, called after each iteration. Called as callback(xk), where xk is the current value of x0.

### Returns

**xopt**

[ndarray] Parameters which minimize f, i.e. f(xopt) == fopt.

**fopt**

[float, optional] Minimum value found, f(xopt). Only returned if full_output is True.

**func_calls**

[int, optional] The number of function calls made. Only returned if full_output is True.

**grad_calls**

[int, optional] The number of gradient calls made. Only returned if full_output is True.

**warnflag**

[int, optional] Integer value with warning status, only returned if full_output is True.

- 0: Success.
- 1: The maximum number of iterations was exceeded.
- 2: [Gradient and/or function calls were not changing. May indicate] that precision was lost, i.e., the routine did not converge.
- 3: NaN result encountered.

**allvecs**

[list of ndarray, optional] List of arrays, containing the results at each iteration. Only returned if retall is True.

### See also:

**minimize**

common interface to all scipy.optimize algorithms for unconstrained and constrained minimization of multivariate functions. It provides an alternative way to call fmin_cg, by specifying method='CG'.

### Notes

This conjugate gradient algorithm is based on that of Polak and Ribiere [1].

Conjugate gradient methods tend to work better when:

1. f has a unique global minimizing point, and no local minima or other stationary points,
2. f is, at least locally, reasonably well approximated by a quadratic function of the variables,
3. $f$ is continuous and has a continuous gradient,
4. $f'$ is not too large, e.g., has a norm less than 1000,
5. The initial guess, $x_0$, is reasonably close to $f$’s global minimizing point, $x_{opt}$.

[1]

Examples

Example 1: seek the minimum value of the expression $a*u^2 + b*u*v + c*v^2 + d*u + e*v + f$ for given values of the parameters and an initial guess $(u, v) = (0, 0)$.

```python
>>> args = (2, 3, 7, 8, 9, 10) # parameter values
>>> def f(x, *args):
...    u, v = x
...    a, b, c, d, e, f = args
...    return a*u**2 + b*u*v + c*v**2 + d*u + e*v + f
>>> def gradf(x, *args):
...    u, v = x
...    a, b, c, d, e, f = args
...    gu = 2*a*u + b*v + d # u-component of the gradient
...    gv = b*u + 2*c*v + e # v-component of the gradient
...    return np.asarray((gu, gv))

>>> x0 = np.asarray((0, 0)) # Initial guess.
>>> from scipy import optimize

>>> res1 = optimize.fmin_cg(f, x0, fprime=gradf, args=args)
Optimization terminated successfully.
Current function value: 1.617021
Iterations: 4
Function evaluations: 8
Gradient evaluations: 8

array([-1.80851064, -0.25531915])
```

Example 2: solve the same problem using the `minimize` function. (This `myopts` dictionary shows all of the available options, although in practice only non-default values would be needed. The returned value will be a dictionary.)

```python
>>> opts = {'maxiter': None, # default value.
...          'disp': True,   # non-default value.
...          'gtol': 1e-5,  # default value.
...          'norm': np.inf, # default value.
...          'eps': 1.4901161193847656e-08} # default value.

>>> res2 = optimize.minimize(f, x0, jac=gradf, args=args,
...          method='CG', options=opts)
Optimization terminated successfully.
Current function value: 1.617021
Iterations: 4
Function evaluations: 8
Gradient evaluations: 8
```

(continues on next page)
scipy.optimize.fmin_bfgs

scipy.optimize.fmin_bfgs(f, x0, fprime=None, args=(), gtol=1e-05, norm=inf, epsilon=1.4901161193847656e-08, maxiter=None, full_output=0, disp=1, retall=0, callback=None)

Minimize a function using the BFGS algorithm.

Parameters

- **f**: [callable f(x,*args)] Objective function to be minimized.
- **x0**: [ndarray] Initial guess.
- **fprime**: [callable f'(x,*args), optional] Gradient of f.
- **args**: [tuple, optional] Extra arguments passed to f and fprime.
- **gtol**: [float, optional] Gradient norm must be less than gtol before successful termination.
- **norm**: [float, optional] Order of norm (Inf is max, -Inf is min)
- **epsilon**: [int or ndarray, optional] If fprime is approximated, use this value for the step size.
- **callback**: [callable, optional] An optional user-supplied function to call after each iteration. Called as callback(xk), where xk is the current parameter vector.
- **maxiter**: [int, optional] Maximum number of iterations to perform.
- **full_output**: [bool, optional] If True, return fopt, func_calls, grad_calls, and warnflag in addition to xopt.
- **disp**: [bool, optional] Print convergence message if True.
- **retall**: [bool, optional] Return a list of results at each iteration if True.

Returns

- **xopt**: [ndarray] Parameters which minimize f, i.e. f(xopt) == fopt.
- **fopt**: [float] Minimum value.
- **gopt**: [ndarray] Value of gradient at minimum, f'(xopt), which should be near 0.
- **Bopt**: [ndarray] Value of 1/f''(xopt), i.e. the inverse hessian matrix.
- **func_calls**: [int] Number of function_calls made.
- **grad_calls**: [int] Number of gradient calls made.
- **warnflag**: [integer] 1 : Maximum number of iterations exceeded. 2 : Gradient and/or function calls not changing. 3 : NaN result encountered.
- **allvecs**: [list] The value of xopt at each iteration. Only returned if retall is True.

See also:

**minimize**

Interface to minimization algorithms for multivariate functions. See the 'BFGS' method in particular.

Notes

Optimize the function, f, whose gradient is given by fprime using the quasi-Newton method of Broyden, Fletcher, Goldfarb, and Shanno (BFGS)

References

scipy.optimize.fmin_ncg

Parameters

- **f**: [callable `f(x, *args)`] Objective function to be minimized.
- **x0**: [ndarray] Initial guess.
- **fprime**: [callable `f'(x, *args)`] Gradient of f.
- **fhess_p**: [callable `fhess_p(x, p, *args)`, optional] Function which computes the Hessian of f times an arbitrary vector, p.
- **fhess**: [callable `fhess(x, *args)`, optional] Function to compute the Hessian matrix of f.
- **args**: [tuple, optional] Extra arguments passed to f, fprime, fhess_p, and fhess (the same set of extra arguments is supplied to all of these functions).
- **epsilon**: [float or ndarray, optional] If fhess is approximated, use this value for the step size.
- **callback**: [callable, optional] An optional user-supplied function which is called after each iteration. Called as callback(xk), where xk is the current parameter vector.
- **avextol**: [float, optional] Convergence is assumed when the average relative error in the minimizer falls below this amount.
- **maxiter**: [int, optional] Maximum number of iterations to perform.
- **full_output**: [bool, optional] If True, return the optional outputs.
- **disp**: [bool, optional] If True, print convergence message.
- **retall**: [bool, optional] If True, return a list of results at each iteration.

Returns

- **xopt**: [ndarray] Parameters which minimize f, i.e. \( f(x_{opt}) = f_{opt} \).
- **fopt**: [float] Value of the function at xopt, i.e. \( f_{opt} = f(x_{opt}) \).
- **fcalls**: [int] Number of function calls made.
- **gcalls**: [int] Number of gradient calls made.
- **hcalls**: [int] Number of hessian calls made.
- **allvecs**: [list] The result at each iteration, if retall is True (see below).

See also:

- **minimize**

  Interface to minimization algorithms for multivariate functions. See the ‘Newton-CG’ method in particular.

Notes

Only one of fhess_p or fhess need to be given. If fhess is provided, then fhess_p will be ignored. If neither fhess nor fhess_p is provided, then the hessian product will be approximated using finite differences on fprime. fhess_p must compute the hessian times an arbitrary vector. If it is not given, finite-differences on fprime are used to compute it.

Newton-CG methods are also called truncated Newton methods. This function differs from scipy.optimize.fmin_tnc because

1. **scipy.optimize.fmin_ncg is written purely in python using numpy**

   and scipy while scipy.optimize.fmin_tnc calls a C function.
2. `scipy.optimize.fmin_ncg` is only for unconstrained minimization

while `scipy.optimize.fmin_tnc` is for unconstrained minimization or box constrained minimization. (Box constraints give lower and upper bounds for each variable separately.)

`scipy.optimize.fmin_l_bfgs_b`

`scipy.optimize.fmin_l_bfgs_b(func, x0, fprime=None, args=(), approx_grad=0, bounds=None, m=10, factr=10000000.0, pgtol=1e-05, epsilon=1e-08, iprint=-1, maxfun=15000, maxiter=15000, disp=None, callback=None, maxls=20)`

Minimize a function func using the L-BFGS-B algorithm.

**Parameters**

- `func` [callable f(x,*args)] Function to minimise.
- `x0` [ndarray] Initial guess.
- `fprime` [callable fprime(x,*args), optional] The gradient of `func`. If None, then `func` returns the function value and the gradient((f, g = func(x, *args)), unless `approx_grad` is True in which case `func` returns only f.
- `args` [sequence, optional] Arguments to pass to `func` and `fprime`.
- `approx_grad` [bool, optional] Whether to approximate the gradient numerically (in which case `func` returns only the function value).
- `bounds` [list, optional] (min, max) pairs for each element in x, defining the bounds on that parameter. Use None or +inf for one of min or max when there is no bound in that direction.
- `m` [int, optional] The maximum number of variable metric corrections used to define the limited memory matrix. (The limited memory BFGS method does not store the full hessian but uses this many terms in an approximation to it.)
- `factr` [float, optional] The iteration stops when \((f^k - f^{(k+1)}) / \max(|f^k|, |f^{(k+1)}|, 1) < factr * eps\), where eps is the machine precision, which is automatically generated by the code. Typical values for `factr` are: 1e12 for low accuracy; 1e7 for moderate accuracy; 10.0 for extremely high accuracy. See Notes for relationship to `ftol`, which is exposed (instead of `factr`) by the `scipy.optimize.minimize` interface to L-BFGS-B.
- `pgtol` [float, optional] The iteration will stop when \(\max(|\text{proj
g_i}| | i = 1, \ldots, n) <= pgtol \) where pg_i is the i-th component of the projected gradient.
epsilon [float, optional] Step size used when approx_grad is True, for numerically calculating the gradient

iprint [int, optional] Controls the frequency of output. iprint < 0 means no output; iprint = 0 print only one line at the last iteration; 0 < iprint < 99 print also f and |proj g| every iprint iterations; iprint = 99 print details of every iteration except n-vectors; iprint = 100 print also the changes of active set and final x; iprint > 100 print details of every iteration including x and g.

disp [int, optional] If zero, then no output. If a positive number, then this over-rides iprint (i.e., iprint gets the value of disp).

maxfun [int, optional] Maximum number of function evaluations.

maxiter [int, optional] Maximum number of iterations.

callback [callable, optional] Called after each iteration, as callback(xk), where xk is the current parameter vector.

maxls [int, optional] Maximum number of line search steps (per iteration). Default is 20.

Returns

x [array_like] Estimated position of the minimum.

f [float] Value of func at the minimum.

d [dict] Information dictionary.
• d['warnflag'] is
  – 0 if converged,
  – 1 if too many function evaluations or too many iterations,
  – 2 if stopped for another reason, given in d['task']
• d['grad'] is the gradient at the minimum (should be 0 ish)
• d['funcalls'] is the number of function calls made.
• d['nit'] is the number of iterations.

**scipy.optimize.fmin_tnc**

```python
scipy.optimize.fmin_tnc(func, x0, fprime=None, args=(), approx_grad=0, bounds=None, epsilon=1e-08, scale=None, offset=None, messages=15, maxCGit=-1, maxfun=None, eta=-1, stepmx=0, accuracy=0, fmin=0, ftol=-1, xtol=-1, pgtol=-1, rescale=-1, disp=None, callback=None)
```

Minimize a function with variables subject to bounds, using gradient information in a truncated Newton algorithm. This method wraps a C implementation of the algorithm.

**Parameters**

- `func` [callable func(x, *args)] Function to minimize. Must do one of:
  1. Return f and g, where f is the value of the function and g its gradient (a list of floats).
  2. Return the function value but supply gradient function separately as `fprime`.
  3. Return the function value and set `approx_grad=True`

- `x0` [array_like] Initial estimate of minimum.

- `fprime` [callable fprime(x, *args), optional] Gradient of `func`. If None, then either `func` must return the function value and the gradient \((f, g = func(x, *args))\) or `approx_grad` must be True.

- `args` [tuple, optional] Arguments to pass to function.

- `approx_grad` [bool, optional] If true, approximate the gradient numerically.

- `bounds` [list, optional] (min, max) pairs for each element in `x0`, defining the bounds on that parameter. Use None or +/-inf for one of min or max when there is no bound in that direction.

- `epsilon` [float, optional] Used if `approx_grad` is True. The stepsize in a finite difference approximation for `fprime`.

- `scale` [array_like, optional] Scaling factors to apply to each variable. If None, the factors are up-low for interval bounded variables and 1+|x| for the others. Defaults to None.

- `offset` [array_like, optional] Value to subtract from each variable. If None, the offsets are (up+low)/2 for interval bounded variables and x for the others.

- `messages` [int, optional] Bit mask used to select messages display during minimization values defined in the MSGS dict. Defaults to MGS_ALL.

- `disp` [int, optional] Integer interface to messages. 0 = no message, 5 = all messages

- `maxCGit` [int, optional] Maximum number of hessian*vector evaluations per main iteration. If `maxCGit == 0`, the direction chosen is -gradient if `maxCGit < 0`, `maxCGit` is set to max(1,min(50,n/2)). Defaults to -1.

- `maxfun` [int, optional] Maximum number of function evaluation. If None, maxfun is set to max(100, 10*len(x0)). Defaults to None.

- `eta` [float, optional] Severity of the line search. If < 0 or > 1, set to 0.25. Defaults to -1.

- `stepmx` [float, optional] Maximum step for the line search. May be increased during call. If too small, it will be set to 10.0. Defaults to 0.

- `accuracy` [float, optional] Relative precision for finite difference calculations. If <= machine_precision, set to sqrt(machine_precision). Defaults to 0.

- `fmin` [float, optional] Minimum function value estimate. Defaults to 0.

- `ftol` [float, optional] Precision goal for the value of f in the stopping criterion. If ftol < 0.0, ftol is set to 0.0 defaults to -1.

- `xtol` [float, optional] Precision goal for the value of x in the stopping criterion (after applying x scaling factors). If xtol < 0.0, xtol is set to sqrt(machine_precision). Defaults to -1.

- `pgtol` [float, optional] Precision goal for the value of the projected gradient in the stopping criterion (after applying x scaling factors). If pgtol < 0.0, pgtol is set to 1e-2 * sqrt(accuracy). Setting it to 0.0 is not recommended. Defaults to -1.
rescale  [float, optional] Scaling factor (in log10) used to trigger f value rescaling. If 0, rescale at each iteration. If a large value, never rescale. If < 0, rescale is set to 1.3.

callback  [callable, optional] Called after each iteration, as callback(xk), where xk is the current parameter vector.

Returns

x  [ndarray] The solution.
nfeval  [int] The number of function evaluations.
rc  [int] Return code, see below

See also:

minimize

Interface to minimization algorithms for multivariate functions. See the ‘TNC’ method in particular.

Notes

The underlying algorithm is truncated Newton, also called Newton Conjugate-Gradient. This method differs from scipy.optimize.fmin_ncg in that

1. It wraps a C implementation of the algorithm
2. It allows each variable to be given an upper and lower bound.

The algorithm incorporates the bound constraints by determining the descent direction as in an unconstrained truncated Newton, but never taking a step-size large enough to leave the space of feasible x's. The algorithm keeps track of a set of currently active constraints, and ignores them when computing the minimum allowable step size. (The x's associated with the active constraint are kept fixed.) If the maximum allowable step size is zero then a new constraint is added. At the end of each iteration one of the constraints may be deemed no longer active and removed. A constraint is considered no longer active if it is currently active but the gradient for that variable points inward from the constraint. The specific constraint removed is the one associated with the variable of largest index whose constraint is no longer active.

Return codes are defined as follows:

-1: Infeasible (lower bound > upper bound)
0: Local minimum reached (|pg| ~ 0)
1: Converged (|f_n-f_(n-1)| ~ 0)
2: Converged (|x_n-x_(n-1)| ~ 0)
3: Max. number of function evaluations reached
4: Linear search failed
5: All lower bounds are equal to the upper bounds
6: Unable to progress
7: User requested end of minimization

References

Wright S., Nocedal J. (2006), ‘Numerical Optimization’
scipy.optimize.fmin_cobyla

`scipy.optimize.fmin_cobyla(func, x0, cons, args=(), consargs=None, rhobeg=1.0, rhoend=0.0001, maxfun=1000, disp=None, catol=0.0002)`

Minimize a function using the Constrained Optimization BY Linear Approximation (COBYLA) method. This method wraps a FORTRAN implementation of the algorithm.

**Parameters**

- `func` [callable] Function to minimize. In the form `func(x, *args)`.
- `x0` [ndarray] Initial guess.
- `cons` [sequence] Constraint functions; must all be >=0 (a single function if only 1 constraint). Each function takes the parameters `x` as its first argument, and it can return either a single number or an array or list of numbers.
- `args` [tuple, optional] Extra arguments to pass to function.
- `consargs` [tuple, optional] Extra arguments to pass to constraint functions (default of None means use same extra arguments as those passed to `func`). Use () for no extra arguments.
- `rhobeg` [float, optional] Reasonable initial changes to the variables.
- `rhoend` [float, optional] Final accuracy in the optimization (not precisely guaranteed). This is a lower bound on the size of the trust region.
- `disp` [{0, 1, 2, 3}, optional] Controls the frequency of output; 0 implies no output.
- `maxfun` [int, optional] Maximum number of function evaluations.

**Returns**

- `x` [ndarray] The argument that minimises `f`.

**See also:**

- `minimize`

  Interface to minimization algorithms for multivariate functions. See the ‘COBYLA’ method in particular.

**Notes**

This algorithm is based on linear approximations to the objective function and each constraint. We briefly describe the algorithm.

Suppose the function is being minimized over `k` variables. At the `j`th iteration the algorithm has `k+1` points `v_1, ..., v_(k+1)`, an approximate solution `x_j`, and a radius `RHO_j` (i.e. linear plus a constant) approximations to the objective function and constraint functions such that their function values agree with the linear approximation on the `k+1` points `v_1, ..., v_(k+1)`. This gives a linear program to solve (where the linear approximations of the constraint functions are constrained to be non-negative).

However the linear approximations are likely only good approximations near the current simplex, so the linear program is given the further requirement that the solution, which will become `x_(j+1)`, must be within `RHO_j` from `x_j`. `RHO_j` only decreases, never increases. The initial `RHO_j` is `rhobeg` and the final `RHO_j` is `rhoend`. In this way COBYLA’s iterations behave like a trust region algorithm.

Additionally, the linear program may be inconsistent, or the approximation may give poor improvement. For details about how these issues are resolved, as well as how the points `v_j` are updated, refer to the source code or the references below.
References

Examples

Minimize the objective function \( f(x,y) = x \cdot y \) subject to the constraints \( x^2 + y^2 < 1 \) and \( y > 0 \):

```python
>>> def objective(x):
    ...     return x[0]*x[1]
    ...
>>> def constr1(x):
    ...     return 1 - (x[0]**2 + x[1]**2)
    ...
>>> def constr2(x):
    ...     return x[1]
    ...
>>> from scipy.optimize import fmin_cobyla
>>> fmin_cobyla(objective, [0.0, 0.1], [constr1, constr2], rhoend=1e-7)
array([-0.70710685, 0.70710671])
```

The exact solution is \((-\sqrt{2})/2, \sqrt{2})/2\).

`scipy.optimize.fmin_slsqp`

Python interface function for the SLSQP Optimization subroutine originally implemented by Dieter Kraft.

**Parameters**

- `func`  
  [callable f(x,*args)] Objective function. Must return a scalar.

- `x0`  
  [1-D ndarray of float] Initial guess for the independent variable(s).

- `eqcons`  
  [list, optional] A list of functions of length \( n \) such that \( \text{eqcons}[j](x,*args) = 0.0 \) in a successfully optimized problem.

- `f_eqcons`  
  [callable f(x,*args), optional] Returns a 1-D array in which each element must equal 0.0 in a successfully optimized problem. If f_eqcons is specified, eqcons is ignored.

- `ieqcons`  
  [list, optional] A list of functions of length \( n \) such that \( \text{ieqcons}[j](x,*args) \geq 0.0 \) in a successfully optimized problem.

- `f_ieqcons`  
  [callable f(x,*args), optional] Returns a 1-D ndarray in which each element must be greater or equal to 0.0 in a successfully optimized problem. If f_ieqcons is specified, ieqcons is ignored.

- `bounds`  
  [list, optional] A list of tuples specifying the lower and upper bound for each independent variable \([xl0, xu0],[xl1, xu1],...\). Infinite values will be interpreted as large floating values.

- `fprime`  
  [callable f(x,*args), optional] A function that evaluates the partial derivatives of func.
fprime_eqcons
[callable f(x,*args), optional] A function of the form f(x, *args) that returns the m by n array of equality constraint normals. If not provided, the normals will be approximated. The array returned by fprime_eqcons should be sized as ( len(eqcons), len(x0) ).

fprime_ieqcons
[callable f(x,*args), optional] A function of the form f(x, *args) that returns the m by n array of inequality constraint normals. If not provided, the normals will be approximated. The array returned by fprime_ieqcons should be sized as ( len(ieqcons), len(x0) ).

args
[sequence, optional] Additional arguments passed to func and fprime.
iter
[int, optional] The maximum number of iterations.
acc
[float, optional] Requested accuracy.
iprint
[int, optional] The verbosity of fmin_slsqp:
- iprint <= 0: Silent operation
- iprint == 1: Print summary upon completion (default)
- iprint >= 2: Print status of each iterate and summary

disp
[int, optional] Over-rides the iprint interface (preferred).
full_output
[bool, optional] If False, return only the minimizer of func (default). Otherwise, output final objective function and summary information.
epsilon
[float, optional] The step size for finite-difference derivative estimates.
callback
[callable, optional] Called after each iteration, as callback(x), where x is the current parameter vector.

Returns
out
[ndarray of float] The final minimizer of func.
fx
[ndarray of float, if full_output is true] The final value of the objective function.
its
[int, if full_output is true] The number of iterations.
imode
[int, if full_output is true] The exit mode from the optimizer (see below).
smode
[string, if full_output is true] Message describing the exit mode from the optimizer.

See also:
minimize

Interface to minimization algorithms for multivariate functions. See the ‘SLSQP’ method in particular.

Notes

Exit modes are defined as follows

**scipy.optimize.fminbound**

`scipy.optimize.fminbound(func, x1, x2, args=(), xtol=1e-05, maxfun=500, full_output=0, disp=1)`

Bounded minimization for scalar functions.

**Parameters**

- `func` [callable f(x,*args)] Objective function to be minimized (must accept and return scalars).
- `x1, x2` [float or array scalar] The optimization bounds.
- `args` [tuple, optional] Extra arguments passed to function.
- `xtol` [float, optional] The convergence tolerance.
- `maxfun` [int, optional] Maximum number of function evaluations allowed.
- `full_output` [bool, optional] If True, return optional outputs.
- `disp` [int, optional] If non-zero, print messages.
  - 0: no message printing. 1: non-convergence notification messages only. 2: print a message on convergence too. 3: print iteration results.

**Returns**

- `xopt` [ndarray] Parameters (over given interval) which minimize the objective function.
- `fval` [number] The function value at the minimum point.
- `ierr` [int] An error flag (0 if converged, 1 if maximum number of function calls reached).
- `numfun` [int] The number of function calls made.

**See also:**

`minimize_scalar`

Interface to minimization algorithms for scalar univariate functions. See the ‘Bounded’ method in particular.

**Notes**

Finds a local minimizer of the scalar function `func` in the interval `x1 < xopt < x2` using Brent’s method. (See `brent` for auto-bracketing).

**Examples**

`fminbound` finds the minimum of the function in the given range. The following examples illustrate the same

```python
>>> def f(x):
...     return x**2
```
```python
>>> from scipy import optimize

>>> minimum = optimize.fminbound(f, -1, 2)
>>> minimum
0.0
>>> minimum = optimize.fminbound(f, 1, 2)
>>> minimum
1.0000059608609866
```

**scipy.optimize.brent**

`scipy.optimize.brent(func, args=(), brack=None, tol=1.48e-08, full_output=0, maxiter=500)`

Given a function of one-variable and a possible bracket, return the local minimum of the function isolated to a fractional precision of `tol`.

**Parameters**

- `func` [callable f(x,*args)] Objective function.
- `args` [tuple, optional] Additional arguments (if present).
- `brack` [tuple, optional] Either a triple (xa,xb,xc) where xa<xb<xc and func(xb) < func(xa), func(xc) or a pair (xa,xb) which are used as a starting interval for a downhill bracket search (see `bracket`). Providing the pair (xa,xb) does not always mean the obtained solution will satisfy xa<=x<=xb.
- `tol` [float, optional] Stop if between iteration change is less than `tol`.
- `full_output` [bool, optional] If True, return all output args (xmin, fval, iter, funcalls).
- `maxiter` [int, optional] Maximum number of iterations in solution.

**Returns**

- `xmin` [ndarray] Optimum point.
- `fval` [float] Optimum value.
- `iter` [int] Number of iterations.
- `funcalls` [int] Number of objective function evaluations made.

**See also:**

- `minimize_scalar`

Interface to minimization algorithms for scalar univariate functions. See the ‘Brent’ method in particular.

**Notes**

Uses inverse parabolic interpolation when possible to speed up convergence of golden section method.

Does not ensure that the minimum lies in the range specified by `brack`. See `fminbound`.

**Examples**

We illustrate the behaviour of the function when `brack` is of size 2 and 3 respectively. In the case where `brack` is of the form (xa,xb), we can see for the given values, the output need not necessarily lie in the range (xa,xb).

```python
>>> def f(x):
...     return x**2
```
>>> from scipy import optimize

```python
>>> minimum = optimize.brent(f, brack=(1, 2))
>>> minimum
0.0
>>> minimum = optimize.brent(f, brack=(-1, 0.5, 2))
>>> minimum
-2.7755575615628914e-17
```

**scipy.optimize.golden**

`scipy.optimize.golden(func, args=(), brack=None, tol=1.4901161193847656e-08, full_output=0, maxiter=5000)`

Return the minimum of a function of one variable using golden section method.

Given a function of one variable and a possible bracketing interval, return the minimum of the function isolated to a fractional precision of tol.

**Parameters**

- `func` : callablefunc(x,*args) Objective function to minimize.
- `args` : tuple, optional Additional arguments (if present), passed to func.
- `brack` : tuple, optional Triple (a,b,c), where (a<b<c) and func(b) < func(a),func(c). If bracket consists of two numbers (a, c), then they are assumed to be a starting interval for a downhill bracket search (see `bracket`); it doesn’t always mean that obtained solution will satisfy a<=x<=c.
- `tol` : float, optional x tolerance stop criterion
- `full_output` : bool, optional If True, return optional outputs.
- `maxiter` : int Maximum number of iterations to perform.

**See also:**

`minimize_scalar`

Interface to minimization algorithms for scalar univariate functions. See the ‘Golden’ method in particular.

**Notes**

Uses analog of bisection method to decrease the bracketed interval.

**Examples**

We illustrate the behaviour of the function when `brack` is of size 2 and 3 respectively. In the case where `brack` is of the form (xa, xb), we can see for the given values, the output need not necessarily lie in the range (xa, xb).

```python
>>> def f(x):
...     return x**2

>>> from scipy import optimize
```
```python
>>> minimum = optimize.golden(f, brack=(1, 2))
1.571277788484873e-162
>>> minimum = optimize.golden(f, brack=(-1, 0.5, 2))
-1.571277788484873e-162
```

### Least-Squares

**leastsq** *(func, x0[, args, Dfun, full_output, ...])*  
Minimize the sum of squares of a set of equations.

#### scipy.optimize.leastsq

```python
scipy.optimize.leastsq(func, x0, args=(), Dfun=None, full_output=0, col_deriv=0, ftol=1.49012e-08, xtol=1.49012e-08, gtol=0.0, maxfev=0, epsfcn=None, factor=100, diag=None)
```

Minimize the sum of squares of a set of equations.

```python
x = arg min(sum(func(y)**2, axis=0))
y
```

**Parameters**

- **func**: [callable] should take at least one (possibly length N vector) argument and returns M floating point numbers. It must not return NaNs or fitting might fail.
- **x0**: [ndarray] The starting estimate for the minimization.
- **args**: [tuple, optional] Any extra arguments to func are placed in this tuple.
- **Dfun**: [callable, optional] A function or method to compute the Jacobian of func with derivatives across the rows. If this is None, the Jacobian will be estimated.
- **full_output**: [bool, optional] non-zero to return all optional outputs.
- **col_deriv**: [bool, optional] non-zero to specify that the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).
- **ftol**: [float, optional] Relative error desired in the sum of squares.
- **xtol**: [float, optional] Relative error desired in the approximate solution.
- **gtol**: [float, optional] Orthogonality desired between the function vector and the columns of the Jacobian.
- **maxfev**: [int, optional] The maximum number of calls to the function. If Dfun is provided then the default maxfev is 100*(N+1) where N is the number of elements in x0, otherwise the default maxfev is 200*(N+1).
- **epsfcn**: [float, optional] A variable used in determining a suitable step length for the forward- difference approximation of the Jacobian (for Dfun=None). Normally the actual step length will be sqrt(epsfcn)*x If epsfcn is less than the machine precision, it is assumed that the relative errors are of the order of the machine precision.
- **factor**: [float, optional] A parameter determining the initial step bound (factor * || diag * x ||). Should be in interval (0.1, 100).
- **diag**: [sequence, optional] N positive entries that serve as a scale factors for the variables.

**Returns**

- **x**: [ndarray] The solution (or the result of the last iteration for an unsuccessful call).
cov_x  [ndarray] The inverse of the Hessian. fjac and ipvt are used to construct an estimate of
the Hessian. A value of None indicates a singular matrix, which means the curvature in
parameters x is numerically flat. To obtain the covariance matrix of the parameters x, cov_x
must be multiplied by the variance of the residuals – see curve_fit.

infodict  [dict] a dictionary of optional outputs with the keys:

nfev  The number of function calls
fvec  The function evaluated at the output
fjac  A permutation of the R matrix of a QR factorization of the final approximate
      Jacobian matrix, stored column wise. Together with ipvt, the covariance of the
      estimate can be approximated.
ipvt  An integer array of length N which defines a permutation matrix, p, such that
      fjac*p = q*r, where r is upper triangular with diagonal elements of nonincreas-
      ing magnitude. Column j of p is column ipvt(j) of the identity matrix.
qtf  The vector (transpose(q)*fvec).

mesg  [str] A string message giving information about the cause of failure.
ier  [int] An integer flag. If it is equal to 1, 2, 3 or 4, the solution was found. Otherwise, the
      solution was not found. In either case, the optional output variable ‘mesg’ gives more infor-
      mation.

Notes

“leastsq” is a wrapper around MINPACK’s lmdif and lmder algorithms.

cov_x is a Jacobian approximation to the Hessian of the least squares objective function. This approximation
assumes that the objective function is based on the difference between some observed target data (ydata) and a
(non-linear) function of the parameters f(xdata, params)

\[ \text{func}(\text{params}) = ydata - f(xdata, \text{params}) \]

so that the objective function is

\[ \text{min}_\text{params} \sum ((ydata - f(xdata, \text{params}))^2, \text{axis}=0) \]

The solution, x, is always a 1D array, regardless of the shape of x0, or whether x0 is a scalar.

Root Finding

General nonlinear solvers:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

scipy.optimize.fsolve

scipy.optimize.fsolve(func, x0, args=(), fprime=None, full_output=0, col_deriv=0, xtol=1.49012e-08,
maxfev=0, band=None, epsfcn=None, factor=100, diag=None)

Find the roots of a function.

Return the roots of the (non-linear) equations defined by func(x) = 0 given a starting estimate.
Parameters

- **func** [callable f(x, *args)] A function that takes at least one (possibly vector) argument, and returns a value of the same length.
- **x0** [ndarray] The starting estimate for the roots of func(x) = 0.
- **args** [tuple, optional] Any extra arguments to func.
- **fprime** [callable f(x, *args), optional] A function to compute the Jacobian of func with derivatives across the rows. By default, the Jacobian will be estimated.
- **full_output** [bool, optional] If True, return optional outputs.
- **col_deriv** [bool, optional] Specify whether the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).
- **xtol** [float, optional] The calculation will terminate if the relative error between two consecutive iterates is at most xtol.
- **maxfev** [int, optional] The maximum number of calls to the function. If zero, then 100*(N+1) is the maximum where N is the number of elements in x0.
- **band** [tuple, optional] If set to a two-sequence containing the number of sub- and super-diagonals within the band of the Jacobi matrix, the Jacobi matrix is considered banded (only for fprime=None).
- **epsfcn** [float, optional] A suitable step length for the forward-difference approximation of the Jacobian (for fprime=None). If epsfcn is less than the machine precision, it is assumed that the relative errors in the functions are of the order of the machine precision.
- **factor** [float, optional] A parameter determining the initial step bound (factor * || diag * x||). Should be in the interval (0.1, 100).
- **diag** [sequence, optional] N positive entries that serve as a scale factors for the variables.

Returns

- **x** [ndarray] The solution (or the result of the last iteration for an unsuccessful call).
- **infodict** [dict] A dictionary of optional outputs with the keys:
  - **nfev** number of function calls
  - **njev** number of Jacobian calls
  - **fvec** function evaluated at the output
  - **fjac** the orthogonal matrix, q, produced by the QR factorization of the final approximate Jacobian matrix, stored column wise
  - **r** upper triangular matrix produced by QR factorization of the same matrix
  - **qt** the vector (transpose(q) * fvec)
  - **ier** [int] An integer flag. Set to 1 if a solution was found, otherwise refer to mesg for more information.
  - **mesg** [str] If no solution is found, mesg details the cause of failure.

See also:

- **root**

  Interface to root finding algorithms for multivariate functions. See the method=''hybr'' in particular.

Notes

- **fsolve** is a wrapper around MINPACK’s hybrd and hybrj algorithms.
scipy.optimize.broyden1

Find a root of a function, using Broyden’s first Jacobian approximation.

This method is also known as “Broyden’s good method”.

Parameters

- **F** [function(x) -> f] Function whose root to find; should take and return an array-like object.
- **xin** [array_like] Initial guess for the solution
- **alpha** [float, optional] Initial guess for the Jacobian is $(-1/\alpha)$.
- **reduction_method** [str or tuple, optional] Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form (method, param1, param2, ...) that gives the name of the method and values for additional parameters.
  - **restart**: drop all matrix columns. Has no extra parameters.
  - **simple**: drop oldest matrix column. Has no extra parameters.
  - **svd**: keep only the most significant SVD components. Takes an extra parameter, **to_retain**, which determines the number of SVD components to retain when rank reduction is done. Default is max_rank - 2.
- **max_rank** [int, optional] Maximum rank for the Broyden matrix. Default is infinity (ie., no rank reduction).
- **iter** [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- **verbose** [bool, optional] Print status to stdout on every iteration.
- **maxiter** [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, **NoConvergence** is raised.
- **f_tol** [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- **f_rtol** [float, optional] Relative tolerance for the residual. If omitted, not used.
- **x_tol** [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- **x_rtol** [float, optional] Relative minimum step size. If omitted, not used.
- **tol_norm** [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
- **line_search** [None, ‘armijo’ (default), ‘wolfe’], optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.
- **callback** [function, optional] Optional callback function. It is called on every iteration as **callback(x, f)** where **x** is the current solution and **f** the corresponding residual.

Returns

- **sol** [ndarray] An array (of similar array type as **x0**) containing the final solution.

Raises

- **NoConvergence**
  - When a solution was not found.
Notes

This algorithm implements the inverse Jacobian Quasi-Newton update

\[ H_+ = H + (dx - H df) dx^\dagger H / (dx^\dagger H df) \]

which corresponds to Broyden’s first Jacobian update

\[ J_+ = J + (df - J dx) dx^\dagger / dx^\dagger dx \]

References

[1] scipy.optimize.broyden2

Find a root of a function, using Broyden’s second Jacobian approximation.

This method is also known as “Broyden’s bad method”.

Parameters

- \(F\) [function(x) -> f] Function whose root to find; should take and return an array-like object.
- \(xin\) [array_like] Initial guess for the solution
- \(alpha\) [float, optional] Initial guess for the Jacobian is \((-1/alpha)\).
- \(reduction\_method\) [str or tuple, optional] Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form (method, param1, param2, ...) that gives the name of the method and values for additional parameters. Methods available:
  - \(restart\): drop all matrix columns. Has no extra parameters.
  - \(simple\): drop oldest matrix column. Has no extra parameters.
  - \(svd\): keep only the most significant SVD components. Takes an extra parameter, to_retain, which determines the number of SVD components to retain when rank reduction is done. Default is max_rank - 2.
- \(max\_rank\) [int, optional] Maximum rank for the Broyden matrix. Default is infinity (ie., no rank reduction).
- \(iter\) [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- \(verbose\) [bool, optional] Print status to stdout on every iteration.
- \(maxiter\) [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, NoConvergence is raised.
- \(f\_tol\) [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- \(f\_rtol\) [float, optional] Relative tolerance for the residual. If omitted, not used.
- \(x\_tol\) [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- \(x\_rtol\) [float, optional] Relative minimum step size. If omitted, not used.
- \(tol\_norm\) [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
line_search

[[None, 'armijo' (default), 'wolfe'], optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.

callback

[function, optional] Optional callback function. It is called on every iteration as callback(x, f) where x is the current solution and f the corresponding residual.

Returns

sol

[ndarray] An array (of similar array type as x0) containing the final solution.

Raises

NoConvergence

When a solution was not found.

Notes

This algorithm implements the inverse Jacobian Quasi-Newton update

\[ H_+ = H + \frac{(dx - H df)df^\dagger}{(df^\dagger df)} \]

corresponding to Broyden’s second method.

Large-scale nonlinear solvers:

<table>
<thead>
<tr>
<th>newton_krylov(F, xin[, iter, rdiff, method, ...])</th>
<th>Find a root of a function, using Krylov approximation for inverse Jacobian.</th>
</tr>
</thead>
<tbody>
<tr>
<td>anderson(F, xin[, iter, alpha, w0, M, ...])</td>
<td>Find a root of a function, using (extended) Anderson mixing.</td>
</tr>
</tbody>
</table>

scipy.optimize.newton_krylov

scipy.optimize.newton_krylov(F, xin, iter=None, rdiff=None, method='lgmres', inner_maxiter=20, inner_M=None, outer_k=10, verbose=False, maxiter=None, f_tol=None, f_rtol=None, x_tol=None, x_rtol=None, tol_norm=None, line_search='armijo', callback=None, **kw)

Find a root of a function, using Krylov approximation for inverse Jacobian.

This method is suitable for solving large-scale problems.

Parameters

F

[function(x) -> f] Function whose root to find; should take and return an array-like object.

xin

[array_like] Initial guess for the solution

rdiff

[float, optional] Relative step size to use in numerical differentiation.

method

[{'lgmres', 'gmres', 'bicgstab', 'cgs', 'minres'} or function] Krylov method to use to approximate the Jacobian. Can be a string, or a function implementing the same interface as the iterative solvers in scipy.sparse.linalg. The default is scipy.sparse.linalg.lgmres.

inner_M

[LinearOperator or InverseJacobian] Preconditioner for the inner Krylov iteration. Note that you can use also inverse Jacobians as (adaptive) preconditioners. For example,
from scipy.optimize.nonlin import BroydenFirst, ...
KrylovJacobian
>>> from scipy.optimize.nonlin import InverseJacobian
>>> jac = BroydenFirst()
>>> kjac = KrylovJacobian(inner_M=InverseJacobian(jac))

If the preconditioner has a method named ‘update’, it will be called as update(x, f) after each nonlinear step, with x giving the current point, and f the current function value.

inner_tol, inner_maxiter, ...
Parameters to pass on to the “inner” Krylov solver. See scipy.sparse.linalg.gmres for details.

outer_k [int, optional] Size of the subspace kept across LGMRES nonlinear iterations. See scipy.sparse.linalg.lgmres for details.
iter [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
verbose [bool, optional] Print status to stdout on every iteration.
maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, NoConvergence is raised.
f_tol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
f_rtol [float, optional] Relative tolerance for the residual. If omitted, not used.
x_tol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
x_rtol [float, optional] Relative minimum step size. If omitted, not used.
tol_norm [function(vector)->scalar, optional] Norm to use in convergence check. Default is the maximum norm.
line_search [{None, ‘armijo’ (default), ‘wolfe’}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.
callback [function, optional] Optional callback function. It is called on every iteration as callback(x, f) where x is the current solution and f the corresponding residual.

Returns
sol [ndarray] An array (of similar array type as x0) containing the final solution.

Raises
NoConvergence
When a solution was not found.

scipy.sparse.linalg.gmres
scipy.sparse.linalg.lgmres

Notes
This function implements a Newton-Krylov solver. The basic idea is to compute the inverse of the Jacobian with an iterative Krylov method. These methods require only evaluating the Jacobian-vector products, which are conveniently approximated by a finite difference:

$$Jv \approx (f(x + \omega * v/|v|) - f(x))/\omega$$
Due to the use of iterative matrix inverses, these methods can deal with large nonlinear problems.

SciPy’s `scipy.sparse.linalg` module offers a selection of Krylov solvers to choose from. The default here is `lgmres`, which is a variant of restarted GMRES iteration that reuses some of the information obtained in the previous Newton steps to invert Jacobians in subsequent steps.

For a review on Newton-Krylov methods, see for example [1], and for the LGMRES sparse inverse method, see [2].

[1], [2]

`scipy.optimize.anderson`

Find a root of a function, using (extended) Anderson mixing.

The Jacobian is formed by for a ‘best’ solution in the space spanned by last $M$ vectors. As a result, only a $M \times M$ matrix inversions and $M \times N$ multiplications are required. [Ey]

**Parameters**

- `F` [function(x) -> f] Function whose root to find; should take and return an array-like object.
- `xin` [array_like] Initial guess for the solution.
- `alpha` [float, optional] Initial guess for the Jacobian is $(-1/alpha)$.
- `M` [float, optional] Number of previous vectors to retain. Defaults to 5.
- `w0` [float, optional] Regularization parameter for numerical stability. Compared to unity, good values of the order of 0.01.
- `iter` [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- `verbose` [bool, optional] Print status to stdout on every iteration.
- `maxiter` [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.
- `f_tol` [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is $6e^{-6}$.
- `f_rtol` [float, optional] Relative tolerance for the residual. If omitted, not used.
- `x_tol` [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- `x_rtol` [float, optional] Relative minimum step size. If omitted, not used.
- `tol_norm` [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
- `line_search` [[None, ‘armijo’ (default), ‘wolfe’], optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.
- `callback` [function, optional] Optional callback function. It is called on every iteration as `callback(x, f)` where `x` is the current solution and `f` the corresponding residual.

**Returns**

- `sol` [ndarray] An array (of similar array type as `x0`) containing the final solution.

**Raises**
NoConvergence
When a solution was not found.

scipy.optimize.excitingmixing

Find a root of a function, using a tuned diagonal Jacobian approximation.

The Jacobian matrix is diagonal and is tuned on each iteration.

**Warning:** This algorithm may be useful for specific problems, but whether it will work may depend strongly on the problem.

**Parameters**

F      [function(x) -> f] Function whose root to find; should take and return an array-like object.
xin    [array_like] Initial guess for the solution
alpha  [float, optional] Initial Jacobian approximation is (-1/alpha).
alphamax [float, optional] The entries of the diagonal Jacobian are kept in the range [alpha, alphamax].
iter   [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
verbose [bool, optional] Print status to stdout on every iteration.
maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, NoConvergence is raised.
f_tol   [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
f_rtol  [float, optional] Relative tolerance for the residual. If omitted, not used.
x_tol   [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
x_rtol  [float, optional] Relative minimum step size. If omitted, not used.
tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
line_search  [[None, ‘armijo’ (default), ‘wolfe’], optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.
**callback** [function, optional] Optional callback function. It is called on every iteration as callback(x, f) where x is the current solution and f the corresponding residual.

**Returns**

**sol** [ndarray] An array (of similar array type as x0) containing the final solution.

**Raises**

**NoConvergence**
When a solution was not found.

**scipy.optimize.linearmixing**

scipy.optimize.linearmixing(F, xin, iter=None, alpha=None, verbose=False, maxiter=None, f_tol=None, f_rtol=None, x_tol=None, x_rtol=None, tol_norm=None, line_search='armijo', callback=None, **kw)

Find a root of a function, using a scalar Jacobian approximation.

**Warning:** This algorithm may be useful for specific problems, but whether it will work may depend strongly on the problem.

**Parameters**

- **F** [function(x) -> f] Function whose root to find; should take and return an array-like object.
- **xin** [array_like] Initial guess for the solution.
- **alpha** [float, optional] The Jacobian approximation is (-1/alpha).
- **iter** [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- **verbose** [bool, optional] Print status to stdout on every iteration.
- **maxiter** [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, **NoConvergence** is raised.
- **f_tol** [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- **f_rtol** [float, optional] Relative tolerance for the residual. If omitted, not used.
- **x_tol** [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- **x_rtol** [float, optional] Relative minimum step size. If omitted, not used.
- **tol_norm** [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
- **line_search** [{None, ‘armijo’ (default), ‘wolfe’}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.
- **callback** [function, optional] Optional callback function. It is called on every iteration as callback(x, f) where x is the current solution and f the corresponding residual.

**Returns**

**sol** [ndarray] An array (of similar array type as x0) containing the final solution.

**Raises**

**NoConvergence**
When a solution was not found.
Scipy Reference Guide, Release 1.3.2

`scipy.optimize.diagbroyden`

`scipy.optimize.diagbroyden(F, xin, iter=None, alpha=None, verbose=False, maxiter=None, f_tol=None, f_rtol=None, x_tol=None, x_rtol=None, tol_norm=None, line_search='armijo', callback=None, **kw)`

Find a root of a function, using diagonal Broyden Jacobian approximation.

The Jacobian approximation is derived from previous iterations, by retaining only the diagonal of Broyden matrices.

**Warning:** This algorithm may be useful for specific problems, but whether it will work may depend strongly on the problem.

**Parameters**

- `F` ([function(x) -> f]) Function whose root to find; should take and return an array-like object.
- `xin` ([array_like]) Initial guess for the solution
- `alpha` ([float, optional]) Initial guess for the Jacobian is (-1/alpha).
- `iter` ([int, optional]) Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- `verbose` ([bool, optional]) Print status to stdout on every iteration.
- `maxiter` ([int, optional]) Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.
- `f_tol` ([float, optional]) Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- `f_rtol` ([float, optional]) Relative tolerance for the residual. If omitted, not used.
- `x_tol` ([float, optional]) Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- `x_rtol` ([float, optional]) Relative minimum step size. If omitted, not used.
- `tol_norm` ([function(vector) -> scalar, optional]) Norm to use in convergence check. Default is the maximum norm.
- `line_search` ([None, ‘armijo’ (default), ‘wolfe’], optional) Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.
- `callback` ([function, optional]) Optional callback function. It is called on every iteration as `callback(x, f)` where `x` is the current solution and `f` the corresponding residual.

**Returns**

- `sol` ([ndarray]) An array (of similar array type as `xin`) containing the final solution.

**Raises**

- `NoConvergence` When a solution was not found.

Additional information on the nonlinear solvers

### 6.19 Nonlinear solvers

This is a collection of general-purpose nonlinear multidimensional solvers. These solvers find \( x \) for which \( F(x) = 0 \). Both \( x \) and \( F \) can be multidimensional.
6.19.1 Routines

Large-scale nonlinear solvers:

- `newton_krylov(F, xin[, iter, rdiff, method, ...])`: Find a root of a function, using Krylov approximation for inverse Jacobian.
- `anderson(F, xin[, iter, alpha, w0, M, ...])`: Find a root of a function, using (extended) Anderson mixing.

General nonlinear solvers:

- `broyden1(F, xin[, iter, alpha, ...])`: Find a root of a function, using Broyden’s first Jacobian approximation.
- `broyden2(F, xin[, iter, alpha, ...])`: Find a root of a function, using Broyden’s second Jacobian approximation.

Simple iterations:

- `excitingmixing(F, xin[, iter, alpha, ...])`: Find a root of a function, using a tuned diagonal Jacobian approximation.
- `linearmixing(F, xin[, iter, alpha, verbose, ...])`: Find a root of a function, using a scalar Jacobian approximation.
- `diagbroyden(F, xin[, iter, alpha, verbose, ...])`: Find a root of a function, using diagonal Broyden Jacobian approximation.

6.19.2 Examples

Small problem

```python
>>> def F(x):
...    return np.cos(x) + x[::] - [1, 2, 3, 4]
>>> import scipy.optimize
>>> x = scipy.optimize.broyden1(F, [1,1,1,1], f_tol=1e-14)
>>> x
array([ 4.04674914, 3.91158389, 2.71791677, 1.61756251])
>>> np.cos(x) + x[:-1]
array([ 1., 2., 3., 4.])
```

Large problem

Suppose that we needed to solve the following integrodifferential equation on the square $[0, 1] \times [0, 1]$:

$$
\nabla^2 P = 10 \left( \int_0^1 \int_0^1 \cosh(P) \, dx \, dy \right)^2
$$

with $P(x, 1) = 1$ and $P = 0$ elsewhere on the boundary of the square.

The solution can be found using the `newton_krylov` solver:

```python
import numpy as np
from scipy.optimize import newton_krylov
from numpy import cosh, zeros_like, mgrid, zeros
```
# parameters
nx, ny = 75, 75
hx, hy = 1. / (nx - 1), 1. / (ny - 1)

P_left, P_right = 0, 0
P_top, P_bottom = 1, 0

def residual(P):
    d2x = zeros_like(P)
    d2y = zeros_like(P)

    d2x[1:-1] = (P[2:] - 2 * P[1:-1] + P[:-2]) / hx / hx
    d2x[0] = (P[1] - 2 * P[0] + P_left) / hx / hx
    d2x[-1] = (P_right - 2 * P[1] + P[2]) / hx / hx

    d2y[:, 1:-1] = (P[:, 2:] - 2 * P[:, 1:-1] + P[:, :-2]) / hy / hy
    d2y[:, 0] = (P[:, 1] - 2 * P[:, 0] + P_bottom) / hy / hy
    d2y[:, -1] = (P_top - 2 * P[:, 1] + P[:, -2]) / hy / hy

    return d2x + d2y - 10 * cosh(P).mean() ** 2

# solve
guess = zeros((nx, ny), float)
sol = newton_krylov(residual, guess, method='lgmres', verbose=1)
print('Residual: %g % abs(residual(sol)).max()')

# visualize
import matplotlib.pyplot as plt
x, y = mgrid[0:1:(nx+1j), 0:1:(ny+1j)]
plt.pcolor(x, y, sol)
plt.colorbar()
plt.show()}
6.20 Cython Optimize Zeros API

The underlying C functions for the following root finders can be accessed directly using Cython:

- \texttt{bisect}
- \texttt{ridder}
- \texttt{brent}
- \texttt{brentq}

The Cython API for the zeros functions is similar except there is no \texttt{disp} argument. Import the zeros functions using \texttt{cimport from scipy.optimize.cython_optimize}.

```python
from scipy.optimize.cython_optimize cimport bisect, ridder, brentq, brent
```

6.20.1 Callback Signature

The zeros functions in \texttt{cython_optimize} expect a callback that takes a double for the scalar independent variable as the 1st argument and a user defined \texttt{struct} with any extra parameters as the 2nd argument.

```python
double (*callback_type)(double, void*)
```

6.20.2 Examples

Usage of \texttt{cython_optimize} requires Cython to write callbacks that are compiled into C. For more information on compiling Cython see the Cython Documentation.

These are the basic steps:

1. Create a Cython \texttt{.pyx} file, for example: \texttt{myexample.pyx}.
2. Import the desired root finder from \texttt{cython_optimize}.
3. Write the callback function, and call the selected zeros function passing the callback, any extra arguments, and the other solver parameters.

```python
from scipy.optimize.cython_optimize cimport brentq
# import math from Cython
from libc cimport math
myargs = {'C0': 1.0, 'C1': 0.7}  # a dictionary of extra arguments
XLO, XHI = 0.5, 1.0  # lower and upper search boundaries
XTOL, RTOL, MITR = 1e-3, 1e-3, 10  # other solver parameters

# user defined struct for extra parameters
ctypedef struct test_params:
    double C0
    double C1

# user defined callback
cdef double f(double x, void *args):
```

(continues on next page)
4. If you want to call your function from Python, create a Cython wrapper, and a Python function that calls the wrapper, or use `cpdef`. Then in Python you can import and run the example.

```python
from myexample import brentq_example
x = brentq_example()
# 0.6999942848231314
```

5. Create a Cython `.pxd` file if you need to export any Cython functions.

### 6.20.3 Full Output

The functions in `cython_optimize` can also copy the full output from the solver to a C struct that is passed as its last argument. If you don’t want the full output just pass `NULL`. The full output struct must be type `zeros_full_output`, which is defined in `scipy.optimize.cython_optimize` with the following fields:

- `int funcalls`: number of function calls
- `int iterations`: number of iterations
- `int error_num`: error number
- `double root`: root of function

The root is copied by `cython_optimize` to the full output struct. An error number of -1 means a sign error, -2 means a convergence error, and 0 means the solver converged. Continuing from the previous example:

```python
from scipy.optimize.cython_optimize cimport zeros_full_output

cdef brent_full_output brentq_full_output_wrapper_example(  
dict args, double xa, double xb, double xtol, double rtol,  
int mitr):
    # Cython brentq solver with full output
    cdef test_params myargs = args
    return myargs.C0 - math.exp(-(x - myargs.C1))
```

(continues on next page)
cdef zeros_full_output my_full_output
    # use my_full_output instead of NULL
brentq(f, xa, xb, &myargs, xtol, rtol, mitr, &my_full_output)
return my_full_output

# Python function
def brent_full_output_example(args=myargs, xa=XLO, xb=XHI, xtol=XTOL,
                            rtol=RTOL, mitr=MTR):
    """Returns full output""
    return brentq_full_output_wrapper_example(args, xa, xb, xtol, rtol,
                                              mitr)
result = brent_full_output_example()
    # {'error_num': 0,
    #  'funcalls': 5,
    #  'iterations': 5,
    #  'root': 0.6999942848231314)

6.21 Signal processing (scipy.signal)

6.21.1 Convolution

**convolve**<br>**correlate**<br>**fftconvolve**<br>**convolve2d**<br>**correlate2d**<br>**sepfir2d()**

### scipy.signal.convolve

**scipy.signal.convolve**<br>Convolve two N-dimensional arrays.

Convolve *in1* and *in2*, with the output size determined by the *mode* argument.

#### Parameters

- **in1**<br>[
array_like]<br>First input.

- **in2**<br>[
array_like]<br>Second input. Should have the same number of dimensions as *in1*.

- **mode**<br>[str{'full', 'valid', 'same'}, optional]<br>A string indicating the size of the output:
  - **full**<br>The output is the full discrete linear convolution of the inputs. (Default)
  - **valid**<br>The output consists only of those elements that do not rely on the zero-padding. In 'valid' mode, either *in1* or *in2* must be at least as large as the other in every dimension.
  - **same**<br>The output is the same size as *in1*, centered with respect to the 'full' output.

- **method**<br>[str{'auto', 'direct', 'fft'}, optional]<br>A string indicating which method to use to calculate the convolution.
The convolution is determined directly from sums, the definition of convolution.

The Fourier Transform is used to perform the convolution by calling `fftconvolve`.

Automatically chooses direct or Fourier method based on an estimate of which is faster (default). See Notes for more detail. New in version 0.19.0.

**Returns**

- `convolve`  
  [array] An N-dimensional array containing a subset of the discrete linear convolution of `in1` with `in2`.

See also:

- `numpy.polymul`  
  performs polynomial multiplication (same operation, but also accepts `poly1d` objects)

- `choose_conv_method`  
  chooses the fastest appropriate convolution method

**fftconvolve**

**Notes**

By default, `convolve` and `correlate` use `method='auto'`, which calls `choose_conv_method` to choose the fastest method using pre-computed values (`choose_conv_method` can also measure real-world timing with a keyword argument). Because `fftconvolve` relies on floating point numbers, there are certain constraints that may force `method='direct'` (more detail in `choose_conv_method` docstring).

**Examples**

Smooth a square pulse using a Hann window:

```python
>>> from scipy import signal  
>>> sig = np.repeat([0., 1., 0.], 100)  
>>> win = signal.hann(50)  
>>> filtered = signal.convolve(sig, win, mode='same') / sum(win)
```

```python
>>> import matplotlib.pyplot as plt  
>>> fig, (ax_orig, ax_win, ax_filt) = plt.subplots(3, 1, sharex=True)  
>>> ax_orig.plot(sig)  
>>> ax_orig.set_title('Original pulse')  
>>> ax_orig.margins(0, 0.1)  
>>> ax_win.plot(win)  
>>> ax_win.set_title('Filter impulse response')  
>>> ax_win.margins(0, 0.1)  
>>> ax_filt.plot(filtered)  
>>> ax_filt.set_title('Filtered signal')  
>>> ax_filt.margins(0, 0.1)  
>>> fig.tight_layout()  
>>> fig.show()
```
scipy.signal.correlate

scipy.signal.correlate(in1, in2, mode='full', method='auto')

Cross-correlate two N-dimensional arrays.

Cross-correlate `in1` and `in2`, with the output size determined by the `mode` argument.

**Parameters**

- `in1` [array_like] First input. Should have the same number of dimensions as `in1`.
- `in2` [array_like] Second input. Should have the same number of dimensions as `in1`.
- `mode` [str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:
  - `full` The output is the full discrete linear cross-correlation of the inputs. (Default)
  - `valid` The output consists only of those elements that do not rely on the zero-padding. In 'valid' mode, either `in1` or `in2` must be at least as large as the other in every dimension.
  - `same` The output is the same size as `in1`, centered with respect to the 'full' output.
- `method` [str {'auto', 'direct', 'fft'}, optional] A string indicating which method to use to calculate the correlation:
  - `direct` The correlation is determined directly from sums, the definition of correlation.
  - `fft` The Fast Fourier Transform is used to perform the correlation more quickly (only available for numerical arrays.)
  - `auto` Automatically chooses direct or Fourier method based on an estimate of which is faster (default). See `convolve` Notes for more detail. New in version 0.19.0.

**Returns**

- `correlate` [array] An N-dimensional array containing a subset of the discrete linear cross-correlation of `in1` with `in2`.

See also:

- `choose_conv_method`
  - contains more documentation on `method`. 
Notes

The correlation z of two d-dimensional arrays x and y is defined as:

\[ z[\ldots, k, \ldots] = \sum[\ldots, i_1, \ldots] x[\ldots, i_1, \ldots] \times \text{conj}(y[\ldots, i_1 - k, \ldots \leftarrow]) \]

This way, if x and y are 1-D arrays and \( z = \text{correlate}(x, y, \text{'full'}) \) then

\[ z[k] = (x \star y)(k - N + 1) = \sum_{l=0}^{||x||-1} x_l y_{l-k+N-1} \]

for \( k = 0, 1, \ldots, ||x|| + ||y|| - 2 \)

where \( ||x|| \) is the length of x, \( N = \max(||x||, ||y||) \), and \( y_m \) is 0 when m is outside the range of y.

method='fft' only works for numerical arrays as it relies on \texttt{fftconvolve}. In certain cases (i.e., arrays of objects or when rounding integers can lose precision), method='direct' is always used.

Examples

Implement a matched filter using cross-correlation, to recover a signal that has passed through a noisy channel.

```python
>>> from scipy import signal
>>> sig = np.repeat([0., 1., 1., 0., 1., 0., 0., 1.], 128)
>>> sig_noise = sig + np.random.randn(len(sig))
>>> corr = signal.correlate(sig_noise, np.ones(128), mode='same') / 128

>>> import matplotlib.pyplot as plt
>>> clock = np.arange(64, len(sig), 128)
>>> fig, (ax_orig, ax_noise, ax_corr) = plt.subplots(3, 1, sharex=True)
>>> ax_orig.plot(sig)
>>> ax_orig.plot(clock, sig[clock], 'ro')
>>> ax_orig.set_title('Original signal')
>>> ax_noise.plot(sig_noise)
>>> ax_noise.set_title('Signal with noise')
>>> ax_corr.plot(corr)
>>> ax_corr.plot(clock, corr[clock], 'ro')
>>> ax_corr.axhline(0.5, ls=':')
>>> ax_corr.set_title('Cross-correlated with rectangular pulse')
>>> ax_orig.margins(0, 0.1)
>>> fig.tight_layout()
>>> fig.show()
```

\texttt{scipy.signal.fftconvolve}

\texttt{scipy.signal.fftconvolve}(\textit{in1, in2, mode='full', axes=None})

Convolve two N-dimensional arrays using FFT.

Convolve \textit{in1} and \textit{in2} using the fast Fourier transform method, with the output size determined by the \textit{mode} argument.

This is generally much faster than \texttt{convolve} for large arrays (\( n > 500 \)), but can be slower when only a few output values are needed, and can only output float arrays (int or object array inputs will be cast to float).
As of v0.19, \texttt{convolve} automatically chooses this method or the direct method based on an estimation of which is faster.

**Parameters**

- \texttt{in1} \[\text{array_like}\] First input.
- \texttt{in2} \[\text{array_like}\] Second input. Should have the same number of dimensions as \texttt{in1}.
- \texttt{mode} \[\text{str} \{\text{‘full’, ‘valid’, ‘same’}\}, \text{optional}\] A string indicating the size of the output:
  - \texttt{full} The output is the full discrete linear convolution of the inputs. (Default)
  - \texttt{valid} The output consists only of those elements that do not rely on the zero-padding. In ‘valid’ mode, either \texttt{in1 or in2} must be at least as large as the other in every dimension.
  - \texttt{same} The output is the same size as \texttt{in1}, centered with respect to the ‘full’ output. \texttt{axis} : tuple, optional
- \texttt{axes} \[\text{int or array_like of ints or None, optional}\] Axes over which to compute the convolution. The default is over all axes.

**Returns**

- \texttt{out} \[\text{array}\] An N-dimensional array containing a subset of the discrete linear convolution of \texttt{in1} with \texttt{in2}.

**Examples**

Autocorrelation of white noise is an impulse.

```python
>>> from scipy import signal
>>> sig = np.random.randn(1000)
>>> autocorr = signal.fftconvolve(sig, sig[::-1], mode='full')
```

```python
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_mag) = plt.subplots(2, 1)
>>> ax_orig.plot(sig)
>>> ax_orig.set_title('White noise')
```

(continues on next page)
Gaussian blur implemented using FFT convolution. Notice the dark borders around the image, due to the zero-padding beyond its boundaries. The `convolve2d` function allows for other types of image boundaries, but is far slower.

```python
>>> from scipy import misc
>>> face = misc.face(gray=True)
>>> kernel = np.outer(signal.gaussian(70, 8), signal.gaussian(70, 8))
>>> blurred = signal.fftconvolve(face, kernel, mode='same')
```

```python
>>> fig, (ax_orig, ax_kernel, ax_blurred) = plt.subplots(3, 1, ...
                                        figsize=(6, 15))
>>> ax_orig.imshow(face, cmap='gray')
>>> ax_orig.set_title('Original')
>>> ax_orig.set_axis_off()
>>> ax_kernel.imshow(kernel, cmap='gray')
>>> ax_kernel.set_title('Gaussian kernel')
>>> ax_kernel.set_axis_off()
>>> ax_blurred.imshow(blurred, cmap='gray')
>>> ax_blurred.set_title('Blurred')
>>> ax_blurred.set_axis_off()
>>> fig.show()
```

**scipy.signal.convolve2d**

*scipy.signal.convolve2d*(in1, in2, mode='full', boundary='fill', fillvalue=0)

Convolve two 2-dimensional arrays.
Convolve in1 and in2 with output size determined by mode, and boundary conditions determined by boundary and fillvalue.

**Parameters**

in1  [array_like]  First input.

in2  [array_like]  Second input. Should have the same number of dimensions as in1.

mode  [str {'full', 'valid', 'same'}, optional]  A string indicating the size of the output:

    full  The output is the full discrete linear convolution of the inputs. (Default)

    valid  The output consists only of those elements that do not rely on the zero-padding.

    In 'valid' mode, either in1 or in2 must be at least as large as the other in every dimension.

    same  The output is the same size as in1, centered with respect to the 'full' output.

boundary  [str {'fill', 'wrap', 'symm'}, optional]  A flag indicating how to handle boundaries:

    fill  pad input arrays with fillvalue. (default)

    wrap  circular boundary conditions.

    symm  symmetrical boundary conditions.

fillvalue  [scalar, optional]  Value to fill pad input arrays with. Default is 0.

**Returns**

out  [ndarray]  A 2-dimensional array containing a subset of the discrete linear convolution of in1 with in2.

**Examples**

Compute the gradient of an image by 2D convolution with a complex Scharr operator. (Horizontal operator is real, vertical is imaginary.) Use symmetric boundary condition to avoid creating edges at the image boundaries.

```python
>>> from scipy import signal
>>> from scipy import misc
>>> ascent = misc.ascent()
>>> scharr = np.array([[-3, 0-10j, +3], [-10+0j, 0+0j, +10+0j], [-3+3j, 0+10j, +3+3j]]) # Gx + j*Gy
>>> grad = signal.convolve2d(ascent, scharr, boundary='symm', mode='same')
```

```python
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_mag, ax_ang) = plt.subplots(3, 1, figsize=(6, 15))
>>> ax_orig.imshow(ascent, cmap='gray')
>>> ax_orig.set_title('Original')
>>> ax_orig.set_axis_off()
>>> ax_mag.imshow(np.abs(grad), cmap='gray')
>>> ax_mag.set_title('Gradient magnitude')
>>> ax_mag.set_axis_off()
>>> ax_ang.imshow(np.angle(grad), cmap='hsv') # hsv is cyclic, like angles
>>> ax_ang.set_title('Gradient orientation')
>>> ax_ang.set_axis_off()
>>> fig.show()
```

**scipy.signal.correlate2d**

`scipy.signal.correlate2d`(in1, in2, mode='full', boundary='fill', fillvalue=0)

Cross-correlate two 2-dimensional arrays.
Cross correlate \(in1\) and \(in2\) with output size determined by \(mode\), and boundary conditions determined by \(boundary\) and \(fillvalue\).

**Parameters**

- **in1** [array_like] First input.
- **in2** [array_like] Second input. Should have the same number of dimensions as \(in1\).
- **mode** [str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:
  - **full** The output is the full discrete linear cross-correlation of the inputs. (Default)
  - **valid** The output consists only of those elements that do not rely on the zero-padding.
    - In 'valid' mode, either \(in1\) or \(in2\) must be at least as large as the other in every dimension.
  - **same** The output is the same size as \(in1\), centered with respect to the 'full' output.
- **boundary** [str {'fill', 'wrap', 'symm'}, optional] A flag indicating how to handle boundaries:
  - **fill** pad input arrays with \(fillvalue\). (default)
  - **wrap** circular boundary conditions.
  - **symm** symmetrical boundary conditions.
- **fillvalue** [scalar, optional] Value to fill pad input arrays with. Default is 0.

**Returns**

**correlate2d** [ndarray] A 2-dimensional array containing a subset of the discrete linear cross-correlation of \(in1\) with \(in2\).

**Examples**

Use 2D cross-correlation to find the location of a template in a noisy image:

```python
>>> from scipy import signal
>>> from scipy import misc
>>> face = misc.face(gray=True) - misc.face(gray=True).mean()
>>> template = np.copy(face[300:365, 670:750])  # right eye
>>> template -= template.mean()
>>> face = face + np.random.randn(*face.shape) * 50  # add noise
>>> corr = signal.correlate2d(face, template, boundary='symm', mode='same')
>>> y, x = np.unravel_index(np.argmax(corr), corr.shape)  # find the match
```

```python
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_template, ax_corr) = plt.subplots(3, 1, figsize=(6, 15))
>>> ax_orig.imshow(face, cmap='gray')
>>> ax_orig.set_title('Original')
>>> ax_orig.set_axis_off()
>>> ax_template.imshow(template, cmap='gray')
>>> ax_template.set_title('Template')
>>> ax_template.set_axis_off()
>>> ax_corr.imshow(corr, cmap='gray')
>>> ax_corr.set_title('Cross-correlation')
>>> ax_corr.set_axis_off()
>>> ax_orig.plot(x, y, 'ro')
>>> fig.show()
```
Cross-correlation
scipy.signal.sepfir2d

scipy.signal.sepfir2d()

Description:

scipy.signal.choose_conv_method

scipy.signal.choose_conv_method(in1, in2, mode='full', measure=False)

Findthefastestconvolution/correlationmethod.

Thisprimarilyexiststobecalledduringthemethod='auto'optioninconvolveandcorrelate, butcan
alsobeusedwhenperformingmanyconvolutionsofthesameinputshapesanddtypes,determiningwhichmethod
touseforallofthem, either to avoid the overhead of the 'auto' option or to use accurate real-world measurements.

Parameters
in1 [array_like] Thefirstargumentpassedintotheconvolutionfunction.
in2 [array_like] Thesecondargumentpassedintotheconvolutionfunction.
mode [str {'full', 'valid', 'same'},optional] Astringindicatingthesizeoftheoutput:
full Theoutputisthefulldiscretelinearconvolutionoftheinputs. (Default)
valid Theoutputconsistsonlyofthoseelementsthatdonotrelyonthezeropadding.
same Theoutputisthesamesizeasin1, centeredwithrespecttothe'full'output.
measure [bool,optional] If True, run and time the convolution of in1 and in2 with both methods and
returnthefastest. If False (default), predict the fastest method using precomputed values.

Returns
method [str] Astringindicatingwhichconvolutionmethodisfastest, either 'direct' or 'fft'
times [dict,optional] A dictionarycontainingthetimes(inseconds)neededforeachmethod. This
valueisonlyreturnedifmeasure=True.

See also:
convolve
correlate

Notes
Forlarge n, measure=False is accurate and can quickly determine the fastest method to perform the convolu-
tion. However, this is not as accurate for small n (when any dimension in the input or output is small).

Inpractice,wefoundthatthisfunctionestimatesthefastermethoduptoamultiplicativefactorof5 (i.e., the
estimated method is at most 5 times slower than the fastest method). The estimationvaluesweretunedonan
early2015MacBookProwith8GBRAMbutwefoundthatthepredictionheldfairlyaccuratelyacrossdifferent
machines.

Ifmeasure=True, timetheconvolutions. Because thisfunctionusesfftconvolve, an error will be thrown if
itdoesnotsupporttheinputs. Therearecaseswhenfftconvolumesupportstheinputsbutthisfunctionreturns
direct (e.g., to protect against floating point integer precision).

New in version 0.19.
Examples

Estimate the fastest method for a given input:

```python
>>> from scipy import signal
>>> a = np.random.randn(1000)
>>> b = np.random.randn(1000000)
>>> method = signal.choose_conv_method(a, b, mode='same')
>>> method
'fft'
```

This can then be applied to other arrays of the same dtype and shape:

```python
>>> c = np.random.randn(1000)
>>> d = np.random.randn(1000000)
>>> # `method` works with correlate and convolve
>>> corr1 = signal.correlate(a, b, mode='same', method=method)
>>> corr2 = signal.correlate(c, d, mode='same', method=method)
>>> conv1 = signal.convolve(a, b, mode='same', method=method)
>>> conv2 = signal.convolve(c, d, mode='same', method=method)
```

**scipy.signal.bspline**

`scipy.signal.bspline`(x, n)

B-spline basis function of order n.

**Notes**

Uses numpy.piecewise and automatic function-generator.

**scipy.signal.cubic**

`scipy.signal.cubic`(x)

A cubic B-spline.
This is a special case of \texttt{bspline}, and equivalent to \texttt{bspline(x, 3)}.

\texttt{scipy.signal.quadratic}

\texttt{scipy.signal.quadratic(x)}

A quadratic B-spline.

This is a special case of \texttt{bspline}, and equivalent to \texttt{bspline(x, 2)}.

\texttt{scipy.signal.gauss_spline}

\texttt{scipy.signal.gauss_spline(x, n)}

Gaussian approximation to B-spline basis function of order \( n \).

\begin{description}
  \item[Parameters]  
    \begin{itemize}
      \item \( n \) [int] The order of the spline. Must be nonnegative, i.e. \( n \geq 0 \).
    \end{itemize}
\end{description}

\textbf{References}

[1]

\texttt{scipy.signal.cspline1d}

\texttt{scipy.signal.cspline1d(signal, lamb=0.0)}

Compute cubic spline coefficients for rank-1 array.

Find the cubic spline coefficients for a 1-D signal assuming mirror-symmetric boundary conditions. To obtain the signal back from the spline representation mirror-symmetric-convolve these coefficients with a length 3 FIR window \([1.0, 4.0, 1.0]/6.0\).

\begin{description}
  \item[Parameters]  
    \begin{itemize}
      \item signal [ndarray] A rank-1 array representing samples of a signal.
      \item lamb [float, optional] Smoothing coefficient, default is 0.0.
    \end{itemize}
\end{description}

\textbf{Returns}

\begin{description}
  \item c [ndarray] Cubic spline coefficients.
\end{description}

\texttt{scipy.signal.qspline1d}

\texttt{scipy.signal.qspline1d(signal, lamb=0.0)}

Compute quadratic spline coefficients for rank-1 array.

Find the quadratic spline coefficients for a 1-D signal assuming mirror-symmetric boundary conditions. To obtain the signal back from the spline representation mirror-symmetric-convolve these coefficients with a length 3 FIR window \([1.0, 6.0, 1.0]/8.0\).

\begin{description}
  \item[Parameters]  
    \begin{itemize}
      \item signal [ndarray] A rank-1 array representing samples of a signal.
      \item lamb [float, optional] Smoothing coefficient (must be zero for now).
    \end{itemize}
\end{description}

\textbf{Returns}

\begin{description}
  \item c [ndarray] Cubic spline coefficients.
scipy.signal.cspline2d

scipy.signal.cspline2d()

Description:
Return the third-order B-spline coefficients over a regularly spaced input grid for the two-dimensional input image. The lambda argument specifies the amount of smoothing. The precision argument allows specifying the precision used when computing the infinite sum needed to apply mirror-symmetric boundary conditions.

scipy.signal.qspline2d

scipy.signal.qspline2d()

Description:
Return the second-order B-spline coefficients over a regularly spaced input grid for the two-dimensional input image. The lambda argument specifies the amount of smoothing. The precision argument allows specifying the precision used when computing the infinite sum needed to apply mirror-symmetric boundary conditions.

scipy.signal.cspline1d_eval

scipy.signal.cspline1d_eval(cj, newx, dx=1.0, x0=0)

Evaluate a spline at the new set of points.

dx is the old sample-spacing while x0 was the old origin. In other-words the old-sample points (knot-points) for which the cj represent spline coefficients were at equally-spaced points of:

\[ \text{oldx = x0 + j*dx, j=0...N-1, with N=len(cj)} \]

Edges are handled using mirror-symmetric boundary conditions.

scipy.signal.qspline1d_eval

scipy.signal.qspline1d_eval(cj, newx, dx=1.0, x0=0)

Evaluate a quadratic spline at the new set of points.

dx is the old sample-spacing while x0 was the old origin. In other-words the old-sample points (knot-points) for which the cj represent spline coefficients were at equally-spaced points of:

\[ \text{oldx = x0 + j*dx, j=0...N-1, with N=len(cj)} \]

Edges are handled using mirror-symmetric boundary conditions.

scipy.signal.spline_filter

scipy.signal.spline_filter(Iin, lmbda=5.0)

Smoothing spline (cubic) filtering of a rank-2 array.

Filter an input data set, Iin, using a (cubic) smoothing spline of fall-off lmbda.

6.21.3 Filtering
**order_filter**

**(a, domain, rank)**

Perform an order filter on an N-dimensional array.

*Parameters*

- **a**  
  [ndarray] The N-dimensional input array.

- **domain**  
  [array_like] A mask array with the same number of dimensions as *a*. Each dimension should have an odd number of elements.

- **rank**  
  [int] A non-negative integer which selects the element from the sorted list (0 corresponds to the smallest element, 1 is the next smallest element, etc.).

*Returns*

- **out**  
  [ndarray] The results of the order filter in an array with the same shape as *a*. 

---

**scipy.signal.order_filter**

The `scipy.signal.order_filter` function allows you to perform an order filter on an N-dimensional array. The domain argument acts as a mask centered over each pixel. The non-zero elements of domain are used to select elements surrounding each input pixel which are placed in a list. The list is sorted, and the output for that pixel is the element corresponding to rank in the sorted list.
Examples

```python
>>> from scipy import signal
>>> x = np.arange(25).reshape(5, 5)
>>> domain = np.identity(3)
>>> x
array([[0, 1, 2, 3, 4],
       [5, 6, 7, 8, 9],
       [10, 11, 12, 13, 14],
       [15, 16, 17, 18, 19],
       [20, 21, 22, 23, 24]])
>>> signal.order_filter(x, domain, 0)
array([[0., 0., 0., 0., 0.],
       [0., 0., 1., 2., 0.],
       [0., 5., 6., 7., 0.],
       [0., 10., 11., 12., 0.],
       [0., 0., 0., 0., 0.]])
>>> signal.order_filter(x, domain, 2)
array([[6., 7., 8., 9., 4.],
       [16., 17., 18., 19., 14.],
       [21., 22., 23., 24., 19.],
       [20., 21., 22., 23., 24.]])
```

**scipy.signal.medfilt**

`scipy.signal.medfilt(volume, kernel_size=None)`

Perform a median filter on an N-dimensional array.

Apply a median filter to the input array using a local window-size given by `kernel_size`. The array will automatically be zero-padded.

**Parameters**

- `kernel_size` [array_like, optional] A scalar or an N-length list giving the size of the median filter window in each dimension. Elements of `kernel_size` should be odd. If `kernel_size` is a scalar, then this scalar is used as the size in each dimension. Default size is 3 for each dimension.

**Returns**

- `out` [ndarray] An array the same size as input containing the median filtered result.

**See also:**

`scipy.ndimage.median_filter`

**Notes**

The more general function `scipy.ndimage.median_filter` has a more efficient implementation of a median filter and therefore runs much faster.
**scipy.signal.medfilt2d**

`scipy.signal.medfilt2d(input, kernel_size=3)`  
Median filter a 2-dimensional array.

Apply a median filter to the `input` array using a local window-size given by `kernel_size` (must be odd). The array is zero-padded automatically.

**Parameters**
- `kernel_size` : [array_like, optional] A scalar or a list of length 2, giving the size of the median filter window in each dimension. Elements of `kernel_size` should be odd. If `kernel_size` is a scalar, then this scalar is used as the size in each dimension. Default is a kernel of size (3, 3).

**Returns**
- `out` : [ndarray] An array the same size as `input` containing the median filtered result.

**See also:**
- `scipy.ndimage.median_filter`

**Notes**

The more general function `scipy.ndimage.median_filter` has a more efficient implementation of a median filter and therefore runs much faster.

**scipy.signal.wiener**

`scipy.signal.wiener(im, mysize=None, noise=None)`  
Perform a Wiener filter on an N-dimensional array.

Apply a Wiener filter to the N-dimensional array `im`.

**Parameters**
- `mysize` : [int or array_like, optional] A scalar or an N-length list giving the size of the Wiener filter window in each dimension. Elements of `mysize` should be odd. If `mysize` is a scalar, then this scalar is used as the size in each dimension.
- `noise` : [float, optional] The noise-power to use. If None, then noise is estimated as the average of the local variance of the input.

**Returns**
- `out` : [ndarray] Wiener filtered result with the same shape as `im`.

**scipy.signal.symiirorder1**

`scipy.signal.symiirorder1()`  
Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of first-order sections. The second section uses a reversed sequence. This implements a system with the following transfer function and mirror-symmetric boundary conditions:
The resulting signal will have mirror symmetric boundary conditions as well.

**Parameters**
- **input** [ndarray] The input signal.
- **c0, z1** [scalar] Parameters in the transfer function.
- **precision** : Specifies the precision for calculating initial conditions of the recursive filter based on mirror-symmetric input.

**Returns**
- **output** [ndarray] The filtered signal.

**scipy.signal.symiirorder2**

Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of second-order sections. The second section uses a reversed sequence. This implements the following transfer function:

\[
H(z) = \frac{cs^2}{(1 - a2/z - a3/z^2)(1 - a2 \cdot z - a3 \cdot z^2)}
\]

where:
- \(a2 = (2 \cdot r \cdot \cos \omega)\)
- \(a3 = -r^2\)
- \(cs = 1 - 2 \cdot r \cdot \cos \omega + r^2\)

**Parameters**
- **input** [ndarray] The input signal.
- **r, omega** [scalar] Parameters in the transfer function.
- **precision** : Specifies the precision for calculating initial conditions of the recursive filter based on mirror-symmetric input.

**Returns**
- **output** [ndarray] The filtered signal.

**scipy.signal.lfilter**

Filter data along one-dimension with an IIR or FIR filter.

Filter a data sequence, \(x\), using a digital filter. This works for many fundamental data types (including Object type). The filter is a direct form II transposed implementation of the standard difference equation (see Notes).

**Parameters**
- **b** [array_like] The numerator coefficient vector in a 1-D sequence.
- **a** [array_like] The denominator coefficient vector in a 1-D sequence. If \(a[0]\) is not 1, then both \(a\) and \(b\) are normalized by \(a[0]\).
SciPy Reference Guide, Release 1.3.2

**x**  
[array_like] An N-dimensional input array.

**axis**  
[int, optional] The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.

**zi**  
[array_like, optional] Initial conditions for the filter delays. It is a vector (or array of vectors for an N-dimensional input) of length \( \max(\text{len}(a), \text{len}(b)) - 1 \). If \( zi \) is None or is not given then initial rest is assumed. See `lfilter` for more information.

**Returns**

**y**  
[array] The output of the digital filter.

**zf**  
[array, optional] If \( zi \) is None, this is not returned, otherwise, \( zf \) holds the final filter delay values.

See also:

`lfilter`

Construct initial conditions for `lfilter`.

`lfilter_zi`

Compute initial state (steady state of step response) for `lfilter`.

`filtfilt`

A forward-backward filter, to obtain a filter with linear phase.

`savgol_filter`

A Savitzky-Golay filter.

`sosfilt`

Filter data using cascaded second-order sections.

`sosfiltfilt`

A forward-backward filter using second-order sections.

**Notes**

The filter function is implemented as a direct II transposed structure. This means that the filter implements:

\[
\begin{align*}
\sum_{k=0}^{M} a[k] y[n] &= \sum_{k=0}^{N-1} b[k] x[n-k] + d[0] y[n-1]
\end{align*}
\]

where \( M \) is the degree of the numerator, \( N \) is the degree of the denominator, and \( n \) is the sample number. It is implemented using the following difference equations (assuming \( M = N \)):

\[
\begin{align*}
\sum_{k=0}^{M} a[k] y[n] &= \sum_{k=0}^{N-1} b[k] x[n-k] \\
\sum_{k=0}^{N-2} d[k] y[n-k] &= \sum_{k=0}^{N-1} b[k] x[n-k] - a[k] y[n-k] \\
\end{align*}
\]

where \( d \) are the state variables.

The rational transfer function describing this filter in the z-transform domain is:
Examples

Generate a noisy signal to be filtered:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(-1, 1, 201)
>>> x = (np.sin(2*np.pi*0.75*t*(1-t) + 2.1) +
     ... 0.1*np.sin(2*np.pi*1.25*t + 1) +
     ... 0.18*np.cos(2*np.pi*3.85*t))
>>> xn = x + np.random.randn(len(t)) * 0.08
```

Create an order 3 lowpass butterworth filter:

```python
>>> b, a = signal.butter(3, 0.05)
```

Apply the filter to xn. Use `lfilter_zi` to choose the initial condition of the filter:

```python
>>> zi = signal.lfilter_zi(b, a)
>>> z, _ = signal.lfilter(b, a, xn, zi=zi*xn[0])
```

Apply the filter again, to have a result filtered at an order the same as `filtfilt`:

```python
>>> z2, _ = signal.lfilter(b, a, z, zi=zi*z[0])
```

Use `filtfilt` to apply the filter:

```python
>>> y = signal.filtfilt(b, a, xn)
```

Plot the original signal and the various filtered versions:

```python
>>> plt.figure
>>> plt.plot(t, xn, 'b', alpha=0.75)
>>> plt.plot(t, z, 'r--', t, z2, 'r', t, y, 'k')
>>> plt.legend(['noisy signal', 'lfilter, once', 'lfilter, twice',
              'filtfilt'], loc='best')
>>> plt.grid(True)
>>> plt.show()
```

`sipy.signal.lfiltic`

`scipy.signal.lfiltic(b, a, y=None)`

Construct initial conditions for `lfilter` given input and output vectors.

Given a linear filter (b, a) and initial conditions on the output y and the input x, return the initial conditions on the state vector zi which is used by `lfilter` to generate the output given the input.
Parameters

- **b** [array_like] Linear filter term.
- **a** [array_like] Linear filter term.
- **y** [array_like] Initial conditions.
  - If \( N = \text{len}(a) - 1 \), then \( y = \{y[-1], y[-2], \ldots, y[-N]\} \).
  - If \( y \) is too short, it is padded with zeros.
- **x** [array_like, optional] Initial conditions.
  - If \( M = \text{len}(b) - 1 \), then \( x = \{x[-1], x[-2], \ldots, x[-M]\} \).
  - If \( x \) is not given, its initial conditions are assumed zero.
  - If \( x \) is too short, it is padded with zeros.

Returns

- **zi** [ndarray] The state vector \( zi = \{z_0[-1], z_1[-1], \ldots, z_K[-1]\} \), where \( K = \text{max}(M, N) \).

See also:

- `lfilter`, `lfilter_zi`

**scipy.signal.lfilter_zi**

**scipy.signal.lfilter_zi(b, a)**

Construct initial conditions for `lfilter` for step response steady-state.

Compute an initial state \( zi \) for the `lfilter` function that corresponds to the steady state of the step response.

A typical use of this function is to set the initial state so that the output of the filter starts at the same value as the first element of the signal to be filtered.

Parameters

- **b, a** [array_like (1-D)] The IIR filter coefficients. See `lfilter` for more information.

Returns

- **zi** [1-D ndarray] The initial state for the filter.
See also:

`lfilter, lfiltic, filtfilt`

Notes

A linear filter with order m has a state space representation (A, B, C, D), for which the output y of the filter can be expressed as:

\[
\begin{align*}
    z(n+1) &= Az(n) + Bx(n) \\
    y(n) &= Cz(n) + Dx(n)
\end{align*}
\]

where \(z(n)\) is a vector of length m, \(A\) has shape (m, m), \(B\) has shape (m, 1), \(C\) has shape (1, m) and \(D\) has shape (1, 1) (assuming \(x(n)\) is a scalar). `lfilter_zi` solves:

\[
   zi = Azi + B
\]

In other words, it finds the initial condition for which the response to an input of all ones is a constant.

Given the filter coefficients \(a\) and \(b\), the state space matrices for the transposed direct form II implementation of the linear filter, which is the implementation used by `scipy.signal.lfilter`, are:

\[
\begin{align*}
    A &= scipy.linalg.companion(a).T \\
    B &= b[1:] - a[1:] * b[0]
\end{align*}
\]

assuming \(a[0]\) is 1.0; if \(a[0]\) is not 1, \(a\) and \(b\) are first divided by \(a[0]\).

Examples

The following code creates a lowpass Butterworth filter. Then it applies that filter to an array whose values are all 1.0; the output is also all 1.0, as expected for a lowpass filter. If the \(zi\) argument of `lfilter` had not been given, the output would have shown the transient signal.

```python
>>> from numpy import array, ones
>>> from scipy.signal import lfilter, lfilter_zi, butter
>>> b, a = butter(5, 0.25)
>>> zi = lfilter_zi(b, a)
>>> y, zo = lfilter(b, a, ones(10), zi=zi)
>>> y
array([1., 1., 1., 1., 1., 1., 1., 1., 1., 1.])
```

Another example:

```python
>>> x = array([0.5, 0.5, 0.5, 0.0, 0.0, 0.0, 0.0])
>>> y, zf = lfilter(b, a, x, zi=zi*x[0])
>>> y
array([ 0.5 , 0.5 , 0.5 , 0.49836039, 0.48610528, 0.44399389, 0.35505241])
```

Note that the \(zi\) argument to `lfilter` was computed using `lfilter_zi` and scaled by \(x[0]\). Then the output \(y\) has no transient until the input drops from 0.5 to 0.0.
scipy.signal.filtfilt

scipy.signal.filtfilt(b, a, x, axis=-1, padtype='odd', padlen=None, method='pad', irlen=None)

Apply a digital filter forward and backward to a signal.

This function applies a linear digital filter twice, once forward and once backwards. The combined filter has zero phase and a filter order twice that of the original.

The function provides options for handling the edges of the signal.

Parameters

- **b** [(N,) array_like] The numerator coefficient vector of the filter.
- **a** [(N,) array_like] The denominator coefficient vector of the filter. If \( a[0] \) is not 1, then both \( a \) and \( b \) are normalized by \( a[0] \).
- **x** [array_like] The array of data to be filtered.
- **axis** [int, optional] The axis of \( x \) to which the filter is applied. Default is -1.
- **padtype** [str or None, optional] Must be 'odd', 'even', 'constant', or None. This determines the type of extension to use for the padded signal to which the filter is applied. If \( \text{padtype} \) is None, no padding is used. The default is 'odd'.
- **padlen** [int or None, optional] The number of elements by which to extend \( x \) at both ends of \( \text{axis} \) before applying the filter. This value must be less than \( x\text{.shape[\text{axis}] - 1} \). \( \text{padlen=0} \) implies no padding. The default value is \( 3 \times \max(\text{len}(a), \text{len}(b)) \).
- **method** [str, optional] Determines the method for handling the edges of the signal, either “pad” or “gust”. When \( \text{method} \) is “pad”, the signal is padded; the type of padding is determined by \( \text{padtype} \) and \( \text{padlen} \), and \( \text{irlen} \) is ignored. When \( \text{method} \) is “gust”, Gustafsson’s method is used, and \( \text{padtype} \) and \( \text{padlen} \) are ignored.
- **irlen** [int or None, optional] When \( \text{method} \) is “gust”, \( \text{irlen} \) specifies the length of the impulse response of the filter. If \( \text{irlen} \) is None, no part of the impulse response is ignored. For a long signal, specifying \( \text{irlen} \) can significantly improve the performance of the filter.

Returns

- **y** [ndarray] The filtered output with the same shape as \( x \).

See also:

- sosfiltfilt
- lfilter_zi
- lfilter
- lfiltic
- savgol_filter
- sosfilt

Notes

When \( \text{method} \) is “pad”, the function pads the data along the given axis in one of three ways: odd, even or constant. The odd and even extensions have the corresponding symmetry about the end point of the data. The constant extension extends the data with the values at the end points. On both the forward and backward passes, the initial condition of the filter is found by using \( \text{lfilter_zi} \) and scaling it by the end point of the extended data.

When \( \text{method} \) is “gust”, Gustafsson’s method [1] is used. Initial conditions are chosen for the forward and backward passes so that the forward-backward filter gives the same result as the backward-forward filter.

The option to use Gustaffson’s method was added in scipy version 0.16.0.

References

[1]
Examples

The examples will use several functions from `scipy.signal`.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

First we create a one second signal that is the sum of two pure sine waves, with frequencies 5 Hz and 250 Hz, sampled at 2000 Hz.

```python
>>> t = np.linspace(0, 1.0, 2001)
>>> xlow = np.sin(2 * np.pi * 5 * t)
>>> xhigh = np.sin(2 * np.pi * 250 * t)
>>> x = xlow + xhigh
```

Now create a lowpass Butterworth filter with a cutoff of 0.125 times the Nyquist frequency, or 125 Hz, and apply it to `x` with `filtfilt`. The result should be approximately `xlow`, with no phase shift.

```python
>>> b, a = signal.butter(8, 0.125)
>>> y = signal.filtfilt(b, a, x, padlen=150)
>>> np.abs(y - xlow).max()
9.1086182074789912e-06
```

We get a fairly clean result for this artificial example because the odd extension is exact, and with the moderately long padding, the filter's transients have dissipated by the time the actual data is reached. In general, transient effects at the edges are unavoidable.

The following example demonstrates the option `method="gust"`.

First, create a filter.

```python
>>> b, a = signal.ellip(4, 0.01, 120, 0.125)  # Filter to be applied.
>>> np.random.seed(123456)
```

`sig` is a random input signal to be filtered.

```python
>>> n = 60
>>> sig = np.random.randn(n)**3 + 3*np.random.randn(n).cumsum()
```

Apply `filtfilt` to `sig`, once using the Gustafsson method, and once using padding, and plot the results for comparison.

```python
>>> fgust = signal.filtfilt(b, a, sig, method="gust")
>>> fpad = signal.filtfilt(b, a, sig, padlen=50)
>>> plt.plot(sig, 'k-', label='input')
>>> plt.plot(fgust, 'b-', linewidth=4, label='gust')
>>> plt.plot(fpad, 'c-', linewidth=1.5, label='pad')
>>> plt.legend(loc='best')
>>> plt.show()
```

The `irlen` argument can be used to improve the performance of Gustafsson's method.

Estimate the impulse response length of the filter.

```python
>>> z, p, k = signal.tf2zpk(b, a)
>>> eps = 1e-9
```
Apply the filter to a longer signal, with and without the \texttt{irlen} argument. The difference between \texttt{y1} and \texttt{y2} is small. For long signals, using \texttt{irlen} gives a significant performance improvement.

$$\text{>>> } x = \text{np.random.randn}(5000)$$
$$\text{>>> } y1 = \text{signal.filtfilt}(b, a, x, \text{method='gust'})$$
$$\text{>>> } y2 = \text{signal.filtfilt}(b, a, x, \text{method='gust', irlen=approx_impulse_len})$$
$$\text{>>> } \text{print}(\text{np.max(np.abs(y1 - y2)))}$$
1.80056858312e-10

\texttt{scipy.signal.savgol\_filter}

\texttt{scipy.signal.savgol\_filter}(x, \text{window\_length, polyorder, deriv=0, delta=1.0, axis=-1, mode='interp', cval=0.0)

Apply a Savitzky-Golay filter to an array.

This is a 1-d filter. If \texttt{x} has dimension greater than 1, \texttt{axis} determines the axis along which the filter is applied.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{x} [array_like] The data to be filtered. If \texttt{x} is not a single or double precision floating point array, it will be converted to type \texttt{numpy.float64} before filtering.
  \item \texttt{window\_length} [int] The length of the filter window (i.e. the number of coefficients). \texttt{window\_length} must be a positive odd integer. If \texttt{mode} is `interp`, \texttt{window\_length} must be less than or equal to the size of \texttt{x}.
  \item \texttt{polyorder} [int] The order of the polynomial used to fit the samples. \texttt{polyorder} must be less than \texttt{window\_length}.
  \item \texttt{deriv} [int, optional] The order of the derivative to compute. This must be a nonnegative integer. The default is 0, which means to filter the data without differentiating.
\end{itemize}
delta [float, optional] The spacing of the samples to which the filter will be applied. This is only used if deriv > 0. Default is 1.0.

axis [int, optional] The axis of the array x along which the filter is to be applied. Default is -1.

mode [str, optional] Must be 'mirror', 'constant', 'nearest', 'wrap' or 'interp'. This determines the type of extension to use for the padded signal to which the filter is applied. When mode is 'constant', the padding value is given by cval. See the Notes for more details on 'mirror', 'constant', 'wrap', and 'nearest'. When the 'interp' mode is selected (the default), no extension is used. Instead, a degree polyorder polynomial is fit to the last window_length values of the edges, and this polynomial is used to evaluate the last window_length // 2 output values.

cval [scalar, optional] Value to fill past the edges of the input if mode is 'constant'. Default is 0.0.

Returns

y [ndarray, same shape as x] The filtered data.

See also:
savgol_coeffs

Notes

Details on the mode options:

'mirror':
Repeat the values at the edges in reverse order. The value closest to the edge is not included.

'nearest':
The extension contains the nearest input value.

'constant':
The extension contains the value given by the cval argument.

'wrap':
The extension contains the values from the other end of the array.

For example, if the input is [1, 2, 3, 4, 5, 6, 7, 8], and window_length is 7, the following shows the extended data for the various mode options (assuming cval is 0):

<table>
<thead>
<tr>
<th>mode</th>
<th>Ext</th>
<th>Input</th>
<th>Ext</th>
</tr>
</thead>
<tbody>
<tr>
<td>'mirror'</td>
<td>4 3 2</td>
<td>1 2 3 4 5 6 7 8</td>
<td>7 6 5</td>
</tr>
<tr>
<td>'nearest'</td>
<td>1 1 1</td>
<td>1 2 3 4 5 6 7 8</td>
<td>8 8 8</td>
</tr>
<tr>
<td>'constant'</td>
<td>0 0 0</td>
<td>1 2 3 4 5 6 7 8</td>
<td>0 0 0</td>
</tr>
<tr>
<td>'wrap'</td>
<td>6 7 8</td>
<td>1 2 3 4 5 6 7 8</td>
<td>1 2 3</td>
</tr>
</tbody>
</table>

New in version 0.14.0.

Examples

```python
>>> from scipy.signal import savgol_filter
>>> np.set_printoptions(precision=2)  # For compact display.
>>> x = np.array([2, 2, 5, 2, 1, 0, 1, 4, 9])
```

Filter with a window length of 5 and a degree 2 polynomial. Use the defaults for all other parameters.

```python
>>> savgol_filter(x, 5, 2)
aarray([1.66, 3.17, 3.54, 2.86, 0.66, 0.17, 1. , 4. , 9. ])
```
Note that the last five values in x are samples of a parabola, so when mode='interp' (the default) is used with polyorder=2, the last three values are unchanged. Compare that to, for example, mode='nearest':

```python
>>> savgol_filter(x, 5, 2, mode='nearest')
array([1.74, 3.03, 3.54, 2.86, 0.66, 0.17, 1. , 4.6 , 7.97])
```

### scipy.signal.deconvolve

**scipy.signal.deconvolve** *(signal, divisor)*

Deconvolves divisor out of signal using inverse filtering. Returns the quotient and remainder such that signal = convolve(divisor, quotient) + remainder

**Parameters**

- **signal** [array_like] Signal data, typically a recorded signal
- **divisor** [array_like] Divisor data, typically an impulse response or filter that was applied to the original signal

**Returns**

- **quotient** [ndarray] Quotient, typically the recovered original signal
- **remainder** [ndarray] Remainder

**See also:**

**numpy.polydiv**

performs polynomial division (same operation, but also accepts poly1d objects)

### Examples

Deconvolve a signal that's been filtered:

```python
>>> from scipy import signal
>>> original = [0, 1, 0, 0, 1, 1, 0, 0]
>>> impulse_response = [2, 1]
>>> recorded = signal.convolve(impulse_response, original)
>>> recorded
array([0, 2, 1, 0, 2, 3, 1, 0, 0])
>>> recovered, remainder = signal.deconvolve(recorded, impulse_response)
>>> recovered
array([ 0., 1., 0., 0., 1., 1., 0., 0.])
```

### scipy.signal.sosfilt

**scipy.signal.sosfilt** *(sos, x, axis=-1, zi=None)*

Filter data along one dimension using cascaded second-order sections.

Filter a data sequence, x, using a digital IIR filter defined by sos. This is implemented by performing *lfilter* for each second-order section. See *lfilter* for details.

**Parameters**
sos  [array_like] Array of second-order filter coefficients, must have shape (n_sections, 6). Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.

x  [array_like] An N-dimensional input array.

axis  [int, optional] The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.

zi  [array_like, optional] Initial conditions for the cascaded filter delays. It is a (at least 2D) vector of shape (n_sections, ..., 2, ...), where ..., 2, ... denotes the shape of x, but with x.shape[axis] replaced by 2. If zi is None or is not given then initial rest (i.e. all zeros) is assumed. Note that these initial conditions are not the same as the initial conditions given by lfilter or lfilter_zi.

Returns

y  [ndarray] The output of the digital filter.

zf  [ndarray, optional] If zi is None, this is not returned, otherwise, zf holds the final filter delay values.

See also:

zpk2sos, sos2zpk, sosfilt_zi, sosfiltfilt, sosfreqz

Notes

The filter function is implemented as a series of second-order filters with direct-form II transposed structure. It is designed to minimize numerical precision errors for high-order filters.

New in version 0.16.0.

Examples

Plot a 13th-order filter's impulse response using both lfilter and sosfilt, showing the instability that results from trying to do a 13th-order filter in a single stage (the numerical error pushes some poles outside of the unit circle):

```python
>>> import matplotlib.pyplot as plt
>>> from scipy import signal
>>> b, a = signal.ellip(13, 0.009, 80, 0.05, output='ba')
>>> sos = signal.ellip(13, 0.009, 80, 0.05, output='sos')
>>> x = signal.unit_impulse(700)
>>> y_tf = signal.lfilter(b, a, x)
>>> y_sos = signal.sosfilt(sos, x)
>>> plt.plot(y_tf, 'r', label='TF')
>>> plt.plot(y_sos, 'k', label='SOS')
>>> plt.legend(loc='best')
>>> plt.show()
```

scipy.signal.sosfilt_zi

scipy.signal.sosfilt_zi(sos)

Construct initial conditions for sosfilt for step response steady-state.

Compute an initial state zi for the sosfilt function that corresponds to the steady state of the step response.
A typical use of this function is to set the initial state so that the output of the filter starts at the same value as the first element of the signal to be filtered.

**Parameters**

- `sos` [array_like] Array of second-order filter coefficients, must have shape `(n_sections, 6)`. See `sosfilt` for the SOS filter format specification.

**Returns**

- `zi` [ndarray] Initial conditions suitable for use with `sosfilt`. Shape `(n_sections, 2)`. See also:

  - `sosfilt`, `zpk2sos`

**Notes**

New in version 0.16.0.

**Examples**

Filter a rectangular pulse that begins at time 0, with and without the use of the `zi` argument of `scipy.signal.sosfilt`.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> sos = signal.butter(9, 0.125, output='sos')
>>> zi = signal.sosfilt_zi(sos)
>>> x = (np.arange(250) < 100).astype(int)
>>> f1 = signal.sosfilt(sos, x)
>>> f2, zo = signal.sosfilt(sos, x, zi=zi)
```
scipy.signal.sosfiltfilt

scipy.signal.sosfiltfilt \((sos, x, axis=-1, padtype='odd', padlen=None)\)

A forward-backward digital filter using cascaded second-order sections.

See \texttt{filtfilt} for more complete information about this method.

\textbf{Parameters}

- **sos** [array_like] Array of second-order filter coefficients, must have shape \((n\_sections, 6)\). Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.
- **x** [array_like] The array of data to be filtered.
- **axis** [int, optional] The axis of \(x\) to which the filter is applied. Default is -1.
- **padtype** [str or None, optional] Must be ‘odd’, ‘even’, ‘constant’, or None. This determines the type of extension to use for the padded signal to which the filter is applied. If \texttt{padtype} is None, no padding is used. The default is ‘odd’.
- **padlen** [int or None, optional] The number of elements by which to extend \(x\) at both ends of \(axis\) before applying the filter. This value must be less than \(x\).shape[axis] - 1. padlen=0 implies no padding. The default value is:

\[
3 \times (2 \times \text{len}(\text{sos}) + 1 - \min((\text{sos}[:, 2] == 0).\text{sum()}, (\text{sos}[:, 5] == 0).\text{sum}()))
\]

The extra subtraction at the end attempts to compensate for poles and zeros at the origin (e.g. for odd-order filters) to yield equivalent estimates of \texttt{padlen} to those of \texttt{filtfilt} for second-order section filters built with \texttt{scipy.signal} functions.

\textbf{Returns}

...
y

[ndarray] The filtered output with the same shape as x.

See also:

filtfilt, sosfilt, sosfilt_zi, sosfreqz

Notes

New in version 0.18.0.

Examples

```python
>>> from scipy.signal import sosfiltfilt, butter
>>> import matplotlib.pyplot as plt

Create an interesting signal to filter.

```python
>>> n = 201
>>> t = np.linspace(0, 1, n)
>>> np.random.seed(123)
>>> x = 1 + (t < 0.5) - 0.25*t**2 + 0.05*np.random.randn(n)
```  
Create a lowpass Butterworth filter, and use it to filter x.

```python
>>> sos = butter(4, 0.125, output='sos')
>>> y = sosfiltfilt(sos, x)

For comparison, apply an 8th order filter using sosfilt. The filter is initialized using the mean of the first four values of x.

```python
>>> from scipy.signal import sosfilt, sosfilt_zi
>>> sos8 = butter(8, 0.125, output='sos')
>>> zi = x[:4].mean() * sosfilt_zi(sos8)
>>> y2, zo = sosfilt(sos8, x, zi=zi)
```  
Plot the results. Note that the phase of y matches the input, while y2 has a significant phase delay.

```python
>>> plt.plot(t, x, alpha=0.5, label='x(t)')
>>> plt.plot(t, y, label='y(t)')
>>> plt.plot(t, y2, label='y2(t)')
>>> plt.legend(framealpha=1, shadow=True)
>>> plt.grid(alpha=0.25)
>>> plt.xlabel('t')
>>> plt.ylabel('t')
>>> plt.show()
```

scipy.signal.hilbert

scipy.signal.hilbert(x, N=None, axis=-1)

Compute the analytic signal, using the Hilbert transform.

The transformation is done along the last axis by default.

Parameters
x | array_like | Signal data. Must be real.
N | [int, optional] | Number of Fourier components. Default: x.shape[axis]
axis | [int, optional] | Axis along which to do the transformation. Default: -1.

Returns

xa | [ndarray] | Analytic signal of x, of each 1-D array along axis

See also:

scipy.fftpack.hilbert

Return Hilbert transform of a periodic sequence x.

Notes

The analytic signal \( x_a(t) \) of signal \( x(t) \) is:

\[
x_a = F^{-1}(F(x)2U) = x + iy
\]

where \( F \) is the Fourier transform, \( U \) the unit step function, and \( y \) the Hilbert transform of \( x \). [1]

In other words, the negative half of the frequency spectrum is zeroed out, turning the real-valued signal into a complex signal. The Hilbert transformed signal can be obtained from \( \text{np.imag(hilbert(x))} \), and the original signal from \( \text{np.real(hilbert(x))} \).

References

[1], [2], [3]

Examples

In this example we use the Hilbert transform to determine the amplitude envelope and instantaneous frequency of an amplitude-modulated signal.
We create a chirp of which the frequency increases from 20 Hz to 100 Hz and apply an amplitude modulation.

```python
>>> signal = chirp(t, 20.0, t[-1], 100.0)
>>> signal *= (1.0 + 0.5 * np.sin(2.0*np.pi*3.0*t) )
```

The amplitude envelope is given by magnitude of the analytic signal. The instantaneous frequency can be obtained by differentiating the instantaneous phase in respect to time. The instantaneous phase corresponds to the phase angle of the analytic signal.

```python
>>> analytic_signal = hilbert(signal)
>>> amplitude_envelope = np.abs(analytic_signal)
>>> instantaneous_phase = np.unwrap(np.angle(analytic_signal))
>>> instantaneous_frequency = (np.diff(instantaneous_phase) / (2.0*np.pi) * fs)
```

```python
>>> fig = plt.figure()
>>> ax0 = fig.add_subplot(211)
>>> ax0.plot(t, signal, label='signal')
>>> ax0.plot(t, amplitude_envelope, label='envelope')
>>> ax0.set_xlabel("time in seconds")
>>> ax0.legend()
>>> ax1 = fig.add_subplot(212)
>>> ax1.plot(t[1:], instantaneous_frequency)
>>> ax1.set_xlabel("time in seconds")
>>> ax1.set_ylim(0.0, 120.0)
```

**scipy.signal.hilbert2**

`scipy.signal.hilbert2(x, N=None)`

Compute the '2-D' analytic signal of `x`

**Parameters**

- `x` [array_like] 2-D signal data.
- `N` [int or tuple of two ints, optional] Number of Fourier components. Default is `x.shape`

**Returns**

- `xa` [ndarray] Analytic signal of `x` taken along axes (0,1).

**References**

[1]
scipy.signal.decimate

scipy.signal.decimate(x, q, n=None, ftype='iir', axis=-1, zero_phase=True)

Downsample the signal after applying an anti-aliasing filter.

By default, an order 8 Chebyshev type I filter is used. A 30 point FIR filter with Hamming window is used if ftype is ‘fir’.

**Parameters**

- **x** [array_like] The signal to be downsampled, as an N-dimensional array.
- **q** [int] The downsampling factor. When using IIR downsampling, it is recommended to call `decimate` multiple times for downsampling factors higher than 13.
- **n** [int, optional] The order of the filter (1 less than the length for ‘fir’). Defaults to 8 for ‘iir’ and 20 times the downsampling factor for ‘fir’.
- **ftype** [str {‘iir’, ‘fir’} or dlti instance, optional] If ‘iir’ or ‘fir’, specifies the type of lowpass filter. If an instance of an dlti object, uses that object to filter before downsampling.
- **axis** [int, optional] The axis along which to decimate.
- **zero_phase** [bool, optional] Prevent phase shift by filtering with `filtfilt` instead of `lfilter` when using an IIR filter, and shifting the outputs back by the filter’s group delay when using an FIR filter. The default value of `True` is recommended, since a phase shift is generally not desired.

New in version 0.18.0.

**Returns**

- **y** [ndarray] The down-sampled signal.

See also:

- **resample**
  Resample up or down using the FFT method.

- **resample_poly**
  Resample using polyphase filtering and an FIR filter.
Notes

The zero_phase keyword was added in 0.18.0. The possibility to use instances of dlti as ftype was added in 0.18.0.

scipy.signal.detrend

scipy.signal.detrend(data, axis=-1, type='linear', bp=0, overwrite_data=False)

Remove linear trend along axis from data.

Parameters

- data [array_like] The input data.
- axis [int, optional] The axis along which to detrend the data. By default this is the last axis (-1).
- type [{'linear', 'constant'}, optional] The type of detrending. If type == 'linear' (default), the result of a linear least-squares fit to data is subtracted from data. If type == 'constant', only the mean of data is subtracted.
- bp [array_like of ints, optional] A sequence of break points. If given, an individual linear fit is performed for each part of data between two break points. Break points are specified as indices into data.
- overwrite_data [bool, optional] If True, perform in place detrending and avoid a copy. Default is False

Returns

- ret [ndarray] The detrended input data.

Examples

```python
>>> from scipy import signal
>>> randgen = np.random.RandomState(9)
>>> npoints = 1000
>>> noise = randgen.randn(npoints)
>>> x = 3 + 2*np.linspace(0, 1, npoints) + noise
>>> (signal.detrend(x) - noise).max() < 0.01
True
```

scipy.signal.resample

scipy.signal.resample(x, num, t=None, axis=0, window=None)

Resample x to num samples using Fourier method along the given axis.

The resampled signal starts at the same value as x but is sampled with a spacing of len(x) / num * (spacing of x). Because a Fourier method is used, the signal is assumed to be periodic.

Parameters

- x [array_like] The data to be resampled.
- num [int] The number of samples in the resampled signal.
- t [array_like, optional] If t is given, it is assumed to be the sample positions associated with the signal data in x.
- axis [int, optional] The axis of x that is resampled. Default is 0.
- window [array_like, callable, string, float, or tuple, optional] Specifies the window applied to the signal in the Fourier domain. See below for details.
Returns

resampled_x or (resampled_x, resampled_t)

Either the resampled array, or, if t was given, a tuple containing the resampled array and the corresponding resampled positions.

See also:

decimate

Downsample the signal after applying an FIR or IIR filter.

resample_poly

Resample using polyphase filtering and an FIR filter.

Notes

The argument window controls a Fourier-domain window that tapers the Fourier spectrum before zero-padding to alleviate ringing in the resampled values for sampled signals you didn't intend to be interpreted as band-limited.

If window is a function, then it is called with a vector of inputs indicating the frequency bins (i.e. fftfreq(x.shape[axis])).

If window is an array of the same length as x.shape[axis] it is assumed to be the window to be applied directly in the Fourier domain (with dc and low-frequency first).

For any other type of window, the function scipy.signal.get_window is called to generate the window.

The first sample of the returned vector is the same as the first sample of the input vector. The spacing between samples is changed from dx to dx * len(x) / num.

If t is not None, then it represents the old sample positions, and the new sample positions will be returned as well as the new samples.

As noted, resample uses FFT transformations, which can be very slow if the number of input or output samples is large and prime; see scipy.fftpack.fft.

Examples

Note that the end of the resampled data rises to meet the first sample of the next cycle:

```python
>>> from scipy import signal

>>> x = np.linspace(0, 10, 20, endpoint=False)
>>> y = np.cos(-x**2/6.0)
>>> f = signal.resample(y, 100)
>>> xnew = np.linspace(0, 10, 100, endpoint=False)

>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'go-', xnew, f, '.-', 10, y[0], 'ro')
>>> plt.legend(['data', 'resampled'], loc='best')
>>> plt.show()
```
scipy.signal.resample_poly

scipy.signal.resample_poly(x, up, down, axis=0, window=('kaiser', 5.0))

Resample x along the given axis using polyphase filtering.

The signal x is upsampled by the factor up, a zero-phase low-pass FIR filter is applied, and then it is downsampled by the factor down. The resulting sample rate is \( \frac{up}{\text{down}} \) times the original sample rate. Values beyond the boundary of the signal are assumed to be zero during the filtering step.

Parameters

- x [array_like] The data to be resampled.
- up [int] The upsampling factor.
- down [int] The downsampling factor.
- axis [int, optional] The axis of x that is resampled. Default is 0.
- window [string, tuple, or array_like, optional] Desired window to use to design the low-pass filter, or the FIR filter coefficients to employ. See below for details.

Returns

- resampled_x [array] The resampled array.

See also:

decimate

Downsample the signal after applying an FIR or IIR filter.

resample

Resample up or down using the FFT method.

Notes

This polyphase method will likely be faster than the Fourier method in scipy.signal.resample when the number of samples is large and prime, or when the number of samples is large and \( up \) and \( down \) share a large greatest common denominator. The length of the FIR filter used will depend on \( \max(up, down) \div \gcd(up, down) \).
down), and the number of operations during polyphase filtering will depend on the filter length and down (see scipy.signal.upfirdn for details).

The argument window specifies the FIR low-pass filter design.

If window is an array_like it is assumed to be the FIR filter coefficients. Note that the FIR filter is applied after the upsampling step, so it should be designed to operate on a signal at a sampling frequency higher than the original by a factor of up/gcd(up, down). This function’s output will be centered with respect to this array, so it is best to pass a symmetric filter with an odd number of samples if, as is usually the case, a zero-phase filter is desired.

For any other type of window, the functions scipy.signal.get_window and scipy.signal.firwin are called to generate the appropriate filter coefficients.

The first sample of the returned vector is the same as the first sample of the input vector. The spacing between samples is changed from dx to dx * down / float(up).

Examples

Note that the end of the resampled data rises to meet the first sample of the next cycle for the FFT method, and gets closer to zero for the polyphase method:

```python
>>> from scipy import signal

>>> x = np.linspace(0, 10, 20, endpoint=False)
>>> y = np.cos(-x**2/6.0)
>>> f_fft = signal.resample(y, 100)
>>> f_poly = signal.resample_poly(y, 100, 20)
>>> xnew = np.linspace(0, 10, 100, endpoint=False)

>>> import matplotlib.pyplot as plt
>>> plt.plot(xnew, f_fft, 'b-'
>>> plt.plot(xnew, f_poly, 'r-'
>>> plt.plot(10, y[0], 'bo'
>>> plt.plot(10, 0., 'ro')  # boundaries
>>> plt.legend(['resample', 'resamp_poly', 'data'], loc='best')
>>> plt.show()
```

resample
resamp_poly
data
scipy.signal.upfirdn

scipy.signal.upfirdn(h, x, up=1, down=1, axis=-1)
Upsample, FIR filter, and downsample

Parameters

h [array_like] 1-dimensional FIR (finite-impulse response) filter coefficients.

x [array_like] Input signal array.

up [int, optional] Upsampling rate. Default is 1.

down [int, optional] Downsampling rate. Default is 1.

axis [int, optional] The axis of the input data array along which to apply the linear filter. The filter
is applied to each subarray along this axis. Default is -1.

Returns

y [ndarray] The output signal array. Dimensions will be the same as x except for along axis,
which will change size according to the h, up, and down parameters.

Notes

The algorithm is an implementation of the block diagram shown on page 129 of the Vaidyanathan text [1] (Figure
4.3-8d).
The direct approach of upsampling by factor of P with zero insertion, FIR filtering of length h, and downsampling
by factor of Q is O(N*Q) per output sample. The polyphase implementation used here is O(N/P).
New in version 0.18.

Examples

Simple operations:

```python
>>> from scipy.signal import upfirdn
>>> upfirdn([1, 1, 1], [1, 1, 1])  # FIR filter
array([ 1., 2., 3., 2., 1.])
>>> upfirdn([1], [1, 2, 3], 3)  # upsampling with zeros insertion
array([ 1., 0., 0., 2., 0., 0., 3., 0., 0.])
>>> upfirdn([1, 1, 1], [1, 2, 3], 3)  # upsampling with sample-and-hold
array([ 1., 1., 1., 2., 2., 2., 3., 3., 3.])
>>> upfirdn([.5, 1, .5], [1, 1, 1], 2)  # linear interpolation
array([ 0.5, 1. , 1. , 1. , 1. , 0.5, 0.0])
>>> upfirdn([1], np.arange(10), 1, 3)  # decimation by 3
array([ 0., 3., 6., 9.])
>>> upfirdn([.5, 1, .5], np.arange(10), 2, 3)  # linear interp, rate 2/3
array([ 0., 1., 2.5, 4., 5.5, 7., 8.5, 0.])
```

Apply a single filter to multiple signals:

```python
>>> x = np.reshape(np.arange(8), (4, 2))
>>> x
array([[0, 1],
       [2, 3],
       [4, 5],
       [6, 7]])
```
Apply along the last dimension of x:

```python
>>> h = [1, 1]
>>> upfirdn(h, x, 2)
array([[ 0., 0., 1., 1.],
       [ 2., 2., 3., 3.],
       [ 4., 4., 5., 5.],
       [ 6., 6., 7., 7.]])
```

Apply along the 0th dimension of x:

```python
>>> upfirdn(h, x, 2, axis=0)
array([[ 0., 1.],
       [ 0., 1.],
       [ 2., 3.],
       [ 2., 3.],
       [ 4., 5.],
       [ 4., 5.],
       [ 6., 7.],
       [ 6., 7.]])
```

### 6.21.4 Filter design

- **bilinear** *(b, a[, fs])* Return a digital IIR filter from an analog one using a bilinear transform.
- **bilinear_zpk** *(z, p, k, fs)* Return a digital IIR filter from an analog one using a bilinear transform.
- **findfreqs** *(num, den, N[, kind])* Find array of frequencies for computing the response of an analog filter.
- **firls** *(numtaps, bands, desired[, weight, nyq, fs])* FIR filter design using least-squares error minimization.
- **firwin** *(numtaps, cutoff[, width, window, ...])* FIR filter design using the window method.
- **firwin2** *(numtaps, freq, gain[, nfreqs, ...])* FIR filter design using the window method.
- **freqs** *(b, a[, worN, plot])* Compute frequency response of analog filter.
- **freqs_zpk** *(z, p, k[, worN])* Compute frequency response of analog filter.
- **freqz** *(b[, a, worN, whole, plot, fs])* Compute the frequency response of a digital filter.
- **freqz_zpk** *(z, p, k[, worN, whole, fs])* Compute the frequency response of a digital filter in ZPK form.
- **sosfreqz** *(sos[, worN, whole, fs])* Compute the frequency response of a digital filter in SOS format.
- **group_delay** *(system[, w, whole, fs])* Compute the group delay of a digital filter.
- **iirdesign** *(wp, ws, gpass, gstop[, analog, ...])* Complete IIR digital and analog filter design.
- **iirfilter** *(N, Wn[, rp, rs, btype, analog, ...])* IIR digital and analog filter design given order and critical points.
- **kaiser_atten** *(numtaps, width)* Compute the attenuation of a Kaiser FIR filter.
- **kaiser_beta** *(a)* Compute the Kaiser parameter beta, given the attenuation a.
- **kaiserord** *(ripple, width)* Determine the filter window parameters for the Kaiser window method.
- **minimum_phase** *(h[, method, n_fft])* Convert a linear-phase FIR filter to minimum phase.
- **savgol_coeffs** *(window_length, polyorder[, ...])* Compute the coefficients for a 1-d Savitzky-Golay FIR filter.

### scipy.signal.bilinear

**scipy.signal.bilinear** *(b, a, fs=1.0)*  
Return a digital IIR filter from an analog one using a bilinear transform.

Transform a set of poles and zeros from the analog s-plane to the digital z-plane using Tustin’s method, which substitutes \((z-1) / (z+1)\) for \(s\), maintaining the shape of the frequency response.

**Parameters**

- **b**  
  [array_like] Numerator of the analog filter transfer function.
- **a**  
  [array_like] Denominator of the analog filter transfer function.
- **fs**  
  [float] Sample rate, as ordinary frequency (e.g. hertz). No prewarping is done in this function.

**Returns**

- **z**  
  [ndarray] Numerator of the transformed digital filter transfer function.
- **p**  
  [ndarray] Denominator of the transformed digital filter transfer function.

**See also:**

- `lp2lp`, `lp2hp`, `lp2bp`, `lp2bs`
- `bilinear_zpk`

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> fs = 100
>>> bf = 2 * np.pi * np.array([7, 13])
>>> filts = signal.lti('signal.butter(4, bf, btype='bandpass',...
    analog=True))
>>> filtz = signal.lti('signal.bilinear(filts.num, filts.den, fs))
>>> wz, hz = signal.freqz(filtz.num, filtz.den)
>>> ws, hs = signal.freqs(filts.num, filts.den, worN=fs*wz)

>>> plt.semilogx(wz*fs/(2*np.pi), 20*np.log10(np.abs(hz).clip(1e-15)),...
    label=r'$|H(j \omega)|$')
>>> plt.semilogx(wz*fs/(2*np.pi), 20*np.log10(np.abs(hs).clip(1e-15)),...
    label=r'$|H_z(e^{j \omega})|$')
>>> plt.legend()
```

(continues on next page)
```python
>>> plt.xlabel('Frequency [Hz]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.grid()
```

### scipy.signal.bilinear_zpk

**scipy.signal.bilinear_zpk** *(z, p, k, fs)*

Return a digital IIR filter from an analog one using a bilinear transform.

Transform a set of poles and zeros from the analog s-plane to the digital z-plane using Tustin’s method, which substitutes \((z-1) / (z+1)\) for \(s\), maintaining the shape of the frequency response.

**Parameters**

- **z** [array_like] Zeros of the analog filter transfer function.
- **p** [array_like] Poles of the analog filter transfer function.
- **k** [float] System gain of the analog filter transfer function.
- **fs** [float] Sample rate, as ordinary frequency (e.g. hertz). No prewarping is done in this function.

**Returns**

- **z** [ndarray] Zeros of the transformed digital filter transfer function.
- **p** [ndarray] Poles of the transformed digital filter transfer function.
- **k** [float] System gain of the transformed digital filter.

See also:

- `lp2lp_zpk`, `lp2hp_zpk`, `lp2bp_zpk`, `lp2bs_zpk`
- `bilinear`

**Notes**

New in version 1.1.0.
Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> fs = 100
>>> bf = 2 * np.pi * np.array([7, 13])
>>> filts = signal.lti(*signal.butter(4, bf, btype='bandpass',
                    analog=True, output='zp'))
>>> filtz = signal.lti(*signal.bilinear_zpk(filts.zeros, filts.poles,
                    filts.gain, fs))
>>> wz, hz = signal.freqz_zpk(filtz.zeros, filtz.poles, filtz.gain)
>>> ws, hs = signal.freqs_zpk(filts.zeros, filts.poles, filts.gain,
                    worN=fs * wz)
>>> plt.semilogx(wz * fs / (2 * np.pi), 20 * np.log10(np.abs(hz).clip(1e-15)),
                label=r'$|H(j \omega)|$')
>>> plt.semilogx(wz * fs / (2 * np.pi), 20 * np.log10(np.abs(hs).clip(1e-15)),
                label=r'$|H_z(e^{j \omega})|$')
>>> plt.legend()
>>> plt.xlabel('Frequency [Hz]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.grid()
```

scipy.signal.findfreqs

**scipy.signal.findfreqs**\(num, den, N, kind='ba')\)

Find array of frequencies for computing the response of an analog filter.

**Parameters**

- **num, den** \([\text{array_like, 1-D}]\) The polynomial coefficients of the numerator and denominator of the transfer function of the filter or LTI system, where the coefficients are ordered from highest to lowest degree. Or, the roots of the transfer function numerator and denominator (i.e. zeroes and poles).
SciPy Reference Guide, Release 1.3.2

N
kind

[int] The length of the array to be computed.

[str {'ba', 'zp'}, optional] Specifies whether the numerator and denominator are specified by
their polynomial coefficients ('ba'), or their roots ('zp').

Returns

w

Examples

Find a set of nine frequencies that span the “interesting part” of the frequency response for the filter with the transfer
function

\[ H(s) = \frac{s}{s^2 + 8s + 25} \]

```python
>>> from scipy import signal
>>> signal.findfreqs([1, 0], [1, 8, 25], N=9)
array([ 1.00000000e-02, 3.16227766e-02, 1.00000000e-01,
        3.16227766e-01, 1.00000000e+00, 3.16227766e+00,
        1.00000000e+01, 3.16227766e+01, 1.00000000e+02])
```

scipy.signal.firls

scipy.signal.firls(numtaps, bands, desired, weight=None, nyq=None, fs=None)

FIR filter design using least-squares error minimization.

Calculate the filter coefficients for the linear-phase finite impulse response (FIR) filter which has the best approxi-
mation to the desired frequency response described by bands and desired in the least squares sense (i.e., the integral
of the weighted mean-squared error within the specified bands is minimized).

Parameters

- numtaps [int] The number of taps in the FIR filter. numtaps must be odd.
- bands [array_like] A monotonic nondecreasing sequence containing the band edges in Hz. All
elements must be non-negative and less than or equal to the Nyquist frequency given by nyq.
- desired [array_like] A sequence the same size as bands containing the desired gain at the start and
  end point of each band.
- weight [array_like, optional] A relative weighting to give to each band region when solving the least
  squares problem. weight has to be half the size of bands.
  must be between 0 and nyq (inclusive). Default is 1.
- fs [float, optional] The sampling frequency of the signal. Each frequency in bands must be
  between 0 and fs/2 (inclusive). Default is 2.

Returns

coeffs [ndarray] Coefficients of the optimal (in a least squares sense) FIR filter.

See also:

- firwin
- firwin2
- minimum_phase
- remez
Notes

This implementation follows the algorithm given in [1]. As noted there, least squares design has multiple advantages:

1. Optimal in a least-squares sense.
2. Simple, non-iterative method.
3. The general solution can obtained by solving a linear system of equations.
4. Allows the use of a frequency dependent weighting function.

This function constructs a Type I linear phase FIR filter, which contains an odd number of \( \text{coeffs} \) satisfying for \( n < \text{numtaps} \):

\[
\text{coeffs}(n) = \text{coeffs}(\text{numtaps} - 1 - n)
\]

The odd number of coefficients and filter symmetry avoid boundary conditions that could otherwise occur at the Nyquist and 0 frequencies (e.g., for Type II, III, or IV variants).

New in version 0.18.

References

[1]

Examples

We want to construct a band-pass filter. Note that the behavior in the frequency ranges between our stop bands and pass bands is unspecified, and thus may overshoot depending on the parameters of our filter:

```python
from scipy import signal
import matplotlib.pyplot as plt
fig, axs = plt.subplots(2)
fs = 10.0  # Hz
desired = (0, 0, 1, 1, 0, 0)
for bi, bands in enumerate(((0, 1, 2, 3, 4, 5), (0, 1, 2, 4, 4.5, 5))):
    fir_firls = signal.firls(73, bands, desired, fs=fs)
    fir_remez = signal.remez(73, bands, desired[::2], fs=fs)
    fir_firwin2 = signal.firwin2(73, bands, desired, fs=fs)
    hs = list()
    ax = axs[bi]
    for fir in (fir_firls, fir_remez, fir_firwin2):
        freq, response = signal.freqz(fir)
        hs.append(ax.semilogy(0.5*fs*freq/np.pi, np.abs(response))[0])
    for band, gains in zip(zip(bands[::2], bands[1::2]),
                            zip(desired[::2], desired[1::2])):
        ax.semilogy(band, np.maximum(gains, 1e-7), 'k--', linewidth=2)
    if bi == 0:
        ax.legend(hs, ['firls', 'remez', 'firwin2'],
                  loc='lower center', frameon=False)
    else:
        ax.set_xlabel('Frequency (Hz)')
    ax.grid(True)
```

(continues on next page)
scipy.signal.firwin

scipy.signal.firwin

FIR filter design using the window method.

This function computes the coefficients of a finite impulse response filter. The filter will have linear phase; it will be Type I if `numtaps` is odd and Type II if `numtaps` is even.

Type II filters always have zero response at the Nyquist frequency, so a ValueError exception is raised if firwin is called with `numtaps` even and having a passband whose right end is at the Nyquist frequency.

**Parameters**

- `numtaps` [int] Length of the filter (number of coefficients, i.e. the filter order + 1). `numtaps` must be odd if a passband includes the Nyquist frequency.
- `cutoff` [float or 1D array_like] Cutoff frequency of filter (expressed in the same units as `fs`) OR an array of cutoff frequencies (that is, band edges). In the latter case, the frequencies in `cutoff` should be positive and monotonically increasing between 0 and `fs/2`. The values 0 and `fs/2` must not be included in `cutoff`.
- `width` [float or None, optional] If `width` is not None, then assume it is the approximate width of the transition region (expressed in the same units as `fs`) for use in Kaiser FIR filter design. In this case, the `window` argument is ignored.
- `window` [string or tuple of string and parameter values, optional] Desired window to use. See `scipy.signal.get_window` for a list of windows and required parameters.
- `pass_zero` [{True, False, 'bandpass', 'lowpass', 'highpass', 'bandstop'}, optional] If True, the gain at the frequency 0 (i.e. the “DC gain”) is 1. If False, the DC gain is 0. Can also be a string argument for the desired filter type (equivalent to `btype` in IIR design functions).
New in version 1.3.0: Support for string arguments.

**scale** [bool, optional] Set to True to scale the coefficients so that the frequency response is exactly unity at a certain frequency. That frequency is either:
- 0 (DC) if the first passband starts at 0 (i.e. pass_zero is True)
- fs/2 (the Nyquist frequency) if the first passband ends at fs/2 (i.e. the filter is a single band highpass filter); center of first passband otherwise

**nyq** [float, optional] Deprecated. Use 'fs' instead. This is the Nyquist frequency. Each frequency in cutoff must be between 0 and nyq. Default is 1.

**fs** [float, optional] The sampling frequency of the signal. Each frequency in cutoff must be between 0 and fs/2. Default is 2.

**Returns**

- h [(numtaps,)]ndarray Coefficients of length numtaps FIR filter.

**Raises**

**ValueError** If any value in cutoff is less than or equal to 0 or greater than or equal to fs/2, if the values in cutoff are not strictly monotonically increasing, or if numtaps is even but a passband includes the Nyquist frequency.

**See also:**

- firwin2
- firls
- minimum_phase
- remez

**Examples**

Low-pass from 0 to f:

```python
>>> from scipy import signal
>>> numtaps = 3
>>> f = 0.1
>>> signal.firwin(numtaps, f)
array([ 0.06799017, 0.86401967, 0.06799017])
```

Use a specific window function:

```python
>>> signal.firwin(numtaps, f, window='nuttall')
array([ 3.56607041e-04, 9.99286786e-01, 3.56607041e-04])
```

High-pass ('stop' from 0 to f):

```python
>>> signal.firwin(numtaps, f, pass_zero=False)
array([-0.00859313, 0.98281375, -0.00859313])
```

Band-pass:

```python
>>> f1, f2 = 0.1, 0.2
>>> signal.firwin(numtaps, [f1, f2], pass_zero=False)
array([ 0.06301614, 0.88770441, 0.06301614])
```
Band-stop:

```python
>>> signal.firwin(numtaps, [f1, f2])
array([-0.00801395, 1.0160279 , -0.00801395])
```

Multi-band (passbands are [0, f1], [f2, f3] and [f4, 1]):

```python
>>> f3, f4 = 0.3, 0.4
>>> signal.firwin(numtaps, [f1, f2, f3, f4])
array([-0.01376344, 1.02752689, -0.01376344])
```

Multi-band (passbands are [f1, f2] and [f3,f4]):

```python
>>> signal.firwin(numtaps, [f1, f2, f3, f4], pass_zero=False)
array([ 0.04890915, 0.91284326, 0.04890915])
```

**scipy.signal.firwin2**

`scipy.signal.firwin2(numtaps, freq, gain, nfreqs=None, window='hamming', nyq=None, antisymmetric=False, fs=None)`

FIR filter design using the window method.

From the given frequencies `freq` and corresponding gains `gain`, this function constructs an FIR filter with linear phase and (approximately) the given frequency response.

**Parameters**

- `numtaps` [int] The number of taps in the FIR filter. `numtaps` must be less than `nfreqs`.
- `freq` [array_like, 1D] The frequency sampling points. Typically 0.0 to 1.0 with 1.0 being Nyquist. The Nyquist frequency is half `fs`. The values in `freq` must be nondecreasing. A value can be repeated once to implement a discontinuity. The first value in `freq` must be 0, and the last value must be `fs/2`.
- `gain` [array_like] The filter gains at the frequency sampling points. Certain constraints to gain values, depending on the filter type, are applied, see Notes for details.
- `nfreqs` [int, optional] The size of the interpolation mesh used to construct the filter. For most efficient behavior, this should be a power of 2 plus 1 (e.g., 129, 257, etc). The default is one more than the smallest power of 2 that is not less than `numtaps`. `nfreqs` must be greater than `numtaps`.
- `window` [string or (string, float) or float, or None, optional] Window function to use. Default is “hamming”. See `scipy.signal.get_window` for the complete list of possible values. If None, no window function is applied.
- `nyq` [float, optional] Deprecated. Use `fs` instead. This is the Nyquist frequency. Each frequency in `freq` must be between 0 and `nyq`. Default is 1.
- `antisymmetric` [bool, optional] Whether resulting impulse response is symmetric/antisymmetric. See Notes for more details.
- `fs` [float, optional] The sampling frequency of the signal. Each frequency in `cutoff` must be between 0 and `fs/2`. Default is 2.

**Returns**

- `taps` [ndarray] The filter coefficients of the FIR filter, as a 1-D array of length `numtaps`.

See also:

- `firls`
- `firwin`
minimum_phase
remez

Notes

From the given set of frequencies and gains, the desired response is constructed in the frequency domain. The inverse FFT is applied to the desired response to create the associated convolution kernel, and the first `numtaps` coefficients of this kernel, scaled by `window`, are returned.

The FIR filter will have linear phase. The type of filter is determined by the value of `numtaps` and `antisymmetric` flag. There are four possible combinations:

- odd `numtaps`, `antisymmetric` is False, type I filter is produced
- even `numtaps`, `antisymmetric` is False, type II filter is produced
- odd `numtaps`, `antisymmetric` is True, type III filter is produced
- even `numtaps`, `antisymmetric` is True, type IV filter is produced

Magnitude response of all but type I filters are subject to following constraints:

- type II – zero at the Nyquist frequency
- type III – zero at zero and Nyquist frequencies
- type IV – zero at zero frequency

New in version 0.9.0.

References

[1], [2]

Examples

A lowpass FIR filter with a response that is 1 on [0.0, 0.5], and that decreases linearly on [0.5, 1.0] from 1 to 0:

```python
>>> from scipy import signal
>>> taps = signal.firwin2(150, [0.0, 0.5, 1.0], [1.0, 1.0, 0.0])
>>> print(taps[72:78])
[-0.02286961 -0.06362756 0.57310236 0.57310236 -0.06362756 -0.02286961]
```

**scipy.signal.freqs**

`scipy.signal.freqs(b, a, worN=200, plot=None)`

Compute frequency response of analog filter.

Given the M-order numerator `b` and N-order denominator `a` of an analog filter, compute its frequency response:

\[
H(w) = \frac{b[0]* (jw)^M + b[1]* (jw)^{(M-1)} + \ldots + b[M]}{a[0]* (jw)^N + a[1]* (jw)^{(N-1)} + \ldots + a[N]}
\]

Parameters
```markdown
b  [array_like] Numerator of a linear filter.
a  [array_like] Denominator of a linear filter.
worN  [{None, int, array_like}, optional] If None, then compute at 200 frequencies around the interesting parts of the response curve (determined by pole-zero locations). If a single integer, then compute at that many frequencies. Otherwise, compute the response at the angular frequencies (e.g. rad/s) given in worN.
plot  [callable, optional] A callable that takes two arguments. If given, the return parameters w and h are passed to plot. Useful for plotting the frequency response inside freqs.

Returns

w  [ndarray] The angular frequencies at which h was computed.
h  [ndarray] The frequency response.

See also:

freqz

Compute the frequency response of a digital filter.

Notes

Using Matplotlib’s “plot” function as the callable for plot produces unexpected results, this plots the real part of the complex transfer function, not the magnitude. Try lambda w, h: plot(w, abs(h)).

Examples

```python
>>> from scipy.signal import freqs, iirfilter
```
```python
>>> b, a = iirfilter(4, [1, 10], 1, 60, analog=True, ftype='cheby1')
```
```python
>>> w, h = freqs(b, a, worN=np.logspace(-1, 2, 1000))
```
```python
>>> import matplotlib.pyplot as plt
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.xlabel('Frequency')
>>> plt.ylabel('Amplitude response [dB]')
>>> plt.grid()
>>> plt.show()
```

**scipy.signal.freqs_zpk**

```python
scipy.signal.freqs_zpk(z, p, k, worN=200)
```

Compute frequency response of analog filter.

Given the zeros z, poles p, and gain k of a filter, compute its frequency response:

\[
H(w) = k \prod_{i=0}^{n} \frac{(jw-z[i])}{(jw-p[i])}
\]

Parameters
z [array_like] Zeroes of a linear filter
p [array_like] Poles of a linear filter
k [scalar] Gain of a linear filter
worN [{None, int, array_like}, optional] If None, then compute at 200 frequencies around the interesting parts of the response curve (determined by pole-zero locations). If a single integer, then compute at that many frequencies. Otherwise, compute the response at the angular frequencies (e.g. rad/s) given in worN.

Returns
w [ndarray] The angular frequencies at which h was computed.
h [ndarray] The frequency response.

See also:
freqs
Compute the frequency response of an analog filter in TF form
freqz
Compute the frequency response of a digital filter in TF form
freqz_zpk
Compute the frequency response of a digital filter in ZPK form

Notes
New in version 0.19.0.

Examples

```python
>>> from scipy.signal import freqs_zpk, iirfilter
```
```python
>>> z, p, k = iirfilter(4, [1, 10], 1, 60, analog=True, ftype='cheby1',
                     output='zpk')
```

```python
>>> w, h = freqs_zpk(z, p, k, worN=np.logspace(-1, 2, 1000))
```

```python
>>> import matplotlib.pyplot as plt
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.xlabel('Frequency')
>>> plt.ylabel('Amplitude response [dB]')
>>> plt.grid()
>>> plt.show()
```

**scipy.signal.freqz**

*scipy.signal.freqz(b, a=1, worN=512, whole=False, plot=None, fs=6.283185307179586)*

Compute the frequency response of a digital filter.

Given the M-order numerator \( b \) and N-order denominator \( a \) of a digital filter, compute its frequency response:

\[
H(e^{jw}) = \frac{jw}{jw - b[0] - jw - jwM + \ldots + b[M]e^{-jwN}}
\]

\[
A(e^{jw}) = \frac{jw}{jw - a[0] - jw - jwN + \ldots + a[N]e^{-jwN}}
\]

**Parameters**

- **b** [array_like] Numerator of a linear filter. If \( b \) has dimension greater than 1, it is assumed that the coefficients are stored in the first dimension, and \( b.shape[1:], a.shape[1:] \), and the shape of the frequencies array must be compatible for broadcasting.

- **a** [array_like] Denominator of a linear filter. If \( b \) has dimension greater than 1, it is assumed that the coefficients are stored in the first dimension, and \( b.shape[1:], a.shape[1:] \), and the shape of the frequencies array must be compatible for broadcasting.
worN  
[[None, int, array_like], optional] If a single integer, then compute at that many frequencies (default is N=512). This is a convenient alternative to:

```
np.linspace(0, fs if whole else fs/2, N, endpoint=False)
```

Using a number that is fast for FFT computations can result in faster computations (see Notes).

If an array_like, compute the response at the frequencies given. These are in the same units as fs.

whole  
[bool, optional] Normally, frequencies are computed from 0 to the Nyquist frequency, fs/2 (upper-half of unit-circle). If whole is True, compute frequencies from 0 to fs. Ignored if w is array_like.

plot  
[callable] A callable that takes two arguments. If given, the return parameters w and h are passed to plot. Useful for plotting the frequency response inside freqz.

fs  
[float, optional] The sampling frequency of the digital system. Defaults to 2*pi radians/sample (so w is from 0 to pi).

New in version 1.2.0.

Returns

- w  
  [ndarray] The frequencies at which h was computed, in the same units as fs. By default, w is normalized to the range [0, pi) (radians/sample).
- h  
  [ndarray] The frequency response, as complex numbers.

See also:

- freqz_zpk
- sosfreqz

Notes

Using Matplotlib's `matplotlib.pyplot.plot` function as the callable for plot produces unexpected results, as this plots the real part of the complex transfer function, not the magnitude. Try `lambda w, h: plot(w, np.abs(h))`.

A direct computation via (R)FFT is used to compute the frequency response when the following conditions are met:

1. An integer value is given for worN.
2. worN is fast to compute via FFT (i.e., `next_fast_len(worN)` equals worN).
3. The denominator coefficients are a single value (`a.shape[0] == 1`).
4. worN is at least as long as the numerator coefficients (`worN >= b.shape[0]`).
5. If `b.ndim > 1`, then `b.shape[-1] == 1`.

For long FIR filters, the FFT approach can have lower error and be much faster than the equivalent direct polynomial calculation.

Examples

```python
>>> from scipy import signal
>>> b = signal.firwin(80, 0.5, window=('kaiser', 8))
>>> w, h = signal.freqz(b)
```
>>> import matplotlib.pyplot as plt
>>> fig, ax1 = plt.subplots()
>>> ax1.set_title('Digital filter frequency response')

>>> ax1.plot(w, 20 * np.log10(abs(h)), 'b')
>>> ax1.set_ylabel('Amplitude [dB]', color='b')
>>> ax1.set_xlabel('Frequency [rad/sample]')

>>> ax2 = ax1.twinx()
>>> angles = np.unwrap(np.angle(h))
>>> ax2.plot(w, angles, 'g')
>>> ax2.set_ylabel('Angle (radians)', color='g')
>>> ax2.grid()
>>> ax2.axis('tight')
>>> plt.show()

Broadcasting Examples

Suppose we have two FIR filters whose coefficients are stored in the rows of an array with shape (2, 25). For this demonstration we’ll use random data:

>>> np.random.seed(42)
>>> b = np.random.rand(2, 25)

To compute the frequency response for these two filters with one call to \texttt{freqz}, we must pass in \texttt{b.T}, because \texttt{freqz} expects the first axis to hold the coefficients. We must then extend the shape with a trivial dimension of length 1 to allow broadcasting with the array of frequencies. That is, we pass in \texttt{b.T[...,
np.newaxis]}, which has shape (25, 2, 1):

```python
>>> w, h = signal.freqz(b.T[...,
np.newaxis], worN=1024)
```
Now suppose we have two transfer functions, with the same numerator coefficients \( \mathbf{b} = [0.5, 0.5] \). The coefficients for the two denominators are stored in the first dimension of the two-dimensional array \( \mathbf{a} \):

\[
\mathbf{a} = \begin{bmatrix} 1 & 1 \\ -0.25 & -0.5 \end{bmatrix}
\]

```python
>>> b = np.array([0.5, 0.5])
>>> a = np.array([[[1, 1], [-0.25, -0.5]]])
```

Only \( \mathbf{a} \) is more than one-dimensional. To make it compatible for broadcasting with the frequencies, we extend it with a trivial dimension in the call to \( \text{freqz} \):

```python
>>> w, h = signal.freqz(b, a[..., np.newaxis], worN=1024)
>>> w.shape
(1024,)
>>> h.shape
(2, 1024)
```

### scipy.signal.freqz_zpk

**scipy.signal.freqz_zpk**(\( \mathbf{z} \), \( \mathbf{p} \), \( \mathbf{k} \), \( \text{worN=512} \), \( \text{whole=False} \), \( \text{fs=6.283185307179586} \))

Compute the frequency response of a digital filter in ZPK form.

Given the Zeros, Poles and Gain of a digital filter, compute its frequency response:

\[
H(z) = k \prod_{i} (z - Z[i]) / \prod_{j} (z - P[j])
\]

where \( k \) is the gain, \( Z \) are the zeros and \( P \) are the poles.

**Parameters**

- \( \mathbf{z} \) [array_like] Zeros of a linear filter
- \( \mathbf{p} \) [array_like] Poles of a linear filter
- \( \mathbf{k} \) [scalar] Gain of a linear filter
- \( \text{worN} \) [{None, int, array_like}, optional] If a single integer, then compute at that many frequencies (default is \( N=512 \)).
  
If an array_like, compute the response at the frequencies given. These are in the same units as \( fs \).
- \( \text{whole} \) [bool, optional] Normally, frequencies are computed from 0 to the Nyquist frequency, \( fs/2 \) (upper-half of unit-circle). If \( \text{whole} \) is True, compute frequencies from 0 to \( fs \). Ignored if \( w \) is array_like.
- \( \text{fs} \) [float, optional] The sampling frequency of the digital system. Defaults to \( 2*\pi \) radians/sample (so \( w \) is from 0 to \( \pi \)).
  
New in version 1.2.0.

**Returns**

- \( w \) [ndarray] The frequencies at which \( h \) was computed, in the same units as \( fs \). By default, \( w \) is normalized to the range \( [0, \pi) \) (radians/sample).
- \( h \) [ndarray] The frequency response, as complex numbers.

Compute the frequency response of an analog filter in TF form
\textbf{freqs\_zpk}

Compute the frequency response of an analog filter in ZPK form

\textbf{freqz}

Compute the frequency response of a digital filter in TF form

\section*{Notes}

New in version 0.19.0.

\section*{Examples}

Design a 4th-order digital Butterworth filter with cut-off of 100 Hz in a system with sample rate of 1000 Hz, and plot the frequency response:

```python
>>> from scipy import signal
>>> z, p, k = signal.butter(4, 100, output='zpk', fs=1000)
>>> w, h = signal.freqz_zpk(z, p, k, fs=1000)
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(1, 1, 1)
>>> ax1.set_title('Digital filter frequency response')
>>> ax1.plot(w, 20 * np.log10(abs(h)), 'b')
>>> ax1.set_ylabel('Amplitude [dB]', color='b')
>>> ax1.set_xlabel('Frequency [Hz]')
>>> ax1.grid()
>>> ax2 = ax1.twinx()
>>> angles = np.unwrap(np.angle(h))
>>> ax2.plot(w, angles, 'g')
>>> ax2.set_ylabel('Angle [radians]', color='g')
>>> plt.axis('tight')
>>> plt.show()
```

\textbf{scipy.signal.sosfreqz}

\texttt{scipy.signal.sosfreqz} \texttt{(sos, worN=512, whole=False, fs=6.283185307179586)}

Compute the frequency response of a digital filter in SOS format.

Given \texttt{sos}, an array with shape (n, 6) of second order sections of a digital filter, compute the frequency response of the system function:

\[
H(z) = \frac{B_0(z) \cdot B_1(z) \cdot \ldots \cdot B_{n-1}(z)}{A_0(z) \cdot A_1(z) \cdot \ldots \cdot A_{n-1}(z)}
\]

for \(z = \exp(\omega \cdot \mathbf{j})\), where \(B[k](z)\) and \(A[k](z)\) are numerator and denominator of the transfer function of the \(k\)-th second order section.
Parameters

sos: [array_like] Array of second-order filter coefficients, must have shape \((n\_sections, 6)\). Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.

worN: [{None, int, array_like}, optional] If a single integer, then compute at that many frequencies (default is \(N=512\)). Using a number that is fast for FFT computations can result in faster computations (see Notes of freqz).

If an array_like, compute the response at the frequencies given (must be 1D). These are in the same units as \(fs\).

whole: [bool, optional] Normally, frequencies are computed from 0 to the Nyquist frequency, \(fs/2\) (upper-half of unit-circle). If whole is True, compute frequencies from 0 to \(fs\).

fs: [float, optional] The sampling frequency of the digital system. Defaults to \(2*\pi\) radians/sample (so w is from 0 to \(\pi\)).

New in version 1.2.0.

Returns

w: [ndarray] The frequencies at which \(h\) was computed, in the same units as \(fs\). By default, \(w\) is normalized to the range \([0, \pi]\) (radians/sample).

h: [ndarray] The frequency response, as complex numbers.

See also:

freqz, sosfilt

Notes

New in version 0.19.0.

Examples

Design a 15th-order bandpass filter in SOS format.
```python
>>> from scipy import signal
>>> sos = signal.ellip(15, 0.5, 60, (0.2, 0.4), btype='bandpass',
...                      output='sos')

Compute the frequency response at 1500 points from DC to Nyquist.

```python
>>> w, h = signal.sosfreqz(sos, worN=1500)

Plot the response.

```python
>>> import matplotlib.pyplot as plt
>>> plt.subplot(2, 1, 1)
>>> db = 20*np.log10(np.maximum(np.abs(h), 1e-5))
>>> plt.plot(w/np.pi, db)
>>> plt.ylim(-75, 5)
>>> plt.grid(True)
>>> plt.yticks([0, -20, -40, -60])
>>> plt.ylabel('Gain [dB]')
>>> plt.title('Frequency Response')
>>> plt.subplot(2, 1, 2)
>>> plt.plot(w/np.pi, np.angle(h))
>>> plt.grid(True)
>>> plt.yticks([-np.pi, -0.5*np.pi, 0, 0.5*np.pi, np.pi],
...             [r'$\pi$', r'$\pi/2$', '0', r'$\pi/2$', r'$\pi$'])
>>> plt.ylabel('Phase [rad]')
>>> plt.xlabel('Normalized frequency (1.0 = Nyquist)')
>>> plt.show()
```

If the same filter is implemented as a single transfer function, numerical error corrupts the frequency response:

```python
>>> b, a = signal.ellip(15, 0.5, 60, (0.2, 0.4), btype='bandpass',
...                      output='ba')
>>> w, h = signal.freqz(b, a, worN=1500)
```
```python
>>> db = 20 * np.log10(np.maximum(np.abs(h), 1e-5))
>>> plt.plot(w/np.pi, db)
>>> plt.ylim(-75, 5)
>>> plt.grid(True)
>>> plt.yticks([0, -20, -40, -60])
>>> plt.ylabel('Gain [dB]')
>>> plt.title('Frequency Response')
>>> plt.subplot(2, 1, 2)
>>> plt.plot(w/np.pi, np.angle(h))
>>> plt.grid(True)
>>> plt.yticks([-np.pi, -0.5*np.pi, 0, 0.5*np.pi, np.pi],
              [r'$-\pi$', r'$-\pi/2$', '0', r'$\pi/2$', r'$\pi$'])
>>> plt.ylabel('Phase [rad]')
>>> plt.xlabel('Normalized frequency (1.0 = Nyquist)')
>>> plt.show()
```

**scipy.signal.group_delay**

`scipy.signal.group_delay(system, w=512, whole=False, fs=6.283185307179586)`

Compute the group delay of a digital filter.

The group delay measures by how many samples amplitude envelopes of various spectral components of a signal are delayed by a filter. It is formally defined as the derivative of continuous (unwrapped) phase:

\[
D(w) = - \frac{d}{dw} \arg H(e)
\]

**Parameters**

- `system` [tuple of array_like (b, a)] Numerator and denominator coefficients of a filter transfer function.

---

6.21. Signal processing (`scipy.signal`) 1475
w [{None, int, array_like}, optional] If a single integer, then compute at that many frequencies (default is N=512).
   If an array_like, compute the delay at the frequencies given. These are in the same units as fs.
whole [bool, optional] Normally, frequencies are computed from 0 to the Nyquist frequency, fs/2
   (upper-half of unit-circle). If whole is True, compute frequencies from 0 to fs. Ignored if w is array_like.
fs [float, optional] The sampling frequency of the digital system. Defaults to 2*pi radians/sample (so w is from 0 to pi).
   New in version 1.2.0.

Returns

w [ndarray] The frequencies at which group delay was computed, in the same units as fs. By default, w is normalized to the range [0, pi) (radians/sample).
gd [ndarray] The group delay.

See also:

dfreqzi Frequency response of a digital filter

Notes

The similar function in MATLAB is called grpdelay.

If the transfer function $H(z)$ has zeros or poles on the unit circle, the group delay at corresponding frequencies is undefined. When such a case arises the warning is raised and the group delay is set to 0 at those frequencies.

For the details of numerical computation of the group delay refer to [1].

New in version 0.16.0.

References

[1]

Examples

```python
>>> from scipy import signal
>>> b, a = signal.iirfilter(0.1, 0.3, 5, 50, ftype='cheby1')
>>> w, gd = signal.group_delay((b, a))
```

```python
>>> import matplotlib.pyplot as plt
>>> plt.title('Digital filter group delay')
>>> plt.plot(w, gd)
>>> plt.ylabel('Group delay [samples]')
>>> plt.xlabel('Frequency [rad/sample]')
>>> plt.show()
```
scipy.signal.iirdesign

**scipy.signal.iirdesign** (wp, ws, gpass, gstop, analog=False, ftype='ellip', output='ba', fs=None)

Complete IIR digital and analog filter design.

Given passband and stopband frequencies and gains, construct an analog or digital IIR filter of minimum order for a given basic type. Return the output in numerator, denominator ('ba'), pole-zero ('zpk') or second order sections ('sos') form.

**Parameters**

- **wp**, **ws** [float] Passband and stopband edge frequencies. For digital filters, these are in the same units as *fs*. By default, *fs* is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. For example:
  - Lowpass: *wp*=0.2, *ws*=0.3
  - Highpass: *wp*=0.3, *ws*=0.2
  - Bandpass: *wp*=[0.2, 0.5], *ws*=[0.1, 0.6]
  - Bandstop: *wp*=[0.1, 0.6], *ws*=[0.2, 0.5]

For analog filters, *wp* and *ws* are angular frequencies (e.g. rad/s).

- **gpass** [float] The maximum loss in the passband (dB).

- **gstop** [float] The minimum attenuation in the stopband (dB).

- **analog** [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

- **ftype** [str, optional] The type of IIR filter to design:
  - Butterworth: ‘butter’
  - Chebyshev I: ‘cheby1’
  - Chebyshev II: ‘cheby2’
  - Cauer/elliptic: ‘ellip’
  - Bessel/Thomson: ‘bessel’

- **output** [{'ba', 'zpk', 'sos'}, optional] Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is ‘ba’.

- **fs** [float, optional] The sampling frequency of the digital system.
  New in version 1.2.0.

**Returns**

- **b**, **a** [ndarray, ndarray] Numerator (*b*) and denominator (*a*) polynomials of the IIR filter. Only returned if *output*='ba'.

6.21. Signal processing (scipy.signal) 1477
z, p, k  [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if output='zpk'.
sos  [ndarray] Second-order sections representation of the IIR filter. Only returned if output=='sos'.

Notes

The 'sos' output parameter was added in 0.16.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> wp = 0.2
>>> ws = 0.3
>>> gpass = 1
>>> gstop = 40

>>> system = signal.iirdesign(wp, ws, gpass, gstop)
>>> w, h = signal.freqz(system)

>>> fig, ax1 = plt.subplots()
>>> ax1.set_title('Digital filter frequency response')
>>> ax1.plot(w, 20 * np.log10(abs(h)), 'b')
>>> ax1.set_ylabel('Amplitude [dB]', color='b')
>>> ax1.set_xlabel('Frequency [rad/sample]')
>>> ax1.grid()
>>> ax1.set_ylim([-120, 20])
>>> ax2 = ax1.twinx()
>>> angles = np.unwrap(np.angle(h))
>>> ax2.plot(w, angles, 'g')
>>> ax2.set_ylabel('Angle (radians)', color='g')
>>> ax2.grid()
>>> ax2.axis('tight')
```

(continues on next page)
```python
>>> ax2.set_ymargin([-6, 1])
>>> nticks = 8
>>> ax1.yaxis.set_major_locator(matplotlib.ticker.LinearLocator(nticks))
>>> ax2.yaxis.set_major_locator(matplotlib.ticker.LinearLocator(nticks))
```

**scipy.signal.iirfilter**

The SciPy function `scipy.signal.iirfilter` designs an Nth-order digital or analog filter and returns the filter coefficients.

### Parameters

- **N** [int] The order of the filter.
- **Wn** [array_like] A scalar or length-2 sequence giving the critical frequencies. For digital filters, Wn are in the same units as fs. By default, fs is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (Wn is thus in half-cycles/sample.) For analog filters, Wn is an angular frequency (e.g. rad/s).
- **rp** [float, optional] For Chebyshev and elliptic filters, provides the maximum ripple in the passband. (dB)
- **rs** [float, optional] For Chebyshev and elliptic filters, provides the minimum attenuation in the stop band. (dB)
- **analog** [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.
- **ftype** [str, optional] The type of IIR filter to design:
  - Butterworth: ‘butter’
  - Chebyshev I: ‘cheby1’
  - Chebyshev II: ‘cheby2’
  - Cauer/elliptic: ‘ellip’
  - Bessel/Thomson: ‘bessel’
output: [{'ba', 'zpk', 'sos'}, optional] Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

fs: [float, optional] The sampling frequency of the digital system. New in version 1.2.0.

Returns:

b, a: [ndarray, ndarray] Numerator (b) and denominator (a) polynomials of the IIR filter. Only returned if output='ba'.

z, p, k: [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if output='zpk'.

sos: [ndarray] Second-order sections representation of the IIR filter. Only returned if output=='sos'.

See also:

butter
Filter design using order and critical points

cheby1, cheby2, ellip, bessel

buttord
Find order and critical points from passband and stopband spec

cheb1ord, cheb2ord, ellipord

iirdesign
General filter design using passband and stopband spec

Notes

The 'sos' output parameter was added in 0.16.0.

Examples

Generate a 17th-order Chebyshev II analog bandpass filter from 50 Hz to 200 Hz and plot the frequency response:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.iirfilter(17, [2*np.pi*50, 2*np.pi*200], rs=60, ...      btype='band', analog=True, ftype='cheby2')
>>> w, h = signal.freqs(b, a, 1000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1, 1, 1)
>>> ax.semilogx(w / (2*np.pi), 20 * np.log10(np.maximum(abs(h), 1e-5)))
>>> ax.set_title('Chebyshev Type II bandpass frequency response')
>>> ax.set_xlabel('Frequency [Hz]')
>>> ax.set_ylabel('Amplitude [dB]')
>>> ax.axis((10, 1000, -100, 10))
>>> ax.grid(which='both', axis='both')
>>> plt.show()
```
Create a digital filter with the same properties, in a system with sampling rate of 2000 Hz, and plot the frequency response. (Second-order sections implementation is required to ensure stability of a filter of this order):

```python
>>> sos = signal.iirfilter(17, [50, 200], rs=60, btype='band',
...                        analog=False, ftype='cheby2', fs=2000,
...                        output='sos')
>>> w, h = signal.sosfreqz(sos, 2000, fs=2000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1, 1, 1)
>>> ax.semilogx(w, 20 * np.log10(np.maximum(abs(h), 1e-5))
>>> ax.set_title('Chebyshev Type II bandpass frequency response')
>>> ax.set_xlabel('Frequency [Hz]')
>>> ax.set_ylabel('Amplitude [dB]')
>>> ax.axis((10, 1000, -100, 10))
>>> ax.grid(which='both', axis='both')
>>> plt.show()
```

**scipy.signal.kaiser_atten**

`scipy.signal.kaiser_atten(numtaps, width)`

Compute the attenuation of a Kaiser FIR filter.

Given the number of taps $N$ and the transition width $width$, compute the attenuation $a$ in dB, given by Kaiser's formula:

$$a = 2.285 \times (N - 1) \times \pi \times width + 7.95$$

**Parameters**

- `numtaps` [int] The number of taps in the FIR filter.
- `width` [float] The desired width of the transition region between passband and stopband (or, in general, at any discontinuity) for the filter, expressed as a fraction of the Nyquist frequency.

**Returns**

- `a` [float] The attenuation of the ripple, in dB.
Chebyshev Type II bandpass frequency response

See also:

kaiserord, kaiser_beta

Examples

Suppose we want to design a FIR filter using the Kaiser window method that will have 211 taps and a transition width of 9 Hz for a signal that is sampled at 480 Hz. Expressed as a fraction of the Nyquist frequency, the width is 9/(0.5*480) = 0.0375. The approximate attenuation (in dB) is computed as follows:

```python
>>> from scipy.signal import kaiser_atten
>>> kaiser_atten(211, 0.0375)
64.48099630593983
```

scipy.signal.kaiser_beta

scipy.signal.kaiser_beta(a)

Compute the Kaiser parameter beta, given the attenuation a.

Parameters

- **a** [float] The desired attenuation in the stopband and maximum ripple in the passband, in dB. This should be a positive number.

Returns

- **beta** [float] The beta parameter to be used in the formula for a Kaiser window.

References

Examples

Suppose we want to design a lowpass filter, with 65 dB attenuation in the stop band. The Kaiser window parameter to be used in the window method is computed by $kaiser\_beta(65)$:

```python
>>> from scipy.signal import kaiser_beta
>>> kaiser_beta(65)
6.20426
```

`scipy.signal.kaiserord`

`scipy.signal.kaiserord(ripple, width)`

Determine the filter window parameters for the Kaiser window method.

The parameters returned by this function are generally used to create a finite impulse response filter using the window method, with either `firwin` or `firwin2`.

**Parameters**

- `ripple` [float] Upper bound for the deviation (in dB) of the magnitude of the filter’s frequency response from that of the desired filter (not including frequencies in any transition intervals). That is, if $w$ is the frequency expressed as a fraction of the Nyquist frequency, $A(w)$ is the actual frequency response of the filter and $D(w)$ is the desired frequency response, the design requirement is that:

  $$\text{abs}(A(w) - D(w)) < 10^{-\frac{\text{ripple}}{20}}$$

  for $0 \leq w \leq 1$ and $w$ not in a transition interval.

- `width` [float] Width of transition region, normalized so that 1 corresponds to pi radians / sample. That is, the frequency is expressed as a fraction of the Nyquist frequency.

**Returns**

- `numtaps` [int] The length of the Kaiser window.
- `beta` [float] The beta parameter for the Kaiser window.

**See also:**

`kaiser_beta`, `kaiser_atten`

**Notes**

There are several ways to obtain the Kaiser window:

- `signal.kaiser(numtaps, beta, sym=True)`
- `signal.get_window(beta, numtaps)`
- `signal.get_window(('kaiser', beta), numtaps)`

The empirical equations discovered by Kaiser are used.

**References**

Examples

We will use the Kaiser window method to design a lowpass FIR filter for a signal that is sampled at 1000 Hz.

We want at least 65 dB rejection in the stop band, and in the pass band the gain should vary no more than 0.5%.

We want a cutoff frequency of 175 Hz, with a transition between the pass band and the stop band of 24 Hz. That is, in the band \([0, 163]\), the gain varies no more than 0.5%, and in the band \([187, 500]\), the signal is attenuated by at least 65 dB.

```python
>>> from scipy.signal import kaiserord, firwin, freqz
>>> import matplotlib.pyplot as plt
>>> fs = 1000.0
>>> cutoff = 175
>>> width = 24
```

The Kaiser method accepts just a single parameter to control the pass band ripple and the stop band rejection, so we use the more restrictive of the two. In this case, the pass band ripple is 0.005, or 46.02 dB, so we will use 65 dB as the design parameter.

Use `kaiserord` to determine the length of the filter and the parameter for the Kaiser window.

```python
>>> numtaps, beta = kaiserord(65, width/(0.5*fs))
>>> numtaps
167
>>> beta
6.20426
```

Use `firwin` to create the FIR filter.

```python
>>> taps = firwin(numtaps, cutoff, window='kaiser', beta=beta, scale=False, nyq=0.5*fs)
```

Compute the frequency response of the filter. `w` is the array of frequencies, and `h` is the corresponding complex array of frequency responses.

```python
>>> w, h = freqz(taps, worN=8000)
>>> w *= 0.5*fs/np.pi  # Convert w to Hz.
```

Compute the deviation of the magnitude of the filter’s response from that of the ideal lowpass filter. Values in the transition region are set to `nan`, so they won’t appear in the plot.

```python
>>> ideal = w < cutoff  # The "ideal" frequency response.
>>> deviation = np.abs(h) - ideal
>>> deviation[(w > cutoff - 0.5*width) & (w < cutoff + 0.5*width)] = np.nan
```

Plot the deviation. A close look at the left end of the stop band shows that the requirement for 65 dB attenuation is violated in the first lobe by about 0.125 dB. This is not unusual for the Kaiser window method.

```python
>>> plt.plot(w, 20*np.log10(np.abs(deviation)))
>>> plt.xlim(0, 0.5*fs)
>>> plt.ylim(-90, -60)
>>> plt.grid(alpha=0.25)
>>> plt.axhline(-65, color='r', ls='--', alpha=0.3)
>>> plt.xlabel('Frequency (Hz)')
```

(continues on next page)
>>> plt.ylabel('Deviation from ideal (dB)')
>>> plt.title('Lowpass Filter Frequency Response')
>>> plt.show()

```
Lowpass Filter Frequency Response
```

![Lowpass Filter Frequency Response](image)

**scipy.signal.minimum_phase**

*scipy.signal* .minimum_phase(\(h\), \(method='homomorphic'\), \(n_fft=None\))  
Convert a linear-phase FIR filter to minimum phase

**Parameters**

- **h**  
  [array] Linear-phase FIR filter coefficients.
- **method**  
  [\{'hilbert', 'homomorphic'\}] The method to use:
  - **homomorphic** (default)  
    This method \[4\] \[5\] works best with filters with an odd number of taps, and the resulting minimum phase filter will have a magnitude response that approximates the square root of the the original filter’s magnitude response.
  - **hilbert**  
    This method \[1\] is designed to be used with equiripple filters (e.g., from \texttt{remez}) with unity or zero gain regions.
- **n_fft**  
  [int] The number of points to use for the FFT. Should be at least a few times larger than the signal length (see Notes).

**Returns**

- **h_minimum**  
  [array] The minimum-phase version of the filter, with length \((\text{length}(h) + 1) \div 2\).

**See also:**

- \texttt{firwin}
- \texttt{firwin2}
- \texttt{remez}

6.21. Signal processing (**scipy.signal**)
Notes

In the case of the Hilbert method, the deviation from the ideal spectrum $\epsilon$ is related to the number of stopband zeros $n_{\text{stop}}$ and FFT length $n_{\text{fft}}$ as:

$$\epsilon = 2. \times \frac{n_{\text{stop}}}{n_{\text{fft}}}$$

For example, with 100 stopband zeros and a FFT length of 2048, $\epsilon = 0.0976$. If we conservatively assume that the number of stopband zeros is one less than the filter length, we can take the FFT length to be the next power of 2 that satisfies $\epsilon=0.01$ as:

$$n_{\text{fft}} = 2 ** \text{int}(\text{np.ceil}(\text{np.log2}(2 \times (\text{len}(h) - 1) / 0.01 )))$$

This gives reasonable results for both the Hilbert and homomorphic methods, and gives the value used when $n_{\text{fft}}=\text{None}$.

Alternative implementations exist for creating minimum-phase filters, including zero inversion [2] and spectral factorization [3] [4]. For more information, see:

http://dspguru.com/dsp/howtos/how-to-design-minimum-phase-fir-filters

References

[1], [2], [3], [4], [5]

Examples

Create an optimal linear-phase filter, then convert it to minimum phase:

```python
>>> from scipy.signal import remez, minimum_phase, freqz, group_delay
>>> import matplotlib.pyplot as plt
>>> freq = [0, 0.2, 0.3, 1.0]
>>> desired = [1, 0]
>>> h_linear = remez(151, freq, desired, Hz=2)
```

Convert it to minimum phase:

```python
>>> h_min_hom = minimum_phase(h_linear, method='homomorphic')
>>> h_min_hil = minimum_phase(h_linear, method='hilbert')
```

Compare the three filters:

```python
>>> fig, axs = plt.subplots(4, figsize=(4, 8))
>>> for h, style, color in zip((h_linear, h_min_hom, h_min_hil),
... ('-', '-', '-'), ('k', 'r', 'c')):
...     w, H = freqz(h)
...     w, gd = group_delay((h, 1))
...     w /= np.pi
...     axs[0].plot(h, color=color, linestyle=style)
...     axs[1].plot(w, np.abs(H), color=color, linestyle=style)
...     axs[2].plot(w, 20 * np.log10(np.abs(H)), color=color,...
...     axs[3].plot(w, linestyle=style)
```

(continues on next page)
scipy.signal.savgol_coeffs

scipy.signal.savgol_coeffs(window_length, polyorder, deriv=0, delta=1.0, pos=None, use='conv')

Compute the coefficients for a 1-d Savitzky-Golay FIR filter.

Parameters

- **window_length**
  
  [int] The length of the filter window (i.e. the number of coefficients). window_length must be an odd positive integer.

- **polyorder**
  
  [int] The order of the polynomial used to fit the samples. polyorder must be less than window_length.

- **deriv**
  
  [int, optional] The order of the derivative to compute. This must be a nonnegative integer. The default is 0, which means to filter the data without differentiating.

- **delta**
  
  [float, optional] The spacing of the samples to which the filter will be applied. This is only used if deriv > 0.

- **pos**
  
  [int or None, optional] If pos is not None, it specifies evaluation position within the window. The default is the middle of the window.

- **use**
  
  [str, optional] Either ‘conv’ or ‘dot’. This argument chooses the order of the coefficients. The default is ‘conv’, which means that the coefficients are ordered to be used in a convolution. With use=’dot’, the order is reversed, so the filter is applied by dotting the coefficients with the data set.

Returns

- **coeffs**
  
  [1-d ndarray] The filter coefficients.

See also:

savgol_filter

Notes

New in version 0.14.0.
References

Examples

```python
>>> from scipy.signal import savgol_coeffs
>>> savgol_coeffs(5, 2)
array([-0.08571429, 0.34285714, 0.48571429, 0.34285714, -0.08571429])
>>> savgol_coeffs(5, 2, deriv=1)
array([ 2.00000000e-01, 1.00000000e-01, 2.07548111e-16, -1.00000000e-01,
-2.00000000e-01])
```

Note that use='dot' simply reverses the coefficients.

```python
>>> savgol_coeffs(5, 2, pos=3)
array([ 0.25714286, 0.37142857, 0.34285714, 0.17142857, -0.14285714])
>>> savgol_coeffs(5, 2, pos=3, use='dot')
array([-0.14285714, 0.17142857, 0.34285714, 0.37142857, 0.25714286])
```

$x$ contains data from the parabola $x = t^2$, sampled at $t = -1, 0, 1, 2, 3$. $c$ holds the coefficients that will compute the derivative at the last position. When dotted with $x$ the result should be 6.

```python
>>> x = np.array([1, 0, 1, 4, 9])
>>> c = savgol_coeffs(5, 2, pos=4, deriv=1, use='dot')
>>> c.dot(x)
6.0
```

scipy.signal.remez

`scipy.signal.remez(numtaps, bands, desired, weight=None, Hz=None, type='bandpass', maxiter=25, grid_density=16, fs=None)`

Calculate the minimax optimal filter using the Remez exchange algorithm.

Calculate the filter-coefficients for the finite impulse response (FIR) filter whose transfer function minimizes the maximum error between the desired gain and the realized gain in the specified frequency bands using the Remez exchange algorithm.

**Parameters**

- `numtaps` [int] The desired number of taps in the filter. The number of taps is the number of terms in the filter, or the filter order plus one.
- `bands` [array_like] A monotonic sequence containing the band edges. All elements must be non-negative and less than half the sampling frequency as given by `fs`.
- `desired` [array_like] A sequence half the size of `bands` containing the desired gain in each of the specified bands.
- `weight` [array_like, optional] A relative weighting to give to each band region. The length of `weight` has to be half the length of `bands`.
- `type` [{'bandpass', 'differentiator', 'hilbert'}, optional] The type of filter:
  - `bandpass`: flat response in bands. This is the default.
  - `differentiator`: frequency proportional response in bands.
'hilbert'  [filter with odd symmetry, that is, type III] (for even order) or type IV (for odd order) linear phase filters.

maxiter  [int, optional] Maximum number of iterations of the algorithm. Default is 25.

grid_density  [int, optional] Grid density. The dense grid used in remez is of size (numtaps + 1) * grid_density. Default is 16.

fs  [float, optional] The sampling frequency of the signal. Default is 1.

Returns

out  [ndarray] A rank-1 array containing the coefficients of the optimal (in a minimax sense) filter.

[1],[2]

Examples

In these examples remez gets used creating a bandpass, bandstop, lowpass and highpass filter. The used parameters are the filter order, an array with according frequency boundaries, the desired attenuation values and the sampling frequency. Using freqz the corresponding frequency response gets calculated and plotted.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> def plot_response(fs, w, h, title):
...     "Utility function to plot response functions"
...     fig = plt.figure()
...     ax = fig.add_subplot(111)
...     ax.plot(0.5*fs*w/np.pi, 20*np.log10(np.abs(h))
...     ax.set_ylim(-40, 5)
...     ax.set_xlim(0, 0.5*fs)
...     ax.grid(True)
...     ax.set_xlabel('Frequency (Hz)')
...     ax.set_ylabel('Gain (dB)')
...     ax.set_title(title)
```

This example shows a steep low pass transition according to the small transition width and high filter order:

```python
>>> fs = 22050.0 # Sample rate, Hz
>>> cutoff = 8000.0 # Desired cutoff frequency, Hz
>>> trans_width = 100 # Width of transition from pass band to stop band,
... Hz
>>> numtaps = 400 # Size of the FIR filter.
```

(continues on next page)
>>> taps = signal.remez(numtaps, [0, cutoff, cutoff + trans_width, 0. -5*fs], [1, 0], Hz=fs)
>>> w, h = signal.freqz(taps, [1], worN=2000)
>>> plot_response(fs, w, h, "Low-pass Filter")

This example shows a high pass filter:

```python
>>> fs = 22050.0 # Sample rate, Hz
>>> cutoff = 2000.0 # Desired cutoff frequency, Hz
>>> trans_width = 250 # Width of transition from pass band to stop band, Hz
>>> numtaps = 125 # Size of the FIR filter.
>>> taps = signal.remez(numtaps, [0, cutoff - trans_width, cutoff, 0. -5*fs], ...
... [0, 1], Hz=fs)
>>> w, h = signal.freqz(taps, [1], worN=2000)
>>> plot_response(fs, w, h, "High-pass Filter")
```

For a signal sampled with 22 kHz a bandpass filter with a pass band of 2-5 kHz gets calculated using the Remez algorithm. The transition width is 260 Hz and the filter order 10:

```python
>>> fs = 22000.0 # Sample rate, Hz
>>> band = [2000, 5000] # Desired pass band, Hz
>>> trans_width = 250 # Width of transition from pass band to stop band, Hz
>>> numtaps = 10 # Size of the FIR filter.
>>> edges = [0, band[0] - trans_width, band[0], band[1], ...
... band[1] + trans_width, 0.5*fs]
>>> taps = signal.remez(numtaps, edges, [0, 1, 0], Hz=fs)
>>> w, h = signal.freqz(taps, [1], worN=2000)
>>> plot_response(fs, w, h, "Band-pass Filter")
```

It can be seen that for this bandpass filter, the low order leads to higher ripple and less steep transitions. There is very low attenuation in the stop band and little overshoot in the pass band. Of course the desired gain can be better approximated with a higher filter order.

The next example shows a bandstop filter. Because of the high filter order the transition is quite steep:

```python
>>> fs = 20000.0 # Sample rate, Hz
>>> band = [6000, 8000] # Desired stop band, Hz
>>> trans_width = 200 # Width of transition from pass band to stop band, Hz
>>> numtaps = 175 # Size of the FIR filter.
>>> edges = [0, band[0] - trans_width, band[0], band[1], band[1] + trans_width, 0.5*fs]
>>> taps = signal.remez(numtaps, edges, [1, 0, 1], Hz=fs)
>>> w, h = signal.freqz(taps, [1], worN=2000)
>>> plot_response(fs, w, h, "Band-stop Filter")
```

```python
>>> plt.show()
```
6.21. Signal processing (scipy.signal)
scipy.signal.unique_roots

scipy.signal.unique_roots(p, tol=0.001, rtype='min')
Determine unique roots and their multiplicities from a list of roots.

Parameters
- p [array_like] The list of roots.
- tol [float, optional] The tolerance for two roots to be considered equal in terms of the distance between them. Default is 1e-3. Refer to Notes about the details on roots grouping.
- rtype [{'max', 'maximum', 'min', 'minimum', 'avg', 'mean'}, optional] How to determine the returned root if multiple roots are within tol of each other.
  - 'max', 'maximum': pick the maximum of those roots
  - 'min', 'minimum': pick the minimum of those roots
  - 'avg', 'mean': take the average of those roots
When finding minimum or maximum among complex roots they are compared first by the real part and then by the imaginary part.

Returns
- unique [ndarray] The list of unique roots.
- multiplicity [ndarray] The multiplicity of each root.

Notes
If we have 3 roots a, b and c, such that a is close to b and b is close to c (distance is less than tol), then it doesn’t necessarily mean that a is close to c. It means that roots grouping is not unique. In this function we use “greedy” grouping going through the roots in the order they are given in the input p.

This utility function is not specific to roots but can be used for any sequence of values for which uniqueness and multiplicity has to be determined. For a more general routine, see numpy.unique.

Examples

```python
>>> from scipy import signal
>>> vals = [0, 1.3, 1.31, 2.8, 2.25, 10.3]
>>> uniq, mult = signal.unique_roots(vals, tol=2e-2, rtype='avg')
```

Check which roots have multiplicity larger than 1:

```python
>>> uniq[mult > 1]
array([ 1.305])
```

scipy.signal.residue

scipy.signal.residue(b, a, tol=0.001, rtype='avg')
Compute partial-fraction expansion of b(s) / a(s).

If $M$ is the degree of numerator $b$ and $N$ the degree of denominator $a$:

$$
\frac{b(s)}{a(s)} = \frac{b[0] s^{*}(M) + b[1] s^{*}(M-1) + \ldots + b[M]}{a[0] s^{*}(N) + a[1] s^{*}(N-1) + \ldots + a[N]}
$$
then the partial-fraction expansion $H(s)$ is defined as:

\[
\frac{r[0]}{(s-p[0])} + \frac{r[1]}{(s-p[1])} + \cdots + \frac{r[-1]}{(s-p[-1])} + k(s)
\]

If there are any repeated roots (closer together than `tol`), then $H(s)$ has terms like:

\[
\frac{r[i]}{(s-p[i])} + \frac{r[i+1]}{(s-p[i])**2} + \cdots + \frac{r[i+n-1]}{(s-p[i])**n}
\]

This function is used for polynomials in positive powers of $s$ or $z$, such as analog filters or digital filters in controls engineering. For negative powers of $z$ (typical for digital filters in DSP), use `residuez`.

**Parameters**

- `b` : [array_like] Numerator polynomial coefficients.
- `a` : [array_like] Denominator polynomial coefficients.

**Returns**

- `r` : [ndarray] Residues.
- `p` : [ndarray] Poles.
- `k` : [ndarray] Coefficients of the direct polynomial term.

**See also:**

`invres, residuez, numpy.poly, unique_roots`

**scipy.signal.residue**

**scipy.signal.residue** $(b, a, tol=0.001, rtype='avg')$

Compute partial-fraction expansion of $b(z) / a(z)$.

If $M$ is the degree of numerator $b$ and $N$ the degree of denominator $a$:

\[
H(z) = \frac{b(z)}{a(z)} = \frac{b[0] + b[1] z**(-1) + \cdots + b[M] z**(-M)}{a[0] + a[1] z**(-1) + \cdots + a[N] z**(-N)}
\]

then the partial-fraction expansion $H(z)$ is defined as:

\[
\frac{r[0]}{(1-p[0] z**(-1))} + \frac{r[1]}{(1-p[1] z**(-1))} + \cdots + \frac{k[0] + k[1] z**(-1)}{(1-p[-1] z**(-1))}
\]

If there are any repeated roots (closer than `tol`), then the partial fraction expansion has terms like:

\[
\frac{r[i]}{(1-p[i] z**(-1))} + \frac{r[i+1]}{(1-p[i] z**(-1))**2} + \cdots + \frac{r[i+n-1]}{(1-p[i] z**(-1))**n}
\]

This function is used for polynomials in negative powers of $z$, such as digital filters in DSP. For positive powers, use `residue`.

**Parameters**
scipy.signal.invres

scipy.signal.invres \(r, p, k, tol=0.001, rtype='avg'\)

Compute \(b(s)\) and \(a(s)\) from partial fraction expansion.

If \(M\) is the degree of numerator \(b\) and \(N\) the degree of denominator \(a\):

\[
H(s) = \frac{b(s)}{a(s)} = \frac{b[0] s^{*(M)} + b[1] s^{*(M-1)} + \ldots + b[M]}{a[0] s^{*(N)} + a[1] s^{*(N-1)} + \ldots + a[N]}
\]

then the partial-fraction expansion \(H(s)\) is defined as:

\[
\begin{align*}
\frac{r[0]}{(s-p[0])} &+ \frac{r[1]}{(s-p[1])} + \ldots + \frac{r[-1]}{(s-p[-1])} + k(s) \\
\end{align*}
\]

If there are any repeated roots (closer together than \(tol\)), then \(H(s)\) has terms like:

\[
\begin{align*}
\frac{r[i]}{(s-p[i])} &+ \frac{r[i+1]}{(s-p[i])^2} + \ldots + \frac{r[i+n-1]}{(s-p[i])^n} \\
\end{align*}
\]

This function is used for polynomials in positive powers of \(s\) or \(z\), such as analog filters or digital filters in controls engineering. For negative powers of \(z\) (typical for digital filters in DSP), use \(invresz\).

**Parameters**

- \(r\) [array_like] Residues.
- \(p\) [array_like] Poles.
- \(k\) [array_like] Coefficients of the direct polynomial term.
- \(tol\) [float, optional] The tolerance for two roots to be considered equal. Default is 1e-3.
- \(rtype\) [\{'max', 'min', 'avg'\}, optional] How to determine the returned root if multiple roots are within \(tol\) of each other.
  - 'max': pick the maximum of those roots.
  - 'min': pick the minimum of those roots.
  - 'avg': take the average of those roots.

**Returns**

- \(b\) [ndarray] Numerator polynomial coefficients.
- \(a\) [ndarray] Denominator polynomial coefficients.

See also:

\(invresz, residue, unique_roots\)
residue, invresz, unique_roots

scipy.signal.invresz

scipy.signal.invresz(r, p, k, tol=0.001, rtype='avg')

Compute \( b(z) \) and \( a(z) \) from partial fraction expansion.

If \( M \) is the degree of numerator \( b \) and \( N \) the degree of denominator \( a \):

\[
H(z) = \frac{b(z)}{a(z)} = \frac{b[0] + b[1] z**(-1) + \ldots + b[M] z**(-M)}{a[0] + a[1] z**(-1) + \ldots + a[N] z**(-N)}
\]

then the partial-fraction expansion \( H(z) \) is defined as:

\[
\frac{r[0]}{(1-p[0]z**(-1))} + \ldots + \frac{r[-1]}{(1-p[-1]z**(-1))}
\]

If there are any repeated roots (closer than \( tol \)), then the partial fraction expansion has terms like:

\[
\frac{r[i]}{(1-p[i]z**(-1))} + \frac{r[i+1]}{(1-p[i]z**(-1))**2} + \ldots + \frac{r[i+n-1]}{(1-p[i]z**(-1))**n}
\]

This function is used for polynomials in negative powers of \( z \), such as digital filters in DSP. For positive powers, use \textit{invres}.

Parameters

- \( r \) [array_like] Residues.
- \( p \) [array_like] Poles.
- \( k \) [array_like] Coefficients of the direct polynomial term.
- \( tol \) [float, optional] The tolerance for two roots to be considered equal. Default is 1e-3.
- \( rtype \) [\{‘max’, ‘min’, ‘avg’\}, optional] How to determine the returned root if multiple roots are within \( tol \) of each other.
  - ‘max’: pick the maximum of those roots.
  - ‘min’: pick the minimum of those roots.
  - ‘avg’: take the average of those roots.

Returns

- \( b \) [ndarray] Numerator polynomial coefficients.
- \( a \) [ndarray] Denominator polynomial coefficients.

**scipy.signal.abcd_normalize**

`scipy.signal.abcd_normalize(A=None, B=None, C=None, D=None)`  
Check state-space matrices and ensure they are two-dimensional.

If enough information on the system is provided, that is, enough properly-shaped arrays are passed to the function, the missing ones are built from this information, ensuring the correct number of rows and columns. Otherwise a `ValueError` is raised.

**Parameters**

- `A`, `B`, `C`, `D` [array_like, optional] State-space matrices. All of them are `None` (missing) by default. See `ss2tf` for format.

**Returns**

**Raises**

`ValueError`

If not enough information on the system was provided.

**scipy.signal.band_stop_obj**

`scipy.signal.band_stop_obj(wp, ind, passb, stopb, gpass, gstop, type)`  
Band Stop Objective Function for order minimization.
Returns the non-integer order for an analog band stop filter.

**Parameters**

- `wp` ([scalar]) Edge of passband `passb`.
- `ind` ([int, `{0, 1}`]) Index specifying which `passb` edge to vary (0 or 1).
- `passb` ([ndarray]) Two element sequence of fixed passband edges.
- `stopb` ([ndarray]) Two element sequence of fixed stopband edges.
- `gstop` ([float]) Amount of attenuation in stopband in dB.
- `gpass` ([float]) Amount of ripple in the passband in dB.
- `type` ([`{butter`, `cheby`, `ellip}`]) Type of filter.

**Returns**

- `n` ([scalar]) Filter order (possibly non-integer).

```python
scipy.signal.besselap
```

Return `z`, `p`, `k`) for analog prototype of an Nth-order Bessel filter.

**Parameters**

- `N` ([int]) The order of the filter.
- `norm` ([`{phase`, `delay`, `mag`}, optional]) Frequency normalization:
  - `phase` The filter is normalized such that the phase response reaches its midpoint at an angular (e.g. rad/s) cutoff frequency of 1. This happens for both low-pass and high-pass filters, so this is the “phase-matched” case. [6]
  - The magnitude response asymptotes are the same as a Butterworth filter of the same order with a cutoff of $W_n$.
  - This is the default, and matches MATLAB’s implementation.
  - `delay` The filter is normalized such that the group delay in the passband is 1 (e.g. 1 second). This is the “natural” type obtained by solving Bessel polynomials
  - `mag` The filter is normalized such that the gain magnitude is -3 dB at angular frequency 1. This is called “frequency normalization” by Bond. [1]

New in version 0.18.0.

**Returns**

- `z` ([ndarray]) Zeros of the transfer function. Is always an empty array.
- `p` ([ndarray]) Poles of the transfer function.
- `k` ([scalar]) Gain of the transfer function. For phase-normalized, this is always 1.

**See also:**

- `bessel`
  Filter design function using this prototype

**Notes**

To find the pole locations, approximate starting points are generated [2] for the zeros of the ordinary Bessel polynomial [3], then the Aberth-Ehrlich method [4] [5] is used on the Kv(x) Bessel function to calculate more accurate zeros, and these locations are then inverted about the unit circle.
References

[1], [2], [3], [4], [5], [6]

scipy.signal.buttap

scipy.signal.buttap\( (N) \)

Return \((z,p,k)\) for analog prototype of \(N\)th-order Butterworth filter.

The filter will have an angular (e.g. \(\text{rad/s}\)) cutoff frequency of 1.

See also:

butter

Filter design function using this prototype

scipy.signal.cheb1ap

scipy.signal.cheb1ap\( (N, rp) \)

Return \((z,p,k)\) for \(N\)th-order Chebyshev type I analog lowpass filter.

The returned filter prototype has \(rp\) decibels of ripple in the passband.

The filter’s angular (e.g. \(\text{rad/s}\)) cutoff frequency is normalized to 1, defined as the point at which the gain first drops below \(-rp\).

See also:

cheby1

Filter design function using this prototype

scipy.signal.cheb2ap

scipy.signal.cheb2ap\( (N, rs) \)

Return \((z,p,k)\) for \(N\)th-order Chebyshev type I analog lowpass filter.

The returned filter prototype has \(rs\) decibels of ripple in the stopband.

The filter’s angular (e.g. \(\text{rad/s}\)) cutoff frequency is normalized to 1, defined as the point at which the gain first reaches \(-rs\).

See also:

cheby2

Filter design function using this prototype

scipy.signal.cmplx_sort

scipy.signal.cmplx_sort\( (p) \)

Sort roots based on magnitude.

Parameters

\(p\) [array_like] The roots to sort, as a 1-D array.
Returns

- **p_sorted** [ndarray] Sorted roots.
- **indx** [ndarray] Array of indices needed to sort the input p.

Examples

```python
>>> from scipy import signal
>>> vals = [1, 4, 1+1.j, 3]
>>> p_sorted, indx = signal.cmplx_sort(vals)
>>> p_sorted
array([1.+0.j, 1.+1.j, 3.+0.j, 4.+0.j])
>>> indx
array([0, 2, 3, 1])
```

**scipy.signal.ellipap**

`scipy.signal.ellipap(N, rp, rs)`

Return (z,p,k) of Nth-order elliptic analog lowpass filter.

The filter is a normalized prototype that has $rp$ decibels of ripple in the passband and a stopband $rs$ decibels down.

The filter’s angular (e.g. rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first drops below $-rp$.

- **ellip**
  Filter design function using this prototype

**References**

[1]

**scipy.signal.lp2bp**

`scipy.signal.lp2bp(b, a, wo=1.0, bw=1.0)`

Transform a lowpass filter prototype to a bandpass filter.

Return an analog band-pass filter with center frequency $wo$ and bandwidth $bw$ from an analog low-pass filter prototype with unity cutoff frequency, in transfer function (‘ba’) representation.

**Parameters**

- **b** [array_like] Numerator polynomial coefficients.
- **a** [array_like] Denominator polynomial coefficients.
- **wo** [float] Desired passband center, as angular frequency (e.g. rad/s). Defaults to no change.
- **bw** [float] Desired passband width, as angular frequency (e.g. rad/s). Defaults to 1.

**Returns**

- **b** [array_like] Numerator polynomial coefficients of the transformed band-pass filter.
- **a** [array_like] Denominator polynomial coefficients of the transformed band-pass filter.

See also:
lp2lp, lp2hp, lp2bs, bilinear

lp2bp_zpk

Notes

This is derived from the s-plane substitution

\[ s \rightarrow \frac{s^2 + \omega_0^2}{s \cdot BW} \]

This is the “wideband” transformation, producing a passband with geometric (log frequency) symmetry about \( \omega_0 \).

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> lp = signal.lti([1.0], [1.0, 1.0])
>>> bp = signal.lti(signal.lp2bp(lp.num, lp.den))
>>> w, mag_lp, p_lp = lp.bode()
>>> w, mag_bp, p_bp = bp.bode(w)

>>> plt.plot(w, mag_lp, label='Lowpass')
>>> plt.plot(w, mag_bp, label='Bandpass')
>>> plt.semilogx()
>>> plt.grid()
>>> plt.xlabel('Frequency [rad/s]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.legend()
```

![Graph](image.png)
scipy.signal.lp2bp_zpk

**scipy.signal.lp2bp_zpk** *(z, p, k, wo=1.0, bw=1.0)*

Transform a lowpass filter prototype to a bandpass filter.

Return an analog band-pass filter with center frequency *wo* and bandwidth *bw* from an analog low-pass filter prototype with unity cutoff frequency, using zeros, poles, and gain (‘zpk’) representation.

**Parameters**

- **z** [array_like] Zeros of the analog filter transfer function.
- **p** [array_like] Poles of the analog filter transfer function.
- **k** [float] System gain of the analog filter transfer function.
- **wo** [float] Desired passband center, as angular frequency (e.g. rad/s). Defaults to no change.
- **bw** [float] Desired passband width, as angular frequency (e.g. rad/s). Defaults to 1.

**Returns**

- **z** [ndarray] Zeros of the transformed band-pass filter transfer function.
- **p** [ndarray] Poles of the transformed band-pass filter transfer function.
- **k** [float] System gain of the transformed band-pass filter.

See also:

- *lp2lp_zpk*, *lp2hp_zpk*, *lp2bs_zpk*, *bilinear*
- *lp2bp*

**Notes**

This is derived from the s-plane substitution

\[ s \rightarrow \frac{s^2 + \omega_0^2}{s \cdot BW} \]

This is the "wideband" transformation, producing a passband with geometric (log frequency) symmetry about *wo*. New in version 1.1.0.

scipy.signal.lp2bs

**scipy.signal.lp2bs** *(b, a, wo=1.0, bw=1.0)*

Transform a lowpass filter prototype to a bandstop filter.

Return an analog band-stop filter with center frequency *wo* and bandwidth *bw* from an analog low-pass filter prototype with unity cutoff frequency, in transfer function (‘ba’) representation.

**Parameters**

- **b** [array_like] Numerator polynomial coefficients.
- **a** [array_like] Denominator polynomial coefficients.
- **wo** [float] Desired stopband center, as angular frequency (e.g. rad/s). Defaults to no change.
- **bw** [float] Desired stopband width, as angular frequency (e.g. rad/s). Defaults to 1.

**Returns**

- **b** [array_like] Numerator polynomial coefficients of the transformed band-stop filter.
- **a** [array_like] Denominator polynomial coefficients of the transformed band-stop filter.

See also:
lp2lp, lp2hp, lp2bp, bilinear
lp2bs_zpk

Notes

This is derived from the s-plane substitution

\[ s \rightarrow \frac{s \cdot BW}{s^2 + \omega_0^2} \]

This is the “wideband” transformation, producing a stopband with geometric (log frequency) symmetry about \( \omega_0 \).

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> lp = signal.lti([1.0], [1.0, 1.5])
>>> bs = signal.lti(*signal.lp2bs(lp.num, lp.den))
>>> w, mag_lp, p_lp = lp.bode()
>>> w, mag_bs, p_bs = bs.bode(w)
>>> plt.plot(w, mag_lp, label='Lowpass')
>>> plt.plot(w, mag_bs, label='Bandstop')
>>> plt.semilogx()
>>> plt.grid()
>>> plt.xlabel('Frequency [rad/s]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.legend()
```

![Graph showing Lowpass and Bandstop frequency responses](image-url)
scipy.signal.lp2bs_zpk

scipy.signal.lp2bs_zpk(z, p, k, wo=1.0, bw=1.0)

Transform a lowpass filter prototype to a bandstop filter.

Return an analog band-stop filter with center frequency wo and stopband width bw from an analog low-pass filter prototype with unity cutoff frequency, using zeros, poles, and gain ('zpk') representation.

Parameters

- z [array_like] Zeros of the analog filter transfer function.
- p [array_like] Poles of the analog filter transfer function.
- k [float] System gain of the analog filter transfer function.
- wo [float] Desired stopband center, as angular frequency (e.g. rad/s). Defaults to no change.
- bw [float] Desired stopband width, as angular frequency (e.g. rad/s). Defaults to 1.

Returns

- z [ndarray] Zeros of the transformed band-stop filter transfer function.
- p [ndarray] Poles of the transformed band-stop filter transfer function.
- k [float] System gain of the transformed band-stop filter.

See also:

lp2lp_zpk, lp2hp_zpk, lp2bp_zpk, bilinear

lp2bs

Notes

This is derived from the s-plane substitution

\[ s \mapsto \frac{s \cdot BW}{s^2 + \omega_0^2} \]

This is the “wideband” transformation, producing a stopband with geometric (log frequency) symmetry about wo.

New in version 1.1.0.

scipy.signal.lp2hp

scipy.signal.lp2hp(b, a, wo=1.0)

Transform a lowpass filter prototype to a highpass filter.

Return an analog high-pass filter with cutoff frequency wo from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

Parameters

- b [array_like] Numerator polynomial coefficients.
- a [array_like] Denominator polynomial coefficients.
- wo [float] Desired cutoff, as angular frequency (e.g. rad/s). Defaults to no change.

Returns

- b [array_like] Numerator polynomial coefficients of the transformed high-pass filter.
- a [array_like] Denominator polynomial coefficients of the transformed high-pass filter.

See also:
lp2lp, lp2bp, lp2bs, bilinear
lp2hp_zpk

Notes

This is derived from the s-plane substitution

\[ s \rightarrow \frac{\omega_0}{s} \]

This maintains symmetry of the lowpass and highpass responses on a logarithmic scale.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> lp = signal.lti([1.0], [1.0, 1.0])
>>> hp = signal.lti(*signal.lp2hp(lp.num, lp.den))
>>> w, mag_lp, p_lp = lp.bode()
>>> w, mag_hp, p_hp = hp.bode(w)

>>> plt.plot(w, mag_lp, label='Lowpass')
>>> plt.plot(w, mag_hp, label='Highpass')
>>> plt.semilogx()
>>> plt.grid()
>>> plt.xlabel('Frequency [rad/s]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.legend()
```
scipy.signal.lp2hp_zpk

scipy.signal.lp2hp_zpk(z, p, k, wo=1.0)
Transform a lowpass filter prototype to a highpass filter.

Return an analog high-pass filter with cutoff frequency wo from an analog low-pass filter prototype with unity cutoff frequency, using zeros, poles, and gain ('zpk') representation.

Parameters
- z [array_like] Zeros of the analog filter transfer function.
- p [array_like] Poles of the analog filter transfer function.
- k [float] System gain of the analog filter transfer function.
- wo [float] Desired cutoff, as angular frequency (e.g. rad/s). Defaults to no change.

Returns
- z [ndarray] Zeros of the transformed high-pass filter transfer function.
- p [ndarray] Poles of the transformed high-pass filter transfer function.
- k [float] System gain of the transformed high-pass filter.

See also:
lp2lp_zpk, lp2bp_zpk, lp2bs_zpk, bilinear
lp2hp

Notes
This is derived from the s-plane substitution
\[ s \rightarrow \frac{\omega_0}{s} \]
This maintains symmetry of the lowpass and highpass responses on a logarithmic scale.
New in version 1.1.0.

scipy.signal.lp2lp

scipy.signal.lp2lp(b, a, wo=1.0)
Transform a lowpass filter prototype to a different frequency.

Return an analog low-pass filter with cutoff frequency wo from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

Parameters
- b [array_like] Numerator polynomial coefficients.
- a [array_like] Denominator polynomial coefficients.
- wo [float] Desired cutoff, as angular frequency (e.g. rad/s). Defaults to no change.

Returns
- b [array_like] Numerator polynomial coefficients of the transformed low-pass filter.
- a [array_like] Denominator polynomial coefficients of the transformed low-pass filter.

See also:
lp2hp, lp2bp, lp2bs, bilinear
lp2lp_zpk
Notes

This is derived from the s-plane substitution

\[ s \rightarrow \frac{s}{\omega_0} \]

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> lp = signal.lti([1.0], [1.0, 1.0])
>>> lp2 = signal.lti(*signal.lp2lp(lp.num, lp.den, 2))
>>> w, mag_LP, p_LP = lp.bode()
>>> w, mag_LP2, p_LP2 = lp2.bode(w)

>>> plt.plot(w, mag_LP, label='Lowpass')
>>> plt.plot(w, mag_LP2, label='Transformed Lowpass')
>>> plt.semilogx()
>>> plt.grid()
>>> plt.xlabel('Frequency [rad/s]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.legend()
```

![Bode plots of a lowpass and transformed lowpass filter](image)

**scipy.signal.lp2lp_zpk**

`scipy.signal.lp2lp_zpk(z, p, k, wo=1.0)`

Transform a lowpass filter prototype to a different frequency.

Return an analog low-pass filter with cutoff frequency `wo` from an analog low-pass filter prototype with unity cutoff frequency, using zeros, poles, and gain (‘zpk’) representation.
**Parameters**

- **z** [array_like] Zeros of the analog filter transfer function.
- **p** [array_like] Poles of the analog filter transfer function.
- **k** [float] System gain of the analog filter transfer function.
- **wo** [float] Desired cutoff, as angular frequency (e.g. rad/s). Defaults to no change.

**Returns**

- **z** [ndarray] Zeros of the transformed low-pass filter transfer function.
- **p** [ndarray] Poles of the transformed low-pass filter transfer function.
- **k** [float] System gain of the transformed low-pass filter.

**See also:**

`lp2hp_zpk`, `lp2bp_zpk`, `lp2bs_zpk`, `bilinear`, `lp2lp`

**Notes**

This is derived from the s-plane substitution

\[ s \rightarrow \frac{s}{\omega_0} \]

New in version 1.1.0.

---

**scipy.signal.normalize**

**scipy.signal.normalize***(b, a)*

Normalize numerator/denominator of a continuous-time transfer function.

If values of *b* are too close to 0, they are removed. In that case, a BadCoefficients warning is emitted.

**Parameters**

- **b**: array_like
  Numerator of the transfer function. Can be a 2d array to normalize multiple transfer functions.
- **a**: array_like
  Denominator of the transfer function. At most 1d.

**Returns**

- **num**: array
  The numerator of the normalized transfer function. At least a 1d array. A 2d-array if the input *num* is a 2d array.
- **den**: 1d-array
  The denominator of the normalized transfer function.

**Notes**

Coefficients for both the numerator and denominator should be specified in descending exponent order (e.g., \(s^2 + 3s + 5\) would be represented as \([1, 3, 5]\)).

<td>[ndarray] Second-order sections representation of the IIR filter. Only returned if output=='sos'.</td>
</tr>
</tbody>
</table>

See also:

`buttord`, `buttap`
Notes

The Butterworth filter has maximally flat frequency response in the passband. The 'sos' output parameter was added in 0.16.0.

Examples

Design an analog filter and plot its frequency response, showing the critical points:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.butter(4, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Butterworth filter frequency response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cuttoff frequency
>>> plt.show()
```

![Butterworth filter frequency response](image)

Generate a signal made up of 10 Hz and 20 Hz, sampled at 1 kHz

```python
>>> t = np.linspace(0, 1, 1000, False) # 1 second
>>> sig = np.sin(2*np.pi*10*t) + np.sin(2*np.pi*20*t)
>>> fig, (ax1, ax2) = plt.subplots(2, 1, sharex=True)
>>> ax1.plot(t, sig)
>>> ax1.set_title('10 Hz and 20 Hz sinusoids')
>>> ax1.axis([0, 1, -2, 2])
```

Design a digital high-pass filter at 15 Hz to remove the 10 Hz tone, and apply it to the signal. (It’s recommended to use second-order sections format when filtering, to avoid numerical error with transfer function (b,a) format):
```python
>>> sos = signal.butter(10, 15, 'hp', fs=1000, output='sos')
>>> filtered = signal.sosfilt(sos, sig)
>>> ax2.plot(t, filtered)
>>> ax2.set_title('After 15 Hz high-pass filter')
>>> ax2.axis([0, 1, -2, 2])
>>> ax2.set_xlabel('Time [seconds]')
>>> plt.tight_layout()
>>> plt.show()
```

**scipy.signal.buttord**

`scipy.signal.buttord(wp, ws, gpass, gstop, analog=False, fs=None)`

Butterworth filter order selection.

Return the order of the lowest order digital or analog Butterworth filter that loses no more than \(gpass\) dB in the passband and has at least \(gstop\) dB attenuation in the stopband.

**Parameters**

- **wp, ws** [float] Passband and stopband edge frequencies. For digital filters, these are in the same units as \(fs\). By default, \(fs\) is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (\(wp\) and \(ws\) are thus in half-cycles / sample.) For example:
  - Lowpass: \(wp = 0.2, ws = 0.3\)
  - Highpass: \(wp = 0.3, ws = 0.2\)
  - Bandpass: \(wp = [0.2, 0.5], ws = [0.1, 0.6]\)
  - Bandstop: \(wp = [0.1, 0.6], ws = [0.2, 0.5]\)

  For analog filters, \(wp\) and \(ws\) are angular frequencies (e.g. rad/s).

- **gpass** [float] The maximum loss in the passband (dB).

- **gstop** [float] The minimum attenuation in the stopband (dB).

- **analog** [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

- **fs** [float, optional] The sampling frequency of the digital system.

**Returns**

New in version 1.2.0.
ord [int] The lowest order for a Butterworth filter which meets specs.

wn [ndarray or float] The Butterworth natural frequency (i.e. the “3dB frequency”). Should be used with `butter` to give filter results. If `fs` is specified, this is in the same units, and `fs` must also be passed to `butter`.

`iirdesign`
General filter design using passband and stopband spec

Examples

Design an analog bandpass filter with passband within 3 dB from 20 to 50 rad/s, while rejecting at least -40 dB below 14 and above 60 rad/s. Plot its frequency response, showing the passband and stopband constraints in gray.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> N, Wn = signal.buttord([20, 50], [14, 60], 3, 40, True)
>>> b, a = signal.butter(N, Wn, 'band', True)
>>> w, h = signal.freqs(b, a, np.logspace(1, 2, 500))
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Butterworth bandpass filter fit to constraints')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([1, 14, 14, 1], [-40, -40, 99, 99], '0.9', lw=0) # stop
>>> plt.fill([20, 20, 50, 50], [-3, -3, -99, -99], '0.9', lw=0) # pass
>>> plt.fill([60, 60, 1e9, 1e9], [99, -40, -40, 99], '0.9', lw=0) # stop
>>> plt.axis([10, 100, -60, 3])
>>> plt.show()
```

`scipy.signal.cheby1`

`scipy.signal.cheby1` $(N, rp, Wn, btype='low', analog=False, output='ba', fs=None)$
Chebyshev type I digital and analog filter design.

Design an Nth-order digital or analog Chebyshev type I filter and return the filter coefficients.

Butterworth bandpass filter fit to constraints

**rp** [float] The maximum ripple allowed below unity gain in the passband. Specified in decibels, as a positive number.

**Wn** [array_like] A scalar or length-2 sequence giving the critical frequencies. For Type I filters, this is the point in the transition band at which the gain first drops below -rp. For digital filters, Wn are in the same units as fs. By default, fs is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (Wn is thus in half-cycles / sample.) For analog filters, Wn is an angular frequency (e.g. rad/s).

**btype** [{'lowpass', 'highpass', 'bandpass', 'bandstop' }, optional] The type of filter. Default is 'low-pass'.

**analog** [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

**output** [{'ba', 'zpk', 'sos'}, optional] Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

**fs** [float, optional] The sampling frequency of the digital system. New in version 1.2.0.

**Returns**

- **b, a** [ndarray, ndarray] Numerator (b) and denominator (a) polynomials of the IIR filter. Only returned if output='ba'.
- **z, p, k** [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if output='zpk'.
- **sos** [ndarray] Second-order sections representation of the IIR filter. Only returned if output='sos'.

See also:

- cheb1ord, cheb1ap

Notes

The Chebyshev type I filter maximizes the rate of cutoff between the frequency response’s passband and stopband, at the expense of ripple in the passband and increased ringing in the step response.

Type I filters roll off faster than Type II (cheby2), but Type II filters do not have any ripple in the passband.
The equiripple passband has \( N \) maxima or minima (for example, a 5th-order filter has 3 maxima and 2 minima). Consequently, the DC gain is unity for odd-order filters, or \(-\text{rp \, dB}\) for even-order filters.

The 'sos' output parameter was added in 0.16.0.

**Examples**

Design an analog filter and plot its frequency response, showing the critical points:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.cheby1(4, 5, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev Type I frequency response (rp=5)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.axhline(-5, color='green') # rp
>>> plt.show()
```

![Chebyshev Type I frequency response (rp=5)](image)

Generate a signal made up of 10 Hz and 20 Hz, sampled at 1 kHz

```python
>>> t = np.linspace(0, 1, 1000, False) # 1 second
>>> sig = np.sin(2*np.pi*10*t) + np.sin(2*np.pi*20*t)
>>> fig, (ax1, ax2) = plt.subplots(2, 1, sharex=True)
>>> ax1.plot(t, sig)
>>> ax1.set_title('10 Hz and 20 Hz sinusoids')
>>> ax1.axis([0, 1, -2, 2])
```

Design a digital high-pass filter at 15 Hz to remove the 10 Hz tone, and apply it to the signal. (It’s recommended to use second-order sections format when filtering, to avoid numerical error with transfer function \((ba)\) format):

```python
>>> t = np.linspace(0, 1, 1000, False) # 1 second
>>> sig = np.sin(2*np.pi*10*t) + np.sin(2*np.pi*20*t)
>>> fig, (ax1, ax2) = plt.subplots(2, 1, sharex=True)
>>> ax1.plot(t, sig)
>>> ax1.set_title('10 Hz and 20 Hz sinusoids')
>>> ax1.axis([0, 1, -2, 2])
```
```python
>>> sos = signal.cheby1(10, 1, 15, 'hp', fs=1000, output='sos')
>>> filtered = signal.sosfilt(sos, sig)
>>> ax2.plot(t, filtered)
>>> ax2.set_title('After 15 Hz high-pass filter')
>>> ax2.axis([0, 1, -2, 2])
>>> ax2.set_xlabel('Time [seconds]')
>>> plt.tight_layout()
>>> plt.show()
```

![Graph showing 10 Hz and 20 Hz sinusoids before and after 15 Hz high-pass filter]

### scipy.signal.cheb1ord

The function `scipy.signal.cheb1ord(wp, ws, gpass, gstop, analog=False, fs=None)` selects the order of the lowest order digital or analog Chebyshev Type I filter that loses no more than `gpass` dB in the passband and has at least `gstop` dB attenuation in the stopband.

**Parameters**

- `wp, ws` [float] Passband and stopband edge frequencies.
  - For digital filters, these are in the same units as `fs`. By default, `fs` is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (`wp` and `ws` are thus in half-cycles/sample.) For example:
  - Lowpass: `wp = 0.2, ws = 0.3`
  - Highpass: `wp = 0.3, ws = 0.2`
  - Bandpass: `wp = [0.2, 0.5], ws = [0.1, 0.6]`
  - Bandstop: `wp = [0.1, 0.6], ws = [0.2, 0.5]`
  - For analog filters, `wp` and `ws` are angular frequencies (e.g. rad/s).
- `gpass` [float] The maximum loss in the passband (dB).
- `gstop` [float] The minimum attenuation in the stopband (dB).
- `analog` [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.
- `fs` [float, optional] The sampling frequency of the digital system.
  - New in version 1.2.0.

**Returns**

- The order of the filter (an integer).
ord [int] The lowest order for a Chebyshev type I filter that meets specs.

wn [ndarray or float] The Chebyshev natural frequency (the “3dB frequency”) for use with `cheby1` to give filter results. If `fs` is specified, this is in the same units, and `fs` must also be passed to `cheby1`.

General filter design using order and critical frequencies

iirdesign
General filter design using passband and stopband spec

Examples

Design a digital lowpass filter such that the passband is within 3 dB up to 0.2*(fs/2), while rejecting at least -40 dB above 0.3*(fs/2). Plot its frequency response, showing the passband and stopband constraints in gray.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> N, Wn = signal.cheb1ord(0.2, 0.3, 3, 40)
>>> b, a = signal.cheby1(N, 3, Wn, 'low')
>>> w, h = signal.freqz(b, a)
>>> plt.semilogx(w / np.pi, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev I lowpass filter fit to constraints')
>>> plt.xlabel('Normalized frequency')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([.01, 0.2, 0.2, .01], [-3, -3, -99, -99], '0.9', lw=0) # stop
>>> plt.fill([0.3, 0.3, 2, 2], [9, -40, -40, 9], '0.9', lw=0) # pass
>>> plt.axis([0.08, 1, -60, 3])
>>> plt.show()
```

scipy.signal.cheby2

Design an Nth-order digital or analog Chebyshev type II filter and return the filter coefficients.

Parameters

- N [int] The order of the filter.
- rs [float] The minimum attenuation required in the stop band. Specified in decibels, as a positive number.
Chebyshev I lowpass filter fit to constraints

<table>
<thead>
<tr>
<th>Amplitude [dB]</th>

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Wn [array_like] A scalar or length-2 sequence giving the critical frequencies. For Type II filters, this is the point in the transition band at which the gain first reaches -rs. For digital filters, Wn are in the same units as fs. By default, fs is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (Wn is thus in half-cycles / sample.) For analog filters, Wn is an angular frequency (e.g. rad/s).

analog [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

output [{‘ba’, ‘zpk’, ‘sos’}, optional] Type of output: numerator/denominator (‘ba’), pole-zero (‘zpk’), or second-order sections (‘sos’). Default is ‘ba’.

Returns

b, a [ndarray, ndarray] Numerator (b) and denominator (a) polynomials of the IIR filter. Only returned if output='ba'.

z, p, k [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if output='zpk'.

sos [ndarray] Second-order sections representation of the IIR filter. Only returned if output=='sos'.

See also:

cheb2ord, cheb2ap

Notes

The Chebyshev type II filter maximizes the rate of cutoff between the frequency response’s passband and stopband, at the expense of ripple in the stopband and increased ringing in the step response.

Type II filters do not roll off as fast as Type I (cheby1).

The ‘sos’ output parameter was added in 0.16.0.
Examples

Design an analog filter and plot its frequency response, showing the critical points:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.cheby2(4, 40, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev Type II frequency response (rs=40)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green')  # cutoff frequency
>>> plt.axhline(-40, color='green')  # rs
>>> plt.show()
```

Generate a signal made up of 10 Hz and 20 Hz, sampled at 1 kHz

```python
>>> t = np.linspace(0, 1, 1000, False)  # 1 second
>>> sig = np.sin(2*np.pi*10*t) + np.sin(2*np.pi*20*t)
>>> fig, (ax1, ax2) = plt.subplots(2, 1, sharex=True)
>>> ax1.plot(t, sig)
>>> ax1.set_title('10 Hz and 20 Hz sinusoids')
>>> ax1.axis([0, 1, -2, 2])
```

Design a digital high-pass filter at 17 Hz to remove the 10 Hz tone, and apply it to the signal. (It’s recommended to use second-order sections format when filtering, to avoid numerical error with transfer function (ba) format):

```python
>>> sos = signal.cheby2(12, 20, 17, 'hp', fs=1000, output='sos')
>>> filtered = signal.sosfilt(sos, sig)
>>> ax2.plot(t, filtered)
```

(continues on next page)
scipy.signal.cheb2ord

Return the order of the lowest order digital or analog Chebyshev Type II filter that loses no more than \( g_{pass} \) dB in the passband and has at least \( g_{stop} \) dB attenuation in the stopband.

**Parameters**

- **wp, ws** [float] Passband and stopband edge frequencies.
  For digital filters, these are in the same units as \( fs \). By default, \( fs \) is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. \( (wp \) and \( ws \) are thus in half-cycles / sample.) For example:
  - Lowpass: \( wp = 0.2, ws = 0.3 \)
  - Highpass: \( wp = 0.3, ws = 0.2 \)
  - Bandpass: \( wp = [0.2, 0.5], ws = [0.1, 0.6] \)
  - Bandstop: \( wp = [0.1, 0.6], ws = [0.2, 0.5] \)
  For analog filters, \( wp \) and \( ws \) are angular frequencies (e.g. rad/s).
- **gpass** [float] The maximum loss in the passband (dB).
- **gstop** [float] The minimum attenuation in the stopband (dB).
- **analog** [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.
- **fs** [float, optional] The sampling frequency of the digital system.

**Returns**

- **ord** [int] The lowest order for a Chebyshev type II filter that meets specs.
wn [ndarray or float] The Chebyshev natural frequency (the “3dB frequency”) for use with cheby2 to give filter results. If fs is specified, this is in the same units, and fs must also be passed to cheby2.

iirfilter
General filter design using order and critical frequencies
iirdesign
General filter design using passband and stopband spec

Examples
Design a digital bandstop filter which rejects -60 dB from 0.2*(fs/2) to 0.5*(fs/2), while staying within 3 dB below 0.1*(fs/2) or above 0.6*(fs/2). Plot its frequency response, showing the passband and stopband constraints in gray.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> N, Wn = signal.cheb2ord([0.1, 0.6], [0.2, 0.5], 3, 60)
>>> b, a = signal.cheby2(N, 60, Wn, 'stop')
>>> w, h = signal.freqz(b, a)
>>> plt.semilogx(w / np.pi, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev II bandstop filter fit to constraints')
>>> plt.xlabel('Normalized frequency')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([.01, .1, .1, .01], [-3, -3, -99, -99], '0.9', lw=0) # stop
>>> plt.fill([.2, .5, .5], [-60, -60, 9], '0.9', lw=0) # pass
>>> plt.fill([.6, .6, 2, 2], [-99, -3, -99, 0.9], '0.9', lw=0) # stop
>>> plt.axis([0.06, 1, -80, 3])
>>> plt.show()
```

scipy.signal.ellip

scipy.signal.ellip(N, rp, rs, Wn, btype='low', analog=False, output='ba', fs=None)
Elliptic (Cauer) digital and analog filter design.

Design an Nth-order digital or analog elliptic filter and return the filter coefficients.

Parameters

- `N` [int] The order of the filter.
- `rp` [float] The maximum ripple allowed below unity gain in the passband. Specified in decibels, as a positive number.
Chebyshev II bandstop filter fit to constraints

Normalized frequency

Amplitude [dB]

0
-20
-40
-60
-80
10^{-1}
10^{0}

rs
[float] The minimum attenuation required in the stop band. Specified in decibels, as a positive number.

Wn
[array_like] A scalar or length-2 sequence giving the critical frequencies. For elliptic filters, this is the point in the transition band at which the gain first drops below $-rp$.

For digital filters, $Wn$ are in the same units as $fs$. By default, $fs$ is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. ($Wn$ is thus in half-cycles/sample.)

For analog filters, $Wn$ is an angular frequency (e.g. rad/s).

btype

analog
[bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

output
[{‘ba’, ‘zpk’, ‘sos’}, optional] Type of output: numerator/denominator (‘ba’), pole-zero (‘zpk’), or second-order sections (‘sos’). Default is ‘ba’.

fs
[float, optional] The sampling frequency of the digital system.

New in version 1.2.0.

Returns

b, a
[ndarray, ndarray] Numerator ($b$) and denominator ($a$) polynomials of the IIR filter. Only returned if output=’ba’.

z, p, k
[ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if output=’zpk’.

sos
[ndarray] Second-order sections representation of the IIR filter. Only returned if output=’sos’.

See also:

ellipord, ellipap

Notes

Also known as Cauer or Zolotarev filters, the elliptical filter maximizes the rate of transition between the frequency response’s passband and stopband, at the expense of ripple in both, and increased ringing in the step response.
As $rp$ approaches 0, the elliptical filter becomes a Chebyshev type II filter (cheby2). As $rs$ approaches 0, it becomes a Chebyshev type I filter (cheby1). As both approach 0, it becomes a Butterworth filter (butter).

The equiripple passband has $N$ maxima or minima (for example, a 5th-order filter has 3 maxima and 2 minima). Consequently, the DC gain is unity for odd-order filters, or $-rp$ dB for even-order filters.

The 'sos' output parameter was added in 0.16.0.

Examples

Design an analog filter and plot its frequency response, showing the critical points:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.ellip(4, 5, 40, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Elliptic filter frequency response (rp=5, rs=40)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green')  # cutoff frequency
>>> plt.axhline(-40, color='green')  # rs
>>> plt.axhline(-5, color='green')   # rp
>>> plt.show()
```

Generate a signal made up of 10 Hz and 20 Hz, sampled at 1 kHz

```python
>>> t = np.linspace(0, 1, 1000, False)  # 1 second
>>> sig = np.sin(2*np.pi*10*t) + np.sin(2*np.pi*20*t)
>>> fig, (ax1, ax2) = plt.subplots(2, 1, sharex=True)
>>> ax1.plot(t, sig)
(continues on next page)
Design a digital high-pass filter at 17 Hz to remove the 10 Hz tone, and apply it to the signal. (It’s recommended to use second-order sections format when filtering, to avoid numerical error with transfer function (b,a) format):

```python
>>> sos = signal.ellip(8, 1, 100, 17, 'hp', fs=1000, output='sos')
>>> filtered = signal.sosfilt(sos, sig)
>>> ax2.plot(t, filtered)
>>> ax2.set_title('After 17 Hz high-pass filter')
>>> ax2.axis([0, 1, -2, 2])
>>> ax2.set_xlabel('Time [seconds]')
>>> plt.tight_layout()
>>> plt.show()
```

SciPy Reference Guide, Release 1.3.2

SciPy.signal.ellipord

`scipy.signal.ellipord(wp, ws, gpass, gstop, analog=False, fs=None)`

Elliptic (Cauer) filter order selection.

Return the order of the lowest order digital or analog elliptic filter that loses no more than `gpass` dB in the passband and has at least `gstop` dB attenuation in the stopband.

**Parameters**

- `wp, ws` [float] Passband and stopband edge frequencies.
- For digital filters, these are in the same units as `fs`. By default, `fs` is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (`wp` and `ws` are thus in half-cycles / sample.) For example:
  - Lowpass: `wp = 0.2, ws = 0.3`
  - Highpass: `wp = 0.3, ws = 0.2`
  - Bandpass: `wp = [0.2, 0.5], ws = [0.1, 0.6]`
  - Bandstop: `wp = [0.1, 0.6], ws = [0.2, 0.5]`
- For analog filters, `wp` and `ws` are angular frequencies (e.g. rad/s).

gpass  [float] The maximum loss in the passband (dB).
gstop  [float] The minimum attenuation in the stopband (dB).
analog [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.
fs    [float, optional] The sampling frequency of the digital system.

New in version 1.2.0.

Returns

ord  [int] The lowest order for an Elliptic (Cauer) filter that meets specs.
wn   [ndarray or float] The Chebyshev natural frequency (the “3dB frequency”) for use with
      ellip to give filter results. If fs is specified, this is in the same units, and fs must also
      be passed to ellip.

butord
Find order and critical points from passband and stopband spec

cheb1ord, cheb2ord

iirfilter
General filter design using order and critical frequencies

iirdesign
General filter design using passband and stopband spec

Examples

Design an analog highpass filter such that the passband is within 3 dB above 30 rad/s, while rejecting -60 dB at 10
rad/s. Plot its frequency response, showing the passband and stopband constraints in gray.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> N, Wn = signal.ellipord(30, 10, 3, 60, True)
>>> b, a = signal.ellip(N, 3, 60, Wn, 'high', True)
>>> w, h = signal.freqs(b, a, np.logspace(0, 3, 500))
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Elliptical highpass filter fit to constraints')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([.1, 10, 10, .1], [1e4, 1e4, -60, -60], '0.9', lw=0) # stop
>>> plt.fill([30, 30, 1e9, 1e9], [-99, -3, -3, -99], '0.9', lw=0) # pass
>>> plt.axis([1, 300, -80, 3])
>>> plt.show()
```
**scipy.signal.bessel**

**scipy.signal.bessel** *(N, Wn, btype='low', analog=False, output='ba', norm='phase', fs=None)*

Elliptical highpass filter fit to constraints

Design an Nth-order digital or analog Bessel filter and return the filter coefficients.

*Parameters*

- **N** [int] The order of the filter.
- **Wn** [array_like] A scalar or length-2 sequence giving the critical frequencies (defined by the `norm` parameter). For analog filters, `Wn` is an angular frequency (e.g. rad/s). For digital filters, `Wn` are in the same units as `fs`. By default, `fs` is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (`Wn` is thus in half-cycles / sample.)
- **btype** [{'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional] The type of filter. Default is 'low-pass'.
- **analog** [bool, optional] When True, return an analog filter, otherwise a digital filter is returned. (See Notes.)
- **output** [{'ba', 'zpk', 'sos'}, optional] Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.
- **norm** [{'phase', 'delay', 'mag'}, optional] Critical frequency normalization:
  - **phase** The filter is normalized such that the phase response reaches its midpoint at angular (e.g. rad/s) frequency `Wn`. This happens for both low-pass and high-pass filters, so this is the “phase-matched” case. The magnitude response asymptotes are the same as a Butterworth filter of the same order with a cutoff of `Wn`. This is the default, and matches MATLAB's implementation.
  - **delay** The filter is normalized such that the group delay in the passband is 1/`Wn` (e.g. seconds). This is the “natural” type obtained by solving Bessel polynomials.
  - **mag** The filter is normalized such that the gain magnitude is -3 dB at angular frequency `Wn`. New in version 0.18.0.
- **fs** [float, optional] The sampling frequency of the digital system. New in version 1.2.0.
Returns

- `b, a` [ndarray, ndarray] Numerator \((b)\) and denominator \((a)\) polynomials of the IIR filter. Only returned if `output='ba'`.
- `z, p, k` [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.

Notes

Also known as a Thomson filter, the analog Bessel filter has maximally flat group delay and maximally linear phase response, with very little ringing in the step response. [1]

The Bessel is inherently an analog filter. This function generates digital Bessel filters using the bilinear transform, which does not preserve the phase response of the analog filter. As such, it is only approximately correct at frequencies below about \(fs/4\). To get maximally-flat group delay at higher frequencies, the analog Bessel filter must be transformed using phase-preserving techniques.

See `besselap` for implementation details and references.

The 'sos' output parameter was added in 0.16.0.

References

[1]

Examples

Plot the phase-normalized frequency response, showing the relationship to the Butterworth’s cutoff frequency (green):

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.butter(4, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)), color='silver', ls='dashed')
>>> b, a = signal.bessel(4, 100, 'low', analog=True, norm='phase')
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)))
>>> plt.title('Bessel filter magnitude response (with Butterworth)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green')  # cutoff frequency
>>> plt.show()
```

and the phase midpoint:
Plot the magnitude-normalized frequency response, showing the -3 dB cutoff:
```python
>>> b, a = signal.bessel(3, 10, 'low', analog=True, norm='mag')
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)))
>>> plt.axhline(-3, color='red')  # -3 dB magnitude
>>> plt.axvline(10, color='green')  # cutoff frequency
>>> plt.title('Magnitude-normalized Bessel filter frequency response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()
```

Plot the delay-normalized filter, showing the maximally-flat group delay at 0.1 seconds:

```python
>>> b, a = signal.bessel(5, 1/0.1, 'low', analog=True, norm='delay')
>>> w, h = signal.freqs(b, a)
>>> plt.figure()
>>> plt.semilogx(w[1:], -np.diff(np.unwrap(np.angle(h)))/np.diff(w))
>>> plt.axhline(0.1, color='red')  # 0.1 seconds group delay
>>> plt.title('Bessel filter group delay')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Group delay [seconds]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()
```

### scipy.signal.iirnotch

**scipy.signal.iirnotch(w0, Q, fs=2.0)**

Design second-order IIR notch digital filter.

A notch filter is a band-stop filter with a narrow bandwidth (high quality factor). It rejects a narrow frequency band and leaves the rest of the spectrum little changed.
Parameters

- \( w_0 \) [float] Frequency to remove from a signal. If \( fs \) is specified, this is in the same units as \( fs \). By default, it is a normalized scalar that must satisfy \( 0 < w_0 < 1 \), with \( w_0 = 1 \) corresponding to half of the sampling frequency.
- \( Q \) [float] Quality factor. Dimensionless parameter that characterizes notch filter -3 dB bandwidth \( bw \) relative to its center frequency, \( Q = w_0/bw \).
- \( fs \) [float, optional] The sampling frequency of the digital system. New in version 1.2.0.

Returns

- \( b, a \) [ndarray, ndarray] Numerator \( (b) \) and denominator \( (a) \) polynomials of the IIR filter.

See also:

- iirpeak

Notes

New in version 0.19.0.

References

[1]

Examples

Design and plot filter to remove the 60 Hz component from a signal sampled at 200 Hz, using a quality factor \( Q = 30 \).

```bash
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```
```python
>>> fs = 200.0  # Sample frequency (Hz)
>>> f0 = 60.0  # Frequency to be removed from signal (Hz)
>>> Q = 30.0  # Quality factor
>>> # Design notch filter
>>> b, a = signal.iirnotch(f0, Q, fs)

>>> # Frequency response
>>> freq, h = signal.freqz(b, a, fs=fs)
>>> # Plot
>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20*np.log10(abs(h)), color='blue')
>>> ax[0].set_title("Frequency Response")
>>> ax[0].set_xlabel("Frequency (Hz)")
>>> ax[0].set_ylabel("Amplitude (dB)", color='blue')
>>> ax[0].set_xlim([0, 100])
>>> ax[0].set_ylim([-25, 10])
>>> ax[0].grid()
>>> ax[1].plot(freq, np.unwrap(np.angle(h))*180/np.pi, color='green')
>>> ax[1].set_xlabel("Frequency (Hz)")
>>> ax[1].set_ylabel("Angle (degrees)", color='green')
>>> ax[1].set_xlim([0, 100])
>>> ax[1].set_xticks([-90, -60, -30, 0, 30, 60, 90])
>>> ax[1].set_yticks([-90, 90])
>>> ax[1].grid()
>>> plt.show()
```

### scipy.signal.iirpeak

**scipy.signal.iirpeak**(*w0, Q, fs=2.0*)

Design second-order IIR peak (resonant) digital filter.

A peak filter is a band-pass filter with a narrow bandwidth (high quality factor). It rejects components outside a narrow frequency band.

**Parameters**

- **w0** [float] Frequency to be retained in a signal. If `fs` is specified, this is in the same units as `fs`. By default, it is a normalized scalar that must satisfy $0 < w0 < 1$, with $w0 = 1$ corresponding to half of the sampling frequency.

- **Q** [float] Quality factor. Dimensionless parameter that characterizes peak filter -3 dB bandwidth $bw$ relative to its center frequency, $Q = w0/bw$.

- **fs** [float, optional] The sampling frequency of the digital system. New in version 1.2.0.

**Returns**

- **b, a** [ndarray, ndarray] Numerator ($b$) and denominator ($a$) polynomials of the IIR filter.

**See also:**

- iirnotch

**Notes**

New in version 0.19.0.

6.21. Signal processing (**scipy.signal**) 1531
References

[1]

Examples

Design and plot filter to remove the frequencies other than the 300 Hz component from a signal sampled at 1000 Hz, using a quality factor Q = 30

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> fs = 1000.0  # Sample frequency (Hz)
>>> f0 = 300.0   # Frequency to be retained (Hz)
>>> Q = 30.0    # Quality factor

# Design peak filter
>>> b, a = signal.iirpeak(f0, Q, fs)

# Frequency response
>>> freq, h = signal.freqz(b, a, fs=fs)

# Plot
>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20*np.log10(np.maximum(abs(h), 1e-5)), color='blue')
>>> ax[0].set_title('Frequency Response')
>>> ax[0].set_ylabel('Amplitude (dB)', color='blue')
>>> ax[0].set_xlim([0, 500])
>>> ax[0].set_ylim([-50, 10])
>>> ax[0].grid()

>>> ax[1].plot(freq, np.unwrap(np.angle(h))*180/np.pi, color='green')
>>> ax[1].set_ylabel('Angle (degrees)', color='green')
>>> ax[1].set_xlim([0, 500])
>>> ax[1].set_ylim([-90, 90])
>>> ax[1].set_yticks([-90, -60, -30, 0, 30, 60, 90])
>>> ax[1].set_xlim([-90, 90])
>>> ax[1].grid()
>>> plt.show()
```

**scipy.signal.lti**

```python
class scipy.signal.lti(*system)
```

Continuous-time linear time invariant system base class.

**Parameters**

*system [arguments] The lti class can be instantiated with either 2, 3 or 4 arguments. The following gives the number of arguments and the corresponding continuous-time subclass that is created:

- **2**: `TransferFunction`: (numerator, denominator)
- **3**: `ZerosPolesGain`: (zeros, poles, gain)
- **4**: `StateSpace`: (A, B, C, D)

Each argument can be an array or a sequence.

**See also:**

`ZerosPolesGain`, `StateSpace`, `TransferFunction`, `dlti`

**Notes**

lti instances do not exist directly. Instead, lti creates an instance of one of its subclasses: `StateSpace`, `TransferFunction` or `ZerosPolesGain`.

If (numerator, denominator) is passed in for *system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g., \(s^2 + 3s + 5\) would be represented as \([1, 3, 5]\)).

Changing the value of properties that are not directly part of the current system representation (such as the zeros of a `StateSpace` system) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.

**Examples**

```python
>>> from scipy import signal

>>> signal.lti(1, 2, 3, 4)
StateSpaceContinuous(
    array([[1]]),
    array([[2]]),
    array([[3]]),
    array([[4]]),
    dt: None
)```
6.21. Signal processing (`scipy.signal`)
>> signal.lti([1, 2], [3, 4], 5)
ZerosPolesGainContinuous(
    array([1, 2]),
    array([3, 4]),
    5,
    dt: None
)

>> signal.lti([3, 4], [1, 2])
TransferFunctionContinuous(
    array([3., 4.]),
    array([1., 2.]),
    dt: None
)

Attributes
- **dt**: Return the sampling time of the system, *None* for *lti* systems.
- **poles**: Poles of the system.
- **zeros**: Zeros of the system.

Methods

- **bode**(self[, w, n])
  Calculate Bode magnitude and phase data of a continuous-time system.
  Returns a 3-tuple containing arrays of frequencies [rad/s], magnitude [dB] and phase [deg]. See *bode* for details.

- **freqresp**(self[, w, n])
  Calculate the frequency response of a continuous-time system.

- **impulse**(self[, X0, T, N])
  Return the impulse response of a continuous-time system.

- **output**(self, U, T[, X0])
  Return the response of a continuous-time system to input U.

- **step**(self[, X0, T, N])
  Return the step response of a continuous-time system.

- **to_discrete**(self[, dt[, method, alpha]])
  Return a discretized version of the current system.

scipy.signal.lti.bode

**lti.bode**(self, w=\*None, n=100)
Calculate Bode magnitude and phase data of a continuous-time system.

Returns a 3-tuple containing arrays of frequencies [rad/s], magnitude [dB] and phase [deg]. See *bode* for details.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> sys = signal.TransferFunction([1], [1, 1])
>>> w, mag, phase = sys.bode()
```
```python
>>> plt.figure()
>>> plt.semilogx(w, mag)  # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()
```

**scipy.signal.lti.freqresp**

`lti.freqresp(self, w=None, n=10000)`

Calculate the frequency response of a continuous-time system.

Returns a 2-tuple containing arrays of frequencies [rad/s] and complex magnitude. See `freqresp` for details.
scipy.signal.lti.impulse

lti.impulse(self, X0=None, T=None, N=None)
Return the impulse response of a continuous-time system. See impulse for details.

scipy.signal.lti.output

lti.output(self, U, T, X0=None)
Return the response of a continuous-time system to input U. See lsim for details.

scipy.signal.lti.step

lti.step(self, X0=None, T=None, N=None)
Return the step response of a continuous-time system. See step for details.

scipy.signal.lti.to_discrete

lti.to_discrete(self, dt, method='zoh', alpha=None)
Return a discretized version of the current system.

Parameters:
- *system: arguments
  The StateSpace class can be instantiated with 1 or 3 arguments. The following gives the
  number of input arguments and their interpretation:
  * 1: lti or dlti system: (StateSpace, TransferFunction or ZerosPolesGain)
  * 4: array_like: (A, B, C, D)

  - dt: float, optional
    Sampling time [s] of the discrete-time systems. Defaults to None (continuous-time). Must
    be specified as a keyword argument, for example, dt=0.1.

See also:
- TransferFunction, ZerosPolesGain, lti, dlti
- ss2zpk, ss2tf, zpk2sos

Notes

Changing the value of properties that are not part of the StateSpace system representation (such as zeros or poles) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call sys = sys.to_zpk() before accessing/changing the zeros, poles or gain.
Examples

```python
from scipy import signal

>>> a = np.array([[0, 1], [0, 0]])
>>> b = np.array([[0], [1]])
>>> c = np.array([[1, 0]])
>>> d = np.array([[0]])

>>> sys = signal.StateSpace(a, b, c, d)
>>> print(sys)
StateSpaceContinuous(
    array([[0, 1],
            [0, 0]]),
    array([[0],
            [1]]),
    array([[1, 0]]),
    array([[0]]),
    dt: None)

>>> sys.to_discrete(0.1)
StateSpaceDiscrete(
    array([[1. , 0.1],
            [0. , 1. ]]),
    array([[0.005],
            [0.1 ]]),
    array([[1, 0]]),
    array([[0]]),
    dt: 0.1)

>>> a = np.array([[1, 0.1], [0, 1]])
>>> b = np.array([[0.005], [0.1]])

>>> signal.StateSpace(a, b, c, d, dt=0.1)
StateSpaceDiscrete(
    array([[1. , 0.1],
            [0. , 1. ]]),
    array([[0.005],
            [0.1 ]]),
    array([[1, 0]]),
    array([[0]]),
    dt: 0.1)
```

Attributes

- **A**: State matrix of the `StateSpace` system.
- **B**: Input matrix of the `StateSpace` system.
- **C**: Output matrix of the `StateSpace` system.
- **D**: Feedthrough matrix of the `StateSpace` system.
dt
Return the sampling time of the system, None for lti systems.
poles
Poles of the system.
zeros
Zeros of the system.

Methods

<table>
<thead>
<tr>
<th>Method</th>

</tbody>
</table>

scipy.signal.StateSpace.__mul__

StateSpace.__mul__(self, other)
Post-multiply another system or a scalar

Handles multiplication of systems in the sense of a frequency domain multiplication. That means, given two systems $E_1(s)$ and $E_2(s)$, their multiplication, $H(s) = E_1(s) * E_2(s)$, means that applying $H(s)$ to $U(s)$ is equivalent to first applying $E_2(s)$, and then $E_1(s)$.

Notes

For SISO systems the order of system application does not matter. However, for MIMO systems, where the two systems are matrices, the order above ensures standard Matrix multiplication rules apply.

scipy.signal.StateSpace.to_ss

StateSpace.to_ss(self)
Return a copy of the current StateSpace system.

Returns

* sys ![instance of StateSpace] The current system (copy)

scipy.signal.StateSpace.to_tf

StateSpace.to_tf(self, **kwargs)
Convert system representation to TransferFunction.

Parameters

* kwargs [dict, optional] Additional keywords passed to ss2zpk

Returns

* sys ![instance of TransferFunction] Transfer function of the current system

scipy.signal.StateSpace.to_zpk

StateSpace.to_zpk(self, **kwargs)
Convert system representation to ZerosPolesGain.

Parameters

* kwargs [dict, optional] Additional keywords passed to ss2zpk

Returns
scipy.signal.TransferFunction

class scipy.signal.TransferFunction(*system, **kwargs)

Linear Time Invariant system class in transfer function form.

Represents the system as the continuous-time transfer function \( H(s) = \sum_{i=0}^{N} b[N - i]s^i / \sum_{j=0}^{M} a[M - j]s^j \)
or the discrete-time transfer function \( H(s) = \sum_{i=0}^{N} b[N - i]z^i / \sum_{j=0}^{M} a[M - j]z^j \), where \( b \) are elements of the numerator \( \text{num} \), \( a \) are elements of the denominator \( \text{den} \), and \( N == \text{len(b)} - 1 \), \( M == \text{len(a)} - 1 \). \( \text{TransferFunction} \) systems inherit additional functionality from the \( \text{lti} \), respectively the \( \text{dlti} \) classes, depending on which system representation is used.

Parameters

*system: arguments

The \( \text{TransferFunction} \) class can be instantiated with 1 or 2 arguments. The following gives the number of input arguments and their interpretation:

• 1: \( \text{lti} \) or \( \text{dlti} \) system: \( \text{(StateSpace, TransferFunction or ZerosPolesGain)} \)
• 2: array_like: (numerator, denominator)

dt: float, optional

Sampling time [s] of the discrete-time systems. Defaults to \( \text{None} \) (continuous-time). Must be specified as a keyword argument, for example, \( \text{dt=0.1} \).

See also:

\( \text{ZerosPolesGain, StateSpace, lti, dlti} \)

\( \text{tf2ss, tf2zpk, tf2sos} \)

Notes

Changing the value of properties that are not part of the \( \text{TransferFunction} \) system representation (such as the \( A, B, C, D \) state-space matrices) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call \( \text{sys = sys.to_ss()} \) before accessing/changing the \( A, B, C, D \) system matrices.

If (numerator, denominator) is passed in for *system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \( s^2 + 3s + 5 \) or \( z^2 + 3z + 5 \) would be represented as \([1, 3, 5]\))

Examples

Construct the transfer function:

\[ H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1} \]

```python
>>> from scipy import signal

>>> num = [1, 3, 3]
>>> den = [1, 2, 1]
```
```python
>>> signal.TransferFunction(num, den)
TransferFunctionContinuous(
    array([1., 3., 3.]),
    array([1., 2., 1.]),
    dt: None
)

Construct the transfer function with a sampling time of 0.1 seconds:

\[
H(z) = \frac{z^2 + 3z + 3}{z^2 + 2z + 1}
\]

```

```python
>>> signal.TransferFunction(num, den, dt=0.1)
TransferFunctionDiscrete(
    array([1., 3., 3.]),
    array([1., 2., 1.]),
    dt: 0.1
)
```

**Attributes**
- `den` Denominator of the `TransferFunction` system.
- `dt` Return the sampling time of the system, `None` for `lti` systems.
- `num` Numerator of the `TransferFunction` system.
- `poles` Poles of the system.
- `zeros` Zeros of the system.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>to_ss(self)</code></td>
<td>Convert system representation to <code>StateSpace</code>.</td>

```python
def scipy.signal.TransferFunction.to_ss
    TransferFunction.to_ss(self)
    Convert system representation to `StateSpace`.

    Returns
    -------
    sys       [instance of `StateSpace`] State space model of the current system
```

```python
def scipy.signal.TransferFunction.to_tf
    TransferFunction.to_tf(self)
    Return a copy of the current `TransferFunction` system.

    Returns
    -------
    sys       [instance of `TransferFunction`] The current system (copy)
```
scipy.signal.TransferFunction.to_zpk

TransferFunction.to_zpk(self)
Convert system representation to ZerosPolesGain.

Returns
sys [instance of ZerosPolesGain] Zeros, poles, gain representation of the current system

scipy.signal.ZerosPolesGain

class scipy.signal.ZerosPolesGain(*system, **kwargs)
Linear Time Invariant system class in zeros, poles, gain form.

Represents the system as the continuous- or discrete-time transfer function
\[ H(s) = \frac{k \prod_i (s - z[i])}{\prod_j (s - p[j])} \]
where \( k \) is the gain, \( z \) are the zeros and \( p \) are the poles. ZerosPolesGain systems inherit additional functionality from the \( lti \), respectively the \( dlti \) classes, depending on which system representation is used.

Parameters
*system [arguments] The ZerosPolesGain class can be instantiated with 1 or 3 arguments. The following gives the number of input arguments and their interpretation:
  • 1: \( lti \) or \( dlti \) system: (StateSpace, TransferFunction or ZerosPolesGain)
  • 3: array_like: (zeros, poles, gain)

dt: float, optional
Sampling time [s] of the discrete-time systems. Defaults to None (continuous-time). Must be specified as a keyword argument, for example, \( dt=0.1 \).

See also:
TransferFunction, StateSpace, lti, dlti
zpk2ss, zpk2tf, zpk2sos

Notes
Changing the value of properties that are not part of the ZerosPolesGain system representation (such as the \( A, B, C, D \) state-space matrices) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call \( sys = sys.to_ss() \) before accessing/changing the \( A, B, C, D \) system matrices.

Examples

```python
>>> from scipy import signal

Transfer function: \( H(s) = \frac{5(s - 1)(s - 2)}{(s - 3)(s - 4)} \)

>>> signal.ZerosPolesGain([[1, 2]], [[3, 4]], 5)
ZerosPolesGainContinuous(
  array([[1, 2]]),
  array([[3, 4]]),
  5,
(continues on next page)
```
Transfer function: $H(z) = \frac{5(z - 1)(z - 2)}{(z - 3)(z - 4)}$

```python
>>> signal.ZerosPolesGain([1, 2], [3, 4], 5, dt=0.1)
ZerosPolesGainDiscrete(
    array([1, 2]),
    array([3, 4]),
    5,
    dt: 0.1
)
```

**Attributes**

- `dt`: Return the sampling time of the system, `None` for LTI systems.
- `gain`: Gain of the `ZerosPolesGain` system.
- `poles`: Poles of the `ZerosPolesGain` system.
- `zeros`: Zeros of the `ZerosPolesGain` system.

**Methods**

- `to_ss(self)`: Convert system representation to `StateSpace`.
- `to_tf(self)`: Convert system representation to `TransferFunction`.
- `to_zpk(self)`: Return a copy of the current `ZerosPolesGain` system.

**scipy.signal.ZerosPolesGain.to_ss**

`ZerosPolesGain.to_ss(self)`

Convert system representation to `StateSpace`.

**Returns**

- `sys`: [instance of `StateSpace`] State space model of the current system

**scipy.signal.ZerosPolesGain.to_tf**

`ZerosPolesGain.to_tf(self)`

Convert system representation to `TransferFunction`.

**Returns**

- `sys`: [instance of `TransferFunction`] Transfer function of the current system

**scipy.signal.ZerosPolesGain.to_zpk**

`ZerosPolesGain.to_zpk(self)`

Return a copy of the current `ZerosPolesGain` system.

**Returns**

- `sys`: [instance of `ZerosPolesGain`] The current system (copy)
scipy.signal.lsim

scipy.signal.lsim(system, U, T, X0=None, interp=True)
Simulate output of a continuous-time linear system.

Parameters

- **system** [an instance of the LTI class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
  - 1: (instance of lti)
  - 2: (num, den)
  - 3: (zeros, poles, gain)
  - 4: (A, B, C, D)
- **U** [array_like] An input array describing the input at each time T (interpolation is assumed between given times). If there are multiple inputs, then each column of the rank-2 array represents an input. If U = 0 or None, a zero input is used.
- **T** [array_like] The time steps at which the input is defined and at which the output is desired. Must be nonnegative, increasing, and equally spaced.
- **X0** [array_like, optional] The initial conditions on the state vector (zero by default).
- **interp** [bool, optional] Whether to use linear (True, the default) or zero-order-hold (False) interpolation for the input array.

Returns

- **T** [1D ndarray] Time values for the output.
- **yout** [1D ndarray] System response.
- **xout** [ndarray] Time evolution of the state vector.

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. $s^2 + 3s + 5$ would be represented as [1, 3, 5]).

Examples

Simulate a double integrator $y'' = u$, with a constant input $u = 1$

```python
>>> from scipy import signal
>>> system = signal.lti([[0., 1.], [0., 0.]], [[0.], [1.]], [[1., 0.]], 0.0)
>>> t = np.linspace(0, 5)
>>> u = np.ones_like(t)
>>> tout, y, x = signal.lsim(system, u, t)
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, y)
```

scipy.signal.lsim2

scipy.signal.lsim2(system, U=None, T=None, X0=None, **kwargs)
Simulate output of a continuous-time linear system, by using the ODE solver scipy.integrate.odeint.

Parameters
system [an instance of the \texttt{lti} class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:

- 1: (instance of \texttt{lti})
- 2: (num, den)
- 3: (zeros, poles, gain)
- 4: (A, B, C, D)

\textbf{U} [array\_like (1D or 2D), optional] An input array describing the input at each time \(T\). Linear interpolation is used between given times. If there are multiple inputs, then each column of the rank-2 array represents an input. If \(U\) is not given, the input is assumed to be zero.

\textbf{T} [array\_like (1D or 2D), optional] The time steps at which the input is defined and at which the output is desired. The default is 101 evenly spaced points on the interval \([0, 10.0]\).

\textbf{X0} [array\_like (1D), optional] The initial condition of the state vector. If \(X0\) is not given, the initial conditions are assumed to be 0.

\textbf{kwargs} [dict] Additional keyword arguments are passed on to the function \texttt{odeint}. See the notes below for more details.

\textbf{Returns}

- \textbf{T} [1D ndarray] The time values for the output.
- \textbf{yout} [ndarray] The response of the system.

\textbf{Notes}

This function uses \texttt{scipy.integrate.odeint} to solve the system's differential equations. Additional keyword arguments given to \texttt{lsim2} are passed on to \texttt{odeint}. See the documentation for \texttt{scipy.integrate.odeint} for the full list of arguments.

If (num, den) is passed in for \texttt{system}, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \(s^2 + 3s + 5\) would be represented as \([1, 3, 5]\)).
scipy.signal.impulse

scipy.signal.impulse(system, X0=None, T=None, N=None)

Impulse response of continuous-time system.

Parameters

- **system** [an instance of the LTI class or a tuple of array_like] describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of lti)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
- **X0** [array_like, optional] Initial state-vector. Defaults to zero.
- **T** [array_like, optional] Time points. Computed if not given.
- **N** [int, optional] The number of time points to compute (if T is not given).

Returns

- **T** [ndarray] A 1-D array of time points.
- **yout** [ndarray] A 1-D array containing the impulse response of the system (except for singularities at zero).

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \(s^2 + 3s + 5\) would be represented as \([1, 3, 5]\)).

Examples

Second order system with a repeated root: \(x''(t) + 2x(t) + x(t) = u(t)\)

```python
>>> from scipy import signal
>>> system = ([1.0], [1.0, 2.0, 1.0])
>>> t, y = signal.impulse2(system)
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, y)
```

scipy.signal.impulse2

scipy.signal.impulse2(system, X0=None, T=None, N=None, **kwargs)

Impulse response of a single-input, continuous-time linear system.

Parameters

- **system** [an instance of the LTI class or a tuple of array_like] describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of lti)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
- **X0** [1-D array_like, optional] The initial condition of the state vector. Default: 0 (the zero vector).
T  [1-D array_like, optional] The time steps at which the input is defined and at which the output is desired. If \( T \) is not given, the function will generate a set of time samples automatically.

N  [int, optional] Number of time points to compute. Default: 100.

kwargs  [various types] Additional keyword arguments are passed on to the function \texttt{scipy.signal.lsim2}, which in turn passes them on to \texttt{scipy.integrate.odeint}; see the latter’s documentation for information about these arguments.

\textit{Returns}

\begin{description}
  \item \texttt{T}  [ndarray] The time values for the output.
  \item \texttt{yout}  [ndarray] The output response of the system.
\end{description}

\textit{See also:}

\texttt{impulse, lsim2, scipy.integrate.odeint}

\textbf{Notes}

The solution is generated by calling \texttt{scipy.signal.lsim2}, which uses the differential equation solver \texttt{scipy.integrate.odeint}.

If \texttt{(num, den)} is passed in for \texttt{system}, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \( s^2 + 3s + 5 \) would be represented as \([1, 3, 5] \)).

New in version 0.8.0.

\textbf{Examples}

Second order system with a repeated root: \( x''(t) + 2x(t) + x(t) = u(t) \)

```python
>>> from scipy import signal
>>> system = ([1.0], [1.0, 2.0, 1.0])
>>> t, y = signal.impulse2(system)
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, y)
```
scipy.signal.step

scipy.signal.step(system, X0=None, T=None, N=None)

Step response of continuous-time system.

Parameters

- system [an instance of the LTI class or a tuple of array_like] describing the system. The following gives the number of elements in the tuple and the interpretation:
  * 1 (instance of lti)
  * 2 (num, den)
  * 3 (zeros, poles, gain)
  * 4 (A, B, C, D)
- X0 [array_like, optional] Initial state-vector (default is zero).
- T [array_like, optional] Time points (computed if not given).
- N [int, optional] Number of time points to compute if T is not given.

Returns

- T [1D ndarray] Output time points.
- yout [1D ndarray] Step response of system.

See also:

scipy.signal.step2

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \( s^2 + 3s + 5 \) would be represented as \([1, 3, 5]\)).

Examples
```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> lti = signal.lti([1.0], [1.0, 1.0])
>>> t, y = signal.step(lti)
>>> plt.plot(t, y)
>>> plt.xlabel('Time [s]')
>>> plt.ylabel('Amplitude')
>>> plt.title('Step response for 1. Order Lowpass')
>>> plt.grid()
```

### scipy.signal.step2

**scipy.signal.step2** *(system, X0=None, T=None, N=None, **kwargs)*

Step response of continuous-time system.

This function is functionally the same as `scipy.signal.step`, but it uses the function `scipy.signal.lsim2` to compute the step response.

**Parameters**

- **system** [an instance of the LTI class or a tuple of array_like] describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of `lti`)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
- **X0** [array_like, optional] Initial state-vector (default is zero).
- **T** [array_like, optional] Time points (computed if not given).
- **N** [int, optional] Number of time points to compute if T is not given.
- **kwargs** [various types] Additional keyword arguments are passed on the function `scipy.signal.lsim2`, which in turn passes them on to `scipy.integrate.odeint`. See the documentation for `scipy.integrate.odeint` for information about these arguments.

**Returns**
**T**  [1D ndarray] Output time points.

**yout**  [1D ndarray] Step response of system.

See also:

`scipy.signal.step`

Notes

If `(num, den)` is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \( s^2 + 3s + 5 \) would be represented as `[1, 3, 5]`).

New in version 0.8.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> lti = signal.lti([1.0], [1.0, 1.0])
>>> t, y = signal.step2(lti)
>>> plt.plot(t, y)
>>> plt.xlabel('Time [s]')
>>> plt.ylabel('Amplitude')
>>> plt.title('Step response for 1. Order Lowpass')
>>> plt.grid()
```

`scipy.signal.freqresp`

`scipy.signal.freqresp(system, w=None, n=10000)`

Calculate the frequency response of a continuous-time system.

*Parameters*
**system** [an instance of the `lti` class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
- 1 (instance of `lti`)
- 2 (num, den)
- 3 (zeros, poles, gain)
- 4 (A, B, C, D)

**w** [array_like, optional] Array of frequencies (in rad/s). Magnitude and phase data is calculated for every value in this array. If not given, a reasonable set will be calculated.

**n** [int, optional] Number of frequency points to compute if `w` is not given. The `n` frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

**Returns**
- `w` [1D ndarray] Frequency array [rad/s]
- `H` [1D ndarray] Array of complex magnitude values

**Notes**
If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. $s^2 + 3s + 5$ would be represented as `[1, 3, 5]`).

**Examples**
Generating the Nyquist plot of a transfer function

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Transfer function: $H(s) = \frac{5}{(s-1)^3}$

```python
>>> s1 = signal.ZerosPolesGain([], [1, 1, 1], [5])
```py

```python
>>> w, H = signal.freqresp(s1)
```py

```python
>>> plt.figure()
>>> plt.plot(H.real, H.imag, "b")
>>> plt.plot(H.real, -H.imag, "r")
>>> plt.show()
```py

**scipy.signal.bode**

`scipy.signal.bode` *(system, w=’None’, n=’100’)*

Calculate Bode magnitude and phase data of a continuous-time system.

**Parameters**
- `system` [an instance of the LTI class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of `lti`)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
w  [array_like, optional] Array of frequencies (in rad/s). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.

n  [int, optional] Number of frequency points to compute if w is not given. The n frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

Returns

- w  [1D ndarray] Frequency array [rad/s]
- mag  [1D ndarray] Magnitude array [dB]
- phase  [1D ndarray] Phase array [deg]

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. $s^2 + 3s + 5$ would be represented as $[1, 3, 5]$).

New in version 0.11.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> sys = signal.TransferFunction([1], [1, 1])
>>> w, mag, phase = signal.bode(sys)

>>> plt.figure()
>>> plt.semilogx(w, mag)  # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()
```

`scipy.signal.dlti`

class `scipy.signal.dlti(*system, **kwargs)`

Discrete-time linear time invariant system base class.

Parameters

*system: arguments

The `dlti` class can be instantiated with either 2, 3 or 4 arguments. The following gives the number of arguments and the corresponding discrete-time subclass that is created:

- 2: `TransferFunction`: (numerator, denominator)
- 3: `ZerosPolesGain`: (zeros, poles, gain)
- 4: `StateSpace`: (A, B, C, D)

Each argument can be an array or a sequence.

dt: float, optional

Sampling time [s] of the discrete-time systems. Defaults to True (unspecified sampling time). Must be specified as a keyword argument, for example, `dt=0.1`.

See also:

`ZerosPolesGain, StateSpace, TransferFunction, lti`

Notes

`dlti` instances do not exist directly. Instead, `dlti` creates an instance of one of its subclasses: `StateSpace, TransferFunction` or `ZerosPolesGain`.

Changing the value of properties that are not directly part of the current system representation (such as the zeros of a `StateSpace` system) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.

If (numerator, denominator) is passed in for *system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g., $z^2 + 3z + 5$ would be represented as [1, 3, 5]).

New in version 0.18.0.
Examples

```python
>>> from scipy import signal

>>> signal.dlti(1, 2, 3, 4)
StateSpaceDiscrete(
array([[1]]),
array([[2]]),
array([[3]]),
daT: True)
```

```python
>>> signal.dlti(1, 2, 3, 4, dt=0.1)
StateSpaceDiscrete(
array([[1]]),
array([[2]]),
array([[3]]),
daT: 0.1)
```

```python
>>> signal.dlti([1, 2], [3, 4], 5, dt=0.1)
ZerosPolesGainDiscrete(
array([1, 2]),
array([3, 4]),
5,
daT: 0.1)
```

```python
>>> signal.dlti([3, 4], [1, 2], dt=0.1)
TransferFunctionDiscrete(
array([3., 4.]),
array([1., 2.]),
daT: 0.1)
```

Attributes

- **dt**: Return the sampling time of the system.
- **poles**: Poles of the system.
- **zeros**: Zeros of the system.

Methods

- **bode**(self[, w, n]) Calculate Bode magnitude and phase data of a discrete-time system.
- **freqresp**(self[, w, n, whole]) Calculate the frequency response of a discrete-time system.

**scipy.signal.dlti.bode**

dlti.bode \((self, w=None, n=100)\)

Calculate Bode magnitude and phase data of a discrete-time system.

Returns a 3-tuple containing arrays of frequencies [rad/s], magnitude [dB] and phase [deg]. See dbode for details.

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Transfer function: \(H(z) = 1 / (z^2 + 2z + 3)\) with sampling time 0.5s

```py
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.5)
```

Equivalent: signal.dbode(sys)

```py
>>> w, mag, phase = sys.bode()
```

```py
>>> plt.figure()
>>> plt.semilogx(w, mag)  # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase) # Bode phase plot
>>> plt.show()
```
scipy.signal.dlti.freqresp

dlti.freqresp(self, w=None, n=10000, whole=False)

Calculate the frequency response of a discrete-time system.

Returns a 2-tuple containing arrays of frequencies [rad/s] and complex magnitude. See dfreqresp for details.

scipy.signal.dlti.impulse

dlti.impulse(self, x0=None, t=None, n=None)

Return the impulse response of the discrete-time dlti system. See dimpulse for details.

scipy.signal.dlti.output

dlti.output(self, u, t, x0=None)

Return the response of the discrete-time system to input u. See dlsim for details.

scipy.signal.dlti.step

dlti.step(self, x0=None, t=None, n=None)

Return the step response of the discrete-time dlti system. See dstep for details.

scipy.signal.dlsim

scipy.signal.dlsim(system, u, t=None, x0=None)

Simulate output of a discrete-time linear system.

Parameters

- system [tuple of array_like or instance of dlti] A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1: (instance of dlti)
  - 3: (num, den, dt)
  - 4: (zeros, poles, gain, dt)
  - 5: (A, B, C, D, dt)
SciPy Reference Guide, Release 1.3.2

**SciPy Reference Guide, Release 1.3.2**

- **u** [array_like] An input array describing the input at each time \( t \) (interpolation is assumed between given times). If there are multiple inputs, then each column of the rank-2 array represents an input.

- **t** [array_like, optional] The time steps at which the input is defined. If \( t \) is given, it must be the same length as \( u \), and the final value in \( t \) determines the number of steps returned in the output.

- **x0** [array_like, optional] The initial conditions on the state vector (zero by default).

**Returns**

- **tout** [ndarray] Time values for the output, as a 1-D array.

- **yout** [ndarray] System response, as a 1-D array.

- **xout** [ndarray, optional] Time-evolution of the state-vector. Only generated if the input is a StateSpace system.

See also:

- `lsim`, `dstep`, `dimpulse`, `cont2discrete`

**Examples**

A simple integrator transfer function with a discrete time step of 1.0 could be implemented as:

```python
>>> from scipy import signal
>>> tf = ([1.0], [1.0, -1.0], 1.0)
>>> t_in = [0.0, 1.0, 2.0, 3.0]
>>> u = np.asarray([0.0, 0.0, 1.0, 1.0])
>>> t_out, y = signal.dlsim(tf, u, t=t_in)
>>> y.T
array([[ 0., 0., 0., 1.]])
```

**scipy.signal.dimpulse**

- **scipy.signal.dimpulse** *(system, x0=None, t=None, n=None)*

  Impulse response of discrete-time system.

  **Parameters**

  - **system** [tuple of array_like or instance of dlti] A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:
    - 1: (instance of dlti)
    - 3: (num, den, dt)
    - 4: (zeros, poles, gain, dt)
    - 5: (A, B, C, D, dt)

  - **x0** [array_like, optional] Initial state-vector. Defaults to zero.

  - **t** [array_like, optional] Time points. Computed if not given.

  - **n** [int, optional] The number of time points to compute (if \( t \) is not given).

  **Returns**

  - **tout** [ndarray] Time values for the output, as a 1-D array.

  - **yout** [tuple of ndarray] Impulse response of system. Each element of the tuple represents the output of the system based on an impulse in each input.

  See also:
impulse, dstep, dlsim, cont2discrete

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> butter = signal.dlti(signal.butter(3, 0.5))
>>> t, y = signal.dimpulse(butter, n=25)
>>> plt.step(t, np.squeeze(y))
>>> plt.grid()
>>> plt.xlabel('n [samples]')
>>> plt.ylabel('Amplitude')
```

`scipy.signal.dstep`

`scipy.signal.dstep` *(system, x0=None, t=None, n=None)*

Step response of discrete-time system.

**Parameters**

- **system** [tuple of array_like] A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1: (instance of `dlti`)
  - 3: (num, den, dt)
  - 4: (zeros, poles, gain, dt)
  - 5: (A, B, C, D, dt)
- **x0** [array_like, optional] Initial state-vector. Defaults to zero.
- **t** [array_like, optional] Time points. Computed if not given.
- **n** [int, optional] The number of time points to compute (if `t` is not given).

**Returns**

- **tout** [ndarray] Output time points, as a 1-D array.
yout  
[tuple of ndarrays] Step response of system. Each element of the tuple represents the output of the system based on a step response to each input.

See also:

*step, dimpulse, dlsim, cont2discrete*

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> butter = signal.dlti(*signal.butter(3, 0.5))
>>> t, y = signal.dstep(butter, n=25)
>>> plt.step(t, np.squeeze(y))
>>> plt.grid()
>>> plt.xlabel('n [samples]')
>>> plt.ylabel('Amplitude')
```

![Graph showing step response of a system](image)

**scipy.signal.dfreqresp**

`scipy.signal.dfreqresp(system, w=None, n=10000, whole=False)`

Calculate the frequency response of a discrete-time system.

**Parameters**

- **system** [an instance of the `dlti` class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of `dlti`)
  - 2 (numerator, denominator, dt)
  - 3 (zeros, poles, gain, dt)
  - 4 (A, B, C, D, dt)
SciPy Reference Guide, Release 1.3.2

**w** [array_like, optional] Array of frequencies (in radians/sample). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.

**n** [int, optional] Number of frequency points to compute if **w** is not given. The **n** frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

**whole** [bool, optional] Normally, if ‘**w**’ is not given, frequencies are computed from 0 to the Nyquist frequency, pi radians/sample (upper-half of unit-circle). If **whole** is True, compute frequencies from 0 to 2*pi radians/sample.

**Returns**

- **w** [1D ndarray] Frequency array [radians/sample]
- **H** [1D ndarray] Array of complex magnitude values

**Notes**

If (num, den) is passed in for **system**, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \( z^2 + 3z + 5 \) would be represented as \([1, 3, 5]\)).

New in version 0.18.0.

**Examples**

Generating the Nyquist plot of a transfer function

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Transfer function: \( H(z) = \frac{1}{z^2 + 2z + 3} \)

```  

```python
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.05)

```  

```python
>>> w, H = signal.dfreqresp(sys)

```  

```python
>>> plt.figure()
>>> plt.plot(H.real, H.imag, "b")
>>> plt.plot(H.real, -H.imag, "r")
>>> plt.show()
```

**scipy.signal.dbode**

`scipy.signal.dbode(system, w=None, n=100)`

Calculate Bode magnitude and phase data of a discrete-time system.

**Parameters**

- **system** [an instance of the LTI class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of `dlti`)
  - 2 (num, den, dt)
  - 3 (zeros, poles, gain, dt)
  - 4 (A, B, C, D, dt)
w  [array_like, optional] Array of frequencies (in radians/sample). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.

n  [int, optional] Number of frequency points to compute if w is not given. The n frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

Returns

w  [1D ndarray] Frequency array [rad/time_unit]
mag  [1D ndarray] Magnitude array [dB]
phase  [1D ndarray] Phase array [deg]

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. $z^2 + 3z + 5$ would be represented as [1, 3, 5]).

New in version 0.18.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Transfer function: $H(z) = 1 / (z^2 + 2z + 3)$

```
>>> plt.figure()
>>> plt.semilogx(w, mag)  # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()

scipy.signal.tf2zpk

scipy.signal.tf2zpk(b, a)

Return zero, pole, gain (z, p, k) representation from a numerator, denominator representation of a linear filter.

**Parameters**

- **b** : array_like, Numerator polynomial coefficients.
- **a** : array_like, Denominator polynomial coefficients.

**Returns**

- **z** : ndarray, Zeros of the transfer function.
- **p** : ndarray, Poles of the transfer function.
- **k** : float, System gain.

**Notes**

If some values of b are too close to 0, they are removed. In that case, a BadCoefficients warning is emitted.

The b and a arrays are interpreted as coefficients for positive, descending powers of the transfer function variable. So the inputs \( b = [b_0, b_1, ..., b_M] \) and \( a = [a_0, a_1, ..., a_N] \) can represent an analog filter of the form:

\[
H(s) = \frac{b_0 s^M + b_1 s^{(M-1)} + \cdots + b_M}{a_0 s^N + a_1 s^{(N-1)} + \cdots + a_N}
\]

or a discrete-time filter of the form:

\[
H(z) = \frac{b_0 z^M + b_1 z^{(M-1)} + \cdots + b_M}{a_0 z^N + a_1 z^{(N-1)} + \cdots + a_N}
\]

This “positive powers” form is found more commonly in controls engineering. If \( M \) and \( N \) are equal (which is true for all filters generated by the bilinear transform), then this happens to be equivalent to the “negative powers” discrete-time form preferred in DSP:

\[
H(z) = \frac{b_0 + b_1 z^{-1} + \cdots + b_M z^{-M}}{a_0 + a_1 z^{-1} + \cdots + a_N z^{-N}}
\]

Although this is true for common filters, remember that this is not true in the general case. If \( M \) and \( N \) are not equal, the discrete-time transfer function coefficients must first be converted to the “positive powers” form before finding the poles and zeros.
scipy.signal.tf2sos

scipy.signal.tf2sos(b, a, pairing='nearest')

Return second-order sections from transfer function representation

Parameters

b: array_like
    Numerator polynomial coefficients.
a: array_like
    Denominator polynomial coefficients.
pairing: {'nearest', 'keep_odd'}, optional
    The method to use to combine pairs of poles and zeros into sections. See zpk2sos.

Returns

sos: ndarray
    Array of second-order filter coefficients, with shape (n_sections, 6). See sosfilt for the SOS filter format specification.

See also:

zpk2sos, sosfilt

Notes

It is generally discouraged to convert from TF to SOS format, since doing so usually will not improve numerical precision errors. Instead, consider designing filters in ZPK format and converting directly to SOS. TF is converted to SOS by first converting to ZPK format, then converting ZPK to SOS.

New in version 0.16.0.

scipy.signal.tf2ss

scipy.signal.tf2ss(num, den)

Transfer function to state-space representation.

Parameters

num, den: array_like
    Sequences representing the coefficients of the numerator and denominator polynomials, in order of descending degree. The denominator needs to be at least as long as the numerator.

Returns

A, B, C, D: ndarray
    State space representation of the system, in controller canonical form.

Examples

Convert the transfer function:

\[ H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1} \]

```python
>>> num = [1, 3, 3]
>>> den = [1, 2, 1]
```
to the state-space representation:

\[
x(t) = \begin{bmatrix} -2 & -1 \\ 1 & 0 \end{bmatrix} x(t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix} u(t)
\]

\[
y(t) = \begin{bmatrix} 1 & 2 \end{bmatrix} x(t) + \begin{bmatrix} 1 \end{bmatrix} u(t)
\]

```python
>>> from scipy.signal import tf2ss
>>> A, B, C, D = tf2ss(num, den)
>>> A
array([[-2., -1.],
       [ 1.,  0.]])
>>> B
array([[ 1.],
       [ 0.]])
>>> C
array([[ 1.,  2.]])
>>> D
array([[ 1.]])
```

### scipy.signal.zpk2tf

**scipy.signal.zpk2tf**(*z*, *p*, *k*)

Return polynomial transfer function representation from zeros and poles

**Parameters**

- *z* : array_like
  Zeros of the transfer function.

- *p* : array_like
  Poles of the transfer function.

- *k* : float
  System gain.

**Returns**

- *b* : ndarray
  Numerator polynomial coefficients.

- *a* : ndarray
  Denominator polynomial coefficients.

### scipy.signal.zpk2sos

**scipy.signal.zpk2sos**(*z*, *p*, *k*, *pairing='nearest'*)

Return second-order sections from zeros, poles, and gain of a system

**Parameters**

- *z* : array_like
  Zeros of the transfer function.

- *p* : array_like
  Poles of the transfer function.

- *k* : float
  System gain.

- *pairing* : {'nearest', 'keep_odd'}, optional
  The method to use to combine pairs of poles and zeros into sections. See Notes below.

**Returns**

- *sos* : ndarray
  Array of second-order filter coefficients, with shape `(n_sections, 6)`. See `sosfilt` for the SOS filter format specification.

See also:
sosfilt

Notes
The algorithm used to convert ZPK to SOS format is designed to minimize errors due to numerical precision issues. The pairing algorithm attempts to minimize the peak gain of each biquadratic section. This is done by pairing poles with the nearest zeros, starting with the poles closest to the unit circle.

Algorithms
The current algorithms are designed specifically for use with digital filters. (The output coefficients are not correct for analog filters.)

The steps in the pairing='nearest' and pairing='keep_odd' algorithms are mostly shared. The nearest algorithm attempts to minimize the peak gain, while 'keep_odd' minimizes peak gain under the constraint that odd-order systems should retain one section as first order. The algorithm steps and are as follows:

As a pre-processing step, add poles or zeros to the origin as necessary to obtain the same number of poles and zeros for pairing. If pairing == 'nearest' and there are an odd number of poles, add an additional pole and a zero at the origin.

The following steps are then iterated over until no more poles or zeros remain:

1. Take the (next remaining) pole (complex or real) closest to the unit circle to begin a new filter section.
2. If the pole is real and there are no other remaining real poles, add the closest real zero to the section and leave it as a first order section. Note that after this step we are guaranteed to be left with an even number of real poles, complex poles, real zeros, and complex zeros for subsequent pairing iterations.
3. Else:
   1. If the pole is complex and the zero is the only remaining real zero, then pair the pole with the next closest zero (guaranteed to be complex). This is necessary to ensure that there will be a real zero remaining to eventually create a first-order section (thus keeping the odd order).
   2. Else pair the pole with the closest remaining zero (complex or real).
   3. Proceed to complete the second-order section by adding another pole and zero to the current pole and zero in the section:
      1. If the current pole and zero are both complex, add their conjugates.
      2. Else if the pole is complex and the zero is real, add the conjugate pole and the next closest real zero.
      3. Else if the pole is real and the zero is complex, add the conjugate zero and the real pole closest to those zeros.
      4. Else (we must have a real pole and real zero) add the next real pole closest to the unit circle, and then add the real zero closest to that pole.

New in version 0.16.0.

Examples
Design a 6th order low-pass elliptic digital filter for a system with a sampling rate of 8000 Hz that has a pass-band corner frequency of 1000 Hz. The ripple in the pass-band should not exceed 0.087 dB, and the attenuation in the stop-band should be at least 90 dB.

In the following call to signal.ellip, we could use output='sos', but for this example, we'll use output='zpk', and then convert to SOS format with zpk2sos:

1 This conditional can only be met for specific odd-order inputs with the pairing == 'keep_odd' method.
```python
>>> from scipy import signal
>>> z, p, k = signal.ellip(6, 0.087, 90, 1000/(0.5*8000), output='zpk')
```

Now convert to SOS format.

```python
>>> sos = signal.zpk2sos(z, p, k)
```

The coefficients of the numerators of the sections:

```python
>>> sos[:, :3]
array([[ 0.0014154, 0.00248707, 0.0014154 ],
       [ 1. , 0.72965193, 1.   ],
       [ 1. , 0.17594966, 1.   ]])
```

The symmetry in the coefficients occurs because all the zeros are on the unit circle.

The coefficients of the denominators of the sections:

```python
>>> sos[:, 3:]
array([[ 1. , -1.32543251, 0.46989499],
       [ 1. , -1.26117915, 0.6262586 ],
       [ 1. , -1.25707217, 0.86199667]])
```

The next example shows the effect of the pairing option. We have a system with three poles and three zeros, so the SOS array will have shape (2, 6). The means there is, in effect, an extra pole and an extra zero at the origin in the SOS representation.

```python
>>> z1 = np.array([-1, -0.5-0.5j, -0.5+0.5j])
>>> p1 = np.array([0.75, 0.8+0.1j, 0.8-0.1j])
```

With `pairing='nearest'` (the default), we obtain

```python
>>> signal.zpk2sos(z1, p1, 1)
array([[ 1. , 1. , 0.5 , 1. , -0.75, 0.  ],
       [ 1. , 1. , 0.  , 1. , -1.6 , 0.65]])
```

The first section has the zeros {-0.5-0.05j, -0.5+0.5j} and the poles {0, 0.75}, and the second section has the zeros {-1, 0} and poles {0.8+0.1j, 0.8-0.1j}. Note that the extra pole and zero at the origin have been assigned to different sections.

With `pairing='keep_odd'`, we obtain:

```python
>>> signal.zpk2sos(z1, p1, 1, pairing='keep_odd')
array([[ 1. , 1. , 0.5 , 1. , -0.75, 0.  ],
       [ 1. , 1. , 0.  , 1. , -1.6 , 0.65]])
```

The extra pole and zero at the origin are in the same section. The first section is, in effect, a first-order section.

**scipy.signal.zpk2ss**

**scipy.signal.zpk2ss**(z, p, k)

Zero-pole-gain representation to state-space representation

**Parameters**

- z, p [sequence] Zeros and poles.
SciPy Reference Guide, Release 1.3.2

k  [float] System gain.

Returns
A, B, C, D  [ndarray] State space representation of the system, in controller canonical form.

scipy.signal.ss2tf

scipy.signal.ss2tf(A, B, C, D, input=0)

State-space to transfer function.
A, B, C, D defines a linear state-space system with p inputs, q outputs, and n state variables.

Parameters
A  [array_like] State (or system) matrix of shape (n, n)
B  [array_like] Input matrix of shape (n, p)
C  [array_like] Output matrix of shape (q, n)
D  [array_like] Feedthrough (or feedforward) matrix of shape (q, p)
input  [int, optional] For multiple-input systems, the index of the input to use.

Returns
num  [2-D ndarray] Numerator(s) of the resulting transfer function(s). num has one row for each of the system’s outputs. Each row is a sequence representation of the numerator polynomial.
den  [1-D ndarray] Denominator of the resulting transfer function(s). den is a sequence representation of the denominator polynomial.

Examples

Convert the state-space representation:

\[
\dot{x}(t) = \begin{bmatrix} -2 & -1 \\ 1 & 0 \end{bmatrix} x(t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix} u(t)
\]

\[
y(t) = \begin{bmatrix} 1 & 2 \end{bmatrix} x(t) + \begin{bmatrix} 1 \end{bmatrix} u(t)
\]

>>> A = [[-2, -1], [1, 0]]
>>> B = [[1], [0]]  # 2-dimensional column vector
>>> C = [[1, 2]]    # 2-dimensional row vector
>>> D = 1

to the transfer function:

\[
H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1}
\]

>>> from scipy.signal import ss2tf
>>> ss2tf(A, B, C, D)
(array([[1, 3, 3]]), array([[ 1., 2., 1.]]))
scipy.signal.ss2zpk

scipy.signal.ss2zpk(A, B, C, D, input=0)

State-space representation to zero-pole-gain representation.

A, B, C, D defines a linear state-space system with p inputs, q outputs, and n state variables.

Parameters

- A : [array_like] State (or system) matrix of shape (n, n)
- B : [array_like] Input matrix of shape (n, p)
- C : [array_like] Output matrix of shape (q, n)
- D : [array_like] Feedthrough (or feedforward) matrix of shape (q, p)
- input : [int, optional] For multiple-input systems, the index of the input to use.

Returns

- z, p : [sequence] Zeros and poles.
- k : [float] System gain.

scipy.signal.sos2zpk

scipy.signal.sos2zpk(sos)

Return zeros, poles, and gain of a series of second-order sections

Parameters

- sos : [array_like] Array of second-order filter coefficients, must have shape (n_sections, 6). See sosfilt for the SOS filter format specification.

Returns

- z : [ndarray] Zeros of the transfer function.
- p : [ndarray] Poles of the transfer function.
- k : [float] System gain.

Notes

New in version 0.16.0.

scipy.signal.sos2tf

scipy.signal.sos2tf(sos)

Return a single transfer function from a series of second-order sections

Parameters

- sos : [array_like] Array of second-order filter coefficients, must have shape (n_sections, 6). See sosfilt for the SOS filter format specification.

Returns

- b : [ndarray] Numerator polynomial coefficients.
- a : [ndarray] Denominator polynomial coefficients.
**Notes**

New in version 0.16.0.

**scipy.signal.cont2discrete**

`scipy.signal.cont2discrete(system, dt, method='zoh', alpha=None)`

Transform a continuous to a discrete state-space system.

**Parameters**

- **system** [a tuple describing the system or an instance of `lti`] The following gives the number of elements in the tuple and the interpretation:
  - 1: (instance of `lti`)
  - 2: (num, den)
  - 3: (zeros, poles, gain)
  - 4: (A, B, C, D)

- **dt** [float] The discretization time step.

- **method** [str, optional] Which method to use:
  - gbt: generalized bilinear transformation
  - bilinear: Tustin’s approximation (“gbt” with alpha=0.5)
  - euler: Euler (or forward differencing) method (“gbt” with alpha=0)
  - backward_diff: Backwards differencing (“gbt” with alpha=1.0)
  - zoh: zero-order hold (default)
  - foh: first-order hold (versionadded: 1.3.0)
  - impulse: equivalent impulse response (versionadded: 1.3.0)

- **alpha** [float within [0, 1], optional] The generalized bilinear transformation weighting parameter, which should only be specified with method=”gbt”, and is ignored otherwise

**Returns**

- **sysd** [tuple containing the discrete system] Based on the input type, the output will be of the form:
  - (num, den, dt) for transfer function input
  - (zeros, poles, gain, dt) for zeros-poles-gain input
  - (A, B, C, D, dt) for state-space system input

**Notes**

By default, the routine uses a Zero-Order Hold (zoh) method to perform the transformation. Alternatively, a generalized bilinear transformation may be used, which includes the common Tustin’s bilinear approximation, an Euler’s method technique, or a backwards differencing technique.

The Zero-Order Hold (zoh) method is based on [1], the generalized bilinear approximation is based on [2] and [3], the First-Order Hold (foh) method is based on [4].

**References**

[1], [2], [3], [4]
The function `scipy.signal.place_poles` is used to compute a gain matrix `K` such that the eigenvalues of \( A - B*K \) are as close as possible to the requested poles. This function is useful for designing controllers in control systems. It supports SISO, MISO, and MIMO systems.

**Parameters**

- **A, B** [ndarray] State-space representation of linear system \( AX + BU \).
- **poles** [array_like] Desired real poles and/or complex conjugate poles. Complex poles are only supported with the method `method='YT'` (default).
- **method** : {'YT', 'KNV0'}, optional
  Which method to choose to find the gain matrix `K`. One of:
  - `'YT'`: Yang Tits
  - `'KNV0'`: Kautsky, Nichols, Van Dooren update method 0
  See References and Notes for details on the algorithms.
- **rtol** : float, optional
  After each iteration the determinant of the eigenvectors of \( A - B*K \) is compared to its previous value, when the relative error between these two values becomes lower than `rtol` the algorithm stops. Default is \( 1e^{-3} \).
- **maxiter** : int, optional
  Maximum number of iterations to compute the gain matrix. Default is 30.

**Returns**

- **full_state_feedback** [Bunch object]
  - **gain_matrix** [1-D ndarray] The closed loop matrix `K` such as the eigenvalues of \( A - B*K \) are as close as possible to the requested poles.
  - **computed_poles** [1-D ndarray] The poles corresponding to \( A - B*K \) sorted as first the real poles in increasing order, then the complex conjugates in lexicographic order.
  - **requested_poles** [1-D ndarray] The poles the algorithm was asked to place sorted as above, they may differ from what was achieved.
  - **X** [2-D ndarray] The transfer matrix such as \( X * \text{diag}(poles) = (A - B*K) * X \) (see Notes)
  - **rtol** [float] The relative tolerance achieved on \( \det(X) \) (see Notes). `rtol` will be NaN if it is possible to solve the system \( \text{diag}(poles) = (A - B*K) \), or 0 when the optimization algorithms can't do anything i.e when \( B\.shape[1] == 1 \).
  - **nb_iter** [int] The number of iterations performed before converging. `nb_iter` will be NaN if it is possible to solve the system \( \text{diag}(poles) = (A - B*K) \), or 0 when the optimization algorithms can't do anything i.e when \( B\.shape[1] == 1 \).
Notes

The Tits and Yang (YT), [2] paper is an update of the original Kautsky et al. (KNV) paper [1]. KNV relies on rank-1 updates to find the transfer matrix X such that \( X \cdot \text{diag}(\text{poles}) = (A - B\cdot K)\cdot X \), whereas YT uses rank-2 updates. This yields on average more robust solutions (see [2] pp 21-22), furthermore the YT algorithm supports complex poles whereas KNV does not in its original version. Only update method 0 proposed by KNV has been implemented here, hence the name 'KNV0'.

KNV extended to complex poles is used in Matlab's place function, YT is distributed under a non-free licence by Slicot under the name robpole. It is unclear and undocumented how KNV0 has been extended to complex poles (Tits and Yang claim on page 14 of their paper that their method cannot be used to extend KNV to complex poles), therefore only YT supports them in this implementation.

As the solution to the problem of pole placement is not unique for MIMO systems, both methods start with a tentative transfer matrix which is altered in various way to increase its determinant. Both methods have been proven to converge to a stable solution, however depending on the way the initial transfer matrix is chosen they will converge to different solutions and therefore there is absolutely no guarantee that using 'KNV0' will yield results similar to Matlab's or any other implementation of these algorithms.

Using the default method 'YT' should be fine in most cases; 'KNV0' is only provided because it is needed by 'YT' in some specific cases. Furthermore 'YT' gives on average more robust results than 'KNV0' when abs(det(X)) is used as a robustness indicator.

References

[1], [2]

Examples

A simple example demonstrating real pole placement using both KNV and YT algorithms. This is example number 1 from section 4 of the reference KNV publication ([1]):

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> A = np.array([[ 1.380, -0.2077,  6.715, -5.676 ],
...               [-0.5814, -4.290,  0,  0.6750 ],
...               [ 1.067,  4.273, -6.654,  5.893 ],
...               [ 0.0480,  4.273,  1.343, -2.104 ]])
>>> B = np.array([[ 0,  5.679 ],
...               [ 1.136,  1.136 ],
...               [ 0,  0 ],
...               [-3.146,  0 ]])
>>> P = np.array([-0.2, -0.5, -5.0566, -8.6659])

Now compute K with KNV method 0, with the default YT method and with the YT method while forcing 100 iterations of the algorithm and print some results after each call.

```python
>>> fsf1 = signal.place_poles(A, B, P, method='KNV0')
>>> fsf1.gain_matrix
array([[ 0.20071427, -0.96665799,  0.24066128, -0.10279785],
       [ 0.50587268,  0.5779091,  0.51795763, -0.41991442]])
```
>>> fsf2 = signal.place_poles(A, B, P)  # uses YT method
>>> fsf2.computed_poles
array([[-8.6659, -5.0566, -0.5 , -0.2 ]])

>>> fsf3 = signal.place_poles(A, B, P, rtol=-1, maxiter=100)
>>> fsf3.X
array([[ 0.52072442+0.j, -0.08409372+0.j, -0.56847937+0.j, 0.74823657+0.j],
       [-0.04977751+0.j, -0.80872954+0.j, 0.13566234+0.j, -0.43815060+0.j],
       [-0.82266932+0.j, -0.19168026+0.j, -0.56348322+0.j, -0.40271926+0.j],
       [ 0.22267347+0.j, 0.54967577+0.j, -0.58387806+0.j, -0.40271926+0.j]])

The absolute value of the determinant of X is a good indicator to check the robustness of the results, both 'KNV0' and 'YT' aim at maximizing it. Below a comparison of the robustness of the results above:

>>> abs(np.linalg.det(fsf1.X)) < abs(np.linalg.det(fsf2.X))
True
>>> abs(np.linalg.det(fsf2.X)) < abs(np.linalg.det(fsf3.X))
True

Now a simple example for complex poles:

```python
>>> A = np.array([[ 0, 7/3., 0, 0 ],
                [ 0, 0, 7/9., 0 ],
                [ 0, 0, 0, 0 ],
                [ 0, 0, 0, 0 ]])
>>> B = np.array([[ 0, 0 ],
                [ 0, 0 ],
                [ 1, 0 ],
                [ 0, 1 ]])
>>> P = np.array([-3, -1, -2-j, -2+1j]) / 3.
>>> fsf = signal.place_poles(A, B, P, method='YT')
```

We can plot the desired and computed poles in the complex plane:

```python
>>> t = np.linspace(0, 2*np.pi, 401)
>>> plt.plot(np.cos(t), np.sin(t), 'k--')  # unit circle
>>> plt.plot(fsf.requested_poles.real, fsf.requested_poles.imag, 'wo', label='Desired')
>>> plt.plot(fsf.computed_poles.real, fsf.computed_poles.imag, 'bx', label='Placed')
>>> plt.grid()
>>> plt.axis('image')
>>> plt.axis([-1.1, 1.1, -1.1, 1.1])
>>> plt.legend(bbox_to_anchor=(1.05, 1), loc=2, numpoints=1)
```

### 6.21.9 Waveforms
SciPy Reference Guide, Release 1.3.2

1.0
0.5
0.0
0.5
1.0
 Desired
Placed

chirp(t, f0, t1, f1[, method, phi, vertex_zero]) Frequency-swept cosine generator.

gausspulse(t[, fc, bw, bwr, tpr, retquad, ...]) Return a Gaussian modulated sinusoid.

max_len_seq(nbits[, state, length, taps]) Maximum length sequence (MLS) generator.

sawtooth(t[, width]) Return a periodic sawtooth or triangle waveform.

square(t[, duty]) Return a periodic square-wave waveform.

sweep_poly(t, poly[, phi]) Frequency-swept cosine generator, with a time-dependent frequency.

unit_impulse(shape[, idx, dtype]) Unit impulse signal (discrete delta function) or unit basis vector.

scipy.signal.chirp

scipy.signal.chirp(t, f0, t1, f1, method='linear', phi=0, vertex_zero=True)
Frequency-swept cosine generator.

In the following, 'Hz' should be interpreted as 'cycles per unit'; there is no requirement here that the unit is one second. The important distinction is that the units of rotation are cycles, not radians. Likewise, t could be a measurement of space instead of time.

Parameters

- t [array_like] Times at which to evaluate the waveform.
- f0 [float] Frequency (e.g. Hz) at time t=0.
- t1 [float] Time at which f1 is specified.
- f1 [float] Frequency (e.g. Hz) of the waveform at time t1.
- phi [float, optional] Phase offset, in degrees. Default is 0.
- vertex_zero [bool, optional] This parameter is only used when method is ‘quadratic’. It determines whether the vertex of the parabola that is the graph of the frequency is at t=0 or t=t1.

Returns

- y [ndarray] A numpy array containing the signal evaluated at t with the requested time-varying frequency. More precisely, the function returns cos(phase + (pi/180)*phi) where phase is the integral (from 0 to t) of 2*pi*f(t). f(t) is defined below.

See also:

sweep_poly

Chapter 6. API Reference
else:
    \[ f(t) = f_1 - (f_1 - f_0) \times (t_1 - t)^2 / t_1^2 \]

To use a more general quadratic function, or an arbitrary polynomial, use the function `scipy.signal.sweep_poly`.

logarithmic, log, lo:
\[ f(t) = f_0 \times (f_1/f_0)^{(t/t_1)} \]
f_0 and f_1 must be nonzero and have the same sign.
This signal is also known as a geometric or exponential chirp.

hyperbolic, hyp:
\[ f(t) = f_0*f_1*t_1 / ((f_0 - f_1)*t + f_1*t_1) \]
f_0 and f_1 must be nonzero.

**Examples**

The following will be used in the examples:

```python
>>> from scipy.signal import chirp, spectrogram
>>> import matplotlib.pyplot as plt
```

For the first example, we'll plot the waveform for a linear chirp from 6 Hz to 1 Hz over 10 seconds:

```python
>>> t = np.linspace(0, 10, 5001)
>>> w = chirp(t, f0=6, f1=1, t1=10, method='linear')
>>> plt.plot(t, w)
>>> plt.title("Linear Chirp, f(0)=6, f(10)=1")
>>> plt.xlabel('t (sec)')
>>> plt.show()
```

![Linear Chirp, f(0)=6, f(10)=1](image)

For the remaining examples, we'll use higher frequency ranges, and demonstrate the result using `scipy.signal.spectrogram`. We'll use a 10 second interval sampled at 8000 Hz.
Quadratic chirp from 1500 Hz to 250 Hz over 10 seconds (vertex of the parabolic curve of the frequency is at t=0):

```python
>>> fs = 8000
>>> T = 10
>>> t = np.linspace(0, T, T*fs, endpoint=False)
```

```python
Quadratic chirp from 1500 Hz to 250 Hz over 10 seconds (vertex of the parabolic curve of the frequency is at t=0):
```

```python
>>> w = chirp(t, f0=1500, f1=250, t1=10, method='quadratic',
            vertex_zero=False)
>>> ff, tt, Sxx = spectrogram(w, fs=fs, noverlap=256, nperseg=512,
                             nfft=2048)
>>> plt.pcolorshesh(tt, ff[:,513], Sxx[:,513], cmap='gray_r')
>>> plt.title('Quadratic Chirp, f(0)=1500, f(10)=250')
>>> plt.xlabel('t (sec)')
>>> plt.ylabel('Frequency (Hz)')
>>> plt.grid()
>>> plt.show()
```

Logarithmic chirp from 1500 Hz to 250 Hz over 10 seconds:

```python
>>> w = chirp(t, f0=1500, f1=250, t1=10, method='quadratic',
            vertex_zero=True)
>>> ff, tt, Sxx = spectrogram(w, fs=fs, noverlap=256, nperseg=512,
                             nfft=2048)
>>> plt.pcolormesh(tt, ff[:,513], Sxx[:,513], cmap='gray_r')
>>> plt.title('Quadratic Chirp, f(0)=1500, f(10)=250
            (vertex_zero=True)')
>>> plt.xlabel('t (sec)')
>>> plt.ylabel('Frequency (Hz)')
>>> plt.grid()
>>> plt.show()
```
Hyperbolic chirp from 1500 Hz to 250 Hz over 10 seconds:

```python
>>> w = chirp(t, f0=1500, f1=250, t1=10, method='hyperbolic')
>>> ff, tt, Sxx = spectrogram(w, fs=fs, noverlap=256, nperseg=512,
... nfft=2048)
>>> plt.pcolormesh(tt, ff[:513], Sxx[:513], cmap='gray_r')
>>> plt.title('Logarithmic Chirp, f(0)=1500, f(10)=250')
>>> plt.xlabel('t (sec)')
>>> plt.ylabel('Frequency (Hz)')
>>> plt.grid()
>>> plt.show()
```
SciPy Reference Guide, Release 1.3.2

(continued from previous page)

```python
... nfft=2048)
>>> plt.pcolormesh(tt, ff[:513], Sxx[:513], cmap='gray_r')
>>> plt.title('Hyperbolic Chirp, f(0)=1500, f(10)=250')
>>> plt.xlabel('t (sec)')
>>> plt.ylabel('Frequency (Hz)')
>>> plt.grid()
>>> plt.show()
```

![Hyperbolic Chirp, f(0)=1500, f(10)=250]

```scipy.signal.gausspulse```

**scipy.signal.gausspulse** *(t, fc=1000, bw=0.5, bwr=-6, tpr=-60, retquad=False, retenv=False)*

Return a Gaussian modulated sinusoid:

\[
\exp(-a t^2) \exp(1j*2\pi*fc*t).
\]

If `retquad` is True, then return the real and imaginary parts (in-phase and quadrature). If `retenv` is True, then return the envelope (unmodulated signal). Otherwise, return the real part of the modulated sinusoid.

**Parameters**

- **t** [ndarray or the string ‘cutoff’] Input array.
- **fc** [int, optional] Center frequency (e.g. Hz). Default is 1000.
- **bw** [float, optional] Fractional bandwidth in frequency domain of pulse (e.g. Hz). Default is 0.5.
- **bwr** [float, optional] Reference level at which fractional bandwidth is calculated (dB). Default is -6.
- **tpr** [float, optional] If `t` is ‘cutoff’, then the function returns the cutoff time for when the pulse amplitude falls below `tpr` (in dB). Default is -60.
- **retquad** [bool, optional] If True, return the quadrature (imaginary) as well as the real part of the signal. Default is False.
- **retenv** [bool, optional] If True, return the envelope of the signal. Default is False.

**Returns**

- **yI** [ndarray] Real part of signal. Always returned.
- **yQ** [ndarray] Imaginary part of signal. Only returned if `retquad` is True.
yenv  [ndarray] Envelope of signal. Only returned if retenv is True.

See also:
scipy.signal.morlet

Examples
Plot real component, imaginary component, and envelope for a 5 Hz pulse, sampled at 100 Hz for 2 seconds:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(-1, 1, 2*100, endpoint=False)
>>> i, q, e = signal.gausspulse(t, fc=5, retquad=True, retenv=True)
>>> plt.plot(t, i, t, q, t, e, '-
```

scipy.signal.max_len_seq

scipy.signal.max_len_seq(nbits, state=None, length=None, taps=None)

Maximum length sequence (MLS) generator.

Parameters

- **nbits** [int] Number of bits to use. Length of the resulting sequence will be \((2^{*nbits}) - 1\). Note that generating long sequences (e.g., greater than \(nbits == 16\)) can take a long time.
- **state** [array_like, optional] If array, must be of length nbits, and will be cast to binary (bool) representation. If None, a seed of ones will be used, producing a repeatable representation. If state is all zeros, an error is raised as this is invalid. Default: None.
- **length** [int, optional] Number of samples to compute. If None, the entire length \((2^{*nbits}) - 1\) is computed.
- **taps** [array_like, optional] Polynomial taps to use (e.g., [7, 6, 1] for an 8-bit sequence). If None, taps will be automatically selected (for up to \(nbits == 32\)).
seq  [array] Resulting MLS sequence of 0's and 1's.
state  [array] The final state of the shift register.

Notes

The algorithm for MLS generation is generically described in:

https://en.wikipedia.org/wiki/Maximum_length_sequence

The default values for taps are specifically taken from the first option listed for each value of nbits in:

http://www.newwaveinstruments.com/resources/articles/m_sequence_linear_feedback_shift_register_lfsr.htm

New in version 0.15.0.

Examples

MLS uses binary convention:

```python
>>> from scipy.signal import max_len_seq
>>> max_len_seq(4)[0]
array([1, 1, 1, 1, 0, 1, 0, 1, 1, 0, 0, 1, 0, 0, 0], dtype=int8)
```

MLS has a white spectrum (except for DC):

```python
>>> import matplotlib.pyplot as plt
>>> from numpy.fft import fft, ifft, fftshift, fftfreq
>>> seq = max_len_seq(6)[0]*2-1  # +1 and -1
>>> spec = fft(seq)
>>> N = len(seq)
>>> plt.plot(fftshift(fftfreq(N)), fftshift(np.abs(spec)), '.' ')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```
Circular autocorrelation of MLS is an impulse:

```python
>>> acorrcirc = ifft(spec * np.conj(spec)).real
>>> plt.figure()
>>> plt.plot(np.arange(-N/2+1, N/2+1), fftshift(acorrcirc), '.-')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```

Linear autocorrelation of MLS is approximately an impulse:

```python
>>> acorr = np.correlate(seq, seq, 'full')
>>> plt.figure()
>>> plt.plot(np.arange(-N+1, N), acorr, '.-')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```

**scipy.signal.sawtooth**

**scipy.signal.sawtooth**(t, width=1)

Return a periodic sawtooth or triangle waveform.

The sawtooth waveform has a period 2*pi, rises from -1 to 1 on the interval 0 to width*2*pi, then drops from 1 to -1 on the interval width*2*pi to 2*pi. width must be in the interval [0, 1].

Note that this is not band-limited. It produces an infinite number of harmonics, which are aliased back and forth across the frequency spectrum.

**Parameters**

- **t**  
  [array_like] Time.
- **width**  
  [array_like, optional] Width of the rising ramp as a proportion of the total cycle. Default is 1, producing a rising ramp, while 0 produces a falling ramp. width = 0.5 produces a triangle wave. If an array, causes wave shape to change over time, and must be the same length as t.
Returns

```
y     [ndarray] Output array containing the sawtooth waveform.
```

Examples

A 5 Hz waveform sampled at 500 Hz for 1 second:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(0, 1, 500)
>>> plt.plot(t, signal.sawtooth(2 * np.pi * 5 * t))
```
scipy.signal.square

scipy.signal.square (t, duty=0.5)

Return a periodic square-wave waveform.

The square wave has a period \(2\pi\), has value +1 from 0 to \(2\pi\cdot\text{duty}\) and -1 from \(2\pi\cdot\text{duty}\) to \(2\pi\). duty must be in the interval [0,1].

Note that this is not band-limited. It produces an infinite number of harmonics, which are aliased back and forth across the frequency spectrum.

**Parameters**

- **t** [array_like] The input time array.
- **duty** [array_like, optional] Duty cycle. Default is 0.5 (50% duty cycle). If an array, causes wave shape to change over time, and must be the same length as t.

**Returns**

- **y** [ndarray] Output array containing the square waveform.

**Examples**

A 5 Hz waveform sampled at 500 Hz for 1 second:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(0, 1, 500, endpoint=False)
>>> plt.plot(t, signal.square(2 * np.pi * 5 * t))
>>> plt.ylim(-2, 2)
```

A pulse-width modulated sine wave:

```python
>>> plt.figure()
>>> sig = np.sin(2 * np.pi * t)
>>> pwm = signal.square(2 * np.pi * 30 * t, duty=(sig + 1)/2)
>>> plt.subplot(2, 1, 1)
>>> plt.plot(t, sig)
>>> plt.subplot(2, 1, 2)
>>> plt.plot(t, pwm)
>>> plt.ylim(-1.5, 1.5)
```

scipy.signal.sweep_poly

scipy.signal.sweep_poly (t, poly, phi=0)

Frequency-swept cosine generator, with a time-dependent frequency.

This function generates a sinusoidal function whose instantaneous frequency varies with time. The frequency at time \(t\) is given by the polynomial \(\text{poly}\).

**Parameters**

- **t** [ndarray] Times at which to evaluate the waveform.
- **poly** [1-D array_like or instance of numpy.poly1d] The desired frequency expressed as a polynomial. If \(\text{poly}\) is a list or ndarray of length \(n\), then the elements of \(\text{poly}\) are the coefficients of the polynomial, and the instantaneous frequency is...
\[ f(t) = \text{poly}[0] \cdot t^{(n-1)} + \text{poly}[1] \cdot t^{(n-2)} + \ldots + \text{poly}[n-1] \]

If `poly` is an instance of `numpy.poly1d`, then the instantaneous frequency is
\[ f(t) = \text{poly}(t) \]

\[ \phi \]
[optional] Phase offset, in degrees, Default: 0.

Returns

`sweep_poly`

[ndarray] A numpy array containing the signal evaluated at `t` with the requested time-varying frequency. More precisely, the function returns \( \cos(\text{phase} + (\pi/180) \cdot \phi) \), where `phase` is the integral (from 0 to `t`) of \( 2 \cdot \pi \cdot f(t) \); \( f(t) \) is defined above.

See also:

`chirp`

Notes

New in version 0.8.0.

If `poly` is a list or ndarray of length `n`, then the elements of `poly` are the coefficients of the polynomial, and the instantaneous frequency is:
\[ f(t) = \text{poly}[0] \cdot t^{(n-1)} + \text{poly}[1] \cdot t^{(n-2)} + \ldots + \text{poly}[n-1] \]

If `poly` is an instance of `numpy.poly1d`, then the instantaneous frequency is:
\[ f(t) = \text{poly}(t) \]

Finally, the output `s` is:
\[ \cos(\text{phase} + (\pi/180) \cdot \phi) \]

where `phase` is the integral from 0 to `t` of \( 2 \cdot \pi \cdot f(t) \); \( f(t) \) as defined above.

Examples

Compute the waveform with instantaneous frequency:

\[
f(t) = 0.025 \cdot t^3 - 0.36 \cdot t^2 + 1.25 \cdot t + 2
\]

over the interval \( 0 \leq t \leq 10 \).

```python
>>> from scipy.signal import sweep_poly
>>> p = np.poly1d([0.025, -0.36, 1.25, 2.0])
>>> t = np.linspace(0, 10, 5001)
>>> w = sweep_poly(t, p)
```

Plot it:

```python
>>> import matplotlib.pyplot as plt
>>> plt.subplot(2, 1, 1)
>>> plt.plot(t, w)
>>> plt.title("Sweep Poly\nwith frequency 
... 
"+$f(t) = 0.025t^3 - 0.36t^2 + 1.25t + 2$")
>>> plt.subplot(2, 1, 2)
```

(continues on next page)
>>> plt.plot(t, p(t), 'r', label='f(t)')
>>> plt.legend()
>>> plt.xlabel('t')
>>> plt.tight_layout()
>>> plt.show()

Sweep Poly
with frequency $f(t) = 0.025t^3 - 0.36t^2 + 1.25t + 2$

scipy.signal.unit_impulse

`scipy.signal.unit_impulse(shape, idx=None, dtype=<class 'float'>)`
Unit impulse signal (discrete delta function) or unit basis vector.

**Parameters**

- `shape` [int or tuple of int] Number of samples in the output (1-D), or a tuple that represents the shape of the output (N-D).
- `idx` [None or int or tuple of int or 'mid', optional] Index at which the value is 1. If None, defaults to the 0th element. If `idx='mid'`, the impulse will be centered at `shape // 2` in all dimensions. If an int, the impulse will be at `idx` in all dimensions.
- `dtype` [data-type, optional] The desired data-type for the array, e.g., `numpy.int8`. Default is `numpy.float64`.

**Returns**

- `y` [ndarray] Output array containing an impulse signal.

**Notes**

The 1D case is also known as the Kronecker delta.

New in version 0.19.0.
Examples

An impulse at the 0th element ($\delta[n]$):

```python
>>> from scipy import signal
>>> signal.unit_impulse(8)
array([ 1., 0., 0., 0., 0., 0., 0., 0.])
```

Impulse offset by 2 samples ($\delta[n - 2]$):

```python
>>> signal.unit_impulse(7, 2)
array([ 0., 0., 1., 0., 0., 0., 0.])
```

2-dimensional impulse, centered:

```python
>>> signal.unit_impulse((3, 3), 'mid')
array([[ 0., 0., 0.],
       [ 0., 1., 0.],
       [ 0., 0., 0.]])
```

Impulse at (2, 2), using broadcasting:

```python
>>> signal.unit_impulse((4, 4), 2)
array([[ 0., 0., 0., 0.],
       [ 0., 0., 0., 0.],
       [ 0., 0., 1., 0.],
       [ 0., 0., 0., 0.]])
```

Plot the impulse response of a 4th-order Butterworth lowpass filter:

```python
>>> imp = signal.unit_impulse(100, 'mid')
>>> b, a = signal.butter(4, 0.2)
>>> response = signal.lfilter(b, a, imp)

>>> import matplotlib.pyplot as plt
>>> plt.plot(np.arange(-50, 50), imp)
>>> plt.plot(np.arange(-50, 50), response)
>>> plt.margins(0.1, 0.1)
>>> plt.xlabel('Time [samples]')
>>> plt.ylabel('Amplitude')
>>> plt.grid(True)
>>> plt.show()
```

6.21.10 Window functions

For window functions, see the `scipy.signal.windows` namespace.

In the `scipy.signal` namespace, there is a convenience function to obtain these windows by name:

```python
get_window(window, Nx[, fftbins]) Return a window of a given length and type.
```
scipy.signal.get_window

scipy.signal.get_window(window, Nx, fftbins=True)

Return a window of a given length and type.

Parameters

- **window** [string, float, or tuple] The type of window to create. See below for more details.
- **Nx** [int] The number of samples in the window.
- **fftbins** [bool, optional] If True (default), create a “periodic” window, ready to use with ifftshift and be multiplied by the result of an FFT (see also fftpack.fftfreq). If False, create a “symmetric” window, for use in filter design.

Returns

- **get_window** [ndarray] Returns a window of length Nx and type window

Notes

Window types:

- boxcar
- triang
- blackman
- hamming
- hann
- bartlett
- flattop
- parzen
- bohman
• blackmanharris
• nuttall
• barthann
• kaiser (needs beta)
• gaussian (needs standard deviation)
• general_gaussian (needs power, width)
• slepian (needs width)
• dpss (needs normalized half-bandwidth)
• chebwin (needs attenuation)
• exponential (needs decay scale)
• tukey (needs taper fraction)

If the window requires no parameters, then window can be a string.

If the window requires parameters, then window must be a tuple with the first argument the string name of the window, and the next arguments the needed parameters.

If window is a floating point number, it is interpreted as the beta parameter of the kaiser window.

Each of the window types listed above is also the name of a function that can be called directly to create a window of that type.

Examples

```python
>>> from scipy import signal
>>> signal.get_window('triang', 7)
array([ 0.125, 0.375, 0.625, 0.875, 0.875, 0.625, 0.375])
>>> signal.get_window(('kaiser', 4.0), 9)
array([ 0.08848053, 0.29425961, 0.56437221, 0.82160913, 0.97885093,
        0.97885093, 0.82160913, 0.56437221, 0.29425961])
>>> signal.get_window(4.0, 9)
array([ 0.08848053, 0.29425961, 0.56437221, 0.82160913, 0.97885093,
        0.97885093, 0.82160913, 0.56437221, 0.29425961])
```

6.21. Signal processing (scipy.signal)
**scipy.signal.cascade**

`scipy.signal.cascade(hk, J=7)`

Return \((x, \phi, \psi)\) at dyadic points \(K/2^J\) from filter coefficients.

**Parameters**

- `hk` : array_like
  Coefficients of low-pass filter.
- `J` : int, optional
  Values will be computed at grid points \(K/2^J\). Default is 7.

**Returns**

- `x` : ndarray
  The dyadic points \(K/2^J\) for \(K=0 \ldots N \times (2^J)-1\) where \(|\text{len}(hk)| = \text{len}(gk) = N+1\).
- `phi` : ndarray
  The scaling function \(\phi(x)\) at \(x\): \(\phi(x) = \sum(hk \times \phi(2x-k))\), where \(k\) is from 0 to \(N\).
- `psi` : ndarray, optional
  The wavelet function \(\psi(x)\) at \(x\): \(\psi(x) = \sum(gk \times \phi(2x-k))\), where \(k\) is from 0 to \(N\). \(\psi\) is only returned if \(gk\) is not None.

**Notes**

The algorithm uses the vector cascade algorithm described by Strang and Nguyen in “Wavelets and Filter Banks”. It builds a dictionary of values and slices for quick reuse. Then inserts vectors into final vector at the end.

**scipy.signal.daub**

`scipy.signal.daub(p)`

The coefficients for the FIR low-pass filter producing Daubechies wavelets.

\(p \geq 1\) gives the order of the zero at \(f=1/2\). There are \(2^p\) filter coefficients.

**Parameters**

- `p` : int
  Order of the zero at \(f=1/2\), can have values from 1 to 34.

**Returns**

- `daub` : ndarray
  Return

**scipy.signal.morlet**

`scipy.signal.morlet(M, w=5.0, s=1.0, complete=True)`

Complex Morlet wavelet.

**Parameters**

- `M` : int
  Length of the wavelet.
- `w` : float, optional
  Omega0. Default is 5
- `s` : float, optional
  Scaling factor, windowed from \(-s\times2\times\pi\) to \(+s\times2\times\pi\). Default is 1.
- `complete` : bool, optional
  Whether to use the complete or the standard version.

**Returns**

- `morlet` : ([M,] ndarray]

See also:

`scipy.signal.gausspulse`
Notes

The standard version:

\[ \pi^{**-0.25} \times \exp(1j \cdot w \cdot x) \times \exp(-0.5 \cdot (x^2)) \]

This commonly used wavelet is often referred to simply as the Morlet wavelet. Note that this simplified version can cause admissibility problems at low values of \( w \).

The complete version:

\[ \pi^{**-0.25} \times (\exp(1j \cdot w \cdot x) - \exp(-0.5 \cdot (w^2))) \times \exp(-0.5 \cdot (x^2)) \]

This version has a correction term to improve admissibility. For \( w \) greater than 5, the correction term is negligible. Note that the energy of the return wavelet is not normalised according to \( s \).

The fundamental frequency of this wavelet in Hz is given by \( f = \frac{2 \cdot s \cdot w \cdot r}{M} \) where \( r \) is the sampling rate.

Note: This function was created before \texttt{cwt} and is not compatible with it.

\texttt{scipy.signal.qmf}

\texttt{scipy.signal.qmf(hk)}

Return high-pass qmf filter from low-pass

\texttt{Parameters}

\texttt{hk} [array_like] Coefficients of high-pass filter.

\texttt{scipy.signal.ricker}

\texttt{scipy.signal.ricker(points, a)}

Return a Ricker wavelet, also known as the “Mexican hat wavelet”.

It models the function:

\[ A \cdot (1 - x^2/a^2) \cdot \exp(-x^2/2 \cdot a^2), \]

where \( A = \frac{2}{\sqrt{3a}} \cdot \pi^{1/4} \).

\texttt{Parameters}

\texttt{points} [int] Number of points in \texttt{vector}. Will be centered around 0.

\texttt{a} [scalar] Width parameter of the wavelet.

\texttt{Returns}

\texttt{vector} [(N,) ndarray] Array of length \texttt{points} in shape of ricker curve.

\texttt{Examples}

\begin{verbatim}
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
\end{verbatim}
```python
>>> points = 100
>>> a = 4.0
>>> vec2 = signal.ricker(points, a)
>>> print(len(vec2))
100
>>> plt.plot(vec2)
>>> plt.show()
```

**scipy.signal.cwt**

`scipy.signal.cwt(data, wavelet, widths)`

Continuous wavelet transform.

Performs a continuous wavelet transform on `data`, using the `wavelet` function. A CWT performs a convolution with `data` using the `wavelet` function, which is characterized by a width parameter and length parameter.

**Parameters**

- **data** ([N,] ndarray): data on which to perform the transform.
- **wavelet** ([function]): Wavelet function, which should take 2 arguments. The first argument is the number of points that the returned vector will have (len(wavelet(length, width)) == length). The second is a width parameter, defining the size of the wavelet (e.g. standard deviation of a gaussian). See `ricker`, which satisfies these requirements.
- **widths** ([M,] sequence): Widths to use for transform.

**Returns**

- **cwt**: (M, N) ndarray

  Will have shape of (len(widths), len(data)).

**Notes**
length = min(10 * width[ii], len(data))
cwt[ii, :] = signal.convolve(data, wavelet(length, width[ii]), mode='same')

Examples

```python
>>> from scipy import signal
data = np.linspace(-1, 1, 200, endpoint=False)
sig = np.cos(2 * np.pi * 7 * t) + signal.gausspulse(t - 0.4, fc=2)
>>>
```
Parameters

- **data** [ndarray] Array in which to find the relative minima.
- **axis** [int, optional] Axis over which to select from `data`. Default is 0.
- **order** [int, optional] How many points on each side to use for the comparison to consider \( \text{comparator}(n, n+x) \) to be True.
- **mode** [str, optional] How the edges of the vector are treated. Available options are 'wrap' (wrap around) or 'clip' (treat overflow as the same as the last (or first) element). Default 'clip'. See numpy.take

Returns

- **extrema** [tuple of ndarrays] Indices of the minima in arrays of integers. \( \text{extrema}[k] \) is the array of indices of axis \( k \) of `data`. Note that the return value is a tuple even when `data` is one-dimensional.

See also:

argrelextrema, argrelmax, find_peaks

Notes

This function uses argrelextrema with np.less as comparator. Therefore it requires a strict inequality on both sides of a value to consider it a minimum. This means flat minima (more than one sample wide) are not detected. In case of one-dimensional `data` find_peaks can be used to detect all local minima, including flat ones, by calling it with negated `data`.

New in version 0.11.0.

Examples

```python
>>> from scipy.signal import argrelmin
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelmin(x)
(array([1, 5]),)
>>> y = np.array([[1, 2, 1, 2],
...               [2, 2, 0, 0],
...               [5, 3, 4, 4]])
... >>> argrelmin(y, axis=1)
(array([0, 2]), array([2, 1]))
```

scipy.signal.argrelmax

`scipy.signal.argrelmax(data, axis=0, order=1, mode='clip')`

Calculate the relative maxima of `data`.

Parameters

- **data** [ndarray] Array in which to find the relative maxima.
- **axis** [int, optional] Axis over which to select from `data`. Default is 0.
- **order** [int, optional] How many points on each side to use for the comparison to consider \( \text{comparator}(n, n+x) \) to be True.
mode [str, optional] How the edges of the vector are treated. Available options are ‘wrap’ (wrap around) or ‘clip’ (treat overflow as the same as the last (or first) element). Default ‘clip’. See numpy.take.

Returns

extrema [tuple of ndarrays] Indices of the maxima in arrays of integers. extrema[k] is the array of indices of axis k of data. Note that the return value is a tuple even when data is one-dimensional.

See also:

argrelextrema, argrelmin, find_peaks

Notes

This function uses argrelextrema with np.greater as comparator. Therefore it requires a strict inequality on both sides of a value to consider it a maximum. This means flat maxima (more than one sample wide) are not detected. In case of one-dimensional data find_peaks can be used to detect all local maxima, including flat ones.

New in version 0.11.0.

Examples

```python
>>> from scipy.signal import argrelmax
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelmax(x)
(array([3, 6]),)
>>> y = np.array([[[1, 2, 1, 2],
...               [2, 2, 0, 0],
...               [5, 3, 4, 4]]])
... >>> argrelmax(y, axis=1)
(array([0]), array([1]))
```

scipy.signal.argrelextrema

scipy.signal.argrelextrema(data, comparator, axis=0, order=1, mode='clip')

Calculate the relative extrema of data.

Parameters

data [ndarray] Array in which to find the relative extrema.
comparator [callable] Function to use to compare two data points. Should take two arrays as arguments.
axis [int, optional] Axis over which to select from data. Default is 0.
order [int, optional] How many points on each side to use for the comparison to consider comparator(n, n+x) to be True.
mode [str, optional] How the edges of the vector are treated. ‘wrap’ (wrap around) or ‘clip’ (treat overflow as the same as the last (or first) element). Default is ‘clip’. See numpy.take.

Returns
**extrema** [tuple of ndarrays] Indices of the maxima in arrays of integers. `extrema[k]` is the array of indices of axis \( k \) of `data`. Note that the return value is a tuple even when `data` is one-dimensional.

See also:

`argrelmin`, `argrelmax`

**Notes**

New in version 0.11.0.

**Examples**

```python
>>> from scipy.signal import argrelextrema
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelextrema(x, np.greater)
(array([3, 6]),)
>>> y = np.array([[1, 2, 1, 2],
...               [2, 2, 0, 0],
...               [5, 3, 4, 4]])
>>> argrelextrema(y, np.less, axis=1)
(array([0, 2]), array([2, 1]))
```

**scipy.signal.find_peaks**

`scipy.signal.find_peaks(x, height=None, threshold=None, distance=None, prominence=None, width=None, wlen=None, rel_height=0.5, plateau_size=None)`

Find peaks inside a signal based on peak properties.

This function takes a one-dimensional array and finds all local maxima by simple comparison of neighbouring values. Optionally, a subset of these peaks can be selected by specifying conditions for a peak's properties.

**Parameters**

- `x` [sequence] A signal with peaks.
- `height` [number or ndarray or sequence, optional] Required height of peaks. Either a number, `None`, an array matching `x` or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required height.
- `threshold` [number or ndarray or sequence, optional] Required threshold of peaks, the vertical distance to its neighbouring samples. Either a number, `None`, an array matching `x` or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required threshold.
- `distance` [number, optional] Required minimal horizontal distance (\( \geq 1 \)) in samples between neighbouring peaks. Smaller peaks are removed first until the condition is fulfilled for all remaining peaks.
- `prominence` [number or ndarray or sequence, optional] Required prominence of peaks. Either a number, `None`, an array matching `x` or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required prominence.
width [number or ndarray or sequence, optional] Required width of peaks in samples. Either a number, None, an array matching x or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required width.

wlen [int, optional] Used for calculation of the peaks prominences, thus it is only used if one of the arguments prominence or width is given. See argument wlen in peak_prominences for a full description of its effects.

rel_height [float, optional] Used for calculation of the peaks width, thus it is only used if width is given. See argument rel_height in peak_widths for a full description of its effects.

plateau_size [number or ndarray or sequence, optional] Required size of the flat top of peaks in samples. Either a number, None, an array matching x or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied as the maximal required plateau size.

New in version 1.2.0.

Returns

peaks [ndarray] Indices of peaks in x that satisfy all given conditions.

properties [dict] A dictionary containing properties of the returned peaks which were calculated as intermediate results during evaluation of the specified conditions:

• ‘peak_heights’
  If height is given, the height of each peak in x.

• ‘left_thresholds’, ‘right_thresholds’
  If threshold is given, these keys contain a peaks vertical distance to its neighbouring samples.

• ‘prominences’, ‘right_bases’, ‘left_bases’
  If prominence is given, these keys are accessible. See peak_prominences for a description of their content.

• ‘width_heights’, ‘left_ips’, ‘right_ips’
  If width is given, these keys are accessible. See peak_widths for a description of their content.

• ‘plateau_sizes’, ‘left_edges’, ‘right_edges’
  If plateau_size is given, these keys are accessible and contain the indices of a peak’s edges (edges are still part of the plateau) and the calculated plateau sizes.
  New in version 1.2.0.

To calculate and return properties without excluding peaks, provide the open interval (None, None) as a value to the appropriate argument (excluding distance).

Warns

PeakPropertyWarning
Raised if a peak’s properties have unexpected values (see peak_prominences and peak_widths).

Warning: This function may return unexpected results for data containing NaNs. To avoid this, NaNs should either be removed or replaced.

See also:

find_peaks_cwt

Find peaks using the wavelet transformation.
**peak_prominences**

Directly calculate the prominence of peaks.

**peak_widths**

Directly calculate the width of peaks.

**Notes**

In the context of this function, a peak or local maximum is defined as any sample whose two direct neighbours have a smaller amplitude. For flat peaks (more than one sample of equal amplitude wide) the index of the middle sample is returned (rounded down in case the number of samples is even). For noisy signals the peak locations can be off because the noise might change the position of local maxima. In those cases consider smoothing the signal before searching for peaks or use other peak finding and fitting methods (like `find_peaks_cwt`).

Some additional comments on specifying conditions:

- Almost all conditions (excluding `distance`) can be given as half-open or closed intervals, e.g 1 or (1, None) defines the half-open interval $[1, \infty)$ while (None, 1) defines the interval $[-\infty, 1]$. The open interval (None, None) can be specified as well, which returns the matching properties without exclusion of peaks.
- The border is always included in the interval used to select valid peaks.
- For several conditions the interval borders can be specified with arrays matching $x$ in shape which enables dynamic constrains based on the sample position.
- The conditions are evaluated in the following order: plateau_size, height, threshold, distance, prominence, width. In most cases this order is the fastest one because faster operations are applied first to reduce the number of peaks that need to be evaluated later.
- While indices in `peaks` are guaranteed to be at least `distance` samples apart, edges of flat peaks may be closer than the allowed `distance`.
- Use `wlen` to reduce the time it takes to evaluate the conditions for prominence or width if $x$ is large or has many local maxima (see `peak_prominences`).

New in version 1.1.0.

**Examples**

To demonstrate this function’s usage we use a signal $x$ supplied with SciPy (see `scipy.misc.electrocardiogram`). Let’s find all peaks (local maxima) in $x$ whose amplitude lies above 0.

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.misc import electrocardiogram
>>> from scipy.signal import find_peaks
>>> x = electrocardiogram()[2000:4000]
>>> peaks, _ = find_peaks(x, height=0)
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.plot(np.zeros_like(x), "--", color="gray")
>>> plt.show()
```

We can select peaks below 0 with `height=(None, 0)` or use arrays matching $x$ in size to reflect a changing condition for different parts of the signal.
Another useful condition for periodic signals can be given with the `distance` argument. In this case we can easily select the positions of QRS complexes within the electrocardiogram (ECG) by demanding a distance of at least 150 samples.

```python
>>> peaks, _ = find_peaks(x, distance=150)
>>> np.diff(peaks)
```

(continues on next page)
array([186, 180, 177, 171, 177, 169, 167, 164, 158, 162, 172])

```python
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.show()
```

Especially for noisy signals peaks can be easily grouped by their prominence (see `peak_prominences`). E.g. we can select all peaks except for the mentioned QRS complexes by limiting the allowed prominence to 0.6.

```python
>>> peaks, properties = find_peaks(x, prominence=(None, 0.6))
>>> properties["prominences"].max() 0.5049999999999999
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.show()
```
And finally let’s examine a different section of the ECG which contains beat forms of different shape. To select only the atypical heart beats we combine two conditions: a minimal prominence of 1 and width of at least 20 samples.

```python
>>> x = electrocardiogram()[17000:18000]
>>> peaks, properties = find_peaks(x, prominence=1, width=20)
>>> properties["prominences"], properties["widths"]
(array([1.495, 2.3]), array([36.9373946, 39.32723577]))
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.vlines(x=peaks, ymin=x[peaks] - properties["prominences"], ymax=x[peaks], color="C1")
>>> plt.hlines(y=properties["width_heights"], xmin=properties["left_ips"], xmax=properties["right_ips"], color="C1")
>>> plt.show()
```

**scipy.signal.find_peaks_cwt**

The general approach is to smooth `vector` by convolving it with `wavelet(width)` for each width in `widths`. Relative maxima which appear at enough length scales, and with sufficiently high SNR, are accepted.

**Parameters**

- **vector** [ndarray] 1-D array in which to find the peaks.
- **widths** [sequence] 1-D array of widths to use for calculating the CWT matrix. In general, this range should cover the expected width of peaks of interest.
- **wavelet** [callable, optional] Should take two parameters and return a 1-D array to convolve with `vector`. The first parameter determines the number of points of the returned wavelet array, the second parameter is the scale (width) of the wavelet. Should be normalized and symmetric. Default is the ricker wavelet.
- **max_distances**
[ndarray, optional] At each row, a ridge line is only connected if the relative max at row[n] is within max_distances[n] from the relative max at row[n+1]. Default value is widths/4.

gap_thresh
[float, optional] If a relative maximum is not found within max_distances, there will be a gap. A ridge line is discontinued if there are more than gap_thresh points without connecting a new relative maximum. Default is the first value of the widths array i.e. widths[0].

min_length
[int, optional] Minimum length a ridge line needs to be acceptable. Default is cwt.shape[0] / 4, i.e. 1/4-th the number of widths.

min_snr
[float, optional] Minimum SNR ratio. Default 1. The signal is the value of the cwt matrix at the shortest length scale (cwt[0, loc]), the noise is the noise_perc'th percentile of datapoints contained within a window of window_size around cwt[0, loc].

noise_perc
[float, optional] When calculating the noise floor, percentile of data points examined below which to consider noise. Calculated using stats.scoreatpercentile. Default is 10.

Returns

peaks_indices
[ndarray] Indices of the locations in the vector where peaks were found. The list is sorted.

See also:

cwt
Continuous wavelet transform.

find_peaks
Find peaks inside a signal based on peak properties.

Notes

This approach was designed for finding sharp peaks among noisy data, however with proper parameter selection it should function well for different peak shapes.

The algorithm is as follows:

1. Perform a continuous wavelet transform on vector, for the supplied widths. This is a convolution of vector with wavelet(width) for each width in widths. See cwt
2. Identify “ridge lines” in the cwt matrix. These are relative maxima at each row, connected across adjacent rows. See identify_ridge_lines
3. Filter the ridge_lines using filter_ridge_lines.

New in version 0.11.0.

References

[1]
Examples

```python
>>> from scipy import signal
>>> xs = np.arange(0, np.pi, 0.05)
>>> data = np.sin(xs)
>>> peakind = signal.find_peaks_cwt(data, np.arange(1,10))
>>> peakind, xs[peakind], data[peakind]
([32], array([ 1.6]), array([ 0.9995736]))
```

**scipy.signal.peak_prominences**

`scipy.signal.peak_prominences(x, peaks, wlen=None)`

Calculate the prominence of each peak in a signal.

The prominence of a peak measures how much a peak stands out from the surrounding baseline of the signal and is defined as the vertical distance between the peak and its lowest contour line.

**Parameters**

- `x` [sequence] A signal with peaks.
- `peaks` [sequence] Indices of peaks in `x`.
- `wlen` [int, optional] A window length in samples that optionally limits the evaluated area for each peak to a subset of `x`. The peak is always placed in the middle of the window therefore the given length is rounded up to the next odd integer. This parameter can speed up the calculation (see Notes).

**Returns**

- `prominences` [ndarray] The calculated prominences for each peak in `peaks`.
- `left_bases`, `right_bases` [ndarray] The peaks’ bases as indices in `x` to the left and right of each peak. The higher base of each pair is a peak’s lowest contour line.

**Raises**

- `ValueError` If a value in `peaks` is an invalid index for `x`.

**Warns**

- `PeakPropertyWarning` For indices in `peaks` that don’t point to valid local maxima in `x` the returned prominence will be 0 and this warning is raised. This also happens if `wlen` is smaller than the plateau size of a peak.

**Warning:** This function may return unexpected results for data containing NaNs. To avoid this, NaNs should either be removed or replaced.

**See also:**

- `find_peaks` Find peaks inside a signal based on peak properties.
**peak_widths**

Calculate the width of peaks.

**Notes**

Strategy to compute a peak’s prominence:

1. Extend a horizontal line from the current peak to the left and right until the line either reaches the window border (see `wlen`) or intersects the signal again at the slope of a higher peak. An intersection with a peak of the same height is ignored.

2. On each side find the minimal signal value within the interval defined above. These points are the peak’s bases.

3. The higher one of the two bases marks the peak’s lowest contour line. The prominence can then be calculated as the vertical difference between the peak’s height itself and its lowest contour line.

Searching for the peak’s bases can be slow for large `x` with periodic behavior because large chunks or even the full signal need to be evaluated for the first algorithmic step. This evaluation area can be limited with the parameter `wlen` which restricts the algorithm to a window around the current peak and can shorten the calculation time if the window length is short in relation to `x`. However, this may stop the algorithm from finding the true global contour line if the peak’s true bases are outside this window. Instead, a higher contour line is found within the restricted window leading to a smaller calculated prominence. In practice, this is only relevant for the highest set of peaks in `x`. This behavior may even be used intentionally to calculate “local” prominences.

New in version 1.1.0.

**References**

[1]

**Examples**

```python
>>> from scipy.signal import find_peaks, peak_prominences
>>> import matplotlib.pyplot as plt

Create a test signal with two overlayed harmonics

```python
>>> x = np.linspace(0, 6 * np.pi, 1000)
>>> x = np.sin(x) + 0.6 * np.sin(2.6 * x)
```  
Find all peaks and calculate prominences

```python
>>> peaks, _ = find_peaks(x)
>>> prominences = peak_prominences(x, peaks)[0]
>>> prominences
array([1.24159486, 0.47840168, 0.28470524, 3.10716793, 0.284603 , 0.47822491, 2.48340261, 0.47822491])
```  
Calculate the height of each peak’s contour line and plot the results
Let's evaluate a second example that demonstrates several edge cases for one peak at index 5.

```python
>>> x = np.array([0, 1, 0, 3, 1, 3, 0, 4, 0])
>>> peaks = np.array([5])
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.show()
```
>>> peak_prominences(x, peaks)  # -> (prominences, left_bases, right_bases)
(array([3.]), array([2]), array([6]))

Note how the peak at index 3 of the same height is not considered as a border while searching for the left base. Instead two minima at 0 and 2 are found in which case the one closer to the evaluated peak is always chosen. On the right side however the base must be placed at 6 because the higher peak represents the right border to the evaluated area.

>>> peak_prominences(x, peaks, wlen=3.1)
(array([2.]), array([4]), array([6]))

Here we restricted the algorithm to a window from 3 to 7 (the length is 5 samples because \texttt{wlen} was rounded up to the next odd integer). Thus the only two candidates in the evaluated area are the two neighbouring samples and a smaller prominence is calculated.

\texttt{scipy.signal.peak_widths}

\texttt{scipy.signal.peak_widths(x, peaks, rel_height=0.5, prominence_data=None, wlen=None)}

Calculate the width of each peak in a signal.

This function calculates the width of a peak in samples at a relative distance to the peak’s height and prominence.

**Parameters**

\texttt{x} [sequence] A signal with peaks.

\texttt{peaks} [sequence] Indices of peaks in \texttt{x}.

\texttt{rel_height} [float, optional] Chooses the relative height at which the peak width is measured as a percentage of its prominence. 1.0 calculates the width of the peak at its lowest contour line while 0.5 evaluates at half the prominence height. Must be at least 0. See notes for further explanation.

\texttt{prominence_data} [tuple, optional] A tuple of three arrays matching the output of \texttt{peak_prominences} when called with the same arguments \texttt{x} and \texttt{peaks}. This data is calculated internally if not provided.

\texttt{wlen} [int, optional] A window length in samples passed to \texttt{peak_prominences} as an optional argument for internal calculation of \texttt{prominence_data}. This argument is ignored if \texttt{prominence_data} is given.

**Returns**

\texttt{widths} [ndarray] The widths for each peak in samples.

\texttt{width_heights} [ndarray] The height of the contour lines at which the \texttt{widths} were evaluated.

\texttt{left_ips, right_ips} [ndarray] Interpolated positions of left and right intersection points of a horizontal line at the respective evaluation height.

**Raises**

\texttt{ValueError}\n
If \texttt{prominence_data} is supplied but doesn’t satisfy the condition \(0 \leq \text{left} \_\text{base} \leq \text{peak} \leq \text{right} \_\text{base} < \text{x}\.\text{shape}[0]\) for each peak, has the wrong dtypes, is not C-contiguous or does not have the same shape.

**Warns**
PeakPropertyWarning

Raised if any calculated width is 0. This may stem from the supplied prominence_data or if rel_height is set to 0.

Warning: This function may return unexpected results for data containing NaNs. To avoid this, NaNs should either be removed or replaced.

See also:

find_peaks

Find peaks inside a signal based on peak properties.

peak_prominences

Calculate the prominence of peaks.

Notes

The basic algorithm to calculate a peak’s width is as follows:

- Calculate the evaluation height \( h_{eval} \) with the formula \( h_{eval} = h_{Peak} - P \cdot R \), where \( h_{Peak} \) is the height of the peak itself, \( P \) is the peak’s prominence and \( R \) a positive ratio specified with the argument rel_height.

- Draw a horizontal line at the evaluation height to both sides, starting at the peak’s current vertical position until the lines either intersect a slope, the signal border or cross the vertical position of the peak’s base (see peak_prominences for an definition). For the first case, intersection with the signal, the true intersection point is estimated with linear interpolation.

- Calculate the width as the horizontal distance between the chosen endpoints on both sides. As a consequence of this the maximal possible width for each peak is the horizontal distance between its bases.

As shown above to calculate a peak’s width its prominence and bases must be known. You can supply these yourself with the argument prominence_data. Otherwise they are internally calculated (see peak_prominences).

New in version 1.1.0.

Examples

```python
>>> from scipy.signal import chirp, find_peaks, peak_widths
>>> import matplotlib.pyplot as plt
```

Create a test signal with two overlayed harmonics

```python
>>> x = np.linspace(0, 6 * np.pi, 1000)
>>> x = np.sin(x) + 0.6 * np.sin(2.6 * x)
```

Find all peaks and calculate their widths at the relative height of 0.5 (contour line at half the prominence height) and 1 (at the lowest contour line at full prominence height).

```python
>>> peaks, _ = find_peaks(x)
>>> results_half = peak_widths(x, peaks, rel_height=0.5)
>>> results_half[0]  # widths
array([ 64.25172825, 41.29465463, 35.46943289, 104.71586081,...])
```
>>> results_full = peak_widths(x, peaks, rel_height=1)
>>> results_full[0]  # widths
array([181.9396084 , 72.99284945, 61.28657872, 373.84622694,
       61.78404617, 72.48822812, 253.09161876, 79.36860878])

Plot signal, peaks and contour lines at which the widths where calculated

```python
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.hlines(*results_half[1:], color="C2")
>>> plt.hlines(*results_full[1:], color="C3")
>>> plt.show()
```

### 6.21.13 Spectral Analysis

- **periodogram(x[, fs, window, nfft, detrend, …])**
  Estimate power spectral density using a periodogram.

- **welch(x[, fs, window, nperseg, noverlap, …])**
  Estimate power spectral density using Welch's method.

- **csd(x, y[, fs, window, nperseg, noverlap, …])**
  Estimate the cross power spectral density, $P_{xy}$, using Welch's method.

- **coherence(x, y[, fs, window, nperseg, …])**
  Estimate the magnitude squared coherence estimate, $C_{xy}$, of discrete-time signals $X$ and $Y$ using Welch's method.

- **spectrogram(x[, fs, window, nperseg, …])**
  Compute a spectrogram with consecutive Fourier transforms.

- **lombscargle(x, y, freqs)**
  Computes the Lomb-Scargle periodogram.

- **vectorstrength(events, period)**
  Determine the vector strength of the events corresponding to the given period.

- **stft(x[, fs, window, nperseg, noverlap, …])**
  Compute the Short Time Fourier Transform (STFT).

- **istft(Zxx[, fs, window, nperseg, noverlap, …])**
  Perform the inverse Short Time Fourier transform (iSTFT).

### scipy.signal.periodogram

**scipy.signal.periodogram** *(x, fs=1.0, window='boxcar', nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1)*

Estimate power spectral density using a periodogram.

**Parameters**

- **x** [array_like] Time series of measurement values
- **fs** [float, optional] Sampling frequency of the x time series. Defaults to 1.0.
- **window** [str or tuple or array_like, optional] Desired window to use. If window is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array_like, it will be used directly as the window and its length must be nperseg. Defaults to 'boxcar'.
- **nfft** [int, optional] Length of the FFT used. If None the length of x will be used.
- **detrend** [str or function or False, optional] Specifies how to detrend each segment. If `detrend` is a string, it is passed as the type argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If `detrend` is False, no detrending is done. Defaults to 'constant'.
- **return_onesided** [bool, optional] If True, return a one-sided spectrum for real data. If False return a two-sided spectrum. Defaults to True, but for complex data, a two-sided spectrum is always returned.
- **scaling** [{'density', 'spectrum'}, optional] Selects between computing the power spectral density ('density') where \( P_{xx} \) has units of \( V^2/\text{Hz} \) and computing the power spectrum ('spectrum') where \( P_{xx} \) has units of \( V^2 \), if \( x \) is measured in \( V \) and \( fs \) is measured in \( \text{Hz} \). Defaults to 'density'.
- **axis** [int, optional] Axis along which the periodogram is computed; the default is over the last axis (i.e. axis=-1).

**Returns**

- **f** [ndarray] Array of sample frequencies.
- **Pxx** [ndarray] Power spectral density or power spectrum of \( x \).

**See also:**

- `welch`
  Estimate power spectral density using Welch’s method
- `lombscargle`
  Lomb-Scargle periodogram for unevenly sampled data

**Notes**

New in version 0.12.0.
**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234)

Generate a test signal, a 2 Vrms sine wave at 1234 Hz, corrupted by 0.001 V**2/Hz of white noise sampled at 10 kHz.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2*np.sqrt(2)
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> x = amp*np.sin(2*np.pi*freq*time)
>>> x += np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
```  
Compute and plot the power spectral density.

```python
>>> f, Pxx_den = signal.periodogram(x, fs)
>>> plt.semilogy(f, Pxx_den)
>>> plt.ylim([1e-7, 1e2])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.show()
```

![Plot of power spectral density](image)

If we average the last half of the spectral density, to exclude the peak, we can recover the noise power on the signal.

```python
>>> np.mean(Pxx_den[25000:])
0.00099728892368242854
```

Now compute and plot the power spectrum.
The peak height in the power spectrum is an estimate of the RMS amplitude.

```python
>>> np.sqrt(Pxx_spec.max())
2.0077340678640727
```

**scipy.signal.welch**

`scipy.signal.welch(x, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1, average='mean')`

Estimate power spectral density using Welch’s method.

Welch’s method [1] computes an estimate of the power spectral density by dividing the data into overlapping segments, computing a modified periodogram for each segment and averaging the periodograms.

**Parameters**

- `x` [array_like] Time series of measurement values
- `fs` [float, optional] Sampling frequency of the x time series. Defaults to 1.0.
- `window` [str or tuple or array_like, optional] Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Hann window.
- `nperseg` [int, optional] Length of each segment. Defaults to None, but if `window` is str or tuple, is set to 256, and if `window` is array_like, is set to the length of the window.
- `noverlap` [int, optional] Number of points to overlap between segments. If `None`, `noverlap = nperseg // 2`. Defaults to `None`.

---

[1]: Scipy Reference Guide, Release 1.3.2
nfft [int, optional] Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is nperseg. Defaults to None.
detrend [str or function or False, optional] Specifies how to detrend each segment. If detrend is a string, it is passed as the type argument to the detrend function. If it is a function, it takes a segment and returns a detrended segment. If detrend is False, no detrending is done. Defaults to ‘constant’.
return_onesided [bool, optional] If True, return a one-sided spectrum for real data. If False return a two-sided spectrum. Defaults to True, but for complex data, a two-sided spectrum is always returned.
scaling [{‘density’, ‘spectrum’}, optional] Selects between computing the power spectral density (‘density’) where \( P_{xx} \) has units of V**2/Hz and computing the power spectrum (‘spectrum’) where \( P_{xx} \) has units of V**2, if \( x \) is measured in V and \( fs \) is measured in Hz. Defaults to ‘density’.
axis [int, optional] Axis along which the periodogram is computed; the default is over the last axis (i.e. axis=-1).

Returns

f [ndarray] Array of sample frequencies.
Pxx [ndarray] Power spectral density or power spectrum of x.

See also:
periodogram
Simple, optionally modified periodogram
lombscargle
Lomb-Scargle periodogram for unevenly sampled data

Notes

An appropriate amount of overlap will depend on the choice of window and on your requirements. For the default Hann window an overlap of 50% is a reasonable trade off between accurately estimating the signal power, while not over counting any of the data. Narrower windows may require a larger overlap.

If noverlap is 0, this method is equivalent to Bartlett’s method [2].

New in version 0.12.0.

References

[1], [2]

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234)
```
Generate a test signal, a 2 Vrms sine wave at 1234 Hz, corrupted by 0.001 V**2/Hz of white noise sampled at 10 kHz.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2*np.sqrt(2)
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> x = amp*np.sin(2*np.pi*freq*time)
>>> x += np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
```

Compute and plot the power spectral density.

```python
>>> f, Pxx_den = signal.welch(x, fs, nperseg=1024)
>>> plt.semilogy(f, Pxx_den)
>>> plt.ylim([0.5e-3, 1])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.show()
```

If we average the last half of the spectral density, to exclude the peak, we can recover the noise power on the signal.

```python
>>> np.mean(Pxx_den[256:])
0.000992486544379191
```

Now compute and plot the power spectrum.

```python
>>> f, Pxx_spec = signal.welch(x, fs, 'flattop', 1024, scaling='spectrum')
>>> plt.figure()
>>> plt.semilogy(f, np.sqrt(Pxx_spec))
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('Linear spectrum [V RMS]')
>>> plt.show()
```

The peak height in the power spectrum is an estimate of the RMS amplitude.
If we now introduce a discontinuity in the signal, by increasing the amplitude of a small portion of the signal by 50, we can see the corruption of the mean average power spectral density, but using a median average better estimates the normal behaviour.

```python
>>> x[int(N/2):int(N/2)+10] *= 50.
>>> f, Pxx_den = signal.welch(x, fs, nperseg=1024)
>>> f_med, Pxx_den_med = signal.welch(x, fs, nperseg=1024, average='median')
>>> plt.semilogy(f, Pxx_den, label='mean')
>>> plt.semilogy(f_med, Pxx_den_med, label='median')
>>> plt.ylim([0.5e-3, 1])
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.legend()
>>> plt.show()
```

### scipy.signal.csd

**scipy.signal.csd**

Estimate the cross power spectral density, Pxy, using Welch's method.

**Parameters**

- **x** [array_like] Time series of measurement values
- **y** [array_like] Time series of measurement values
- **fs** [float, optional] Sampling frequency of the x and y time series. Defaults to 1.0.
- **window** [str or tuple or array_like, optional] Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array_like
it will be used directly as the window and its length must be nperseg. Defaults to a Hann window.

*nperseg* [int, *optional*] Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array_like, is set to the length of the window.

*noverlap*: *int*, *optional*  
Number of points to overlap between segments. If *None*, *noverlap* = *nperseg // 2*. Defaults to *None*.

*nfft* [int, *optional*] Length of the FFT used, if a zero padded FFT is desired. If *None*, the FFT length is *nperseg*. Defaults to *None*.

*detrend* [str or function or *False*, *optional*] Specifies how to detrend each segment. If *detrend* is a string, it is passed as the *type* argument to the *detrend* function. If it is a function, it takes a segment and returns a detrended segment. If *detrend* is *False*, no detrending is done. Defaults to 'constant'.

*return_onesided*  
[bool, *optional*] If *True*, return a one-sided spectrum for real data. If *False* return a two-sided spectrum. Defaults to *True*, but for complex data, a two-sided spectrum is always returned.

*scaling* [‘density’, ‘spectrum’], *optional* Selects between computing the cross spectral density (‘density’) where *Pxy* has units of *V**2/Hz* and computing the cross spectrum (‘spectrum’) where *Pxy* has units of *V**2*, if *x* and *y* are measured in *V* and *fs* is measured in *Hz*. Defaults to ‘density’

*axis* [int, *optional*] Axis along which the CSD is computed for both inputs; the default is over the last axis (i.e. *axis=-1*).

*average* [‘mean’, ‘median’], *optional* Method to use when averaging periodograms. Defaults to ‘mean’. New in version 1.2.0.

**Returns**

- *f* [ndarray] Array of sample frequencies.
- *Pxy* [ndarray] Cross spectral density or cross power spectrum of *x*, *y*.

**See also:**

- *periodogram*  
  Simple, optionally modified periodogram
lombscargle
Lomb-Scargle periodogram for unevenly sampled data
welch
Power spectral density by Welch’s method. [Equivalent to csd(x,x)]
coherence
Magnitude squared coherence by Welch’s method.

Notes
By convention, \( P_{xy} \) is computed with the conjugate FFT of \( X \) multiplied by the FFT of \( Y \).
If the input series differ in length, the shorter series will be zero-padded to match.
An appropriate amount of overlap will depend on the choice of window and on your requirements. For the default Hann window an overlap of 50\% is a reasonable trade off between accurately estimating the signal power, while not over counting any of the data. Narrower windows may require a larger overlap.
New in version 0.16.0.

References
[1],[2]

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Generate two test signals with some common features.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 20
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> b, a = signal.butter(2, 0.25, 'low')
>>> x = np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
>>> y = signal.lfilter(b, a, x)
>>> x += amp*np.sin(2*np.pi*freq*time)
>>> y += np.random.normal(scale=0.1*np.sqrt(noise_power), size=time.shape)
```

Compute and plot the magnitude of the cross spectral density.

```python
>>> f, Pxy = signal.csd(x, y, fs, nperseg=1024)
>>> plt.semilogy(f, np.abs(Pxy))
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('CSD [V**2/Hz]')
>>> plt.show()
```
scipy.signal.coherence

scipy.signal.coherence(x, y, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, detrend='constant', axis=-1)

Estimate the magnitude squared coherence estimate, \( C_{xy} \), of discrete-time signals \( X \) and \( Y \) using Welch’s method.

\[
C_{xy} = \frac{|P_{xy}|^2}{P_{xx}P_{yy}},
\]

where \( P_{xx} \) and \( P_{yy} \) are power spectral density estimates of \( X \) and \( Y \), and \( P_{xy} \) is the cross spectral density estimate of \( X \) and \( Y \).

**Parameters**

- **x** [array_like] Time series of measurement values
- **y** [array_like] Time series of measurement values
- **fs** [float, optional] Sampling frequency of the \( x \) and \( y \) time series. Defaults to 1.0.
- **window** [str or tuple or array_like, optional] Desired window to use. If \( \text{window} \) is a string or tuple, it is passed to \( \text{get_window} \) to generate the window values, which are DFT-even by default. See \( \text{get_window} \) for a list of windows and required parameters. If \( \text{window} \) is array_like it will be used directly as the window and its length must be \( \text{nperseg} \). Defaults to a Hann window.
- **nperseg** [int, optional] Length of each segment. Defaults to None, but if \( \text{window} \) is str or tuple, is set to 256, and if \( \text{window} \) is array_like, is set to the length of the window.
- **noverlap**: int, optional
  Number of points to overlap between segments. If \( \text{None} \), \( \text{noverlap} = \text{nperseg} \) // 2. Defaults to \( \text{None} \).
- **nfft** [int, optional] Length of the FFT used, if a zero padded FFT is desired. If \( \text{None} \), the FFT length is \( \text{nperseg} \). Defaults to \( \text{None} \).
- **detrend** [str or function or \( \text{False} \), optional] Specifies how to detrend each segment. If \( \text{detrend} \) is a string, it is passed as the \( \text{type} \) argument to the \( \text{detrend} \) function. If it is a function, it takes a segment and returns a detrended segment. If \( \text{detrend} \) is \( \text{False} \), no detrending is done. Defaults to ‘constant’.
- **axis** [int, optional] Axis along which the coherence is computed for both inputs; the default is over the last axis (i.e. \( \text{axis} = -1 \)).

**Returns**

- **f** [ndarray] Array of sample frequencies.
- **Cxy** [ndarray] Magnitude squared coherence of \( x \) and \( y \).

scipy.signal.spectrogram(x, fs=1.0, window=('tukey', 0.25), nperseg=None, noverlap=None, nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1, mode='psd')
```

Compute a spectrogram with consecutive Fourier transforms.

Spectrograms can be used as a way of visualizing the change of a nonstationary signal's frequency content over time.

**Parameters**

- `x` : array_like
  Time series of measurement values
- `fs` : float, optional
  Sampling frequency of the `x` time series. Defaults to 1.0.
- `window` : str or tuple or array_like, optional
  Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array-like, it will be used directly as the window and its length must be nperseg. Defaults to a Tukey window with shape parameter of 0.25.
- `nperseg` : int, optional
  Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array_like, is set to the length of the window.
- `noverlap` : int, optional
  Number of points to overlap between segments. If `None`, `noverlap = nperseg // 8`. Defaults to `None`.
- `nfft` : int, optional
  Length of the FFT used, if a zero padded FFT is desired. If `None`, the FFT length is `nperseg`. Defaults to `None`.
- `detrend` : str or function or `False`, optional
  Specifies how to detrend each segment. If `detrend` is a string, it is passed as the `type` argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If `detrend` is `False`, no detrending is done. Defaults to ‘constant’.
- `return_onesided` : bool
  If `True`, return a one-sided spectrum for real input. If `False`, return a two-sided spectrum. Defaults to `True`.

---

6.21. Signal processing (scipy.signal)
[bool, optional] If True, return a one-sided spectrum for real data. If False return a two-sided spectrum. Defaults to True, but for complex data, a two-sided spectrum is always returned.

scaling [[‘density’, ‘spectrum’], optional] Selects between computing the power spectral density (‘density’) where \( S_{xx} \) has units of \( V^2/Hz \) and computing the power spectrum (‘spectrum’) where \( S_{xx} \) has units of \( V^2 \), if \( x \) is measured in V and \( fs \) is measured in Hz. Defaults to ‘density’.

axis [int, optional] Axis along which the spectrogram is computed; the default is over the last axis (i.e. axis=-1).

mode [str, optional] Defines what kind of return values are expected. Options are [‘psd’, ‘complex’, ‘magnitude’, ‘angle’, ‘phase’]. ‘complex’ is equivalent to the output of \( \text{stft} \) with no padding or boundary extension. ‘magnitude’ returns the absolute magnitude of the STFT. ‘angle’ and ‘phase’ return the complex angle of the STFT, with and without unwrapping, respectively.

**Returns**

\( f \) [ndarray] Array of sample frequencies.

\( t \) [ndarray] Array of segment times.

\( S_{xx} \) [ndarray] Spectrogram of \( x \). By default, the last axis of \( S_{xx} \) corresponds to the segment times.

**See also:**

periodogram
Simple, optionally modified periodogram

lombscargle
Lomb-Scargle periodogram for unevenly sampled data

welch
Power spectral density by Welch’s method.

csd
Cross spectral density by Welch’s method.

**Notes**

An appropriate amount of overlap will depend on the choice of window and on your requirements. In contrast to welch’s method, where the entire data stream is averaged over, one may wish to use a smaller overlap (or perhaps none at all) when computing a spectrogram, to maintain some statistical independence between individual segments. It is for this reason that the default window is a Tukey window with 1/8th of a window’s length overlap at each end.

New in version 0.16.0.

**References**

[1]

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```
Generate a test signal, a 2 Vrms sine wave whose frequency is slowly modulated around 3kHz, corrupted by white noise of exponentially decreasing magnitude sampled at 10 kHz.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.01 * fs / 2
>>> time = np.arange(N) / float(fs)
>>> mod = 500 * np.cos(2 * np.pi * 0.25 * time)
>>> carrier = amp * np.sin(2 * np.pi * 3e3 * time + mod)
>>> noise = np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
>>> noise *= np.exp(-time/5)
>>> x = carrier + noise
```

Compute and plot the spectrogram.

```python
>>> f, t, Sxx = signal.spectrogram(x, fs)
>>> plt.pcolormesh(t, f, Sxx)
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.show()
```

Note, if using output that is not one sided, then use the following:

```python
>>> f, t, Sxx = signal.spectrogram(x, fs, return_onesided=False)
>>> plt.pcolormesh(t, np.fft.fftshift(f), np.fft.fftshift(Sxx, axes=0))
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.show()
```

**scipy.signal.lombscargle**

**scipy.signal.lombscargle***(x, y, freqs)*

Computes the Lomb-Scargle periodogram.
The Lomb-Scargle periodogram was developed by Lomb [1] and further extended by Scargle [2] to find, and test the significance of weak periodic signals with uneven temporal sampling.

When `normalize` is False (default) the computed periodogram is unnormalized, it takes the value $(A^2 \times N/4)$ for a harmonic signal with amplitude A for sufficiently large N.

When `normalize` is True the computed periodogram is normalized by the residuals of the data around a constant reference model (at zero).

Input arrays should be one-dimensional and will be cast to float64.

Parameters

- **x** [array_like] Sample times.
- **y** [array_like] Measurement values.
- **freqs** [array_like] Angular frequencies for output periodogram.
- **precenter** [bool, optional] Pre-center amplitudes by subtracting the mean.
- **normalize** [bool, optional] Compute normalized periodogram.

Returns

- **pgram** [array_like] Lomb-Scargle periodogram.

Raises

- **ValueError**

If the input arrays x and y do not have the same shape.

See also:

- **istft**
  Inverse Short Time Fourier Transform

  Check whether the Constant OverLap Add (COLA) constraint is met
- **welch**
  Power spectral density by Welch’s method
spectrogram

Spectrogram by Welch’s method

csd

Cross spectral density by Welch’s method

Notes

This subroutine calculates the periodogram using a slightly modified algorithm due to Townsend [3] which allows the periodogram to be calculated using only a single pass through the input arrays for each frequency.

The algorithm running time scales roughly as $O(x \times \text{freqs})$ or $O(N^2)$ for a large number of samples and frequencies.

References

[1], [2], [3]

Examples

```python
>>> import matplotlib.pyplot as plt
```

First define some input parameters for the signal:

```python
>>> A = 2.
>>> w = 1.
>>> phi = 0.5 * np.pi
>>> nin = 1000
>>> nout = 10000
>>> frac_points = 0.9 # Fraction of points to select
```

Randomly select a fraction of an array with timesteps:

```python
>>> r = np.random.rand(nin)
>>> x = np.linspace(0.01, 10*np.pi, nin)
>>> x = x[r >= frac_points]
```

Plot a sine wave for the selected times:

```python
>>> y = A * np.sin(w*x+phi)
```

Define the array of frequencies for which to compute the periodogram:

```python
>>> f = np.linspace(0.01, 10, nout)
```

Calculate Lomb-Scargle periodogram:

```python
>>> import scipy.signal as signal
>>> pgram = signal.lombscargle(x, y, f, normalize=True)
```

Now make a plot of the input data:
>>> plt.subplot(2, 1, 1)
>>> plt.plot(x, y, 'b+')

Then plot the normalized periodogram:

>>> plt.subplot(2, 1, 2)
>>> plt.plot(f, pgram)
>>> plt.show()

scipy.signal.vectorstrength

scipy.signal.vectorstrength(events, period)

Determine the vector strength of the events corresponding to the given period.

The vector strength is a measure of phase synchrony, how well the timing of the events is synchronized to a single period of a periodic signal.

If multiple periods are used, calculate the vector strength of each. This is called the “resonating vector strength”.

Parameters

- `events` [1D array_like] An array of time points containing the timing of the events.
- `period` [float or array_like] The period of the signal that the events should synchronize to. The period is in the same units as `events`. It can also be an array of periods, in which case the outputs are arrays of the same length.

Returns

- `strength` [float or 1D array] The strength of the synchronization. 1.0 is perfect synchronization and 0.0 is no synchronization. If `period` is an array, this is also an array with each element containing the vector strength at the corresponding period.
- `phase` [float or array] The phase that the events are most strongly synchronized to in radians. If `period` is an array, this is also an array with each element containing the phase for the corresponding period.

scipy.signal.stft

scipy.signal.stft(x, fs=1.0, window='hann', nperseg=256, noverlap=None, nfft=None, detrend=False, return_onesided=True, boundary='zeros', padded=True, axis=-1)

Compute the Short Time Fourier Transform (STFT).

STFTs can be used as a way of quantifying the change of a nonstationary signal’s frequency and phase content over time.

Parameters

- **x**: [array_like] Time series of measurement values
- **fs**: [float, optional] Sampling frequency of the x time series. Defaults to 1.0.
- **window**: [str or tuple or array_like, optional] Desired window to use. If window is a string or tuple, it is passed to get_window to generate the window values, which are DFT-even by default. See get_window for a list of windows and required parameters. If window is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Hann window.
- **nperseg**: [int, optional] Length of each segment. Defaults to 256.
- **noverlap**: [int, optional] Number of points to overlap between segments. If None, noverlap = nperseg // 2. Defaults to None. When specified, the COLA constraint must be met (see Notes below).
- **nfft**: [int, optional] Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is nperseg. Defaults to None.
- **detrend**: [str or function or False, optional] Specifies how to detrend each segment. If detrend is a string, it is passed as the type argument to the detrend function. If it is a function, it takes a segment and returns a detrended segment. If detrend is False, no detrending is done. Defaults to False.
- **return_onesided**: [bool, optional] If True, return a one-sided spectrum for real data. If False return a two-sided spectrum. Defaults to True, but for complex data, a two-sided spectrum is always returned.
- **boundary**: [str or None, optional] Specifies whether the input signal is extended at both ends, and how to generate the new values, in order to center the first windowed segment on the first input point. This has the benefit of enabling reconstruction of the first input point when the employed window function starts at zero. Valid options are ['even', 'odd', 'constant', 'zeros', None]. Defaults to ‘zeros’, for zero padding extension. i.e. [1, 2, 3, 4] is extended to [0, 1, 2, 3, 4, 0] for nperseg=3.
- **padded**: [bool, optional] Specifies whether the input signal is zero-padded at the end to make the signal fit exactly into an integer number of window segments, so that all of the signal is included in the output. Defaults to True. Padding occurs after boundary extension, if boundary is not None, and padded is True, as is the default.
axis  [int, optional] Axis along which the STFT is computed; the default is over the last axis (i.e. axis=-1).

Returns

f  [ndarray] Array of sample frequencies.
t  [ndarray] Array of segment times.
Zxx  [ndarray] STFT of x. By default, the last axis of Zxx corresponds to the segment times.

Notes

In order to enable inversion of an STFT via the inverse STFT in istft, the signal windowing must obey the constraint of “Nonzero OverLap Add” (NOLA), and the input signal must have complete windowing coverage (i.e. (x.shape[axis] - nperseg) % (nperseg-noverlap) == 0). The padded argument may be used to accomplish this.

Given a time-domain signal x[n], a window w[n], and a hop size H = nperseg - noverlap, the windowed frame at time index t is given by

\[ x_t[n] = x[n]w[n - tH] \]

The overlap-add (OLA) reconstruction equation is given by

\[ x[n] = \frac{\sum_t x_t[n]w[n - tH]}{\sum_t w^2[n - tH]} \]

The NOLA constraint ensures that every normalization term that appears in the denominator of the OLA reconstruction equation is nonzero. Whether a choice of window, nperseg, and noverlap satisfy this constraint can be tested with check_NOLA.

New in version 0.19.0.

[1], [2]

Examples

```python
from scipy import signal
import matplotlib.pyplot as plt
```

Generate a test signal, a 2 Vrms sine wave whose frequency is slowly modulated around 3kHz, corrupted by white noise of exponentially decreasing magnitude sampled at 10 kHz.

```python
fs = 10e3
N = 1e5
amp = 2 * np.sqrt(2)
noise_power = 0.01 * fs / 2
time = np.arange(N) / float(fs)
mod = 500 * np.cos(2 * np.pi * 0.25 * time)
carrier = amp * np.sin(2 * np.pi * 3e3 * time + mod)
noise = np.random.normal(scale=np.sqrt(noise_power),...
size=time.shape)
noise *= np.exp(-time/5)
x = carrier + noise
```

Compute and plot the STFT’s magnitude.

```python
f, t, Zxx = signal.stft(x, fs, nperseg=1000)
plt.pcolormesh(t, f, np.abs(Zxx), vmin=0, vmax=amp)
plt.title('STFT Magnitude')
plt.ylabel('Frequency [Hz]')
plt.xlabel('Time [sec]')
plt.show()
```
scipy.signal.istft

```python
scipy.signal.istft(Zxx, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, input_onesided=True, boundary=True, time_axis=-1, freq_axis=-2)
```

Perform the inverse Short Time Fourier transform (iSTFT).

**Parameters**

- `Zxx` [array_like] STFT of the signal to be reconstructed. If a purely real array is passed, it will be cast to a complex data type.
- `fs` [float, optional] Sampling frequency of the time series. Defaults to 1.0.
- `window` [str or tuple or array_like, optional] Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array_like it will be used directly as the window and its length must be `nperseg`. Defaults to a Hann window. Must match the window used to generate the STFT for faithful inversion.
- `nperseg` [int, optional] Number of data points corresponding to each STFT segment. This parameter must be specified if the number of data points per segment is odd, or if the STFT was padded via `nfft > nperseg`. If `None`, the value depends on the shape of `Zxx` and `input_onesided`. If `input_onesided` is `True`, `nperseg=2*(Zxx.shape[freq_axis] - 1)`. Otherwise, `nperseg=Zxx.shape[freq_axis]`. Defaults to `None`.
- `noverlap` [int, optional] Number of points to overlap between segments. If `None`, half of the segment length. Defaults to `None`. When specified, the COLA constraint must be met (see Notes below), and should match the parameter used to generate the STFT. Defaults to `None`.
- `nfft` [int, optional] Number of FFT points corresponding to each STFT segment. This parameter must be specified if the STFT was padded via `nfft > nperseg`. If `None`, the default values are the same as for `nperseg`, detailed above, with one exception: if `input_onesided` is `True` and `nperseg==2*Zxx.shape[freq_axis] - 1`, `nfft` also takes on that value. This case allows the proper inversion of an odd-length unpadded STFT using `nfft=None`. Defaults to `None`.
- `input_onesided` [bool, optional] If `True`, interpret the input array as one-sided FFTs, such as is returned by `stft` with `return_onesided=True` and `numpy.fft.rfft`. If `False`, interpret the input as a a two-sided FFT. Defaults to `True`.
- `boundary` [bool, optional] Specifies whether the input signal was extended at its boundaries by supplying a non-`None` `boundary` argument to `stft`. Defaults to `True`.
- `time_axis` [int, optional] Where the time segments of the STFT is located; the default is the last axis (i.e. `axis=-1`).
- `freq_axis` [int, optional] Where the frequency axis of the STFT is located; the default is the penultimate axis (i.e. `axis=-2`).

**Returns**

- `t` [ndarray] Array of output data times.
- `x` [ndarray] iSTFT of `Zxx`.

See also:

- `stft`
  Short Time Fourier Transform
- `check_COLA`
  Check whether the Constant OverLap Add (COLA) constraint is met
- `check_NOLA`
  Check whether the Nonzero OverLap Add (NOLA) constraint is met
Notes

In order to enable inversion of an STFT via the inverse STFT with `istft`, the signal windowing must obey the constraint of “nonzero overlap add” (NOLA):

\[ \sum_{t} w^2[n - tH] \neq 0 \]

This ensures that the normalization factors that appear in the denominator of the overlap-add reconstruction equation

\[ x[n] = \frac{\sum_{t} x[n|w[n - tH]]}{\sum_{t} w^2[n - tH]} \]

are not zero. The NOLA constraint can be checked with the `check_NOLA` function.

An STFT which has been modified (via masking or otherwise) is not guaranteed to correspond to a exactly realizable signal. This function implements the iSTFT via the least-squares estimation algorithm detailed in [2], which produces a signal that minimizes the mean squared error between the STFT of the returned signal and the modified STFT.

New in version 0.19.0.

References

[1], [2]

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Generate a test signal, a 2 Vrms sine wave at 50Hz corrupted by 0.001 V**2/Hz of white noise sampled at 1024 Hz.

```python
>>> fs = 1024
>>> N = 10*fs
>>> nperseg = 512
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / float(fs)
>>> carrier = amp * np.sin(2*np.pi*50*time)
>>> noise = np.random.normal(scale=np.sqrt(noise_power), ...
## size=time.shape)
>>> x = carrier + noise
```

Compute the STFT, and plot its magnitude

```python
>>> f, t, Zxx = signal.stft(x, fs=fs, nperseg=nperseg)
>>> plt.figure()
>>> plt.pcolormesh(t, f, np.abs(Zxx), vmin=0, vmax=amp)
>>> plt.ylim([f[1], f[-1]])
>>> plt.title('STFT Magnitude')
>>> plt.ylabel('Frequency [Hz]')
```
>>> plt.xlabel('Time [sec]')
>>> plt.yscale('log')
>>> plt.show()

Zero the components that are 10% or less of the carrier magnitude, then convert back to a time series via inverse
STFT

```python
>>> Zxx = np.where(np.abs(Zxx) >= amp/10, Zxx, 0)
>>> _, xrec = signal.istft(Zxx, fs)
```

Compare the cleaned signal with the original and true carrier signals.

```python
>>> plt.figure()
>>> plt.plot(time, x, time, xrec, time, carrier)
>>> plt.xlim([2, 2.1])
>>> plt.xlabel('Time [sec]')
>>> plt.ylabel('Signal')
>>> plt.legend(['Carrier + Noise', 'Filtered via STFT', 'True Carrier'])
>>> plt.show()
```

Note that the cleaned signal does not start as abruptly as the original, since some of the coefficients of the transient
were also removed:

```python
>>> plt.figure()
>>> plt.plot(time, x, time, xrec, time, carrier)
>>> plt.xlim([0, 0.1])
>>> plt.xlabel('Time [sec]')
>>> plt.ylabel('Signal')
>>> plt.legend(['Carrier + Noise', 'Filtered via STFT', 'True Carrier'])
>>> plt.show()
```
6.21. Signal processing (scipy.signal)
scipy.signal.check_COLA

scipy.signal.check_COLA(window, nperseg, noverlap, tol=1e-10)

Check whether the Constant OverLap Add (COLA) constraint is met

Parameters

window [str or tuple or array_like] Desired window to use. If window is a string or tuple, it is passed to get_window to generate the window values, which are DFT-even by default. See get_window for a list of windows and required parameters. If window is array_like it will be used directly as the window and its length must be nperseg.

nperseg [int] Length of each segment.

noverlap [int] Number of points to overlap between segments.

tol [float, optional] The allowed variance of a bin’s weighted sum from the median bin sum.

Returns

verdict [bool] True if chosen combination satisfies COLA within tol, False otherwise

See also:

check_NOLA

Check whether the Nonzero Overlap Add (NOLA) constraint is met

stft

Short Time Fourier Transform

istft

Inverse Short Time Fourier Transform

Notes

In order to enable inversion of an STFT via the inverse STFT in istft, it is sufficient that the signal windowing obeys the constraint of “Constant OverLap Add” (COLA). This ensures that every point in the input data is equally weighted, thereby avoiding aliasing and allowing full reconstruction.

Some examples of windows that satisfy COLA:

- Rectangular window at overlap of 0, 1/2, 2/3, 3/4, …
- Bartlett window at overlap of 1/2, 3/4, 5/6, …
- Hann window at 1/2, 2/3, 3/4, …
- Any Blackman family window at 2/3 overlap
- Any window with noverlap = nperseg-1

A very comprehensive list of other windows may be found in [2], wherein the COLA condition is satisfied when the “Amplitude Flatness” is unity.

New in version 0.19.0.

References

[1], [2]
Examples

```python
from scipy import signal

# Confirm COLA condition for rectangular window of 75% (3/4) overlap:
>>> signal.check_COLA(signal.boxcar(100), 100, 75)
True

# COLA is not true for 25% (1/4) overlap, though:
>>> signal.check_COLA(signal.boxcar(100), 100, 25)
False

# “Symmetrical” Hann window (for filter design) is not COLA:
>>> signal.check_COLA(signal.hann(120, sym=True), 120, 60)
False

# “Periodic” or “DFT-even” Hann window (for FFT analysis) is COLA for overlap of 1/2, 2/3, 3/4, etc.:
>>> signal.check_COLA(signal.hann(120, sym=False), 120, 60)
True
>>> signal.check_COLA(signal.hann(120, sym=False), 120, 80)
True
>>> signal.check_COLA(signal.hann(120, sym=False), 120, 90)
True
```

### scipy.signal.check_NOLA

**scipy.signal.check_NOLA**(window, nperseg, noverlap, tol=1e-10)

Check whether the Nonzero Overlap Add (NOLA) constraint is met.

- **Parameters**
  - `window` [str or tuple or array_like] Desired window to use. If window is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If window is array_like it will be used directly as the window and its length must be nperseg.
  - `nperseg` [int] Length of each segment.
  - `noverlap` [int] Number of points to overlap between segments.
  - `tol` [float, optional] The allowed variance of a bin’s weighted sum from the median bin sum.

- **Returns**
  - `verdict` [bool] True if chosen combination satisfies the NOLA constraint within tol, False otherwise.

### See also:

**check_COLA**

Check whether the Constant OverLap Add (COLA) constraint is met.
**Notes**

In order to enable inversion of an STFT via the inverse STFT in `istft`, the signal windowing must obey the constraint of “nonzero overlap add” (NOLA):

\[
\sum_t w^2[n - tH] \neq 0
\]

for all \( n \), where \( w \) is the window function, \( t \) is the frame index, and \( H \) is the hop size \((H = nperseg - noverlap)\).

This ensures that the normalization factors in the denominator of the overlap-add inversion equation are not zero. Only very pathological windows will fail the NOLA constraint.

New in version 1.2.0.

**References**

[1], [2]

**Examples**

```python
>>> from scipy import signal
```

Confirm NOLA condition for rectangular window of 75% (3/4) overlap:

```python
>>> signal.check_NOLA(signal.boxcar(100), 100, 75)
True
```

NOLA is also true for 25% (1/4) overlap:

```python
>>> signal.check_NOLA(signal.boxcar(100), 100, 25)
True
```

“Symmetrical” Hann window (for filter design) is also NOLA:

```python
>>> signal.check_NOLA(signal.hann(120, sym=True), 120, 60)
True
```

As long as there is overlap, it takes quite a pathological window to fail NOLA:

```python
>>> w = np.ones(64, dtype="float")
>>> w[::2] = 0
>>> signal.check_NOLA(w, 64, 32)
False
```

If there is not enough overlap, a window with zeros at the ends will not work:
>>> signal.check_NOLA(signal.hann(64), 64, 0)
False
>>> signal.check_NOLA(signal.hann(64), 64, 1)
False
>>> signal.check_NOLA(signal.hann(64), 64, 2)
True

Block Sparse Row matrix

*This can be instantiated in several ways:*

- `bsr_matrix(D, [blocksize=(R,C)])`
  where D is a dense matrix or 2-D ndarray.
- `bsr_matrix(S, [blocksize=(R,C)])`
  with another sparse matrix S (equivalent to S.tobsr())
- `bsr_matrix((M, N), [blocksize=(R,C), dtype])`
  to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.
- `bsr_matrix((data, ij), [blocksize=(R,C), shape=(M, N)])`
  where data and ij satisfy a[ij[0, k], ij[1, k]] = data[k]
- `bsr_matrix((data, indices, indptr), [shape=(M, N)])`
  is the standard BSR representation where the block column indices for row i are stored in indices[indptr[i]:indptr[i+1]] and their corresponding block values are stored in data[ indptr[i]: indptr[i+1] ]. If the shape parameter is not supplied, the matrix dimensions are inferred from the index arrays.
Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Summary of BSR format

The Block Compressed Row (BSR) format is very similar to the Compressed Sparse Row (CSR) format. BSR is appropriate for sparse matrices with dense sub matrices like the last example below. Block matrices often arise in vector-valued finite element discretizations. In such cases, BSR is considerably more efficient than CSR and CSC for many sparse arithmetic operations.

Blocksize

The blocksize (R,C) must evenly divide the shape of the matrix (M,N). That is, R and C must satisfy the relationship \( M \% R = 0 \) and \( N \% C = 0 \).

If no blocksize is specified, a simple heuristic is applied to determine an appropriate blocksize.

Examples

```python
>>> from scipy.sparse import bsr_matrix
>>> bsr_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```python
>>> row = np.array([0, 0, 1, 2, 2])
>>> col = np.array([0, 2, 2, 0, 1])
>>> data = np.array([1, 2, 3, 4, 5])
>>> bsr_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])
```

```python
>>> indptr = np.array([0, 2, 3])
>>> indices = np.array([0, 2, 2, 0, 1])
>>> data = np.array([1, 2, 3, 4, 5]).repeat(4).reshape(6, 2)
>>> bsr_matrix((data, indices, indptr), shape=(6, 6)).toarray()
array([[1, 0, 0, 2, 2],
       [1, 0, 0, 2, 2],
       [0, 0, 0, 3, 3],
       [0, 0, 0, 3, 3],
       [4, 4, 5, 5, 6],
       [4, 4, 5, 5, 6]])
```

Attributes

- `dtype`  [dtype] Data type of the matrix
- `ndim`   [int] Number of dimensions (this is always 2)
- `nnz`    Number of stored values, including explicit zeros.
- `data`   Data array of the matrix
- `indices` BSR format index array
- `indptr` BSR format index pointer array
**blocksize**  
Block size of the matrix

**has_sorted_indices**  
Determine whether the matrix has sorted indices

### Methods

```python
__len__(self)  
interpret other and call one of the following

__mul__(self, other)  
Element-wise arccsin.

arcsin(self)  
Element-wise arcsin.

arcsinh(self)  
Element-wise arcsinh.

arctan(self)  
Element-wise arctan.

arctanh(self)  
Element-wise arctanh.

argmax(self[, axis, out])  
Return indices of maximum elements along an axis.

argmin(self[, axis, out])  
Return indices of minimum elements along an axis.

asformat(self, format[, copy])  
Return this matrix in the passed format.

asfptype(self)  
Upcast matrix to a floating point format (if necessary)

cast(self, dtype[, casting, copy])  
Cast the matrix elements to a specified type.

ceil(self)  
Element-wise ceil.

cast_format(self[, full_check])  
check whether the matrix format is valid

copy(self)  
Element-wise complex conjugation.

copy(self)  
Element-wise complex conjugation.

copy(self)  
Returns a copy of this matrix.

count_nonzero(self)  
Number of non-zero entries, equivalent to

deg2rad(self)  
Element-wise deg2rad.

diagonal(self[, k])  
Returns the k-th diagonal of the matrix.

dot(self, other)  
Ordinary dot product

eliminate_zeros(self)  
Remove zero elements in-place.

expm1(self)  
Element-wise expm1.

floor(self)  
Element-wise floor.

getH(self)  
Return the Hermitian transpose of this matrix.

get_shape(self)  
Get shape of a matrix.

getcol(self, j)  
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

getformat(self)  
Format of a matrix representation as a string.

getmaxprint(self)  
Maximum number of elements to display when printed.

getnnz(self[, axis])  
Number of stored values, including explicit zeros.

getrow(self, i)  
Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

log1p(self)  
Element-wise log1p.

matmat(*args, **kwds)  
matmat is deprecated! BSR matmat is deprecated in scipy 0.19.0.

matvec(*args, **kwds)  
matvec is deprecated! BSR matvec is deprecated in scipy 0.19.0.

max(self[, axis, out])  
Return the maximum of the matrix or maximum along an axis.

maximum(self, other)  
Element-wise maximum between this and another matrix.

mean(self[, axis, dtype, out])  
Compute the arithmetic mean along the specified axis.
```

</tbody>
</table>

**scipy.sparse.bsr_matrix.__len__**

`bsr_matrix.__len__(self)`

**scipy.sparse.bsr_matrix.__mul__**

`bsr_matrix.__mul__(self, other)`

interpret other and call one of the following
self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()

**scipy.sparse.bsr_matrix.arcsin**

```python
csr_matrix.arcsin(self)
```

Element-wise arcsin.

See numpy.arcsin for more information.

**scipy.sparse.bsr_matrix.arcsinh**

```python
csr_matrix.arcsinh(self)
```

Element-wise arcsinh.

See numpy.arcsinh for more information.

**scipy.sparse.bsr_matrix.arctan**

```python
csr_matrix.arctan(self)
```

Element-wise arctan.

See numpy.arctan for more information.

**scipy.sparse.bsr_matrix.arctanh**

```python
csr_matrix.arctanh(self)
```

Element-wise arctanh.

See numpy.arctanh for more information.

**scipy.sparse.bsr_matrix.argmax**

```python
csr_matrix.argmax(self, axis=None, out=None)
```

Return indices of maximum elements along an axis.

Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

**Parameters**

- **axis**
  - [None, -2, -1, 0, 1], optional
  - Axis along which the argmax is computed. If None (default), index of the maximum element in the flattened data is returned.

- **out**
  - [None, optional]
  - This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- **ind**
  - [numpy.matrix or int]
  - Indices of maximum elements. If matrix, its size along axis is 1.
scipy.sparse.bsr_matrix.argmin

bsr_matrix.argmin(self, axis=None, out=None)
Return indices of minimum elements along an axis.
Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

Parameters

axis [{-2, -1, 0, 1, None}, optional] Axis along which the argmin is computed. If None (default), index of the minimum element in the flattened data is returned.

out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

ind [numpy.matrix or int] Indices of minimum elements. If matrix, its size along axis is 1.

scipy.sparse.bsr_matrix.asformat

bsr_matrix.asformat(self, format, copy=False)
Return this matrix in the passed format.

Parameters

format [{str, None}] The desired matrix format (“csr”, “csc”, “lil”, “dok”, “array”, …) or None for no conversion.

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [This matrix in the passed format.]

scipy.sparse.bsr_matrix.asfptype

bsr_matrix.asfptype(self)
Upcast matrix to a floating point format (if necessary)

scipy.sparse.bsr_matrix.astype

bsr_matrix.astype(self, dtype, casting=’unsafe’, copy=True)
Cast the matrix elements to a specified type.

Parameters

dtype [string or numpay dtype] Typecode or data-type to which to cast the data.

casting [{‘no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’}, optional] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all, ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.

copy [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.
**scipy.sparse.bsr_matrix.ceil**

`bsr_matrix.ceil(self)`

Element-wise ceil.

See numpy.ceil for more information.

**scipy.sparse.bsr_matrix.check_format**

`bsr_matrix.check_format(self, full_check=True)`

Check whether the matrix format is valid

**Parameters:**

`full_check`:

- True - rigorous check, O(N) operations: default
- False - basic check, O(1) operations

**scipy.sparse.bsr_matrix.conj**

`bsr_matrix.conj(self, copy=True)`

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

`copy` [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

`A` [The element-wise complex conjugate.]

**scipy.sparse.bsr_matrix.conjugate**

`bsr_matrix.conjugate(self, copy=True)`

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

`copy` [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

`A` [The element-wise complex conjugate.]

**scipy.sparse.bsr_matrix.copy**

`bsr_matrix.copy()`

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.
scipy.sparse.bsr_matrix.count_nonzero

csr_matrix.count_nonzero(self)
    Number of non-zero entries, equivalent to
    np.count_nonzero(a.toarray())
    Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data
    attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.bsr_matrix.deg2rad

bsr_matrix.deg2rad(self)
    Element-wise deg2rad.
    See numpy.deg2rad for more information.

scipy.sparse.bsr_matrix.diagonal

bsr_matrix.diagonal(self, k=0)
    Returns the k-th diagonal of the matrix.
    Parameters
    k [int, optional] Which diagonal to set, corresponding to elements a[i, i+k]. Default: 0
    (the main diagonal).
    New in version 1.0.
    See also:
    
    numpy.diagonal
    Equivalent numpy function.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

scipy.sparse.bsr_matrix.dot

csr_matrix.dot(self, other)
    Ordinary dot product
Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

**scipy.sparse.bsr_matrix.eliminate_zeros**

`bsr_matrix.eliminate_zeros(self)`  
Remove zero elements in-place.

**scipy.sparse.bsr_matrix.expm1**

`bsr_matrix.expm1(self)`  
Element-wise expm1.  
See numpy.expm1 for more information.

**scipy.sparse.bsr_matrix.floor**

`bsr_matrix.floor(self)`  
Element-wise floor.  
See numpy.floor for more information.

**scipy.sparse.bsr_matrix.getH**

`bsr_matrix.getH(self)`  
Return the Hermitian transpose of this matrix.  
See also:  
`numpy.matrix.getH`  
NumPy’s implementation of `getH` for matrices

**scipy.sparse.bsr_matrix.get_shape**

`bsr_matrix.get_shape(self)`  
Get shape of a matrix.

**scipy.sparse.bsr_matrix.getcol**

`bsr_matrix.getcol(self, j)`  
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
scipy.sparse.bsr_matrix.getformat

bsr_matrix.getformat(self)
Format of a matrix representation as a string.

scipy.sparse.bsr_matrix.getmaxprint

bsr_matrix.getmaxprint(self)
Maximum number of elements to display when printed.

scipy.sparse.bsr_matrix.getnnz

bsr_matrix.getnnz(self, axis=None)
Number of stored values, including explicit zeros.

Parameters
axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:
count_nonzero
Number of non-zero entries

scipy.sparse.bsr_matrix.getrow

bsr_matrix.getrow(self, i)
Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

scipy.sparse.bsr_matrix.log1p

bsr_matrix.log1p(self)
Element-wise log1p.
See numpy.log1p for more information.

scipy.sparse.bsr_matrix.matmat

bsr_matrix.matmat(*args, **kwds)
matmat is deprecated! BSR matmat is deprecated in scipy 0.19.0. Use * operator instead.
Multiply this sparse matrix by other matrix.

scipy.sparse.bsr_matrix.matvec

bsr_matrix.matvec(*args, **kwds)
matvec is deprecated! BSR matvec is deprecated in scipy 0.19.0. Use * operator instead.
Multiply matrix by vector.
scipy.sparse.bsr_matrix.max

bsr_matrix.max(self, axis=None, out=None)

Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters
axis [-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e. axis = None).
out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns
amax [coo_matrix or scalar] Maximum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:
min
The minimum value of a sparse matrix along a given axis.

numpy.matrix.max
NumPy’s implementation of ‘max’ for matrices

scipy.sparse.bsr_matrix.maximum

bsr_matrix.maximum(self, other)

Element-wise maximum between this and another matrix.

scipy.sparse.bsr_matrix.mean

bsr_matrix.mean(self, axis=None, dtype=None, out=None)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters
axis [-2, -1, 0, 1, None] optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. axis = None).
dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype. New in version 0.18.0.
out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

Returns
m [np.matrix]
See also:

**numpy.matrix.mean**

NumPy's implementation of 'mean' for matrices

**scipy.sparse.bsr_matrix.min**

bsr_matrix.min(self, axis=None, out=None)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters**

- **axis**
  - [-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e. axis = None).
- **out**
  - [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- **amin**
  - [coo_matrix or scalar] Minimum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

**max**

The maximum value of a sparse matrix along a given axis.

**numpy.matrix.min**

NumPy's implementation of 'min' for matrices

**scipy.sparse.bsr_matrix.minimum**

bsr_matrix.minimum(self, other)

Element-wise minimum between this and another matrix.

**scipy.sparse.bsr_matrix.multiply**

bsr_matrix.multiply(self, other)

Point-wise multiplication by another matrix, vector, or scalar.

**scipy.sparse.bsr_matrix.nonzero**

bsr_matrix.nonzero(self)

nonzero indices

Returns a tuple of arrays (row, col) containing the indices of the non-zero elements of the matrix.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

**scipy.sparse.bsr_matrix.power**

```python
csr_matrix.power(self, n, dtype=None)
```

This function performs element-wise power.

**Parameters**

- `n` [n is a scalar]
- `dtype` [If dtype is not specified, the current dtype will be preserved.]

**scipy.sparse.bsr_matrix.prune**

```python
bsr_matrix.prune(self)
```

Remove empty space after all non-zero elements.

**scipy.sparse.bsr_matrix.rad2deg**

```python
bsr_matrix.rad2deg(self)
```

Element-wise rad2deg.

See numpy.rad2deg for more information.

**scipy.sparse.bsr_matrix.reshape**

```python
bsr_matrix.reshape(self, shape, order='C', copy=False)
```

Gives a new shape to a sparse matrix without changing its data.

**Parameters**

- `shape` [length-2 tuple of ints] The new shape should be compatible with the original shape.
- `order` [{'C', 'F'}, optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g. read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g. read entire first column, then second column, etc.
- `copy` [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- `reshaped_matrix` [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:
**numpy.matrix.reshape**

NumPy's implementation of ‘reshape’ for matrices

**scipy.sparse.bsr_matrix.resize**

```
bsr_matrix.resize(self, *shape)
```

Resize the matrix in-place to dimensions given by `shape`

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

**Parameters**

- `shape` [(int, int)] number of rows and columns in the new matrix

**Notes**

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

**scipy.sparse.bsr_matrix.rint**

```
bsr_matrix.rint(self)
```

Element-wise rint.

See `numpy.rint` for more information.

**scipy.sparse.bsr_matrix.set_shape**

```
bsr_matrix.set_shape(self, shape)
```

See `reshape`.

**scipy.sparse.bsr_matrix.setdiag**

```
bsr_matrix.setdiag(self, values, k=0)
```

Set diagonal or off-diagonal elements of the array.

**Parameters**

- `values` [array_like] New values of the diagonal elements.
  
  Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored.
  
  If a scalar value is given, all of the diagonal is set to it.

- `k` [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).
scipy.sparse.bsr_matrix.sign

bsr_matrix.sign(self)
   Element-wise sign.
   See numpy.sign for more information.

scipy.sparse.bsr_matrix.sin

bsr_matrix.sin(self)
   Element-wise sin.
   See numpy.sin for more information.

scipy.sparse.bsr_matrix.sinh

bsr_matrix.sinh(self)
   Element-wise sinh.
   See numpy.sinh for more information.

scipy.sparse.bsr_matrix.sort_indices

bsr_matrix.sort_indices(self)
   Sort the indices of this matrix in place

scipy.sparse.bsr_matrix.sorted_indices

bsr_matrix.sorted_indices(self)
   Return a copy of this matrix with sorted indices

scipy.sparse.bsr_matrix.sqrt

bsr_matrix.sqrt(self)
   Element-wise sqrt.
   See numpy.sqrt for more information.

scipy.sparse.bsr_matrix.sum

bsr_matrix.sum(self, axis=None, dtype=None, out=None)
   Sum the matrix elements over a given axis.

   Parameters
   axis  [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. axis = None).
**dtype**  [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of \( a \) is used by default unless \( a \) has an integer dtype of less precision than the default platform integer. In that case, if \( a \) is signed then the platform integer is used while if \( a \) is unsigned then an unsigned integer of the same precision as the platform integer is used.
New in version 0.18.0.

**out**  [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

**Returns**

**sum_along_axis**  [np.matrix] A matrix with the same shape as \( self \), with the specified axis removed.

**See also:**

*numpy.matrix.sum*

NumPy's implementation of 'sum' for matrices

**scipy.sparse.bsr_matrix.sum_duplicates**

`bsr_matrix.sum_duplicates(self)`

Eliminate duplicate matrix entries by adding them together
The is an *in place* operation

**scipy.sparse.bsr_matrix.tan**

`bsr_matrix.tan(self)`

Element-wise tan.
See numpy.tan for more information.

**scipy.sparse.bsr_matrix.tanh**

`bsr_matrix.tanh(self)`

Element-wise tanh.
See numpy.tanh for more information.

**scipy.sparse.bsr_matrix.toarray**

`bsr_matrix.toarray(self, order=None, out=None)`

Return a dense ndarray representation of this matrix.

**Parameters**

**order**  [[‘C’, ‘F’], optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the \( out \) argument.
out [ndarray, 2-dimensional, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, out is required to be memory contiguous (either C or Fortran ordered).

Returns

arr [ndarray, 2-dimensional] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed, the same object is returned after being modified in-place to contain the appropriate values.

scipy.sparse.bsr_matrix.tobsr

bsr_matrix.tobsr(self, blocksize=None, copy=False)
Convert this matrix into Block Sparse Row Format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

If blocksize=(R, C) is provided, it will be used for determining block size of the bsr_matrix.

scipy.sparse.bsr_matrix.tocoo

bsr_matrix.tocoo(self, copy=True)
Convert this matrix to COOrdinate format.

When copy=False the data array will be shared between this matrix and the resultant coo_matrix.

scipy.sparse.bsr_matrix.tocsc

bsr_matrix.tocsc(self, copy=False)
Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.bsr_matrix.tocsr

bsr_matrix.tocsr(self, copy=False)
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.bsr_matrix.todense

bsr_matrix.todense(self, order=None, out=None)
Return a dense matrix representation of this matrix.

Parameters

order [{‘C’, ‘F’}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.
scipy.sparse.bsr_matrix.todia

bsr_matrix.todia(self, copy=False)

Convert this matrix to sparse DIAGONAL format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.bsr_matrix.todok

bsr_matrix.todok(self, copy=False)

Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.bsr_matrix.tolil

bsr_matrix.tolil(self, copy=False)

Convert this matrix to LINKED List format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.bsr_matrix.transpose

bsr_matrix.transpose(self, axes=None, copy=False)

Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [self with the dimensions reversed.]

See also:

numpy.matrix.transpose

NumPy's implementation of 'transpose' for matrices
scipy.sparse.bsr_matrix.trunc

bsr_matrix.trunc(self)
Element-wise trunc.

See numpy.trunc for more information.

__getitem__

scipy.sparse.coo_matrix

class scipy.sparse.coo_matrix(arg1, shape=None, dtype=None, copy=False)
A sparse matrix in COOrdinate format.

Also known as the ‘ijv’ or ‘triplet’ format.

This can be instantiated in several ways:

    coo_matrix(D)
    with a dense matrix D

    coo_matrix(S)
    with another sparse matrix S (equivalent to S.tocoo())

    coo_matrix((M, N), [dtype])
    to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

    coo_matrix((data, (i, j)), [shape=(M, N)])
    to construct from three arrays:
    1. data[:] the entries of the matrix, in any order
    2. i[:] the row indices of the matrix entries
    3. j[:] the column indices of the matrix entries

    Where A[i[k], j[k]] = data[k]. When shape is not specified, it is inferred from the index arrays

Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Advantages of the COO format

• facilitates fast conversion among sparse formats
• permits duplicate entries (see example)
• very fast conversion to and from CSR/CSC formats

Disadvantages of the COO format

• does not directly support:
-- arithmetic operations
-- slicing

**Intended Usage**

- COO is a fast format for constructing sparse matrices
- Once a matrix has been constructed, convert to CSR or CSC format for fast arithmetic and matrix vector operations
- By default when converting to CSR or CSC format, duplicate (i,j) entries will be summed together. This facilitates efficient construction of finite element matrices and the like. (see example)

**Examples**

```python
>>> # Constructing an empty matrix
>>> from scipy.sparse import coo_matrix
>>> coo_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)

>>> # Constructing a matrix using ijk format
>>> row = np.array([0, 3, 1, 0])
>>> col = np.array([0, 3, 1, 2])
>>> data = np.array([4, 5, 7, 9])
>>> coo_matrix((data, (row, col)), shape=(4, 4)).toarray()
array([[4, 0, 9, 0],
       [0, 7, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 5]])

>>> # Constructing a matrix with duplicate indices
>>> row = np.array([0, 0, 1, 3, 1, 0])
>>> col = np.array([0, 2, 1, 3, 1, 0])
>>> data = np.array([1, 1, 1, 1, 1, 1])
>>> coo = coo_matrix((data, (row, col)), shape=(4, 4))
>>> # Duplicate indices are maintained until implicitly or explicitly summed
>>> np.max(coo.data)
1
>>> coo.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

**Attributes**

- `dtype` [dtype] Data type of the matrix
- `ndim` [int] Number of dimensions (this is always 2)
- `nnz` Number of stored values, including explicit zeros.
data  COO format data array of the matrix
row  COO format row index array of the matrix
col  COO format column index array of the matrix

Methods

```python
__len__(self)
__mul__(self, other) interpret other and call one of the following
arcsin(self) Element-wise arcsin.
arcsinh(self) Element-wise arcsinh.
arctan(self) Element-wise arctan.
arctanh(self) Element-wise arctanh.
argmax(self[, axis, out]) Return indices of maximum elements along an axis.
argmin(self[, axis, out]) Return indices of minimum elements along an axis.
asformat(self, format[, copy]) Return this matrix in the passed format.
asfptype(self) Upcast matrix to a floating point format (if necessary)
astype(self, dtype[, casting, copy]) Cast the matrix elements to a specified type.
ceil(self) Element-wise ceil.
conj(self[, copy]) Element-wise complex conjugation.
conjugate(self[, copy]) Element-wise complex conjugation.
copy(self) Returns a copy of this matrix.
count_nonzero(self) Number of non-zero entries, equivalent to
deg2rad(self) Element-wise deg2rad.
diagonal(self[, k]) Returns the k-th diagonal of the matrix.
dot(self, other) Ordinary dot product
eliminate_zeros(self) Remove zero entries from the matrix
expm1(self) Element-wise expm1.
floor(self) Element-wise floor.
getH(self) Return the Hermitian transpose of this matrix.
get_shape(self) Get shape of a matrix.
getcol(self, j) Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
getformat(self) Format of a matrix representation as a string.
getmaxprint(self) Maximum number of elements to display when printed.
getnnz(self[, axis]) Number of stored values, including explicit zeros.
getrow(self, i) Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
log1p(self) Element-wise log1p.
max(self[, axis, out]) Return the maximum of the matrix or maximum along an axis.
maximum(self, other) Element-wise maximum between this and another matrix.
mean(self[, axis, dtype, out]) Compute the arithmetic mean along the specified axis.
min(self[, axis, out]) Return the minimum of the matrix or maximum along an axis.
minimum(self, other) Element-wise minimum between this and another matrix.
multiply(self, other) Point-wise multiplication by another matrix
nonzero(self) nonzero indices
```

**scipy.sparse.coo_matrix.__len__**

```python
coo_matrix.__len__(self)
```

**scipy.sparse.coo_matrix.__mul__**

```python
coo_matrix.__mul__(self, other)
```

Interpret `other` and call one of the following:

- `self._mul_scalar()`
- `self._mul_vector()`
- `self._mul_multivector()`
- `self._mul_sparse_matrix()`

**scipy.sparse.coo_matrix.arcsin**

```python
coo_matrix.arcsin(self)
```

Element-wise arcsin.

See `numpy.arcsin` for more information.
scipy.sparse.coo_matrix.arcsinh

```python
coo_matrix.arcsinh(self)
```
Element-wise arcsinh.

See numpy.arcsinh for more information.

scipy.sparse.coo_matrix.arctan

```python
coo_matrix.arctan(self)
```
Element-wise arctan.

See numpy.arctan for more information.

scipy.sparse.coo_matrix.arctanh

```python
coo_matrix.arctanh(self)
```
Element-wise arctanh.

See numpy.arctanh for more information.

scipy.sparse.coo_matrix.argmax

```python
coo_matrix.argmax(self, axis=None, out=None)
```
Return indices of maximum elements along an axis.
Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

**Parameters**

- `axis` : [-2, -1, 0, 1, None], optional
  Axis along which the argmax is computed. If None (default), index of the maximum element in the flattened data is returned.

- `out` : [None, optional]
  This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- `ind` : [numpy.matrix or int] Indices of maximum elements. If matrix, its size along `axis` is 1.

scipy.sparse.coo_matrix.argmin

```python
coo_matrix.argmin(self, axis=None, out=None)
```
Return indices of minimum elements along an axis.
Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters**

- `axis` : [-2, -1, 0, 1, None], optional
  Axis along which the argmin is computed. If None (default), index of the minimum element in the flattened data is returned.

- `out` : [None, optional]
  This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.
Returns
ind [numpy.matrix or int] Indices of minimum elements. If matrix, its size along axis is 1.

scipy.sparse.coo_matrix.asformat

coo_matrix.asformat(self, format, copy=False)
Return this matrix in the passed format.

Parameters
format [{str, None}] The desired matrix format (“csr”, “csc”, “lil”, “dok”, “array”, …) or None for no conversion.
copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns
A [This matrix in the passed format.]

scipy.sparse.coo_matrix.asfptype

coo_matrix.asfptype(self)
Upcast matrix to a floating point format (if necessary)

scipy.sparse.coo_matrix.astype

coo_matrix.astype(self, dtype, casting='unsafe', copy=True)
Cast the matrix elements to a specified type.

Parameters
dtype [string or numpy dtype] Typecode or data-type to which to cast the data.
casting [{‘no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’}, optional] Controls what kind of data casting may occur. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
copy [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.

scipy.sparse.coo_matrix.ceil

coo_matrix.ceil(self)
Element-wise ceil.
See numpy.ceil for more information.
scipy.sparse.coo_matrix.conj

coo_matrix.conj(self, copy=True)
Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters

- copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

- A [The element-wise complex conjugate.]

scipy.sparse.coo_matrix.conjugate

coo_matrix.conjugate(self, copy=True)
Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters

- copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

- A [The element-wise complex conjugate.]

scipy.sparse.coo_matrix.copy

coo_matrix.copy(self)
Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

scipy.sparse.coo_matrix.count_nonzero

coo_matrix.count_nonzero(self)
Number of non-zero entries, equivalent to
np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.coo_matrix.deg2rad

coo_matrix.deg2rad(self)
Element-wise deg2rad.

See numpy.deg2rad for more information.
scipy.sparse.coo_matrix.diagonal

coo_matrix.diagonal(self, k=0)
Returns the k-th diagonal of the matrix.

Parameters

k [int, optional] Which diagonal to set, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
New in version 1.0.

See also:

numpy.diagonal
Equivalent numpy function.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

scipy.sparse.coo_matrix.dot

coo_matrix.dot(self, other)
Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.coo_matrix.eliminate_zeros

coo_matrix.eliminate_zeros(self)
Remove zero entries from the matrix

This is an in place operation
scipy.sparse.coo_matrix.expm1

coo_matrix.expm1(self)
    Element-wise expm1.
    See numpy.expm1 for more information.

scipy.sparse.coo_matrix.floor

c oo_matrix.floor(self)
    Element-wise floor.
    See numpy.floor for more information.

scipy.sparse.coo_matrix.getH

coo_matrix.getH(self)
    Return the Hermitian transpose of this matrix.
    See also:
        numpy.matrix.getH
            NumPy's implementation of getH for matrices

scipy.sparse.coo_matrix.get_shape

coo_matrix.get_shape(self)
    Get shape of a matrix.

scipy.sparse.coo_matrix.getcol

coo_matrix.getcol(self, j)
    Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.coo_matrix.getformat

coo_matrix.getformat(self)
    Format of a matrix representation as a string.

scipy.sparse.coo_matrix.getmaxprint

coo_matrix.getmaxprint(self)
    Maximum number of elements to display when printed.
scipy.sparse.coo_matrix.getnnz

coo_matrix.getnnz (self, axis=None)

Number of stored values, including explicit zeros.

Parameters

axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:

count_nonzero

Number of non-zero entries

scipy.sparse.coo_matrix.getrow

coo_matrix.getrow (self, i)

Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

scipy.sparse.coo_matrix.log1p

coo_matrix.log1p (self)

Element-wise log1p.

See numpy.log1p for more information.

scipy.sparse.coo_matrix.max

coo_matrix.max (self, axis=None, out=None)

Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e. axis = None).

out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amax [coo_matrix or scalar] Maximum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

min

The minimum value of a sparse matrix along a given axis.

numpy.matrix.max

NumPy's implementation of 'max' for matrices
**scipy.sparse.coo_matrix.maximum**

coo_matrix.maximum(self, other)

Element-wise maximum between this and another matrix.

**scipy.sparse.coo_matrix.mean**

coo_matrix.mean(self, axis=None, dtype=None, out=None)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

### Parameters

- **axis**
  
  [-2, -1, 0, 1, None] optional
  
  Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. axis = None).

- **dtype**
  
  [data-type, optional]
  
  Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype.
  
  New in version 0.18.0.

- **out**
  
  [np.matrix, optional]
  
  Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
  
  New in version 0.18.0.

### Returns

- **m**
  
  [np.matrix]

See also:

- **numpy.matrix.mean**

  NumPy’s implementation of ‘mean’ for matrices

**scipy.sparse.coo_matrix.min**

coo_matrix.min(self, axis=None, out=None)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

### Parameters

- **axis**
  
  [-2, -1, 0, 1, None] optional
  
  Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e. axis = None).

- **out**
  
  [None, optional]
  
  This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

### Returns

- **amin**
  
  [coo_matrix or scalar]
  
  Minimum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension `a.ndim - 1`.

See also:
**max**

The maximum value of a sparse matrix along a given axis.

**numpy.matrix.min**

NumPy’s implementation of ‘min’ for matrices

**scipy.sparse.coo_matrix.minimum**

coo_matrix.minimum(self, other)

Element-wise minimum between this and another matrix.

**scipy.sparse.coo_matrix.multiply**

coo_matrix.multiply(self, other)

Point-wise multiplication by another matrix

**scipy.sparse.coo_matrix.nonzero**

coo_matrix.nonzero(self)

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

**scipy.sparse.coo_matrix.power**

coo_matrix.power(self, n, dtype=None)

This function performs element-wise power.

**Parameters**

- **n**
  
  [n is a scalar]

- **dtype**
  
  [If dtype is not specified, the current dtype will be preserved.]

**scipy.sparse.coo_matrix.rad2deg**

coo_matrix.rad2deg(self)

Element-wise rad2deg.

See numpy.rad2deg for more information.
**scipy.sparse.coo_matrix.reshape**

```python
coo_matrix.reshape(self, shape, order='C', copy=False)
```

Gives a new shape to a sparse matrix without changing its data.

**Parameters**

- **shape**: [length-2 tuple of ints] The new shape should be compatible with the original shape.
- **order**: [{'C', 'F'}, optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g. read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g. read entire first column, then second column, etc.
- **copy**: [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- **reshaped_matrix**: [sparse matrix] A sparse matrix with the given `shape`, not necessarily of the same format as the current object.

**See also:**

- `numpy.matrix.reshape`

NumPy’s implementation of ‘reshape’ for matrices

---

**scipy.sparse.coo_matrix.resize**

```python
coo_matrix.resize(self, *shape)
```

Resize the matrix in-place to dimensions given by `shape`

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

**Parameters**

- **shape**: [(int, int)] number of rows and columns in the new matrix

**Notes**

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

---

**scipy.sparse.coo_matrix.rint**

```python
coo_matrix.rint(self)
```

Element-wise rint.

See `numpy.rint` for more information.
scipy.sparse.coo_matrix.set_shape

coo_matrix.set_shape(self, shape)

See reshape.

scipy.sparse.coo_matrix.setdiag

coo_matrix.setdiag(self, values, k=0)

Set diagonal or off-diagonal elements of the array.

Parameters

values [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining
diagonal entries will not be set. If values if longer than the diagonal, then the remaining
values are ignored.
If a scalar value is given, all of the diagonal is set to it.
k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0
(the main diagonal).

scipy.sparse.coo_matrix.sign

coo_matrix.sign(self)

Element-wise sign.
See numpy.sign for more information.

scipy.sparse.coo_matrix.sin

coo_matrix.sin(self)

Element-wise sin.
See numpy.sin for more information.

scipy.sparse.coo_matrix.sinh

coo_matrix.sinh(self)

Element-wise sinh.
See numpy.sinh for more information.

scipy.sparse.coo_matrix.sqrt

coo_matrix.sqrt(self)

Element-wise sqrt.
See numpy.sqrt for more information.
scipy.sparse.coo_matrix.sum

coo_matrix.sum(self, axis=None, dtype=None, out=None)
Sum the matrix elements over a given axis.

Parameters
axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. axis = None).
dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used. New in version 0.18.0.
out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

Returns
sum_along_axis [np.matrix] A matrix with the same shape as self, with the specified axis removed.

See also:
numpy.matrix.sum
NumPy's implementation of 'sum' for matrices

scipy.sparse.coo_matrix.sum_duplicates

coo_matrix.sum_duplicates(self)
Eliminate duplicate matrix entries by adding them together

This is an in place operation

scipy.sparse.coo_matrix.tan

coo_matrix.tan(self)
Element-wise tan.

See numpy.tan for more information.

scipy.sparse.coo_matrix.tanh

coo_matrix.tanh(self)
Element-wise tanh.

See numpy.tanh for more information.
scipy.sparse.coo_matrix.toarray

coo_matrix.toarray(self, order=None, out=None)
See the docstring for spmatrix.toarray.

scipy.sparse.coo_matrix.tobsr

coo_matrix.tobsr(self, blocksize=None, copy=False)
Convert this matrix to Block Sparse Row format.
With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.
When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

scipy.sparse.coo_matrix.tocoo

coo_matrix.tocoo(self, copy=False)
Convert this matrix to COOrdinate format.
With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

scipy.sparse.coo_matrix.tocsc

coo_matrix.tocsc(self, copy=False)
Convert this matrix to Compressed Sparse Column format
Duplicate entries will be summed together.

Examples

```python
>>> from numpy import array
>>> from scipy.sparse import coo_matrix
>>> row = array([0, 0, 1, 3, 1, 0, 0])
>>> col = array([0, 2, 1, 3, 1, 0, 0])
>>> data = array([1, 1, 1, 1, 1, 1, 1])
>>> A = coo_matrix((data, (row, col)), shape=(4, 4)).tocsc()
>>> A.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

scipy.sparse.coo_matrix.tocsr

coo_matrix.tocsr(self, copy=False)
Convert this matrix to Compressed Sparse Row format
Duplicate entries will be summed together.
Examples

```python
>>> from numpy import array
>>> from scipy.sparse import coo_matrix
>>> row = array([0, 0, 1, 3, 1, 0, 0])
>>> col = array([0, 2, 1, 3, 1, 0, 0])
>>> data = array([1, 1, 1, 1, 1, 1, 1])
>>> A = coo_matrix((data, (row, col)), shape=(4, 4)).tocsr()
>>> A.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

`scipy.sparse.coo_matrix.todense`

coo_matrix.todense(self, order=None, out=None)

Return a dense matrix representation of this matrix.

Parameters

- **order** : [‘C’, ‘F’], optional
  Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

- **out** : ndarray, 2-dimensional, optional
  If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

- **arr** : [numpy.matrix, 2-dimensional]
  A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

`scipy.sparse.coo_matrix.todia`

coo_matrix.todia(self, copy=False)

Convert this matrix to sparse DIAgonal format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant dia_matrix.

`scipy.sparse.coo_matrix.todok`

coo_matrix.todok(self, copy=False)

Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant dok_matrix.
**scipy.sparse.coo_matrix.tolil**

```python
coo_matrix.tolil(self, copy=False)
```

Convert this matrix to List Linked Format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

**scipy.sparse.coo_matrix.transpose**

```python
coo_matrix.transpose(self, axes=None, copy=False)
```

Reverses the dimensions of the sparse matrix.

**Parameters**

- **axes** ([None, optional]) This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
- **copy** ([bool, optional]) Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- **p**  
  [self with the dimensions reversed.]

See also:

- `numpy.matrix.transpose`
  NumPy’s implementation of ‘transpose’ for matrices

**scipy.sparse.coo_matrix.trunc**

```python
coo_matrix.trunc(self)
```

Element-wise trunc.

See `numpy.trunc` for more information.

**scipy.sparse.csc_matrix**

```python
class scipy.sparse.csc_matrix(arg1, shape=None, dtype=None, copy=False)
```

Compressed Sparse Column matrix

This can be instantiated in several ways:

- `csc_matrix(D)`  
  with a dense matrix or rank-2 ndarray D
- `csc_matrix(S)`  
  with another sparse matrix S (equivalent to S.tocsc())
- `csc_matrix((M, N), [dtype])`  
  to construct an empty matrix with shape (M, N); dtype is optional, defaulting to dtype='d'.
- `csc_matrix((data, (row_ind, col_ind)), [shape=(M, N)])`  
  where data, row_ind and col_ind satisfy the relationship a[row_ind[k], col_ind[k]] = data[k].
- `csc_matrix((data, indices, indptr), [shape=(M, N)])`  
  is the standard CSC representation where the row indices for column i are stored in indices[indptr[i]:indptr[i+1]] and their corresponding values are stored in
data[indptr[i]:indptr[i+1]]. If the shape parameter is not supplied, the matrix dimensions are inferred from the index arrays.

Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Advantages of the CSC format

- efficient arithmetic operations CSC + CSC, CSC * CSC, etc.
- efficient column slicing
- fast matrix vector products (CSR, BSR may be faster)

Disadvantages of the CSC format

- slow row slicing operations (consider CSR)
- changes to the sparsity structure are expensive (consider LIL or DOK)

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csc_matrix
>>> csc_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)

>>> row = np.array([0, 2, 2, 0, 1, 2])
>>> col = np.array([0, 0, 1, 2, 2, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csc_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 4],
       [0, 0, 5],
       [2, 3, 6]])
```

Attributes

- **dtype** [dtype] Data type of the matrix
- **ndim** [int] Number of dimensions (this is always 2)
- **nnz** Number of stored values, including explicit zeros.

6.22. Sparse matrices (scipy.sparse)
data  Data array of the matrix
indices  CSC format index array
indptr  CSC format index pointer array
has_sorted_indices  Determine whether the matrix has sorted indices

Methods

__len__(self)  interpret other and call one of the following
__mul__(self, other)  Element-wise arcsin.
arcsin(self)  Element-wise arcsinh.
arcsinh(self)  Element-wise arctan.
arctan(self)  Element-wise arctanh.
arctanh(self)  Return indices of maximum elements along an axis.
argmax(self[, axis, out])  Return indices of minimum elements along an axis.
argmin(self[, axis, out])  Return this matrix in the passed format.
astype(self, dtype[, casting, copy])  Cast the matrix elements to a specified type.
astype(self)  Element-wise ceil.
check_format(self[, full_check])  check whether the matrix format is valid
copy(self)  Element-wise complex conjugation.
conjugate(self[, copy])  Element-wise complex conjugation.
copy(self)  Returns a copy of this matrix.
count_nonzero(self)  Number of non-zero entries, equivalent to
deg2rad(self)  Element-wise deg2rad.
diagonal(self[, k])  Returns the k-th diagonal of the matrix.
dot(self, other)  Ordinary dot product
eliminate_zeros(self)  Remove zero entries from the matrix
expm1(self)  Element-wise expm1.
floor(self)  Element-wise floor.
getH(self)  Return the Hermitian transpose of this matrix.
gest_shape(self)  Get shape of a matrix.
getcol(self, i)  Returns a copy of column i of the matrix, as a (m x 1) CSC matrix (column vector).
getformat(self)  Format of a matrix representation as a string.
getmaxprint(self)  Maximum number of elements to display when printed.
getnnz(self[, axis])  Number of stored values, including explicit zeros.
getrow(self, i)  Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).
log1p(self)  Element-wise log1p.
max(self[, axis, out])  Return the maximum of the matrix or maximum along an axis.
maximum(self, other)  Element-wise maximum between this and another matrix.
mean(self[, axis, dtype, out])  Compute the arithmetic mean along the specified axis.
min(self[, axis, out])  Return the minimum of the matrix or maximum along an axis.

```python
scipy.sparse.csc_matrix.__len__

csc_matrix.__len__(self)
```

```python
scipy.sparse.csc_matrix.__mul__

csc_matrix.__mul__(self, other)
```

Interpret other and call one of the following

```python
self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()
```
scipy.sparse.csc_matrix.arcsin

```
csc_matrix.arcsin(self)
   Element-wise arcsin.
   See numpy.arcsin for more information.
```

scipy.sparse.csc_matrix.arcsinh

```
csc_matrix.arcsinh(self)
   Element-wise arcsinh.
   See numpy.arcsinh for more information.
```

scipy.sparse.csc_matrix.arctan

```
csc_matrix.arctan(self)
   Element-wise arctan.
   See numpy.arctan for more information.
```

scipy.sparse.csc_matrix.arctanh

```
csc_matrix.arctanh(self)
   Element-wise arctanh.
   See numpy.arctanh for more information.
```

scipy.sparse.csc_matrix.argmax

```
csc_matrix.argmax(self, axis=None, out=None)
   Return indices of maximum elements along an axis.
   Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

   Parameters
   axis : {-2, -1, 0, 1, None}, optional
      Axis along which the argmax is computed. If None (default), index of the maximum element in the flattened data is returned.

   Returns
   ind : [numpy.matrix or int]
      Indices of maximum elements. If matrix, its size along axis is 1.
```

scipy.sparse.csc_matrix.argmin

```
csc_matrix.argmin(self, axis=None, out=None)
   Return indices of minimum elements along an axis.
   Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

   Parameters
   axis : {-2, -1, 0, 1, None}, optional
      Axis along which the argmin is computed. If None (default), index of the minimum element in the flattened data is returned.

   Returns
   ind : [numpy.matrix or int]
      Indices of minimum elements. If matrix, its size along axis is 1.
```
Parameters

axis  
[-2, -1, 0, 1, None], optional] Axis along which the argmin is computed. If None (default), index of the minimum element in the flattened data is returned.

out  
[None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

ind  
[numpy.matrix or int] Indices of minimum elements. If matrix, its size along axis is 1.

scipy.sparse.csc_matrix.asformat

csc_matrix.asformat(self, format, copy=False)

Return this matrix in the passed format.

Parameters

format  
[[str, None]] The desired matrix format ("csr", "csc", “lil”, “dok”, “array”, ...) or None for no conversion.

copy  
[bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A  
[This matrix in the passed format.]

scipy.sparse.csc_matrix.asfptype

csc_matrix.asfptype(self)

Upcast matrix to a floating point format (if necessary)

scipy.sparse.csc_matrix.astype

csc_matrix.astype(self, dtype, casting='unsafe', copy=True)

Cast the matrix elements to a specified type.

Parameters

dtype  
[string or numpy dtype] Typecode or data-type to which to cast the data.

casting  
[‘no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’], optional] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.

copy  
[bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.

scipy.sparse.csc_matrix.ceil

csc_matrix.ceil(self)

Element-wise ceil.

See numpy.ceil for more information.
scipy.sparse.csc_matrix.check_format

csc_matrix.check_format (self, full_check=True)
check whether the matrix format is valid

Parameters

full_check [bool, optional] If True, rigorous check, O(N) operations. Otherwise basic check, O(1) operations (default True).

scipy.sparse.csc_matrix.conj

csc_matrix.conj (self, copy=True)
Element-wise complex conjugation.
If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.csc_matrix.conjugate

csc_matrix.conjugate (self, copy=True)
Element-wise complex conjugation.
If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.csc_matrix.copy

csc_matrix.copy (self)
Returns a copy of this matrix.
No data/indices will be shared between the returned value and current matrix.

scipy.sparse.csc_matrix.count_nonzero

csc_matrix.count_nonzero (self)
Number of non-zero entries, equivalent to
np.count_nonzero(a.toarray())
Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

**scipy.sparse.csc_matrix.deg2rad**

csc_matrix.deg2rad(self)

Element-wise deg2rad.

See numpy.deg2rad for more information.

**scipy.sparse.csc_matrix.diagonal**

csc_matrix.diagonal(self, k=0)

Returns the k-th diagonal of the matrix.

**Parameters**

- **k**
  
  [int, optional] Which diagonal to set, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).

  New in version 1.0.

**See also:**

- **numpy.diagonal**

  Equivalent numpy function.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

**scipy.sparse.csc_matrix.dot**

csc_matrix.dot(self, other)

Ordinary dot product.

**Examples**

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```
scipy.sparse.csc_matrix.eliminate_zeros

csc_matrix.eliminate_zeros(self)

Remove zero entries from the matrix

This is an in place operation

scipy.sparse.csc_matrix.expm1

csc_matrix.expm1(self)

Element-wise expm1.

See numpy.expm1 for more information.

scipy.sparse.csc_matrix.floor

csc_matrix.floor(self)

Element-wise floor.

See numpy.floor for more information.

scipy.sparse.csc_matrix.getH

csc_matrix.getH(self)

Return the Hermitian transpose of this matrix.

See also:
	numpy.matrix.getH

NumPy's implementation of getH for matrices

scipy.sparse.csc_matrix.get_shape

csc_matrix.get_shape(self)

Get shape of a matrix.

scipy.sparse.csc_matrix.getcol

csc_matrix.getcol(self, i)

Returns a copy of column i of the matrix, as a (m x 1) CSC matrix (column vector).

scipy.sparse.csc_matrix.getformat

csc_matrix.getformat(self)

Format of a matrix representation as a string.
scipy.sparse.csc_matrix.getmaxprint

csc_matrix.getmaxprint(self)
Maximum number of elements to display when printed.

scipy.sparse.csc_matrix.getnnz

csc_matrix.getnnz(self, axis=None)
Number of stored values, including explicit zeros.

Parameters
axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:
count_nonzero
Number of non-zero entries

scipy.sparse.csc_matrix.getrow

csc_matrix.getrow(self, i)
Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).

scipy.sparse.csc_matrix.log1p

csc_matrix.log1p(self)
Element-wise log1p.
See numpy.log1p for more information.

scipy.sparse.csc_matrix.max

csc_matrix.max(self, axis=None, out=None)
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters
axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e. axis = None).
out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns
amax [coo_matrix or scalar] Maximum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:
min

The minimum value of a sparse matrix along a given axis.

numpy.matrix.max

NumPy’s implementation of ‘max’ for matrices

scipy.sparse.csc_matrix.maximum

csc_matrix.maximum(self, other)

Element-wise maximum between this and another matrix.

scipy.sparse.csc_matrix.mean

csc_matrix.mean(self, axis=None, dtype=None, out=None)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters

axis [-2, -1, 0, 1, None] optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. axis = None).

dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype.

New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

New in version 0.18.0.

Returns

m [np.matrix]

See also:

numpy.matrix.mean

NumPy’s implementation of ‘mean’ for matrices

scipy.sparse.csc_matrix.min

csc_matrix.min(self, axis=None, out=None)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters

axis [-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e. axis = None).

out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.
Returns

amin [coo_matrix or scalar] Minimum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

max

The maximum value of a sparse matrix along a given axis.

numpy.matrix.min

NumPy’s implementation of ‘min’ for matrices

scipy.sparse.csc_matrix.minimum
csc_matrix.minimum(self, other)

Element-wise minimum between this and another matrix.

scipy.sparse.csc_matrix.multiply
csc_matrix.multiply(self, other)

Point-wise multiplication by another matrix, vector, or scalar.

scipy.sparse.csc_matrix.nonzero
csc_matrix.nonzero(self)

nonzero indices

Returns a tuple of arrays (row, col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.csc_matrix.power
csc_matrix.power(self, n, dtype=None)

This function performs element-wise power.

Parameters

n [n is a scalar]
dtype [If dtype is not specified, the current dtype will be preserved.]
scipy.sparse.csc_matrix.prune

csc_matrix.prune(self)
Remove empty space after all non-zero elements.

scipy.sparse.csc_matrix.rad2deg

csc_matrix.rad2deg(self)
Element-wise rad2deg.
See numpy.rad2deg for more information.

scipy.sparse.csc_matrix.reshape

csc_matrix.reshape(self, shape, order='C', copy=False)
Gives a new shape to a sparse matrix without changing its data.

Parameters

shape [length-2 tuple of ints] The new shape should be compatible with the original shape.
order [{'C', 'F'}, optional] Read the elements using this index order. ‘C’ means to read and
write the elements using C-like index order; e.g. read entire first row, then second row,
etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g. read
entire first column, then second column, etc.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever
possible. The degree to which attributes are copied varies depending on the type of
sparse matrix being used.

Returns

reshaped_matrix [sparse matrix] A sparse matrix with the given shape, not necessarily of the same
format as the current object.

See also:

numpy.matrix.reshape
NumPy’s implementation of ‘reshape’ for matrices

scipy.sparse.csc_matrix.resize

csc_matrix.resize(self, *shape)
Resize the matrix in-place to dimensions given by shape
Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying
outside the new shape are removed.

Parameters

shape [(int, int)] number of rows and columns in the new matrix
Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

```python
scipy.sparse.csc_matrix.rint

csc_matrix.rint(self)
Element-wise rint.

See numpy.rint for more information.
```

```python
scipy.sparse.csc_matrix.set_shape

csc_matrix.set_shape(self, shape)
See reshape.
```

```python
scipy.sparse.csc_matrix.setdiag

csc_matrix.setdiag(self, values, k=0)
Set diagonal or off-diagonal elements of the array.

Parameters:
- values [array_like] New values of the diagonal elements.
  Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored.
  If a scalar value is given, all of the diagonal is set to it.
- k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).
```

```python
scipy.sparse.csc_matrix.sign

csc_matrix.sign(self)
Element-wise sign.

See numpy.sign for more information.
```

```python
scipy.sparse.csc_matrix.sin

csc_matrix.sin(self)
Element-wise sin.

See numpy.sin for more information.
```
**scipy.sparse.csc_matrix.sinh**

csc_matrix.sinh(self)

Element-wise sinh.

See numpy.sinh for more information.

**scipy.sparse.csc_matrix.sort_indices**

csc_matrix.sort_indices(self)

Sort the indices of this matrix in place

**scipy.sparse.csc_matrix.sorted_indices**

csc_matrix.sorted_indices(self)

Return a copy of this matrix with sorted indices

**scipy.sparse.csc_matrix.sqrt**

csc_matrix.sqrt(self)

Element-wise sqrt.

See numpy.sqrt for more information.

**scipy.sparse.csc_matrix.sum**

csc_matrix.sum(self, axis=None, dtype=None, out=None)

Sum the matrix elements over a given axis.

*Parameters*

axis  
[: -2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. `axis=None`).

dtype  
[dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of `a` is used by default unless `a` has an integer dtype of less precision than the default platform integer. In that case, if `a` is signed then the platform integer is used while if `a` is unsigned then an unsigned integer of the same precision as the platform integer is used. New in version 0.18.0.

out  
[np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

*Returns*

sum_along_axis  
[np.matrix] A matrix with the same shape as `self`, with the specified axis removed.

See also:

*numpy.matrix.sum*

NumPy's implementation of 'sum' for matrices
**scipy.sparse.csc_matrix.sum_duplicates**

csc_matrix.sum_duplicates(self)
   Eliminate duplicate matrix entries by adding them together
   The is an in place operation

**scipy.sparse.csc_matrix.tan**

csc_matrix.tan(self)
   Element-wise tan.
   See numpy.tan for more information.

**scipy.sparse.csc_matrix.tanh**

csc_matrix.tanh(self)
   Element-wise tanh.
   See numpy.tanh for more information.

**scipy.sparse.csc_matrix.toarray**

csc_matrix.toarray(self, order=None, out=None)
   Return a dense ndarray representation of this matrix.
   
   **Parameters**
   
   order : [{‘C’, ‘F’}, optional]
      Whether to store multi-dimensional data in C (row-major) or For-
      tran (column-major) order in memory. The default is ‘None’, indicating the NumPy
      default of C-ordered. Cannot be specified in conjunction with the out argument.
   
   out : [ndarray, 2-dimensional, optional]
      If specified, uses this array as the output buffer instead of allocating a new array to return.
      The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.
      For most sparse types, out is required to be memory contiguous (either C or Fortran ordered).
   
   **Returns**
   
   arr : [ndarray, 2-dimensional]
      An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order.
      If out was passed, the same object is returned after being modified in-place to contain the appropriate values.

**scipy.sparse.csc_matrix.tobsr**

csc_matrix.tobsr(self, blocksize=None, copy=False)
   Convert this matrix to Block Sparse Row format.
   
   With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.
   
   When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.
scipy.sparse.csc_matrix.tocoo

csc_matrix.tocoo(self, copy=True)
Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

scipy.sparse.csc_matrix.tocsc

csc_matrix.tocsc(self, copy=False)
Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.csc_matrix.tocsr

csc_matrix.tocsr(self, copy=False)
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.csc_matrix.todense

csc_matrix.todense(self, order=None, out=None)
Return a dense matrix representation of this matrix.

Parameters

- order [{'C', 'F'}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.
- out [ndarray, 2-dimensional, optional] If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

- arr [numpy.matrix, 2-dimensional] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

scipy.sparse.csc_matrix.todia

csc_matrix.todia(self, copy=False)
Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.
**scipy.sparse.csc_matrix.todok**

```python
csc_matrix.todok(self, copy=False)
```
Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

**scipy.sparse.csc_matrix.tolil**

```python
csc_matrix.tolil(self, copy=False)
```
Convert this matrix to Linked List format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

**scipy.sparse.csc_matrix.transpose**

```python
csc_matrix.transpose(self, axes=None, copy=False)
```
Reverses the dimensions of the sparse matrix.

**Parameters**

- **axes**
  
  [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.

- **copy**
  
  [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- **p**
  
  [self with the dimensions reversed.]

**See also:**

- `numpy.matrix.transpose`
  
  NumPy’s implementation of ‘transpose’ for matrices

**scipy.sparse.csc_matrix.trunc**

```python
csc_matrix.trunc(self)
```
Element-wise trunc.

See `numpy.trunc` for more information.

**scipy.sparse.csr_matrix**

```python
class scipy.sparse.csr_matrix(arg1, shape=None, dtype=None, copy=False)
```
Compressed Sparse Row matrix

This can be instantiated in several ways:

- `csr_matrix(D)`
  
  with a dense matrix or rank-2 ndarray D
csr_matrix(S)
with another sparse matrix S (equivalent to S.tocsr())

csr_matrix((M, N), [dtype])
to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

csr_matrix((data, (row_ind, col_ind)), [shape=(M, N)])
where data, row_ind and col_ind satisfy the relationship a[row_ind[k],
col_ind[k]] = data[k].

csr_matrix((data, indices, indptr), [shape=(M, N)])
is the standard CSR representation where the column indices for row i are stored in
indices[indptr[i]:indptr[i+1]] and their corresponding values are stored in
data[indptr[i]:indptr[i+1]]. If the shape parameter is not supplied, the matrix di-
mensions are inferred from the index arrays.

Notes
Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Advantages of the CSR format

• efficient arithmetic operations CSR + CSR, CSR * CSR, etc.
• efficient row slicing
• fast matrix vector products

Disadvantages of the CSR format

• slow column slicing operations (consider CSC)
• changes to the sparsity structure are expensive (consider LIL or DOK)

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> csr_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```python
>>> row = np.array([0, 0, 1, 2, 2, 2])
>>> col = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csr_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])
```
```python
>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csr_matrix((data, indices, indptr), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])
```

As an example of how to construct a CSR matrix incrementally, the following snippet builds a term-document matrix from texts:

```python
>>> docs = [['hello', 'world', 'hello'], ['goodbye', 'cruel', 'world']]
>>> indptr = [0]
>>> indices = []
>>> data = []
>>> vocabulary = {}
>>> for d in docs:
...     for term in d:
...         index = vocabulary.setdefault(term, len(vocabulary))
...         indices.append(index)
...         data.append(1)
...         indptr.append(len(indices))
...
>>> csr_matrix((data, indices, indptr), dtype=int).toarray()
array([[2, 1, 0, 0],
       [0, 1, 1, 1]])
```

**Attributes**

- `dtype` [dtype] Data type of the matrix
- `ndim` [int] Number of dimensions (this is always 2)
- `nnz` Number of stored values, including explicit zeros.
- `data` CSR format data array of the matrix
- `indices` CSR format index array of the matrix
- `indptr` CSR format index pointer array of the matrix
- `has_sorted_indices` Determine whether the matrix has sorted indices

**Methods**

- `__len__`(self) interpret other and call one of the following
- `__mul__`(self, other) Element-wise arcsin.
- `arcsin`(self) Element-wise arcsinh.
- `arccos`(self) Element-wise arccos.
- `arctan`(self) Element-wise arctan.
- `asformat`(self, format[, copy]) Return this matrix in the passed format.
- `asfptype`(self) Upcast matrix to a floating point format (if necessary)

**scipy.sparse.csr_matrix.__len__**

```python
scipy.sparse.csr_matrix.__len__(self)
```

**scipy.sparse.csr_matrix.__mul__**

```python
scipy.sparse.csr_matrix.__mul__(self, other)

interpret other and call one of the following

- self._mul_scalar()
- self._mul_vector()
- self._mul_multivector()
- self._mul_sparse_matrix()
```

**scipy.sparse.csr_matrix.arcsin**

```python
scipy.sparse.csr_matrix.arcsin(self)

Element-wise arcsin.

See numpy.arcsin for more information.
```

**scipy.sparse.csr_matrix.arcsinh**

```python
scipy.sparse.csr_matrix.arcsinh(self)

Element-wise arcsinh.

See numpy.arcsinh for more information.
```

**scipy.sparse.csr_matrix.arctan**

```python
scipy.sparse.csr_matrix.arctan(self)

Element-wise arctan.
```
See numpy.arctan for more information.

**scipy.sparse.csr_matrix.arctanh**

csr_matrix.

```
    arctanh(self)
```

Element-wise arctanh.

See numpy.arctanh for more information.

**scipy.sparse.csr_matrix.argmax**

csr_matrix.

```
    argmax(self, axis=None, out=None)
```

Return indices of maximum elements along an axis.

Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

**Parameters**

- **axis**  
  [-2, -1, 0, 1, None], optional] Axis along which the argmax is computed. If None (default), index of the maximum element in the flattened data is returned.

- **out**  
  [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- **ind**  
  [numpy.matrix or int] Indices of maximum elements. If matrix, its size along axis is 1.

**scipy.sparse.csr_matrix.argmin**

csr_matrix.

```
    argmin(self, axis=None, out=None)
```

Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters**

- **axis**  
  [-2, -1, 0, 1, None], optional] Axis along which the argmin is computed. If None (default), index of the minimum element in the flattened data is returned.

- **out**  
  [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- **ind**  
  [numpy.matrix or int] Indices of minimum elements. If matrix, its size along axis is 1.

**scipy.sparse.csr_matrix.asformat**

csr_matrix.

```
    asformat(self, format, copy=False)
```

Return this matrix in the passed format.

**Parameters**

- **format**  
  [str, None] The desired format matrix ("csr", “csc”, “lil”, “dok”, “array”, …) or None for no conversion.
copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [This matrix in the passed format.]

**scipy.sparse.csr_matrix.asfptype**

`csr_matrix.asfptype(self)`

Upcast matrix to a floating point format (if necessary)

**scipy.sparse.csr_matrix.astype**

`csr_matrix.astype(self, dtype, casting='unsafe', copy=True)`

Cast the matrix elements to a specified type.

Parameters

- **dtype** [string or numpy dtype] Typecode or data-type to which to cast the data.
- **casting** [['no', 'equiv', 'safe', 'same_kind', 'unsafe'], optional] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
- **copy** [bool, optional] If `copy` is False, the result might share some memory with this matrix. If `copy` is True, it is guaranteed that the result and this matrix do not share any memory.

**scipy.sparse.csr_matrix.ceil**

`csr_matrix.ceil(self)`

Element-wise ceiling.

See numpy.ceil for more information.

**scipy.sparse.csr_matrix.check_format**

`csr_matrix.check_format(self, full_check=True)`

Check whether the matrix format is valid.

Parameters

- **full_check** [bool, optional] If True, rigorous check, O(N) operations. Otherwise basic check, O(1) operations (default True).

**scipy.sparse.csr_matrix.conj**

`csr_matrix.conj(self, copy=True)`

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.
Parameters
copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns
A [The element-wise complex conjugate.]

scipy.sparse.csr_matrix.conjugate
csr_matrix.conjugate(self, copy=True)
Element-wise complex conjugation.
If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters
copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns
A [The element-wise complex conjugate.]

scipy.sparse.csr_matrix.copy
csr_matrix.copy(self)
Returns a copy of this matrix.
No data/indices will be shared between the returned value and current matrix.

scipy.sparse.csr_matrix.count_nonzero
csr_matrix.count_nonzero(self)
Number of non-zero entries, equivalent to
np.count_nonzero(a.toarray())
Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.csr_matrix.deg2rad
csr_matrix.deg2rad(self)
Element-wise deg2rad.
See numpy.deg2rad for more information.

scipy.sparse.csr_matrix.diagonal
csr_matrix.diagonal(self, k=0)
Returns the k-th diagonal of the matrix.

Parameters
k [int, optional] Which diagonal to set, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
New in version 1.0.

See also:

numpy.diagonal
Equivalent numpy function.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

scipy.sparse.csr_matrix.dot

csr_matrix.dot(self, other)
Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([1, -3, -1], dtype=int64)
```

scipy.sparse.csr_matrix.eliminate_zeros

csr_matrix.eliminate_zeros(self)
Remove zero entries from the matrix
This is an in place operation

scipy.sparse.csr_matrix.expm1

csr_matrix.expm1(self)
Element-wise expm1.
See numpy.expm1 for more information.
**scipy.sparse.csr_matrix.floor**

csr_matrix.floor(self)
Element-wise floor.

See numpy.floor for more information.

**scipy.sparse.csr_matrix.getH**

csr_matrix.getH(self)
Return the Hermitian transpose of this matrix.

See also:

numpy.matrix.getH
NumPy’s implementation of $\text{getH}$ for matrices

**scipy.sparse.csr_matrix.get_shape**

csr_matrix.get_shape(self)
Get shape of a matrix.

**scipy.sparse.csr_matrix.getcol**

csr_matrix.getcol(self, i)
Returns a copy of column $i$ of the matrix, as a $(m \times 1)$ CSR matrix (column vector).

**scipy.sparse.csr_matrix.getformat**

csr_matrix.getformat(self)
Format of a matrix representation as a string.

**scipy.sparse.csr_matrix.getmaxprint**

csr_matrix.getmaxprint(self)
Maximum number of elements to display when printed.

**scipy.sparse.csr_matrix.getnnz**

csr_matrix.getnnz(self, axis=None)
Number of stored values, including explicit zeros.

Parameters
axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:
count_nonzero
Number of non-zero entries

scipy.sparse.csr_matrix.getrow

csr_matrix.getrow(self, i)
Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).

scipy.sparse.csr_matrix.log1p

csr_matrix.log1p(self)
Element-wise log1p.
See numpy.log1p for more information.

scipy.sparse.csr_matrix.max

csr_matrix.max(self, axis=None, out=None)
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters
axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e. axis = None).
out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns
amax [coo_matrix or scalar] Maximum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

min
The minimum value of a sparse matrix along a given axis.

numpy.matrix.max
NumPy's implementation of 'max' for matrices

scipy.sparse.csr_matrix.maximum

csr_matrix.maximum(self, other)
Element-wise maximum between this and another matrix.
scipy.sparse.csr_matrix.mean

csr_matrix.mean(self, axis=None, dtype=None, out=None)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters

- **axis** ([{-2, -1, 0, 1, None} optional]) Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. axis = None).
- **dtype** ([data-type, optional]) Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype. New in version 0.18.0.
- **out** ([np.matrix, optional]) Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

Returns

- **m** [np.matrix]

See also:

- **numpy.matrix.mean**
  NumPy's implementation of ‘mean’ for matrices

scipy.sparse.csr_matrix.min

csr_matrix.min(self, axis=None, out=None)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters

- **axis** ([{-2, -1, 0, 1, None} optional]) Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e. axis = None).
- **out** [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

- **amin** [coo_matrix or scalar] Minimum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

- **max**
  The maximum value of a sparse matrix along a given axis.

- **numpy.matrix.min**
  NumPy's implementation of ‘min’ for matrices
**scipy.sparse.csr_matrix.minimum**

```
csr_matrix.minimum(self, other)
```

Element-wise minimum between this and another matrix.

**scipy.sparse.csr_matrix.multiply**

```
csr_matrix.multiply(self, other)
```

Point-wise multiplication by another matrix, vector, or scalar.

**scipy.sparse.csr_matrix.nonzero**

```
csr_matrix.nonzero(self)
```

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

**scipy.sparse.csr_matrix.power**

```
csr_matrix.power(self, n, dtype=None)
```

This function performs element-wise power.

**Parameters**

- **n** : [n is a scalar]
- **dtype** : [If dtype is not specified, the current dtype will be preserved.]

**scipy.sparse.csr_matrix.prune**

```
csr_matrix.prune(self)
```

Remove empty space after all non-zero elements.

**scipy.sparse.csr_matrix.rad2deg**

```
csr_matrix.rad2deg(self)
```

Element-wise rad2deg.

See numpy.rad2deg for more information.
**scipy.sparse.csr_matrix.reshape**

```python
csr_matrix.reshape(self, shape, order='C', copy=False)
```

Gives a new shape to a sparse matrix without changing its data.

**Parameters**

- `shape` [length-2 tuple of ints] The new shape should be compatible with the original shape.
- `order` [{'C', 'F'}, optional] Read the elements using this index order. 'C' means to read and write the elements using C-like index order; e.g. read entire first row, then second row, etc. 'F' means to read and write the elements using Fortran-like index order; e.g. read entire first column, then second column, etc.
- `copy` [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- `reshaped_matrix` [sparse matrix] A sparse matrix with the given `shape`, not necessarily of the same format as the current object.

**See also:**

- `numpy.matrix.reshape`
  NumPy's implementation of 'reshape' for matrices

**scipy.sparse.csr_matrix.resize**

```python
csr_matrix.resize(self, *shape)
```

Resizes the matrix in-place to dimensions given by `shape`.

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

**Parameters**

- `shape` [(int, int)] number of rows and columns in the new matrix

**Notes**

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

**scipy.sparse.csr_matrix.rint**

```python
csr_matrix.rint(self)
```

Element-wise rint.

See `numpy.rint` for more information.
**scipy.sparse.csr_matrix.set_shape**

csr_matrix.set_shape (self, shape)

See reshape.

**scipy.sparse.csr_matrix.setdiag**

csr_matrix.setdiag (self, values, k=0)

Set diagonal or off-diagonal elements of the array.

**Parameters**

values [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored.
If a scalar value is given, all of the diagonal is set to it.

k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

**scipy.sparse.csr_matrix.sign**

csr_matrix.sign (self)

Element-wise sign.

See numpy.sign for more information.

**scipy.sparse.csr_matrix.sin**

csr_matrix.sin (self)

Element-wise sin.

See numpy.sin for more information.

**scipy.sparse.csr_matrix.sinh**

csr_matrix.sinh (self)

Element-wise sinh.

See numpy.sinh for more information.

**scipy.sparse.csr_matrix.sort_indices**

csr_matrix.sort_indices (self)

Sort the indices of this matrix in place

**scipy.sparse.csr_matrix.sorted_indices**

csr_matrix.sorted_indices (self)

Return a copy of this matrix with sorted indices
scipy.sparse.csr_matrix.sqrt

csr_matrix.sqrt(self)
   Element-wise sqrt.
   See numpy.sqrt for more information.

scipy.sparse.csr_matrix.sum

csr_matrix.sum(self, axis=None, dtype=None, out=None)
   Sum the matrix elements over a given axis.

   Parameters
   axis [[-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. axis = None).
   dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used. New in version 0.18.0.
   out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

   Returns
   sum_along_axis [np.matrix] A matrix with the same shape as self, with the specified axis removed.

   See also:

   numpy.matrix.sum
   NumPy's implementation of ‘sum’ for matrices

scipy.sparse.csr_matrix.sum_duplicates

csr_matrix.sum_duplicates(self)
   Eliminate duplicate matrix entries by adding them together
   The is an in place operation

scipy.sparse.csr_matrix.tan

csr_matrix.tan(self)
   Element-wise tan.
   See numpy.tan for more information.
**scipy.sparse.csr_matrix.tanh**

csr_matrix.tanh(self)

Element-wise tanh.

See numpy.tanh for more information.

**scipy.sparse.csr_matrix.toarray**

csr_matrix.toarray(self, order=None, out=None)

Return a dense ndarray representation of this matrix.

**Parameters**

order : [‘C’, ‘F’], optional
    Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

out : ndarray, 2-dimensional, optional
    If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, `out` is required to be memory contiguous (either C or Fortran ordered).

**Returns**

arr : ndarray, 2-dimensional
    An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed, the same object is returned after being modified in-place to contain the appropriate values.

**scipy.sparse.csr_matrix.tobsr**

csr_matrix.tobsr(self, blocksize=None, copy=True)

Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

**scipy.sparse.csr_matrix.tocoo**

csr_matrix.tocoo(self, copy=True)

Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

**scipy.sparse.csr_matrix.tocsc**

csr_matrix.tocsc(self, copy=False)

Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.
scipy.sparse.csr_matrix.tocsr

csr_matrix.tocsr (self, copy=False)

Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.csr_matrix.todense

csr_matrix.todense (self, order=None, out=None)

Return a dense matrix representation of this matrix.

Parameters

- order: [{'C', 'F'}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.
- out: [ndarray, 2-dimensional, optional] If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

- arr: [numpy.matrix, 2-dimensional] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

scipy.sparse.csr_matrix.todia

csr_matrix.todia (self, copy=False)

Convert this matrix to sparse DIAGONal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.csr_matrix.todok

csr_matrix.todok (self, copy=False)

Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.csr_matrix.tolil

csr_matrix.tolil (self, copy=False)

Convert this matrix to Linked List format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.
scipy.sparse.csr_matrix.transpose

csr_matrix.transpose(self, axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.

copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [self with the dimensions reversed.]

See also:

numpy.matrix.transpose

NumPy's implementation of 'transpose' for matrices

scipy.sparse.csr_matrix.trunc

csr_matrix.trunc(self)
Element-wise trunc.

See numpy.trunc for more information.

__getitem__

scipy.sparse.dia_matrix

class scipy.sparse.dia_matrix(arg1, shape=None, dtype=None, copy=False)
Sparse matrix with DIAgonal storage

This can be instantiated in several ways:

dia_matrix(D)
with a dense matrix
dia_matrix(S)
with another sparse matrix S (equivalent to S.todia())
dia_matrix((M, N), [dtype])
to construct an empty matrix with shape (M, N), dtype is optional, defaulting to dtype='d'.
dia_matrix((data, offsets), shape=(M, N))
where the data[k, :) stores the diagonal entries for diagonal offsets[k] (See example below)
Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import dia_matrix
>>> dia_matrix((3, 4), dtype=np.int8).toarray()
dtype=int8)
array([[0, 0, 0, 0],
      [0, 0, 0, 0],
      [0, 0, 0, 0]], dtype=int8)
```

```python
>>> data = np.array([[1, 2, 3, 4]]).repeat(3, axis=0)
>>> offsets = np.array([0, -1, 2])
>>> dia_matrix((data, offsets), shape=(4, 4)).toarray()
array([[1, 0, 3, 0],
      [1, 2, 0, 4],
      [0, 2, 3, 0],
      [0, 0, 3, 4]])
```

Attributes

- **dtype** [dtype] Data type of the matrix
- **ndim** [int] Number of dimensions (this is always 2)
- **nnz** Number of stored values, including explicit zeros.
- **data** DIA format data array of the matrix
- **offsets** DIA format offset array of the matrix

Methods

- **__len__(self)**
- **__mul__(self, other)** interpret other and call one of the following
- **arcsin(self)** Element-wise arcsin.
- **arcsinh(self)** Element-wise arcsinh.
- **arctan(self)** Element-wise arctan.
- **arctanh(self)** Element-wise arctanh.
- **asformat(self, format[, copy])** Return this matrix in the passed format.
- **astype(self, dtype[, casting, copy])** Cast the matrix elements to a specified type.
- **ceil(self)** Element-wise ceil.
- **conj(self[, copy])** Element-wise complex conjugation.
- **conjugate(self[, copy])** Element-wise complex conjugation.
- **copy(self)** Returns a copy of this matrix.
- **count_nonzero(self)** Number of non-zero entries, equivalent to
- **deg2rad(self)** Element-wise deg2rad.
- **diagonal(self[, k])** Returns the k-th diagonal of the matrix.

</table>
`scipy.sparse.dia_matrix.__len__`

dia_matrix.__len__(self)

`scipy.sparse.dia_matrix.__mul__`

dia_matrix.__mul__(self, other)

interpret other and call one of the following

self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()

`scipy.sparse.dia_matrix.arcsin`

dia_matrix.arcsin(self)

Element-wise arcsin.

See numpy.arcsin for more information.

`scipy.sparse.dia_matrix.arcsinh`

dia_matrix.arcsinh(self)

Element-wise arcsinh.

See numpy.arcsinh for more information.

`scipy.sparse.dia_matrix.arctan`

dia_matrix.arctan(self)

Element-wise arctan.

See numpy.arctan for more information.

`scipy.sparse.dia_matrix.arctanh`

dia_matrix.arctanh(self)

Element-wise arctanh.

See numpy.arctanh for more information.

`scipy.sparse.dia_matrix.asformat`

dia_matrix.asformat(self, format, copy=False)

Return this matrix in the passed format.

Parameters

- **format** ([str, None]) The desired matrix format (“csr”, “csc”, “lil”, “dok”, “array”, ...) or None for no conversion.

- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

Returns
A [This matrix in the passed format.]

**scipy.sparse.dia_matrix.asfptype**

dia_matrix.asfptype(self)

Upcast matrix to a floating point format (if necessary)

**scipy.sparse.dia_matrix.astype**

dia_matrix.astype(self, dtype, casting='unsafe', copy=True)

Cast the matrix elements to a specified type.

*Parameters*

dtype [string or numpy dtype] Typecode or data-type to which to cast the data.
casting [{‘no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’}, optional] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
copy [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.

**scipy.sparse.dia_matrix.ceil**

dia_matrix.ceil(self)

Element-wise ceil.

See numpy.ceil for more information.

**scipy.sparse.dia_matrix.conj**

dia_matrix.conj(self, copy=True)

Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

*Parameters*

copy [bool, optional] If True, the result is guaranteed to not share data with self.

*Returns*

A [The element-wise complex conjugate.]

**scipy.sparse.dia_matrix.conjugate**

dia_matrix.conjugate(self, copy=True)

Element-wise complex conjugation.
If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- `copy` [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- `A` [The element-wise complex conjugate.]

### scipy.sparse.dia_matrix.copy

**dia_matrix.copy(self)**

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

### scipy.sparse.dia_matrix.count_nonzero

**dia_matrix.count_nonzero(self)**

Number of non-zero entries, equivalent to `np.count_nonzero(a.toarray())`

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

### scipy.sparse.dia_matrix.deg2rad

**dia_matrix.deg2rad(self)**

Element-wise deg2rad.

See `numpy.deg2rad` for more information.

### scipy.sparse.dia_matrix.diagonal

**dia_matrix.diagonal(self, k=0)**

Returns the k-th diagonal of the matrix.

**Parameters**

- `k` [int, optional] Which diagonal to set, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).

New in version 1.0.

**See also:**

- `numpy.diagonal`

Equivalent numpy function.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

**scipy.sparse.dia_matrix.dot**

dia_matrix.dot(self, other)

Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

**scipy.sparse.dia_matrix.expm1**

dia_matrix.expm1(self)

Element-wise expm1.

See numpy.expm1 for more information.

**scipy.sparse.dia_matrix.floor**

dia_matrix.floor(self)

Element-wise floor.

See numpy.floor for more information.

**scipy.sparse.dia_matrix.getH**

dia_matrix.getH(self)

Return the Hermitian transpose of this matrix.

See also:

numpy.matrix.getH

NumPy's implementation of getH for matrices
scipy.sparse.dia_matrix.get_shape

dia_matrix.get_shape(self)
    Get shape of a matrix.

scipy.sparse.dia_matrix.getcol

dia_matrix.getcol(self, j)
    Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.dia_matrix.getformat

dia_matrix.getformat(self)
    Format of a matrix representation as a string.

scipy.sparse.dia_matrix.getmaxprint

dia_matrix.getmaxprint(self)
    Maximum number of elements to display when printed.

scipy.sparse.dia_matrix.getnnz

dia_matrix.getnnz(self, axis=None)
    Number of stored values, including explicit zeros.

    Parameters
    axis
        [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

    See also:

    count_nonzero
        Number of non-zero entries

scipy.sparse.dia_matrix.getrow

dia_matrix.getrow(self, i)
    Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

scipy.sparse.dia_matrix.log1p

dia_matrix.log1p(self)
    Element-wise log1p.

    See numpy.log1p for more information.
scipy.sparse.dia_matrix.maximum

dia_matrix.maximum(self, other)
Element-wise maximum between this and another matrix.

scipy.sparse.dia_matrix.mean

dia_matrix.mean(self, axis=None, dtype=None, out=None)
Compute the arithmetic mean along the specified axis.
Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters

axis \([-2,-1,0,1,None\) optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. \(axis = None\)).
dtype \([\text{data-type, optional}]\) Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype.
out \([\text{np.matrix, optional}]\) Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

Returns

\(m\) \([\text{np.matrix}]\)

See also:

numpy.matrix.mean
NumPy's implementation of 'mean' for matrices

scipy.sparse.dia_matrix.minimum

dia_matrix.minimum(self, other)
Element-wise minimum between this and another matrix.

scipy.sparse.dia_matrix.multiply

dia_matrix.multiply(self, other)
Point-wise multiplication by another matrix

scipy.sparse.dia_matrix.nonzero

dia_matrix.nonzero(self)
nonzero indices
Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

**scipy.sparse.dia_matrix.power**

dia_matrix.power(self, n, dtype=None)

This function performs element-wise power.

**Parameters**

- **n** [n is a scalar]
- **dtype** [If dtype is not specified, the current dtype will be preserved.]

**scipy.sparse.dia_matrix.rad2deg**

dia_matrix.rad2deg(self)

Element-wise rad2deg.

See numpy.rad2deg for more information.

**scipy.sparse.dia_matrix.reshape**

dia_matrix.reshape(self, shape, order='C', copy=False)

Gives a new shape to a sparse matrix without changing its data.

**Parameters**

- **shape** [length-2 tuple of ints] The new shape should be compatible with the original shape.
- **order** [‘C’, ‘F’], optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g. read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g. read entire first column, then second column, etc.
- **copy** [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- **reshaped_matrix** [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

- **numpy.matrix.reshape**

NumPy’s implementation of ‘reshape’ for matrices
scipy.sparse.dia_matrix.resize

dia_matrix.resize(self, *shape)
    Resize the matrix in-place to dimensions given by shape
    Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying
    outside the new shape are removed.
    Parameters
    shape [(int, int)] number of rows and columns in the new matrix

Notes
    The semantics are not identical to numpy.ndarray.resize or numpy.resize. Here, the same data
    will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.
    We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

scipy.sparse.dia_matrix.rint

dia_matrix.rint(self)
    Element-wise rint.
    See numpy.rint for more information.

scipy.sparse.dia_matrix.set_shape

dia_matrix.set_shape(self, shape)
    See reshape.

scipy.sparse.dia_matrix.setdiag

dia_matrix.setdiag(self, values, k=0)
    Set diagonal or off-diagonal elements of the array.
    Parameters
    values [array_like] New values of the diagonal elements.
    Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored.
    If a scalar value is given, all of the diagonal is set to it.
    k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).
scipy.sparse.dia_matrix.sign

dia_matrix.sign(self)

Element-wise sign.
See numpy.sign for more information.

scipy.sparse.dia_matrix.sin

dia_matrix.sin(self)

Element-wise sin.
See numpy.sin for more information.

scipy.sparse.dia_matrix.sinh

dia_matrix.sinh(self)

Element-wise sinh.
See numpy.sinh for more information.

scipy.sparse.dia_matrix.sqrt

dia_matrix.sqrt(self)

Element-wise sqrt.
See numpy.sqrt for more information.

scipy.sparse.dia_matrix.sum

dia_matrix.sum(self, axis=None, dtype=None, out=None)

Sum the matrix elements over a given axis.

Parameters

axis

[-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. axis = None).

dtype

[dttype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used.

New in version 0.18.0.

out

[np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

New in version 0.18.0.

Returns

sum_along_axis

[np.matrix] A matrix with the same shape as self, with the specified axis removed.

See also:
**numpy.matrix.sum**

NumPy's implementation of 'sum' for matrices

**scipy.sparse.dia_matrix.tan**

dia_matrix.tan(self)

Element-wise tan.

See numpy.tan for more information.

**scipy.sparse.dia_matrix.tanh**

dia_matrix.tanh(self)

Element-wise tanh.

See numpy.tanh for more information.

**scipy.sparse.dia_matrix.toarray**

dia_matrix.toarray(self, order=None, out=None)

Return a dense ndarray representation of this matrix.

*Parameters*

order [{'C', 'F'}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.

out [ndarray, 2-dimensional, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, out is required to be memory contiguous (either C or Fortran ordered).

*Returns*

arr [ndarray, 2-dimensional] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed, the same object is returned after being modified in-place to contain the appropriate values.

**scipy.sparse.dia_matrix.tobsr**

dia_matrix.tobsr(self, blocksize=None, copy=False)

Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.
scipy.sparse.dia_matrix.tocoo

dia_matrix.tocoo(self, copy=False)
Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

scipy.sparse.dia_matrix.tocsc

dia_matrix.tocsc(self, copy=False)
Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.dia_matrix.tocsr

dia_matrix.tocsr(self, copy=False)
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.dia_matrix.todense

dia_matrix.todense(self, order=None, out=None)
Return a dense matrix representation of this matrix.

Parameters

- order [{‘C’, ‘F’}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.

- out [ndarray, 2-dimensional, optional] If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

- arr [numpy.matrix, 2-dimensional] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

scipy.sparse.dia_matrix.todia

dia_matrix.todia(self, copy=False)
Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.
scipy.sparse.dia_matrix.todok

dia_matrix.todok(self, copy=False)
    Convert this matrix to Dictionary Of Keys format.
    With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.dia_matrix.tolil

dia_matrix.tolil(self, copy=False)
    Convert this matrix to LInked List format.
    With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.dia_matrix.transpose

dia_matrix.transpose(self, axes=None, copy=False)
    Reverses the dimensions of the sparse matrix.

    Parameters
    axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
    copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

    Returns
    p [self with the dimensions reversed.]

    See also:
    
    numpy.matrix.transpose
    NumPy’s implementation of ‘transpose’ for matrices

scipy.sparse.dia_matrix.trunc

dia_matrix.trunc(self)
    Element-wise trunc.
    See numpy.trunc for more information.

scipy.sparse.dok_matrix

class scipy.sparse.dok_matrix(arg1, shape=None, dtype=None, copy=False)
    Dictionary Of Keys based sparse matrix.
    This is an efficient structure for constructing sparse matrices incrementally.
    This can be instantiated in several ways:

    dok_matrix(D)
        with a dense matrix, D
dok_matrix(S)

with a sparse matrix, S

dok_matrix((M,N), [dtype])

create the matrix with initial shape (M,N) dtype is optional, defaulting to dtype='d'

**Notes**

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Allows for efficient O(1) access of individual elements. Duplicates are not allowed. Can be efficiently converted to a coo_matrix once constructed.

**Examples**

```python
>>> import numpy as np
>>> from scipy.sparse import dok_matrix
>>> S = dok_matrix((5, 5), dtype=np.float32)
>>> for i in range(5):
...     for j in range(5):
...         S[i, j] = i + j  # Update element
```

**Attributes**

- **dtype** [dtype] Data type of the matrix
- **ndim** [int] Number of dimensions (this is always 2)
- **nnz** Number of stored values, including explicit zeros.

**Methods**

- `__len__`(self) Return len(self).
- `__mul__`(self, other) interpret other and call one of the following
- `asformat`(self, format[, copy]) Return this matrix in the passed format.
- `astype`(self, dtype[, casting, copy]) Cast the matrix elements to a specified type.
- `clear`()  
- `conj`(self[, copy]) Element-wise complex conjugation.
- `conjtrans`(self) Return the conjugate transpose.
- `conjugate`(self[, copy]) Element-wise complex conjugation.
- `copy`(self) Returns a copy of this matrix.
- `count_nonzero`(self) Number of non-zero entries, equivalent to
- `diagonal`(self[, k]) Returns the k-th diagonal of the matrix.
- `dot`(self, other) Ordinary dot product
- `fromkeys`(iterable[, value]) Returns a new dict with keys from iterable and values equal to value.
- `get`(self, key[, default]) This overrides the dict.get method, providing type checking but otherwise equivalent functionality.

</tbody>
</table>
scipy.sparse.dok_matrix.__len__

dok_matrix.__len__(self)

Return len(self).

scipy.sparse.dok_matrix.__mul__

dok_matrix.__mul__(self, other)

interpret other and call one of the following
self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()

scipy.sparse.dok_matrix.asformat

dok_matrix.asformat (self, format, copy=False)

Return this matrix in the passed format.

Parameters

format [str, None] The desired matrix format ("csr", "csc", "lil", "dok", "array", ...) or None for no conversion.
copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [This matrix in the passed format.]

scipy.sparse.dok_matrix.asfptype

dok_matrix.asfptype (self)

Upcast matrix to a floating point format (if necessary)

scipy.sparse.dok_matrix.astype

dok_matrix.astype (self, dtype, casting='unsafe', copy=True)

Cast the matrix elements to a specified type.

Parameters

dtype [string or numpy dtype] Typecode or data-type to which to cast the data.
casting [{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same_kind' means only casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.
copy [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.

scipy.sparse.dok_matrix.clear

dok_matrix.clear()
scipy.sparse.dok_matrix.conj

dok_matrix.conj(self, copy=True)

Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters

- copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

- A [The element-wise complex conjugate.]

scipy.sparse.dok_matrix.conjtransp

dok_matrix.conjtransp(self)

Return the conjugate transpose.

scipy.sparse.dok_matrix.conjugate

dok_matrix.conjugate(self, copy=True)

Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters

- copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

- A [The element-wise complex conjugate.]

scipy.sparse.dok_matrix.copy

dok_matrix.copy(self)

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

scipy.sparse.dok_matrix.count_nonzero

dok_matrix.count_nonzero(self)

Number of non-zero entries, equivalent to

np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.
**scipy.sparse.dok_matrix.diagonal**

dok_matrix.diagonal(self, k=0)

Returns the k-th diagonal of the matrix.

**Parameters**

- **k** : [int, optional] Which diagonal to set, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
  New in version 1.0.

**See also:**

numpy.diagonal

Equivalent numpy function.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

**scipy.sparse.dok_matrix.dot**

dok_matrix.dot(self, other)

Ordinary dot product

**Examples**

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

**scipy.sparse.dok_matrix.fromkeys**

dok_matrix.fromkeys(iterable, value=None, /)

Returns a new dict with keys from iterable and values equal to value.

**scipy.sparse.dok_matrix.get**

dok_matrix.get(self, key, default=0.0)

This overrides the dict.get method, providing type checking but otherwise equivalent functionality.
SciPy Reference Guide, Release 1.3.2

scipy.sparse.dok_matrix.getH

dok_matrix.getH(self)
    Return the Hermitian transpose of this matrix.

    See also:

    numpy.matrix.getH
        NumPy's implementation of getH for matrices

scipy.sparse.dok_matrix.get_shape

dok_matrix.get_shape(self)
    Get shape of a matrix.

scipy.sparse.dok_matrix.getcol

dok_matrix.getcol(self, j)
    Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.dok_matrix.getformat

dok_matrix.getformat(self)
    Format of a matrix representation as a string.

scipy.sparse.dok_matrix.getmaxprint

dok_matrix.getmaxprint(self)
    Maximum number of elements to display when printed.

scipy.sparse.dok_matrix.getnnz

dok_matrix.getnnz(self, axis=None)
    Number of stored values, including explicit zeros.

    Parameters

    axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

    See also:

    count_nonzero
        Number of non-zero entries

6.22. Sparse matrices (scipy.sparse)  1727
**scipy.sparse.dok_matrix.getrow**

```python
dok_matrix.getrow(self, i)
```

Returns a copy of row `i` of the matrix, as a `(1 x n)` sparse matrix (row vector).

**scipy.sparse.dok_matrix.items**

```python
dok_matrix.items()
```

**scipy.sparse.dok_matrix.keys**

```python
dok_matrix.keys()
```

**scipy.sparse.dok_matrix.maximum**

```python
dok_matrix.maximum(self, other)
```

Element-wise maximum between this and another matrix.

**scipy.sparse.dok_matrix.mean**

```python
dok_matrix.mean(self, axis=None, dtype=None, out=None)
```

Computes the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. `float64` intermediate and return values are used for integer inputs.

**Parameters**

- `axis` ([-2, -1, 0, 1, None] optional) Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. `axis = None`).
- `dtype` [data-type, optional] Type to use in computing the mean. For integer inputs, the default is `float64`; for floating point inputs, it is the same as the input dtype.
- `out` [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns**

- `m` [np.matrix]

See also:

- `numpy.matrix.mean`

NumPy's implementation of 'mean' for matrices

**scipy.sparse.dok_matrix.minimum**

```python
dok_matrix.minimum(self, other)
```

Element-wise minimum between this and another matrix.
**scipy.sparse.dok_matrix.multiply**

```python
dok_matrix . multiply ( self , other )
```

Point-wise multiplication by another matrix

**scipy.sparse.dok_matrix.nonzero**

```python
dok_matrix . nonzero ( self )
```

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```python
from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

**scipy.sparse.dok_matrix.pop**

```python
dok_matrix . pop ()
```

If key is not found, d is returned if given, otherwise KeyError is raised

**scipy.sparse.dok_matrix.popitem**

```python
dok_matrix . popitem ()
```

2-tuple; but raise KeyError if D is empty.

**scipy.sparse.dok_matrix.power**

```python
dok_matrix . power ( self , n , dtype=None)
```

Element-wise power.

**scipy.sparse.dok_matrix.reshape**

```python
dok_matrix . reshape ( self , shape , order='C' , copy=False)
```

Gives a new shape to a sparse matrix without changing its data.

**Parameters**

- **shape**
  - [length-2 tuple of ints] The new shape should be compatible with the original shape.
- **order**
  - [{‘C’, ‘F’}, optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g. read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g. read entire first column, then second column, etc.
copy  [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

reshaped_matrix  [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

   numpy.matrix.reshape

   NumPy's implementation of 'reshape' for matrices

scipy.sparse.dok_matrix.resize
dok_matrix.resize(self, *shape)

Resize the matrix in-place to dimensions given by shape

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

   shape  [(int, int)] number of rows and columns in the new matrix

Notes

The semantics are not identical to numpy.ndarray.resize or numpy.resize. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

scipy.sparse.dok_matrix.set_shape
dok_matrix.set_shape(self, shape)

See reshape.

scipy.sparse.dok_matrix.setdefault
dok_matrix.setdefault()

scipy.sparse.dok_matrix.setdiag
dok_matrix.setdiag(self, values, k=0)

Set diagonal or off-diagonal elements of the array.

Parameters
values [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining
diagonal entries will not be set. If values if longer than the diagonal, then the remaining
values are ignored.
If a scalar value is given, all of the diagonal is set to it.

k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0
(the main diagonal).

scipy.sparse.dok_matrix.sum
dok_matrix.sum(self, axis=None, dtype=None, out=None)
Sum the matrix elements over a given axis.

Parameters
axis [-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is to
compute the sum of all the matrix elements, returning a scalar (i.e. axis = None).
dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the
elements are summed. The dtype of a is used by default unless a has an integer dtype
of less precision than the default platform integer. In that case, if a is signed then the
platform integer is used while if a is unsigned then an unsigned integer of the same
precision as the platform integer is used.
New in version 0.18.0.
out [np.matrix, optional] Alternative output matrix in which to place the result. It must have
the same shape as the expected output, but the type of the output values will be cast if
necessary.
New in version 0.18.0.

Returns
sum_along_axis [np.matrix] A matrix with the same shape as self, with the specified axis removed.

See also:

numpy.matrix.sum
NumPy’s implementation of ‘sum’ for matrices

scipy.sparse.dok_matrix.toarray
dok_matrix.toarray(self, order=None, out=None)
Return a dense ndarray representation of this matrix.

Parameters
order [‘C’, ‘F’], optional] Whether to store multi-dimensional data in C (row-major) or For-
tran (column-major) order in memory. The default is ‘None’, indicating the NumPy
default of C-ordered. Cannot be specified in conjunction with the out argument.
out [ndarray, 2-dimensional, optional] If specified, uses this array as the output buffer in-
stead of allocating a new array to return. The provided array must have the same shape
dtype as the sparse matrix on which you are calling the method. For most sparse
types, out is required to be memory contiguous (either C or Fortran ordered).

Returns
arr

[ndarray, 2-dimensional] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed, the same object is returned after being modified in-place to contain the appropriate values.

**scipy.sparse.dok_matrix.tobsr**

dok_matrix.tobsr(self, blocksize=None, copy=False)

Convert this matrix to Block Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When `blocksize=(R, C)` is provided, it will be used for construction of the bsr_matrix.

**scipy.sparse.dok_matrix.tocoo**

dok_matrix.tocoo(self, copy=False)

Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant coo_matrix.

**scipy.sparse.dok_matrix.tocsc**

dok_matrix.tocsc(self, copy=False)

Convert this matrix to Compressed Sparse Column format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant csc_matrix.

**scipy.sparse.dok_matrix.tocsr**

dok_matrix.tocsr(self, copy=False)

Convert this matrix to Compressed Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant csr_matrix.

**scipy.sparse.dok_matrix.todense**

dok_matrix.todense(self, order=None, out=None)

Return a dense matrix representation of this matrix.

**Parameters**

- **order**
  [{‘C’, ‘F’}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

- **out**
  [ndarray, 2-dimensional, optional] If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**
arr [numpy.matrix, 2-dimensional] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

scipy.sparse.dok_matrix.todia

dok_matrix.todia(self, copy=False)
Convert this matrix to sparse DIAgonal format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.dok_matrix.todok

dok_matrix.todok(self, copy=False)
Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.dok_matrix.tolil

dok_matrix.tolil(self, copy=False)
Convert this matrix to LInked List format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.dok_matrix.transpose

dok_matrix.transpose(self, axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.

copy [bool, optional] Indicates whether or not attributes of `self` should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [self with the dimensions reversed.]

See also:

numpy.matrix.transpose

NumPy’s implementation of ‘transpose’ for matrices
scipy.sparse.dok_matrix.update

dok_matrix.update(self, val)

If E is present and has a .keys() method, then does: for k in E: D[k] = E[k] If E is present and lacks a .keys() method, then does: for k, v in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]

scipy.sparse.dok_matrix.values

dok_matrix.values()

scipy.sparse.lil_matrix

class scipy.sparse.lil_matrix(arg1, shape=None, dtype=None, copy=False)

Row-based linked list sparse matrix

This is a structure for constructing sparse matrices incrementally. Note that inserting a single item can take linear time in the worst case; to construct a matrix efficiently, make sure the items are pre-sorted by index, per row.

This can be instantiated in several ways:

lil_matrix(D)

with a dense matrix or rank-2 ndarray D

lil_matrix(S)

with another sparse matrix S (equivalent to S.tolil())

lil_matrix((M, N), [dtype])

to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Advantages of the LIL format

• supports flexible slicing
• changes to the matrix sparsity structure are efficient

Disadvantages of the LIL format

• arithmetic operations LIL + LIL are slow (consider CSR or CSC)
• slow column slicing (consider CSC)
• slow matrix vector products (consider CSR or CSC)

Intended Usage

• LIL is a convenient format for constructing sparse matrices
• once a matrix has been constructed, convert to CSR or CSC format for fast arithmetic and matrix vector operations
• consider using the COO format when constructing large matrices

**Data Structure**

• An array (`self.rows`) of rows, each of which is a sorted list of column indices of non-zero elements.
• The corresponding nonzero values are stored in similar fashion in `self.data`.

**Attributes**

- `dtype` [dtype] Data type of the matrix
- `ndim` [int] Number of dimensions (this is always 2)
- `nnz` Number of stored values, including explicit zeros.
- `data` LIL format data array of the matrix
- `rows` LIL format row index array of the matrix

**Methods**

- `__len__(self)`
- `__mul__(self, other)` interpret other and call one of the following
- `asformat(self, format[, copy])` Return this matrix in the passed format.
- `asfptype(self)` Upcast matrix to a floating point format (if necessary)
- `astype(self, dtype[, casting, copy])` Cast the matrix elements to a specified type.
- `conj(self[, copy])` Element-wise complex conjugation.
- `conjugate(self[, copy])` Element-wise complex conjugation.
- `copy(self)` Returns a copy of this matrix.
- `count_nonzero(self)` Number of non-zero entries, equivalent to
- `diagonal(self[, k])` Returns the k-th diagonal of the matrix.
- `dot(self, other)` Ordinary dot product
- `getH(self)` Return the Hermitian transpose of this matrix.
- `get_shape(self)` Get shape of a matrix.
- `getcol(self, j)` Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
- `getformat(self)` Format of a matrix representation as a string.
- `getmaxprint(self)` Maximum number of elements to display when printed.
- `getnnz(self[, axis])` Number of stored values, including explicit zeros.
- `getrow(self, i)` Returns a copy of the i’th row.
- `getrowview(self, i)` Returns a view of the i’th row (without copying).
- `maximum(self, other)` Element-wise maximum between this and another matrix.
- `mean(self[, axis, dtype, out])` Compute the arithmetic mean along the specified axis.
- `minimum(self, other)` Element-wise minimum between this and another matrix.
- `multiply(self, other)` Point-wise multiplication by another matrix
- `nonzero(self)` nonzero indices
- `power(self, n[, dtype])` Element-wise power.

**scipy.sparse.lil_matrix.__len__**

lil_matrix.__len__ (self)

**scipy.sparse.lil_matrix.__mul__**

lil_matrix.__mul__ (self, other)

interpret other and call one of the following

- self._mul_scalar()
- self._mul_vector()
- self._mul_multivector()
- self._mul_sparse_matrix()

**scipy.sparse.lil_matrix.asformat**

lil_matrix.asformat (self, format, copy=False)

Return this matrix in the passed format.

**Parameters**

- format [str, None] The desired matrix format (“csr”, “csc”, “lil”, “dok”, “array”, …) or None for no conversion.
- copy [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- A [This matrix in the passed format.]

**scipy.sparse.lil_matrix.asfptype**

lil_matrix.asfptype (self)

Upcast matrix to a floating point format (if necessary)
**scipy.sparse.lil_matrix.astype**

`lil_matrix.astype(self, dtype, casting='unsafe', copy=True)`

Cast the matrix elements to a specified type.

**Parameters**

- **dtype** [string or numpy dtype] Typecode or data-type to which to cast the data.
- **casting** [[optimal]] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
- **copy** [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.

**scipy.sparse.lil_matrix.conj**

`lil_matrix.conj(self, copy=True)`

Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

**Parameters**

- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- **A** [The element-wise complex conjugate.]

**scipy.sparse.lil_matrix.conjugate**

`lil_matrix.conjugate(self, copy=True)`

Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

**Parameters**

- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- **A** [The element-wise complex conjugate.]

**scipy.sparse.lil_matrix.copy**

`lil_matrix.copy(self)`

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.
**scipy.sparse.lil_matrix.count_nonzero**

lil_matrix.count_nonzero(self)

Number of non-zero entries, equivalent to

np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

**scipy.sparse.lil_matrix.diagonal**

lil_matrix.diagonal(self, k=0)

Returns the k-th diagonal of the matrix.

Parameters

- **k** [int, optional] Which diagonal to set, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal). New in version 1.0.

See also:

- **numpy.diagonal**

  Equivalent numpy function.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

**scipy.sparse.lil_matrix.dot**

lil_matrix.dot(self, other)

Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```
scipy.sparse.lil_matrix.getH

lil_matrix.getH(self)
Return the Hermitian transpose of this matrix.

See also:
numpy.matrix.getH
NumPy's implementation of getH for matrices

scipy.sparse.lil_matrix.get_shape

lil_matrix.get_shape(self)
Get shape of a matrix.

scipy.sparse.lil_matrix.getcol

lil_matrix.getcol(self, j)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.lil_matrix.getformat

lil_matrix.getformat(self)
Format of a matrix representation as a string.

scipy.sparse.lil_matrix.getmaxprint

lil_matrix.getmaxprint(self)
Maximum number of elements to display when printed.

scipy.sparse.lil_matrix.getnnz

lil_matrix.getnnz(self, axis=None)
Number of stored values, including explicit zeros.

Parameters
axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:
count_nonzero
Number of non-zero entries
scipy.sparse.lil_matrix.getrow

lil_matrix.getrow(self, i)

Returns a copy of the ‘i’th row.

scipy.sparse.lil_matrix.getrowview

lil_matrix.getrowview(self, i)

Returns a view of the ‘i’th row (without copying).

scipy.sparse.lil_matrix.maximum

lil_matrix.maximum(self, other)

Element-wise maximum between this and another matrix.

scipy.sparse.lil_matrix.mean

lil_matrix.mean(self, axis=None, dtype=None, out=None)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters

axis  
[[-2, -1, 0, 1, None] optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. axis = None).

dtype  
[data-type, optional] Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype. New in version 0.18.0.

out  
[np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

Returns

m  
[np.matrix]

See also:

numpy.matrix.mean

NumPy’s implementation of ‘mean’ for matrices

scipy.sparse.lil_matrix.minimum

lil_matrix.minimum(self, other)

Element-wise minimum between this and another matrix.
scipy.sparse.lil_matrix.multiply

lil_matrix.multiply (self, other)
Point-wise multiplication by another matrix

scipy.sparse.lil_matrix.nonzero

lil_matrix.nonzero (self)
nonzero indices
Returns a tuple of arrays (row, col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.lil_matrix.power

lil_matrix.power (self, n, dtype=None)
Element-wise power.

scipy.sparse.lil_matrix.reshape

lil_matrix.reshape (self, shape, order='C', copy=False)
Gives a new shape to a sparse matrix without changing its data.

Parameters:

- shape [length-2 tuple of ints] The new shape should be compatible with the original shape.
- order [{‘C’, ‘F’}, optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g. read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g. read entire first column, then second column, etc.
- copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns:

- reshaped_matrix [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

- numpy.matrix.reshape
  NumPy’s implementation of ‘reshape’ for matrices
**scipy.sparse.lil_matrix.resize**

```python
lil_matrix.resize(self, *shape)
```

Resize the matrix in-place to dimensions given by `shape`.

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

**Parameters**

- `shape` [(int, int)] number of rows and columns in the new matrix

**Notes**

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

**scipy.sparse.lil_matrix.set_shape**

```python
lil_matrix.set_shape(self, shape)
```

See `reshape`.

**scipy.sparse.lil_matrix.setdiag**

```python
lil_matrix.setdiag(self, values, k=0)
```

Set diagonal or off-diagonal elements of the array.

**Parameters**

- `values` [array_like] New values of the diagonal elements.
  Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored.
  If a scalar value is given, all of the diagonal is set to it.
- `k` [int, optional] Which off-diagonal to set, corresponding to elements \( a[i,i+k] \). Default: 0 (the main diagonal).

**scipy.sparse.lil_matrix.sum**

```python
lil_matrix.sum(self, axis=None, dtype=None, out=None)
```

Sum the matrix elements over a given axis.

**Parameters**

- `axis` [{-2, -1, 0, 1}, None] optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. `axis = None`).
**dtype**  
[dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used.  
New in version 0.18.0.

**out**  
[np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.  
New in version 0.18.0.

**Returns**

**sum_along_axis**  
[np.matrix] A matrix with the same shape as self, with the specified axis removed.

**See also:**

* numpy.matrix.sum  
  NumPy’s implementation of ‘sum’ for matrices

### scipy.sparse.lil_matrix.toarray

**lil_matrix.toarray**(self, order=None, out=None)  
Return a dense ndarray representation of this matrix.

**Parameters**

**order**  
[‘C’, ‘F’, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

**out**  
[ndarray, 2-dimensional, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, `out` is required to be memory contiguous (either C or Fortran ordered).

**Returns**

**arr**  
[ndarray, 2-dimensional] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed, the same object is returned after being modified in-place to contain the appropriate values.

### scipy.sparse.lil_matrix.tobsr

**lil_matrix.tobsr**(self, blocksize=None, copy=False)  
Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.
**scipy.sparse.lil_matrix.tocoo**

```python
lil_matrix.tocoo(self, copy=False)
```

Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

**scipy.sparse.lil_matrix.tocsc**

```python
lil_matrix.tocsc(self, copy=False)
```

Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

**scipy.sparse.lil_matrix.tocsr**

```python
lil_matrix.tocsr(self, copy=False)
```

Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

**scipy.sparse.lil_matrix.todense**

```python
lil_matrix.todense(self, order=None, out=None)
```

Return a dense matrix representation of this matrix.

**Parameters**

- **order** [‘C’, ‘F’], optional] Whether to store multi-dimensional data in C (row-major) or For
tran (column-major) order in memory. The default is ‘None’, indicating the NumPy
default of C-ordered. Cannot be specified in conjunction with the out argument.

- **out** [ndarray, 2-dimensional, optional] If specified, uses this array (or numpy.matrix)
as the output buffer instead of allocating a new array to return. The provided array must
have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**

- **arr** [numpy.matrix, 2-dimensional] A NumPy matrix object with the same shape and con-
taining the same data represented by the sparse matrix, with the requested memory
order. If out was passed and was an array (rather than a numpy.matrix), it will be
filled with the appropriate values and returned wrapped in a numpy.matrix object
that shares the same memory.

**scipy.sparse.lil_matrix.todia**

```python
lil_matrix.todia(self, copy=False)
```

Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.
scipy.sparse.lil_matrix.todok

lil_matrix.todok(self, copy=False)
Convert this matrix to Dictionary Of Keys format.
With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.lil_matrix.tolil

lil_matrix.tolil(self, copy=False)
Convert this matrix to Linked List format.
With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.lil_matrix.transpose

lil_matrix.transpose(self, axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters
axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns
p [self with the dimensions reversed.]

See also:
numpy.matrix.transpose
NumPy’s implementation of ‘transpose’ for matrices

scipy.sparse.spmatrix

class scipy.sparse.spmatrix(maxprint=50)
This class provides a base class for all sparse matrices. It cannot be instantiated. Most of the work is provided by subclasses.

Attributes
nnz Number of stored values, including explicit zeros.
shape Get shape of a matrix.

```python
c scipy.sparse.spmatrix.__len__

default_len(self)
```

```python
c scipy.sparse.spmatrix.__mul__

__mul__(self, other)

interpret other and call one of the following

self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()
```

```python
c scipy.sparse.spmatrix.asformat

asformat(self, format, copy=False)

Return this matrix in the passed format.

**Parameters**

- **format**
  
  [{str, None}] The desired matrix format ("csr", “csc”, “lil”, “dok”, “array”, …) or None for no conversion.

- **copy**
  
  [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- **A**
  
  [This matrix in the passed format.]
```

```python
c scipy.sparse.spmatrix.asfptype

asfptype(self)

Upcast matrix to a floating point format (if necessary)
```

```python
c scipy.sparse.spmatrix.astype

astype(self, dtype, casting='unsafe', copy=True)

Cast the matrix elements to a specified type.

**Parameters**

- **dtype**
  
  [string or numpy dtype] Typecode or data-type to which to cast the data.

- **casting**
  
  [{‘no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’}, optional] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.

- **copy**
  
  [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.
**scipy.sparse.spmatrix.conj**

```
cspamatrix.conj(self, copy=True)
```

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- `copy` [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- `A` [The element-wise complex conjugate.]

**scipy.sparse.spmatrix.conjugate**

```
cspamatrix.conjugate(self, copy=True)
```

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- `copy` [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- `A` [The element-wise complex conjugate.]

**scipy.sparse.spmatrix.copy**

```
cspamatrix.copy(self)
```

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

**scipy.sparse.spmatrix.count_nonzero**

```
cspamatrix.count_nonzero(self)
```

Number of non-zero entries, equivalent to

```
np.count_nonzero(a.toarray())
```

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

**scipy.sparse.spmatrix.diagonal**

```
cspamatrix.diagonal(self, k=0)
```

Returns the k-th diagonal of the matrix.

**Parameters**
**scipy.sparse.spmatrix.dot**

**spmatrix.dot(self, other)**

Ordinary dot product

**Examples**

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

**scipy.sparse.spmatrix.getH**

**spmatrix.getH(self)**

Return the Hermitian transpose of this matrix.

**See also:**

**numpy.matrix.getH**

NumPy's implementation of getH for matrices

**scipy.sparse.spmatrix.get_shape**

**spmatrix.get_shape(self)**

Get shape of a matrix.
**scipy.sparse.spmatrix.getcol**

```python
spmatrix.getcol(self, j)
```

Returns a copy of column `j` of the matrix, as an (m x 1) sparse matrix (column vector).

**scipy.sparse.spmatrix.getformat**

```python
spmatrix.getformat(self)
```

Format of a matrix representation as a string.

**scipy.sparse.spmatrix.getmaxprint**

```python
spmatrix.getmaxprint(self)
```

Maximum number of elements to display when printed.

**scipy.sparse.spmatrix.getnnz**

```python
spmatrix.getnnz(self, axis=None)
```

Number of stored values, including explicit zeros.

**Parameters**

- `axis` [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

- `count_nonzero`

  Number of non-zero entries

**scipy.sparse.spmatrix.getrow**

```python
spmatrix.getrow(self, i)
```

Returns a copy of row `i` of the matrix, as a (1 x n) sparse matrix (row vector).

**scipy.sparse.spmatrix.maximum**

```python
spmatrix.maximum(self, other)
```

Element-wise maximum between this and another matrix.

**scipy.sparse.spmatrix.mean**

```python
spmatrix.mean(self, axis=None, dtype=None, out=None)
```

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

**Parameters**
**axis**
[-2, -1, 0, 1, None] optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. `axis = None`).

**dtype**
[data-type, optional] Type to use in computing the mean. For integer inputs, the default is `float64`; for floating point inputs, it is the same as the input dtype.
New in version 0.18.0.

**out**
[np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

**Returns**

m
[np.matrix]

See also:

`numpy.matrix.mean`
NumPy's implementation of ‘mean’ for matrices

**scipy.sparse.spmatrix.minimum**

`spmatrix.minimum(self, other)`
Element-wise minimum between this and another matrix.

**scipy.sparse.spmatrix.multiply**

`spmatrix.multiply(self, other)`
Point-wise multiplication by another matrix

**scipy.sparse.spmatrix.nonzero**

`spmatrix.nonzero(self)`
nonzero indices
Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

**scipy.sparse.spmatrix.power**

`spmatrix.power(self, n, dtype=None)`
Element-wise power.
**scipy.sparse.spmatrix.reshape**

`spmatrix.reshape(self, shape, order='C', copy=False)`  
Gives a new shape to a sparse matrix without changing its data.

**Parameters**

- **shape** [length-2 tuple of ints] The new shape should be compatible with the original shape.
- **order** [{'C', 'F'}, optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g. read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g. read entire first column, then second column, etc.
- **copy** [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- **reshaped_matrix** [sparse matrix] A sparse matrix with the given `shape`, not necessarily of the same format as the current object.

**See also:**

- `numpy.matrix.reshape`  
  NumPy's implementation of 'reshape' for matrices

**scipy.sparse.spmatrix.resize**

`spmatrix.resize(self, shape)`  
Resizes the matrix in-place to dimensions given by `shape`  
Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

**Parameters**

- **shape** [(int, int)] number of rows and columns in the new matrix

**Notes**

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

**scipy.sparse.spmatrix.set_shape**

`spmatrix.set_shape(self, shape)`  
See `reshape`. 
**scipy.sparse.spmatrix.setdiag**

```python
spmatrix.setdiag(self, values, k=0)
```

Set diagonal or off-diagonal elements of the array.

**Parameters**

- **values** (array_like) New values of the diagonal elements.
- **k** (int, optional) Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

**scipy.sparse.spmatrix.sum**

```python
spmatrix.sum(self, axis=None, dtype=None, out=None)
```

Sum the matrix elements over a given axis.

**Parameters**

- **axis** ([-2, -1, 0, 1, None], optional) Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. `axis = None`).
- **dtype** ([dtype, optional]) The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of `a` is used by default unless `a` has an integer dtype of less precision than the default platform integer. In that case, if `a` is signed then the platform integer is used while if `a` is unsigned then an unsigned integer of the same precision as the platform integer is used. New in version 0.18.0.
- **out** ([np.matrix, optional]) Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

**Returns**

- **sum_along_axis** ([np.matrix]) A matrix with the same shape as `self`, with the specified axis removed.

**See also:**

- `numpy.matrix.sum`
  NumPy's implementation of 'sum' for matrices

**scipy.sparse.spmatrix.toarray**

```python
spmatrix.toarray(self, order=None, out=None)
```

Return a dense ndarray representation of this matrix.

**Parameters**

- **order** (['C', 'F'], optional) Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.
out  [ndarray, 2-dimensional, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, out is required to be memory contiguous (either C or Fortran ordered).

Returns

arr  [ndarray, 2-dimensional] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed, the same object is returned after being modified in-place to contain the appropriate values.

scipy.sparse.spmatrix.tobsr

spmatrix.tobsr(self, blocksize=None, copy=False)
Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

scipy.sparse.spmatrix.tocoo

spmatrix.tocoo(self, copy=False)
Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

scipy.sparse.spmatrix.tocsc

spmatrix.tocsc(self, copy=False)
Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.spmatrix.tocsr

spmatrix.tocsr(self, copy=False)
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.spmatrix.todense

spmatrix.todense(self, order=None, out=None)
Return a dense matrix representation of this matrix.

Parameters

order  [{'C', 'F'}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.
out [ndarray, 2-dimensional, optional] If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

arr [numpy.matrix, 2-dimensional] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

scipy.sparse.spmatrix.todia

spmatrix.todia(self, copy=False)
Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.spmatrix.todok

spmatrix.todok(self, copy=False)
Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.spmatrix.tolil

spmatrix.tolil(self, copy=False)
Convert this matrix to LInked List format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.spmatrix.transpose

spmatrix.transpose(self, axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [self with the dimensions reversed.]

### scipy.sparse.eye

`scipy.sparse.eye(m, n=None, k=0, dtype=<class 'float'>, format=None)`

Sparse matrix with ones on diagonal

Returns a sparse (m x n) matrix where the k-th diagonal is all ones and everything else is zeros.

**Parameters**

- **m**: [int] Number of rows in the matrix.
- **n**: [int, optional] Number of columns. Default: m.
- **k**: [int, optional] Number of columns. Default: 0 (main diagonal).
- **dtype**: [dtype, optional] Data type of the matrix.
- **format**: [str, optional] Sparse format of the result, e.g. format="csr", etc.

### Examples

```python
>>> from scipy import sparse
>>> sparse.eye(3).toarray()
array([[ 1., 0., 0.],
       [ 0., 1., 0.],
       [ 0., 0., 1.]])
>>> sparse.eye(3, dtype=np.int8)
<3x3 sparse matrix of type '<class 'numpy.int8'>'
with 3 stored elements (1 diagonals) in DIAgonal format>
```

### scipy.sparse.identity

`scipy.sparse.identity(n, dtype='d', format=None)`

Identity matrix in sparse format
Returns an identity matrix with shape (n,n) using a given sparse format and dtype.

**Parameters**

- `n` [int] Shape of the identity matrix.
- `dtype` [dtype, optional] Data type of the matrix
- `format` [str, optional] Sparse format of the result, e.g. format="csr", etc.

**Examples**

```python
>>> from scipy.sparse import identity
>>> identity(3).toarray()
density([[ 1., 0., 0.],
         [ 0., 1., 0.],
         [ 0., 0., 1.]])
>>> identity(3, dtype='int8', format='dia')
<3x3 sparse matrix of type '<class 'numpy.int8'>'
  with 3 stored elements (1 diagonals) in DIAGonal format>
```

**scipy.sparse.kron**

**scipy.sparse.kron**(A, B, format=None)

Kronecker product of sparse matrices A and B

**Parameters**

- `A` [sparse or dense matrix] first matrix of the product
- `B` [sparse or dense matrix] second matrix of the product
- `format` [str, optional] format of the result (e.g. "csr")

**Returns**

Kronecker product in a sparse matrix format

**Examples**

```python
>>> from scipy.sparse import kron
>>> A = sparse.csr_matrix(np.array([[0, 2], [5, 0]]))
>>> B = sparse.csr_matrix(np.array([[1, 2], [3, 4]]))
>>> kron(A, B).toarray()
density([[ 0, 0, 2, 4],
         [ 0, 0, 6, 8],
         [ 5, 10, 0, 0],
         [15, 20, 0, 0]])
```

```python
>>> kron(A, [[1, 2], [3, 4]]).toarray()
density([[ 0, 0, 2, 4],
         [ 0, 0, 6, 8],
         [ 5, 10, 0, 0],
         [15, 20, 0, 0]])
```
scipy.sparse.kronsum

scipy.sparse.kronsum(A, B, format=None)

Kronecker sum of two sparse matrices A and B

Kronecker sum of two sparse matrices is a sum of two Kronecker products kron(I_n,A) + kron(B,I_m) where A
has shape (m,m) and B has shape (n,n) and I_m and I_n are identity matrices of shape (m,m) and (n,n) respectively.

Parameters

A  square matrix
B  square matrix
format  [str] format of the result (e.g. “csr”)

Returns

kronecker sum in a sparse matrix format

scipy.sparse.diags

scipy.sparse.diags(diagonals, offsets=0, shape=None, format=None, dtype=None)

Constructs a sparse matrix from diagonals.

Parameters

diagonals  [sequence of array_like] Sequence of arrays containing the matrix diagonals, corresponding to offsets.
offsets  [sequence of int or an int, optional]
Diagonals to set:

• k = 0 the main diagonal (default)
• k > 0 the k-th upper diagonal
• k < 0 the k-th lower diagonal

shape  [tuple of int, optional] Shape of the result. If omitted, a square matrix large enough to contain the
diagonals is returned.
format  [{“dia”, “csr”, “csc”, “lil”, …}, optional] Matrix format of the result. By default (format=None) an appropriate sparse matrix format is returned. This choice is subject to change.
dtype  [dtype, optional] Data type of the matrix.

See also:

spdiags

construct matrix from diagonals

Notes

This function differs from spdiags in the way it handles off-diagonals.

The result from diags is the sparse equivalent of:

```python
np.diag(diagonals[0], offsets[0]) +
... +
np.diag(diagonals[k], offsets[k])
```

Repeated diagonal offsets are disallowed.

New in version 0.11.
Examples

```python
>>> from scipy.sparse import diags
>>> diagonals = [[1, 2, 3, 4], [1, 2, 3], [1, 2]]
>>> diags(diagonals, [0, -1, 2]).toarray()
array([[1, 0, 1, 0],
       [1, 2, 0, 2],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
```

Broadcasting of scalars is supported (but shape needs to be specified):

```python
>>> diags([[1, -2, 1], [-1, 0, 1], shape=(4, 4)]).toarray()
array([[ 1., -2., 1., 0.],
       [ 1.,  0., 2., 0.],
       [ 0.,  1., -2., 1.],
       [ 0.,  0.,  1., -2.]])
```

If only one diagonal is wanted (as in `numpy.diag`), the following works as well:

```python
>>> diags([1, 2, 3], 1).toarray()
array([[ 0.,  1.,  0.,  0.],
       [ 0.,  0.,  2.,  0.],
       [ 0.,  0.,  0.,  3.],
       [ 0.,  0.,  0.,  0.]])
```

**scipy.sparse.spdiags**

`scipy.sparse.spdiags(data, diags, m, n, format=None)`

Return a sparse matrix from diagonals.

**Parameters**

- `data` [array_like] matrix diagonals stored row-wise
- `diags` [diagonals to set]  
  - `k = 0` the main diagonal  
  - `k > 0` the k-th upper diagonal  
  - `k < 0` the k-th lower diagonal  
- `m, n` [int] shape of the result
- `format` [str, optional] Format of the result. By default (format=None) an appropriate sparse matrix format is returned. This choice is subject to change.

**See also:**

- `diags`  
  more convenient form of this function

- `dia_matrix`  
  the sparse DIAgonal format.

**Examples**
```python
>>> from scipy.sparse import spdiags
>>> data = np.array([[1, 2, 3, 4], [1, 2, 3, 4], [1, 2, 3, 4]])
>>> diags = np.array([0, -1, 2])
>>> spdiags(data, diags, 4, 4).toarray()
array([[1, 0, 3, 0],
       [1, 2, 0, 4],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
```

**scipy.sparse.block_diag**

`scipy.sparse.block_diag(mats, format=None, dtype=None)`

Build a block diagonal sparse matrix from provided matrices.

**Parameters**

- **mats** [sequence of matrices] Input matrices.
- **format** [str, optional] The sparse format of the result (e.g. “csr”). If not given, the matrix is returned in “coo” format.
- **dtype** [dtype specifier, optional] The data-type of the output matrix. If not given, the dtype is determined from that of `blocks`.

**Returns**

- **res** [sparse matrix]

**See also:**

cimat, diags

**Notes**

New in version 0.11.0.

**Examples**

```python
>>> from scipy.sparse import coo_matrix, block_diag
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> C = coo_matrix([[7]])
>>> block_diag((A, B, C)).toarray()
array([[1, 2, 0, 0],
       [3, 4, 0, 0],
       [0, 0, 5, 0],
       [0, 0, 6, 0],
       [0, 0, 0, 7]])
```

**scipy.sparse.tril**

`scipy.sparse.tril(A, k=0, format=None)`

Return the lower triangular portion of a matrix in sparse format

**Returns the elements on or below the k-th diagonal of the matrix A.**

- k = 0 corresponds to the main diagonal
• k > 0 is above the main diagonal
• k < 0 is below the main diagonal

Parameters
- A [dense or sparse matrix] Matrix whose lower triangular portion is desired.
- k [integer] The top-most diagonal of the lower triangle.
- format [string] Sparse format of the result, e.g. format="csr", etc.

Returns
- L [sparse matrix] Lower triangular portion of A in sparse format.

See also:
- triu
  upper triangle in sparse format

Examples

```python
>>> from scipy.sparse import csr_matrix, triu
>>> A = csr_matrix([[1, 2, 0, 0, 3], [4, 5, 0, 6, 7], [0, 0, 8, 9, 0]],
                 dtype='int32')
>>> A.toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A).toarray()
array([[1, 0, 0, 0, 0],
       [4, 5, 0, 0, 0],
       [0, 0, 8, 0, 0]])
>>> triu(A).nnz
4
>>> triu(A, k=1).toarray()
array([[1, 2, 0, 0, 0],
       [4, 5, 0, 0, 0],
       [0, 0, 8, 9, 0]])
>>> triu(A, k=-1).toarray()
array([[0, 0, 0, 0, 0],
       [4, 0, 0, 0, 0],
       [0, 0, 0, 0, 0]])
>>> triu(A, format='csc')
<3x5 sparse matrix of type '<class 'numpy.int32'>'
     with 4 stored elements in Compressed Sparse Column format>
```

scipy.sparse.triu

scipy.sparse.triu(A, k=0, format=None)

Return the upper triangular portion of a matrix in sparse format

Returns the elements on or above the k-th diagonal of the matrix A.

• k = 0 corresponds to the main diagonal

6.22. Sparse matrices (scipy.sparse) 1761
• \( k > 0 \) is above the main diagonal
• \( k < 0 \) is below the main diagonal

**Parameters**

- **A** \[dense or sparse matrix\] Matrix whose upper triangular portion is desired.
- **k** \[integer\] The bottom-most diagonal of the upper triangle.
- **format** \[string\] Sparse format of the result, e.g. format="csr", etc.

**Returns**

- **L** \[sparse matrix\] Upper triangular portion of \( A \) in sparse format.

**See also:**

*tril*

lower triangle in sparse format

**Examples**

```python
>>> from scipy.sparse import csr_matrix, triu
>>> A = csr_matrix([[1, 2, 0, 0, 3], [4, 5, 0, 6, 7], [0, 0, 8, 9, 0]],
                 dtype='int32')
>>> A.toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A).toarray()
array([[1, 2, 0, 0, 3],
       [0, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A).nnz
8
>>> triu(A, k=1).toarray()
array([[0, 2, 0, 0, 3],
       [0, 0, 0, 6, 7],
       [0, 0, 0, 9, 0]])
>>> triu(A, k=-1).toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A, format='csc')<3x5 sparse matrix of type '<class 'numpy.int32'>'
    with 8 stored elements in Compressed Sparse Column format>
```

**scipy.sparse.bmat**

*scipy.sparse.bmat* \( \text{(blocks, format=None, dtype=None)} \)
Build a sparse matrix from sparse sub-blocks

**Parameters**

- **blocks** \[array_like\] Grid of sparse matrices with compatible shapes. An entry of None implies an all-zero matrix.
**format**

[‘bsr’, ‘coo’, ‘csc’, ‘csr’, ‘dia’, ‘dok’, ‘lil’], optional] The sparse format of the result (e.g. “csr”). By default an appropriate sparse matrix format is returned. This choice is subject to change.

**dtype**

[dtype, optional] The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

Returns

**bmat**

[sparse matrix]

See also:

`block_diag`, `diags`

**Examples**

```python
>>> from scipy.sparse import coo_matrix, bmat
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> C = coo_matrix([[7]])
>>> bmat([[A, B], [None, C]]).toarray()
array([[1, 2, 5],
       [3, 4, 6],
       [0, 0, 7]])
```

```python
>>> bmat([[A, None], [None, C]]).toarray()
array([[1, 2, 0],
       [3, 4, 0],
       [0, 0, 7]])
```

---

**scipy.sparse.hstack**

`scipy.sparse.hstack` (*blocks*, *format=None*, *dtype=None*)

Stack sparse matrices horizontally (column wise)

**Parameters**

- **blocks**: sequence of sparse matrices with compatible shapes
- **format**: [str] sparse format of the result (e.g. “csr”) by default an appropriate sparse matrix format is returned. This choice is subject to change.
- **dtype**: [dtype, optional] The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

See also:

`vstack`

stack sparse matrices vertically (row wise)

**Examples**

```python
>>> from scipy.sparse import coo_matrix, hstack
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> hstack([A, B]).toarray()
```

(continues on next page)
scipy.sparse.vstack

scipy.sparse.vstack (blocks, format=None, dtype=None)

Stack sparse matrices vertically (row wise)

Parameters
- **blocks**: sequence of sparse matrices with compatible shapes
- **format**: [str, optional] sparse format of the result (e.g. “csr”) by default an appropriate sparse matrix format is returned. This choice is subject to change.
- **dtype**: [dtype, optional] The data-type of the output matrix. If not given, the dtype is determined from that of blocks.

See also:

hstack

stack sparse matrices horizontally (column wise)

Examples

```python
>>> from scipy.sparse import coo_matrix, vstack
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5, 6]])
>>> vstack([A, B]).toarray()
array([[1, 2],
       [3, 4],
       [5, 6]])
```

scipy.sparse.rand

scipy.sparse.rand (m, n, density=0.01, format='coo', dtype=None, random_state=None)

Generate a sparse matrix of the given shape and density with uniformly distributed values.

Parameters
- **m**, **n**: [int] shape of the matrix
- **density**: [real, optional] density of the generated matrix: density equal to one means a full matrix, density of 0 means a matrix with no non-zero items.
- **format**: [str, optional] sparse matrix format.
- **dtype**: [dtype, optional] type of the returned matrix values.
- **random_state**: [{numpy.random.RandomState, int}, optional] Random number generator or random seed. If not given, the singleton numpy.random will be used.

Returns
- **res**: [sparse matrix]

See also:

scipy.sparse.random

Similar function that allows a user-specified random data source.
Notes

Only float types are supported for now.

Examples

```python
>>> from scipy.sparse import rand
>>> matrix = rand(3, 4, density=0.25, format='csr', random_state=42)
>>> matrix
<3x4 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in Compressed Sparse Row format>
>>> matrix.todense()
matrix([[0.05641158, 0., 0., 0.65088847],
        [0., 0., 0., 0.14286682],
        [0., 0., 0., 0.]])
```

**scipy.sparse.random**

Generate a sparse matrix of the given shape and density with randomly distributed values.

**Parameters**

- **m, n** : [int] shape of the matrix
- **density** : [real, optional] density of the generated matrix: density equal to one means a full matrix, density of 0 means a matrix with no non-zero items.
- **format** : [str, optional] sparse matrix format.
- **dtype** : [dtype, optional] type of the returned matrix values.
- **random_state** : [{numpy.random.RandomState, int}, optional] Random number generator or random seed. If not given, the singleton numpy.random will be used. This random state will be used for sampling the sparsity structure, but not necessarily for sampling the values of the structurally nonzero entries of the matrix.
- **data_rvs** : [callable, optional] Samples a requested number of random values. This function should take a single argument specifying the length of the ndarray that it will return. The structurally nonzero entries of the sparse random matrix will be taken from the array sampled by this function. By default, uniform [0, 1) random values will be sampled using the same random state as is used for sampling the sparsity structure.

**Returns**

- **res** : [sparse matrix]

Notes

Only float types are supported for now.

Examples

```python
>>> from scipy.sparse import random
>>> from scipy import stats
```
```python
>>> class CustomRandomState(np.random.RandomState):
...     def randint(self, k):
...         i = np.random.randint(k)
...         return i - i % 2

>>> np.random.seed(12345)
>>> rs = CustomRandomState()
>>> rvs = stats.poisson(25, loc=10).rvs
>>> S = random(3, 4, density=0.25, random_state=rs, data_rvs=rvs)
>>> S.A
array([[ 36.,  0.,  33.,  0.],
       [  0.,  0.,  0.,  0.],
       [  0.,  36.,  0.,  0.]])

>>> from scipy.sparse import random
>>> from scipy.stats import rv_continuous
>>> class CustomDistribution(rv_continuous):
...     def _rvs(self, *args, **kwargs):
...         return self._random_state.randn(*self._size)

>>> X = CustomDistribution(seed=2906)
>>> Y = X()  # get a frozen version of the distribution
>>> S = random(3, 4, density=0.25, random_state=2906, data_rvs=Y.rvs)
>>> S.A
array([[ 0. ,  0. ,  0. ,  0. ],
       [ 0.13569738,  1.9467163 , -0.81205367,  0. ],
       [ 0. ,  0. ,  0. ,  0. ]])
```

Save and load sparse matrices:

```python
save_npz(file, matrix[, compressed])  # Save a sparse matrix to a file using .npz format.
load_npz(file)                         # Load a sparse matrix from a file using .npz format.
```

**scipy.sparse.save_npz**

Save a sparse matrix to a file using .npz format.

- **Parameters**
  - **file** [str or file-like object] Either the file name (string) or an open file (file-like object) where the data will be saved. If file is a string, the .npz extension will be appended to the file name if it is not already there.
  - **matrix** : spmatrix (format: “csc”, “csr”, “bsr”, “dia” or coo“) The sparse matrix to save.
  - **compressed** [bool, optional] Allow compressing the file. Default: True

- **See also:**
  - **scipy.sparse.load_npz**
  - **numpy.savez**

Save several arrays into a .npz archive.
numpy.savez_compressed

Save several arrays into a compressed .npz archive.

Examples

Store sparse matrix to disk, and load it again:

```python
>>> import scipy.sparse
>>> sparse_matrix = scipy.sparse.csc_matrix(np.array([[0, 0, 3], [4, 0, 0]]))
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
  with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)
```

```python
>>> scipy.sparse.save_npz('/tmp/sparse_matrix.npz', sparse_matrix)
```

```python
>>> sparse_matrix = scipy.sparse.load_npz('/tmp/sparse_matrix.npz')
```

```python
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
  with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)
```

scipy.sparse.load_npz

scipy.sparse.load_npz(file)

Load a sparse matrix from a file using .npz format.

Parameters

- **file** [str or file-like object] Either the file name (string) or an open file (file-like object) where the data will be loaded.

Returns

- **result** [csc_matrix, csr_matrix, bsr_matrix, dia_matrix or coo_matrix] A sparse matrix containing the loaded data.

Raises

- IOError If the input file does not exist or cannot be read.

See also:

- scipy.sparse.save_npz
  Save a sparse matrix to a file using .npz format.

- numpy.load
  Load several arrays from a .npz archive.
Examples

Store sparse matrix to disk, and load it again:

```python
>>> import scipy.sparse
>>> sparse_matrix = scipy.sparse.csc_matrix(np.array([[0, 0, 3], [4, 0, -2]]))
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
    with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)
```

```python
>>> scipy.sparse.save_npz('/tmp/sparse_matrix.npz', sparse_matrix)
>>> sparse_matrix = scipy.sparse.load_npz('/tmp/sparse_matrix.npz')
```

Sparse matrix tools:

`find(A)`

Return the indices and values of the nonzero elements of a matrix

**scipy.sparse.find**

`scipy.sparse.find(A)`

Return the indices and values of the nonzero elements of a matrix

**Parameters**

A : [dense or sparse matrix] Matrix whose nonzero elements are desired.

**Returns**

(I, J, V) : [tuple of arrays] I, J, and V contain the row indices, column indices, and values of the nonzero matrix entries.

**Examples**

```python
>>> from scipy.sparse import csr_matrix, find
>>> A = csr_matrix([[7.0, 8.0, 0], [0, 0, 9.0]])
>>> find(A)
(array([0, 0, 1], dtype=int32), array([0, 1, 2], dtype=int32), array([7., 8., 9.]))
```

Identifying sparse matrices:
scipy.sparse.issparse

scipy.sparse.issparse(x)
Is x of a sparse matrix type?

Parameters

x  object to check for being a sparse matrix

Returns

bool  True if x is a sparse matrix, False otherwise

Notes

issparse and isspmatrix are aliases for the same function.

Examples

>>> from scipy.sparse import csr_matrix, isspmatrix
>>> isspmatrix(csr_matrix([[5]]))
True

>>> from scipy.sparse import isspmatrix
>>> isspmatrix(5)
False

scipy.sparse.isspmatrix

scipy.sparse.isspmatrix(x)
Is x of a sparse matrix type?

Parameters

x  object to check for being a sparse matrix

Returns

bool  True if x is a sparse matrix, False otherwise

Notes

issparse and isspmatrix are aliases for the same function.
Examples

```python
>>> from scipy.sparse import csr_matrix, isspmatrix
>>> isspmatrix(csr_matrix([[5]]))
True

>>> from scipy.sparse import isspmatrix
>>> isspmatrix(5)
False
```

`scipy.sparse.isspmatrix_csc`

`scipy.sparse.isspmatrix_csc(x)`  
Is x of csc_matrix type?

**Parameters**

- `x` : object to check for being a csc matrix

**Returns**

- `bool` : True if x is a csc matrix, False otherwise

Examples

```python
>>> from scipy.sparse import csc_matrix, isspmatrix_csc
>>> isspmatrix_csc(csc_matrix([[5]]))
True

>>> from scipy.sparse import csc_matrix, csr_matrix, isspmatrix_csc
>>> isspmatrix_csc(csr_matrix([[5]]))
False
```

`scipy.sparse.isspmatrix_csr`

`scipy.sparse.isspmatrix_csr(x)`  
Is x of csr_matrix type?

**Parameters**

- `x` : object to check for being a csr matrix

**Returns**

- `bool` : True if x is a csr matrix, False otherwise

Examples

```python
>>> from scipy.sparse import csr_matrix, isspmatrix_csr
>>> isspmatrix_csr(csr_matrix([[5]]))
True

>>> from scipy.sparse import csc_matrix, csr_matrix, isspmatrix_csc
>>> isspmatrix_csc(csc_matrix([[5]]))
False
```
scipy.sparse.isspmatrix_bsr
scipy.sparse.isspmatrix_bsr(x)
Is x of a bsr_matrix type?

Parameters
x object to check for being a bsr matrix

Returns
bool True if x is a bsr matrix, False otherwise

Examples
>>> from scipy.sparse import bsr_matrix, isspmatrix_bsr
>>> isspmatrix_bsr(bsr_matrix([[5]]))
True

>>> from scipy.sparse import bsr_matrix, csr_matrix, isspmatrix_bsr
>>> isspmatrix_bsr(csr_matrix([[5]]))
False

scipy.sparse.isspmatrix_lil
scipy.sparse.isspmatrix_lil(x)
Is x of lil_matrix type?

Parameters
x object to check for being a lil matrix

Returns
bool True if x is a lil matrix, False otherwise

Examples
>>> from scipy.sparse import lil_matrix, isspmatrix_lil
>>> isspmatrix_lil(lil_matrix([[5]]))
True

>>> from scipy.sparse import lil_matrix, csr_matrix, isspmatrix_lil
>>> isspmatrix_lil(csr_matrix([[5]]))
False

scipy.sparse.isspmatrix_dok
scipy.sparse.isspmatrix_dok(x)
Is x of dok_matrix type?

Parameters
x object to check for being a dok matrix

Returns
bool True if x is a dok matrix, False otherwise
Examples

```python
>>> from scipy.sparse import dok_matrix, isspmatrix_dok
>>> isspmatrix_dok(dok_matrix([[5]]))
True
```

```python
>>> from scipy.sparse import dok_matrix, csr_matrix, isspmatrix_dok
>>> isspmatrix_dok(csr_matrix([[5]]))
False
```

scipy.sparse.isspmatrix_coo

`scipy.sparse.isspmatrix_coo(x)`

Is x of coo_matrix type?

Parameters

- `x` : object to check for being a coo matrix

Returns

- `bool` : True if x is a coo matrix, False otherwise

Examples

```python
>>> from scipy.sparse import coo_matrix, isspmatrix_coo
>>> isspmatrix_coo(coo_matrix([[5]]))
True
```

```python
>>> from scipy.sparse import coo_matrix, csr_matrix, isspmatrix_coo
>>> isspmatrix_coo(csr_matrix([[5]]))
False
```

scipy.sparse.isspmatrix_dia

`scipy.sparse.isspmatrix_dia(x)`

Is x of dia_matrix type?

Parameters

- `x` : object to check for being a dia matrix

Returns

- `bool` : True if x is a dia matrix, False otherwise

Examples

```python
>>> from scipy.sparse import dia_matrix, isspmatrix_dia
>>> isspmatrix_dia(dia_matrix([[5]]))
True
```

```python
>>> from scipy.sparse import dia_matrix, csr_matrix, isspmatrix_dia
>>> isspmatrix_dia(csr_matrix([[5]]))
False
```

### 6.22.2 Usage information

There are seven available sparse matrix types:

1. `csc_matrix`: Compressed Sparse Column format
2. `csr_matrix`: Compressed Sparse Row format
3. `bsr_matrix`: Block Sparse Row format
4. `lil_matrix`: List of Lists format
5. `dok_matrix`: Dictionary of Keys format
6. `coo_matrix`: COOrdinate format (aka IJV, triplet format)
7. `dia_matrix`: DIAgonal format

To construct a matrix efficiently, use either `dok_matrix` or `lil_matrix`. The `lil_matrix` class supports basic slicing and fancy indexing with a similar syntax to NumPy arrays. As illustrated below, the COO format may also be used to efficiently construct matrices. Despite their similarity to NumPy arrays, it is **strongly discouraged** to use NumPy functions directly on these matrices because NumPy may not properly convert them for computations, leading to unexpected (and incorrect) results. If you do want to apply a NumPy function to these matrices, first check if SciPy has its own implementation for the given sparse matrix class, or **convert the sparse matrix to a NumPy array** (e.g. using the `toarray()` method of the class) before applying the method.

To perform manipulations such as multiplication or inversion, first convert the matrix to either CSC or CSR format. The `lil_matrix` format is row-based, so conversion to CSR is efficient, whereas conversion to CSC is less so.

All conversions among the CSR, CSC, and COO formats are efficient, linear-time operations.
Matrix vector product

To do a vector product between a sparse matrix and a vector simply use the matrix `dot` method, as described in its docstring:

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

**Warning:** As of NumPy 1.7, `np.dot` is not aware of sparse matrices, therefore using it will result on unexpected results or errors. The corresponding dense array should be obtained first instead:

```python
>>> np.dot(A.toarray(), v)
array([ 1, -3, -1], dtype=int64)
```

but then all the performance advantages would be lost.

The CSR format is specially suitable for fast matrix vector products.

**Example 1**

Construct a 1000x1000 lil_matrix and add some values to it:

```python
>>> from scipy.sparse import lil_matrix
>>> from scipy.sparse.linalg import spsolve
>>> from numpy.linalg import solve, norm
>>> from numpy.random import rand

>>> A = lil_matrix((1000, 1000))
>>> A[0, :100] = rand(100)
>>> A[1, 100:200] = A[0, :100]
>>> A.setdiag(rand(1000))

Now convert it to CSR format and solve $Ax = b$ for $x$:

```python
>>> A = A.tocsr()
>>> b = rand(1000)
>>> x = spsolve(A, b)
```

Convert it to a dense matrix and solve, and check that the result is the same:

```python
>>> x_ = solve(A.toarray(), b)
```

Now we can compute norm of the error with:

```python
>>> err = norm(x-x_)
>>> err < 1e-10
True
```

It should be small :)
Example 2

Construct a matrix in COO format:

```python
>>> from scipy import sparse
>>> from numpy import array
>>> I = array([0,3,1,0])
>>> J = array([0,3,1,2])
>>> V = array([4,5,7,9])
>>> A = sparse.coo_matrix((V,(I,J)),shape=(4,4))
```

Notice that the indices do not need to be sorted.

Duplicate (i,j) entries are summed when converting to CSR or CSC.

```python
>>> I = array([0,0,1,3,1,0])
>>> J = array([0,2,1,3,1,0])
>>> V = array([1,1,1,1,1,1])
>>> B = sparse.coo_matrix((V,(I,J)),shape=(4,4)).tocsr()
```

This is useful for constructing finite-element stiffness and mass matrices.

Further Details

CSR column indices are not necessarily sorted. Likewise for CSC row indices. Use the .sorted_indices() and .sort_indices() methods when sorted indices are required (e.g. when passing data to other libraries).

6.23 Sparse linear algebra (scipy.sparse.linalg)

6.23.1 Abstract linear operators

```python
LinearOperator(dtype, shape)  Common interface for performing matrix vector products
aslinearoperator(A)          Return A as a LinearOperator.
```

scipy.sparse.linalg.LinearOperator

class scipy.sparse.linalg.LinearOperator(dtype, shape)

Common interface for performing matrix vector products

Many iterative methods (e.g. cg, gmres) do not need to know the individual entries of a matrix to solve a linear system A*x=b. Such solvers only require the computation of matrix vector products, A*v where v is a dense vector. This class serves as an abstract interface between iterative solvers and matrix-like objects.

To construct a concrete LinearOperator, either pass appropriate callables to the constructor of this class, or subclass it.

A subclass must implement either one of the methods _matvec and _matmat, and the attributes/properties shape (pair of integers) and dtype (may be None). It may call the __init__ on this class to have these attributes validated. Implementing _matvec automatically implements _matmat (using a naive algorithm) and vice-versa.

Optionally, a subclass may implement _rmatvec or _adjoint to implement the Hermitian adjoint (conjugate transpose). As with _matvec and _matmat, implementing either _rmatvec or _adjoint implements the
other automatically. Implementing _adjoint is preferable; _rmatvec is mostly there for backwards compatibility.

**Parameters**

- matvec [callable f(v)] Returns returns A * v.
- rmatvec [callable f(v)] Returns A^H * v, where A^H is the conjugate transpose of A.
- matmat [callable f(V)] Returns A * V, where V is a dense matrix with dimensions (N,K).
- dtype [dtype] Data type of the matrix.

**See also:**

`aslinearoperator`  
Construct LinearOperators

**Notes**

The user-defined matvec() function must properly handle the case where v has shape (N,) as well as the (N,1) case. The shape of the return type is handled internally by LinearOperator.

LinearOperator instances can also be multiplied, added with each other and exponentiated, all lazily: the result of these operations is always a new, composite LinearOperator, that defers linear operations to the original operators and combines the results.

More details regarding how to subclass a LinearOperator and several examples of concrete LinearOperator instances can be found in the external project PyLops.

**Examples**

```python
>>> import numpy as np
>>> from scipy.sparse.linalg import LinearOperator
>>> def mv(v):
...     return np.array([2*v[0], 3*v[1]])
... >>> A = LinearOperator((2,2), matvec=mv)
>>> A  
<2x2 _CustomLinearOperator with dtype=float64>
>>> A.matvec(np.ones(2))
array([ 2.,  3.])
>>> A * np.ones(2)
array([ 2.,  3.])
```

**Attributes**

- args [tuple] For linear operators describing products etc. of other linear operators, the operands of the binary operation.

**Methods**

```python
__call__(self, x)   # Call self as a function.
```
### Table 182 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>

</tr>
</tbody>
</table>

#### scipy.sparse.linalg.LinearOperator.__call__

LinearOperator.__call__(self, x)

Call self as a function.

#### scipy.sparse.linalg.LinearOperator.adjoint

LinearOperator.adjoint(self)

Hermitian adjoint.

Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.

Can be abbreviated self.H instead of self.adjoint().

Return

#### scipy.sparse.linalg.LinearOperator.dot

LinearOperator.dot(self, x)

Matrix-matrix or matrix-vector multiplication.

Parameters

- x [array_like] 1-d or 2-d array, representing a vector or matrix.

Returns

- Ax [array] 1-d or 2-d array (depending on the shape of x) that represents the result of applying this linear operator on x.

#### scipy.sparse.linalg.LinearOperator.matmat

LinearOperator.matmat(self, X)

Matrix-matrix multiplication.

Performs the operation y=A*X where A is an MxN linear operator and X dense N*K matrix or ndarray.

Parameters

- X [[matrix, ndarray]] An array with shape (N,K).

Returns

- Y [[matrix, ndarray]] A matrix or ndarray with shape (M,K) depending on the type of the X argument.

Notes

This matmat wraps any user-specified matmat routine or overridden _matmat method to ensure that y has the correct type.
scipy.sparse.linalg.LinearOperator.matvec

LinearOperator.matvec(self, x)

Matrix-vector multiplication.

Perform the operation y=A*x where A is an MxN linear operator and x is a column vector or 1-d array.

Parameters

- x
  - [matrix, ndarray] An array with shape (N,) or (N,1).

Returns

- y
  - [matrix, ndarray] A matrix or ndarray with shape (M,) or (M,1) depending on the type and shape of the x argument.

Notes

This matvec wraps the user-specified matvec routine or overridden _matvec method to ensure that y has the correct shape and type.

scipy.sparse.linalg.LinearOperator.rmatvec

LinearOperator.rmatvec(self, x)

Adjoint matrix-vector multiplication.

Perform the operation y = A^H * x where A is an MxN linear operator and x is a column vector or 1-d array.

Parameters

- x
  - [matrix, ndarray] An array with shape (M,) or (M,1).

Returns

- y
  - [matrix, ndarray] A matrix or ndarray with shape (N,) or (N,1) depending on the type and shape of the x argument.

Notes

This rmatvec wraps the user-specified rmatvec routine or overridden _rmatvec method to ensure that y has the correct shape and type.

scipy.sparse.linalg.LinearOperator.transpose

LinearOperator.transpose(self)

Transpose this linear operator.

Returns a LinearOperator that represents the transpose of this one. Can be abbreviated self.T instead of self.transpose().

__mul__

scipy.sparse.linalg.aslinearoperator

scipy.sparse.linalg.aslinearoperator(A)

Return A as a LinearOperator.

‘A’ may be any of the following types:
• ndarray
• matrix
• sparse matrix (e.g. csr_matrix, lil_matrix, etc.)
• LinearOperator
• An object with .shape and .matvec attributes

See the LinearOperator documentation for additional information.

Notes

If ‘A’ has no .dtype attribute, the data type is determined by calling \texttt{LinearOperator.matvec} - set the .dtype attribute to prevent this call upon the linear operator creation.

Examples

```python
>>> from scipy.sparse.linalg import aslinearoperator
>>> M = np.array([[1,2,3],[4,5,6]], dtype=np.int32)
>>> aslinearoperator(M)
<2x3 MatrixLinearOperator with dtype=int32>
```

6.23.2 Matrix Operations

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inv(A)</td>
<td>Compute the inverse of a sparse matrix</td>
</tr>
<tr>
<td>expm(A)</td>
<td>Compute the matrix exponential using Pade approxima-</td>
</tr>
<tr>
<td>expm_multiply(A, B[, start, stop, num, endpoint])</td>
<td>Compute the action of the matrix exponential of A on B.</td>
</tr>
</tbody>
</table>

\texttt{scipy.sparse.linalg.inv}

\texttt{scipy.sparse.linalg.inv(A)}

Compute the inverse of a sparse matrix

\textbf{Parameters}

\begin{itemize}
\item \texttt{A} [(M,M) ndarray or sparse matrix] square matrix to be inverted
\end{itemize}

\textbf{Returns}

\begin{itemize}
\item \texttt{Ainv} [(M,M) ndarray or sparse matrix] inverse of \texttt{A}
\end{itemize}

\textbf{Notes}

This computes the sparse inverse of \texttt{A}. If the inverse of \texttt{A} is expected to be non-sparse, it will likely be faster to convert \texttt{A} to dense and use \texttt{scipy.linalg.inv}.  

6.23. Sparse linear algebra (\texttt{scipy.sparse.linalg})
Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import inv
>>> A = csc_matrix([[1., 0.], [1., 2.]])
>>> Ainv = inv(A)
>>> Ainv
<2x2 sparse matrix of type '<class 'numpy.float64'>'
    with 3 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv)
<2x2 sparse matrix of type '<class 'numpy.float64'>'
    with 2 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv).todense()
matrix([[ 1., 0.],
        [ 0., 1.]])
```

New in version 0.12.0.

**scipy.sparse.linalg.expm**

`scipy.sparse.linalg.expm(A)`

Compute the matrix exponential using Pade approximation.

**Parameters**

- `A` : [(M,M) array_like or sparse matrix] 2D Array or Matrix (sparse or dense) to be exponentiated

**Returns**

- `expA` : [(M,M) ndarray] Matrix exponential of `A`

**Notes**

This is algorithm (6.1) which is a simplification of algorithm (5.1).

New in version 0.12.0.

**References**

[1]

**Examples**

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import expm
>>> A = csc_matrix([[1, 0, 0], [0, 2, 0], [0, 0, 3]])
>>> A.todense()
matrix([[1, 0, 0],
        [0, 2, 0],
        [0, 0, 3]], dtype=int64)
>>> Aexp = expm(A)
```
scipy.sparse.linalg.expm_multiply

__scipy.sparse.linalg.expm_multiply__(\(A, B, \text{start=None, stop=None, num=None, endpoint=None}\))

Compute the action of the matrix exponential of \(A\) on \(B\).

**Parameters**

- **A** [transposable linear operator] The operator whose exponential is of interest.
- **B** [ndarray] The matrix or vector to be multiplied by the matrix exponential of \(A\).
- **start** [scalar, optional] The starting time point of the sequence.
- **stop** [scalar, optional] The end time point of the sequence, unless endpoint is set to False. In that case, the sequence consists of all but the last of \(\text{num} + 1\) evenly spaced time points, so that \(\text{stop}\) is excluded. Note that the step size changes when endpoint is False.
- **num** [int, optional] Number of time points to use.
- **endpoint** [bool, optional] If True, \(\text{stop}\) is the last time point. Otherwise, it is not included.

**Returns**

- **expm_A_B** [ndarray] The result of the action \(e^{tA}B\).

**Notes**

The optional arguments defining the sequence of evenly spaced time points are compatible with the arguments of `numpy.linspace`.

The output ndarray shape is somewhat complicated so I explain it here. The ndim of the output could be either 1, 2, or 3. It would be 1 if you are computing the expm action on a single vector at a single time point. It would be 2 if you are computing the expm action on a vector at multiple time points, or if you are computing the expm action on a matrix at a single time point. It would be 3 if you want the action on a matrix with multiple columns at multiple time points. If multiple time points are requested, expm_A_B[0] will always be the action of the expm at the first time point, regardless of whether the action is on a vector or a matrix.

**References**

[1], [2]

**Examples**

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import expm, expm_multiply
>>> A = csc_matrix([[1, 0], [0, 1]])
```
>>> A.todense()
matrix([[1, 0],
        [0, 1]], dtype=int64)
>>> B = np.array([np.exp(-1.), np.exp(-2.)])
>>> B
array([ 0.36787944, 0.13533528])
>>> expm_multiply(A, B, start=1, stop=2, num=3, endpoint=True)
array([[ 1.       , 0.36787944],
        [ 1.64872127, 0.60653066],
        [ 2.71828183, 1.       ]])
>>> expm(A).dot(B)  # Verify 1st timestep
array([ 1.0, 0.36787944])
>>> expm(1.5*A).dot(B)  # Verify 2nd timestep
array([ 1.64872127, 0.60653066])
>>> expm(2*A).dot(B)  # Verify 3rd timestep
array([ 2.71828183, 1.0])

6.23.3 Matrix norms

<table>
<thead>
<tr>
<th>norm(x[, ord, axis])</th>
<th>Norm of a sparse matrix</th>
</tr>
</thead>
<tbody>
<tr>
<td>onenormest(A[, t, itmax, compute_v, compute_w])</td>
<td>Compute a lower bound of the 1-norm of a sparse matrix.</td>
</tr>
</tbody>
</table>

**scipy.sparse.linalg.norm**

scipy.sparse.linalg.norm(x, ord=None, axis=None)

Norm of a sparse matrix

This function is able to return one of seven different matrix norms, depending on the value of the ord parameter.

**Parameters**

- x 
  [a sparse matrix] Input sparse matrix.
- ord 
- axis 
  [\{int, 2-tuple of ints, None\}, optional] If axis is an integer, it specifies the axis of x along which to compute the vector norms. If axis is a 2-tuple, it specifies the axes that hold 2-D matrices, and the matrix norms of these matrices are computed. If axis is None then either a vector norm (when x is 1-D) or a matrix norm (when x is 2-D) is returned.

**Returns**

- n 
  [float or nd array]

**Notes**

Some of the ord are not implemented because some associated functions like, _multi_svd_norm, are not yet available for sparse matrix.

This docstring is modified based on numpy.linalg.norm. [https://github.com/numpy/numpy/blob/master/numpy/linalg/linalg.py](https://github.com/numpy/numpy/blob/master/numpy/linalg/linalg.py)

The following norms can be calculated:
The Frobenius norm is given by [1]:

\[ \|A\|_F = \left( \sum_{i,j} |a_{i,j}|^2 \right)^{1/2} \]

References

[1]

Examples

```python
>>> from scipy.sparse import *
>>> import numpy as np
>>> from scipy.sparse.linalg import norm
>>> a = np.arange(9) - 4
>>> a
array([-4, -3, -2, -1,  0,  1,  2,  3,  4])
>>> b = a.reshape((3, 3))
>>> b
array([[-4, -3, -2],
       [-1,  0,  1],
       [ 2,  3,  4]])

>>> b = csr_matrix(b)
>>> norm(b)
7.74596692414834
>>> norm(b, 'fro')
7.74596692414834
>>> norm(b, np.inf)
9
>>> norm(b, -np.inf)
2
>>> norm(b, 1)
7
>>> norm(b, -1)
6
```
scipy.sparse.linalg.onenormest

scipy.sparse.linalg.onenormest (A, t=2, itmax=5, compute_v=False, compute_w=False)

Compute a lower bound of the 1-norm of a sparse matrix.

Parameters

A [ndarray or other linear operator] A linear operator that can be transposed and that can produce matrix products.

t [int, optional] A positive parameter controlling the tradeoff between accuracy versus time and memory usage. Larger values take longer and use more memory but give more accurate output.

itmax [int, optional] Use at most this many iterations.

compute_v [bool, optional] Request a norm-maximizing linear operator input vector if True.

compute_w [bool, optional] Request a norm-maximizing linear operator output vector if True.

Returns

est [float] An underestimate of the 1-norm of the sparse matrix.

v [ndarray, optional] The vector such that \|Av\|_1 == est*\|v\|_1. It can be thought of as an input to the linear operator that gives an output with particularly large norm.

w [ndarray, optional] The vector Av which has relatively large 1-norm. It can be thought of as an output of the linear operator that is relatively large in norm compared to the input.

Notes

This is algorithm 2.4 of [1].

In [2] it is described as follows. “This algorithm typically requires the evaluation of about 4t matrix-vector products and almost invariably produces a norm estimate (which is, in fact, a lower bound on the norm) correct to within a factor 3.”

New in version 0.13.0.

[1], [2]

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import onenormest
>>> A = csc_matrix([[1., 0., 0.], [5., 8., 2.], [0., -1., 0.]], dtype=float)
>>> A.todense()
matrix([[ 1.,  0.,  0.],
        [ 5.,  8.,  2.],
        [ 0., -1.,  0.]])
>>> onenormest(A)
9.0
>>> np.linalg.norm(A.todense(), ord=1)
9.0
```
6.23.4 Solving linear problems

Direct methods for linear equation systems:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>spsolve(A, b[, permc_spec, use_umfpack])</code></td>
<td>Solve the sparse linear system $Ax=b$, where $b$ may be a vector or a matrix.</td>
</tr>
<tr>
<td><code>spsolve_triangular(A, b[, lower, …])</code></td>
<td>Solve the equation $Ax = b$ for $x$, assuming $A$ is a triangular matrix.</td>
</tr>
<tr>
<td><code>factorized(A)</code></td>
<td>Return a function for solving a sparse linear system, with $A$ pre-factorized.</td>
</tr>
<tr>
<td><code>MatrixRankWarning</code></td>
<td></td>
</tr>
<tr>
<td><code>use_solver(**kwargs)</code></td>
<td>Select default sparse direct solver to be used.</td>
</tr>
</tbody>
</table>

**scipy.sparse.linalg.spsolve**

scipy.sparse.linalg.spsolve($A$, $b$, permc_spec=None, use_umfpack=True)

Solve the sparse linear system $Ax=b$, where $b$ may be a vector or a matrix.

**Parameters**

- $A$ [ndarray or sparse matrix] The square matrix $A$ will be converted into CSC or CSR form.
- $b$ [ndarray or sparse matrix] The matrix or vector representing the right hand side of the equation. If a vector, $b$.shape must be ($n,$) or ($n,$ 1).

- `permc_spec` [str, optional] How to permute the columns of the matrix for sparsity preservation. (default: ‘COLAMD’)
  - `NATURAL`: natural ordering.
  - `MMD_ATA`: minimum degree ordering on the structure of $A^TA$.
  - `MMD_AT_PLUS_A`: minimum degree ordering on the structure of $A^T+A$.
  - `COLAMD`: approximate minimum degree column ordering.

- `use_umfpack` [bool, optional] if True (default) then use umfpack for the solution. This is only referenced if $b$ is a vector and scikit-umfpack is installed.

**Returns**

- $x$ [ndarray or sparse matrix] the solution of the sparse linear equation. If $b$ is a vector, then $x$ is a vector of size $A$.shape[1] If $b$ is a matrix, then $x$ is a matrix of size ($A$.shape[1], $b$.shape[1]).

**Notes**

For solving the matrix expression $AX = B$, this solver assumes the resulting matrix $X$ is sparse, as is often the case for very sparse inputs. If the resulting $X$ is dense, the construction of this sparse result will be relatively expensive. In that case, consider converting $A$ to a dense matrix and using scipy.linalg.solve or its variants.

**Examples**

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spsolve
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> B = csc_matrix([[2, 0], [-1, 0], [2, 0]], dtype=float)
>>> x = spsolve(A, B)
```

(continues on next page)
```python
>>> np.allclose(A.dot(x).todense(), B.todense())
True
```

**scipy.sparse.linalg.spsolve_triangular**

`scipy.sparse.linalg.spsolve_triangular(A, b, lower=True, overwrite_A=False, overwrite_b=False)`

Solve the equation $A x = b$ for $x$, assuming $A$ is a triangular matrix.

**Parameters**

- **A**: [(M, M) sparse matrix] A sparse square triangular matrix. Should be in CSR format.
- **b**: [(M,) or (M, N) array_like] Right-hand side matrix in $A x = b$
- **lower**: [bool, optional] Whether $A$ is a lower or upper triangular matrix. Default is lower triangular matrix.
- **overwrite_A**: [bool, optional] Allow changing $A$. The indices of $A$ are going to be sorted and zero entries are going to be removed. Enabling gives a performance gain. Default is False.
- **overwrite_b**: [bool, optional] Allow overwriting data in $b$. Enabling gives a performance gain. Default is False. If `overwrite_b` is True, it should be ensured that $b$ has an appropriate dtype to be able to store the result.

**Returns**

- **x**: [(M,) or (M, N) ndarray] Solution to the system $A x = b$. Shape of return matches shape of $b$.

**Raises**

- **LinAlgError**
  - If $A$ is singular or not triangular.
- **ValueError**
  - If shape of $A$ or shape of $b$ do not match the requirements.

**Notes**

New in version 0.19.0.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.linalg import spsolve_triangular
>>> A = csr_matrix([[3, 0, 0], [1, -1, 0], [2, 0, 1]], dtype=float)
>>> B = np.array([[2, 0], [-1, 0], [2, 0]], dtype=float)
>>> x = spsolve_triangular(A, B)
>>> np.allclose(A.dot(x), B)
True
```
scipy.sparse.linalg.factorized

scipy.sparse.linalg.factorized(A)
Return a function for solving a sparse linear system, with A pre-factorized.

Parameters
A : (N, N) array_like Input.

Returns
solve : [callable] To solve the linear system of equations given in A, the solve callable should be passed an ndarray of shape (N,).

Examples

```python
>>> from scipy.sparse.linalg import factorized
>>> A = np.array([[[ 3.,  2., -1.],
                 ..., [ 2., -2.,  4.],
                 ..., [-1.,  0.5, -1.]]])
>>> solve = factorized(A)  # Makes LU decomposition.
>>> rhs1 = np.array([1, -2, 0])
>>> solve(rhs1)  # Uses the LU factors.
array([ 1., -2., -2.])
```

scipy.sparse.linalg.MatrixRankWarning

exception  scipy.sparse.linalg.MatrixRankWarning

with_traceback()  
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

scipy.sparse.linalg.use_solver

scipy.sparse.linalg.use_solver(**kwargs)
Select default sparse direct solver to be used.

Parameters
useUmfpack : [bool, optional] Use UMFPACK over SuperLU. Has effect only if scikits.umfpack is installed. Default: True
assumeSortedIndices : [bool, optional] Allow UMFPACK to skip the step of sorting indices for a CSR/CSC matrix. Has effect only if useUmfpack is True and scikits.umfpack is installed. Default: False

Notes
The default sparse solver is umfpack when available (scikits.umfpack is installed). This can be changed by passing useUmfpack = False, which then causes the always present SuperLU based solver to be used.

Umfpack requires a CSR/CSC matrix to have sorted column/row indices. If sure that the matrix fulfills this, pass assumeSortedIndices=True to gain some speed.
Iterative methods for linear equation systems:

- **bicg**\(A, b, [x_0, \text{tol}, \text{maxiter}, M, \text{callback}, \text{atol}]\) Use BIConjugate Gradient iteration to solve \(Ax = b\).
- **bicgstab**\(A, b, [x_0, \text{tol}, \text{maxiter}, M, \ldots]\) Use BIConjugate Gradient STABilized iteration to solve \(Ax = b\).
- **cg**\(A, b, [x_0, \text{tol}, \text{maxiter}, M, \text{callback}, \text{atol}]\) Use Conjugate Gradient iteration to solve \(Ax = b\).
- **cgs**\(A, b, [x_0, \text{tol}, \text{maxiter}, M, \text{callback}, \text{atol}]\) Use Conjugate Gradient Squared iteration to solve \(Ax = b\).
- **gmres**\(A, b, [x_0, \text{tol}, \text{restart}, \text{maxiter}, M, \ldots]\) Use Generalized Minimal RESidual iteration to solve \(Ax = b\).
- **lgmres**\(A, b, [x_0, \text{tol}, \text{maxiter}, M, \ldots]\) Solve a matrix equation using the LGMRES algorithm.
- **minres**\(A, b, [x_0, \text{shift}, \text{tol}, \text{maxiter}, M, \ldots]\) Use MINimum RESidual iteration to solve \(Ax = b\).
- **qmr**\(A, b, [x_0, \text{tol}, \text{maxiter}, M_1, M_2, \ldots]\) Use Quasi-Minimal Residual iteration to solve \(Ax = b\).
- **gcrotmk**\(A, b, [x_0, \text{tol}, \text{maxiter}, M, \ldots]\) Solve a matrix equation using flexible GCROT(m,k) algorithm.

**scipy.sparse.linalg.bicg**

Use BIConjugate Gradient iteration to solve \(Ax = b\).

### Parameters

- **A** [[sparse matrix, dense matrix, LinearOperator]] The real or complex N-by-N matrix of the linear system. Alternatively, \(A\) can be a linear operator which can produce \(Ax\) and \(A^T x\) using, e.g., `scipy.sparse.linalg.LinearOperator`.
- **b** [[array, matrix]] Right hand side of the linear system. Has shape (N,) or (N,1).

### Returns
- **x** [[array, matrix]] The converged solution.
- **info** [integer]

**Provides convergence information:**

- 0 : successful exit
- >0 : convergence to tolerance not achieved, number of iterations
- <0 : illegal input or breakdown

### Other Parameters

- **x0** [[array, matrix]] Starting guess for the solution.
- **tol, atol** [float, optional] Tolerances for convergence, \(\text{norm(residual)} \leq \max(\text{tol} \times \text{norm(b)}, \text{atol})\). The default for \(\text{atol}\) is 'legacy', which emulates a different legacy behavior.

**Warning**: The default value for \(\text{atol}\) will be changed in a future release. For future compatibility, specify \(\text{atol}\) explicitly.

- **maxiter** [integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **M** [[sparse matrix, dense matrix, LinearOperator]] Preconditioner for \(A\). The preconditioner should approximate the inverse of \(A\). Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- **callback** [function] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.
scipy.sparse.linalg.bicgstab

Use BiConjugate Gradient STABilized iteration to solve $Ax = b$.

**Parameters**

- $A$ ([sparse matrix, dense matrix, LinearOperator]) The real or complex $N$-by-$N$ matrix of the linear system. Alternatively, $A$ can be a linear operator which can produce $Ax$ using, e.g., scipy.sparse.linalg.LinearOperator.
- $b$ ([array, matrix]) Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- $x$ ([array, matrix]) The converged solution.
- $info$ [integer]

Provides convergence information:

- $0$ : successful exit
- $>0$ : convergence to tolerance not achieved, number of iterations
- $<0$ : illegal input or breakdown

**Other Parameters**

- $x0$ ([array, matrix]) Starting guess for the solution.
- $tol$, $atol$ [float, optional] Tolerances for convergence, $\text{norm(residual)} \leq \max(tol*\text{norm(b)}, \text{atol})$. The default for $atol$ is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for $atol$ will be changed in a future release. For future compatibility, specify $atol$ explicitly.

- $maxiter$ [integer] Maximum number of iterations. Iteration will stop after $maxiter$ steps even if the specified tolerance has not been achieved.
- $M$ ([sparse matrix, dense matrix, LinearOperator]) Preconditioner for $A$. The preconditioner should approximate the inverse of $A$. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- $callback$ [function] User-supplied function to call after each iteration. It is called as $callback(xk)$, where $xk$ is the current solution vector.

scipy.sparse.linalg.cg

Use Conjugate Gradient iteration to solve $Ax = b$.

**Parameters**

- $A$ ([sparse matrix, dense matrix, LinearOperator]) The real or complex $N$-by-$N$ matrix of the linear system. $A$ must represent a hermitian, positive definite matrix. Alternatively, $A$ can be a linear operator which can produce $Ax$ using, e.g., scipy.sparse.linalg.LinearOperator.
- $b$ ([array, matrix]) Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- $x$ ([array, matrix]) The converged solution.
- $info$ [integer]
Provides convergence information:

- 0: successful exit
- >0: convergence to tolerance not achieved, number of iterations
- <0: illegal input or breakdown

Other Parameters

- **x0** [{array, matrix}] Starting guess for the solution.
- **tol, atol** [float, optional] Tolerances for convergence, \( \text{norm(residual)} \leq \max(\text{tol*norm(b)}, \text{atol}) \). The default for atol is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for atol will be changed in a future release. For future compatibility, specify atol explicitly.

- **maxiter** [integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **M** [{sparse matrix, dense matrix, LinearOperator}] Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- **callback** [function] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

**scipy.sparse.linalg.cgs**

```python
scipy.sparse.linalg.cgs(A, b, x0=None, tol=1e-05, maxiter=None, M=None, callback=None, atol=None)
```

Use Conjugate Gradient Squared iteration to solve \( Ax = b \).

**Parameters**

- **A** [{sparse matrix, dense matrix, LinearOperator}] The real-valued N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce Ax using, e.g., scipy.sparse.linalg.LinearOperator.
- **b** [{array, matrix}] Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- **x** [{array, matrix}] The converged solution.
- **info** [integer]

Provides convergence information:

- 0: successful exit
- >0: convergence to tolerance not achieved, number of iterations
- <0: illegal input or breakdown

Other Parameters

- **x0** [{array, matrix}] Starting guess for the solution.
- **tol, atol** [float, optional] Tolerances for convergence, \( \text{norm(residual)} \leq \max(\text{tol*norm(b)}, \text{atol}) \). The default for atol is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for atol will be changed in a future release. For future compatibility, specify atol explicitly.

- **maxiter** [integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
**M**

[[sparse matrix, dense matrix, LinearOperator]] Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback**

[function] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

### scipy.sparse.linalg.gmres

**scipy.sparse.linalg.gmres** (A, b, x0=None, tol=1e-05, maxiter=None, M=None, callback=None, restrt=None, atol=None)

Use Generalized Minimal RESidual iteration to solve \( Ax = b \).

**Parameters**

- **A**
  
  [[sparse matrix, dense matrix, LinearOperator]] The real or complex N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce \( Ax \) using, e.g., `scipy.sparse.linalg.LinearOperator`.

- **b**
  
  [[array, matrix]] Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- **x**
  
  [[array, matrix]] The converged solution.

- **info**
  
  [int]

  Provides convergence information:

  - 0 : successful exit
  - >0: convergence to tolerance not achieved, number of iterations
  - <0 : illegal input or breakdown

**Other Parameters**

- **x0**
  
  [[array, matrix]] Starting guess for the solution (a vector of zeros by default).

- **tol, atol**
  
  [float, optional] Tolerances for convergence, \( \text{norm(residual)} \leq \max(\text{tol} \times \text{norm(b)}, \text{atol}) \). The default for atol is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for atol will be changed in a future release. For future compatibility, specify atol explicitly.

- **restart**
  
  [int, optional] Number of iterations between restarts. Larger values increase iteration cost, but may be necessary for convergence. Default is 20.

- **maxiter**
  
  [int, optional] Maximum number of iterations (restart cycles). Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

- **M**
  
  [[sparse matrix, dense matrix, LinearOperator]] Inverse of the preconditioner of A. M should approximate the inverse of A and be easy to solve for (see Notes). Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance. By default, no preconditioner is used.

- **callback**
  
  [function] User-supplied function to call after each iteration. It is called as callback(rk), where rk is the current residual vector.

- **restrt**
  
  [int, optional] DEPRECATED - use restart instead.

**See also:**

`LinearOperator`

---

6.23. Sparse linear algebra (**scipy.sparse.linalg**)
Notes

A preconditioner, $P$, is chosen such that $P$ is close to $A$ but easy to solve for. The preconditioner parameter required by this routine is $M = P^{-1}$. The inverse should preferably not be calculated explicitly. Rather, use the following template to produce $M$:

```python
# Construct a linear operator that computes $P^{-1} \times x$.
import scipy.sparse.linalg as spla
M_x = lambda x: spla.spsolve(P, x)
M = spla.LinearOperator((n, n), M_x)
```

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import gmres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = gmres(A, b)
>>> print(exitCode)  # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

`scipy.sparse.linalg.lgmres`

The LGMRES algorithm [1] [2] is designed to avoid some problems in the convergence in restarted GMRES, and often converges in fewer iterations.

Parameters

- **A** ([sparse matrix, dense matrix, LinearOperator]) The real or complex $N$-by-$N$ matrix of the linear system. Alternatively, $A$ can be a linear operator which can produce $Ax$ using, e.g., `scipy.sparse.linalg.LinearOperator`.
- **b** ([array, matrix]) Right hand side of the linear system. Has shape $(N,)$ or $(N,1)$.
- **x0** ([array, matrix]) Starting guess for the solution.
- **tol, atol** [float, optional] Tolerances for convergence, $\| \text{residual} \| \leq \max(\text{tol} \times \| b \|, \text{atol})$. The default for `atol` is `tol`.
- **maxiter** [int, optional] Maximum number of iterations. Iteration will stop after `maxiter` steps even if the specified tolerance has not been achieved.
- **M** ([sparse matrix, dense matrix, LinearOperator], optional) Preconditioner for $A$. The preconditioner should approximate the inverse of $A$. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

Warning: The default value for `atol` will be changed in a future release. For future compatibility, specify `atol` explicitly.
callback  [function, optional] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

inner_m  [int, optional] Number of inner GMRES iterations per each outer iteration.

outer_k  [int, optional] Number of vectors to carry between inner GMRES iterations. According to [1], good values are in the range of 1...3. However, note that if you want to use the additional vectors to accelerate solving multiple similar problems, larger values may be beneficial.

outer_v  [list of tuples, optional] List containing tuples (v, Av) of vectors and corresponding matrix-vector products, used to augment the Krylov subspace, and carried between inner GMRES iterations. The element Av can be None if the matrix-vector product should be re-evaluated. This parameter is modified in-place by lgmres, and can be used to pass “guess” vectors in and out of the algorithm when solving similar problems.

store_outer_Av  [bool, optional] Whether LGMRES should store also A*v in addition to vectors v in the outer_v list. Default is True.

Returns

x  [array or matrix] The converged solution.
info  [int] Provides convergence information:
• 0 : successful exit
• >0 : convergence to tolerance not achieved, number of iterations
• <0 : illegal input or breakdown

Notes

The LGMRES algorithm [1] [2] is designed to avoid the slowing of convergence in restarted GMRES, due to alternating residual vectors. Typically, it often outperforms GMRES(m) of comparable memory requirements by some measure, or at least is not much worse.

Another advantage in this algorithm is that you can supply it with ‘guess’ vectors in the outer_v argument that augment the Krylov subspace. If the solution lies close to the span of these vectors, the algorithm converges faster. This can be useful if several very similar matrices need to be inverted one after another, such as in Newton-Krylov iteration where the Jacobian matrix often changes little in the nonlinear steps.

References

[1], [2]

Examples

```python
g>>> from scipy.sparse import csc_matrix
g>>> from scipy.sparse.linalg import lgmres
g>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
g>>> b = np.array([2, 4, -1], dtype=float)
g>>> x, exitCode = lgmres(A, b)
g>>> print(exitCode)  # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```
scipy.sparse.linalg.minres

\[
\text{scipy.sparse.linalg.minres}(A, b, x0=None, shift=0.0, tol=1e-05, maxiter=None, M=None, callback=None, show=False, check=False)
\]

Use MINimum RESidual iteration to solve \(Ax=b\)

MINRES minimizes \(\|Ax-b\|\) for a real symmetric matrix \(A\). Unlike the Conjugate Gradient method, \(A\) can be indefinite or singular.

If \(\text{shift} \neq 0\) then the method solves \((A - \text{shift}I)x = b\)

**Parameters**
- \(A\)  
  \([\text{sparse matrix, dense matrix, LinearOperator}]\) The real symmetric \(N\)-by-\(N\) matrix of the linear system. Alternatively, \(A\) can be a linear operator which can produce \(Ax\) using, e.g., `scipy.sparse.linalg.LinearOperator`.
- \(b\)  
  \([\text{array, matrix}]\) Right hand side of the linear system. Has shape \((N,)\) or \((N,1)\).

**Returns**
- \(x\)  
  \([\text{array, matrix}]\) The converged solution.
- \(\text{info}\)  
  \([\text{integer}]\) Provides convergence information:
  - 0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**
- \(x0\)  
  \([\text{array, matrix}]\) Starting guess for the solution.
- \(\text{tol}\)  
  \([\text{float}]\) Tolerance to achieve. The algorithm terminates when the relative residual is below \(\text{tol}\).
- \(\text{maxiter}\)  
  \([\text{integer}]\) Maximum number of iterations. Iteration will stop after \(\text{maxiter}\) steps even if the specified tolerance has not been achieved.
- \(M\)  
  \([\text{sparse matrix, dense matrix, LinearOperator}]\) Preconditioner for \(A\). The preconditioner should approximate the inverse of \(A\). Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- \(\text{callback}\)  
  \([\text{function}]\) User-supplied function to call after each iteration. It is called as \(\text{callback}(xk)\), where \(xk\) is the current solution vector.

scipy.sparse.linalg.qmr

\[
\text{scipy.sparse.linalg.qmr}(A, b, x0=None, tol=1e-05, maxiter=None, M1=None, M2=None, callback=None, atol=None)
\]

Use Quasi-Minimal Residual iteration to solve \(Ax = b\).

**Parameters**
- \(A\)  
  \([\text{sparse matrix, dense matrix, LinearOperator}]\) The real symmetric \(N\)-by-\(N\) matrix of the linear system. Alternatively, \(A\) can be a linear operator which can produce \(Ax\) using, e.g., `scipy.sparse.linalg.LinearOperator`.
- \(b\)  
  \([\text{array, matrix}]\) Right hand side of the linear system. Has shape \((N,)\) or \((N,1)\).

**Other Parameters**
- \(x0\)  
  \([\text{array, matrix}]\) Starting guess for the solution.
- \(\text{tol}\)  
  \([\text{float}]\) Tolerance to achieve. The algorithm terminates when the relative residual is below \(\text{tol}\).
- \(\text{maxiter}\)  
  \([\text{integer}]\) Maximum number of iterations. Iteration will stop after \(\text{maxiter}\) steps even if the specified tolerance has not been achieved.
- \(M1\)  
  \([\text{sparse matrix, dense matrix, LinearOperator}]\) Preconditioner for \(A\). The preconditioner should approximate the inverse of \(A\). Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- \(M2\)  
  \([\text{sparse matrix, dense matrix, LinearOperator}]\) Preconditioner for \(B\). If \(B = M1^{-1}M2\), the method converges at least as fast as CCG.
- \(\text{callback}\)  
  \([\text{function}]\) User-supplied function to call after each iteration. It is called as \(\text{callback}(xk)\), where \(xk\) is the current solution vector.

>>> print(exitCode)  # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

**scipy.sparse.linalg.gcrotmk**

`scipy.sparse.linalg.gcrotmk(A, b, x0=None, tol=1e-05, maxiter=1000, M=None, callback=None, m=20, k=None, CU=None, discard_C=False, truncate='oldest', atol=None)`

Solve a matrix equation using flexible GCROT(m,k) algorithm.

6.23. Sparse linear algebra (**scipy.sparse.linalg**) 1795
Parameters

A [{sparse matrix, dense matrix, LinearOperator}] The real or complex N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce Ax using, e.g., scipy.sparse.linalg.LinearOperator.

b [{array, matrix}] Right hand side of the linear system. Has shape (N,) or (N,1).

x0 [{array, matrix}] Starting guess for the solution.

tol, atol [float, optional] Tolerances for convergence, \( \text{norm}(\text{residual}) \leq \max(\text{tol} \times \text{norm}(b), \text{atol}) \). The default for atol is tol.

Warning: The default value for atol will be changed in a future release. For future compatibility, specify atol explicitly.

maxiter [int, optional] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

M [{sparse matrix, dense matrix, LinearOperator}, optional] Preconditioner for A. The preconditioner should approximate the inverse of A. gcrotmk is a 'flexible' algorithm and the preconditioner can vary from iteration to iteration. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

callback [function, optional] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

m [int, optional] Number of inner FGMRES iterations per each outer iteration. Default: 20

k [int, optional] Number of vectors to carry between inner FGMRES iterations. According to [2], good values are around m. Default: m

CU [list of tuples, optional] List of tuples \((c, u)\) which contain the columns of the matrices C and U in the GCROT(m,k) algorithm. For details, see [2]. The list given and vectors contained in it are modified in-place. If not given, start from empty matrices. The c elements in the tuples can be None, in which case the vectors are recomputed via \( c = A \cdot u \) on start and orthogonalized as described in [3].

discard_C [bool, optional] Discard the C-vectors at the end. Useful if recycling Krylov subspaces for different linear systems.

truncate [{'oldest', 'smallest'}, optional] Truncation scheme to use. Drop: oldest vectors, or vectors with smallest singular values using the scheme discussed in [1,2]. See [2] for detailed comparison. Default: 'oldest'

Returns

x [array or matrix] The solution found.

info [int] Provides convergence information:

- 0: successful exit
- >0: convergence to tolerance not achieved, number of iterations

References

[1], [2], [3]

Iterative methods for least-squares problems:

```
lsqr(A, b[, damp, atol, btol, conlim, ...]) Find the least-squares solution to a large, sparse, linear system of equations.

lsmr(A, b[, damp, atol, btol, conlim, ...]) Iterative solver for least-squares problems.
```
scipy.sparse.linalg.lsqr

scipy.sparse.linalg.lsqr(A, b, damp=0.0, atol=1e-08, btol=1e-08, conlim=100000000.0, iter_lim=None, show=False, calc_var=False, x0=None)

Find the least-squares solution to a large, sparse, linear system of equations.

The function solves \( Ax = b \) or \( \min ||b - Ax||^2 \) or \( \min ||Ax - b||^2 + d^2 ||x||^2 \).

The matrix \( A \) may be square or rectangular (over-determined or under-determined), and may have any rank.

1. Unsymmetric equations -- solve \( A^T x = b \)
2. Linear least squares -- solve \( A^T x = b \) in the least-squares sense
3. Damped least squares -- solve \( (A^T A + \text{damp}^2 I)x = (b^T \text{damp} I) \) in the least-squares sense

**Parameters**

- \( A \) [[sparse matrix, ndarray, LinearOperator]] Representation of an \( m \)-by-\( n \) matrix. Alternatively, \( A \) can be a linear operator which can produce \( Ax \) and \( A^T x \) using, e.g., scipy.sparse.linalg.LinearOperator.
- \( b \) [array_like, shape (\( m, \))] Right-hand side vector \( b \).
- \( \text{damp} \) [float] Damping coefficient.
- \( \text{atol, btol} \) [float, optional] Stopping tolerances. If both are 1.0e-9 (say), the final residual norm should be accurate to about 9 digits. (The final \( x \) will usually have fewer correct digits, depending on \( \text{cond}(A) \) and the size of \( \text{damp} \).)
- \( \text{conlim} \) [float, optional] Another stopping tolerance. lsqr terminates if an estimate of \( \text{cond}(A) \) exceeds \( \text{conlim} \). For compatible systems \( Ax = b \), \( \text{conlim} \) could be as large as 1.0e+12 (say). For least-squares problems, \( \text{conlim} \) should be less than 1.0e+8. Maximum precision can be obtained by setting \( \text{atol} = \text{btol} = \text{conlim} = 0.0 \), but the number of iterations may then be excessive.
- \( \text{iter_lim} \) [int, optional] Explicit limitation on number of iterations (for safety).
- \( \text{show} \) [bool, optional] Display an iteration log.
- \( \text{calc_var} \) [bool, optional] Whether to estimate diagonals of \( (A^T A + \text{damp}^2 I)^{-1} \). If \( \text{calc_var} \) is True, estimates all diagonals of \( (A^T A) \) (if \( \text{damp} = 0 \)) or more generally \( (A^T A + \text{damp}^2 I) \). This is well defined if \( A \) has full

**Returns**

- \( x \) [ndarray of float] The final solution.
- \( \text{istop} \) [int] Gives the reason for termination. 1 means \( x \) is an approximate solution to \( Ax = b \). 2 means \( x \) approximately solves the least-squares problem.
- \( \text{itn} \) [int] Iteration number upon termination.
- \( \text{r1norm} \) [float] \( \| r \|_2 \), where \( r = b - Ax \).
- \( \text{r2norm} \) [float] \( \sqrt{ \| r \|_2^2 + \text{damp}^2 \| x \|_2^2 } \). Equal to \( \text{r1norm} \) if \( \text{damp} = 0 \).
- \( \text{anorm} \) [float] Estimate of Frobenius norm of \( A^T A + \text{damp}^2 I \).
- \( \text{acond} \) [float] Estimate of \( \text{cond}(A^T A + \text{damp}^2 I) \).
- \( \text{arnorm} \) [float] Estimate of \( \text{norm}(A^T r - \text{damp}^2 x) \).
- \( \text{xnorm} \) [float] \( \| x \|_2 \).
- \( \text{var} \) [ndarray of float] If \( \text{calc_var} \) is True, estimates all diagonals of \( (A^T A) \) (if \( \text{damp} = 0 \)) or more generally \( (A^T A + \text{damp}^2 I) \). This is well defined if \( A \) has full
column rank or \( \text{damp} > 0 \). (Not sure what var means if \( \text{rank}(A) < n \) and \( \text{damp} = 0 \).)

**Notes**

LSQR uses an iterative method to approximate the solution. The number of iterations required to reach a certain accuracy depends strongly on the scaling of the problem. Poor scaling of the rows or columns of \( A \) should therefore be avoided where possible.

For example, in problem 1 the solution is unaltered by row-scaling. If a row of \( A \) is very small or large compared to the other rows of \( A \), the corresponding row of \( (A b) \) should be scaled up or down.

In problems 1 and 2, the solution \( x \) is easily recovered following column-scaling. Unless better information is known, the nonzero columns of \( A \) should be scaled so that they all have the same Euclidean norm (e.g., 1.0).

In problem 3, there is no freedom to re-scale if \( \text{damp} \) is nonzero. However, the value of \( \text{damp} \) should be assigned only after attention has been paid to the scaling of \( A \).

The parameter \( \text{damp} \) is intended to help regularize ill-conditioned systems, by preventing the true solution from being very large. Another aid to regularization is provided by the parameter \( \text{acond} \), which may be used to terminate iterations before the computed solution becomes very large.

If some initial estimate \( x_0 \) is known and if \( \text{damp == 0} \), one could proceed as follows:

1. Compute a residual vector \( r_0 = b - A*x_0 \).
2. Use LSQR to solve the system \( A^*dx = r_0 \).
3. Add the correction \( dx \) to obtain a final solution \( x = x_0 + dx \).

This requires that \( x_0 \) be available before and after the call to LSQR. To judge the benefits, suppose LSQR takes \( k_1 \) iterations to solve \( A*x = b \) and \( k_2 \) iterations to solve \( A^*dx = r_0 \). If \( x_0 \) is “good”, \( \| r_0 \| \) will be smaller than \( \| b \| \). If the same stopping tolerances \( \text{atol} \) and \( \text{btol} \) are used for each system, \( k_1 \) and \( k_2 \) will be similar, but the final solution \( x_0 + dx \) should be more accurate. The only way to reduce the total work is to use a larger stopping tolerance for the second system. If some value \( \text{btol} \) is suitable for \( A*x = b \), the larger value \( \text{btol}^*\| b \|/\| r_0 \| \) should be suitable for \( A^*dx = r_0 \).

Preconditioning is another way to reduce the number of iterations. If it is possible to solve a related system \( M*x = b \) efficiently, where \( M \) approximates \( A \) in some helpful way (e.g. \( M - A \) has low rank or its elements are small relative to those of \( A \)), LSQR may converge more rapidly on the system \( A^*(M^{-1})*z = b \), after which \( x \) can be recovered by solving \( M^*x = z \).

If \( A \) is symmetric, LSQR should not be used!

Alternatives are the symmetric conjugate-gradient method (\( \text{cg} \)) and/or \( \text{SYMMLQ} \). \( \text{SYMMLQ} \) is an implementation of symmetric \( \text{cg} \) that applies to any symmetric \( A \) and will converge more rapidly than LSQR. If \( A \) is positive definite, there are other implementations of symmetric \( \text{cg} \) that require slightly less work per iteration than \( \text{SYMMLQ} \) (but will take the same number of iterations).

**References**

[1], [2], [3]

**Examples**
```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsqr
>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)
```

The first example has the trivial solution \([0, 0]\)

```python
>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
The exact solution is \(x = 0\)
>>> istop
0
>>> x
array([ 0., 0.])
```

The stopping code \(\text{istop}=0\) returned indicates that a vector of zeros was found as a solution. The returned solution \(x\) indeed contains \([0, 0]\). The next example has a non-trivial solution:

```python
>>> b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, r1norm = lsqr(A, b)[:4]
>>> istop
1
>>> x
array([ 1., -1.])
>>> itn
1
>>> r1norm
4.40892098500627e-16
```

As indicated by \(\text{istop}=1\), \(\text{lsqr}\) found a solution obeying the tolerance limits. The given solution \([1., -1.]\) obviously solves the equation. The remaining return values include information about the number of iterations (\(\text{itn}=1\)) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```python
>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, r1norm = lsqr(A, b)[:4]
>>> istop
2
>>> x
array([[ 1.00333333, -0.99666667]])
>>> A.dot(x) - b
array([[ 0.00333333, -0.00333333, 0.00333333]])
>>> r1norm
0.005773502691896255
```

\(\text{istop}\) indicates that the system is inconsistent and thus \(x\) is rather an approximate solution to the corresponding least-squares problem. \(\text{r1norm}\) contains the norm of the minimal residual that was found.

**scipy.sparse.linalg.lsqr**

```
scipy.sparse.linalg.lsqr(A, b, damp=0.0, atol=1e-06, btol=1e-06, conlim=1000000000.0, maxiter=None, show=False, x0=None)
```

Iterative solver for least-squares problems.
lsmr solves the system of linear equations \( Ax = b \). If the system is inconsistent, it solves the least-squares problem 
\[
\min ||b - Ax||_2
\]
. A is a rectangular matrix of dimension \( m \)-by-\( n \), where all cases are allowed: \( m = n \), \( m > n \), or \( m < n \). \( B \) is a vector of length \( m \). The matrix \( A \) may be dense or sparse (usually sparse).

**Parameters**

- **A** ([matrix, sparse matrix, ndarray, LinearOperator]) Matrix \( A \) in the linear system. Alternatively, \( A \) can be a linear operator which can produce \( Ax \) and \( A^T x \) using, e.g., scipy.sparse.linalg.LinearOperator.

- **b** [array_like, shape (m,)] Vector \( b \) in the linear system.

- **damp** [float] Damping factor for regularized least-squares. \( lsmr \) solves the regularized least-squares problem:

\[
\min \left|\left| \begin{pmatrix} b \end{pmatrix} - \begin{pmatrix} A \end{pmatrix}x \right|\right|_2
\]

where \( \text{damp} \) is a scalar. If \( \text{damp} \) is None or 0, the system is solved without regularization.

- **atol, btol** [float, optional] Stopping tolerances. \( lsmr \) continues iterations until a certain backward error estimate is smaller than some quantity depending on atol and btol. Let \( r = b - Ax \) be the residual vector for the current approximate solution \( x \). If \( Ax = b \) seems to be consistent, \( lsmr \) terminates when \( \text{norm}(r) \leq \text{atol} \times \text{norm}(A) \times \text{norm}(x) + \text{btol} \times \text{norm}(b) \). Otherwise, \( lsmr \) terminates when \( \text{norm}(A^T r) \leq \text{atol} \times \text{norm}(A) \times \text{norm}(r) \). If both tolerances are 1.0e-6 (say), the final \( \text{norm}(r) \) should be accurate to about 6 digits. (The final \( x \) will usually have fewer correct digits, depending on \( \text{cond}(A) \) and the size of \( \text{LAMBDA} \).) If \( \text{atol} \) or \( \text{btol} \) is None, a default value of 1.0e-6 will be used. Ideally, they should be estimates of the relative error in the entries of \( A \) and \( B \) respectively. For example, if the entries of \( A \) have 7 correct digits, set \( \text{atol} = 1e-7 \). This prevents the algorithm from doing unnecessary work beyond the uncertainty of the input data.

- **conlim** [float, optional] \( lsmr \) terminates if an estimate of \( \text{cond}(A) \) exceeds \( \text{conlim} \). For compatible systems \( Ax = b \), \( \text{conlim} \) could be as large as 1.0e+12 (say). For least-squares problems, \( \text{conlim} \) should be less than 1.0e+8. If \( \text{conlim} \) is None, the default value is 1e+8. Maximum precision can be obtained by setting \( \text{atol} = \text{btol} = \text{conlim} = 0 \), but the number of iterations may then be excessive.

- **maxiter** [int, optional] \( lsmr \) terminates if the number of iterations reaches \( \text{maxiter} \). The default is \( \text{maxiter} = \min(m, n) \). For ill-conditioned systems, a larger value of \( \text{maxiter} \) may be needed.

- **show** [bool, optional] Print iterations logs if \( \text{show}=\text{True} \).

- **x0** [array_like, shape (n,), optional] Initial guess of \( x \), if None zeros are used. New in version 1.0.0.

**Returns**

- **x** [ndarray of float] Least-square solution returned.

- **istop** [int] istop gives the reason for stopping:

\[
\text{istop} = 0 \text{ means } x = 0 \text{ is a solution. If } x0 \text{ was given, } x = x0 \text{ is a solution.}
\]

\[
\text{istop} = 1 \text{ means } x \text{ is an approximate solution to } A^T x = B, \text{ according to atol and btol.}
\]

\[
\text{istop} = 2 \text{ means } x \text{ approximately solves the least-squares problem according to atol.}
\]

\[
\text{istop} = 3 \text{ means } \text{cond}(A) \text{ seems to be greater than CONLIM.}
\]

\[
\text{istop} = 4 \text{ is the same as 1 with atol = btol = eps.}
\]

(continues on next page)
precision)
    = 5 is the same as 2 with atol = eps.
    = 6 is the same as 3 with CONLIM = 1/eps.
    = 7 means ITN reached maxiter before the other...
←stopping
    conditions were satisfied.

itn    [int] Number of iterations used.
normr   [float] norm(b-Ax)
normar  [float] norm(A^T (b - Ax))
norma   [float] norm(A)
conda   [float] Condition number of A.
normx   [float] norm(x)

Notes

New in version 0.11.0.

References

[1], [2]

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsmr
>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)

The first example has the trivial solution [0, 0]

```python
>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsmr(A, b)[:4]
>>> istop
0
>>> x
array([ 0., 0.])
```

The stopping code istop=0 returned indicates that a vector of zeros was found as a solution. The returned solution x indeed contains [0, 0]. The next example has a non-trivial solution:

```python
>>> b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, normr = lsmr(A, b)[:4]
>>> istop
1
>>> x
array([ 1., -1.])
>>> itn
1
>>> normr
4.440892098500627e-16
```
As indicated by $istop=1$, $lsmr$ found a solution obeying the tolerance limits. The given solution $[1., -1.]$ obviously solves the equation. The remaining return values include information about the number of iterations ($itn=1$) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```python
>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, normr = lsmr(A, b)[:4]
>>> istop
2
>>> x
array([1.00333333, -0.99666667])
>>> A.dot(x) - b
array([0.00333333, -0.00333333, 0.00333333])
>>> normr
0.005773502691896255
```

$istop$ indicates that the system is inconsistent and thus $x$ is rather an approximate solution to the corresponding least-squares problem. $normr$ contains the minimal distance that was found.

### 6.23.5 Matrix factorizations

Eigenvalue problems:

- **$eigs(A[, k, M, sigma, which, v0, ncv, …])$** Find $k$ eigenvalues and eigenvectors of the square matrix $A$.
- **$eigsh(A[, k, M, sigma, which, v0, ncv, …])$** Find $k$ eigenvalues and eigenvectors of the real symmetric square matrix or complex hermitian matrix $A$.
- **$lobpcg(A, X[, B, M, Y, tol, maxiter, …])$** Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

**scipy.sparse.linalg.eigs**

Find $k$ eigenvalues and eigenvectors of the square matrix $A$.

Solves $A * x[i] = w[i] * x[i]$, the standard eigenvalue problem for $w[i]$ eigenvalues with corresponding eigenvectors $x[i]$.

If $M$ is specified, solves $A * x[i] = M * w[i] * x[i]$, the generalized eigenvalue problem for $w[i]$ eigenvalues with corresponding eigenvectors $x[i]$.

**Parameters**

- **$A$** [ndarray, sparse matrix or LinearOperator] An array, sparse matrix, or LinearOperator representing the operation $A * x$, where $A$ is a real or complex square matrix.
- **$k$** [int, optional] The number of eigenvalues and eigenvectors desired. $k$ must be smaller than $N-1$. It is not possible to compute all eigenvectors of a matrix.
- **$M$** [ndarray, sparse matrix or LinearOperator, optional] An array, sparse matrix, or LinearOperator representing the operation $M*x$ for the generalized eigenvalue problem $A * x = M * x$.
M must represent a real, symmetric matrix if A is real, and must represent a complex, hermitian matrix if A is complex. For best results, the data type of M should be the same as that of A. Additionally:

If `sigma` is None, M is positive definite

If `sigma` is specified, M is positive semi-definite

If `sigma` is None, `eigs` requires an operator to compute the solution of the linear equation \( M \times x = b \). This is done internally via a (sparse) LU decomposition for an explicit matrix M, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator Minv, which gives \( x = \text{Minv} \times b = M^{-1} \times b \).

`sigma` ([real or complex, optional]) Find eigenvalues near sigma using shift-invert mode. This requires an operator to compute the solution of the linear system \([A - \sigma M] \times x = b\), where M is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices A & M, or via an iterative solver if either A or M is a general linear operator. Alternatively, the user can supply the matrix or operator OPinv, which gives \( x = \text{OPinv} \times b = [A - \sigma M]^{-1} \times b \). For a real matrix A, shift-invert can either be done in imaginary mode or real mode, specified by the parameter OPpart (‘r’ or ‘i’). Note that when `sigma` is specified, the keyword ‘which’ (below) refers to the shifted eigenvalues \( w'[i] \) where:

If A is real and OPpart == ‘r’ (default),
\[
w'[i] = \frac{1}{2} \times \left[ \frac{1}{w[i] - \sigma} + \frac{1}{w[i] - \overline{\sigma}} \right].
\]

If A is real and OPpart == ‘i’,
\[
w'[i] = \frac{1}{2i} \times \left[ \frac{1}{w[i] - \sigma} - \frac{1}{w[i] - \overline{\sigma}} \right].
\]

If A is complex,
\[
w'[i] = \frac{1}{w[i] - \sigma}.
\]

`v0` ([ndarray, optional]) Starting vector for iteration. Default: random

`ncv` [int, optional] The number of Lanczos vectors generated. `ncv` must be greater than `k`; it is recommended that `ncv > 2k`. Default: \( \min(n, \max(2k + 1, 20)) \)

‘LM’ : largest magnitude
‘SM’ : smallest magnitude
‘LR’ : largest real part
‘SR’ : smallest real part
‘LI’ : largest imaginary part
‘SI’ : smallest imaginary part

When `sigma` != None, ‘which’ refers to the shifted eigenvalues \( w'[i] \) (see discussion in ‘sigma’, above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

`maxiter` [int, optional] Maximum number of Arnoldi update iterations allowed. Default: \( n \times 10 \)

`tol` [float, optional] Relative accuracy for eigenvalues (stopping criterion). The default value of 0 implies machine precision.

`return_eigenvectors` [bool, optional] Return eigenvectors (True) in addition to eigenvalues

`Minv` [ndarray, sparse matrix or LinearOperator, optional] See notes in M, above.

`OPinv` [ndarray, sparse matrix or LinearOperator, optional] See notes in sigma, above.

`OPpart` [‘r’ or ‘i’], optional] See notes in sigma, above

**Returns**

`w` [ndarray] Array of k eigenvalues.

`v` [ndarray] An array of k eigenvectors. \( v[:, i] \) is the eigenvector corresponding to the eigenvalue \( w[i] \).

**Raises**

6.23. Sparse linear algebra (`scipy.sparse.linalg`) 1803
ArpackNoConvergence

When the requested convergence is not obtained. The currently converged eigenvalues and eigenvectors can be found as `eigenvalues` and `eigenvectors` attributes of the exception object.

See also:

- `eigsh`
  eigenvalues and eigenvectors for symmetric matrix A

- `svds`
  singular value decomposition for a matrix A

Notes

This function is a wrapper to the ARPACK [1] SNEUPD, DNEUPD, CNEUPD, ZNEUPD, functions which use the Implicitly Restarted Arnoldi Method to find the eigenvalues and eigenvectors [2].

References

[1], [2]

Examples

Find 6 eigenvectors of the identity matrix:

```python
>>> from scipy.sparse.linalg import eigs
>>> id = np.eye(13)
>>> vals, vecs = eigs(id, k=6)
>>> vals
array([ 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j])
>>> vecs.shape
(13, 6)
```

scipy.sparse.linalg.eigsh

Find k eigenvalues and eigenvectors of the real symmetric square matrix or complex hermitian matrix A.

Solves $A * x[i] = w[i] * x[i]$, the standard eigenvalue problem for $w[i]$ eigenvalues with corresponding eigenvectors $x[i]$.

If $M$ is specified, solves $A * x[i] = w[i] * M * x[i]$, the generalized eigenvalue problem for $w[i]$ eigenvalues with corresponding eigenvectors $x[i]$.

Parameters

- **A** [ndarray, sparse matrix or LinearOperator] A square operator representing the operation $A * x$, where $A$ is real symmetric or complex hermitian. For buckling mode (see below) $A$ must additionally be positive-definite.
k [int, optional] The number of eigenvalues and eigenvectors desired. k must be smaller than N. It is not possible to compute all eigenvectors of a matrix.

Returns

w [array] Array of k eigenvalues.
v [array] An array representing the k eigenvectors. The column v[:, i] is the eigenvector corresponding to the eigenvalue w[i].

Other Parameters

M [An N x N matrix, array, sparse matrix, or linear operator representing] the operation M @ x for the generalized eigenvalue problem

\[ A @ x = w * M @ x. \]

M must represent a real, symmetric matrix if A is real, and must represent a complex, hermitian matrix if A is complex. For best results, the data type of M should be the same as that of A. Additionally:

- If sigma is None, M is symmetric positive definite.
- If sigma is specified, M is symmetric positive semi-definite.
- In buckling mode, M is symmetric indefinite.

If sigma is None, eigsh requires an operator to compute the solution of the linear equation M @ x = b. This is done internally via a (sparse) LU decomposition for an explicit matrix M, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator Minv, which gives x = Minv @ b = M^-1 @ b.

sigma [real] Find eigenvalues near sigma using shift-invert mode. This requires an operator to compute the solution of the linear system [A - sigma * M] x = b, where M is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices A & M, or via an iterative solver if either A or M is a general linear operator. Alternatively, the user can supply the matrix or operator OPinv, which gives x = OPinv @ b = [A - sigma * M]^-1 @ b. Note that when sigma is specified, the keyword 'which' refers to the shifted eigenvalues w'[i] where:

- if mode == 'normal', w'[i] = 1 / (w[i] - sigma).
- if mode == 'cayley', w'[i] = (w[i] + sigma) / (w[i] - sigma).
- if mode == 'buckling', w'[i] = w[i] / (w[i] - sigma).

(see further discussion in 'mode' below)

v0 [ndarray, optional] Starting vector for iteration. Default: random

ncv [int, optional] The number of Lanczos vectors generated ncv must be greater than k and smaller than n; it is recommended that ncv > 2*k. Default: min(n, max(2*k + 1, 20))

which [str ['LM' | 'SM' | 'LA' | 'SA' | 'BE']] If A is a complex hermitian matrix, 'BE' is invalid. Which k eigenvectors and eigenvalues to find:

- 'LM': Largest (in magnitude) eigenvalues.
- 'SM': Smallest (in magnitude) eigenvalues.
- 'LA': Largest (algebraic) eigenvalues.
- 'SA': Smallest (algebraic) eigenvalues.
- 'BE': Half (k/2) from each end of the spectrum.

When k is odd, return one more (k/2+1) from the high end. When sigma != None, 'which' refers to the shifted eigenvalues w'[i] (see discussion in 'sigma', above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

maxiter [int, optional] Maximum number of Arnoldi update iterations allowed. Default: n*10

tol [float] Relative accuracy for eigenvalues (stopping criterion). The default value of 0 implies machine precision.

Minv [N x N matrix, array, sparse matrix, or LinearOperator] See notes in M, above.

OPinv [N x N matrix, array, sparse matrix, or LinearOperator] See notes in sigma, above.
return_eigenvectors

[bool] Return eigenvectors (True) in addition to eigenvalues. This value determines the order in which eigenvalues are sorted. The sort order is also dependent on the which variable.

For which = ‘LM’ or ‘SA’:

If return_eigenvectors is True, eigenvalues are sorted by algebraic value.
If return_eigenvectors is False, eigenvalues are sorted by absolute value.

For which = ‘BE’ or ‘LA’:

eigenvalues are always sorted by algebraic value.

For which = ‘SM’:

If return_eigenvectors is True, eigenvalues are sorted by algebraic value.
If return_eigenvectors is False, eigenvalues are sorted by decreasing absolute value.

mode

[string ['normal' | 'buckling' | 'cayley']] Specify strategy to use for shift-invert mode. This argument applies only for real-valued A and sigma != None. For shift-invert mode, ARPACK internally solves the eigenvalue problem \( \mathbf{OP} \mathbf{x'}[i] = w'[i] \mathbf{B} \mathbf{x'}[i] \) and transforms the resulting Ritz vectors \( \mathbf{x'}[i] \) and Ritz values \( w'[i] \) into the desired eigenvectors and eigenvalues of the problem \( \mathbf{A} \mathbf{x}[i] = w[i] \mathbf{M} \mathbf{x}[i] \). The modes are as follows:

‘normal’ : \( \mathbf{OP} = (\mathbf{A} - \text{sigma} \mathbf{M})^{-1} \mathbf{M}, \mathbf{B} = \mathbf{M}, w'[i] = 1 / (w[i] - \text{sigma}) \)

‘buckling’ : \( \mathbf{OP} = (\mathbf{A} - \text{sigma} \mathbf{M})^{-1} \mathbf{A}, \mathbf{B} = \mathbf{A}, w'[i] = w[i] / (w[i] - \text{sigma}) \)

‘cayley’ : \( \mathbf{OP} = (\mathbf{A} - \text{sigma} \mathbf{M})^{-1} (\mathbf{A} + \text{sigma} \mathbf{M}), \mathbf{B} = \mathbf{M}, w'[i] = (w[i] + \text{sigma}) / (w[i] - \text{sigma}) \)

The choice of mode will affect which eigenvalues are selected by the keyword ‘which’, and can also impact the stability of convergence (see [2] for a discussion).

Raises

ArpackNoConvergence

When the requested convergence is not obtained.

The currently converged eigenvalues and eigenvectors can be found as eigenvalues and eigenvectors attributes of the exception object.

See also:

eigs
eigenvalues and eigenvectors for a general (nonsymmetric) matrix A

svds

singular value decomposition for a matrix A

Notes

This function is a wrapper to the ARPACK [1] SSEUPD and DSEUPD functions which use the Implicitly Restarted Lanczos Method to find the eigenvalues and eigenvectors [2].

[1], [2]
Examples

```python
>>> from scipy.sparse.linalg import eigsh
>>> identity = np.eye(13)
>>> eigenvalues, eigenvectors = eigsh(identity, k=6)
>>> eigenvalues
array([1., 1., 1., 1., 1., 1.])
>>> eigenvectors.shape
(13, 6)
```

**scipy.sparse.linalg.lobpcg**

scipy.sparse.linalg.lobpcg(A, X, B=None, M=None, Y=None, tol=None, maxiter=20, largest=True, verbosityLevel=0, retLambdaHistory=False, retResidualNormsHistory=False)

Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

LOBPCG is a preconditioned eigen solver for large symmetric positive definite (SPD) generalized eigenproblems.

**Parameters**

- **A** ([sparse matrix, dense matrix, LinearOperator]) The symmetric linear operator of the problem, usually a sparse matrix. Often called the “stiffness matrix”.
- **X** ([array_like]) Initial approximation to the k eigenvectors. If A has shape=(n,n) then X should have shape shape=(n,k).
- **B** ([dense matrix, sparse matrix, LinearOperator], optional) the right hand side operator in a generalized eigenproblem. by default, B = Identity often called the “mass matrix”
- **M** ([dense matrix, sparse matrix, LinearOperator], optional) preconditioner to A; by default M = Identity M should approximate the inverse of A
- **Y** ([array_like, optional]) n-by-sizeY matrix of constraints, sizeY < n The iterations will be performed in the B-orthogonal complement of the column-space of Y. Y must be full rank.
- **tol** [scalar, optional] Solver tolerance (stopping criterion) by default: tol=n*sqrt(eps)
- **maxiter** [integer, optional] maximum number of iterations by default: maxiter=min(n,20)
- **largest** [bool, optional] when True, solve for the largest eigenvalues, otherwise the smallest
- **verbosityLevel** [integer, optional] controls solver output. default: verbosityLevel = 0.
- **retLambdaHistory** [boolean, optional] whether to return eigenvalue history
- **retResidualNormsHistory** [boolean, optional] whether to return history of residual norms

**Returns**

- **w** [array] Array of k eigenvalues
- **v** [array] An array of k eigenvectors. V has the same shape as X.
- **lambdas** [list of arrays, optional] The eigenvalue history, if retLambdaHistory is True.
- **rnorms** [list of arrays, optional] The history of residual norms, if retResidualNormsHistory is True.

**Notes**

If both retLambdaHistory and retResidualNormsHistory are True, the return tuple has the following format (lambdas, V, lambda history, residual norms history).

In the following n denotes the matrix size and m the number of required eigenvalues (smallest or largest).
The LOBPCG code internally solves eigenproblems of the size $3^m$ on every iteration by calling the “standard” dense eigensolver, so if $m$ is not small enough compared to $n$, it does not make sense to call the LOBPCG code, but rather one should use the “standard” eigensolver, e.g. numpy or scipy function in this case. If one calls the LOBPCG algorithm for $5^m$>“n”, it will most likely break internally, so the code tries to call the standard function instead.

It is not that $n$ should be large for the LOBPCG to work, but rather the ratio $n/m$ should be large. It you call LOBPCG with $m`=1 and ``n``=10, it works though `n` is small. The method is intended for extremely large $n/m$, see e.g., reference [28] in https://arxiv.org/abs/0705.2626

The convergence speed depends basically on two factors:

1. How well relatively separated the seeking eigenvalues are from the rest of the eigenvalues. One can try to vary $m$ to make this better.

2. How well conditioned the problem is. This can be changed by using proper preconditioning. For example, a rod vibration test problem (under tests directory) is ill-conditioned for large $n$, so convergence will be slow, unless efficient preconditioning is used. For this specific problem, a good simple preconditioner function would be a linear solve for $A$, which is easy to code since $A$ is tridiagonal.

Acknowledgements

lobpcg.py code was written by Robert Cimrman. Many thanks belong to Andrew Knyazev, the author of the algorithm, for lots of advice and support.

References

[1], [2], [3]

Examples

Solve $A \times = \lambda B \times$ with constraints and preconditioning.

```python
>>> from scipy.sparse import spdiags, issparse
>>> from scipy.sparse.linalg import lobpcg, LinearOperator
>>> n = 100
>>> vals = [np.arange(n, dtype=np.float64) + 1]
>>> A = spdiags(vals, 0, n, n)
>>> A.toarray()
array([[ 1., 0., 0., ..., 0., 0., 0.],
[ 0., 2., 0., ..., 0., 0., 0.],
[ 0., 0., 3., ..., 0., 0., 0.],
...,
[ 0., 0., 0., ..., 98., 0., 0.],
[ 0., 0., 0., ..., 0., 99., 0.],
[ 0., 0., 0., ..., 0., 0., 100.]])
```

Constraints.

```python
>>> Y = np.eye(n, 3)
```

Initial guess for eigenvectors, should have linearly independent columns. Column dimension = number of requested eigenvalues.

```python
>>> X = np.random.rand(n, 3)
```

Preconditioner – inverse of $A$ (as an abstract linear operator).
>> invA = spdiags([1./vals[0]], 0, n, n)
>>> def precond( x ):
...       return invA * x
>>> M = LinearOperator(matvec=precond, shape=(n, n), dtype=float)

Here, invA could of course have been used directly as a preconditioner. Let us then solve the problem:

```python
>>> eigs, vecs = lobpcg(A, X, Y=Y, M=M, largest=False)
>>> eigs
array([4., 5., 6.])
```

Note that the vectors passed in Y are the eigenvectors of the 3 smallest eigenvalues. The results returned are orthogonal to those.

Singular values problems:

```python
svds(A[, k, ncv, tol, which, v0, maxiter, …])
```

Compute the largest k singular values/vectors for a sparse matrix.

### scipy.sparse.linalg.svds

**scipy.sparse.linalg.svds** *(A, k=6, ncv=None, tol=0, which='LM', v0=None, maxiter=None, return_singular_vectors=True)*

Compute the largest k singular values/vectors for a sparse matrix.

**Parameters**

- **A** ([sparse matrix, LinearOperator]) Array to compute the SVD on, of shape (M, N)
- **k** [int, optional] Number of singular values and vectors to compute. Must be 1 <= k < min(A.shape).
- **ncv** [int, optional] The number of Lanczos vectors generated ncv must be greater than k+1 and smaller than n; it is recommended that ncv > 2*k Default: min(n, max(2*k + 1, 20))
- **which** [str, ['LM' | 'SM'], optional] Which k singular values to find:
  - 'LM': largest singular values
  - 'SM': smallest singular values
  New in version 0.12.0.
- **v0** [ndarray, optional] Starting vector for iteration, of length min(A.shape). Should be an (approximate) left singular vector if N > M and a right singular vector otherwise. Default: random
  New in version 0.12.0.
- **maxiter** [int, optional] Maximum number of iterations.
  New in version 0.12.0.
- **return_singular_vectors**
  - [bool or str, optional]
    - True: return singular vectors (True) in addition to singular values.
    New in version 0.12.0.
    - “u”: only return the u matrix, without computing vh (if N > M).
    - “vh”: only return the vh matrix, without computing u (if N <= M).
    New in version 0.16.0.

**Returns**

6.23. Sparse linear algebra (**scipy.sparse.linalg**)
SciPy Reference Guide, Release 1.3.2

SciPy Reference Guide, Release 1.3.2

u [ndarray, shape=(M, k)] Unitary matrix having left singular vectors as columns. If `return_singular_vectors` is “vh”, this variable is not computed, and None is returned instead.

s [ndarray, shape=(k,)] The singular values.

vt [ndarray, shape=(k, N)] Unitary matrix having right singular vectors as rows. If `return_singular_vectors` is “u”, this variable is not computed, and None is returned instead.

**Notes**

This is a naive implementation using ARPACK as an eigensolver on A.H * A or A * A.H, depending on which one is more efficient.

**Examples**

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import svds, eigs
>>> A = csc_matrix([[1, 0, 0], [5, 0, 2], [0, -1, 0], [0, 0, 3]], dtype=float)
>>> u, s, vt = svds(A, k=2)
>>> s
array([ 2.75193379, 5.6059665 ])
>>> np.sqrt(eigs(A.dot(A.T), k=2)[0]).real
array([ 5.6059665 , 2.75193379])
```

Complete or incomplete LU factorizations

<table>
<thead>
<tr>

**scipy.sparse.linalg.splu**

`scipy.sparse.linalg.splu(A, permc_spec=None, diag_pivot_thresh=None, relax=None, panel_size=None, options={})`

Compute the LU decomposition of a sparse, square matrix.

**Parameters**

- `A` [sparse matrix] Sparse matrix to factorize. Should be in CSR or CSC format.
- `permc_spec` [str, optional] How to permute the columns of the matrix for sparsity preservation. (default: ‘COLAMD’)
  - NATURAL: natural ordering.
  - MMD_ATA: minimum degree ordering on the structure of A^T A.
  - MMD_AT_PLUS_A: minimum degree ordering on the structure of A^T+A.
  - COLAMD: approximate minimum degree column ordering
- `diag_pivot_thresh` [float, optional] Threshold used for a diagonal entry to be an acceptable pivot. See SuperLU user’s guide for details [1]
- `relax` [int, optional] Expert option for customizing the degree of relaxing supernodes. See SuperLU user’s guide for details [1]
panel_size  [int, optional] Expert option for customizing the panel size. See SuperLU user's guide for details [1].

options  [dict, optional] Dictionary containing additional expert options to SuperLU. See SuperLU user guide [1] (section 2.4 on the 'Options' argument) for more details. For example, you can specify options=dict(Equil=False, IterRefine='SINGLE')) to turn equilibration off and perform a single iterative refinement.

Returns

See also:

spilu

incomplete LU decomposition

Notes

This function uses the SuperLU library.

References

[1]

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import splu
>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]],
                 dtype=float)
>>> B = splu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([ 1. , -3. , -1.5])
>>> A.dot(B.solve(x))
array([ 1., 2., 3.])
>>> B.solve(A.dot(x))
array([ 1., 2., 3.])
```

scipy.sparse.linalg.spilu

scipy.sparse.linalg.spilu(A, drop_tol=None, fill_factor=None, drop_rule=None, permc_spec=None, diag_pivot_thresh=None, relax=None, panel_size=None, options=None)

Compute an incomplete LU decomposition for a sparse, square matrix.

The resulting object is an approximation to the inverse of A.

Parameters

A  [(N, N) array_like] Sparse matrix to factorize

drop_tol  [float, optional] Drop tolerance (0 <= tol <= 1) for an incomplete LU decomposition. (default: 1e-4)

fill_factor  [float, optional] Specifies the fill ratio upper bound (>= 1.0) for ILU. (default: 10)

Remaining other options
Same as for splu

Returns

invA_approx
[scipy.sparse.linalg.SuperLU] Object, which has a solve method.

See also:
splu
complete LU decomposition

Notes

To improve the better approximation to the inverse, you may need to increase fill_factor AND decrease drop_tol. This function uses the SuperLU library.

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import splu
>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]],
                 dtype=float)
>>> B = splu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([ 1. , -3. , -1.5])
>>> A.dot(B.solve(x))
array([ 1. ,  2. ,  3. ])
>>> B.solve(A.dot(x))
array([ 1. ,  2. ,  3. ])
```

scipy.sparse.linalg.SuperLU

class scipy.sparse.linalg.SuperLU
LU factorization of a sparse matrix.

Factorization is represented as:

\[ Pr * A * Pc = L * U \]

To construct these SuperLU objects, call the splu and spilu functions.

Notes

New in version 0.14.0.
Examples

The LU decomposition can be used to solve matrix equations. Consider:

```python
>>> import numpy as np
>>> from scipy.sparse import csc_matrix, linalg as sla
>>> A = csc_matrix([[1,2,0,4],[1,0,0,1],[1,0,2,1],[2,2,1,0]])
```

This can be solved for a given right-hand side:

```python
>>> lu = sla.splu(A)
>>> b = np.array([1, 2, 3, 4])
>>> x = lu.solve(b)
>>> A.dot(x)
array([ 1., 2., 3., 4.])
```

The \texttt{lu} object also contains an explicit representation of the decomposition. The permutations are represented as mappings of indices:

```python
>>> lu.perm_r
array([0, 2, 1, 3], dtype=int32)
>>> lu.perm_c
array([2, 0, 1, 3], dtype=int32)
```

The L and U factors are sparse matrices in CSC format:

```python
>>> lu.L.A
array([[ 1. , 0. , 0. , 0. ],
       [ 0. , 1. , 0. , 0. ],
       [ 0. , 0. , 1. , 0. ],
       [ 1. , 0.5, 0.5, 1. ]])
>>> lu.U.A
array([[ 2., 0., 1., 4.],
       [ 0., 2., 1., 1.],
       [ 0., 0., 1., 1.],
       [ 0., 0., 0., -5.]])
```

The permutation matrices can be constructed:

```python
>>> Pr = csc_matrix((np.ones(4), (lu.perm_r, np.arange(4))))
>>> Pc = csc_matrix((np.ones(4), (np.arange(4), lu.perm_c)))
```

We can reassemble the original matrix:

```python
>>> (Pr.T * (lu.L * lu.U) * Pc.T).A
array([[ 1., 2., 0., 4.],
       [ 1., 0., 0., 1.],
       [ 1., 0., 2., 1.],
       [ 2., 2., 1., 0.]])
```

**Attributes**

- **shape**: Shape of the original matrix as a tuple of ints.
- **nnz**: Number of nonzero elements in the matrix.
- **perm_c**: Permutation Pc represented as an array of indices.
perm_r  Permutation Pr represented as an array of indices.
L      Lower triangular factor with unit diagonal as a `scipy.sparse.csc_matrix`.
U      Upper triangular factor as a `scipy.sparse.csc_matrix`.

## Methods

```
solve(rhs[, trans])
```
Solves linear system of equations with one or several right-hand sides.

#### scipy.sparse.linalg.SuperLU.solve

`SuperLU.solve(rhs[, trans])`
Solves linear system of equations with one or several right-hand sides.

**Parameters**

- **rhs** [ndarray, shape (n,) or (n, k)] Right hand side(s) of equation
- **trans** [{'N', 'T', 'H'}, optional] Type of system to solve:
  
<table>
<thead>
<tr>
<th>trans</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'N'</td>
<td>$A \times x = rhs$ (default)</td>
</tr>
<tr>
<td>'T'</td>
<td>$A^T \times x = rhs$</td>
</tr>
<tr>
<td>'H'</td>
<td>$A^H \times x = rhs$</td>
</tr>
</tbody>
</table>

i.e., normal, transposed, and hermitian conjugate.

**Returns**

- **x** [ndarray, shape rhs.shape] Solution vector(s)

### 6.23.6 Exceptions

- `ArpackNoConvergence(msg, eigenvalues, …)` ARPACK iteration did not converge
- `ArpackError(info[, infodict])` ARPACK error

#### scipy.sparse.linalg.ArpackNoConvergence

**exception** `scipy.sparse.linalg.ArpackNoConvergence(msg, eigenvalues, eigenvectors)` ARPACK iteration did not converge

**Attributes**

- **eigenvalues** [ndarray] Partial result. Converged eigenvalues.
- **eigenvectors** [ndarray] Partial result. Converged eigenvectors.

**with_traceback** ()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
scipy.sparse.linalg.ArpackError

exception scipy.sparse.linalg.ArpackError(info, infodict=`c`): -9999: 'Could not build an Arnoldi factorization. IPARAM(5) returns the size of the current Arnoldi factorization. `scipy.sparse.csgraph.connected_components`

`scipy.sparse.csgraph.connected_components(csgraph[, directed=True, return_labels=True])`

Analyze the connected components of a sparse graph

New in version 0.11.0.

Parameters

- `csgraph` [array_like or sparse matrix] The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- `directed` [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].
connection
[\text{str, optional}] [\text{'weak'|\text{'strong'}}]. For directed graphs, the type of connection to use. Nodes \text{i} and \text{j} are strongly connected if a path exists both from \text{i} to \text{j} and from \text{j} to \text{i}. Nodes \text{i} and \text{j} are weakly connected if only one of these paths exists. If directed == False, this keyword is not referenced.

return_labels
[\text{bool, optional}] If True (default), then return the labels for each of the connected components.

Returns

\text{n\_components: int}
The number of connected components.

\text{labels: ndarray}
The length-\text{N} array of labels of the connected components.

References

[1]

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import connected_components

>>> graph = [
... [ 0, 1, 1, 0, 0 ],
... [ 0, 0, 1, 0, 0 ],
... [ 0, 0, 0, 0, 0 ],
... [ 0, 0, 0, 0, 1 ],
... [ 0, 0, 0, 0, 0 ],
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 1
(1, 2) 1
(3, 4) 1

>>> n_components, labels = connected_components(csgraph=graph,
... directed=False, return_labels=True)
>>> n_components
2
>>> labels
array([0, 0, 0, 1, 1], dtype=int32)
```

\text{scipy.sparse.csgraph.laplacian}

\text{scipy.sparse.csgraph.laplacian}(\text{csgraph}, \text{normed=False}, \text{return\_diag=False}, \text{use\_out\_degree=False})

Return the Laplacian matrix of a directed graph.
**Parameters**

- **csgraph**  
  [array_like or sparse matrix, 2 dimensions] compressed-sparse-graph, with shape (N, N).
- **normed**  
  [bool, optional] If True, then compute normalized Laplacian.
- **return_diag**  
  [bool, optional] If True, then also return an array related to vertex degrees.
- **use_out_degree**  
  [bool, optional] If True, then use out-degree instead of in-degree. This distinction matters only if the graph is asymmetric. Default: False.

**Returns**

- **lap**  
  [ndarray or sparse matrix] The N x N laplacian matrix of csgraph. It will be a numpy array (dense) if the input was dense, or a sparse matrix otherwise.
- **diag**  
  [ndarray, optional] The length-N diagonal of the Laplacian matrix. For the normalized Laplacian, this is the array of square roots of vertex degrees or 1 if the degree is zero.

**Notes**

The Laplacian matrix of a graph is sometimes referred to as the “Kirchoff matrix” or the “admittance matrix”, and is useful in many parts of spectral graph theory. In particular, the eigen-decomposition of the laplacian matrix can give insight into many properties of the graph.

**Examples**

```python
>>> from scipy.sparse import csgraph
>>> G = np.arange(5) * np.arange(5)[ :, np.newaxis]
>>> G
array([[ 0,  0,  0,  0,  0],
       [ 0,  1,  2,  3,  4],
       [ 0,  2,  4,  6,  8],
       [ 0,  3,  6,  9, 12],
       [ 0,  4,  8, 12, 16]])
>>> csgraph.laplacian(G, normed=False)
array([[ 0,  0,  0,  0,  0],
       [ 0,  9, -2, -3, -4],
       [ 0, -2, 16, -6, -8],
       [ 0, -3, -6, 21, -12],
       [ 0, -4, -8, -12, 24]])
```

**scipy.sparse.csgraph.shortest_path**

`scipy.sparse.csgraph.shortest_path(csgraph, method='auto', directed=True, return_predecessors=False, unweighted=False, overwrite=False, indices=None)`

Perform a shortest-path graph search on a positive directed or undirected graph.

New in version 0.11.0.

**Parameters**

- **csgraph**  
  [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.
- **method**  
  [string ['auto'|'FW'|'D'], optional] Algorithm to use for shortest paths. Options are:

‘FW’ – Floyd-Warshall algorithm. Computational cost is approximately $O[N^3]$. The input csgraph will be converted to a dense representation.

‘D’ – Dijkstra’s algorithm with Fibonacci heaps. Computational cost is approximately $O[N(N*k + N*log(N))]$, where $k$ is the average number of connected edges per node. The input csgraph will be converted to a csr representation.

‘BF’ – Bellman-Ford algorithm. This algorithm can be used when weights are negative. If a negative cycle is encountered, an error will be raised. Computational cost is approximately $O[N(N^2 k)]$, where $k$ is the average number of connected edges per node. The input csgraph will be converted to a csr representation.

‘J’ – Johnson’s algorithm. Like the Bellman-Ford algorithm, Johnson’s algorithm is designed for use when the weights are negative. It combines the Bellman-Ford algorithm with Dijkstra’s algorithm for faster computation.

directed [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]

return_predecessors [bool, optional] If True, return the size $(N, N)$ predecessor matrix

unweighted [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

overwrite [bool, optional] If True, overwrite csgraph with the result. This applies only if method == ‘FW’ and csgraph is a dense, c-ordered array with dtype=float64.

indices [array_like or int, optional] If specified, only compute the paths for the points at the given indices. Incompatible with method == ‘FW’.

Returns

dist_matrix [ndarray] The $N \times N$ matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.

predecessors [ndarray] Returned only if return_predecessors == True. The $N \times N$ matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999.

Raises

NegativeCycleError: if there are negative cycles in the graph

Notes

As currently implemented, Dijkstra’s algorithm and Johnson’s algorithm do not work for graphs with direction-dependent distances when directed == False. i.e., if csgraph[i,j] and csgraph[j,i] are non-equal edges, method='D' may yield an incorrect result.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import shortest_path

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
    (0, 1) 1
    (0, 2) 2
    (1, 3) 1
    (2, 0) 2
    (2, 3) 3

>>> dist_matrix, predecessors = shortest_path(csgraph=graph,
                                           directed=False, indices=0,
                                           return_predecessors=True)
>>> dist_matrix
array([ 0., 1., 2., 2.])
>>> predecessors
array([-9999, 0, 0, 1], dtype=int32)
```

`scipy.sparse.csgraph.dijkstra`

`scipy.sparse.csgraph.dijkstra(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False, limit=np.inf)`

Dijkstra algorithm using Fibonacci Heaps

New in version 0.11.0.

**Parameters**

- `csgraph` [array, matrix, or sparse matrix, 2 dimensions] The N x N array of non-negative distances representing the input graph.
- `directed` [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j] and from point j to i along paths csgraph[j, i]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j or j to i along either csgraph[i, j] or csgraph[j, i].
- `indices` [array_like or int, optional] if specified, only compute the paths for the points at the given indices.
- `return_predecessors` [bool, optional] If True, return the size (N, N) predecessor matrix
- `unweighted` [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- `limit` [float, optional] The maximum distance to calculate, must be >= 0. Using a smaller limit will decrease computation time by aborting calculations between pairs that are separated by a distance > limit. For such pairs, the distance will be equal to np.inf (i.e., not connected). New in version 0.14.0.
min_only  [bool, optional] If False (default), for every node in the graph, find the shortest path to every node in indices. If True, for every node in the graph, find the shortest path to any of the nodes in indices (which can be substantially faster). New in version 1.3.0.

Returns

dist_matrix

[ndarray, shape ([n_indices, ]n_nodes,)] The matrix of distances between graph nodes. If min_only=False, dist_matrix has shape (n_indices, n_nodes) and dist_matrix[i, j] gives the shortest distance from point i to point j along the graph. If min_only=True, dist_matrix has shape (n_nodes,) and contains the shortest path from each node to any of the nodes in indices.

predecessors

[ndarray, shape ([n_indices, ]n_nodes,)] If min_only=False, this has shape (n_indices, n_nodes), otherwise it has shape (n_nodes,). Returned only if return_predecessors == True. The matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

sources

[ndarray, shape (n_nodes,)] Returns only if min_only=True and return_predecessors=True. Contains the index of the source which had the shortest path to each target. If no path exists within the limit, this will contain -9999. The value at the indices passed will be equal to that index (i.e. the fastest way to reach node i, is to start on node i).

Notes

As currently implemented, Dijkstra’s algorithm does not work for graphs with direction-dependent distances when directed == False. i.e., if csgraph[i,j] and csgraph[j,i] are not equal and both are nonzero, setting directed=Flutter will not yield the correct result.

Also, this routine does not work for graphs with negative distances. Negative distances can lead to infinite cycles that must be handled by specialized algorithms such as Bellman-Ford’s algorithm or Johnson’s algorithm.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import dijkstra

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 3) 3
```
>>> dist_matrix, predecessors = dijkstra(csgraph=graph, directed=False, \n    indices=0, return_predecessors=True)
>>> dist_matrix
array([[ 0.,  1.,  2.,  2.],
       [ 1.,  0.,  1.,  1.],
       [ 2.,  1.,  0.,  1.],
       [ 2.,  1.,  1.,  0.]])
>>> predecessors
array([[-9999,  0,  0,  1],
       [  0, -9999,  1,  1],
       [  0,  1, -9999,  1],
       [  0,  1,  1, -9999]], dtype=int32)

scipy.sparse.csgraph.floyd_warshall

`scipy.sparse.csgraph.floyd_warshall(csgraph, directed=True, return_predecessors=False, \n    unweighted=False, overwrite=False)`

Computes the shortest path lengths using the Floyd-Warshall algorithm

New in version 0.11.0.

**Parameters**

- `csgraph` [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.
- `directed` [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
- `return_predecessors` [bool, optional] If True, return the size (N, N) predecessor matrix
- `unweighted` [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- `overwrite` [bool, optional] If True, overwrite csgraph with the result. This applies only if csgraph is a dense, c-ordered array with dtype=float64.

**Returns**

- `dist_matrix` [ndarray] The N x N matrix of distances between graph nodes. dist_matrix[i, j] gives the shortest distance from point i to point j along the graph.
- `predecessors` [ndarray] Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

**Raises**

- `NegativeCycleError:` if there are negative cycles in the graph

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import floyd_warshall
```
```python
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 1],
... [2, 0, 3],
... [0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3
```

```python
>>> dist_matrix, predecessors = floyd_warshall(csgraph=graph,
... directed=False, return_predecessors=True)
>>> dist_matrix
array([[0., 1., 2., 2.],
       [1., 0., 3., 1.],
       [2., 3., 0., 3.],
       [2., 1., 3., 0.]])
>>> predecessors
array([[-9999,  0,  0,  1],
       [ 1, -9999,  0,  1],
       [ 2,   0, -9999,  2],
       [ 1,   3,   3, -9999]], dtype=int32)
```

**scipy.sparse.csgraph.bellman_ford**

`scipy.sparse.csgraph.bellman_ford(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False)`

Compute the shortest path lengths using the Bellman-Ford algorithm.

The Bellman-Ford algorithm can robustly deal with graphs with negative weights. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, dijkstra’s algorithm may be faster.

New in version 0.11.0.

**Parameters**

- **csgraph** [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.
- **directed** [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
- **indices** [array_like or int, optional] if specified, only compute the paths for the points at the given indices.
- **return_predecessors** [bool, optional] if specified, return the size (N, N) predecessor matrix
- **unweighted** [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
Returns

dist_matrix
[ndarray] The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.

predecessors
[ndarray] Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

Raises

NegativeCycleError:
if there are negative cycles in the graph

Notes

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra's algorithm is a better choice.

Examples

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import bellman_ford

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> dist_matrix, predecessors = bellman_ford(csgraph=graph,
                                           directed=False, indices=0, return_predecessors=True)
>>> dist_matrix
array([ 0., 1., 2., 2.])
>>> predecessors
array([-9999,  0,  0,  1], dtype=int32)
scipy.sparse.csgraph.johnson

`scipy.sparse.csgraph.johnson(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False)`

Compute the shortest path lengths using Johnson’s algorithm.

Johnson’s algorithm combines the Bellman-Ford algorithm and Dijkstra’s algorithm to quickly find shortest paths in a way that is robust to the presence of negative cycles. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, dijkstra() may be faster.

New in version 0.11.0.

Parameters

- `csgraph` [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.
- `directed` [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].
- `indices` [array_like or int, optional] if specified, only compute the paths for the points at the given indices.
- `return_predecessors` [bool, optional] If True, return the size (N, N) predecessor matrix
- `unweighted` [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

Returns

- `dist_matrix` [ndarray] The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.
- `predecessors` [ndarray] Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

Raises

- `NegativeCycleError:` if there are negative cycles in the graph

Notes

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra’s algorithm is a better choice.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import johnson
```
```python
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 1, 0],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]

>>> graph = csr_matrix(graph)

>>> print(graph)

(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> dist_matrix, predecessors = johnson(csgraph=graph, directed=False,
... indices=0, return_predecessors=True)

>>> dist_matrix

array([ 0., 1., 2., 2.])

>>> predecessors

array([-9999, 0, 0, 1], dtype=int32)
```

scipy.sparse.csgraph.breadth_first_order

The function `scipy.sparse.csgraph.breadth_first_order(csgraph, i_start, directed=True, return_predecessors=True)` returns a breadth-first ordering starting with specified node.

Note that a breadth-first order is not unique, but the tree which it generates is unique.

New in version 0.11.0.

**Parameters**

- **csgraph** [array_like or sparse matrix] The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- **i_start** [int] The index of starting node.
- **directed** [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].
- **return_predecessors** [bool, optional] If True (default), then return the predecessor array (see below).

**Returns**

- **node_array** [ndarray, one dimension] The breadth-first list of nodes, starting with specified node. The length of node_array is the number of nodes reachable from the specified node.
- **predecessors** [ndarray, one dimension] Returned only if return_predecessors is True. The length-N list of predecessors of each node in a breadth-first tree. If node i is in the tree, then its parent is given by predecessors[i]. If node i is not in the tree (and for the parent node) then predecessors[i] = -9999.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_order

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 3],
... [0, 0, 0]
...]

>>> graph = csr_matrix(graph)

>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> breadth_first_order(graph, 0)
(array([0, 1, 2, 3], dtype=int32), array([-9999, 0, 0, 1], dtype=int32))
```

**scipy.sparse.csgraph.depth_first_order**

scipy.sparse.csgraph.\texttt{depth\_first\_order}(\texttt{csgraph}, \texttt{i\_start}, \texttt{directed=True}, \texttt{return\_predecessors=True})

Return a depth-first ordering starting with specified node.

Note that a depth-first order is not unique. Furthermore, for graphs with cycles, the tree generated by a depth-first search is not unique either.

New in version 0.11.0.

**Parameters**

- **csgraph** [array_like or sparse matrix] The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- **i_start** [int] The index of starting node.
- **directed** [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].
- **return_predecessors** [bool, optional] If True (default), then return the predecessor array (see below).

**Returns**

- **node_array** [ndarray, one dimension] The depth-first list of nodes, starting with specified node. The length of node_array is the number of nodes reachable from the specified node.
- **predecessors** [ndarray, one dimension] Returned only if return_predecessors is True. The length-N list of predecessors of each node in a depth-first tree. If node i is in the tree, then its parent is given by predecessors[i]. If node i is not in the tree (and for the parent node) then predecessors[i] = -9999.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_order

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 1, 0],
... [2, 0, 3, 0],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> depth_first_order(graph, 0)
(array([0, 1, 3, 2], dtype=int32), array([-9999, 0, 0, 1],
    dtype=int32))
```

`scipy.sparse.csgraph.breadth_first_tree`

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:
In compressed sparse representation, the solution looks like this:

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
    ...                  [0, 0, 2, 5],
    ...                  [0, 0, 0, 6],
    ...                  [0, 0, 0, 0]])
>>> Tcsr = breadth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 3],
       [0, 0, 2, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])
```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. A breadth-first tree from a given node is unique.

**scipy.sparse.csgraph.depth_first_tree**

```python
scipy.sparse.csgraph.depth_first_tree(csgraph, i_start, directed=True)
```

Return a tree generated by a depth-first search.

Note that a tree generated by a depth-first search is not unique: it depends on the order that the children of each node are searched.

New in version 0.11.0.

**Parameters**

- **csgraph** [array_like or sparse matrix] The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- **i_start** [int] The index of starting node.
- **directed** [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

**Returns**

- **cstree** [csr matrix] The N x N directed compressed-sparse representation of the depth-first tree drawn from csgraph, starting at the specified node.
Examples

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

```
input graph       depth first tree from (0)

    (0)               (0)
    / \                / \  
  3  8                8
    / \                /  
(3)---5---(1)      (3)---(1)
    \ /                \  
  6  2                6  2
    \ /                \  
  (2)                  (2)
```

In compressed sparse representation, the solution looks like this:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
                 ... [0, 0, 2, 5],
                 ... [0, 0, 0, 6],
                 ... [0, 0, 0, 0]])
>>> Tcsr = depth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 0],
       [0, 0, 2, 0],
       [0, 0, 0, 6],
       [0, 0, 0, 0]])
```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. Unlike a breadth-first tree, a depth-first tree of a given graph is not unique if the graph contains cycles. If the above solution had begun with the edge connecting nodes 0 and 3, the result would have been different.

**scipy.sparse.csgraph.minimum_spanning_tree**

`scipy.sparse.csgraph.minimum_spanning_tree(csgraph, overwrite=False)`

Return a minimum spanning tree of an undirected graph

A minimum spanning tree is a graph consisting of the subset of edges which together connect all connected nodes, while minimizing the total sum of weights on the edges. This is computed using the Kruskal algorithm.

New in version 0.11.0.

**Parameters**

- `csgraph` [array_like or sparse matrix, 2 dimensions] The N x N matrix representing an undirected graph over N nodes (see notes below).
- `overwrite` [bool, optional] if true, then parts of the input graph will be overwritten for efficiency.

**Returns**

- `span_tree` [csr matrix] The N x N compressed-sparse representation of the undirected minimum spanning tree over the input (see notes below).
Notes

This routine uses undirected graphs as input and output. That is, if \( \text{graph}[i, j] \) and \( \text{graph}[j, i] \) are both zero, then nodes \( i \) and \( j \) do not have an edge connecting them. If either is nonzero, then the two are connected by the minimum nonzero value of the two.

Examples

The following example shows the computation of a minimum spanning tree over a simple four-component graph:

```
input graph                minimum spanning tree
(0)  (0)
/  /  /
3  8  3
/  /  /
(3)---5---(1) (3)---5---(1)
/  /  /
6  2  2
\  \  /
(2)  (2)
```

It is easy to see from inspection that the minimum spanning tree involves removing the edges with weights 8 and 6. In compressed sparse representation, the solution looks like this:

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import minimum_spanning_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                 [0, 0, 2, 5],
...                 [0, 0, 0, 6],
...                 [0, 0, 0, 0]])
>>> Tcsr = minimum_spanning_tree(X)
>>> Tcsr.tocoo().astype(int)
array([[0, 0, 0, 3],
       [0, 0, 2, 5],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])
```

`scipy.sparse.csgraph.reverse_cuthill_mckee`

`scipy.sparse.csgraph.reverse_cuthill_mckee(graph, symmetric_mode=False)`

Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.

It is assumed by default, `symmetric_mode=False`, that the input matrix is not symmetric and works on the matrix \( A + A^T \). If you are guaranteed that the matrix is symmetric in structure (values of matrix elements do not matter) then set `symmetric_mode=True`.

**Parameters**

- `graph` [sparse matrix] Input sparse in CSC or CSR sparse matrix format.
- `symmetric_mode` [bool, optional] Is input matrix guaranteed to be symmetric.

**Returns**
perm [ndarray] Array of permuted row and column indices.

Notes

New in version 0.15.0.

References

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import reverse_cuthill_mckee

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 1, 0],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> reverse_cuthill_mckee(graph)
array([3, 2, 1, 0], dtype=int32)
```

scipy.sparse.csgraph.maximum_bipartite_matching

`scipy.sparse.csgraph.maximum_bipartite_matching(graph, perm_type='row')`

Returns an array of row or column permutations that makes the diagonal of a nonsingular square CSC sparse matrix zero free.

Such a permutation is always possible provided that the matrix is nonsingular. This function looks at the structure of the matrix only. The input matrix will be converted to CSC matrix format if necessary.

Parameters

- `graph` [sparse matrix] Input sparse in CSC format
- `perm_type` [str, {'row', 'column'}] Type of permutation to generate.

Returns

- `perm` [ndarray] Array of row or column permutations.
Notes

This function relies on a maximum cardinality bipartite matching algorithm based on a breadth-first search (BFS) of the underlying graph.

New in version 0.15.0.

References

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import maximum_bipartite_matching

>>> graph = [
... [0, 1, 2, 0],
... [1, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 1, 3, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 0) 1
(1, 3) 1
(2, 0) 2
(2, 3) 3
(3, 1) 1
(3, 2) 3

>>> maximum_bipartite_matching(graph, perm_type='row')
array([1, 0, 3, 2], dtype=int32)
```

scipy.sparse.csgraph.structural_rank

scipy.sparse.csgraph.structural_rank(graph)

Compute the structural rank of a graph (matrix) with a given sparsity pattern.

The structural rank of a matrix is the number of entries in the maximum transversal of the corresponding bipartite graph, and is an upper bound on the numerical rank of the matrix. A graph has full structural rank if it is possible to permute the elements to make the diagonal zero-free.

New in version 0.19.0.

Parameters

- **graph** [sparse matrix] Input sparse matrix.

Returns

...
rank  [int] The structural rank of the sparse graph.

References

[1], [2]

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import structural_rank

>>> graph = [
... [0, 1, 2, 0],
... [1, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 1, 3, 0]
... ]

>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 0) 1
(1, 3) 1
(2, 0) 2
(2, 3) 3
(3, 1) 1
(3, 2) 3

>>> structural_rank(graph)
4
```

scipy.sparse.csgraph.NegativeCycleError

exception  scipy.sparse.csgraph.NegativeCycleError

```
with_traceback()
    Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

**scipy.sparse.csgraph.construct_dist_matrix**

`scipy.sparse.csgraph.construct_dist_matrix(graph, predecessors[, directed=True, null_value=np.inf])`

Construct distance matrix from a predecessor matrix

New in version 0.11.0.

**Parameters**

- `graph` [array_like or sparse] The N x N matrix representation of a directed or undirected graph. If dense, then non-edges are indicated by zeros or infinities.
- `predecessors` [array_like] The N x N matrix of predecessors of each node (see Notes below).
- `directed` [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then operate on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`.
- `null_value` [bool, optional] value to use for distances between unconnected nodes. Default is `np.inf`

**Returns**

- `dist_matrix` [ndarray] The N x N matrix of distances between nodes along the path specified by the predecessor matrix. If no path exists, the distance is zero.

**Notes**

The predecessor matrix is of the form returned by `shortest_path`. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry `predecessors[i, j]` gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then `predecessors[i, j] = -9999`

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import construct_dist_matrix

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 1) 1
(2, 3) 3
```
```python
>>> pred = np.array([[-9999, 0, 0, 2],
                   ... [1, -9999, 0, 1],
                   ... [2, 0, -9999, 2],
                   ... [1, 3, 3, -9999]], dtype=np.int32)
```

```python
>>> construct_dist_matrix(graph=graph, predecessors=pred, directed=False)
array([[ 0.,  1.,  2.,  5.],
       [ 1.,  0.,  3.,  1.],
       [ 2.,  3.,  0.,  3.],
       [ 2.,  1.,  3.,  0.]])
```

### scipy.sparse.csgraph.csgraph_from_dense

```python
scipy.sparse.csgraph.csgraph_from_dense(graph, null_value=0, nan_null=True, infinity_null=True)
```

Construct a CSR-format sparse graph from a dense matrix.

New in version 0.11.0.

**Parameters**

- `graph` : array_like, Input graph. Shape should be (n_nodes, n_nodes).
- `null_value` : float or None (optional), Value that denotes non-edges in the graph. Default is zero.
- `infinity_null` : bool, If True (default), then infinite entries (both positive and negative) are treated as null edges.
- `nan_null` : bool, If True (default), then NaN entries are treated as non-edges

**Returns**

- `csgraph` : csr_matrix, Compressed sparse representation of graph.

### Examples

```python
>>> from scipy.sparse.csgraph import csgraph_from_dense
```

```python
>>> graph = [
            ... [0, 1, 2, 0],
            ... [0, 0, 0, 1],
            ... [0, 0, 0, 3],
            ... [0, 0, 0, 0],
            ... ]
```

```python
>>> csgraph_from_dense(graph)
<4x4 sparse matrix of type '<class 'numpy.float64'>'
  with 4 stored elements in Compressed Sparse Row format>
```

### scipy.sparse.csgraph.csgraph_from_masked

```python
scipy.sparse.csgraph.csgraph_from_masked(graph)
```

Construct a CSR-format graph from a masked array.
New in version 0.11.0.

Parameters

- **graph**  [MaskedArray] Input graph. Shape should be (n_nodes, n_nodes).

Returns

- **csgraph**  [csr_matrix] Compressed sparse representation of graph.

Examples

```python
>>> import numpy as np
>>> from scipy.sparse.csgraph import csgraph_from_masked

>>> graph_masked = np.ma.masked_array(data = [
    ... [0, 1, 2, 0],
    ... [0, 0, 0, 1],
    ... [0, 0, 0, 3],
    ... [0, 0, 0, 0]
    ... ],
    ... mask = [[True, False, False, True],
    ... [True, True, True, False],
    ... [True, True, True, False],
    ... [True, True, True, True]],
    ... fill_value = 0)

>>> csgraph_from_masked(graph_masked)
<4x4 sparse matrix of type '<class 'numpy.float64'>'
  with 4 stored elements in Compressed Sparse Row format>
```

scipy.sparse.csgraph.csgraph_masked_from_dense

scipy.sparse.csgraph.**csgraph_masked_from_dense**  

Construct a masked array graph representation from a dense matrix.

New in version 0.11.0.

Parameters

- **graph**  [array_like] Input graph. Shape should be (n_nodes, n_nodes).
- **null_value**  [float or None (optional)] Value that denotes non-edges in the graph. Default is zero.
- **infinity_null**  [bool] If True (default), then infinite entries (both positive and negative) are treated as null edges.
- **nan_null**  [bool] If True (default), then NaN entries are treated as non-edges

Returns

- **csgraph**  [MaskedArray] masked array representation of graph
Examples

```python
>>> from scipy.sparse.csgraph import csgraph_masked_from_dense

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 1],
... [0, 0, 3],
... [0, 0, 0]
... ]

>>> csgraph_masked_from_dense(graph)
masked_array(
data=[[--, 1, 2, --],
     [--, --, --, 1],
     [--, --, --, 3],
     [--, --, --, --]],
mask=[[ True, False, False, True],
      [ True, True, True, False],
      [ True, True, True, False],
      [ True, True, True, True]],
fill_value=0)
```

**scipy.sparse.csgraph.csgraph_to_dense**

Convert a sparse graph representation to a dense representation

New in version 0.11.0.

**Parameters**

- `csgraph` [csr_matrix, csc_matrix, or lil_matrix] Sparse representation of a graph.
- `null_value` [float, optional] The value used to indicate null edges in the dense representation. Default is 0.

**Returns**

**Notes**

For normal sparse graph representations, calling `csgraph_to_dense` with `null_value=0` produces an equivalent result to using dense format conversions in the main sparse package. When the sparse representations have repeated values, however, the results will differ. The tools in scipy.sparse will add repeating values to obtain a final value. This function will select the minimum among repeating values to obtain a final value. For example, here we’ll create a two-node directed sparse graph with multiple edges from node 0 to node 1, of weights 2 and 3. This illustrates the difference in behavior:

```python
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([2, 3])
>>> indices = np.array([1, 1])
>>> indptr = np.array([0, 2, 2])
```
The reason for this difference is to allow a compressed sparse graph to represent multiple edges between any two nodes. As most sparse graph algorithms are concerned with the single lowest-cost edge between any two nodes, the default `scipy.sparse` behavior of summing multiple weights does not make sense in this context.

The other reason for using this routine is to allow for graphs with zero-weight edges. Let’s look at the example of a two-node directed graph, connected by an edge of weight zero:

```python
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([0.0])
>>> indices = np.array([1])
>>> indptr = np.array([0, 1, 1])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 0],
       [0, 0]])
>>> csgraph.csgraph_to_dense(M, np.inf)
array([[inf, 0.],
       [inf, inf]])
```

In the first case, the zero-weight edge gets lost in the dense representation. In the second case, we can choose a different null value and see the true form of the graph.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import csgraph_to_dense

>>> graph = csr_matrix( [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]
)
>>> graph
<4x4 sparse matrix of type '<class 'numpy.int64'>'
with 4 stored elements in Compressed Sparse Row format>

>>> csgraph_to_dense(graph)
array([[0., 1., 2., 0.],
       [0., 0., 0., 1.],
       [0., 0., 0., 3.],
       [0., 0., 0., 0.]])
```
**scipy.sparse.csgraph.csgraph_to_masked**

Convert a sparse graph representation to a masked array representation.

New in version 0.11.0.

**Parameters**

- **csgraph** [csr_matrix, csc_matrix, or lil_matrix] Sparse representation of a graph.

**Returns**

- **graph** [MaskedArray] The masked dense representation of the sparse graph.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import csgraph_to_masked

>>> graph = csr_matrix( 
... [0, 1, 2, 0],
... [0, 0, 1],
... [0, 0, 3],
... [0, 0, 0]
... )
>>> graph
<4x4 sparse matrix of type '<class 'numpy.int64'>'
with 4 stored elements in Compressed Sparse Row format>

>>> csgraph_to_masked(graph)
masked_array(
  data=[[ --, 1.0, 2.0, --],
        [ --, --, --, 1.0],
        [ --, --, --, 3.0],
        [ --, --, --, --]],
  mask=[ [ True, False, False, True],
         [ True, True, True, False],
         [ True, True, True, False],
         [ True, True, True, True]],
  fill_value=1e+20)
```

**scipy.sparse.csgraph.reconstruct_path**

Construct a tree from a graph and a predecessor list.

New in version 0.11.0.

**Parameters**

- **csgraph** [array_like or sparse matrix] The N x N matrix representing the directed or undirected graph from which the predecessors are drawn.
predecessors
[array_like, one dimension] The length-N array of indices of predecessors for the tree. The index of the parent of node i is given by predecessors[i].

directed
[bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then operate on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

Returns
cstree
[csr matrix] The N x N directed compressed-sparse representation of the tree drawn from csgraph which is encoded by the predecessor list.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import reconstruct_path

>>> graph = [
... [0, 1, 2], 0],
... [0, 0, 1],
... [0, 0, 3],
... [0, 0, 0],
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 3) 3

>>> pred = np.array([-9999, 0, 0, 1], dtype=np.int32)

>>> cstree = reconstruct_path(csgraph=graph, predecessors=pred, directed=False)
>>> cstree.todense()
matrix([[ 0., 1., 2., 0.],
[ 0., 0., 0., 1.],
[ 0., 0., 0., 0.],
[ 0., 0., 0., 0.]])
```

6.24.2 Graph Representations

This module uses graphs which are stored in a matrix format. A graph with N nodes can be represented by an (N x N) adjacency matrix G. If there is a connection from node i to node j, then G[i, j] = w, where w is the weight of the connection. For nodes i and j which are not connected, the value depends on the representation:

- for dense array representations, non-edges are represented by G[i, j] = 0, infinity, or NaN.
- for dense masked representations (of type np.ma.MaskedArray), non-edges are represented by masked values. This can be useful when graphs with zero-weight edges are desired.
- for sparse array representations, non-edges are represented by non-entries in the matrix. This sort of sparse representation also allows for edges with zero weights.
As a concrete example, imagine that you would like to represent the following undirected graph:

```
G
(0) /
1 2 /
(2) \ (1)
```

This graph has three nodes, where node 0 and 1 are connected by an edge of weight 2, and nodes 0 and 2 are connected by an edge of weight 1. We can construct the dense, masked, and sparse representations as follows, keeping in mind that an undirected graph is represented by a symmetric matrix:

```python
>>> G_dense = np.array([[0, 2, 1],
                      ...                      [2, 0, 0],
                      ...                      [1, 0, 0]])
>>> G_masked = np.ma.masked_values(G_dense, 0)
>>> from scipy.sparse import csr_matrix
>>> G_sparse = csr_matrix(G_dense)
```

This becomes more difficult when zero edges are significant. For example, consider the situation when we slightly modify the above graph:

```
G2
(0) /
0 2 /
(2) \ (1)
```

This is identical to the previous graph, except nodes 0 and 2 are connected by an edge of zero weight. In this case, the dense representation above leads to ambiguities: how can non-edges be represented if zero is a meaningful value? In this case, either a masked or sparse representation must be used to eliminate the ambiguity:

```python
>>> G2_data = np.array([[np.inf, 2, 0],
                      ...                      [2, np.inf, np.inf],
                      ...                      [0, np.inf, np.inf]])
>>> G2_masked = np.ma.masked_invalid(G2_data)
>>> from scipy.sparse.csgraph import csgraph_from_dense
>>> # G2_sparse = csr_matrix(G2_data) would give the wrong result
>>> G2_sparse = csgraph_from_dense(G2_data, null_value=np.inf)
>>> G2_sparse.data
array([2., 0., 2., 0.])
```

Here we have used a utility routine from the csgraph submodule in order to convert the dense representation to a sparse representation which can be understood by the algorithms in submodule. By viewing the data array, we can see that the zero values are explicitly encoded in the graph.

**Directed vs. Undirected**

Matrices may represent either directed or undirected graphs. This is specified throughout the csgraph module by a boolean keyword. Graphs are assumed to be directed by default. In a directed graph, traversal from node i to node j can be
accomplished over the edge $G[i, j]$, but not the edge $G[j, i]$. Consider the following dense graph:

```python
>>> G_dense = np.array([[0, 1, 0],
                      ...                    [2, 0, 3],
                      ...                    [0, 4, 0]])
```

When `directed=True` we get the graph:

```
---1---  ---3---
(0)    (1)    (2)
<--2--  <--4--
```

In a non-directed graph, traversal from node $i$ to node $j$ can be accomplished over either $G[i, j]$ or $G[j, i]$. If both edges are not null, and the two have unequal weights, then the smaller of the two is used.

So for the same graph, when `directed=False` we get the graph:

```
(0)--1--(1)--2--(2)
```

Note that a symmetric matrix will represent an undirected graph, regardless of whether the ‘directed’ keyword is set to True or False. In this case, using `directed=True` generally leads to more efficient computation.

The routines in this module accept as input either scipy.sparse representations (csr, csc, or lil format), masked representations, or dense representations with non-edges indicated by zeros, infinities, and NaN entries.

### 6.25 Spatial algorithms and data structures (**scipy.spatial**)  

#### 6.25.1 Spatial Transformations

These are contained in the `scipy.spatial.transform` submodule.

#### 6.25.2 Nearest-neighbor Queries

**scipy.spatial.KDTree**

```python
class scipy.spatial.KDTree (data, leafsize=10)
```

This class provides an index into a set of k-dimensional points which can be used to rapidly look up the nearest neighbors of any point.

**Parameters**

- **data** [(N,K) array_like] The data points to be indexed. This array is not copied, and so modifying this data will result in bogus results.
- **leafsize** [int, optional] The number of points at which the algorithm switches over to brute-force. Has to be positive.

**Raises**
RuntimeError

The maximum recursion limit can be exceeded for large data sets. If this happens, either increase the value for the leafsize parameter or increase the recursion limit by:

```python
>>> import sys
>>> sys.setrecursionlimit(10000)
```

See also:

- cKDTree
  
  Implementation of KDTree in Cython

Notes

The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary tree, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value.

During construction, the axis and splitting point are chosen by the “sliding midpoint” rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the $r$ closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the $r$ approximate closest neighbors.

For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

The tree also supports all-neighbors queries, both with arrays of points and with other kd-trees. These do use a reasonably efficient algorithm, but the kd-tree is not necessarily the best data structure for this sort of calculation.

Methods

count_neighbors(self, other, r[, p]) Count how many nearby pairs can be formed.

query(self, x[, k, eps, p, distance_upper_bound]) Query the kd-tree for nearest neighbors

query_ball_point(self, x, r[, p, eps]) Find all points within distance $r$ of point(s) $x$.

query_ball_tree(self, other, r[, p, eps]) Find all pairs of points whose distance is at most $r$.

query_pairs(self, r[, p, eps]) Find all pairs of points within a distance.

sparsity_matrix(self, other, max_distance) Compute a sparse distance matrix.

scipy.spatial.KDTree.count_neighbors

KDTree.count_neighbors (self, other, r=2.0)

Count how many nearby pairs can be formed.

Count the number of pairs $(x_1, x_2)$ can be formed, with $x_1$ drawn from self and $x_2$ drawn from other, and where $\text{distance}(x_1, x_2, p) \leq r$. This is the “two-point correlation” described in Gray and Moore 2000, “N-body problems in statistical learning”, and the code here is based on their algorithm.

Parameters

other [KDTree instance] The other tree to draw points from.

r [float or one-dimensional array of floats] The radius to produce a count for. Multiple radii are searched with a single tree traversal.
SciPy Reference Guide, Release 1.3.2

p
[float, 1<=p<=infinity, optional] Which Minkowski p-norm to use

Returns
result
[int or 1-D array of ints] The number of pairs. Note that this is internally stored in a
numpy int, and so may overflow if very large (2e9).

scipy.spatial.KDTree.query

KDTree.query (self, x, k=1, eps=0, p=2, distance_upper_bound=inf)
Query the kd-tree for nearest neighbors

Parameters
x
[array_like, last dimension self.m] An array of points to query.
k
[int, optional] The number of nearest neighbors to return.
eps
[nonnegative float, optional] Return approximate nearest neighbors; the kth returned
value is guaranteed to be no further than (1+eps) times the distance to the real kth
nearest neighbor.
p
[float, 1<=p<=infinity, optional] Which Minkowski p-norm to use. 1 is the sum-of-
absolute-values “Manhattan” distance 2 is the usual Euclidean distance infinity is the
maximum-coordinate-difference distance
distance_upper_bound
[nonnegative float, optional] Return only neighbors within this distance. This is used to
prune tree searches, so if you are doing a series of nearest-neighbor queries, it may help
to supply the distance to the nearest neighbor of the most recent point.

Returns
d
[float or array of floats] The distances to the nearest neighbors. If x has shape tu-
ple+(self.m,), then d has shape tuple if k is one, or tuple+(k,) if k is larger than one.
Missing neighbors (e.g. when k > n or distance_upper_bound is given) are indicated
with infinite distances. If k is None, then d is an object array of shape tuple, containing
lists of distances. In either case the hits are sorted by distance (nearest first).
i
[integer or array of integers] The locations of the neighbors in self.data. i is the same
shape as d.

Examples

```python
>>> from scipy import spatial
>>> x, y = np.mgrid[0:5, 2:8]
>>> tree = spatial.KDTree(list(zip(x.ravel(), y.ravel())))
>>> tree.data
array([[0, 2],
       [0, 3],
       [0, 4],
       [0, 5],
       [0, 6],
       [0, 7],
       [1, 2],
       [1, 3],
       [1, 4],
       [1, 5],
       [1, 6],
       [1, 7],
       [2, 2],
```

(continues on next page)
scipy.spatial.KDTree.query_ball_point

**KDTree.query_ball_point** *(self, x, r=2.0, eps=0)*

Find all points within distance r of point(s) x.

**Parameters**

- **x**
  - [array_like, shape tuple + (self.m,)] The point or points to search for neighbors of.
- **r**
  - [positive float] The radius of points to return.
- **p**
  - [float, optional] Which Minkowski p-norm to use. Should be in the range [1, inf].
- **eps**
  - [nonnegative float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than r / (1 + eps), and branches are added in bulk if their furthest points are nearer than r * (1 + eps).

**Returns**

- **results**
  - [list or array of lists] If x is a single point, returns a list of the indices of the neighbors of x. If x is an array of points, returns an object array of shape tuple containing lists of neighbors.

**Notes**

If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a KDTree and using query_ball_tree.

**Examples**

```python
>>> from scipy import spatial
>>> x, y = np.mgrid[0:5, 0:5]
```
>>> points = np.c_[x.ravel(), y.ravel()]
>>> tree = spatial.KDTree(points)
>>> tree.query_ball_point([[2, 0], 1])
[5, 10, 11, 15]

Query multiple points and plot the results:

>>> import matplotlib.pyplot as plt
>>> points = np.asarray(points)
>>> plt.plot(points[:, 0], points[:, 1], '.')
>>> for results in tree.query_ball_point(((2, 0), (3, 3)), 1):
... nearby_points = points[results]
... plt.plot(nearby_points[:, 0], nearby_points[:, 1], 'o')
>>> plt.margins(0.1, 0.1)
>>> plt.show()
scipy.spatial.KDTree.query_pairs

KDTree.query_pairs(self, r=2.0, eps=0)

Find all pairs of points within a distance.

Parameters
- r [positive float] The maximum distance.
- p [float, optional] Which Minkowski norm to use. p has to meet the condition 1 <= p <= infinity.
- eps [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than r/(1+eps), and branches are added in bulk if their furthest points are nearer than r * (1+eps). eps has to be non-negative.

Returns
- results [set] Set of pairs (i, j), with i < j, for which the corresponding positions are close.

scipy.spatial.KDTree.sparse_distance_matrix

KDTree.sparse_distance_matrix(self, other, max_distance, p=2.0)

Compute a sparse distance matrix

Computes a distance matrix between two KDTree, leaving as zero any distance greater than max_distance.

Parameters
- other [KDTree]
- max_distance [positive float]
- p [float, optional]

Returns
- result [dok_matrix] Sparse matrix representing the results in “dictionary of keys” format.

scipy.spatial.cKDTree

class scipy.spatial.cKDTree(data, leafsize=16, compact_nodes=True, copy_data=False, balanced_tree=True, boxsize=None)

kd-tree for quick nearest-neighbor lookup

This class provides an index into a set of k-dimensional points which can be used to rapidly look up the nearest neighbors of any point.

The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary trie, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value.

During construction, the axis and splitting point are chosen by the “sliding midpoint” rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the r closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the r approximate closest neighbors.
For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

**Parameters**

- **data**
  
  [array_like, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles, and so modifying this data will result in bogus results. The data are also copied if the kd-tree is built with `copy_data=True`.

- **leafsize**
  
  [positive int, optional] The number of points at which the algorithm switches over to brute-force. Default: 16.

- **compact_nodes**
  
  [bool, optional] If True, the kd-tree is built to shrink the hyperrectangles to the actual data range. This usually gives a more compact tree that is robust against degenerated input data and gives faster queries at the expense of longer build time. Default: True.

- **copy_data**
  
  [bool, optional] If True the data is always copied to protect the kd-tree against data corruption. Default: False.

- **balanced_tree**
  
  [bool, optional] If True, the median is used to split the hyperrectangles instead of the midpoint. This usually gives a more compact tree and faster queries at the expense of longer build time. Default: True.

- **boxsize**
  
  [array_like or scalar, optional] Apply a m-d toroidal topology to the KDTree. The topology is generated by \(x_i + n_i L_i\) where \(n_i\) are integers and \(L_i\) is the boxsize along i-th dimension. The input data shall be wrapped into \([0, L_i)\). A ValueError is raised if any of the data is outside of this bound.

See also:

**KDTree**

Implementation of cKDTree in pure Python

**Attributes**

- **data**
  
  [ndarray, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles. The data are also copied if the kd-tree is built with `copy_data=True`.

- **leafsize**
  
  [positive int] The number of points at which the algorithm switches over to brute-force.

- **m**
  
  [int] The dimension of a single data-point.

- **n**
  
  [int] The number of data points.

- **maxes**
  
  [ndarray, shape (m,)] The maximum value in each dimension of the n data points.

- **mins**
  
  [ndarray, shape (m,)] The minimum value in each dimension of the n data points.

- **tree**
  
  [object, class cKDTreeNode] This class exposes a Python view of the root node in the cKDTree object.

- **size**
  
  [int] The number of nodes in the tree.

**Methods**

- `count_neighbors(self, other, r[, p, …])`  
  Count how many nearby pairs can be formed.

- `query(self, x[, k, eps, p, …])`  
  Query the kd-tree for nearest neighbors

- `query_ball_point(self, x, r[, p, eps])`  
  Find all points within distance r of point(s) x.

- `query_ball_tree(self, other, r[, p, eps])`  
  Find all pairs of points whose distance is at most r

- `query_pairs(self, r[, p, eps])`  
  Find all pairs of points whose distance is at most r.

Continued on next page
Table 197 – continued from previous page

sparse_distance_matrix(self, other, max_distance)

scipy.spatial.cKDTree.count_neighbors
cKDTree.count_neighbors(self, other, r, p=2., weights=None, cumulative=True)

Count how many nearby pairs can be formed. (pair-counting)

Count the number of pairs \((x_1,x_2)\) can be formed, with \(x_1\) drawn from self and \(x_2\) drawn from other, and where \(\text{distance}(x_1, x_2, p) \leq r\).

Data points on self and other are optionally weighted by the weights argument. (See below)

The algorithm we implement here is based on [1]. See notes for further discussion.

Parameters

other [cKDTree instance] The other tree to draw points from, can be the same tree as self.
r [float or one-dimensional array of floats] The radius to produce a count for. Multiple radii are searched with a single tree traversal. If the count is non-cumulative (cumulative=False), \(r\) defines the edges of the bins, and must be non-decreasing.
p [float, optional] \(1 \leq p \leq \infty\). Which Minkowski p-norm to use. Default 2.0. A finite large \(p\) may cause a ValueError if overflow can occur.
weights [tuple, array_like, or None, optional] If None, the pair-counting is unweighted. If given as a tuple, weights[0] is the weights of points in self, and weights[1] is the weights of points in other; either can be None to indicate the points are unweighted. If given as an array_like, weights is the weights of points in self and other. For this to make sense, self and other must be the same tree. If self and other are two different trees, a ValueError is raised. Default: None

cumulative [bool, optional] Whether the returned counts are cumulative. When cumulative is set to False the algorithm is optimized to work with a large number of bins (>10) specified by r. When cumulative is set to True, the algorithm is optimized to work with a small number of r. Default: True

Returns

result [scalar or 1-D array] The number of pairs. For unweighted counts, the result is integer. For weighted counts, the result is float. If cumulative is False, result[i] contains the counts with \((-\infty \text{ if } i == 0 \text{ else } r[i-1]) < R \leq r[i]\)

Notes

Pair-counting is the basic operation used to calculate the two point correlation functions from a data set composed of position of objects.

Two point correlation function measures the clustering of objects and is widely used in cosmology to quantify the large scale structure in our Universe, but it may be useful for data analysis in other fields where self-similar assembly of objects also occur.

The Landy-Szalay estimator for the two point correlation function of \(\mathcal{D}\) measures the clustering signal in \(\mathcal{D}\). [2]

For example, given the position of two sets of objects,

- objects \(\mathcal{D}\) (data) contains the clustering signal, and
objects $\mathbb{R}$ (random) that contains no signal,

$$\xi(r) = \frac{-2f < D, D > + f^2 < R, R >}{f^2 < R, R >},$$

where the brackets represents counting pairs between two data sets in a finite bin around $r$ (distance), corresponding to setting $cumulative=False$, and $f = \frac{\text{float}(\text{len}(D))}{\text{float}(\text{len}(R))}$ is the ratio between number of objects from data and random.

The algorithm implemented here is loosely based on the dual-tree algorithm described in [1]. We switch between two different pair-cumulation scheme depending on the setting of $cumulative$. The computing time of the method we use when for $cumulative == False$ does not scale with the total number of bins. The algorithm for $cumulative == True$ scales linearly with the number of bins, though it is slightly faster when only 1 or 2 bins are used. [5].

As an extension to the naive pair-counting, weighted pair-counting counts the product of weights instead of number of pairs. Weighted pair-counting is used to estimate marked correlation functions ([3], section 2.2), or to properly calculate the average of data per distance bin (e.g. [4], section 2.1 on redshift).

**scipy.spatial.cKDTree.query**

```
cKDTree.query (self, x, k=1, eps=0, p=2, distance_upper_bound=np.inf, n_jobs=1)
```

Query the kd-tree for nearest neighbors

**Parameters**

- **x** [array_like, last dimension self.m] An array of points to query.
- **k** [list of integer or integer] The list of k-th nearest neighbors to return. If k is an integer it is treated as a list of [1, … k] (range(1, k+1)). Note that the counting starts from 1.
- **eps** [non-negative float] Return approximate nearest neighbors; the k-th returned value is guaranteed to be no further than (1+eps) times the distance to the real k-th nearest neighbor.
- **p** [float, 1<=p<=infinity] Which Minkowski p-norm to use. 1 is the sum-of-absolute-values “Manhattan” distance 2 is the usual Euclidean distance infinity is the maximum-coordinate-difference distance A finite large p may cause a ValueError if overflow can occur.
- **distance_upper_bound** [nonnegative float] Return only neighbors within this distance. This is used to prune tree searches, so if you are doing a series of nearest-neighbor queries, it may help to supply the distance to the nearest neighbor of the most recent point.
- **n_jobs** [int, optional] Number of jobs to schedule for parallel processing. If -1 is given all processors are used. Default: 1.

**Returns**

- **d** [array of floats] The distances to the nearest neighbors. If x has shape tuple+(self.m,), then d has shape tuple+(k,). When k == 1, the last dimension of the output is squeezed. Missing neighbors are indicated with infinite distances.
- **i** [ndarray of ints] The locations of the neighbors in self.data. If x has shape tuple+(self.m,), then i has shape tuple+(k,). When k == 1, the last dimension of the output is squeezed. Missing neighbors are indicated with self.n.

**Notes**

If the KD-Tree is periodic, the position x is wrapped into the box.

When the input k is a list, a query for range(max(k)) is performed, but only columns that store the requested values of k are preserved. This is implemented in a manner that reduces memory usage.
Examples

```python
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> x, y = np.mgrid[0:5, 2:8]
>>> tree = cKDTree(np.c_[x.ravel(), y.ravel()])

To query the nearest neighbours and return squeezed result, use

```python
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=1)
>>> print(dd, ii)
[2. 0.14142136] [ 0 13]
```  
To query the nearest neighbours and return unsqueezed result, use

```python
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=1)
>>> print(dd, ii)
[[2. 0.14142136]] [[ 0]
 [13]]
```  
To query the second nearest neighbours and return unsqueezed result, use

```python
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=2)
>>> print(dd, ii)
[[2.23606798 0.90553851]] [[ 6]
 [12]]
```  
To query the first and second nearest neighbours, use

```python
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=2)
>>> print(dd, ii)
[[2. 2.23606798 0.90553851] [[ 0 6]
 [13 12]]
```  
or, be more specific

```python
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1, 2])
>>> print(dd, ii)
[[2. 2.23606798 0.90553851] [[ 0 6]
 [13 12]]
```

scipy.spatial.cKDTree.query_ball_point

`cKDTree.query_ball_point(self, x, r, p=2., eps=0)`

Find all points within distance r of point(s) x.

**Parameters**

- **x** [array_like, shape tuple + (self.m,)] The point or points to search for neighbors of.
- **r** [array_like, float] The radius of points to return, shall broadcast to the length of x.
- **p** [float, optional] Which Minkowski p-norm to use. Should be in the range [1, inf]. A finite large p may cause a ValueError if overflow can occur.
**eps** [nonnegative float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than \( r / (1 + \text{eps}) \), and branches are added in bulk if their furthest points are nearer than \( r * (1 + \text{eps}) \). eps has to be non-negative.

**n_jobs** [int, optional] Number of jobs to schedule for parallel processing. If -1 is given all processors are used. Default: 1.

**return_sorted** [bool, optional] Sorts returned indicies if True and does not sort them if False. If None, does not sort single point queries, but does sort multi-point queries which was the behavior before this option was added. New in version 1.2.0.

**return_length** bool, optional
Return the number of points inside the radius instead of a list of the indices. .. version-added:: 1.3.0

**Returns**
results [list or array of lists] If \( x \) is a single point, returns a list of the indices of the neighbors of \( x \). If \( x \) is an array of points, returns an object array of shape tuple containing lists of neighbors.

**Notes**
If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a cKDTree and using query_ball_tree.

**Examples**

```python
>>> from scipy import spatial
>>> x, y = np.mgrid[0:4, 0:4]
>>> points = np.c_[x.ravel(), y.ravel()]
>>> tree = spatial.cKDTree(points)
>>> tree.query_ball_point([[2, 0]], 1)
[4, 8, 9, 12]
```

scipy.spatial.cKDTree.query_ball_tree

`cKDTree.query_ball_tree(self, other, r, p=2., eps=0)`
Find all pairs of points whose distance is at most \( r \)

**Parameters**

other [cKDTree instance] The tree containing points to search against.
r [float] The maximum distance, has to be positive.
p [float, optional] Which Minkowski norm to use. \( p \) has to meet the condition \( 1 <= p <= \infty \). A finite large \( p \) may cause a ValueError if overflow can occur.
eps [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than \( r/(1+\text{eps}) \), and branches are added in bulk if their furthest points are nearer than \( r * (1+\text{eps}) \). eps has to be non-negative.

**Returns**
results [list of lists] For each element `self.data[i]` of this tree, `results[i]` is a list of the indices of its neighbors in `other.data`. 

6.25. Spatial algorithms and data structures (`scipy.spatial`)
**scipy.spatial.cKDTree.query_pairs**

`cKDTree.query_pairs(self, r, p=2., eps=0)`

Find all pairs of points whose distance is at most \( r \).

**Parameters**
- **r** [positive float] The maximum distance.
- **p** [float, optional] Which Minkowski norm to use. \( p \) has to meet the condition \( 1 \leq p \leq \infty \). A finite large \( p \) may cause a `ValueError` if overflow can occur.
- **eps** [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than \( r/(1+\text{eps}) \), and branches are added in bulk if their furthest points are nearer than \( r \cdot (1+\text{eps}) \). \( \text{eps} \) has to be non-negative.
- **output_type** [string, optional] Choose the output container, ‘set’ or ‘ndarray’. Default: ‘set’

**Returns**
- **results** [set or ndarray] Set of pairs \( (i, j) \), with \( i < j \), for which the corresponding positions are close. If `output_type` is ‘ndarray’, an `ndarray` is returned instead of a `set`.

**scipy.spatial.cKDTree.sparse_distance_matrix**

`cKDTree.sparse_distance_matrix(self, other, max_distance, p=2.)`

Computes a sparse distance matrix

Computes a distance matrix between two cKDTrees, leaving as zero any distance greater than `max_distance`.

**Parameters**
- **other** [cKDTree]
- **max_distance** [positive float]
- **p** [float, \( 1 \leq p \leq \infty \)] Which Minkowski p-norm to use. A finite large \( p \) may cause a `ValueError` if overflow can occur.

**Returns**
- **result** [dok_matrix, coo_matrix, dict or ndarray] Sparse matrix representing the results in “dictionary of keys” format. If a dict is returned the keys are \((i, j)\) tuples of indices. If `output_type` is ‘ndarray’ a record array with fields ‘i’, ‘j’, and ‘k’ is returned.

**scipy.spatial.Rectangle**

**class scipy.spatial.Rectangle(maxes, mins)**

Hyperrectangle class.

Represents a Cartesian product of intervals.

**Methods**

- **max_distance_point** (self, x[, p])
  Return the maximum distance between input and points in the hyperrectangle.

---

#### scipy.spatial.Rectangle.max_distance_point

**Rectangle.max_distance_point** *(self, x, p=2.0)*

Return the maximum distance between input and points in the hyperrectangle.

**Parameters**

- `x` [array_like] Input array.
- `p` [float, optional] Input.

#### scipy.spatial.Rectangle.max_distance_rectangle

**Rectangle.max_distance_rectangle** *(self, other, p=2.0)*

Compute the maximum distance between points in the two hyperrectangles.

**Parameters**

- `other` [hyperrectangle] Input.
- `p` [float, optional] Input.

#### scipy.spatial.Rectangle.min_distance_point

**Rectangle.min_distance_point** *(self, x, p=2.0)*

Return the minimum distance between input and points in the hyperrectangle.

**Parameters**

- `x` [array_like] Input.
- `p` [float, optional] Input.

#### scipy.spatial.Rectangle.min_distance_rectangle

**Rectangle.min_distance_rectangle** *(self, other, p=2.0)*

Compute the minimum distance between points in the two hyperrectangles.

**Parameters**

- `other` [hyperrectangle] Input.
- `p` [float] Input.

#### scipy.spatial.Rectangle.split

**Rectangle.split** *(self, d, split)*

Produce two hyperrectangles by splitting.

In general, if you need to compute maximum and minimum distances to the children, it can be done more efficiently by updating the maximum and minimum distances to the parent.

**Parameters**

- `d` [int] Axis to split hyperrectangle along.
- `split` [float] Position along axis `d` to split at.
scipy.spatial.Rectangle.volume

Rectangle.volume(self)
Total volume.

Distance metrics are contained in the scipy.spatial.distance submodule.

6.25.3 Delaunay Triangulation, Convex Hulls and Voronoi Diagrams

</tbody>
</table>

scipy.spatial.Delaunay

class scipy.spatial.Delaunay(points, furthest_site=False, incremental=False, qhull_options=None)
Delaunay tessellation in N dimensions.
New in version 0.9.

Parameters

points : [ndarray of floats, shape (npoints, ndim)]
Coordinates of points to triangulate

furthest_site : [bool, optional]
Whether to compute a furthest-site Delaunay triangulation. Default: False
New in version 0.12.0.

incremental : [bool, optional]
Allow adding new points incrementally. This takes up some additional resources.

qhull_options : [str, optional]
Additional options to pass to Qhull. See Qhull manual for details. Option “Qt” is always enabled. Default: “Qbb Qc Qz Qx Q12” for ndim > 4 and “Qbb Qc Qz Q12” otherwise. Incremental mode omits “Qz”. New in version 0.12.0.

Raises

QhullError
Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

ValueError
Raised if an incompatible array is given as input.

Notes

The tessellation is computed using the Qhull library Qhull library.

Note: Unless you pass in the Qhull option “QJ”, Qhull does not guarantee that each input point appears as a vertex in the Delaunay triangulation. Omitted points are listed in the coplanar attribute.
Examples

Triangulation of a set of points:

```python
>>> points = np.array([[0, 0], [0, 1.1], [1, 0], [1, 1]])
>>> from scipy.spatial import Delaunay
>>> tri = Delaunay(points)
```

We can plot it:

```python
>>> import matplotlib.pyplot as plt
>>> plt.triplot(points[:,0], points[:,1], tri.simplices)
>>> plt.plot(points[:,0], points[:,1], 'o')
>>> plt.show()
```

Point indices and coordinates for the two triangles forming the triangulation:

```python
>>> tri.simplices
array([[ 2,  3,  0], # may vary
        [ 3,  1,  0]], dtype=int32)
```

Note that depending on how rounding errors go, the simplices may be in a different order than above.

```python
>>> points[tri.simplices]
array([[[ 1., 0.], # may vary
        [ 1., 1.],
        [ 0., 1.]],
        [[ 1., 1.],
        [ 0., 1.1],
        [ 0., 0.]]])
```

Triangle 0 is the only neighbor of triangle 1, and it’s opposite to vertex 1 of triangle 1:

```python
>>> tri.neighbors[1]
array([-1,  0, -1], dtype=int32)
```
We can find out which triangle points are in:

```python
>>> p = np.array([(0.1, 0.2), (1.5, 0.5), (0.5, 1.05)])
>>> tri.find_simplex(p)
array([ 1, -1, 1], dtype=int32)
```

The returned integers in the array are the indices of the simplex the corresponding point is in. If -1 is returned, the point is in no simplex. Be aware that the shortcut in the following example only works correctly for valid points as invalid points result in -1 which is itself a valid index for the last simplex in the list.

```python
>>> p_valids = np.array([(0.1, 0.2), (0.5, 1.05)])
>>> tri(simplices=tri.find_simplex(p_valids))
array([[3, 1, 0], # may vary
       [3, 1, 0]], dtype=int32)
```

We can also compute barycentric coordinates in triangle 1 for these points:

```python
>>> b = tri.transform[1,:2].dot(np.transpose(p - tri.transform[1,2]))
>>> np.c_[np.transpose(b), 1 - b.sum(axis=0)]
array([[ 0.1, 0.09090909, 0.80909091],
       [ 1.5, -0.90909091, 0.40909091],
       [ 0.5, 0.5, 0. ]])
```

The coordinates for the first point are all positive, meaning it is indeed inside the triangle. The third point is on a vertex, hence its null third coordinate.

**Attributes**

- **points** [ndarray of double, shape (npoints, ndim)] Coordinates of input points.
- **simplices** [ndarray of ints, shape (nsimplex, ndim+1)] Indices of the points forming the simplices in the triangulation. For 2-D, the points are oriented counterclockwise.
- **neighbors** [ndarray of ints, shape (nsimplex, ndim+1)] Indices of neighbor simplices for each simplex. The kth neighbor is opposite to the kth vertex. For simplices at the boundary, -1 denotes no neighbor.
- **equations** [ndarray of double, shape (nsimplex, ndim+2)] [normal, offset] forming the hyperplane equation of the facet on the paraboloid (see Qhull documentation for more).
- **paraboloid_scale, paraboloid_shift** [float] Scale and shift for the extra paraboloid dimension (see Qhull documentation for more).
- **transform** [ndarray of double, shape (nsimplex, ndim+1, ndim)] Affine transform from x to the barycentric coordinates c.
- **vertex_to_simplex** [ndarray of int, shape (npoints,)] Lookup array, from a vertex, to some simplex which it is a part of.
- **convex_hull** [ndarray of int, shape (nfaces, ndim)] Vertices of facets forming the convex hull of the point set.
- **coplanar** [ndarray of int, shape (ncoplanar, 3)] Indices of coplanar points and the corresponding indices of the nearest facet and the nearest vertex. Coplanar points are input points which were not included in the triangulation due to numerical precision issues. If option “Qc” is not specified, this list is not computed.
New in version 0.12.0.

vertices  Same as simplices, but deprecated.
vertex_neighbor_vertices  [tuple of two ndarrays of int; (indptr, indices)] Neighboring vertices of vertices.

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>add_points(points[, restart])</td>
<td>Process a set of additional new points.</td>
</tr>
<tr>
<td>close()</td>

</tr>
</tbody>
</table>

**scipy.spatial.Delaunay.add_points**

Delaunay.add_points (points, restart=False)

Process a set of additional new points.

**Parameters**

- **points** [ndarray] New points to add. The dimensionality should match that of the initial points.
- **restart** [bool, optional] Whether to restart processing from scratch, rather than adding points incrementally.

**Raises**

- **QhullError**
  Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**See also:**

- **close**

**Notes**

You need to specify incremental=True when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after close has been called.

**scipy.spatial.Delaunay.close**

Delaunay.close

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

**scipy.spatial.Delaunay.find_simplex**

Delaunay.find_simplex (self, xi, bruteforce=False, tol=None)

Find the simplices containing the given points.

**Parameters**

- **tri** [DelaunayInfo] Delaunay triangulation
- **xi** [ndarray of double, shape (…, ndim)] Points to locate
bruteforce [bool, optional] Whether to only perform a brute-force search
tol [float, optional] Tolerance allowed in the inside-triangle check. Default is 100*eps.

Returns

i [ndarray of int, same shape as xi] Indices of simplices containing each point. Points outside the triangulation get the value -1.

Notes

This uses an algorithm adapted from Qhull's qh_findbestfacet, which makes use of the connection between a convex hull and a Delaunay triangulation. After finding the simplex closest to the point in N+1 dimensions, the algorithm falls back to directed search in N dimensions.

scipy.spatial.Delaunay.lift_points

Delaunay.lift_points(self, x)
Lift points to the Qhull paraboloid.

scipy.spatial.Delaunay.plane_distance

Delaunay.plane_distance(self, xi)
Compute hyperplane distances to the point xi from all simplices.

scipy.spatial.ConvexHull

class scipy.spatial.ConvexHull(points, incremental=False, qhull_options=None)
Convex hulls in N dimensions.
New in version 0.12.0.

Parameters

points [ndarray of floats, shape (npoints, ndim)] Coordinates of points to construct a convex hull from
incremental [bool, optional] Allow adding new points incrementally. This takes up some additional resources.
qhull_options [str, optional] Additional options to pass to Qhull. See Qhull manual for details. (Default: "Qx" for ndim > 4 and "" otherwise) Option "Qt" is always enabled.

Raises

QhullError Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

ValueError Raised if an incompatible array is given as input.

Notes

The convex hull is computed using the Qhull library.
References

[Refc41737eb6-Qhull]

Examples

Convex hull of a random set of points:

```python
>>> from scipy.spatial import ConvexHull, convex_hull_plot_2d
>>> points = np.random.rand(30, 2)  # 30 random points in 2-D
>>> hull = ConvexHull(points)
```

Plot it:

```python
>>> import matplotlib.pyplot as plt
>>> plt.plot(points[:,0], points[:,1], 'o')
>>> for simplex in hull.simplices:
...     plt.plot(points[simplex, 0], points[simplex, 1], 'k-')
```

We could also have directly used the vertices of the hull, which for 2-D are guaranteed to be in counterclockwise order:

```python
>>> plt.plot(points[hull.vertices,0], points[hull.vertices,1], 'r--', lw=2)
>>> plt.plot(points[hull.vertices[0],0], points[hull.vertices[0],1], 'ro')
>>> plt.show()
```

Facets visible from a point:

Create a square and add a point above the square.

```python
>>> generators = np.array([[0.2, 0.2],
...                         [0.2, 0.4],
...                         [0.4, 0.4]],
...                        dtype=float)
```

(continues on next page)
Call ConvexHull with the QG option. QG4 means compute the portions of the hull not including point 4, indicating the facets that are visible from point 4.

```python
>>> hull = ConvexHull(points=generators,
...                    qhull_options='QG4')
```

The “good” array indicates which facets are visible from point 4.

```python
>>> print(hull.simplices)
[[1 0]
 [1 2]
 [3 0]
 [3 2]]
>>> print(hull.good)
 [False  True False False]
```

Now plot it, highlighting the visible facets.

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1,1,1)
>>> for visible_facet in hull.simplices[hull.good]:
...     ax.plot(hull.points[visible_facet, 0],
...             hull.points[visible_facet, 1],
...             color='violet',
...             lw=6)
>>> convex_hull_plot_2d(hull, ax=ax)
<Figure size 640x480 with 1 Axes> # may vary
>>> plt.show()
```

![Graph and plot](image)

**Attributes**
**points** [ndarray of double, shape (npoints, ndim)] Coordinates of input points.

**vertices** [ndarray of ints, shape (nvertices,)] Indices of points forming the vertices of the convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order.

**simplices** [ndarray of ints, shape (nfacet, ndim)] Indices of points forming the simplical facets of the convex hull.

**neighbors** [ndarray of ints, shape (nfacet, ndim)] Indices of neighbor facets for each facet. The kth neighbor is opposite to the kth vertex. -1 denotes no neighbor.

**equations** [ndarray of double, shape (nfacet, ndim+1)] [normal, offset] forming the hyperplane equation of the facet (see [Qhull documentation](https://www.qhull.org/documentation) for more).

**coplanar** [ndarray of int, shape (ncoplanar, 3)] Indices of coplanar points and the corresponding indices of the nearest facets and nearest vertex indices. Coplanar points are input points which were not included in the triangulation due to numerical precision issues. If option “Qc” is not specified, this list is not computed.

**good** [ndarray of bool or None] A one-dimensional Boolean array indicating which facets are good. Used with options that compute good facets, e.g. QGn and QG-n. Good facets are defined as those that are visible (n) or invisible (-n) from point n, where n is the nth point in ‘points’. The ‘good’ attribute may be used as an index into ‘simplices’ to return the good (visible) facets: simplices[good]. A facet is visible from the outside of the hull only, and neither coplanarity nor degeneracy count as cases of visibility. If a “QGn” or “QG-n” option is not specified, None is returned. New in version 1.3.0.

**area** [float] Area of the convex hull. New in version 0.17.0.

**volume** [float] Volume of the convex hull. New in version 0.17.0.

#### scipy.spatial.ConvexHull.add_points

ConvexHull.add_points(points, restart=False)

Process a set of additional new points.

**Parameters**

- **points** [ndarray] New points to add. The dimensionality should match that of the initial points.
- **restart** [bool, optional] Whether to restart processing from scratch, rather than adding points incrementally.

**Raises**

- **QhullError** Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**See also:**

- **close**
Notes

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after `close` has been called.

**scipy.spatial.ConvexHull.close**

`ConvexHull.close`

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

**scipy.spatial.Voronoi**

class scipy.spatial.Voronoi (points, furthest_site=False, incremental=False, qhull_options=None)

Voronoi diagrams in N dimensions.

New in version 0.12.0.

Parameters

points [ndarray of floats, shape (npoints, ndim)] Coordinates of points to construct a convex hull from

furthest_site [bool, optional] Whether to compute a furthest-site Voronoi diagram. Default: False

incremental [bool, optional] Allow adding new points incrementally. This takes up some additional resources.

qhull_options [str, optional] Additional options to pass to Qhull. See Qhull manual for details. (Default: “Qbb Qc Qz Qx” for ndim > 4 and “Qbb Qc Qz” otherwise. Incremental mode omits “Qz”.)

Raises

QhullError Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

ValueError Raised if an incompatible array is given as input.

Notes

The Voronoi diagram is computed using the Qhull library.

Examples

Voronoi diagram for a set of point:

```python
>>> points = np.array([[0, 0], [0, 1], [0, 2], [1, 0], [1, 1], [1, 2],
                      [2, 0], [2, 1], [2, 2]])
>>> from scipy.spatial import Voronoi, voronoi_plot_2d
>>> vor = Voronoi(points)
>>> voronoi_plot_2d(vor)
```

Plot it:
```python
>>> import matplotlib.pyplot as plt
>>> fig = voronoi_plot_2d(vor)
>>> plt.show()
```

The Voronoi vertices:

```python
>>> vor.vertices
array([[ 0.5, 0.5],
       [ 1.5, 0.5],
       [ 0.5, 1.5],
       [ 1.5, 1.5]])
```

There is a single finite Voronoi region, and four finite Voronoi ridges:

```python
>>> vor.regions
[[], [-1, 0], [-1, 1], [1, -1, 0], [3, -1, 2], [-1, 3], [-1, 2], [3, 2, 0, -1], [2, -1, 0], [3, -1, 1]]
```

The ridges are perpendicular between lines drawn between the following input points:

```python
>>> vor.ridge_points
array([[0, 1],
       [0, 3],
       [6, 3],
       [6, 7],
       [3, 4],
       [5, 8],
       [5, 2],
       [5, 4],
       [8, 7],
       [2, 1],
       [2, 1],
       [0, 2],
       [1, 3]])
```
Attributes

points [ndarray of double, shape (npoints, ndim)] Coordinates of input points.
vertices [ndarray of double, shape (nvertices, ndim)] Coordinates of the Voronoi vertices.
ridge_points [ndarray of ints, shape (nridges, 2)] Indices of the points between which each Voronoi ridge lies.
ridge_vertices [list of list of ints, shape (nridges, *)] Indices of the Voronoi vertices forming each Voronoi ridge.
regions [list of list of ints, shape (nregions, *)] Indices of the Voronoi vertices forming each Voronoi region. -1 indicates vertex outside the Voronoi diagram.
point_region [list of ints, shape (npoints)] Index of the Voronoi region for each input point. If qhull option “Qc” was not specified, the list will contain -1 for points that are not associated with a Voronoi region.

Methods

add_points(points[, restart]) Process a set of additional new points.
close() Finish incremental processing.

scipy.spatial.Voronoi.add_points

Voronoi.add_points (points, restart=False) Process a set of additional new points.

Parameters

points [ndarray] New points to add. The dimensionality should match that of the initial points.
restart [bool, optional] Whether to restart processing from scratch, rather than adding points incrementally.

Raises

QhullError Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

See also:

close

Notes

You need to specify incremental=True when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after close has been called.
**scipy.spatial.Voronoi.close**

**Voronoi.close**

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

**scipy.spatial.SphericalVoronoi**

**class scipy.spatial.SphericalVoronoi** *(points, radius=None, center=None, threshold=1e-06)*

Voronoi diagrams on the surface of a sphere.

New in version 0.18.0.

**Parameters**

- **points** [ndarray of floats, shape (npoints, 3)] Coordinates of points from which to construct a spherical Voronoi diagram.
- **radius** [float, optional] Radius of the sphere (Default: 1)
- **center** [ndarray of floats, shape (3,)] Center of sphere (Default: origin)
- **threshold** [float] Threshold for detecting duplicate points and mismatches between points and sphere parameters. (Default: 1e-06)

**Raises**

**ValueError**

If there are duplicates in *points*. If the provided *radius* is not consistent with *points*.

**See also:**

**Voronoi**

Conventional Voronoi diagrams in N dimensions.

**Notes**

The spherical Voronoi diagram algorithm proceeds as follows. The Convex Hull of the input points (generators) is calculated, and is equivalent to their Delaunay triangulation on the surface of the sphere [R9133a064969a-Caroli]. A 3D Delaunay tetrahedralization is obtained by including the origin of the coordinate system as the fourth vertex of each simplex of the Convex Hull. The circumcenters of all tetrahedra in the system are calculated and projected to the surface of the sphere, producing the Voronoi vertices. The Delaunay tetrahedralization neighbour information is then used to order the Voronoi region vertices around each generator. The latter approach is substantially less sensitive to floating point issues than angle-based methods of Voronoi region vertex sorting.

The surface area of spherical polygons is calculated by decomposing them into triangles and using L’Huilier’s Theorem to calculate the spherical excess of each triangle [R9133a064969a-Weisstein]. The sum of the spherical excesses is multiplied by the square of the sphere radius to obtain the surface area of the spherical polygon. For nearly-degenerate spherical polygons an area of approximately 0 is returned by default, rather than attempting the unstable calculation.

Empirical assessment of spherical Voronoi algorithm performance suggests quadratic time complexity (loglinear is optimal, but algorithms are more challenging to implement). The reconstitution of the surface area of the sphere, measured as the sum of the surface areas of all Voronoi regions, is closest to 100% for larger (>> 10) numbers of generators.
References

[R9133a064969a-Caroli], [R9133a064969a-Weisstein]

Examples

Do some imports and take some points on a cube:

```python
>>> from matplotlib import colors
>>> from mpl_toolkits.mplot3d.art3d import Poly3DCollection
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import SphericalVoronoi
>>> from mpl_toolkits.mplot3d import proj3d

>>> # set input data
>>> points = np.array([[0, 0, 1], [0, 0, -1], [1, 0, 0],
                      [0, 1, 0], [0, -1, 0], [-1, 0, 0]])

Calculate the spherical Voronoi diagram:

```python
```python
>>> radius = 1
>>> center = np.array([0, 0, 0])
>>> sv = SphericalVoronoi(points, radius, center)

Generate plot:

```python
```python
```python
```python
```python
```python
```

Attributes

- **points**: [double array of shape (npoints, 3)] the points in 3D to generate the Voronoi diagram from
- **radius**: [double] radius of the sphere Default: None (forces estimation, which is less precise)
SciPy Reference Guide, Release 1.3.2

Methods

```python
scipy.spatial.SphericalVoronoi.sort_vertices_of_regions
SphericalVoronoi.sort_vertices_of_regions (self)
Sort indices of the vertices to be (counter-)clockwise ordered.
```

Notes

For each region in regions, it sorts the indices of the Voronoi vertices such that the resulting points are in a clockwise or counterclockwise order around the generator point.

This is done as follows: Recall that the n-th region in regions surrounds the n-th generator in points and that the k-th Voronoi vertex in vertices is the projected circumcenter of the tetrahedron obtained by the k-th triangle in _tri.simplices (and the origin). For each region n, we choose the first triangle (=Voronoi vertex) in _tri.simplices and a vertex of that triangle not equal to the center n. These determine a unique neighbor of that triangle, which is then chosen as the second triangle. The second triangle will have a unique vertex not equal to the current vertex or the center. This determines a unique neighbor of the second triangle, which is then chosen as the third triangle and so forth. We proceed through all the triangles (=Voronoi vertices) belonging to the generator in points and obtain a sorted version of the vertices of its surrounding region.

```python
scipy.spatial.HalfspaceIntersection
```

New in version 0.19.0.

Parameters

- `halfspaces` [ndarray of floats, shape (ne, ndim+1)] Stacked Inequalities of the form \(Ax + b \leq 0\) in format \([A;b]\)
- `interior_point` [ndarray of floats, shape (ndim,)] Point clearly inside the region defined by halfspaces. Also called a feasible point, it can be obtained by linear programming.
- `incremental` [bool, optional] Allow adding new halfspaces incrementally. This takes up some additional resources.
- `qhull_options` [str, optional] Additional options to pass to Qhull. See Qhull manual for details. (Default: "Qx" for ndim>4 and "" otherwise) Option "H" is always enabled.
**QhullError**  
Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**ValueError**  
Raised if an incompatible array is given as input.

**Notes**

The intersections are computed using the Qhull library. This reproduces the “qhalf” functionality of Qhull.

**References**

[R9b902253b317-Qhull], [R9b902253b317-1]

**Examples**

Halfspace intersection of planes forming some polygon

```python
>>> from scipy.spatial import HalfspaceIntersection
>>> halfspaces = np.array([[-1, 0., 0.],
                       [0., -1., 0.],
                       [2., 1., -4.],
                       [-0.5, 1., -2.]])
>>> feasible_point = np.array([0.5, 0.5])
>>> hs = HalfspaceIntersection(halfspaces, feasible_point)
```

Plot halfspaces as filled regions and intersection points:

```python
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot('111', aspect='equal')
>>> x, ylim = (-1, 3), (-1, 3)
>>> ax.set_xlim(xlim)
>>> ax.set_ylim(ylim)
>>> x = np.linspace(-1, 3, 100)
>>> symbols = ['-', '+', 'x', '*']
>>> signs = [0, 0, -1, -1]
>>> fmt = {'color': 'None', 'edgecolor': 'b', 'alpha': 0.5}
>>> for h, sym, sign in zip(halfspaces, symbols, signs):
...     hlist = h.tolist()
...     if h[1]== 0:
...         ax.axline((-h[2]/h[0], label='{}x+{}y+{}=0'.format(*hlist))
...         xi = np.linspace(xlim[sign], -h[2]/h[0], 100)
...         ax.fill_between(xi, ylim[0], ylim[1], **fmt)
...     else:
...         ax.plot(x, (-h[2]-h[0]*x)/h[1], label='{}x+{}y+{}=0'.format(*hlist))
...         ax.fill_between(x, (-h[2]-h[0]*x)/h[1], ylim[sign], **fmt)
>>> x, y = zip(*hs.intersections)
>>> ax.plot(x, y, 'o', markersize=8)
```
By default, qhull does not provide with a way to compute an interior point. This can easily be computed using linear programming. Considering halfspaces of the form $Ax + b \leq 0$, solving the linear program:

$$\max y$$
$$s.t. Ax + y||A_i|| \leq -b$$

With $A_i$ being the rows of $A$, i.e. the normals to each plane.

Will yield a point $x$ that is furthest inside the convex polyhedron. To be precise, it is the center of the largest hypersphere of radius $y$ inscribed in the polyhedron. This point is called the Chebyshev center of the polyhedron (see [R9b902253b317-1] 4.3.1, pp148-149). The equations outputted by Qhull are always normalized.

```python
>>> from scipy.optimize import linprog
>>> from matplotlib.patches import Circle
>>> norm_vector = np.reshape(np.linalg.norm(halfspaces[:, :-1], axis=1),
... (halfspaces.shape[0], 1))
>>> c = np.zeros((halfspaces.shape[1],))
>>> c[-1] = -1
>>> A = np.hstack((halfspaces[:, :-1], norm_vector))
>>> b = - halfspaces[:, -1:]
>>> res = linprog(c, A_ub=A, b_ub=b)
>>> x = res.x[:-1]
>>> y = res.x[-1]
>>> circle = Circle(x, radius=y, alpha=0.3)
>>> ax.add_patch(circle)
>>> plt.legend(bbox_to_anchor=(1.6, 1.0))
>>> plt.show()
```

**Attributes**

- `halfspaces` [ndarray of double, shape (nineq, ndim+1)] Input halfspaces.
- `interior_point` [ndarray of floats, shape (ndim,)] Input interior point.
- `intersections` [ndarray of double, shape (ninter, ndim)] Intersections of all halfspaces.
dual_points
[ndarray of double, shape (nlineq, ndim)] Dual points of the input halfspaces.

dual_facets
[listen of lists of ints] Indices of points forming the (non necessarily simplicial) facets of the dual convex hull.

dual_vertices
[ndarray of ints, shape (nvertices,)] Indices of halfspaces forming the vertices of the dual convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order.

dual_equations
[ndarray of double, shape (nfacet, ndim+1)] [normal, offset] forming the hyperplane equation of the dual facet (see Qhull documentation for more).

dual_area
[float] Area of the dual convex hull

dual_volume
[float] Volume of the dual convex hull

Methods

add_halfspaces(halfspaces[, restart]) Process a set of additional new halfspaces.
close() Finish incremental processing.

scipy.spatial.HalfspaceIntersection.add_halfspaces
HalfspaceIntersection.add_halfspaces (halfspaces, restart=False)
Process a set of additional new halfspaces.

Parameters

halfspaces [ndarray] New halfspaces to add. The dimensionality should match that of the initial halfspaces.
restart [bool, optional] Whether to restart processing from scratch, rather than adding halfspaces incrementally.

Raises

QhullError Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

See also:

close

Notes

You need to specify incremental=True when constructing the object to be able to add halfspaces incrementally. Incremental addition of halfspaces is also not possible after close has been called.

scipy.spatial.HalfspaceIntersection.close
HalfspaceIntersection.close Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.
6.25.4 Plotting Helpers

```python
scipy.spatial.delaunay_plot_2d
```

Plot the given Delaunay triangulation in 2-D

**Parameters**

- `tri`  
  [scipy.spatial.Delaunay instance] Triangulation to plot

- `ax`  
  [matplotlib.axes.Axes instance, optional] Axes to plot on

**Returns**

- `fig`  
  [matplotlib.figure.Figure instance] Figure for the plot

**See also:**

- `Delaunay`
- `matplotlib.pyplot.triplot`

**Notes**

Requires Matplotlib.

**Examples**

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import Delaunay, delaunay_plot_2d
```

The Delaunay triangulation of a set of random points:

```python
>>> points = np.random.rand(30, 2)
>>> tri = Delaunay(points)
```

Plot it:

```python
>>> _ = delaunay_plot_2d(tri)
>>> plt.show()
```

```python
scipy.spatial.convex_hull_plot_2d
```

Plot the given convex hull diagram in 2-D

**Parameters**

- `hull`  
  [scipy.spatial.ConvexHull instance] Convex hull to plot

- `ax`  
  [matplotlib.axes.Axes instance, optional] Axes to plot on
Returns

fig [matplotlib.figure.Figure instance] Figure for the plot

See also:

ConvexHull

Notes

Requires Matplotlib.

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import ConvexHull, convex_hull_plot_2d

The convex hull of a random set of points:

```python
defpoints = np.random.rand(30, 2)
defhull = ConvexHull(points)
```

Plot it:

```python
>>> _ = convex_hull_plot_2d(hull)
>>> plt.show()
```

scipy.spatial.voronoi_plot_2d

scipy.spatial.voronoi_plot_2d(vor, ax=None, **kw)

Plot the given Voronoi diagram in 2-D

Parameters
Voronoi diagram of the points:

```
>>> import matplotlib.pyplot as plt
>>> points = np.random.rand(10,2)  # random
```

Voronoi diagram of the points:
```python
>>> from scipy.spatial import Voronoi, voronoi_plot_2d
>>> vor = Voronoi(points)

using `voronoi_plot_2d` for visualisation:
```n
```python
>>> fig = voronoi_plot_2d(vor)
```

using `voronoi_plot_2d` for visualisation with enhancements:
```python
>>> fig = voronoi_plot_2d(vor, show_vertices=False, line_colors='orange',
... line_width=2, line_alpha=0.6, point_size=2)
>>> plt.show()
```

See also:

* Tutorial
6.25.5 Simplex representation

The simplices (triangles, tetrahedra, ...) appearing in the Delaunay tessellation (N-dim simplices), convex hull facets, and Voronoi ridges (N-1 dim simplices) are represented in the following scheme:

```
tess = Delaunay(points)
hull = ConvexHull(points)
voro = Voronoi(points)

# coordinates of the j-th vertex of the i-th simplex
tess.points[tess.simplices[i, j], :]
# tessellation element
hull.points[hull.simplices[i, j], :]
# convex hull facet
voro.vertices[voro.ridge_vertices[i, j], :]
# ridge between Voronoi cells
```

For Delaunay triangulations and convex hulls, the neighborhood structure of the simplices satisfies the condition:

```
tess.neighbors[i, j] is the neighboring simplex of the i-th simplex, opposite to the j-vertex. It is -1 in case of no neighbor.
```

Convex hull facets also define a hyperplane equation:

```
(hull.equations[i, -1] * coord).sum() + hull.equations[i, -1] == 0
```

Similar hyperplane equations for the Delaunay triangulation correspond to the convex hull facets on the corresponding N+1 dimensional paraboloid.

The Delaunay triangulation objects offer a method for locating the simplex containing a given point, and barycentric coordinate computations.

**Functions**

```
tsearch(tri, xi) Find simplices containing the given points.

distance_matrix(x, y[, p, threshold]) Compute the distance matrix.

minkowski_distance(x, y[, p]) Compute the L**p distance between two arrays.

minkowski_distance_p(x, y[, p]) Compute the p-th power of the L**p distance between two arrays.

procrustes(data1, data2) Procrustes analysis, a similarity test for two data sets.
```

**scipy.spatial.tsearch**

`scipy.spatial.tsearch(tri, xi)`

Find simplices containing the given points. This function does the same thing as `Delaunay.find_simplex`.

New in version 0.9.

See also:

`Delaunay.find_simplex`

**Examples**

```
>>> import numpy as np
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import Delaunay, delaunay_plot_2d, tsearch
```
The Delaunay triangulation of a set of random points:

```python
>>> pts = np.random.rand(20, 2)
>>> tri = Delaunay(pts)
>>> _ = delaunay_plot_2d(tri)
```

Find the simplices containing a given set of points:

```python
>>> loc = np.random.uniform(0.2, 0.8, (5, 2))
>>> s = tsearch(tri, loc)
>>> plt.triplot(pts[:, 0], pts[:, 1], tri.simplices[s], 'b-', mask=s==-1)
>>> plt.scatter(loc[:, 0], loc[:, 1], c='r', marker='x')
>>> plt.show()
```

### scipy.spatial.distance_matrix

**scipy.spatial.distance_matrix**

`scipy.spatial.distance_matrix(x, y, p=2, threshold=1000000)`

**Description**

Compute the distance matrix.

**Returns**

- **result**
  - `(M, N)` ndarray: Matrix containing the distance from every vector in `x` to every vector in `y`.

**Parameters**

- **x**
  - `(M, K)` array_like: Matrix of `M` vectors in `K` dimensions.
- **y**
  - `(N, K)` array_like: Matrix of `N` vectors in `K` dimensions.
- **p**
  - float, `1 <= p <= infinity`: Which Minkowski p-norm to use.
- **threshold**
  - positive int: If `M * N * K > threshold`, algorithm uses a Python loop instead of large temporary arrays.

**Examples**
```python
>>> from scipy.spatial import distance_matrix
>>> distance_matrix([[0, 0], [0, 1]], [[1, 0], [1, 1]])
array([[ 1., 1.41421356],
       [ 1.41421356,  1.]])
```

**scipy.spatial.minkowski_distance**

scipy.spatial.minkowski_distance(x, y, p=2)

Compute the \(L^p\) distance between two arrays.

**Parameters**

- \(x\) : \([M, K]\) array_like
  - Input array.
- \(y\) : \([N, K]\) array_like
  - Input array.
- \(p\) : float, \(1 \leq p \leq \infty\)
  - Which Minkowski p-norm to use.

**Examples**

```python
>>> from scipy.spatial import minkowski_distance
>>> minkowski_distance([[0, 0], [0, 0]], [[1, 1], [0, 1]])
array([1.41421356, 1.])
```

**scipy.spatial.minkowski_distance_p**

scipy.spatial.minkowski_distance_p(x, y, p=2)

Compute the \(p\)-th power of the \(L^p\) distance between two arrays.

For efficiency, this function computes the \(L^p\) distance but does not extract the \(p\)th root. If \(p\) is 1 or infinity, this is equal to the actual \(L^p\) distance.

**Parameters**

- \(x\) : \([M, K]\) array_like
  - Input array.
- \(y\) : \([N, K]\) array_like
  - Input array.
- \(p\) : float, \(1 \leq p \leq \infty\)
  - Which Minkowski p-norm to use.

**Examples**

```python
>>> from scipy.spatial import minkowski_distance_p
>>> minkowski_distance_p([[0, 0], [0, 0]], [[1, 1], [0, 1]])
array([2., 1.])
```

**scipy.spatial.procrustes**

scipy.spatial.procrustes(data1, data2)

Procrustes analysis, a similarity test for two data sets.

Each input matrix is a set of points or vectors (the rows of the matrix). The dimension of the space is the number of columns of each matrix. Given two identically sized matrices, procrustes standardizes both such that:

- \( \text{tr}(AA^T) = 1 \).
- Both sets of points are centered around the origin.
Procrustes ([1], [2]) then applies the optimal transform to the second matrix (including scaling/dilation, rotations, and reflections) to minimize $M^2 = \sum (data1 - data2)^2$, or the sum of the squares of the pointwise differences between the two input datasets.

This function was not designed to handle datasets with different numbers of datapoints (rows). If two data sets have different dimensionality (different number of columns), simply add columns of zeros to the smaller of the two.

**Parameters**

- `data1` [array_like] Matrix, n rows represent points in k (columns) space. `data1` is the reference data, after it is standardised, the data from `data2` will be transformed to fit the pattern in `data1` (must have >1 unique points).

- `data2` [array_like] n rows of data in k space to be fit to `data1`. Must be the same shape (numrows, numcols) as `data1` (must have >1 unique points).

**Returns**

- `mtx1` [array_like] A standardized version of `data1`.

- `mtx2` [array_like] The orientation of `data2` that best fits `data1`. Centered, but not necessarily $tr(AA^T) = 1$.

- `disparity` [float] $M^2$ as defined above.

**Raises**

- `ValueError` If the input arrays are not two-dimensional. If the shape of the input arrays is different. If the input arrays have zero columns or zero rows.

**See also:**

- `scipy.linalg.orthogonal_procrustes`

- `scipy.spatial.distance.directed_hausdorff`

   Another similarity test for two data sets

**Notes**

- The disparity should not depend on the order of the input matrices, but the output matrices will, as only the first output matrix is guaranteed to be scaled such that $tr(AA^T) = 1$.

- Duplicate data points are generally ok, duplicating a data point will increase its effect on the procrustes fit.

- The disparity scales as the number of points per input matrix.

**References**

[1], [2]

**Examples**

```python
>>> from scipy.spatial import procrustes
```

The matrix b is a rotated, shifted, scaled and mirrored version of a here:
>>> a = np.array([[1, 3], [1, 2], [1, 1], [2, 1]], 'd')
>>> b = np.array([[4, -2], [4, -4], [4, -6], [2, -6]], 'd')
>>> mtx1, mtx2, disparity = procrustes(a, b)
>>> round(disparity)
0.0

6.26 Distance computations (scipy.spatial.distance)

6.26.1 Function Reference

Distance matrix computation from a collection of raw observation vectors stored in a rectangular array.

scipy.spatial.distance.pdist

scipy.spatial.distance.pdist(X, metric='euclidean', *args, **kwargs)

Pairwise distances between observations in n-dimensional space.

Parameters

- **X** [ndarray] An m by n array of m original observations in an n-dimensional space.
- **metric** [str or function, optional] The distance metric to use. The distance function can be 'braycurtis', 'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'euclidean', 'hamming', 'jaccard', 'jensenshannon', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'.
- **args** [(tuple. Deprecated.) Additional arguments should be passed as keyword arguments]
- **kwargs** [dict, optional] Extra arguments to metric: refer to each metric documentation for a list of all possible arguments.

Some possible arguments:
- **p** : scalar The p-norm to apply for Minkowski, weighted and unweighted. Default: 2.
- **w** : ndarray The weight vector for metrics that support weights (e.g., Minkowski).
- **V** : ndarray The variance vector for standardized Euclidean. Default: var(X, axis=0, ddof=1)
- **VI** : ndarray The inverse of the covariance matrix for Mahalanobis. Default: inv(cov(X.T)).T
- **out** : ndarray. The output array If not None, condensed distance matrix Y is stored in this array. Note: metric independent, it will become a regular keyword arg in a future scipy version

Returns

- **Y** [ndarray] Returns a condensed distance matrix Y. For each i and j (where i < j < m), where m is the number of original observations. The metric dist{u=X[i], v=X[j]} is computed and stored in entry ij.
See also:

`squareform`

converts between condensed distance matrices and square distance matrices.

Notes

See `squareform` for information on how to calculate the index of this entry or to convert the condensed distance matrix to a redundant square matrix.

The following are common calling conventions.

1. `Y = pdist(X, 'euclidean')`
   Computes the distance between m points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as m n-dimensional row vectors in the matrix X.

2. `Y = pdist(X, 'minkowski', p=2.)`
   Computes the distances using the Minkowski distance $||u - v||_p$ (p-norm) where $p \geq 1$.

3. `Y = pdist(X, 'cityblock')`
   Computes the city block or Manhattan distance between the points.

4. `Y = pdist(X, 'seuclidean', V=None)`
   Computes the standardized Euclidean distance. The standardized Euclidean distance between two n-vectors $u$ and $v$ is
   \[
   \sqrt{\sum \left(\frac{u_i - v_i}{\sqrt{V[i]}}\right)^2}
   \]
   $V$ is the variance vector; $V[i]$ is the variance computed over all the i'th components of the points. If not passed, it is automatically computed.

5. `Y = pdist(X, 'sqeuclidean')`
   Computes the squared Euclidean distance $||u - v||_2^2$ between the vectors.

6. `Y = pdist(X, 'cosine')`
   Computes the cosine distance between vectors $u$ and $v$,
   \[
   1 - \frac{u \cdot v}{||u||_2 ||v||_2}
   \]
   where $|| \cdot ||_2$ is the 2-norm of its argument $\cdot$, and $u \cdot v$ is the dot product of $u$ and $v$.

7. `Y = pdist(X, 'correlation')`
   Computes the correlation distance between vectors $u$ and $v$. This is
   \[
   1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{||u - \bar{u}||_2 ||(v - \bar{v})||_2}
   \]
   where $\bar{v}$ is the mean of the elements of vector $v$, and $x \cdot y$ is the dot product of $x$ and $y$.

8. `Y = pdist(X, 'hamming')`
   Computes the normalized Hamming distance, or the proportion of those vector elements between two n-vectors $u$ and $v$ which disagree. To save memory, the matrix $X$ can be of type boolean.
9. \( Y = \text{pdist}(X, 'jaccard') \)

Computes the Jaccard distance between the points. Given two vectors, \( u \) and \( v \), the Jaccard distance is the proportion of those elements \( u[i] \) and \( v[i] \) that disagree.

10. \( Y = \text{pdist}(X, 'chebyshev') \)

Computes the Chebyshev distance between the points. The Chebyshev distance between two n-vectors \( u \) and \( v \) is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

\[
d(u, v) = \max_i |u_i - v_i|
\]

11. \( Y = \text{pdist}(X, 'canberra') \)

Computes the Canberra distance between the points. The Canberra distance between two points \( u \) and \( v \) is

\[
d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}
\]

12. \( Y = \text{pdist}(X, 'braycurtis') \)

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points \( u \) and \( v \) is

\[
d(u, v) = \frac{\sum_i |u_i - v_i|}{\sum_i |u_i| + |v_i|}
\]

13. \( Y = \text{pdist}(X, 'mahalanobis', VI=None) \)

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points \( u \) and \( v \) is \( \sqrt{(u - v)(1/V)(u - v)^T} \) where \((1/V)\) (the \( VI \) variable) is the inverse covariance. If \( VI \) is not None, \( VI \) will be used as the inverse covariance matrix.

14. \( Y = \text{pdist}(X, 'yule') \)

Computes the Yule distance between each pair of boolean vectors. (see yule function documentation)

15. \( Y = \text{pdist}(X, 'matching') \)

Synonym for 'hamming'.

16. \( Y = \text{pdist}(X, 'dice') \)

Computes the Dice distance between each pair of boolean vectors. (see dice function documentation)

17. \( Y = \text{pdist}(X, 'kulsinski') \)

Computes the Kulinski distance between each pair of boolean vectors. (see kulsinski function documentation)

18. \( Y = \text{pdist}(X, 'rogerstanimoto') \)

Computes the Rogers-Tanimoto distance between each pair of boolean vectors. (see rogerstanimoto function documentation)
19. \( Y = \text{pdist}(X, \ 'russellrao' \) \\

Computes the Russell-Rao distance between each pair of boolean vectors. (see russellrao function documentation)

20. \( Y = \text{pdist}(X, \ 'sokalmichener' \) \\

Computes the Sokal-Michener distance between each pair of boolean vectors. (see sokalmichener function documentation)

21. \( Y = \text{pdist}(X, \ 'sokalsneath' \) \\

Computes the Sokal-Sneath distance between each pair of boolean vectors. (see sokalsneath function documentation)

22. \( Y = \text{pdist}(X, \ 'wminkowski', \ p=2, \ w=w \) \\

Computes the weighted Minkowski distance between each pair of vectors. (see wminkowski function documentation)

23. \( Y = \text{pdist}(X, \ f \) \\

Computes the distance between all pairs of vectors in X using the user supplied 2-arity function \( f \). For example, Euclidean distance between the vectors could be computed as follows:

\[
\text{dm} = \text{pdist}(X, \lambda u, v: \text{np.sqrt}(((u-v)**2).sum()))
\]

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example:

\[
\text{dm} = \text{pdist}(X, \ 'sokalsneath')
\]

would calculate the pair-wise distances between the vectors in X using the Python function sokalsneath. This would result in sokalsneath being called \( \binom{n}{2} \) times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax:

\[
\text{dm} = \text{pdist}(X, \ 'sokalsneath')
\]

**scipy.spatial.distance.cdist**

**scipy.spatial.distance.cdist** \((XA, XB, \text{metric}='\text{euclidean}', \ *args, **kwargs)\)

Compute distance between each pair of the two collections of inputs.

See Notes for common calling conventions.

*Parameters*

- **XA** [ndarray] An \( n_A \) by \( n \) array of \( n_A \) original observations in an \( n \)-dimensional space. Inputs are converted to float type.
- **XB** [ndarray] An \( n_B \) by \( n \) array of \( n_B \) original observations in an \( n \)-dimensional space. Inputs are converted to float type.
*args  [tuple. Deprecated.] Additional arguments should be passed as keyword arguments
**kwargs  [dict, optional] Extra arguments to *metric*: refer to each metric documentation for a list of all possible arguments.

Some possible arguments:
p : scalar The p-norm to apply for Minkowski, weighted and unweighted. Default: 2.
w : ndarray The weight vector for metrics that support weights (e.g., Minkowski).
V : ndarray The variance vector for standardized Euclidean. Default: var(vstack([XA, XB]), axis=0, ddof=1)
VI : ndarray The inverse of the covariance matrix for Mahalanobis. Default: inv(cov(vstack([XA, XB]).T)).T
out : ndarray The output array If not None, the distance matrix Y is stored in this array.

Note: metric independent, it will become a regular keyword arg in a future scipy version

Returns

Y  [ndarray] A \( m_A \times m_B \) distance matrix is returned. For each \( i \) and \( j \), the metric \( \text{dist}(u=XA[i], v=XB[j]) \) is computed and stored in the \( ij \) th entry.

Raises

ValueError  An exception is thrown if \( XA \) and \( XB \) do not have the same number of columns.

Notes

The following are common calling conventions:

1. \( Y = \text{cdist}(XA, XB, 'euclidean') \)

   Computes the distance between \( m \) points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as \( m n \)-dimensional row vectors in the matrix \( X \).

2. \( Y = \text{cdist}(XA, XB, 'minkowski', p=2.) \)

   Computes the distances using the Minkowski distance \( ||u-v||_p \) (p-norm) where \( p \geq 1 \).

3. \( Y = \text{cdist}(XA, XB, 'cityblock') \)

   Computes the city block or Manhattan distance between the points.

4. \( Y = \text{cdist}(XA, XB, 'seuclidean', V=None) \)

   Computes the standardized Euclidean distance. The standardized Euclidean distance between two \( n \)-vectors \( u \) and \( v \) is

   \[
   \sqrt{\sum (u_i - v_i)^2 / V[i]}. 
   \]

   \( V \) is the variance vector; \( V[i] \) is the variance computed over all the \( i \)'th components of the points. If not passed, it is automatically computed.

5. \( Y = \text{cdist}(XA, XB, 'sqeuclidean') \)

   Computes the squared Euclidean distance \( ||u-v||_2^2 \) between the vectors.

6. \( Y = \text{cdist}(XA, XB, 'cosine') \)

   Computes the cosine distance between vectors \( u \) and \( v \),

   \[
   1 - \frac{u \cdot v}{||u||_2 ||v||_2} 
   \]

   where \( || \cdot ||_2 \) is the 2-norm of its argument *, and \( u \cdot v \) is the dot product of \( u \) and \( v \).
7. \( Y = \text{cdist}(XA, XB, \text{'correlation'}) \)

Computes the correlation distance between vectors \( u \) and \( v \). This is

\[
1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{||u - \bar{u}||_2 ||v - \bar{v}||_2}
\]

where \( \bar{v} \) is the mean of the elements of vector \( v \), and \( x \cdot y \) is the dot product of \( x \) and \( y \).

8. \( Y = \text{cdist}(XA, XB, \text{'hamming'}) \)

Computes the normalized Hamming distance, or the proportion of those vector elements between two n-vectors \( u \) and \( v \) which disagree. To save memory, the matrix \( X \) can be of type boolean.

9. \( Y = \text{cdist}(XA, XB, \text{'jaccard'}) \)

Computes the Jaccard distance between the points. Given two vectors, \( u \) and \( v \), the Jaccard distance is the proportion of those elements \( u[i] \) and \( v[i] \) that disagree where at least one of them is non-zero.

10. \( Y = \text{cdist}(XA, XB, \text{'chebyshev'}) \)

Computes the Chebyshev distance between the points. The Chebyshev distance between two n-vectors \( u \) and \( v \) is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

\[
d(u, v) = \max_i |u_i - v_i|.
\]

11. \( Y = \text{cdist}(XA, XB, \text{'canberra'}) \)

Computes the Canberra distance between the points. The Canberra distance between two points \( u \) and \( v \) is

\[
d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}.
\]

12. \( Y = \text{cdist}(XA, XB, \text{'braycurtis'}) \)

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points \( u \) and \( v \) is

\[
d(u, v) = \frac{\sum_i (|u_i - v_i|)}{\sum_i (|u_i + v_i|)}
\]

13. \( Y = \text{cdist}(XA, XB, \text{'mahalanobis'}, \text{VI=None}) \)

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points \( u \) and \( v \) is \( \sqrt{(u - v)'(1/V)(u - v)} \) where \( (1/V) \) (the \( \text{VI} \) variable) is the inverse covariance. If \( \text{VI} \) is not None, \( \text{VI} \) will be used as the inverse covariance matrix.

14. \( Y = \text{cdist}(XA, XB, \text{'yule'}) \)

Computes the Yule distance between the boolean vectors. (see \text{yule} function documentation)

15. \( Y = \text{cdist}(XA, XB, \text{'matching'}) \)

Synonym for ‘hamming’.

16. \( Y = \text{cdist}(XA, XB, \text{'dice'}) \)
Computes the Dice distance between the boolean vectors. (see `dice` function documentation)

17. \( Y = \text{cdist}(X_A, X_B, 'kulsinski') \)

Computes the Kulsinski distance between the boolean vectors. (see `kulsinski` function documentation)

18. \( Y = \text{cdist}(X_A, X_B, 'rogerstanimoto') \)

Computes the Rogers-Tanimoto distance between the boolean vectors. (see `rogerstanimoto` function documentation)

19. \( Y = \text{cdist}(X_A, X_B, 'russellrao') \)

Computes the Russell-Rao distance between the boolean vectors. (see `russellrao` function documentation)

20. \( Y = \text{cdist}(X_A, X_B, 'sokalmichener') \)

Computes the Sokal-Michener distance between the boolean vectors. (see `sokalmichener` function documentation)

21. \( Y = \text{cdist}(X_A, X_B, 'sokalsneath') \)

Computes the Sokal-Sneath distance between the vectors. (see `sokalsneath` function documentation)

22. \( Y = \text{cdist}(X_A, X_B, 'wminkowski', p=2., w=w) \)

Computes the weighted Minkowski distance between the vectors. (see `wminkowski` function documentation)

23. \( Y = \text{cdist}(X_A, X_B, f) \)

Computes the distance between all pairs of vectors in \( X \) using the user supplied 2-arity function \( f \). For example, Euclidean distance between the vectors could be computed as follows:

\[
\text{dm} = \text{cdist}(X_A, X_B, \lambda u, v: \text{np.sqrt}((u-v)**2).sum())
\]

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example:

\[
\text{dm} = \text{cdist}(X_A, X_B, \text{'sokalsneath'})
\]

would calculate the pair-wise distances between the vectors in \( X \) using the Python function `sokalsneath`. This would result in `sokalsneath` being called \( \binom{n}{2} \) times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax:

\[
\text{dm} = \text{cdist}(X_A, X_B, \text{'sokalsneath'})
\]

**Examples**

Find the Euclidean distances between four 2-D coordinates:
```python
>>> from scipy.spatial import distance
>>> coords = [(35.0456, -85.2672),
            (35.1174, -89.9711),
            (35.9728, -83.9422),
            (36.1667, -86.7833)]
>>> distance.cdist(coords, coords, 'euclidean')
array([[ 0. , 4.7044, 1.6172, 1.8856],
       [ 4.7044, 0. , 6.0893, 3.3561],
       [ 1.6172, 6.0893, 0. , 2.8477],
       [ 1.8856, 3.3561, 2.8477, 0. ]])
```

Find the Manhattan distance from a 3-D point to the corners of the unit cube:

```python
>>> a = np.array([[0, 0, 0],
                [0, 0, 1],
                [0, 1, 0],
                [0, 1, 1],
                [1, 0, 0],
                [1, 0, 1],
                [1, 1, 0],
                [1, 1, 1]])
>>> b = np.array([[0.1, 0.2, 0.4]])
>>> distance.cdist(a, b, 'cityblock')
array([[ 0.7],
       [ 0.9],
       [ 1.3],
       [ 1.5],
       [ 1.5],
       [ 1.7],
       [ 2.1],
       [ 2.3]])
```

**scipy.spatial.distance.squareform**

**scipy.spatial.distance.squareform(X, force=’no’, checks=True)**

Convert a vector-form distance vector to a square-form distance matrix, and vice-versa.

**Parameters**

- **X** [ndarray] Either a condensed or redundant distance matrix.
- **force** [str, optional] As with MATLAB(TM), if force is equal to 'tovector' or 'tomatrix', the input will be treated as a distance matrix or distance vector respectively.
- **checks** [bool, optional] If set to False, no checks will be made for matrix symmetry nor zero diagonals. This is useful if it is known that X - X.T1 is small and diag(X) is close to zero. These values are ignored any way so they do not disrupt the squareform transformation.

**Returns**

- **Y** [ndarray] If a condensed distance matrix is passed, a redundant one is returned, or if a redundant one is passed, a condensed distance matrix is returned.

**Notes**

1. \( v = \text{squareform}(X) \)
Given a square d-by-d symmetric distance matrix $X$, $v = \text{squareform}(X)$ returns a $d \times (d-1) / 2$ (or $\binom{n}{2}$) sized vector $v$.

$v[\binom{n}{2} - \binom{n-i}{2} + (j - i - 1)]$ is the distance between points $i$ and $j$. If $X$ is non-square or asymmetric, an error is returned.

2. $X = \text{squareform}(v)$

Given a $d \times (d-1) / 2$ sized $v$ for some integer $d >= 2$ encoding distances as described, $X = \text{squareform}(v)$ returns a $d \times d$ distance matrix $X$. The $X[i, j]$ and $X[j, i]$ values are set to $v[\binom{n}{2} - \binom{n-i}{2} + (j - i - 1)]$ and all diagonal elements are zero.

In SciPy 0.19.0, $\text{squareform}$ stopped casting all input types to float64, and started returning arrays of the same dtype as the input.

**scipy.spatial.distance.directed_hausdorff**

```
scipy.spatial.distance.directed_hausdorff(u, v, seed=0)
```

Compute the directed Hausdorff distance between two N-D arrays.

Distances between pairs are calculated using a Euclidean metric.

**Parameters**

- $u$ [(M,N) ndarray] Input array.
- $v$ [(O,N) ndarray] Input array.
- $seed$ [int or None] Local numpy.random.mtrand.RandomState seed. Default is 0, a random shuffling of $u$ and $v$ that guarantees reproducibility.

**Returns**

- $d$ [double] The directed Hausdorff distance between arrays $u$ and $v$.
- $index_1$ [int] index of point contributing to Hausdorff pair in $u$
- $index_2$ [int] index of point contributing to Hausdorff pair in $v$

**Raises**

- ValueError

An exception is thrown if $u$ and $v$ do not have the same number of columns.

**See also:**

**scipy.spatial.procrustes**

Another similarity test for two data sets

**Notes**

Uses the early break technique and the random sampling approach described by [1]. Although worst-case performance is $O(m \times o)$ (as with the brute force algorithm), this is unlikely in practice as the input data would have to require the algorithm to explore every single point interaction, and after the algorithm shuffles the input points at that. The best case performance is $O(m)$, which is satisfied by selecting an inner loop distance that is less than $c_{\text{max}}$ and leads to an early break as often as possible. The authors have formally shown that the average runtime is closer to $O(m)$.

New in version 0.19.0.
References

[1]

Examples

Find the directed Hausdorff distance between two 2-D arrays of coordinates:

```python
>>> from scipy.spatial.distance import directed_hausdorff
>>> u = np.array([(1.0, 0.0),
                 (0.0, 1.0),
                 (-1.0, 0.0),
                 (0.0, -1.0)])
>>> v = np.array([(2.0, 0.0),
                 (0.0, 2.0),
                 (-2.0, 0.0),
                 (0.0, -4.0)])
```

```python
>>> directed_hausdorff(u, v)[0]
2.23606797749979
>>> directed_hausdorff(v, u)[0]
3.0
```

Find the general (symmetric) Hausdorff distance between two 2-D arrays of coordinates:

```python
>>> max(directed_hausdorff(u, v)[0], directed_hausdorff(v, u)[0])
3.0
```

Find the indices of the points that generate the Hausdorff distance (the Hausdorff pair):

```python
>>> directed_hausdorff(v, u)[1:]
(3, 3)
```

Predicates for checking the validity of distance matrices, both condensed and redundant. Also contained in this module are functions for computing the number of observations in a distance matrix.

```python
scipy.spatial.distance.is_valid_dm
```

Returns True if input array is a valid distance matrix. Distance matrices must be 2-dimensional numpy arrays. They must have a zero-diagonal, and they must be symmetric.
The candidate object to test for validity. 

**tol** [float, optional] The distance matrix should be symmetric. \( tol \) is the maximum difference between entries \( ij \) and \( ji \) for the distance metric to be considered symmetric.

**throw** [bool, optional] An exception is thrown if the distance matrix passed is not valid.

**name** [str, optional] The name of the variable to checked. This is useful if throw is set to True so the offending variable can be identified in the exception message when an exception is thrown.

**warning** [bool, optional] Instead of throwing an exception, a warning message is raised.

**Returns**

**valid** [bool] True if the variable \( D \) passed is a valid distance matrix.

**Notes**

Small numerical differences in \( D \) and \( D.T \) and non-zeroness of the diagonal are ignored if they are within the tolerance specified by \( tol \).

**scipy.spatial.distance.is_valid_y**

**scipy.spatial.distance.is_valid_y**(y, warning=False, throw=False, name=None) 

Return True if the input array is a valid condensed distance matrix.

Condensed distance matrices must be 1-dimensional numpy arrays. Their length must be a binomial coefficient \( \binom{n}{2} \) for some positive integer \( n \).

**Parameters**

**y** [ndarray] The condensed distance matrix.

**warning** [bool, optional] Invokes a warning if the variable passed is not a valid condensed distance matrix. The warning message explains why the distance matrix is not valid. \( name \) is used when referencing the offending variable.

**throw** [bool, optional] Throws an exception if the variable passed is not a valid condensed distance matrix.

**name** [bool, optional] Used when referencing the offending variable in the warning or exception message.

**scipy.spatial.distance.num_obs_dm**

**scipy.spatial.distance.num_obs_dm**(d) 

Return the number of original observations that correspond to a square, redundant distance matrix.

**Parameters**

**d** [ndarray] The target distance matrix.

**Returns**

**num_obs_dm** [int] The number of observations in the redundant distance matrix.
scipy.spatial.distance.num_obs_y

scipy.spatial.distance.num_obs_y(Y)

Return the number of original observations that correspond to a condensed distance matrix.

Parameters

Y [ndarray] Condensed distance matrix.

Returns

n [int] The number of observations in the condensed distance matrix Y.

Distance functions between two numeric vectors u and v. Computing distances over a large collection of vectors is inefficient for these functions. Use pdist for this purpose.

braycurtis(u, v[, w]) Compute the Bray-Curtis distance between two 1-D arrays.

canberra(u, v[, w]) Compute the Canberra distance between two 1-D arrays.

chebyshev(u, v[, w]) Compute the Chebyshev distance.

cityblock(u, v[, w]) Compute the City Block (Manhattan) distance.

correlation(u, v[, w, centered]) Compute the correlation distance between two 1-D arrays.

cosine(u, v[, w]) Compute the Cosine distance between 1-D arrays.

euclidean(u, v[, w]) Computes the Euclidean distance between two 1-D arrays.

jensenshannon(p, q[, base]) Compute the Jensen-Shannon distance (metric) between two 1-D probability arrays.

mahalanobis(u, v, VI) Compute the Mahalanobis distance between two 1-D arrays.

minkowski(u, v[, p, w]) Compute the Minkowski distance between two 1-D arrays.

seuclidean(u, v, V) Return the standardized Euclidean distance between two 1-D arrays.

sqeuclidean(u, v[, w]) Compute the squared Euclidean distance between two 1-D arrays.

wminkowski(u, v, p, w) Compute the weighted Minkowski distance between two 1-D arrays.

scipy.spatial.distance.braycurtis

scipy.spatial.distance.braycurtis(u, v, w= None)

Compute the Bray-Curtis distance between two 1-D arrays.

Bray-Curtis distance is defined as

\[ \frac{\sum |u_i - v_i|}{\sum |u_i + v_i|} \]

The Bray-Curtis distance is in the range [0, 1] if all coordinates are positive, and is undefined if the inputs are of length zero.

Parameters

u [(N,) array_like] Input array.

v [(N,) array_like] Input array.

w [(N,) array_like, optional] The weights for each value in u and v. Default is None, which gives each value a weight of 1.0
Returns

braycurtis [double] The Bray-Curtis distance between 1-D arrays u and v.

Examples

```python
>>> from scipy.spatial import distance
>>> distance.braycurtis([1, 0, 0], [0, 1, 0])
1.0
>>> distance.braycurtis([1, 1, 0], [0, 1, 0])
0.33333333333333331
```

scipy.spatial.distance.canberra

scipy.spatial.distance.canberra (u, v, w=None)

Compute the Canberra distance between two 1-D arrays.

The Canberra distance is defined as

\[ d(u, v) = \sum \frac{|u_i - v_i|}{|u_i| + |v_i|} \]

Parameters

- u [(N,) array_like] Input array.
- v [(N,) array_like] Input array.
- w [(N,) array_like, optional] The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns

- canberra [double] The Canberra distance between vectors u and v.

Notes

When \( u[i] \) and \( v[i] \) are 0 for given i, then the fraction \( 0/0 = 0 \) is used in the calculation.

Examples

```python
>>> from scipy.spatial import distance
>>> distance.canberra([1, 0, 0], [0, 1, 0])
2.0
>>> distance.canberra([1, 1, 0], [0, 1, 0])
1.0
```

scipy.spatial.distance.chebyshev

scipy.spatial.distance.chebyshev (u, v, w=None)

Compute the Chebyshev distance.

Computes the Chebyshev distance between two 1-D arrays \( u \) and \( v \), which is defined as

\[ \max_i |u_i - v_i|. \]
Parameters

\(u\) [(N,) array_like] Input vector.
\(v\) [(N,) array_like] Input vector.
\(w\) [(N,) array_like, optional] The weights for each value in \(u\) and \(v\). Default is None, which gives each value a weight of 1.0

Returns

\(\text{chebyshev}\) [double] The Chebyshev distance between vectors \(u\) and \(v\).

Examples

```python
>>> from scipy.spatial import distance
>>> distance chebyshev([1, 0, 0], [0, 1, 0])
1
>>> distance chebyshev([1, 1, 0], [0, 1, 0])
1
```

**scipy.spatial.distance.cityblock**

\(\text{scipy.spatial.distance.cityblock}(u, v, w=None)\)

Computes the Manhattan distance between two 1-D arrays \(u\) and \(v\), which is defined as

\[
\sum_i |u_i - v_i|.
\]

Parameters

\(u\) [(N,) array_like] Input array.
\(v\) [(N,) array_like] Input array.
\(w\) [(N,) array_like, optional] The weights for each value in \(u\) and \(v\). Default is None, which gives each value a weight of 1.0

Returns

\(\text{cityblock}\) [double] The City Block (Manhattan) distance between vectors \(u\) and \(v\).

Examples

```python
>>> from scipy.spatial import distance
>>> distance.cityblock([1, 0, 0], [0, 1, 0])
2
>>> distance.cityblock([1, 0, 0], [0, 2, 0])
3
>>> distance.cityblock([1, 0, 0], [1, 1, 0])
1
```
scipy.spatial.distance.correlation

**scipy.spatial.distance.correlation** *(u, v, w=None, centered=True)*

Compute the correlation distance between two 1-D arrays.

The correlation distance between \( u \) and \( v \), is defined as

\[
1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\| (u - \bar{u}) \|_2 \| (v - \bar{v}) \|_2}
\]

where \( \bar{u} \) is the mean of the elements of \( u \) and \( x \cdot y \) is the dot product of \( x \) and \( y \).

**Parameters**

- **u**: [(N,) array_like] Input array.
- **v**: [(N,) array_like] Input array.
- **w**: [(N,) array_like, optional] The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

**Returns**

- **correlation**: [double] The correlation distance between 1-D array \( u \) and \( v \).

scipy.spatial.distance.cosine

**scipy.spatial.distance.cosine** *(u, v, w=None)*

Compute the Cosine distance between 1-D arrays.

The Cosine distance between \( u \) and \( v \), is defined as

\[
1 - \frac{u \cdot v}{\| u \|_2 \| v \|_2}
\]

where \( u \cdot v \) is the dot product of \( u \) and \( v \).

**Parameters**

- **u**: [(N,) array_like] Input array.
- **v**: [(N,) array_like] Input array.
- **w**: [(N,) array_like, optional] The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

**Returns**

- **cosine**: [double] The Cosine distance between vectors \( u \) and \( v \).

**Examples**

```python
>>> from scipy.spatial import distance
>>> distance.cosine([1, 0, 0], [0, 1, 0])
1.0
>>> distance.cosine([100, 0, 0], [0, 1, 0])
1.0
>>> distance.cosine([1, 1, 0], [0, 1, 0])
0.29289321881345254
```
scipy.spatial.distance.euclidean

scipy.spatial.distance.euclidean(u, v, w=None)

Computes the Euclidean distance between two 1-D arrays.

The Euclidean distance between 1-D arrays $u$ and $v$, is defined as

$$
||u - v||_2 \left( \sum (w_i(u_i - v_i)^2) \right)^{1/2}
$$

Parameters

- **u** [(N,) array_like] Input array.
- **v** [(N,) array_like] Input array.
- **w** [(N,) array_like, optional] The weights for each value in $u$ and $v$. Default is None, which gives each value a weight of 1.0

Returns

- **euclidean** [double] The Euclidean distance between vectors $u$ and $v$.

Examples

```python
>>> from scipy.spatial import distance
>>> distance.euclidean([1, 0, 0], [0, 1, 0])
1.4142135623730951
>>> distance.euclidean([1, 1, 0], [0, 1, 0])
1.0
```

scipy.spatial.distance.jensenshannon

scipy.spatial.distance.jensenshannon(p, q, base=None)

Compute the Jensen-Shannon distance (metric) between two 1-D probability arrays. This is the square root of the Jensen-Shannon divergence.

The Jensen-Shannon distance between two probability vectors $p$ and $q$ is defined as,

$$
\sqrt{D(p \parallel m) + D(q \parallel m) \over 2}
$$

where $m$ is the pointwise mean of $p$ and $q$ and $D$ is the Kullback-Leibler divergence.

This routine will normalize $p$ and $q$ if they don’t sum to 1.0.

Parameters

- **p** [(N,) array_like] left probability vector
- **q** [(N,) array_like] right probability vector
- **base** [double, optional] the base of the logarithm used to compute the output if not given, then the routine uses the default base of scipy.stats.entropy.

Returns

- **js** [double] The Jensen-Shannon distance between $p$ and $q$

New in version 1.2.0: ..
Examples

```python
>>> from scipy.spatial import distance
>>> distance.jensenshannon([1.0, 0.0, 0.0], [0.0, 1.0, 0.0], 2.0)
1.0
>>> distance.jensenshannon([1.0, 0.0], [0.5, 0.5])
0.46450140402245893
>>> distance.jensenshannon([1.0, 0.0, 0.0], [1.0, 0.0, 0.0])
0.0
```

### scipy.spatial.distance.mahalanobis

#### scipy.spatial.distance.mahalanobis(u, v, VI)

Compute the Mahalanobis distance between two 1-D arrays.

The Mahalanobis distance between 1-D arrays $u$ and $v$, is defined as

$$\sqrt{(u - v)V^{-1}(u - v)^T}$$

where $V$ is the covariance matrix. Note that the argument $VI$ is the inverse of $V$.

**Parameters**

- $u$ : (N,) array_like, Input array.
- $v$ : (N,) array_like, Input array.
- $VI$ : ndarray, The inverse of the covariance matrix.

**Returns**

- mahalanobis : [double], The Mahalanobis distance between vectors $u$ and $v$.

#### Examples

```python
>>> from scipy.spatial import distance
>>> iv = [[1, 0.5, 0.5], [0.5, 1, 0.5], [0.5, 0.5, 1]]
>>> distance.mahalanobis([1, 0, 0], [0, 1, 0], iv)
1.0
>>> distance.mahalanobis([0, 2, 0], [0, 1, 0], iv)
1.0
>>> distance.mahalanobis([2, 0, 0], [0, 1, 0], iv)
1.7320508075688772
```

### scipy.spatial.distance.minkowski

#### scipy.spatial.distance.minkowski(u, v, p=2, w=None)

Compute the Minkowski distance between two 1-D arrays.

The Minkowski distance between 1-D arrays $u$ and $v$, is defined as

$$||u - v||_p = \left( \sum w_i ((u_i - v_i)^p)^{1/p} \right)$

where $w_i$ are weights, $p$ is a parameter that determines the type of Minkowski distance.

**Parameters**

- $u$ : (N,) array_like, Input array.
- $v$ : (N,) array_like, Input array.
- $p$ : int, $p$-th power of the Minkowski norm.
- $w$ : (N,) array_like, optional, weights.

**Returns**

- minkowski : [double], The Minkowski distance between vectors $u$ and $v$. 

6.26. Distance computations (scipy.spatial.distance)
**Parameters**

- **u** [(N,) array_like] Input array.
- **v** [(N,) array_like] Input array.
- **p** [int] The order of the norm of the difference \(|u - v|^p\).
- **w** [(N,) array_like, optional] The weights for each value in \(u\) and \(v\). Default is None, which gives each value a weight of 1.0

**Returns**

- **minkowski** [double] The Minkowski distance between vectors \(u\) and \(v\).

**Examples**

```python
>>> from scipy.spatial import distance
>>> distance.minkowski([1, 0, 0], [0, 1, 0], 1)
2.0
>>> distance.minkowski([1, 0, 0], [0, 1, 0], 2)
1.4142135623730951
>>> distance.minkowski([1, 0, 0], [0, 1, 0], 3)
1.2599210498948732
>>> distance.minkowski([1, 1, 0], [0, 1, 0], 1)
1.0
>>> distance.minkowski([1, 1, 0], [0, 1, 0], 2)
1.0
>>> distance.minkowski([1, 1, 0], [0, 1, 0], 3)
1.0
```

**scipy.spatial.distance.seuclidean**

**scipy.spatial.distance.seuclidean(u, v, V)**

Return the standardized Euclidean distance between two 1-D arrays.

The standardized Euclidean distance between \(u\) and \(v\).

**Parameters**

- **u** [(N,) array_like] Input array.
- **v** [(N,) array_like] Input array.
- **V** [(N,) array_like] \(V\) is an 1-D array of component variances. It is usually computed among a larger collection vectors.

**Returns**

- **seuclidean** [double] The standardized Euclidean distance between vectors \(u\) and \(v\).

**Examples**

```python
>>> from scipy.spatial import distance
>>> distance.seuclidean([1, 0, 0], [0, 1, 0], [0.1, 0.1, 0.1])
4.4721359549995796
>>> distance.seuclidean([1, 0, 0], [0, 1, 0], [0.1, 0.1, 0.1])
3.3166247903553998
```
scipy.spatial.distance.sqeuclidean

scipy.spatial.distance.sqeuclidean(u, v, w=None)

Compute the squared Euclidean distance between two 1-D arrays.

The squared Euclidean distance between u and v is defined as

\[ \sqrt{\sum (w_i |u_i - v_i|^2)} \]

Parameters

- u [(N,) array_like] Input array.
- v [(N,) array_like] Input array.
- w [(N,) array_like, optional] The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns

sqeuclidean [double] The squared Euclidean distance between vectors u and v.

Examples

```python
from scipy.spatial import distance
>>> distance.sqeuclidean([1, 0, 0], [0, 1, 0])
2.0
>>> distance.sqeuclidean([1, 1, 0], [0, 1, 0])
1.0
```

scipy.spatial.distance.wminkowski

scipy.spatial.distance.wminkowski(u, v, p, w)

Compute the weighted Minkowski distance between two 1-D arrays.

The weighted Minkowski distance between u and v, defined as

\[ \left( \sum (w_i |u_i - v_i|^p) \right)^{1/p} \]

Parameters

- u [(N,) array_like] Input array.
- v [(N,) array_like] Input array.
- p [int] The order of the norm of the difference ||u - v||_p.
- w [(N,) array_like] The weight vector.

Returns

wminkowski [double] The weighted Minkowski distance between vectors u and v.
Notes

`wminkowski` is DEPRECATED. It implements a definition where weights are powered. It is recommended to use the weighted version of `minkowski` instead. This function will be removed in a future version of scipy.

Examples

```python
>>> from scipy.spatial import distance
>>> distance.wminkowski([1, 0, 0], [0, 1, 0], 1, np.ones(3))
2.0
>>> distance.wminkowski([1, 0, 0], [0, 1, 0], 2, np.ones(3))
1.4142135623730951
>>> distance.wminkowski([1, 0, 0], [0, 1, 0], 3, np.ones(3))
1.2599210498948732
>>> distance.wminkowski([1, 1, 0], [0, 1, 0], 1, np.ones(3))
1.0
>>> distance.wminkowski([1, 1, 0], [0, 1, 0], 2, np.ones(3))
1.0
>>> distance.wminkowski([1, 1, 0], [0, 1, 0], 3, np.ones(3))
1.0
```

Distance functions between two boolean vectors (representing sets) `u` and `v`. As in the case of numerical vectors, `pdist` is more efficient for computing the distances between all pairs.

**scipy.spatial.distance.dice**

`scipy.spatial.distance.dice(u, v, w=None)`

Compute the Dice dissimilarity between two boolean 1-D arrays.

The Dice dissimilarity between `u` and `v`, is

\[
\frac{c_{TF} + c_{FT}}{2c_{TT} + c_{FT} + c_{TF}}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \).
Parameters

\( u \) [(N,) ndarray, bool] Input 1-D array.
\( v \) [(N,) ndarray, bool] Input 1-D array.
\( w \) [(N,) array_like, optional] The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

Returns

dice [double] The Dice dissimilarity between 1-D arrays \( u \) and \( v \).

Examples

```python
>>> from scipy.spatial import distance
>>> distance.dice([1, 0, 0], [0, 1, 0])
1.0
>>> distance.dice([1, 0, 0], [1, 1, 0])
0.3333333333333333
>>> distance.dice([1, 0, 0], [2, 0, 0])
-0.3333333333333333
```

**scipy.spatial.distance.hamming**

scipy.spatial.distance.hamming \((u, v, \text{w=None})\)

Compute the Hamming distance between two 1-D arrays.

The Hamming distance between 1-D arrays \( u \) and \( v \), is simply the proportion of disagreeing components in \( u \) and \( v \). If \( u \) and \( v \) are boolean vectors, the Hamming distance is

\[
\frac{c_{01} + c_{10}}{n}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \).

Parameters

\( u \) [(N,) array_like] Input array.
\( v \) [(N,) array_like] Input array.
\( w \) [(N,) array_like, optional] The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

Returns

hamming [double] The Hamming distance between vectors \( u \) and \( v \).

Examples

```python
>>> from scipy.spatial import distance
>>> distance.hamming([1, 0, 0], [0, 1, 0])
0.6666666666666666
>>> distance.hamming([1, 0, 0], [1, 1, 0])
0.3333333333333333
>>> distance.hamming([1, 0, 0], [2, 0, 0])
0.3333333333333333
>>> distance.hamming([1, 0, 0], [3, 0, 0])
0.3333333333333333
```
scipy.spatial.distance.jaccard

scipy.spatial.distance.jaccard(u, v, w=None)

Compute the Jaccard-Needham dissimilarity between two boolean 1-D arrays.

The Jaccard-Needham dissimilarity between 1-D boolean arrays \( u \) and \( v \), is defined as

\[
\frac{c_{TF} + c_{FT}}{c_{TT} + c_{FT} + c_{TF}}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \).

**Parameters**

- **u** [(N,) array_like, bool] Input array.
- **v** [(N,) array_like, bool] Input array.
- **w** [(N,) array_like, optional] The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

**Returns**

- **jaccard** [double] The Jaccard distance between vectors \( u \) and \( v \).

**Notes**

When both \( u \) and \( v \) lead to a 0/0 division i.e. there is no overlap between the items in the vectors the returned distance is 0. See the Wikipedia page on the Jaccard index [1], and this paper [2].

Changed in version 1.2.0: Previously, when \( u \) and \( v \) lead to a 0/0 division, the function would return NaN. This was changed to return 0 instead.

**References**

[1],[2]

**Examples**

```python
>>> from scipy.spatial import distance
>>> distance.jaccard([1, 0, 0], [0, 1, 0])
1.0
>>> distance.jaccard([1, 0, 0], [1, 1, 0])
0.5
>>> distance.jaccard([1, 0, 0], [1, 2, 0])
0.5
>>> distance.jaccard([1, 0, 0], [1, 1, 1])
0.6666666666666666
```

scipy.spatial.distance.kulsinski

scipy.spatial.distance.kulsinski(u, v, w=None)

Compute the Kulsinski dissimilarity between two boolean 1-D arrays.
The Kulsinski dissimilarity between two boolean 1-D arrays \( u \) and \( v \), is defined as

\[
\frac{c_{TF} + c_{FT} - c_{TT} + n}{c_{FT} + c_{TF} + n}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \).

**Parameters**
- \( u \) [(N,) array_like, bool] Input array.
- \( v \) [(N,) array_like, bool] Input array.
- \( w \) [(N,) array_like, optional] The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

**Returns**
- **kulsinski** [double] The Kulsinski distance between vectors \( u \) and \( v \).

**Examples**

```python
>>> from scipy.spatial import distance
>>> distance.kulsinski([1, 0, 0], [0, 1, 0])
1.0
>>> distance.kulsinski([1, 0, 0], [1, 1, 0])
0.75
>>> distance.kulsinski([1, 0, 0], [2, 1, 0])
0.33333333333333334
>>> distance.kulsinski([1, 0, 0], [3, 1, 0])
-0.5
```

**scipy.spatial.distance.rogerstanimoto**

**scipy.spatial.distance.rogerstanimoto** \((u, v, w=None)\)

Compute the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.

The Rogers-Tanimoto dissimilarity between two boolean 1-D arrays \( u \) and \( v \), is defined as

\[
R \frac{c_{TT} + c_{FF} - R}{c_{TT} + c_{FF} + R}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \) and \( R = 2(c_{TF} + c_{FT}) \).

**Parameters**
- \( u \) [(N,) array_like, bool] Input array.
- \( v \) [(N,) array_like, bool] Input array.
- \( w \) [(N,) array_like, optional] The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

**Returns**
- **rogerstanimoto** [double] The Rogers-Tanimoto dissimilarity between vectors \( u \) and \( v \).

**Examples**
from scipy.spatial import distance
distance.rogerstanimoto([1, 0, 0], [0, 1, 0])
0.8
distance.rogerstanimoto([1, 0, 0], [1, 1, 0])
0.5
distance.rogerstanimoto([1, 0, 0], [2, 0, 0])
-1.0

scipy.spatial.distance.russellrao

scipy.spatial.distance.russellrao(u, v, w=None)
Compute the Russell-Rao dissimilarity between two boolean 1-D arrays.

The Russell-Rao dissimilarity between two boolean 1-D arrays, u and v, is defined as

\[
\frac{n - c_{TT}}{n}
\]

where \(c_{ij}\) is the number of occurrences of \(u[k] = i\) and \(v[k] = j\) for \(k < n\).

Parameters
- **u** [(N,) array_like, bool] Input array.
- **v** [(N,) array_like, bool] Input array.
- **w** [(N,) array_like, optional] The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns
- **russellrao** [double] The Russell-Rao dissimilarity between vectors u and v.

Examples

```python
>>> from scipy.spatial import distance
>>> distance.russellrao([1, 0, 0], [0, 1, 0])
1.0
>>> distance.russellrao([1, 0, 0], [1, 1, 0])
0.6666666666666666
>>> distance.russellrao([1, 0, 0], [2, 0, 0])
0.3333333333333333
```

scipy.spatial.distance.sokalmichener

scipy.spatial.distance.sokalmichener(u, v, w=None)
Compute the Sokal-Michener dissimilarity between two boolean 1-D arrays.

The Sokal-Michener dissimilarity between boolean 1-D arrays u and v, is defined as

\[
\frac{R}{S + R}
\]

where \(c_{ij}\) is the number of occurrences of \(u[k] = i\) and \(v[k] = j\) for \(k < n\), \(R = 2 \times (c_{TF} + c_{FT})\) and \(S = c_{FF} + c_{TT}\).

Parameters

```python
>>> from scipy.spatial import distance
>>> distance.sokalmichener([1, 0, 0], [0, 1, 0])
1.0
>>> distance.sokalmichener([1, 0, 0], [1, 1, 0])
0.6666666666666666
>>> distance.sokalmichener([1, 0, 0], [2, 0, 0])
0.3333333333333333
```
SciPy Reference Guide, Release 1.3.2

**u** [(N,) array_like, bool] Input array.

**v** [(N,) array_like, bool] Input array.

**w** [(N,) array_like, optional] The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

**Returns**

**sokalmichener**

[double] The Sokal-Michener dissimilarity between vectors \( u \) and \( v \).

**Examples**

```python
>>> from scipy.spatial import distance
>>> distance.sokalmichener([1, 0, 0], [0, 1, 0])
0.8
>>> distance.sokalmichener([1, 0, 0], [1, 1, 0])
0.5
>>> distance.sokalmichener([1, 0, 0], [2, 0, 0])
-1.0
```

**scipy.spatial.distance.sokalsneath**

**scipy.spatial.distance.sokalsneath** \((u, v, w=None)\)

Compute the Sokal-Sneath dissimilarity between two boolean 1-D arrays.

The Sokal-Sneath dissimilarity between \( u \) and \( v \),

\[
R \frac{c_{TT}}{c_{TT} + \bar{R}}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \) and \( R = 2(c_{TF} + c_{FT}) \).

**Parameters**

**u** [(N,) array_like, bool] Input array.

**v** [(N,) array_like, bool] Input array.

**w** [(N,) array_like, optional] The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

**Returns**

**sokalsneath**

[double] The Sokal-Sneath dissimilarity between vectors \( u \) and \( v \).

**Examples**

```python
>>> from scipy.spatial import distance
>>> distance.sokalsneath([1, 0, 0], [0, 1, 0])
1.0
>>> distance.sokalsneath([1, 0, 0], [1, 1, 0])
0.6666666666666663
>>> distance.sokalsneath([1, 0, 0], [2, 1, 0])
0.0
>>> distance.sokalsneath([1, 0, 0], [3, 1, 0])
-2.0
```
scipy.spatial.distance.yule

scipy.spatial.distance.yule(u, v, w=None)

Compute the Yule dissimilarity between two boolean 1-D arrays.

The Yule dissimilarity is defined as

\[
\frac{R}{c_{TT} * c_{FF} + \frac{R}{2}}
\]

where \(c_{ij}\) is the number of occurrences of \(u[k] = i\) and \(v[k] = j\) for \(k < n\) and \(R = 2.0 * c_{TF} * c_{FT}\).

Parameters

- **u** [(N,) array_like, bool] Input array.
- **v** [(N,) array_like, bool] Input array.
- **w** [(N,) array_like, optional] The weights for each value in \(u\) and \(v\). Default is None, which gives each value a weight of 1.0

Returns

- **yule** [double] The Yule dissimilarity between vectors \(u\) and \(v\).

Examples

```python
>>> from scipy.spatial import distance
>>> distance.yule([1, 0, 0], [0, 1, 0])
2.0
>>> distance.yule([1, 1, 0], [0, 1, 0])
0.0
```

*hamming* also operates over discrete numerical vectors.

### 6.27 Special functions (scipy.special)

Nearly all of the functions below are universal functions and follow broadcasting and automatic array-looping rules. Exceptions are noted.

See also:

- scipy.special.cython_special – Typed Cython versions of special functions

#### 6.27.1 Error handling

Errors are handled by returning NaNs or other appropriate values. Some of the special function routines can emit warnings or raise exceptions when an error occurs. By default this is disabled; to query and control the current error handling state the following functions are provided.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>geterr()</td>
<td>Get the current way of handling special-function errors.</td>
</tr>
<tr>
<td>seterr()</td>
<td>Set how special-function errors are handled.</td>
</tr>
<tr>
<td>errstate</td>
<td>Context manager for special-function error handling.</td>
</tr>
<tr>
<td>SpecialFunctionWarning</td>
<td>Warning that can be emitted by special functions.</td>
</tr>
<tr>
<td>SpecialFunctionError</td>
<td>Exception that can be raised by special functions.</td>
</tr>
</tbody>
</table>
scipy.special.geterr

scipy.special.geterr()

Get the current way of handling special-function errors.

Returns

err [dict] A dictionary with keys “singular”, “underflow”, “overflow”, “slow”, “loss”, “no_result”, “domain”, “arg”, and “other”, whose values are from the strings “ignore”, “warn”, and “raise”. The keys represent possible special-function errors, and the values define how these errors are handled.

See also:

seterr

set how special-function errors are handled
errstate

context manager for special-function error handling

numpy.geterr

similar numpy function for floating-point errors

Notes

For complete documentation of the types of special-function errors and treatment options, see seterr.

Examples

By default all errors are ignored.

```python
>>> import scipy.special as sp
>>> for key, value in sorted(sp.geterr().items()):
...     print(f"{key}: {value}")
...  arg: ignore
domain: ignore
loss: ignore
no_result: ignore
other: ignore
overflow: ignore
singular: ignore
slow: ignore
underflow: ignore
```

scipy.special.seterr

scipy.special.seterr()

Set how special-function errors are handled.

Parameters
all  [[‘ignore’, ‘warn’, ‘raise’], optional] Set treatment for all type of special-function errors at once. The options are:
  • ‘ignore’ Take no action when the error occurs
  • ‘warn’ Print a.SpecialFunctionWarning when the error occurs (via the Python
    warnings module)
  • ‘raise’ Raise a.SpecialFunctionError when the error occurs.
The default is to not change the current behavior. If behaviors for additional categories of
special-function errors are specified, then all is applied first, followed by the additional
categories.
no_result  [[‘ignore’, ‘warn’, ‘raise’], optional] Treatment for failing to find a result.

Returns
olderr   [dict] Dictionary containing the old settings.

See also:

geterr
  get the current way of handling special-function errors
errstate
  context manager for special-function error handling
numpy.seterr
  similar numpy function for floating-point errors

Examples

>>> import scipy.special as sc
>>> from pytest import raises
>>> sc.gammaln(0)
inf
>>> olderr = sc.seterr(singular='raise')
>>> with raises(sc.SpecialFunctionError):
...    sc.gammaln(0)
...
_ = sc.seterr(**olderr)

We can also raise for every category except one.

>>> olderr = sc.seterr(all='raise', singular='ignore')
>>> sc.gammaln(0)
inf
>>> with raises(sc.SpecialFunctionError):
...    sc.spence(-1)
scipy.special.errstate

class scipy.special.errstate
Context manager for special-function error handling.

Using an instance of errstate as a context manager allows statements in that context to execute with a known error handling behavior. Upon entering the context the error handling is set with seterr, and upon exiting it is restored to what it was before.

Parameters

kwargs
{[all, singular, underflow, overflow, slow, loss, no_result, domain, arg, other]} Keyword arguments. The valid keywords are possible special-function errors. Each keyword should have a string value that defines the treatment for the particular type of error. Values must be 'ignore', 'warn', or 'other'. See seterr for details.

See also:

geterr
get the current way of handling special-function errors

seterr
set how special-function errors are handled

numpy.errstate
similar numpy function for floating-point errors

Examples

>>> import scipy.special as sc
>>> from pytest import raises
>>> sc.gammaln(0)
inf
>>> with sc.errstate(singular='raise'):
...   with raises(sc.SpecialFunctionError):
...     sc.gammaln(0)
...     inf

We can also raise on every category except one.

>>> with sc.errstate(all='raise', singular='ignore'):
...   sc.gammaln(0)
...   with raises(sc.SpecialFunctionError):
...     sc.spence(-1)
...     inf
scipy.special.SpecialFunctionWarning

exception scipy.special.SpecialFunctionWarning
Warning that can be emitted by special functions.

with_traceback()  
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

scipy.special.SpecialFunctionError

exception scipy.special.SpecialFunctionError  
Exception that can be raised by special functions.

with_traceback()  
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

6.27.2 Available functions

Airy functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>airy(z)</td>
<td>Airy functions and their derivatives.</td>
</tr>
<tr>
<td>airy(y)</td>
<td>Exponentially scaled Airy functions and their derivatives.</td>
</tr>
<tr>
<td>ai_zeros(nt)</td>
<td>Compute nt zeros and values of the Airy function Ai and its derivative.</td>
</tr>
<tr>
<td>bi_zeros(nt)</td>
<td>Compute nt zeros and values of the Airy function Bi and its derivative.</td>
</tr>
<tr>
<td>itairy(x)</td>
<td>Integrals of Airy functions</td>
</tr>
</tbody>
</table>

scipy.special.airy

scipy.special.airy(z) = <ufunc 'airy'>  
Airy functions and their derivatives.

Parameters

- z  
[array_like] Real or complex argument.

Returns

- Ai, Aip, Bi, Bip  
[ndarrays] Airy functions Ai and Bi, and their derivatives Aip and Bip.

See also:

- airy

exponentially scaled Airy functions.

Notes

The Airy functions Ai and Bi are two independent solutions of

\[ y''(x) = xy(x). \]
For real \(z\) in \([-10, 10]\), the computation is carried out by calling the Cephes [1] `airy` routine, which uses power series summation for small \(z\) and rational minimax approximations for large \(z\).

Outside this range, the AMOS [2] `zairy` and `zbiry` routines are employed. They are computed using power series for \(|z| < 1\) and the following relations to modified Bessel functions for larger \(z\) (where \(t \equiv 2 z^{3/2}/3\)):

\[
\begin{align*}
    Ai(z) &= \frac{1}{\pi \sqrt{3}} K_{1/3}(t) \\
    Ai'(z) &= -\frac{z}{\pi \sqrt{3}} K_{2/3}(t) \\
    Bi(z) &= \sqrt{\frac{z}{3}} (I_{-1/3}(t) + I_{1/3}(t)) \\
    Bi'(z) &= \frac{z}{\sqrt{3}} (I_{-2/3}(t) + I_{2/3}(t))
\end{align*}
\]

References

[1], [2]

Examples

Compute the Airy functions on the interval \([-15, 5]\).

```python
>>> from scipy import special
>>> x = np.linspace(-15, 5, 201)
>>> ai, aip, bi, bip = special.airy(x)
```

Plot \(Ai(x)\) and \(Bi(x)\).

```python
>>> import matplotlib.pyplot as plt
>>> plt.plot(x, ai, 'r', label='Ai(x)')
>>> plt.plot(x, bi, 'b--', label='Bi(x)')
>>> plt.ylim(-0.5, 1.0)
>>> plt.grid()
>>> plt.legend(loc='upper left')
>>> plt.show()
```

**scipy.special.airye**

`scipy.special.airye(z) = <ufunc 'airye'>`

Exponentially scaled Airy functions and their derivatives.

Scaling:

\[
\begin{align*}
    eAi &= Ai \times \exp(2.0/3.0*z*\sqrt{z}) \\
    eAip &= Aip \times \exp(2.0/3.0*z*\sqrt{z}) \\
    eBi &= Bi \times \exp(-\text{abs}(2.0/3.0*(z*\sqrt{z}).\text{real})) \\
    eBip &= Bip \times \exp(-\text{abs}(2.0/3.0*(z*\sqrt{z}).\text{real}))
\end{align*}
\]

**Parameters**

\(z\) [array_like] Real or complex argument.

**Returns**
eAi, eAip, eBi, eBip

[array_like] Airy functions Ai and Bi, and their derivatives Aip and Bip

See also:

airy

Notes

Wrapper for the AMOS [1] routines zairy and zbiry.

References

[1]

scipy.special.ai_zeros

scipy.special.ai_zeros(nt)

Compute nt zeros and values of the Airy function Ai and its derivative.

Computes the first nt zeros, a, of the Airy function Ai(x); first nt zeros, ap, of the derivative of the Airy function Aip(x); the corresponding values Ai(a'); and the corresponding values Aip(a).

Parameters

nt [int] Number of zeros to compute

Returns

a [ndarray] First nt zeros of Ai(x)
ap [ndarray] First nt zeros of Aip(x)
ai [ndarray] Values of Ai(x) evaluated at first nt zeros of Aip(x)
aip [ndarray] Values of Aip(x) evaluated at first nt zeros of Ai(x)
References

[1]

Examples

```python
>>> from scipy import special
>>> a, ap, ai, aip = special.ai_zeros(3)
>>> a
array([-2.33810741, -4.08794944, -5.52055983])
>>> ap
array([-1.01879297, -3.24819758, -4.82009921])
>>> ai
array([ 0.53565666, -0.41901548, 0.38040647])
>>> aip
array([ 0.70121082, -0.80311137, 0.86520403])
```

**scipy.special.ai_zeros**

**scipy.special.ai_zeros** *(nt)*

Compute *nt* zeros and values of the Airy function :math:`Bi` and its derivative.

Computes the first *nt* zeros, :math:`b`, of the Airy function :math:`Bi(x)`; first *nt* zeros, :math:`b'`, of the derivative of the Airy function :math:`Bi'(x)`; the corresponding values :math:`Bi(b')`; and the corresponding values :math:`Bi'(b)`.

**Parameters**

- **nt** : [int] Number of zeros to compute

**Returns**

- **b** : [ndarray] First *nt* zeros of :math:`Bi(x)`
- **bp** : [ndarray] First *nt* zeros of :math:`Bi'(x)`
- **bi** : [ndarray] Values of :math:`Bi(x)` evaluated at first *nt* zeros of :math:`Bi'(x)`
- **bip** : [ndarray] Values of :math:`Bi'(x)` evaluated at first *nt* zeros of :math:`Bi(x)`

References

[1]

Examples

```python
>>> from scipy import special
>>> b, bp, bi, bip = special.bi_zeros(3)
>>> b
array([-1.17371322, -3.2710933 , -4.83073784])
>>> bp
array([-2.29443968, -4.07315509, -5.51239573])
>>> bi
array([-0.45494438, 0.39652284, -0.36796916])
>>> bip
array([ 0.60195789, -0.76031014, 0.83699101])
```
**scipy.special.itairy**

```python
scipy.special.itairy(x) = <ufunc 'itairy'>
```

Integrals of Airy functions

Calculates the integrals of Airy functions from 0 to \( x \).

**Parameters**

- **x**: `array_like`  
  Upper limit of integration (float).

**Returns**

- **Apt**: Integral of \( \text{Ai}(t) \) from 0 to \( x \).
- **Bpt**: Integral of \( \text{Bi}(t) \) from 0 to \( x \).
- **Ant**: Integral of \( \text{Ai}(-t) \) from 0 to \( x \).
- **Bnt**: Integral of \( \text{Bi}(-t) \) from 0 to \( x \).

**Notes**

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

<td>Incomplete elliptic integral of the second kind</td>
</tr>
</tbody>
</table>

**scipy.special.ellipj**

```python
scipy.special.ellipj(u, m) = <ufunc 'ellipj'>
```

Jacobian elliptic functions

Calculates the Jacobian elliptic functions of parameter \( m \) between 0 and 1, and real argument \( u \).

**Parameters**

- **m**: `array_like`  
  Parameter.
- **u**: `array_like`  
  Argument.

**Returns**

- **sn, cn, dn, ph**: `[ndarrays]` The returned functions:

  ```
  sn(u|m), cn(u|m), dn(u|m)
  ```

  The value \( ph \) is such that if \( u = ellipkinc(ph, m) \), then \( sn(ulm) = sin(ph) \) and \( cn(ulm) = cos(ph) \).
ellipk
Complete elliptic integral of the first kind

ellipkinc
Incomplete elliptic integral of the first kind

Notes
These functions are periodic, with quarter-period on the real axis equal to the complete elliptic integral \( \text{ellipk}(m) \).
Relation to incomplete elliptic integral: If \( u = \text{ellipkinc}(\phi, m) \), then \( \text{sn}(u|m) = \sin(\phi) \) and \( \text{cn}(u|m) = \cos(\phi) \).
The \( \phi \) is called the amplitude of \( u \).
Computation is by means of the arithmetic-geometric mean algorithm, except when \( m \) is within 1e-9 of 0 or 1. In the latter case with \( m \) close to 1, the approximation applies only for \( \phi < \pi/2 \).

References
[1]

scipy.special.ellipk

scipy.special.ellipk(m)
Complete elliptic integral of the first kind.
This function is defined as
\[
K(m) = \int_{0}^{\pi/2} \frac{dt}{\sqrt{1 - m \sin^2(t)}}
\]

Parameters
m
[array_like] The parameter of the elliptic integral.

Returns
K
[array_like] Value of the elliptic integral.

See also:

ellipkm1
Complete elliptic integral of the first kind around \( m = 1 \)

ellipkinc
Incomplete elliptic integral of the first kind

eellipse
Complete elliptic integral of the second kind

ellipeinc
Incomplete elliptic integral of the second kind
Notes

For more precision around point \( m = 1 \), use \( \text{ellipkm1} \), which this function calls.

The parameterization in terms of \( m \) follows that of section 17.2 in [1]. Other parameterizations in terms of the complementary parameter \( 1 - m \), modular angle \( \sin^2(\alpha) = m \), or modulus \( k^2 = m \) are also used, so be careful that you choose the correct parameter.

References

[1]

scipy.special.ellipkm1

scipy.special.ellipkm1 \( (p) = \) <ufunc 'ellipkm1'>

Complete elliptic integral of the first kind around \( m = 1 \)

This function is defined as

\[
K(p) = \int_{0}^{\pi/2} [1 - m \sin(t)^2]^{-1/2} dt
\]

where \( m = 1 - p \).

Parameters

\( p \) [array_like] Defines the parameter of the elliptic integral as \( m = 1 - p \).

Returns

\( K \) [ndarray] Value of the elliptic integral.

See also:

\texttt{ellipk}

Complete elliptic integral of the first kind

\texttt{ellipkinc}

Incomplete elliptic integral of the first kind

\texttt{ellipe}

Complete elliptic integral of the second kind

\texttt{ellipeinc}

Incomplete elliptic integral of the second kind

Notes

Wrapper for the Cephes [1] routine \texttt{ellpk}.

For \( p \leq 1 \), computation uses the approximation,

\[
K(p) \approx P(p) - \log(p)Q(p),
\]

where \( P \) and \( Q \) are tenth-order polynomials. The argument \( p \) is used internally rather than \( m \) so that the logarithmic singularity at \( m = 1 \) will be shifted to the origin; this preserves maximum accuracy. For \( p > 1 \), the identity

\[
K(p) = K(1/p) / \sqrt(p)
\]

is used.
References

[1]

scipy.special.ellipinc

scipy.special.ellipinc(phi, m) = <ufunc 'ellipinc'>

Incomplete elliptic integral of the first kind

This function is defined as

\[ K(\phi, m) = \int_0^\phi \frac{1}{\sqrt{1 - m \sin^2(t)}} dt \]

This function is also called \( F(\phi, m) \).

Parameters

phi [array_like] amplitude of the elliptic integral
m [array_like] parameter of the elliptic integral

Returns

K [ndarray] Value of the elliptic integral

See also:

ellipkm1

Complete elliptic integral of the first kind, near \( m = 1 \)

ellipk

Complete elliptic integral of the first kind

ellipe

Complete elliptic integral of the second kind

ellipeinc

Incomplete elliptic integral of the second kind

Notes

Wrapper for the Cephes [1] routine ellik. The computation is carried out using the arithmetic-geometric mean algorithm.

The parameterization in terms of \( m \) follows that of section 17.2 in [2]. Other parameterizations in terms of the complementary parameter \( 1 - m \), modular angle \( \sin^2(\alpha) = m \), or modulus \( k^2 = m \) are also used, so be careful that you choose the correct parameter.

References

[1], [2]
scipy.special.ellipe

`scipy.special.ellipe(m) = <ufunc 'ellipe'>`

Complete elliptic integral of the second kind

This function is defined as

\[
E(m) = \int_0^{\pi/2} \left[1 - m \sin^2(t)\right]^{1/2} dt
\]

**Parameters**

- `m` [array_like] Defines the parameter of the elliptic integral.

**Returns**

- `E` [ndarray] Value of the elliptic integral.

**See also:**

- `ellipkm1`
  Complete elliptic integral of the first kind, near \( m = 1 \)

- `ellip`
  Complete elliptic integral of the first kind

- `ellipkinc`
  Incomplete elliptic integral of the first kind

- `ellipeinc`
  Incomplete elliptic integral of the second kind

**Notes**

For \( m > 0 \) the computation uses the approximation,

\[
E(m) \approx P(1 - m) - (1 - m) \log(1 - m) Q(1 - m),
\]

where \( P \) and \( Q \) are tenth-order polynomials. For \( m < 0 \), the relation

\[
E(m) = E(m/(m - 1)) \sqrt{1 - m}
\]

is used.

The parameterization in terms of \( m \) follows that of section 17.2 in [2]. Other parameterizations in terms of the complementary parameter \( 1 - m \), modular angle \( \sin^2(\alpha) = m \), or modulus \( k^2 = m \) are also used, so be careful that you choose the correct parameter.

[1], [2]
Examples

This function is used in finding the circumference of an ellipse with semi-major axis $a$ and semi-minor axis $b$.

```python
>>> from scipy import special
```

```python
>>> a = 3.5
>>> b = 2.1
>>> e_sq = 1.0 - b**2/a**2  # eccentricity squared
```

Then the circumference is found using the following:

```python
>>> C = 4*a*special.ellipe(e_sq)  # circumference formula
>>> C
17.868899204378693
```

When $a$ and $b$ are the same (meaning eccentricity is 0), this reduces to the circumference of a circle.

```python
>>> 4*a*special.ellipe(0.0)  # formula for ellipse with a = b
21.991148575128552
>>> 2*np.pi*a  # formula for circle of radius a
21.991148575128552
```

**scipy.special.ellipeinc**

`scipy.special.ellipeinc(phi, m) = <ufunc 'ellipeinc'>`

Incomplete elliptic integral of the second kind

This function is defined as

\[
E(\phi, m) = \int_0^\phi \frac{1 - m \sin(t)^2}{\sqrt{1 - m \sin(t)^2}} dt
\]

**Parameters**

- **phi** : array_like  
  amplitude of the elliptic integral.
- **m** : array_like  
  parameter of the elliptic integral.

**Returns**

- **E** : ndarray  
  Value of the elliptic integral.

See also:

- **ellipkm1**  
  Complete elliptic integral of the first kind, near $m = 1$
- **ellip**  
  Complete elliptic integral of the first kind
- **ellipkinc**  
  Incomplete elliptic integral of the first kind
- **ellipe**  
  Complete elliptic integral of the second kind
Notes

Computation uses arithmetic-geometric means algorithm.

The parameterization in terms of $m$ follows that of section 17.2 in [2]. Other parameterizations in terms of the complementary parameter $1 - m$, modular angle $\sin^2(\alpha) = m$, or modulus $k^2 = m$ are also used, so be careful that you choose the correct parameter.

scipy.special.jv

scipy.special.jv(v, z) = <ufunc 'jv'>

Bessel function of the first kind of real order and complex argument.

Parameters

- v [array_like] Order (float).
- z [array_like] Argument (float or complex).

Returns

- J [ndarray] Value of the Bessel function, $J_v(z)$.

See also:
jve

$J_v$ with leading exponential behavior stripped off.

spherical_jn

Spherical Bessel functions.

Notes

For positive $v$ values, the computation is carried out using the AMOS [1] $zbesj$ routine, which exploits the connection to the modified Bessel function $I_v$,

$$ J_v(z) = \exp(v\pi i/2)I_v(-iz) \quad (\Im z > 0) $$
$$ J_v(z) = \exp(-v\pi i/2)I_v(iz) \quad (\Im z < 0) $$

For negative $v$ values the formula,

$$ J_{-v}(z) = J_v(z) \cos(\pi v) - Y_v(z) \sin(\pi v) $$

is used, where $Y_v(z)$ is the Bessel function of the second kind, computed using the AMOS routine $zbesy$. Note that the second term is exactly zero for integer $v$; to improve accuracy the second term is explicitly omitted for $v$ values such that $v = \text{floor}(v)$.

Not to be confused with the spherical Bessel functions (see spherical_jn).

References

[1]

scipy.special.jve

scipy.special.jve(v, z) = <ufunc 'jve'>

Exponentially scaled Bessel function of order $v$.

Defined as:

$$ jve(v, z) = jv(v, z) * \exp(-\text{abs}(z.\text{imag})) $$

Parameters

- $v$ [array_like] Order (float).
- $z$ [array_like] Argument (float or complex).

Returns

- $J$ [ndarray] Value of the exponentially scaled Bessel function.

Notes

For positive $v$ values, the computation is carried out using the AMOS [1] $zbesj$ routine, which exploits the connection to the modified Bessel function $I_v$,

$$ J_v(z) = \exp(v\pi i/2)I_v(-iz) \quad (\Im z > 0) $$
$$ J_v(z) = \exp(-v\pi i/2)I_v(iz) \quad (\Im z < 0) $$
For negative $v$ values the formula,

$$J_{-v}(z) = J_v(z) \cos(\pi v) - Y_v(z) \sin(\pi v)$$

is used, where $Y_v(z)$ is the Bessel function of the second kind, computed using the AMOS routine $zbesy$. Note that the second term is exactly zero for integer $v$, to improve accuracy the second term is explicitly omitted for $v$ values such that $v = \text{floor}(v)$.

References

[1]

**scipy.special.yn**

scipy.special.yn($n$, $x$) = <ufunc 'yn'>

Bessel function of the second kind of integer order and real argument.

*Parameters*

$n$ [array_like] Order (integer).

$z$ [array_like] Argument (float).

*Returns*

$Y$ [ndarray] Value of the Bessel function, $Y_n(x)$.

See also:

$yv$

For real order and real or complex argument.

**Notes**

The function is evaluated by forward recurrence on $n$, starting with values computed by the Cephes routines $y0$ and $y1$. If $n = 0$ or 1, the routine for $y0$ or $y1$ is called directly.

References

[1]

**scipy.special.yv**

scipy.special.yv($v$, $z$) = <ufunc 'yv'>

Bessel function of the second kind of real order and complex argument.

*Parameters*

$v$ [array_like] Order (float).

$z$ [array_like] Argument (float or complex).

*Returns*

$Y$ [ndarray] Value of the Bessel function of the second kind, $Y_v(x)$.

See also:
yve

$Y_v$ with leading exponential behavior stripped off.

Notes

For positive $v$ values, the computation is carried out using the AMOS [1] $zbesy$ routine, which exploits the connection to the Hankel Bessel functions $H_v^{(1)}$ and $H_v^{(2)}$,

$$Y_v(z) = \frac{1}{2i} (H_v^{(1)} - H_v^{(2)}).$$

For negative $v$ values the formula,

$$Y_{-v}(z) = Y_v(z) \cos(\pi v) + J_v(z) \sin(\pi v)$$

is used, where $J_v(z)$ is the Bessel function of the first kind, computed using the AMOS routine $zbesj$. Note that the second term is exactly zero for integer $v$; to improve accuracy the second term is explicitly omitted for $v$ values such that $v = \text{floor}(v)$.

References

[1]

scipy.special.yve

scipy.special.yve(v, z) = <ufunc 'yve'>

Exponentially scaled Bessel function of the second kind of real order.

Returns the exponentially scaled Bessel function of the second kind of real order $v$ at complex $z$:

$$yve(v, z) = yv(v, z) \times \exp(-\text{abs}(z \cdot \text{imag}))$$

Parameters

$v$ [array_like] Order (float).

$z$ [array_like] Argument (float or complex).

Returns

$Y$ [ndarray] Value of the exponentially scaled Bessel function.

Notes

For positive $v$ values, the computation is carried out using the AMOS [1] $zbesy$ routine, which exploits the connection to the Hankel Bessel functions $H_v^{(1)}$ and $H_v^{(2)}$,

$$Y_v(z) = \frac{1}{2i} (H_v^{(1)} - H_v^{(2)}).$$

For negative $v$ values the formula,

$$Y_{-v}(z) = Y_v(z) \cos(\pi v) + J_v(z) \sin(\pi v)$$

is used, where $J_v(z)$ is the Bessel function of the first kind, computed using the AMOS routine $zbesj$. Note that the second term is exactly zero for integer $v$; to improve accuracy the second term is explicitly omitted for $v$ values such that $v = \text{floor}(v)$. 
References

[1]

scipy.special.kn

scipy.special.kn(n, x) = <ufunc 'kn'>
Modified Bessel function of the second kind of integer order n

Returns the modified Bessel function of the second kind for integer order n at real x.
These are also sometimes called functions of the third kind, Basset functions, or Macdonald functions.

Parameters

- n: [array_like of int] Order of Bessel functions (floats will truncate with a warning)
- z: [array_like of float] Argument at which to evaluate the Bessel functions

Returns

- out: [ndarray] The results

See also:

kv
Same function, but accepts real order and complex argument

kvp
Derivative of this function

Notes

References

[1], [2]

Examples

Plot the function of several orders for real input:

```python
>>> from scipy.special import kn
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 5, 1000)
>>> for N in range(6):
...     plt.plot(x, kn(N, x), label='$K_{}(x)$'.format(N))
>>> plt.ylim(0, 10)
>>> plt.legend()
>>> plt.title(r'Modified Bessel function of the second kind $K_n(x)$')
>>> plt.show()
```

Calculate for a single value at multiple orders:
Modified Bessel function of the second kind \( K_n(x) \)

```
>>> kn([4, 5, 6], 1)
array([ 44.23241585, 360.9605896 , 3653.83831186])
```

**scipy.special.kv**

\[ \text{scipy.special.kv}(v, z) = \text{<ufunc 'kv'>} \]

Modified Bessel function of the second kind of real order \( v \)

Returns the modified Bessel function of the second kind for real order \( v \) at complex \( z \).

These are also sometimes called functions of the third kind, Basset functions, or Macdonald functions. They are defined as those solutions of the modified Bessel equation for which,

\[
K_v(x) \sim \sqrt{\pi/(2x)} \exp(-x)
\]

as \( x \to \infty \) [3].

**Parameters**

- \( v \) [array_like of float] Order of Bessel functions
- \( z \) [array_like of complex] Argument at which to evaluate the Bessel functions

**Returns**

- \( \text{out} \) [ndarray] The results. Note that input must be of complex type to get complex output, e.g. \( \text{kv}(3, -2+0j) \) instead of \( \text{kv}(3, -2) \).

**See also:**

- \( \text{kv} \)
  - This function with leading exponential behavior stripped off.

- \( \text{kv} \)
  - Derivative of this function
Notes

References

[1], [2], [3]

Examples

Plot the function of several orders for real input:

```python
>>> from scipy.special import kv
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 5, 1000)
>>> for N in np.linspace(0, 6, 5):
...     plt.plot(x, kv(N, x), label='$K_{{{}}}({})$'.format(N))
>>> plt.ylim(0, 10)
>>> plt.legend()
>>> plt.title(r'Modified Bessel function of the second kind $K_{\nu}(x)$')
>>> plt.show()
```

![Modified Bessel function of the second kind](image)

Calculate for a single value at multiple orders:

```python
>>> kv([4, 4.5, 5], 1+2j)
array([[ 0.1992+2.3892j, 2.3493+3.6j , 7.2827+3.8104j]])
```

\texttt{scipy.special.kve}

\texttt{scipy.special.kve}(v, z) = <ufunc 'kve'>

Exponentially scaled modified Bessel function of the second kind.

Returns the exponentially scaled, modified Bessel function of the second kind (sometimes called the third kind) for real order \( v \) at complex \( z \):
\[ kve(v, z) = kv(v, z) * \exp(z) \]

**Parameters**

- \( v \) [array_like of float] Order of Bessel functions
- \( z \) [array_like of complex] Argument at which to evaluate the Bessel functions

**Returns**

- \( out \) [ndarray] The exponentially scaled modified Bessel function of the second kind.

**Notes**

**References**

[1], [2]

**scipy.special.iv**

\[
\text{scipy.special.iv}(v, z) = \text{ufunc 'iv'}
\]

Modified Bessel function of the first kind of real order.

**Parameters**

- \( v \) [array_like] Order. If \( z \) is of real type and negative, \( v \) must be integer valued.
- \( z \) [array_like of float or complex] Argument.

**Returns**

- \( out \) [ndarray] Values of the modified Bessel function.

**See also:**

**kve**

This function with leading exponential behavior stripped off.

**Notes**

For real \( z \) and \( v \in [-50, 50] \), the evaluation is carried out using Temme’s method [1]. For larger orders, uniform asymptotic expansions are applied.

For complex \( z \) and positive \( v \), the AMOS [2] \( zbesi \) routine is called. It uses a power series for small \( z \), the asymptotic expansion for large \( \abs{z} \), the Miller algorithm normalized by the Wronskian and a Neumann series for intermediate magnitudes, and the uniform asymptotic expansions for \( I_v(z) \) and \( J_v(z) \) for large orders. Backward recurrence is used to generate sequences or reduce orders when necessary.

The calculations above are done in the right half plane and continued into the left half plane by the formula,

\[
I_v(z \exp(\pm i\pi)) = \exp(\pm \pi v)I_v(z)
\]

(valid when the real part of \( z \) is positive). For negative \( v \), the formula

\[
I_{-v}(z) = I_v(z) + \frac{2}{\pi} \sin(\pi v)K_v(z)
\]

is used, where \( K_v(z) \) is the modified Bessel function of the second kind, evaluated using the AMOS routine \( zbesk \).
scipy.special.ive

scipy.special.ive(v, z) = <ufunc 'ive'>
Exponentially scaled modified Bessel function of the first kind

Defined as:

\[ \text{ive}(v, z) = \text{iv}(v, z) \times \exp(-|z|) \]

Parameters

- v : array_like of float
  Order.
- z : array_like of float or complex
  Argument.

Returns

- out : ndarray
  Values of the exponentially scaled modified Bessel function.

Notes

For positive \( v \), the AMOS [1] \texttt{zbesi} routine is called. It uses a power series for small \( z \), the asymptotic expansion for large \( |z| \), the Miller algorithm normalized by the Wronskian and a Neumann series for intermediate magnitudes, and the uniform asymptotic expansions for \( I_v(z) \) and \( J_v(z) \) for large orders. Backward recurrence is used to generate sequences or reduce orders when necessary.

The calculations above are done in the right half plane and continued into the left half plane by the formula,

\[ I_v(z \exp(\pm i\pi)) = \exp(\pm \pi v) I_v(z) \]

(valid when the real part of \( z \) is positive). For negative \( v \), the formula

\[ I_{-v}(z) = I_v(z) + \frac{2}{\pi} \sin(\pi v) K_v(z) \]

is used, where \( K_v(z) \) is the modified Bessel function of the second kind, evaluated using the AMOS routine \texttt{zbesk}.

References

[1]
**hankel1e**

this function with leading exponential behavior stripped off.

**Notes**

A wrapper for the AMOS [1] routine _zbesh_, which carries out the computation using the relation,

\[ H_v^{(1)}(z) = \frac{2}{\pi} \exp(-i\pi v/2)K_v(z \exp(-i\pi/2)) \]

where \( K_v \) is the modified Bessel function of the second kind. For negative orders, the relation

\[ H_{-v}^{(1)}(z) = H_v^{(1)}(z) \exp(i\pi v) \]

is used.

**References**

[1]
**scipy.special.hankel2**

```python
scipy.special.hankel2(v, z) = <ufunc 'hankel2'>
```

Hankel function of the second kind

**Parameters**

- `v` : [array_like] Order (float).
- `z` : [array_like] Argument (float or complex).

**Returns**

- `out` : [Values of the Hankel function of the second kind.]

See also:

- `hankel2e`

this function with leading exponential behavior stripped off.

**Notes**

A wrapper for the AMOS [1] routine zbesh, which carries out the computation using the relation,

\[
H^{(2)}_v(z) = -\frac{2}{\pi} \exp(i\pi v/2)K_v(z \exp(i\pi/2))
\]

where \(K_v\) is the modified Bessel function of the second kind. For negative orders, the relation

\[
H^{(2)}_{-v}(z) = H^{(2)}_v(z) \exp(-i\pi v)
\]

is used.

**References**

[1]

**scipy.special.hankel2e**

```python
scipy.special.hankel2e(v, z) = <ufunc 'hankel2e'>
```

Exponentially scaled Hankel function of the second kind

Defined as:

\[
hankel2e(v, z) = hankel2(v, z) \cdot \exp(1j \cdot z)
\]

**Parameters**

- `v` : [array_like] Order (float).
- `z` : [array_like] Argument (float or complex).

**Returns**

- `out` : [Values of the exponentially scaled Hankel function of the second kind.]
Notes

A wrapper for the AMOS [1] routine zbesh, which carries out the computation using the relation,

\[ H^{(2)}_v(z) = -\frac{2}{i\pi} \exp\left(\frac{i\pi v}{2}\right)K_v\left(z\exp\left(\frac{i\pi}{2}\right)\right) \]

where \( K_v \) is the modified Bessel function of the second kind. For negative orders, the relation

\[ H^{(2)}_{-v}(z) = H^{(2)}_v(z) \exp(-i\pi v) \]

is used.

The following is not an universal function:

### lmbda(v, x)
Jahnke-Emden Lambda function, Lambda(v(x)).

**scipy.special.lmbda**

This function is defined as [2],

\[ \Lambda_v(x) = \Gamma(v + 1) \frac{J_v(x)}{(x/2)^v}, \]

where \( \Gamma \) is the gamma function and \( J_v \) is the Bessel function of the first kind.

**Parameters**

- **v** [float] Order of the Lambda function
- **x** [float] Value at which to evaluate the function and derivatives

**Returns**

- **vl** [ndarray] Values of Lambda_vi(x), for vi=v-int(v), vi=1+v-int(v), ..., vi=v.
- **dl** [ndarray] Derivatives Lambda_vi'(x), for vi=v-int(v), vi=1+v-int(v), ..., vi=v.

**scipy.special.jnjnp_zeros**

`scipy.special.jnjnp_zeros(nt)`

Compute zeros of integer-order Bessel functions $J_n$ and $J_n'$. Results are arranged in order of the magnitudes of the zeros.

**Parameters**

- **nt** [int] Number (<=1200) of zeros to compute

**Returns**

- **zo[l-1]** [ndarray] Value of the lth zero of $J_n(x)$ and $J_n'(x)$. Of length `nt`.
- **n[l-1]** [ndarray] Order of the $J_n(x)$ or $J_n'(x)$ associated with lth zero. Of length `nt`.
- **m[l-1]** [ndarray] Serial number of the zeros of $J_n(x)$ or $J_n'(x)$ associated with lth zero. Of length `nt`.
- **t[l-1]** [ndarray] 0 if lth zero in zo is zero of $J_n(x)$, 1 if it is a zero of $J_n'(x)$. Of length `nt`.

**See also:**

- `jn_zeros`, `jnp_zeros`
  to get separated arrays of zeros.

**References**

[1]

**scipy.special.jnyn_zeros**

`scipy.special.jnyn_zeros(n, nt)`

Compute nt zeros of Bessel functions $J_n(x)$, $J_n'(x)$, $Y_n(x)$, and $Y_n'(x)$.

Returns 4 arrays of length `nt`, corresponding to the first `nt` zeros of $J_n(x)$, $J_n'(x)$, $Y_n(x)$, and $Y_n'(x)$, respectively.

**Parameters**

- **n** [int] Order of the Bessel functions
- **nt** [int] Number (<=1200) of zeros to compute

See `jn_zeros`, `jnp_zeros`, `yn_zeros`, `ynp_zeros` to get separate arrays.
References

[1]

**scipy.special.jn_zeros**

```python
scipy.special.jn_zeros(n, nt)
```

Compute zeros of integer-order Bessel function $J_n(x)$.

**Parameters**

- `n` ([int]) Order of Bessel function
- `nt` ([int]) Number of zeros to return

**References**

[1]

---

**scipy.special.jnp_zeros**

```python
scipy.special.jnp_zeros(n, nt)
```

Compute zeros of integer-order Bessel function derivative $J'_n(x)$.

**Parameters**

- `n` ([int]) Order of Bessel function
- `nt` ([int]) Number of zeros to return

**References**

[1]

---

**scipy.special.yn_zeros**

```python
scipy.special.yn_zeros(n, nt)
```

Compute zeros of integer-order Bessel function $Y_n(x)$.

**Parameters**

- `n` ([int]) Order of Bessel function
- `nt` ([int]) Number of zeros to return

**References**

[1]
scipy.special.ynp_zeros

scipy.special.ynp_zeros(n, nt)
Compute zeros of integer-order Bessel function derivative \( Y_n'(x) \).

Parameters
- n [int] Order of Bessel function
- nt [int] Number of zeros to return

References
[1]

scipy.special.y0_zeros

scipy.special.y0_zeros(nt, complex=False)
Compute nt zeros of Bessel function \( Y_0(z) \), and derivative at each zero.
The derivatives are given by \( Y_0'(z_0) = -Y_1(z_0) \) at each zero \( z_0 \).

Parameters
- nt [int] Number of zeros to return
- complex [bool, default False] Set to False to return only the real zeros; set to True to return only the
  complex zeros with negative real part and positive imaginary part. Note that the complex
  conjugates of the latter are also zeros of the function, but are not returned by this routine.

Returns
- z0n [ndarray] Location of nth zero of \( Y_0(z) \)
- y0pz0n [ndarray] Value of derivative \( Y_0'(z_0) \) for nth zero

References
[1]

scipy.special.y1_zeros

scipy.special.y1_zeros(nt, complex=False)
Compute nt zeros of Bessel function \( Y_1(z) \), and derivative at each zero.
The derivatives are given by \( Y_1'(z_1) = Y_0(z_1) \) at each zero \( z_1 \).

Parameters
- nt [int] Number of zeros to return
- complex [bool, default False] Set to False to return only the real zeros; set to True to return only the
  complex zeros with negative real part and positive imaginary part. Note that the complex
  conjugates of the latter are also zeros of the function, but are not returned by this routine.

Returns
- z1n [ndarray] Location of nth zero of \( Y_1(z) \)
- y1pz1n [ndarray] Value of derivative \( Y_1'(z_1) \) for nth zero
References

[1]

scipy.special.y1p_zeros

scipy.special.y1p_zeros(nt, complex=False)

Compute \( nt \) zeros of Bessel derivative \( Y_1'(z) \), and value at each zero.

The values are given by \( Y_1(z_1) \) at each \( z_1 \) where \( Y_1'(z_1) = 0 \).

Parameters

- \( nt \): [int] Number of zeros to return
- \( complex \): [bool, default False] Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

Returns

- \( z1pn \): [ndarray] Location of \( nt \)th zero of \( Y_1'(z) \)
- \( y1z1pn \): [ndarray] Value of derivative \( Y_1(z_1) \) for \( nt \)th zero

scipy.special.j0

scipy.special.j0(x) = <ufunc 'j0'>

Bessel function of the first kind of order 0.

Parameters

- \( x \): [array_like] Argument (float).
Returns

\[ J \] [ndarray] Value of the Bessel function of the first kind of order 0 at \( x \).

See also:

\[ jv \]
Bessel function of real order and complex argument.

\[ \text{spherical}_\text{jn} \]
spherical Bessel functions.

Notes

The domain is divided into the intervals \([0, 5]\) and \((5, \infty)\). In the first interval the following rational approximation is used:

\[
J_0(x) \approx (w - r_1^2)(w - r_2^2) \frac{P_3(w)}{Q_8(w)},
\]

where \( w = x^2 \) and \( r_1, r_2 \) are the zeros of \( J_0 \), and \( P_3 \) and \( Q_8 \) are polynomials of degrees 3 and 8, respectively.

In the second interval, the Hankel asymptotic expansion is employed with two rational functions of degree 6/6 and 7/7.

This function is a wrapper for the Cephes \([1]\) routine \( j0 \). It should not be confused with the spherical Bessel functions (see \( \text{spherical}_\text{jn} \)).

References

[1]

\[ \text{scipy.special.j1} \]

```
scipy.special.j1(x) = <ufunc 'j1'>
```

Bessel function of the first kind of order 1.

Parameters

\( x \) [array_like] Argument (float).

Returns

\[ J \] [ndarray] Value of the Bessel function of the first kind of order 1 at \( x \).

See also:

\[ jv \]
\[ \text{spherical}_\text{jn} \]

spherical Bessel functions.
Notes

The domain is divided into the intervals [0, 8] and (8, infinity). In the first interval a 24 term Chebyshev expansion is used. In the second, the asymptotic trigonometric representation is employed using two rational functions of degree 5/5.

This function is a wrapper for the Cephes [1] routine \texttt{j1}. It should not be confused with the spherical Bessel functions (see \texttt{spherical_jn}).

References

[1]

\texttt{scipy.special.y0}

\texttt{scipy.special.y0(x) = <ufunc 'y0'>}

Bessel function of the second kind of order 0.

Parameters

\texttt{x} [array_like] Argument (float).

Returns

\texttt{Y} [ndarray] Value of the Bessel function of the second kind of order 0 at \texttt{x}.

See also:

\texttt{j0}

\texttt{yv}

Notes

The domain is divided into the intervals [0, 5] and (5, infinity). In the first interval a rational approximation \( R(x) \) is employed to compute,

\[ Y_0(x) = R(x) + \frac{2\log(x)J_0(x)}{\pi}, \]

where \( J_0 \) is the Bessel function of the first kind of order 0.

In the second interval, the Hankel asymptotic expansion is employed with two rational functions of degree 6/6 and 7/7.

This function is a wrapper for the Cephes [1] routine \texttt{y0}.

References

[1]
scipy.special.y1

```
scipy.special.y1(x) = <ufunc 'y1'>
```

Bessel function of the second kind of order 1.

**Parameters**

- `x` : array_like
  Argument (float).

**Returns**

- `Y` : ndarray
  Value of the Bessel function of the second kind of order 1 at `x`.

**See also:**

j1, yn, yv

**Notes**

The domain is divided into the intervals [0, 8] and (8, infinity). In the first interval a 25 term Chebyshev expansion is used, and computing $J_1$ (the Bessel function of the first kind) is required. In the second, the asymptotic trigonometric representation is employed using two rational functions of degree 5/5.

This function is a wrapper for the Cephes [1] routine `y1`.

**References**

[1]

scipy.special.i0

```
scipy.special.i0(x) = <ufunc 'i0'>
```

Modified Bessel function of order 0.

Defined as,

$$I_0(x) = \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{(k!)^2} = J_0(ix),$$

where $J_0$ is the Bessel function of the first kind of order 0.

**Parameters**

- `x` : array_like
  Argument (float)

**Returns**

- `I` : ndarray
  Value of the modified Bessel function of order 0 at `x`.

**See also:**

iv, i0e
Notes

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine \texttt{i0}.

References

[1]

\texttt{scipy.special.i0e}

\texttt{scipy.special.i0e(x) = <ufunc 'i0e'>}

Exponentially scaled modified Bessel function of order 0.

Defined as:

\[ i0e(x) = \exp(-\text{abs}(x)) \times i0(x). \]

Parameters

- \(x\) [array_like] Argument (float)

Returns

- \(I\) [ndarray] Value of the exponentially scaled modified Bessel function of order 0 at \(x\).

See also:

- \texttt{iv}
- \texttt{i0}

Notes

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval. The polynomial expansions used are the same as those in \texttt{i0}, but they are not multiplied by the dominant exponential factor.

This function is a wrapper for the Cephes [1] routine \texttt{i0e}.

References

[1]

\texttt{scipy.special.i1}

\texttt{scipy.special.i1(x) = <ufunc 'i1'>}

Modified Bessel function of order 1.
Defined as,

\[ I_1(x) = \frac{1}{2} \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{k!(k+1)!} = -iJ_1(ix), \]

where \( J_1 \) is the Bessel function of the first kind of order 1.

**Parameters**

- **x** [array_like] Argument (float)

**Returns**

- **I** [ndarray] Value of the modified Bessel function of order 1 at \( x \).

**See also:**

- iv
- i1e

**Notes**

The range is partitioned into the two intervals \([0, 8] \) and \((8, \infty)\). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes routine \( i1e \).

**References**

[1]

`scipy.special.i1e`

`scipy.special.i1e(x) = <ufunc 'i1e'>`

Exponentially scaled modified Bessel function of order 1.

Defined as:

\[ i1e(x) = \exp(-\text{abs}(x)) \times i1(x) \]

**Parameters**

- **x** [array_like] Argument (float)

**Returns**

- **I** [ndarray] Value of the exponentially scaled modified Bessel function of order 1 at \( x \).

**See also:**

- iv
- i1
Notes

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval. The polynomial expansions used are the same as those in \( i1 \), but they are not multiplied by the dominant exponential factor.

This function is a wrapper for the Cephes [1] routine \( i1e \).

References

[1]

**scipy.special.k0**

```python
scipy.special.k0(x) = <ufunc 'k0'>
```

Modified Bessel function of the second kind of order 0, \( K_0 \).

This function is also sometimes referred to as the modified Bessel function of the third kind of order 0.

**Parameters**

- \( x \) [array_like] Argument (float).

**Returns**

- \( K \) [ndarray] Value of the modified Bessel function \( K_0 \) at \( x \).

See also:

- \( kv \)
- \( k0e \)

Notes

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine \( k0 \).

References

[1]

**scipy.special.k0e**

```python
scipy.special.k0e(x) = <ufunc 'k0e'>
```

Exponentially scaled modified Bessel function \( K \) of order 0

Defined as:

\[
\text{k0e}(x) = \exp(x) \times \text{k0}(x).
\]

**Parameters**
x [array_like] Argument (float)

Returns
K [ndarray] Value of the exponentially scaled modified Bessel function K of order 0 at x.

See also:
kv
k0

Notes
The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine k0e.

References
[1]

scipy.special.k1

scipy.special.k1(x) = <ufunc 'k1'>
Modified Bessel function of the second kind of order 1, \(K_1(x)\).

Parameters
x [array_like] Argument (float)

Returns
K [ndarray] Value of the modified Bessel function K of order 1 at x.

See also:
kv
k1e

Notes
The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine k1.

References
[1]
scipy.special.k1e

scipy.special.k1e(x) = <ufunc 'k1e'>
Exponentially scaled modified Bessel function K of order 1
Defined as:

\[ k1e(x) = \exp(x) \times k1(x) \]

**Parameters**

- x [array_like] Argument (float)

**Returns**

- K [ndarray] Value of the exponentially scaled modified Bessel function K of order 1 at x.

**See also:**

- kv
- k1

**Notes**

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine k1e.

scipy.special.itj0y0

scipy.special.itj0y0(x) = <ufunc 'itj0y0'>
Integrals of Bessel functions of order 0
Returns simple integrals from 0 to x of the zeroth order Bessel functions j0 and y0.

**Returns**

- ij0, iy0
SciPy Reference Guide, Release 1.3.2

**scipy.special.it2j0y0**

```
scipy.special.it2j0y0(x) = <ufunc 'it2j0y0'>
```

Integrals related to Bessel functions of order 0

Returns

- **ij0** integral((1-j0(t))/t, t=0..x)
- **iy0** integral(y0(t)/t, t=x..inf)

**scipy.special.iti0k0**

```
scipy.special.iti0k0(x) = <ufunc 'iti0k0'>
```

Integrals of modified Bessel functions of order 0

Returns simple integrals from 0 to x of the zeroth order modified Bessel functions \(i_0\) and \(k_0\).

Returns

- **ii0**
- **ik0**

**scipy.special.it2i0k0**

```
scipy.special.it2i0k0(x) = <ufunc 'it2i0k0'>
```

Integrals related to modified Bessel functions of order 0

Returns

- **ii0** integral((i0(t)-1)/t, t=0..x)
- **ik0** integral(k0(t)/t, t=x..inf)

**scipy.special.besselpoly**

```
scipy.special.besselpoly(a, lmb, nu) = <ufunc 'besselpoly'>
```

Weighted integral of a Bessel function.

\[
\int_0^1 x^\lambda J_\nu(2ax) \, dx
\]

where \(J_\nu\) is a Bessel function and \(\lambda = lmb, \nu = nu\).

**Derivatives of Bessel Functions**

- **jvp(v, z, [n])** Compute nth derivative of Bessel function \(J_v(z)\) with respect to \(z\).
- **yvp(v, z, [n])** Compute nth derivative of Bessel function \(Y_v(z)\) with respect to \(z\).
- **kvp(v, z, [n])** Compute nth derivative of real-order modified Bessel function \(K_v(z)\).
- **ivp(v, z, [n])** Compute nth derivative of modified Bessel function \(I_v(z)\) with respect to \(z\).
- **h1vp(v, z, [n])** Compute nth derivative of Hankel function \(H_1^v(z)\) with respect to \(z\).

Continued on next page
Computes the nth derivative of the Hankel function $H_2^\nu(z)$ with respect to $z$.

\[ \text{h2vp}(\nu, z[, n]) \]

**Parameters**
- $\nu$: [float] Order of Bessel function
- $z$: [complex] Argument at which to evaluate the derivative
- $n$: [int, default 1] Order of derivative

**Notes**

The derivative is computed using the relation DLMF 10.6.7 [2].

**References**

[1], [2]

---

**scipy.special.jvp**

Computes the nth derivative of the Bessel function $J_\nu(z)$ with respect to $z$.

\[ \text{scipy.special.jvp}(\nu, z[, n=1]) \]

**Parameters**
- $\nu$: [float] Order of Bessel function
- $z$: [complex] Argument at which to evaluate the derivative
- $n$: [int, default 1] Order of derivative

**Notes**

The derivative is computed using the relation DLMF 10.6.7 [2].

**References**

[1], [2]

**scipy.special.yvp**

Computes the nth derivative of the Bessel function $Y_\nu(z)$ with respect to $z$.

\[ \text{scipy.special.yvp}(\nu, z[, n=1]) \]

**Parameters**
- $\nu$: [float] Order of Bessel function
- $z$: [complex] Argument at which to evaluate the derivative
- $n$: [int, default 1] Order of derivative

**Notes**

The derivative is computed using the relation DLMF 10.6.7 [2].

**References**

[1], [2]

---

**scipy.special.kvp**

Computes the nth derivative of the real-order modified Bessel function $K_\nu(z)$.

\[ \text{scipy.special.kvp}(\nu, z[, n=1]) \]

$K_\nu(z)$ is the modified Bessel function of the second kind. Derivative is calculated with respect to $z$.

**Parameters**
- $\nu$: [array_like of float] Order of Bessel function
SciPy Reference Guide, Release 1.3.2

```
z    [array_like of complex] Argument at which to evaluate the derivative
n    [int] Order of derivative. Default is first derivative.

Returns

out   [ndarray] The results

Notes
The derivative is computed using the relation DLFM 10.29.5 [2].

References
[1], [2]

Examples
Calculate multiple values at order 5:

```python
>>> from scipy.special import kvp
>>> kvp(5, (1, 2, 3+5j))
array([-1.84903536e+03+0.j , -2.57735387e+01+0.j ,
       -3.06627741e-02+0.08750845j])
```

Calculate for a single value at multiple orders:

```python
>>> kvp((4, 4.5, 5), 1)
array([-184.0309, -568.9585, -1849.0354])
```

scipy.special.ivp

```python
scipy.special.ivp(v, z, n=1)
```
Compute nth derivative of modified Bessel function Iv(z) with respect to z.

Parameters

v    [array_like of float] Order of Bessel function
z    [array_like of complex] Argument at which to evaluate the derivative
n    [int, default 1] Order of derivative

Notes
The derivative is computed using the relation DLFM 10.29.5 [2].

scipy.special.spherical_jn

scipy.special.\texttt{spherical\_jn}(n, z, \texttt{derivative=False})

Spherical Bessel function of the first kind or its derivative.

Defined as \cite{1},
\[ j_n(z) = \sqrt{\frac{\pi}{2z}} J_{n+1/2}(z), \]

where \( J_n \) is the Bessel function of the first kind.

**Parameters**

- \( n \) [int, array_like] Order of the Bessel function (\( n \geq 0 \)).
- \( z \) [complex or float, array_like] Argument of the Bessel function.
- \( \text{derivative} \) [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

- \( jn \) [ndarray]

**Notes**

For real arguments greater than the order, the function is computed using the ascending recurrence \cite{2}. For small real or complex arguments, the definitional relation to the cylindrical Bessel function of the first kind is used.

The derivative is computed using the relations \cite{3},
\[ j_n'(z) = j_{n-1}(z) - \frac{n+1}{z} j_n(z), \]
\[ j_0'(z) = -j_1(z). \]

New in version 0.18.0.

**References**

\cite{1}, \cite{2}, \cite{3}

scipy.special.spherical_yn

scipy.special.\texttt{spherical\_yn}(n, z, \texttt{derivative=False})

Spherical Bessel function of the second kind or its derivative.

Defined as \cite{1},
\[ y_n(z) = \sqrt{\frac{\pi}{2z}} Y_{n+1/2}(z), \]

where \( Y_n \) is the Bessel function of the second kind.

**Parameters**

- \( n \) [int, array_like] Order of the Bessel function (\( n \geq 0 \)).
- \( z \) [complex or float, array_like] Argument of the Bessel function.
- \( \text{derivative} \) [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

- \( yn \) [ndarray]
Notes

For real arguments, the function is computed using the ascending recurrence [2]. For complex arguments, the definitional relation to the cylindrical Bessel function of the second kind is used.

The derivative is computed using the relations [3],

\[
y'_n = y_{n-1} - \frac{n + 1}{z} y_n,
\]

\[
y'_0 = -y_1
\]

New in version 0.18.0.

References

[1], [2], [3]

**scipy.special.spherical_in**

*scipy.special.spherical_in(n, z, derivative=False)*

Modified spherical Bessel function of the first kind or its derivative.

Defined as [1],

\[
i_n(z) = \sqrt{\frac{\pi}{2z}} I_{n+1/2}(z),
\]

where \(I_n\) is the modified Bessel function of the first kind.

**Parameters**

- **n** [int, array_like] Order of the Bessel function (n >= 0).
- **z** [complex or float, array_like] Argument of the Bessel function.
- **derivative** [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

- **in** [ndarray]

**Notes**

The function is computed using its definitional relation to the modified cylindrical Bessel function of the first kind.

The derivative is computed using the relations [2],

\[
i'_n = i_{n-1} - \frac{n + 1}{z} i_n.
\]

\[
i'_1 = i_0
\]

New in version 0.18.0.

**References**

[1], [2]
scipy.special.spherical_kn

**scipy.special.spherical_kn** *(n, z, derivative=False)*

Modified spherical Bessel function of the second kind or its derivative.

Defined as [1],

\[ k_n(z) = \sqrt{\frac{\pi}{2z}} K_{n+1/2}(z), \]

where \( K_n \) is the modified Bessel function of the second kind.

**Parameters**

- **n** [int, array_like] Order of the Bessel function (\( n \geq 0 \)).
- **z** [complex or float, array_like] Argument of the Bessel function.
- **derivative** [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

- **kn** [ndarray]

**Notes**

The function is computed using its definitional relation to the modified cylindrical Bessel function of the second kind.

The derivative is computed using the relations [2],

\[ k'_n = -k_{n-1} - \frac{n+1}{z} k_n. \]

\[ k'_0 = -k_1 \]

New in version 0.18.0.

</tr>
</tbody>
</table>

**scipy.special.riccati_jn**

**scipy.special.riccati_jn** *(n, x)*

Compute Ricatti-Bessel function of the first kind and its derivative.

The Ricatti-Bessel function of the first kind is defined as \( x j_n(x) \), where \( j_n \) is the spherical Bessel function of the first kind of order \( n \).
This function computes the value and first derivative of the Ricatti-Bessel function for all orders up to and including $n$.

**Parameters**

- $n$  
  [int] Maximum order of function to compute
- $x$  
  [float] Argument at which to evaluate

**Returns**

- $jn$  
  [ndarray] Value of $j_0(x), ..., j_n(x)$
- $jnp$  
  [ndarray] First derivative $j_0'(x), ..., j_n'(x)$

**Notes**

The computation is carried out via backward recurrence, using the relation DLMF 10.51.1 [2].

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

**References**

</tbody>
</table>

scipy.special.struve

scipy.special.struve(v, x) = <ufunc 'struve'>

Struve function.

Return the value of the Struve function of order \( v \) at \( x \). The Struve function is defined as,

\[
H_v(x) = \left( \frac{z}{2} \right)^v \sum_{n=0}^{\infty} \frac{(-1)^n (z/2)^{2n}}{\Gamma(n + \frac{3}{2}) \Gamma(n + v + \frac{3}{2})},
\]

where \( \Gamma \) is the gamma function.

Parameters

- \( v \) : [array_like] Order of the Struve function (float).
- \( x \) : [array_like] Argument of the Struve function (float; must be positive unless \( v \) is an integer).

Returns

- \( H \) : [ndarray] Value of the Struve function of order \( v \) at \( x \).

See also:

modstruve

Notes

Three methods discussed in [1] are used to evaluate the Struve function:

- power series
- expansion in Bessel functions (if \( |z| < |v| + 20 \))
- asymptotic large-z expansion (if \( z \geq 0.7v + 12 \))

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.

References

[1]

scipy.special.modstruve

scipy.special.modstruve(v, x) = <ufunc 'modstruve'>

Modified Struve function.

Return the value of the modified Struve function of order \( v \) at \( x \). The modified Struve function is defined as,

\[
L_v(x) = -i \exp(-\pi v/2) H_v(x),
\]
where $H_v$ is the Struve function.

**Parameters**

- $v$ [array_like] Order of the modified Struve function (float).
- $x$ [array_like] Argument of the Struve function (float; must be positive unless $v$ is an integer).

**Returns**

- $L$ [ndarray] Value of the modified Struve function of order $v$ at $x$.

**See also:**

`struve`

**Notes**

Three methods discussed in [1] are used to evaluate the function:

- power series
- expansion in Bessel functions (if $|z| < |v| + 20$)
- asymptotic large-$z$ expansion (if $z \geq 0.7v + 12$

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.

`scipy.special.itstruve0`

`scipy.special.itstruve0(x) = <ufunc 'itstruve0'>`

Integral of the Struve function of order 0.

\[
I = \int_0^x H_0(t) \, dt
\]

**Parameters**

- $x$ [array_like] Upper limit of integration (float).

**Returns**

- $I$ [ndarray] The integral of $H_0$ from 0 to $x$.

**See also:**

`struve`

**Notes**

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

**References**

[1]
**scipy.special.it2struve0**

\[ \text{scipy.special.it2struve0}(x) = \texttt{ufunc 'it2struve0'} \]

Integral related to the Struve function of order 0.

Returns the integral,

\[ \int_x^\infty \frac{H_0(t)}{t} \, dt \]

where \( H_0 \) is the Struve function of order 0.

**Parameters**

- \( x \) [array_like] Lower limit of integration.

**Returns**

- \( I \) [ndarray] The value of the integral.

**See also:**

- `struve`

**Notes**

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

**References**

scipy.special.bdtr

scipy.special.bdtr(k, n, p) = <ufunc 'bdtr'>

Binomial distribution cumulative distribution function.

Sum of the terms 0 through \( k \) of the Binomial probability density.

\[
bdtr(k, n, p) = \sum_{j=0}^{k} \binom{n}{j} p^j (1 - p)^{n-j}
\]

Parameters

- **k** [array_like] Number of successes (int).
- **n** [array_like] Number of events (int).
- **p** [array_like] Probability of success in a single event (float).

Returns

- **y** [ndarray] Probability of \( k \) or fewer successes in \( n \) independent events with success probabilities of \( p \).
Notes

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

\[ \text{bdtr}(k, n, p) = I_{1-p}(n - k, k + 1). \]

Wrapper for the Cephes [1] routine \texttt{bdtr}.

References

[1]

\texttt{scipy.special.bdtrc}

\texttt{scipy.special.bdtrc}(k, n, p) = <ufunc ‘bdtrc’>

Binomial distribution survival function.

Sum of the terms \( k + 1 \) through \( n \) of the binomial probability density,

\[ \text{bdtrc}(k, n, p) = \sum_{j=k+1}^{n} \binom{n}{j} p^j (1 - p)^{n-j} \]

Parameters

- \( k \) [array_like] Number of successes (int).
- \( n \) [array_like] Number of events (int)
- \( p \) [array_like] Probability of success in a single event.

Returns

- \( y \) [ndarray] Probability of \( k + 1 \) or more successes in \( n \) independent events with success probabilities of \( p \).

See also:

\texttt{bdtr}

\texttt{betainc}

Notes

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

\[ \text{bdtrc}(k, n, p) = I_p(k + 1, n - k). \]

Wrapper for the Cephes [1] routine \texttt{bdtrc}.

References

[1]
scipy.special.bdtri

\[
s\text{scipy.special.bdtri}(k, n, y) = \text{<ufunc 'bdtri'>}
\]

Inverse function to \text{bdtr} with respect to \(p\).

Finds the event probability \(p\) such that the sum of the terms 0 through \(k\) of the binomial probability density is equal to the given cumulative probability \(y\).

**Parameters**

- **k** [array_like] Number of successes (float).
- **n** [array_like] Number of events (float)
- **y** [array_like] Cumulative probability (probability of \(k\) or fewer successes in \(n\) events).

**Returns**

- **p** [ndarray] The event probability such that \(\text{bdtr}(k, n, p) = y\).

See also:

- \text{bdtr}
- \text{betaincinv}

**Notes**

The computation is carried out using the inverse beta integral function and the relation:

\[
1 - p = \text{betaincinv}(n - k, k + 1, y).
\]

Wrapper for the Cephes [1] routine \text{bdtri}.

**References**

[1]

scipy.special.bdtrik

\[
s\text{scipy.special.bdtrik}(y, n, p) = \text{<ufunc 'bdtrik'>}
\]

Inverse function to \text{bdtr} with respect to \(k\).

Finds the number of successes \(k\) such that the sum of the terms 0 through \(k\) of the Binomial probability density for \(n\) events with probability \(p\) is equal to the given cumulative probability \(y\).

**Parameters**

- **y** [array_like] Cumulative probability (probability of \(k\) or fewer successes in \(n\) events).
- **n** [array_like] Number of events (float).
- **p** [array_like] Success probability (float).

**Returns**

- **k** [ndarray] The number of successes \(k\) such that \(\text{bdtr}(k, n, p) = y\).

See also:

- \text{bdtr}
Notes

Formula 26.5.24 of [1] is used to reduce the binomial distribution to the cumulative incomplete beta distribution. Computation of \( k \) involves a search for a value that produces the desired value of \( y \). The search relies on the monotonicity of \( y \) with \( k \).

References

[1], [2]

\texttt{scipy.special.bdtrin}

\texttt{scipy.special.bdtrin}(k, y, p) = \texttt{ufunc 'bdtrin'>}

Inverse function to \textit{bdtr} with respect to \( n \).

Finds the number of events \( n \) such that the sum of the terms 0 through \( k \) of the Binomial probability density for events with probability \( p \) is equal to the given cumulative probability \( y \).

Parameters

- \texttt{k} [array_like] Number of successes (float).
- \texttt{y} [array_like] Cumulative probability (probability of \( k \) or fewer successes in \( n \) events).
- \texttt{p} [array_like] Success probability (float).

Returns

- \texttt{n} [ndarray] The number of events \( n \) such that \( \text{bdtr}(k, n, p) = y \).

See also:

\textit{bdtr}

Notes

Formula 26.5.24 of [1] is used to reduce the binomial distribution to the cumulative incomplete beta distribution. Computation of \( n \) involves a search for a value that produces the desired value of \( y \). The search relies on the monotonicity of \( y \) with \( n \).

References

[1], [2]

\texttt{scipy.special.btdtr}

\texttt{scipy.special.btdtr}(a, b, x) = \texttt{ufunc 'btdtr'>}

Cumulative distribution function of the beta distribution.

Returns the integral from zero to \( x \) of the beta probability density function,

\[
I = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1}(1-t)^{b-1} \, dt
\]

where \( \Gamma \) is the gamma function.
Parameters

\(a\) [array_like] Shape parameter \((a > 0)\).
\(b\) [array_like] Shape parameter \((b > 0)\).
\(x\) [array_like] Upper limit of integration, in \([0, 1]\).

Returns

\(I\) [ndarray] Cumulative distribution function of the beta distribution with parameters \(a\) and \(b\) at \(x\).

See also:

betainc

Notes

This function is identical to the incomplete beta integral function \texttt{betainc}.
Wrapper for the Cephes \cite{cephes} routine \texttt{btdtr}.

References

\cite{cephes}

\texttt{scipy.special.btdtri}

\texttt{scipy.special.btdtri\((a, b, p) = <ufunc \ 'btdtri'>\)}

The \(p\)-th quantile of the beta distribution.

This function is the inverse of the beta cumulative distribution function, \texttt{btdtr}, returning the value of \(x\) for which \texttt{btdtr\((a, b, x) = p\)}.

\[ p = \int_{0}^{x} \frac{\Gamma(a + b)}{\Gamma(a)\Gamma(b)} t^{a-1}(1 - t)^{b-1} dt \]

Parameters

\(a\) [array_like] Shape parameter \((a > 0)\).
\(b\) [array_like] Shape parameter \((b > 0)\).
\(p\) [array_like] Cumulative probability, in \([0, 1]\).

Returns

\(x\) [ndarray] The quantile corresponding to \(p\).

See also:

betaincinv

btdtr

Notes

The value of \(x\) is found by interval halving or Newton iterations.
Wrapper for the Cephes \cite{cephes} routine \texttt{incbi}, which solves the equivalent problem of finding the inverse of the incomplete beta integral.
References

[1]

scipy.special.btdtria

scipy.special.btdtria(p, b, x) = <ufunc 'btdtria'>
Inverse of btdtr with respect to a.

This is the inverse of the beta cumulative distribution function, btdtr, considered as a function of a, returning the value of a for which btdtr(a, b, x) = p, or

\[ p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1 - t)^{b-1} dt \]

Parameters

- p [array_like] Cumulative probability, in [0, 1].
- b [array_like] Shape parameter (b > 0).
- x [array_like] The quantile, in [0, 1].

Returns

- a [ndarray] The value of the shape parameter a such that btdtr(a, b, x) = p.

See also:

btdtr
Cumulative distribution function of the beta distribution.

btdtri
Inverse with respect to x.

btdtrib
Inverse with respect to b.

Notes

The cumulative distribution function p is computed using a routine by DiDinato and Morris [2]. Computation of a involves a search for a value that produces the desired value of p. The search relies on the monotonicity of p with a.

References

[1], [2]

scipy.special.btdtrib

scipy.special.btdtrib(a, p, x) = <ufunc 'btdtrib'>
Inverse of btdtr with respect to b.

This is the inverse of the beta cumulative distribution function, btdtr, considered as a function of b, returning the value of b for which btdtr(a, b, x) = p, or

\[ p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1 - t)^{b-1} dt \]
Parameters

- **a** [array_like] Shape parameter ($a > 0$).
- **p** [array_like] Cumulative probability, in [0, 1].
- **x** [array_like] The quantile, in [0, 1].

Returns

- **b** [ndarray] The value of the shape parameter $b$ such that $btdtr(a, b, x) = p$.

See also:

- **btdtr**
  Cumulative distribution function of the beta distribution.
- **btdtri**
  Inverse with respect to $x$.
- **btdtria**
  Inverse with respect to $a$.

Notes

The cumulative distribution function $p$ is computed using a routine by DiDinato and Morris [2]. Computation of $b$ involves a search for a value that produces the desired value of $p$. The search relies on the monotonicity of $p$ with $b$.

References

[1], [2]

**scipy.special.fdtr**

scipy.special.fdtr(dfn, dfd, x) = <ufunc 'fdtr'>

F cumulative distribution function.

Returns the value of the cumulative distribution function of the F-distribution, also known as Snedecor’s F-distribution or the Fisher-Snedecor distribution.

The F-distribution with parameters $d_n$ and $d_d$ is the distribution of the random variable,

$$ X = \frac{U_n/d_n}{U_d/d_d}, $$

where $U_n$ and $U_d$ are random variables distributed $\chi^2$, with $d_n$ and $d_d$ degrees of freedom, respectively.

Parameters

- **dfn** [array_like] First parameter (positive float).
- **dfd** [array_like] Second parameter (positive float).
- **x** [array_like] Argument (nonnegative float).

Returns

- **y** [ndarray] The CDF of the F-distribution with parameters $dfn$ and $dfd$ at $x$. 
Notes

The regularized incomplete beta function is used, according to the formula,

\[ F(d_n, d_d; x) = I_{x d_n/(d_d + x d_n)}(d_n/2, d_d/2). \]

References

[1]

scipy.special.fdtrc

scipy.special.fdtrc(dfn, dfd, x) = <ufunc 'fdtrc'>

F survival function.

Returns the complemented F-distribution function (the integral of the density from \(x\) to infinity).

Parameters

- \(dfn\) [array_like] First parameter (positive float).
- \(dfd\) [array_like] Second parameter (positive float).
- \(x\) [array_like] Argument (nonnegative float).

Returns

- \(y\) [ndarray] The complemented F-distribution function with parameters \(dfn\) and \(dfd\) at \(x\).

See also:

`fdtr`

Notes

The regularized incomplete beta function is used, according to the formula,

\[ F(d_n, d_d; x) = I_{d_d/(d_d + x d_n)}(d_d/2, d_n/2). \]

References

[1]

scipy.special.fdtri

scipy.special.fdtri(dfn, dfd, p) = <ufunc 'fdtri'>

The \(p\)-th quantile of the F-distribution.

This function is the inverse of the F-distribution CDF, `fdtr`, returning the \(x\) such that \(fdtr(df, df, x) = p\).

Parameters

- \(dfn\) [array_like] First parameter (positive float).
- \(dfd\) [array_like] Second parameter (positive float).
- \(p\) [array_like] Cumulative probability, in \([0, 1]\).
Returns

x  [ndarray] The quantile corresponding to p.

Notes

The computation is carried out using the relation to the inverse regularized beta function, $I^{-1}_{x}(a, b)$. Let $z = I^{-1}_{p}(d_d/2, d_n/2)$. Then,

$$x = \frac{d_d(1 - z)}{d_n z}.$$

If $p$ is such that $x < 0.5$, the following relation is used instead for improved stability: let $z' = I^{-1}_{1-p}(d_n/2, d_d/2)$. Then,

$$x = \frac{d_d z'}{d_n (1 - z')}.$$

References

[1]

`scipy.special.fdtridfd`

`scipy.special.fdtridfd(dfn, p, x) = <ufunc 'fdtridfd'>`

Inverse to `fdtr` vs dfd

Finds the F density argument dfd such that `fdtr(dfn, dfd, x) == p`.

`scipy.special.gdtr`

`scipy.special.gdtr(a, b, x) = <ufunc 'gdtr'>`

Gamma distribution cumulative distribution function.

Returns the integral from zero to $x$ of the gamma probability density function,

$$F = \int_{0}^{x} \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at} dt,$$

where $\Gamma$ is the gamma function.

Parameters

a  [array_like] The rate parameter of the gamma distribution, sometimes denoted $\beta$ (float). It is also the reciprocal of the scale parameter $\theta$.

b  [array_like] The shape parameter of the gamma distribution, sometimes denoted $\alpha$ (float).

x  [array_like] The quantile (upper limit of integration; float).

Returns

F  [ndarray] The CDF of the gamma distribution with parameters $a$ and $b$ evaluated at $x$.

See also:

`gdtrc`

$1 - \text{CDF of the gamma distribution}$.
Notes

The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function).

References

[1]

scipy.special.gdtrc

scipy.special.gdtrc(a, b, x) = <ufunc 'gdtrc'>
Gamma distribution survival function.

Integral from x to infinity of the gamma probability density function,
\[ F = \int_x^\infty \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at} dt, \]
where \( \Gamma \) is the gamma function.

Parameters

a   [array_like] The rate parameter of the gamma distribution, sometimes denoted \( \beta \) (float). It is also the reciprocal of the scale parameter \( \theta \).
b   [array_like] The shape parameter of the gamma distribution, sometimes denoted \( \alpha \) (float).
x   [array_like] The quantile (lower limit of integration; float).

Returns

F   [ndarray] The survival function of the gamma distribution with parameters \( a \) and \( b \) evaluated at \( x \).

See also:

gdtr, gdtrix

Notes

The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function).

References

[1]

scipy.special.gdtria

scipy.special.gdtria(p, b, x, out=None) = <ufunc 'gdtria'>
Inverse of \( gdtr \) vs \( a \).

Returns the inverse with respect to the parameter \( a \) of \( p = gdtr(a, b, x) \), the cumulative distribution function of the gamma distribution.

Parameters

p   [array_like] Probability values.
SciPy Reference Guide, Release 1.3.2

b [array_like] $b$ parameter values of $gdtr(a, b, x)$. $b$ is the “shape” parameter of the gamma distribution.

x [array_like] Nonnegative real values, from the domain of the gamma distribution.

out [ndarray, optional] If a fourth argument is given, it must be a numpy.ndarray whose size matches the broadcast result of $a$, $b$ and $x$. out is then the array returned by the function.

Returns

a [ndarray] Values of the $a$ parameter such that $p = gdtr(a, b, x)$. $1/a$ is the “scale” parameter of the gamma distribution.

See also:

gdtr  
CDF of the gamma distribution.

gdtrib  
Inverse with respect to $b$ of $gdtr(a, b, x)$.

gdtrix  
Inverse with respect to $x$ of $gdtr(a, b, x)$.

Notes

The cumulative distribution function $p$ is computed using a routine by DiDinato and Morris [2]. Computation of $a$ involves a search for a value that produces the desired value of $p$. The search relies on the monotonicity of $p$ with $a$.

References

[1], [2]

Examples

First evaluate $gdtr$.

```python
>>> from scipy.special import gdtr, gdtria
>>> p = gdtr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```python
>>> gdtria(p, 3.4, 5.6)
1.2
```
scipy.special.gdtrib

scipy.special.gdtrib(a, p, x, out=None) = <ufunc 'gdtrib'>

Inverse of gdtr vs b.

Returns the inverse with respect to the parameter b of \( p = gdtr(a, b, x) \), the cumulative distribution function of the gamma distribution.

**Parameters**

- **a** [array_like] a parameter values of \( gdtr(a, b, x) \). \( 1/a \) is the “scale” parameter of the gamma distribution.
- **p** [array_like] Probability values.
- **x** [array_like] Nonnegative real values, from the domain of the gamma distribution.
- **out** [ndarray, optional] If a fourth argument is given, it must be a numpy.ndarray whose size matches the broadcast result of \( a, b \) and \( x \). out is then the array returned by the function.

**Returns**

- **b** [ndarray] Values of the b parameter such that \( p = gdtr(a, b, x) \). b is the “shape” parameter of the gamma distribution.

**See also:**

gdtr

CDF of the gamma distribution.

gdtria

Inverse with respect to a of \( gdtr(a, b, x) \).

gdtrix

Inverse with respect to x of \( gdtr(a, b, x) \).

**Notes**

The cumulative distribution function \( p \) is computed using a routine by DiDinato and Morris [2]. Computation of \( b \) involves a search for a value that produces the desired value of \( p \). The search relies on the monotonicity of \( p \) with \( b \).

**References**

[1], [2]

**Examples**

First evaluate \( gdtr \).

```python
>>> from scipy.special import gdtr, gdtrib
>>> p = gdtr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.
>>> gdtrib(1.2, p, 5.6)
3.3999999999723882

scipy.special.gdtrib

`scipy.special.gdtrib(a, b, p, out=None) = <ufunc 'gdtrib'>`

Inverse of `gdtr` vs x.

Returns the inverse with respect to the parameter x of \( p = gdtr(a, b, x) \), the cumulative distribution function of the gamma distribution. This is also known as the p’th quantile of the distribution.

**Parameters**

- `a`  
  [array_like] `a` parameter values of `gdtr(a, b, x)`. \(1/a\) is the “scale” parameter of the gamma distribution.

- `b`  
  [array_like] `b` parameter values of `gdtr(a, b, x)`. \(b\) is the “shape” parameter of the gamma distribution.

- `p`  
  [array_like] Probability values.

- `out`  
  [ndarray, optional] If a fourth argument is given, it must be a numpy.ndarray whose size matches the broadcast result of `a`, `b` and `x`. `out` is then the array returned by the function.

**Returns**

- `x`  
  [ndarray] Values of the `x` parameter such that \( p = gdtr(a, b, x) \).

**See also:**

- `gdtr`  
  CDF of the gamma distribution.

- `gdtrib`  
  Inverse with respect to `a` of `gdtr(a, b, x)`.

- `gdtria`  
  Inverse with respect to `b` of `gdtr(a, b, x)`.

**Notes**

The cumulative distribution function \( p \) is computed using a routine by DiDinato and Morris [2]. Computation of \( x \) involves a search for a value that produces the desired value of \( p \). The search relies on the monotonicity of \( p \) with \( x \).

**References**

[1],[2]

**Examples**

First evaluate `gdtr`. 
```python
>>> from scipy.special import gdtr, gdtrix
>>> p = gdtr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
>>> gdtrix(1.2, 3.4, p)
5.5999999999999996
```

**scipy.special.nbdtr**

```python
scipy.special.nbdtr(k, n, p) = <ufunc 'nbdtr'>
```

Negative binomial cumulative distribution function.

Returns the sum of the terms 0 through k of the negative binomial distribution probability mass function,

\[ F = \sum_{j=0}^{k} \binom{n+j-1}{j} p^n (1-p)^j. \]

In a sequence of Bernoulli trials with individual success probabilities \( p \), this is the probability that \( k \) or fewer failures precede the \( n \)th success.

**Parameters**

- \( k \) [array_like] The maximum number of allowed failures (nonnegative int).
- \( n \) [array_like] The target number of successes (positive int).
- \( p \) [array_like] Probability of success in a single event (float).

**Returns**

- \( F \) [ndarray] The probability of \( k \) or fewer failures before \( n \) successes in a sequence of events with individual success probability \( p \).

**See also:**

- `nbdtrc`

**Notes**

If floating point values are passed for \( k \) or \( n \), they will be truncated to integers.

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

\[ \text{nbdtr}(k, n, p) = I_p(n, k + 1). \]

**References**

[1]
scipy.special.nbdtrc

scipy.special.nbdtrc(k, n, p) = <ufunc 'nbdtrc'>
Negative binomial survival function.
Returns the sum of the terms k + 1 to infinity of the negative binomial distribution probability mass function,

\[ F = \sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j. \]

In a sequence of Bernoulli trials with individual success probabilities p, this is the probability that more than k failures precede the nth success.

Parameters

- k : array_like The maximum number of allowed failures (nonnegative int).
- n : array_like The target number of successes (positive int).
- p : array_like Probability of success in a single event (float).

Returns

- F : ndarray The probability of k + 1 or more failures before n successes in a sequence of events with individual success probability p.

Notes

If floating point values are passed for k or n, they will be truncated to integers.
The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

\[ \text{nbdtrc}(k, n, p) = I_{1-p}(k+1, n). \]

References

[1]

scipy.special.nbdtri

scipy.special.nbdtri(k, n, y) = <ufunc 'nbdtri'>
Inverse of nbdtr vs p.
Returns the inverse with respect to the parameter p of y = nbdtr(k, n, p), the negative binomial cumulative distribution function.

Parameters

- k : array_like The maximum number of allowed failures (nonnegative int).
- n : array_like The target number of successes (positive int).
- y : array_like The probability of k or fewer failures before n successes (float).

Returns

- p : ndarray Probability of success in a single event (float) such that nbdtr(k, n, p) = y.

See also:
nbdtr

Cumulative distribution function of the negative binomial.

nbdtrik

Inverse with respect to k of nbdtr(k, n, p).

nbdtrin

Inverse with respect to n of nbdtr(k, n, p).

Notes

References

[1]

scipy.special.nbdtrik

scipy.special.nbdtrik(y, n, p) = <ufunc 'nbdtrik'>

Inverse of nbdtr vs k.

Returns the inverse with respect to the parameter k of y = nbdtr(k, n, p), the negative binomial cumulative distribution function.

Parameters

y [array_like] The probability of k or fewer failures before n successes (float).

n [array_like] The target number of successes (positive int).

p [array_like] Probability of success in a single event (float).

Returns

k [ndarray] The maximum number of allowed failures such that nbdtr(k, n, p) = y.

See also:

nbdtr

Cumulative distribution function of the negative binomial.

nbdtri

Inverse with respect to p of nbdtr(k, n, p).

nbdtrin

Inverse with respect to n of nbdtr(k, n, p).

Notes

Formula 26.5.26 of [2],

\[ \sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j = I_{1-p}(k+1, n), \]
is used to reduce calculation of the cumulative distribution function to that of a regularized incomplete beta $I$.

Computation of $k$ involves a search for a value that produces the desired value of $y$. The search relies on the monotonicity of $y$ with $k$.

References
[1], [2]

**scipy.special.nbdtrin**

```python
c scipy.special.nbdtrin(k, y, p) = <ufunc 'nbdtrin'>
```

Inverse of $nbdtr$ vs $n$.

Returns the inverse with respect to the parameter $n$ of $y = nbdtr(k, n, p)$, the negative binomial cumulative distribution function.

**Parameters**
- `k` [array_like] The maximum number of allowed failures (nonnegative int).
- `y` [array_like] The probability of $k$ or fewer failures before $n$ successes (float).

**Returns**
- `n` [ndarray] The number of successes $n$ such that $nbdtr(k, n, p) = y$.

See also:
- `nbdtr` Cumulative distribution function of the negative binomial.
- `nbdtri` Inverse with respect to $p$ of $nbdtr(k, n, p)$.
- `nbdtrik` Inverse with respect to $k$ of $nbdtr(k, n, p)$.

Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfnbn*.

Formula 26.5.26 of [2],

$$\sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j = I_{1-p}(k+1, n),$$

is used to reduce calculation of the cumulative distribution function to that of a regularized incomplete beta $I$.

Computation of $n$ involves a search for a value that produces the desired value of $y$. The search relies on the monotonicity of $y$ with $n$.

References
[1], [2]
**scipy.special.ncfdtr**

**scipy.special.ncfdtr**(dfn, dfd, nc, f) = <ufunc 'ncfdtr'>

Cumulative distribution function of the non-central F distribution.

The non-central F describes the distribution of,

\[ Z = \frac{X}{Y/d_d}, \]

where \( X \) and \( Y \) are independently distributed, with \( X \) distributed non-central \( \chi^2 \) with noncentrality parameter \( nc \) and \( d_n \) degrees of freedom, and \( Y \) distributed \( \chi^2 \) with \( d_d \) degrees of freedom.

**Parameters**

- **dfn** [array_like]: Degrees of freedom of the numerator sum of squares. Range (0, inf).
- **dfd** [array_like]: Degrees of freedom of the denominator sum of squares. Range (0, inf).
- **nc** [array_like]: Noncentrality parameter. Should be in range (0, 1e4).
- **f** [array_like]: Quantiles, i.e. the upper limit of integration.

**Returns**

- **cdf** [float or ndarray]: The calculated CDF. If all inputs are scalar, the return will be a float. Otherwise it will be an array.

**See also:**

- **ncfdtri**: Quantile function; inverse of \( \text{ncfdtr} \) with respect to \( f \).
- **ncfdtridfd**: Inverse of \( \text{ncfdtr} \) with respect to \( dfd \).
- **ncfdtridfn**: Inverse of \( \text{ncfdtr} \) with respect to \( dfn \).
- **ncfdtrinc**: Inverse of \( \text{ncfdtr} \) with respect to \( nc \).

**Notes**

The cumulative distribution function is computed using Formula 26.6.20 of [2]:

\[ F(d_n, d_d, n_c, f) = \sum_{j=0}^{\infty} e^{-n_c/2}(n_c/2)^j I_j\left(\frac{d_n^2}{d_d + d_d^2}\right), \]

where \( I \) is the regularized incomplete beta function, and \( x = fd_n/(fd_n + d_d) \).

The computation time required for this routine is proportional to the noncentrality parameter \( nc \). Very large values of this parameter can consume immense computer resources. This is why the search range is bounded by 10,000.

**References**

[1], [2]
Examples

```python
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt

Plot the CDF of the non-central F distribution, for $nc=0$. Compare with the F-distribution from scipy.stats:

```python
>>> x = np.linspace(-1, 8, num=500)
>>> dfn = 3
>>> dfd = 2
>>> ncf_stats = stats.f.cdf(x, dfn, dfd)
>>> ncf_special = special.ncfdtr(dfn, dfd, 0, x)
```  
```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, ncf_stats, 'b-', lw=3)
>>> ax.plot(x, ncf_special, 'r-')
>>> plt.show()
```

`scipy.special.ncfdtridfd`

`scipy.special.ncfdtridfd(dfn, p, nc, f) = <ufunc 'ncfdtridfd'>`

Calculate degrees of freedom (denominator) for the noncentral F-distribution.

This is the inverse with respect to $dfd$ of `ncfdr`. See `ncfdtr` for more details.

**Parameters**

- `dfn` [array_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).
- `p` [array_like] Value of the cumulative distribution function. Must be in the range [0, 1].
- `nc` [array_like] Noncentrality parameter. Should be in range (0, 1e4).
- `f` [array_like] Quantiles, i.e. the upper limit of integration.

**Returns**

- `dfd` [float] Degrees of freedom of the denominator sum of squares.
See also:

ncfdtr

CDF of the non-central F distribution.

ncfdtri

Quantile function; inverse of ncfdtr with respect to \( f \).

ncfdtridfn

Inverse of ncfdtr with respect to dfn.

ncfdtrinc

Inverse of ncfdtr with respect to nc.

Notes

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom. There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an arbitrary one of the two values.

Examples

```python
>>> from scipy.special import ncfdtr, ncfdtridfd

Compute the CDF for several values of \( dfd \):

```python
>>> dfd = [1, 2, 3]
>>> p = ncfdtr(2, dfd, 0.25, 15)
>>> p
array([ 0.8097138 , 0.93020416, 0.96787852])
```

Compute the inverse. We recover the values of \( dfd \), as expected:

```python
>>> ncfdtridfd(2, p, 0.25, 15)
array([ 1., 2., 3.])
```

scipy.special.ncfdtridfn

scipy.special.ncfdtridfn \( (p, dfd, nc, f) \) = <ufunc 'ncfdtridfn'>

Calculate degrees of freedom (numerator) for the noncentral F-distribution.

This is the inverse with respect to \( dfn \) of ncfdtr. See ncfdtr for more details.

Parameters

- \( p \)  
  array_like  
  Value of the cumulative distribution function. Must be in the range [0, 1].

- \( dfd \)  
  array_like  
  Degrees of freedom of the denominator sum of squares. Range (0, inf).

- \( nc \)  
  array_like  
  Noncentrality parameter. Should be in range (0, 1e4).

- \( f \)  
  float  
  Quantiles, i.e. the upper limit of integration.

Returns

- \( dfn \)  
  float  
  Degrees of freedom of the numerator sum of squares.
ncfdtr

CDF of the non-central F distribution.

ncfdtri

Quantile function; inverse of ncfdtr with respect to $f$.

ncfdtridfd

Inverse of ncfdtr with respect to $dfd$.

ncfdtrinc

Inverse of ncfdtr with respect to $nc$.

Notes

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom. There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an arbitrary one of the two values.

Examples

```python
>>> from scipy.special import ncfdtr, ncfdtridfn

Compute the CDF for several values of $dfn$:

```python
>>> dfn = [1, 2, 3]
>>> p = ncfdtr(dfn, 2, 0.25, 15)
>>> p
array([0.92562363, 0.93020416, 0.93188394])
```

Compute the inverse. We recover the values of $dfn$, as expected:

```python
>>> ncfdtridfn(p, 2, 0.25, 15)
array([1., 2., 3.])
```

scipy.special.ncfdtri

scipy.special.ncfdtri($dfn, dfd, nc, p$) = <ufunc 'ncfdtri'>

Inverse with respect to $f$ of the CDF of the non-central F distribution.

See ncfdtr for more details.

Parameters

- $dfn$ [array_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).
- $dfd$ [array_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).
- $nc$ [array_like] Noncentrality parameter. Should be in range (0, 1e4).
- $p$ [array_like] Value of the cumulative distribution function. Must be in the range [0, 1].

Returns

- $f$ [float] Quantiles, i.e. the upper limit of integration.

See also:
ncfdtr
CDF of the non-central F distribution.

ncfdtridf
Inverse of ncfdtr with respect to dfd.

ncfdtridfn
Inverse of ncfdtr with respect to dfn.

ncfdtrinc
Inverse of ncfdtr with respect to nc.

Examples

```python
>>> from scipy.special import ncfdtr, ncfdtri

Compute the CDF for several values of f:

```python
>>> f = [0.5, 1, 1.5]
>>> p = ncfdtr(2, 3, 1.5, f)
>>> p
array([ 0.20782291, 0.36107392, 0.47345752])
``` Compute the inverse. We recover the values of f, as expected:

```python
>>> ncfdtri(2, 3, 1.5, p)
array([ 0.5, 1., 1.5])
```

scipy.special.ncfdtrinc

```
scipy.special.ncfdtrinc(dfn, dfd, p, f) = <ufunc 'ncfdtrinc'>
```
Calculate non-centrality parameter for non-central F distribution.

This is the inverse with respect to nc of ncfdtr. See ncfdtr for more details.

Parameters

- **dfn**  
  [array_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).
- **dfd**  
  [array_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).
- **p**  
  [array_like] Value of the cumulative distribution function. Must be in the range [0, 1].
- **f**  
  [array_like] Quantiles, i.e. the upper limit of integration.

Returns

- **nc**  
  [float] Noncentrality parameter.

See also:

- **ncfdtr**
  CDF of the non-central F distribution.
- **ncfdtri**
  Quantile function; inverse of ncfdtr with respect to f.
ncfdtridfd
Inverse of \textit{ncfdtr} with respect to \textit{dfd}.

ncfdtridfn
Inverse of \textit{ncfdtr} with respect to \textit{dfn}.

Examples

```python
>>> from scipy.special import ncfdtr, ncfdtrinc

Compute the CDF for several values of \textit{nc}:

```python
>>> nc = [0.5, 1.5, 2.0]
>>> p = ncfdtr(2, 3, nc, 15)
>>> p
array([ 0.96309246, 0.94327955, 0.93304098])
```

Compute the inverse. We recover the values of \textit{nc}, as expected:

```python
>>> ncfdtrinc(2, 3, p, 15)
array([ 0.5, 1.5, 2. ])
```

\texttt{scipy.special.nctdtr}
\texttt{scipy.special.\texttt{nctdtr}(df, nc, t) = \texttt{<ufunc }'\texttt{nctdtr}'>}
Cumulative distribution function of the non-central \textit{t} distribution.

\textbf{Parameters}
\begin{itemize}
\item \texttt{df} [array_like] Degrees of freedom of the distribution. Should be in range (0, inf).
\item \texttt{nc} [array_like] Noncentrality parameter. Should be in range (-1e6, 1e6).
\item \texttt{t} [array_like] Quantiles, i.e. the upper limit of integration.
\end{itemize}

\textbf{Returns}
\begin{itemize}
\item \texttt{cdf} [float or ndarray] The calculated CDF. If all inputs are scalar, the return will be a float. Otherwise it will be an array.
\end{itemize}

\textbf{See also:}
\begin{itemize}
\item \texttt{nctdtrit}
Inverse CDF (iCDF) of the non-central \textit{t} distribution.
\item \texttt{nctdtridf}
Calculate degrees of freedom, given CDF and iCDF values.
\item \texttt{nctdtrinc}
Calculate non-centrality parameter, given CDF iCDF values.
\end{itemize}

Examples

```python
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```
Plot the CDF of the non-central t distribution, for nc=0. Compare with the t-distribution from scipy.stats:

```python
>>> x = np.linspace(-5, 5, num=500)
>>> df = 3
>>> nct_stats = stats.t.cdf(x, df)
>>> nct_special = special.nctdtr(df, 0, x)

>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, nct_stats, 'b-', lw=3)
>>> ax.plot(x, nct_special, 'r-')
>>> plt.show()
```

**scipy.special.nctdtridf**

scipy.special.nctdtridf($p$, $nc$, $t$) = *ufunc 'nctdtridf'*

Calculate degrees of freedom for non-central t distribution.

See `nctdtr` for more details.

**Parameters**

- $p$ [array_like] CDF values, in range (0, 1].
- $nc$ [array_like] Noncentrality parameter. Should be in range (-1e6, 1e6).
- $t$ [array_like] Quantiles, i.e. the upper limit of integration.

**scipy.special.nctdtrit**

scipy.special.nctdtrit($df$, $nc$, $p$) = *ufunc 'nctdtrit'*

Inverse cumulative distribution function of the non-central t distribution.

See `nctdtr` for more details.

**Parameters**

- $df$ [array_like] Degrees of freedom of the distribution. Should be in range (0, inf).
- $nc$ [array_like] Noncentrality parameter. Should be in range (-1e6, 1e6).
- $p$ [array_like] CDF values, in range (0, 1].
scipy.special.nctdtrinc
scipy.special.nctdtrinc(df, p, t) = <ufunc 'nctdtrinc'>
Calculate non-centrality parameter for non-central t distribution.
See nctdtr for more details.

Parameters

- df [array_like] Degrees of freedom of the distribution. Should be in range (0, inf).
- p [array_like] CDF values, in range (0, 1].
- t [array_like] Quantiles, i.e. the upper limit of integration.

scipy.special.nrdtrimn
scipy.special.nrdtrimn(p, x, std) = <ufunc 'nrdtrimn'>
Calculate mean of normal distribution given other params.

Parameters

- p [array_like] CDF values, in range (0, 1].
- x [array_like] Quantiles, i.e. the upper limit of integration.

Returns

- mn [float or ndarray] The mean of the normal distribution.

See also:

nrdtrimn, ndtr

scipy.special.nrdtrisd
scipy.special.nrdtrisd(p, x, mn) = <ufunc 'nrdtrisd'>
Calculate standard deviation of normal distribution given other params.

Parameters

- p [array_like] CDF values, in range (0, 1].
- x [array_like] Quantiles, i.e. the upper limit of integration.
- mn [float or ndarray] The mean of the normal distribution.

Returns

See also:

ndtr

scipy.special.pdtr
scipy.special.pdtr(k, m) = <ufunc 'pdtr'>
Poisson cumulative distribution function

Returns the sum of the first k terms of the Poisson distribution: 
\sum(\exp(-m) * m**j / j!, j=0..k) = \text{gammaincc}(k+1, m). Arguments must both be positive and k an integer.
**scipy.special.pdtrc**

\[
\text{scipy.special.pdtrc}(k, m) = \texttt{ufunc 'pdtrc'}
\]

Poisson survival function

Returns the sum of the terms from \(k+1\) to infinity of the Poisson distribution: 
\[
\text{sum}(\exp(-m) \cdot m^j / j!, j=k+1..\infty) = \text{gammainc}(k+1, m).
\]
Arguments must both be positive and \(k\) an integer.

**scipy.special.pdtri**

\[
\text{scipy.special.pdtri}(k, y) = \texttt{ufunc 'pdtri'}
\]

Inverse to \(pdtr\) vs \(m\)

Returns the Poisson variable \(m\) such that the sum from 0 to \(k\) of the Poisson density is equal to the given probability \(y\): calculated by gammaincinv\((k+1, y)\). \(k\) must be a nonnegative integer and \(y\) between 0 and 1.

**scipy.special.pdtrik**

\[
\text{scipy.special.pdtrik}(p, m) = \texttt{ufunc 'pdtrik'}
\]

Inverse to \(pdtr\) vs \(k\)

Returns the quantile \(k\) such that \(pdtr(k, m) = p\)

**scipy.special.stdtr**

\[
\text{scipy.special.stdtr}(df, t) = \texttt{ufunc 'stdtr'}
\]

Student t distribution cumulative distribution function

Returns the integral from minus infinity to \(t\) of the Student t distribution with \(df > 0\) degrees of freedom:

\[
\frac{1}{2^{(df+1)/2}} \cdot \text{sqrt}(df\pi) \cdot \text{gamma}(df/2) \cdot 
\int_{-\infty}^{t} \frac{1+x^2/df}{(-df/2-1/2)} \cdot \exp(-x/2) \, dx
\]

**scipy.special.stdtridf**

\[
\text{scipy.special.stdtridf}(p, t) = \texttt{ufunc 'stdtridf'}
\]

Inverse of \(stdtr\) vs \(df\)

Returns the argument \(df\) such that \(stdtr(df, t)\) is equal to \(p\).

**scipy.special.stdtrit**

\[
\text{scipy.special.stdtrit}(df, p) = \texttt{ufunc 'stdtrit'}
\]

Inverse of \(stdtr\) vs \(t\)

Returns the argument \(t\) such that \(stdtr(df, t)\) is equal to \(p\).

**scipy.special.chdtr**

\[
\text{scipy.special.chdtr}(v, x) = \texttt{ufunc 'chdtr'}
\]

Chi square cumulative distribution function

Returns the area under the left hand tail (from 0 to \(x\)) of the Chi square probability density function with \(v\) degrees of freedom:

\[
\frac{1}{2^{(v/2)} \cdot \text{gamma}(v/2)} \cdot \int_{0}^{x} t^{(v/2-1)} \cdot \exp(-t/2) \, dt
\]

**scipy.special.chdtrc**

\[
\text{scipy.special.chdtrc}(v, x) = \texttt{ufunc 'chdtrc'}
\]

Chi square survival function

---

**6.27. Special functions (scipy.special)** 1981
Returns the area under the right hand tail (from \( x \) to infinity) of the Chi square probability density function with \( v \) degrees of freedom:

\[
\frac{1}{(2^\frac{v}{2} \cdot \Gamma(\frac{v}{2}))} \int_{x}^{\infty} t^{\frac{v}{2}-1} \cdot \exp(-\frac{t}{2}) \, dt
\]

**scipy.special.chdtri**

\[
\text{scipy.special.chdtri}(v, p) = \texttt{ufunc 'chdtri'}
\]

Inverse to chdtrc

Returns the argument \( x \) such that \( \text{chdtrc}(v, x) = p \).

**scipy.special.chdtriv**

\[
\text{scipy.special.chdtriv}(p, x) = \texttt{ufunc 'chdtriv'}
\]

Inverse to chdtr vs \( v \)

Returns the argument \( v \) such that \( \text{chdtr}(v, x) = p \).

**scipy.special.ndtr**

\[
\text{scipy.special.ndtr}(x) = \texttt{ufunc 'ndtr'}
\]

Gaussian cumulative distribution function.

Returns the area under the standard Gaussian probability density function, integrated from minus infinity to \( x \):

\[
\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} \exp(-\frac{t^2}{2}) \, dt
\]

**Parameters**

- \( x \) : [array_like, real or complex] Argument

**Returns**

- ndarray : The value of the normal CDF evaluated at \( x \)

See also:

- \texttt{erf}
- \texttt{erfc}
- \texttt{scipy.stats.norm}
- \texttt{log_ndtr}

**scipy.special.log_ndtr**

\[
\text{scipy.special.log_ndtr}(x) = \texttt{ufunc 'log_ndtr'}
\]

Logarithm of Gaussian cumulative distribution function.

Returns the log of the area under the standard Gaussian probability density function, integrated from minus infinity to \( x \):

\[
\log\left(\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} \exp(-\frac{t^2}{2}) \, dt\right)
\]

**Parameters**

- \( x \) : [array_like, real or complex] Argument

**Returns**
The value of the log of the normal CDF evaluated at $x$.

See also:

- `erf`
- `erfc`
- `scipy.stats.norm`
- `ndtr`

#### `scipy.special.ndtri`

$\text{scipy.special.ndtri}(y) = \text{<ufunc 'ndtri'}$

Inverse of `ndtr` vs $x$

Returns the argument $x$ for which the area under the Gaussian probability density function (integrated from minus infinity to $x$) is equal to $y$.

#### `scipy.special.chndtr`

$\text{scipy.special.chndtr}(x, df, nc) = \text{<ufunc 'chndtr'}$

Non-central chi square cumulative distribution function

#### `scipy.special.chndtridf`

$\text{scipy.special.chndtridf}(x, p, nc) = \text{<ufunc 'chndtridf'}$

Inverse to `chndtr` vs $df$

#### `scipy.special.chndtrinc`

$\text{scipy.special.chndtrinc}(x, df, p) = \text{<ufunc 'chndtrinc'}$

Inverse to `chndtr` vs $nc$

#### `scipy.special.chndtrix`

$\text{scipy.special.chndtrix}(p, df, nc) = \text{<ufunc 'chndtrix'}$

Inverse to `chndtr` vs $x$

#### `scipy.special.smirnov`

$\text{scipy.special.smirnov}(n, d) = \text{<ufunc 'smirnov'}$

Kolmogorov-Smirnov complementary cumulative distribution function

Returns the exact Kolmogorov-Smirnov complementary cumulative distribution function, (aka the Survival Function) of $D_n^+$ (or $D_n^-$) for a one-sided test of equality between an empirical and a theoretical distribution. It is equal to the probability that the maximum difference between a theoretical distribution and an empirical one based on $n$ samples is greater than $d$.

**Parameters**

- **n** [int] Number of samples
- **d** [float array_like] Deviation between the Empirical CDF (ECDF) and the target CDF.

**Returns**

- **float** The value(s) of `smirnov(n, d)`, $\text{Prob}(D_n^+ >= d)$ (Also $\text{Prob}(D_n^- >= d)$)

See also:
smirnov

The Inverse Survival Function for the distribution

scipy.stats.ksone

Provides the functionality as a continuous distribution

kolmogorov, kolmogi

Functions for the two-sided distribution

Notes

smirnov is used by stats.kstest in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in scipy.special, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the stats.ksone distribution.

Examples

```python
>>> from scipy.special import smirnov

Show the probability of a gap at least as big as 0, 0.5 and 1.0 for a sample of size 5

>>> smirnov(5, [0, 0.5, 1.0])
array([ 1. , 0.056, 0. ])

Compare a sample of size 5 drawn from a source N(0.5, 1) distribution against a target N(0, 1) CDF.

```
Dn-=0.563278, Dn+=0.001005
>>> probs = smirnov(n, Dnpm)
>>> print(chr(10).join(['For a sample of size %d drawn from a N(0, 1) distribution:
  Smirnov n=%d: Prob(Dn- >= %f) = %.4f' % (n, Dnpm[0],
  probs[0]),
  ' Smirnov n=%d: Prob(Dn+ >= %f) = %.4f' % (n, Dnpm[1],
  probs[1])])
For a sample of size 5 drawn from a N(0, 1) distribution:
  Smirnov n=5: Prob(Dn- >= 0.563278) = 0.0250
  Smirnov n=5: Prob(Dn+ >= 0.001005) = 0.9990

Plot the Empirical CDF against the target N(0, 1) CDF

```python
>>> import matplotlib.pyplot as plt
>>> plt.step(np.concatenate([[-3], x]]), ecdfs, where='post', label='Empirical CDF')
>>> x3 = np.linspace(-3, 3, 100)
>>> plt.plot(x3, target.cdf(x3), label='CDF for N(0, 1)')
>>> plt.ylim([0, 1]); plt.grid(True); plt.legend();
# Add vertical lines marking Dn+ and Dn-
>>> inminus, iplus = np.argmax(gaps, axis=0)
>>> plt.vlines([x[inminus]], ecdfs[inminus], cdfs[inminus], color='r',
  linestyle='dashed', lw=4)
>>> plt.vlines([x[iplus]], cdfs[iplus], ecdfs[iplus+1], color='m',
  linestyle='dashed', lw=4)
>>> plt.show()
```

**scipy.special.smirnovi**

`scipy.special.smirnovi(n, p) = <ufunc 'smirnovi'>`

Inverse to `smirnov`

Returns $d$ such that $\text{smirnov}(n, d) = p$, the critical value corresponding to $p$. 

6.27. Special functions (scipy.special)
Parameters

- **n**  [int] Number of samples
- **p**  [float array_like] Probability

Returns

- float  The value(s) of smirnovi(n, p), the critical values.

See also:

- **smirnov**
  The Survival Function (SF) for the distribution

- **scipy.stats.ksone**
  Provides the functionality as a continuous distribution

- **kolmogorov, kolmogi, scipy.stats.kstwobign**
  Functions for the two-sided distribution

Notes

**smirnov** is used by **stats.ktest** in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in scipy.special, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the **stats.ksone** distribution.

**scipy.special.kolmogorov**

```
scipy.special.kolmogorov(y) = <ufunc 'kolmogorov'>
```

Complementary cumulative distribution (Survival Function) function of Kolmogorov distribution.

Returns the complementary cumulative distribution function of Kolmogorov’s limiting distribution ($D_n \sqrt{n}$ as $n$ goes to infinity) of a two-sided test for equality between an empirical and a theoretical distribution. It is equal to the (limit as $n \to \infty$ of the) probability that $\sqrt{n} \cdot \text{max absolute deviation} > y$.

Parameters

- **y**  [float array_like] Absolute deviation between the Empirical CDF (ECDF) and the target CDF, multiplied by $\sqrt{n}$.

Returns

- float  The value(s) of kolmogorov(y)

See also:

- **kolmogi**
  The Inverse Survival Function for the distribution

- **scipy.stats.kstwobign**
  Provides the functionality as a continuous distribution

- **smirnov, smirnovi**
  Functions for the one-sided distribution
Notes

kolmogorov is used by stats.kstest in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in scipy.special, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the stats.kstwobign distribution.

Examples

Show the probability of a gap at least as big as 0, 0.5 and 1.0.

```python
>>> from scipy.special import kolmogorov
>>> kolmogorov([0, 0.5, 1.0])
array([ 1. , 0.96394524, 0.26999967])
```

Compare a sample of size 1000 drawn from a Laplace(0, 1) distribution against the target distribution, a Normal(0, 1) distribution.

```python
>>> n = 1000
>>> np.random.seed(seed=233423)
>>> lap01 = laplace(0, 1)
>>> x = np.sort(lap01.rvs(n))
>>> np.mean(x), np.std(x)
(-0.083073685397609842, 1.3676426568399822)
```

Construct the Empirical CDF and the K-S statistic Dn.

```python
>>> target = norm(0,1) # Normal mean 0, stddev 1
>>> cdfs = target.cdf(x)
>>> ecdfs = np.arange(n+1, dtype=float)/n
>>> gaps = np.column_stack([cdfs - ecdfs[:n], ecdfs[1:] - cdfs])
>>> Dn = np.max(gaps)
>>> Kn = np.sqrt(n) * Dn
>>> print('Dn=%f, sqrt(n)*Dn=%f' % (Dn, Kn))
Dn=0.058286, sqrt(n)*Dn=1.843153
```

Plot the Empirical CDF against the target N(0, 1) CDF.

```python
>>> import matplotlib.pyplot as plt
>>> plt.step(np.concatenate([[3], x]), ecdfs, where='post', label=
'Empirical CDF')
```

(continues on next page)
>>> x3 = np.linspace(-3, 3, 100)
>>> plt.plot(x3, target.cdf(x3), label='CDF for N(0, 1)')
>>> plt.ylim([0, 1]); plt.grid(True); plt.legend();
>>> # Add vertical lines marking Dn+ and Dn-
>>> iminus, iplus = np.argmax(gaps, axis=0)
>>> plt.vlines([x[iminus]], ecdfs[iminus], cdfs[iminus], color='r',
              linestyle='dashed', lw=4)
>>> plt.vlines([x[iplus]], cdfs[iplus], ecdfs[iplus+1], color='r',
              linestyle='dashed', lw=4)
>>> plt.show()

scipy.special.kolmogi

scipy.special.kolmogi(p) = <ufunc 'kolmogi'>
Inverse Survival Function of Kolmogorov distribution

It is the inverse function to kolmogorov. Returns y such that kolmogorov(y) == p.

Parameters

p [float array_like] Probability

Returns

float The value(s) of kolmogi(p)

See also:

kolmogorov

The Survival Function for the distribution

scipy.stats.kstwobign

Provides the functionality as a continuous distribution

smirnov, smirnovi

Functions for the one-sided distribution
Notes

Kolmogorov is used by stats.kstest in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in scipy.special, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the stats.kstwobign distribution.

Examples

```python
>>> from scipy.special import kolmogi
>>> kolmogi([0, 0.1, 0.25, 0.5, 0.75, 0.9, 1.0])
array([inf, 1.22384787, 1.01918472, 0.82757356, 0.67644769, 0.57117327, 0.])
```

scipy.special.tklmbda

scipy.special.tklmbda(x, lmbda) = <ufunc 'tklmbda'>

Tukey-Lambda cumulative distribution function

scipy.special.logit

scipy.special.logit(x) = <ufunc 'logit'>

Logit ufunc for ndarrays.

The logit function is defined as \( \text{logit}(p) = \log(p/(1-p)) \). Note that \( \text{logit}(0) = -\infty \), \( \text{logit}(1) = \infty \), and \( \text{logit}(p) \) for \( p < 0 \) or \( p > 1 \) yields nan.

Parameters

- x [ndarray] The ndarray to apply logit to element-wise.

Returns

- out [ndarray] An ndarray of the same shape as x. Its entries are logit of the corresponding entry of x.

See also:

expit

Notes

As a ufunc logit takes a number of optional keyword arguments. For more information see ufuncs

New in version 0.10.0.

Examples

```python
>>> from scipy.special import logit, expit

array([-inf, -1.09861229, 0. , 1.09861229, inf])
```

expit is the inverse of logit:
scipy.special.expit

The expit function, also known as the logistic sigmoid function, is defined as \( \text{expit}(x) = 1/(1+\exp(-x)) \). It is the inverse of the logit function.

**Parameters**

- \( x \) [ndarray] The ndarray to apply expit to element-wise.

**Returns**

- \( \text{out} \) [ndarray] An ndarray of the same shape as \( x \). Its entries are \( \text{expit} \) of the corresponding entry of \( x \).

**See also:**

logit
Notes

As a ufunc expit takes a number of optional keyword arguments. For more information see ufuncs

New in version 0.10.0.

Examples

```python
>>> from scipy.special import expit, logit

>>> expit([-np.inf, -1.5, 0, 1.5, np.inf])
array([ 0.   , 0.18242552, 0.5   , 0.81757448, 1.   ])

logit is the inverse of expit:

>>> logit(expit([-2.5, 0, 3.1, 5.0]))
array([-2.5, 0.   , 3.1, 5.   ])

Plot expit(x) for x in [-6, 6]:

```
The Box-Cox transformation is:
\[ y = (x^{\lambda} - 1) / \lambda \text{ if } \lambda \neq 0 \]
\[ \log(x) \text{ if } \lambda = 0 \]

Returns `nan` if \( x < 0 \). Returns `-inf` if \( x = 0 \) and \( \lambda < 0 \).

**Parameters**
- **x** [array_like] Data to be transformed.
- **\lambda** [array_like] Power parameter of the Box-Cox transform.

**Returns**
- **y** [array] Transformed data.

**Notes**
New in version 0.14.0.

**Examples**

```python
>>> from scipy.special import boxcox
>>> boxcox([1, 4, 10], 2.5)
array([ 0.        , 12.4      , 126.09110641])
>>> boxcox(2, [0, 1, 2])
array([ 0.69314718, 1.        , 1.5       ])
```

scipy.special.boxcox1p

`scipy.special.boxcox1p(x, \lambda) = <ufunc 'boxcox1p'>`  
Compute the Box-Cox transformation of \( 1 + x \).

The Box-Cox transformation computed by `boxcox1p` is:

\[ y = (((1+x)^{\lambda} - 1) / \lambda \text{ if } \lambda \neq 0 \]
\[ \log(1+x) \text{ if } \lambda = 0 \]

Returns `nan` if \( x < -1 \). Returns `-inf` if \( x = -1 \) and \( \lambda < 0 \).

**Parameters**
- **x** [array_like] Data to be transformed.
- **\lambda** [array_like] Power parameter of the Box-Cox transform.

**Returns**
- **y** [array] Transformed data.

**Notes**
New in version 0.14.0.
Examples

```python
>>> from scipy.special import boxcox1p
>>> boxcox1p(1e-4, [0, 0.5, 1])
array([ 9.99950003e-05, 9.99975001e-05, 1.00000000e-04])
>>> boxcox1p([0.01, 0.1], 0.25)
array([ 0.00996272, 0.09645476])
```

**scipy.special.inv_boxcox**

`scipy.special.inv_boxcox(y, lmbda) = <ufunc 'inv_boxcox'>`

Compute the inverse of the Box-Cox transformation.

Find \( x \) such that:

\[
\begin{align*}
y &= \frac{x^\ast lmbda - 1}{lmbda} \quad \text{if } lmbda \neq 0 \\
 &\quad \log(x) \quad \text{if } lmbda = 0
\end{align*}
\]

**Parameters**

- `y` : [array_like] Data to be transformed.
- `lmbda` : [array_like] Power parameter of the Box-Cox transform.

**Returns**

- `x` : [array] Transformed data.

**Notes**

New in version 0.16.0.

**Examples**

```python
>>> from scipy.special import boxcox, inv_boxcox
>>> y = boxcox([1, 4, 10], 2.5)
>>> inv_boxcox(y, 2.5)
array([1., 4., 10.])
```

**scipy.special.inv_boxcox1p**

`scipy.special.inv_boxcox1p(y, lmbda) = <ufunc 'inv_boxcox1p'>`

Compute the inverse of the Box-Cox transformation.

Find \( x \) such that:

\[
\begin{align*}
y &= \frac{(1+x)^\ast lmbda - 1}{lmbda} \quad \text{if } lmbda \neq 0 \\
 &\quad \log(1+x) \quad \text{if } lmbda = 0
\end{align*}
\]

**Parameters**

- `y` : [array_like] Data to be transformed.
- `lmbda` : [array_like] Power parameter of the Box-Cox transform.

**Returns**

- `x` : [array] Transformed data.
Notes

New in version 0.16.0.

Examples

```python
>>> from scipy.special import boxcox1p, inv_boxcox1p
>>> y = boxcox1p([1, 4, 10], 2.5)
>>> inv_boxcox1p(y, 2.5)
array([1., 4., 10.])
```

**scipy.special.owens_t**

```python
scipy.special.owens_t(h, a) = <ufunc 'owens_t'>
```

**Owen’s T Function.**

The function T(h, a) gives the probability of the event \((X > h \text{ and } 0 < Y < a * X)\) where \(X\) and \(Y\) are independent standard normal random variables.

**Parameters**

- **h**: array_like
  Input value.
- **a**: array_like
  Input value.

**Returns**

- **t**: scalar or ndarray
  Probability of the event \((X > h \text{ and } 0 < Y < a * X)\), where \(X\) and \(Y\) are independent standard normal random variables.

**References**

[1]

**Examples**

```python
>>> from scipy import special
>>> a = 3.5
>>> h = 0.78
>>> special.owens_t(h, a)
0.10877216734852274
```

Information Theory Functions

- **entr(x)**: Elementwise function for computing entropy.
- **rel_entr(x, y)**: Elementwise function for computing relative entropy.
- **kl_div(x, y)**: Elementwise function for computing Kullback-Leibler divergence.
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>

<tbody>
<tr>
<td><code>huber(delta, r)</code></td>
<td>Huber loss function.</td>
</tr>
<tr>
<td><code>pseudo_huber(delta, r)</code></td>
<td>Pseudo-Huber loss function.</td>
</tr>
</tbody>
</table>

**scipy.special.entr**

```python
scipy.special.entr(x) = <ufunc 'entr'>
```

Elementwise function for computing entropy.

\[
\text{entr}(x) = \begin{cases} 
-x \log(x) & x > 0 \\
0 & x = 0 \\
-\infty & \text{otherwise}
\end{cases}
\]

**Parameters**
- `x` [ndarray] Input array.

**Returns**
- `res` [ndarray] The value of the elementwise entropy function at the given points `x`.

**See also:**
- `kl_div`, `rel_entr`

**Notes**
This function is concave.

New in version 0.15.0.

**scipy.special.rel_entr**

```python
scipy.special.rel_entr(x, y) = <ufunc 'rel_entr'>
```

Elementwise function for computing relative entropy.

\[
\text{rel}_\text{entr}(x, y) = \begin{cases} 
x \log(x/y) & x > 0, y > 0 \\
0 & x = 0, y \geq 0 \\
\infty & \text{otherwise}
\end{cases}
\]

**Parameters**
- `x` [ndarray] First input array.
- `y` [ndarray] Second input array.

**Returns**

**See also:**
- `entr`, `kl_div`

**Notes**
This function is jointly convex in `x` and `y`.

New in version 0.15.0.
\texttt{scipy.special.kl}\_\texttt{div}

\texttt{scipy.special.kl}\_\texttt{div}(x, y) = <ufunc 'kl\_div'>

Elementwise function for computing Kullback-Leibler divergence.

\[
\text{kl}_\text{div}(x, y) = \begin{cases} 
    x \log(x/y) - x + y & x > 0, y > 0 \\
    y & x = 0, y \geq 0 \\
    \infty & \text{otherwise}
\end{cases}
\]

\textbf{Parameters}

\begin{itemize}
    \item \texttt{x} [ndarray] First input array.
    \item \texttt{y} [ndarray] Second input array.
\end{itemize}

\textbf{Returns}

\begin{itemize}
    \item \texttt{res} [ndarray] Output array.
\end{itemize}

\textbf{See also:}

\texttt{entr}, \texttt{rel\_entr}

\textbf{Notes}

This function is non-negative and is jointly convex in \( x \) and \( y \).

New in version 0.15.0.

\texttt{scipy.special.huber}

\texttt{scipy.special.huber}(\texttt{delta}, \texttt{r}) = <ufunc 'huber'>

Huber loss function.

\[
\text{huber}(\delta, r) = \begin{cases} 
    \infty & \delta < 0 \\
    \frac{1}{2}r^2 & 0 \leq \delta, |r| \leq \delta \\
    \delta(|r| - \frac{1}{2}\delta) & \text{otherwise}
\end{cases}
\]

\textbf{Parameters}

\begin{itemize}
    \item \texttt{delta} [ndarray] Input array, indicating the quadratic vs. linear loss changepoint.
    \item \texttt{r} [ndarray] Input array, possibly representing residuals.
\end{itemize}

\textbf{Returns}

\begin{itemize}
    \item \texttt{res} [ndarray] The computed Huber loss function values.
\end{itemize}

\textbf{Notes}

This function is convex in \( r \).

New in version 0.15.0.
scipy.special.pseudo_huber

\[
\text{pseudo\_huber}(\delta, r) = \delta^2 \left( \sqrt{1 + \left( \frac{r}{\delta} \right)^2} - 1 \right)
\]

**Parameters**

- **delta** [ndarray] Input array, indicating the soft quadratic vs. linear loss changepoint.
- **r** [ndarray] Input array, possibly representing residuals.

**Returns**

- **res** [ndarray] The computed Pseudo-Huber loss function values.

**Notes**

This function is convex in \( r \).

New in version 0.15.0.

### Gamma and Related Functions

- **gamma**(z) Gamma function.
- **gammaln**(x, [out, where, casting, order, ...]) Logarithm of the absolute value of the Gamma function.
- **loggamma**(z[, out]) Principal branch of the logarithm of the Gamma function.
- **gammasgn**(x) Sign of the gamma function.
- **gammainc**(a, x) Regularized lower incomplete gamma function.
- **gammaincc**(a, x) Regularized upper incomplete gamma function.
- **gammainccinv**(a, y) Inverse to gammaincc
- **gamma**(a, b) Beta function.
- **betainc**(a, b, x) Incomplete beta integral.
- **betaincinv**(a, b, y) Inverse function to beta integral.
- **psi**(z[, out]) The digamma function.
- **rgamma**(z) Gamma function inverted
- **polygamma**(n, x) Polygamma function n.
- **multigammaln**(a, d) Returns the log of multivariate gamma, also sometimes called the generalized gamma.
- **digamma**(z[, out]) The digamma function.
- **poch**(z, m) Rising factorial \((z)_m\)

### scipy.special.gamma

\[
\Gamma(z) = \int_0^\infty x^{z-1}e^{-x}dx = (z - 1)!
\]

The gamma function is often referred to as the generalized factorial since \( z*gamma(z) = gamma(z+1) \) and \( gamma(n+1) = n! \) for natural number \( n \).
Parameters

\( z \) \[\text{float or complex array_like} \]

Returns

float or complex

The value(s) of gamma(z)

Examples

```python
>>> from scipy.special import gamma, factorial

>>> gamma([0, 0.5, 1, 5])
array([   inf, 1.77245385, 1. , 24. ])

>>> z = 2.5 + 1j
>>> gamma(z)
(0.77476210455108352+0.70763120437959293j)

>>> gamma(z+1), z*gamma(z)  # Recurrence property
((1.2292740569981158+2.5438401155000658j),
 (1.2292740569981158+2.5438401155000658j))

>>> gamma(0.5)**2  # gamma(0.5) = sqrt(pi)
3.1415926535897927
```

Plot gamma(x) for real x

```python
>>> x = np.linspace(-3.5, 5.5, 2251)
>>> y = gamma(x)

>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'b', alpha=0.6, label='gamma(x)')
>>> k = np.arange(1, 7)
>>> plt.plot(k, factorial(k-1), 'k*', alpha=0.6,
...          label='(x-1)!, x = 1, 2, ...')
>>> plt.xlim(-3.5, 5.5)
>>> plt.ylim(-10, 25)
>>> plt.grid()
>>> plt.legend(loc='lower right')
>>> plt.show()
```

`scipy.special.gammaln`

`scipy.special.gammaln(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature, extobj]) = <ufunc 'gammaln'>`

Logarithm of the absolute value of the Gamma function.

Parameters

\( x \) \[\text{array-like}\] Values on the real line at which to compute gammaln

Returns

\( \text{gammaln} \) \[\text{ndarray}\] Values of gammaln at x.
See also:

* **gammasgn**
  
  sign of the gamma function

* **loggamma**
  
  principal branch of the logarithm of the gamma function

**Notes**

When used in conjunction with `gammasgn`, this function is useful for working in logspace on the real axis without having to deal with complex numbers, via the relation \( \exp(\text{gammaln}(x)) = \text{gammasgn}(x) \cdot \text{gamma}(x) \).

For complex-valued log-gamma, use `loggamma` instead of `gammaln`.

**scipy.special.loggamma**

`scipy.special.loggamma(z, out=None) = <ufunc 'loggamma'>`

Principal branch of the logarithm of the Gamma function.

Defined to be \( \log(\Gamma(x)) \) for \( x > 0 \) and extended to the complex plane by analytic continuation. The function has a single branch cut on the negative real axis.

New in version 0.18.0.

**Parameters**

* \( z \) [array-like] Values in the complex plain at which to compute `loggamma`

* \( \text{out} \) [ndarray, optional] Output array for computed values of `loggamma`

**Returns**

* `loggamma` [ndarray] Values of `loggamma` at \( z \).

See also:
gammaln

logarithm of the absolute value of the Gamma function

gammasgn

sign of the gamma function

Notes

It is not generally true that \( \log(\Gamma(z)) = \log(\Gamma(z)) \), though the real parts of the functions do agree. The benefit of not defining \( \loggamma \) as \( \log((z)) \) is that the latter function has a complicated branch cut structure whereas \( \loggamma \) is analytic except for on the negative real axis.

The identities

\[
\exp(\log(\Gamma(z))) = \Gamma(z) \\
\log(\Gamma(z+1)) = \log(z) + \log(\Gamma(z))
\]

make \( \loggamma \) useful for working in complex logspace.

On the real line \( \loggamma \) is related to \( \gammaln \) via \( \exp(\loggamma(x + 0j)) = \gammasgn(x) \ast \exp(\gammaln(x)) \), up to rounding error.

The implementation here is based on [hare1997].

References

[hare1997]

scipy.special.gammasgn

scipy.special.gammasgn(x) = <ufunc 'gammasgn'>

Sign of the gamma function.

See also:

gammaln
loggamma

scipy.special.gammainc

scipy.special.gammainc(a, x) = <ufunc 'gammainc'>

Regularized lower incomplete gamma function.

Defined as

\[
\frac{1}{\Gamma(a)} \int_0^x t^{a-1}e^{-t}dt
\]

for \( a > 0 \) and \( x \geq 0 \). The function satisfies the relation \( \text{gammainc}(a, x) + \text{gammaincc}(a, x) = 1 \) where \( \text{gammaincc} \) is the regularized upper incomplete gamma function.

See also:

gammaincc

regularized upper incomplete gamma function
\texttt{gammaincinv} \\
inverse to \texttt{gammainc} versus \texttt{x}

\texttt{gammainccinv} \\
inverse to \texttt{gammaincc} versus \texttt{x}

**Notes**

The implementation largely follows that of [1].

**References**

[1]
scipy.special.gammainccinv

scipy.special.gammainccinv(a, y) = <ufunc 'gammainccinv'>

Inverse to gammaincc

Returns x such that gammaincc(a, x) == y.

scipy.special.beta

scipy.special.beta(a, b) = <ufunc 'beta'>

Beta function.

\[
\text{beta}(a, b) = \frac{\Gamma(a) \times \Gamma(b)}{\Gamma(a + b)}
\]

scipy.special.betaln

scipy.special.betaln(a, b) = <ufunc 'betaln'>

Natural logarithm of absolute value of beta function.

Computes \(\ln(\text{abs}(\text{beta}(a, b)))\).

scipy.special.betainc

scipy.special.betainc(a, b, x) = <ufunc 'betainc'>

Incomplete beta integral.

Compute the incomplete beta integral of the arguments, evaluated from zero to \(x\):

\[
\frac{\Gamma(a+b)}{(\Gamma(a) \times \Gamma(b))} \times \int_0^x t^{a-1} (1-t)^{b-1} dt
\]

Notes

The incomplete beta is also sometimes defined without the terms in \(\Gamma\), in which case the above definition is the so-called regularized incomplete beta. Under this definition, you can get the incomplete beta by multiplying the result of the scipy function by beta(a, b).

scipy.special.betaincinv

scipy.special.betaincinv(a, b, y) = <ufunc 'betaincinv'>

Inverse function to betainc integral.

Compute \(x\) such that betainc(a, b, x) = y.

scipy.special.psi

scipy.special.psi(z, out=None) = <ufunc 'psi'>

The digamma function.

The logarithmic derivative of the gamma function evaluated at \(z\).

Parameters

- \(z\) [array_like] Real or complex argument.
- \(out\) [ndarray, optional] Array for the computed values of psi.

Returns

- \(\text{digamma}\) [ndarray] Computed values of psi.
Notes

For large values not close to the negative real axis psi is computed using the asymptotic series (5.11.2) from [1]. For small arguments not close to the negative real axis the recurrence relation (5.5.2) from [1] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis the reflection formula (5.5.4) from [1] is used first. Note that psi has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [2], so the function should maintain full accuracy around the origin.

References

[1], [2]

scipy.special.rgamma

scipy.special.rgamma(z) = <ufunc 'rgamma'>
Gamma function inverted
Returns 1/gamma(x)

scipy.special.polygamma

scipy.special.polygamma(n, x)
Polygamma function n.
This is the nth derivative of the digamma (psi) function.

Parameters

n [array_like of int] The order of the derivative of psi.
x [array_like] Where to evaluate the polygamma function.

Returns

polygamma [ndarray] The result.

Examples

>>> from scipy import special
>>> x = [2, 3, 25.5]
>>> special.polygamma(1, x)
array([ 0.64493407, 0.39493407, 0.03999467])
>>> special.polygamma(0, x) == special.psi(x)
array([ True, True, True], dtype=bool)

scipy.special.multigammaln

scipy.special.multigammaln(a, d)
Returns the log of multivariate gamma, also sometimes called the generalized gamma.

Parameters

a [ndarray] The multivariate gamma is computed for each item of a.
d [int] The dimension of the space of integration.

Returns
The values of the log multivariate gamma at the given points $a$.

Notes

The formal definition of the multivariate gamma of dimension $d$ for a real $a$ is

$$\Gamma_d(a) = \int_{A>0} e^{-tr(A)}|A|^{a-(d+1)/2} dA$$

with the condition $a > (d - 1)/2$, and $A > 0$ being the set of all the positive definite matrices of dimension $d$. Note that $a$ is a scalar: the integrand only is multivariate, the argument is not (the function is defined over a subset of the real set).

This can be proven to be equal to the much friendlier equation

$$\Gamma_d(a) = \pi^{d(d-1)/4} \prod_{i=1}^{d} \Gamma(a - (i - 1)/2).$$

References

```python
scipy.special.digamma
```

The digamma function.

The logarithmic derivative of the gamma function evaluated at $z$.

**Parameters**

- $z$ : [array_like] Real or complex argument.
- `out` : [ndarray, optional] Array for the computed values of $\psi$.

**Returns**

- `digamma` : [ndarray] Computed values of $\psi$.

Notes

For large values not close to the negative real axis $\psi$ is computed using the asymptotic series (5.11.2) from [1]. For small arguments not close to the negative real axis the recurrence relation (5.5.2) from [1] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis the reflection formula (5.5.4) from [1] is used first. Note that $\psi$ has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [2], so the function should maintain full accuracy around the origin.

References

[1], [2]
**scipy.special.poch**

```python
scipy.special.poch(z, m) = <ufunc 'poch'>
```

Rising factorial $(z)_m$

The Pochhammer symbol (rising factorial), is defined as

$$(z)_m = \frac{\Gamma(z + m)}{\Gamma(z)}$$

For positive integer $m$ it reads

$$(z)_m = z(z + 1)...(z + m - 1)$$

**Parameters**
- `z` : array_like (int or float)
- `m` : array_like (int or float)

**Returns**
- `poch` : [ndarray] The value of the function.

**scipy.special.erf**

```python
scipy.special.erf(z) = <ufunc 'erf'>
```

Returns the error function of complex argument.

It is defined as $2/\sqrt{\pi} \times \text{integral}(\exp(-t^2), t=0..z)$.

**Parameters**
- `x` : [ndarray] Input array.

**Returns**
- `res` : [ndarray] The values of the error function at the given points $x$.

**See also:**
- `erfc`, `erfinv`, `erfcinv`, `wofz`, `erfcx`, `erfi`
Notes

The cumulative of the unit normal distribution is given by \( \Phi(z) = \frac{1}{2}[1 + \text{erf}(z/\sqrt{2})] \).

```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt
```
```python
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erfcx(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$erfcx(x)$')
>>> plt.show()
```

![Graph of erfcx(x)](image)

### scipy.special.erfi

**scipy.special.erfi(z) = <ufunc 'erfi'>**

Imaginary error function, \(-i \text{erf}(i \, z)\).

See also:

- erf, erfc, erfcx, dawsn, wofz

**Notes**

New in version 0.12.0.

**References**

[1]

**Examples**

```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erfi(x))
>>> plt.xlabel('$x$')
```
scipy.special.erfinv

scipy.special.erfinv(y)

Inverse of the error function erf.

Computes the inverse of the error function.

In complex domain, there is no unique complex number \( w \) satisfying \( \text{erf}(w) = z \). This indicates a true inverse function would have multi-value. When the domain restricts to the real, \(-1 < x < 1\), there is a unique real number satisfying \( \text{erf}(\text{erfinv}(x)) = x \).

Parameters

- \( y \) [ndarray] Argument at which to evaluate. Domain: \([-1, 1]\)

Returns

- \( \text{erfinv} \) [ndarray] The inverse of \( \text{erf} \) of \( y \), element-wise

Examples

1) evaluating a float number

```python
>>> from scipy import special
>>> special.erfinv(0.5)
0.4769362762044698
```

2) evaluating a ndarray
```python
>>> from scipy import special
>>> y = np.linspace(-1.0, 1.0, num=10)
>>> special.erfinv(y)
array([-inf, -0.86312307, -0.5407314 , -0.30457019, -0.0987901 ,
      0.0987901 , 0.30457019,  0.5407314 ,  0.86312307, inf])
```

**scipy.special.erfinv**

scipy.special.erfinv(y)

Inverse of the complementary error function erfc.

Computes the inverse of the complementary error function erfc.

In complex domain, there is no unique complex number w satisfying erfc(w)=z. This indicates a true inverse function would have multi-value. When the domain restricts to the real, 0 < x < 2, there is a unique real number satisfying erfc(erfcinv(x)) = erfcinv(erfc(x)).

It is related to inverse of the error function by erfcinv(1-x) = erfinv(x)

**Parameters**

- **y**: [ndarray] Argument at which to evaluate. Domain: [0, 2]

**Returns**

- **erfcinv**: [ndarray] The inverse of erfc of y, element-wise

**Examples**

1) evaluating a float number

```python
>>> from scipy import special
>>> special.erfcinv(0.5)
0.4769362762044698
```

2) evaluating a ndarray

```python
>>> from scipy import special
>>> y = np.linspace(0.0, 2.0, num=11)
>>> special.erfcinv(y)
array([ inf, 0.9061938 , 0.59511608, 0.37080716, 0.17914345,
      -0., -0.17914345, -0.37080716, -0.59511608, -0.9061938 ,
      -inf])
```

**scipy.special.wofz**

scipy.special.wofz(z) = <ufunc 'wofz'>

Faddeeva function

Returns the value of the Faddeeva function for complex argument:

\[ \exp(-z^*z) \ast \text{erfc}(-i*z) \]

See also:

dawsn, erf, erfc, erfcx, erfi
References

[1]

Examples

```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt

>>> x = np.linspace(-3, 3)
>>> z = special.wofz(x)

>>> plt.plot(x, z.real, label='wofz(x).real')
>>> plt.plot(x, z.imag, label='wofz(x).imag')
>>> plt.xlabel('$x$')
>>> plt.legend(framealpha=1, shadow=True)
>>> plt.grid(alpha=0.25)
>>> plt.show()
```

`scipy.special.dawsn`

`scipy.special.dawsn(x) = <ufunc 'dawsn'>`

Dawson's integral.

Computes:

\[
\exp(-x^2) \times \text{integral}(\exp(t^2), t=0..x).
\]

See also:

`wofz, erf, erfc, erfcx, erfi`
References

[1]

Examples

```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-15, 15, num=1000)
>>> plt.plot(x, special.dawsn(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$dawsn(x)$')
>>> plt.show()
```

![Graph of dawsn(x)](image)

**scipy.special.fresnel**

`scipy.special.fresnel(z) = <ufunc 'fresnel'>`

Fresnel sin and cos integrals

Defined as:

\[
ssa = \text{integral} (\sin(\pi/2 * t^2), t=0..z)
\]

\[
\text{csa} = \text{integral} (\cos(\pi/2 * t^2), t=0..z)
\]

**Parameters**

- **z**  
  [float or complex array_like] Argument

**Returns**

- **ssa, csa**  
  Fresnel sin and cos integral values

**scipy.special.fresnel_zeros**

`scipy.special.fresnel_zeros(nt)`

Compute nt complex zeros of sine and cosine Fresnel integrals \( S(z) \) and \( C(z) \).
References

[1]

**scipy.special.modfresnelp**

```
scipy.special.modfresnelp(x) = <ufunc 'modfresnelp'>
```

Modified Fresnel positive integrals

**Returns**

- `fp`: Integral $F_+(x)$: integral(exp(1j*t*t), t=x..inf)
- `kp`: Integral $K_+(x)$: \( \frac{1}{\sqrt{\pi}} \exp(-1j(x^2+\pi/4)) \times fp \)

**scipy.special.modfresnelm**

```
scipy.special.modfresnelm(x) = <ufunc 'modfresnelm'>
```

Modified Fresnel negative integrals

**Returns**

- `fm`: Integral $F_-(x)$: integral(exp(-1j*t*t), t=x..inf)
- `km`: Integral $K_-(x)$: \( \frac{1}{\sqrt{\pi}} \exp(1j(x^2+\pi/4)) \times fp \)

These are not universal functions:

```
erf_zeros(nt)
erf_zeros(nt) Compute the first nt zero in the first quadrant, ordered by absolute value.
fresnelc_zeros(nt) Compute nt complex zeros of cosine Fresnel integral C(z).
fresnels_zeros(nt) Compute nt complex zeros of sine Fresnel integral S(z).
```

**scipy.special.erf_zeros**

```
scipy.special.erf_zeros(nt)
```

Compute the first nt zero in the first quadrant, ordered by absolute value.

Zeros in the other quadrants can be obtained by using the symmetries erf(-z) = erf(z) and erf(conj(z)) = conj(erf(z)).

**Parameters**

- `nt`: [int] The number of zeros to compute

**Returns**

The locations of the zeros of erf

- `[ndarray (complex)]` Complex values at which zeros of erf(z)

References

[1]

Examples

```python
>>> from scipy import special
>>> special.erf_zeros(1)
array([1.45061616+1.880943j])
```
Check that erf is (close to) zero for the value returned by erf_zeros

```python
>>> special.erf(special.erf_zeros(1))
array([4.95159469e-14-1.16407394e-16j])
```

**scipy.special.fresnelc_zeros**

`scipy.special.fresnelc_zeros(nt)`

Compute nt complex zeros of cosine Fresnel integral C(z).

**References**

[1]

**scipy.special.fresnels_zeros**

`scipy.special.fresnels_zeros(nt)`

Compute nt complex zeros of sine Fresnel integral S(z).

**Legendre Functions**

<table>
<thead>
<tr>
<th><code>lpmv(m, v, x)</code></th>
<th>Associated Legendre function of integer order and real degree.</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sph_harm(m, n, theta, phi)</code></td>
<td>Compute spherical harmonics.</td>
</tr>
</tbody>
</table>

**scipy.special.lpmv**

`scipy.special.lpmv(m, v, x) = <ufunc 'lpmv'>`

Associated Legendre function of integer order and real degree.

Defined as

\[
P_v^m = (-1)^m (1 - x^2)^{m/2} \frac{d^m}{dx^m} P_v(x)
\]

where

\[
P_v = \sum_{k=0}^{\infty} \frac{(-v)_k (v + 1)_k}{(k!)^2} \left( \frac{1 - x}{2} \right)^k
\]

is the Legendre function of the first kind. Here \((\cdot)_k\) is the Pochhammer symbol; see `poch`.

**Parameters**

- `m`  
  [array_like] Order (int or float). If passed a float not equal to an integer the function returns NaN.
- `v`  
  [array_like] Degree (float).
- `x`  
  [array_like] Argument (float). Must have \(|x| \leq 1\).

**Returns**

- `pmv`  
  [ndarray] Value of the associated Legendre function.
See also:

lpmn

Compute the associated Legendre function for all orders $0, \ldots, m$ and degrees $0, \ldots, n$.

clpmn

Compute the associated Legendre function at complex arguments.

Notes

Note that this implementation includes the Condon-Shortley phase.

References

[1]

scipy.special.sph_harm

\[
\text{scipy.special.sph} \text{\_harm}(m, n, \theta, \phi) = \text{\langle ufunc 'sph\_harm'\rangle}
\]

Compute spherical harmonics.

The spherical harmonics are defined as

\[
Y_n^m(\theta, \phi) = \sqrt{\frac{2n + 1}{4\pi} \frac{(n - m)!}{(n + m)!}} e^{im\theta} P_n^m(\cos(\phi))
\]

where $P_n^m$ are the associated Legendre functions; see \texttt{lpmv}.

Parameters

- **m** [array_like] Order of the harmonic (int); must have $|m| \leq n$.
- **n** [array_like] Degree of the harmonic (int); must have $n \geq 0$. This is often denoted by $l$ (lower case L) in descriptions of spherical harmonics.
- **theta** [array_like] Azimuthal (longitudinal) coordinate; must be in [0, 2*pi].
- **phi** [array_like] Polar (colatitudinal) coordinate; must be in [0, pi].

Returns

- **y_mn** [complex float] The harmonic $Y_n^m$ sampled at theta and phi.

Notes

There are different conventions for the meanings of the input arguments theta and phi. In SciPy theta is the azimuthal angle and phi is the polar angle. It is common to see the opposite convention, that is, theta as the polar angle and phi as the azimuthal angle.

Note that SciPy’s spherical harmonics include the Condon-Shortley phase [2] because it is part of \texttt{lpmv}.  

6.27. Special functions (scipy.special) 2015
With SciPy’s conventions, the first several spherical harmonics are

\[ Y_0^0(\theta, \phi) = \frac{1}{2} \sqrt{\frac{1}{\pi}} \]
\[ Y_1^{-1}(\theta, \phi) = \frac{1}{2} \sqrt{\frac{3}{2\pi}} e^{-i\phi} \sin(\phi) \]
\[ Y_1^0(\theta, \phi) = \frac{1}{2} \sqrt{\frac{3}{\pi}} \cos(\phi) \]
\[ Y_1^1(\theta, \phi) = \frac{1}{2} \sqrt{\frac{3}{2\pi}} e^{i\phi} \sin(\phi). \]

References

[1], [2]

These are not universal functions:

</tbody>
</table>

**scipy.special.clpmn**

`scipy.special.clpmn(m, n, z[, type=3])`

Associated Legendre function of the first kind for complex arguments.

Computes the associated Legendre function of the first kind of order \( m \) and degree \( n \), \( P_{m n}(z) = P^m_n(z) \), and its derivative, \( P_{mn}'(z) \). Returns two arrays of size \((m+1, n+1)\) containing \( P_{mn}(z) \) and \( P_{mn}'(z) \) for all orders from \( 0 \ldots m \) and degrees from \( 0 \ldots n \).

**Parameters**

- **m** [int] \( |m| \leq n \); the order of the Legendre function.
- **n** [int] \( n \geq 0 \); the degree of the Legendre function. Often called \( l \) (lower case \( L \)) in descriptions of the associated Legendre function.
- **z** [float or complex] Input value.
- **type** [int, optional] takes values 2 or 3: cut on the real axis \( |x| > 1 \); cut on the real axis \(-1 < x < 1\) (default)

**Returns**

- **Pmn_z** \([(m+1, n+1)\ \text{array}]\) Values for all orders \( 0 \ldots m \) and degrees \( 0 \ldots n \)
- **Pmn_d_z** \([(m+1, n+1)\ \text{array}]\) Derivatives for all orders \( 0 \ldots m \) and degrees \( 0 \ldots n \)

See also:

- lpmn

associated Legendre functions of the first kind for real \( z \)
Notes

By default, i.e. for type=3, phase conventions are chosen according to [1] such that the function is analytic. The cut lies on the interval (-1, 1). Approaching the cut from above or below in general yields a phase factor with respect to Ferrer’s function of the first kind (cf. lpmn).

For type=2 a cut at |x| > 1 is chosen. Approaching the real values on the interval (-1, 1) in the complex plane yields Ferrer’s function of the first kind.

[1], [2]

scipy.special.lpn

scipy.special.lpn(n, z)
Legendre function of the first kind.

Compute sequence of Legendre functions of the first kind (polynomials), Pn(z) and derivatives for all degrees from 0 to n (inclusive).

See also special.legendsre for polynomial class.

References

[1]

scipy.special.lqn

scipy.special.lqn(n, z)
Legendre function of the second kind.

Compute sequence of Legendre functions of the second kind, Qn(z) and derivatives for all degrees from 0 to n (inclusive).

References

[1]

scipy.special.lpmn

scipy.special.lpmn(m, n, z)
Sequence of associated Legendre functions of the first kind.

Computes the associated Legendre function of the first kind of order m and degree n, Pmn(z) = Pnm(z), and its derivative, Pmn'(z). Returns two arrays of size (m+1, n+1) containing Pmn(z) and Pmn'(z) for all orders from 0..m and degrees from 0..n.

This function takes a real argument z. For complex arguments z use clpmn instead.

Parameters

m [int] |m| <= n; the order of the Legendre function.

n [int] where n >= 0; the degree of the Legendre function. Often called l (lower case L) in descriptions of the associated Legendre function.

z [float] Input value.

Returns
**Pmn_z** \[(m+1,n+1)\text{array}\] Values for all orders 0..m and degrees 0..n

**Pmn_d_z** \[(m+1,n+1)\text{array}\] Derivatives for all orders 0..m and degrees 0..n

See also:

*clpmn*

associated Legendre functions of the first kind for complex \(z\)

**Notes**

In the interval (-1, 1), Ferrer’s function of the first kind is returned. The phase convention used for the intervals (1, inf) and (-inf, -1) is such that the result is always real.

**References**

[1],[2]

**scipy.special.lqmn**

*scipy.special.lqmn* \((m, n, z)\)

Sequence of associated Legendre functions of the second kind.

Computes the associated Legendre function of the second kind of order \(m\) and degree \(n\), \(Q^{m\,n}_n(z) = Q^m_n(z)\), and its derivative, \(Q^{m\,n}_n'(z)\). Returns two arrays of size \((m+1, n+1)\) containing \(Q^{m\,n}_n(z)\) and \(Q^{m\,n}_n'(z)\) for all orders from 0..\(m\) and degrees from 0..\(n\).

**Parameters**

- \(m\) [int] |\(m| \leq n\); the order of the Legendre function.
- \(n\) [int] where \(n \geq 0\); the degree of the Legendre function. Often called \(l\) (lower case L) in descriptions of the associated Legendre function.
- \(z\) [complex] Input value.

**Returns**

- \(Q^{m\,n}_n\) \[(m+1,n+1)\text{array}\] Values for all orders 0..\(m\) and degrees 0..\(n\)
- \(Q^{m\,n}_n\)' \[(m+1,n+1)\text{array}\] Derivatives for all orders 0..\(m\) and degrees 0..\(n\)

**References**

**Ellipsoidal Harmonics**

*ellip_harm* \((h2, k2, n, p, s[, signm, signn])\)

Ellipsoidal harmonic functions \(E^p_n(l)\)

*ellip_harm_2* \((h2, k2, n, p, s)\)

Ellipsoidal harmonic functions \(F^p_n(l)\)

*ellip_normal* \((h2, k2, n, p)\)

Ellipsoidal harmonic normalization constants \(\gamma^p_n\)

**scipy.special.ellip_harm**

*scipy.special.ellip_harm* \((h2, k2, n, p, s[, signm=1, signn=1])\)

Ellipsoidal harmonic functions \(E^p_n(l)\)
These are also known as Lame functions of the first kind, and are solutions to the Lame equation:

\[(s^2 - h^2)(s^2 - k^2)E''(s) + s(2s^2 - h^2 - k^2)E'(s) + (a - qs^2)E(s) = 0\]

where \(q = (n + 1)n\) and \(a\) is the eigenvalue (not returned) corresponding to the solutions.

**Parameters**

- \(h^2\) [float] \(h**2\)
- \(k^2\) [float] \(k**2\); should be larger than \(h**2\)
- \(n\) [int] Degree
- \(s\) [float] Coordinate
- \(p\) [int] Order, can range between \([1,2n+1]\)
- \(\text{signm}\) \([\{1,-1\}, \text{optional}]\) Sign of prefactor of functions. Can be +/-1. See Notes.
- \(\text{signn}\) \([\{1,-1\}, \text{optional}]\) Sign of prefactor of functions. Can be +/-1. See Notes.

**Returns**

- \(E\) [float] the harmonic \(E_n^p(s)\)

See also:

`ellip_harm_2`, `ellip_normal`

**Notes**

The geometric interpretation of the ellipsoidal functions is explained in [2], [3], [4]. The \(\text{signm}\) and \(\text{signn}\) arguments control the sign of prefactors for functions according to their type:

- \(K\) : +1
- \(L\) : \(\text{signm}\)
- \(M\) : \(\text{signn}\)
- \(N\) : \(\text{signm}^\ast\text{signn}\)

New in version 0.15.0.

**References**

[1], [2], [3], [4]

**Examples**

```python
>>> from scipy.special import ellip_harm
>>> w = ellip_harm(5, 8, 1, 1, 2.5)
>>> w
2.5
```

Check that the functions indeed are solutions to the Lame equation:

```python
>>> from scipy.interpolate import UnivariateSpline
>>> def eigenvalue(f, df, ddf):
...     r = ((s**2 - h**2)*(s**2 - k**2)*ddf + s*(2*s**2 - h**2 - k**2)*df - n*(n+1)*s**2*f)/f
...     return -r.mean(), r.std()
...r = ((s**2 - h**2)*(s**2 - k**2)*ddf + s*(2*s**2 - h**2 - k**2)*df - n*(n+1)*s**2*f)/f
...return -r.mean(), r.std()
```

(continues on next page)
```python
>>> s = np.linspace(0.1, 10, 200)
>>> k, h, n, p = 8.0, 2.2, 3, 2
>>> E = ellip_harm(h**2, k**2, n, p, s)
>>> E_spl = UnivariateSpline(s, E)
>>> a, a_err = eigenvalue(E_spl(s), E_spl(s, 1), E_spl(s, 2))
>>> a, a_err
(583.44366156701483, 6.4580890640310646e-11)
```

**scipy.special.ellip_harm_2**

The ellip_harm_2 function corresponds to the second kind of Lame harmonic functions $F^{p}_n(l)$.

These are also known as Lame functions of the second kind, and are solutions to the Lame equation:

\[
(s^2 - h^2)(s^2 - k^2)F''(s) + s(2s^2 - h^2 - k^2)F'(s) + (a - qs^2)F(s) = 0
\]

where $q = (n + 1)n$ and $a$ is the eigenvalue (not returned) corresponding to the solutions.

**Parameters**

- `h2` : [float] \(h^2\)
- `k2` : [float] \(k^2\); should be larger than \(h^2\)
- `n` : [int] Degree.
- `p` : [int] Order, can range between \([1, 2n+1]\).
- `s` : [float] Coordinate

**Returns**

- `F` : [float] The harmonic \(F^{p}_n(s)\)

See also:

- `ellip_harm`, `ellip_normal`

**Notes**

Lame functions of the second kind are related to the functions of the first kind:

\[
F^{p}_n(s) = (2n + 1)E^{p}_n(s) \int_0^{1/s} \frac{du}{(E^{p}_n(1/u))^2 \sqrt{(1 - u^2k^2)(1 - u^2h^2)}}
\]

New in version 0.15.0.

**Examples**

```python
>>> from scipy.special import ellip_harm_2
>>> w = ellip_harm_2(5, 8, 2, 1, 10)
>>> w
0.00108056853382
```
scipy.special.ellip_normal

scipy.special.ellip_normal(h2, k2, n, p)

Ellipsoidal harmonic normalization constants \( \gamma^p_n \)

The normalization constant is defined as

\[
\gamma^p_n = 8 \int_0^h dx \int_h^k dy \frac{(y^2 - x^2)(E_p(y)E_n(x))^2}{\sqrt{(k^2 - y^2)(y^2 - h^2)(h^2 - x^2)(k^2 - x^2)}}
\]

**Parameters**

- **h2** [float] \( h^2 \)
- **k2** [float] \( k^2 \); should be larger than \( h^2 \)
- **n** [int] Degree.
- **p** [int] Order, can range between \([1, 2n+1]\).

**Returns**

- **gamma** [float] The normalization constant \( \gamma^p_n \)

See also:

ellip_harm, ellip_harm_2

**Notes**

New in version 0.15.0.

**Examples**

```python
>>> from scipy.special import ellip_normal
>>> w = ellip_normal(5, 8, 3, 7)
>>> w
1723.38796997
```

**scipy.special.assoc_laguerre**

`scipy.special.assoc_laguerre(x, n, k=0.0)`  
  Compute the generalized (associated) Laguerre polynomial of degree n and order k.

  The polynomial $L_n^{(k)}(x)$ is orthogonal over $[0, \infty)$, with weighting function $\exp(-x) * x^k$ with $k > -1$.

**Notes**

`assoc_laguerre` is a simple wrapper around `eval_genlaguerre`, with reversed argument order $(x, n, k=0.0) \rightarrow (n, k, x)$.

**scipy.special.eval_legendre**

`scipy.special.eval_legendre(n, x, out=None)`  
  Evaluate Legendre polynomial at a point.

  The Legendre polynomials can be defined via the Gauss hypergeometric function $2F_1$ as

  $$P_n(x) = 2F_1(-n, n + 1; 1; (1 - x)/2).$$

  When n is an integer the result is a polynomial of degree n.

**Parameters**

- `n`  
  [array_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.

- `x`  
  [array_like] Points at which to evaluate the Legendre polynomial

**Returns**

- `P`  
  [ndarray] Values of the Legendre polynomial

**See also:**

- `roots_legendre`  
  roots and quadrature weights of Legendre polynomials

- `legendre`  
  Legendre polynomial object

- `hyp2f1`  
  Gauss hypergeometric function
**numpy.polynomial.legendre.Legendre**

Legendre series

**scipy.special.eval_chebyt**

```python
def scipy.special.eval_chebyt(n, x, out=None):
    """ufunc 'eval_chebyt'"
    Evaluate Chebyshev polynomial of the first kind at a point.

    The Chebyshev polynomials of the first kind can be defined via the Gauss hypergeometric function \( {}_2F_1 \) as
    \[
    T_n(x) = {}_2F_1(n, -n; 1/2; (1 - x)/2).
    \]

    When \( n \) is an integer the result is a polynomial of degree \( n \).

    **Parameters**
    
    n : array_like
        Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
    x : array_like
        Points at which to evaluate the Chebyshev polynomial

    **Returns**
    
    T : ndarray
        Values of the Chebyshev polynomial
```

See also:

- **roots_chebyt**
  roots and quadrature weights of Chebyshev polynomials of the first kind
- **chebyu**
  Chebyshev polynomial object
- **eval_chebyu**
  evaluate Chebyshev polynomials of the second kind
- **hyp2f1**
  Gauss hypergeometric function

**Notes**

This routine is numerically stable for \( x \) in \([-1, 1]\) at least up to order 10000.

**scipy.special.eval_chebyu**

```python
def scipy.special.eval_chebyu(n, x, out=None):
    """ufunc 'eval_chebyu'"
    Evaluate Chebyshev polynomial of the second kind at a point.

    The Chebyshev polynomials of the second kind can be defined via the Gauss hypergeometric function \( {}_2F_1 \) as
    \[
    U_n(x) = (n + 1) {}_2F_1(-n, n + 2; 3/2; (1 - x)/2).
    \]

    When \( n \) is an integer the result is a polynomial of degree \( n \).

    **Parameters**
    
    n : array_like
        Degree of the polynomial.
n [array_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
x [array_like] Points at which to evaluate the Chebyshev polynomial

Returns
U [ndarray] Values of the Chebyshev polynomial

See also:

roots_chebyu
roots and quadrature weights of Chebyshev polynomials of the second kind

chebyu
Chebyshev polynomial object
eval_chebyt
evaluate Chebyshev polynomials of the first kind

hyp2f1
Gauss hypergeometric function

scipy.special.eval_chebyc
scipy.special.eval_chebyc(n, x, out=None) = <ufunc 'eval_chebyc'>
Evaluate Chebyshev polynomial of the first kind on [-2, 2] at a point.

These polynomials are defined as
\[ S_n(x) = T_n(x/2) \]

where \( T_n \) is a Chebyshev polynomial of the first kind.

Parameters
n [array_like] Degree of the polynomial. If not an integer, the result is determined via the relation to eval_chebyt.
x [array_like] Points at which to evaluate the Chebyshev polynomial

Returns
C [ndarray] Values of the Chebyshev polynomial

See also:

roots_chebyc
roots and quadrature weights of Chebyshev polynomials of the first kind on [-2, 2]

chebyc
Chebyshev polynomial object

numpy.polynomial.chebyshev.Chebyshev
Chebyshev series
eval_chebyt
evaluate Chebyshev polynomials of the first kind
scipy.special.eval_chebys

scipy.special.eval_chebys(n, x, out=None) = <ufunc 'eval_chebys'>
Evaluate Chebyshev polynomial of the second kind on [-2, 2] at a point.

These polynomials are defined as

\[ S_n(x) = U_n(x/2) \]

where \( U_n \) is a Chebyshev polynomial of the second kind.

Parameters

- n [array_like] Degree of the polynomial. If not an integer, the result is determined via the relation to eval_chebyu.
- x [array_like] Points at which to evaluate the Chebyshev polynomial

Returns

- S [ndarray] Values of the Chebyshev polynomial

See also:

- roots_chebys
  roots and quadrature weights of Chebyshev polynomials of the second kind on [-2, 2]
- chebys
  Chebyshev polynomial object
- eval_chebyu
  evaluate Chebyshev polynomials of the second kind

scipy.special.eval_jacobi

scipy.special.eval_jacobi(n, alpha, beta, x, out=None) = <ufunc 'eval_jacobi'>
Evaluate Jacobi polynomial at a point.

The Jacobi polynomials can be defined via the Gauss hypergeometric function \( _2F_1 \) as

\[ P_n^{(\alpha,\beta)}(x) = \frac{(\alpha + 1)_n}{\Gamma(n + 1)} \frac{\alpha + \beta + n + 1}{2} \frac{\Gamma(-n, 1 + \alpha + \beta + n; \alpha + 1; (1 - z)/2)}{2F_1(-n, 1 + \alpha + \beta + n; \alpha + 1; (1 - z)/2)} \]

where \( (\cdot)_n \) is the Pochhammer symbol; see poch. When \( n \) is an integer the result is a polynomial of degree \( n \).

Parameters

- n [array_like] Degree of the polynomial. If not an integer the result is determined via the relation to the Gauss hypergeometric function.
- alpha [array_like] Parameter
- beta [array_like] Parameter
- x [array_like] Points at which to evaluate the polynomial

Returns

- P [ndarray] Values of the Jacobi polynomial

See also:

- roots_jacobi
  roots and quadrature weights of Jacobi polynomials
jacobi

Jacobi polynomial object

hyp2f1

Gauss hypergeometric function

scipy.special.eval_laguerre

scipy.special.eval_laguerre(n, x, out=None) = <ufunc 'eval_laguerre'>

Evaluate Laguerre polynomial at a point.

The Laguerre polynomials can be defined via the confluent hypergeometric function \( _1F_1 \) as

\[
L_n(x) = _1F_1(-n, 1, x).
\]

When \( n \) is an integer the result is a polynomial of degree \( n \).

Parameters

- \( n \) [array_like] Degree of the polynomial. If not an integer the result is determined via the relation to the confluent hypergeometric function.
- \( x \) [array_like] Points at which to evaluate the Laguerre polynomial

Returns

- \( L \) [ndarray] Values of the Laguerre polynomial

See also:

- roots_laguerre
  roots and quadrature weights of Laguerre polynomials
- laguerre
  Laguerre polynomial object
- numpy.polynomial.laguerre.Laguerre
  Laguerre series
- eval_genlaguerre
  evaluate generalized Laguerre polynomials

scipy.special.eval_genlaguerre

scipy.special.eval_genlaguerre(n, alpha, x, out=None) = <ufunc 'eval_genlaguerre'>

Evaluate generalized Laguerre polynomial at a point.

The generalized Laguerre polynomials can be defined via the confluent hypergeometric function \( _1F_1 \) as

\[
L_n^{(\alpha)}(x) = \binom{n + \alpha}{n} _1F_1(-n, \alpha + 1, x).
\]

When \( n \) is an integer the result is a polynomial of degree \( n \). The Laguerre polynomials are the special case where \( \alpha = 0 \).

Parameters

- \( n \) [array_like] Degree of the polynomial. If not an integer the result is determined via the relation to the confluent hypergeometric function.
**alpha** [array_like] Parameter; must have \( \alpha > -1 \)

**x** [array_like] Points at which to evaluate the generalized Laguerre polynomial

**Returns**

**L** [ndarray] Values of the generalized Laguerre polynomial

See also:

**roots_genlaguerre**
roots and quadrature weights of generalized Laguerre polynomials

**genlaguerre**
generalized Laguerre polynomial object

**hyp1f1**
confluent hypergeometric function

**eval_laguerre**
evaluate Laguerre polynomials

**scipy.special.eval_hermite**

**scipy.special.eval_hermite**(n, x, out=None) = <ufunc 'eval_hermite'>
Evaluate physicist’s Hermite polynomial at a point.

Defined by

\[ H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2}; \]

\( H_n \) is a polynomial of degree \( n \).

**Parameters**

**n** [array_like] Degree of the polynomial

**x** [array_like] Points at which to evaluate the Hermite polynomial

**Returns**

**H** [ndarray] Values of the Hermite polynomial

See also:

**roots_hermite**
roots and quadrature weights of physicist’s Hermite polynomials

**hermite**
physicist’s Hermite polynomial object

**numpy.polynomial.hermite.Hermite**
Physicist’s Hermite series

**eval_hermitenorm**
evaluate Probabilist’s Hermite polynomials
```
scipy.special.eval_hermitenorm

scipy.special.eval_hermitenorm(n, x, out=None) = <ufunc 'eval_hermitenorm'>

Evaluate probabilist's (normalized) Hermite polynomial at a point.

Defined by

\[ H_n(x) = (-1)^n e^{x^2/2} \frac{d^n}{dx^n} e^{-x^2/2}; \]

\( H_n \) is a polynomial of degree \( n \).

**Parameters**

- `n` [array_like]: Degree of the polynomial
- `x` [array_like]: Points at which to evaluate the Hermite polynomial

**Returns**

- `He` [ndarray]: Values of the Hermite polynomial

**See also:**

- `roots_hermitenorm`
  
  roots and quadrature weights of probabilist’s Hermite polynomials

- `hermitenorm`
  
  probabilist’s Hermite polynomial object

- `numpy.polynomial.hermite_e.HermiteE`
  
  Probabilist’s Hermite series

- `eval_hermite`
  
  evaluate physicist’s Hermite polynomials

```

```
scipy.special.eval_gegenbauer

scipy.special.eval_gegenbauer(n, alpha, x, out=None) = <ufunc 'eval_gegenbauer'>

Evaluate Gegenbauer polynomial at a point.

The Gegenbauer polynomials can be defined via the Gauss hypergeometric function \( {}_2F_1 \) as

\[ C_n^{(\alpha)} = \frac{(2\alpha)_n}{\Gamma(n+1)} {}_2F_1(-n, 2\alpha + n; \alpha + 1/2; (1 - z)/2). \]

When \( n \) is an integer the result is a polynomial of degree \( n \).

**Parameters**

- `n` [array_like]: Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
- `alpha` [array_like]: Parameter
- `x` [array_like]: Points at which to evaluate the Gegenbauer polynomial

**Returns**

- `C` [ndarray]: Values of the Gegenbauer polynomial

**See also:**

- `roots_gegenbauer`
  
  roots and quadrature weights of Gegenbauer polynomials
```
**gegenbauer**
Gegenbauer polynomial object

**hyp2f1**
Gauss hypergeometric function

**scipy.special.eval_sh_legendre**

```python
scipy.special.eval_sh_legendre(n, x, out=None) = <ufunc 'eval_sh_legendre'>
```
Evaluate shifted Legendre polynomial at a point.

These polynomials are defined as

$$P_n^*(x) = P_n(2x - 1)$$

where $P_n$ is a Legendre polynomial.

**Parameters**

- **n** [array_like] Degree of the polynomial. If not an integer, the value is determined via the relation to `eval_legendre`.
- **x** [array_like] Points at which to evaluate the shifted Legendre polynomial

**Returns**

- **P** [ndarray] Values of the shifted Legendre polynomial

**See also:**

- **roots_sh_legendre**
  roots and quadrature weights of shifted Legendre polynomials

- **sh_legendre**
  shifted Legendre polynomial object

- **eval_legendre**
  evaluate Legendre polynomials

- **numpy.polynomial.legendre.Legendre**
  Legendre series

**scipy.special.eval_sh_chebyt**

```python
scipy.special.eval_sh_chebyt(n, x, out=None) = <ufunc 'eval_sh_chebyt'>
```
Evaluate shifted Chebyshev polynomial of the first kind at a point.

These polynomials are defined as

$$T_n^*(x) = T_n(2x - 1)$$

where $T_n$ is a Chebyshev polynomial of the first kind.

**Parameters**

- **n** [array_like] Degree of the polynomial. If not an integer, the result is determined via the relation to `eval_chebyt`.
- **x** [array_like] Points at which to evaluate the shifted Chebyshev polynomial

**Returns**
T  [ndarray] Values of the shifted Chebyshev polynomial

See also:

roots_sh_chebyt
roots and quadrature weights of shifted Chebyshev polynomials of the first kind

sh_chebyt
shifted Chebyshev polynomial object
eval_chebyt
evaluate Chebyshev polynomials of the first kind

numpy.polynomial.chebyshev.Chebyshev
Chebyshev series

scipy.special.eval_sh_chebyu

scipy.special.eval_sh_chebyu(n, x, out=None) = <ufunc 'eval_sh_chebyu'>
Evaluate shifted Chebyshev polynomial of the second kind at a point.

These polynomials are defined as

\[ U_n(x) = U_n(2x - 1) \]

where \( U_n \) is a Chebyshev polynomial of the first kind.

Parameters

n  [array_like] Degree of the polynomial. If not an integer, the result is determined via the relation to eval_chebyu.
x  [array_like] Points at which to evaluate the shifted Chebyshev polynomial

Returns

U  [ndarray] Values of the shifted Chebyshev polynomial

See also:

roots_sh_chebyu
roots and quadrature weights of shifted Chebyshev polynomials of the second kind

sh_chebyu
shifted Chebyshev polynomial object
eval_chebyu
evaluate Chebyshev polynomials of the second kind

scipy.special.eval_sh_jacobi

scipy.special.eval_sh_jacobi(n, p, q, x, out=None) = <ufunc 'eval_sh_jacobi'>
Evaluate shifted Jacobi polynomial at a point.

Defined by

\[ G_{n}^{(p,q)}(x) = \binom{2n + p - 1}{n}^{-1} P_{n}^{(p-q,q-1)}(2x - 1), \]

where \( P_{n}^{(\cdot, \cdot)} \) is the n-th Jacobi polynomial.
Parameters

- **n** [int] Degree of the polynomial. If not an integer, the result is determined via the relation to `binom` and `eval_jacobi`.
- **p** [float] Parameter
- **q** [float] Parameter

Returns

- **G** [ndarray] Values of the shifted Jacobi polynomial.

See also:

- `roots_sh_jacobi`
  roots and quadrature weights of shifted Jacobi polynomials
- `sh_jacobi`
  shifted Jacobi polynomial object
- `eval_jacobi`
  evaluate Jacobi polynomials

The following functions compute roots and quadrature weights for orthogonal polynomials:

```python
roots_legendre(n[, mu])
Gauss-Legendre quadrature.

roots_chebyt(n[, mu])
Gauss-Chebyshev (first kind) quadrature.

roots_chebyu(n[, mu])
Gauss-Chebyshev (second kind) quadrature.

roots_chebys(n[, mu])
Gauss-Chebyshev (second kind) quadrature.

roots_jacobi(n, alpha, beta[, mu])
Gauss-Jacobi quadrature.

roots_laguerre(n[, mu])
Gauss-Laguerre quadrature.

roots_genlaguerre(n, alpha[, mu])
Gauss-generalized Laguerre quadrature.

roots_hermite(n[, mu])
Gauss-Hermite (physicist’s) quadrature.

roots_hermitenorm(n[, mu])
Gauss-Hermite (statistician’s) quadrature.

roots_gegenbauer(n, alpha[, mu])
Gauss-Gegenbauer quadrature.

roots_sh_legendre(n[, mu])
Gauss-Legendre (shifted) quadrature.

roots_sh_chebyt(n[, mu])
Gauss-Chebyshev (first kind, shifted) quadrature.

roots_sh_chebyu(n[, mu])
Gauss-Chebyshev (second kind, shifted) quadrature.

roots_sh_jacobi(n, p, q[, mu])
Gauss-Jacobi (shifted) quadrature.
```

**scipy.special.roots_legendre**

scipy.special.roots_legendre(n, mu=False)
Gauss-Legendre quadrature.

Computes the sample points and weights for Gauss-Legendre quadrature. The sample points are the roots of the n-th degree Legendre polynomial \(P_n(x)\). These sample points and weights correctly integrate polynomials of degree \(2n - 1\) or less over the interval \([-1, 1]\] with weight function \(f(x) = 1.0\).

Parameters

- **n** [int] Quadrature order
- **mu** [bool, optional] If True, return the sum of the weights, optional.

Returns

- **x** [ndarray] Sample points
w [ndarray] Weights
mu [float] Sum of the weights

See also:

scipy.integrate.quadrature
scipy.integrate.fixed_quad
numpy.polynomial.orthogonal.orthgauss

scipy.special.roots_chebyt

scipy.special.roots_chebyt(n, mu=False)
Gauss-Chebyshev (first kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the n-th degree Chebyshev polynomial of the first kind, $T_n(x)$. These sample points and weights correctly integrate polynomials of degree $2n - 1$ or less over the interval $[-1, 1]$ with weight function $f(x) = 1/\sqrt{1-x^2}$.

Parameters

n [int] quadrature order
mu [bool, optional] If True, return the sum of the weights, optional.

Returns

x [ndarray] Sample points
w [ndarray] Weights
mu [float] Sum of the weights

See also:

scipy.integrate.quadrature
scipy.integrate.fixed_quad
numpy.polynomial.chebyshev.chebgauss

scipy.special.roots_chebyu

scipy.special.roots_chebyu(n, mu=False)
Gauss-Chebyshev (second kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the n-th degree Chebyshev polynomial of the second kind, $U_n(x)$. These sample points and weights correctly integrate polynomials of degree $2n - 1$ or less over the interval $[-1, 1]$ with weight function $f(x) = \sqrt{1-x^2}$.

Parameters

n [int] quadrature order
mu [bool, optional] If True, return the sum of the weights, optional.

Returns

x [ndarray] Sample points
w [ndarray] Weights
mu [float] Sum of the weights

See also:

scipy.integrate.quadrature
scipy.integrate.fixed_quad
**scipy.special.roots_chebyc**

`scipy.special.roots_chebyc(n, mu=False)`

Gauss-Chebyshev (first kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the \( n \)-th degree Chebyshev polynomial of the first kind, \( C_n(x) \). These sample points and weights correctly integrate polynomials of degree \( 2n - 1 \) or less over the interval \([-2, 2]\) with weight function \( f(x) = 1/\sqrt{1 - (x/2)^2} \).

**Parameters**

- `n` [int] quadrature order
- `mu` [bool, optional] If True, return the sum of the weights, optional.

**Returns**

- `x` [ndarray] Sample points
- `w` [ndarray] Weights
- `mu` [float] Sum of the weights

See also:

- `scipy.integrate.quadrature`
- `scipy.integrate.fixed_quad`

**scipy.special.roots_chebys**

`scipy.special.roots_chebys(n, mu=False)`

Gauss-Chebyshev (second kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the \( n \)-th degree Chebyshev polynomial of the second kind, \( S_n(x) \). These sample points and weights correctly integrate polynomials of degree \( 2n - 1 \) or less over the interval \([-2, 2]\) with weight function \( f(x) = \sqrt{1 - (x/2)^2} \).

**Parameters**

- `n` [int] quadrature order
- `mu` [bool, optional] If True, return the sum of the weights, optional.

**Returns**

- `x` [ndarray] Sample points
- `w` [ndarray] Weights
- `mu` [float] Sum of the weights

See also:

- `scipy.integrate.quadrature`
- `scipy.integrate.fixed_quad`

**scipy.special.roots_jacobi**

`scipy.special.roots_jacobi(n, alpha, beta, mu=False)`

Gauss-Jacobi quadrature.

Computes the sample points and weights for Gauss-Jacobi quadrature. The sample points are the roots of the \( n \)-th degree Jacobi polynomial, \( P_n^{\alpha, \beta}(x) \). These sample points and weights correctly integrate polynomials of degree \( 2n - 1 \) or less over the interval \([-1, 1]\) with weight function \( f(x) = (1 - x)^\alpha(1 + x)^\beta \).

**Parameters**

- `n` [int] quadrature order
SciPy Reference Guide, Release 1.3.2

**alpha** [float] alpha must be > -1

**beta** [float] beta must be > -1

**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

- **x** [ndarray] Sample points
- **w** [ndarray] Weights
- **mu** [float] Sum of the weights

See also:

- *scipy.integrate.quadrature*
- *scipy.integrate.fixed_quad*

**scipy.special.roots_laguerre**

*scipy.special.roots_laguerre*(n, mu=False)

Gauss-Laguerre quadrature.

Computes the sample points and weights for Gauss-Laguerre quadrature. The sample points are the roots of the n-th degree Laguerre polynomial, \( L_n(x) \). These sample points and weights correctly integrate polynomials of degree \( 2n - 1 \) or less over the interval \([0, \infty]\) with weight function \( f(x) = e^{-x} \).

**Parameters**

- **n** [int] quadrature order
- **mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

- **x** [ndarray] Sample points
- **w** [ndarray] Weights
- **mu** [float] Sum of the weights

See also:

- *scipy.integrate.quadrature*
- *scipy.integrate.fixed_quad*
- *numpy.polynomial.laguerre.laggauss*

**scipy.special.roots_genlaguerre**

*scipy.special.roots_genlaguerre*(n, alpha, mu=False)

Gauss-generalized Laguerre quadrature.

Computes the sample points and weights for Gauss-generalized Laguerre quadrature. The sample points are the roots of the n-th degree generalized Laguerre polynomial, \( L_n^{\alpha}(x) \). These sample points and weights correctly integrate polynomials of degree \( 2n - 1 \) or less over the interval \([0, \infty]\) with weight function \( f(x) = x^\alpha e^{-x} \).

**Parameters**

- **n** [int] quadrature order
- **alpha** [float] alpha must be > -1
- **mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

- **x** [ndarray] Sample points
- **w** [ndarray] Weights
mu [float] Sum of the weights

See also:

scipy.integrate.quadrature
scipy.integrate.fixed_quad

scipy.special.roots_hermite

scipy.special.roots_hermite(n, mu=False)
Gauss-Hermite (physicist's) quadrature.

Computes the sample points and weights for Gauss-Hermite quadrature. The sample points are the roots of the n-th degree Hermite polynomial, $H_n(x)$. These sample points and weights correctly integrate polynomials of degree $2n - 1$ or less over the interval $[-\infty, \infty]$ with weight function $f(x) = e^{-x^2}$.

Parameters

n [int] quadrature order
mu [bool, optional] If True, return the sum of the weights, optional.

Returns

x [ndarray] Sample points
w [ndarray] Weights
mu [float] Sum of the weights

See also:

scipy.integrate.quadrature
scipy.integrate.fixed_quad
numpy.polynomial.hermite.hermgauss
roots_hermitenorm

Notes

For small n up to 150 a modified version of the Golub-Welsch algorithm is used. Nodes are computed from the eigenvalue problem and improved by one step of a Newton iteration. The weights are computed from the well-known analytical formula.

For n larger than 150 an optimal asymptotic algorithm is applied which computes nodes and weights in a numerically stable manner. The algorithm has linear runtime making computation for very large n (several thousand or more) feasible.

scipy.special.roots_hermitenorm

scipy.special.roots_hermitenorm(n, mu=False)
Gauss-Hermite (statistician's) quadrature.

Computes the sample points and weights for Gauss-Hermite quadrature. The sample points are the roots of the n-th degree Hermite polynomial, $He_n(x)$. These sample points and weights correctly integrate polynomials of degree $2n - 1$ or less over the interval $[-\infty, \infty]$ with weight function $f(x) = e^{-x^2/2}$. 

6.27. Special functions (scipy.special)
Parameters

`n` [int] quadrature order
`mu` [bool, optional] If True, return the sum of the weights, optional.

Returns

`x` [ndarray] Sample points
`w` [ndarray] Weights
`mu` [float] Sum of the weights

`scipy.special.roots_gegenbauer`

`scipy.special.roots_gegenbauer(n, alpha, mu=False)`
Gauss-Gegenbauer quadrature.

Computes the sample points and weights for Gauss-Gegenbauer quadrature. The sample points are the roots of the \( n \)-th degree Gegenbauer polynomial, \( C_{2n}^\alpha(x) \). These sample points and weights correctly integrate polynomials of degree \( 2n - 1 \) or less over the interval \([-1, 1]\) with weight function \( f(x) = (1 - x^2)^{\alpha-1/2} \).

Parameters

`n` [int] quadrature order
`alpha` [float] alpha must be > -0.5
`mu` [bool, optional] If True, return the sum of the weights, optional.

Returns

`x` [ndarray] Sample points
`w` [ndarray] Weights
`mu` [float] Sum of the weights

See also:

`scipy.integrate.quadrature`
`scipy.integrate.fixed_quad`
scipy.special.roots_sh_legendre

Gauss-Legendre (shifted) quadrature.

Computes the sample points and weights for Gauss-Legendre quadrature. The sample points are the roots of the n-th degree shifted Legendre polynomial $P_n^*(x)$. These sample points and weights correctly integrate polynomials of degree $2n - 1$ or less over the interval $[0, 1]$ with weight function $f(x) = 1.0$.

Parameters

- **n** [int] quadrature order
- **mu** [bool, optional] If True, return the sum of the weights, optional.

Returns

- **x** [ndarray] Sample points
- **w** [ndarray] Weights
- **mu** [float] Sum of the weights

See also:

- scipy.integrate.quadrature
- scipy.integrate.fixed_quad

scipy.special.roots_sh_chebyt

Gauss-Chebyshev (first kind, shifted) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the n-th degree shifted Chebyshev polynomial of the first kind, $T_n(x)$. These sample points and weights correctly integrate polynomials of degree $2n - 1$ or less over the interval $[0, 1]$ with weight function $f(x) = 1/\sqrt{1-x^2}$.

Parameters

- **n** [int] quadrature order
- **mu** [bool, optional] If True, return the sum of the weights, optional.

Returns

- **x** [ndarray] Sample points
- **w** [ndarray] Weights
- **mu** [float] Sum of the weights

See also:

- scipy.integrate.quadrature
- scipy.integrate.fixed_quad

scipy.special.roots_sh_chebyu

Gauss-Chebyshev (second kind, shifted) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the n-th degree shifted Chebyshev polynomial of the second kind, $U_n(x)$. These sample points and weights correctly integrate polynomials of degree $2n - 1$ or less over the interval $[0, 1]$ with weight function $f(x) = \sqrt{x-x^2}$.

Parameters

- **n** [int] quadrature order
SciPy Reference Guide, Release 1.3.2

```
mu [bool, optional] If True, return the sum of the weights, optional.

Returns
x [ndarray] Sample points
w [ndarray] Weights
mu [float] Sum of the weights

See also:
scipy.integrate.quadrature
scipy.integrate.fixed_quad

scipy.special.roots_sh_jacobi
scipy.special.roots_sh_jacobi(n, p1, q1, mu=False)
Gauss-Jacobi (shifted) quadrature.
Computes the sample points and weights for Gauss-Jacobi (shifted) quadrature. The sample points are the roots of the n-th degree shifted Jacobi polynomial, \( G^{p,q}_n(x) \). These sample points and weights correctly integrate polynomials of degree \( 2n - 1 \) or less over the interval \([0, 1]\) with weight function \( f(x) = (1 - x)^{p-q}x^{q-1} \)

Parameters
n [int] quadrature order
p1 [float] \((p1 - q1)\) must be > -1
q1 [float] \(q1\) must be > 0
mu [bool, optional] If True, return the sum of the weights, optional.

Returns
x [ndarray] Sample points
w [ndarray] Weights
mu [float] Sum of the weights

See also:
scipy.integrate.quadrature
scipy.integrate.fixed_quad

The functions below, in turn, return the polynomial coefficients in orthopoly1d objects, which function similarly as numpy.poly1d. The orthopoly1d class also has an attribute weights which returns the roots, weights, and total weights for the appropriate form of Gaussian quadrature. These are returned in an \( n \times 3 \) array with roots in the first column, weights in the second column, and total weights in the final column. Note that orthopoly1d objects are converted to poly1d when doing arithmetic, and lose information of the original orthogonal polynomial.

**scipy.special.legendre**

scipy.special.legendre($n$, monic=False)

Legendre polynomial.

Defined to be the solution of

$$
\frac{d}{dx} \left[ (1 - x^2) \frac{d}{dx} P_n(x) \right] + n(n + 1) P_n(x) = 0;
$$

$P_n(x)$ is a polynomial of degree $n$.

**Parameters**

- $n$ [int] Degree of the polynomial.
- monic [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

**Returns**

- $P$ [orthopoly1d] Legendre polynomial.

**Notes**

The polynomials $P_n$ are orthogonal over $[-1, 1]$ with weight function 1.

**Examples**

Generate the 3rd-order Legendre polynomial $1/2*(5x^3 + 0x^2 - 3x + 0)$:

```python
>>> from scipy.special import legendre
>>> legendre(3)
poly1d([ 2.5, 0. , -1.5, 0. ])
```

**scipy.special.chebyt**

scipy.special.chebyt($n$, monic=False)

Chebyshev polynomial of the first kind.

Defined to be the solution of

$$
(1 - x^2) \frac{d^2}{dx^2} T_n - x \frac{d}{dx} T_n + n^2 T_n = 0;
$$

$T_n$ is a polynomial of degree $n$.

**Parameters**

- $n$ [int] Degree of the polynomial.
- monic [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

**Returns**

- $T$ [orthopoly1d] Chebyshev polynomial of the first kind.
See also:

`chebyu`

Chebyshev polynomial of the second kind.

**Notes**

The polynomials $T_n$ are orthogonal over $[-1, 1]$ with weight function $(1 - x^2)^{-1/2}$.

`scipy.special.chebyu`

`scipy.special.chebyu(n, monic=False)`

Chebyshev polynomial of the second kind.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} U_n - 3x \frac{d}{dx} U_n + n(n+2)U_n = 0;$$

$U_n$ is a polynomial of degree $n$.

**Parameters**

- `n` [int] Degree of the polynomial.
- `monic` [bool, optional] If `True`, scale the leading coefficient to be 1. Default is `False`.

**Returns**

- `U` [orthopoly1d] Chebyshev polynomial of the second kind.

See also:

`chebyt`

Chebyshev polynomial of the first kind.

**Notes**

The polynomials $U_n$ are orthogonal over $[-1, 1]$ with weight function $(1 - x^2)^{1/2}$.

`scipy.special.chebyc`

`scipy.special.chebyc(n, monic=False)`

Chebyshev polynomial of the first kind on $[-2, 2]$.

Defined as $C_n(x) = 2 T_n(x/2)$, where $T_n$ is the nth Chebychev polynomial of the first kind.

**Parameters**

- `n` [int] Degree of the polynomial.
- `monic` [bool, optional] If `True`, scale the leading coefficient to be 1. Default is `False`.

**Returns**

- `C` [orthopoly1d] Chebyshev polynomial of the first kind on $[-2, 2]$.

See also:

`chebyt`

Chebyshev polynomial of the first kind.
Notes

The polynomials $C_n(x)$ are orthogonal over $[-2, 2]$ with weight function $1/\sqrt{1 - (x/2)^2}$.

References

[1]

scipy.special.chebys

scipy.special.chebys($n$, $monic=False$)

Chebyshev polynomial of the second kind on $[-2, 2]$.

Defined as $S_n(x) = U_n(x/2)$ where $U_n$ is the $n$th Chebychev polynomial of the second kind.

Parameters

- $n$: [int] Degree of the polynomial.
- $monic$: [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

Returns

- $S$: [orthopoly1d] Chebyshev polynomial of the second kind on $[-2, 2]$.

See also:

cheby

Chebyshev polynomial of the second kind

Notes

The polynomials $S_n(x)$ are orthogonal over $[-2, 2]$ with weight function $\sqrt{1 - (x/2)^2}$.

References

[1]

scipy.special.jacobi

scipy.special.jacobi($n$, $alpha$, $beta$, $monic=False$)

Jacobi polynomial.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} P_n^{(\alpha, \beta)} + (\beta - \alpha - (\alpha + \beta + 2)x) \frac{d}{dx} P_n^{(\alpha, \beta)} + n(n + \alpha + \beta + 1) P_n^{(\alpha, \beta)} = 0$$

for $\alpha, \beta > -1$; $P_n^{(\alpha, \beta)}$ is a polynomial of degree $n$.

Parameters

- $n$: [int] Degree of the polynomial.
- $alpha$: [float] Parameter, must be greater than -1.
- $beta$: [float] Parameter, must be greater than -1.
- $monic$: [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

Returns

- $P$: [orthopoly1d] Jacobi polynomial.
Notes

For fixed $\alpha, \beta$, the polynomials $P_n^{(\alpha,\beta)}$ are orthogonal over $[-1, 1]$ with weight function $(1 - x)^\alpha(1 + x)^\beta$.

**scipy.special.laguerre**

```
scipy.special.laguerre(n, monic=False)
```

Laguerre polynomial.

Defined to be the solution of

\[
x \frac{d^2}{dx^2} L_n + (1 - x) \frac{d}{dx} L_n + n L_n = 0;
\]

$L_n$ is a polynomial of degree $n$.

**Parameters**

- `n` [int] Degree of the polynomial.
- `monic` [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

**Returns**

- `L` [orthopoly1d] Laguerre Polynomial.

**Notes**

The polynomials $L_n$ are orthogonal over $[0, \infty)$ with weight function $e^{-x}$.

**scipy.special.genlaguerre**

```
scipy.special.genlaguerre(n, alpha, monic=False)
```

Generalized (associated) Laguerre polynomial.

Defined to be the solution of

\[
x \frac{d^2}{dx^2} L_n^{(\alpha)} + (\alpha + 1 - x) \frac{d}{dx} L_n^{(\alpha)} + n L_n^{(\alpha)} = 0,
\]

where $\alpha > -1$; $L_n^{(\alpha)}$ is a polynomial of degree $n$.

**Parameters**

- `n` [int] Degree of the polynomial.
- `alpha` [float] Parameter, must be greater than -1.
- `monic` [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

**Returns**

**See also:**

- `laguerre`
  Laguerre polynomial.

**Notes**

For fixed $\alpha$, the polynomials $L_n^{(\alpha)}$ are orthogonal over $[0, \infty)$ with weight function $e^{-x}x^\alpha$.

The Laguerre polynomials are the special case where $\alpha = 0$. 

**scipy.special.hermite**

**scipy.special.hermite**(n, monic=False)

Physicist’s Hermite polynomial.

Defined by

\[ H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2}; \]

\( H_n \) is a polynomial of degree \( n \).

**Parameters**

- **n** [int] Degree of the polynomial.
- **monic** [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

**Returns**

- **H** [orthopoly1d] Hermite polynomial.

**Notes**

The polynomials \( H_n \) are orthogonal over \((-\infty, \infty)\) with weight function \( e^{-x^2} \).

**scipy.special.hermitenorm**

**scipy.special.hermitenorm**(n, monic=False)

Normalized (probabilist’s) Hermite polynomial.

Defined by

\[ H_n(x) = (-1)^n e^{x^2/2} \frac{d^n}{dx^n} e^{-x^2/2}; \]

\( H_n \) is a polynomial of degree \( n \).

**Parameters**

- **n** [int] Degree of the polynomial.
- **monic** [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

**Returns**

- **He** [orthopoly1d] Hermite polynomial.

**Notes**

The polynomials \( H_n \) are orthogonal over \((-\infty, \infty)\) with weight function \( e^{-x^2/2} \).

**scipy.special.gegenbauer**

**scipy.special.gegenbauer**(n, alpha, monic=False)

Gegenbauer (ultraspherical) polynomial.

Defined to be the solution of

\[ (1 - x^2) \frac{d^2}{dx^2} C_n^{(\alpha)} - (2\alpha + 1)x \frac{d}{dx} C_n^{(\alpha)} + n(n + 2\alpha)C_n^{(\alpha)} = 0 \]

for \( \alpha > -1/2; C_n^{(\alpha)} \) is a polynomial of degree \( n \).
Parameters

**n**  
[int] Degree of the polynomial.

**monic**  
[bool, optional] If True, scale the leading coefficient to be 1. Default is False.

Returns

**C**  
[orthopoly1d] Gegenbauer polynomial.

Notes

The polynomials $C_n^{(\alpha)}$ are orthogonal over $[-1, 1]$ with weight function $(1 - x^2)^{(\alpha-1/2)}$.

**scipy.special.sh_legendre**

**scipy.special.sh_legendre** *(n, monic=False)*

Shifted Legendre polynomial.

Defined as $P_n^*(x) = P_n(2x - 1)$ for $P_n$ the nth Legendre polynomial.

Parameters

**n**  
[int] Degree of the polynomial.

**monic**  
[bool, optional] If True, scale the leading coefficient to be 1. Default is False.

Returns

**P**  
[orthopoly1d] Shifted Legendre polynomial.

Notes

The polynomials $P_n^*$ are orthogonal over $[0, 1]$ with weight function 1.

**scipy.special.sh_chebyt**

**scipy.special.sh_chebyt** *(n, monic=False)*

Shifted Chebyshev polynomial of the first kind.

Defined as $T_n^*(x) = T_n(2x - 1)$ for $T_n$ the nth Chebyshev polynomial of the first kind.

Parameters

**n**  
[int] Degree of the polynomial.

**monic**  
[bool, optional] If True, scale the leading coefficient to be 1. Default is False.

Returns

**T**  
[orthopoly1d] Shifted Chebyshev polynomial of the first kind.

Notes

The polynomials $T_n^*$ are orthogonal over $[0, 1]$ with weight function $(x - x^2)^{-1/2}$.
**scipy.special.sh_chebyu**

```python
scipy.special.sh_chebyu(n,monic=False)
```

Shifted Chebyshev polynomial of the second kind.

Defined as \( U_n^*(x) = U_n(2x - 1) \) for \( U_n \) the \( n \)th Chebyshev polynomial of the second kind.

**Parameters**

- **n** [int] Degree of the polynomial.
- **monic** [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

**Returns**

- **U** [orthopoly1d] Shifted Chebyshev polynomial of the second kind.

**Notes**

The polynomials \( U_n^* \) are orthogonal over \([0, 1]\) with weight function \((x - x^2)^{1/2}\).

**scipy.special.sh_jacobi**

```python
scipy.special.sh_jacobi(n, p, q,monic=False)
```

Shifted Jacobi polynomial.

Defined by

\[
G_n^{(p,q)}(x) = \binom{2n + p - 1}{n}^{-1} P_n^{(p-q,q-1)}(2x - 1),
\]

where \( P_n^{(p,q)} \) is the \( n \)th Jacobi polynomial.

**Parameters**

- **n** [int] Degree of the polynomial.
- **p** [float] Parameter, must have \( p > q - 1 \).
- **q** [float] Parameter, must be greater than 0.
- **monic** [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

**Returns**

- **G** [orthopoly1d] Shifted Jacobi polynomial.

**Notes**

For fixed \( p, q \), the polynomials \( G_n^{(p,q)} \) are orthogonal over \([0, 1]\) with weight function \((1 - x)^{p-q} x^{q-1}\).

---

**Hypergeometric Functions**

- **hyp2f1(a, b, c, z)** Gauss hypergeometric function \( 2F1(a, b; c; z) \)
- **hyp1f1(a, b, x)** Confluent hypergeometric function \( 1F1(a, b; x) \)

**scipy.special.hyp2f1**

Gauss hypergeometric function 2F1(a, b; c; z)

Parameters:
- `a, b, c` : array_like, Arguments, should be real-valued.
- `z` : array_like, Argument, real or complex.

Returns:
- `hyp2f1` : scalar or ndarray, The values of the gaussian hypergeometric function.

See also:

- `hyp0f1`: confluent hypergeometric limit function.
- `hyp1f1`: Kummer’s (confluent hypergeometric) function.

Notes:

This function is defined for $|z| < 1$ as

$$hyp2f1(a, b, c, z) = \sum_{n=0}^{\infty} \frac{(a)_n(b)_n}{(c)_n} \frac{z^n}{n!},$$

and defined on the rest of the complex $z$-plane by analytic continuation. Here $(\cdot)_n$ is the Pochhammer symbol; see `poch`. When $n$ is an integer the result is a polynomial of degree $n$.

The implementation for complex values of $z$ is described in [1].

References:

[1], [2], [3]

**scipy.special.hyp1f1**

Confluent hypergeometric function 1F1(a, b; x)

Parameters:
- `a, b` : array_like, Arguments, should be real-valued.
- `x` : array_like, Argument, real or complex.

Returns:
- `hyp1f1` : scalar or ndarray, The values of the confluent hypergeometric function.

Notes:

Kummer’s (confluent hypergeometric) function.
**SciPy Reference Guide, Release 1.3.2**

**scipy.special.hyperu**

```python
scipy.special.hyperu(a, b, x) = <ufunc 'hyperu'>
```

Confluent hypergeometric function \( U(a, b, x) \) of the second kind.

**scipy.special.hyp0f1**

```python
scipy.special.hyp0f1(v, x) = <ufunc 'hyp0f1'>
```

Confluent hypergeometric limit function \( {}_0F_1 \).

**Parameters**

- **v**, **z**
  - `[array_like]` Input values.

**Returns**

- **hyp0f1**
  - `[ndarray]` The confluent hypergeometric limit function.

**Notes**

This function is defined as:

\[
{}_0F_1(v, z) = \sum_{k=0}^{\infty} \frac{z^k}{(v)_k k!}.
\]

It’s also the limit as \( q \to \infty \) of \( {}_1F_1(q; v; z/q) \), and satisfies the differential equation \( f''(z) + vf'(z) = f(z) \).

**scipy.special.hyp2f0**

```python
scipy.special.hyp2f0(a, b, x, type)
```

`hyp2f0` is deprecated! `hyp2f0` is deprecated in SciPy 1.2

Hypergeometric function \( {}_2F_0 \) in \( y \) and an error estimate.

The parameter \( type \) determines a convergence factor and can be either 1 or 2.

**Returns**

- **y** Value of the function
- **err** Error estimate

**scipy.special.hyp1f2**

```python
scipy.special.hyp1f2(a, b, c, x)
```

`hyp1f2` is deprecated! `hyp1f2` is deprecated in SciPy 1.2

Hypergeometric function \( {}_1F_2 \) and error estimate.

**Returns**

- **y** Value of the function
- **err** Error estimate

**scipy.special.hyp3f0**

```python
scipy.special.hyp3f0(a, b, c, x)
```

`hyp3f0` is deprecated! `hyp3f0` is deprecated in SciPy 1.2

Hypergeometric function \( {}_3F_0 \) in \( y \) and an error estimate.

**Returns**

- **y** Value of the function
- **err** Error estimate
Parabolic Cylinder Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>pbdv</strong></td>
<td>Parabolic cylinder function D</td>
</tr>
<tr>
<td><strong>pbvv</strong></td>
<td>Parabolic cylinder function V</td>
</tr>
<tr>
<td><strong>pbwa</strong></td>
<td>Parabolic cylinder function W.</td>
</tr>
</tbody>
</table>

**scipy.special.pbdv**

```
scipy.special.pbdv(v, x) = <ufunc 'pbdv'>
```

Parabolic cylinder function D

Returns (d, dp) the parabolic cylinder function Dv(x) in d and the derivative, Dv'(x) in dp.

**Returns**

- **d** Value of the function
- **dp** Value of the derivative vs x

**scipy.special.pbvv**

```
scipy.special.pbvv(v, x) = <ufunc 'pbvv'>
```

Parabolic cylinder function V

Returns the parabolic cylinder function Vv(x) in v and the derivative, Vv'(x) in vp.

**Returns**

- **v** Value of the function
- **vp** Value of the derivative vs x

**scipy.special.pbwa**

```
scipy.special.pbwa(a, x) = <ufunc 'pbwa'>
```

Parabolic cylinder function W.

The function is a particular solution to the differential equation

\[ y'' + \left( \frac{1}{4}x^2 - a \right) y = 0, \]

for a full definition see section 12.14 in [1].

**Parameters**

- **a** [array_like] Real parameter
- **x** [array_like] Real argument

**Returns**

- **w** [scalar or ndarray] Value of the function
- **wp** [scalar or ndarray] Value of the derivative in x

**Notes**

The function is a wrapper for a Fortran routine by Zhang and Jin [2]. The implementation is accurate only for \(|a|, |x| < 5\) and returns NaN outside that range.
These are not universal functions:

- `pbdv_seq(v, x)` Parabolic cylinder functions $D_v(x)$ and derivatives.
- `pbvv_seq(v, x)` Parabolic cylinder functions $V_v(x)$ and derivatives.
- `pbdn_seq(n, z)` Parabolic cylinder functions $D_n(z)$ and derivatives.

**scipy.special.pbdv_seq**

`scipy.special.pbdv_seq(v, x)`
Parabolic cylinder functions $D_v(x)$ and derivatives.

**Parameters**

- `v` [float] Order of the parabolic cylinder function
- `x` [float] Value at which to evaluate the function and derivatives

**Returns**

- `dv` [ndarray] Values of $D_{v_i}(x)$, for $v_i = v - \text{int}(v)$, $v_i = 1 + v - \text{int}(v)$, ..., $v_i = v$.
- `dp` [ndarray] Derivatives $D_{v_i}'(x)$, for $v_i = v - \text{int}(v)$, $v_i = 1 + v - \text{int}(v)$, ..., $v_i = v$.

**References**

[1]

**scipy.special.pbvv_seq**

`scipy.special.pbvv_seq(v, x)`
Parabolic cylinder functions $V_v(x)$ and derivatives.

**Parameters**

- `v` [float] Order of the parabolic cylinder function
- `x` [float] Value at which to evaluate the function and derivatives

**Returns**

- `dv` [ndarray] Values of $V_{v_i}(x)$, for $v_i = v - \text{int}(v)$, $v_i = 1 + v - \text{int}(v)$, ..., $v_i = v$.
- `dp` [ndarray] Derivatives $V_{v_i}'(x)$, for $v_i = v - \text{int}(v)$, $v_i = 1 + v - \text{int}(v)$, ..., $v_i = v$.

**References**

[1]

**scipy.special.pbdn_seq**

`scipy.special.pbdn_seq(n, z)`
Parabolic cylinder functions $D_n(z)$ and derivatives.

**Parameters**

- `n` [int] Order of the parabolic cylinder function
- `z` [complex] Value at which to evaluate the function and derivatives

**Returns**

...
References

[1]

Mathieu and Related Functions

\[ \text{mathieu}_a(m, q) \]
Characteristic value of even Mathieu functions

\[ \text{mathieu}_b(m, q) \]
Characteristic value of odd Mathieu functions

\[ \text{scipy.special.mathieu}_a(m, q) \]
Characteristic value of even Mathieu functions

Returns the characteristic value for the even solution, \( ce_m(z, q) \), of Mathieu’s equation.

\[ \text{scipy.special.mathieu}_b(m, q) \]
Characteristic value of odd Mathieu functions

Returns the characteristic value for the odd solution, \( se_m(z, q) \), of Mathieu’s equation.

These are not universal functions:

\[ \text{mathieu}_\text{even}_\text{coef}(m, q) \]
Fourier coefficients for even Mathieu and modified Mathieu functions.

\[ \text{mathieu}_\text{odd}_\text{coef}(m, q) \]
Fourier coefficients for even Mathieu and modified Mathieu functions.

\[ \text{scipy.special.mathieu}_\text{even}_\text{coef}(m, q) \]
Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the even solutions of the Mathieu differential equation are of the form

\[
\begin{align*}
cc_{2n}(z, q) &= \sum_{k=0}^{\infty} A_{(2n)}^{(2k)} \cos 2kz \\
cc_{2n+1}(z, q) &= \sum_{k=0}^{\infty} A_{(2n+1)}^{(2k+1)} \cos(2k + 1)z
\end{align*}
\]

This function returns the coefficients \( A_{(2n)}^{(2k)} \) for even input \( m=2n \), and the coefficients \( A_{(2n+1)}^{(2k+1)} \) for odd input \( m=2n+1 \).

Parameters

\[ m \quad [\text{int}] \quad \text{Order of Mathieu functions. Must be non-negative.} \]

\[ q \quad [\text{float (>=0)}] \quad \text{Parameter of Mathieu functions. Must be non-negative.} \]

Returns

\[ Ak \quad [\text{ndarray}] \quad \text{Even or odd Fourier coefficients, corresponding to even or odd m.} \]
References

[1], [2]

**scipy.special.mathieu_odd_coef**

**scipy.special.mathieu_odd_coef(m, q)**

Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the odd solutions of the Mathieu differential equation are of the form

\[ se_{2n+1}(z, q) = \sum_{k=0}^{\infty} B_{(2n+1)}^{(2k+1)} \sin(2k + 1)z \]

\[ se_{2n+2}(z, q) = \sum_{k=0}^{\infty} B_{(2n+2)}^{(2k+2)} \sin(2k + 2)z \]

This function returns the coefficients \( B_{(2n+1)}^{(2k+1)} \) for even input \( m=2n+2 \), and the coefficients \( B_{(2n+1)}^{(2k+1)} \) for odd input \( m=2n+1 \).

**Parameters**

- **m** ([int]) Order of Mathieu functions. Must be non-negative.
- **q** ([float (>=0)]) Parameter of Mathieu functions. Must be non-negative.

**Returns**

- **Bk** ([ndarray]) Even or odd Fourier coefficients, corresponding to even or odd \( m \).

</tbody>
</table>

**scipy.special.mathieu_cem**

**scipy.special.mathieu_cem(m, q, x) = <ufunc 'mathieu_cem'>**

Even Mathieu function and its derivative

Returns the even Mathieu function, \( ce_m(x, q) \), of order \( m \) and parameter \( q \) evaluated at \( x \) (given in degrees). Also returns the derivative with respect to \( x \) of \( ce_m(x, q) \).

**Parameters**

- **m** Order of the function
Parameter of the function

x  Argument of the function, *given in degrees, not radians*

Returns

y  Value of the function

yp Value of the derivative vs x

**scipy.special.mathieu_sem**

`scipy.special.mathieu_sem(m, q, x) = <ufunc 'mathieu_sem'>`

Odd Mathieu function and its derivative

Returns the odd Mathieu function, \( \text{se}_m(x, q) \), of order \( m \) and parameter \( q \) evaluated at \( x \) (given in degrees). Also returns the derivative with respect to \( x \) of \( \text{se}_m(x, q) \).

Parameters

- \( m \): Order of the function
- \( q \): Parameter of the function
- \( x \): Argument of the function, *given in degrees, not radians*.

Returns

- \( y \): Value of the function

- \( yp \): Value of the derivative vs \( x \)

**scipy.special.mathieu_modcem1**

`scipy.special.mathieu_modcem1(m, q, x) = <ufunc 'mathieu_modcem1'>`

Even modified Mathieu function of the first kind and its derivative

Evaluates the even modified Mathieu function of the first kind, \( \text{Mc}_1m(x, q) \), and its derivative at \( x \) for order \( m \) and parameter \( q \).

Returns

- \( y \): Value of the function

- \( yp \): Value of the derivative vs \( x \)

**scipy.special.mathieu_modcem2**

`scipy.special.mathieu_modcem2(m, q, x) = <ufunc 'mathieu_modcem2'>`

Even modified Mathieu function of the second kind and its derivative

Evaluates the even modified Mathieu function of the second kind, \( \text{Mc}_2m(x, q) \), and its derivative at \( x \) (given in degrees) for order \( m \) and parameter \( q \).

Returns

- \( y \): Value of the function

- \( yp \): Value of the derivative vs \( x \)

**scipy.special.mathieu_modsem1**

`scipy.special.mathieu_modsem1(m, q, x) = <ufunc 'mathieu_modsem1'>`

Odd modified Mathieu function of the first kind and its derivative

Evaluates the odd modified Mathieu function of the first kind, \( \text{Ms}_1m(x, q) \), and its derivative at \( x \) (given in degrees) for order \( m \) and parameter \( q \).

Returns

- \( y \): Value of the function
**scipy.special.mathieu_modsem2**

*scipy.special.mathieu_modsem2*(m, q, x) = <ufunc 'mathieu_modsem2'>

Odd modified Mathieu function of the second kind and its derivative

Evaluates the odd modified Mathieu function of the second kind, Ms2m(x, q), and its derivative at x (given in degrees) for order m and parameter q.

**Returns**

- **y**: Value of the function
- **yp**: Value of the derivative vs x

---

**Spheroidal Wave Functions**

- **pro_ang1**(m, n, c, x): Prolate spheroidal angular function of the first kind and its derivative
- **pro_rad1**(m, n, c, x): Prolate spheroidal radial function of the first kind and its derivative
- **pro_rad2**(m, n, c, x): Prolate spheroidal radial function of the second kind and its derivative
- **obl_ang1**(m, n, c, x): Oblate spheroidal angular function of the first kind and its derivative
- **obl_rad1**(m, n, c, x): Oblate spheroidal radial function of the first kind and its derivative
- **obl_rad2**(m, n, c, x): Oblate spheroidal radial function of the second kind and its derivative

- **pro_cv**(m, n, c): Characteristic value of prolate spheroidal function
- **obl_cv**(m, n, c): Characteristic value of oblate spheroidal function
- **pro_cv_seq**(m, n, c): Characteristic values for prolate spheroidal wave functions.
- **obl_cv_seq**(m, n, c): Characteristic values for oblate spheroidal wave functions.

---

**scipy.special.pro_ang1**

*scipy.special.pro_ang1*(m, n, c, x) = <ufunc 'pro_ang1'>

Prolate spheroidal angular function of the first kind and its derivative

Computes the prolate spheroidal angular function of the first kind and its derivative (with respect to x) for mode parameters m>=0 and n>=m, spheroidal parameter c and |x| < 1.0.

**Returns**

- **s**: Value of the function
- **sp**: Value of the derivative vs x

**scipy.special.pro_rad1**

*scipy.special.pro_rad1*(m, n, c, x) = <ufunc 'pro_rad1'>

Prolate spheroidal radial function of the first kind and its derivative

Computes the prolate spheroidal radial function of the first kind and its derivative (with respect to x) for mode parameters m>=0 and n>=m, spheroidal parameter c and |x| < 1.0.

**Returns**
scipy.special.pro_rad2

scipy.special.pro_rad2(m, n, c, x) = <ufunc 'pro_rad2'>

Prolate spheroidal radial function of the second kind and its derivative

Computes the prolate spheroidal radial function of the second kind and its derivative (with respect to $x$) for mode parameters $m \geq 0$ and $n \geq m$, spheroidal parameter $c$ and $|x| < 1.0$.

Returns

- s: Value of the function
- sp: Value of the derivative vs $x$

scipy.special.obl_ang1

scipy.special.obl_ang1(m, n, c, x) = <ufunc 'obl_ang1'>

Oblate spheroidal angular function of the first kind and its derivative

Computes the oblate spheroidal angular function of the first kind and its derivative (with respect to $x$) for mode parameters $m \geq 0$ and $n \geq m$, spheroidal parameter $c$ and $|x| < 1.0$.

Returns

- s: Value of the function
- sp: Value of the derivative vs $x$

scipy.special.obl_rad1

scipy.special.obl_rad1(m, n, c, x) = <ufunc 'obl_rad1'>

Oblate spheroidal radial function of the first kind and its derivative

Computes the oblate spheroidal radial function of the first kind and its derivative (with respect to $x$) for mode parameters $m \geq 0$ and $n \geq m$, spheroidal parameter $c$ and $|x| < 1.0$.

Returns

- s: Value of the function
- sp: Value of the derivative vs $x$

scipy.special.obl_rad2

scipy.special.obl_rad2(m, n, c, x) = <ufunc 'obl_rad2'>

Oblate spheroidal radial function of the second kind and its derivative.

Computes the oblate spheroidal radial function of the second kind and its derivative (with respect to $x$) for mode parameters $m \geq 0$ and $n \geq m$, spheroidal parameter $c$ and $|x| < 1.0$.

Returns

- s: Value of the function
- sp: Value of the derivative vs $x$

scipy.special.pro_cv

scipy.special.pro_cv(m, n, c) = <ufunc 'pro_cv'>

Characteristic value of prolate spheroidal function

Computes the characteristic value of prolate spheroidal wave functions of order $m$, $n$ ($n \geq m$) and spheroidal parameter $c$. 
**scipy.special.obl_cv**

scipy.special.obl_cv\((m, n, c)\) = <ufunc 'obl_cv'>

Characteristic value of oblate spheroidal function

Computes the characteristic value of oblate spheroidal wave functions of order \(m, n\) \((n \geq m)\) and spheroidal parameter \(c\).

**scipy.special.pro_cv_seq**

scipy.special.pro_cv_seq\((m, n, c)\)

Characteristic values for prolate spheroidal wave functions.

Compute a sequence of characteristic values for the prolate spheroidal wave functions for mode \(m\) and \(n'=m..n\) and spheroidal parameter \(c\).

**References**

[1]

**scipy.special.obl_cv_seq**

scipy.special.obl_cv_seq\((m, n, c)\)

Characteristic values for oblate spheroidal wave functions.

Compute a sequence of characteristic values for the oblate spheroidal wave functions for mode \(m\) and \(n'=m..n\) and spheroidal parameter \(c\).

**References**

[1]

</tbody>
</table>

**scipy.special.pro_ang1_cv**

scipy.special.pro_ang1_cv\((m, n, c, cv, x)\) = <ufunc 'pro_ang1_cv'>

Prolate spheroidal angular function pro_ang1 for precomputed characteristic value

Computes the prolate spheroidal angular function of the first kind and its derivative (with respect to \(x\)) for mode parameters \(m\geq0\) and \(n\geq m\), spheroidal parameter \(c\) and \(|x| < 1.0\). Requires pre-computed characteristic value.

**Returns**
SciPy Reference Guide, Release 1.3.2

s Value of the function
sp Value of the derivative vs x

scipy.special.pro_rad1_cv

scipy.special.pro_rad1_cv(m, n, c, cv, x) = <ufunc 'pro_rad1_cv'>

Prolate spheroidal radial function pro_rad1 for precomputed characteristic value

Computes the prolate spheroidal radial function of the first kind and its derivative (with respect to x) for mode parameters m>=0 and n>=m, spheroidal parameter c and |x| < 1.0. Requires pre-computed characteristic value.

Returns
s Value of the function
sp Value of the derivative vs x

scipy.special.pro_rad2_cv

scipy.special.pro_rad2_cv(m, n, c, cv, x) = <ufunc 'pro_rad2_cv'>

Prolate spheroidal radial function pro_rad2 for precomputed characteristic value

Computes the prolate spheroidal radial function of the second kind and its derivative (with respect to x) for mode parameters m>=0 and n>=m, spheroidal parameter c and |x| < 1.0. Requires pre-computed characteristic value.

Returns
s Value of the function
sp Value of the derivative vs x

scipy.special.obl_ang1_cv

scipy.special.obl_ang1_cv(m, n, c, cv, x) = <ufunc 'obl_ang1_cv'>

Oblate spheroidal angular function obl_ang1 for precomputed characteristic value

Computes the oblate spheroidal angular function of the first kind and its derivative (with respect to x) for mode parameters m>=0 and n>=m, spheroidal parameter c and |x| < 1.0. Requires pre-computed characteristic value.

Returns
s Value of the function
sp Value of the derivative vs x

scipy.special.obl_rad1_cv

scipy.special.obl_rad1_cv(m, n, c, cv, x) = <ufunc 'obl_rad1_cv'>

Oblate spheroidal radial function obl_rad1 for precomputed characteristic value

Computes the oblate spheroidal radial function of the first kind and its derivative (with respect to x) for mode parameters m>=0 and n>=m, spheroidal parameter c and |x| < 1.0. Requires pre-computed characteristic value.

Returns
s Value of the function
sp Value of the derivative vs x
scipy.special.obl_rad2_cv

scipy.special.obl_rad2_cv\( (m, n, c, cv, x) \) = <ufunc 'obl_rad2_cv'>
Oblate spheroidal radial function obl_rad2 for precomputed characteristic value

Computes the oblate spheroidal radial function of the second kind and its derivative (with respect to \( x \)) for mode parameters \( m \geq 0 \) and \( n \geq m \), spheroidal parameter \( c \) and \(|x| < 1.0\). Requires pre-computed characteristic value.

Returns

- \( s \) Value of the function
- \( sp \) Value of the derivative vs \( x \)

Kelvin Functions

- kelvin\( (x) \) Kelvin functions as complex numbers
- kelvin_zeros\( (nt) \) Compute \( nt \) zeros of all Kelvin functions.
- ber\( (x) \) Kelvin function ber.
- bei\( (x) \) Kelvin function bei
- berp\( (x) \) Derivative of the Kelvin function ber
- beip\( (x) \) Derivative of the Kelvin function bei
- ker\( (x) \) Kelvin function ker
- kei\( (x) \) Kelvin function kei
- kerp\( (x) \) Derivative of the Kelvin function ker
- keip\( (x) \) Derivative of the Kelvin function kei

scipy.special.kelvin

scipy.special.kelvin\( (x) \) = <ufunc 'kelvin'>
Kelvin functions as complex numbers

Returns

- \( Be, Ke, Bep, Kep \) The tuple \((Be, Ke, Bep, Kep)\) contains complex numbers representing the real and imaginary Kelvin functions and their derivatives evaluated at \( x \). For example, \( \text{kelvin}(x)[0].\text{real} = \text{ber} \ x \) and \( \text{kelvin}(x)[0].\text{imag} = \text{bei} x \) with similar relationships for ker and kei.

scipy.special.kelvin_zeros

scipy.special.kelvin_zeros\( (nt) \)
Compute \( nt \) zeros of all Kelvin functions.

Returned in a length-8 tuple of arrays of length nt. The tuple contains the arrays of zeros of \((\text{ber, bei, ker, kei, ber', bei', ker', kei'})\).

References

Combinatorics

\texttt{comb}(N, k[, exact, repetition]) The number of combinations of \(N\) things taken \(k\) at a time.

\texttt{perm}(N, k[, exact]) Permutations of \(N\) things taken \(k\) at a time, i.e., \(k\)-permutations of \(N\).

\texttt{scipy.special.comb}

\texttt{scipy.special.comb}(N, k, exact=False, repetition=False)

The number of combinations of \(N\) things taken \(k\) at a time.

This is often expressed as “\(N\) choose \(k\)”.  

Parameters

- \(N\) [int, ndarray] Number of things.
- \(k\) [int, ndarray] Number of elements taken.
- \texttt{exact} [bool, optional] If \texttt{exact} is False, then floating point precision is used, otherwise exact long integer is computed.
- \texttt{repetition} [bool, optional] If \texttt{repetition} is True, then the number of combinations with repetition is computed.

Returns

- \texttt{val} [int, float, ndarray] The total number of combinations.

See also:

\texttt{binom}

Binomial coefficient ufunc

Notes

- Array arguments accepted only for \texttt{exact=False} case.
- If \(k > N\), \(N < 0\), or \(k < 0\), then a 0 is returned.

Examples

```python
>>> from scipy.special import comb
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> comb(n, k, exact=False)
array([ 120.,  210.])
>>> comb(10, 3, exact=True)
120L
>>> comb(10, 3, exact=True, repetition=True)
220L
```
scipy.special.perm

scipy.special.perm(N, k, exact=False)

Permutations of N things taken k at a time, i.e., k-permutations of N.

It’s also known as “partial permutations”.

Parameters

N [int, ndarray] Number of things.

k [int, ndarray] Number of elements taken.

exact [bool, optional] If exact is False, then floating point precision is used, otherwise exact long integer is computed.

Returns

val [int, ndarray] The number of k-permutations of N.

Notes

• Array arguments accepted only for exact=False case.

• If k > N, N < 0, or k < 0, then a 0 is returned.

Examples

```python
>>> from scipy.special import perm
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> perm(n, k)
array([[  720.,  5040.]]
>>> perm(10, 3, exact=True)
720
```

Lambert W and Related Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lambertw(z[, k, tol])</td>
<td>Lambert W function.</td>
</tr>
<tr>
<td>wrightomega(z[, out])</td>
<td>Wright Omega function.</td>
</tr>
</tbody>
</table>

scipy.special.lambertw

scipy.special.lambertw(z, k=0, tol=1e-8)

Lambert W function.

The Lambert W function $W(z)$ is defined as the inverse function of $w \times \exp(w)$. In other words, the value of $W(z)$ is such that $z = W(z) \times \exp(W(z))$ for any complex number $z$.

The Lambert W function is a multivalued function with infinitely many branches. Each branch gives a separate solution of the equation $z = w \times \exp(w)$. Here, the branches are indexed by the integer $k$.

Parameters

z [array_like] Input argument.

k [int, optional] Branch index.

Returns

w

[array] w will have the same shape as z.

See also:

wrightomega

the Wright Omega function

Notes

All branches are supported by lambertw:

• lambertw(z) gives the principal solution (branch 0)
• lambertw(z, k) gives the solution on branch k

The Lambert W function has two partially real branches: the principal branch (k = 0) is real for real z > -1/e, and the k = -1 branch is real for -1/e < z < 0. All branches except k = 0 have a logarithmic singularity at z = 0.

Possible issues

The evaluation can become inaccurate very close to the branch point at -1/e. In some corner cases, lambertw might currently fail to converge, or can end up on the wrong branch.

Algorithm

Halley’s iteration is used to invert \( w \exp(w) \), using a first-order asymptotic approximation (\( O(\log(w)) \) or \( O(w) \)) as the initial estimate.

The definition, implementation and choice of branches is based on [2].

References

[1], [2]

Examples

The Lambert W function is the inverse of \( w \exp(w) \):

```python
>>> from scipy.special import lambertw
>>> w = lambertw(1)
>>> w
(0.56714329040978384+0j)
>>> w * np.exp(w)
(1.0+0j)
```

Any branch gives a valid inverse:

```python
>>> w = lambertw(1, k=3)
>>> w
(-2.8535817554090377+17.113535539412148j)
>>> w*np.exp(w)
(1.0000000000000002+1.609823385706477e-15j)
```
Applications to equation-solving

The Lambert W function may be used to solve various kinds of equations, such as finding the value of the infinite power tower $z^{z^{\ddots}}$:

```python
>>> def tower(z, n):
...     if n == 0:
...         return z
...     return z ** tower(z, n-1)
...
>>> tower(0.5, 100)
0.641185744504986
>>> -lambertw(-np.log(0.5)) / np.log(0.5)
(0.64118574450498589+0j)
```

scipy.special.wrightomega

scipy.special.wrightomega($z$, out=None) = <ufunc 'wrightomega'>

Wright Omega function.

Defined as the solution to

$$\omega + \log(\omega) = z$$

where $\log$ is the principal branch of the complex logarithm.

**Parameters**

- $z$ [array_like] Points at which to evaluate the Wright Omega function

**Returns**

- omega [ndarray] Values of the Wright Omega function

**See also:**

lambertw

The Lambert W function

**Notes**

New in version 0.19.0.

The function can also be defined as

$$\omega(z) = W_{K(z)}(e^z)$$

where $K(z) = \lceil(3(z - \pi)/(2\pi)\rceil$ is the unwinding number and $W$ is the Lambert W function.

The implementation here is taken from [1].

**References**

[1]

Other Special Functions
### scipy.special.agm

**scipy.special.agm**(a, b) = <ufunc 'agm'>

Compute the arithmetic-geometric mean of \( a \) and \( b \).

Start with \( a_0 = a \) and \( b_0 = b \) and iteratively compute:

\[
\begin{align*}
    a_{n+1} &= (a_n + b_n) / 2 \\
    b_{n+1} &= \sqrt{a_n \times b_n}
\end{align*}
\]

\( a_n \) and \( b_n \) converge to the same limit as \( n \) increases; their common limit is \( \text{agm}(a, b) \).

**Parameters**

- **a**, **b**
  
  [array_like] Real values only. If the values are both negative, the result is negative. If one value is negative and the other is positive, \( \text{nan} \) is returned.

**Returns**

- **float**
  
  The arithmetic-geometric mean of \( a \) and \( b \).

**Examples**

```python
>>> from scipy.special import agm
>>> a, b = 24.0, 6.0
>>> agm(a, b)
13.458171481725614
```

Compare that result to the iteration:

```python
>>> while a != b:
...     a, b = (a + b) / 2, np.sqrt(a*b)
...     print("a = %19.16f  b=%19.16f" % (a, b))
...     print("a = %19.16f  b=%19.16f" % (a, b))
...     a = 15.0000000000000000  b=12.0000000000000000
...     a = 13.5000000000000000  b=13.4164078649987388
```

(continues on next page)
When array-like arguments are given, broadcasting applies:

```python
>>> a = np.array([[1.5], [3], [6]])  # a has shape (3, 1).
>>> b = np.array([6, 12, 24, 48])   # b has shape (4,).
>>> agm(a, b)
array([[ 3.36454287,  5.42363427,  9.05798751, 15.53650756],
       [ 4.37037309,  6.72908574, 10.84726853, 18.11597502],
       [ 6.        ,  8.74074619, 13.45817148, 21.69453707]])
```

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scipy.special.dirc</td>
<td>Periodic sinc function, also called the Dirichlet function.</td>
</tr>
</tbody>
</table>

The Dirichlet function is defined as:

\[
diric(x, n) = \frac{\sin(x \times \frac{n}{2})}{(n \times \sin(\frac{x}{2}))},
\]

where \( n \) is a positive integer.

**Parameters**

- \( x \) : [array_like] Input data
- \( n \) : [int] Integer defining the periodicity.

**Returns**

- \( \text{diric} \) : [ndarray]
Examples

```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt

>>> x = np.linspace(-8*np.pi, 8*np.pi, num=201)
>>> plt.figure(figsize=(8, 8));
>>> for idx, n in enumerate([2, 3, 4, 9]):
...     plt.subplot(2, 2, idx+1)
...     plt.plot(x, special.diric(x, n))
...     plt.title('diric, n={} \n'.format(n))
>>> plt.show()
```

```
20
  0  20
1.0
0.5
0.0
0.5
1.0
diric, n=2
20
  0  20
0.2
0.0
0.2
0.4
0.6
0.8
1.0
diric, n=3
20
  0  20
1.0

  0  20
0.2
0.0
0.2
0.4
0.6
0.8
1.0
diric, n=9
```
The following example demonstrates that `diric` gives the magnitudes (modulo the sign and scaling) of the Fourier coefficients of a rectangular pulse.

Suppress output of values that are effectively 0:

```python
>>> np.set_printoptions(suppress=True)
```

Create a signal \( x \) of length \( m \) with \( k \) ones:

```python
>>> m = 8
>>> k = 3
>>> x = np.zeros(m)
>>> x[:k] = 1
```

Use the FFT to compute the Fourier transform of \( x \), and inspect the magnitudes of the coefficients:

```python
>>> np.abs(np.fft.fft(x))
array([3. , 2.41421356, 1. , 0.41421356, 1. , 0.41421356, 1. , 2.41421356])
```

Now find the same values (up to sign) using `diric`. We multiply by \( k \) to account for the different scaling conventions of `numpy.fft.fft` and `diric`:

```python
>>> theta = np.linspace(0, 2*np.pi, m, endpoint=False)
>>> k * special.diric(theta, k)
array([3. , 2.41421356, 1. , -0.41421356, -1. , -0.41421356, 1. , 2.41421356])
```

### scipy.special.euler

**scipy.special.euler**

Euler numbers \( E(0), E(1), \ldots, E(n) \).

The Euler numbers \([1]\) are also known as the secant numbers.

Because `euler(n)` returns floating point values, it does not give exact values for large \( n \). The first inexact value is \( E(22) \).

**Parameters**

- \( n \)  
  [int] The highest index of the Euler number to be returned.

**Returns**

- `ndarray`  
  The Euler numbers \([E(0), E(1), \ldots, E(n)]\). The odd Euler numbers, which are all zero, are included.

**References**

[1], [2]

**Examples**

```python
>>> from scipy.special import euler
>>> euler(6)
array([1., 0., -1., 0., 5., 0., -61.])
```
```python
>>> euler(13).astype(np.int64)
array([ 1,  0, -1,  0,  5,  0, -61,  0, 1385,  0, -50521,  0, 2702765,  0])

>>> euler(22)[-1]  # Exact value of E(22) is -6348874393137901.
-69348874393137976.0
```

**scipy.special.expmn**

```python
scipy.special.expmn(n, x) = <ufunc 'expmn'>
```

Exponential integral $E_n$

Returns the exponential integral for integer $n$ and non-negative $x$ and $n$:

$$\int \frac{e^{-x^t}}{t^n} \, dt$$

**scipy.special.exp1**

```python
scipy.special.exp1(z) = <ufunc 'exp1'>
```

Exponential integral $E_1$ of complex argument $z$

$$\int \frac{e^{-z^t}}{t} \, dt$$

**scipy.special.expi**

```python
scipy.special.expi(x) = <ufunc 'expi'>
```

Exponential integral $Ei$

Defined as:

$$\int \frac{e^t}{t} \, dt$$

See `expn` for a different exponential integral.

**scipy.special.factorial**

```python
scipy.special.factorial(n, exact=False)
```

The factorial of a number or array of numbers.

The factorial of non-negative integer $n$ is the product of all positive integers less than or equal to $n$:

$$n! = n \times (n-1) \times (n-2) \times \ldots \times 1$$

**Parameters**

- **n** [int or array_like of ints] Input values. If $n < 0$, the return value is 0.
- **exact** [bool, optional] If True, calculate the answer exactly using long integer arithmetic. If False, result is approximated in floating point rapidly using the `gamma` function. Default is False.

**Returns**

- **nf** [float or int or ndarray] Factorial of $n$, as integer or float depending on `exact`.

**Notes**

For arrays with `exact=True`, the factorial is computed only once, for the largest input, with each other result computed in the process. The output dtype is increased to `int64` or `object` if necessary.
With `exact=False` the factorial is approximated using the gamma function:

\[ n! = \Gamma(n + 1) \]

**Examples**

```python
>>> from scipy.special import factorial
>>> arr = np.array([3, 4, 5])
>>> factorial(arr, exact=False)
array([ 6., 24., 120.])
>>> factorial(arr, exact=True)
array([ 6, 24, 120])
>>> factorial(5, exact=True)
120L
```

**scipy.special.factorial2**

`scipy.special.factorial2(n, exact=False)`

Double factorial.

This is the factorial with every second value skipped. E.g., \(7!! = 7 \times 5 \times 3 \times 1\). It can be approximated numerically as:

\[
    n!! = \begin{cases} 
        \text{special.gamma}(n/2+1) \times 2^{(n+1)/2} / \sqrt{\pi} & \text{if } n \text{ odd} \\
        2^{n/2} \times (n/2)! & \text{if } n \text{ even}
    \end{cases}
\]

**Parameters**

- `n` [int or array_like] Calculate \(n!!\). Arrays are only supported with `exact` set to False. If \(n < 0\), the return value is 0.
- `exact` [bool, optional] The result can be approximated rapidly using the gamma-formula above (default). If `exact` is set to True, calculate the answer exactly using integer arithmetic.

**Returns**

- `nff` [float or int] Double factorial of `n`, as an int or a float depending on `exact`.

**Examples**

```python
>>> from scipy.special import factorial2
>>> factorial2(7, exact=False)
array(105.00000000000001)
>>> factorial2(7, exact=True)
105L
```

**scipy.special.factorialk**

`scipy.special.factorialk(n, k, exact=True)`

Multifactorial of \(n\) of order \(k\), \(n!!...!\).

This is the multifactorial of \(n\) skipping \(k\) values. For example,

\[
    \text{factorialk}(17, 4) = 17!!!! = 17 \times 13 \times 9 \times 5 \times 1
\]

In particular, for any integer \(n\), we have
factorialk(n, 1) = factorial(n)
factorialk(n, 2) = factorial2(n)

Parameters
n    [int] Calculate multifactorial. If n < 0, the return value is 0.
k    [int] Order of multifactorial.
exact [bool, optional] If exact is set to True, calculate the answer exactly using integer arithmetic.

Returns

Raises
NotImplementedError
Raises when exact is False

Examples

```python
>>> from scipy.special import factorialk
>>> factorialk(5, 1, exact=True)
120L
>>> factorialk(5, 3, exact=True)
10L
```

scipy.special.shichi

scipy.special.shichi(x, out=None) = <ufunc 'shichi'>

Hyperbolic sine and cosine integrals.

The hyperbolic sine integral is

\[ \int_0^x \frac{\sinh t}{t} dt \]

and the hyperbolic cosine integral is

\[ \gamma + \log(x) + \int_0^x \frac{\cosh t - 1}{t} dt \]

where \(\gamma\) is Euler's constant and \(\log\) is the principal branch of the logarithm.

Parameters
x    [array_like] Real or complex points at which to compute the hyperbolic sine and cosine integrals.

Returns
si   [ndarray] Hyperbolic sine integral at x
ci   [ndarray] Hyperbolic cosine integral at x

Notes

For real arguments with \(x < 0\), \(\text{chi}\) is the real part of the hyperbolic cosine integral. For such points \(\text{chi}(x)\) and \(\text{chi}(x + 0j)\) differ by a factor of \(ij\pi\).

For real arguments the function is computed by calling Cephes' [1] shichi routine. For complex arguments the algorithm is based on Mpmath's [2] shi and chi routines.
scipy.special.sici

scipy.special.sici(x, out=None) = <ufunc 'sici'>

Sine and cosine integrals.

The sine integral is
\[ \int_0^x \frac{\sin t}{t} dt \]

and the cosine integral is
\[ \gamma + \log(x) + \int_0^x \frac{\cos t - 1}{t} dt \]

where \( \gamma \) is Euler’s constant and \( \log \) is the principle branch of the logarithm.

Parameters

- **x**
  - [array_like] Real or complex points at which to compute the sine and cosine integrals.

Returns

- **si**
  - [ndarray] Sine integral at \( x \)
- **ci**
  - [ndarray] Cosine integral at \( x \)

Notes

For real arguments with \( x < 0 \), \( \text{ci} \) is the real part of the cosine integral. For such points \( \text{ci}(x) \) and \( \text{ci}(x + 0j) \) differ by a factor of \( 1j \pi i \).

For real arguments the function is computed by calling Cephes’ [1] \( sici \) routine. For complex arguments the algorithm is based on Mpmath’s [2] \( si \) and \( ci \) routines.

References

[1], [2]

scipy.special.softmax

scipy.special.softmax(x, axis=None)

Softmax function

The softmax function transforms each element of a collection by computing the exponential of each element divided by the sum of the exponentials of all the elements. That is, if \( x \) is a one-dimensional numpy array:

\[
\text{softmax}(x) = \frac{\text{np.exp}(x)}{\text{sum}(\text{np.exp}(x))}
\]

Parameters

- **x**
  - [array_like] Input array.
- **axis**
  - [int or tuple of ints, optional] Axis to compute values along. Default is None and softmax will be computed over the entire array \( x \).

Returns

- **s**
  - [ndarray] An array the same shape as \( x \). The result will sum to 1 along the specified axis.
Notes

The formula for the softmax function $\sigma(x)$ for a vector $x = \{x_0, x_1, \ldots, x_{n-1}\}$ is

$$
\sigma(x)_j = \frac{e^{x_j}}{\sum_k e^{x_k}}
$$

The softmax function is the gradient of logsumexp.

New in version 1.2.0.

Examples

```python
>>> from scipy.special import softmax
>>> np.set_printoptions(precision=5)

>>> x = np.array([[1, 0.5, 0.2, 3],
                [1, -1, 7, 3],
                [2, 12, 13, 3]])

Compute the softmax transformation over the entire array.

```python
>>> m = softmax(x)
>>> m
array([[ 4.48309e-06,  2.71913e-06,  2.01438e-06,  3.31258e-05],
        [ 4.48309e-06,  6.06720e-07,  1.80861e-03,  3.31258e-05],
        [ 1.21863e-05,  2.68421e-01,  7.29644e-01,  3.31258e-05]])
```  

```python
>>> m.sum()
1.0000000000000002
```

Compute the softmax transformation along the first axis (i.e. the columns).

```python
>>> m = softmax(x, axis=0)
>>> m
array([[ 2.11942e-01,  1.01300e-05,  2.75394e-06,  3.33333e-01],
        [ 2.11942e-01,  2.26030e-06,  2.47262e-03,  3.33333e-01],
        [ 5.76117e-01,  9.99988e-01,  9.97525e-01,  3.33333e-01]])
```  

```python
>>> m.sum(axis=0)
array([ 1.,  1.,  1.,  1.])
```

Compute the softmax transformation along the second axis (i.e. the rows).

```python
>>> m = softmax(x, axis=1)
>>> m
array([[ 1.05877e-01,  6.42177e-02,  4.75736e-02,  7.82332e-01],
        [ 2.42746e-03,  3.28521e-04,  9.79307e-01,  1.79366e-02],
        [ 1.22094e-05,  2.68929e-01,  7.31025e-01,  3.31885e-05]])
```
```python
>>> m.sum(axis=1)
array([ 1., 1., 1.])
```

**scipy.special.spence**

scipy.special.spence(z, out=None) = <ufunc 'spence'>

Spence's function, also known as the dilogarithm.

It is defined to be

\[ \int_{0}^{z} \frac{\log(t)}{1-t} \, dt \]

for complex \( z \), where the contour of integration is taken to avoid the branch cut of the logarithm. Spence's function is analytic everywhere except the negative real axis where it has a branch cut.

**Parameters**

- **z** ([array_like]) Points at which to evaluate Spence's function

**Returns**

- **s** ([ndarray]) Computed values of Spence's function

**Notes**

There is a different convention which defines Spence's function by the integral

\[ -\int_{0}^{z} \frac{\log(1-t)}{t} \, dt; \]

this is our \( \text{spence}(1 - z) \).

**scipy.special.zeta**

scipy.special.zeta(x, q=None, out=None)

Riemann or Hurwitz zeta function.

**Parameters**

- **x** ([array_like of float]) Input data, must be real
- **q** ([array_like of float, optional]) Input data, must be real. Defaults to Riemann zeta.
- **out** ([ndarray, optional]) Output array for the computed values.

**Returns**

- **out** ([array_like]) Values of zeta(x).

**See also:**

**zetac**

**Notes**

The two-argument version is the Hurwitz zeta function:

\[ \zeta(x, q) = \sum_{k=0}^{\infty} \frac{1}{(k+q)^x}, \]

Riemann zeta function corresponds to \( q = 1 \).
Examples

```python
>>> from scipy.special import zeta, polygamma, factorial

Some specific values:

```python
>>> zeta(2), np.pi**2/6
(1.6449340668482266, 1.6449340668482264)
```

```python
>>> zeta(4), np.pi**4/90
(1.0823233711381, 1.082323371138)
```

Relation to the `polygamma` function:

```python
>>> m = 3
>>> x = 1.25
>>> polygamma(m, x)
array(2.782144009188397)
```

```python
>>> (-1)**(m+1) * factorial(m) * zeta(m+1, x)
2.7821440091883969
```

`scipy.special.zetac`

`scipy.special.zetac(x) = <ufunc 'zetac'>`

Riemann zeta function minus 1.

This function is defined as

\[ \zeta(x) = \sum_{k=2}^{\infty} \frac{1}{k^x}, \]

where \( x > 1 \). For \( x < 1 \), the analytic continuation is computed.

Because of limitations of the numerical algorithm, `zetac(x)` returns `nan` for \( x \) less than -30.8148.

**Parameters**

- `x` [array_like of float] Values at which to compute \( \zeta(x) - 1 \) (must be real).

**Returns**

- `out` [array_like] Values of \( \zeta(x) - 1 \).

**See also:**

`zeta`

Examples

```python
>>> from scipy.special import zetac, zeta

Some special values:

```python
>>> zetac(2), np.pi**2/6 - 1
(0.64493406684822641, 0.6449340668482264)
```
>>> zetac(-1), -1.0/12 - 1
(-1.0833333333333333, -1.0833333333333333)

Compare zetac(x) to zeta(x) - 1 for large x:

>>> zetac(60), zeta(60) - 1
(8.673617380119933e-19, 0.0)

Convenience Functions

* `cbrt(x)` Element-wise cube root of x.
* `exp10(x)` Compute $10^x$ element-wise.
* `exp2(x)` Compute $2^x$ element-wise.
* `radian(d, m, s)` Convert from degrees to radians.
* `cosdg(x)` Cosine of the angle x given in degrees.
* `sindg(x)` Sine of angle given in degrees.
* `tandg(x)` Tangent of angle x given in degrees.
* `cotdg(x)` Cotangent of the angle x given in degrees.
* `log1p(x)` Calculates log(1+x) for use when x is near zero.
* `expm1(x)` Compute $e^x - 1$.
* `cosm1(x)` $\cos(x) - 1$ for use when x is near zero.
* `round(x)` Round to nearest integer.
* `xlogy(x, y)` Compute $x \log(y)$ so that the result is 0 if $x = 0$.
* `xlog1py(x, y)` Compute $x \log1p(y)$ so that the result is 0 if $x = 0$.
* `logsumexp(a[, axis, b, keepdims, return_sign])` Compute the log of the sum of exponentials of input elements.
* `exprel(x)` Relative error exponential, $(e^x - 1)/x$.
* `sinc(x)` Return the sinc function.

**scipy.special.cbrt**

`scipy.special.cbrt(x) = <ufunc 'cbrt'>`

Element-wise cube root of x.

* **Parameters**
  * x [array_like] x must contain real numbers.

* **Returns**
  * float The cube root of each value in x.

**Examples**

```python
>>> from scipy.special import cbrt

>>> cbrt(8)
2.0
>>> cbrt([-8, -3, 0.125, 1.331])
array([-2.      , -1.44224957,  0.5      ,  1.1      ])```

6.27. Special functions (`scipy.special`) 2075
scipy.special.exp10

scipy.special.exp10(x) = <ufunc 'exp10'>

Compute $10^x$ element-wise.

Parameters

x [array_like] x must contain real numbers.

Returns

float $10^x$, computed element-wise.

Examples

```python
>>> from scipy.special import exp10

>>> exp10(3)
1000.0
>>> x = np.array([[-1, -0.5, 0], [0.5, 1, 1.5]])
>>> exp10(x)
array([[ 0.1 , 0.31622777, 1. ],
       [ 3.16227766, 10. , 31.6227766 ]])
```

scipy.special.exp2

scipy.special.exp2(x) = <ufunc 'exp2'>

Compute $2^x$ element-wise.

Parameters

x [array_like] x must contain real numbers.

Returns

float $2^x$, computed element-wise.

Examples

```python
>>> from scipy.special import exp2

>>> exp2(3)
8.0
>>> x = np.array([[-1, -0.5, 0], [0.5, 1, 1.5]])
>>> exp2(x)
array([[ 0.5 , 0.70710678, 1. ],
       [ 1.41421356, 2. , 2.82842712]])
```

scipy.special.radian

scipy.special.radian(d, m, s) = <ufunc 'radian'>

Convert from degrees to radians

Returns the angle given in (d)egrees, (m)inutes, and (s)econds in radians.
**scipy.special.cosdg**

\[ \text{scipy.special.cosdg}(x) = \text{ufunc 'cosdg'} \]

Cosine of the angle \( x \) given in degrees.

**scipy.special.sindg**

\[ \text{scipy.special.sindg}(x) = \text{ufunc 'sindg'} \]

Sine of angle given in degrees

**scipy.special.tandg**

\[ \text{scipy.special.tandg}(x) = \text{ufunc 'tandg'} \]

Tangent of angle \( x \) given in degrees.

**scipy.special.cotdg**

\[ \text{scipy.special.cotdg}(x) = \text{ufunc 'cotdg'} \]

Cotangent of the angle \( x \) given in degrees.

**scipy.special.log1p**

\[ \text{scipy.special.log1p}(x) = \text{ufunc 'log1p'} \]

Calculates \( \log(1+x) \) for use when \( x \) is near zero

**scipy.special.expm1**

\[ \text{scipy.special.expm1}(x) = \text{ufunc 'expm1'} \]

Compute \( \exp(x) - 1 \). When \( x \) is near zero, \( \exp(x) \) is near 1, so the numerical calculation of \( \exp(x) - 1 \) can suffer from catastrophic loss of precision. \( \text{expm1}(x) \) is implemented to avoid the loss of precision that occurs when \( x \) is near zero.

**Parameters**

- \( x \) [array_like] \( x \) must contain real numbers.

**Returns**

- float \( \exp(x) - 1 \) computed element-wise.

**Examples**

```python
>>> from scipy.special import expm1

>>> expm1(1.0)
1.7182818284590451
>>> expm1([-0.2, -0.1, 0, 0.1, 0.2])
array([-0.18126925, -0.09516258, 0. , 0.10517092, 0.22140276])
```

The exact value of \( \exp(7.5\times10^{-13}) - 1 \) is:

```
7.5000000000002812500000000070312500000001318...*10**-13.
```

Here is what \( \text{expm1}(7.5\times10^{-13}) \) gives:

```python
>>> expm1(7.5e-13)
7.5000000000028135e-13
```
Compare that to $\exp(7.5e-13) - 1$, where the subtraction results in a “catastrophic” loss of precision:

```python
>>> np.exp(7.5e-13) - 1
7.5006667543675576e-13
```

**scipy.special.cosm1**

`scipy.special.cosm1(x) = <ufunc 'cosm1'>`

$\cos(x) - 1$ for use when $x$ is near zero.

**scipy.special.round**

`scipy.special.round(x) = <ufunc 'round'>`

Round to nearest integer

Returns the nearest integer to $x$ as a double precision floating point result. If $x$ ends in 0.5 exactly, the nearest even integer is chosen.

**scipy.special.xlogy**

`scipy.special.xlogy(x, y) = <ufunc 'xlogy'>`

Compute $x \log(y)$ so that the result is 0 if $x = 0$.

**Parameters**

- `x` [array_like] Multiplier
- `y` [array_like] Argument

**Returns**

- `z` [array_like] Computed $x \log(y)$

**Notes**

New in version 0.13.0.

**scipy.special.xlog1py**

`scipy.special.xlog1py(x, y) = <ufunc 'xlog1py'>`

Compute $x \log1p(y)$ so that the result is 0 if $x = 0$.

**Parameters**

- `x` [array_like] Multiplier
- `y` [array_like] Argument

**Returns**

- `z` [array_like] Computed $x \log1p(y)$

**Notes**

New in version 0.13.0.
scipy.special.logsumexp

scipy.special.logsumexp(a, axis=None, b=None, keepdims=False, return_sign=False)

Compute the log of the sum of exponentials of input elements.

Parameters

- **a** [array_like] Input array.
- **axis** [None or int or tuple of ints, optional] Axis or axes over which the sum is taken. By default axis is None, and all elements are summed.
  - New in version 0.11.0.
- **keepdims** [bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array.
  - New in version 0.15.0.
- **b** [array-like, optional] Scaling factor for \( \exp(a) \) must be of the same shape as \( a \) or broadcastable to \( a \). These values may be negative in order to implement subtraction.
  - New in version 0.12.0.
- **return_sign** [bool, optional] If this is set to True, the result will be a pair containing sign information; if False, results that are negative will be returned as NaN. Default is False (no sign information).
  - New in version 0.16.0.

Returns

- **res** [ndarray] The result, \( \log(\text{np.sum}(\exp(a))) \) calculated in a numerically more stable way. If \( b \) is given then \( \log(\text{np.sum}(b \times \exp(a))) \) is returned.
- **sgn** [ndarray] If return_sign is True, this will be an array of floating-point numbers matching res and +1, 0, or -1 depending on the sign of the result. If False, only one result is returned.

See also:

numpy.logaddexp, numpy.logaddexp2

Notes

NumPy has a logaddexp function which is very similar to \texttt{logsumexp}, but only handles two arguments. \texttt{logaddexp.reduce} is similar to this function, but may be less stable.

Examples

```python
>>> from scipy.special import logsumexp
>>> a = np.arange(10)
>>> np.log(np.sum(np.exp(a)))
9.458629744267107
>>> logsumexp(a)
9.458629744267107
```

With weights

```python
>>> a = np.arange(10)
>>> b = np.arange(10, 0, -1)
>>> logsumexp(a, b=b)
9.9170178533034665
```
```python
>>> np.log(np.sum(b*np.exp(a)))
9.9170178533034647

Returning a sign flag

```nput
```python
>>> logsumexp([1,2],b=[1,-1],return_sign=True)
(1.5413248546129181, -1.0)

Notice that logsumexp does not directly support masked arrays. To use it on a masked array, convert the mask into zero weights:

```python
>>> a = np.ma.array([np.log(2), 2, np.log(3)],
...                  mask=[False, True, False])
>>> b = (~a.mask).astype(int)
>>> logsumexp(a.data, b=b), np.log(5)
1.6094379124341005, 1.6094379124341005

scipy.special.exprel

scipy.special.exprel(x) = <ufunc 'exprel'>
Relative error exponential, (exp(x) - 1)/x.

When x is near zero, exp(x) is near 1, so the numerical calculation of exp(x) - 1 can suffer from catastrophic loss of precision. exprel(x) is implemented to avoid the loss of precision that occurs when x is near zero.

Parameters

x [ndarray] Input array. x must contain real numbers.

Returns

float (exp(x) - 1)/x, computed element-wise.

See also:

expm1

Notes

New in version 0.17.0.

Examples

```python
>>> from scipy.special import exprel
```

```python
>>> exprel(0.01)
1.0050167084168056
```

```python
>>> exprel([-0.25, -0.1, 0, 0.1, 0.25])
array([ 0.88479687, 0.95162582, 1. , 1.05170918, 1.13610167])
```

Compare exprel(5e-9) to the naive calculation. The exact value is 1.00000000250000000416....

```python
>>> exprel(5e-9)
1.0000000025
```
```python
c scipy.special.sinc

scipy.special.sinc(x)
Return the sinc function.

The sinc function is \( \sin(\pi x) / (\pi x) \).

Parameters
x: array (possibly multi-dimensional)
    Values for which to calculate sinc(x).

Returns
out: ndarray
    sinc(x), which has the same shape as the input.

Notes
sinc(0) is the limit value 1.

The name sinc is short for “sine cardinal” or “sinus cardinalis”.

The sinc function is used in various signal processing applications, including in anti-aliasing, in the construction of a Lanczos resampling filter, and in interpolation.

For bandlimited interpolation of discrete-time signals, the ideal interpolation kernel is proportional to the sinc function.

References
[1], [2]

Examples
```
>>> plt.plot(x, np.sinc(x))
[<matplotlib.lines.Line2D object at 0x...>]
>>> plt.title("Sinc Function")
Text(0.5, 1.0, 'Sinc Function')
>>> plt.ylabel("Amplitude")
Text(0, 0.5, 'Amplitude')
>>> plt.xlabel("X")
Text(0.5, 0, 'X')
>>> plt.show()

It works in 2-D as well:

```python
>>> x = np.linspace(-4, 4, 401)
>>> xx = np.outer(x, x)
>>> plt.imshow(np.sinc(xx))
<matplotlib.image.AxesImage object at 0x...>
```

### 6.28 Statistical functions (scipy.stats)

This module contains a large number of probability distributions as well as a growing library of statistical functions.

Each univariate distribution is an instance of a subclass of `rv_continuous` (`rv_discrete` for discrete distributions):

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>rv_continuous</code></td>
<td>A generic continuous random variable class meant for subclassing.</td>
</tr>
<tr>
<td><code>rv_discrete</code></td>
<td>A generic discrete random variable class meant for subclassing.</td>
</tr>
<tr>
<td><code>rv_histogram</code></td>
<td>Generates a distribution given by a histogram.</td>
</tr>
</tbody>
</table>
6.28.1 scipy.stats.rv_continuous

class scipy.stats.rv_continuous (momtype=1, a=None, b=None, xtol=1e-14, badvalue=None, name=None, longname=None, shapes=None, extradoc=None, seed=None)

A generic continuous random variable class meant for subclassing.

rv_continuous is a base class to construct specific distribution classes and instances for continuous random variables. It cannot be used directly as a distribution.

Parameters

momtype [int, optional] The type of generic moment calculation to use: 0 for pdf, 1 (default) for ppf.
a [float, optional] Lower bound of the support of the distribution, default is minus infinity.
b [float, optional] Upper bound of the support of the distribution, default is plus infinity.
xtol [float, optional] The tolerance for fixed point calculation for generic ppf.
badvalue [float, optional] The value in a result arrays that indicates a value that for which some argument restriction is violated, default is np.nan.
name [str, optional] The name of the instance. This string is used to construct the default example for distributions.
longname [str, optional] This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: longname exists for backwards compatibility, do not use for new subclasses.
shapes [str, optional] The shape of the distribution. For example "m, n" for a distribution that takes two integers as the two shape arguments for all its methods. If not provided, shape parameters will be inferred from the signature of the private methods, _pdf and _cdf of the instance.
extradoc [str, optional, deprecated] This string is used as the last part of the docstring returned when a subclass has no docstring of its own. Note: extradoc exists for backwards compatibility, do not use for new subclasses.
seed [None or int or numpy.random.RandomState instance, optional] This parameter defines the RandomState object to use for drawing random variates. If None (or np.random), the global np.random state is used. If integer, it is used to seed the local RandomState instance. Default is None.
Notes

Public methods of an instance of a distribution class (e.g., pdf, cdf) check their arguments and pass valid arguments to private, computational methods (_pdf, _cdf). For pdf(x), x is valid if it is within the support of the distribution. Whether a shape parameter is valid is decided by an _argcheck method (which defaults to checking that its arguments are strictly positive.)

Subclassing

New random variables can be defined by subclassing the rv_continuous class and re-defining at least the _pdf or the _cdf method (normalized to location 0 and scale 1).

If positive argument checking is not correct for your RV then you will also need to re-define the _argcheck method.

For most of the scipy.stats distributions, the support interval doesn’t depend on the shape parameters. x being in the support interval is equivalent to self.a <= x <= self.b. If either of the endpoints of the support do depend on the shape parameters, then i) the distribution must implement the _get_support method; and ii) those dependent endpoints must be omitted from the distribution’s call to the rv_continuous initializer.

Correct, but potentially slow defaults exist for the remaining methods but for speed and/or accuracy you can override:

_logpdf, _cdf, _logcdf, _ppf, _rvs, _isf, _sf, _logsf

The default method _rvs relies on the inverse of the cdf, _ppf, applied to a uniform random variate. In order to generate random variates efficiently, either the default _ppf needs to be overwritten (e.g. if the inverse cdf can expressed in an explicit form) or a sampling method needs to be implemented in a custom _rvs method.

If possible, you should override _isf, _sf or _logsf. The main reason would be to improve numerical accuracy: for example, the survival function _sf is computed as 1 - _cdf which can result in loss of precision if _cdf(x) is close to one.

Methods that can be overwritten by subclasses

_rvs
_pdf
_cdf
_sf
_ppf
_isf
_stats
_munp
_entropy
_argcheck
_get_support

There are additional (internal and private) generic methods that can be useful for cross-checking and for debugging, but might work in all cases when directly called.

A note on shapes: subclasses need not specify them explicitly. In this case, shapes will be automatically deduced from the signatures of the overridden methods (pdf, cdf etc). If, for some reason, you prefer to avoid relying on introspection, you can specify shapes explicitly as an argument to the instance constructor.

Frozen Distributions

Normally, you must provide shape parameters (and, optionally, location and scale parameters to each call of a method of a distribution.)
Alternatively, the object may be called (as a function) to fix the shape, location, and scale parameters returning a “frozen” continuous RV object:

\[
rv = \text{generic}(\text{shape}(s), \text{loc}=0, \text{scale}=1)
\]

\(rv\_frozen\) object with the same methods but holding the given shape, location, and scale fixed

**Statistics**

Statistics are computed using numerical integration by default. For speed you can redefine this using \_stats:

- take shape parameters and return \(\mu, \mu_2, g_1, g_2\)
- If you can't compute one of these, return it as None
- Can also be defined with a keyword argument \text{moments}, which is a string composed of “m”, “v”, “s”, and/or “k”. Only the components appearing in string should be computed and returned in the order “m”, “v”, “s”, or “k” with missing values returned as None.

Alternatively, you can override \_munp, which takes \(n\) and shape parameters and returns the \(n\)-th non-central moment of the distribution.

**Examples**

To create a new Gaussian distribution, we would do the following:

```python
>>> from scipy.stats import rv_continuous
>>> class gaussian_gen(rv_continuous):
...    "Gaussian distribution"
...    def _pdf(self, x):
...        return np.exp(-x**2 / 2.) / np.sqrt(2.0 * np.pi)
>>> gaussian = gaussian_gen(name='gaussian')
```

\texttt{scipy.stats} distributions are \textit{instances}, so here we subclass \texttt{rv_continuous} and create an instance. With this, we now have a fully functional distribution with all relevant methods automatically generated by the framework.

Note that above we defined a standard normal distribution, with zero mean and unit variance. Shifting and scaling of the distribution can be done by using \texttt{loc} and \texttt{scale} parameters: \texttt{gaussian.pdf(x, loc, scale)} essentially computes \(y = (x - \texttt{loc}) / \texttt{scale}\) and \texttt{gaussian._pdf(y) / scale}.

**Attributes**

- \texttt{random_state}
  Get or set the RandomState object for generating random variates.

**Methods**

<table>

**scipy.stats.rv_continuous.rvs**

`rv_continuous.rvs`(self, *args, **kwds)

Random variates of given type.

**Parameters**

- `arg1, arg2, arg3,…`
  - [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- `loc`
  - [array_like, optional] Location parameter (default=0).
- `scale`
  - [array_like, optional] Scale parameter (default=1).
- `size`
  - [int or tuple of ints, optional] Defining number of random variates (default is 1).
- `random_state`
  - [None or int or np.random.RandomState instance, optional] If int or RandomState, use it for drawing the random variates. If None, rely on self.random_state. Default is None.

**Returns**

- `rvs` [ndarray or scalar] Random variates of given size.

**scipy.stats.rv_continuous.pdf**

`rv_continuous.pdf`(self, x, *args, **kwds)

Probability density function at x of the given RV.

**Parameters**

- `x`
  - [array_like] quantiles
arg1, arg2, arg3,…
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc
[array_like, optional] location parameter (default=0)
scale
[array_like, optional] scale parameter (default=1)

Returns
pdf
[ndarray] Probability density function evaluated at x

scipy.stats.rv_continuous.logpdf

rv_continuous.logpdf(self, x, *args, **kwds)
Log of the probability density function at x of the given RV.
This uses a more numerically accurate calculation if available.

Parameters
x
[array_like] quantiles
arg1, arg2, arg3,…
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc
[array_like, optional] location parameter (default=0)
scale
[array_like, optional] scale parameter (default=1)

Returns
logpdf
[array_like] Log of the probability density function evaluated at x

scipy.stats.rv_continuous.cdf

rv_continuous.cdf(self, x, *args, **kwds)
Cumulative distribution function of the given RV.

Parameters
x
[array_like] quantiles
arg1, arg2, arg3,…
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc
[array_like, optional] location parameter (default=0)
scale
[array_like, optional] scale parameter (default=1)

Returns
cdf
[ndarray] Cumulative distribution function evaluated at x

scipy.stats.rv_continuous.logcdf

rv_continuous.logcdf(self, x, *args, **kwds)
Log of the cumulative distribution function at x of the given RV.

Parameters
x
[array_like] quantiles
arg1, arg2, arg3,…

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc

[array_like, optional] location parameter (default=0)

scale

[array_like, optional] scale parameter (default=1)

Returns

logcdf

[array_like] Log of the cumulative distribution function evaluated at x

scipy.stats.rv_continuous.sf

rv_continuous.sf(self, x, *args, **kwds)

Survival function \((1 - cdf)\) at \(x\) of the given RV.

Parameters

x

[array_like] quantiles

arg1, arg2, arg3,…

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc

[array_like, optional] location parameter (default=0)

scale

[array_like, optional] scale parameter (default=1)

Returns

sf

[array_like] Survival function evaluated at \(x\)

scipy.stats.rv_continuous.logsf

rv_continuous.logsf(self, x, *args, **kwds)

Log of the survival function of the given RV.

Returns the log of the “survival function,” defined as \((1 - cdf)\), evaluated at \(x\).

Parameters

x

[array_like] quantiles

arg1, arg2, arg3,…

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc

[array_like, optional] location parameter (default=0)

scale

[array_like, optional] scale parameter (default=1)

Returns

logsf

[ndarray] Log of the survival function evaluated at \(x\).

scipy.stats.rv_continuous.ppf

rv_continuous.ppf(self, q, *args, **kwds)

Percent point function (inverse of \(cdf\)) at \(q\) of the given RV.

Parameters

q

[array_like] lower tail probability
arg1, arg2, arg3, ...
    [array_like] The shape parameter(s) for the distribution (see docstring of the instance
    object for more information)
loc
    [array_like, optional] location parameter (default=0)
scale
    [array_like, optional] scale parameter (default=1)

Returns
x
    [array_like] quantile corresponding to the lower tail probability q.

scipy.stats.rv_continuous.isf

rv_continuous.isf(self, q, *args, **kwds)
Inversesurvivalfunction(inverseof sf)atat q of the given RV.

Parameters
q
    [array_like] upper tail probability
arg1, arg2, arg3, ...
    [array_like] The shape parameter(s) for the distribution (see docstring of the instance
    object for more information)
loc
    [array_like, optional] location parameter (default=0)
scale
    [array_like, optional] scale parameter (default=1)

Returns
x
    [ndarray or scalar] Quantile corresponding to the upper tail probability q.

scipy.stats.rv_continuous.moment

rv_continuous.moment(self, n, *args, **kwds)
n-th ordernon-centralmomentofdistribution.

Parameters
n
    [int, n >= 1] Order of moment.
arg1, arg2, arg3, ...
    [float] The shape parameter(s) for the distribution (see docstring of the instance object
    for more information).
loc
    [array_like, optional] location parameter (default=0)
scale
    [array_like, optional] scale parameter (default=1)

scipy.stats.rv_continuous.stats

rv_continuous.stats(self, *args, **kwds)
Some statisticsof the given RV.

Parameters
arg1, arg2, arg3, ...
    [array_like] The shape parameter(s) for the distribution (see docstring of the instance object
    for more information)
loc
    [array_like, optional] location parameter (default=0)
scale
    [array_like, optional (continuous RVs only)] scale parameter (default=1)
moments
    [str, optional] composed of letters ['mvsk'] defining which moments to compute: ‘m’ =
    mean, ‘v’ = variance, ‘s’ = (Fisher’s) skew, ‘k’ = (Fisher’s) kurtosis. (default is ‘mv’)

6.28. Statistical functions (scipy.stats)
Returns

stats  [sequence] of requested moments.

scipy.stats.rv_continuous.entropy

rv_continuous.entropy(self, *args, **kwds)

Differential entropy of the RV.

Parameters

arg1, arg2, arg3,...
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc  [array_like, optional] Location parameter (default=0).
scale  [array_like, optional (continuous distributions only).] Scale parameter (default=1).

Notes

Entropy is defined base e:

```python
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

scipy.stats.rv_continuous.expect

rv_continuous.expect(self, func=None, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)

Calculate expected value of a function with respect to the distribution by numerical integration.

The expected value of a function \( f(x) \) with respect to a distribution \( \text{dist} \) is defined as:

\[
\text{E}[f(x)] = \int_{lb}^{ub} f(x) \cdot \text{dist.pdf}(x),
\]

where \( lb \) and \( ub \) are arguments and \( x \) has the \( \text{dist.pdf}(x) \) distribution. If the bounds \( lb \) and \( ub \) correspond to the support of the distribution, e.g. \([-\infty, \infty]\) in the default case, then the integral is the unrestricted expectation of \( f(x) \). Also, the function \( f(x) \) may be defined such that \( f(x) = 0 \) outside a finite interval in which case the expectation is calculated within the finite range \([lb, ub]\).

Parameters

func  [callable, optional] Function for which integral is calculated. Takes only one argument. The default is the identity mapping \( f(x) = x \).
args  [tuple, optional] Shape parameters of the distribution.
loc  [float, optional] Location parameter (default=0).
scale  [float, optional] Scale parameter (default=1).
lb, ub  [scalar, optional] Lower and upper bound for integration. Default is set to the support of the distribution.
conditional  [bool, optional] If True, the integral is corrected by the conditional probability of the integration interval. The return value is the expectation of the function, conditional on being in the given interval. Default is False.
Additional keyword arguments are passed to the integration routine.

Returns

**expect**

[float] The calculated expected value.

Notes

The integration behavior of this function is inherited from `scipy.integrate.quad`. Neither this function nor `scipy.integrate.quad` can verify whether the integral exists or is finite. For example `cauchy(0).mean()` returns `np.nan` and `cauchy(0).expect()` returns `0.0`.

Examples

To understand the effect of the bounds of integration consider

```python
>>> from scipy.stats import expon
>>> expon(1).expect(lambdax: 1, lb=0.0, ub=2.0)
0.6321205588285578
```

This is close to

```python
>>> expon(1).cdf(2.0) - expon(1).cdf(0.0)
0.6321205588285577
```

If `conditional=True`

```python
>>> expon(1).expect(lambdax: 1, lb=0.0, ub=2.0, conditional=True)
1.0000000000000002
```

The slight deviation from 1 is due to numerical integration.

**scipy.stats.rv_continuous.median**

`rv_continuous.median`  
Median of the distribution.

Parameters

```
arg1, arg2, arg3,...
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc
[array_like, optional] Location parameter, Default is 0.
scale
[array_like, optional] Scale parameter, Default is 1.
```

Returns

**median**

[float] The median of the distribution.

See also:

**rv_discrete.ppf**

Inverse of the CDF
scipy.stats.rv_continuous.mean

rv_continuous.mean(self, *args, **kwds)
Mean of the distribution.

Parameters
arg1, arg2, arg3,...
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns
mean [float] the mean of the distribution

scipy.stats.rv_continuous.std

rv_continuous.std(self, *args, **kwds)
Standard deviation of the distribution.

Parameters
arg1, arg2, arg3,...
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns
std [float] standard deviation of the distribution

scipy.stats.rv_continuous.var

rv_continuous.var(self, *args, **kwds)
Variance of the distribution.

Parameters
arg1, arg2, arg3,...
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns
var [float] the variance of the distribution

scipy.stats.rv_continuous.interval

rv_continuous.interval(self, alpha, *args, **kwds)
Confidence interval with equal areas around the median.

Parameters
SciPy Reference Guide, Release 1.3.2

alpha [array_like of float] Probability that an rv will be drawn from the returned range. Each value should be in the range \([0, 1]\).

arg1, arg2, ...
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] location parameter, Default is 0.
scale [array_like, optional] scale parameter, Default is 1.

Returns

a, b [ndarray of float] end-points of range that contain \(100 \times \alpha\) % of the rv's possible values.

scipy.stats.rv_continuous.__call__

scipy.stats.rv_continuous.__call__(self, *args, **kwds)
Freeze the distribution for the given arguments.

Parameters

arg1, arg2, arg3, ...
[array_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include loc and scale.

Returns

rv_frozen [rv_frozen instance] The frozen distribution.

scipy.stats.rv_continuous.fit

scipy.stats.rv_continuous.fit(self, data, *args, **kwds)
Return MLEs for shape (if applicable), location, and scale parameters from data.

MLE stands for Maximum Likelihood Estimate. Starting estimates for the fit are given by input arguments; for any arguments not provided with starting estimates, self._fitstart(data) is called to generate such.

One can hold some parameters fixed to specific values by passing in keyword arguments f0, f1, ..., fn (for shape parameters) and floc and fscale (for location and scale parameters, respectively).

Parameters

data [array_like] Data to use in calculating the MLEs.
args [floats, optional] Starting value(s) for any shape-characterizing arguments (those not provided will be determined by a call to _fitstart(data)). No default value.
kwds [floats, optional] Starting values for the location and scale parameters; no default. Special keyword arguments are recognized as holding certain parameters fixed:
• f0...fn : hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if self.shapes == "a, b", fa" and "fix_a are equivalent to f0, and fb and fix_b are equivalent to f1.
• floc : hold location parameter fixed to specified value.
• fscale : hold scale parameter fixed to specified value.
• optimizer : The optimizer to use. The optimizer must take func, and starting position as the first two arguments, plus args (for extra arguments to pass to the function to be optimized) and disp=0 to suppress output as keyword arguments.

Returns
mle_tuple  [tuple of floats] MLEs for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. norm).

Notes

This fit is computed by maximizing a log-likelihood function, with penalty applied for samples outside of range of the distribution. The returned answer is not guaranteed to be the globally optimal MLE, it may only be locally optimal, or the optimization may fail altogether.

Examples

Generate some data to fit: draw random variates from the beta distribution

```python
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (a, b, loc and scale):

```python
>>> a1, b1, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let’s keep loc and scale fixed:

```python
>>> a1, b1, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0, 1)
```

We can also keep shape parameters fixed by using f-keywords. To keep the zero-th shape parameter a equal 1, use f0=1 or, equivalently, fa=1:

```python
>>> a1, b1, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> a1
1
```

Not all distributions return estimates for the shape parameters. norm for example just returns estimates for location and scale:

```python
>>> from scipy.stats import norm
>>> x = norm.rvs(a, b, size=1000, random_state=123)
>>> loc1, scale1 = norm.fit(x)
>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)
```

scipy.stats.rv_continuous.fit_loc_scale

rv_continuous.fit_loc_scale(self, data, *args)

Estimate loc and scale parameters from data using 1st and 2nd moments.

Parameters

data  [array_like] Data to fit.
arg1, arg2, arg3,...
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**Returns**

Lhat: [float] Estimated location parameter for the data.
Shat: [float] Estimated scale parameter for the data.

**scipy.stats.rv_continuous.nnlf**

rv_continuous.nnlf(self, theta, x)
Return negative log likelihood function.

**Notes**

This is \(-\sum(\log pdf(x, \theta), \text{axis}=0)\) where \(\theta\) are the parameters (including loc and scale).

**scipy.stats.rv_continuous.support**

rv_continuous.support(self, *args, **kwargs)
Return the support of the distribution.

**Parameters**

arg1, arg2, ...
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc: [array_like, optional] location parameter, Default is 0.
scale: [array_like, optional] scale parameter, Default is 1.

**Returns**

a, b: [float] end-points of the distribution’s support.

### 6.28.2 scipy.stats.rv_discrete

class scipy.stats.rv_discrete(a=0, b=inf, name=None, badvalue=None, moment_tol=1e-08, values=None, inc=1, longname=None, shapes=None, extradoc=None, seed=None)
A generic discrete random variable class meant for subclassing.

rv_discrete is a base class to construct specific distribution classes and instances for discrete random variables. It can also be used to construct an arbitrary distribution defined by a list of support points and corresponding probabilities.

**Parameters**

a: [float, optional] Lower bound of the support of the distribution, default: 0
b: [float, optional] Upper bound of the support of the distribution, default: plus infinity
moment_tol: [float, optional] The tolerance for the generic calculation of moments.
values [tuple of two array_like, optional] \((x_k, p_k)\) where \(x_k\) are integers and \(p_k\) are the non-zero probabilities between 0 and 1 with \(\sum p_k = 1\). \(x_k\) and \(p_k\) must have the same shape.

inc [integer, optional] Increment for the support of the distribution. Default is 1. (other values have not been tested)

badvalue [float, optional] The value in a result arrays that indicates a value that for which some argument restriction is violated, default is np.nan.

name [str, optional] The name of the instance. This string is used to construct the default example for distributions.

longname [str, optional] This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: longname exists for backwards compatibility, do not use for new subclasses.

shapes [str, optional] The shape of the distribution. For example “m, n” for a distribution that takes two integers as the two shape arguments for all its methods If not provided, shape parameters will be inferred from the signatures of the private methods, \_pmf and \_cdf of the instance.

extradoc [str, optional] This string is used as the last part of the docstring returned when a subclass has no docstring of its own. Note: extradoc exists for backwards compatibility, do not use for new subclasses.

seed [None or int or numpy.random.RandomState instance, optional] This parameter defines the RandomState object to use for drawing random variates. If None, the global np.random state is used. If integer, it is used to seed the local RandomState instance. Default is None.

Notes

This class is similar to \texttt{rv\_continuous}. Whether a shape parameter is valid is decided by an \_argcheck method (which defaults to checking that its arguments are strictly positive.) The main differences are:

- the support of the distribution is a set of integers
- instead of the probability density function, \texttt{pdf} (and the corresponding private \_pdf), this class defines the probability mass function, \texttt{pmf} (and the corresponding private \_pmf.)
- scale parameter is not defined.

To create a new discrete distribution, we would do the following:

```python
>>> from scipy.stats import rv_discrete
>>> class poisson_gen(rv_discrete):
...     "Poisson distribution"
...     def _pmf(self, k, mu):
...         return exp(-mu) * mu**k / factorial(k)
```

and create an instance:

```python
>>> poisson = poisson_gen(name="poisson")
```

Note that above we defined the Poisson distribution in the standard form. Shifting the distribution can be done by providing the \texttt{loc} parameter to the methods of the instance. For example, \texttt{poisson.pmf(x, mu, loc)} delegates the work to \texttt{poisson._pmf(x-loc, mu)}.

Discrete distributions from a list of probabilities

Alternatively, you can construct an arbitrary discrete \texttt{rv} defined on a finite set of values \(x_k\) with \(\text{Prob}\{X=x_k\} = p_k\) by using the \texttt{values} keyword argument to the \texttt{rv\_discrete} constructor.
Examples

Custom made discrete distribution:

```python
>>> from scipy import stats
>>> xk = np.arange(7)
>>> pk = (0.1, 0.2, 0.3, 0.1, 0.0, 0.0, 0.2)
>>> custm = stats.rv_discrete(name='custm', values=(xk, pk))
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
>>> ax.plot(xk, custm.pmf(xk), 'ro', ms=12, mec='r')
>>> ax.vlines(xk, 0, custm.pmf(xk), colors='r', lw=4)
>>> plt.show()
```

Random number generation:

```python
>>> R = custm.rvs(size=100)
```

Attributes

`random_state`
Get or set the RandomState object for generating random variates.

Methods

- `rvs(self, *args, **kwargs)` Random variates of given type.
- `pmf(self, k, *args, **kwargs)` Probability mass function at k of the given RV.
- `logpmf(self, k, *args, **kwargs)` Log of the probability mass function at k of the given RV.
- `cdf(self, k, *args, **kwargs)` Cumulative distribution function of the given RV.

\texttt{scipy.stats.rv_discrete.rvs}

\texttt{rv_discrete.rvs}(self, *args, **kwargs)

Random variates of given type.

**Parameters**

arg1, arg2, arg3,...

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc

[array_like, optional] Location parameter (default=0).

size

[int or tuple of ints, optional] Defining number of random variates (Default is 1). Note that size has to be given as keyword, not as positional argument.

random_state

[None or int or np.random.RandomState instance, optional] If int or RandomState, use it for drawing the random variates. If None, rely on self. random_state. Default is None.

**Returns**

rvs

[ndarray or scalar] Random variates of given size.

\texttt{scipy.stats.rv_discrete.pmf}

\texttt{rv_discrete.pmf}(self, k, *args, **kwds)

Probability mass function at k of the given RV.

**Parameters**

k

[array_like] Quantiles.
arg1, arg2, arg3,…  
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc  
[array_like, optional] Location parameter (default=0).

Returns

pmf  
[array_like] Probability mass function evaluated at k

scipy.stats.rv_discrete.logpmf

rv_discrete.logpmf (self, k, *args, **kwargs)  
Log of the probability mass function at k of the given RV.

Parameters

k  
[array_like] Quantiles.
arg1, arg2, arg3,…  
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc  
[array_like, optional] Location parameter. Default is 0.

Returns

logpmf  
[array_like] Log of the probability mass function evaluated at k.

scipy.stats.rv_discrete.cdf

rv_discrete.cdf (self, k, *args, **kwargs)  
Cumulative distribution function of the given RV.

Parameters

k  
[array_like, int] Quantiles.
arg1, arg2, arg3,…  
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc  
[array_like, optional] Location parameter (default=0).

Returns

cdf  
[ndarray] Cumulative distribution function evaluated at k.

scipy.stats.rv_discrete.logcdf

rv_discrete.logcdf (self, k, *args, **kwargs)  
Log of the cumulative distribution function at k of the given RV.

Parameters

k  
[array_like, int] Quantiles.
arg1, arg2, arg3,…  
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc  
[array_like, optional] Location parameter (default=0).

Returns

logcdf  
[array_like] Log of the cumulative distribution function evaluated at k.
scipy.stats.rv_discrete.sf

```
rv_discrete.sf (self, k, *args, **kwds)
```
Survival function (1 - cdf) at k of the given RV.

**Parameters**

- `k` [array_like] Quantiles.
- `arg1, arg2, arg3,..` [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- `loc` [array_like, optional] Location parameter (default=0).

**Returns**

- `sf` [array_like] Survival function evaluated at k.

scipy.stats.rv_discrete.logsf

```
rv_discrete.logsf (self, k, *args, **kwds)
```
Log of the survival function of the given RV.
Returns the log of the “survival function,” defined as 1 - cdf, evaluated at k.

**Parameters**

- `k` [array_like] Quantiles.
- `arg1, arg2, arg3,..` [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- `loc` [array_like, optional] Location parameter (default=0).

**Returns**

- `logsf` [ndarray] Log of the survival function evaluated at k.

scipy.stats.rv_discrete.ppf

```
rv_discrete.ppf (self, q, *args, **kwds)
```
Percent point function (inverse of cdf) at q of the given RV.

**Parameters**

- `q` [array_like] Lower tail probability.
- `arg1, arg2, arg3,..` [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- `loc` [array_like, optional] Location parameter (default=0).

**Returns**

- `k` [array_like] Quantile corresponding to the lower tail probability, q.
scipy.stats.rv_discrete.isf

```
sf = rv_discrete.isf(self, q, *args, **kwds)
```

Inversesurvival function (inverse of \( sf \)) at \( q \) of the given RV.

**Parameters**

- \( q \) : [array_like] Upper tail probability.
- \( \text{arg1, arg2, arg3,...} \) : [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- \( \text{loc} \) : [array_like, optional] Location parameter (default=0).

**Returns**

- \( k \) : [ndarray or scalar] Quantile corresponding to the upper tail probability, \( q \).

scipy.stats.rv_discrete.moment

```
moment = rv_discrete.moment(self, n, *args, **kwds)
```

n-th order non-central moment of distribution.

**Parameters**

- \( n \) : [int, \( n \geq 1 \)] Order of moment.
- \( \text{arg1, arg2, arg3,...} \) : [float] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- \( \text{loc} \) : [array_like, optional] Location parameter (default=0)
- \( \text{scale} \) : [array_like, optional] Scale parameter (default=1)

scipy.stats.rv_discrete.stats

```
stats = rv_discrete.stats(self, *args, **kwds)
```

Some statistics of the given RV.

**Parameters**

- \( \text{arg1, arg2, arg3,...} \) : [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- \( \text{loc} \) : [array_like, optional] Location parameter (default=0)
- \( \text{scale} \) : [array_like, optional (continuous RVs only)] Scale parameter (default=1)
- \( \text{moments} \) : [str, optional] Composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

**Returns**

- \( \text{stats} \) : [sequence] of requested moments.

scipy.stats.rv_discrete.entropy

```
entropy = rv_discrete.entropy(self, *args, **kwds)
```

Differential entropy of the RV.

**Parameters**
arg1, arg2, arg3, …

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc

[array_like, optional] Location parameter (default=0).

scale

[array_like, optional (continuous distributions only).] Scale parameter (default=1).

Notes

Entropy is defined base e:

```python
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

scipy.stats.rv_discrete.expect

`rv_discrete.expect` (self, func=None, args=(), loc=0, lb=None, ub=None, conditional=False, maxcount=1000, tolerance=1e-10, chunksize=32)

Calculate expected value of a function with respect to the distribution for discrete distribution by numerical summation.

Parameters

- **func** [callable, optional] Function for which the expectation value is calculated. Takes only one argument. The default is the identity mapping \( f(k) = k \).
- **args** [tuple, optional] Shape parameters of the distribution.
- **loc** [float, optional] Location parameter. Default is 0.
- **lb, ub** [int, optional] Lower and upper bound for the summation, default is set to the support of the distribution, inclusive \((ul <= k <= ub)\).
- **conditional** [bool, optional] If true then the expectation is corrected by the conditional probability of the summation interval. The return value is the expectation of the function, func, conditional on being in the given interval \((k \text{ such that } ul <= k <= ub)\). Default is False.
- **maxcount** [int, optional] Maximal number of terms to evaluate (to avoid an endless loop for an infinite sum). Default is 1000.
- **tolerance** [float, optional] Absolute tolerance for the summation. Default is 1e-10.
- **chunksize** [int, optional] Iterate over the support of a distributions in chunks of this size. Default is 32.

Returns

- **expect** [float] Expected value.

Notes

For heavy-tailed distributions, the expected value may or may not exist, depending on the function, func. If it does exist, but the sum converges slowly, the accuracy of the result may be rather low. For instance, for `zipf(4)`, accuracy for mean, variance in example is only 1e-5. increasing `maxcount` and/or `chunksize` may improve the result, but may also make `zipf` very slow.

The function is not vectorized.
**scipy.stats.rv_discrete.median**

`rv_discrete.median(self, *args, **kwds)`

Median of the distribution.

**Parameters**

- `arg1, arg2, arg3, ...`
  - `[array_like]` The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- `loc`
  - `[array_like, optional]` Location parameter, Default is 0.
- `scale`
  - `[array_like, optional]` Scale parameter, Default is 1.

**Returns**

- `median`
  - `[float]` The median of the distribution.

See also:

- `rv_discrete.ppf`
  - Inverse of the CDF

**scipy.stats.rv_discrete.mean**

`rv_discrete.mean(self, *args, **kwds)`

Mean of the distribution.

**Parameters**

- `arg1, arg2, arg3, ...`
  - `[array_like]` The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- `loc`
  - `[array_like, optional]` Location parameter (default=0)
- `scale`
  - `[array_like, optional]` Scale parameter (default=1)

**Returns**

- `mean`
  - `[float]` The mean of the distribution

**scipy.stats.rv_discrete.std**

`rv_discrete.std(self, *args, **kwds)`

Standard deviation of the distribution.

**Parameters**

- `arg1, arg2, arg3, ...`
  - `[array_like]` The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- `loc`
  - `[array_like, optional]` Location parameter (default=0)
- `scale`
  - `[array_like, optional]` Scale parameter (default=1)

**Returns**

- `std`
  - `[float]` Standard deviation of the distribution
scipy.stats.rv_discrete.var

rv_discrete.var(self, *args, **kwds)
Variance of the distribution.

Parameters

arg1, arg2, arg3, ...
[array_like] The shape parameter(s) for the distribution (see docstring of the instance
object for more information)

loc
[array_like, optional] location parameter (default=0)
scale
[array_like, optional] scale parameter (default=1)

Returns

var [float] the variance of the distribution

scipy.stats.rv_discrete.interval

rv_discrete.interval(self, alpha, *args, **kwds)
Confidence interval with equal areas around the median.

Parameters

alpha [array_like of float] Probability that an rv will be drawn from the returned range. Each
value should be in the range [0, 1].

arg1, arg2, ...
[array_like] The shape parameter(s) for the distribution (see docstring of the instance
object for more information).

loc
[array_like, optional] location parameter. Default is 0.
scale
[array_like, optional] scale parameter. Default is 1.

Returns

a, b [ndarray of float] end-points of range that contain 100 * alpha % of the rv's possible values.

scipy.stats.rv_discrete.__call__

rv_discrete.__call__(self, *args, **kwds)
Freeze the distribution for the given arguments.

Parameters

arg1, arg2, arg3, ...
[array_like] The shape parameter(s) for the distribution. Should include all the non-
optional arguments, may include loc and scale.

Returns

rv_frozen [rv_frozen instance] The frozen distribution.
scipy.stats.rv_discrete.support

```
rv_discrete.support(self, *args, **kwargs)
```

Return the support of the distribution.

**Parameters**

arg1, arg2, ...
- [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc
- [array_like, optional] location parameter, Default is 0.

scale
- [array_like, optional] scale parameter, Default is 1.

**Returns**

a, b
- [float] end-points of the distribution’s support.

6.28.3 scipy.stats.rv_histogram

```
class scipy.stats.rv_histogram(histogram, *args, **kwargs)
```

Generates a distribution given by a histogram. This is useful to generate a template distribution from a binned datasample.

As a subclass of the `rv_continuous` class, `rv_histogram` inherits from it a collection of generic methods (see `rv_continuous` for the full list), and implements them based on the properties of the provided binned datasample.

**Parameters**

histogram
- [tuple of array_like] Tuple containing two array_like objects The first containing the content of n bins The second containing the (n+1) bin boundaries In particular the return value np.histogram is accepted

**Notes**

There are no additional shape parameters except for the loc and scale. The pdf is defined as a stepwise function from the provided histogram The cdf is a linear interpolation of the pdf.

New in version 0.19.0.

**Examples**

Create a scipy.stats distribution from a numpy histogram

```
>>> import scipy.stats
>>> import numpy as np
>>> data = scipy.stats.norm.rvs(size=100000, loc=0, scale=1.5, random_state=123)
>>> hist = np.histogram(data, bins=100)
>>> hist_dist = scipy.stats.rv_histogram(hist)
```

Behaves like an ordinary scipy `rv_continuous` distribution
PDF is zero above (below) the highest (lowest) bin of the histogram, defined by the max (min) of the original dataset.

```
>>> hist_dist.pdf(np.max(data))
0.0
>>> hist_dist.cdf(np.max(data))
1.0
>>> hist_dist.pdf(np.min(data))
7.7591907244498314e-05
>>> hist_dist.cdf(np.min(data))
0.0
```

PDF and CDF follow the histogram.

```
>>> import matplotlib.pyplot as plt
>>> X = np.linspace(-5.0, 5.0, 100)
>>> plt.title("PDF from Template")
>>> plt.hist(data, density=True, bins=100)
>>> plt.plot(X, hist_dist.pdf(X), label='PDF')
>>> plt.plot(X, hist_dist.cdf(X), label='CDF')
>>> plt.show()
```

```python

Attributes

random_state

Get or set the RandomState object for generating random variates.

Methods

PDF from Template

2106 Chapter 6. API Reference
__call__ (self, *args, **kwds) Freeze the distribution for the given arguments.

cdf (self, x, *args, **kwds) Cumulative distribution function of the given RV.

entropy (self, *args, **kwds) Differential entropy of the RV.

expect (self[, func, args, loc, scale, lb, ...]) Calculate expected value of a function with respect to the distribution by numerical integration.

fit (self, data, *args, **kwds) Return MLEs for shape (if applicable), location, and scale parameters from data.

fit_loc_scale (self, data, *args) Estimate loc and scale parameters from data using 1st and 2nd moments.

freeze (self, *args, **kwds) Freeze the distribution for the given arguments.

interval (self, alpha, *args, **kwds) Confidence interval with equal areas around the median.

isf (self, q, *args, **kwds) Inverse survival function (inverse of sf) at q of the given RV.

logcdf (self, x, *args, **kwds) Log of the cumulative distribution function at x of the given RV.

logpdf (self, x, *args, **kwds) Log of the probability density function at x of the given RV.

logsf (self, x, *args, **kwds) Log of the survival function of the given RV.

mean (self, *args, **kwds) Mean of the distribution.

median (self, *args, **kwds) Median of the distribution.

moment (self, n, *args, **kwds) n-th order non-central moment of distribution.

nnlf (self, theta, x) Return negative loglikelihood function.

pdf (self, x, *args, **kwds) Probability density function at x of the given RV.

ppf (self, q, *args, **kwds) Percent point function (inverse of cdf) at q of the given RV.

rvs (self, *args, **kwds) Random variates of given type.

sf (self, x, *args, **kwds) Survival function (1 - cdf) at x of the given RV.

stats (self, *args, **kwds) Some statistics of the given RV.

support (self, *args, **kwds) Return support of the distribution.

var (self, *args, **kwds) Variance of the distribution.

scipy.stats.rv_histogram.__call__

rv_histogram.__call__ (self, *args, **kwds) Freeze the distribution for the given arguments.

Parameters

arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include loc and scale.

Returns

rv_frozen [rv_frozen instance] The frozen distribution.

scipy.stats.rv_histogram.cdf

rv_histogram.cdf (self, x, *args, **kwds) Cumulative distribution function of the given RV.

Parameters
SciPy Reference Guide, Release 1.3.2

x      [array_like]  quantiles
arg1, arg2, arg3,...
      [array_like]  The shape parameter(s) for the distribution (see docstring of the instance
loc    [array_like, optional]  location parameter (default=0)
scale  [array_like, optional]  scale parameter (default=1)

Returns
cdf    [ndarray]  Cumulative distribution function evaluated at x

scipy.stats.rv_histogram.entropy

rv_histogram.entropy(self, *args, **kwds)
Differential entropy of the RV.

Parameters
arg1, arg2, arg3,...
      [array_like]  The shape parameter(s) for the distribution (see docstring of the instance
loc    [array_like, optional]  Location parameter (default=0).
scale  [array_like, optional]  Scale parameter (default=1).

Notes
Entropy is defined base e:

```python
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

scipy.stats.rv_histogram.expect

rv_histogram.expect(self, func=None, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)
Calculate expected value of a function with respect to the distribution by numerical integration.

The expected value of a function \( f(x) \) with respect to a distribution \( \text{dist} \) is defined as:

\[
E[f(x)] = \int_{lb}^{ub} f(x) \times \text{dist.pdf}(x) \, dx
\]

where \( ub \) and \( lb \) are arguments and \( x \) has the \( \text{dist.pdf}(x) \) distribution. If the bounds \( lb \) and \( ub \) correspond to the support of the distribution, e.g. \([\text{-inf}, \text{inf}]\) in the default case, then the integral is the unrestricted expectation of \( f(x) \). Also, the function \( f(x) \) may be defined such that \( f(x) = 0 \) outside a finite interval in which case the expectation is calculated within the finite range \([lb, ub]\).

Parameters
func  [callable, optional]  Function for which integral is calculated. Takes only one argument.
     The default is the identity mapping \( f(x) = x \).
args  [tuple, optional]  Shape parameters of the distribution.
loc   [float, optional]  Location parameter (default=0).
scale  [float, optional] Scale parameter (default=1).
lb, ub  [scalar, optional] Lower and upper bound for integration. Default is set to the support
        of the distribution.
conditional  [bool, optional] If True, the integral is corrected by the conditional probability of the
            integration interval. The return value is the expectation of the function, conditional on
            being in the given interval. Default is False.

Additional keyword arguments are passed to the integration routine.

Returns

expect  [float] The calculated expected value.

Notes

The integration behavior of this function is inherited from SciPy's \texttt{scipy.integrate.quad}. Neither this
function nor \texttt{scipy.integrate.quad} can verify whether the integral exists or is finite. For example
\texttt{cauchy(0).mean()} returns \texttt{np.nan} and \texttt{cauchy(0).expect()} returns \texttt{0.0}.

Examples

To understand the effect of the bounds of integration consider >>> from scipy.stats import expon >>> ex-
pon(1).expect(lambda x: 1, lb=0.0, ub=2.0) 0.6321205588285578

This is close to

\begin{verbatim}
>>> expon(1).cdf(2.0) - expon(1).cdf(0.0)
0.6321205588285577
\end{verbatim}

If conditional=True

\begin{verbatim}
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0, conditional=True)
1.0000000000000002
\end{verbatim}

The slight deviation from 1 is due to numerical integration.

\texttt{scipy.stats.rv_histogram.fit}

\texttt{rv_histogram.fit}(self, data, *args, **kwds)

Return MLEs for shape (if applicable), location, and scale parameters from data.

MLE stands for Maximum Likelihood Estimate. Starting estimates for the fit are given by input arguments;
for any arguments not provided with starting estimates, \texttt{self._fitstart(data)} is called to generate
such.

One can hold some parameters fixed to specific values by passing in keyword arguments \texttt{f0, f1, ..., fn}
(for shape parameters) and \texttt{floc} and \texttt{fscale} (for location and scale parameters, respectively).

Parameters

data  [array_like] Data to use in calculating the MLEs.
args  [floats, optional] Starting value(s) for any shape-characterizing arguments (those not
    provided will be determined by a call to \texttt{self._fitstart(data)}). No default value.
kwds  [floats, optional] Starting values for the location and scale parameters; no default. Special
    keyword arguments are recognized as holding certain parameters fixed:
• `f0...fn`: hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if `self.shapes == "a, b"`, `fa` and `fix_a` are equivalent to `f0`, and `fb` and `fix_b` are equivalent to `f1`.
• `floc`: hold location parameter fixed to specified value.
• `fscale`: hold scale parameter fixed to specified value.
• `optimizer`: The optimizer to use. The optimizer must take `func`, and starting position as the first two arguments, plus `args` (for extra arguments to pass to the function to be optimized) and `disp=0` to suppress output as keyword arguments.

**Returns**

`mle_tuple` [tuple of floats] MLEs for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. `norm`).

**Notes**

This fit is computed by maximizing a log-likelihood function, with penalty applied for samples outside of range of the distribution. The returned answer is not guaranteed to be the globally optimal MLE, it may only be locally optimal, or the optimization may fail altogether.

**Examples**

Generate some data to fit: draw random variates from the `beta` distribution

```python
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (`a`, `b`, `loc` and `scale`):

```python
>>> a1, b1, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let's keep `loc` and `scale` fixed:

```python
>>> a1, b1, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0, 1)
```

We can also keep shape parameters fixed by using `f`-keywords. To keep the zero-th shape parameter `a` equal 1, use `f0=1` or, equivalently, `fa=1`:

```python
>>> a1, b1, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> a1
1
```

Not all distributions return estimates for the shape parameters. `norm` for example just returns estimates for location and scale:

```python
>>> from scipy.stats import norm
>>> x = norm.rvs(a, b, size=1000, random_state=123)
>>> loc1, scale1 = norm.fit(x)
```

(continues on next page)
```python
>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)
```

**scipy.stats.rv_histogram.fit_loc_scale**

`rv_histogram.fit_loc_scale(self, data, *args)`

Estimate loc and scale parameters from data using 1st and 2nd moments.

**Parameters**

- **data** [array_like] Data to fit.
- **arg1, arg2, arg3,**
  [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**Returns**

- **Lhat** [float] Estimated location parameter for the data.
- **Shat** [float] Estimated scale parameter for the data.

**scipy.stats.rv_histogram.freeze**

`rv_histogram.freeze(self, *args, **kwds)`

Freeze the distribution for the given arguments.

**Parameters**

- **arg1, arg2, arg3,**
  [array_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include loc and scale.

**Returns**

- **rv_frozen** [rv_frozen instance] The frozen distribution.

**scipy.stats.rv_histogram.interval**

`rv_histogram.interval(self, alpha, *args, **kwds)`

Confidence interval with equal areas around the median.

**Parameters**

- **alpha** [array_like of float] Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].
- **arg1, arg2,**
  [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- **loc** [array_like, optional] location parameter. Default is 0.
- **scale** [array_like, optional] scale parameter. Default is 1.

**Returns**

- **a, b** [ndarray of float] end-points of range that contain 100 * alpha % of the rv's possible values.
scipy.stats.rv_histogram.isf

```
rv_histogram.isf(self, q, *args, **kwds)
```

Inverse survival function (inverse of \(sf\)) at \(q\) of the given RV.

**Parameters**

- **q** [array_like] upper tail probability
- **arg1, arg2, arg3,...** [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- **loc** [array_like, optional] location parameter (default=0)
- **scale** [array_like, optional] scale parameter (default=1)

**Returns**

- **x** [ndarray or scalar] Quantile corresponding to the upper tail probability \(q\).

scipy.stats.rv_histogram.logcdf

```
rv_histogram.logcdf(self, x, *args, **kwds)
```

Log of the cumulative distribution function at \(x\) of the given RV.

**Parameters**

- **x** [array_like] quantiles
- **arg1, arg2, arg3,...** [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- **loc** [array_like, optional] location parameter (default=0)
- **scale** [array_like, optional] scale parameter (default=1)

**Returns**

- **logcdf** [array_like] Log of the cumulative distribution function evaluated at \(x\)

scipy.stats.rv_histogram.logpdf

```
rv_histogram.logpdf(self, x, *args, **kwds)
```

Log of the probability density function at \(x\) of the given RV.

This uses a more numerically accurate calculation if available.

**Parameters**

- **x** [array_like] quantiles
- **arg1, arg2, arg3,...** [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- **loc** [array_like, optional] location parameter (default=0)
- **scale** [array_like, optional] scale parameter (default=1)

**Returns**

- **logpdf** [array_like] Log of the probability density function evaluated at \(x\)
scipy.stats.rv_histogram.logsf

rv_histogram.logsf(self, x, *args, **kwds)

Log of the survival function of the given RV.

Returns the log of the “survival function,” defined as \((1 - cdf)\), evaluated at \(x\).

Parameters

- \(x\): [array_like] quantiles
- \(arg1, arg2, arg3,...\): [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- \(loc\): [array_like, optional] location parameter (default=0)
- \(scale\): [array_like, optional] scale parameter (default=1)

Returns

- \(logsf\): [ndarray] Log of the survival function evaluated at \(x\).

scipy.stats.rv_histogram.mean

rv_histogram.mean(self, *args, **kwds)

Mean of the distribution.

Parameters

- \(arg1, arg2, arg3,...\): [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- \(loc\): [array_like, optional] location parameter (default=0)
- \(scale\): [array_like, optional] scale parameter (default=1)

Returns

- \(mean\): [float] the mean of the distribution

scipy.stats.rv_histogram.median

rv_histogram.median(self, *args, **kwds)

Median of the distribution.

Parameters

- \(arg1, arg2, arg3,...\): [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- \(loc\): [array_like, optional] Location parameter, Default is 0.
- \(scale\): [array_like, optional] Scale parameter, Default is 1.

Returns

- \(median\): [float] The median of the distribution.

See also:

rv_discrete.ppf

Inverse of the CDF
**scipy.stats.rv_histogram.moment**

`rv_histogram.moment(self, n, *args, **kwds)`

n-th order non-central moment of distribution.

**Parameters**

- `n` : [int, n >= 1] Order of moment.
- `arg1, arg2, arg3,...` : [float] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- `loc` : [array_like, optional] location parameter (default=0)
- `scale` : [array_like, optional] scale parameter (default=1)

**scipy.stats.rv_histogram.nnlf**

`rv_histogram.nnlf(self, theta, x)`

Return negative loglikelihood function.

**Notes**

This is \(-\sum(\log \text{ pdf}(x, \theta))\), axis=0) where \(\theta\) are the parameters (including loc and scale).

**scipy.stats.rv_histogram.pdf**

`rv_histogram.pdf(self, x, *args, **kwds)`

Probability density function at \(x\) of the given RV.

**Parameters**

- `x` : [array_like] quantiles
- `arg1, arg2, arg3,...` : [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- `loc` : [array_like, optional] location parameter (default=0)
- `scale` : [array_like, optional] scale parameter (default=1)

**Returns**

- `pdf` : [ndarray] Probability density function evaluated at \(x\)

**scipy.stats.rv_histogram.ppf**

`rv_histogram.ppf(self, q, *args, **kwds)`

Percent point function (inverse of \(cdf\)) at \(q\) of the given RV.

**Parameters**

- `q` : [array_like] lower tail probability
- `arg1, arg2, arg3,...` : [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- `loc` : [array_like, optional] location parameter (default=0)
- `scale` : [array_like, optional] scale parameter (default=1)
**Returns**

\[ x \] (array_like) quantile corresponding to the lower tail probability \( q \).

### scipy.stats.rv_histogram.rvs

**rv_histogram.rvs** (*self*, *args, **kwds*)

Random variates of given type.

**Parameters**

- arg1, arg2, arg3,...
  [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc
  [array_like, optional] Location parameter (default=0).
- scale
  [array_like, optional] Scale parameter (default=1).
- size
  [int or tuple of ints, optional] Defining number of random variates (default is 1).
- random_state
  [None or int or np.random.RandomState instance, optional] If int or RandomState, use it for drawing the random variates. If None, rely on self.random_state. Default is None.

**Returns**

\[ rvs \] (ndarray or scalar) Random variates of given size.

### scipy.stats.rv_histogram.sf

**rv_histogram.sf** (*self, x, *args, **kwds*)

Survival function \((1 - cdf)\) at \( x \) of the given RV.

**Parameters**

- x
  [array_like] quantiles
- arg1, arg2, arg3,...
  [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- loc
  [array_like, optional] location parameter (default=0)
- scale
  [array_like, optional] scale parameter (default=1)

**Returns**

\[ sf \] (array_like) Survival function evaluated at \( x \)

### scipy.stats.rv_histogram.stats

**rv_histogram.stats** (*self, *args, **kwds*)

Some statistics of the given RV.

**Parameters**

- arg1, arg2, arg3,...
  [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- loc
  [array_like, optional] location parameter (default=0)
- scale
  [array_like, optional (continuous RVs only)] scale parameter (default=1)
moments  [str, optional] composed of letters ['mvsk'] defining which moments to compute: ‘m’ = mean, ‘v’ = variance, ‘s’ = (Fisher’s) skew, ‘k’ = (Fisher’s) kurtosis. (default is ‘mv’)

Returns

stats  [sequence] of requested moments.

scipy.stats.rv_histogram.std

rv_histogram.std(self, *args, **kwds)

Standard deviation of the distribution.

Parameters

arg1, arg2, arg3,...
    [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc  [array_like, optional] location parameter (default=0)
scale  [array_like, optional] scale parameter (default=1)

Returns

std  [float] standard deviation of the distribution

scipy.stats.rv_histogram.support

rv_histogram.support(self, *args, **kwargs)

Return the support of the distribution.

Parameters

arg1, arg2, ...
    [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc  [array_like, optional] location parameter, Default is 0.
scale  [array_like, optional] scale parameter, Default is 1.

Returns

——
a, b  [float] end-points of the distribution’s support.

scipy.stats.rv_histogram.var

rv_histogram.var(self, *args, **kwds)

Variance of the distribution.

Parameters

arg1, arg2, arg3,...
    [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc  [array_like, optional] location parameter (default=0)
scale  [array_like, optional] scale parameter (default=1)

Returns

var  [float] the variance of the distribution

### scipy.stats.alpha

```python
def scipy.stats.alpha(*args, **kwds) = <scipy.stats._continuous_distns.alpha_gen object>
```

An alpha continuous random variable.

As an instance of the `rv_continuous` class, `alpha` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

#### Notes

The probability density function for `alpha` is:

\[
f(x, a) = \frac{1}{x^2 \Phi(a) \sqrt{2\pi}} \exp\left(-\frac{1}{2}(a - 1/x)^2\right)
\]

where \( \Phi \) is the normal CDF, \( x > 0 \), and \( a > 0 \).

`alpha` takes \( a \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `alpha.pdf(x, a, loc, scale)` is identically equivalent to `alpha.pdf(y, a) / scale` with \( y = (x - loc) / scale \).

#### Examples

```python
>>> from scipy.stats import alpha
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a = 3.57
>>> mean, var, skew, kurt = alpha.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(alpha.ppf(0.01, a), ...
                      alpha.ppf(0.99, a), 100)
>>> ax.plot(x, alpha.pdf(x, a), ...
                      'r-', lw=5, alpha=0.6, label='alpha pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
>>> rv = alpha(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

Check accuracy of cdf and ppf:

>>> vals = alpha.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], alpha.cdf(vals, a))
True

Generate random numbers:

>>> r = alpha.rvs(a, size=1000)

And compare the histogram:

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

</tr>
</tbody>
</table>

scipy.stats.anglit

scipy.stats.anglit(*args, **kwds) = <scipy.stats._continuous_distns.anglit_gen object>

An anglit continuous random variable.

As an instance of the rv_continuous class, anglit object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for anglit is:

\[ f(x) = \sin(2x + \pi/2) = \cos(2x) \]

for \(-\pi/4 \leq x \leq \pi/4\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, anglit.pdf(x, loc, scale) is identically equivalent to anglit.pdf(y) / scale with y = (x - loc) / scale.

Examples
Calculate a few first moments:

```python
>>> mean, var, skew, kurt = anglit.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(anglit.ppf(0.01),
...                 anglit.ppf(0.99), 100)
>>> ax.plot(x, anglit.pdf(x),
...          'r-', lw=5, alpha=0.6, label='anglit pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = anglit()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = anglit.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], anglit.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = anglit.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.arcsine**

```python
scipy.stats.arcsine(*args, **kwds) = <scipy.stats._continuous_distns.arcsine_gen object>
```

An arcsine continuous random variable.
As an instance of the `rv_continuous` class, `arcsine` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `arcsine` is:

\[
    f(x) = \frac{1}{\pi \sqrt{x(1-x)}}
\]

for \(0 < x < 1\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, \(\text{arcsine.pdf}(x, \text{loc}, \text{scale})\) is identically equivalent to \(\text{arcsine.pdf}(y) / \text{scale}\) with \(y = (x - \text{loc}) / \text{scale}\).

**Examples**

```python
>>> from scipy.stats import arcsine
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = arcsine.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(arcsine.ppf(0.01),
                 ...                 arcsine.ppf(0.99), 100)
>>> ax.plot(x, arcsine.pdf(x),
          ...          'r-', lw=5, alpha=0.6, label='arcsine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = arcsine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = arcsine.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], arcsine.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = arcsine.rvs(size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.argus

scipy.stats.argus(*args, **kwds) = <scipy.stats._continuous_distns.argus_gen object>

Argus distribution

As an instance of the rv_continuous class, argus object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for argus is:

\[ f(x, \chi) = \frac{\chi^3}{\sqrt{2\pi} \Psi(\chi)} x \sqrt{1 - x^2} \exp(-\chi^2(1 - x^2)/2) \]

for \(0 < x < 1\), where

\[ \Psi(\chi) = \Phi(\chi) - \chi \phi(\chi) - 1/2 \]

with \(\Phi\) and \(\phi\) being the CDF and PDF of a standard normal distribution, respectively.

argus takes \(\chi\) as shape a parameter.

References

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, argus.pdf(x, \(\chi\), loc, scale) is identically equivalent to argus.pdf(y, \(\chi\)) / scale with y = (x - loc) / scale.

New in version 0.19.0.

[1]

Examples

```python
>>> from scipy.stats import argus
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> chi = 1
>>> mean, var, skew, kurt = argus.stats(chi, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(argus.ppf(0.01, chi), ... argus.ppf(0.99, chi), 100)
>>> ax.plot(x, argus.pdf(x, chi), ... 'r-', lw=5, alpha=0.6, label='argus pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
>>> rv = argus(chi)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

Check accuracy of cdf and ppf:

>>> vals = argus.ppf([0.001, 0.5, 0.999], chi)
>>> np.allclose([0.001, 0.5, 0.999], argus.cdf(vals, chi))
True

Generate random numbers:

>>> r = argus.rvs(chi, size=1000)

And compare the histogram:

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

**scipy.stats.beta**

`scipy.stats.beta(*args, **kwds) = <scipy.stats._continuous_distns.beta_gen object>`

A beta continuous random variable.

As an instance of the `rv_continuous` class, `beta` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `beta` is:

\[
f(x, a, b) = \frac{\Gamma(a + b)}{\Gamma(a)\Gamma(b)} x^{a-1}(1 - x)^{b-1}
\]

for \(0 \leq x \leq 1, a > 0, b > 0\), where \(\Gamma\) is the gamma function (`scipy.special.gamma`).

`beta` takes \(a\) and \(b\) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, \(\text{beta.pdf}(x, a, b, \text{loc}, \text{scale})\) is identically equivalent to \(\text{beta.pdf}(y, a, b) / \text{scale with } y = (x - \text{loc}) / \text{scale}\).
Examples

```python
>>> from scipy.stats import beta
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a, b = 2.31, 0.627
>>> mean, var, skew, kurt = beta.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(beta.ppf(0.01, a, b),
...                 beta.ppf(0.99, a, b), 100)
>>> ax.plot(x, beta.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='beta pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = beta(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = beta.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], beta.cdf(vals, a, b))
True
```

Generate random numbers:

```python
>>> r = beta.rvs(a, b, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.betaprime**

```python
scipy.stats.betaprime(*args, **kwds) = <scipy.stats._continuous_distns.betaprime_gen object>
```

A beta prime continuous random variable.
As an instance of the `rv_continuous` class, `betaprime` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `betaprime` is:

\[
 f(x, a, b) = \frac{x^{a-1}(1 + x)^{-a-b}}{\beta(a, b)}
\]

for \( x \geq 0, a > 0, b > 0 \), where \( \beta(a, b) \) is the beta function (see `scipy.special.beta`).

`betaprime` takes \( a \) and \( b \) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `betaprime.pdf(x, a, b, loc, scale)` is identically equivalent to `betaprime.pdf(y, a, b) / scale` with \( y = (x - loc) / scale \).

### Examples

```python
>>> from scipy.stats import betaprime
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a, b = 5, 6
>>> mean, var, skew, kurt = betaprime.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(betaprime.ppf(0.01, a, b), betaprime.ppf(0.99, a, b), 100)
>>> ax.plot(x, betaprime.pdf(x, a, b), 'r-', lw=5, alpha=0.6, label='betaprime pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = betaprime(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

```python
>>> vals = betaprime.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], betaprime.cdf(vals, a, b))
```

Generate random numbers:

```python
>>> r = betaprime.rvs(a, b, size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

- `rvs(a, b, loc=0, scale=1, size=1, random_state=None)`
  - Random variates.
- `pdf(x, a, b, loc=0, scale=1)`
  - Probability density function.
- `logpdf(x, a, b, loc=0, scale=1)`
  - Log of the probability density function.
- `cdf(x, a, b, loc=0, scale=1)`
  - Cumulative distribution function.
- `logcdf(x, a, b, loc=0, scale=1)`
  - Log of the cumulative distribution function.
- `sf(x, a, b, loc=0, scale=1)`
  - Survival function (also defined as \(1 - cdf\), but `sf` is sometimes more accurate).
- `logsf(x, a, b, loc=0, scale=1)`
  - Log of the survival function.
- `ppf(q, a, b, loc=0, scale=1)`
  - Percent point function (inverse of `cdf` — percentiles).
- `isf(q, a, b, loc=0, scale=1)`
  - Inverse survival function (inverse of `sf`).
- `moment(n, a, b, loc=0, scale=1)`
  - Non-central moment of order `n`.
- `stats(a, b, loc=0, scale=1, moments='mv')`
  - Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
- `entropy(a, b, loc=0, scale=1)`
  - (Differential) entropy of the RV.
- `fit(data, a, b, loc=0, scale=1)`
  - Parameter estimates for generic data.
- `expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)`
  - Expected value of a function (of one argument) with respect to the distribution.
- `median(a, b, loc=0, scale=1)`
  - Median of the distribution.
- `mean(a, b, loc=0, scale=1)`
  - Mean of the distribution.
- `var(a, b, loc=0, scale=1)`
  - Variance of the distribution.
- `std(a, b, loc=0, scale=1)`
  - Standard deviation of the distribution.
- `interval(alpha, a, b, loc=0, scale=1)`
  - Endpoints of the range that contains alpha percent of the distribution.
scipy.stats.bradford

scipy.stats.bradford(*args, **kwds) = <scipy.stats._continuous_distns.bradford_gen object>

A Bradford continuous random variable.

As an instance of the rv_continuous class, bradford object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for bradford is:

\[ f(x; c) = \frac{c}{\log(1 + c)(1 + cx)} \]

for \(0 \leq x \leq 1\) and \(c > 0\).

bradford takes \(c\) as a shape parameter for \(c\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, bradford.pdf(x, c, loc, scale) is identically equivalent to bradford.pdf(y, c) / scale with 
\[ y = (x - \text{loc}) / \text{scale} \].

Examples

```python
>>> from scipy.stats import bradford
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 0.299
>>> mean, var, skew, kurt = bradford.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(bradford.ppf(0.01, c),
...                 b Bradford.ppf(0.99, c), 100)
>>> ax.plot(x, b Bradford.pdf(x, c),
...          'r-', lw=5, alpha=0.6, label='bradford pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = b Bradford(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = b Bradford.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], b Bradford.cdf(vals, c))
```

6.28. Statistical functions (scipy.stats)
Generate random numbers:

```python
>>> r = bradford.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

</table>

**scipy.stats.burr**

As an instance of the `rv_continuous` class, `burr` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `burr` is:

\[ f(x, c, d) = cd x^{c-1} (1 + x^{-c})^{-d-1} \]

for \( x \geq 0 \) and \( c, d > 0 \).
The Burr distribution is defined by three parameters, $c$ (shape), $d$ (shape), and an optional location parameter, $loc$. The probability density function (PDF) for the Burr distribution is given by:

$$f(x; c, d, loc) = \frac{c x^{c-1}}{d} \left(1 + \left(\frac{x}{d}\right)^c\right)^{-(c+1)}$$

This PDF is defined for $x > loc$ and $c, d > 0$. The parameter $c$ controls the shape of the distribution, while $d$ controls the scale. The location parameter $loc$ shifts the distribution along the x-axis.

For example, to generate random numbers from a Burr distribution with specific parameters and compare the histogram:

```python
from scipy.stats import burr
import matplotlib.pyplot as plt

fig, ax = plt.subplots(1, 1)

r = burr.rvs(10.5, 4.3, size=1000)

ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
ax.legend(loc='best', frameon=False)
plt.show()
```

References

Examples

```python
>>> from scipy.stats import burr
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
c, d = 10.5, 4.3
mean, var, skew, kurt = burr.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```python
x = np.linspace(burr.ppf(0.01, c, d),
                burr.ppf(0.99, c, d), 100)
ax.plot(x, burr.pdf(x, c, d),
        r'-', lw=5, alpha=0.6, label='burr pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
rv = burr(c, d)
ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
vals = burr.ppf([0.001, 0.5, 0.999], c, d)
np.allclose([0.001, 0.5, 0.999], burr.cdf(vals, c, d))
```

Generate random numbers:

```python
r = burr.rvs(c, d, size=1000)
And compare the histogram:

```python
ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
ax.legend(loc='best', frameon=False)
plt.show()
```

**scipy.stats.burr12**

```
scipy.stats.burr12__(*args, **kwds) = <scipy.stats._continuous_distns.burr12_gen object>
```

A Burr (Type XII) continuous random variable.

6.28. Statistical functions (scipy.stats)
As an instance of the `rv_continuous` class, `burr12` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

- **fisk**
  - a special case of either `burr` or `burr12` with $d=1$

- **burr**
  - Burr Type III distribution

**Notes**

The probability density function for `burr` is:

$$f(x, c, d) = cdx^{-1}(1 + x^c)^{-d-1}$$

for $x \geq 0$ and $c, d > 0$.

`burr12` takes $c$ and $d$ as shape parameters for $c$ and $d$.

This is the PDF corresponding to the twelfth CDF given in Burr’s list; specifically, it is equation (20) in Burr’s paper [1].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `burr12.pdf(x, c, d, loc, scale)` is identically equivalent to `burr12.pdf(y, c, d) / scale` with $y = (x - loc) / scale$.

The Burr type 12 distribution is also sometimes referred to as the Singh-Maddala distribution from NIST [2].

**References**

[1], [2]

**Examples**

```python
>>> from scipy.stats import burr12
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> c, d = 10, 4
>>> mean, var, skew, kurt = burr12.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(burr12.ppf(0.01, c, d),
...                 burr12.ppf(0.99, c, d), 100)
>>> ax.plot(x, burr12.pdf(x, c, d),
...         'r-', lw=5, alpha=0.6, label='burr12 pdf')
```
Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = burr12(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = burr12.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], burr12.cdf(vals, c, d))
True
```

Generate random numbers:

```python
>>> r = burr12.rvs(c, d, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### scipy.stats.cauchy

`scipy.stats.cauchy(*args, **kwds) = <scipy.stats._continuous_distns.cauchy_gen object>`

A Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `cauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `cauchy` is

\[ f(x) = \frac{1}{\pi(1 + x^2)} \]

for a real number \( x \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `cauchy.pdf(x, loc, scale)` is identically equivalent to `cauchy.pdf(y) / scale` with \( y = (x - \text{loc}) / \text{scale} \).
Examples

```python
>>> from scipy.stats import cauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = cauchy.stats(moments='mvsk')
```  
Display the probability density function (pdf):

```python
>>> x = np.linspace(cauchy.ppf(0.01),
...                 cauchy.ppf(0.99), 100)
>>> ax.plot(x, cauchy.pdf(x),
...          'r-', lw=5, alpha=0.6, label='cauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = cauchy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = cauchy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], cauchy.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = cauchy.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.chi**

```python
scipy.stats.chi(*args, **kwds) = <scipy.stats._continuous_distns.chi_gen object>
```

A chi continuous random variable.
As an instance of the `rv_continuous` class, `chi` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `chi` is:

\[
f(x, k) = \frac{1}{2^{k/2-1}\Gamma(k/2)} x^{k-1} \exp\left(-\frac{x^2}{2}\right)
\]

for \(x \geq 0\) and \(k > 0\) (degrees of freedom, denoted df in the implementation). \(\Gamma\) is the gamma function (scipy.special.gamma).

Special cases of `chi` are:

- `chi(1, loc, scale)` is equivalent to `halfnorm`
- `chi(2, 0, scale)` is equivalent to `rayleigh`
- `chi(3, 0, scale)` is equivalent to `maxwell`

`chi` takes `df` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `chi.pdf(x, df, loc, scale)` is identically equivalent to `chi.pdf(y, df) / scale` with \(y = (x - loc) / scale\).

**Examples**

```python
>>> from scipy.stats import chi
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> df = 78
>>> mean, var, skew, kurt = chi.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(chi.ppf(0.01, df),
...                 chi.ppf(0.99, df), 100)
>>> ax.plot(x, chi.pdf(x, df),
...         'r-', lw=5, alpha=0.6, label='chi pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = chi(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=5, alpha=0.6, label='frozen pdf')
```

Check accuracy of cdf and ppf:
```python
>>> vals = chi.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi.cdf(vals, df))
True

Generate random numbers:

```python
>>> r = chi.rvs(df, size=1000)
```n
And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.chi2**

`scipy.stats.chi2(*args, **kwds) = <scipy.stats._continuous_distns.chi2_gen object>`

A chi-squared continuous random variable.

As an instance of the `rv_continuous` class, `chi2` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `chi2` is:

\[ f(x, k) = \frac{1}{2^{k/2} \Gamma(k/2)} x^{k/2 - 1} \exp(-x/2) \]

for \( x > 0 \) and \( k > 0 \) (degrees of freedom, denoted \( df \) in the implementation).

`chi2` takes \( df \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `chi2.pdf(x, df, loc, scale)` is identically equivalent to `chi2.pdf(y, df) / scale` with \( y = (x - loc) / scale \).
Examples

```python
>>> from scipy.stats import chi2
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> df = 55
>>> mean, var, skew, kurt = chi2.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(chi2.ppf(0.01, df),
...                 chi2.ppf(0.99, df), 100)
>>> ax.plot(x, chi2.pdf(x, df),
...          'r-', lw=5, alpha=0.6, label='chi2 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = chi2(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = chi2.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi2.cdf(vals, df))
True
```

Generate random numbers:

```python
>>> r = chi2.rvs(df, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.cosine

scipy.stats.cosine(*args, **kwds) = <scipy.stats._continuous_distns.cosine_gen object>
A cosine continuous random variable.
As an instance of the `rv_continuous` class, `cosine` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The cosine distribution is an approximation to the normal distribution. The probability density function for `cosine` is:

\[
f(x) = \frac{1}{2\pi} (1 + \cos(x))
\]

for \(-\pi \leq x \leq \pi\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, \(\text{cosine.pdf}(x, \text{loc}, \text{scale})\) is identically equivalent to \(\text{cosine.pdf}(y) / \text{scale} \) with \(y = (x - \text{loc}) / \text{scale}\).

**Examples**

```python
>>> from scipy.stats import cosine
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = cosine.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(cosine.ppf(0.01),
...                 cosine.ppf(0.99), 100)
>>> ax.plot(x, cosine.pdf(x),
...          'r-', lw=5, alpha=0.6, label='cosine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = cosine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = cosine.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], cosine.cdf(vals))
```

Generate random numbers:

```python
>>> r = cosine.rvs(size=1000)
```

And compare the histogram:
```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.crystalball

`scipy.stats.crystalball(*args, **kwds) = <scipy.stats._continuous_distns.crystalball_gen object>`

Crystalball distribution

As an instance of the `rv_continuous` class, `crystalball` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `crystalball` is:

\[
  f(x; \beta, m) = \begin{cases} 
  N \exp(-x^2/2), & \text{for } x > -\beta \\
  NA(B - x)^{-m} & \text{for } x \leq -\beta 
\end{cases}
\]

where \( A = (m/|\beta|)^n \exp(-\beta^2/2), \ B = m/|\beta| - |\beta| \) and \( N \) is a normalisation constant.

`crystalball` takes \( \beta > 0 \) and \( m > 1 \) as shape parameters. \( \beta \) defines the point where the pdf changes from a power-law to a Gaussian distribution. \( m \) is the power of the power-law tail.

References

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `crystalball.pdf(x, beta, m, loc, scale)` is identically equivalent to `crystalball.pdf(y, beta, m) / scale` with \( y = (x - loc) / scale \).

New in version 0.19.0.

[1]

Examples

```python
>>> from scipy.stats import crystalball
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> beta, m = 2, 3
>>> mean, var, skew, kurt = crystalball.stats(beta, m, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(crystalball.ppf(0.01, beta, m),
...                 crystalball.ppf(0.99, beta, m), 100)
>>> ax.plot(x, crystalball.pdf(x, beta, m),
...          'r-', lw=5, alpha=0.6, label='crystalball pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
```python
>>> rv = crystalball(beta, m)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = crystalball.ppf([0.001, 0.5, 0.999], beta, m)
>>> np.allclose([0.001, 0.5, 0.999], crystalball.cdf(vals, beta, m))
True
```

Generate random numbers:

```python
>>> r = crystalball.rvs(beta, m, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=1, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

<tr>
<td><code>scipy.stats.dgamma</code></td>
<td>A double gamma continuous random variable.</td>
</tr>
</tbody>
</table>

### scipy.stats.dgamma

```python
scipy.stats.dgamma(*args, **kwds) = <scipy.stats._continuous_distns.dgamma_gen object>
```

As an instance of the `rv_continuous` class, `dgamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `dgamma` is:

\[
f(x, a) = \frac{1}{2\Gamma(a)} |x|^{a-1} \exp(-|x|)
\]

for a real number \(x\) and \(a > 0\). \(\Gamma\) is the gamma function (`scipy.special.gamma`).

`dgamma` takes \(a\) as a shape parameter for \(a\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `dgamma.pdf(x, a, loc, scale)` is identically equivalent to `dgamma.pdf(y, a) / scale` with \(y = (x - loc) / scale\).
Examples

```python
>>> from scipy.stats import dgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> a = 1.1
>>> mean, var, skew, kurt = dgamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(dgamma.ppf(0.01, a),
...                 dgamma.ppf(0.99, a), 100)
>>> ax.plot(x, dgamma.pdf(x, a),
...          'r-', lw=5, alpha=0.6, label='dgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = dgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = dgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], dgamma.cdf(vals, a))
True
```

Generate random numbers:

```python
>>> r = dgamma.rvs(a, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.dweibull**

```python
scipy.stats.dweibull(*args, **kwds) = <scipy.stats._continuous_distns.dweibull_gen object>
```

A double Weibull continuous random variable.
As an instance of the `rv_continuous` class, `dweibull` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `dweibull` is given by

\[ f(x, c) = \frac{c}{2|x|^c-1} \exp(-|x|^c) \]

for a real number \( x \) and \( c > 0 \).

`dweibull` takes \( c \) as a shape parameter for \( c \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `dweibull.pdf(x, c, loc, scale)` is identically equivalent to `dweibull.pdf(y, c) / scale` with \( y = (x - loc) / scale \).

**Examples**

```python
>>> from scipy.stats import dweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 2.07
>>> mean, var, skew, kurt = dweibull.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(dweibull.ppf(0.001, c),
...                 dweibull.ppf(0.999, c), 100)
>>> ax.plot(x, dweibull.pdf(x, c),
...          'r-', lw=5, alpha=0.6, label='dweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = dweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = dweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], dweibull.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = dweibull.rvs(c, size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

An Erlang continuous random variable.

As an instance of the `rv_continuous` class, `erlang` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

gamma

Notes

The Erlang distribution is a special case of the Gamma distribution, with the shape parameter $a$ an integer. Note that this restriction is not enforced by `erlang`. It will, however, generate a warning the first time a non-integer value is used for the shape parameter.

Refer to `gamma` for examples.

scipy.stats.expon

scipy.stats.expon(*args, **kwds) = <scipy.stats._continuous_distns.expon_gen
object>

An exponential continuous random variable.
As an instance of the rv_continuous class, expon object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for expon is:

\[ f(x) = \exp(-x) \]

for \( x \geq 0 \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, expon.pdf(x, loc, scale) is identically equivalent to expon.pdf(y) / scale with y = (x - loc) / scale.

A common parameterization for expon is in terms of the rate parameter lambda, such that pdf = lambda * exp(-lambda * x). This parameterization corresponds to using scale = 1 / lambda.

Examples

```python
>>> from scipy.stats import expon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = expon.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(expon.ppf(0.01),
...                 expon.ppf(0.99), 100)
>>> ax.plot(x, expon.pdf(x),
...          'r-', lw=5, alpha=0.6, label='expon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = expon()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = expon.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], expon.cdf(vals))
```

True
Generate random numbers:

```python
>>> r = expon.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

</tbody>
</table>

**scipy.stats.exponnorm**

```python
scipy.stats.exponnorm(*args, **kwds) = <scipy.stats._continuous_distns.exponnorm_gen object>
```

An exponentially modified Normal continuous random variable.

As an instance of the `rv_continuous` class, `exponnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `exponnorm` is:

\[ f(x, K) = \frac{1}{2K} \exp \left( \frac{1}{2K^2} - \frac{x}{K} \right) \text{erfc} \left( -\frac{x - 1/K}{\sqrt{2}} \right) \]

where \(x\) is a real number and \(K > 0\).

It can be thought of as the sum of a standard normal random variable and an independent exponentially distributed random variable with rate \(1/K\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `exponnorm.pdf(x, K, loc, scale)` is identically equivalent to `exponnorm.pdf(y, K) / scale` with \(y = (x - \text{loc}) / \text{scale}\).
An alternative parameterization of this distribution (for example, in Wikipedia) involves three parameters, $\mu$, $\lambda$ and $\sigma$. In the present parameterization this corresponds to having `loc` and `scale` equal to $\mu$ and $\sigma$, respectively, and shape parameter $K = 1/(\sigma \lambda)$.

New in version 0.16.0.

**Examples**

```python
>>> from scipy.stats import exponnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> K = 1.5
>>> mean, var, skew, kurt = exponnorm.stats(K, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(exponnorm.ppf(0.01, K),
...                 exponnorm.ppf(0.99, K), 100)
>>> ax.plot(x, exponnorm.pdf(x, K),
...          'r-', lw=5, alpha=0.6, label='exponnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = exponnorm(K)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = exponnorm.ppf([0.001, 0.5, 0.999], K)
>>> np.allclose([0.001, 0.5, 0.999], exponnorm.cdf(vals, K))
    True
```

Generate random numbers:

```python
>>> r = exponnorm.rvs(K, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.exponweib**

`scipy.stats.exponweib(*args, **kwds) = scipy.stats._continuous_distns.exponweib_gen object`  
An exponentiated Weibull continuous random variable.
As an instance of the `rv_continuous` class, `exponweib` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `exponweib` is:

\[
    f(x, a, c) = ac(1 - \exp(-x^c))^{a-1} \exp(-x^c)x^{c-1}
\]

for \( x \geq 0, a > 0, c > 0 \).

`exponweib` takes \( a \) and \( c \) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, \( \text{exponweib.pdf}(x, a, c, \text{loc}, \text{scale}) \) is identically equivalent to \( \text{exponweib.pdf}(y, a, c) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

**Examples**

```python
>>> from scipy.stats import exponweib
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
code
>>> a, c = 2.89, 1.95
>>> mean, var, skew, kurt = exponweib.stats(a, c, moments='mvsk')
```

Display the probability density function (pdf):

```python
code
>>> x = np.linspace(exponweib.ppf(0.01, a, c),
                      exponweib.ppf(0.99, a, c), 100)
>>> ax.plot(x, exponweib.pdf(x, a, c),
          'r-', lw=5, alpha=0.6, label='exponweib pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
code
>>> rv = exponweib(a, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

```python
code
>>> vals = exponweib.ppf([0.001, 0.5, 0.999], a, c)
>>> np.allclose([0.001, 0.5, 0.999], exponweib.cdf(vals, a, c))
```

Generate random numbers:

```python
code
>>> r = exponweib.rvs(a, c, size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.exponpow

scipy.stats.exponpow(*args, **kwds) = <scipy.stats._continuous_distns.exponpow_gen object>

An exponential power continuous random variable.

As an instance of the rv_continuous class, exponpow object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for exponpow is:

\[ f(x; b) = bx^{b-1} \exp(1 + x^b - \exp(x^b)) \]

for \( x \geq 0, \ b > 0 \). Note that this is a different distribution from the exponential power distribution that is also known under the names “generalized normal” or “generalized Gaussian”.

exponpow takes \( b \) as a shape parameter for \( b \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, exponpow.pdf(x, b, loc, scale) is identically equivalent to exponpow.pdf(y, b) / scale with y = (x - loc) / scale.

References

http://www.math.wm.edu/~leemis/chart/UDR/PDFs/Exponentialpower.pdf

Examples

```python
>>> from scipy.stats import exponpow
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> b = 2.7
>>> mean, var, skew, kurt = exponpow.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(exponpow.ppf(0.01, b), ...
...                  exponpow.ppf(0.99, b), 100)
>>> ax.plot(x, exponpow.pdf(x, b), ...
...         'r-', lw=5, alpha=0.6, label='exponpow pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = exponpow(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```
Check accuracy of cdf and ppf:

```python
>>> vals = exponpow.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], exponpow.cdf(vals, b))
True
```

Generate random numbers:

```python
>>> r = exponpow.rvs(b, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.f**

`scipy.stats.f(*args, **kwds) = <scipy.stats._continuous_distns.f_gen object>`

An F continuous random variable.

As an instance of the `rv_continuous` class, `f` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `f` is:

\[
f(x, df_1, df_2) = \frac{df_2^{df_2/2} df_1^{df_1/2} x^{df_1/2-1}}{(df_2 + df_1 x)^{(df_1+df_2)/2} B(df_1/2, df_2/2)}
\]

for \( x > 0 \).

`f` takes `dfn` and `dfd` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `f.pdf(x, dfn, dfd, loc, scale)` is identically equivalent to `f.pdf(y, dfn, dfd) / scale` with `y = (x - loc) / scale`. 

---

6.28. Statistical functions (`scipy.stats`)  2167
Examples

```python
>>> from scipy.stats import f
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> dfn, dfd = 29, 18
>>> mean, var, skew, kurt = f.stats(dfn, dfd, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(f.ppf(0.01, dfn, dfd),
...                 f.ppf(0.99, dfn, dfd), 100)
>>> ax.plot(x, f.pdf(x, dfn, dfd),
...          'r-', lw=5, alpha=0.6, label='f pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = f(dfn, dfd)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = f.ppf([0.001, 0.5, 0.999], dfn, dfd)
>>> np.allclose([0.001, 0.5, 0.999], f.cdf(vals, dfn, dfd))
True
```

Generate random numbers:

```python
>>> r = f.rvs(dfn, dfd, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

sciPy.stats.fatiguelife

scipy.stats.fatiguelife(*args, **kwds) = <scipy.stats._continuous_distns.fatiguelife_gen object>

A fatigue-life (Birnbaum-Saunders) continuous random variable.

As an instance of the rv_continuous class, fatiguelife object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for fatiguelife is:

\[ f(x,c) = \frac{x+1}{2c\sqrt{2\pi}x^{3/2}} \exp\left(-\frac{(x-1)^2}{2cx^2}\right) \]

for \( x \geq 0 \) and \( c > 0 \).

fatiguelife takes \( c \) as a shape parameter for \( c \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, fatiguelife.pdf(x, c, loc, scale) is identically equivalent to fatiguelife.pdf(y, c) / scale with \( y = (x - \text{loc}) / \text{scale} \).

References

[1]

Examples

```python
>>> from scipy.stats import fatiguelife
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
c = 29
mean, var, skew, kurt = fatiguelife.stats(c, moments='mvsk')
```
>>> vals = fatiguelife.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], fatiguelife.cdf(vals, c))
True

Generate random numbers:

>>> r = fatiguelife.rvs(c, size=1000)

And compare the histogram:

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)

scipy.stats.fisk

scipy.stats.fisk(*args, **kwds) = <scipy.stats._continuous_distns.fisk_gen object>

A Fisk continuous random variable.

The Fisk distribution is also known as the log-logistic distribution.

As an instance of the rv_continuous class, fisk object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

burr

Notes

The probability density function for fisk is:

$$f(x, c) = cx^{-c-1}(1 + x^{-c})^{-2}$$

for $x \geq 0$ and $c > 0$.

fisk takes $c$ as a shape parameter for $c$.

fisk is a special case of burr or burr12 with $d=1$. 
The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, \( fisk.pdf(x, c, \text{loc}, \text{scale}) \) is identically equivalent to \( fisk.pdf(y, c) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

**Examples**

```python
>>> from scipy.stats import fisk
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 3.09
>>> mean, var, skew, kurt = fisk.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(fisk.ppf(0.01, c),
...                 fisk.ppf(0.99, c), 100)
>>> ax.plot(x, fisk.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='fisk pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = fisk(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = fisk.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], fisk.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = fisk.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### scipy.stats.foldcauchy

```python
scipy.stats.foldcauchy(*args, **kwds) = <scipy.stats._continuous_distns.foldcauchy_gen object>
```

A folded Cauchy continuous random variable.
As an instance of the `rv_continuous` class, `foldcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `foldcauchy` is:

\[
f(x, c) = \frac{1}{\pi(1 + (x - c)^2)} + \frac{1}{\pi(1 + (x + c)^2)}
\]

for \(x \geq 0\).

`foldcauchy` takes \(c\) as a shape parameter for \(c\).

**Examples**

```python
>>> from scipy.stats import foldcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
c = 4.72
mean, var, skew, kurt = foldcauchy.stats(c, moments='mvsk')
```  
Display the probability density function (pdf):

```python
x = np.linspace(foldcauchy.ppf(0.01, c),
                ...  foldcauchy.ppf(0.99, c), 100)
ax.plot(x, foldcauchy.pdf(x, c),
        ...  'r-', lw=5, alpha=0.6, label='foldcauchy pdf')
```  
Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
rv = foldcauchy(c)
ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```  
Check accuracy of cdf and ppf:

```python
vals = foldcauchy.ppf([0.001, 0.5, 0.999], c)
np.allclose([0.001, 0.5, 0.999], foldcauchy.cdf(vals, c))
```  
Generate random numbers:

```python
r = foldcauchy.rvs(c, size=1000)
```  
And compare the histogram:

```python
ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
ax.legend(loc='best', frameon=False)
ax.legend(loc='best', frameon=False)
```

**scipy.stats.foldnorm**

`scipy.stats.foldnorm(*args, **kwds) = <scipy.stats._continuous_distns.foldnorm_gen object>`

A folded normal continuous random variable.
As an instance of the `rv_continuous` class, `foldnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `foldnorm` is:

\[
f(x, c) = \sqrt{\frac{2}{\pi \cosh(cx)}} \exp(-\frac{x^2 + c^2}{2})
\]

for \(c \geq 0\).

`foldnorm` takes \(c\) as a shape parameter for \(c\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `foldnorm.pdf(x, c, loc, scale)` is identically equivalent to `foldnorm.pdf(y, c) / scale` with \(y = (x - loc) / scale\).

**Examples**

```python
>>> from scipy.stats import foldnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> c = 1.95
>>> mean, var, skew, kurt = foldnorm.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(foldnorm.ppf(0.01, c), ...
... foldnorm.ppf(0.99, c), 100)
>>> ax.plot(x, foldnorm.pdf(x, c), ...
... 'r-', lw=5, alpha=0.6, label='foldnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = foldnorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = foldnorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], foldnorm.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = foldnorm.rvs(c, size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.frechet_r

scipy.stats.frechet_r(*args, **kwds) = <scipy.stats._continuous_distns.frechet_r_gen object>

A Frechet right (or Weibull minimum) continuous random variable.

As an instance of the rv_continuous class, frechet_r object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

weibull_min

The same distribution as frechet_r.

Notes

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, frechet_r.pdf(x, c, loc, scale) is identically equivalent to frechet_r.pdf(y, c) / scale with y = (x - loc) / scale.

Examples

```python
>>> from scipy.stats import frechet_r
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 1.89
>>> mean, var, skew, kurt = frechet_r.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(frechet_r.ppf(0.01, c),
...                 frechet_r.ppf(0.99, c), 100)
>>> ax.plot(x, frechet_r.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='frechet_r pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = frechet_r(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = frechet_r.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], frechet_r.cdf(vals, c))
True
```

Generate random numbers:
>>> \( r = \text{frechet}_r.\text{rvs}(c, \text{size}=1000) \)

And compare the histogram:

```python
>>> ax.\text{hist}(r, \text{density=True, histtype='stepfilled'}, \text{alpha=0.2})
>>> ax.\text{legend(loc='best', frameon=False})
>>> \text{plt.show()}
```

### scipy.stats.frechet_l

`scipy.stats.frechet_l(*args, **kwds) = <scipy.stats._continuous_distns.frechet_l_gen object>`

A Frechet left (or Weibull maximum) continuous random variable.

As an instance of the `rv_continuous` class, `frechet_l` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

- `weibull_max`

  The same distribution as `frechet_l`.

### Notes

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `frechet_l.pdf(x, c, loc, scale)` is identically equivalent to `frechet_l.pdf(y, c) / scale` with `y = (x - loc) / scale`. 
Examples

```python
>>> from scipy.stats import frechet_l
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> c = 3.63
>>> mean, var, skew, kurt = frechet_l.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(frechet_l.ppf(0.01, c),
...                   frechet_l.ppf(0.99, c), 100)
>>> ax.plot(x, frechet_l.pdf(x, c),
...          'r-', lw=5, alpha=0.6, label='frechet_l pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = frechet_l(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = frechet_l.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], frechet_l.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = frechet_l.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.genlogistic`

`scipy.stats.genlogistic(*args, **kwds) = <scipy.stats._continuous_distns.genlogistic_gen object>`

A generalized logistic continuous random variable.
As an instance of the `rv_continuous` class, `genlogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `genlogistic` is:

\[
f(x, c) = c \frac{\exp(-x)}{(1 + \exp(-x))^{c+1}}
\]

for \(x \geq 0, c > 0\).

`genlogistic` takes \(c\) as a shape parameter for \(c\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genlogistic.pdf(x, c, loc, scale)` is identically equivalent to `genlogistic.pdf(y, c) / scale` with \(y = (x - loc) / scale\).

**Examples**

```python
>>> from scipy.stats import genlogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> c = 0.412
>>> mean, var, skew, kurt = genlogistic.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(genlogistic.ppf(0.01, c),
...                 genlogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genlogistic.pdf(x, c),
...          'r-', lw=5, alpha=0.6, label='genlogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = genlogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = genlogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genlogistic.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = genlogistic.rvs(c, size=1000)
```

And compare the histogram:
```python

scipy.stats.gennorm

scipy.stats.gennorm(*args, **kwds) = <scipy.stats._continuous_distns.gennorm_gen object>

A generalized normal continuous random variable.

As an instance of the `rv_continuous` class, `gennorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

laplace

Laplace distribution

norm

normal distribution

Notes

The probability density function for `gennorm` is [1]:

\[ f(x; \beta) = \frac{\beta}{2 \Gamma(1/\beta)} \exp(-|x|^\beta) \]

\( \Gamma \) is the gamma function (`scipy.special.gamma`).

`gennorm` takes `beta` as a shape parameter for \( \beta \). For \( \beta = 1 \), it is identical to a Laplace distribution. For \( \beta = 2 \), it is identical to a normal distribution (with `scale=1/sqrt(2)`).

References

[1]

Examples

```python
>>> from scipy.stats import gennorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> beta = 1.3
>>> mean, var, skew, kurt = gennorm.stats(beta, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(gennorm.ppf(0.01, beta),
...                 gennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, gennorm.pdf(x, beta),
...         'r-', lw=5, alpha=0.6, label='gennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
>>> rv = gennorm(beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

Check accuracy of cdf and ppf:

>>> vals = gennorm.ppf([0.001, 0.5, 0.999], beta)
>>> np.allclose([0.001, 0.5, 0.999], gennorm.cdf(vals, beta))
True

Generate random numbers:

>>> r = gennorm.rvs(beta, size=1000)

And compare the histogram:

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

**scipy.stats.genpareto**

```
scipy.stats.genpareto(*args, **kwds) = <scipy.stats._continuous_distns.genpareto_gen object>
```

A generalized Pareto continuous random variable.

As an instance of the `rv_continuous` class, `genpareto` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `genpareto` is:

\[
f(x, c) = (1 + cx)^{-1-1/c}
\]

defined for \(x \geq 0\) if \(c \geq 0\), and for \(0 \leq x \leq -1/c\) if \(c < 0\).

`genpareto` takes \(c\) as a shape parameter for \(c\).

For \(c = 0\), `genpareto` reduces to the exponential distribution, `expon`:

\[
f(x, 0) = \exp(-x)
\]

For \(c = -1\), `genpareto` is uniform on \([0, 1]\):

\[
f(x, -1) = 1
\]
The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the
loc and scale parameters. Specifically, \( \text{genpareto.pdf}(x, c, \text{loc}, \text{scale}) \) is identically equivalent
to \( \text{genpareto.pdf}(y, c) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

**Examples**

```python
>>> from scipy.stats import genpareto
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 0.1
>>> mean, var, skew, kurt = genpareto.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(genpareto.ppf(0.01, c),
...                 genpareto.ppf(0.99, c), 100)
>>> ax.plot(x, genpareto.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='genpareto pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters.
This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = genpareto(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = genpareto.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genpareto.cdf(vals, c))
```

Generate random numbers:

```python
>>> r = genpareto.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.genexpon**

```python
scipy.stats.genexpon(*args, **kwds) = <scipy.stats._continuous_distns.genexpon_gen object>
```

A generalized exponential continuous random variable.
As an instance of the \texttt{rv_continuous} class, \texttt{genexpon} object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for \texttt{genexpon} is:

\[
f(x, a, b, c) = (a + b(1 - \exp(-cx))) \exp(-ax - bx + \frac{b}{c}(1 - \exp(-cx)))
\]

for \(x \geq 0, a, b, c > 0\).

\texttt{genexpon} takes \(a, b\) and \(c\) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{genexpon.pdf}(x, a, b, c, loc, scale) is identically equivalent to \texttt{genexpon.pdf}(y, a, b, c) / scale with \(y = (x - \text{loc}) / \text{scale}\).

**References**

**Examples**

```python
>>> from scipy.stats import genexpon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> a, b, c = 9.13, 16.2, 3.28
>>> mean, var, skew, kurt = genexpon.stats(a, b, c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(genexpon.ppf(0.01, a, b, c), ...
...   genexpon.ppf(0.99, a, b, c), 100)
>>> ax.plot(x, genexpon.pdf(x, a, b, c), ...
...   'r-', lw=5, alpha=0.6, label='genexpon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = genexpon(a, b, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of \texttt{cdf} and \texttt{ppf}:
>>> vals = genexpon.ppf([0.001, 0.5, 0.999], a, b, c)
>>> np.allclose([0.001, 0.5, 0.999], genexpon.cdf(vals, a, b, c))
True

Generate random numbers:

>>> r = genexpon.rvs(a, b, c, size=1000)

And compare the histogram:

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

scipy.stats.genextreme

scipy.stats.genextreme(*args, **kwds) = <scipy.stats._continuous_distns.genextreme_gen object>

A generalized extreme value continuous random variable.

As an instance of the rv_continuous class, genextreme object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

gumbel_r

Notes

For $c = 0$, genextreme is equal to gumbel_r. The probability density function for genextreme is:

$$f(x, c) = \begin{cases} 
\exp(-\exp(-x))\exp(-x) & \text{for } c = 0 \\
\exp(-(1 - cx)^{1/c})(1 - cx)^{1/c - 1} & \text{for } x \leq 1/c, c > 0 
\end{cases}$$

Note that several sources and software packages use the opposite convention for the sign of the shape parameter $c$. genextreme takes $c$ as a shape parameter for $c$. 
The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genextreme.pdf(x, c, loc, scale)` is identically equivalent to `genextreme.pdf(y, c) / scale` with `y = (x - loc) / scale`.

**Examples**

```python
>>> from scipy.stats import genextreme
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> c = -0.1
>>> mean, var, skew, kurt = genextreme.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(genextreme.ppf(0.01, c), ...
...     genextreme.ppf(0.99, c), 100)
>>> ax.plot(x, genextreme.pdf(x, c), ...
...     'r-', lw=5, alpha=0.6, label='genextreme pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = genextreme(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = genextreme.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genextreme.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = genextreme.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### scipy.stats.gausshyper

scipy.stats.gausshyper(*args, **kwds) = <scipy.stats._continuous_distns.gausshyper_gen object>

A Gauss hypergeometric continuous random variable.

---

6.28. Statistical functions (scipy.stats) 2195
As an instance of the `rv_continuous` class, `gausshyper` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `gausshyper` is:

\[
f(x; a, b, c, z) = C x^{a-1}(1-x)^{b-1}(1+zx)^{-c}
\]

for \(0 \leq x \leq 1, a > 0, b > 0, \) and \(C = \frac{1}{B(a,b)F[2,1](c,a; a+b; -z)}, \) \(F[2,1] \) is the Gauss hypergeometric function `scipy.special.hyp2f1`.

`gausshyper` takes \(a, b, c\) and \(z\) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gausshyper.pdf(x, a, b, c, z, loc, scale)` is identically equivalent to `gausshyper.pdf(y, a, b, c, z) / scale` with \(y = (x - loc) / scale\).

**Examples**

```python
>>> from scipy.stats import gausshyper
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a, b, c, z = 13.8, 3.12, 2.51, 5.18
>>> mean, var, skew, kurt = gausshyper.stats(a, b, c, z, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(gausshyper.ppf(0.01, a, b, c, z),
...                 gausshyper.ppf(0.99, a, b, c, z), 100)
>>> ax.plot(x, gausshyper.pdf(x, a, b, c, z),
...         'r-', lw=5, alpha=0.6, label='gausshyper pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = gausshyper(a, b, c, z)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = gausshyper.ppf([0.001, 0.5, 0.999], a, b, c, z)
>>> np.allclose([0.001, 0.5, 0.999], gausshyper.cdf(vals, a, b, c, z))
```

Generate random numbers:

```python
>>> r = gausshyper.rvs(a, b, c, z, size=1000)
```
And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.gamma**

As an instance of the `rv_continuous` class, `gamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

- `erlang`, `expon`

**Notes**

The probability density function for `gamma` is:

\[
f(x; a) = \frac{x^{a-1} \exp(-x)}{\Gamma(a)}
\]

for \(x \geq 0, a > 0\). Here \(\Gamma(a)\) refers to the gamma function.

`gamma` takes \(a\) as a shape parameter for \(a\).

When \(a\) is an integer, `gamma` reduces to the Erlang distribution, and when \(a = 1\) to the exponential distribution.
The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{gamma.pdf(x, a, loc, scale)} is identically equivalent to \texttt{gamma.pdf(y, a) / scale} with \( y = (x - \text{loc}) / \text{scale} \).

**Examples**

```python
>>> from scipy.stats import gamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> a = 1.99
>>> mean, var, skew, kurt = gamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(gamma.ppf(0.01, a), ...
...                   gamma.ppf(0.99, a), 100)
>>> ax.plot(x, gamma.pdf(x, a), ...
...         'r-', lw=5, alpha=0.6, label='gamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = gamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of \texttt{cdf} and \texttt{ppf}:

```python
>>> vals = gamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], gamma.cdf(vals, a))
True
```

Generate random numbers:

```python
>>> r = gamma.rvs(a, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
```

**scipy.stats.gengamma**

scipy.stats.gengamma(*args, **kwds) = <scipy.stats._continuous_distns.gengamma_gen object>

A generalized gamma continuous random variable.
As an instance of the `rv_continuous` class, `gengamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `gengamma` is:

\[ f(x; a, c) = \frac{|c|x^{a-1}\exp(-x^c)}{\Gamma(a)} \]

for \( x \geq 0, a > 0, \text{ and } c \neq 0 \). \( \Gamma \) is the gamma function (scipy.special.gamma).

`gengamma` takes \( a \) and \( c \) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \( \text{loc} \) and \( \text{scale} \) parameters. Specifically, \( \text{gengamma.pdf}(x, a, c, \text{loc}, \text{scale}) \) is identically equivalent to \( \text{gengamma.pdf}(y, a, c) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

**Examples**

```python
>>> from scipy.stats import gengamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a, c = 4.42, -3.12
>>> mean, var, skew, kurt = gengamma.stats(a, c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(gengamma.ppf(0.01, a, c),
...                 gengamma.ppf(0.99, a, c), 100)
>>> ax.plot(x, gengamma.pdf(x, a, c),
...         'r-', lw=5, alpha=0.6, label='gengamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = gengamma(a, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = gengamma.ppf([0.001, 0.5, 0.999], a, c)
>>> np.allclose([0.001, 0.5, 0.999], gengamma.cdf(vals, a, c))
True
```

Generate random numbers:

```python
>>> r = gengamma.rvs(a, c, size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.genhalflogistic**

`scipy.stats.genhalflogistic(*args, **kwds) = <scipy.stats._continuous_distns.genhalflogistic_gen object>`

A generalized half-logistic continuous random variable.

As an instance of the `rv_continuous` class, `genhalflogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `genhalflogistic` is:

\[
 f(x,c) = \frac{2(1 - cx)^{1/(c-1)}}{[1 + (1 - cx)^{1/c}]^2} 
\]

for \(0 \leq x \leq 1/c\), and \(c > 0\).

`genhalflogistic` takes \(c\) as a shape parameter for \(c\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genhalflogistic.pdf(x, c, loc, scale)` is identically equivalent to `genhalflogistic.pdf(y, c) / scale` with \(y = (x - loc) / scale\).

**Examples**

```python
>>> from scipy.stats import genhalflogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 0.773
>>> mean, var, skew, kurt = genhalflogistic.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(genhalflogistic.ppf(0.01, c),
...                  genhalflogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genhalflogistic.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='genhalflogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = genhalflogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

```python
>>> vals = genhalflogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genhalflogistic.cdf(vals, c))
```

6.28. Statistical functions (`scipy.stats`)
Generate random numbers:

```python
>>> r = genhalflogistic.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### scipy.stats.gilbrat

**scipy.stats.gilbrat (*args,** **kwds) = <scipy.stats._continuous_distns.gilbrat_gen object>**

A Gilbrat continuous random variable.

As an instance of the `rv_continuous` class, `gilbrat` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `gilbrat` is:

$$f(x) = \frac{1}{x\sqrt{2\pi}} \exp\left(-\frac{1}{2}(\log(x))^2\right)$$

`gilbrat` is a special case of `lognorm` with $s=1$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gilbrat.pdf(x, loc, scale)` is identically equivalent to `gilbrat.pdf(y) / scale` with $y = (x - loc) / scale$. 

---

**6.28. Statistical functions (scipy.stats)** 2205
Examples

```python
>>> from scipy.stats import gilbrat
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = gilbrat.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(gilbrat.ppf(0.01),
...                  gilbrat.ppf(0.99), 100)
>>> ax.plot(x, gilbrat.pdf(x),
...         'r-', lw=5, alpha=0.6, label='gilbrat pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = gilbrat()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = gilbrat.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gilbrat.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = gilbrat.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.gompertz

```
scipy.stats.gompertz(*args, **kwds) = <scipy.stats._continuous_distns. gompertz_gen object>
```

A Gompertz (or truncated Gumbel) continuous random variable.
As an instance of the `rv_continuous` class, `gompertz` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `gompertz` is:

\[ f(x, c) = c \exp(x) \exp(-c(e^x - 1)) \]

for \( x \geq 0, c > 0 \).

`gompertz` takes `c` as a shape parameter for `c`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gompertz.pdf(x, c, loc, scale)` is identically equivalent to `gompertz.pdf(y, c) / scale` with \( y = (x - loc) / scale \).

**Examples**

```python
>>> from scipy.stats import gompertz
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> c = 0.947
>>> mean, var, skew, kurt = gompertz.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(gompertz.ppf(0.01, c),
...                 gompertz.ppf(0.99, c), 100)
>>> ax.plot(x, gompertz.pdf(x, c),
...          'r-', lw=5, alpha=0.6, label='gompertz pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = gompertz(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = gompertz.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], gompertz.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = gompertz.rvs(c, size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

</table>
scipy.stats.gumbel_r

scipy.stats.gumbel_r(*args, **kwds) = <scipy.stats._continuous_distns.gumbel_r_gen object>

A right-skewed Gumbel continuous random variable.

As an instance of the rv_continuous class, gumbel_r object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

gumbel_l, gompertz, genextreme

Notes

The probability density function for gumbel_r is:

\[ f(x) = \exp(-(x + e^x)) \]

The Gumbel distribution is sometimes referred to as a type I Fisher-Tippett distribution. It is also related to the extreme value distribution, log-Weibull and Gompertz distributions.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, gumbel_r.pdf(x, loc, scale) is identically equivalent to gumbel_r.pdf(y) / scale with y = (x - loc) / scale.

Examples

```python
>>> from scipy.stats import gumbel_r
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = gumbel_r.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(gumbel_r.ppf(0.01),
...                  gumbel_r.ppf(0.99), 100)
... ax.plot(x, gumbel_r.pdf(x),
...         'r-', lw=5, alpha=0.6, label='gumbel_r pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = gumbel_r()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = gumbel_r.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gumbel_r.cdf(vals))
True
```
Generate random numbers:

```python
>>> r = gumbel_r.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.gumbel_l

scipy.stats.gumbel_l(*args, **kwds) = <scipy.stats._continuous_distns.gumbel_l_gen object>

A left-skewed Gumbel continuous random variable.

As an instance of the rv_continuous class, gumbel_l object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

gumbel_r, gompertz, genextreme

Notes

The probability density function for gumbel_l is:

\[ f(x) = \exp(x - e^x) \]

The Gumbel distribution is sometimes referred to as a type I Fisher-Tippett distribution. It is also related to the extreme value distribution, log-Weibull and Gompertz distributions.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, gumbel_l.pdf(x, loc, scale) is identically equivalent to gumbel_l.pdf(y) / scale with y = (x - loc) / scale.
Examples

```python
>>> from scipy.stats import gumbel_l
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = gumbel_l.stats(moments='mvsk')
```  
Display the probability density function (pdf):

```python
>>> x = np.linspace(gumbel_l.ppf(0.01),
...                  gumbel_l.ppf(0.99), 100)
>>> ax.plot(x, gumbel_l.pdf(x),
...          'r-', lw=5, alpha=0.6, label='gumbel_l pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = gumbel_l()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```  
Check accuracy of cdf and ppf:

```python
>>> vals = gumbel_l.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gumbel_l.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = gumbel_l.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.halfcauchy

scipy.stats.halfcauchy(*args, **kwds) = <scipy.stats._continuous_distns.halfcauchy_gen object>

A Half-Cauchy continuous random variable.
As an instance of the `rv_continuous` class, `halfcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `halfcauchy` is:

\[
f(x) = \frac{2}{\pi(1 + x^2)}
\]

for \( x \geq 0 \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halfcauchy.pdf(x, loc, scale)` is identically equivalent to `halfcauchy.pdf(y) / scale` with \( y = (x - loc) / scale \).

**Examples**

```python
>>> from scipy.stats import halfcauchy
click to view code
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:
```n
```python
>>> mean, var, skew, kurt = halfcauchy.stats(moments='mvsk')
```

Display the probability density function (pdf):
```python
>>> x = np.linspace(halfcauchy.ppf(0.01), ...
                    halfcauchy.ppf(0.99), 100)
>>> ax.plot(x, halfcauchy.pdf(x), ...
           'r-', lw=5, alpha=0.6, label='halfcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
```python
>>> rv = halfcauchy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:
```python
>>> vals = halfcauchy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halfcauchy.cdf(vals))
True
```

Generate random numbers:
```python
>>> r = halfcauchy.rvs(size=1000)
```

And compare the histogram:

scipy.stats.halflogistic

scipy.stats.halflogistic(*args, **kwds) = <scipy.stats._continuous_distns.halflogistic_gen object>

A half-logistic continuous random variable.

As an instance of the rv_continuous class, halflogistic object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for halflogistic is:

\[ f(x) = \frac{2e^{-x}}{(1 + e^{-x})^2} = \frac{1}{2} \text{sech}(x/2)^2 \]

for \( x \geq 0 \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, halflogistic.pdf(x, loc, scale) is identically equivalent to halflogistic.pdf(y) / scale with y = (x - loc) / scale.

Examples

```python
from scipy.stats import halflogistic
import matplotlib.pyplot as plt

fig, ax = plt.subplots(1, 1)

Calculate a few first moments:
```n
mean, var, skew, kurt = halflogistic.stats(moments='mvsk')

Display the probability density function (pdf):
```n
x = np.linspace(halflogistic.ppf(0.01),
                halflogistic.ppf(0.99), 100)
ax.plot(x, halflogistic.pdf(x),
        r'-', lw=5, alpha=0.6, label='halflogistic pdf')

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
```n
rv = halflogistic()
ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

Check accuracy of cdf and ppf:

scipy.stats.halfnorm

scipy.stats.halfnorm(*args, **kwds) = <scipy.stats._continuous_distns.halfnorm_gen object>
A half-normal continuous random variable.

As an instance of the rv_continuous class, halfnorm object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for halfnorm is:

\[ f(x) = \sqrt{2/\pi} \exp(-x^2/2) \]

for \(x \geq 0\).

halfnorm is a special case of chi with df=1.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, halfnorm.pdf(x, loc, scale) is identically equivalent to halfnorm.pdf(y) / scale with y = (x - loc) / scale.
Examples

```python
>>> from scipy.stats import halfnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = halfnorm.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(halfnorm.ppf(0.01), halfnorm.ppf(0.99), 100)
>>> ax.plot(x, halfnorm.pdf(x), 'r-', lw=5, alpha=0.6, label='halfnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = halfnorm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = halfnorm.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halfnorm.cdf(vals))
True
```

Generate random numbers:

```python

**scipy.stats.halfgennorm**

`scipy.stats.halfgennorm(*args, **kwds) = <scipy.stats._continuous_distns.halfgennorm_gen object>`

The upper half of a generalized normal continuous random variable.

6.28. Statistical functions (scipy.stats) 2221
As an instance of the `rv_continuous` class, `halfgennorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`gennorm`
- generalized normal distribution

`expon`
- exponential distribution

`halfnorm`
- half normal distribution

**Notes**

The probability density function for `halfgennorm` is:

\[
f(x, \beta) = \frac{\beta}{\Gamma(1/\beta)} \exp(-|x|^\beta)
\]

for \( x > 0 \). \( \Gamma \) is the gamma function (scipy.special.gamma).

`gennorm` takes `beta` as a shape parameter for \( \beta \). For \( \beta = 1 \), it is identical to an exponential distribution. For \( \beta = 2 \), it is identical to a half normal distribution (with `scale=1/sqrt(2)`).

**References**

[1]

**Examples**

```python
>>> from scipy.stats import gennorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> beta = 0.675
>>> mean, var, skew, kurt = gennorm.stats(beta, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(halfgennorm.ppf(0.01, beta),
...                 halfgennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, halfgennorm.pdf(x, beta),
...         'r-', lw=5, alpha=0.6, label='halfgennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
>>> rv = halfgennorm(beta)

Check accuracy of cdf and ppf:

>>> vals = halfgennorm.ppf([0.001, 0.5, 0.999], beta)

Generate random numbers:

And compare the histogram:

```python
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

>>> vals = halfgennorm.ppf([0.001, 0.5, 0.999], beta)

>>> np.allclose([0.001, 0.5, 0.999], halfgennorm.cdf(vals, beta))

True

>>> r = halfgennorm.rvs(beta, size=1000)

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)

>>> ax.legend(loc='best', frameon=False)

>>> plt.show()
```

### scipy.stats.hypsecant

`scipy.stats.hypsecant(*args, **kwds) = <scipy.stats._continuous_distns.hypsecant_gen object>`

A hyperbolic secant continuous random variable.

As an instance of the `rv_continuous` class, `hypsecant` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `hypsecant` is:

$$f(x) = \frac{1}{\pi} \text{sech}(x)$$

for a real number $x$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `hypsecant.pdf(x, loc, scale)` is identically equivalent to `hypsecant.pdf(y) / scale` with $y = (x - \text{loc}) / \text{scale}$. 

---

2224 Chapter 6. API Reference
Examples

```python
>>> from scipy.stats import hypsecant
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = hypsecant.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(hypsecant.ppf(0.01),
...                 hypsecant.ppf(0.99), 100)
>>> ax.plot(x, hypsecant.pdf(x),
...          'r-', lw=5, alpha=0.6, label='hypsecant pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = hypsecant()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = hypsecant.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], hypsecant.cdf(vals))
```

Generate random numbers:

```python
>>> r = hypsecant.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.invgamma**

```python
scipy.stats.invgamma(*args, **kwds) = <scipy.stats._continuous_distns.invgamma_gen object>
```

An inverted gamma continuous random variable.
As an instance of the \texttt{rv\_continuous} class, \texttt{invgamma} object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

\textbf{Notes}

The probability density function for \texttt{invgamma} is:

\[ f(x, a) = \frac{x^{-a-1}}{\Gamma(a)} \exp\left(-\frac{1}{x}\right) \]

for \( x > 0, \ a > 0 \). \( \Gamma \) is the gamma function (\texttt{scipy.special.gamma}).

\texttt{invgamma} takes \( a \) as a shape parameter for \( a \).

\texttt{invgamma} is a special case of \texttt{gengamma} with \( c=-1 \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{invgamma.pdf(x, a, loc, scale)} is identically equivalent to \texttt{invgamma.pdf(y, a) / scale} with \( y = (x - \text{loc}) / \text{scale} \).

\textbf{Examples}

```python
>>> from scipy.stats import invgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> a = 4.07
>>> mean, var, skew, kurt = invgamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(invgamma.ppf(0.01, a), ...
...                 invgamma.ppf(0.99, a), 100)
>>> ax.plot(x, invgamma.pdf(x, a), ...
...         'r-', lw=5, alpha=0.6, label='invgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” \texttt{RV} object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = invgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = invgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], invgamma.cdf(vals, a))
True
```

Generate random numbers:
```python
>>> r = invgamma.rvs(a, size=1000)

And compare the histogram:
```

### scipy.stats.invgauss

`scipy.stats.invgauss(*args, **kwds) = <scipy.stats._continuous_distns.invgauss_gen object>`

An inverse Gaussian continuous random variable.

As an instance of the `rv_continuous` class, `invgauss` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

#### Notes

The probability density function for `invgauss` is:

\[
f(x, \mu) = \frac{1}{\sqrt{2\pi x^3}} \exp \left( -\frac{(x - \mu)^2}{2x\mu^2} \right)
\]

for \(x > 0\) and \(\mu > 0\).

`invgauss` takes \(\mu\) as a shape parameter for \(\mu\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invgauss.pdf(x, mu, loc, scale)` is identically equivalent to `invgauss.pdf(y, mu) / scale` with \(y = (x - loc) / scale\).

When \(\mu\) is too small, evaluating the cumulative distribution function will be inaccurate due to `cdf(mu -> 0) = inf * 0`. NaNs are returned for \(\mu \leq 0.0028\).
Examples

```python
>>> from scipy.stats import invgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:
```n
```python
>>> mu = 0.145
>>> mean, var, skew, kurt = invgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):
```python
>>> x = np.linspace(invgauss.ppf(0.01, mu), ...
...                   invgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, invgauss.pdf(x, mu), ...
...         'r-', lw=5, alpha=0.6, label='invgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
```python
>>> rv = invgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:
```python
>>> vals = invgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], invgauss.cdf(vals, mu))
True
```

Generate random numbers:
```python
>>> r = invgauss.rvs(mu, size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.invweibull**

```python
scipy.stats.invweibull(*args, **kwds) = <scipy.stats._continuous_distns.invweibull_gen object>
```

An inverted Weibull continuous random variable.
This distribution is also known as the Fréchet distribution or the type II extreme value distribution.

As an instance of the `rv_continuous` class, `invweibull` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `invweibull` is:

\[ f(x; c) = cx^{-c-1} \exp(-x^{-c}) \]

for \( x > 0, c > 0 \).

`invweibull` takes \( c \) as a shape parameter for \( c \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invweibull.pdf(x, c)` is identically equivalent to `invweibull.pdf(y, c) / scale` with \( y = (x - \text{loc}) / \text{scale} \).

**References**

**Examples**

```python
>>> from scipy.stats import invweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> c = 10.6
>>> mean, var, skew, kurt = invweibull.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(invweibull.ppf(0.01, c),
...                  invweibull.ppf(0.99, c), 100)
>>> ax.plot(x, invweibull.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='invweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = invweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = invweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], invweibull.cdf(vals, c))
True
```
Generate random numbers:

```python
>>> r = invweibull.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.johnsonsb**

`scipy.stats.johnsonsb(*args, **kwds) = <scipy.stats._continuous_distns.johnsonsb_gen object>`

A Johnson SB continuous random variable.

As an instance of the `rv_continuous` class, `johnsonsb` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`johnsonsu`

**Notes**

The probability density function for `johnsonsb` is:

\[
f(x, a, b) = \frac{b}{x(1-x)} \phi(a + b \log \frac{x}{1-x})
\]

for \(0 \leq x \leq 1\) and \(a, b > 0\), and \(\phi\) is the normal pdf.

`johnsonsb` takes \(a\) and \(b\) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `johnsonsb.pdf(x, a, b, loc, scale)` is identically equivalent to `johnsonsb.pdf(y, a, b) / scale` with \(y = (x - loc) / scale\).
Examples

```python
from scipy.stats import johnsonsb
import matplotlib.pyplot as plt

fig, ax = plt.subplots(1, 1)

Calculate a few first moments:
```n
```python
a, b = 4.32, 3.18
mean, var, skew, kurt = johnsonsb.stats(a, b, moments='mvsk')
```n
Display the probability density function (pdf):
```python
x = np.linspace(johnsonsb.ppf(0.01, a, b), ...
... johnsonsb.ppf(0.99, a, b), 100)
ax.plot(x, johnsonsb.pdf(x, a, b), ...
... 'r-', lw=5, alpha=0.6, label='johnsonsb pdf')
```n
Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
```python
rv = johnsonsb(a, b)
ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```n
Check accuracy of cdf and ppf:
```python
vals = johnsonsb.ppf([0.001, 0.5, 0.999], a, b)
np.allclose([0.001, 0.5, 0.999], johnsonsb.cdf(vals, a, b)) # True
```n
Generate random numbers:
```python
r = johnsonsb.rvs(a, b, size=1000)
```n
And compare the histogram:
```python
ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
ax.legend(loc='best', frameon=False)
plt.show()
```

### scipy.stats.johnsonsu

```python
scipy.stats.johnsonsu(*args, **kwds) = <scipy.stats._continuous_distns.johnsonsu_gen object>
```

A Johnson SU continuous random variable.
As an instance of the `rv_continuous` class, `johnsonsu` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`johnsonsb`

**Notes**

The probability density function for `johnsonsu` is:

\[
f(x, a, b) = \frac{b}{\sqrt{x^2 + 1}} \phi(a + b \log(x + \sqrt{x^2 + 1}))
\]

for all \(x, a, b > 0\), and \(\phi\) is the normal pdf.

`johnsonsu` takes \(a\) and \(b\) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `johnsonsu.pdf(x, a, b, loc, scale)` is identically equivalent to `johnsonsu.pdf(y, a, b) / scale` with \(y = (x - loc) / scale\).

**Examples**

```python
>>> from scipy.stats import johnsonsu
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a, b = 2.55, 2.25
>>> mean, var, skew, kurt = johnsonsu.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(johnsonsu.ppf(0.01, a, b), ...
...                  johnsonsu.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsu.pdf(x, a, b), ...
...         'r-', lw=5, alpha=0.6, label='johnsonsu pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = johnsonsu(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

```python
>>> vals = johnsonsu.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsu.cdf(vals, a, b))
True
```

Generate random numbers:
```python
>>> r = johnsonsu.rvs(a, b, size=1000)
And compare the histogram:
```

### scipy.stats.kappa4

#### scipy.stats.kappa4(*args, **kwds) = <scipy.stats._continuous_distns.kappa4_gen object>

Kappa 4 parameter distribution.

As an instance of the rv_continuous class, kappa4 object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for kappa4 is:

\[
f(x, h, k) = (1 - kx)^{1/k - 1}(1 - h(1 - kx)^{1/k})^{1/h - 1}
\]

if \( h \) and \( k \) are not equal to 0.

If \( h \) or \( k \) are zero then the pdf can be simplified:

- \( h = 0 \) and \( k \neq 0 \):
  
  \[
  \text{kappa4.pdf}(x, h, k) = (1.0 - k \cdot x)^{(1.0/k - 1.0) \cdot \exp(- (1.0 - k \cdot x) \cdot (1.0/k))}
  \]

- \( h \neq 0 \) and \( k = 0 \):
\[
\text{kappa4.pdf}(x, h, k) = \exp(-x) * (1.0 - h \exp(-x))^{*(1.0/h - 1.0)}
\]

\[h=0 \text{ and } k=0:\]
\[
\text{kappa4.pdf}(x, h, k) = \exp(-x) * \exp(-\exp(-x))
\]

cappa4 takes \(h\) and \(k\) as shape parameters.

The \text{kappa4} distribution returns other distributions when certain \(h\) and \(k\) values are used.

<table>

</tr>
</tbody>
</table>

(1) There are at least five generalized logistic distributions. Four are described here: https://en.wikipedia.org/wiki/Generalized_logistic_distribution The “fifth” one is the one \text{kappa4} should match which currently isn’t implemented in scipy: https://en.wikipedia.org/wiki/Talk:Generalized_logistic_distribution https://www.mathwave.com/help/easyfit/html/analyses/distributions/gen_logistic.html

(2) This distribution is currently not in scipy.

References

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \text{loc} and \text{scale} parameters. Specifically, \text{kappa4.pdf}(x, h, k, \text{loc}, \text{scale}) is identically equivalent to \text{kappa4.pdf}(y, h, k) / \text{scale} with \(y = (x - \text{loc}) / \text{scale}.

Examples

```python
>>> from scipy.stats import kappa4
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> h, k = 0.1, 0
>>> mean, var, skew, kurt = kappa4.stats(h, k, moments='mvsk')
```
Display the probability density function (pdf):

```python
>>> x = np.linspace(kappa4.ppf(0.01, h, k),
...                   kappa4.ppf(0.99, h, k), 100)
>>> ax.plot(x, kappa4.pdf(x, h, k),
...          'r-', lw=5, alpha=0.6, label='kappa4 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = kappa4(h, k)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = kappa4.ppf([0.001, 0.5, 0.999], h, k)
>>> np.allclose([0.001, 0.5, 0.999], kappa4.cdf(vals, h, k))
True
```

Generate random numbers:

```python
>>> r = kappa4.rvs(h, k, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.kappa3**

```python
scipy.stats.kappa3(*args, **kwds) = <scipy.stats._continuous_distns.kappa3_gen object>
```

Kappa 3 parameter distribution.

As an instance of the `rv_continuous` class, `kappa3` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `kappa3` is:

\[ f(x, a) = a(a + x^a)^{-\frac{a+1}{a}} \]

for \( x > 0 \) and \( a > 0 \).

`kappa3` takes \( a \) as a shape parameter for \( a \).

### References

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kappa3.pdf(x, a, loc, scale)` is identically equivalent to `kappa3.pdf(y, a) / scale` with `y = (x - loc) / scale`.

Examples

```python
>>> from scipy.stats import kappa3
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> a = 1
>>> mean, var, skew, kurt = kappa3.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(kappa3.ppf(0.01, a),
...                  kappa3.ppf(0.99, a), 100)
>>> ax.plot(x, kappa3.pdf(x, a),
...          'r-', lw=5, alpha=0.6, label='kappa3 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = kappa3(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = kappa3.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], kappa3.cdf(vals, a))
```

Generate random numbers:

```python
>>> r = kappa3.rvs(a, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

</table>

**scipy.stats.ksone**

```python
scipy.stats.ksone(*args, **kwds) = <scipy.stats._continuous_distns.ksone_gen object>
```

General Kolmogorov-Smirnov one-sided test.
This is the distribution of the one-sided Kolmogorov-Smirnov (KS) statistics $D_n^+$ and $D_n^-$ for a finite sample size $n$ (the shape parameter).

As an instance of the `rv_continuous` class, `ksone` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`kstwobign`, `kstest`

**Notes**

$D_n^+$ and $D_n^-$ are given by

$$D_n^+ = \sup_x (F_n(x) - F(x)),$$
$$D_n^- = \sup_x (F(x) - F_n(x)),$$

where $F$ is a CDF and $F_n$ is an empirical CDF. `ksone` describes the distribution under the null hypothesis of the KS test that the empirical CDF corresponds to $n$ i.i.d. random variates with CDF $F$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ksone.pdf(x, n, loc, scale)` is identically equivalent to `ksone.pdf(y, n) / scale` with $y = (x - \text{loc}) / \text{scale}$.

**References**

[1]

**Examples**

```python
>>> from scipy.stats import ksone
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> n = 1e+03
>>> mean, var, skew, kurt = ksone.stats(n, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(ksone.ppf(0.01, n),
...                 ksone.ppf(0.99, n), 100)
>>> ax.plot(x, ksone.pdf(x, n),
...         'r-', lw=5, alpha=0.6, label='ksone pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = ksone(n)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```
Check accuracy of \texttt{cdf} and \texttt{ppf}:
\begin{verbatim}
>>> vals = ksone.ppf([0.001, 0.5, 0.999], n)
>>> np.allclose([0.001, 0.5, 0.999], ksone.cdf(vals, n))
True
\end{verbatim}

Generate random numbers:
\begin{verbatim}
>>> r = ksone.rvs(n, size=1000)
\end{verbatim}

And compare the histogram:
\begin{verbatim}
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
\end{verbatim}

</tbody>
</table>

**scipy.stats.kstwobign**

`scipy.stats.kstwobign(*args, **kwds) = <scipy.stats._continuous_distns.kstwobign_gen object>`

Kolmogorov-Smirnov two-sided test for large N.

This is the asymptotic distribution of the two-sided Kolmogorov-Smirnov statistic $\sqrt{n}D_n$ that measures the maximum absolute distance of the theoretical CDF from the empirical CDF (see `kstest`).

As an instance of the `rv_continuous` class, `kstwobign` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`ksone, kstest`

**Notes**

$\sqrt{n}D_n$ is given by

$$D_n = \sup_x |F_n(x) - F(x)|$$

where $F$ is a CDF and $F_n$ is an empirical CDF. `kstwobign` describes the asymptotic distribution (i.e. the limit of $\sqrt{n}D_n$) under the null hypothesis of the KS test that the empirical CDF corresponds to i.i.d. random variates with CDF $F$. 

6.28. Statistical functions (scipy.stats) 2247
The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the
loc and scale parameters. Specifically, kstwobign.pdf(x, loc, scale) is identically equivalent to
kstwobign.pdf(y) / scale with y = (x - loc) / scale.

References

[1]

Examples

```python
>>> from scipy.stats import kstwobign
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = kstwobign.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(kstwobign.ppf(0.01),
...                 kstwobign.ppf(0.99), 100)
>>> ax.plot(x, kstwobign.pdf(x),
...         'r-', lw=5, alpha=0.6, label='kstwobign pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = kstwobign()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = kstwobign.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], kstwobign.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = kstwobign.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

#### scipy.stats.laplace

scipy.stats.laplace(*args, **kwds) = <scipy.stats._continuous_distns.laplace_gen object>

A Laplace continuous random variable.
As an instance of the `rv_continuous` class, `laplace` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `laplace` is

\[ f(x) = \frac{1}{2} \exp(-|x|) \]

for a real number \( x \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `laplace.pdf(x, loc, scale)` is identically equivalent to `laplace.pdf(y) / scale` with \( y = (x - loc) / scale \).

**Examples**

```python
>>> from scipy.stats import laplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = laplace.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(laplace.ppf(0.01), laplace.ppf(0.99), 100)
>>> ax.plot(x, laplace.pdf(x), 'r-', lw=5, alpha=0.6, label='laplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = laplace()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = laplace.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], laplace.cdf(vals))
```

Generate random numbers:

```python
>>> r = laplace.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.levy**

```python
scipy.stats.levy(*args, **kwds) = <scipy.stats._continuous_distns.levy_gen object>
```

A Levy continuous random variable.
As an instance of the `rv_continuous` class, `levy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`levy_stable`, `levy_l`

**Notes**

The probability density function for `levy` is:

\[
f(x) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{1}{2x}\right)
\]

for \(x \geq 0\).

This is the same as the Levy-stable distribution with \(a = 1/2\) and \(b = 1\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy.pdf(x, loc, scale)` is identically equivalent to `levy.pdf(y) / scale` with \(y = (x - loc) / scale\).

**Examples**

```python
>>> from scipy.stats import levy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = levy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(levy.ppf(0.01),
...                 levy.ppf(0.99), 100)
>>> ax.plot(x, levy.pdf(x),
...         'r-', lw=5, alpha=0.6, label='levy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = levy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

```python
>>> vals = levy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy.cdf(vals))
True
```

Generate random numbers:
>>> r = levy.rvs(size=1000)

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.levy_l**

```python
scipy.stats.levy_l(*args, **kwds) = <scipy.stats._continuous_distns.levy_l_gen object>
```

A left-skewed Levy continuous random variable.

As an instance of the `rv_continuous` class, `levy_l` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

- `levy`
- `levy_stable`

**Notes**

The probability density function for `levy_l` is:

\[
f(x) = \frac{1}{|x| \sqrt{2\pi}|x|} \exp\left( -\frac{1}{2|x|} \right)
\]

for \( x \leq 0 \).

This is the same as the Levy-stable distribution with \( a = 1/2 \) and \( b = -1 \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy_l.pdf(x, loc, scale)` is identically equivalent to `levy_l.pdf(y) / scale` with \( y = (x - \text{loc}) / \text{scale} \).
Examples

```python
>>> from scipy.stats import levy_l
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = levy_l.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(levy_l.ppf(0.01),
...                 levy_l.ppf(0.99), 100)
>>> ax.plot(x, levy_l.pdf(x), # r-', lw=5, alpha=0.6, label='levy_l pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = levy_l()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = levy_l.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy_l.cdf(vals))
```

Generate random numbers:

```python
>>> r = levy_l.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.levy_stable**

```python
scipy.stats.levy_stable(*args, **kwds) = <scipy.stats._continuous_distns.levy_stable_gen object>
```

A Levy-stable continuous random variable.
As an instance of the `rv_continuous` class, `levy_stable` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`levy, levy_1`

**Notes**

The distribution for `levy_stable` has characteristic function:

\[
\phi(t, \alpha, \beta, c, \mu) = e^{it\mu - |ct|^{\alpha}(1-i\beta \text{sign}(t))\Phi(\alpha, t)}
\]

where:

\[
\Phi = \begin{cases} 
\tan\left(\frac{\pi\alpha}{2}\right) & \alpha \neq 1 \\
-\frac{2\pi}{\log |t|} & \alpha = 1 
\end{cases}
\]

The probability density function for `levy_stable` is:

\[
f(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \phi(t) e^{-ixt} dt
\]

where \(-\infty < t < \infty\). This integral does not have a known closed form.

For evaluation of pdf we use either Zolotarev \( S_0 \) parameterization with integration, direct integration of standard parameterization of characteristic function or FFT of characteristic function. If set to other than None and if number of points is greater than `levy_stable.pdf_fft_min_points_threshold` (defaults to None) we use FFT otherwise we use one of the other methods.

The default method is ‘best’ which uses Zolotarev’s method if alpha = 1 and integration of characteristic function otherwise. The default method can be changed by setting `levy_stable.pdf_default_method` to either ‘zolotarev’, ‘quadrature’ or ‘best’.

To increase accuracy of FFT calculation one can specify `levy_stable.pdf_fft_grid_spacing` (defaults to 0.001) and `pdf_fft_n_points_two_power` (defaults to a value that covers the input range * 4). Setting `pdf_fft_n_points_two_power` to 16 should be sufficiently accurate in most cases at the expense of CPU time.

For evaluation of cdf we use Zolotarev \( S_0 \) parameterization with integration or integral of the pdf FFT interpolated spline. The settings affecting FFT calculation are the same as for pdf calculation. Setting the threshold to None (default) will disable FFT. For cdf calculations the Zolotarev method is superior in accuracy, so FFT is disabled by default.

Fitting estimate uses quantile estimation method in [MC]. MLE estimation of parameters in fit method uses this quantile estimate initially. Note that MLE doesn’t always converge if using FFT for pdf calculations; so it’s best that `pdf_fft_min_points_threshold` is left unset.

**Warning:** For pdf calculations implementation of Zolotarev is unstable for values where alpha = 1 and beta != 0. In this case the quadrature method is recommended. FFT calculation is also considered experimental.

For cdf calculations FFT calculation is considered experimental. Use Zolotarev’s method instead (default).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy_stable.pdf(x, alpha, beta, loc, scale)` is identically equivalent to `levy_stable.pdf(y, alpha, beta) / scale` with \( y = (x - \text{loc}) / \text{scale} \).
References

[MC], [MS], [BS]

Examples

```python
from scipy.stats import levy_stable
import matplotlib.pyplot as plt

fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
alpha, beta = 1.8, -0.5
mean, var, skew, kurt = levy_stable.stats(alpha, beta, moments='mvsk')
```

Display the probability density function (pdf):

```python
x = np.linspace(levy_stable.ppf(0.01, alpha, beta),
                ...                     levy_stable.ppf(0.99, alpha, beta), 100)
ax.plot(x, levy_stable.pdf(x, alpha, beta),
        ...                     'r-', lw=5, alpha=0.6, label='levy_stable_pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
rv = levy_stable(alpha, beta)
ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
vals = levy_stable.ppf([0.001, 0.5, 0.999], alpha, beta)
np.allclose([0.001, 0.5, 0.999], levy_stable.cdf(vals, alpha, beta))
```

Generate random numbers:

```python
r = levy_stable.rvs(alpha, beta, size=1000)
```

And compare the histogram:

```python
ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
ax.legend(loc='best', frameon=False)
plt.show()```

scipy.stats.logistic

scipy.stats.logistic(*args, **kwds) = <scipy.stats._continuous_distns.logistic_gen object>

A logistic (or Sech-squared) continuous random variable.

As an instance of the rv_continuous class, logistic object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for logistic is:

\[ f(x) = \frac{\exp(-x)}{(1 + \exp(-x))^2} \]

logistic is a special case of genlogistic with c=1.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, logistic.pdf(x, loc, scale) is identically equivalent to logistic.pdf(y) / scale with y = (x - loc) / scale.

Examples

```python
>>> from scipy.stats import logistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = logistic.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(logistic.ppf(0.01),
...                 logistic.ppf(0.99), 100)
>>> ax.plot(x, logistic.pdf(x),
...          'r-', lw=5, alpha=0.6, label='logistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = logistic()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = logistic.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], logistic.cdf(vals))
```

Generate random numbers:
```python
>>> r = logistic.rvs(size=1000)
And compare the histogram:
```

**scipy.stats.loggamma**

A log gamma continuous random variable.

As an instance of the `rv_continuous` class, `loggamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `loggamma` is:

\[
f(x, c) = \frac{\exp(cx - \exp(x))}{\Gamma(c)}
\]

for all \( x, c > 0 \). Here, \( \Gamma \) is the gamma function (scipy.special.gamma).

`loggamma` takes \( c \) as a shape parameter for \( c \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `loggamma.pdf(x, c, loc, scale)` is identically equivalent to `loggamma.pdf(y, c) / scale` with \( y = (x - loc) / scale \).
Examples

```python
>>> from scipy.stats import loggamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 0.414
>>> mean, var, skew, kurt = loggamma.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(loggamma.ppf(0.01, c),
...                 loggamma.ppf(0.99, c), 100)
>>> ax.plot(x, loggamma.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='loggamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = loggamma(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = loggamma.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loggamma.cdf(vals, c))
```

Generate random numbers:

```python
>>> r = loggamma.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Methods

- `rvs(c, loc=0, scale=1, size=1, random_state=None)`: Random variates.
- `pdf(x, c, loc=0, scale=1)`: Probability density function.
- `logpdf(x, c, loc=0, scale=1)`: Log of the probability density function.
- `cdf(x, c, loc=0, scale=1)`: Cumulative distribution function.
- `logcdf(x, c, loc=0, scale=1)`: Log of the cumulative distribution function.
- `sf(x, c, loc=0, scale=1)`: Survival function (also defined as 1 - cdf, but sf is sometimes more accurate).
- `logsf(x, c, loc=0, scale=1)`: Log of the survival function.
- `ppf(q, c, loc=0, scale=1)`: Percent point function (inverse of cdf — percentiles).
- `isf(q, c, loc=0, scale=1)`: Inverse survival function (inverse of sf).
- `moment(n, c, loc=0, scale=1)`: Non-central moment of order n.
- `stats(c, loc=0, scale=1, moments='mv')`: Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
- `entropy(c, loc=0, scale=1)`: (Differential) entropy of the RV.
- `fit(data, c, loc=0, scale=1)`: Parameter estimates for generic data.
- `expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)`: Expected value of a function (of one argument) with respect to the distribution.
- `median(c, loc=0, scale=1)`: Median of the distribution.
- `mean(c, loc=0, scale=1)`: Mean of the distribution.
- `var(c, loc=0, scale=1)`: Variance of the distribution.
- `std(c, loc=0, scale=1)`: Standard deviation of the distribution.
- `interval(alpha, c, loc=0, scale=1)`: Endpoints of the range that contains alpha percent of the distribution.

`scipy.stats.loglaplace`

`scipy.stats.loglaplace(*args, **kwds) = <scipy.stats._continuous_distns.loglaplace_gen object>`

A log-Laplace continuous random variable.
As an instance of the `rv_continuous` class, `loglaplace` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `loglaplace` is:

\[
f(x, c) = \begin{cases} 
\frac{c}{x} x^{c-1} & \text{for } 0 < x < 1 \\
\frac{c}{x} x^{-c-1} & \text{for } x \geq 1
\end{cases}
\]

for \( c > 0 \).

`loglaplace` takes \( c \) as a shape parameter for \( c \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `loglaplace.pdf(x, c, loc, scale)` is identically equivalent to `loglaplace.pdf(y, c) / scale` with \( y = (x - loc) / scale \).

**References**

**Examples**

```python
>>> from scipy.stats import loglaplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 3.25
>>> mean, var, skew, kurt = loglaplace.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(loglaplace.ppf(0.01, c),
... loglaplace.ppf(0.99, c), 100)
>>> ax.plot(x, loglaplace.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='loglaplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = loglaplace(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = loglaplace.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loglaplace.cdf(vals, c))
```

6.28. Statistical functions (`scipy.stats`)
Generate random numbers:

```python
>>> r = loglaplace.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.lognorm

scipy.stats.lognorm(*args, **kwds) = <scipy.stats._continuous_distns.lognorm_gen object>

A lognormal continuous random variable.

As an instance of the rv_continuous class, lognorm object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for lognorm is:

\[ f(x; s) = \frac{1}{sx\sqrt{2\pi}} \exp\left(-\frac{\log^2(x)}{2s^2}\right) \]

for \( x > 0, s > 0 \).

lognorm takes \( s \) as a shape parameter for \( s \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \( \text{loc} \) and \( \text{scale} \) parameters. Specifically, lognorm.pdf \( (x, s, \text{loc}, \text{scale}) \) is identically equivalent to lognorm.pdf \( (y, s) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

A common parametrization for a lognormal random variable \( Y \) is in terms of the mean, \( \mu \), and standard deviation, \( \sigma \), of the unique normally distributed random variable \( X \) such that \( \exp(X) = Y \). This parametrization corresponds to setting \( s = \sigma \) and \( \text{scale} = \exp(\mu) \).
Examples

```python
>>> from scipy.stats import lognorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> s = 0.954
>>> mean, var, skew, kurt = lognorm.stats(s, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(lognorm.ppf(0.01, s),
... lognorm.ppf(0.99, s), 100)
>>> ax.plot(x, lognorm.pdf(x, s),
... 'r-', lw=5, alpha=0.6, label='lognorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = lognorm(s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = lognorm.ppf([0.001, 0.5, 0.999], s)
>>> np.allclose([0.001, 0.5, 0.999], lognorm.cdf(vals, s))
True
```

Generate random numbers:

```python
>>> r = lognorm.rvs(s, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.lomax`  

`scipy.stats.lomax(*args, **kwds) = <scipy.stats._continuous_distns.lomax_gen object>`  

A Lomax (Pareto of the second kind) continuous random variable.
As an instance of the `rv_continuous` class, `lomax` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `lomax` is:

\[ f(x, c) = \frac{c}{(1 + x)^{c+1}} \]

for \( x \geq 0, c > 0 \).

`lomax` takes `c` as a shape parameter for `c`.

`lomax` is a special case of `pareto` with `loc=-1.0`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `lomax.pdf(x, c, loc, scale)` is identically equivalent to `lomax.pdf(y, c) / scale` with \( y = (x - \text{loc}) / \text{scale} \).

**Examples**

```python
>>> from scipy.stats import lomax
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 1.88
>>> mean, var, skew, kurt = lomax.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(lomax.ppf(0.01, c), ...
>>> lomax.ppf(0.99, c), 100)
>>> ax.plot(x, lomax.pdf(x, c), ...
>>> 'r-', lw=5, alpha=0.6, label='lomax pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = lomax(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = lomax.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], lomax.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = lomax.rvs(c, size=1000)
```
And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.maxwell

```python
scipy.stats.maxwell(*args, **kwds) = <scipy.stats._continuous_distns.maxwell_gen object>
```

A Maxwell continuous random variable.

As an instance of the `rv_continuous` class, `maxwell` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

A special case of a chi distribution, with df=3, loc=0.0, and given scale = a, where a is the parameter used in the Mathworld description [1].

The probability density function for `maxwell` is:

\[
f(x) = \sqrt{2/\pi} x^2 \exp(-x^2/2)
\]

for \(x \geq 0\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `maxwell.pdf(x, loc, scale)` is identically equivalent to `maxwell.pdf(y) / scale` with \(y = (x - loc) / scale\).

References

[1]

Examples

```python
>>> from scipy.stats import maxwell
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = maxwell.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(maxwell.ppf(0.01),
...                  maxwell.ppf(0.99), 100)
>>> ax.plot(x, maxwell.pdf(x),
...          'r-', lw=5, alpha=0.6, label='maxwell pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = maxwell()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:
>>> vals = maxwell.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], maxwell.cdf(vals))
True

Generate random numbers:

>>> r = maxwell.rvs(size=1000)

And compare the histogram:

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

`scipy.stats.mielke`

`scipy.stats.mielke(*args, **kwds) = <scipy.stats._continuous_distns.mielke_gen object>`

A Mielke Beta-Kappa continuous random variable.

As an instance of the `rv_continuous` class, `mielke` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `mielke` is:

\[ f(x; k, s) = \frac{k x^{k-1}}{(1 + x^s)^{1+k/s}} \]

for $x \geq 0$ and $k, s > 0$.

`mielke` takes $k$ and $s$ as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `mielke.pdf(x, k, s, loc, scale)` is identically equivalent to `mielke.pdf(y, k, s) / scale` with $y = (x - \text{loc}) / \text{scale}$. 
References

[1]

Examples

```python
>>> from scipy.stats import mielke
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> k, s = 10.4, 4.6
>>> mean, var, skew, kurt = mielke.stats(k, s, moments='mvsk')
```  
Display the probability density function (pdf):

```python
>>> x = np.linspace(mielke.ppf(0.01, k, s),
...                  mielke.ppf(0.99, k, s), 100)
>>> ax.plot(x, mielke.pdf(x, k, s),
...          'r-', lw=5, alpha=0.6, label='mielke pdf')
```  
Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = mielke(k, s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```  
Check accuracy of cdf and ppf:

```python
>>> vals = mielke.ppf([0.001, 0.5, 0.999], k, s)
>>> np.allclose([0.001, 0.5, 0.999], mielke.cdf(vals, k, s))
True
```  
Generate random numbers:

```python
>>> r = mielke.rvs(k, s, size=1000)
```  
And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### scipy.stats.moyal

```python
scipy.stats.moyal(*args, **kwds) = <scipy.stats._continuous_distns.moyal_gen object>
```

A Moyal continuous random variable.
As an instance of the \texttt{rv_continuous} class, \texttt{moyal} object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for \texttt{moyal} is:

\[
f(x) = \exp \left( -\frac{x + \exp(-x)}{2} \right) / \sqrt{2\pi}
\]

for a real number \(x\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{moyal.pdf(x, \texttt{loc}, \texttt{scale})} is identically equivalent to \texttt{moyal.pdf(y) / scale} with \(y = (x - \texttt{loc}) / \texttt{scale}\).

This distribution has utility in high-energy physics and radiation detection. It describes the energy loss of a charged relativistic particle due to ionization of the medium [1]. It also provides an approximation for the Landau distribution. For an in depth description see [2]. For additional description, see [3].

**References**

New in version 1.1.0.

[1], [2], [3]

**Examples**

```python
>>> from scipy.stats import moyal
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = moyal.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(moyal.ppf(0.01),
...                 moyal.ppf(0.99), 100)
>>> ax.plot(x, moyal.pdf(x),
...          'r-', lw=5, alpha=0.6, label='moyal pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = moyal()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of \texttt{cdf} and \texttt{ppf}:

```python
>>> vals = moyal.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], moyal.cdf(vals))
```

```python
True
```
Generate random numbers:

```python
>>> r = moyal.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.nakagami**

`scipy.stats.nakagami(*args, **kwds) = <scipy.stats._continuous_distns.nakagami_gen object>`

A Nakagami continuous random variable.

As an instance of the `rv_continuous` class, `nakagami` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `nakagami` is:

$$f(x, \nu) = \frac{2\nu^\nu}{\Gamma(\nu)} x^{2\nu-1} \exp(-\nu x^2)$$

for $x \geq 0, \nu > 0$.

`nakagami` takes $\nu$ as a shape parameter for $\nu$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `nakagami.pdf(x, nu, loc, scale)` is identically equivalent to `nakagami.pdf(y, nu) / scale` with $y = (x - loc) / scale$. 

6.28. Statistical functions (scipy.stats) 2279
Examples

```python
>>> from scipy.stats import nakagami
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> nu = 4.97
>>> mean, var, skew, kurt = nakagami.stats(nu, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(nakagami.ppf(0.01, nu),
...                  nakagami.ppf(0.99, nu), 100)
>>> ax.plot(x, nakagami.pdf(x, nu),
...         'r-', lw=5, alpha=0.6, label='nakagami pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = nakagami(nu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = nakagami.ppf([0.001, 0.5, 0.999], nu)
>>> np.allclose([0.001, 0.5, 0.999], nakagami.cdf(vals, nu))
True
```

Generate random numbers:

```python
>>> r = nakagami.rvs(nu, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.ncx2

scipy.stats.ncx2(*args,     **kwds) = <scipy.stats._continuous_distns.ncx2_gen object>

A non-central chi-squared continuous random variable.
As an instance of the `rv_continuous` class, `ncx2` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `ncx2` is:

\[
f(x, k, \lambda) = \frac{1}{2} \exp\left(-\frac{(\lambda + x)/2}{x/\lambda}\right) (x/\lambda)^{(k-2)/4} I_{(k-2)/2}(\sqrt{\lambda x})
\]

for \( x \geq 0 \) and \( k, \lambda > 0 \). \( k \) specifies the degrees of freedom (denoted \( df \) in the implementation) and \( \lambda \) is the non-centrality parameter (denoted \( nc \) in the implementation). \( I_\nu \) denotes the modified Bessel function of first order of degree \( \nu \) (scipy.special.iv).

`ncx2` takes \( df \) and \( nc \) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \( loc \) and \( scale \) parameters. Specifically, `ncx2.pdf(x, df, nc)` is identically equivalent to `ncx2.pdf(y, df, nc) / scale` with \( y = (x - loc) / scale \).

**Examples**

```python
>>> from scipy.stats import ncx2
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> df, nc = 21, 1.06
>>> mean, var, skew, kurt = ncx2.stats(df, nc, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(ncx2.ppf(0.01, df, nc), ...
...                 ncx2.ppf(0.99, df, nc), 100)
>>> ax.plot(x, ncx2.pdf(x, df, nc), ...
...         'r-', lw=5, alpha=0.6, label='ncx2 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = ncx2(df, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = ncx2.ppf([0.001, 0.5, 0.999], df, nc)
>>> np.allclose([0.001, 0.5, 0.999], ncx2.cdf(vals, df, nc))
True
```

Generate random numbers:
```python
>>> r = ncx2.rvs(df, nc, size=1000)

And compare the histogram:
```

### scipy.stats.ncf

**scipy.stats.ncf (**args, **kwds)** = <scipy.stats._continuous_distns.ncf_gen object>

A non-central F distribution continuous random variable.

As an instance of the `rv_continuous` class, `ncf` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `ncf` is:

\[
 f(x, n_1, n_2, \lambda) = \exp\left(\frac{\lambda}{2} + \frac{x}{2(n_1 x + n_2)}\right) n_1^{n_1/2} n_2^{n_2/2} (n_2 + n_1 x)^{- (n_1 + n_2)/2} \gamma(n_1/2) \gamma(1 + n_2/2) \left( L_{n/2}^{-1} (\lambda n_1 2(n_1 x + n_2)) / B(v_1/2, v_2/2) \gamma(\frac{v_1 + v_2}{2}) \right) 
\]

for \( n_1 > 1 \), \( n_2 \geq 0 \). Here \( n_1 \) is the degrees of freedom in the numerator, \( n_2 \) the degrees of freedom in the denominator, \( \lambda \) the non-centrality parameter, \( \gamma \) is the logarithm of the Gamma function, \( L_n^k \) is a generalized Laguerre polynomial and \( B \) is the beta function.
The SciPy Reference Guide, Release 1.3.2

\texttt{ncf} takes \texttt{df1}, \texttt{df2} and \texttt{nc} as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{ncf.pdf(x, dfn, dfd, nc, loc, scale)} is identically equivalent to \texttt{ncf.pdf(y, dfn, dfd, nc) / scale with } \texttt{y = (x - loc) / scale}.

\textbf{Examples}

```python
>>> from scipy.stats import ncf
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> dfn, dfd, nc = 27, 27, 0.416
>>> mean, var, skew, kurt = ncf.stats(dfn, dfd, nc, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(ncf.ppf(0.01, dfn, dfd, nc),
...                 ncf.ppf(0.99, dfn, dfd, nc), 100)
>>> ax.plot(x, ncf.pdf(x, dfn, dfd, nc),
...          'r-', lw=5, alpha=0.6, label='ncf pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = ncf(dfn, dfd, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = ncf.ppf([0.001, 0.5, 0.999], dfn, dfd, nc)
>>> np.allclose([0.001, 0.5, 0.999], ncf.cdf(vals, dfn, dfd, nc))
True
```

Generate random numbers:

```python
>>> r = ncf.rvs(dfn, dfd, nc, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

</tbody>
</table>
scipy.stats.nct

scipy.stats.nct(*args, **kwds) = <scipy.stats._continuous_distns.nct_gen object>

A non-central Student’s t continuous random variable.

As an instance of the rv_continuous class, nct object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

If Y is a standard normal random variable and V is an independent chi-square random variable (\texttt{chi2}) with k degrees of freedom, then

\[ X = \frac{Y + c}{\sqrt{V/k}} \]

has a non-central Student’s t distribution on the real line. The degrees of freedom parameter k (denoted df in the implementation) satisfies \( k > 0 \) and the noncentrality parameter c (denoted nct in the implementation) is a real number.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{nct.pdf}(x, df, nc) / scale is identically equivalent to \texttt{nct.pdf}(y, df, nc) / scale with y = (x - loc) / scale.

Examples

```
>>> from scipy.stats import nct
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df, nc = 14, 0.24
>>> mean, var, skew, kurt = nct.stats(df, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(nct.ppf(0.01, df, nc), ...
>>> nct.ppf(0.99, df, nc), 100)
>>> ax.plot(x, nct.pdf(x, df, nc), ...
>>> 'r-', lw=5, alpha=0.6, label='nct pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = nct(df, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of \texttt{cdf} and \texttt{ppf}:
```python
>>> vals = nct.ppf([0.001, 0.5, 0.999], df, nc)
>>> np.allclose([0.001, 0.5, 0.999], nct.cdf(vals, df, nc))
True

Generate random numbers:
```nct.rvs(df, nc, size=1000)`

And compare the histogram:
```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

</table>

**scipy.stats.norm**

`scipy.stats.norm(*args, **kwds) = <scipy.stats._continuous_distns.norm_gen object>`

A normal continuous random variable.

The location (loc) keyword specifies the mean. The scale (scale) keyword specifies the standard deviation.

As an instance of the `rv_continuous` class, `norm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `norm` is:

$$f(x) = \frac{\exp(-x^2/2)}{\sqrt{2\pi}}$$

for a real number $x$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `norm.pdf(x, loc, scale)` is identically equivalent to `norm.pdf(y) / scale` with $y = (x - \text{loc}) / \text{scale}$. 

6.28. Statistical functions (`scipy.stats`)
Examples

```python
>>> from scipy.stats import norm
>>> import matplotlib.pyplot as plt

Calculate a few first moments:
```n
```python
>>> mean, var, skew, kurt = norm.stats(moments='mvsk')
```

Display the probability density function (pdf):
```python
>>> x = np.linspace(norm.ppf(0.01),
...                 norm.ppf(0.99), 100)
>>> ax.plot(x, norm.pdf(x),
...          'r-', lw=5, alpha=0.6, label='norm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
```python
>>> rv = norm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:
```python
>>> vals = norm.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], norm.cdf(vals))
```

Generate random numbers:
```python
>>> r = norm.rvs(size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
```

**scipy.stats.norminvgauss**

**scipy.stats.norminvgauss(**args,**kwds) = <scipy.stats._continuous_distns.norminvgauss_gen object>**

A Normal Inverse Gaussian continuous random variable.
As an instance of the `rv_continuous` class, `norminvgauss` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `norminvgauss` is:

\[
f(x, a, b) = \frac{a \exp(\sqrt{a^2 - b^2} + bx)}{\pi \sqrt{1 + x^2}} K_1(a \sqrt{1 + x^2})
\]

where \(x\) is a real number, the parameter \(a\) is the tail heaviness and \(b\) is the asymmetry parameter satisfying \(a > 0\) and \(|b| <= a\). \(K_1\) is the modified Bessel function of second kind (scipy.special.k1).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `norminvgauss.pdf(x, a, b, loc, scale)` is identically equivalent to `norminvgauss.pdf(y, a, b) / scale` with \(y = (x - \text{loc}) / \text{scale}\).

A normal inverse Gaussian random variable \(Y\) with parameters \(a\) and \(b\) can be expressed as a normal mean-variance mixture: \(Y = b * V + \sqrt{V} * X\) where \(X\) is `norm(0,1)` and \(V\) is `invgauss(mu=1/sqrt(a**2 - b**2))`. This representation is used to generate random variates.

**References**

**Examples**

```python
>>> from scipy.stats import norminvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> a, b = 1, 0.5
>>> mean, var, skew, kurt = norminvgauss.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(norminvgauss.ppf(0.01, a, b),
... norminvgauss.ppf(0.99, a, b), 100)
>>> ax.plot(x, norminvgauss.pdf(x, a, b),
... 'r-', lw=5, alpha=0.6, label='norminvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = norminvgauss(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```
Check accuracy of \( \text{cdf} \) and \( \text{ppf} \):

```python
>>> vals = norminvgauss.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], norminvgauss.cdf(vals, a, b))
True
```

Generate random numbers:

```python
>>> r = norminvgauss.rvs(a, b, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.pareto**

```python
scipy.stats.pareto(*args, **kwds) = <scipy.stats._continuous_distns.pareto_gen object>
```

A Pareto continuous random variable.

As an instance of the `rv_continuous` class, `pareto` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `pareto` is:

$$f(x; b) = \frac{b}{x^{b+1}}$$

for $x \geq 1$, $b > 0$.

`pareto` takes $b$ as a shape parameter for $b$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `pareto.pdf(x, b, loc, scale)` is identically equivalent to `pareto.pdf(y, b) / scale` with $y = (x - loc) / scale$. 

2294 Chapter 6. API Reference
Examples

```python
>>> from scipy.stats import pareto
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> b = 2.62
>>> mean, var, skew, kurt = pareto.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(pareto.ppf(0.01, b),
...                 pareto.ppf(0.99, b), 100)
>>> ax.plot(x, pareto.pdf(x, b),
...          'r-', lw=5, alpha=0.6, label='pareto pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = pareto(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = pareto.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], pareto.cdf(vals, b))
True
```

Generate random numbers:

```python
>>> r = pareto.rvs(b, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.pearson3**

```python
scipy.stats.pearson3(*args, **kwds) = <scipy.stats._continuous_distns.pearson3_gen object>
```

A pearson type III continuous random variable.
As an instance of the `rv_continuous` class, `pearson3` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `pearson3` is:

\[
f(x, \text{skew}) = \frac{|\beta|}{\Gamma(\alpha)} (\beta(x - \zeta))^{\alpha-1} \exp(-\beta(x - \zeta))
\]

where:

\[
\beta = \frac{2}{\text{skewstddev}} = \frac{(\text{stddev} \beta)^2}{\zeta} = \frac{\text{loc} - \alpha}{\beta}
\]

\(\Gamma\) is the gamma function (scipy.special.gamma). `pearson3` takes `skew` as a shape parameter for `skew`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `pearson3.pdf(x, skew, loc, scale)` is identically equivalent to `pearson3.pdf(y, skew) / scale` with \(y = (x - \text{loc}) / \text{scale}\).

**References**

**Examples**

```python
>>> from scipy.stats import pearson3
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> skew = 0.1
>>> mean, var, skew, kurt = pearson3.stats(skew, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(pearson3.ppf(0.01, skew),
...                 pearson3.ppf(0.99, skew), 100)
>>> ax.plot(x, pearson3.pdf(x, skew),
...         'r-', lw=5, alpha=0.6, label='pearson3 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
>>> rv = pearson3(skew)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

Check accuracy of cdf and ppf:

>>> vals = pearson3.ppf([0.001, 0.5, 0.999], skew)
>>> np.allclose([0.001, 0.5, 0.999], pearson3.cdf(vals, skew))
True

Generate random numbers:

>>> r = pearson3.rvs(skew, size=1000)

And compare the histogram:

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

#### scipy.stats.powerlaw

`scipy.stats.powerlaw(*args, **kwds) = <scipy.stats._continuous_distns.powerlaw_gen object>`

A power-function continuous random variable.

As an instance of the `rv_continuous` class, `powerlaw` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

#### Notes

The probability density function for `powerlaw` is:

\[ f(x, a) = ax^{a-1} \]

for \(0 \leq x \leq 1, a > 0\).

`powerlaw` takes \(a\) as a shape parameter for \(a\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `powerlaw.pdf(x, a, loc, scale)` is identically equivalent to `powerlaw.pdf(y, a) / scale` with \(y = (x - loc) / scale\).

`powerlaw` is a special case of `beta` with \(b=1\).
Examples

```python
>>> from scipy.stats import powerlaw
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a = 1.66
>>> mean, var, skew, kurt = powerlaw.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(powerlaw.ppf(0.01, a),
...     powerlaw.ppf(0.99, a), 100)
>>> ax.plot(x, powerlaw.pdf(x, a),
...     'r-', lw=5, alpha=0.6, label='powerlaw pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = powerlaw(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = powerlaw.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], powerlaw.cdf(vals, a))
True
```

Generate random numbers:

```python
>>> r = powerlaw.rvs(a, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.powerlognorm**

```python
scipy.stats.powerlognorm(*args, **kwds) = <scipy.stats._continuous_distns.powerlognorm_gen object>
```

A power log-normal continuous random variable.
As an instance of the `rv_continuous` class, `powerlognorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `powerlognorm` is:

\[ f(x; c, s) = \frac{c}{xs} \phi\left(\frac{\log(x)}{s}\right)\Phi\left(-\frac{\log(x)}{s}\right)^{c-1} \]

where \( \phi \) is the normal pdf, and \( \Phi \) is the normal cdf, and \( x > 0, s, c > 0 \).

`powerlognorm` takes \( c \) and \( s \) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `powerlognorm.pdf(x, c, s)` is identically equivalent to `powerlognorm.pdf(y, c, s) / scale` with \( y = (x - \text{loc}) / \text{scale} \).

**Examples**

```python
>>> from scipy.stats import powerlognorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> c, s = 2.14, 0.446
>>> mean, var, skew, kurt = powerlognorm.stats(c, s, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(powerlognorm.ppf(0.01, c, s),
...     powerlognorm.ppf(0.99, c, s), 100)
>>> ax.plot(x, powerlognorm.pdf(x, c, s),
...     'r-', lw=5, alpha=0.6, label='powerlognorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = powerlognorm(c, s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = powerlognorm.ppf([0.001, 0.5, 0.999], c, s)
>>> np.allclose([0.001, 0.5, 0.999], powerlognorm.cdf(vals, c, s))
True
```

Generate random numbers:

```python
>>> r = powerlognorm.rvs(c, s, size=1000)
```

And compare the histogram:

scipy.stats.powernorm

scipy.stats.powernorm(*args, **kwds) = <scipy.stats._continuous_distns.powernorm_gen object>

A power normal continuous random variable.

As an instance of the rv_continuous class, powernorm object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for powernorm is:

\[ f(x; c) = c \varphi(x)(\Phi(-x))^c \]

where \( \varphi \) is the normal pdf, and \( \Phi \) is the normal cdf, and \( x \geq 0, c > 0 \).

powernorm takes \( c \) as a shape parameter for \( c \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, \( \text{powernorm.pdf}(x, c, \text{loc}, \text{scale}) \) is identically equivalent to \( \text{powernorm.pdf}(y, c) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import powernorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 4.45
>>> mean, var, skew, kurt = powernorm.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(powernorm.ppf(0.01, c),
...                  powernorm.ppf(0.99, c), 100)
>>> ax.plot(x, powernorm.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='powernorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = powernorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = powernorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], powernorm.cdf(vals, c))
True
```
Generate random numbers:

```python
>>> r = powernorm.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### scipy.stats.rdist

`scipy.stats.rdist(*args, **kwds) = <scipy.stats._continuous_distns.rdist_gen object>`

An R-distributed continuous random variable.

As an instance of the `rv_continuous` class, `rdist` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `rdist` is:

\[
f(x, c) = \frac{(1 - x^2)^{c/2-1}}{B(1/2, c/2)}
\]

for \(-1 \leq x \leq 1, c > 0\).

`rdist` takes `c` as a shape parameter for `c`.

This distribution includes the following distribution kernels as special cases:

- `c = 2`: uniform
- `c = 4`: Epanechnikov (parabolic)
- `c = 6`: quartic (biweight)
- `c = 8`: triweight
The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{rdist.pdf(x, c, loc, scale)} is identically equivalent to \texttt{rdist.pdf(y, c) / scale with y = (x - loc) / scale}.

**Examples**

```python
>>> from scipy.stats import rdist
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> c = 0.9
>>> mean, var, skew, kurt = rdist.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(rdist.ppf(0.01, c),
...                  rdist.ppf(0.99, c), 100)
>>> ax.plot(x, rdist.pdf(x, c),
...          'r-', lw=5, alpha=0.6, label='rdist pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = rdist(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of \texttt{cdf} and \texttt{ppf}:

```python
>>> vals = rdist.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], rdist.cdf(vals, c))
```

Generate random numbers:

```python
>>> r = rdist.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

#### scipy.stats.reciprocal

```python
scipy.stats.reciprocal(*args, **kwds) = <scipy.stats._continuous_distns.reciprocal_gen object>
```

A reciprocal continuous random variable.
As an instance of the \texttt{rv_continuous} class, \texttt{reciprocal} object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for \texttt{reciprocal} is:

\[
f(x,a,b) = \frac{1}{x \log(b/a)}
\]

for \(a \leq x \leq b, b > a > 0\).

\texttt{reciprocal} takes \(a\) and \(b\) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{reciprocal.pdf}(x, a, b, loc, scale) is identically equivalent to \texttt{reciprocal.pdf}(y, a, b) / scale with \(y = (x - \text{loc}) / \text{scale}\).

**Examples**

```python
>>> from scipy.stats import reciprocal
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> a, b = 0.00623, 1.01
>>> mean, var, skew, kurt = reciprocal.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(reciprocal.ppf(0.01, a, b),
...                 reciprocal.ppf(0.99, a, b), 100)
>>> ax.plot(x, reciprocal.pdf(x, a, b),
...          'r-', lw=5, alpha=0.6, label='reciprocal pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = reciprocal(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = reciprocal.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], reciprocal.cdf(vals, a, b))
True
```

Generate random numbers:

```python
>>> r = reciprocal.rvs(a, b, size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.rayleigh

scipy.stats.rayleigh(*args, **kwds) = <scipy.stats._continuous_distns.rayleigh_gen object>

A Rayleigh continuous random variable.

As an instance of the rv_continuous class, rayleigh object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for rayleigh is:

\[ f(x) = x \exp(-x^2/2) \]

for \( x \geq 0 \).

rayleigh is a special case of chi with df=2.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, rayleigh.pdf(x, loc, scale) is identically equivalent to rayleigh.pdf(y) / scale with y = (x - loc) / scale.

Examples

```python
>>> from scipy.stats import rayleigh
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = rayleigh.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(rayleigh.ppf(0.01), ...
...                 rayleigh.ppf(0.99), 100)
>>> ax.plot(x, rayleigh.pdf(x), ...
...          'r-', lw=5, alpha=0.6, label='rayleigh pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = rayleigh()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = rayleigh.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], rayleigh.cdf(vals))
```

Generate random numbers:
>>> \texttt{r = rayleigh.rvs(size=1000)}

And compare the histogram:

### scipy.stats.rice

**scipy.stats.rice(*args, **kwds)** = `<scipy.stats._continuous_distns.rice_gen object>`

A Rice continuous random variable.

As an instance of the `rv_continuous` class, `rice` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `rice` is:

$$f(x, b) = x \exp\left(-\frac{x^2 + b^2}{2}\right)I_0(xb)$$

for $x \geq 0$, $b > 0$. $I_0$ is the modified Bessel function of order zero (`scipy.special.i0`).

`rice` takes $b$ as a shape parameter for $b$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `rice.pdf(x, b, loc, scale)` is identically equivalent to `rice.pdf(y, b) / scale` with $y = (x - loc) / scale$.

The Rice distribution describes the length, $r$, of a 2-D vector with components $(U + u, V + v)$, where $U, V$ are constant, $u, v$ are independent Gaussian random variables with standard deviation $s$. Let $R = \sqrt{U^2 + V^2}$. Then the pdf of $r$ is `rice.pdf(x, R/s, scale=s`).

---

**6.28. Statistical functions (`scipy.stats`)**
Examples

```python
>>> from scipy.stats import rice
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> b = 0.775
>>> mean, var, skew, kurt = rice.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(rice.ppf(0.01, b), ...
...                 rice.ppf(0.99, b), 100)
>>> ax.plot(x, rice.pdf(x, b), ...
...          'r-', lw=5, alpha=0.6, label='rice pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = rice(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = rice.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], rice.cdf(vals, b))
True
```

Generate random numbers:

```python
>>> r = rice.rvs(b, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.recipinvgauss

scipy.stats.recipinvgauss(*args, **kwds) = <scipy.stats._continuous_distns.recipinvgauss_gen object>

A reciprocal inverse Gaussian continuous random variable.
As an instance of the \texttt{rv_continuous} class, \texttt{recipinvgauss} object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for \texttt{recipinvgauss} is:

\[
    f(x; \mu) = \frac{1}{\sqrt{2\pi x}} \exp \left( -\frac{(1 - \mu x)^2}{2\mu^2 x} \right)
\]

for \( x \geq 0 \).

\texttt{recipinvgauss} takes \( \mu \) as a shape parameter for \( \mu \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{recipinvgauss.pdf(x, mu, loc, scale)} is identically equivalent to \texttt{recipinvgauss.pdf(y, mu) \div scale} with \( y = (x - \text{loc}) \div \text{scale} \).

**Examples**

```python
>>> from scipy.stats import recipinvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mu = 0.63
>>> mean, var, skew, kurt = recipinvgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(recipinvgauss.ppf(0.01, mu),
...                 recipinvgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, recipinvgauss.pdf(x, mu),
...         'r-', lw=5, alpha=0.6, label='recipinvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = recipinvgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of \texttt{cdf} and \texttt{ppf}:

```python
>>> vals = recipinvgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], recipinvgauss.cdf(vals, mu))
True
```

Generate random numbers:

```python
>>> r = recipinvgauss.rvs(mu, size=1000)
```

And compare the histogram:
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
scipy.stats.semicircular

scipy.stats.semicircular(*args, **kwds) = <scipy.stats._continuous_distns.semicircular_gen object>

A semicircular continuous random variable.

As an instance of the rv_continuous class, semicircular object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for semicircular is:

$$f(x) = \frac{2}{\pi \sqrt{1 - x^2}}$$

for $-1 \leq x \leq 1$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, semicircular.pdf(x, loc, scale) is identically equivalent to semicircular.pdf(y) / scale with $y = (x - loc) / scale$.

Examples

```python
>>> from scipy.stats import semicircular
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = semicircular.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(semicircular.ppf(0.01),
...                 semicircular.ppf(0.99), 100)
>>> ax.plot(x, semicircular.pdf(x),
...         'r-', lw=5, alpha=0.6, label='semicircular pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = semicircular()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = semicircular.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], semicircular.cdf(vals))
```

Generate random numbers:
```python
>>> r = semicircular.rvs(size=1000)

And compare the histogram:
```

**scipy.stats.skewnorm**

scipy.stats.skewnorm(*args, **kwds) = <scipy.stats._continuous_distns.skew_norm_gen object>

A skew-normal random variable.

As an instance of the `rv_continuous` class, `skewnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The pdf is:

\[
skewnorm.pdf(x, a) = 2 * \text{norm.pdf}(x) * \text{norm.cdf}(a^x)
\]

`skewnorm` takes a real number \(a\) as a skewness parameter. When \(a = 0\) the distribution is identical to a normal distribution (\text{norm}). \text{rvs} implements the method of [1].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \text{loc} and \text{scale} parameters. Specifically, \text{skewnorm.pdf}(x, a, \text{loc}, \text{scale}) is identically equivalent to \text{skewnorm.pdf}(y, a) / \text{scale} with \(y = (x - \text{loc}) / \text{scale}.

**References**

[1]
Examples

```python
>>> from scipy.stats import skewnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> a = 4
>>> mean, var, skew, kurt = skewnorm.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(skewnorm.ppf(0.01, a), ...
... skewnorm.ppf(0.99, a), 100)
>>> ax.plot(x, skewnorm.pdf(x, a), ...
... 'r-', lw=5, alpha=0.6, label='skewnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = skewnorm(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = skewnorm.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], skewnorm.cdf(vals, a))
True
```

Generate random numbers:

```python
>>> r = skewnorm.rvs(a, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.t**

scipy.stats.t(*args, **kwds) = <scipy.stats._continuous_distns.t_gen object>

A Student’s t continuous random variable.
As an instance of the `rv_continuous` class, the object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for $t$ is:

$$f(x, \nu) = \frac{\Gamma((\nu + 1)/2)}{\sqrt{\pi}\Gamma(\nu)}(1 + x^2/\nu)^{-(\nu+1)/2}$$

where $x$ is a real number and the degrees of freedom parameter $\nu$ (denoted df in the implementation) satisfies $\nu > 0$. $\Gamma$ is the gamma function (`scipy.special.gamma`).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, $t.pdf(x, \nu, \text{loc}, \text{scale})$ is identically equivalent to $t.pdf(y, \nu) / \text{scale}$ with $y = (x - \text{loc}) / \text{scale}$.

**Examples**

```python
>>> from scipy.stats import t
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> df = 2.74
>>> mean, var, skew, kurt = t.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(t.ppf(0.01, df),
...                 t.ppf(0.99, df), 100)
>>> ax.plot(x, t.pdf(x, df),
...          'r-', lw=5, alpha=0.6, label='t pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = t(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = t.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], t.cdf(vals, df))
True
```

Generate random numbers:

```python
>>> r = t.rvs(df, size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

</table>
scipy.stats.trapz

scipy.stats.trapz(*args, **kwds) = <scipy.stats._continuous_distns.trapz_gen object>

A trapezoidal continuous random variable.

As an instance of the rv_continuous class, trapz object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The trapezoidal distribution can be represented with an up-sloping line from loc to (loc + c*scale), then constant to (loc + d*scale) and then downsloping from (loc + d*scale) to (loc+scale).

trapz takes c and d as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, trapz.pdf(x, c, d, loc, scale) is identically equivalent to trapz.pdf(y, c, d) / scale with y = (x - loc) / scale.

The standard form is in the range [0, 1] with c the mode. The location parameter shifts the start to loc. The scale parameter changes the width from 1 to scale.

Examples

```python
>>> from scipy.stats import trapz
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c, d = 0.2, 0.8
>>> mean, var, skew, kurt = trapz.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(trapz.ppf(0.01, c, d),...
...                 trapz.ppf(0.99, c, d), 100)
>>> ax.plot(x, trapz.pdf(x, c, d),...
...          'r-', lw=5, alpha=0.6, label='trapz pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = trapz(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = trapz.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], trapz.cdf(vals, c, d))
True
```

Generate random numbers:
```python
>>> r = trapz.rvs(c, d, size=1000)

And compare the histogram:
```

### scipy.stats.triang

```python
scipy.stats.triang(*args, **kwds) = <scipy.stats._continuous_distns.triang_gen object>
```

A triangular continuous random variable.

As an instance of the `rv_continuous` class, `triang` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The triangular distribution can be represented with an upsloping line from `loc` to `(loc + c*scale)` and then downsloping for `(loc + c*scale)` to `(loc + scale)`. `triang` takes `c` as a shape parameter for `c`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `triang.pdf(x, c, loc, scale)` is identically equivalent to `triang.pdf(y, c) / scale` with `y = (x - loc) / scale`.

The standard form is in the range [0, 1] with `c` the mode. The location parameter shifts the start to `loc`. The scale parameter changes the width from 1 to `scale`.  

---

6.28. **Statistical functions** (scipy.stats) 2327
Examples

```python
>>> from scipy.stats import triang
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> c = 0.158
>>> mean, var, skew, kurt = triang.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(triang.ppf(0.01, c),
...                  triang.ppf(0.99, c), 100)
>>> ax.plot(x, triang.pdf(x, c),
...          'r-', lw=5, alpha=0.6, label='triang pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = triang(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = triang.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], triang.cdf(vals, c))
```

Generate random numbers:

```python
>>> r = triang.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### scipy.stats.truncexpon

`scipy.stats.truncexpon(*args, **kwds)` = `<scipy.stats._continuous_distns.truncexpon_gen object>`

A truncated exponential continuous random variable.
As an instance of the `rv_continuous` class, `truncexpon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `truncexpon` is:

\[
f(x; b) = \frac{\exp(-x)}{1 - \exp(-b)}
\]

for \(0 < x < b\).

`truncexpon` takes \(b\) as a shape parameter for \(b\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `truncexpon.pdf(x, b, loc, scale)` is identically equivalent to `truncexpon.pdf(y, b) / scale` with \(y = (x - loc) / scale\).

**Examples**

```python
>>> from scipy.stats import truncexpon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:
```n
```python
>>> b = 4.69
>>> mean, var, skew, kurt = truncexpon.stats(b, moments='mvsk')
```

Display the probability density function (pdf):
```python
>>> x = np.linspace(truncexpon.ppf(0.01, b), ...
... truncexpon.ppf(0.99, b), 100)
>>> ax.plot(x, truncexpon.pdf(x, b), ...
... 'r-', lw=5, alpha=0.6, label='truncexpon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
```python
>>> rv = truncexpon(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:
```python
>>> vals = truncexpon.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], truncexpon.cdf(vals, b))
True
```

Generate random numbers:
```python
>>> r = truncexpon.rvs(b, size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.truncnorm

```
scipy.stats.truncnorm(*args, **kwds) = <scipy.stats._continuous_distns.
    truncnorm_gen object>
```

A truncated normal continuous random variable.

As an instance of the `rv_continuous` class, `truncnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The standard form of this distribution is a standard normal truncated to the range [a, b] — notice that a and b are defined over the domain of the standard normal. To convert clip values for a specific mean and standard deviation, use:

```
a, b = (myclip_a - my_mean) / my_std, (myclip_b - my_mean) / my_std
```

`truncnorm` takes a and b as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `truncnorm.pdf(x, a, b, loc, scale)` is identically equivalent to `truncnorm.pdf(y, a, b) / scale` with `y = (x - loc) / scale`.

Examples

```
>>> from scipy.stats import truncnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 0.1, 2
>>> mean, var, skew, kurt = truncnorm.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(truncnorm.ppf(0.01, a, b), ...
        truncnorm.ppf(0.99, a, b), 100)
>>> ax.plot(x, truncnorm.pdf(x, a, b), ...
        'r-', lw=5, alpha=0.6, label='truncnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = truncnorm(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = truncnorm.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], truncnorm.cdf(vals, a, b))
True
```
Generate random numbers:

```python
>>> r = truncnorm.rvs(a, b, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.tukeylambda

`scipy.stats.tukeylambda(*args, **kwds) = <scipy.stats._continuous_distns.tukeylambda_gen object>`

A Tukey-Lambda continuous random variable.

As an instance of the `rv_continuous` class, `tukeylambda` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

A flexible distribution, able to represent and interpolate between the following distributions:

- Cauchy ($\lambda = -1$)
- logistic ($\lambda = 0$)
- approx Normal ($\lambda = 0.14$)
- uniform from -1 to 1 ($\lambda = 1$)

`tukeylambda` takes a real number $\lambda$ (denoted $\lambda$ in the implementation) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `tukeylambda.pdf(x, lam, loc, scale)` is identically equivalent to `tukeylambda.pdf(y, lam) / scale with y = (x - loc) / scale`. 
Examples

```python
>>> from scipy.stats import tukeylambda
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> lam = 3.13
>>> mean, var, skew, kurt = tukeylambda.stats(lam, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(tukeylambda.ppf(0.01, lam),  
...                 tukeylambda.ppf(0.99, lam), 100)
>>> ax.plot(x, tukeylambda.pdf(x, lam),  
...          'r-', lw=5, alpha=0.6, label='tukeylambda pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = tukeylambda(lam)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = tukeylambda.ppf([0.001, 0.5, 0.999], lam)
>>> np.allclose([0.001, 0.5, 0.999], tukeylambda.cdf(vals, lam))
True
```

Generate random numbers:

```python
>>> r = tukeylambda.rvs(lam, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### scipy.stats.uniform

```python
scipy.stats.uniform(*args, **kws) = <scipy.stats._continuous_distns.uniform_gen object>
```

A uniform continuous random variable.
In the standard form, the distribution is uniform on \([0, 1]\). Using the parameters \(\text{loc}\) and \(\text{scale}\), one obtains the uniform distribution on \([\text{loc}, \text{loc} + \text{scale}]\).

As an instance of the \texttt{rv_continuous} class, \texttt{uniform} object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Examples**

```python
>>> from scipy.stats import uniform
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = uniform.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(uniform.ppf(0.01),
...                 uniform.ppf(0.99), 100)
>>> ax.plot(x, uniform.pdf(x),
...          'r-', lw=5, alpha=0.6, label='uniform pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = uniform()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = uniform.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], uniform.cdf(vals))
```

Generate random numbers:

```python
>>> r = uniform.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.vonmises`

```python
scipy.stats.vonmises(*args, **kwds) = <scipy.stats._continuous_distns.vonmises_gen object>
```

A Von Mises continuous random variable.
As an instance of the `rv_continuous` class, `vonmises` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `vonmises` and `vonmises_line` is:

\[
    f(x, \kappa) = \frac{\exp(\kappa \cos(x))}{2\pi I_0(\kappa)}
\]

for \(-\pi \leq x \leq \pi, \kappa > 0\). \(I_0\) is the modified Bessel function of order zero (`scipy.special.i0`).

`vonmises` is a circular distribution which does not restrict the distribution to a fixed interval. Currently, there is no circular distribution framework in scipy. The cdf is implemented such that \(\text{cdf}(x + 2*\text{np.pi}) = \text{cdf}(x) + 1\).

`vonmises_line` is the same distribution, defined on \([-\pi, \pi]\) on the real line. This is a regular (i.e. non-circular) distribution.

`vonmises` and `vonmises_line` take kappa as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `vonmises.pdf(x, kappa, loc, scale)` is identically equivalent to `vonmises.pdf(y, kappa) / scale` with \(y = (x - \text{loc}) / \text{scale}\).

**Examples**

```python
globally import scipy.stats import matplotlib.pyplot as plt
fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
globally kappa = 3.99
mean, var, skew, kurt = vonmises.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):

```python
x = np.linspace(vonmises.ppf(0.01, kappa),
    ..., vonmises.ppf(0.99, kappa), 100)
ax.plot(x, vonmises.pdf(x, kappa),
    ... 'r-', lw=5, alpha=0.6, label='vonmises pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
rv = vonmises(kappa)
ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
vals = vonmises.ppf([0.001, 0.5, 0.999], kappa)
np.allclose([0.001, 0.5, 0.999], vonmises.cdf(vals, kappa))
True
```
Generate random numbers:

```python
>>> r = vonmises.rvs(kappa, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.vonmises_line**

A Von Mises continuous random variable.

As an instance of the `rv_continuous` class, `vonmises_line` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `vonmises` and `vonmises_line` is:

\[
f(x, \kappa) = \frac{\exp(\kappa \cos(x))}{2\pi I_0(\kappa)}
\]

for \(-\pi \leq x \leq \pi, \kappa > 0\). \(I_0\) is the modified Bessel function of order zero (`scipy.special.i0`).

`vonmises` is a circular distribution which does not restrict the distribution to a fixed interval. Currently, there is no circular distribution framework in scipy. The `cdf` is implemented such that `cdf(x + 2*np.pi) == cdf(x) + 1`.

`vonmises_line` is the same distribution, defined on \([-\pi, \pi]\) on the real line. This is a regular (i.e. non-circular) distribution.

`vonmises` and `vonmises_line` take kappa as a shape parameter.
The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{vonmises line.pdf(x, kappa, loc, scale)} is identically equivalent to \texttt{vonmises line.pdf(y, kappa) / scale} with \( y = (x - \text{loc}) / \text{scale} \).

**Examples**

```python
>>> from scipy.stats import vonmises_line
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> kappa = 3.99
>>> mean, var, skew, kurt = vonmises_line.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(vonmises_line.ppf(0.01, kappa),
...                 vonmises_line.ppf(0.99, kappa), 100)
>>> ax.plot(x, vonmises_line.pdf(x, kappa),
...          'r-', lw=5, alpha=0.6, label='vonmises line pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = vonmises_line(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of \texttt{cdf} and \texttt{ppf}:

```python
>>> vals = vonmises_line.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], vonmises_line.cdf(vals, kappa))
True
```

Generate random numbers:

```python
>>> r = vonmises_line.rvs(kappa, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.wald

scipy.stats.wald(*args, **kwds) = <scipy.stats._continuous_distns.wald_gen object>

A Wald continuous random variable.

As an instance of the `rv_continuous` class, `wald` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `wald` is:

\[ f(x) = \frac{1}{\sqrt{2\pi x}} \exp\left(-\frac{(x - 1)^2}{2x}\right) \]

for \( x \geq 0 \).

`wald` is a special case of `invgauss` with \( \mu=1 \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `wald.pdf(x, loc, scale)` is identically equivalent to `wald.pdf(y) / scale` with \( y = (x - loc) / scale \).

Examples

```python
>>> from scipy.stats import wald
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = wald.stats(moments='mvsk')
```  
Display the probability density function (pdf):

```python
>>> x = np.linspace(wald.ppf(0.01),
...                 wald.ppf(0.99), 100)
>>> ax.plot(x, wald.pdf(x),
...          'r-', lw=5, alpha=0.6, label='wald pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = wald()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = wald.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], wald.cdf(vals))
True
```

Generate random numbers:
```python
>>> r = wald.rvs(size=1000)

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.weibull_min**

```
scipy.stats.weibull_min(*args, **kwds) = <scipy.stats._continuous_distns.weibull_min_gen object>
```

Weibull minimum continuous random variable.

As an instance of the `rv_continuous` class, `weibull_min` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

- `weibull_max`

**Notes**

The probability density function for `weibull_min` is:

\[ f(x, c) = cx^{c-1} \exp(-x^c) \]

for \( x \geq 0, c > 0 \).

`weibull_min` takes \( c \) as a shape parameter for \( c \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `weibull_min.pdf(x, c, loc, scale)` is identically equivalent to `weibull_min.pdf(y, c) / scale` with \( y = (x - \text{loc}) / \text{scale} \).
Examples

```python
>>> from scipy.stats import weibull_min
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> c = 1.79
>>> mean, var, skew, kurt = weibull_min.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(weibull_min.ppf(0.01, c), ...
...                  weibull_min.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_min.pdf(x, c), ...
...          'r-', lw=5, alpha=0.6, label='weibull_min pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = weibull_min(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = weibull_min.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_min.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = weibull_min.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.weibull_max**

```python
scipy.stats.weibull_max(*args, **kwds) = <scipy.stats._continuous_distns.weibull_max_gen object>
```

Weibull maximum continuous random variable.
As an instance of the `rv_continuous` class, `weibull_max` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`weibull_min`

Notes

The probability density function for `weibull_max` is:

$$f(x, c) = c(-x)^{c-1} \exp(-(-x)^c)$$

for $x < 0, c > 0$.

`weibull_max` takes $c$ as a shape parameter for $c$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `weibull_max.pdf(x, c, loc, scale)` is identically equivalent to `weibull_max.pdf(y, c) / scale` with $y = (x - loc) / scale$.

Examples

```python
>>> from scipy.stats import weibull_max
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 2.87
>>> mean, var, skew, kurt = weibull_max.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(weibull_max.ppf(0.01, c),
...                 weibull_max.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_max.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='weibull_max pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = weibull_max(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = weibull_max.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_max.cdf(vals, c))
```

Generate random numbers:
```python
>>> r = weibull_max.rvs(c, size=1000)

And compare the histogram:
```

**scipy.stats.**

**scipy.stats.wrapcauchy**

```python
scipy.stats.wrapcauchy(*args, **kwds) = <scipy.stats._continuous_distns.wrapcauchy_gen object>
```

A wrapped Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `wrapcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `wrapcauchy` is:

\[
f(x, c) = \frac{1 - c^2}{2\pi(1 + c^2 - 2c\cos(x))}
\]

for \(0 \leq x \leq 2\pi\), \(0 < c < 1\).

`wrapcauchy` takes \(c\) as a shape parameter for \(c\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `wrapcauchy.pdf(x, c, loc, scale)` is identically equivalent to `wrapcauchy.pdf(y, c) / scale` with \(y = (x - \text{loc}) / \text{scale}\).
Examples

```python
>>> from scipy.stats import wrapcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
c = 0.0311
mean, var, skew, kurt = wrapcauchy.stats(c, moments='mvsk')
```Ex

Display the probability density function (pdf):

```python
x = np.linspace(wrapcauchy.ppf(0.01, c), ...
wrapcauchy.ppf(0.99, c), 100)
ax.plot(x, wrapcauchy.pdf(x, c), ...
'r-', lw=5, alpha=0.6, label='wrapcauchy pdf')
```Ex

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
rv = wrapcauchy(c)
ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```Ex

Check accuracy of cdf and ppf:

```python
vals = wrapcauchy.ppf([0.001, 0.5, 0.999], c)
np.allclose([0.001, 0.5, 0.999], wrapcauchy.cdf(vals, c))
True
```Ex

Generate random numbers:

```python
r = wrapcauchy.rvs(c, size=1000)
```Ex

And compare the histogram:

```python
ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
ax.legend(loc='best', frameon=False)
plt.show()
```Ex
Methods

\begin{verbatim}
rvs(c, loc=0, scale=1, size=1, random_state=None)  Random variates.
pdf(x, c, loc=0, scale=1)                         Probability density function.
logpdf(x, c, loc=0, scale=1)                     Log of the probability density function.
cdf(x, c, loc=0, scale=1)                        Cumulative distribution function.
logcdf(x, c, loc=0, scale=1)                    Log of the cumulative distribution function.
sf(x, c, loc=0, scale=1)                        Survival function (also defined as 1 - cdf, but sf is sometimes more accurate).
logsf(x, c, loc=0, scale=1)                     Log of the survival function.
ppf(q, c, loc=0, scale=1)                       Percent point function (inverse of cdf — percentiles).
isf(q, c, loc=0, scale=1)                      Inverse survival function (inverse of sf).
moment(n, c, loc=0, scale=1)                   Non-central moment of order n
stats(c, loc=0, scale=1, moments='mv')         Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(c, loc=0, scale=1)                     (Differential) entropy of the RV.
fit(data, c, loc=0, scale=1)                    Parameter estimates for generic data.
expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)  Expected value of a function (of one argument) with respect to the distribution.
median(c, loc=0, scale=1)                      Median of the distribution.
mean(c, loc=0, scale=1)                        Mean of the distribution.
var(c, loc=0, scale=1)                         Variance of the distribution.
std(c, loc=0, scale=1)                        Standard deviation of the distribution.
interval(alpha, c, loc=0, scale=1)            Endpoints of the range that contains alpha percent of the distribution.
\end{verbatim}

6.28.5 Multivariate distributions
multivariate_normal([mean, cov, ...])
A multivariate normal random variable.

matrix_normal([mean, rowcov, colcov, seed])
A matrix normal random variable.

dirichlet(alpha[, seed])
A Dirichlet random variable.

wishart([df, scale, seed])
A Wishart random variable.

invwishart([df, scale, seed])
An inverse Wishart random variable.

multinomial(n, p[, seed])
A multinomial random variable.

special_ortho_group([dim, seed])
A matrix-valued SO(N) random variable.

ortho_group
A matrix-valued O(N) random variable.

unitary_group
A matrix-valued U(N) random variable.

random_correlation
A random correlation matrix.

scipy.stats.multivariate_normal

scipy.stats.multivariate_normal (mean= None, cov= 1, allow_singular= False, seed= None) = <scipy.stats._multivariate.
multivariate_normal_gen object>

A multivariate normal random variable.

The mean keyword specifies the mean. The cov keyword specifies the covariance matrix.

Parameters

x [array_like] Quantiles, with the last axis of x denoting the components.
mean [array_like, optional] Mean of the distribution (default zero)
cov [array_like, optional] Covariance matrix of the distribution (default one)
allow_singular [bool, optional] Whether to allow a singular covariance matrix. (Default: False)
random_state [None or int or np.random.RandomState instance, optional] If int or RandomState instance, optional] If int or RandomState, use it for
drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

Alternatively, the object may be called (as a function) to fix the mean
and covariance parameters, returning a “frozen” multivariate normal
random variable:
rv = multivariate_normal(mean=None, cov=1, allow_singular=False)

• Frozen object with the same methods but holding the given mean and covariance fixed.

Notes

Setting the parameter mean to None is equivalent to having mean

be the zero-vector. The parameter cov can be a scalar, in which case the covariance matrix is the identity times
that value, a vector of diagonal entries for the covariance matrix, or a two-dimensional array_like.

The covariance matrix cov must be a (symmetric) positive semi-definite matrix. The determinant and inverse of
cov are computed as the pseudo-determinant and pseudo-inverse, respectively, so that cov does not need to have
full rank.

The probability density function for multivariate_normal is

\[ f(x) = \frac{1}{\sqrt{(2\pi)^k \det \Sigma}} \exp \left( -\frac{1}{2} (x - \mu)^T \Sigma^{-1} (x - \mu) \right), \]

where \( \mu \) is the mean, \( \Sigma \) the covariance matrix, and \( k \) is the dimension of the space where \( x \) takes values.

New in version 0.14.0.
Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import multivariate_normal

>>> x = np.linspace(0, 5, 10, endpoint=False)
>>> y = multivariate_normal.pdf(x, mean=2.5, cov=0.5); y
array([ 0.00108914, 0.01033349, 0.05946514, 0.20755375, 0.43939129,
        0.56418958, 0.43939129, 0.20755375, 0.05946514, 0.01033349])
>>> fig1 = plt.figure()
>>> ax = fig1.add_subplot(111)
>>> ax.plot(x, y)
```

The input quantiles can be any shape of array, as long as the last axis labels the components. This allows us for instance to display the frozen pdf for a non-isotropic random variable in 2D as follows:

```python
>>> x, y = np.mgrid[-1:1:.01, -1:1:.01]
>>> pos = np.dstack((x, y))
>>> rv = multivariate_normal([0.5, -0.2], [[2.0, 0.3], [0.3, 0.5]])
>>> fig2 = plt.figure()
>>> ax2 = fig2.add_subplot(111)
>>> ax2.contourf(x, y, rv.pdf(pos))
```
Methods

```
Methods
''pdf(x, mean=None, cov=1, allow_singular=False)'' Probability density function.
''logpdf(x, mean=None, cov=1, allow_singular=False)'' Log of the probability density function.
''cdf(x, mean=None, cov=1, allow_singular=False, maxpts=1000000*dim, abseps=1e-5, releps=1e-5)'' Cumulative distribution function.
''logcdf(x, mean=None, cov=1, allow_singular=False, maxpts=1000000*dim, abseps=1e-5, releps=1e-5)'' Log of the cumulative distribution function.
''rvs(mean=None, cov=1, size=1, random_state=None)'' Draw random samples from a multivariate normal distribution.
''entropy()'' Compute the differential entropy of the multivariate normal.
```

scipy.stats.matrix_normal

```
scipy.stats.matrix_normal (mean=None, rowcov=1, colcov=1, seed=None) = <scipy.stats._multivariate.matrix_normal_gen object>
```

A matrix normal random variable.

The mean keyword specifies the mean. The rowcov keyword specifies the among-row covariance matrix. The ‘colcov’ keyword specifies the among-column covariance matrix.

Parameters

- `X` [array_like] Quantiles, with the last two axes of X denoting the components.
- `mean` [array_like, optional] Mean of the distribution (default: None)
- `rowcov` [array_like, optional] Among-row covariance matrix of the distribution (default: 1)
- `colcov` [array_like, optional] Among-column covariance matrix of the distribution (default: 1)
- `random_state` [None or int or np.random.RandomState instance, optional] If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

Alternatively, the object may be called (as a function) to fix the mean.
and covariance parameters, returning a “frozen” matrix normal random variable:

rv = matrix_normal(mean=None, rowcov=1, colcov=1)

- Frozen object with the same methods but holding the given mean and covariance fixed.

Notes

If **mean** is set to **None** then a matrix of zeros is used for the mean.

The dimensions of this matrix are inferred from the shape of **rowcov** and **colcov**, if these are provided, or set to 1 if ambiguous.

**rowcov** and **colcov** can be two-dimensional array_likes specifying the covariance matrices directly. Alternatively, a one-dimensional array will be be interpreted as the entries of a diagonal matrix, and a scalar or zero-dimensional array will be interpreted as this value times the identity matrix.

The covariance matrices specified by **rowcov** and **colcov** must be (symmetric) positive definite. If the samples in X are \(m \times n\), then **rowcov** must be \(m \times m\) and **colcov** must be \(n \times n\). **mean** must be the same shape as X.

The probability density function for **matrix_normal** is

\[
f(X) = (2\pi)^{-\frac{mn}{2}} |U|^{-\frac{m}{2}} |V|^{-\frac{n}{2}} \exp \left(-\frac{1}{2} \text{Tr} \left[U^{-1}(X - M)V^{-1}(X - M)^T \right]\right),
\]

where \(M\) is the mean, \(U\) the among-row covariance matrix, \(V\) the among-column covariance matrix.

The **allow_singular** behaviour of the **multivariate_normal** distribution is not currently supported. Covariance matrices must be full rank.

The **matrix_normal** distribution is closely related to the **multivariate_normal** distribution. Specifically, \(\text{Vec}(X)\) (the vector formed by concatenating the columns of \(X\)) has a multivariate normal distribution with mean \(\text{Vec}(M)\) and covariance \(V \otimes U\) (where \(\otimes\) is the Kronecker product). Sampling and pdf evaluation are \(O(m^3 + n^3 + m^2n + mn^2)\) for the matrix normal, but \(O(m^3n^3)\) for the equivalent multivariate normal, making this equivalent form algorithmically inefficient.

New in version 0.17.0.

Examples

```python
>>> from scipy.stats import matrix_normal

>>> M = np.arange(6).reshape(3,2); M
array([[0, 1],
       [2, 3],
       [4, 5]])

>>> U = np.diag([1,2,3]); U
array([[1, 0, 0],
       [0, 2, 0],
       [0, 0, 3]])

>>> V = 0.3*np.identity(2); V
array([[ 0.3,  0. ],
       [ 0. ,  0.3]])

>>> X = M + 0.1; X
array([[ 0.1,  1.1],
       [ 0.3,  3.4],
       [ 0.5,  5.5]])
```
```python
>>> [ 2.1, 3.1],
[ 4.1, 5.1])
>>> matrix_normal.pdf(X, mean=M, rowcov=U, colcov=V)
0.023410202050005054
```

```python
# Equivalent multivariate normal
from scipy.stats import multivariate_normal
vectorised_X = X.T.flatten()
equiv_mean = M.T.flatten()
equiv_cov = np.kron(V,U)
multivariate_normal.pdf(vectorised_X, mean=equiv_mean, cov=equiv_cov)
0.023410202050005054
```

### scipy.stats.dirichlet

`scipy.stats.dirichlet(alpha, seed=None) = <scipy.stats._multivariate.dirichlet_gen object>`

A Dirichlet random variable.

The `alpha` keyword specifies the concentration parameters of the distribution.

New in version 0.15.0.

**Parameters**

- `x` : array_like
  Quantiles, with the last axis of `x` denoting the components.

- `alpha` : array_like
  The concentration parameters. The number of entries determines the dimensionality of the distribution.

- `random_state` : [None or int or np.random.RandomState instance, optional]
  If int or RandomState instance, optional] If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

Alternatively, the object may be called (as a function) to fix concentration parameters, returning a “frozen” Dirichlet random variable:

```python
rv = dirichlet(alpha)
```

- Frozen object with the same methods but holding the given concentration parameters fixed.
Notes

Each $\alpha$ entry must be positive. The distribution has only support on the simplex defined by

$$\sum_{i=1}^{K} x_i \leq 1$$

The probability density function for `dirichlet` is

$$f(x) = \frac{1}{B(\alpha)} \prod_{i=1}^{K} x_i^{\alpha_i - 1}$$

where

$$B(\alpha) = \frac{\prod_{i=1}^{K} \Gamma(\alpha_i)}{\Gamma(\sum_{i=1}^{K} \alpha_i)}$$

and $\alpha = (\alpha_1, \ldots, \alpha_K)$, the concentration parameters and $K$ is the dimension of the space where $x$ takes values.

Note that the `dirichlet` interface is somewhat inconsistent. The array returned by the `rvs` function is transposed with respect to the format expected by the `pdf` and `logpdf`.

Examples

```python
>>> from scipy.stats import dirichlet

Generate a dirichlet random variable

```quantiles = np.array([0.2, 0.2, 0.6])  # specify quantiles
>>> alpha = np.array([0.4, 5, 15])  # specify concentration parameters
>>> dirichlet.pdf(quantiles, alpha)
```

0.2843831684937255

The same PDF but following a log scale

```dirichlet.logpdf(quantiles, alpha)
```

-1.2574327653159187

Once we specify the dirichlet distribution we can then calculate quantities of interest

```dirichlet.mean(alpha)  # get the mean of the distribution
array([0.01960784, 0.24509804, 0.73529412])
>>> dirichlet.var(alpha)  # get variance
array([0.00089829, 0.00864603, 0.00909517])
>>> dirichlet.entropy(alpha)  # calculate the differential entropy
-4.3280162474082715
```

We can also return random samples from the distribution

```dirichlet.rvs(alpha, size=1, random_state=1)
array([[0.00766178, 0.24670518, 0.74563305]])
>>> dirichlet.rvs(alpha, size=2, random_state=2)
array([[0.01639427, 0.1292273 , 0.85437844],
       [0.00156917, 0.19033695, 0.80809388]])
```

`scipy.stats.wishart`

The `scipy.stats.wishart` function creates a Wishart random variable. The `df` keyword specifies the degrees of freedom. The `scale` keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal precision matrix (the inverse of the covariance matrix).

**Parameters**

- `x` : array_like
  Quantiles, with the last axis of `x` denoting the components.
- `df` : int
  Degrees of freedom, must be greater than or equal to dimension of the scale matrix
- `scale` : array_like
  Symmetric positive definite scale matrix of the distribution
- `random_state` : [None or int or np.random.RandomState instance, optional]
  If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” Wishart random variable:

```
rv = wishart(df=1, scale=1)
```

- Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

**See also:**

`invwishart`, `chi2`

**Notes**

The scale matrix `scale` must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The Wishart distribution is often denoted

\[ W_p(\nu, \Sigma) \]

where \( \nu \) is the degrees of freedom and \( \Sigma \) is the \( p \times p \) scale matrix.

The probability density function for `wishart` has support over positive definite matrices \( S \); if \( S \sim W_p(\nu, \Sigma) \), then its PDF is given by:

\[
f(S) = \frac{|S|^{\nu-p-1}}{2^{\nu p/2} |\Sigma|^{\nu/2} \Gamma_p (\frac{\nu}{2})} \exp \left( -\text{tr}(\Sigma^{-1} S)/2 \right)
\]
If $S \sim W_p(\nu, \Sigma)$ (Wishart) then $S^{-1} \sim W_p^{-1}(\nu, \Sigma^{-1})$ (inverse Wishart).

If the scale matrix is 1-dimensional and equal to one, then the Wishart distribution $W_1(\nu, 1)$ collapses to the $\chi^2(\nu)$ distribution.

New in version 0.16.0.

References

[1], [2]

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import wishart, chi2
>>> x = np.linspace(1e-5, 8, 100)
>>> w = wishart.pdf(x, df=3, scale=1); w[:5]
array([0.00126156, 0.10892176, 0.14793434, 0.17400548, 0.1929669])
>>> c = chi2.pdf(x, 3); c[:5]
array([0.00126156, 0.10892176, 0.14793434, 0.17400548, 0.1929669])
>>> plt.plot(x, w)
```

The input quantiles can be any shape of array, as long as the last axis labels the components.

Methods

- `pdf(x, df, scale)`
  - Probability density function.
- `logpdf(x, df, scale)`
  - Log of the probability density function.
- `rvs(df, scale, size=1, random_state=None)`
  - Draw random samples from a Wishart distribution.
- `entropy()`
  - Compute the differential entropy of the Wishart distribution.
scipy.stats.invwishart

scipy.stats.invwishart(df=None, scale=None, seed=None) = <scipy.stats._multivariate.invwishart_gen object>

An inverse Wishart random variable.

The df keyword specifies the degrees of freedom. The scale keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal covariance matrix.

Parameters

- x [array_like] Quantiles, with the last axis of x denoting the components.
- df [int] Degrees of freedom, must be greater than or equal to dimension of the scale matrix
- scale [array_like] Symmetric positive definite scale matrix of the distribution
- random_state [None or int or np.random.RandomState instance, optional] If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” inverse Wishart random variable:

```
rv = invwishart(df=1, scale=1)
```

- Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

See also:

wishart

Notes

The scale matrix scale must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The inverse Wishart distribution is often denoted

\[ W_p^{-1}(\nu, \Psi) \]

where \( \nu \) is the degrees of freedom and \( \Psi \) is the \( p \times p \) scale matrix.

The probability density function for \( \text{invwishart} \) has support over positive definite matrices \( S \); if \( S \sim W_p^{-1}(\nu, \Sigma) \), then its PDF is given by:

\[
f(S) = \frac{|\Sigma|^\frac{\nu}{2}}{2^\frac{\nu p}{2} |S|^{\frac{\nu + p + 1}{2}}} \Gamma_p \left( \frac{\nu}{2} \right) \exp \left( -tr(\Sigma S^{-1})/2 \right)
\]

If \( S \sim W_p^{-1}(\nu, \Psi) \) (inverse Wishart) then \( S^{-1} \sim W_p(\nu, \Psi^{-1}) \) (Wishart).

If the scale matrix is 1-dimensional and equal to one, then the inverse Wishart distribution \( W_1(\nu, 1) \) collapses to the inverse Gamma distribution with parameters \( \text{shape} = \frac{\nu}{2} \) and \( \text{scale} = \frac{1}{2} \).

New in version 0.16.0.

```python
scipy.stats.multinomial
```

`scipy.stats.multinomial(n, p, seed=None) = <scipy.stats._multivariate.multinomial_gen object>`

A multinomial random variable.

**Parameters**

- `x` : array_like Quantiles, with the last axis of `x` denoting the components.
- `n` : int Number of trials
- `p` : array_like Probability of a trial falling into each category; should sum to 1
random_state

[None or int or np.random.RandomState instance, optional] If int or RandomState, use it for
drawing the random variates. If None (or np.random), the global np.random state is used.
Default is None.

See also:

scipy.stats.binom
The binomial distribution.
numpy.random.Generator.multinomial
Sampling from the multinomial distribution.

Notes

$n$ should be a positive integer. Each element of $p$ should be in the interval $[0, 1]$ and the elements should sum to 1.
If they do not sum to 1, the last element of the $p$ array is not used and is replaced with the remaining probability
left over from the earlier elements.

Alternatively, the object may be called (as a function) to fix the $n$ and $p$ parameters, returning a “frozen” multinomial
random variable:

The probability mass function for $multinomial$ is

\[
    f(x) = \frac{n!}{x_1! \cdots x_k!} p_1^{x_1} \cdots p_k^{x_k},
\]

supported on $x = (x_1, \ldots, x_k)$ where each $x_i$ is a nonnegative integer and their sum is $n$.

New in version 0.19.0.

Examples

```python
>>> from scipy.stats import multinomial
>>> rv = multinomial(8, [0.3, 0.2, 0.5])
>>> rv.pmf([1, 3, 4])
0.04200000000000072
```

The multinomial distribution for $k = 2$ is identical to the corresponding binomial distribution (tiny numerical
differences notwithstanding):

```python
>>> from scipy.stats import binom
>>> multinomial.pmf([3, 4], n=7, p=[0.4, 0.6])
0.29030399999999973
>>> binom.pmf(3, 7, 0.4)
0.29030400000000012
```

The functions pmf, logpmf, entropy, and cov support broadcasting, under the convention that the vector
parameters ($x$ and $p$) are interpreted as if each row along the last axis is a single object. For instance:

```python
>>> multinomial.pmf([[3, 4], [3, 5]], n=[7, 8], p=[.3, .7])
array([0.2268945, 0.25412184])
```
Here, \(x.\text{shape} == (2, 2)\), \(n.\text{shape} == (2,)\), and \(p.\text{shape} == (2,)\), but following the rules mentioned above they behave as if the rows \([3, 4]\) and \([3, 5]\) in \(x\) and \([.3, .7]\) in \(p\) were a single object, and as if we had \(x.\text{shape} = (2,)\), \(n.\text{shape} = (2,)\), and \(p.\text{shape} = ()\). To obtain the individual elements without broadcasting, we would do this:

```python
>>> multinomial.pmf([3, 4], n=7, p=[.3, .7])
0.2268945
>>> multinomial.pmf([3, 5], 8, p=[.3, .7])
0.25412184
```

This broadcasting also works for `cov`, where the output objects are square matrices of size \(p.\text{shape}[-1]\). For example:

```python
>>> multinomial.cov([4, 5], [[[.3, .7], [.4, .6]])
array([[ 0.84, -0.84, 0.84],
       [-0.84, 0.84],
       [ 1.2 , -1.2 , 1.2 ]])
```

In this example, \(n.\text{shape} == (2,)\) and \(p.\text{shape} == (2, 2)\), and following the rules above, these broadcast as if \(p.\text{shape} == (2,)\). Thus the result should also be of shape \((2,)\), but since each output is a \(2 \times 2\) matrix, the result in fact has shape \((2, 2, 2)\), where \(\text{result[0]}\) is equal to `multinomial.cov(n=4, p=[.3, .7])` and \(\text{result[1]}\) is equal to `multinomial.cov(n=5, p=[.4, .6])`.

### Methods

- **`pmf(x, n, p)`** Probability mass function.
- **`logpmf(x, n, p)`** Log of the probability mass function.
- **`rvs(n, p, size=1, random_state=None)`** Draw random samples from a multinomial distribution.
- **`entropy(n, p)`** Compute the entropy of the multinomial distribution.
- **`cov(n, p)`** Compute the covariance matrix of the multinomial distribution.

### scipy.stats.special_ortho_group

`scipy.stats.special_ortho_group(dim=None, seed=None) = <scipy.stats._multivariate.special_ortho_group_gen object>`

A matrix-valued SO(N) random variable.

Return a random rotation matrix, drawn from the Haar distribution (the only uniform distribution on SO(n)).

The `dim` keyword specifies the dimension \(N\).

#### Parameters

- **`dim`** [scalar] Dimension of matrices

#### Notes

This class is wrapping the random_rot code from the MDP Toolkit, https://github.com/mdp-toolkit/mdp-toolkit

Return a random rotation matrix, drawn from the Haar distribution (the only uniform distribution on SO(n)). The algorithm is described in the paper Stewart, G.W., “The efficient generation of random orthogonal matrices with an
See also the similar ortho_group.

Examples

```python
>>> from scipy.stats import special_ortho_group
>>> x = special_ortho_group.rvs(3)
```

```python
>>> np.dot(x, x.T)
array([[ 1.00000000e+00, 1.13231364e-17, -2.86852790e-16],
      [ 1.13231364e-17, 1.00000000e+00, -1.46845020e-16],
      [ -2.86852790e-16, -1.46845020e-16, 1.00000000e+00]])
```

```python
>>> import scipy.linalg
>>> scipy.linalg.det(x)
1.0
```

This generates one random matrix from SO(3). It is orthogonal and has a determinant of 1.

Methods

```
"""rvs(dim=None, size=1, random_state=None)"""  Draw random samples from SO(N).
```

scipy.stats.ortho_group

scipy.stats.ortho_group = <scipy.stats._multivariate.ortho_group_gen object>
A matrix-valued O(N) random variable.

Return a random orthogonal matrix, drawn from the O(N) Haar distribution (the only uniform distribution on O(N)).

The `dim` keyword specifies the dimension N.

**Parameters**

- `dim` [scalar] Dimension of matrices

**Notes**

This class is closely related to special_ortho_group.

Some care is taken to avoid numerical error, as per the paper by Mezzadri.

**References**

[1]
Examples

```python
>>> from scipy.stats import ortho_group
>>> x = ortho_group.rvs(3)

>>> np.dot(x, x.T)
array([[ 1.00000000e+00, 1.13231364e-17, -2.86852790e-16],
       [ 1.13231364e-17, 1.00000000e+00, -1.46845020e-16],
       [ -2.86852790e-16, -1.46845020e-16, 1.00000000e+00]])

>>> import scipy.linalg
>>> np.fabs(scipy.linalg.det(x))
1.0
```

This generates one random matrix from O(3). It is orthogonal and has a determinant of +1 or -1.

Methods

```
“rvs(dim=None, size=1, random_state=None)“  Draw random samples from O(N).
```

`scipy.stats.unitary_group`

`scipy.stats.unitary_group = <scipy.stats._multivariate.unitary_group_gen object>` A matrix-valued U(N) random variable.

Return a random unitary matrix.

The `dim` keyword specifies the dimension N.

**Parameters**

- `dim`  [scalar] Dimension of matrices

**Notes**

This class is similar to `ortho_group`.

**References**

[1]

**Examples**

```python
>>> from scipy.stats import unitary_group
>>> x = unitary_group.rvs(3)
```
This generates one random matrix from U(3). The dot product confirms that it is unitary up to machine precision.

Methods

| scipy.stats.random_correlation |

scipy.stats.random_correlation = <scipy.stats._multivariate.random_correlation_gen object>

A random correlation matrix.

Return a random correlation matrix, given a vector of eigenvalues.

The eigs keyword specifies the eigenvalues of the correlation matrix, and implies the dimension.

Parameters

- eigs [1d ndarray] Eigenvalues of correlation matrix.

Notes

Generates a random correlation matrix following a numerically stable algorithm spelled out by Davies & Higham. This algorithm uses a single O(N) similarity transformation to construct a symmetric positive semi-definite matrix, and applies a series of Givens rotations to scale it to have ones on the diagonal.

References

[1]

Examples

```python
>>> from scipy.stats import random_correlation
>>> np.random.seed(514)
>>> x = random_correlation.rvs((.5, .8, 1.2, 1.5))
>>> x
array([[ 1.00000000e+00, 1.13231364e-17, -2.86852790e-16],
       [ 1.13231364e-17, 1.00000000e+00, -1.46845020e-16],
       [ -2.86852790e-16, -1.46845020e-16, 1.00000000e+00]])

>>> import scipy.linalg
>>> e, v = scipy.linalg.eigh(x)
>>> e
array([ 0.5, 0.8, 1.2, 1.5])
```
Methods

```
``rvsteigs=None, random_state=None)``

Draw random correlation matrices, all with eigenvalues eigs.

6.28.6 Discrete distributions

```
bernoulli(*args, **kwds)
```
A Bernoulli discrete random variable.

```
binom(*args, **kwds)
```
A binomial discrete random variable.

```
boltzmann(*args, **kwds)
```
A Boltzmann (Truncated Discrete Exponential) random variable.

```
diagplace(*args, **kwds)
```
A Laplacian discrete random variable.

```
geom(*args, **kwds)
```
A geometric discrete random variable.

```
hypergeom(*args, **kwds)
```
A hypergeometric discrete random variable.

```
logser(*args, **kwds)
```
A Logarithmic (Log-Series, Series) discrete random variable.

```
nbinom(*args, **kwds)
```
A negative binomial discrete random variable.

```
planck(*args, **kwds)
```
A Planck discrete exponential random variable.

```
poisson(*args, **kwds)
```
A Poisson discrete random variable.

```
rsize(*args, **kwds)
```
A uniform discrete random variable.

```
skellam(*args, **kwds)
```
A Skellam discrete random variable.

```
zipf(*args, **kwds)
```
A Zipf discrete random variable.

```
yulesimon(*args, **kwds)
```
A Yule-Simon discrete random variable.

scipy.stats.bernoulli

```
scipy.stats.bernoulli(*args, **kwds) = <scipy.stats._discrete_distns.
bernoulli_gen object>
```
A Bernoulli discrete random variable.

As an instance of the `rv_discrete` class, `bernoulli` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability mass function for `bernoulli` is:

\[
f(k) = \begin{cases} 
1 - p & \text{if } k = 0 \\
p & \text{if } k = 1 
\end{cases}
\]

for \( k \in \{0, 1\} \).

`bernoulli` takes \( p \) as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, \( \text{bernoulli.pmf}(k, p, \text{loc}) \) is identically equivalent to \( \text{bernoulli.pmf}(k - \text{loc}, p) \).

Examples
from scipy.stats import bernoulli
import matplotlib.pyplot as plt

fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

p = 0.3
mean, var, skew, kurt = bernoulli.stats(p, moments='mvsk')

Display the probability mass function (pmf):

x = np.arange(bernoulli.ppf(0.01, p), bernoulli.ppf(0.99, p))
ax.plot(x, bernoulli.pmf(x, p), 'bo', ms=8, label='bernoulli pmf')
ax.vlines(x, 0, bernoulli.pmf(x, p), colors='b', lw=5, alpha=0.5)

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

rv = bernoulli(p)
ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
label='frozen pmf')
ax.legend(loc='best', frameon=False)
plt.show()

Check accuracy of cdf and ppf:

prob = bernoulli.cdf(x, p)
np.allclose(x, bernoulli.ppf(prob, p))
True

Generate random numbers:
```python
>>> r = bernoulli.rvs(p, size=1000)
```

**Methods**

**scipy.stats.binom**

`scipy.stats.binom(*args, **kwds) = <scipy.stats._discrete_distns.binom_gen object>`

A binomial discrete random variable.

As an instance of the `rv_discrete` class, `binom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for `binom` is:

\[ f(k) = \binom{n}{k} p^k (1-p)^{n-k} \]

for \( k \) in \( \{0, 1, \ldots, n\} \).

`binom` takes \( n \) and \( p \) as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `binom.pmf(k, n, p, loc)` is identically equivalent to `binom.pmf(k - loc, n, p)`.
Examples

```python
>>> from scipy.stats import binom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> n, p = 5, 0.4
>>> mean, var, skew, kurt = binom.stats(n, p, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(binom.ppf(0.01, n, p),
...                binom.ppf(0.99, n, p))
>>> ax.plot(x, binom.pmf(x, n, p), 'bo', ms=8, label='binom pmf')
>>> ax.vlines(x, 0, binom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = binom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```python
>>> prob = binom.cdf(x, n, p)
>>> np.allclose(x, binom.ppf(prob, n, p))
True
```
```python
>>> r = binom.rvs(n, p, size=1000)
```

### scipy.stats.boltzmann

```python
scipy.stats.boltzmann(*args, **kwds) = <scipy.stats._discrete_distns.boltzmann_gen object>
```

A Boltzmann (Truncated Discrete Exponential) random variable.

As an instance of the `rv_discrete` class, `boltzmann` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `boltzmann` is:

$$f(k) = (1 - \exp(-\lambda)) \exp(-\lambda k)/(1 - \exp(-\lambda N))$$

for $k = 0, ..., N - 1$.

`boltzmann` takes $\lambda > 0$ and $N > 0$ as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `boltzmann.pmf(k, lambda_, N, loc)` is identically equivalent to `boltzmann.pmf(k - loc, lambda_, N)`. 

6.28. Statistical functions (scipy.stats) 2373
Examples

```python
>>> from scipy.stats import boltzmann
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> lambda_, N = 1.4, 19
>>> mean, var, skew, kurt = boltzmann.stats(lambda_, N, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(boltzmann.ppf(0.01, lambda_, N), ...
...               boltzmann.ppf(0.99, lambda_, N))
>>> ax.plot(x, boltzmann.pmf(x, lambda_, N), 'bo', ms=8, label='boltzmann pmf')
>>> ax.vlines(x, 0, boltzmann.pmf(x, lambda_, N), colors='b', lw=5, ...
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = boltzmann(lambda_, N)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1, ...
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:
>>> prob = boltzmann.cdf(x, lambda_, N)
>>> np.allclose(x, boltzmann.ppf(prob, lambda_, N))
True

Generate random numbers:

>>> r = boltzmann.rvs(lambda_, N, size=1000)

Methods

| rvs(lambda_, N, loc=0, size=1, random_state=None) | Random variates. |
| pmf(k, lambda_, N, loc=0) | Probability mass function. |
| logpmf(k, lambda_, N, loc=0) | Log of the probability mass function. |
| cdf(k, lambda_, N, loc=0) | Cumulative distribution function. |
| logcdf(k, lambda_, N, loc=0) | Log of the cumulative distribution function. |
| sf(k, lambda_, N, loc=0) | Survival function (also defined as 1 - cdf, but sf is sometimes more accurate). |
| logsf(k, lambda_, N, loc=0) | Log of the survival function. |
| ppf(q, lambda_, N, loc=0) | Percent point function (inverse of cdf — percentiles). |
| isf(q, lambda_, N, loc=0) | Inverse survival function (inverse of sf). |
| stats(lambda_, N, loc=0, moments='mv') | Mean('m'), variance('v'), skew('s'), and/or kurtosis('k'). |
| entropy(lambda_, N, loc=0) | (Differential) entropy of the RV. |
| expect(func, args=(lambda_, N), loc=0, lb=None, ub=None, conditional=False) | Expected value of a function (of one argument) with respect to the distribution. |
| median(lambda_, N, loc=0) | Median of the distribution. |
| mean(lambda_, N, loc=0) | Mean of the distribution. |
| var(lambda_, N, loc=0) | Variance of the distribution. |
| std(lambda_, N, loc=0) | Standard deviation of the distribution. |
| interval(alpha, lambda_, N, loc=0) | Endpoints of the range that contains alpha percent of the distribution |

scipy.stats.dlaplace

A Laplacian discrete random variable.

As an instance of the rv_discrete class, diaplace object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability mass function for diaplace is:

\[ f(k) = \tanh(a/2) \exp(-a|k|) \]

for integers \( k \) and \( a > 0 \).
dlaplace takes $a$ as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, dlaplace.pmf($k$, $a$, loc) is identically equivalent to dlaplace.pmf($k - loc$, $a$).

### Examples

```python
>>> from scipy.stats import dlaplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a = 0.8
>>> mean, var, skew, kurt = dlaplace.stats(a, moments='mvsk')
```

Display the probability mass function (pmf):  

```python
>>> x = np.arange(dlaplace.ppf(0.01, a), ...
...               dlaplace.ppf(0.99, a))
>>> ax.plot(x, dlaplace.pmf(x, a), 'bo', ms=8, label='dlaplace pmf')
>>> ax.vlines(x, 0, dlaplace.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = dlaplace(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1, ...
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Check accuracy of cdf and ppf:

```python
>>> prob = dlaplace.cdf(x, a)
>>> np.allclose(x, dlaplace.ppf(prob, a))
True
```

Generate random numbers:

```python
>>> r = dlaplace.rvs(a, size=1000)
```

### scipy.stats.geom

```python
scipy.stats.geom(*args, **kwds) = <scipy.stats._discrete_distns.geom_gen object>
```

A geometric discrete random variable.

As an instance of the `rv_discrete` class, `geom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

- `planck`

### Notes

The probability mass function for `geom` is:

\[ f(k) = (1 - p)^{k-1} p \]
for $k \geq 1$.

$geom$ takes $p$ as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the $loc$ parameter. Specifically, $geom.pmf(k, p, loc)$ is identically equivalent to $geom.pmf(k - loc, p)$.

**Examples**

```python
>>> from scipy.stats import geom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> p = 0.5
>>> mean, var, skew, kurt = geom.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(geom.ppf(0.01, p),
...               geom.ppf(0.99, p))
>>> ax.plot(x, geom.pmf(x, p), 'bo', ms=8, label='geom pmf')
>>> ax.vlines(x, 0, geom.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = geom(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

![Graph showing the probability mass function and the frozen pmf.](image)
Check accuracy of `cdf` and `ppf`:

```python
>>> prob = geom.cdf(x, p)
>>> np.allclose(x, geom.ppf(prob, p))
True
```

Generate random numbers:

```python
>>> r = geom.rvs(p, size=1000)
```

### scipy.stats.hypergeom

```python
scipy.stats.hypergeom(*args, **kwds) = <scipy.stats._discrete_distns.hypergeom_gen object>
```

A hypergeometric discrete random variable.

The hypergeometric distribution models drawing objects from a bin. $M$ is the total number of objects, $n$ is total number of Type I objects. The random variate represents the number of Type I objects in $N$ drawn without replacement from the total population.

As an instance of the `rv_discrete` class, `hypergeom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The symbols used to denote the shape parameters ($M$, $n$, and $N$) are not universally accepted. See the Examples for a clarification of the definitions used here.
The probability mass function is defined as,

\[ p(k, M, n, N) = \binom{n}{k} \binom{M-n}{N-k} \binom{M}{N} \]

for \( k \in [\max(0, N - M + n), \min(n, N)] \), where the binomial coefficients are defined as,

\[ \binom{n}{k} \equiv \frac{n!}{k!(n-k)!} \]

The probability mass function above is defined in the “standardized” form. To shift distribution use the \text{loc} parameter. Specifically, \text{hypergeom.pmf}(k, M, n, N, \text{loc}) is identically equivalent to \text{hypergeom.pmf}(k - \text{loc}, M, n, N).

**Examples**

```python
>>> from scipy.stats import hypergeom
>>> import matplotlib.pyplot as plt
```

Suppose we have a collection of 20 animals, of which 7 are dogs. Then if we want to know the probability of finding a given number of dogs if we choose at random 12 of the 20 animals, we can initialize a frozen distribution and plot the probability mass function:

```python
>>> [M, n, N] = [20, 7, 12]
>>> rv = hypergeom(M, n, N)
>>> x = np.arange(0, n+1)
>>> pmf_dogs = rv.pmf(x)
```

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, pmf_dogs, 'bo')
>>> ax.vlines(x, 0, pmf_dogs, lw=2)
>>> ax.set_xlabel('# of dogs in our group of chosen animals')
>>> ax.set_ylabel('hypergeom PMF')
>>> plt.show()
```

Instead of using a frozen distribution we can also use \text{hypergeom} methods directly. To for example obtain the cumulative distribution function, use:

```python
>>> prb = hypergeom.cdf(x, M, n, N)
```

And to generate random numbers:

```python
>>> R = hypergeom.rvs(M, n, N, size=10)
```

**scipy.stats.logser**

```python
scipy.stats.logser(*args, **kwds) = <scipy.stats._discrete_distns.logser_gen object>
```

A Logarithmic (Log-Series, Series) discrete random variable.

As an instance of the `rv_discrete` class, `logser` object inherits from it a collection of generic methods (see
below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for `logser` is:

\[ f(k) = -\frac{p^k}{k \log(1 - p)} \]

for \( k \geq 1 \).

`logser` takes \( p \) as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `logser.pmf(k, p, loc)` is identically equivalent to `logser.pmf(k - loc, p)`.

**Examples**

```python
>>> from scipy.stats import logser
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> p = 0.6
>>> mean, var, skew, kurt = logser.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(logser.ppf(0.01, p), ... logser.ppf(0.99, p))
>>> ax.plot(x, logser.pmf(x, p), 'bo', ms=8, label='logser pmf')
>>> ax.vlines(x, 0, logser.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = logser(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='--', lw=1, ... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```python
>>> prob = logser.cdf(x, p)
>>> np.allclose(x, logser.ppf(prob, p))
True
```

Generate random numbers:
>>> r = logser.rvs(p, size=1000)

scipy.stats.nbinom

scipy.stats.nbinom(*args, **kwds) = <scipy.stats._discrete_distns.nbinom_gen object>
A negative binomial discrete random variable.

6.28. Statistical functions (scipy.stats) 2383
As an instance of the \texttt{rv\_discrete} class, \texttt{nbinom} object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

Negative binomial distribution describes a sequence of i.i.d. Bernoulli trials, repeated until a predefined, non-random number of successes occurs.

The probability mass function of the number of failures for \texttt{nbinom} is:

\[
f(k) = \binom{k + n - 1}{n - 1} p^n (1 - p)^k
\]

for \(k \geq 0\).

\texttt{nbinom} takes \(n\) and \(p\) as shape parameters where \(n\) is the number of successes, whereas \(p\) is the probability of a single success.

The probability mass function above is defined in the “standardized” form. To shift distribution use the \texttt{loc} parameter. Specifically, \texttt{nbinom.pmf(k, n, p, loc)} is identically equivalent to \texttt{nbinom.pmf(k - loc, n, p)}.

**Examples**

```python
>>> from scipy.stats import nbinom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> n, p = 0.4, 0.4
>>> mean, var, skew, kurt = nbinom.stats(n, p, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(nbinom.ppf(0.01, n, p),
...                nbinom.ppf(0.99, n, p))
>>> ax.plot(x, nbinom.pmf(x, n, p), 'bo', ms=8, label='nbinom pmf')
>>> ax.vlines(x, 0, nbinom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = nbinom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of \texttt{cdf} and \texttt{ppf}:

```python
>>> prob = nbinom.cdf(x, n, p)
>>> np.allclose(x, nbinom.ppf(prob, n, p))
True
```
Generate random numbers:

```python
>>> r = nbinom.rvs(n, p, size=1000)
```

scipy.stats.planck

scipy.stats.planck(*args, **kwds) = <scipy.stats._discrete_distns.planck_gen object>

A Planck discrete exponential random variable.

As an instance of the rv_discrete class, planck object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:
geom

Notes

The probability mass function for planck is:

\[ f(k) = (1 - \exp(-\lambda)) \exp(-\lambda k) \]

for \( k \geq 0 \) and \( \lambda > 0 \).

planck takes \( \lambda \) as shape parameter. The Planck distribution can be written as a geometric distribution (geom) with \( p = 1 - \exp(-\lambda) \) shifted by \( \text{loc} = -I \).

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, planck.pmf(k, lambda_, loc) is identically equivalent to planck.pmf(k - loc, lambda_).

Examples

```python
>>> from scipy.stats import planck
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> lambda_ = 0.51
>>> mean, var, skew, kurt = planck.stats(lambda_, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(planck.ppf(0.01, lambda_), ...
...                planck.ppf(0.99, lambda_))
>>> ax.plot(x, planck.pmf(x, lambda_), 'bo', ms=8, label='planck pmf')
>>> ax.vlines(x, 0, planck.pmf(x, lambda_), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = planck(lambda_)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1, ...
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Check accuracy of \texttt{cdf} and \texttt{ppf}:

```python
>>> prob = planck.cdf(x, lambda_)
>>> np.allclose(x, planck.ppf(prob, lambda_))

#### scipy.stats.poisson

```python
scipy.stats.poisson(*args, **kwargs) = <scipy.stats._discrete_distns.poisson_gen object>
```

A Poisson discrete random variable.

As an instance of the `rv_discrete` class, `poisson` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `poisson` is:

\[ f(k) = \exp(-\mu) \frac{\mu^k}{k!} \]

for \( k \geq 0 \).

`poisson` takes \( \mu \) as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `poisson.pmf(k, mu, loc)` is identically equivalent to `poisson.pmf(k - loc, mu)`.

### Examples
>>> from scipy.stats import poisson
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mu = 0.6
>>> mean, var, skew, kurt = poisson.stats(mu, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(poisson.ppf(0.01, mu),
...               poisson.ppf(0.99, mu))
>>> ax.plot(x, poisson.pmf(x, mu), 'bo', ms=8, label='poisson pmf')
``` 

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = poisson(mu)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```python
>>> prob = poisson.cdf(x, mu)
>>> np.allclose(x, poisson.ppf(prob, mu))
True
```

Generate random numbers:
```python
>>> r = poisson.rvs(mu, size=1000)
```

**scipy.stats.randint**

```python
scipy.stats.randint(*args, **kwds) = <scipy.stats._discrete_distns.randint_gen object>
```

A uniform discrete random variable.

As an instance of the `rv_discrete` class, `randint` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `randint` is:

\[
f(k) = \frac{1}{\text{high} - \text{low}}
\]

for \( k = \text{low}, \ldots, \text{high} - 1 \).

`randint` takes `low` and `high` as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `randint.pmf(k, low, high, loc)` is identically equivalent to `randint.pmf(k - loc, low, high).`
Examples

```python
>>> from scipy.stats import randint
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> low, high = 7, 31
>>> mean, var, skew, kurt = randint.stats(low, high, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(randint.ppf(0.01, low, high), ...
...               randint.ppf(0.99, low, high))
>>> ax.plot(x, randint.pmf(x, low, high), 'bo', ms=8, label='randint pmf')
>>> ax.vlines(x, 0, randint.pmf(x, low, high), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = randint(low, high)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1, ...
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```python
>>> prob = randint.cdf(x, low, high)
>>> np.allclose(x, randint.ppf(prob, low, high))
True
```
Generate random numbers:

```python
>>> r = randint.rvs(low, high, size=1000)
```

### scipy.stats.skellam

`scipy.stats.skellam(*args, **kwds) = <scipy.stats._discrete_distns.skellam_gen object>`

A Skellam discrete random variable.

As an instance of the `rv_discrete` class, `skellam` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

Probability distribution of the difference of two correlated or uncorrelated Poisson random variables.

Let $k_1$ and $k_2$ be two Poisson-distributed r.v. with expected values $\lambda_1$ and $\lambda_2$. Then, $k_1 - k_2$ follows a Skellam distribution with parameters $\mu_1 = \lambda_1 - \rho \sqrt{\lambda_1 \lambda_2}$ and $\mu_2 = \lambda_2 - \rho \sqrt{\lambda_1 \lambda_2}$, where $\rho$ is the correlation coefficient between $k_1$ and $k_2$. If the two Poisson-distributed r.v. are independent then $\rho = 0$.

Parameters $\mu_1$ and $\mu_2$ must be strictly positive.

For details see: https://en.wikipedia.org/wiki/Skellam_distribution

`skellam` takes $\mu_1$ and $\mu_2$ as shape parameters.
The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `skellam.pmf(k, mu1, mu2, loc)` is identically equivalent to `skellam.pmf(k - loc, mu1, mu2).

**Examples**

```python
>>> from scipy.stats import skellam
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```text
>>> mu1, mu2 = 15, 8
>>> mean, var, skew, kurt = skellam.stats(mu1, mu2, moments='mvsk')
```

Display the probability mass function (pmf):

```text
>>> x = np.arange(skellam.ppf(0.01, mu1, mu2), ...
... skellam.ppf(0.99, mu1, mu2))
>>> ax.plot(x, skellam.pmf(x, mu1, mu2), 'bo', ms=8, label='skellam pmf')
>>> ax.vlines(x, 0, skellam.pmf(x, mu1, mu2), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```text
>>> rv = skellam(mu1, mu2)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1, ...
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of `cdf` and `ppf:`
```python
>>> prob = skellam.cdf(x, mu1, mu2)
>>> np.allclose(x, skellam.ppf(prob, mu1, mu2))
True
```

Generate random numbers:

```python
>>> r = skellam.rvs(mu1, mu2, size=1000)
```

### scipy.stats.zipf

```python
scipy.stats.zipf(*args, **kwds) = <scipy.stats._discrete_distns.zipf_gen object>
```

A Zipf discrete random variable.

As an instance of the `rv_discrete` class, `zipf` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `zipf` is:

\[
f(k, a) = \frac{1}{\zeta(a)k^a}
\]

for \( k \geq 1 \).
zipf takes $a$ as shape parameter. $\zeta$ is the Riemann zeta function (scipy.special.zeta)

The probability mass function above is defined in the “standardized” form. To shift distribution use the $\text{loc}$ parameter. Specifically, $\text{zipf.pmf}(k, a, \text{loc})$ is identically equivalent to $\text{zipf.pmf}(k - \text{loc}, a)$.

Examples

```python
>>> from scipy.stats import zipf
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a = 6.5
>>> mean, var, skew, kurt = zipf.stats(a, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(zipf.ppf(0.01, a), ...
...               zipf.ppf(0.99, a))
>>> ax.plot(x, zipf.pmf(x, a), 'bo', ms=8, label='zipf pmf')
>>> ax.vlines(x, 0, zipf.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = zipf(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1, ...
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:
>>> prob = zipf.cdf(x, a)
>>> np.allclose(x, zipf.ppf(prob, a))
True

Generate random numbers:

```python
>>> r = zipf.rvs(a, size=1000)
```

### scipy.stats.yulesimon

```python
scipy.stats.yulesimon(*args, **kwds) = <scipy.stats._discrete_distns.yulesimon_gen object>
```

A Yule-Simon discrete random variable.

As an instance of the `rv_discrete` class, `yulesimon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for the `yulesimon` is:

\[
f(k) = \alpha B(k, \alpha + 1)
\]

for \( k = 1, 2, 3, \ldots \), where \( \alpha > 0 \). Here \( B \) refers to the `scipy.special.beta` function.

The sampling of random variates is based on pg 553, Section 6.3 of [1]. Our notation maps to the referenced logic via \( \alpha = a - 1 \).

For details see the wikipedia entry [2].
References

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, \( \text{yulesimon.pmf}(k, \alpha, \text{loc}) \) is identically equivalent to \( \text{yulesimon.pmf}(k - \text{loc}, \alpha) \).

[1],[2]

Examples

```python
>>> from scipy.stats import yulesimon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> alpha = 11
>>> mean, var, skew, kurt = yulesimon.stats(alpha, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(yulesimon.ppf(0.01, alpha), ...
...     yulesimon.ppf(0.99, alpha))
>>> ax.plot(x, yulesimon.pmf(x, alpha), 'bo', ms=8, label='yulesimon pmf')
>>> ax.vlines(x, 0, yulesimon.pmf(x, alpha), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = yulesimon(alpha)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1, ...
...     label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```python
>>> prob = yulesimon.cdf(x, alpha)
>>> np.allclose(x, yulesimon.ppf(prob, alpha))
True
```

Generate random numbers:

```python
>>> r = yulesimon.rvs(alpha, size=1000)
```

<td>Calculate the entropy of a distribution for given probability values.</td>
</tr>
<tr>
<td><code>median_absolute_deviation(x[, axis, center, …])</code></td>
<td>Compute the median absolute deviation of the data along the given axis.</td>
</tr>
</tbody>
</table>

scipy.stats.describe

`scipy.stats.describe(a, axis=0, ddof=1, bias=True, nan_policy='propagate')`

Compute several descriptive statistics of the passed array.

**Parameters**

- `a`: [array_like] Input data.
- `axis`: [int or None, optional] Axis along which statistics are calculated. Default is 0. If None, compute over the whole array `a`.
- `ddof`: [int, optional] Delta degrees of freedom (only for variance). Default is 1.
- `bias`: [bool, optional] If False, then the skewness and kurtosis calculations are corrected for statistical bias.
- `nan_policy`: [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. ’propagate’ returns nan, ’raise’ throws an error, ’omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

**Returns**

6.28. Statistical functions (scipy.stats) 2399
SciPy Reference Guide, Release 1.3.2

nobs [int or ndarray of ints] Number of observations (length of data along axis). When ‘omit’ is chosen as nan_policy, each column is counted separately.

minmax: tuple of ndarrays or floats
Minimum and maximum value of data array.

mean [ndarray or float] Arithmetic mean of data along axis.

variance [ndarray or float] Unbiased variance of the data along axis, denominator is number of observations minus one.

skewness [ndarray or float] Skewness, based on moment calculations with denominator equal to the number of observations, i.e. no degrees of freedom correction.

kurtosis [ndarray or float] Kurtosis (Fisher). The kurtosis is normalized so that it is zero for the normal distribution. No degrees of freedom are used.

See also:

skew, kurtosis

Examples

```python
>>> from scipy import stats
>>> a = np.arange(10)
>>> stats.describe(a)
DescribeResult(nobs=10, minmax=(0, 9), mean=4.5, variance=9.166666666666667,
                skewness=0.0, kurtosis=-1.2242424242424244)
>>> b = [[1, 2], [3, 4]]
>>> stats.describe(b)
DescribeResult(nobs=2, minmax=(array([1, 2]), array([3, 4])),
                mean=array([2., 3.]), variance=array([2., 2.]),
                skewness=array([0., 0.]), kurtosis=array([-2., -2.]))
```

scipy.stats.gmean

scipy.stats.gmean(a, axis=0, dtype=None)
Compute the geometric mean along the specified axis.

Return the geometric average of the array elements. That is: \( n \)-th root of \((x_1 \times x_2 \times \ldots \times x_n)\)

Parameters

- **a** [array_like] Input array or object that can be converted to an array.
- **axis** [int or None, optional] Axis along which the geometric mean is computed. Default is 0. If None, compute over the whole array a.
- **dtype** [dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of a, unless a has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

Returns

- **gmean** [ndarray] see dtype parameter above

See also:

numpy.mean
Arithmetic average
numpy.average

Weighted average

hmean

Harmonic mean

Notes

The geometric average is computed over a single dimension of the input array, axis=0 by default, or all values in the array if axis=None. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.

Examples

```python
>>> from scipy.stats import gmean
>>> gmean([1, 4])
2.0
>>> gmean([1, 2, 3, 4, 5, 6, 7])
3.3800151591412964
```

scipy.stats.hmean

scipy.stats.hmean(a, axis=0, dtype=None)

Calculate the harmonic mean along the specified axis.

That is: \( n / (1/x1 + 1/x2 + ... + 1/xn) \)

Parameters

- a : array_like Input array, masked array or object that can be converted to an array.
- axis : int or None, optional Axis along which the harmonic mean is computed. Default is 0. If None, compute over the whole array a.
- dtype : dtype, optional Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of a, unless a has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

Returns

- hmean : ndarray see dtype parameter above

See also:

- numpy.mean
  Arithmetic average
- numpy.average
  Weighted average
- gmean
  Geometric mean

6.28. Statistical functions (scipy.stats)
Notes

The harmonic mean is computed over a single dimension of the input array, axis=0 by default, or all values in the array if axis=None. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

Examples

```python
>>> from scipy.stats import hmean
>>> hmean([1, 4])
1.6000000000000001
>>> hmean([1, 2, 3, 4, 5, 6, 7])
2.6997245179063363
```

scipy.stats.kurtosis

`scipy.stats.kurtosis(a, axis=0, fisher=True, bias=True, nan_policy='propagate')`

Compute the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher’s definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If bias is False then the kurtosis is calculated using k statistics to eliminate bias coming from biased moment estimators.

Use `kurtosistest` to see if result is close enough to normal.

Parameters

- **a** [array] data for which the kurtosis is calculated
- **axis** [int or None, optional] Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array `a`.
- **fisher** [bool, optional] If True, Fisher’s definition is used (normal ==> 0.0). If False, Pearson’s definition is used (normal ==> 3.0).
- **bias** [bool, optional] If False, then the calculations are corrected for statistical bias.
- **nan_policy** [‘propagate’, ‘raise’, ‘omit’], optional Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

Returns

- **kurtosis** [array] The kurtosis of values along an axis. If all values are equal, return -3 for Fisher’s definition and 0 for Pearson’s definition.

References

[1]
Examples

```python
>>> from scipy.stats import kurtosis
>>> kurtosis([1, 2, 3, 4, 5])
-1.3
```

**scipy.stats.mode**

`scipy.stats.mode(a, axis=0, nan_policy='propagate')`

Return an array of the modal (most common) value in the passed array.

If there is more than one such value, only the smallest is returned. The bin-count for the modal bins is also returned.

- **Parameters**
  - `a` [array_like] n-dimensional array of which to find mode(s).
  - `axis` [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array `a`.
  - `nan_policy` ['propagate', 'raise', 'omit'], optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

- **Returns**
  - `mode` [ndarray] Array of modal values.
  - `count` [ndarray] Array of counts for each mode.

**Examples**

```python
>>> a = np.array([[6, 8, 3, 0],
...                [3, 2, 1, 7],
...                [8, 1, 8, 4],
...                [5, 3, 0, 5],
...                [4, 7, 5, 9]])
>>> from scipy import stats
>>> stats.mode(a)
(array([[3, 1, 0, 0]]), array([[1, 1, 1, 1]]))
```

To get mode of whole array, specify `axis=None`:

```python
>>> stats.mode(a, axis=None)
(array([3]), array([3]))
```

**scipy.stats.moment**

`scipy.stats.moment(a, moment=1, axis=0, nan_policy='propagate')`

Calculate the nth moment about the mean for a sample.

A moment is a specific quantitative measure of the shape of a set of points. It is often used to calculate coefficients of skewness and kurtosis due to its close relationship with them.

- **Parameters**
SciPy Reference Guide, Release 1.3.2

- a [array_like] data
- moment [int or array_like of ints, optional] order of central moment that is returned. Default is 1.
- axis [int or None, optional] Axis along which the central moment is computed. Default is 0. If None, compute over the whole array a.

**Returns**

n-th central moment [ndarray or float] The appropriate moment along the given axis or over all values if axis is None. The denominator for the moment calculation is the number of observations, no degrees of freedom correction is done.

**See also:**

kurtosis, skew, describe

**Notes**

The k-th central moment of a data sample is:

\[ m_k = \frac{1}{n} \sum_{i=1}^{n} (x_i - \bar{x})^k \]

Where n is the number of samples and x-bar is the mean. This function uses exponentiation by squares [1] for efficiency.

**References**

[1]

**Examples**

```python
>>> from scipy.stats import moment
>>> moment([1, 2, 3, 4, 5], moment=1)
0.0
>>> moment([1, 2, 3, 4, 5], moment=2)
2.0
```

**scipy.stats.skew**

scipy.stats.skew \((a, axis=0, bias=True, nan_policy=\text{propagate})\)

Compute the sample skewness of a data set.

For normally distributed data, the skewness should be about 0. For unimodal continuous distributions, a skewness value > 0 means that there is more weight in the right tail of the distribution. The function skewtest can be used to determine if the skewness value is close enough to 0, statistically speaking.

**Parameters**
a        [ndarray] data
axis     [int or None, optional] Axis along which skewness is calculated. Default is 0. If None, compute over the whole array a.
bias     [bool, optional] If False, then the calculations are corrected for statistical bias.

Returns

skewness [ndarray] The skewness of values along an axis, returning 0 where all values are equal.

Notes

The sample skewness is computed as the Fisher-Pearson coefficient of skewness, i.e.

\[ g_1 = \frac{m_3}{m_2^{3/2}} \]

where

\[ m_i = \frac{1}{N} \sum_{n=1}^{N} (x[n] - \bar{x})^i \]

is the biased sample \(i\)th central moment, and \(\bar{x}\) is the sample mean. If bias is False, the calculations are corrected for bias and the value computed is the adjusted Fisher-Pearson standardized moment coefficient, i.e.

\[ G_1 = \frac{k_3}{k_2^{3/2}} = \sqrt{\frac{N(N-1)}{N-2}} \frac{m_3}{m_2^{3/2}}. \]

References

[1]

Examples

```python
>>> from scipy.stats import skew
>>> skew([1, 2, 3, 4, 5])
0.0
>>> skew([2, 8, 0, 4, 1, 9, 9, 0])
0.2650554122698573
```

scipy.stats.kstat

scipy.stats.kstat (data, n=2)

Return the nth k-statistic (1<=n<=4 so far).

The nth k-statistic \(k_n\) is the unique symmetric unbiased estimator of the nth cumulant \(\kappa_n\).

Parameters

data        [array_like] Input array. Note that n-D input gets flattened.
SciPy Reference Guide, Release 1.3.2

**n** [int, {1, 2, 3, 4}, optional] Default is equal to 2.

**Returns**

**kstat** [float] The nth k-statistic.

**See also:**

**kstatvar**

Returns an unbiased estimator of the variance of the k-statistic.

**moment**

Returns the n-th central moment about the mean for a sample.

**Notes**

For a sample size n, the first few k-statistics are given by:

\[ k_1 = \mu k_2 = \frac{n}{n-1} m_2 k_3 = \frac{n^2}{(n-1)(n-2)} m_3 k_4 = \frac{n^2(n+1)m_4 - 3(n-1)m_2^2}{(n-1)(n-2)(n-3)} \]

where \( \mu \) is the sample mean, \( m_2 \) is the sample variance, and \( m_i \) is the i-th sample central moment.

**References**

http://mathworld.wolfram.com/k-Statistic.html

http://mathworld.wolfram.com/Cumulant.html

**Examples**

```python
>>> from scipy import stats
>>> rdm = np.random.RandomState(1234)

As sample size increases, n-th moment and n-th k-statistic converge to the same number (although they aren't identical). In the case of the normal distribution, they converge to zero.

>>> for n in [2, 3, 4, 5, 6, 7]:
...     x = rdm.normal(size=10**n)
...     m, k = stats.moment(x, 3), stats.kstat(x, 3)
...     print("%.3g %.3g %.3g" % (m, k, m-k))
-0.631 -0.651 0.0194
0.0282 0.0283 -8.49e-05
-0.0454 -0.0454 1.36e-05
7.53e-05 7.53e-05 -2.26e-09
0.00166 0.00166 -4.99e-09
-2.88e-06 -2.88e-06 8.63e-13
```
scipy.stats.kstatvar

scipy.stats.kstatvar(data, n=2)

Returns an unbiased estimator of the variance of the k-statistic.

See kstat for more details of the k-statistic.

Parameters

data [array_like] Input array. Note that n-D input gets flattened.
n [int, {1, 2}, optional] Default is equal to 2.

Returns

kstatvar [float] The nth k-statistic variance.

See also:

kstat

Returns the n-th k-statistic.
moment

Returns the n-th central moment about the mean for a sample.

Notes

The variances of the first few k-statistics are given by:

\[ \text{var}(k_1) = \frac{\kappa^2}{n} \]
\[ \text{var}(k_2) = \frac{\kappa^4}{n} + \frac{2\kappa^2}{n-1} \]
\[ \text{var}(k_3) = \frac{\kappa^6}{n} + \frac{9\kappa^2\kappa_4}{n-1} + \frac{9\kappa^4}{n-1} + \frac{6n\kappa^3_2}{(n-1)(n-2)} \]
\[ \text{var}(k_4) = \frac{\kappa^8}{n} + \frac{16\kappa^6\kappa_6}{n-1} + \frac{48\kappa^4\kappa_5}{n-1} \]

scipy.stats.tmean

scipy.stats.tmean(a, limits=None, inclusive=(True, True), axis=None)

Computes the trimmed mean.

This function finds the arithmetic mean of given values, ignoring values outside the given limits.

Parameters

a [array_like] Array of values.
limits [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.
inclusive [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
axis [int or None, optional] Axis along which to compute test. Default is None.

Returns

tmean [float]

See also:

tmean

returns mean after trimming a proportion from both tails.
Examples

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmean(x)
9.5
>>> stats.tmean(x, (3,17))
10.0
```

scipy.stats.tvar

scipy.stats.tvar(a, limits=None, inclusive=(True, True), axis=0, ddof=1)

Compute the trimmed variance.

This function computes the sample variance of an array of values, while ignoring values which are outside of given limits.

Parameters

- `a` [array_like] Array of values.
- `limits` [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.
- `inclusive` [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- `axis` [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array `a`.

Returns

- `tvar` [float] Trimmed variance.

Notes

tvar computes the unbiased sample variance, i.e. it uses a correction factor \( n / (n - 1) \).

Examples

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tvar(x)
35.0
>>> stats.tvar(x, (3,17))
20.0
```
scipy.stats.tmin

scipy.stats.tmin(a, lowerlimit=\(\text{None}\), axis=0, inclusive=True, nan_policy='propagate')

Compute the trimmed minimum.

This function finds the minimum value of an array \(a\) along the specified axis, but only considering values greater than a specified lower limit.

**Parameters**

- **a**: [array_like] array of values
- **lowerlimit**: [None or float, optional] Values in the input array less than the given limit will be ignored. When lowerlimit is None, then all values are used. The default value is None.
- **axis**: [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array \(a\).
- **inclusive**: [\{'True\', \'False\}', optional] This flag determines whether values exactly equal to the lower limit are included. The default value is True.
- **nan_policy**: [\{'propagate\', \'raise\', \'omit\}', optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- **tmin**: [float, int or ndarray]

**Examples**

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmin(x)
0
```

```python
>>> stats.tmin(x, 13)
13
```

```python
>>> stats.tmin(x, 13, inclusive=False)
14
```

scipy.stats.tmax

scipy.stats.tmax(a, upperlimit=\(\text{None}\), axis=0, inclusive=True, nan_policy='propagate')

Compute the trimmed maximum.

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

**Parameters**

- **a**: [array_like] array of values
- **upperlimit**: [None or float, optional] Values in the input array greater than the given limit will be ignored. When upperlimit is None, then all values are used. The default value is None.
- **axis**: [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array \(a\).
inclusive  [{True, False}, optional] This flag determines whether values exactly equal to the upper limit are included. The default value is True.

Returns  
tmax  [float, int or ndarray]

Examples

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmax(x)
19

>>> stats.tmax(x, 13)
13

>>> stats.tmax(x, 13, inclusive=False)
12
```

scipy.stats.tstd

scipy.stats.tstd(a, limits=None, inclusive=(True, True), axis=0, ddof=1)

Compute the trimmed sample standard deviation.

This function finds the sample standard deviation of given values, ignoring values outside the given limits.

Parameters  
a  [array_like] array of values
limits  [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.
inclusive  [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
axis  [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array a.
ddof  [int, optional] Delta degrees of freedom. Default is 1.

Returns  
tstd  [float]

Notes

$tstd$ computes the unbiased sample standard deviation, i.e. it uses a correction factor $n / (n - 1)$.
Examples

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tstd(x)
5.9160797830996161
>>> stats.tstd(x, (3, 17))
4.4721359549995796
```

**scipy.stats.tsem**

Compute the trimmed standard error of the mean.

This function finds the standard error of the mean for given values, ignoring values outside the given limits.

**Parameters**

- `a` [array_like] an array of values
- `limits` [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.
- `inclusive` [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- `axis` [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array `a`.

**Returns**

- `tsem` [float]

**Notes**

tsem uses unbiased sample standard deviation, i.e. it uses a correction factor \( n / (n - 1) \).

**Examples**

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tsem(x)
1.3228756555322954
>>> stats.tsem(x, (3, 17))
1.1547005383792515
```

**scipy.stats.variation**

Compute the coefficient of variation, the ratio of the biased standard deviation to the mean.

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.variation(x)
0.1725144689063638
>>> stats.variation(x, (3, 17))
0.15068465828677832
```
**Parameters**

- **a** [array_like] Input array.
- **axis** [int or None, optional] Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array `a`.
- **nan_policy** [{’propagate’, ’raise’, ’omit’}, optional] Defines how to handle when input contains nan. ’propagate’ returns nan, ’raise’ throws an error, ’omit’ performs the calculations ignoring nan values. Default is ’propagate’.

**Returns**

- **variation** [ndarray] The calculated variation along the requested axis.

**References**

[1]

**Examples**

```python
>>> from scipy.stats import variation
>>> variation([1, 2, 3, 4, 5])
0.47140452079103173
```

**scipy.stats.find_repeats**

`scipy.stats.find_repeats(arr)`

Find repeats and repeat counts.

**Parameters**

- **arr** [array_like] Input array. This is cast to float64.

**Returns**

- **values** [ndarray] The unique values from the (flattened) input that are repeated.
- **counts** [ndarray] Number of times the corresponding ‘value’ is repeated.

**Notes**

In numpy >= 1.9 `numpy.unique` provides similar functionality. The main difference is that `find_repeats` only returns repeated values.

**Examples**

```python
>>> from scipy import stats
>>> stats.find_repeats([[2, 1, 2, 3, 2, 2, 5]])
RepeatedResults(values=array([2.]), counts=array([4]))

>>> stats.find_repeats([[10, 20, 1, 2], [5, 5, 4, 4]])
RepeatedResults(values=array([4., 5.]), counts=array([2, 2]))
```
scipy.stats.trim_mean

\texttt{scipy.stats.trim\_mean}(a, \texttt{proportiontocut}, \texttt{axis}=0)

Return mean of array after trimming distribution from both tails.

If \( \text{proportiontocut} = 0.1 \), slices off ‘leftmost’ and ‘rightmost’ 10\% of scores. The input is sorted before slicing. Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off \( \text{proportiontocut} \)).

\textbf{Parameters}

\begin{itemize}
  \item \texttt{a} \quad \text{[array_like]} \quad \text{Input array}
  \item \texttt{proportiontocut} \quad \text{[float]} \quad \text{Fraction to cut off of both tails of the distribution}
  \item \texttt{axis} \quad \text{[int or None, optional]} \quad \text{Axis along which the trimmed means are computed. Default is 0. If None, compute over the whole array \( a \).}
\end{itemize}

\textbf{Returns}

\texttt{trim\_mean} \quad \text{[ndarray]} \quad \text{Mean of trimmed array.}

\textbf{See also:}

\texttt{trimboth}
\texttt{tmean}

compute the trimmed mean ignoring values outside given \textit{limits}.

\textbf{Examples}

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.trim_mean(x, 0.1)
9.5
>>> x2 = x.reshape(5, 4)
>>> x2
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11],
       [12, 13, 14, 15],
       [16, 17, 18, 19]]
>>> stats.trim_mean(x2, 0.25)
array([ 8.,  9., 10., 11.])
>>> stats.trim_mean(x2, 0.25, axis=1)
array([[ 1.5,  5.5,  9.5, 13.5, 17.5]])
```

scipy.stats.gstd

\texttt{scipy.stats.gstd}(a, \texttt{axis}=0, \texttt{ddof}=1)

Calculate the geometric standard deviation of an array

The geometric standard deviation describes the spread of a set of numbers where the geometric mean is preferred. It is a multiplicative factor, and so a dimensionless quantity.

It is defined as the exponent of the standard deviation of \( \log(a) \). Mathematically the population geometric standard deviation can be evaluated as:
gstd = \exp(\text{std}(\log(a)))

New in version 1.3.0.

**Parameters**

- **a** [array_like] An array like object containing the sample data.
- **axis** [int, tuple or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array \(a\).
- **ddof** [int, optional] Degree of freedom correction in the calculation of the geometric standard deviation. Default is 1.

**Returns**

- **ndarray or float**
  An array of the geometric standard deviation. If \(axis\) is None or \(a\) is a 1d array a float is returned.

**Notes**

As the calculation requires the use of logarithms the geometric standard deviation only supports strictly positive values. Any non-positive or infinite values will raise a Value Error. The geometric standard deviation is sometimes confused with the exponent of the standard deviation, \(\exp(\text{std}(a))\). Instead the geometric standard deviation is \(\exp(\text{std}(\log(a)))\). The default value for \(ddof\) is different to the default value (0) used by other \(ddof\) containing functions, such as `np.std` and `np.nanstd`.

**Examples**

Find the geometric standard deviation of a log-normally distributed sample. Note that the standard deviation of the distribution is one, on a log scale this evaluates to approximately \(\exp(1)\).

```python
>>> from scipy.stats import gstd
>>> np.random.seed(123)
>>> sample = np.random.lognormal(mean=0, sigma=1, size=1000)
>>> gstd(sample)
2.7217860664589946
```

Compute the geometric standard deviation of a multidimensional array and of a given axis.

```python
>>> a = np.arange(1, 25).reshape(2, 3, 4)
>>> gstd(a, axis=None)
2.2944076136018947
>>> gstd(a, axis=2)
array([[1.82424757, 1.22436866, 1.13183117],
       [1.09348306, 1.07244798, 1.05914985]])
```

The geometric standard deviation further handles masked arrays.

```python
>>> a = np.arange(1, 25).reshape(2, 3, 4)
>>> ma = np.ma.masked_where(a > 16, a)
>>> ma
masked_array(continues on next page)
data=[[1, 2, 3, 4],
      [5, 6, 7, 8],
      [9, 10, 11, 12],
      [13, 14, 15, 16],
      [None, None, None, None],
      [None, None, None, None]],
mask=[[False, False, False, False],
      [False, False, False, False],
      [False, False, False, False],
      [True, True, True, True],
      [True, True, True, True]],
fill_value=999999)

>>> gstd(ma, axis=2)
masked_array(
data=[[1.8242475707663655, 1.2243686572447428, 1.1318311657788478],
      [1.0934830582350938, None, None]],
mask=[[False, False, False],
      [False, True, True]],
fill_value=999999)

scipy.stats.iqr

scipy.stats.iqr(x, axis=None, rng=(25, 75), scale='raw', nan_policy='propagate', interpolation='linear', keepdims=False)

Compute the interquartile range of the data along the specified axis.

The interquartile range (IQR) is the difference between the 75th and 25th percentile of the data. It is a measure of the dispersion similar to standard deviation or variance, but is much more robust against outliers [2].

The rng parameter allows this function to compute other percentile ranges than the actual IQR. For example, setting rng=(0, 100) is equivalent to numpy.ptp.

The IQR of an empty array is np.nan.

New in version 0.18.0.

Parameters

x [array_like] Input array or object that can be converted to an array.
axis [int or sequence of int, optional] Axis along which the range is computed. The default is to compute the IQR for the entire array.
rng [Two-element sequence containing floats in range of [0,100] optional] Percentiles over which to compute the range. Each must be between 0 and 100, inclusive. The default is the true IQR: (25, 75). The order of the elements is not important.
scale [scalar or str, optional] The numerical value of scale will be divided out of the final result. The following string values are recognized:
   ‘raw’ : No scaling, just return the raw IQR. ‘normal’ : Scale by \(2\sqrt{2erf^{-1}(\frac{1}{2})} \approx 1.349.\) The default is ‘raw’. Array-like scale is also allowed, as long as it broadcasts correctly to the output such that out / scale is a valid operation. The output dimensions depend on the input array, x, the axis argument, and the keepdims flag.
interpolation
[[‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’], optional] Specifies the interpolation method to use when the percentile boundaries lie between two data points \(i\) and \(j\):

- ‘linear’ \([i + (j - i) \times \text{fraction}], where \text{fraction} is the] fractional part of the index surrounded by \(i\) and \(j\).
- ‘lower’ : \(i\).
- ‘higher’ : \(j\).
- ‘nearest’ : \(i\) or \(j\) whichever is nearest.
- ‘midpoint’ : \((i + j) / 2\).

Default is ‘linear’.

keepdims [bool, optional] If this is set to True, the reduced axes are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array \(x\).

Returns

iqr [scalar or ndarray] If \(axis=\text{None}\), a scalar is returned. If the input contains integers or float of smaller precision than np.float64, then the output data-type is np.float64. Otherwise, the output data-type is the same as that of the input.

See also:

numpy.std, numpy.var

Notes

This function is heavily dependent on the version of numpy that is installed. Versions greater than 1.11.0b3 are highly recommended, as they include a number of enhancements and fixes to numpy.percentile and numpy.nanpercentile that affect the operation of this function. The following modifications apply:

Below 1.10.0

[\text{nan\_policy is poorly defined.}] The default behavior of numpy.percentile is used for ‘propagate’. This is a hybrid of ‘omit’ and ‘propagate’ that mostly yields a skewed version of ‘omit’ since NaNs are sorted to the end of the data. A warning is raised if there are NaNs in the data.

Below 1.9.0: numpy.nanpercentile does not exist.

This means that numpy.percentile is used regardless of \text{nan\_policy} and a warning is issued. See previous item for a description of the behavior.

Below 1.9.0: keepdims and interpolation are not supported.

The keywords get ignored with a warning if supplied with non-default values. However, multiple axes are still supported.

References

[1], [2], [3]

Examples

```python
>>> from scipy.stats import iqr
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10, 7, 4],
       [3, 2, 1]])
```
>>> iqr(x)
4.0

>>> iqr(x, axis=0)
array([ 3.5,  2.5,  1.5])

>>> iqr(x, axis=1)
array([[ 3. ,
    [ 1. ]])

scipy.stats.sem

`scipy.stats.sem(a, axis=0, ddof=1, nan_policy='propagate')`

Calculate the standard error of the mean (or standard error of measurement) of the values in the input array.

**Parameters**

- **a**  
  [array_like] An array containing the values for which the standard error is returned.
- **axis**  
  [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array `a`.
- **ddof**  
  [int, optional] Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.
- **nan_policy**  
  [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

**Returns**

- **s**  
  [ndarray or float] The standard error of the mean in the sample(s), along the input axis.

**Notes**

The default value for `ddof` is different to the default (0) used by other ddof containing routines, such as `np.std` and `np.nanstd`.

**Examples**

Find standard error along the first axis:

```python
>>> from scipy import stats
>>> a = np.arange(20).reshape(5,4)
>>> stats.sem(a)
array([ 2.8284,  2.8284,  2.8284,  2.8284])
```

Find standard error across the whole array, using n degrees of freedom:

```python
>>> stats.sem(a, axis=None, ddof=0)
1.2893796958227628
```
scipy.stats.bayes_mvs

**scipy.stats.bayes_mvs** *(data, alpha=0.9)*

Bayesian confidence intervals for the mean, var, and std.

**Parameters**

- **data** ([array_like]) Input data, if multi-dimensional it is flattened to 1-D by *bayes_mvs*. Requires 2 or more data points.
- **alpha** ([float, optional]) Probability that the returned confidence interval contains the true parameter.

**Returns**

- **mean_cntr, var_cntr, std_cntr**

  [tuple] The three results are for the mean, variance and standard deviation, respectively. Each result is a tuple of the form:

  ```
  (center, (lower, upper))
  ```

  with center the mean of the conditional pdf of the value given the data, and (lower, upper) a confidence interval, centered on the median, containing the estimate to a probability alpha.

**See also:**

mvsdist

**Notes**

Each tuple of mean, variance, and standard deviation estimates represent the (center, (lower, upper)) with center the mean of the conditional pdf of the value given the data and (lower, upper) is a confidence interval centered on the median, containing the estimate to a probability alpha.

Converts data to 1-D and assumes all data has the same mean and variance. Uses Jeffrey's prior for variance and std.

Equivalent to *tuple((x.mean(), x.interval(alpha)) for x in mvsdist(dat))*

**References**

**Examples**

First a basic example to demonstrate the outputs:

```python
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.bayes_mvs(data)
>>> mean
Mean(statistic=9.0, minmax=(7.103650222612533, 10.89634977387467))
>>> var
Variance(statistic=10.0, minmax=(3.176724206..., 24.45910382...))
>>> std
Std_dev(statistic=2.9724954732045084, minmax=(1.7823367265645143, 4.
   945614605014631))
```
Now we generate some normally distributed random data, and get estimates of mean and standard deviation with 95% confidence intervals for those estimates:

```python
>>> n_samples = 100000
>>> data = stats.norm.rvs(size=n_samples)
>>> res_mean, res_var, res_std = stats.bayes_mvs(data, alpha=0.95)
```

```python
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.hist(data, bins=100, density=True, label='Histogram of data')
>>> ax.vlines(res_mean.statistic, 0, 0.5, colors='r', label='Estimated mean')
>>> ax.axvspan(res_mean.minmax[0],res_mean.minmax[1], facecolor='r', alpha=0.2, label=r'Estimated mean (95% limits)')
>>> ax.vlines(res_std.statistic, 0, 0.5, colors='g', label='Estimated scale')
>>> ax.axvspan(res_std.minmax[0],res_std.minmax[1], facecolor='g', alpha=0.2, label=r'Estimated scale (95% limits)')
>>> ax.legend(fontsize=10)
>>> ax.set_xlim([-4, 4])
>>> ax.set_ylim([0, 0.5])
>>> plt.show()
```

**scipy.stats.mvdist**

`scipy.stats.mvdist(data)`

‘Frozen’ distributions for mean, variance, and standard deviation of data.

**Parameters**

- **data** [array_like] Input array. Converted to 1-D using ravel. Requires 2 or more data-points.
Returns

- mdist: ['frozen' distribution object] Distribution object representing the mean of the data
- vdist: ['frozen' distribution object] Distribution object representing the variance of the data
- sdist: ['frozen' distribution object] Distribution object representing the standard deviation of the data

See also:

- bayes_mvs

Notes

The return values from `bayes_mvs(data)` is equivalent to `tuple((x.mean(), x.interval(0.90)) for x in mvsdist(data))`.

In other words, calling `<dist>.mean()` and `<dist>.interval(0.90)` on the three distribution objects returned from this function will give the same results that are returned from `bayes_mvs`.

References

Examples

```python
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.mvsdist(data)
```

We now have frozen distribution objects “mean”, “var” and “std” that we can examine:

```python
>>> mean.mean()
9.0
>>> mean.interval(0.95)
(6.6120585482655692, 11.387941451734431)
>>> mean.std()
1.1952286093343936
```

`scipy.stats.entropy`

`scipy.stats.entropy(pk, qk=None, base=None)`

Calculate the entropy of a distribution for given probability values.

If only probabilities `pk` are given, the entropy is calculated as \(S = -\sum(pk \times \log(pk), \text{axis}=0)\).

If `qk` is not None, then compute the Kullback-Leibler divergence \(S = \sum(pk \times \log(pk / qk), \text{axis}=0)\).

This routine will normalize `pk` and `qk` if they don’t sum to 1.

Parameters
Definesthe (discrete) distribution. \( p_k[i] \) is the (possibly unnormalized) probability of event \( i \).

\( q_k \) [sequence, optional] Sequence against which the relative entropy is computed. Should be in the same format as \( p_k \).

\( \text{base} \) [float, optional] The logarithmic base to use, defaults to \( e \) (natural logarithm).

Returns

\( S \) [float] The calculated entropy.

### scipy.stats.median_absolute_deviation

**scipy.stats.median_absolute_deviation**

```python
scipy.stats.median_absolute_deviation(x, axis=0, center=<function median at 0x7fdaedf172f0>, scale=1.4826, nan_policy='propagate')
```

Compute the median absolute deviation of the data along the given axis.

The median absolute deviation (MAD, [1]) computes the median over the absolute deviations from the median. It is a measure of dispersion similar to the standard deviation, but is more robust to outliers [2].

The MAD of an empty array is \( \text{np.nan} \).

New in version 1.3.0.

**Parameters**

- \( x \) [array_like] Input array or object that can be converted to an array.
- \( \text{axis} \) [int or None, optional] Axis along which the range is computed. Default is 0. If None, compute the MAD over the entire array.
- \( \text{center} \) [callable, optional] A function that will return the central value. The default is to use \( \text{np.median} \). Any user defined function used will need to have the function signature \( \text{func(arr, axis)} \).
- \( \text{scale} \) [int, optional] The scaling factor applied to the MAD. The default scale (1.4826) ensures consistency with the standard deviation for normally distributed data.
- \( \text{nan_policy} \) [\{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

**Returns**

- \( \text{mad} \) [scalar or ndarray] If \( \text{axis} = \text{None} \), a scalar is returned. If the input contains integers or floats of smaller precision than \( \text{np.float64} \), then the output data-type is \( \text{np.float64} \). Otherwise, the output data-type is the same as that of the input.

See also:

- \( \text{numpy.std}, \text{numpy.var}, \text{numpy.median}, \text{scipy.stats.iqr}, \text{scipy.stats.tmean} \)
- \( \text{scipy.stats.tstd}, \text{scipy.stats.tvar} \)

**Notes**

The \( \text{center} \) argument only affects the calculation of the central value around which the MAD is calculated. That is, passing in \( \text{center} = \text{np.mean} \) will calculate the MAD around the mean - it will not calculate the \( \text{mean} \) absolute deviation.
References

[1], [2]

Examples

When comparing the behavior of `median_absolute_deviation` with `np.std`, the latter is affected when we change a single value of an array to have an outlier value while the MAD hardly changes:

```python
>>> from scipy import stats
>>> x = stats.norm.rvs(size=100, scale=1, random_state=123456)
>>> x.std()
0.9973906394005013
>>> stats.median_absolute_deviation(x)
1.2280762773108278
>>> x[0] = 345.6
>>> x.std()
34.42304872314415
>>> stats.median_absolute_deviation(x)
1.2340335571164334
```

Axis handling example:

```python
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10,  7,  4],
       [ 3,  2,  1]])
>>> stats.median_absolute_deviation(x)
array([5.1891, 3.7065, 2.2239])
>>> stats.median_absolute_deviation(x, axis=None)
2.9652
```

### 6.28.8 Frequency statistics

- **cumfreq**

  ```python
  scipy.stats.cumfreq
  ``

  Return a cumulative frequency histogram, using the histogram function.

  A cumulative histogram is a mapping that counts the cumulative number of observations in all of the bins up to the specified bin.
Parameters

- **a** [array_like] Input array.
- **numbins** [int, optional] The number of bins to use for the histogram. Default is 10.
- **defaultreallimits** [tuple (lower, upper), optional] The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than the range of the values in `a` is used. Specifically `(a.min() - s, a.max() + s)`, where `s = (1/2)(a.max() - a.min()) / (numbins - 1)`.
- **weights** [array_like, optional] The weights for each value in `a`. Default is None, which gives each value a weight of 1.0

Returns

- **cumcount** [ndarray] Binned values of cumulative frequency.
- **lowerlimit** [float] Lower real limit
- **binsize** [float] Width of each bin.
- **extrapoints** [int] Extra points.

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> x = [1, 4, 2, 1, 3, 1]
>>> res = stats.cumfreq(x, numbins=4, defaultreallimits=(1.5, 5))
>>> res.cumcount
array([ 1.,  2.,  3.,  3.])
>>> res.extrapoints
3
```

Create a normal distribution with 1000 random values

```python
>>> rng = np.random.RandomState(seed=12345)
>>> samples = stats.norm.rvs(size=1000, random_state=rng)
```

Calculate cumulative frequencies

```python
>>> res = stats.cumfreq(samples, numbins=25)
```

Calculate space of values for `x`

```python
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.cumcount.size, ...
... res.cumcount.size)
```

Plot histogram and cumulative histogram

```python
>>> fig = plt.figure(figsize=(10, 4))
>>> ax1 = fig.add_subplot(1, 2, 1)
>>> ax2 = fig.add_subplot(1, 2, 2)
>>> ax1.hist(samples, bins=25)
>>> ax1.set_title('Histogram')
>>> ax2.bar(x, res.cumcount, width=res.binsize)
>>> ax2.set_title('Cumulative histogram')
>>> ax2.set_xlim([x.min(), x.max()])
```
scipy.stats.itemfreq

`scipy.stats.itemfreq(*args, **kwds)`

`itemfreq` is deprecated! `itemfreq` is deprecated and will be removed in a future version. Use instead `np.unique(..., return_counts=True)`

Return a 2-D array of item frequencies.

**Parameters**

- `a` [(N,) array_like] Input array.

**Returns**

- `itemfreq` [(K, 2) ndarray] A 2-D frequency table. Column 1 contains sorted, unique values from `a`, column 2 contains their respective counts.

**Examples**

```python
>>> from scipy import stats
>>> a = np.array([1, 1, 5, 0, 1, 2, 2, 0, 1, 4])
>>> stats.itemfreq(a)
array([[ 0., 2.],
       [ 1., 4.],
       [ 2., 2.],
       [ 4., 1.],
       [ 5., 1.]]

>>> np.bincount(a)
array([2, 4, 2, 0, 1, 1])

>>> stats.itemfreq(a/10.)
array([[ 0. , 2. ],
       [ 0.1, 4. ]],
(continues on next page)
scipy.stats.percentileofscore

scipy.stats.percentileofscore(a, score, kind='rank')

The percentile rank of a score relative to a list of scores.

A percentileofscore of, for example, 80% means that 80% of the scores in a are below the given score. In the case of gaps or ties, the exact definition depends on the optional keyword, kind.

Parameters

- a : array_like
  Array of scores to which score is compared.
- score : int or float
  Score that is compared to the elements in a.
- kind : {'rank', 'weak', 'strict', 'mean'}, optional
  This optional parameter specifies the interpretation of the resulting score:
  - “rank”: Average percentage ranking of score. In case of multiple matches, average the percentage rankings of all matching scores.
  - “weak”: This kind corresponds to the definition of a cumulative distribution function. A percentileofscore of 80% means that 80% of values are less than or equal to the provided score.
  - “strict”: Similar to “weak”, except that only values that are strictly less than the given score are counted.
  - “mean”: The average of the “weak” and “strict” scores, often used in testing. See https://en.wikipedia.org/wiki/Percentile_rank

Returns

- pcos : float
  Percentile-position of score (0-100) relative to a.

See also:

numpy.percentile

Examples

Three-quarters of the given values lie below a given score:

```
>>> from scipy import stats
>>> stats.percentileofscore([1, 2, 3, 4], 3)
75.0
```

With multiple matches, note how the scores of the two matches, 0.6 and 0.8 respectively, are averaged:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3)
70.0
```

Only 2/5 values are strictly less than 3:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='strict')
40.0
```
But 4/5 values are less than or equal to 3:

```python
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='weak')
80.0
```

The average between the weak and the strict scores is

```python
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='mean')
60.0
```

**scipy.stats.scoreatpercentile**

`scipy.stats.scoreatpercentile(a, per[, limit=(), interpolation_method='fraction', axis=None])`

Calculate the score at a given percentile of the input sequence.

For example, the score at \( \text{per}=50 \) is the median. If the desired quantile lies between two data points, we interpolate between them, according to the value of `interpolation`. If the parameter `limit` is provided, it should be a tuple (lower, upper) of two values.

**Parameters**

- `a` [array_like] A 1-D array of values from which to extract score.
- `per` [array_like] Percentile(s) at which to extract score. Values should be in range [0,100].
- `limit` [tuple, optional] Tuple of two scalars, the lower and upper limits within which to compute the percentile. Values of `a` outside this (closed) interval will be ignored.
- `interpolation_method` [{'fraction', 'lower', 'higher'}, optional] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points \( i \) and \( j \):
  - `fraction`: \( i + (j - i) \times \text{fraction} \) where \( \text{fraction} \) is the fractional part of the index surrounded by \( i \) and \( j \).
  - `lower`: \( i \).
  - `higher`: \( j \).
- `axis` [int, optional] Axis along which the percentiles are computed. Default is None. If None, compute over the whole array `a`.

**Returns**

- `score` [float or ndarray] Score at percentile(s).

**See also:**

`percentileofscore`, `numpy.percentile`

**Notes**

This function will become obsolete in the future. For NumPy 1.9 and higher, `numpy.percentile` provides all the functionality that `scoreatpercentile` provides. And it's significantly faster. Therefore it's recommended to use `numpy.percentile` for users that have numpy >= 1.9.

**Examples**
```python
>>> from scipy import stats
>>> a = np.arange(100)
>>> stats.scoreatpercentile(a, 50)
49.5
```

**scipy.stats.relfreq**

`scipy.stats.relfreq(a, numbins=10, defaultreallimits=None, weights=None)`

Return a relative frequency histogram, using the histogram function.

A relative frequency histogram is a mapping of the number of observations in each of the bins relative to the total of observations.

**Parameters**

- **a** [array_like] Input array.
- **numbins** [int, optional] The number of bins to use for the histogram. Default is 10.
- **defaultreallimits** [tuple (lower, upper), optional] The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than the range of the values in a is used. Specifically \((a.min() - s, a.max() + s)\), where \(s = (1/2)(a.max() - a.min()) / (numbins - 1)\).
- **weights** [array_like, optional] The weights for each value in a. Default is None, which gives each value a weight of 1.0

**Returns**

- **frequency** [ndarray] Binned values of relative frequency.
- **lowerlimit** [float] Lower real limit
- **binsize** [float] Width of each bin.
- **extrapoints** [int] Extra points.

**Examples**

```python
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> a = np.array([2, 4, 1, 2, 3, 2])
>>> res = stats.relfreq(a, numbins=4)
>>> res.frequency
array([ 0.16666667, 0.5 , 0.16666667, 0.16666667])
>>> np.sum(res.frequency)  # relative frequencies should add up to 1
1.0
```

Create a normal distribution with 1000 random values

```python
>>> rng = np.random.RandomState(seed=12345)
>>> samples = stats.norm.rvs(size=1000, random_state=rng)
```

Calculate relative frequencies

```python
>>> res = stats.relfreq(samples, numbins=25)
```

Calculate space of values for x
Plot relative frequency histogram

```python
>>> fig = plt.figure(figsize=(5, 4))
>>> ax = fig.add_subplot(1, 1, 1)
>>> ax.bar(x, res.frequency, width=res.binsize)
>>> ax.set_title('Relative frequency histogram')
>>> ax.set_xlim([x.min(), x.max()])
>>> plt.show()
```

```python
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.frequency.size, ...
   res.frequency.size)
```

---

**binned_statistic**

`binned_statistic(x, values[, statistic, ...])`  
Compute a binned statistic for one or more sets of data.

**binned_statistic_2d**

`binned_statistic_2d(x, y, values[, ...])`  
Compute a bidimensional binned statistic for one or more sets of data.

**binned_statistic_dd**

`binned_statistic_dd(sample, values[, ...])`  
Compute a multidimensional binned statistic for a set of data.

---

**scipy.stats.binned_statistic**

`scipy.stats.binned_statistic(x, values, statistic='mean', bins=10, range=None)`  
Compute a binned statistic for one or more sets of data.

This is a generalization of a histogram function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic.
of the values (or set of values) within each bin.

**Parameters**

- `x` [(N,) array_like] A sequence of values to be binned.
- `values` [(N,) array_like or list of (N,) array_like] The data on which the statistic will be computed. This must be the same shape as `x`, or a set of sequences - each the same shape as `x`. If `values` is a set of sequences, the statistic will be computed on each independently.
- `statistic` [string or callable, optional] The statistic to compute (default is 'mean'). The following statistics are available:
  - 'mean': compute the mean of values for points within each bin. Empty bins will be represented by NaN.
  - 'std': compute the standard deviation within each bin. This is implicitly calculated with ddof=0.
  - 'median': compute the median of values for points within each bin. Empty bins will be represented by NaN.
  - 'count': compute the count of points within each bin. This is identical to an unweighted histogram. `values` array is not referenced.
  - 'sum': compute the sum of values for points within each bin. This is identical to a weighted histogram.
  - 'min': compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
  - 'max': compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
  - function: a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by function([]), or NaN if this returns an error.
- `bins` [int or sequence of scalars, optional] If `bins` is an int, it defines the number of equal-width bins in the given range (10 by default). If `bins` is a sequence, it defines the bin edges, including the rightmost edge, allowing for non-uniform bin widths. Values in `x` that are smaller than lowest bin edge are assigned to bin number 0, values beyond the highest bin are assigned to `bins[-1]`. If the bin edges are specified, the number of bins will be, (nx = len(bins)-1).
- `range` [(float, float) or [(float, float)], optional] The lower and upper range of the bins. If not provided, range is simply `(x.min(), x.max())`. Values outside the range are ignored.

**Returns**

- `statistic` [array] The values of the selected statistic in each bin.
- `bin_edges` [array of dtype float] Return the bin edges (length(statistic)+1).
- `binnumber: 1-D ndarray of ints` Indices of the bins (corresponding to `bin_edges`) in which each value of `x` belongs. Same length as `values`. A binnumber of `i` means the corresponding value is between (bin_edges[i-1], bin_edges[i]).

See also:

- `numpy.digitize`, `numpy.histogram`, `binned_statistic_2d`, `binned_statistic_dd`

**Notes**

All but the last (righthand-most) bin is half-open. In other words, if `bins` is `[1, 2, 3, 4]`, then the first bin is `[1, 2)` (including 1, but excluding 2) and the second `[2, 3)`. The last bin, however, is `[3, 4]`, which includes 4.

New in version 0.11.0.
Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

First some basic examples:

Create two evenly spaced bins in the range of the given sample, and sum the corresponding values in each of those bins:

```python
>>> values = [1.0, 1.0, 2.0, 1.5, 3.0]
>>> stats.binned_statistic([1, 1, 2, 5, 7], values, 'sum', bins=2)
(array([ 4. , 4.5]), array([ 1., 4., 7.]), array([1, 1, 1, 2, 2]))
```

Multiple arrays of values can also be passed. The statistic is calculated on each set independently:

```python
>>> values = [[1.0, 1.0, 2.0, 1.5, 3.0], [2.0, 2.0, 4.0, 3.0, 6.0]]
>>> stats.binned_statistic([1, 1, 2, 5, 7], values, 'sum', bins=2)
(array([[ 4. , 4.5], [8. , 9. ]]), array([1., 4., 7.]), array([1, 1, 1, 2, 2]))
```

```python
>>> stats.binned_statistic([1, 2, 1, 2, 4], np.arange(5), statistic='mean', ... bins=3)
(array([1., 2., 4.]), array([1., 2., 3., 4.]), array([1, 2, 1, 2, 3]))
```

As a second example, we now generate some random data of sailing boat speed as a function of wind speed, and then determine how fast our boat is for certain wind speeds:

```python
>>> windspeed = 8 * np.random.rand(500)
>>> boatspeed = .3 * windspeed**.5 + .2 * np.random.rand(500)
>>> bin_means, bin_edges, binnumber = stats.binned_statistic(windspeed, ... boatspeed, statistic='median', bins=[1,2,3,4,5,6,7])
>>> plt.figure()
>>> plt.plot(windspeed, boatspeed, 'b.', label='raw data')
>>> plt.hlines(bin_means, bin_edges[:-1], bin_edges[1:], colors='g', lw=5, ... label='binned statistic of data')
>>> plt.legend()
```

Now we can use `binnumber` to select all datapoints with a windspeed below 1:

```python
>>> low_boatspeed = boatspeed[binnumber == 0]
```

As a final example, we will use `bin_edges` and `binnumber` to make a plot of a distribution that shows the mean and distribution around that mean per bin, on top of a regular histogram and the probability distribution function:

```python
>>> x = np.linspace(0, 5, num=500)
>>> x_pdf = stats.maxwell.pdf(x)
>>> samples = stats.maxwell.rvs(size=10000)

>>> bin_means, bin_edges, binnumber = stats.binned_statistic(x, x_pdf, ... statistic='mean', bins=25)
```
```python
>>> bin_width = (bin_edges[1] - bin_edges[0])
>>> bin_centers = bin_edges[1:] - bin_width/2

>>> plt.figure()
>>> plt.hist(samples, bins=50, density=True, histtype='stepfilled',
            alpha=0.2, label='histogram of data')
>>> plt.plot(x, x_pdf, 'r-', label='analytical pdf')
>>> plt.hlines(bin_means, bin_edges[:-1], bin_edges[1:], colors='g', lw=2,
             label='binned statistic of data')
>>> plt.plot((binnumber - 0.5) * bin_width, x_pdf, 'g.', alpha=0.5)
>>> plt.legend(fontsize=10)
>>> plt.show()
```
scipy.stats.binned_statistic_2d

Compute a bidimensional binned statistic for one or more sets of data. This is a generalization of a histogram2d function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values (or set of values) within each bin.

Parameters

- **x** [(N,) array_like] A sequence of values to be binned along the first dimension.
- **y** [(N,) array_like] A sequence of values to be binned along the second dimension.
- **values** [(N,) array_like or list of (N,) array_like] The data on which the statistic will be computed. This must be the same shape as x, or a list of sequences - each with the same shape as x. If values is such a list, the statistic will be computed on each independently.
- **statistic** [string or callable, optional] The statistic to compute (default is 'mean'). The following statistics are available:
  - 'mean' : compute the mean of values for points within each bin. Empty bins will be represented by NaN.
  - 'std' : compute the standard deviation within each bin. This is implicitly calculated with ddof=0.
  - 'median' : compute the median of values for points within each bin. Empty bins will be represented by NaN.
  - 'count' : compute the count of points within each bin. This is identical to an unweighted histogram. values array is not referenced.
  - 'sum' : compute the sum of values for points within each bin. This is identical to a weighted histogram.
  - 'min' : compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
  - 'max' : compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
  - function : a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by function([]), or NaN if this returns an error.
- **bins** [int or [int, int] or array_like or [array, array], optional] The bin specification:
  - the number of bins for the two dimensions (nx = ny = bins),
  - the number of bins in each dimension (nx, ny = bins),
  - the bin edges for the two dimensions (x_edge = y_edge = bins),
  - the bin edges in each dimension (x_edge, y_edge = bins).
  If the bin edges are specified, the number of bins will be, (nx = len(x_edge)-1, ny = len(y_edge)-1).
- **range** [(2,2) array_like, optional] The leftmost and rightmost edges of the bins along each dimension (if not specified explicitly in the bins parameters): [[xmin, xmax], [ymin, ymax]]. All values outside of this range will be considered outliers and not tallied in the histogram.
- **expand_binnumbers** [bool, optional] 'False' (default): the returned binnumber is a shape (N,) array of linearized bin indices. 'True': the returned binnumber is 'unraveled' into a shape (2,N) ndarray, where each row gives the bin numbers in the corresponding dimension. See the binnumber returned value, and the Examples section.

New in version 0.17.0.

Returns

- **statistic** [(nx, ny) ndarray] The values of the selected statistic in each two-dimensional bin.
SciPy Reference Guide, Release 1.3.2

**x_edge**

[(nx + 1) ndarray] The bin edges along the first dimension.

**y_edge**

[(ny + 1) ndarray] The bin edges along the second dimension.

**binnumber**

[(N,) array of ints or (2,N) ndarray of ints] This assigns to each element of *sample* an integer that represents the bin in which this observation falls. The representation depends on the `expand_binnumbers` argument. See Notes for details.

See also:

`numpy.digitize`, `numpy.histogram2d`, `binned_statistic`, `binned_statistic_dd`

Notes

Binedges: All but the last (righthand-most) bin is half-open. In other words, if *bins* is [1, 2, 3, 4], then the first bin is [1, 2) (including 1, but excluding 2) and the second [2, 3). The last bin, however, is [3, 4], which includes 4.

*binnumber*: This returned argument assigns to each element of *sample* an integer that represents the bin in which it belongs. The representation depends on the `expand_binnumbers` argument. If 'False' (default): The returned *binnumber* is a shape (N,) array of linearized indices mapping each element of *sample* to its corresponding bin (using row-major ordering). If 'True': The returned *binnumber* is a shape (2,N) ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a *binnumber* of *i* means the corresponding value is between (D_edge[i-1], D_edge[i]), where 'D' is either 'x' or 'y'.

New in version 0.11.0.

Examples

```python
>>> from scipy import stats

Calculate the counts with explicit bin-edges:

```python
>>> x = [0.1, 0.1, 0.1, 0.6]
>>> y = [2.1, 2.6, 2.1, 2.1]
>>> binx = [0.0, 0.5, 1.0]
>>> biny = [2.0, 2.5, 3.0]
>>> ret = stats.binned_statistic_2d(x, y, None, 'count', bins=[binx,biny])
>>> ret.statistic
array([[ 2.,  1.],
       [ 1.,  0.]])
```

The bin in which each sample is placed is given by the *binnumber* returned parameter. By default, these are the linearized bin indices:

```python
>>> ret.binnumber
array([5, 6, 5, 9])
```

The bin indices can also be expanded into separate entries for each dimension using the `expand_binnumbers` parameter:

```python
>>> ret = stats.binned_statistic_2d(x, y, None, 'count', bins=[binx,biny],
... expand_binnumbers=True)
>>> ret.binnumber
```

(continues on next page)
array([[1, 1, 1, 2],
       [1, 2, 1, 1]])

Which shows that the first three elements belong in the xbin 1, and the fourth into xbin 2; and so on for y.

**scipy.stats.binned_statistic_dd**

```
scipy.stats.binned_statistic_dd(sample, values, statistic='mean', bins=10, range=None, expand_binnumbers=False)
```

Compute a multidimensional binned statistic for a set of data.

This is a generalization of a histogramdd function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values within each bin.

**Parameters**

- **sample** [array_like] Data to histogram passed as a sequence of D arrays of length N, or as an (N,D) array.
- **values** [(N,) array_like or list of (N,) array_like] The data on which the statistic will be computed. This must be the same shape as `sample`, or a list of sequences - each with the same shape as `sample`. If `values` is such a list, the statistic will be computed on each independently.
- **statistic** [string or callable, optional] The statistic to compute (default is 'mean'). The following statistics are available:
  - 'mean': compute the mean of values for points within each bin. Empty bins will be represented by NaN.
  - 'median': compute the median of values for points within each bin. Empty bins will be represented by NaN.
  - 'count': compute the count of points within each bin. This is identical to an unweighted histogram. `values` array is not referenced.
  - 'sum': compute the sum of values for points within each bin. This is identical to a weighted histogram.
  - 'std': compute the standard deviation within each bin. This is implicitly calculated with `ddof=0`.
  - 'min': compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
  - 'max': compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
  - function: a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by `function([])`, or NaN if this returns an error.
- **bins** [sequence or int, optional] The bin specification must be in one of the following forms:
  - A sequence of arrays describing the bin edges along each dimension.
  - The number of bins for each dimension (nx, ny, ... = bins).
  - The number of bins for all dimensions (nx = ny = ... = bins).
- **range** [sequence, optional] A sequence of lower and upper bin edges to be used if the edges are not given explicitly in `bins`. Defaults to the minimum and maximum values along each dimension.
- **expand_binnumbers** [bool, optional] 'False' (default): the returned `binnumber` is a shape (N,) array of linearized bin indices. 'True': the returned `binnumber` is 'unraveled' into a shape (D,N) ndarray, where each row gives the bin numbers in the corresponding dimension. See the `binnumber` returned value, and the `Examples` section of `binned_statistic_2d`. New in version 0.17.0.
Returns

- **statistic**  [ndarray, shape(nx1, nx2, nx3,…)] The values of the selected statistic in each two-dimensional bin.
- **bin_edges**  [list of ndarrays] A list of D arrays describing the (nxi + 1) bin edges for each dimension.
- **binnumber**  [(N,) array of ints or (D,N) ndarray of ints] This assigns to each element of *sample* an integer that represents the bin in which this observation falls. The representation depends on the `expand_binnumbers` argument. See Notes for details.

See also:

- `numpy.digitize`
- `numpy.histogramdd`
- `binned_statistic`
- `binned_statistic_2d`

Notes

Binedges: All but the last (righthand-most) bin is half-open in each dimension. In other words, if `bins` is `[1, 2, 3, 4]`, then the first bin is `[1, 2)` (including 1, but excluding 2) and the second `[2, 3)`. The last bin, however, is `[3, 4]`, which includes 4.

*binnumber*: This returned argument assigns to each element of *sample* an integer that represents the bin in which it belongs. The representation depends on the `expand_binnumbers` argument. If ‘False’ (default): The returned *binnumber* is a shape (N,) array of linearized indices mapping each element of *sample* to its corresponding bin (using row-major ordering). If ‘True’: The returned *binnumber* is a shape (D,N) ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a binnumber of *i* means the corresponding value is between (bin_edges[D][i-1], bin_edges[D][i]), for each dimension ‘D’.

New in version 0.11.0.

### 6.28.9 Correlation functions

- **f_oneway**(*args*) Performs a 1-way ANOVA.
- **pearsonr**(x, y) Pearson correlation coefficient and p-value for testing non-correlation.
- **spearmanr**(a[, b, axis, nan_policy]) Calculate a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.
- **pointbiserialr**(x, y) Calculate a point biserial correlation coefficient and its p-value.
- **kendalltau**(x, y[, initial_lexsort, …]) Calculate Kendall’s tau, a correlation measure for ordinal data.
- **weightedtau**(x, y[, rank, weigher, additive]) Compute a weighted version of Kendall’s \( \tau \).
- **linregress**(x[, y]) Calculate a linear least-squares regression for two sets of measurements.
- **siegelslopes**(y[, x, method]) Computes the Siegel estimator for a set of points (x, y).
- **theilslopes**(y[, x, alpha]) Computes the Theil-Sen estimator for a set of points (x, y).

**scipy.stats.f_oneway**

**scipy.stats.f_oneway** (*args*)

Performs a 1-way ANOVA.

The one-way ANOVA tests the null hypothesis that two or more groups have the same population mean. The test
is applied to samples from two or more groups, possibly with differing sizes.

**Parameters**

- `sample1, sample2, ...`
  - [array_like] The sample measurements for each group.

**Returns**

- `statistic` [float] The computed F-value of the test.
- `pvalue` [float] The associated p-value from the F-distribution.

**Notes**

The ANOVA test has important assumptions that must be satisfied in order for the associated p-value to be valid.

1. The samples are independent.
2. Each sample is from a normally distributed population.
3. The population standard deviations of the groups are all equal. This property is known as homoscedasticity.

If these assumptions are not true for a given set of data, it may still be possible to use the Kruskal-Wallis H-test ([`scipy.stats.kruskal`]) although with some loss of power.

The algorithm is from Heiman[2], pp.394-7.

**References**

[1], [2], [3]

**Examples**

```python
>>> import scipy.stats as stats

[3] Here are some data on a shell measurement (the length of the anterior adductor muscle scar, standardized by dividing by length) in the mussel Mytilus trossulus from five locations: Tillamook, Oregon; Newport, Oregon; Petersburg, Alaska; Magadan, Russia; and Tvarminne, Finland, taken from a much larger data set used in McDonald et al. (1991).

```python
>>> tillamook = [0.0571, 0.0813, 0.0831, 0.0976, 0.0817, 0.0859, 0.0735, ... 0.0659, 0.0923, 0.0836]
>>> newport = [0.0873, 0.0662, 0.0672, 0.0819, 0.0749, 0.0649, 0.0835, ... 0.0725]
>>> petersburg = [0.0974, 0.1352, 0.0817, 0.1016, 0.0968, 0.1064, 0.105]
>>> magadan = [0.1033, 0.0915, 0.0781, 0.0685, 0.0677, 0.0697, 0.0764, ... 0.0689]
>>> tvarminne = [0.0703, 0.1026, 0.0956, 0.0973, 0.1039, 0.1045]
```

```python
>>> stats.f_oneway(tillamook, newport, petersburg, magadan, tvarminne)
(7.1210194716424473, 0.00028122423145345439)
```
**scipy.stats.pearsonr**

**scipy.stats.pearsonr(x, y)**

Pearson correlation coefficient and p-value for testing non-correlation.

The Pearson correlation coefficient [1] measures the linear relationship between two datasets. The calculation of the p-value relies on the assumption that each dataset is normally distributed. (See Kowalski [3] for a discussion of the effects of non-normality of the input on the distribution of the correlation coefficient.) Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship. Positive correlations imply that as x increases, so does y. Negative correlations imply that as x increases, y decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Pearson correlation at least as extreme as the one computed from these datasets.

**Parameters**

- **x** : [(N,) array_like] Input
- **y** : [(N,) array_like] Input

**Returns**

- **r** : [float] Pearson’s correlation coefficient
- **p-value** : [float] two-tailed p-value

**Warns**

- **PearsonRConstantInputWarning**
  Raised if an input is a constant array. The correlation coefficient is not defined in this case, so `np.nan` is returned.

- **PearsonRNearConstantInputWarning**
  Raised if an input is “nearly” constant. The array x is considered nearly constant if `norm(x - mean(x)) < 1e-13 * abs(mean(x))`. Numerical errors in the calculation `x - mean(x)` in this case might result in an inaccurate calculation of r.

**See also:**

- **spearmanr**
  Spearman rank-order correlation coefficient.

- **kendalltau**
  Kendall’s tau, a correlation measure for ordinal data.

**Notes**

The correlation coefficient is calculated as follows:

\[
    r = \frac{\sum(x - m_x)(y - m_y)}{\sqrt{\sum(x - m_x)^2 \sum(y - m_y)^2}}
\]

where \( m_x \) is the mean of the vector \( x \) and \( m_y \) is the mean of the vector \( y \).

Under the assumption that \( x \) and \( y \) are drawn from independent normal distributions (so the population correlation coefficient is 0), the probability density function of the sample correlation coefficient \( r \) is ([1], [2]):

\[
    f(r) = \frac{(1 - r^2)^{n/2 - 2}}{B(1/2, n/2 - 1)}
\]

### Notes

The correlation coefficient is calculated as follows:

\[
    r = \frac{\sum(x - m_x)(y - m_y)}{\sqrt{\sum(x - m_x)^2 \sum(y - m_y)^2}}
\]

where \( m_x \) is the mean of the vector \( x \) and \( m_y \) is the mean of the vector \( y \).

Under the assumption that \( x \) and \( y \) are drawn from independent normal distributions (so the population correlation coefficient is 0), the probability density function of the sample correlation coefficient \( r \) is ([1], [2]):

\[
    f(r) = \frac{(1 - r^2)^{n/2 - 2}}{B(1/2, n/2 - 1)}
\]
where \( n \) is the number of samples, and \( B \) is the beta function. This is sometimes referred to as the exact distribution of \( r \). This is the distribution that is used in `pearsonr` to compute the p-value. The distribution is a beta distribution on the interval \([-1, 1]\), with equal shape parameters \( a = b = n/2 - 1 \). In terms of SciPy’s implementation of the beta distribution, the distribution of \( r \) is:

\[
dist = \text{scipy.stats.beta}(n/2 - 1, n/2 - 1, \text{loc}=-1, \text{scale}=2)
\]

The p-value returned by `pearsonr` is a two-sided p-value. For a given sample with correlation coefficient \( r \), the p-value is the probability that \( |r'| \) of a random sample \( x' \) and \( y' \) drawn from the population with zero correlation would be greater than or equal to \( |r| \). In terms of the object `dist` shown above, the p-value for a given \( r \) and length \( n \) can be computed as:

\[
p = 2 \times \text{dist.cdf}(-|r|)
\]

When \( n \) is 2, the above continuous distribution is not well-defined. One can interpret the limit of the beta distribution as the shape parameters \( a \) and \( b \) approach \( a = b = 0 \) as a discrete distribution with equal probability masses at \( r = 1 \) and \( r = -1 \). More directly, one can observe that, given the data \( x = [x_1, x_2] \) and \( y = [y_1, y_2] \), and assuming \( x_1 \neq x_2 \) and \( y_1 \neq y_2 \), the only possible values for \( r \) are 1 and -1. Because \( |r'| \) for any sample \( x' \) and \( y' \) with length 2 will be 1, the two-sided p-value for a sample of length 2 is always 1.

References

[1], [2], [3]

Examples

```python
>>> from scipy import stats
>>> a = np.array([0, 0, 1, 1, 1])
>>> b = np.arange(5)
>>> stats.pearsonr(a, b)
(0.8660254037844386, 0.011724811003954649)
```

```python
>>> stats.pearsonr([1, 2, 3, 4, 5], [10, 9, 2.5, 6, 4])
(-0.7426106572325057, 0.1505558088534455)
```

`scipy.stats.spearmanr`

`scipy.stats.spearmanr(a, b=None, axis=0, nan_policy='propagate')`

Calculate a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.

The Spearman correlation is a nonparametric measure of the monotonicity of the relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact monotonic relationship. Positive correlations imply that as \( x \) increases, \( y \) increases. Negative correlations imply that as \( x \) increases, \( y \) decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

Parameters
a, b  [1D or 2D array_like, b is optional] One or two 1-D or 2-D arrays containing multiple variables and observations. When these are 1-D, each represents a vector of observations of a single variable. For the behavior in the 2-D case, see under axis, below. Both arrays need to have the same length in the axis dimension.

axis  [int or None, optional] If axis=0 (default), then each column represents a variable, with observations in the rows. If axis=1, the relationship is transposed: each row represents a variable, while the columns contain observations. If axis=None, then both arrays will be raveled.

nan_policy  [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

Returns

correlation  [float or ndarray (2-D square)] Spearman correlation matrix or correlation coefficient (if only 2 variables are given as parameters). Correlation matrix is square with length equal to total number of variables (columns or rows) in a and b combined.

pvalue  [float] The two-sided p-value for a hypothesis test whose null hypothesis is that two sets of data are uncorrelated, has same dimension as rho.

       [ 0.06435364 , 0.27592895 , 0.        , 0.73039992],
       [ 0.53617935 , 0.80234077 , 0.73039992 , 0.        ]])
>>> rho, pval = stats.spearmanr(x2n.T, y2n.T, axis=1)
>>> rho
array([[ 1.        , 0.05997    , 0.18569457, 0.06258626],
       [ 0.05997    , 1.        , 0.110003   , 0.02534653],
       [ 0.18569457, 0.110003   , 1.        , 0.03488749],
       [ 0.06258626 , 0.02534653, 0.03488749 , 1.        ]])
```

```python
>>> stats.spearmanr(x2n, y2n, axis=None)
(0.10816770419260482, 0.1273562188027364)
>>> stats.spearmanr(x2n.ravel(), y2n.ravel())
(0.10816770419260482, 0.1273562188027364)

>>> xint = np.random.randint(10, size=(100, 2))
>>> stats.spearmanr(xint)
(0.052760927029710199, 0.60213045837062351)
```

**scipy.stats.pointbiserialr**

`scipy.stats.pointbiserialr(x, y)`

Calculate a point biserial correlation coefficient and its p-value.

The point biserial correlation is used to measure the relationship between a binary variable, x, and a continuous variable, y. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply a determinative relationship.

This function uses a shortcut formula but produces the same result as `pearsonr`.

**Parameters**

- `x` [array_like of bools] Input array.
- `y` [array_like] Input array.

**Returns**

- `correlation` [float] R value
- `pvalue` [float] 2-tailed p-value

**Notes**

`pointbiserialr` uses a t-test with n−1 degrees of freedom. It is equivalent to `pearsonr`.

The value of the point-biserial correlation can be calculated from:

\[
\rho_{pb} = \frac{\bar{Y}_1 - \bar{Y}_0}{s_y} \sqrt{\frac{N_1 N_2}{N(N-1)}}
\]

Where \(\bar{Y}_0\) and \(\bar{Y}_1\) are means of the metric observations coded 0 and 1 respectively; \(N_0\) and \(N_1\) are number of observations coded 0 and 1 respectively; \(N\) is the total number of observations and \(s_y\) is the standard deviation of all the metric observations.

A value of \(\rho_{pb}\) that is significantly different from zero is completely equivalent to a significant difference in means between the two groups. Thus, an independent groups t Test with \(N-2\) degrees of freedom may be used to test whether \(\rho_{pb}\) is nonzero. The relation between the t-statistic for comparing two independent groups and \(\rho_{pb}\) is given by:

\[
t = \sqrt{N-2} \frac{\rho_{pb}}{\sqrt{1-\rho_{pb}^2}}
\]

Examples

```python
>>> from scipy import stats
>>> a = np.array([0, 0, 1, 1, 1])
>>> b = np.arange(7)
>>> stats.pointbiserialr(a, b)
(0.8660254037844386, 0.011724811003954652)
>>> stats.pearsonr(a, b)
(0.86602540378443871, 0.011724811003954626)
>>> np.corrcoef(a, b)
array([[ 1. , 0.8660254],
       [ 0.8660254, 1. ]])
```

scipy.stats.kendalltau

`scipy.stats.kendalltau(x, y, initial_lexsort=None, nan_policy='propagate', method='auto')`

Calculate Kendall’s tau, a correlation measure for ordinal data.

Kendall’s tau is a measure of the correspondence between two rankings. Values close to 1 indicate strong agreement, values close to -1 indicate strong disagreement. This is the 1945 “tau-b” version of Kendall’s tau [2], which can account for ties and which reduces to the 1938 “tau-a” version [1] in absence of ties.

**Parameters**

- **x, y** [array_like] Arrays of rankings, of the same shape. If arrays are not 1-D, they will be flattened to 1-D.
- **initial_lexsort** [bool, optional] Unused (deprecated).
- **nan_policy** [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’. Note that if the input contains nan ‘omit’ delegates to mstats.basic.kendalltau(), which has a different implementation.
- **method** : {'auto', 'asymptotic', 'exact'}, optional Defines which method is used to calculate the p-value [5]. ‘asymptotic’ uses a normal approximation valid for large samples. ‘exact’ computes the exact p-value, but can only be used if no ties are present. ‘auto’ is the default and selects the appropriate method based on a trade-off between speed and accuracy.

**Returns**

- **correlation** [float] The tau statistic.
- **pvalue** [float] The two-sided p-value for a hypothesis test whose null hypothesis is an absence of association, tau = 0.

**See also:**

spearmanr

Calculates a Spearman rank-order correlation coefficient.
theilslopes

Computes the Theil-Sen estimator for a set of points \((x, y)\).

weightedtau

Computes a weighted version of Kendall’s tau.

Notes

The definition of Kendall’s tau that is used is [2]:

\[
\tau = \frac{P - Q}{\sqrt{(P + Q + T)(P + Q + U)}}
\]

where \(P\) is the number of concordant pairs, \(Q\) the number of discordant pairs, \(T\) the number of ties only in \(x\), and \(U\) the number of ties only in \(y\). If a tie occurs for the same pair in both \(x\) and \(y\), it is not added to either \(T\) or \(U\).

Examples

```python
>>> from scipy import stats
>>> x1 = [12, 2, 1, 12, 2]
>>> x2 = [1, 4, 7, 1, 0]
>>> tau, p_value = stats.kendalltau(x1, x2)
>>> tau
-0.47140452079103173
>>> p_value
0.2827454599327748
```

scipy.stats.weightedtau

scipy.stats.weightedtau(x, y, rank=True, weigher=None, additive=True)

Compute a weighted version of Kendall’s \(\tau\).

The weighted \(\tau\) is a weighted version of Kendall’s \(\tau\) in which exchanges of high weight are more influential than exchanges of low weight. The default parameters compute the additive hyperbolic version of the index, \(\tau_h\), which has been shown to provide the best balance between important and unimportant elements [1].

The weighting is defined by means of a rank array, which assigns a nonnegative rank to each element, and a weigher function, which assigns a weight based from the rank to each element. The weight of an exchange is then the sum or the product of the weights of the ranks of the exchanged elements. The default parameters compute \(\tau_h\): an exchange between elements with rank \(r\) and \(s\) (starting from zero) has weight \(1/(r + 1) + 1/(s + 1)\).

Specifying a rank array is meaningful only if you have in mind an external criterion of importance. If, as it usually happens, you do not have in mind a specific rank, the weighted \(\tau\) is defined by averaging the values obtained using the decreasing lexicographical rank by \((x, y)\) and by \((y, x)\). This is the behavior with default parameters.

Note that if you are computing the weighted \(\tau\) on arrays of ranks, rather than of scores (i.e., a larger value implies a lower rank) you must negate the ranks, so that elements of higher rank are associated with a larger value.

Parameters
x, y  [array_like] Arrays of scores, of the same shape. If arrays are not 1-D, they will be flattened to 1-D.

rank: array_like of ints or bool, optional
A nonnegative rank assigned to each element. If it is None, the decreasing lexicographical rank by (x, y) will be used: elements of higher rank will be those with larger x-values, using y-values to break ties (in particular, swapping x and y will give a different result). If it is False, the element indices will be used directly as ranks. The default is True, in which case this function returns the average of the values obtained using the decreasing lexicographical rank by (x, y) and by (y, x).

weigher [callable, optional] The weigher function. Must map nonnegative integers (zero representing the most important element) to a nonnegative weight. The default, None, provides hyperbolic weighing, that is, rank r is mapped to weight 1/(r + 1).

additive [bool, optional] If True, the weight of an exchange is computed by adding the weights of the ranks of the exchanged elements; otherwise, the weights are multiplied. The default is True.

Returns

correlation [float] The weighted \( \tau \) correlation index.
pvalue [float] Presently \( \text{np.nan} \), as the null statistics is unknown (even in the additive hyperbolic case).

See also:
kendalltau
Calculates Kendall's tau.
spearmanr
Calculates a Spearman rank-order correlation coefficient.
theilslopes
Computes the Theil-Sen estimator for a set of points (x, y).

Notes

This function uses an \( O(n \log n) \), mergesort-based algorithm [1] that is a weighted extension of Knight's algorithm for Kendall's \( \tau \) [2]. It can compute Shieh's weighted \( \tau \) [3] between rankings without ties (i.e., permutations) by setting additive and rank to False, as the definition given in [1] is a generalization of Shieh's.

NaNs are considered the smallest possible score.

New in version 0.19.0.

References

[1], [2], [3]

Examples

```python
>>> from scipy import stats
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
(continues on next page)```
NaNs are considered the smallest possible score:

```python
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, np.nan]
>>> tau, _ = stats.weightedtau(x, y)
>>> tau
-0.56694968153682723
```

This is exactly Kendall's tau:

```python
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> tau, _ = stats.weightedtau(x, y, weigher=lambda x: 1)
>>> tau
-0.47140452079103173
```

```python
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> stats.weightedtau(x, y, rank=None)
WeightedTauResult(correlation=-0.4157652301037516, pvalue=nan)
```

```python
>>> stats.weightedtau(y, x, rank=None)
WeightedTauResult(correlation=-0.7181341329699028, pvalue=nan)
```

**scipy.stats.linregress**

`scipy.stats.linregress(x, y=None)`

Calculate a linear least-squares regression for two sets of measurements.

**Parameters**

- `x, y` [array_like] Two sets of measurements. Both arrays should have the same length. If only one set is given (and `y=None`), then it must be a two-dimensional array where one dimension has length 2. The two sets of measurements are then found by splitting the array along the length-2 dimension. In the case where `y=None` and `x` is a 2x2 array, `linregress(x)` is equivalent to `linregress(x[0], x[1])`.

**Returns**

- `slope` [float] Slope of the regression line.
- `intercept` [float] Intercept of the regression line.
- `rvalue` [float] Correlation coefficient.
- `pvalue` [float] Two-sided p-value for a hypothesis test whose null hypothesis is that the slope is zero, using Wald Test with t-distribution of the test statistic.
- `stderr` [float] Standard error of the estimated gradient.
See also:

scipy.optimize.curve_fit

Use non-linear least squares to fit a function to data.

scipy.optimize.leastsq

Minimize the sum of squares of a set of equations.

Notes

Missing values are considered pair-wise: if a value is missing in x, the corresponding value in y is masked.

Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy import stats

Generate some data:

```n
>>> np.random.seed(12345678)
>>> x = np.random.random(10)
>>> y = 1.6*x + np.random.random(10)
```

Perform the linear regression:

```
>>> slope, intercept, r_value, p_value, std_err = stats.linregress(x, y)
>>> print("slope: \$f\$n intercept: \$f\n") % (slope, intercept))
```n
slope: 1.944864 intercept: 0.268578

To get coefficient of determination (R-squared):

```
>>> print("R-squared: \$f\n") % r_value**2)
R-squared: 0.735498
```

Plot the data along with the fitted line:

```
>>> plt.plot(x, y, 'o', label='original data')
>>> plt.plot(x, intercept + slope*x, 'r', label='fitted line')
>>> plt.legend()
>>> plt.show()
```

Example for the case where only x is provided as a 2x2 array:

```
>>> x = np.array([[0, 1], [2, 3]])
>>> r = stats.linregress(x)
>>> r.slope, r.intercept
(2.0, 0.0)
```

scipy.stats.siegelslopes

scipy.stats.siegelslopes(y, x=None, method='hierarchical')

Computes the Siegel estimator for a set of points (x, y).
**siegelslopes** implements a method for robust linear regression using repeated medians (see [1]) to fit a line to the points \((x, y)\). The method is robust to outliers with an asymptotic breakdown point of 50%.

**Parameters**

- **y**
  - array_like: Dependent variable.
- **x**
  - array_like or None, optional: Independent variable. If None, use `arange(len(y))` instead.
- **method**
  - ['hierarchical', 'separate']: If 'hierarchical', estimate the intercept using the estimated slope `medslope` (default option). If 'separate', estimate the intercept independent of the estimated slope. See Notes for details.

**Returns**

- **medslope**
  - float: Estimate of the slope of the regression line.
- **medintercept**
  - float: Estimate of the intercept of the regression line.

**See also:**

**theilslopes**

a similar technique without repeated medians

**Notes**

With \(n = \text{len}(y)\), compute \(m_j\) as the median of the slopes from the point \((x[j], y[j])\) to all other \(n-1\) points. `medslope` is then the median of all slopes \(m_j\). Two ways are given to estimate the intercept in [1] which can be chosen via the parameter `method`. The hierarchical approach uses the estimated slope `medslope` and computes `medintercept` as the median of \(y - medslope \cdot x\). The other approach estimates the intercept separately as follows: for each point \((x[j], y[j])\), compute the intercepts of all the \(n-1\) lines through the remaining points and take the median \(i_j\). `medintercept` is the median of the \(i_j\).

The implementation computes \(n\) times the median of a vector of size \(n\) which can be slow for large vectors. There are more efficient algorithms (see [2]) which are not implemented here.
References

[1], [2]

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt

>>> x = np.linspace(-5, 5, num=150)
>>> y = x + np.random.normal(size=x.size)
>>> y[11:15] += 10  # add outliers
>>> y[-5:] -= 7

Compute the slope and intercept. For comparison, also compute the least-squares fit with `linregress`:

```python
>>> res = stats.siegelslopes(y, x)
>>> lsq_res = stats.linregress(x, y)
```

Plot the results. The Siegel regression line is shown in red. The green line shows the least-squares fit for comparison.

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, y, 'b')
>>> ax.plot(x, res[1] + res[0] * x, 'r-')
>>> ax.plot(x, lsq_res[1] + lsq_res[0] * x, 'g-')
>>> plt.show()
```

**scipy.stats.theilslopes**

`scipy.stats.theilslopes`(y, x=None, alpha=0.95)

Computes the Theil-Sen estimator for a set of points (x, y).
theilslopes implements a method for robust linear regression. It computes the slope as the median of all slopes between paired values.

**Parameters**

- `y` [array_like] Dependent variable.
- `x` [array_like or None, optional] Independent variable. If None, use `arange(len(y))` instead.
- `alpha` [float, optional] Confidence degree between 0 and 1. Default is 95% confidence. Note that `alpha` is symmetric around 0.5, i.e. both 0.1 and 0.9 are interpreted as “find the 90% confidence interval”.

**Returns**

- `medslope` [float] Theil slope.
- `medintercept` [float] Intercept of the Theil line, as `median(y) - medslope*median(x)`.
- `lo_slope` [float] Lower bound of the confidence interval on `medslope`.
- `up_slope` [float] Upper bound of the confidence interval on `medslope`.

See also:

- siegelslopes
  a similar technique using repeated medians

**Notes**

The implementation of theilslopes follows [1]. The intercept is not defined in [1], and here it is defined as `median(y) - medslope*median(x)`, which is given in [3]. Other definitions of the intercept exist in the literature. A confidence interval for the intercept is not given as this question is not addressed in [1].

**References**

[1], [2], [3]

**Examples**

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt

>>> x = np.linspace(-5, 5, num=150)
>>> y = x + np.random.normal(size=x.size)
>>> y[11:15] += 10  # add outliers
>>> y[-5:] -= 7

Compute the slope, intercept and 90% confidence interval. For comparison, also compute the least-squares fit with linregress:
```
```
Plot the results. The Theil-Sen regression line is shown in red, with the dashed red lines illustrating the confidence interval of the slope (note that the dashed red lines are not the confidence interval of the regression as the confidence interval of the intercept is not included). The green line shows the least-squares fit for comparison.

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, y, 'b.'
>>> ax.plot(x, res[1] + res[0] * x, 'r-')
>>> ax.plot(x, lsq_res[1] + lsq_res[0] * x, 'g-')
>>> plt.show()
```

scipy.stats.ttest_1samp

scipy.stats.ttest_1samp(a, popmean, axis=0, nan_policy='propagate')

Calculate the T-test for the mean of ONE group of scores.

This is a two-sided test for the null hypothesis that the expected value (mean) of a sample of independent observations \( a \) is equal to the given population mean, \( \text{popmean} \).

Parameters

- **a** [array_like] sample observation
- **popmean** [float or array_like] expected value in null hypothesis. If array_like, then it must have the same shape as \( a \) excluding the axis dimension
- **axis** [int or None, optional] Axis along which to compute test. If None, compute over the whole array \( a \).
- **nan_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

Returns

- **statistic** [float or array] t-statistic
- **pvalue** [float or array] two-tailed p-value

Examples

```python
from scipy import stats
np.random.seed(7654567)  # fix seed to get the same result
rvs = stats.norm.rvs(loc=5, scale=10, size=(50, 2))

Test if mean of random sample is equal to true mean, and different mean. We reject the null hypothesis in the second case and don’t reject it in the first case.

>>> stats.ttest_1samp(rvs, 5.0)
(array([-0.68014479, -0.04323899]), array([ 0.49961383, 0.96568674]))
```

(continues on next page)
Examples using axis and non-scalar dimension for population mean.

```python
>>> stats.ttest_1samp(rvs, [5.0, 0.0])
(array([-0.68014479, 1.11038784]), array([ 4.9613833e-01, 1.
  9.49986458e-04]))
```  

```python
>>> stats.ttest_1samp(rvs.T, [5.0, 0.0], axis=1)
(array([-0.68014479, 1.11038784]), array([ 4.9613833e-01, 1.
  9.49986458e-04]))
```  

```python
>>> stats.ttest_1samp(rvs, [[5.0], [0.0]])
(array([-0.68014479, -0.04323899],
  [ 2.77025808, 1.11038784]), array([ 4.9613833e-01, 1.
  9.6568743e-03, 1.49986458e-04]))
```  

**scipy.stats.ttest_ind**

`scipy.stats.ttest_ind(a, b, axis=0, equal_var=True, nan_policy='propagate')`

Calculate the T-test for the means of two independent samples of scores.

This is a two-sided test for the null hypothesis that 2 independent samples have identical average (expected) values. This test assumes that the populations have identical variances by default.

**Parameters**

- `a, b` [array_like] The arrays must have the same shape, except in the dimension corresponding to `axis` (the first, by default).
- `axis` [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, `a`, and `b`.
- `equal_var` [bool, optional] If True (default), perform a standard independent 2 sample test that assumes equal population variances [1]. If False, perform Welch’s t-test, which does not assume equal population variance [2]. New in version 0.11.0.

**Returns**

- `statistic` [float or array] The calculated t-statistic.
- `pvalue` [float or array] The two-tailed p-value.

**Notes**

We can use this test, if we observe two independent samples from the same or different population, e.g. exam scores of boys and girls or of two ethnic groups. The test measures whether the average (expected) value differs significantly across samples. If we observe a large p-value, for example larger than 0.05 or 0.1, then we cannot reject the null hypothesis of identical average scores. If the p-value is smaller than the threshold, e.g. 1%, 5% or 10%, then we reject the null hypothesis of equal averages.
References

[1], [2]

Examples

```python
>>> from scipy import stats
>>> np.random.seed(12345678)

Test with sample with identical means:

```python
>>> rvs1 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> rvs2 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> stats.ttest_ind(rvs1, rvs2)
(0.26833823296239279, 0.7884944369564776)
>>> stats.ttest_ind(rvs1, rvs2, equal_var=False)
(0.26833823296239279, 0.788495274500748)
```

`ttest_ind` underestimates p for unequal variances:

```python
>>> rvs3 = stats.norm.rvs(loc=5, scale=20, size=500)
>>> stats.ttest_ind(rvs1, rvs3)
(-0.46580283298287162, 0.64149652749500748)
>>> stats.ttest_ind(rvs1, rvs3, equal_var=False)
(-0.46580283298287162, 0.6414956246569292)
```

When \( n_1 \neq n_2 \), the equal variance t-statistic is no longer equal to the unequal variance t-statistic:

```python
>>> rvs4 = stats.norm.rvs(loc=5, scale=20, size=100)
>>> stats.ttest_ind(rvs1, rvs4)
(-0.9988253942782481, 0.31823709103896)
>>> stats.ttest_ind(rvs1, rvs4, equal_var=False)
(-0.9988253942782481, 0.31823709103896)
```

T-test with different means, variance, and n:

```python
>>> rvs5 = stats.norm.rvs(loc=8, scale=20, size=100)
>>> stats.ttest_ind(rvs1, rvs5)
(-1.4679669854490653, 0.1426389562052915)
>>> stats.ttest_ind(rvs1, rvs5, equal_var=False)
(-1.4679669854490653, 0.1426389562052915)
```

`scipy.stats.ttest_ind_from_stats`

`scipy.stats.ttest_ind_from_stats` (mean1, std1, nobs1, mean2, std2, nobs2, equal_var=True)

T-test for means of two independent samples from descriptive statistics.

This is a two-sided test for the null hypothesis that two independent samples have identical average (expected) values.

**Parameters**

- `mean1` [array_like] The mean(s) of sample 1.
- `std1` [array_like] The standard deviation(s) of sample 1.
SciPy Reference Guide, Release 1.3.2

.. _ttest_ind:

.. _t-test:

.. _two-sample test:

.. _Welch's test:

.. _equal population variance:

.. _Welch's t-test:

.. _assumes equal population variances:

.. _does not assume equal population variance:

.. _two-tailed p-value:

.. _scipy.stats.ttest_ind:

.. _scipy.stats.ttest_ind_from_stats:

Fields

- nobs1 [array_like] The number(s) of observations of sample 1.
- mean2 [array_like] The mean(s) of sample 2
- std2 [array_like] The standard deviations(s) of sample 2.
- nobs2 [array_like] The number(s) of observations of sample 2.
- equal_var [bool, optional] If True (default), perform a standard independent 2 sample test that assumes equal population variances [1]. If False, perform Welch's t-test, which does not assume equal population variance [2].

Returns

- statistic [float or array] The calculated t-statistics
- pvalue [float or array] The two-tailed p-value.

[1], [2]

Examples

Suppose we have the summary data for two samples, as follows:

<table>
<thead>
<tr>
<th></th>
<th>Sample 1</th>
<th>Sample 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Size</td>
<td>13</td>
<td>11</td>
</tr>
<tr>
<td>Mean</td>
<td>15.0</td>
<td>12.0</td>
</tr>
<tr>
<td>Variance</td>
<td>87.5</td>
<td>39.0</td>
</tr>
</tbody>
</table>

Apply the t-test to this data (with the assumption that the population variances are equal):

```python
>>> from scipy.stats import ttest_ind_from_stats
>>> ttest_ind_from_stats(mean1=15.0, std1=np.sqrt(87.5), nobs1=13,
...                      mean2=12.0, std2=np.sqrt(39.0), nobs2=11)
Ttest_indResult(statistic=0.9051358093310269, pvalue=0.3751996797581487)
```

For comparison, here is the data from which those summary statistics were taken. With this data, we can compute the same result using :func:`~scipy.stats.ttest_ind`:

```python
>>> a = np.array([1, 3, 4, 6, 11, 13, 15, 19, 22, 24, 25, 26, 26])
>>> b = np.array([2, 4, 6, 9, 11, 13, 14, 15, 18, 19, 21])
>>> from scipy.stats import ttest_ind
>>> ttest_ind(a, b)
Ttest_indResult(statistic=0.905135809331027, pvalue=0.3751996797581486)
```
scipy.stats.ttest_rel

scipy.stats.ttest_rel(a, b, axis=0, nan_policy='propagate')

Calculate the T-test on TWO RELATED samples of scores, a and b.

This is a two-sided test for the null hypothesis that 2 related or repeated samples have identical average (expected) values.

**Parameters**

- `a, b` [array_like] The arrays must have the same shape.
- `axis` [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, a, and b.
- `nan_policy` ['propagate', 'raise', 'omit', optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- `statistic` [float or array] t-statistic
- `pvalue` [float or array] two-tailed p-value

**Notes**

Examples for the use are scores of the same set of student in different exams, or repeated sampling from the same units. The test measures whether the average score differs significantly across samples (e.g. exams). If we observe a large p-value, for example greater than 0.05 or 0.1 then we cannot reject the null hypothesis of identical average scores. If the p-value is smaller than the threshold, e.g. 1%, 5% or 10%, then we reject the null hypothesis of equal averages. Small p-values are associated with large t-statistics.

**References**

https://en.wikipedia.org/wiki/T-test#Dependent_t-test_for_Paired_Samples

**Examples**

```python
>>> from scipy import stats
>>> np.random.seed(12345678) # fix random seed to get same numbers

>>> rvs1 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> rvs2 = (stats.norm.rvs(loc=5, scale=10, size=500) +
...         stats.norm.rvs(scale=0.2, size=500))
>>> stats.ttest_rel(rvs1, rvs2)
(0.24101764965300962, 0.80964043445811562)
>>> rvs3 = (stats.norm.rvs(loc=8, scale=10, size=500) +
...         stats.norm.rvs(scale=0.2, size=500))
>>> stats.ttest_rel(rvs1, rvs3)
(-3.9995108708727933, 7.3082402191726459e-005)
```
scipy.stats.kstest

Perform the Kolmogorov-Smirnov test for goodness of fit.

This performs a test of the distribution F(x) of an observed random variable against a given distribution G(x). Under the null hypothesis the two distributions are identical, F(x)=G(x). The alternative hypothesis can be either ‘two-sided’ (default), ‘less’ or ‘greater’. The KS test is only valid for continuous distributions.

Parameters

- **rvs** [str, array or callable] If a string, it should be the name of a distribution in `scipy.stats`. If an array, it should be a 1-D array of observations of random variables. If a callable, it should be a function to generate random variables; it is required to have a keyword argument `size`.
- **cdf** [str or callable] If a string, it should be the name of a distribution in `scipy.stats`. If `rvs` is a string then `cdf` can be False or the same as `rvs`. If a callable, that callable is used to calculate the cdf.
- **args** [tuple, sequence, optional] Distribution parameters, used if `rvs` or `cdf` are strings.
- **N** [int, optional] Sample size if `rvs` is string or callable. Default is 20.
- **alternative** [‘two-sided’, ‘less’, ‘greater’], optional] Defines the alternative hypothesis (see explanation above). Default is ‘two-sided’.
- **mode** [‘approx’ (default) or ‘asymp’, optional] Defines the distribution used for calculating the p-value.
  - ‘approx’: use approximation to exact distribution of test statistic
  - ‘asymp’: use asymptotic distribution of test statistic

Returns

- **statistic** [float] KS test statistic, either D, D+ or D-.
- **pvalue** [float] One-tailed or two-tailed p-value.

Notes

In the one-sided test, the alternative is that the empirical cumulative distribution function of the random variable is “less” or “greater” than the cumulative distribution function G(x) of the hypothesis, F(x) <= G(x), resp. F(x) >= G(x).

Examples

```python
>>> from scipy import stats

>>> x = np.linspace(-15, 15, 9)
>>> stats.kstest(x, 'norm')
(0.44435602715924361, 0.038850142705171065)

>>> np.random.seed(987654321)  # set random seed to get the same result
>>> stats.kstest('norm', False, N=100)
(0.058352892479417884, 0.88531190944151261)
```

The above lines are equivalent to:
Test against one-sided alternative hypothesis

Shift distribution to larger values, so that \( \text{cdf}_\text{dgp}(x) < \text{norm.cdf}(x) \):

```python
>>> np.random.seed(987654321)
>>> x = stats.norm.rvs(loc=0.2, size=100)
>>> stats.kstest(x, 'norm', alternative = 'less')
(0.12464329735846891, 0.040989164077641749)
```

Reject equal distribution against alternative hypothesis: less

Don't reject equal distribution against alternative hypothesis: greater

```python
>>> stats.kstest(x, 'norm', alternative = 'greater')
(0.0072115233216311081, 0.98531158590396395)
```

Testing \( t \) distributed random variables against normal distribution

With 100 degrees of freedom the \( t \) distribution looks close to the normal distribution, and the K-S test does not reject the hypothesis that the sample came from the normal distribution:

```python
>>> np.random.seed(987654321)
>>> stats.kstest(stats.t.rvs(100, size=100), 'norm')
(0.072018929165471257, 0.67630062862479168)
```

With 3 degrees of freedom the \( t \) distribution looks sufficiently different from the normal distribution, that we can reject the hypothesis that the sample came from the normal distribution at the 10% level:

```python
>>> np.random.seed(987654321)
>>> stats.kstest(stats.t.rvs(3, size=100), 'norm')
(0.131016895759829, 0.058826222555312224)
```

### scipy.stats.chisquare

#### scipy.stats.chisquare \( f_{\text{obs}}, f_{\text{exp}}=\text{None}, \text{ddof}=0, \text{axis}=0 \)

Calculate a one-way chi square test.

The chi square test tests the null hypothesis that the categorical data has the given frequencies.

**Parameters**

- **f_obs**  
  [array_like] Observed frequencies in each category.

- **f_exp**  
  [array_like, optional] Expected frequencies in each category. By default the categories are assumed to be equally likely.

- **ddof**  
  [int, optional] “Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with \( k - 1 - \text{ddof} \) degrees of freedom, where \( k \) is the number of observed frequencies. The default value of \( \text{ddof} \) is 0.
**axis**  [int or None, optional] The axis of the broadcast result of *f_obs* and *f_exp* along which to apply the test. If axis is None, all values in *f_obs* are treated as a single data set. Default is 0.

**Returns**

- **chisq**  [float or ndarray] The chi-squared test statistic. The value is a float if *axis* is None or *f_obs* and *f_exp* are 1-D.
- **p**  [float or ndarray] The p-value of the test. The value is a float if *ddof* and the return value *chisq* are scalars.

**See also:**

- `scipy.stats.power_divergence`

**Notes**

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

The default degrees of freedom, k-1, are for the case when no parameters of the distribution are estimated. If *p* parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are k-1-*p*. If the parameters are estimated in a different way, then the dof can be between k-1-*p* and k-1. However, it is also possible that the asymptotic distribution is not a chisquare, in which case this test is not appropriate.

**References**

[1], [2]

**Examples**

When just *f_obs* is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies.

```python
>>> from scipy.stats import chisquare
>>> chisquare([16, 18, 16, 14, 12, 12])
(2.0, 0.84914503608460956)
```

With *f_exp* the expected frequencies can be given.

```python
>>> chisquare([16, 18, 16, 14, 12, 12], f_exp=[16, 16, 16, 16, 16, 8])
(3.5, 0.62338762774958223)
```

When *f_obs* is 2-D, by default the test is applied to each column.

```python
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]]).T
>>> obs.shape
(6, 2)
>>> chisquare(obs)
(array([ 2. , 6.66666667]), array([ 0.84914504, 0.24663415]))
```

By setting axis=None, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.
```python
>>> chisquare(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> chisquare(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

`ddof` is the change to make to the default degrees of freedom.

```python
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.7357588234288467)
```

The calculation of the p-values is done by broadcasting the chi-squared statistic with `ddof`.

```python
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504, 0.73575888, 0.5724067 ]))
```

`f_obs` and `f_exp` are also broadcast. In the following, `f_obs` has shape (6,) and `f_exp` has shape (2, 6), so the result of broadcasting `f_obs` and `f_exp` has shape (2, 6). To compute the desired chi-squared statistics, we use `axis=1`:

```python
>>> chisquare([16, 18, 16, 14, 12, 12],
...    f_exp=[[16, 16, 16, 16, 16, 8], [8, 20, 20, 16, 12, 12]],
...    axis=1)
(array([ 3.5 , 9.25]), array([ 0.62338763, 0.09949846]))
```

### scipy.stats.power_divergence

`scipy.stats.power_divergence` is equivalent to `stats.chisquare`.

This function tests the null hypothesis that the categorical data has the given frequencies, using the Cressie-Read power divergence statistic.

#### Parameters

- `f_obs` : [array_like] Observed frequencies in each category.
- `f_exp` : [array_like, optional] Expected frequencies in each category. By default the categories are assumed to be equally likely.
- `ddof` : [int, optional] “Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with \( k - 1 - ddof \) degrees of freedom, where \( k \) is the number of observed frequencies. The default value of `ddof` is 0.
- `axis` : [int or None, optional] The axis of the broadcast result of `f_obs` and `f_exp` along which to apply the test. If `axis` is None, all values in `f_obs` are treated as a single dataset. Default is 0.
- `lambda_` : [float or str, optional] `lambda_` gives the power in the Cressie-Read power divergence statistic. The default is 1. For convenience, `lambda_` may be assigned one of the following strings, in which case the corresponding numerical value is used:

<table>
<thead>
<tr>
<th>String</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;pearson&quot;</td>
<td>1</td>
<td>Pearson’s chi-squared statistic.</td>
</tr>
<tr>
<td>&quot;chisquare&quot;</td>
<td></td>
<td>In this case, the function is equivalent to ‘stats.chisquare’.</td>
</tr>
<tr>
<td>&quot;log-likelihood&quot;</td>
<td>0</td>
<td>Log-likelihood ratio. Also known as &quot;loglikelihood&quot;.</td>
</tr>
</tbody>
</table>

(continues on next page)
the G-test.
"freeman-tukey" -1/2 Freeman-Tukey statistic.
"mod-log-likelihood" -1 Modified log-likelihood ratio.
"neyman" -2 Neyman's statistic.
"cressie-read" 2/3 The power recommended in...

Returns

- **statistic**: [float or ndarray] The Cressie-Read power divergence test statistic. The value is a float if `axis` is None or if `f_obs` and `f_exp` are 1-D.
- **pvalue**: [float or ndarray] The p-value of the test. The value is a float if `ddof` and the return value `stat` are scalars.

See also:

- chisquare

Notes

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

When `lambda_` is less than zero, the formula for the statistic involves dividing by `f_obs`, so a warning or error may be generated if any value in `f_obs` is 0.

Similarly, a warning or error may be generated if any value in `f_exp` is zero when `lambda_` >= 0.

The default degrees of freedom, k-1, are for the case when no parameters of the distribution are estimated. If p parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are k-1-p. If the parameters are estimated in a different way, then the dof can be between k-1-p and k-1. However, it is also possible that the asymptotic distribution is not a chi-square, in which case this test is not appropriate.

This function handles masked arrays. If an element of `f_obs` or `f_exp` is masked, then data at that position is ignored, and does not count towards the size of the data set.

New in version 0.13.0.

References

[1], [2], [3], [4], [5]

Examples

(See chisquare for more examples.)

When just `f_obs` is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies. Here we perform a G-test (i.e. use the log-likelihood ratio statistic):

```python
>>> from scipy.stats import power_divergence
>>> power_divergence([16, 18, 16, 14, 12], lambda_='log-likelihood')
(2.006573162632538, 0.84823476779463769)
```

The expected frequencies can be given with the `f_exp` argument:
When \( f_{\text{obs}} \) is 2-D, by default the test is applied to each column.

```
>>> obs = np.array([[16, 18, 16, 14, 12, 12],
                  [32, 24, 16, 28, 20, 24]]).T
>>> obs.shape
(6, 2)
>>> power_divergence(obs, lambda_="log-likelihood")
(array([ 2.00657316,  6.77634498]), array([ 0.84823477,  0.23781225]))
```

By setting `axis=None`, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```
>>> power_divergence(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> power_divergence(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

`ddof` is the change to make to the default degrees of freedom.

```
>>> power_divergence([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the test statistic with `ddof`.

```
>>> power_divergence([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504,  0.73575888,  0.5724067 ]))
```

`f_{\text{obs}}` and `f_{\text{exp}}` are also broadcast. In the following, \( f_{\text{obs}} \) has shape (6,) and \( f_{\text{exp}} \) has shape (2, 6), so the result of broadcasting \( f_{\text{obs}} \) and \( f_{\text{exp}} \) has shape (2, 6). To compute the desired chi-squared statistics, we must use `axis=1`:

```
>>> power_divergence([16, 18, 16, 14, 12, 12],
                    ...                      f_exp=[[16, 16, 16, 16, 16, 8],
                      ...                      [8, 20, 20, 16, 12, 12]],
                    ...                      axis=1)
(array([ 3.5 ,  9.25]), array([ 0.62338763,  0.09949846]))
```

**scipy.stats.ks_2samp**

`scipy.stats.ks_2samp(data1, data2, alternative='two-sided', mode='auto')`

Compute the Kolmogorov-Smirnov statistic on 2 samples.

This is a two-sided test for the null hypothesis that 2 independent samples are drawn from the same continuous distribution. The alternative hypothesis can be either ‘two-sided’ (default), ‘less’ or ‘greater’.

**Parameters**

- `data1, data2` [sequence of 1-D ndarrays] Two arrays of sample observations assumed to be drawn from a continuous distribution, sample sizes can be different.
alternative

[{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis (see explanation above). Default is ‘two-sided’.

mode

[{'auto', 'exact', 'asymp'}, optional] Defines the method used for calculating the p-value. Default is ‘auto’.
- ‘exact’: use approximation to exact distribution of test statistic
- ‘asymp’: use asymptotic distribution of test statistic
- ‘auto’: use ‘exact’ for small size arrays, ‘asymp’ for large.

Returns

statistic [float] KS statistic
pvalue [float] two-tailed p-value

Notes

This tests whether 2 samples are drawn from the same distribution. Note that, like in the case of the one-sample K-S test, the distribution is assumed to be continuous.

In the one-sided test, the alternative is that the empirical cumulative distribution function \( F(x) \) of the data1 variable is “less” or “greater” than the empirical cumulative distribution function \( G(x) \) of the data2 variable, \( F(x) \leq G(x) \), resp. \( F(x) \geq G(x) \).

If the K-S statistic is small or the p-value is high, then we cannot reject the hypothesis that the distributions of the two samples are the same.

If the mode is ‘auto’, the computation is exact if the sample sizes are less than 10000. For larger sizes, the computation uses the Kolmogorov-Smirnov distributions to compute an approximate value.

We generally follow Hodges’ treatment of Drion/Gnedenko/Korolyuk [1].

References

[1]

Examples

```python
>>> from scipy import stats
>>> np.random.seed(12345678)  # fix random seed to get the same result
>>> n1 = 200  # size of first sample
>>> n2 = 300  # size of second sample
```

For a different distribution, we can reject the null hypothesis since the pvalue is below 1%:

```python
>>> rvs1 = stats.norm.rvs(size=n1, loc=0., scale=1)
>>> rvs2 = stats.norm.rvs(size=n2, loc=0.5, scale=1.5)
>>> stats.ks_2samp(rvs1, rvs2)
(0.20833333333333334, 5.129279597781977e-05)
```

For a slightly different distribution, we cannot reject the null hypothesis at a 10% or lower alpha since the p-value at 0.144 is higher than 10%
```python
>>> rvs3 = stats.norm.rvs(size=n2, loc=0.01, scale=1.0)
>>> stats.ks_2samp(rvs1, rvs3)
(0.10333333333333333, 0.14691437867433876)
```

For an identical distribution, we cannot reject the null hypothesis since the p-value is high, 41%:

```python
>>> rvs4 = stats.norm.rvs(size=n2, loc=0.0, scale=1.0)
>>> stats.ks_2samp(rvs1, rvs4)
(0.07999999999999996, 0.41126949729859719)
```

### scipy.stats.epps_singleton_2samp

```python
scipy.stats.epps_singleton_2samp(x, y, t=(0.4, 0.8))
```

Compute the Epps-Singleton (ES) test statistic.

Test the null hypothesis that two samples have the same underlying probability distribution.

**Parameters**

- **x, y** [array-like] The two samples of observations to be tested. Input must not have more than one dimension. Samples can have different lengths.
- **t** [array-like, optional] The points (t₁, ..., tₙ) where the empirical characteristic function is to be evaluated. It should be positive distinct numbers. The default value (0.4, 0.8) is proposed in [1]. Input must not have more than one dimension.

**Returns**

- **statistic** [float] The test statistic.
- **pvalue** [float] The associated p-value based on the asymptotic chi²-distribution.

**See also:**

- `ks_2samp`, `anderson_ksamp`

**Notes**

Testing whether two samples are generated by the same underlying distribution is a classical question in statistics. A widely used test is the Kolmogorov-Smirnov (KS) test which relies on the empirical distribution function. Epps and Singleton introduce a test based on the empirical characteristic function in [1].

One advantage of the ES test compared to the KS test is that it does not assume a continuous distribution. In [1], the authors conclude that the test also has a higher power than the KS test in many examples. They recommend the use of the ES test for discrete samples as well as continuous samples with at least 25 observations each, whereas `anderson_ksamp` is recommended for smaller sample sizes in the continuous case.

The p-value is computed from the asymptotic distribution of the test statistic which follows a chi² distribution. If the sample size of both x and y is below 25, the small sample correction proposed in [1] is applied to the test statistic.

The default values of t are determined in [1] by considering various distributions and finding good values that lead to a high power of the test in general. Table III in [1] gives the optimal values for the distributions tested in that study. The values of t are scaled by the semi-interquartile range in the implementation, see [1].

[1], [2]

scipy.stats.mannwhitneyu

scipy.stats.mannwhitneyu(x, y, use_continuity=True, alternative=None)

Compute the Mann-Whitney rank test on samples x and y.

Parameters

- x, y [array_like] Array of samples, should be one-dimensional.
- use_continuity [bool, optional] Whether a continuity correction (1/2.) should be taken into account. Default is True.
- alternative [None (deprecated), 'less', 'two-sided', or 'greater'] Whether to get the p-value for the one-sided hypothesis ('less' or 'greater') or for the two-sided hypothesis ('two-sided'). Defaults to None, which results in a p-value half the size of the 'two-sided' p-value and a different U statistic. The default behavior is not the same as using 'less' or 'greater': it only exists for backward compatibility and is deprecated.

Returns

- statistic [float] The Mann-Whitney U statistic, equal to min(U for x, U for y) if alternative is equal to None (deprecated; exists for backward compatibility), and U for y otherwise.
- pvalue [float] p-value assuming an asymptotic normal distribution. One-sided or two-sided, depending on the choice of alternative.

Notes

Use only when the number of observation in each sample is > 20 and you have 2 independent samples of ranks. Mann-Whitney U is significant if the u-obtained is LESS THAN or equal to the critical value of U.

This test corrects for ties and by default uses a continuity correction.

References

[1], [2]

scipy.stats.tiecorrect

scipy.stats.tiecorrect(rankvals)

Tie correction factor for ties in the Mann-Whitney U and Kruskal-Wallis H tests.

Parameters

- rankvals [array_like] A 1-D sequence of ranks. Typically this will be the array returned by rankdata.

Returns

- factor [float] Correction factor for U or H.

See also:
rankdata
Assign ranks to the data

mannwhitneyu
Mann-Whitney rank test

kruskal
Kruskal-Wallis H test

References

[1]

Examples

```python
>>> from scipy.stats import tiecorrect, rankdata
>>> tiecorrect([1, 2.5, 2.5, 4])
0.9
>>> ranks = rankdata([1, 3, 2, 4, 5, 2, 8, 4], method='average')
>>> ranks
array([ 1. , 4. , 2.5, 5.5, 7. , 8. , 2.5, 9. , 5.5])
>>> tiecorrect(ranks)
0.9833333333333333
```

scipy.stats.rankdata

scipy.stats.rankdata(a, method='average')
Assign ranks to data, dealing with ties appropriately.

Ranks begin at 1. The method argument controls how ranks are assigned to equal values. See [1] for further discussion of ranking methods.

Parameters

- `a` [array_like] The array of values to be ranked. The array is first flattened.
- `method` [str, optional] The method used to assign ranks to tied elements. The options are ‘average’, ‘min’, ‘max’, ‘dense’ and ‘ordinal’.
  - ‘average’: The average of the ranks that would have been assigned to all the tied values is assigned to each value.
  - ‘min’: The minimum of the ranks that would have been assigned to all the tied values is assigned to each value. (This is also referred to as “competition” ranking.)
  - ‘max’: The maximum of the ranks that would have been assigned to all the tied values is assigned to each value.
  - ‘dense’: Like ‘min’, but the rank of the next highest element is assigned the rank immediately after those assigned to the tied elements.
  - ‘ordinal’: All values are given a distinct rank, corresponding to the order that the values occur in `a`.
  The default is ‘average’.

Returns

- `ranks` [ndarray] An array of length equal to the size of `a`, containing rank scores.
References

[1]

Examples

```python
>>> from scipy.stats import rankdata
>>> rankdata([0, 2, 3, 2])
array([ 1. , 2.5, 4. , 2.5])
>>> rankdata([0, 2, 3, 2], method='min')
array([ 1, 2, 4, 2])
>>> rankdata([0, 2, 3, 2], method='max')
array([ 1, 3, 4, 3])
>>> rankdata([0, 2, 3, 2], method='dense')
array([ 1, 2, 3, 2])
>>> rankdata([0, 2, 3, 2], method='ordinal')
array([ 1, 2, 4, 3])
```

scipy.stats.ranksums

`scipy.stats.ranksums(x, y)`

Compute the Wilcoxon rank-sum statistic for two samples.

The Wilcoxon rank-sum test tests the null hypothesis that two sets of measurements are drawn from the same
distribution. The alternative hypothesis is that values in one sample are more likely to be larger than the values in
the other sample.

This test should be used to compare two samples from continuous distributions. It does not handle ties
between measurements in x and y. For tie-handling and an optional continuity correction see `scipy.stats.
mannwhitneyu`.

**Parameters**

- `x, y` [array_like] The data from the two samples

**Returns**

- `statistic` [float] The test statistic under the large-sample approximation that the rank sum statistic is
  normally distributed
- `pvalue` [float] The two-sided p-value of the test

References

[1]

scipy.stats.wilcoxon

`scipy.stats.wilcoxon(x, y=None, zero_method='wilcox', correction=False, alternative='two-sided')`

Calculate the Wilcoxon signed-rank test.

The Wilcoxon signed-rank test tests the null hypothesis that two related paired samples come from the same
distribution. In particular, it tests whether the distribution of the differences x - y is symmetric about zero. It is a
non-parametric version of the paired T-test.
Parameters

x [array_like] Either the first set of measurements (in which case y is the second set of measurements), or the differences between two sets of measurements (in which case y is not to be specified.) Must be one-dimensional.

y [array_like, optional] Either the second set of measurements (if x is the first set of measurements), or not specified (if x is the differences between two sets of measurements.) Must be one-dimensional.

zero_method [{“pratt”, “wilcox”, “zsplit”}, optional. Default is “wilcox.”]

"pratt": includes zero-differences in the ranking process, but drops the ranks of the zeros, see [4], (more conservative)

"wilcox": discards all zero-differences, the default

"zsplit": includes zero-differences in the ranking process and split the zero rank between positive and negative ones

correction [bool, optional] If True, apply continuity correction by adjusting the Wilcoxon rank statistic by 0.5 towards the mean value when computing the z-statistic. Default is False.

alternative [{“two-sided”, “greater”, “less”}, optional] The alternative hypothesis to be tested, see Notes. Default is “two-sided”.

Returns

statistic [float] If alternative is “two-sided”, the sum of the ranks of the differences above or below zero, whichever is smaller. Otherwise the sum of the ranks of the differences above zero.

pvalue [float] The p-value for the test depending on alternative.

See also:

kruskal, mannwhitneyu

Notes

The test has been introduced in [4]. Given n independent samples (xi, yi) from a bivariate distribution (i.e. paired samples), it computes the differences di = xi - yi. One assumption of the test is that the differences are symmetric, see [2]. The two-sided test has the null hypothesis that the median of the differences is zero against the alternative that it is different from zero. The one-sided test has the null hypothesis that the median is positive against the alternative that it is negative (alternative == ‘less’), or vice versa (alternative == ‘greater’).

The test uses a normal approximation to derive the p-value (if zero_method == ‘pratt’, the approximation is adjusted as in [5]). A typical rule is to require that n > 20 ([2], p. 383). For smaller n, exact tables can be used to find critical values.

References

[1], [2], [3], [4], [5]

Examples

In [4], the differences in height between cross- and self-fertilized corn plants is given as follows:

```python
>>> d = [6, 8, 14, 16, 23, 24, 28, 29, 41, -48, 49, 56, 60, -67, 75]
```
Cross-fertilized plants appear to be be higher. To test the null hypothesis that there is no height difference, we can apply the two-sided test:

```python
>>> from scipy.stats import wilcoxon
>>> w, p = wilcoxon(d)
>>> w, p
(24.0, 0.04088813291185591)
```

Hence, we would reject the null hypothesis at a confidence level of 5%, concluding that there is a difference in height between the groups. To confirm that the median of the differences can be assumed to be positive, we use:

```python
>>> w, p = wilcoxon(d, alternative='greater')
>>> w, p
(96.0, 0.020444066455927955)
```

This shows that the null hypothesis that the median is negative can be rejected at a confidence level of 5% in favor of the alternative that the median is greater than zero. The p-value based on the approximation is within the range of 0.019 and 0.054 given in [2]. Note that the statistic changed to 96 in the one-sided case (the sum of ranks of positive differences) whereas it is 24 in the two-sided case (the minimum of sum of ranks above and below zero).

**scipy.stats.kruskal**

`scipy.stats.kruskal(*args, **kwargs)`

Compute the Kruskal-Wallis H-test for independent samples

The Kruskal-Wallis H-test tests the null hypothesis that the population median of all of the groups are equal. It is a non-parametric version of ANOVA. The test works on 2 or more independent samples, which may have different sizes. Note that rejecting the null hypothesis does not indicate which of the groups differs. Post-hoc comparisons between groups are required to determine which groups are different.

**Parameters**

- `sample1, sample2, ...`
  [array_like] Two or more arrays with the sample measurements can be given as arguments.

- `nan_policy`
  [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

**Returns**

- `statistic` [float] The Kruskal-Wallis H statistic, corrected for ties
- `pvalue` [float] The p-value for the test using the assumption that H has a chi square distribution

See also:

- `f_oneway`
  1-way ANOVA
- `mannwhitneyu`
  Mann-Whitney rank test on two samples.
- `friedmanchisquare`
  Friedman test for repeated measurements
Notes

Due to the assumption that $H$ has a chi square distribution, the number of samples in each group must not be too small. A typical rule is that each sample must have at least 5 measurements.

References

[1], [2]

Examples

```python
>>> from scipy import stats
>>> x = [1, 3, 5, 7, 9]
>>> y = [2, 4, 6, 8, 10]
>>> stats.kruskal(x, y)
KruskalResult(statistic=0.2727272727272734, pvalue=0.6015081344405895)
```

```python
>>> x = [1, 1, 1]
>>> y = [2, 2, 2]
>>> z = [2, 2]
>>> stats.kruskal(x, y, z)
KruskalResult(statistic=7.0, pvalue=0.0301973834223185)
```

`scipy.stats.friedmanchisquare`

`scipy.stats.friedmanchisquare(*args)`

Compute the Friedman test for repeated measurements

The Friedman test tests the null hypothesis that repeated measurements of the same individuals have the same distribution. It is often used to test for consistency among measurements obtained in different ways. For example, if two measurement techniques are used on the same set of individuals, the Friedman test can be used to determine if the two measurement techniques are consistent.

**Parameters**

- `measurements1, measurements2, measurements3…`
  - `[array_like] Arrays of measurements. All of the arrays must have the same number of elements. At least 3 sets of measurements must be given.

**Returns**

- `statistic` [float] the test statistic, correcting for ties
- `pvalue` [float] the associated p-value assuming that the test statistic has a chi squared distribution

**Notes**

Due to the assumption that the test statistic has a chi squared distribution, the p-value is only reliable for $n > 10$ and more than 6 repeated measurements.

**References**

[1]
scipy.stats.brunnermunzel

scipy.stats.brunnermunzel(x, y, alternative='two-sided', distribution='t', nan_policy='propagate')

Computes the Brunner-Munzel test on samples x and y.

The Brunner-Munzel test is a nonparametric test of the null hypothesis that when values are taken one by one from each group, the probabilities of getting large values in both groups are equal. Unlike the Wilcoxon-Mann-Whitney's U test, this does not require the assumption of equivariance of two groups. Note that this does not assume the distributions are same. This test works on two independent samples, which may have different sizes.

Parameters

- x, y [array_like] Array of samples, should be one-dimensional.
- alternative ['less', 'two-sided', or 'greater', optional] Whether to get the p-value for the one-sided hypothesis ('less' or 'greater') or for the two-sided hypothesis ('two-sided'). Defaults value is 'two-sided'.
- distribution: 't' or 'normal', optional Whether to get the p-value by t-distribution or by standard normal distribution. Defaults value is 't'.
- nan_policy [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

Returns

- pvalue [float] p-value assuming an t distribution. One-sided or two-sided, depending on the choice of alternative and distribution.

See also:
mannwhitneyu

Mann-Whitney rank test on two samples.

Notes

Brunner and Munzel recommended to estimate the p-value by t-distribution when the size of data is 50 or less. If the size is lower than 10, it would be better to use permuted Brunner Munzel test (see [2]).

References

[1], [2]

Examples

```python
>>> from scipy import stats
>>> x1 = [1,2,1,1,1,1,1,1,1,2,4,1,1]
>>> x2 = [3,3,4,3,1,2,3,1,1,5,4]
>>> w, p_value = stats.brunnermunzel(x1, x2)
>>> w
3.1374674823029505
```

(continues on next page)
scipy.stats.combine_pvalues

Methods for combining the p-values of independent tests bearing upon the same hypothesis.

Parameters

- `pvalues` [array_like, 1-D] Array of p-values assumed to come from independent tests.
- `method` [{'fisher', 'pearson', 'tippett', 'stouffer', 'mudholkar_george'},] Name of method to use to combine p-values. The following methods are available:
  - "fisher": Fisher’s method (Fisher’s combined probability test), the default, the sum of the logarithm of the p-values.
  - "pearson": Pearson’s method (similar to Fisher’s but uses sum of the complement of the p-values inside the logarithms).
  - "tippett": Tippett’s method (minimum of p-values).
  - "stouffer": Stouffer’s Z-score method.
  - "mudholkar_george": the difference of Fisher’s and Pearson’s methods divided by 2.
- `weights` [array_like, 1-D, optional] Optional array of weights used only for Stouffer’s Z-score method.

Returns

- `statistic`: float The statistic calculated by the specified method.
- `pval`: float The combined p-value.

Notes

Fisher’s method (also known as Fisher’s combined probability test) [1] uses a chi-squared statistic to compute a combined p-value. The closely related Stouffer’s Z-score method [2] uses Z-scores rather than p-values. The advantage of Stouffer’s method is that it is straightforward to introduce weights, which can make Stouffer’s method more powerful than Fisher’s method when the p-values are from studies of different size [6] [7]. The Pearson’s method uses $\log(1 - p_i)$ inside the sum whereas Fisher’s method uses $\log(p_i)$ [4]. For Fisher’s and Pearson’s method, the sum of the logarithms is multiplied by -2 in the implementation. This quantity has a chi-square distribution that determines the p-value. The `mudholkar_george` method is the difference of the Fisher’s and Pearson’s test statistics, each of which include the -2 factor [4]. However, the `mudholkar_george` method does not include these -2 factors. The test statistic of `mudholkar_george` is the sum of logistic random variables and equation 3.6 in [3] is used to approximate the p-value based on Student’s t-distribution.

Fisher’s method may be extended to combine p-values from dependent tests [5]. Extensions such as Brown’s method and Kost’s method are not currently implemented.

New in version 0.15.0.

[1], [2], [3], [4], [5], [6], [7]
scipy.stats.jarque_bera

scipy.stats.jarque_bera(x)
 Perform the Jarque-Bera goodness of fit test on sample data.

The Jarque-Bera test tests whether the sample data has the skewness and kurtosis matching a normal distribution.
Note that this test only works for a large enough number of data samples (>2000) as the test statistic asymptotically has a Chi-squared distribution with 2 degrees of freedom.

Parameters
x [array_like] Observations of a random variable.

Returns
jb_value [float] The test statistic.
p [float] The p-value for the hypothesis test.

References
[1]

Examples

```python
>>> from scipy import stats
>>> np.random.seed(987654321)
>>> x = np.random.normal(0, 1, 100000)
>>> y = np.random.rayleigh(1, 100000)
>>> stats.jarque_bera(x)
(4.7165707989581342, 0.09458225503041906)
>>> stats.jarque_bera(y)
(6713.7098548143422, 0.0)
```

ansari(x, y) Perform the Ansari-Bradley test for equal scale parameters

bartlett(*args) Perform Bartlett’s test for equal variances

levene(*args, **kwds) Perform Levene test for equal variances.

shapiro(x) Perform the Shapiro-Wilk test for normality.

anderson(x[, dist]) Anderson-Darling test for data coming from a particular distribution

anderson_ksamp(samples[, midrank]) The Anderson-Darling test for k-samples.

binom_test(x[, n, p, alternative]) Perform a test that the probability of success is p.

fligner(*args, **kwds) Perform Fligner-Killeen test for equality of variance.

median_test(*args, **kwds) Mood’s median test.

mood(x[, y[, axis]]) Perform Mood’s test for equal scale parameters.

skewtest(a[, axis, nan_policy]) Test whether the skew is different from the normal distribution.

kurtosistest(a[, axis, nan_policy]) Test whether a dataset has normal kurtosis.

normaltest(a[, axis, nan_policy]) Test whether a sample differs from a normal distribution.
**scipy.stats.ansari**

**scipy.stats.ansari(x, y)**  
Perform the Ansari-Bradley test for equal scale parameters

The Ansari-Bradley test is a non-parametric test for the equality of the scale parameter of the distributions from which two samples were drawn.

**Parameters**

- x, y [array_like] arrays of sample data

**Returns**

- statistic [float] The Ansari-Bradley test statistic
- pvalue [float] The p-value of the hypothesis test

**See also:**

- **fligner**  
A non-parametric test for the equality of k variances

- **mood**  
A non-parametric test for the equality of two scale parameters

**Notes**

The p-value given is exact when the sample sizes are both less than 55 and there are no ties, otherwise a normal approximation for the p-value is used.

**References**

[1]

**scipy.stats.bartlett**

**scipy.stats.bartlett(*args)**  
Perform Bartlett’s test for equal variances

Bartlett’s test tests the null hypothesis that all input samples are from populations with equal variances. For samples from significantly non-normal populations, Levene’s test **levene** is more robust.

**Parameters**

- sample1, sample2,… [array_like] arrays of sample data. Only 1d arrays are accepted, they may have different lengths.

**Returns**

- statistic [float] The test statistic.
- pvalue [float] The p-value of the test.

**See also:**

- **fligner**  
A non-parametric test for the equality of k variances
levene

A robust parametric test for equality of k variances

Notes

Conover et al. (1981) examine many of the existing parametric and nonparametric tests by extensive simulations and they conclude that the tests proposed by Fligner and Killeen (1976) and Levene (1960) appear to be superior in terms of robustness of departures from normality and power ([3]).

References

[1], [2], [3], [4]

scipy.stats.levene

scipy.stats.levene(*args, **kwds)

Perform Levene test for equal variances.

The Levene test tests the null hypothesis that all input samples are from populations with equal variances. Levene’s test is an alternative to Bartlett’s test bartlett in the case where there are significant deviations from normality.

Parameters

- sample1, sample2, ...  
  [array_like] The sample data, possibly with different lengths. Only one-dimensional samples are accepted.
- center  
- proportiontocut  
  [float, optional] When center is ‘trimmed’, this gives the proportion of data points to cut from each end. (See scipy.stats.trim_mean) Default is 0.05.

Returns

- statistic  
  [float] The test statistic.
- pvalue  
  [float] The p-value for the test.

Notes

Three variations of Levene’s test are possible. The possibilities and their recommended usages are:

- ‘median’: Recommended for skewed (non-normal) distributions
- ‘mean’: Recommended for symmetric, moderate-tailed distributions.
- ‘trimmed’: Recommended for heavy-tailed distributions.

The test version using the mean was proposed in the original article of Levene ([2]) while the median and trimmed mean have been studied by Brown and Forsythe ([3]), sometimes also referred to as Brown-Forsythe test.

References

[1], [2], [3]
scipy.stats.shapiro

scipy.stats.shapiro(x)

Perform the Shapiro-Wilk test for normality.

The Shapiro-Wilk test tests the null hypothesis that the data was drawn from a normal distribution.

Parameters

x [array_like] Array of sample data.

Returns

W [float] The test statistic.

p-value [float] The p-value for the hypothesis test.

See also:

anderson

The Anderson-Darling test for normality

kstest

The Kolmogorov-Smirnov test for goodness of fit.

Notes

The algorithm used is described in [4] but censoring parameters as described are not implemented. For N > 5000
the W test statistic is accurate but the p-value may not be.

The chance of rejecting the null hypothesis when it is true is close to 5% regardless of sample size.

References

[1], [2], [3], [4]

Examples

```python
>>> from scipy import stats
>>> np.random.seed(12345678)
>>> x = stats.norm.rvs(loc=5, scale=3, size=100)
>>> stats.shapiro(x)
(0.9772805571556091, 0.08144091814756393)
```

scipy.stats.anderson

scipy.stats.anderson(x, dist='norm')

Anderson-Darling test for data coming from a particular distribution

The Anderson-Darling tests the null hypothesis that a sample is drawn from a population that follows a particular
distribution. For the Anderson-Darling test, the critical values depend on which distribution is being tested against.
This function works for normal, exponential, logistic, or Gumbel (Extreme Value Type I) distributions.

Parameters

SciPy Reference Guide, Release 1.3.2

```py
x [array_like] array of sample data
dist [[‘norm’,’expon’,’logistic’,’gumbel’,’gumbel_l’,’gumbel_r’,]’extreme1’], optional the type of
distribution to test against. The default is ‘norm’ and ‘extreme1’, ‘gumbel_l’ and ‘gumbel’ are
syonyms.

Returns
statistic [float] The Anderson-Darling test statistic
critical_values [list] The critical values for this distribution
significance_level [list] The significance levels for the corresponding critical values in percents. The function
returns critical values for a differing set of significance levels depending on the distribution
that is being tested against.

See also:

kstest

The Kolmogorov-Smirnov test for goodness-of-fit.

Notes

Critical values provided are for the following significance levels:

normal/exponential

15%, 10%, 5%, 2.5%, 1%

logistic

25%, 10%, 5%, 2.5%, 1%, 0.5%

Gumbel

25%, 10%, 5%, 2.5%, 1%

If the returned statistic is larger than these critical values then for the corresponding significance level, the null
hypothesis that the data come from the chosen distribution can be rejected. The returned statistic is referred to as
‘A2’ in the references.

References

[1], [2], [3], [4], [5], [6]

scipy.stats.anderson_ksamp

scipy.stats.anderson_ksamp(samples, midrank=True)
The Anderson-Darling test for k-samples.

The k-sample Anderson-Darling test is a modification of the one-sample Anderson-Darling test. It tests the null
hypothesis that k-samples are drawn from the same population without having to specify the distribution function
of that population. The critical values depend on the number of samples.

Parameters

samples [sequence of 1-D array_like] Array of sample data in arrays.
```

6.28. Statistical functions (scipy.stats) 2475
midrank  [bool, optional] Type of Anderson-Darling test which is computed. Default (True) is the midrank test applicable to continuous and discrete populations. If False, the right side empirical distribution is used.

Returns

statistic  [float] Normalized k-sample Anderson-Darling test statistic.
critical_values  [array] The critical values for significance levels 25%, 10%, 5%, 2.5%, 1%.
significance_level  [float] An approximate significance level at which the null hypothesis for the provided samples can be rejected. The value is floored / capped at 1% / 25%.

Raises

ValueError

If less than 2 samples are provided, a sample is empty, or no distinct observations are in the samples.

See also:

ks_2samp
2 sample Kolmogorov-Smirnov test

anderson
1 sample Anderson-Darling test

Notes

[1] defines three versions of the k-sample Anderson-Darling test: one for continuous distributions and two for discrete distributions, in which ties between samples may occur. The default of this routine is to compute the version based on the midrank empirical distribution function. This test is applicable to continuous and discrete data. If midrank is set to False, the right side empirical distribution is used for a test for discrete data. According to [1], the two discrete test statistics differ only slightly if a few collisions due to round-off errors occur in the test not adjusted for ties between samples.

The critical values corresponding to the significance levels from 0.01 to 0.25 are taken from [1]. p-values are floored / capped at 0.1% / 25%. Since the range of critical values might be extended in future releases, it is recommended not to test p == 0.25, but rather p >= 0.25 (analogously for the lower bound).

New in version 0.14.0.

References

[1]

Examples

```python
>>> from scipy import stats
>>> np.random.seed(314159)
```

The null hypothesis that the two random samples come from the same distribution can be rejected at the 5% level because the returned test value is greater than the critical value for 5% (1.961) but not at the 2.5% level. The interpolation gives an approximate significance level of 3.2%:
```python
>>> stats.anderson_ksamp([np.random.normal(size=50),
... np.random.normal(loc=0.5, size=30)])
(2.4615796189876105,
 array([ 0.325,  1.226,  1.961,  2.718,  3.752,  4.592,  6.546]),
 0.03176687568842282)
```

The null hypothesis cannot be rejected for three samples from an identical distribution. The reported p-value (25%) has been capped and may not be very accurate (since it corresponds to the value 0.449 whereas the statistic is -0.731):

```python
>>> stats.anderson_ksamp([np.random.normal(size=50),
... np.random.normal(size=30), np.random.normal(size=20)])
(-0.73091722665244196,
 array([ 0.44925884,  1.3052767 ,  1.9434184 ,  2.57696569,  3.41634856,
         4.07210043,  5.56419101]),
 0.25)
```

### scipy.stats.binom_test

**scipy.stats.binom_test** *(x, n=None, p=0.5, alternative='two-sided')*

Perform a test that the probability of success is `p`.

This is an exact, two-sided test of the null hypothesis that the probability of success in a Bernoulli experiment is `p`.

- **Parameters**
  - `x` [integer or array_like] the number of successes, or if `x` has length 2, it is the number of successes and the number of failures.
  - `n` [integer] the number of trials. This is ignored if `x` gives both the number of successes and failures.
  - `p` [float, optional] The hypothesized probability of success. 0 <= p <= 1. The default value is `p = 0.5`.
  - `alternative` [{‘two-sided’, ‘greater’, ‘less’}, optional] Indicates the alternative hypothesis. The default value is ‘two-sided’.

- **Returns**
  - `p-value` [float] The p-value of the hypothesis test.

### References

[1]

### Examples

```python
>>> from scipy import stats
```

A car manufacturer claims that no more than 10% of their cars are unsafe. 15 cars are inspected for safety, 3 were found to be unsafe. Test the manufacturer’s claim:

```python
>>> stats.binom_test(3, n=15, p=0.1, alternative='greater')
0.18406106910639114
```
The null hypothesis cannot be rejected at the 5% level of significance because the returned p-value is greater than the critical value of 5%.

**scipy.stats.fligner**

`scipy.stats.fligner(*args, **kwds)`  
Perform Fligner-Killeen test for equality of variance.

Fligner’s test tests the null hypothesis that all input samples are from populations with equal variances. Fligner-Killeen’s test is distribution free when populations are identical [2].

**Parameters**

- `sample1, sample2, ...`
  - [array_like] Arrays of sample data. Need not be the same length.
- `center`
  - [{'mean', 'median', 'trimmed'}, optional] Keyword argument controlling which function of the data is used in computing the test statistic. The default is ‘median’.
- `proportiontocut`
  - [float, optional] When `center` is ‘trimmed’, this gives the proportion of data points to cut from each end. (See `scipy.stats.trim_mean`.) Default is 0.05.

**Returns**

- `statistic` [float] The test statistic.
- `pvalue` [float] The p-value for the hypothesis test.

See also:

- **bartlett**
  - A parametric test for equality of k variances in normal samples
- **levene**
  - A robust parametric test for equality of k variances

**Notes**

As with Levene’s test there are three variants of Fligner’s test that differ by the measure of central tendency used in the test. See `levene` for more information.

Conover et al. (1981) examine many of the existing parametric and nonparametric tests by extensive simulations and they conclude that the tests proposed by Fligner and Killeen (1976) and Levene (1960) appear to be superior in terms of robustness of departures from normality and power [3].

**References**

[1], [2], [3], [4]

**scipy.stats.median_test**

`scipy.stats.median_test(*args, **kwds)`  
Mood’s median test.

Test that two or more samples come from populations with the same median.
Let \( n = \text{len}(\text{args}) \) be the number of samples. The “grand median” of all the data is computed, and a contingency table is formed by classifying the values in each sample as being above or below the grand median. The contingency table, along with \textit{correction} and \textit{lambda\_}, are passed to \texttt{scipy.stats.chi2_contingency} to compute the test statistic and p-value.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{sample1, sample2, …}
    \begin{itemize}
      \item \texttt{[array_like]} The set of samples. There must be at least two samples. Each sample must be a one-dimensional sequence containing at least one value. The samples are not required to have the same length.
    \end{itemize}
  \item \texttt{ties}
    \begin{itemize}
      \item \texttt{[str, optional]} Determines how values equal to the grand median are classified in the contingency table. The string must be one of:
    \begin{verbatim}
    "below":
      Values equal to the grand median are counted as "below ".
    "above":
      Values equal to the grand median are counted as "above ".
    "ignore":
      Values equal to the grand median are not counted.
    \end{verbatim}
    \end{itemize}
  \item \texttt{correction}
    \begin{itemize}
      \item \texttt{[bool, optional]} If True, and there are just two samples, apply Yates’ correction for continuity when computing the test statistic associated with the contingency table. Default is True.
    \end{itemize}
  \item \texttt{lambda\_}
    \begin{itemize}
      \item \texttt{[float or str, optional]} By default, the statistic computed in this test is Pearson’s chi-squared statistic. \texttt{lambda\_} allows a statistic from the Cressie-Read power divergence family to be used instead. See \textit{power_divergence} for details. Default is 1 (Pearson’s chi-squared statistic).
    \end{itemize}
  \item \texttt{nan_policy}
    \begin{itemize}
      \item \texttt{[{'propagate', 'raise', 'omit'}, optional]} Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.
    \end{itemize}
\end{itemize}

\textbf{Returns}

\begin{itemize}
  \item \texttt{stat}
    \begin{itemize}
      \item \texttt{[float]} The test statistic. The statistic that is returned is determined by \textit{lambda\_}. The default is Pearson’s chi-squared statistic.
    \end{itemize}
  \item \texttt{p}
    \begin{itemize}
      \item \texttt{[float]} The p-value of the test.
    \end{itemize}
  \item \texttt{m}
    \begin{itemize}
      \item \texttt{[float]} The grand median.
    \end{itemize}
  \item \texttt{table}
    \begin{itemize}
      \item \texttt{[ndarray]} The contingency table. The shape of the table is (2, n), where n is the number of samples. The first row holds the counts of the values above the grand median, and the second row holds the counts of the values below the grand median. The table allows further analysis with, for example, \texttt{scipy.stats.chi2_contingency}, or with \texttt{scipy.stats.fisher_exact} if there are two samples, without having to recompute the table. If \texttt{nan_policy} is “propagate” and there are nans in the input, the return value for \texttt{table} is None.
    \end{itemize}
\end{itemize}

\textbf{See also:}

\begin{itemize}
  \item \texttt{kruskal}
    \begin{itemize}
      \item Compute the Kruskal-Wallis H-test for independent samples.
    \end{itemize}
  \item \texttt{mannwhitneyu}
    \begin{itemize}
      \item Computes the Mann-Whitney rank test on samples x and y.
    \end{itemize}
\end{itemize}
Notes

New in version 0.15.0.

References

[1], [2]

Examples

A biologist runs an experiment in which there are three groups of plants. Group 1 has 16 plants, group 2 has 15 plants, and group 3 has 17 plants. Each plant produces a number of seeds. The seed counts for each group are:

| Group 1:  | 10 | 14 | 14 | 18 | 20 | 22 | 24 | 25 | 31 | 31 | 32 | 39 | 43 | 43 | 48 | 49 |
| Group 2:  | 28 | 30 | 31 | 33 | 34 | 35 | 36 | 40 | 44 | 45 | 55 | 57 | 61 | 91 | 92 | 99 |
| Group 3:  |  0 |  3 |  9 | 22 | 23 | 25 | 25 | 33 | 34 | 34 | 40 | 45 | 46 | 48 | 62 | 67 | 84 |

The following code applies Mood's median test to these samples.

```
>>> g1 = [10, 14, 14, 18, 20, 22, 24, 25, 31, 31, 32, 39, 43, 43, 48, 49]
>>> g2 = [28, 30, 31, 33, 34, 35, 36, 40, 44, 45, 55, 57, 61, 91, 92, 99]
>>> g3 = [ 0,  3,  9, 22, 23, 25, 25, 33, 34, 34, 40, 45, 46, 48, 62, 67, 84]
>>> from scipy.stats import median_test
>>> stat, p, med, tbl = median_test(g1, g2, g3)

The median is

```
>>> med
34.0
```

and the contingency table is

```
>>> tbl
array([[ 5, 10,  7],
       [11,  5, 10]])
```

$p$ is too large to conclude that the medians are not the same:

```
>>> p
0.12609082774093244
```

The “G-test” can be performed by passing `lambda_="log-likelihood"` to `median_test`.

```
>>> g, p, med, tbl = median_test(g1, g2, g3, lambda_="log-likelihood")
>>> p
0.12224779737117837
```

The median occurs several times in the data, so we’ll get a different result if, for example, `ties="above"` is used:

```
>>> stat, p, med, tbl = median_test(g1, g2, g3, ties="above")
>>> p
0.063873276069553273
```
This example demonstrates that if the data set is not large and there are values equal to the median, the p-value can be sensitive to the choice of ties.

**scipy.stats.mood**

```python
scipy.stats.mood(x, y, axis=0)
```

Perform Mood’s test for equal scale parameters.

Mood’s two-sample test for scale parameters is a non-parametric test for the null hypothesis that two samples are drawn from the same distribution with the same scale parameter.

**Parameters**

- `x`, `y` : array_like
  Arrays of sample data.
- `axis` : int, optional
  The axis along which the samples are tested. `x` and `y` can be of different length along `axis`. If `axis` is None, `x` and `y` are flattened and the test is done on all values in the flattened arrays.

**Returns**

- `z` : scalar or ndarray
  The z-score for the hypothesis test. For 1-D inputs a scalar is returned.
- `p-value` : scalar or ndarray
  The p-value for the hypothesis test.

**See also:**

- `fligner`
  A non-parametric test for the equality of k variances
- `ansari`
  A non-parametric test for the equality of 2 variances
- `bartlett`
  A parametric test for equality of k variances in normal samples
- `levene`
  A parametric test for equality of k variances

**Notes**

The data are assumed to be drawn from probability distributions $f(x)$ and $f(x/s) / s$ respectively, for some probability density function $f$. The null hypothesis is that $s == 1$.

For multi-dimensional arrays, if the inputs are of shapes $(n0, n1, n2, n3)$ and $(n0, m1, n2, n3)$, then if `axis=1`, the resulting z and p values will have shape $(n0, n2, n3)$. Note that `n1` and `m1` don’t have to be equal, but the other dimensions do.

**Examples**
```python
>>> from scipy import stats
>>> np.random.seed(1234)
>>> x2 = np.random.randn(2, 45, 6, 7)
>>> x1 = np.random.randn(2, 30, 6, 7)
>>> z, p = stats.mood(x1, x2, axis=1)
>>> p.shape
(2, 6, 7)
```

Find the number of points where the difference in scale is not significant:

```python
>>> (p > 0.1).sum()
74
```

Perform the test with different scales:

```python
>>> x1 = np.random.randn(2, 30)
>>> x2 = np.random.randn(2, 35) * 10.0
>>> stats.mood(x1, x2, axis=1)
(array([-5.7178125 , -5.25342163]), array([ 1.07904114e-08, 1.49299218e-07]))
```

### scipy.stats.skewtest

`scipy.stats.skewtest (a, axis=0, nan_policy='propagate')`

Test whether the skew is different from the normal distribution.

This function tests the null hypothesis that the skewness of the population that the sample was drawn from is the same as that of a corresponding normal distribution.

**Parameters**

- `a` [array] The data to be tested
- `axis` [int or None, optional] Axis along which statistics are calculated. Default is 0. If None, compute over the whole array `a`.

**Returns**

- `statistic` [float] The computed z-score for this test.
- `pvalue` [float] a 2-sided p-value for the hypothesis test

**Notes**

The sample size must be at least 8.

**References**

[1]
Examples

```python
from scipy.stats import skewtest
>>> skewtest([1, 2, 3, 4, 5, 6, 7, 8])
SkewtestResult(statistic=1.0108048609177787, pvalue=0.3121098361421897)
>>> skewtest([2, 8, 0, 4, 1, 9, 9, 0])
SkewtestResult(statistic=0.44626385374196975, pvalue=0.6554066631275459)
>>> skewtest([1, 2, 3, 4, 5, 6, 7, 8000])
SkewtestResult(statistic=3.571773510360407, pvalue=0.0003545719905823133)
>>> skewtest([100, 100, 100, 100, 100, 100, 100, 101])
SkewtestResult(statistic=3.5717766638478072, pvalue=0.000354567720281634)
```

scipy.stats.kurtosistest

```python
scipy.stats.kurtosistest(a, axis=0, nan_policy='propagate')
```

Test whether a dataset has normal kurtosis.

This function tests the null hypothesis that the kurtosis of the population from which the sample was drawn is that of the normal distribution: kurtosis = 3(n-1)/(n+1).

**Parameters**

- `a` [array] array of the sample data
- `axis` [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array `a`.
- `nan_policy` ['propagate', 'raise', 'omit'], optional Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- `statistic` [float] The computed z-score for this test.
- `pvalue` [float] The 2-sided p-value for the hypothesis test

**Notes**

Valid only for n>20. This function uses the method described in [1].

**References**

[1]

**Examples**

```python
from scipy.stats import kurtosistest
>>> kurtosistest(list(range(20)))
KurtosistestResult(statistic=-1.7058104152122062, pvalue=0.08804338332528348)
```
scipy.stats.normaltest

scipy.stats.normaltest(a, axis=0, nan_policy='propagate')

Test whether a sample differs from a normal distribution.

This function tests the null hypothesis that a sample comes from a normal distribution. It is based on D'Agostino and Pearson's\[1\],\[2\] test that combines skew and kurtosis to produce an omnibus test of normality.

**Parameters**

- **a**
  - [array_like] The array containing the sample to be tested.
- **axis**
  - [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array a.
- **nan_policy**
  - [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- **statistic**
  - [float or array] $s^2 + k^2$, where $s$ is the z-score returned by skewtest and $k$ is the z-score returned by kurtosistest.
- **pvalue**
  - [float or array] A 2-sided chi squared probability for the hypothesis test.

**References**

[1], [2]

**Examples**

```python
>>> from scipy import stats
>>> pts = 1000
>>> np.random.seed(28041990)
>>> a = np.random.normal(0, 1, size=pts)
>>> b = np.random.normal(2, 1, size=pts)
>>> x = np.concatenate((a, b))
>>> k2, p = stats.normaltest(x)
>>> alpha = 1e-3
>>> print("p = \{:g\}.format(p))
p = 3.27207e-11
>>> if p < alpha: # null hypothesis: x comes from a normal distribution
...     print("The null hypothesis can be rejected")
... else:
...     print("The null hypothesis cannot be rejected")
The null hypothesis can be rejected
```

**scipy.stats.boxcox**

`scipy.stats.boxcox(x, lmbda=None, alpha=None)`

Return a positive dataset transformed by a Box-Cox power transformation.

**Parameters**

- `x` : [ndarray] Input array. Should be 1-dimensional.
- `lmbda` : [{None, scalar}, optional] If `lmbda` is not None, do the transformation for that value.
- `alpha` : [{None, float}, optional] If `alpha` is not None, return the `100 * (1-alpha)` % confidence interval for `lmbda` as the third output argument. Must be between 0.0 and 1.0.

**Returns**

- `boxcox` : [ndarray] Box-Cox power transformed array.
- `maxlog` : [float, optional] If the `lmbda` parameter is None, the second returned argument is the lambda that maximizes the log-likelihood function.
- `(min_ci, max_ci)` : [tuple of float, optional] If `lmbda` parameter is None and `alpha` is not None, this returned tuple of floats represents the minimum and maximum confidence limits given `alpha`.

**See also:**

- `probplot`, `boxcox_normplot`, `boxcox_normmax`, `boxcox_llf`

**Notes**

The Box-Cox transform is given by:
\[
    y = \begin{cases} 
    (x^* + \lambda - 1) / \lambda, & \text{for } \lambda > 0 \\
    \log(x), & \text{for } \lambda = 0
    \end{cases}
\]

`boxcox` requires the input data to be positive. Sometimes a Box-Cox transformation provides a shift parameter to achieve this; `boxcox` does not. Such a shift parameter is equivalent to adding a positive constant to \( x \) before calling `boxcox`.

The confidence limits returned when `alpha` is provided give the interval where:

\[
    llf(\hat{\lambda}) - llf(\lambda) < \frac{1}{2} \chi^2(1 - \alpha, 1),
\]

with \( llf \) the log-likelihood function and \( \chi^2 \) the chi-squared function.

**References**

**Examples**

```python
def g(x, alpha):
    return stats.boxcox_normmax(x, brack=(-2.0, 2.0), method='pearsonr')
```

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt

We generate some random variates from a non-normal distribution and make a probability plot for it, to show it is non-normal in the tails:

```python
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(211)
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> prob = stats.probplot(x, dist=stats.norm, plot=ax1)
>>> ax1.set_xlabel('')
>>> ax1.set_title('Probplot against normal distribution')
```

We now use `boxcox` to transform the data so it’s closest to normal:

```python
>>> ax2 = fig.add_subplot(212)
>>> xt, _ = stats.boxcox(x)
>>> prob = stats.probplot(xt, dist=stats.norm, plot=ax2)
>>> ax2.set_title('Probplot after Box-Cox transformation')

```python
```python
```

**scipy.stats.boxcox_normmax**

`scipy.stats.boxcox_normmax(x, brack=(-2.0, 2.0), method='pearsonr')`

Compute optimal Box-Cox transform parameter for input data.

- **Parameters**
  - `x` [array_like] Input array.
  - `brack` [2-tuple, optional] The starting interval for a downhill bracket search with `optimize.brent`. Note that this is in most cases not critical; the final result is allowed to be outside this bracket.
Theoretical quantiles

Ordered Values

Probplot after Box-Cox transformation

Probplot against normal distribution

Ordered Values

method [str, optional] The method to determine the optimal transform parameter (boxcox lmbda parameter). Options are:

‘pearson’ (default) Maximizes the Pearson correlation coefficient between y = boxcox(x) and the expected values for y if x would be normally-distributed.

‘mle’ Minimizes the log-likelihood boxcox_llf. This is the method used in boxcox.

‘all’ Use all optimization methods available, and return all results. Useful to compare different methods.

Returns

maxlog [float or ndarray] The optimal transform parameter found. An array instead of a scalar for method='all'.

See also:

boxcox, boxcox_llf, boxcox_normplot

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234)  # make this example reproducible

Generate some data and determine optimal lmbda in various ways:

```
7.916...
>>> stats.boxcox_normmax(x, method='all')
array([ 7.91667384, 7.17718692])

>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.boxcox_normplot(x, -10, 10, plot=ax)
>>> ax.axvline(lmax_mle, color='r')
>>> ax.axvline(lmax_pearsonr, color='g', ls='--')

>>> plt.show()

**scipy.stats.boxcox_llf**

scipy.stats.boxcox_llf(lmb, data)

The boxcox log-likelihood function.

**Parameters**

- **lmb** [scalar] Parameter for Box-Cox transformation. See boxcox for details.
- **data** [array_like] Data to calculate Box-Cox log-likelihood for. If data is multi-dimensional, the log-likelihood is calculated along the first axis.

**Returns**

- **llf** [float or ndarray] Box-Cox log-likelihood of data given lmb. A float for 1-D data, an array otherwise.

**See also:**

- boxcox, probplot, boxcox_normplot, boxcox_normmax
Notes

The Box-Cox log-likelihood function is defined here as

\[ llf = (\lambda - 1) \sum_i (\log(x_i)) - N/2 \log(\sum_i (y_i - \bar{y})^2/N), \]

where \( y \) is the Box-Cox transformed input data \( x \).

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.axes_grid1.inset_locator import inset_axes
>>> np.random.seed(1245)

Generates some random variates and calculate Box-Cox log-likelihood values for them for a range of \( \lambda \) values:

```python
>>> x = stats.loggamma.rvs(5, loc=10, size=1000)
>>> lmbdas = np.linspace(-2, 10)
>>> llf = np.zeros(lmbdas.shape, dtype=float)
>>> for ii, lmbda in enumerate(lmbdas):
...     llf[ii] = stats.boxcox_llf(lmbda, x)
```

Also find the optimal \( \lambda \) value with \texttt{boxcox}:

```python
>>> x_most_normal, lmbda_optimal = stats.boxcox(x)
```

Plot the log-likelihood as function of \( \lambda \). Add the optimal \( \lambda \) as a horizontal line to check that that's really the optimum:

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(lmbdas, llf, 'b-')
>>> ax.axhline(stats.boxcox_llf(lmbda_optimal, x), color='r')
>>> ax.set_xlabel('\lambda parameter')
>>> ax.set_ylabel('Box-Cox log-likelihood')
```

Now add some probability plots to show that where the log-likelihood is maximized the data transformed with \texttt{boxcox} looks closest to normal:

```python
>>> locs = [3, 10, 4]  # 'lower left', 'center', 'lower right'
>>> for lmbda, loc in zip([-1, lmbda_optimal, 9], locs):
...     xt = stats.boxcox(x, lmbda=lmbda)
...     (osm, osr), (slope, intercept, r_sq) = stats.probplot(xt)
...     ax_inset = inset_axes(ax, width="20\%", height="20\%", loc=loc)
...     ax_inset.plot(osm, osr, 'c.', osm, slope*osm + intercept, 'k-')
...     ax_inset.set_xticklabels([])
...     ax_inset.set_yticklabels([])
...     ax_inset.set_title(r'\$\lambda$=%1.2f' % lmbda)
```

```bash
>>> plt.show()
```
scipy.stats.yeojohnson

scipy.stats.yeojohnson(x, lmbda=None)

Return a dataset transformed by a Yeo-Johnson power transformation.

Parameters

- x [ndarray] Input array. Should be 1-dimensional.
- lmbda [float, optional] If lmbda is None, find the lambda that maximizes the log-likelihood function and return it as the second output argument. Otherwise the transformation is done for the given value.

Returns

- yeojohnson: ndarray Yeo-Johnson power transformed array.
- maxlog [float, optional] If the lmbda parameter is None, the second returned argument is the lambda that maximizes the log-likelihood function.

See also:

probplot, yeojohnson_normplot, yeojohnson_normmax, yeojohnson_llf, boxcox

Notes

The Yeo-Johnson transform is given by:

\[
\begin{align*}
y = \frac{(x + 1)^{\ast\ast\ast\ast lmbda} - 1}{lmbda}, & \quad \text{for } x \geq 0, lmbda \neq 0 \\
\log(x + 1), & \quad \text{for } x \geq 0, lmbda = 0 \\
-(x + 1)^{\ast\ast(2 - lmbda) - 1}/(2 - lmbda), & \quad \text{for } x < 0, lmbda \neq 2 \\
-\log(-x + 1), & \quad \text{for } x < 0, lmbda = 2
\end{align*}
\]

Unlike boxcox, yeojohnson does not require the input data to be positive.

New in version 1.2.0.
References

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

We generate some random variates from a non-normal distribution and make a probability plot for it, to show it is non-normal in the tails:

```python
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(211)
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> prob = stats.probplot(x, dist=stats.norm, plot=ax1)
>>> ax1.set_xlabel('')
>>> ax1.set_title('Probplot against normal distribution')
```

We now use `yeojohnson` to transform the data so it’s closest to normal:

```python
>>> ax2 = fig.add_subplot(212)
>>> xt, lmbda = stats.yeojohnson(x)
>>> prob = stats.probplot(xt, dist=stats.norm, plot=ax2)
>>> ax2.set_title('Probplot after Yeo-Johnson transformation')
```

```python
>>> plt.show()
```

**scipy.stats.yeojohnson_normmax**

`scipy.stats.yeojohnson_normmax(x, brack=(-2, 2))`

Compute optimal Yeo-Johnson transform parameter for input data, using maximum likelihood estimation.
Parameters

- **x** [array_like] Input array.
- **brack** [2-tuple, optional] The starting interval for a downhill bracket search with `optimize.brent`. Note that this is in most cases not critical; the final result is allowed to be outside this bracket.

Returns

- **maxlog** [float] The optimal transform parameter found.

See also:

- `yeojohnson`, `yeojohnson_llf`, `yeojohnson_normplot`

Notes

New in version 1.2.0.

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234)  # make this example reproducible

Generate some data and determine optimal $\lambda$

```python
>>> x = stats.loggamma.rvs(5, size=30) + 5
>>> lmax = stats.yeojohnson_normmax(x)
```

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.yeojohnson_normplot(x, -10, 10, plot=ax)
>>> ax.axvline(lmax, color='r')
```

```python
>>> plt.show()
```

**scipy.stats.yeojohnson_llf**

`scipy.stats.yeojohnson_llf(lmb, data)`

The yeojohnson log-likelihood function.

Parameters

- **lmb** [scalar] Parameter for Yeo-Johnson transformation. See `yeojohnson` for details.
- **data** [array_like] Data to calculate Yeo-Johnson log-likelihood for. If `data` is multi-dimensional, the log-likelihood is calculated along the first axis.

Returns

- **llf** [float] Yeo-Johnson log-likelihood of `data` given `lmb`.

See also:

- `yeojohnson`, `probplot`, `yeojohnson_normplot`, `yeojohnson_normmax`
Notes

The Yeo-Johnson log-likelihood function is defined here as

$$llf = N/2 \log(\hat{\sigma}^2) + (\lambda - 1) \sum \text{sign}(x_i) \log(|x_i| + 1)$$

where $\hat{\sigma}^2$ is estimated variance of the the Yeo-Johnson transformed input data $x$.

New in version 1.2.0.

Examples

>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.axes_grid1.inset_locator import inset_axes
>>> np.random.seed(1234)

Generate some random variates and calculate Yeo-Johnson log-likelihood values for them for a range of lambda values:

```python
>>> x = stats.loggamma.rvs(5, loc=10, size=1000)
>>> lmbdas = np.linspace(-2, 10)
>>> llf = np.zeros(lmbdas.shape, dtype=float)
>>> for ii, lmbda in enumerate(lmbdas):
...    llf[ii] = stats.yeojohnson_llf(lmbda, x)
```

Also find the optimal lambda value with yeojohnson:

```python
>>> x_most_normal, lambda_optimal = stats.yeojohnson(x)
```

Plot the log-likelihood as function of lambda. Add the optimal lambda as a horizontal line to check that that's really the optimum:

```python
```
Now add some probability plots to show that where the log-likelihood is maximized the data transformed with `yeojohnson` looks closest to normal:

```python
>>> locs = [3, 10, 4]  # 'lower left', 'center', 'lower right'
>>> for lmbda, loc in zip([-1, lmbda_optimal, 9], locs):
...     xt = stats.yeojohnson(x, lmbda=lmbda)
...     (osm, osr), (slope, intercept, r_sq) = stats.probplot(xt)
...     ax_inset = inset_axes(ax, width="20\%", height="20\%", loc=loc)
...     ax_inset.plot(osm, osr, 'c.', osm, slope*osm + intercept, 'k-')
...     ax_inset.set_xticklabels([])
...     ax_inset.set_yticklabels([])
...     ax_inset.set_title(r'$\lambda=\$%.2f$' % lmbda)

>>> plt.show()
```

### scipy.stats.obrientransform

**scipy.stats.obrientransform (*args)**

Compute the O'Brien transform on input data (any number of arrays).

Used to test for homogeneity of variance prior to running one-way stats. Each array in *args is one level of a factor. If `f_oneway` is run on the transformed data and found significant, the variances are unequal. From Maxwell and Delaney [1], p.112.

**Parameters**

- **args** : [tuple of array_like] Any number of arrays.
Returns

obrientransform

[ndarray] Transformed data for use in an ANOVA. The first dimension of the result corresponds to the sequence of transformed arrays. If the arrays given are all 1-D of the same length, the return value is a 2-D array; otherwise it is a 1-D array of type object, with each element being an ndarray.

References

[1]

Examples

We'll test the following data sets for differences in their variance.

```
>>> x = [10, 11, 13, 9, 7, 12, 12, 9, 10]
>>> y = [13, 21, 5, 10, 8, 14, 10, 12, 7, 15]
```

Apply the O'Brien transform to the data.

```
>>> from scipy.stats import obrientransform
>>> tx, ty = obrientransform(x, y)
```

Use `scipy.stats.f_oneway` to apply a one-way ANOVA test to the transformed data.

```
>>> from scipy.stats import f_oneway
>>> F, p = f_oneway(tx, ty)
>>> p
0.1314139477040335
```

If we require that p < 0.05 for significance, we cannot conclude that the variances are different.

scipy.stats.sigmaclip

`scipy.stats.sigmaclip(a, low=4.0, high=4.0)`

Iterative sigma-clipping of array elements.

Starting from the full sample, all elements outside the critical range are removed, i.e. all elements of the input array c that satisfy either of the following conditions

\[
\begin{align*}
c &< \text{mean}(c) - \text{std}(c) \times \text{low} \\
c &> \text{mean}(c) + \text{std}(c) \times \text{high}
\end{align*}
\]

The iteration continues with the updated sample until no elements are outside the (updated) range.

Parameters

- **a** [array_like] Data array, will be raveled if not 1-D.
- **low** [float, optional] Lower bound factor of sigma clipping. Default is 4.
- **high** [float, optional] Upper bound factor of sigma clipping. Default is 4.

Returns

- **clipped** [ndarray] Input array with clipped elements removed.
lower  [float] Lower threshold value use for clipping.
upper  [float] Upper threshold value use for clipping.

Examples

```python
>>> from scipy.stats import sigmaclip
>>> a = np.concatenate((np.linspace(9.5, 10.5, 31),
                      np.linspace(0, 20, 5)))
>>> fact = 1.5
>>> c, low, upp = sigmaclip(a, fact, fact)
>>> c
array([ 9.96666667, 10.    , 10.03333333, 10.    ])
>>> c.var(), c.std()
(0.00055555555555555165, 0.023570226039551501)
>>> low, c.mean() - fact*c.std(), c.min()
(9.9646446609406727, 9.9646446609406727, 9.9666666666666668)
>>> upp, c.mean() + fact*c.std(), c.max()
(10.035355339059327, 10.035355339059327, 10.0333333333333333)
```

```python
>>> a = np.concatenate((np.linspace(9.5, 10.5, 11),
                      np.linspace(-100, -50, 3)))
>>> c, low, upp = sigmaclip(a, 1.8, 1.8)
>>> (c == np.linspace(9.5, 10.5, 11)).all()
True
```

**scipy.stats.trimboth**

scipy.stats.trimboth(a, proportiontocut, axis=0)

Slices off a proportion of items from both ends of an array.

Slices off the passed proportion of items from both ends of the passed array (i.e., with proportiontocut = 0.1, slices leftmost 10% and rightmost 10% of scores). The trimmed values are the lowest and highest ones. Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off `proportiontocut`).

**Parameters**

- **a**  
  [array_like] Data to trim.
- **proportiontocut**  
  [float] Proportion (in range 0-1) of total data set to trim of each end.
- **axis**  
  [int or None, optional] Axis along which to trim data. Default is 0. If None, compute over the whole array `a`.

**Returns**

- **out**  
  [ndarray] Trimmed version of array `a`. The order of the trimmed content is undefined.

**See also:**

- trim_mean
Examples

```python
>>> from scipy import stats
>>> a = np.arange(20)
>>> b = stats.trimboth(a, 0.1)
>>> b.shape
(16,)
```

**scipy.stats.trim1**

scipy.stats.trim1(a, proportiontocut, tail='right', axis=0)

Slices off a proportion from ONE end of the passed array distribution.

If proportiontocut = 0.1, slices off ‘leftmost’ or ‘rightmost’ 10% of scores. The lowest or highest values are trimmed (depending on the tail). Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off proportiontocut ).

**Parameters**

- **a** [array_like] Input array
- **proportiontocut** [float] Fraction to cut off of ‘left’ or ‘right’ of distribution
- **tail** ['left', 'right', optional] Defaults to ‘right’.
- **axis** [int or None, optional] Axis along which to trim data. Default is 0. If None, compute over the whole array a.

**Returns**

trim1 [ndarray] Trimmed version of array a. The order of the trimmed content is undefined.

**scipy.stats.zmap**

scipy.stats.zmap(scores, compare, axis=0, ddof=0)

Calculate the relative z-scores.

Return an array of z-scores, i.e., scores that are standardized to zero mean and unit variance, where mean and variance are calculated from the comparison array.

**Parameters**

- **scores** [array_like] The input for which z-scores are calculated.
- **compare** [array_like] The input from which the mean and standard deviation of the normalization are taken; assumed to have the same dimension as scores.
- **axis** [int or None, optional] Axis over which mean and variance of compare are calculated. Default is 0. If None, compute over the whole array scores.
- **ddof** [int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

**Returns**

zscore [array_like] Z-scores, in the same shape as scores.

**Notes**

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses asanyarray instead of asarray for parameters).
Examples

```python
>>> from scipy.stats import zmap
>>> a = [0.5, 2.0, 2.5, 3]
>>> b = [0, 1, 2, 3, 4]
>>> zmap(a, b)
array([-1.06066017, 0. , 0.35355339, 0.70710678])
```

scipy.stats.zscore

`scipy.stats.zscore(a, axis=0, ddof=0)`

Calculate the z score of each value in the sample, relative to the sample mean and standard deviation.

**Parameters**

- `a` [array_like] An array like object containing the sample data.
- `axis` [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array `a`.
- `ddof` [int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

**Returns**

- `zscore` [array_like] The z-scores, standardized by mean and standard deviation of input array `a`.

**Notes**

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses `asanyarray` instead of `asarray` for parameters).

Examples

```python
>>> a = np.array([0.7972, 0.0767, 0.4383, 0.7866, 0.8091,
... 0.1954, 0.6307, 0.6599, 0.1065, 0.0508])
>>> from scipy import stats
>>> stats.zscore(a)
array([ 1.1273, -1.247 , -0.0552, 1.0923, 1.1664, -0.8559, 0.5786,
0.6748, -1.1488, -1.3324])
```

Computing along a specified axis, using n-1 degrees of freedom (`ddof=1`) to calculate the standard deviation:

```python
>>> b = np.array([[0.3148, 0.0478, 0.6243, 0.4608],
... [0.7149, 0.0775, 0.6072, 0.9656],
... [0.6341, 0.1403, 0.9759, 0.4064],
... [0.5918, 0.6948, 0.904 , 0.3721],
... [0.0921, 0.2481, 0.1188, 0.1366]])
>>> stats.zscore(b, axis=1, ddof=1)
array([[-0.19264823, -1.28415119, 1.07259584, 0.40420358],
[-1.12598418, 0.0478, 0.6243, 0.4608],
[-0.6748, -1.1488, -1.3324]])
```
6.28.12 Statistical distances

---

**wasserstein_distance**(u_values, v_values[, ...])  
Compute the first Wasserstein distance between two 1D distributions.

**energy_distance**(u_values, v_values[, ...])  
Compute the energy distance between two 1D distributions.

---

**scipy.stats.wasserstein_distance**  
Compute the first Wasserstein distance between two 1D distributions.

This distance is also known as the earth mover’s distance, since it can be seen as the minimum amount of “work” required to transform \( u \) into \( v \), where “work” is measured as the amount of distribution weight that must be moved, multiplied by the distance it has to be moved.

New in version 1.0.0.

**Parameters**

- **u_values, v_values**  
  array_like Values observed in the (empirical) distribution.

- **u_weights, v_weights**  
  array_like, optional Weight for each value. If unspecified, each value is assigned the same weight. \( u\_weights \) (resp. \( v\_weights \)) must have the same length as \( u\_values \) (resp. \( v\_values \)).
  If the weight sum differs from 1, it must still be positive and finite so that the weights can be normalized to sum to 1.

**Returns**

- **distance**  
  float The computed distance between the distributions.

**Notes**

The first Wasserstein distance between the distributions \( u \) and \( v \) is:

\[
l_1(u, v) = \inf_{\pi \in \Gamma(u, v)} \int_{\mathbb{R} \times \mathbb{R}} |x - y| d\pi(x, y)
\]

where \( \Gamma(u, v) \) is the set of (probability) distributions on \( \mathbb{R} \times \mathbb{R} \) whose marginals are \( u \) and \( v \) on the first and second factors respectively.

If \( U \) and \( V \) are the respective CDFs of \( u \) and \( v \), this distance also equals to:

\[
l_1(u, v) = \int_{-\infty}^{+\infty} |U - V|
\]

See [2] for a proof of the equivalence of both definitions.

The input distributions can be empirical, therefore coming from samples whose values are effectively inputs of the function, or they can be seen as generalized functions, in which case they are weighted sums of Dirac delta functions located at the specified values.

**References**

[1], [2]
Examples

```python
>>> from scipy.stats import wasserstein_distance
>>> wasserstein_distance([0, 1, 3], [5, 6, 8])
5.0
>>> wasserstein_distance([0, 1], [0, 1], [3, 1], [2, 2])
0.25
>>> wasserstein_distance([3.4, 3.9, 7.5, 7.8], [4.5, 1.4],
  ... [1.4, 0.9, 3.1, 7.2], [3.2, 3.5])
4.0781331438047861
```

`scipy.stats.energy_distance`

`scipy.stats.energy_distance(u, v, u_weights=None, v_weights=None)`

Compute the energy distance between two 1D distributions.

New in version 1.0.0.

**Parameters**

- **u_values, v_values**
  
  [array_like] Values observed in the (empirical) distribution.

- **u_weights, v_weights**
  
  [array_like, optional] Weight for each value. If unspecified, each value is assigned the same weight. `u_weights` (resp. `v_weights`) must have the same length as `u_values` (resp. `v_values`). If the weight sum differs from 1, it must still be positive and finite so that the weights can be normalized to sum to 1.

**Returns**

- **distance**
  
  [float] The computed distance between the distributions.

**Notes**

The energy distance between two distributions `u` and `v`, whose respective CDFs are `U` and `V`, equals to:

$$D(u, v) = (2E|X - Y| - E|X - X'| - E|Y - Y'|)^{1/2}$$

where `X` and `X'` (resp. `Y` and `Y'`) are independent random variables whose probability distribution is `u` (resp. `v`). As shown in [2], for one-dimensional real-valued variables, the energy distance is linked to the non-distribution-free version of the Cramer-von Mises distance:

$$D(u, v) = \sqrt{2l_2(u, v)} = \left(2 \int_{-\infty}^{+\infty} (U - V)^2 \right)^{1/2}$$

Note that the common Cramer-von Mises criterion uses the distribution-free version of the distance. See [2] (section 2), for more details about both versions of the distance.

The input distributions can be empirical, therefore coming from samples whose values are effectively inputs of the function, or they can be seen as generalized functions, in which case they are weighted sums of Dirac delta functions located at the specified values.

```

### 6.28.13 Random variate generation

`rvs_ratio_uniforms(pdf, umax, vmin, vmax[, ...])` Generate random samples from a probability density function using the ratio-of-uniforms method.

**scipy.stats.rvs_ratio_uniforms**

Generate random samples from a probability density function using the ratio-of-uniforms method.

**Parameters**

- `pdf` [callable] A function with signature `pdf(x)` that is the probability density function of the distribution.
- `umax` [float] The upper bound of the bounding rectangle in the u-direction.
- `vmin` [float] The lower bound of the bounding rectangle in the v-direction.
- `vmax` [float] The upper bound of the bounding rectangle in the v-direction.
- `size` [int or tuple of ints, optional] Defining number of random variates (default is 1).
- `c` [float, optional.] Shift parameter of ratio-of-uniforms method, see Notes. Default is 0.
- `random_state` [int or np.random.RandomState instance, optional] If already a RandomState instance, use it. If seed is an int, return a new RandomState instance seeded with seed. If None, use np.random.RandomState. Default is None.

**Returns**

- `rvs` [ndarray] The random variates distributed according to the probability distribution defined by the pdf.

**Notes**

Given a univariate probability density function `pdf` and a constant `c`, define the set \( A = \{(u, v) : 0 < u \leq \sqrt{pdf(v/u + c)}\} \). If \((U, V)\) is a random vector uniformly distributed over \( A \), then \( V/U + c \) follows a distribution according to `pdf`.

The above result (see [1], [2]) can be used to sample random variables using only the pdf, i.e. no inversion of the cdf is required. Typical choices of `c` are zero or the mode of `pdf`. The set \( A \) is a subset of the rectangle \( \mathbb{R} = [0, umax] \times [vmin, vmax] \) where

- `umax = sup sqrt(pdf(x))`
- `vmin = inf (x - c) sqrt(pdf(x))`
• $v_{\text{max}} = \sup (x - c) \sqrt{\text{pdf}(x)}$

In particular, these values are finite if $pdf$ is bounded and $x^{**2} \cdot \text{pdf}(x)$ is bounded (i.e. subquadratic tails). One can generate $(U, V)$ uniformly on $R$ and return $V/U + c$ if $(U, V)$ are also in $A$ which can be directly verified.

Intuitively, the method works well if $A$ fills up most of the enclosing rectangle such that the probability is high that $(U, V)$ lies in $A$ whenever it lies in $R$ as the number of required iterations becomes too large otherwise. To be more precise, note that the expected number of iterations to draw $(U, V)$ uniformly distributed on $R$ such that $(U, V)$ is also in $A$ is given by the ratio $\text{area}(R) / \text{area}(A) = 2 \cdot u_{\text{max}} \cdot (v_{\text{max}} - v_{\text{min}})$, using the fact that the area of $A$ is equal to $1/2$ (Theorem 7.1 in [1]). A warning is displayed if this ratio is larger than 20. Moreover, if the sampling fails to generate a single random variate after 50000 iterations (i.e. not a single draw is in $A$), an exception is raised.

If the bounding rectangle is not correctly specified (i.e. if it does not contain $A$), the algorithm samples from a distribution different from the one given by $pdf$. It is therefore recommended to perform a test such as $kstest$ as a check.

References

[1], [2], [3]

Examples

```python
>>> from scipy import stats

Simulate normally distributed random variables. It is easy to compute the bounding rectangle explicitly in that case.

```python
>>> f = stats.norm.pdf
>>> v_bound = np.sqrt(f(np.sqrt(2))) * np.sqrt(2)
>>> umax, vmin, vmax = np.sqrt(f(0)), -v_bound, v_bound
>>> np.random.seed(12345)
>>> rvs = stats.rvs_ratio_uniforms(f, umax, vmin, vmax, size=2500)

The K-S test confirms that the random variates are indeed normally distributed (normality is not rejected at 5% significance level):

```python
>>> stats.kstest(rvs, 'norm')[1]
0.3420173467307603

The exponential distribution provides another example where the bounding rectangle can be determined explicitly.

```python
>>> np.random.seed(12345)
>>> rvs = stats.rvs_ratio_uniforms(lambda x: np.exp(-x), umax=1, ... vmin=0, vmax=2*np.exp(-1), size=1000)
>>> stats.kstest(rvs, 'expon')[1]
0.928454552559516

Sometimes it can be helpful to use a non-zero shift parameter $c$, see e.g. [2] above in the case of the generalized inverse Gaussian distribution.

6.28.14 Circular statistical functions
SciPy Reference Guide, Release 1.3.2

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>circmean</td>
<td>Compute the circular mean for samples in a range.</td>
</tr>
<tr>
<td>circvar</td>
<td>Compute the circular variance for samples assumed to be in a range.</td>
</tr>
<tr>
<td>circstd</td>
<td>Compute the circular standard deviation for samples assumed to be in the range [low to high].</td>
</tr>
</tbody>
</table>

**scipy.stats.circmean**

scipy.stats.circmean(samples, high=6.283185307179586, low=0, axis=None)

Compute the circular mean for samples in a range.

**Parameters**
- samples [array_like] Input array.
- high [float or int, optional] High boundary for circular mean range. Default is $2\pi$.
- low [float or int, optional] Low boundary for circular mean range. Default is 0.
- axis [int, optional] Axis along which means are computed. The default is to compute the mean of the flattened array.

**Returns**
- circmean [float] Circular mean.

**Examples**

```python
>>> from scipy.stats import circmean
>>> circmean([0.1, 2*np.pi+0.2, 6*np.pi+0.3])
0.2
```

```python
>>> from scipy.stats import circmean
>>> circmean([0.2, 1.4, 2.6], high = 1, low = 0)
0.4
```

**scipy.stats.circvar**

scipy.stats.circvar(samples, high=6.283185307179586, low=0, axis=None)

Compute the circular variance for samples assumed to be in a range.

**Parameters**
- samples [array_like] Input array.
- low [float or int, optional] Low boundary for circular variance range. Default is 0.
- high [float or int, optional] High boundary for circular variance range. Default is $2\pi$.
- axis [int, optional] Axis along which variances are computed. The default is to compute the variance of the flattened array.

**Returns**
- circvar [float] Circular variance.

**Notes**

This uses a definition of circular variance that in the limit of small angles returns a number close to the ‘linear’ variance.
Examples

```python
>>> from scipy.stats import circvar
>>> circvar([0, 2*np.pi/3, 5*np.pi/3])
2.19722457734
```

scipy.stats.circstd

```python
scipy.stats.circstd(samples, high=6.283185307179586, low=0, axis=None)
```

Compute the circular standard deviation for samples assumed to be in the range [low to high].

**Parameters**

- `samples`: [array_like] Input array.
- `low`: [float or int, optional] Low boundary for circular standard deviation range. Default is 0.
- `high`: [float or int, optional] High boundary for circular standard deviation range. Default is `2*pi`.
- `axis`: [int, optional] Axis along which standard deviations are computed. The default is to compute the standard deviation of the flattened array.

**Returns**

- `circstd`: [float] Circular standard deviation.

**Notes**

This uses a definition of circular standard deviation that in the limit of small angles returns a number close to the ‘linear’ standard deviation.

Examples

```python
>>> from scipy.stats import circstd
>>> circstd([0, 0.1*np.pi/2, 0.001*np.pi, 0.03*np.pi/2])
0.063564063306
```

## 6.28.15 Contingency table functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>chi2_contingency</code></td>
<td><code>(observed[, lambda_])</code></td>
<td>Chi-square test of independence of variables in a contingency table.</td>

<td>Performs a Fisher exact test on a 2x2 contingency table.</td>
</tr>
</tbody>
</table>

scipy.stats.chi2_contingency

```python
scipy.stats.chi2_contingency(observed, correction=True, lambda_=None)
```

Chi-square test of independence of variables in a contingency table.

This function computes the chi-square statistic and p-value for the hypothesis test of independence of the observed frequencies in the contingency table [1] `observed`. The expected frequencies are computed based on the marginal
sums under the assumption of independence; see `scipy.stats.contingency.expected_freq`. The number of degrees of freedom is (expressed using numpy functions and attributes):

```python
dof = observed.size - sum( observed.shape ) + observed.ndim - 1
```

**Parameters**

- **observed** [array_like] The contingency table. The table contains the observed frequencies (i.e. number of occurrences) in each category. In the two-dimensional case, the table is often described as an “R x C table”.
- **correction** [bool, optional] If True, and the degrees of freedom is 1, apply Yates’ correction for continuity. The effect of the correction is to adjust each observed value by 0.5 towards the corresponding expected value.
- **lambda_** [float or str, optional] By default, the statistic computed in this test is Pearson’s chi-squared statistic \([2]\). `lambda_` allows a statistic from the Cressie-Read power divergence family \([3]\) to be used instead. See `power_divergence` for details.

**Returns**

- **chi2** [float] The test statistic.
- **p** [float] The p-value of the test
- **dof** [int] Degrees of freedom
- **expected** [ndarray, same shape as `observed`] The expected frequencies, based on the marginal sums of the table.

**See also:**

- `contingency.expected_freq`
- `fisher_exact`
- `chisquare`
- `power_divergence`

**Notes**

An often quoted guideline for the validity of this calculation is that the test should be used only if the observed and expected frequencies in each cell are at least 5.

This is a test for the independence of different categories of a population. The test is only meaningful when the dimension of `observed` is two or more. Applying the test to a one-dimensional table will always result in `expected` equal to `observed` and a chi-square statistic equal to 0.

This function does not handle masked arrays, because the calculation does not make sense with missing values.

Like `stats.chisquare`, this function computes a chi-square statistic; the convenience this function provides is to figure out the expected frequencies and degrees of freedom from the given contingency table. If these were already known, and if the Yates’ correction was not required, one could use `stats.chisquare`. That is, if one calls:

```python
chi2, p, dof, ex = chi2_contingency( obs, correction=False )
```

then the following is true:

```python
(chi2, p) == stats.chisquare(obs.ravel(), f_exp=ex.ravel(),
                            ddof=obs.size - 1 - dof)
```

The `lambda_` argument was added in version 0.13.0 of scipy.
References

[1], [2], [3]

Examples

A two-way example (2 x 3):

```python
>>> from scipy.stats import chi2_contingency
>>> obs = np.array([[10, 10, 20], [20, 20, 20]])
>>> chi2_contingency(obs)
(2.7777777777777777, 0.24935220877729619, 2,
array([[ 12.,  12.,  16.],
       [ 18.,  18.,  24.]]))
```

Perform the test using the log-likelihood ratio (i.e. the “G-test”) instead of Pearson’s chi-squared statistic.

```python
>>> g, p = chi2_contingency(obs, lambda_="log-likelihood")
>>> g, p
(2.7688587616781319, 0.25046668010954165)
```

A four-way example (2 x 2 x 2 x 2):

```python
>>> obs = np.array(...
... [[[[12, 17],
    [11, 16]],
   [[11, 12],
    [15, 16]]],
... [[23, 15],
   [30, 22]],
... [[14, 17],
   [15, 16]]])
>>> chi2_contingency(obs)
(8.7584514426741897, 0.64417725029295503, 11,
array([[ 14.15462386,  14.15462386],
      [ 16.49423111, 16.49423111]],
     [[ 11.2461395 , 11.2461395 ],
      [ 13.10500554, 13.10500554]],
     [[ 19.5591166 , 19.5591166 ],
      [ 22.79202844, 22.79202844]],
     [[ 15.54012004, 15.54012004],
      [ 18.10873492, 18.10873492]])))
```

scipy.stats.contingency.expected_freq

scipy.stats.contingency.expected_freq( observed )

Compute the expected frequencies from a contingency table.
Given an n-dimensional contingency table of observed frequencies, compute the expected frequencies for the table based on the marginal sums under the assumption that the groups associated with each dimension are independent.

**Parameters**

- **observed** [array_like] The table of observed frequencies. (While this function can handle a 1-D array, that case is trivial. Generally *observed* is at least 2-D.)

**Returns**

- **expected** [ndarray of float64] The expected frequencies, based on the marginal sums of the table. Same shape as *observed*.

**Examples**

```python
>>> observed = np.array([[10, 10, 20], [20, 20, 20]])
>>> from scipy.stats.contingency import expected_freq
>>> expected_freq(observed)
array([[12., 12., 16.],
       [18., 18., 24.]])
```

### scipy.stats.contingency.margins

scipy.stats.contingency.margins(a)

Return a list of the marginal sums of the array *a*.

**Parameters**

- **a** [ndarray] The array for which to compute the marginal sums.

**Returns**

- **margsums** [list of ndarrays] A list of length *a.ndim*. *margsums[k]* is the result of summing *a* over all axes except *k*; it has the same number of dimensions as *a*, but the length of each axis except axis *k* will be 1.

**Examples**

```python
>>> a = np.arange(12).reshape(2, 6)
>>> a
array([[ 0,  1,  2,  3,  4,  5],
       [ 6,  7,  8,  9, 10, 11]])
>>> from scipy.stats.contingency import margins
>>> m0, m1 = margins(a)
>>> m0
array([[15],
       [51]])
>>> m1
array([[ 6,  8, 10, 12, 14, 16]])

>>> b = np.arange(24).reshape(2, 3, 4)
>>> m0, m1, m2 = margins(b)
>>> m0
```

(continues on next page)
array([[66],
       [210]])

>>> m1
array([[60],
       [92],
       [124]])

>>> m2
array([[60, 66, 72, 78]])

scipy.stats.fisher_exact

Performs a Fisher exact test on a 2x2 contingency table.

Parameters

- **table** [array_like of ints] A 2x2 contingency table. Elements should be non-negative integers.
- **alternative** [{‘two-sided’, ‘less’, ‘greater’}, optional] Which alternative hypothesis to the null hypothesis the test uses. Default is ‘two-sided’.

Returns

- **oddsratio** [float] This is prior odds ratio and not a posterior estimate.
- **p_value** [float] P-value, the probability of obtaining a distribution at least as extreme as the one that was actually observed, assuming that the null hypothesis is true.

See also:

- **chi2_contingency**

Chi-square test of independence of variables in a contingency table.

Notes

The calculated odds ratio is different from the one R uses. This scipy implementation returns the (more common) “unconditional Maximum Likelihood Estimate”, while R uses the “conditional Maximum Likelihood Estimate”.

For tables with large numbers, the (inexact) chi-square test implemented in the function `chi2_contingency` can also be used.

Examples

Say we spend a few days counting whales and sharks in the Atlantic and Indian oceans. In the Atlantic ocean we find 8 whales and 1 shark, in the Indian ocean 2 whales and 5 sharks. Then our contingency table is:

<table>
<thead>
<tr>
<th></th>
<th>Atlantic</th>
<th>Indian</th>
</tr>
</thead>
<tbody>
<tr>
<td>whales</td>
<td>8</td>
<td>2</td>
</tr>
<tr>
<td>sharks</td>
<td>1</td>
<td>5</td>
</tr>
</tbody>
</table>

We use this table to find the p-value:
import scipy.stats as stats

oddsratio, pvalue = stats.fisher_exact([[8, 2], [1, 5]])
pvalue

0.0349...

The probability that we would observe this or an even more imbalanced ratio by chance is about 3.5%. A commonly used significance level is 5%—if we adopt that, we can therefore conclude that our observed imbalance is statistically significant; whales prefer the Atlantic while sharks prefer the Indian ocean.

6.28.16 Plot-tests

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scipy.stats.ppcc_max</td>
<td>Calculate the shape parameter that maximizes the PPCC</td>
</tr>
<tr>
<td>scipy.stats.ppcc_plot</td>
<td>Calculate and optionally plot probability plot correlation coefficient.</td>
</tr>
<tr>
<td>scipy.stats.probplot</td>

</tr>
</tbody>
</table>

**scipy.stats.ppcc_max**

scipy.stats.ppcc_max(x, brack=(0.0, 1.0), dist='tukeylambda')

Calculate the shape parameter that maximizes the PPCC

The probability plot correlation coefficient (PPCC) plot can be used to determine the optimal shape parameter for a one-parameter family of distributions. ppcc_max returns the shape parameter that would maximize the probability plot correlation coefficient for the given data to a one-parameter family of distributions.

**Parameters**

- `x` [array_like] Input array.
- `brack` [tuple, optional] Triple (a,b,c) where (a<b<c). If bracket consists of two numbers (a, c) then they are assumed to be a starting interval for a downhill bracket search (see scipy.optimize.brent).
- `dist` [str or stats.distributions instance, optional] Distribution or distribution function name. Objects that look enough like a stats.distributions instance (i.e. they have a ppf method) are also accepted. The default is 'tukeylambda'.

**Returns**

- `shape_value` [float] The shape parameter at which the probability plot correlation coefficient reaches its max value.

**See also:**

- ppcc_plot, probplot, boxcox

**Notes**

The brack keyword serves as a starting point which is useful in corner cases. One can use a plot to obtain a rough visual estimate of the location for the maximum to start the search near it.
References

[1], [2]

Examples

First we generate some random data from a Tukey-Lambda distribution, with shape parameter -0.7:

```python
>>> from scipy import stats
>>> x = stats.tukeylambda.rvs(-0.7, loc=2, scale=0.5, size=10000,
... random_state=1234567) + 1e4
```

Now we explore this data with a PPCC plot as well as the related probability plot and Box-Cox normplot. A red line is drawn where we expect the PPCC value to be maximal (at the shape parameter -0.7 used above):

```python
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure(figsize=(8, 6))
>>> ax = fig.add_subplot(111)
>>> res = stats.ppcc_plot(x, -5, 5, plot=ax)
```

We calculate the value where the shape should reach its maximum and a red line is drawn there. The line should coincide with the highest point in the ppcc_plot.

```python
>>> max = stats.ppcc_max(x)
>>> ax.vlines(max, 0, 1, colors='r', label='Expected shape value')
```

```python
>>> plt.show()
```

`scipy.stats.ppcc_plot`

`scipy.stats.ppcc_plot(x, a, b, dist='tukeylambda', plot=None, N=80)`

Calculate and optionally plot probability plot correlation coefficient.

The probability plot correlation coefficient (PPCC) plot can be used to determine the optimal shape parameter for a one-parameter family of distributions. It cannot be used for distributions without shape parameters (like the normal distribution) or with multiple shape parameters.

By default a Tukey-Lambda distribution (`stats.tukeylambda`) is used. A Tukey-Lambda PPCC plot interpolates from long-tailed to short-tailed distributions via an approximately normal one, and is therefore particularly useful in practice.

**Parameters**

- `x` [array_like] Input array.
- `a, b`: scalar
  Lower and upper bounds of the shape parameter to use.
- `dist` [str or stats.distributions instance, optional] Distribution or distribution function name. Objects that look enough like a stats.distributions instance (i.e. they have a ppf method) are also accepted. The default is 'tukeylambda'.
- `plot` [object, optional] If given, plots PPCC against the shape parameter. plot is an object that has to have methods “plot” and “text”. The `matplotlib.pyplot` module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is None, which means that no plot is created.
- `N` [int, optional] Number of points on the horizontal axis (equally distributed from a to b).
6.28. Statistical functions (scipy.stats)
Returns

* svals [ndarray] The shape values for which `ppcc` was calculated.
* ppcc [ndarray] The calculated probability plot correlation coefficient values.

See also:

`ppcc_max`, `probplot`, `boxcox_normplot`, `tukeylambda`

References

Examples

First we generate some random data from a Tukey-Lambda distribution, with shape parameter -0.7:

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234567)
>>> x = stats.tukeylambda.rvs(-0.7, loc=2, scale=0.5, size=10000) + 1e4
```

Now we explore this data with a PPCC plot as well as the related probability plot and Box-Cox normplot. A red line is drawn where we expect the PPCC value to be maximal (at the shape parameter -0.7 used above):

```python
>>> fig = plt.figure(figsize=(12, 4))
>>> ax1 = fig.add_subplot(131)
>>> ax2 = fig.add_subplot(132)
>>> ax3 = fig.add_subplot(133)
>>> res = stats.probplot(x, plot=ax1)
>>> res = stats.boxcox_normplot(x, -5, 5, plot=ax2)
>>> res = stats.ppcc_plot(x, -5, 5, plot=ax3)
>>> ax3.vlines(-0.7, 0, 1, colors='r', label='Expected shape value')
>>> plt.show()
```
scipy.stats.probplot

scipy.stats.probplot(x, sparams=(), dist='norm', fit=True, plot=None, rvalue=False)
Calculate quantiles for a probability plot, and optionally show the plot.

Generates a probability plot of sample data against the quantiles of a specified theoretical distribution (the normal distribution by default). probplot optionally calculates a best-fit line for the data and plots the results using Matplotlib or a given plot function.

Parameters

- **x**  
  [array_like] Sample/response data from which probplot creates the plot.
- **sparams**  
  [tuple, optional] Distribution-specific shape parameters (shape parameters plus location and scale).
- **dist**  
  [str or stats.distributions instance, optional] Distribution or distribution function name. The default is ‘norm’ for a normal probability plot. Objects that look enough like a stats.distributions instance (i.e. they have a ppf method) are also accepted.
- **fit**  
  [bool, optional] Fit a least-squares regression (best-fit) line to the sample data if True (default).
- **plot**  
  [object, optional] If given, plots the quantiles and least squares fit. plot is an object that has to have methods “plot” and “text”. The matplotlib.pyplot module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is None, which means that no plot is created.

Returns

- (osm, osr)  
  [tuple of ndarrays] Tuple of theoretical quantiles (osm, or order statistic medians) and ordered responses (osr). osr is simply sorted input x. For details on how osm is calculated see the Notes section.
- (slope, intercept, r)  
  [tuple of floats, optional] Tuple containing the result of the least-squares fit, if that is performed by probplot. r is the square root of the coefficient of determination. If fit=False and plot=None, this tuple is not returned.

Notes

Even if plot is given, the figure is not shown or saved by probplot; plt.show() or plt.savefig('figname.png') should be used after calling probplot.

probplot generates a probability plot, which should not be confused with a Q-Q or a P-P plot. Statsmodels has more extensive functionality of this type, see statsmodels.api.ProbPlot.

The formula used for the theoretical quantiles (horizontal axis of the probability plot) is Filliben’s estimate:

\[
\text{quantiles} = \text{dist}.\text{ppf}(\text{val}), \quad \text{for} \quad 0.5^*(1/n), \quad \text{for} \quad i = n \\
\text{val} = (i - 0.3175) / (n + 0.365), \quad \text{for} \quad i = 2, \ldots, n-1 \\
1 - 0.5^*(1/n), \quad \text{for} \quad i = 1
\]

where i indicates the i-th ordered value and n is the total number of values.

Examples
```python
from scipy import stats
import matplotlib.pyplot as plt

nsample = 100
np.random.seed(7654321)

A t distribution with small degrees of freedom:

```python
>>> ax1 = plt.subplot(221)
>>> x = stats.t.rvs(3, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```  

A t distribution with larger degrees of freedom:

```python
>>> ax2 = plt.subplot(222)
>>> x = stats.t.rvs(25, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```  

A mixture of two normal distributions with broadcasting:

```python
>>> ax3 = plt.subplot(223)
>>> x = stats.norm.rvs(loc=[0, 5], scale=[1, 1.5],
...     size=(nsample//2, 2)).ravel()
>>> res = stats.probplot(x, plot=plt)
```  

A standard normal distribution:

```python
>>> ax4 = plt.subplot(224)
>>> x = stats.norm.rvs(loc=0, scale=1, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```  

Produce a new figure with a loggamma distribution, using the dist and sparams keywords:

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> x = stats.loggamma.rvs(c=2.5, size=500)
>>> res = stats.probplot(x, dist=stats.loggamma, sparams=(2.5,), plot=ax)
>>> ax.set_title("Probplot for loggamma dist with shape parameter 2.5")
```  

Show the results with Matplotlib:

```python
>>> plt.show()
```  

**scipy.stats.boxcox_normplot**

scipy.stats.boxcox_normplot(x, la, lb, plot=None, N=80)

Compute parameters for a Box-Cox normality plot, optionally show it.

A Box-Cox normality plot shows graphically what the best transformation parameter is to use in boxcox to obtain a distribution that is close to normal.

**Parameters**

- x [array_like] Input array.
Theoretical quantiles

Ordered Values

Probability Plot

Probability Plot

Probplot for loggamma dist with shape parameter 2.5

Ordered Values

Theoretical quantiles
**SciPy Reference Guide, Release 1.3.2**

**boxcox_normplot**

```python
la, lb
[scalar] The lower and upper bounds for the \( \lambda \) values to pass to `boxcox` for Box-
Cox transformations. These are also the limits of the horizontal axis of the plot if that is
generated.

plot
[object, optional] If given, plots the quantiles and least squares fit. plot is an object that has
to have methods “plot” and “text”. The `matplotlib.pyplot` module or a Matplotlib
Axes object can be used, or a custom object with the same methods. Default is None, which
means that no plot is created.

N
[int, optional] Number of points on the horizontal axis (equally distributed from \( la \) to \( lb \)).

Returns

lmbdas
[ndarray] The \( \lambda \) values for which a Box-Cox transform was done.

ppcc
[ndarray] Probability Plot Correlation Coefficient, as obtained from `probplot` when fit-
ting the Box-Cox transformed input \( x \) against a normal distribution.

See also:

`probplot`, `boxcox`, `boxcox_normmax`, `boxcox_llf`, `ppcc_max`

Notes

Even if plot is given, the figure is not shown or saved by `boxcox_normplot`; `plt.show()` or `plt.
savefig('figname.png')` should be used after calling `probplot`.

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt

Generate some non-normally distributed data, and create a Box-Cox plot:

```python
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.boxcox_normplot(x, -20, 20, plot=ax)
```

Determine and plot the optimal \( \lambda \) to transform \( x \) and plot it in the same plot:

```python
>>> _, maxlog = stats.boxcox(x)
>>> ax.axvline(maxlog, color='r')
```

```python
>>> plt.show()
```

**scipy.stats.yeojohnson_normplot**

`scipy.stats.yeojohnson_normplot` \((x, la, lb, plot=None, N=80)\)

A Yeo-Johnson normality plot shows graphically what the best transformation parameter is to use in `yeojohnson`
to obtain a distribution that is close to normal.

**Parameters**

- \( x \) [array_like] Input array.
Box-Cox Normality Plot

<table>
<thead>
<tr>
<th>la, lb</th>
<th>[scalar] The lower and upper bounds for the $\lambda$ values to pass to <code>yeojohnson</code> for Yeo-Johnson transformations. These are also the limits of the horizontal axis of the plot if that is generated.</th>
</tr>
</thead>
<tbody>
<tr>
<td>plot</td>
<td>[object, optional] If given, plots the quantiles and least squares fit. <code>plot</code> is an object that has to have methods “plot” and “text”. The <code>matplotlib.pyplot</code> module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is None, which means that no plot is created.</td>
</tr>
<tr>
<td>N</td>
<td>[int, optional] Number of points on the horizontal axis (equally distributed from la to lb).</td>
</tr>
</tbody>
</table>

**Returns**

| lmbdas | [ndarray] The $\lambda$ values for which a Yeo-Johnson transform was done. |
| ppc | [ndarray] Probability Plot Correlation Coefficient, as obtained from `probplot` when fitting the Box-Cox transformed input $x$ against a normal distribution. |

**See also:**

`probplot`, `yeojohnson`, `yeojohnson_normmax`, `yeojohnson_llf`, `ppcc_max`

**Notes**

Even if `plot` is given, the figure is not shown or saved by `boxcox_normplot`; `plt.show()` or `plt.savefig('figname.png')` should be used after calling `probplot`.

New in version 1.2.0.

**Examples**

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Generate some non-normally distributed data, and create a Yeo-Johnson plot:
Determine and plot the optimal \( \lambda \) to transform \( x \) and plot it in the same plot:

```python
>>> _, maxlog = stats.yeojohnson(x)
>>> ax.axvline(maxlog, color='r')
>>> plt.show()
```

### 6.28.17 Masked statistics functions

**Statistical functions for masked arrays (scipy.stats.mstats)**

This module contains a large number of statistical functions that can be used with masked arrays.

Most of these functions are similar to those in `scipy.stats` but might have small differences in the API or in the algorithm used. Since this is a relatively new package, some API changes are still possible.

**Summary statistics**

- `describe(a[, axis, ddof, bias])`: Computes several descriptive statistics of the passed array.
- `gmean(a[, axis, dtype])`: Compute the geometric mean along the specified axis.
- `hmean(a[, axis, dtype])`: Calculate the harmonic mean along the specified axis.
- `kurtosis(a[, axis, fisher, bias])`: Computes the kurtosis (Fisher or Pearson) of a dataset.
- `mode(a[, axis])`: Returns an array of the modal (most common) value in the passed array.
- `mquantiles(a[, prob, alphap, betap, axis, limit])`: Computes empirical quantiles for a data array.

**scipy.stats.mstats.describe**

`scipy.stats.mstats.describe(a, axis=0, ddof=0, bias=True)`

Computes several descriptive statistics of the passed array.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>[array_like] Data array</td>
</tr>
<tr>
<td>axis</td>
<td>[int or None, optional] Axis along which to calculate statistics. Default 0. If None, compute over the whole array a.</td>
</tr>
<tr>
<td>ddof</td>
<td>[int, optional] degree of freedom (default 0); note that default ddof is different from the same routine in stats.describe</td>
</tr>
<tr>
<td>bias</td>
<td>[bool, optional] If False, then the skewness and kurtosis calculations are corrected for statistical bias.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nobs</td>
<td>[int] (size of the data (discarding missing values)</td>
</tr>
<tr>
<td>minmax</td>
<td>[(int, int)] min, max</td>
</tr>
<tr>
<td>mean</td>
<td>[float] arithmetic mean</td>
</tr>
<tr>
<td>variance</td>
<td>[float] unbiased variance</td>
</tr>
<tr>
<td>skewness</td>
<td>[float] biased skewness</td>
</tr>
<tr>
<td>kurtosis</td>
<td>[float] biased kurtosis</td>
</tr>
</tbody>
</table>
Examples

```python
>>> from scipy.stats.mstats import describe
>>> ma = np.ma.array(range(6), mask=[0, 0, 0, 1, 1, 1])
>>> describe(ma)
DescribeResult(nobs=3, minmax=(masked_array(data=0, mask=False, fill_value=999999), masked_array(data=2, mask=False, fill_value=999999)), mean=1.0, variance=0.6666666666666666, skewness=masked_array(data=0., mask=False, fill_value=1e+20), kurtosis=-1.5)
```

**scipy.stats.mstats.gmean**

The geometric mean is computed over a single dimension of the input array, axis=0 by default, or all values in the array if axis=None. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.
Examples

```python
>>> from scipy.stats import gmean
>>> gmean([1, 4])
2.0
>>> gmean([1, 2, 3, 4, 5, 6, 7])
3.3800151591412964
```

**scipy.stats.mstats.hmean**

`scipy.stats.mstats.hmean(a, axis=0, dtype=None)`

Calculate the harmonic mean along the specified axis.

That is: \( n / (1/x_1 + 1/x_2 + \ldots + 1/x_n) \)

**Parameters**

- `a` : array_like Input array, masked array or object that can be converted to an array.
- `axis` : int or None, optional Axis along which the harmonic mean is computed. Default is 0. If None, compute over the whole array `a`.
- `dtype` : dtype, optional Type of the returned array and of the accumulator in which the elements are summed. If `dtype` is not specified, it defaults to the dtype of `a`, unless `a` has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

**Returns**

- `hmean` : ndarray see `dtype` parameter above

**See also:**

- `numpy.mean`
  - Arithmetic average
- `numpy.average`
  - Weighted average
- `gmean`
  - Geometric mean

**Notes**

The harmonic mean is computed over a single dimension of the input array, axis=0 by default, or all values in the array if axis=None. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

**Examples**
```python
>>> from scipy.stats import hmean
>>> hmean([1, 4])
1.6000000000000001
>>> hmean([1, 2, 3, 4, 5, 6, 7])
2.6997245179063363
```

**scipy.stats.mstats.kurtosis**

scipy.stats.mstats.kurtosis(a, axis=0, fisher=True, bias=True)

Computes the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher's definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If bias is False then the kurtosis is calculated using k statistics to eliminate bias coming from biased moment estimators.

Use kurtosistest to see if result is close enough to normal.

**Parameters**

- **a** [array] data for which the kurtosis is calculated
- **axis** [int or None, optional] Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array a.
- **fisher** [bool, optional] If True, Fisher's definition is used (normal ==> 0.0). If False, Pearson's definition is used (normal ==> 3.0).
- **bias** [bool, optional] If False, then the calculations are corrected for statistical bias.

**Returns**

- **kurtosis** [array] The kurtosis of values along an axis. If all values are equal, return -3 for Fisher's definition and 0 for Pearson's definition.

**Notes**

For more details about kurtosis, see stats.kurtosis.

**scipy.stats.mstats.mode**

scipy.stats.mstats.mode(a, axis=0)

Returns an array of the modal (most common) value in the passed array.

**Parameters**

- **a** [array_like] n-dimensional array of which to find mode(s).
- **axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array a.

**Returns**

- **mode** [ndarray] Array of modal values.
- **count** [ndarray] Array of counts for each mode.
Notes

For more details, see `stats.mode`.

Examples

```python
>>> from scipy import stats
>>> from scipy.stats import mstats
>>> m_arr = np.ma.array([1, 1, 0, 0, 0, 0], mask=[0, 0, 1, 1, 1, 0])
>>> stats.mode(m_arr)
ModeResult(mode=array([0]), count=array([4]))
>>> mstats.mode(m_arr)
ModeResult(mode=array([1.]), count=array([2.]))
```

`scipy.stats.mstats.mquantiles`

`scipy.stats.mstats.mquantiles(a, prob=[0.25, 0.5, 0.75], alphap=0.4, betap=0.4, axis=None, limit=())`

Computes empirical quantiles for a data array.

Samples quantile are defined by \(Q(p) = (1-gamma)*x[j] + gamma*x[j+1]\), where \(x[j]\) is the \(j\)-th order statistic, and \(gamma\) is a function of \(j = \text{floor}(n*p + m)\), \(m = \text{alphap} + p*(1 - \text{alphap} - \text{betap})\) and \(g = n*p + m - j\).

Reinterpreting the above equations to compare to R lead to the equation: \(p(k) = (k - \text{alphap})/(n + 1 - \text{alphap} - \text{betap})\)

Typical values of (\(\text{alphap}, \text{betap}\)) are:

- \((0,1)\): \(p(k) = k/n\): linear interpolation of cdf (R type 4)
- \((.5,.5)\): \(p(k) = (k - 1/2.)/n\): piecewise linear function (R type 5)
- \((0,0)\): \(p(k) = k/(n+1)\): (R type 6)
- \((1,1)\): \(p(k) = (k-1)/(n-1)\): \(p(k) = \text{mode}[F(x[k])]\). (R type 7, R default)
- \((1/3,1/3)\): \(p(k) = (k-1/3)/(n+1/3)\): Then \(p(k) \sim \text{median}[F(x[k])]\). The resulting quantile estimates are approximately median-unbiased regardless of the distribution of \(x\). (R type 8)
- \((3/8,3/8)\): \(p(k) = (k-3/8)/(n+1/4)\): Blom. The resulting quantile estimates are approximately unbiased if \(x\) is normally distributed (R type 9)
- \((.4,.4)\): approximately quantile unbiased (Cunnane)
- \((.35,.35)\): APL, used with PWM

Parameters

- `a` [array_like] Input data, as a sequence or array of dimension at most 2.
- `prob` [array_like, optional] List of quantiles to compute.
- `alphap` [float, optional] Plotting positions parameter, default is 0.4.
- `betap` [float, optional] Plotting positions parameter, default is 0.4.
- `axis` [int, optional] Axis along which to perform the trimming. If None (default), the input array is first flattened.
- `limit` [tuple, optional] Tuple of (lower, upper) values. Values of \(a\) outside this open interval are ignored.
Returns

mquantiles

[MaskedArray] An array containing the calculated quantiles.

Notes

This formulation is very similar to R except the calculation of m from alphap and betap, where in R m is defined with each type.

References

[1],[2]

Examples

```python
>>> from scipy.stats.mstats import mquantiles
>>> a = np.array([6., 47., 49., 15., 42., 41., 7., 39., 43., 40., 36.])
>>> mquantiles(a)
array([19.2, 40. , 42.8])
```

Using a 2D array, specifying axis and limit.

```python
>>> data = np.array([[ 6., 7., 1.],
...                   [ 47., 15., 2.],
...                   [ 49., 36., 3.],
...                   [ 15., 39., 4.],
...                   [ 42., 40., -999.],
...                   [ 41., 41., -999.],
...                   [ 7., -999., -999.],
...                   [ 39., -999., -999.],
...                   [ 43., -999., -999.],
...                   [ 40., -999., -999.],
...                   [ 36., -999., -999.]]
>>> print(mquantiles(data, axis=0, limit=(0, 50)))
[[19.2 14.6  1.45]
 [40. 37.5  2.5 ]
 [42.8 40.05 3.55]]
```

```python
>>> data[:, 2] = -999.
>>> print(mquantiles(data, axis=0, limit=(0, 50)))
[[19.200000000000003 14.6 --]
 [40.0 37.5 --]
 [42.800000000000004 40.05 --]]
```

scipy.stats.mstats.hdmedian

`scipy.stats.mstats.hdmedian(data, axis=-1, var=False)`

Returns the Harrell-Davis estimate of the median along the given axis.

Parameters
**scipy.stats.mstats.hdquantiles**

scipy.stats.mstats.hdquantiles(data, prob=[0.25, 0.5, 0.75], axis=None, var=False)

Computes quantile estimates with the Harrell-Davis method.

The quantile estimates are calculated as a weighted linear combination of order statistics.

**Parameters**

- data: *[array_like]* Data array.
- prob: *[sequence, optional]* Sequence of quantiles to compute.
- axis: *[int or None, optional]* Axis along which to compute the quantiles. If None, use a flattened array.
- var: *[bool, optional]* Whether to return the variance of the estimate.

**Returns**

- hdquantiles: *[MaskedArray]* A (p,) array of quantiles (if var is False), or a (2,p) array of quantiles and variances (if var is True), where p is the number of quantiles.

**See also:**

hdquantiles_sd

---

**scipy.stats.mstats.hdquantiles_sd**

scipy.stats.mstats.hdquantiles_sd(data, prob=[0.25, 0.5, 0.75], axis=None)

The standard error of the Harrell-Davis quantile estimates by jackknife.

**Parameters**

- data: *[array_like]* Data array.
- prob: *[sequence, optional]* Sequence of quantiles to compute.
- axis: *[int, optional]* Axis along which to compute the quantiles. If None, use a flattened array.

**Returns**

- hdquantiles_sd: *[MaskedArray]* Standard error of the Harrell-Davis quantile estimates.

**See also:**

hdquantiles
scipy.stats.mstats.idealfourths

scipy.stats.mstats.idealfourths(data, axis=\text{None})

Returns an estimate of the lower and upper quartiles.

Uses the ideal fourths algorithm.

Parameters

- **data**: [array_like] Input array.
- **axis**: [int, optional] Axis along which the quartiles are estimated. If \text{None}, the arrays are flattened.

Returns

- **idealfourths**: [{list of floats, masked array}] Returns the two internal values that divide data into four parts using the ideal fourths algorithm either along the flattened array (if \text{axis} is \text{None}) or along \text{axis} of data.

scipy.stats.mstats.plotting_positions

scipy.stats.mstats.plotting_positions(data, alpha=0.4, beta=0.4)

Returns plotting positions (or empirical percentile points) for the data.

*Plotting positions are defined as *(i-alpha)/(n+1-alpha-beta)**, where:

- \(i\) is the rank order statistics
- \(n\) is the number of unmasked values along the given axis
- \(alpha\) and \(beta\) are two parameters.

*Typical values for alpha and beta are:*

- \((0,1)\): \(p(k) = k/n\), linear interpolation of cdf (R, type 4)
- \((.5,.5)\): \(p(k) = (k-1/2.)/n\), piecewise linear function (R, type 5)
- \((0,0)\): \(p(k) = k/(n+1)\), Weibull (R type 6)
- \((1,1)\): \(p(k) = (k-1)/(n-1)\), in this case, \(p(k) = \text{mode}[F(x[k])]\). That’s R default (R type 7)
- \((1/3,1/3)\): \(p(k) = (k-1/3)/(n+1/3)\), then \(p(k) \sim \text{median}[F(x[k])]\). The resulting quantile estimates are approximately median-unbiased regardless of the distribution of \(x\). (R type 8)
- \((3/8,3/8)\): \(p(k) = (k-3/8)/(n+1/4)\), Blom. The resulting quantile estimates are approximately unbiased if \(x\) is normally distributed (R type 9)
- \((.4,.4)\): approximately quantile unbiased (Cunnane)
- \((.35,.35)\): APL, used with PWM
- \((.3175, .3175)\): used in scipy.stats.probplot

Parameters

- **data**: [array_like] Input data, as a sequence or array of dimension at most 2.
- **alpha**: [float, optional] Plotting positions parameter. Default is 0.4.
- **beta**: [float, optional] Plotting positions parameter. Default is 0.4.

Returns
The calculated plotting positions.

**scipy.stats.mstats.meppf**

Returns plotting positions (or empirical percentile points) for the data.

*Plotting positions are defined as \( \frac{i - \alpha}{n + 1 - \alpha - \beta} \), where:*

- \( i \) is the rank order statistics
- \( n \) is the number of unmasked values along the given axis
- \( \alpha \) and \( \beta \) are two parameters.

*Typical values for \( \alpha \) and \( \beta \) are:*

- \((0,1): p(k) = \frac{k}{n}\), linear interpolation of cdf (R, type 4)
- \((0.5,0.5): p(k) = \frac{(k-1/2)}{n}\), piecewise linear function (R, type 5)
- \((0,0): p(k) = \frac{k}{n+1}\), Weibull (R type 6)
- \((1,1): p(k) = \frac{(k-1)}{(n-1)}\), in this case, \( p(k) = \text{mode}[F(x[k])] \). That’s R default (R type 7)
- \((1/3,1/3): p(k) = \frac{(k-1/3)}{(n+1/3)}\), then \( p(k) \sim \text{median}[F(x[k])] \). The resulting quantile estimates are approximately median-unbiased regardless of the distribution of \( x \). (R type 8)
- \((3/8,3/8): p(k) = \frac{(k-3/8)}{(n+1/4)}\), Blom. The resulting quantile estimates are approximately unbiased if \( x \) is normally distributed (R type 9)
- \((.4,.4): \) approximately quantile unbiased (Cunnane)
- \((.35,.35): \) APL, used with PWM
- \((.3175,.3175): \) used in scipy.stats.probplot

**Parameters**

- **data** [array_like] Input data, as a sequence or array of dimension at most 2.
- **alpha** [float, optional] Plotting positions parameter. Default is 0.4.
- **beta** [float, optional] Plotting positions parameter. Default is 0.4.

**Returns**

- **positions** [MaskedArray] The calculated plotting positions.

**scipy.stats.mstats.moment**

Calculates the nth moment about the mean for a sample.

**Parameters**

- **a** [array_like] data
- **moment** [int, optional] order of central moment that is returned
- **axis** [int or None, optional] Axis along which the central moment is computed. Default is 0. If None, compute over the whole array \( a \).
Returns

\text{n-th central moment}

[ndarray or float] The appropriate moment along the given axis or over all values if axis is None. The denominator for the moment calculation is the number of observations, no degrees of freedom correction is done.

Notes

For more details about \text{moment}, see \text{stats.moment}.

\text{scipy.stats.mstats.skew}

\text{scipy.stats.mstats.skew}(a, axis=0, bias=True)

Computes the skewness of a data set.

Parameters

\text{a} \quad \text{[ndarray]} \text{ data}
\text{axis} \quad \text{[int or None, optional]} \text{ Axis along which skewness is calculated. Default is 0. If None, compute over the whole array a.}
\text{bias} \quad \text{[bool, optional]} \text{ If False, then the calculations are corrected for statistical bias.}

Returns

\text{skewness} \quad \text{[ndarray]} \text{ The skewness of values along an axis, returning 0 where all values are equal.}

Notes

For more details about \text{skew}, see \text{stats.skew}.

\text{scipy.stats.mstats.tmean}

\text{scipy.stats.mstats.tmean}(a, limits=None, inclusive=(True, True), axis=None)

Compute the trimmed mean.

Parameters

\text{a} \quad \text{[array_like]} \text{ Array of values.}
\text{limits} \quad \text{[None or (lower limit, upper limit), optional]} \text{ Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.}
\text{inclusive} \quad \text{[(bool, bool), optional]} \text{ A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).}
\text{axis} \quad \text{[int or None, optional]} \text{ Axis along which to operate. If None, compute over the whole array. Default is None.}

Returns

\text{tmean} \quad \text{[float]}
Notes

For more details on `tmean`, see `stats.tmean`.

Examples

```python
>>> from scipy.stats import mstats
>>> a = np.array([[6, 8, 3, 0],
...                [3, 9, 1, 2],
...                [8, 7, 8, 2],
...                [5, 6, 0, 2],
...                [4, 5, 5, 2]])
>>> mstats.tmean(a, (2,5))
3.3
>>> mstats.tmean(a, (2,5), axis=0)
masked_array(data=[4.0, 5.0, 4.0, 2.0],
             mask=[False, False, False, False],
             fill_value=1e+20)
```

`scipy.stats.mstats.tvar`

`scipy.stats.mstats.tvar(a, limits=None, inclusive=(True, True), axis=0, ddof=1)`

Compute the trimmed variance

This function computes the sample variance of an array of values, while ignoring values which are outside of given limits.

**Parameters**

- `a` ([array_like]) Array of values.
- `limits` ([None or (lower limit, upper limit), optional]) Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.
- `inclusive` ([bool, bool], optional) A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- `axis` ([int or None, optional]) Axis along which to operate. If None, compute over the whole array. Default is zero.
- `ddof` ([int, optional]) Delta degrees of freedom. Default is 1.

**Returns**

- `tvar` ([float]) Trimmed variance.

**Notes**

For more details on `tvar`, see `stats.tvar`.  
2529
scipy.stats.mstats.tmin

`scipy.stats.mstats.tmin(a, lowerlimit=None, axis=0, inclusive=True)`

Compute the trimmed minimum

**Parameters**

- `a` [array_like] array of values
- `lowerlimit` [None or float, optional] Values in the input array less than the given limit will be ignored. When lowerlimit is None, then all values are used. The default value is None.
- `axis` [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array `a`.
- `inclusive` [[`True`, False], optional] This flag determines whether values exactly equal to the lower limit are included. The default value is True.

**Returns**

- `tmin` [float, int or ndarray]

**Notes**

For more details on `tmin`, see `stats.tmin`.

**Examples**

```python
>>> from scipy.stats import mstats
>>> a = np.array([[6, 8, 3, 0],
                ...               [3, 2, 1, 2],
                ...               [8, 1, 8, 2],
                ...               [5, 3, 0, 2],
                ...               [4, 7, 5, 2]])
>>> mstats.tmin(a, 5)
masked_array(data=[5, 7, 5, --],
             mask=[False, False, False, True],
            fill_value=999999)
```

scipy.stats.mstats.tmax

`scipy.stats.mstats.tmax(a, upperlimit=None, axis=0, inclusive=True)`

Compute the trimmed maximum

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

**Parameters**

- `a` [array_like] array of values
- `upperlimit` [None or float, optional] Values in the input array greater than the given limit will be ignored. When upperlimit is None, then all values are used. The default value is None.
- `axis` [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array `a`. 
inclusive  [[True, False], optional] This flag determines whether values exactly equal to the upper limit are included. The default value is True.

Returns

tmax    [float, int or ndarray]

Notes

For more details on tmax, see stats.tmax.

Examples

```python
>>> from scipy.stats import mstats
>>> a = np.array([[6, 8, 3, 0],
...                [3, 9, 1, 2],
...                [8, 7, 8, 2],
...                [5, 6, 0, 2],
...                [4, 5, 5, 2]])
...  ...
>>> mstats.tmax(a, 4)
masked_array(data=[4, --, 3, 2],
             mask=[False, True, False, False],
            fill_value=999999)
```

scipy.stats.mstats.tsem

scipy.stats.mstats.tsem(a, limits=None, inclusive=(True, True), axis=0, ddof=1)

Compute the trimmed standard error of the mean.

This function finds the standard error of the mean for given values, ignoring values outside the given limits.

Parameters

- **a** [array_like] array of values
- **limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.
- **inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- **axis** [int or None, optional] Axis along which to operate. If None, compute over the whole array. Default is zero.
- **ddof** [int, optional] Delta degrees of freedom. Default is 1.

Returns

- **tsem** [float]
Notes

For more details on `tsem`, see `stats.tsem`.

`scipy.stats.mstats.variation`

`scipy.stats.mstats.variation(a, axis=0)`
Computes the coefficient of variation, the ratio of the biased standard deviation to the mean.

**Parameters**

- `a` [array_like] Input array.
- `axis` [int or None, optional] Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array `a`.

**Returns**

- `variation` [ndarray] The calculated variation along the requested axis.

Notes

For more details about `variation`, see `stats.variation`.

`scipy.stats.mstats.find_repeats`

`scipy.stats.mstats.find_repeats(arr)`
Find repeats in `arr` and return a tuple (repeats, repeat_count).

The input is cast to float64. Masked values are discarded.

**Parameters**

- `arr` [sequence] Input array. The array is flattened if it is not 1D.

**Returns**

- `repeats` [ndarray] Array of repeated values.
- `counts` [ndarray] Array of counts.

`scipy.stats.mstats.sem`

`scipy.stats.mstats.sem(a, axis=0, ddof=1)`
Calculates the standard error of the mean of the input array.

Also sometimes called standard error of measurement.

**Parameters**

- `a` [array_like] An array containing the values for which the standard error is returned.
- `axis` [int or None, optional] If axis is None, ravel `a` first. If axis is an integer, this will be the axis over which to operate. Defaults to 0.
- `ddof` [int, optional] Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.

**Returns**

- `s` [ndarray or float] The standard error of the mean in the sample(s), along the input axis.
Notes

The default value for `ddof` changed in scipy 0.15.0 to be consistent with `stats.sem` as well as with the most common definition used (like in the R documentation).

Examples

Find standard error along the first axis:

```python
>>> from scipy import stats
>>> a = np.arange(20).reshape(5, 4)
>>> print(stats.mstats.sem(a))
[2.8284271247461903 2.8284271247461903 2.8284271247461903 2.8284271247461903]
```

Find standard error across the whole array, using n degrees of freedom:

```python
>>> print(stats.mstats.sem(a, axis=None, ddof=0))
1.2893796958227628
```

**scipy.stats.mstats.trimmed_mean**

`scipy.stats.mstats.trimmed_mean(a, limits=(0.1, 0.1), inclusive=(1, 1), relative=True, axis=None)`

**scipy.stats.mstats.trimmed_mean_ci**

`scipy.stats.mstats.trimmed_mean_ci(data, limits=(0.2, 0.2), inclusive=(True, True), alpha=0.05, axis=None)`

Selected confidence interval of the trimmed mean along the given axis.

**Parameters**

- `data` [array_like] Input data.
- `limits` [(None, tuple), optional] None or a two item tuple. Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. If n is the number of unmasked data before trimming, then (n * limits[0])th smallest data and (n * limits[1])th largest data are masked. The total number of unmasked data after trimming is n * (1 - sum(limits)). The value of one limit can be set to None to indicate an open interval. Defaults to (0.2, 0.2).
- `inclusive` [(2,) tuple of boolean, optional] If relative==False, tuple indicating whether values exactly equal to the absolute limits are allowed. If relative==True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False). Defaults to (True, True).
- `alpha` [float, optional] Confidence level of the intervals. Defaults to 0.05.
- `axis` [int, optional] Axis along which to cut. If None, uses a flattened version of `data`. Defaults to None.

**Returns**

- `trimmed_mean_ci` [(2,) ndarray] The lower and upper confidence intervals of the trimmed data.
scipy.stats.mstats.trimmed_std

scipy.stats.mstats.trimmed_std(a, limits=(0.1, 0.1), inclusive=(1, 1), relative=True, axis=None, ddof=0)

scipy.stats.mstats.trimmed_var

scipy.stats.mstats.trimmed_var(a, limits=(0.1, 0.1), inclusive=(1, 1), relative=True, axis=None, ddof=0)

Frequency statistics

scoreatpercentile(data, per[, limit, ...]) Calculate the score at the given ‘per’ percentile of the sequence a.

scipy.stats.mstats.scoreatpercentile

scipy.stats.mstats.scoreatpercentile(data, per, limit=(), alphap=0.4, betap=0.4) Calculating the score at the given ‘per’ percentile of the sequence a. For example, the score at per=50 is the median.

This function is a shortcut to mquantile

Correlation functions

f_oneway(*args) Performs a 1-way ANOVA, returning an F-value and probability given any number of groups. From Heiman, pp.394-7.

Usage: f_oneway(*args), where *args is 2 or more arrays, one per treatment group.

Returns

statistic [float] The computed F-value of the test.
pvalue  [float] The associated p-value from the F-distribution.

**scipy.stats.mstats.pearsonr**

**scipy.stats.mstats.pearsonr**(x, y)

Calculates a Pearson correlation coefficient and the p-value for testing non-correlation.

The Pearson correlation coefficient measures the linear relationship between two datasets. Strictly speaking, Pearson’s correlation requires that each dataset be normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship. Positive correlations imply that as x increases, so does y. Negative correlations imply that as x increases, y decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Pearson correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters**

- **x**  [1-D array_like] Input
- **y**  [1-D array_like] Input

**Returns**

- **pearsonr**  [float] Pearson’s correlation coefficient, 2-tailed p-value.

**References**

http://www.statsoft.com/textbook/glosp.html#Pearson%20Correlation

**scipy.stats.mstats.spearmanr**

**scipy.stats.mstats.spearmanr**(x, y=None, use_ties=True, axis=None, nan_policy='propagate')

Calculates a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.

The Spearman correlation is a nonparametric measure of the linear relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply a monotonic relationship. Positive correlations imply that as x increases, so does y. Negative correlations imply that as x increases, y decreases.

Missing values are discarded pair-wise: if a value is missing in x, the corresponding value in y is masked.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters**

- **x, y**  [1D or 2D array_like, y is optional] One or two 1-D or 2-D arrays containing multiple variables and observations. When these are 1-D, each represents a vector of observations of a single variable. For the behavior in the 2-D case, see under axis, below.
- **use_ties**  [bool, optional] DO NOT USE. Does not do anything. keyword is only left in place for backwards compatibility reasons.
axis  [int or None, optional] If axis=0 (default), then each column represents a variable, with observations in the rows. If axis=1, the relationship is transposed: each row represents a variable, while the columns contain observations. If axis=None, then both arrays will be raveled.

nan_policy  [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

Returns

correlation  [float] Spearman correlation coefficient
pvalue  [float] 2-tailed p-value.

References

scipy.stats.mstats.pointbiserialr

scipy.stats.mstats.pointbiserialr(x, y)
Calculates a point biserial correlation coefficient and its p-value.

Parameters

x  [array_like of bools] Input array.
y  [array_like] Input array.

Returns

correlation  [float] R value
pvalue  [float] 2-tailed p-value

Notes

Missing values are considered pair-wise: if a value is missing in x, the corresponding value in y is masked.

For more details on pointbiserialr, see stats.pointbiserialr.

scipy.stats.mstats.kendalltau

scipy.stats.mstats.kendalltau(x, y, use_ties=True, use_missing=False, method='auto')
Computes Kendall’s rank correlation tau on two variables x and y.

Parameters

x  [sequence] First data list (for example, time).
y  [sequence] Second data list.
use_ties  [{True, False}, optional] Whether ties correction should be performed.
use_missing  [{False, True}, optional] Whether missing data should be allocated a rank of 0 (False) or the average rank (True)
method: {'auto', 'asymptotic', 'exact'}, optional

Defines which method is used to calculate the p-value [1]. ‘asymptotic’ uses a normal approximation valid for large samples. ‘exact’ computes the exact p-value, but can only be used if no ties are present. ‘auto’ is the default and selects the appropriate method based on a trade-off between speed and accuracy.

Returns

correlation
   float] Kendall tau

pvalue

References

[1]

scipy.stats.mstats.kendalltau_seasonal

Computes a multivariate Kendall's rank correlation tau, for seasonal data.

Parameters

x

scipy.stats.mstats.linregress

Linear regression calculation

Note that the non-masked version is used, and that this docstring is replaced by the non-masked docstring + some info on missing data.

scipy.stats.mstats.siegelslopes

Computes the Siegel estimator for a set of points (x, y).

siegelslopes implements a method for robust linear regression using repeated medians to fit a line to the points (x, y). The method is robust to outliers with an asymptotic breakdown point of 50%.

Parameters

y
   [array_like] Dependent variable.

x
   [array_like or None, optional] Independent variable. If None, use arange(len(y)) instead.

method
   [{'hierarchical', 'separate'}] If ‘hierarchical’, estimate the intercept using the estimated slope medslope (default option). If 'separate', estimate the intercept independent of the estimated slope. See Notes for details.

Returns

medslope
   [float] Estimate of the slope of the regression line.

medintercept
   [float] Estimate of the intercept of the regression line.
SciPy Reference Guide, Release 1.3.2

See also:

**theilslopes**

a similar technique without repeated medians

Notes

For more details on `siegelslopes`, see `scipy.stats.siegelslopes`.

```python
scipy.stats.mstats.theilslopes

scipy.stats.mstats.theilslopes(y, x=None, alpha=0.95)

Computes the Theil-Sen estimator for a set of points \((x, y)\).

theilslopes implements a method for robust linear regression. It computes the slope as the median of all slopes between paired values.

Parameters

- **y** [array_like] Dependent variable.
- **x** [array_like or None, optional] Independent variable. If None, use `arange(len(y))` instead.
- **alpha** [float, optional] Confidence degree between 0 and 1. Default is 95% confidence. Note that `alpha` is symmetric around 0.5, i.e. both 0.1 and 0.9 are interpreted as “find the 90% confidence interval”.

Returns

- **medslope** [float] Theil slope.
- **medintercept** [float] Intercept of the Theil line, as \(\text{median}(y) - \text{medslope} \times \text{median}(x)\).
- **lo_slope** [float] Lower bound of the confidence interval on `medslope`.
- **up_slope** [float] Upper bound of the confidence interval on `medslope`.

See also:

**siegelslopes**

a similar technique with repeated medians

Notes

For more details on `theilslopes`, see `stats.theilslopes`.

```python
scipy.stats.mstats.sen_seasonal_slopes

scipy.stats.mstats.sen_seasonal_slopes(x)
```

Statistical tests

**ttest_1samp**(a, popmean[, axis])
Calculates the T-test for the mean of ONE group of scores.

**ttest_onesamp**(a, popmean[, axis])
Calculates the T-test for the mean of ONE group of scores.

**ttest_ind**(a, b[, axis, equal_var])
Calculates the T-test for the means of TWO INDEPENDENT samples of scores.

**ttest_rel**(a, b[, axis])
Calculates the T-test on TWO RELATED samples of scores, a and b.

**chisquare**(f_obs[, f_exp, ddof, axis])
Calculates a one-way chisquare test.

**ks_2samp**(data1, data2[, alternative])
Computes the Kolmogorov-Smirnov test on two samples.

**ks_twosamp**(data1, data2[, alternative])
Computes the Kolmogorov-Smirnov test on two samples.

**mannwhitneyu**(x, y[, use_continuity])
Computes the Mann-Whitney U test.

**rankdata**(data[, axis, use_missing])
Returns the rank (also known as order statistics) of each data point along the given axis.

**kruskal**(\*args)
Computes the Kruskal-Wallis H-test for independent samples.

**kruskalwallis**(\*args)
Computes the Kruskal-Wallis H-test for independent samples.

**friedmanchisquare**(\*args)
Friedman Chi-Square is a non-parametric, one-way within-subjects ANOVA.

**brunnermunzel**(x, y[, alternative, distribution])
Computes the Brunner-Munzel test on samples x and y.

**skewtest**(a[, axis])
Tests whether the skew is different from the normal distribution.

**kurtosistest**(a[, axis])
Tests whether a dataset has normal kurtosis.

**normaltest**(a[, axis])
Tests whether a sample differs from a normal distribution.

### scipy.stats.mstats.ttest_1samp

**scipy.stats.mstats.ttest_1samp**(a, popmean, axis=0)
Calculates the T-test for the mean of ONE group of scores.

**Parameters**

- **a**
  [array_like] sample observation

- **popmean**
  [float or array_like] expected value in null hypothesis, if array_like than it must have the same shape as a excluding the axis dimension

- **axis**
  [int or None, optional] Axis along which to compute test. If None, compute over the whole array a.

**Returns**

- **statistic**
  [float or array] t-statistic

- **pvalue**
  [float or array] two-tailed p-value

**Notes**

For more details on **ttest_1samp**, see **stats.ttest_1samp**.
scipy.stats.mstats.ttest_onesamp

**scipy.stats.mstats.ttest_onesamp** (*a*, *popmean*, *axis=0*)

Calculates the T-test for the mean of ONE group of scores.

**Parameters**

- **a**  
  [array_like] sample observation
- **popmean**  
  [float or array_like] expected value in null hypothesis, if array_like than it must have the same shape as *a* excluding the axis dimension
- **axis**  
  [int or None, optional] Axis along which to compute test. If None, compute over the whole array *a*.

**Returns**

- **statistic**  
  [float or array] t-statistic
- **pvalue**  
  [float or array] two-tailed p-value

**Notes**

For more details on **ttest_1samp**, see **stats.ttest_1samp**.

scipy.stats.mstats.ttest_ind

**scipy.stats.mstats.ttest_ind** (*a*, *b*, *axis=0*, *equal_var=True*)

Calculates the T-test for the means of TWO INDEPENDENT samples of scores.

**Parameters**

- **a**, **b**  
  [array_like] The arrays must have the same shape, except in the dimension corresponding to *axis* (the first, by default).
- **axis**  
  [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, a, and b.
- **equal_var**  
  [bool, optional] If True, perform a standard independent 2 sample test that assumes equal population variances. If False, perform Welch’s t-test, which does not assume equal population variance. New in version 0.17.0.

**Returns**

- **statistic**  
  [float or array] The calculated t-statistic.
- **pvalue**  
  [float or array] The two-tailed p-value.

**Notes**

For more details on **ttest_ind**, see **stats.ttest_ind**.

scipy.stats.mstats.ttest_rel

**scipy.stats.mstats.ttest_rel** (*a*, *b*, *axis=0*)

Calculates the T-test on TWO RELATED samples of scores, a and b.

**Parameters**

- **a**, **b**  
  [array_like] The arrays must have the same shape.
axis [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, $a$, and $b$.

Returns

statistic [float or array] t-statistic
pvalue [float or array] two-tailed p-value

Notes

For more details on ttest_rel, see stats.ttest_rel.

scipy.stats.mstats.chisquare

scipy.stats.mstats.chisquare ($f_{\text{obs}}, f_{\text{exp}}=$None, $ddof=0$, $axis=0$)

Calculate a one-way chi square test.

The chi square test tests the null hypothesis that the categorical data has the given frequencies.

Parameters

$f_{\text{obs}}$ [array_like] Observed frequencies in each category.
$f_{\text{exp}}$ [array_like, optional] Expected frequencies in each category. By default the categories are assumed to be equally likely.
$ddof$ [int, optional] “Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with $k - 1 - ddof$ degrees of freedom, where $k$ is the number of observed frequencies. The default value of $ddof$ is 0.
$axis$ [int or None, optional] The axis of the broadcast result of $f_{\text{obs}}$ and $f_{\text{exp}}$ along which to apply the test. If axis is None, all values in $f_{\text{obs}}$ are treated as a single data set. Default is 0.

Returns

chisq [float or ndarray] The chi-squared test statistic. The value is a float if axis is None or $f_{\text{obs}}$ and $f_{\text{exp}}$ are 1-D.
p [float or ndarray] The p-value of the test. The value is a float if $ddof$ and the return value chisq are scalars.

See also:

scipy.stats.power_divergence

Notes

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

The default degrees of freedom, $k-1$, are for the case when no parameters of the distribution are estimated. If $p$ parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are $k-1-p$. If the parameters are estimated in a different way, then the dof can be between $k-1-p$ and $k-1$. However, it is also possible that the asymptotic distribution is not a chi-square, in which case this test is not appropriate.
References

[1],[2]

Examples

When just f_obs is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies.

```python
>>> from scipy.stats import chisquare
>>> chisquare([16, 18, 16, 14, 12, 12])
(2.0, 0.84914503608460956)
```

With f_exp the expected frequencies can be given.

```python
>>> chisquare([16, 18, 16, 14, 12, 12], f_exp=[16, 16, 16, 16, 16, 8])
(3.5, 0.62338762774958223)
```

When f_obs is 2-D, by default the test is applied to each column.

```python
>>> obs = np.array([[16, 18, 16, 14, 12, 12],
                  [32, 24, 16, 28, 20, 24]]).T
>>> obs.shape
(6, 2)
>>> chisquare(obs)
(array([ 2. , 6.66666667]), array([ 0.84914504, 0.24663415]))
```

By setting axis=None, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```python
>>> chisquare(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> chisquare(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

ddf is the change to make to the default degrees of freedom.

```python
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the chi-squared statistic with ddf.

```python
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504, 0.73575888, 0.5724067 ]))
```

f_obs and f_exp are also broadcast. In the following, f_obs has shape (6,) and f_exp has shape (2, 6), so the result of broadcasting f_obs and f_exp has shape (2, 6). To compute the desired chi-squared statistics, we use axis=1:

```python
>>> chisquare([16, 18, 16, 14, 12, 12],
             ... f_exp=[[16, 16, 16, 16, 16, 8],
                     ... [8, 20, 20, 16, 12, 12]],
             ... axis=1)
(array([ 3.5 , 9.25]), array([ 0.62338763, 0.09949846]))
```
**scipy.stats.mstats.ks_2samp**

`scipy.stats.mstats.ks_2samp(data1, data2, alternative='two-sided')`

Computes the Kolmogorov-Smirnov test on two samples.

Missing values are discarded.

**Parameters**

- **data1** : [array_like] First data set
- **data2** : [array_like] Second data set
- **alternative** : [{'two-sided', 'less', 'greater'}, optional] Indicates the alternative hypothesis. Default is 'two-sided'.

**Returns**

- **d** : [float] Value of the Kolmogorov Smirnov test
- **p** : [float] Corresponding p-value.

**scipy.stats.mstats.ks_twosamp**

`scipy.stats.mstats.ks_twosamp(data1, data2, alternative='two-sided')`

Computes the Kolmogorov-Smirnov test on two samples.

Missing values are discarded.

**Parameters**

- **data1** : [array_like] First data set
- **data2** : [array_like] Second data set
- **alternative** : [{'two-sided', 'less', 'greater'}, optional] Indicates the alternative hypothesis. Default is 'two-sided'.

**Returns**

- **d** : [float] Value of the Kolmogorov Smirnov test
- **p** : [float] Corresponding p-value.

**scipy.stats.mstats.mannwhitneyu**

`scipy.stats.mstats.mannwhitneyu(x, y, use_continuity=True)`

Computes the Mann-Whitney statistic

Missing values in x and/or y are discarded.

**Parameters**

- **x** : [sequence] Input
- **y** : [sequence] Input
- **use_continuity** : [True, False], optional Whether a continuity correction (1/2.) should be taken into account.

**Returns**

- **statistic** : [float] The Mann-Whitney statistic
- **pvalue** : [float] Approximate p-value assuming a normal distribution.
### scipy.stats.mstats.rankdata

**scipy.stats.mstats.rankdata** *(data, axis=None, use_missing=False)*

Returns the rank (also known as order statistics) of each data point along the given axis.

If some values are tied, their rank is averaged. If some values are masked, their rank is set to 0 if use_missing is False, or set to the average rank of the unmasked values if use_missing is True.

**Parameters**

- **data** [sequence] Input data. The data is transformed to a masked array.
- **axis** [[None, int], optional] Axis along which to perform the ranking. If None, the array is first flattened. An exception is raised if the axis is specified for arrays with a dimension larger than 2.
- **use_missing** [bool, optional] Whether the masked values have a rank of 0 (False) or equal to the average rank of the unmasked values (True).

### scipy.stats.mstats.kruskal

**scipy.stats.mstats.kruskal** *(args)*

Compute the Kruskal-Wallis H-test for independent samples.

**Parameters**

- **sample1, sample2, …** [array_like] Two or more arrays with the sample measurements can be given as arguments.

**Returns**

- **statistic** [float] The Kruskal-Wallis H statistic, corrected for ties.
- **pvalue** [float] The p-value for the test using the assumption that H has a chi square distribution.

**Notes**

For more details on kruskal, see stats.kruskal.

**Examples**

``` python
>>> from scipy.stats.mstats import kruskal
```

Random samples from three different brands of batteries were tested to see how long the charge lasted. Results were as follows:

``` python
>>> a = [6.3, 5.4, 5.7, 5.2, 5.0]
>>> b = [6.9, 7.0, 6.1, 7.9]
>>> c = [7.2, 6.9, 6.1, 6.5]
```

Test the hypothesis that the distribution functions for all of the brands’ durations are identical. Use 5% level of significance.

``` python
>>> kruskal(a, b, c)
KruskalResult(statistic=7.113812154696133, pvalue=0.028526948491942164)
```
The null hypothesis is rejected at the 5% level of significance because the returned p-value is less than the critical value of 5%.

**scipy.stats.mstats.kruskalwallis**

**scipy.stats.mstats.kruskalwallis(*args)**

Compute the Kruskal-Wallis H-test for independent samples

**Parameters**

- `sample1, sample2, ...`
  
  [array_like] Two or more arrays with the sample measurements can be given as arguments.

**Returns**

- `statistic` [float] The Kruskal-Wallis H statistic, corrected for ties
- `pvalue` [float] The p-value for the test using the assumption that H has a chi square distribution

**Notes**

For more details on kruskal, see stats.kruskal.

**Examples**

```python
>>> from scipy.stats.mstats import kruskal
```

Random samples from three different brands of batteries were tested to see how long the charge lasted. Results were as follows:

```python
>>> a = [6.3, 5.4, 5.7, 5.2, 5.0]
>>> b = [6.9, 7.0, 6.1, 7.9]
>>> c = [7.2, 6.9, 6.1, 6.5]
```

Test the hypothesis that the distribution functions for all of the brands' durations are identical. Use 5% level of significance.

```python
>>> kruskal(a, b, c)
KruskalResult(statistic=7.113812154696133, pvalue=0.028526948491942164)
```

The null hypothesis is rejected at the 5% level of significance because the returned p-value is less than the critical value of 5%.

**scipy.stats.mstats.friedmanchisquare**

**scipy.stats.mstats.friedmanchisquare(*args)**

Friedman Chi-Square is a non-parametric, one-way within-subjects ANOVA. This function calculates the Friedman Chi-square test for repeated measures and returns the result, along with the associated probability value.

Each input is considered a given group. Ideally, the number of treatments among each group should be equal. If this is not the case, only the first n treatments are taken into account, where n is the number of treatments of the smallest group. If a group has some missing values, the corresponding treatments are masked in the other groups. The test statistic is corrected for ties.

Masked values in one group are propagated to the other groups.
Returns

- **statistic** [float] the test statistic.
- **pvalue** [float] the associated p-value.

**scipy.stats.mstats.brunnermunzel**

**scipy.stats.mstats.brunnermunzel** *(x, y, alternative='two-sided', distribution='t')*

Computes the Brunner-Munzel test on samples x and y.

Missing values in x and/or y are discarded.

**Parameters**

- **x, y** [array_like] Array of samples, should be one-dimensional.
- **alternative** ['less', 'two-sided', or 'greater', optional] Whether to get the p-value for the one-sided hypothesis ('less' or 'greater') or for the two-sided hypothesis ('two-sided'). Defaults value is 'two-sided'.
- **distribution**: 't' or 'normal', optional
  Whether to get the p-value by t-distribution or by standard normal distribution. Defaults value is 't'.

**Returns**

- **statistic** [float] The Brunner-Munzer W statistic.
- **pvalue** [float] p-value assuming and distribution. One-sided or two-sided, depending on the choice of alternative and distribution.

See also:

**mannwhitneyu**

Mann-Whitney rank test on two samples.

**Notes**

For more details on **brunnermunzel**, see **stats.brunnermunzel**.

**scipy.stats.mstats.skewtest**

**scipy.stats.mstats.skewtest** *(a, axis=0)*

Tests whether the skew is different from the normal distribution.

**Parameters**

- **a** [array] The data to be tested
- **axis** [int or None, optional] Axis along which statistics are calculated. Default is 0. If None, compute over the whole array a.

**Returns**

- **statistic** [float] The computed z-score for this test.
- **pvalue** [float] a 2-sided p-value for the hypothesis test
Notes

For more details about `skewtest`, see `stats.skewtest`.

**scipy.stats.mstats.kurtosistest**

**scipy.stats.mstats.kurtosistest** *(a, axis=0)*  
Tests whether a dataset has normal kurtosis

**Parameters**

- **a**  
  [array] array of the sample data
- **axis**  
  [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.

**Returns**

- **statistic**  
  [float] The computed z-score for this test.
- **pvalue**  
  [float] The 2-sided p-value for the hypothesis test

Notes

For more details about `kurtosistest`, see `stats.kurtosistest`.

**scipy.stats.mstats.normaltest**

**scipy.stats.mstats.normaltest** *(a, axis=0)*  
Tests whether a sample differs from a normal distribution.

**Parameters**

- **a**  
  [array_like] The array containing the data to be tested.
- **axis**  
  [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.

**Returns**

- **statistic**  
  [float or array] *s^2 + k^2*, where *s* is the z-score returned by `skewtest` and *k* is the z-score returned by `kurtosistest`.
- **pvalue**  
  [float or array] A 2-sided chi squared probability for the hypothesis test.

Notes

For more details about `normaltest`, see `stats.normaltest`.

Transformations

<table>

</tbody>
</table>

Continued on next page
Table 271 – continued from previous page

- **trimmed_stde**: Returns the standard error of the trimmed mean along the given axis.
- **trimr**: Trims an array by masking some proportion of the data on each end.
- **trimtail**: Trims the data by masking values from one tail.
- **trimboth**: Trims the smallest and largest data values.
- **winsorize**: Returns a Winsorized version of the input array.
- **zmap**: Calculates the relative z-scores.
- **zscore**: Calculates the z score of each value in the sample, relative to the sample mean and standard deviation.

**scipy.stats.mstats.obrientransform**

`scipy.stats.mstats.obrientransform(*args)`

Computes a transform on input data (any number of columns). Used to test for homogeneity of variance prior to running one-way stats. Each array in `*args` is one level of a factor. If an `f_oneway()` run on the transformed data and found significant, variances are unequal. From Maxwell and Delaney, p.112.

Returns: transformed data for use in an ANOVA

**scipy.stats.mstats.trim**

`scipy.stats.mstats.trim(a, limits=None, inclusive=(True, True), relative=False, axis=None)`

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

**Parameters**

- **a**: [sequence] Input array
- **limits**: [(None, tuple), optional] If `relative` is False, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked. If `relative` is True, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data.

Noting the number of unmasked data before trimming, the (n*limits[0])th smallest data and the (n*limits[1])th largest data are masked, and the total number of unmasked data after trimming is n*(1.-sum(limits)) In each case, the value of one limit can be set to None to indicate an open interval.

If limits is None, no trimming is performed.

- **inclusive**: [(bool, bool) tuple], optional] If `relative` is False, tuple indicating whether values exactly equal to the absolute limits are allowed. If `relative` is True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).

- **relative**: [bool, optional] Whether to consider the limits as absolute values (False) or proportions to cut (True).
- **axis**: [int, optional] Axis along which to trim.

**Examples**

```python
>>> from scipy.stats.mstats import trim
>>> z = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
>>> print(trim(z,(3,8)))
```

(continues on next page)
scipy.stats.mstats.trim

**scipy.stats.mstats.trim**

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

**Parameters**

- `a` [array_like] Input array.
- `limits` [[None, tuple], optional] Tuple of (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit will be masked. A limit is None indicates an open interval.
- `inclusive` [(bool, bool) tuple, optional] Tuple of (lower flag, upper flag), indicating whether values exactly equal to the lower (upper) limit are allowed.

scipy.stats.mstats.trimmed_stde

**scipy.stats.mstats.trimmed_stde**

Returns the standard error of the trimmed mean along the given axis.

**Parameters**

- `a` [sequence] Input array
- `limits` [(0.1, 0.1), tuple of float], optional] tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data. If n is the number of unmasked data before trimming, the values smaller than n * `limits[0]` and the values larger than n * `limits[1]` are masked, and the total number of unmasked data after trimming is n * (1.-sum(limits)). In each case, the value of one limit can be set to None to indicate an open interval. If `limits` is None, no trimming is performed.
- `inclusive` [(bool, bool) tuple] optional] Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
- `axis` [int, optional] Axis along which to trim.

**Returns**

- `trimmed_stde` [scalar or ndarray]

scipy.stats.mstats.trimr

**scipy.stats.mstats.trimr**

Trims an array by masking some proportion of the data on each end. Returns a masked version of the input array.

**Parameters**

- `a` [sequence] Input array.
 limits [None, tuple], optional] Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting n the number of unmasked data before trimming, the (n*limits[0])th smallest data and the (n*limits[1])th largest data are masked, and the total number of unmasked data after trimming is n*(1.-sum(limits)). The value of one limit can be set to None to indicate an open interval.

 inclusive [(True,True) tuple], optional] Tuple of flags indicating whether the number of data being masked on the left (right) end should be truncated (True) or rounded (False) to integers.

 axis [None,int], optional] Axis along which to trim. If None, the whole array is trimmed, but its shape is maintained.

`scipy.stats.mstats.trimtail`

`scipy.stats.mstats.trimtail`(data, proportiontocut=0.2, tail='left', inclusive=(True, True), axis=None)

Trims the data by masking values from one tail.

Parameters

- **data** [array_like] Data to trim.
- **proportiontocut** [float, optional] Percentage of trimming. If n is the number of unmasked values before trimming, the number of values after trimming is (1 - proportiontocut) * n. Default is 0.2.
- **tail** ['left','right'], optional] If 'left' the proportiontocut lowest values will be masked. If 'right' the proportiontocut highest values will be masked. Default is 'left'.
- **inclusive** [(bool, bool) tuple], optional] Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False). Default is (True, True).
- **axis** [int, optional] Axis along which to perform the trimming. If None, the input array is first flattened. Default is None.

Returns

- **trimtail** [ndarray] Returned array of same shape as data with masked tail values.

`scipy.stats.mstats.trimboth`

`scipy.stats.mstats.trimboth`(data, proportiontocut=0.2, inclusive=(True, True), axis=None)

Trims the smallest and largest data values.

Trims the data by masking the int(proportiontocut * n) smallest and int(proportiontocut * n) largest values of data along the given axis, where n is the number of unmasked values before trimming.

Parameters

- **data** [ndarray] Data to trim.
- **proportiontocut** [float, optional] Percentage of trimming (as a float between 0 and 1). If n is the number of unmasked values before trimming, the number of values after trimming is (1 - 2*proportiontocut) * n. Default is 0.2.
- **inclusive** [(bool, bool) tuple], optional] Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
- **axis** [int, optional] Axis along which to perform the trimming. If None, the input array is first flattened.
scipy.stats.mstats.winsorize

scipy.stats.mstats.winsorize(a, limits=None, inclusive=(True, True), inplace=False, axis=None)

Returns a Winsorized version of the input array.

The (limits[0])th lowest values are set to the (limits[0])th percentile, and the (limits[1])th highest values are set to the (1 - limits[1])th percentile. Masked values are skipped.

Parameters
- a [sequence] Input array.
- limits [{None, tuple of float}, optional] Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting n the number of unmasked data before trimming, the (n*limits[0])th smallest data and the (n*limits[1])th largest data are masked, and the total number of unmasked data after trimming is n*(1.-sum(limits)). The value of one limit can be set to None to indicate an open interval.
- inclusive [{(True, True) tuple}, optional] Tuple indicating whether the number of data being masked on each side should be truncated (True) or rounded (False).
- inplace [{False, True}, optional] Whether to winsorize in place (True) or to use a copy (False).
- axis [{None, int}, optional] Axis along which to trim. If None, the whole array is trimmed, but its shape is maintained.

Notes

This function is applied to reduce the effect of possibly spurious outliers by limiting the extreme values.

scipy.stats.mstats.zmap

scipy.stats.mstats.zmap(scores, compare, axis=0, ddof=0)

Calculate the relative z-scores.

Return an array of z-scores, i.e., scores that are standardized to zero mean and unit variance, where mean and variance are calculated from the comparison array.

Parameters
- scores [array_like] The input for which z-scores are calculated.
- compare [array_like] The input from which the mean and standard deviation of the normalization are taken; assumed to have the same dimension as scores.
- axis [int or None, optional] Axis over which mean and variance of compare are calculated. Default is 0. If None, compute over the whole array scores.
- ddof [int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

Returns
- zscore [array_like] Z-scores, in the same shape as scores.

Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses asarray instead of asarray for parameters).
Examples

```python
>>> from scipy.stats import zmap
>>> a = [0.5, 2.0, 2.5, 3]
>>> b = [0, 1, 2, 3, 4]
>>> zmap(a, b)
array([-1.06066017, 0.35355339, 0.70710678])
```

**scipy.stats.mstats.zscore**

`scipy.stats.mstats.zscore(a, axis=None, ddof=0)`

Calculate the z score of each value in the sample, relative to the sample mean and standard deviation.

**Parameters**

- `a` [array_like] An array like object containing the sample data.
- `axis` [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array `a`.
- `ddof` [int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

**Returns**

- `zscore` [array_like] The z-scores, standardized by mean and standard deviation of input array `a`.

**Notes**

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses asanyarray instead of asarray for parameters).

**Examples**

```python
>>> a = np.array([ 0.7972, 0.0767, 0.4383, 0.7866, 0.8091,
                  ... 0.1954, 0.6307, 0.6599, 0.1065, 0.0508])
>>> from scipy import stats
>>> stats.zscore(a)
array([ 1.1273, -1.247 , -0.0552, 1.0923, 1.1664, -0.8559, 0.5786,
       0.6748, -1.1488, -1.3324])
```

Computing along a specified axis, using n-1 degrees of freedom (ddof=1) to calculate the standard deviation:

```python
>>> b = np.array([[[ 0.3148, 0.0478, 0.6243, 0.4608],
                  ... [ 0.7149, 0.0775, 0.6072, 0.9656],
                  ... [ 0.6341, 0.1403, 0.9759, 0.4064],
                  ... [ 0.5918, 0.6948, 0.904 , 0.3721],
                  ... [ 0.0921, 0.2481, 0.1188, 0.1366]]])
>>> stats.zscore(b, axis=1, ddof=1)
array([[-0.19264823, -1.28415119, 1.07259584, 0.40420358],
       [ 0.33048416, -1.37380874, 0.04251374, 1.00081084],
       [ 0.26796377, -1.12598418, 1.23283094, -0.37481053],
       [-0.22095197, 0.24468594, 1.19042819, -1.21416216],
       [-0.82780366, 1.4457416 , -0.43867764, -0.1792603 ]])
```

**scipy.stats.mstats.argstoarray**

`scipy.stats.mstats.argstoarray(*args)`<br>Constructs a 2D array from a group of sequences.<br>Sequences are filled with missing values to match the length of the longest sequence.<br>**Parameters**<br>`args` [sequences] Group of sequences.<br>**Returns**<br>`argstoarray` [MaskedArray] A \((m \times n)\) masked array, where \(m\) is the number of arguments and \(n\) the length of the longest argument.<br>**Notes**<br>`numpy.ma.row_stack` has identical behavior, but is called with a sequence of sequences.<br>**scipy.stats.mstats.count_tied_groups**

`scipy.stats.mstats.count_tied_groups(x[, use_missing=False])`<br>Counts the number of tied values.<br>**Parameters**<br>`x` [sequence] Sequence of data on which to counts the ties<br>`use_missing` [bool, optional] Whether to consider missing values as tied.<br>**Returns**<br>`count_tied_groups` [dict] Returns a dictionary \((\text{nb of ties: nb of groups})\).
Examples

```python
>>> from scipy.stats import mstats
>>> z = [0, 0, 0, 2, 2, 2, 3, 3, 4, 5, 6]
>>> mstats.count_tied_groups(z)
{2: 1, 3: 2}
```

In the above example, the ties were 0 (3x), 2 (3x) and 3 (2x).

```python
>>> z = np.ma.array([0, 0, 1, 2, 2, 2, 3, 3, 4, 5, 6])
>>> mstats.count_tied_groups(z)
{2: 2, 3: 1}
>>> z[[1,-1]] = np.ma.masked
>>> mstats.count_tied_groups(z, use_missing=True)
{2: 2, 3: 1}
```

**scipy.stats.mstats.msign**

`scipy.stats.mstats.msign(x)`

Returns the sign of x, or 0 if x is masked.

**scipy.stats.mstats.compare_medians_ms**

`scipy.stats.mstats.compare_medians_ms(group_1, group_2, axis=None)`

Compares the medians from two independent groups along the given axis.

The comparison is performed using the McKean-Schrader estimate of the standard error of the medians.

**Parameters**

- `group_1` [array_like] First dataset. Has to be of size >=7.
- `group_2` [array_like] Second dataset. Has to be of size >=7.
- `axis` [int, optional] Axis along which the medians are estimated. If None, the arrays are flattened. If `axis` is not None, then `group_1` and `group_2` should have the same shape.

**Returns**

- `compare_medians_ms` [{float, ndarray}] If `axis` is None, then returns a float, otherwise returns a 1-D ndarray of floats with a length equal to the length of `group_1` along `axis`.

**scipy.stats.mstats.median_cihs**

`scipy.stats.mstats.median_cihs(data, alpha=0.05, axis=None)`

Computes the alpha-level confidence interval for the median of the data.

Uses the Hettmasperger-Sheather method.

**Parameters**

- `data` [array_like] Input data. Masked values are discarded. The input should be 1D only, or `axis` should be set to None.
- `alpha` [float, optional] Confidence level of the intervals.
axis [int or None, optional] Axis along which to compute the quantiles. If None, use a flattened array.

Returns
median_cihs
Alpha level confidence interval.

scipy.stats.mstats.mjci

scipy.stats.mstats.mjci(data, prob=[0.25, 0.5, 0.75], axis=None)
Returns the Maritz-Jarrett estimators of the standard error of selected experimental quantiles of the data.

Parameters
data [ndarray] Data array.
prob [sequence, optional] Sequence of quantiles to compute.
axis [int or None, optional] Axis along which to compute the quantiles. If None, use a flattened array.

scipy.stats.mstats.mquantiles_cimj

scipy.stats.mstats.mquantiles_cimj(data, prob=[0.25, 0.5, 0.75], alpha=0.05, axis=None)
Computes the alpha confidence interval for the selected quantiles of the data, with Maritz-Jarrett estimators.

Parameters
data [sequence] Input data, should be 1-D. Masked values are ignored.
points [sequence or None, optional] Sequence of points where to evaluate Rosenblatt shifted histogram. If None, use the data.
### scipy.stats.gaussian_kde

**class scipy.stats.gaussian_kde**(dataset, bw_method=None, weights=None)

Representation of a kernel-density estimate using Gaussian kernels.

Kernel density estimation is a way to estimate the probability density function (PDF) of a random variable in a non-parametric way. `gaussian_kde` works for both uni-variate and multi-variate data. It includes automatic bandwidth determination. The estimation works best for a unimodal distribution; bimodal or multi-modal distributions tend to be oversmoothed.

**Parameters**

- **dataset** [array_like] Datapoints to estimate from. In case of univariate data this is a 1-D array, otherwise a 2-D array with shape (# of dims, # of data).

- **bw_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If a scalar, this will be used directly as `kde.factor`. If a callable, it should take a `gaussian_kde` instance as only parameter and return a scalar. If None (default), 'scott' is used. See Notes for more details.

- **weights** [array_like, optional] weights of datapoints. This must be the same shape as dataset. If None (default), the samples are assumed to be equally weighted

**Notes**

Bandwidth selection strongly influences the estimate obtained from the KDE (much more so than the actual shape of the kernel). Bandwidth selection can be done by a "rule of thumb", by cross-validation, by "plug-in methods" or by other means; see [Ra3a8695506c7-3], [Ra3a8695506c7-4] for reviews. `gaussian_kde` uses a rule of thumb, the default is Scott’s Rule.

Scott’s Rule [Ra3a8695506c7-1], implemented as `scotts_factor`, is:

\[
 n^{*} \times (-1. / (d+4)),
\]

with \( n \) the number of data points and \( d \) the number of dimensions. In the case of unequally weighted points, `scotts_factor` becomes:

\[
 neff^{*} \times (-1. / (d+4)),
\]

with \( neff \) the effective number of datapoints. Silverman’s Rule [Ra3a8695506c7-2], implemented as `silverman_factor`, is:

\[
 (n \times (d + 2) / 4.)^{*} \times (-1. / (d + 4)).
\]

or in the case of unequally weighted points:

\[
 (neff \times (d + 2) / 4.)^{*} \times (-1. / (d + 4)).
\]

Good general descriptions of kernel density estimation can be found in [Ra3a8695506c7-1] and [Ra3a8695506c7-2], the mathematics for this multi-dimensional implementation can be found in [Ra3a8695506c7-1].

With a set of weighted samples, the effective number of datapoints \( neff \) is defined by:
neff = \frac{\text{sum}(\text{weights})^2}{\text{sum}(\text{weights}^2)}

as detailed in [Ra3a8695506c7-5].

References

[Ra3a8695506c7-1], [Ra3a8695506c7-2], [Ra3a8695506c7-3], [Ra3a8695506c7-4], [Ra3a8695506c7-5]

Examples

Generate some random two-dimensional data:

```python
>>> from scipy import stats
>>> def measure(n):
...     "Measurement model, return two coupled measurements."
...     m1 = np.random.normal(size=n)
...     m2 = np.random.normal(scale=0.5, size=n)
...     return m1+m2, m1-m2

>>> m1, m2 = measure(2000)
>>> xmin = m1.min()
>>> xmax = m1.max()
>>> ymin = m2.min()
>>> ymax = m2.max()
```

Perform a kernel density estimate on the data:

```python
>>> X, Y = np.mgrid[xmin:xmax:100j, ymin:ymax:100j]
>>> positions = np.vstack([X.ravel(), Y.ravel()])
>>> values = np.vstack([m1, m2])
>>> kernel = stats.gaussian_kde(values)
>>> Z = np.reshape(kernel(positions).T, X.shape)
```

Plot the results:

```python
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> ax.imshow(np.rot90(Z), cmap=plt.cm.gist_earth_r,
...     extent=[xmin, xmax, ymin, ymax])
>>> ax.plot(m1, m2, 'k.', markersize=2)
>>> ax.set_xlim([xmin, xmax])
>>> ax.set_ylim([ymin, ymax])
>>> plt.show()
```

Attributes

- `dataset` [ndarray] The dataset with which `gaussian_kde` was initialized.
- `d` [int] Number of dimensions.
- `n` [int] Number of datapoints.
- `neff` [int] Effective number of datapoints.
  New in version 1.2.0.
factor [float] The bandwidth factor, obtained from `kde.covariance_factor`, with which the covariance matrix is multiplied.
covariance [ndarray] The covariance matrix of `dataset`, scaled by the calculated bandwidth (`kde.factor`).
inv_cov [ndarray] The inverse of `covariance`.

### Methods

- `evaluate(self, points)` Evaluate the estimated pdf on a set of points.
- `__call__(self, points)` Evaluate the estimated pdf on a set of points.
- `integrate_gaussian(self, mean, cov)` Multiply estimated density by a multivariate Gaussian and integrate over the whole space.
- `integrate_box_1d(self, low, high)` Computes the integral of a 1D pdf between two bounds.
- `integrate_box(self, low_bounds, high_bounds)` Computes the integral of a pdf over a rectangular interval.
- `integrate_kde(self, other)` Computes the integral of the product of this kernel density estimate with another.
- `pdf(self, x)` Evaluate the estimated pdf on a provided set of points.
- `logpdf(self, x)` Evaluate the log of the estimated pdf on a provided set of points.
- `resample(self[, size])` Randomly sample a dataset from the estimated pdf.
- `set_bandwidth(self[, bw_method])` Compute the estimator bandwidth with given method.
- `covariance_factor(self)` Computes the coefficient (`kde.factor`) that multiplies the data covariance matrix to obtain the kernel covariance matrix.

**scipy.stats.gaussian_kde.evaluate**

`gaussian_kde.evaluate(self, points)` Evaluate the estimated pdf on a set of points.

**Parameters**

- `points` [(# of dimensions, # of points)-array] Alternatively, a (# of dimensions,) vector can be passed in and treated as a single point.

**Returns**

- `values` [(# of points,)-array] The values at each point.

**Raises**

- `ValueError` [if the dimensionality of the input points is different than the dimensionality of the KDE.]

- `scipy.stats.gaussian_kde.__call__`
values  [(# of points,)-array] The values at each point.

Raises

ValueError

[if the dimensionality of the input points is different than] the dimensionality of the KDE.

**scipy.stats.gaussian_kde.integrate_gaussian**

`gaussian_kde.integrate_gaussian (self, mean, cov)`

Multiply estimated density by a multivariate Gaussian and integrate over the whole space.

**Parameters**

- **mean**  [array_like] A 1-D array, specifying the mean of the Gaussian.
- **cov**  [array_like] A 2-D array, specifying the covariance matrix of the Gaussian.

**Returns**

- **result**  [scalar] The value of the integral.

**Raises**

ValueError

If the mean or covariance of the input Gaussian differs from the KDE’s dimensionality.

**scipy.stats.gaussian_kde.integrate_box_1d**

`gaussian_kde.integrate_box_1d (self, low, high)`

Computes the integral of a 1D pdf between two bounds.

**Parameters**

- **low**  [scalar] Lower bound of integration.
- **high**  [scalar] Upper bound of integration.

**Returns**

- **value**  [scalar] The result of the integral.

**Raises**

ValueError

If the KDE is over more than one dimension.

**scipy.stats.gaussian_kde.integrate_box**

`gaussian_kde.integrate_box (self, low_bounds, high_bounds, maxpts=None)`

Computes the integral of a pdf over a rectangular interval.

**Parameters**

- **low_bounds**  [array_like] A 1-D array containing the lower bounds of integration.
- **high_bounds**  [array_like] A 1-D array containing the upper bounds of integration.
- **maxpts**  [int, optional] The maximum number of points to use for integration.

**Returns**

- **value**  [scalar] The result of the integral.
scipy.stats.gaussian_kde.integrate_kde

`gaussian_kde.integrate_kde(self, other)`
Computes the integral of the product of this kernel density estimate with another.

**Parameters**

- `other` [gaussian_kde instance] The other kde.

**Returns**

- `value` [scalar] The result of the integral.

**Raises**

- `ValueError` If the KDEs have different dimensionality.

scipy.stats.gaussian_kde.pdf

`gaussian_kde.pdf(self, x)`
Evaluate the estimated pdf on a provided set of points.

**Notes**

This is an alias for `gaussian_kde.evaluate`. See the `evaluate` docstring for more details.

scipy.stats.gaussian_kde.logpdf

`gaussian_kde.logpdf(self, x)`
Evaluate the log of the estimated pdf on a provided set of points.

scipy.stats.gaussian_kde.resample

`gaussian_kde.resample(self, size=None)`
Randomly sample a dataset from the estimated pdf.

**Parameters**

- `size` [int, optional] The number of samples to draw. If not provided, then the size is the same as the effective number of samples in the underlying dataset.

**Returns**

scipy.stats.gaussian_kde.set_bandwidth

`gaussian_kde.set_bandwidth(self, bw_method=None)`
Compute the estimator bandwidth with given method.

The new bandwidth calculated after a call to `set_bandwidth` is used for subsequent evaluations of the estimated density.

**Parameters**

- `bw_method` [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If a scalar, this will be used directly as `kde.factor`. If a callable, it should take a `gaussian_kde` instance as only parameter and return a scalar. If None (default), nothing happens; the current `kde.covariance_factor` method is kept.
Notes

New in version 0.11.

Examples

```python
>>> import scipy.stats as stats
>>> x1 = np.array([-7, -5, 1, 4, 5.])
>>> kde = stats.gaussian_kde(x1)
>>> xs = np.linspace(-10, 10, num=50)
>>> y1 = kde(xs)
>>> kde.set_bandwidth(bw_method='silverman')
>>> y2 = kde(xs)
>>> kde.set_bandwidth(bw_method=kde.factor / 3.)
>>> y3 = kde(xs)

>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> ax.plot(x1, np.ones(x1.shape) / (4. * x1.size), 'bo', ...
          label='Data points (rescaled)')
>>> ax.plot(xs, y1, label='Scott (default)')
>>> ax.plot(xs, y2, label='Silverman')
>>> ax.plot(xs, y3, label='Const (1/3 * Silverman)')
>>> ax.legend()
>>> plt.show()
```

```
scipy.stats.gaussian_kde.covariance_factor

```

gaussian_kde.covariance_factor(self)

Computes the coefficient (kde.factor) that multiplies the data covariance matrix to obtain the kernel covariance matrix. The default is scotts_factor. A subclass can overwrite this method to provide a different method, or set it through a call to kde.set_bandwidth.

6.28. Statistical functions (scipy.stats) 2561
6.28.19 Warnings used in scipy.stats

<table>
<thead>
<tr>
<th>Warning Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PearsonRConstantInputWarning</strong></td>
<td>Warning generated by <code>pearson</code> when an input is constant.</td>
</tr>
<tr>
<td><strong>PearsonRNearConstantInputWarning</strong></td>
<td>Warning generated by <code>pearson</code> when an input is nearly constant.</td>
</tr>
</tbody>
</table>

**scipy.stats.PearsonRConstantInputWarning**

```
exception scipy.stats.PearsonRConstantInputWarning (msg=None)
    Warning generated by `pearson` when an input is constant.

    with_traceback ()
        Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

**scipy.stats.PearsonRNearConstantInputWarning**

```
exception scipy.stats.PearsonRNearConstantInputWarning (msg=None)
    Warning generated by `pearson` when an input is nearly constant.

    with_traceback ()
        Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

For many more stat related functions install the software R and the interface package rpy.

6.29 Low-level callback functions

Some functions in SciPy take as arguments callback functions, which can either be python callables or low-level compiled functions. Using compiled callback functions can improve performance somewhat by avoiding wrapping data in Python objects.

Such low-level functions in SciPy are wrapped in `LowLevelCallable` objects, which can be constructed from function pointers obtained from ctypes, cffi, Cython, or contained in Python `PyCapsule` objects.

```
LowLevelCallable
    Low-level callback function.
```

6.29.1 scipy.LowLevelCallable

```
class scipy.LowLevelCallable
    Low-level callback function.

    Parameters

    function  [(PyCapsule, ctypes function pointer, cffi function pointer)] Low-level callback function.
    user_data [(PyCapsule, ctypes void pointer, cffi void pointer)] User data to pass on to the callback function.
    signature  [str, optional] Signature of the function. If omitted, determined from `function`, if possible.
```

Notes

The argument `function` can be one of:
• PyCapsule, whose name contains the C function signature
• ctypes function pointer
• cffi function pointer

The signature of the low-level callback must match one of those expected by the routine it is passed to.

If constructing low-level functions from a PyCapsule, the name of the capsule must be the corresponding signature, in the format:

```
return_type (arg1_type, arg2_type, ...)
```

For example:

```
"void (double)"
"double (double, int *, void *)"
```

The context of a PyCapsule passed in as function is used as user_data, if an explicit value for user_data was not given.

**Attributes**

- `function`: Callback function given.
- `user_data`: User data given.
- `signature`: Signature of the function.

**Methods**

```
from_cython(module, name[, user_data, signature])
```

Create a low-level callback function from an exported Cython function.

**scipy.LowLevelCallable.from_cython**

```
classmethod LowLevelCallable.from_cython(module, name, user_data=None, signature=None)
```

Create a low-level callback function from an exported Cython function.

**Parameters**

- `module` [module] Cython module where the exported function resides
- `name` [str] Name of the exported function
- `user_data` [{PyCapsule, ctypes void pointer, cffi void pointer}, optional] User data to pass on to the callback function.
- `signature` [str, optional] Signature of the function. If omitted, determined from function.

**See also:**

Functions accepting low-level callables:

```
scipy.integrate.quad, scipy.ndimage.generic_filter, scipy.ndimage.generic_filter1d, scipy.ndimage.geometric_transform
```

Usage examples:

*Extending scipy.ndimage in C, Faster integration using low-level callback functions*

triu() (in module scipy.sparse), 1761
trunc() (scipy.sparse.bsr_matrix method), 1655
trunc() (scipy.sparse.coo_matrix method), 1672
U
uniform (in module scipy.stats), 2336
uniform_filter() (in module scipy.ndimage), 1206
uniform_filter1d() (in module scipy.ndimage), 1207
unilinear (in module scipy.odr), 1277
unique_roots() (in module scipy.odr), 1494
unit() (in module scipy.constants), 545
unit_impulse() (in module scipy.signal), 1588
unitary_group() (in module scipy.stats), 2367
UnivariateSpline (class in scipy.interpolate), 704
update() (scipy.optimize.BFGS method), 1302
update() (scipy.optimize.HessianUpdateStrategy method), 1381
update() (scipy.optimize.OptimizeResult method), 1282
update() (scipy.optimize.SR1 method), 1303
update() (scipy.sparse.dok_matrix method), 1734
upfirdn() (in module scipy.signal), 1455
use_solver() (in module scipy.sparse.linalg), 1787
V
value() (in module scipy.constants), 544
values() (scipy.optimize.OptimizeResult method), 1282
values() (scipy.sparse.dok_matrix method), 1734
var() (scipy.stats.rv_continuous method), 2092
var() (scipy.stats.rv_discrete method), 2104
var() (scipy.stats.rv_histogram method), 2116
variance() (in module scipy.ndimage), 1238
variation() (in module scipy.stats), 2411
variation() (in module scipy.stats.mstats), 2532
vectorstrength() (in module scipy.signal), 1626
volume() (scipy.spatial.Rectangle method), 1856
vonmises (in module scipy.stats), 2338
vonmises_line (in module scipy.stats), 2341
Voronoï (class in scipy.spatial), 1864
voronoi_plot_2d() (in module scipy.spatial), 1874
vq() (in module scipy.cluster.vq), 492
vstack() (in module scipy.sparse), 1764

W
wald (in module scipy.stats), 2344
ward() (in module scipy.cluster.hierarchy), 514
wasserstein_distance() (in module scipy.stats), 2499
watershed_transform() (in module scipy.ndimage), 1239
WavFileWarning, 759
weibull_max (in module scipy.stats), 2348
weibull_min (in module scipy.stats), 2346
weighted() (in module scipy.cluster.hierarchy), 510
weightedtau() (in module scipy.stats), 2442
welch() (in module scipy.signal), 1613
white_tophat() (in module scipy.ndimage), 1267
whiten() (in module scipy.cluster.vq), 491
whosmat() (in module scipy.io), 745
wiener() (in module scipy.signal), 1433
wilcoxon() (in module scipy.stats), 2465
winsorize() (in module scipy.stats.mstats), 2551
wishart() (in module scipy.stats), 2360
with_traceback() (scipy.constants.ConstantWarning method), 546
with_traceback() (scipy.integrate.IntegrationWarning method), 599
with_traceback() (scipy.io.arff.ArffError method), 761
with_traceback() (scipy.io.arff.ParseArffError method), 762
with_traceback() (scipy.io.wavfile.WavFileWarning method), 759
with_traceback() (scipy.linalg.LinAlgError method), 785
with_traceback() (scipy.linalg.LinAlgWarning method), 785
with_traceback() (scipy.odr.OdrError method), 1276
with_traceback() (scipy.odr.OdrStop method), 1276
with_traceback() (scipy.odr.OdrWarning method), 1276
with_traceback() (scipy.optimize.OptimizeWarning method), 1282
with_traceback() (scipy.signal.BadCoefficients method), 1497
with_traceback() (scipy.sparse.csgraph.NegativeCycleError method), 1834

with_traceback() (scipy.sparse.linalg.ArpackError method), 1815
with_traceback() (scipy.sparse.linalg.ArpackNoConvergence method), 1814
with_traceback() (scipy.sparse.linalg.MatrixRankWarning method), 1787
with_traceback() (scipy.sparse.SparseEfficiencyWarning method), 1773
with_traceback() (scipy.sparse.SparseWarning method), 1773
with_traceback() (scipy.stats.PearsonRConstantInputWarning method), 1910
with_traceback() (scipy.stats.PearsonRNearConstantInputWarning method), 1910
with_traceback() (scipy.stats.PearsonRWarning method), 2562

wminkowski() (in module scipy.spatial.distance), 1899
wofz (in module scipy.special), 2010
wrapcauchy (in module scipy.stats), 2351
wrightomega (in module scipy.special), 2063
write() (in module scipy.io.wavfile), 758
write_record() (scipy.io.FortranFile method), 751
