In this algorithm, the fail conditions are linked to the symmetry of the product \( U_2 U_1^{-1} \) and condition number of \( U_1 \). Here, \( U \) is the 2m-by-m matrix that holds the eigenvectors spanning the stable subspace with 2m rows and partitioned into two m-row matrices. See [1] and [2] for more details.

In order to improve the QZ decomposition accuracy, the pencil goes through a balancing step where the sum of absolute values of \( H \) and \( J \) rows/cols (after removing the diagonal entries) is balanced following the recipe given in [3]. If the data has small numerical noise, balancing may amplify their effects and some clean up is required.

New in version 0.11.0.

Examples

Given \( a, b, q, \) and \( r \) solve for \( x \):

```python
>>> from scipy import linalg as la
>>> a = np.array([[0, 1], [0, -1]])
>>> b = np.array([[1, 0], [2, 1]])
>>> q = np.array([[[-4, -4], [-4, 7]])
>>> r = np.array([[9, 3], [3, 1]])
>>> x = la.solve_discrete_are(a, b, q, r)
>>> x
array([[-4., -4.],
       [-4., 7.]])
>>> R = la.solve(r + b.T.dot(x).dot(b), b.T.dot(x).dot(a))
>>> np.allclose(a.T.dot(x).dot(a) - x - a.T.dot(x).dot(b).dot(R), -q)
True
```

**scipy.linalg.solve_continuous_lyapunov**

```python
scipy.linalg.solve_continuous_lyapunov(a, q)
```

Solves the continuous Lyapunov equation \( AX + XA^H = Q \).

Uses the Bartels-Stewart algorithm to find \( X \).

**Parameters**

- \( a \) : [array_like] A square matrix
- \( q \) : [array_like] Right-hand side square matrix

**Returns**

- \( x \) : [ndarray] Solution to the continuous Lyapunov equation

**See also:**

- **solve_discrete_lyapunov**
  computes the solution to the discrete-time Lyapunov equation
- **solve_sylvester**
  computes the solution to the Sylvester equation
Notes

The continuous Lyapunov equation is a special form of the Sylvester equation, hence this solver relies on LAPACK routine ?TRSYL.

New in version 0.11.0.

Examples

Given $a$ and $q$ solve for $x$:

```python
>>> from scipy import linalg
>>> a = np.array([[-3, -2, 0], [-1, -1, 0], [0, -5, -1]])
>>> b = np.array([2, 4, -1])
>>> q = np.eye(3)
>>> x = linalg.solve_continuous_lyapunov(a, q)
>>> x
array([[ -0.75 , 0.875 , -3.75 ],
        [ 0.875 , -1.375 , 5.3125],
        [ -3.75 , 5.3125, -27.0625]])
>>> np.allclose(a.dot(x) + x.dot(a.T), q)
True
```

**scipy.linalg.solve_discrete_lyapunov**

`scipy.linalg.solve_discrete_lyapunov(a, q, method=None)`

Solves the discrete Lyapunov equation $AXA^H - X + Q = 0$.

**Parameters**

- **a**, **q** : [(M, M) array_like] Square matrices corresponding to $A$ and $Q$ in the equation above respectively. Must have the same shape.
- **method** : [{'direct', 'bilinear'}, optional] Type of solver.
  If not given, chosen to be `direct` if $M$ is less than 10 and `bilinear` otherwise.

**Returns**

- **x** : [ndarray] Solution to the discrete Lyapunov equation

**See also:**

- `solve_continuous_lyapunov`
  computes the solution to the continuous-time Lyapunov equation
Notes

This section describes the available solvers that can be selected by the ‘method’ parameter. The default method is \( \text{direct} \) if \( M \) is less than 10 and \( \text{bilinear} \) otherwise.

Method \( \text{direct} \) uses a direct analytical solution to the discrete Lyapunov equation. The algorithm is given in, for example, [1]. However, it requires the linear solution of a system with dimension \( M^2 \) so that performance degrades rapidly for even moderately sized matrices.

Method \( \text{bilinear} \) uses a bilinear transformation to convert the discrete Lyapunov equation to a continuous Lyapunov equation \( (BX + XB' = -C) \) where \( B = (A-I)(A+I)^{-1} \) and \( C = 2(A'+I)^{-1}Q(A+I)^{-1} \). The continuous equation can be efficiently solved since it is a special case of a Sylvester equation. The transformation algorithm is from Popov (1964) as described in [2].

New in version 0.11.0.

References

[1], [2]

Examples

Given \( a \) and \( q \) solve for \( x \):

```python
>>> from scipy import linalg
>>> a = np.array([[0.2, 0.5], [0.7, -0.9]])
>>> q = np.eye(2)
>>> x = linalg.solve_discrete_lyapunov(a, q)
>>> x
array([[ 0.70872893, 1.43518822],
       [ 1.43518822, -2.4266315 ]])
>>> np.allclose(a.dot(x).dot(a.T)-x, -q)
True
```

6.10.6 Sketches and Random Projections

```
clarkson_woodruff_transform(input_matrix, ...
```

\texttt{scipy.linalg.clarkson\_woodruff\_transform}

\texttt{scipy.linalg.clarkson\_woodruff\_transform (input\_matrix, sketch\_size, seed=\text{None})}

" Applies a Clarkson-Woodruff Transform/sketch to the input matrix.

Given an input\_matrix \( A \) of size \( (n, d) \), compute a matrix \( A' \) of size \( \text{sketch\_size}, d \) so that

\[
\|Ax\| \approx \|A'x\|
\]

with high probability via the Clarkson-Woodruff Transform, otherwise known as the CountSketch matrix.

\textit{Parameters}
**input_matrix**: array_like
Input matrix, of shape \((n, d)\).

**sketch_size**: int
Number of rows for the sketch.

**seed**
[None or int or numpy.random.RandomState instance, optional] This parameter defines the RandomState object to use for drawing random variates. If None (or np.random), the global np.random state is used. If integer, it is used to seed the local RandomState instance. Default is None.

Returns

\(A'\) [array_like] Sketch of the input matrix \(A\), of size \((\text{sketch\_size}, d)\).

Notes

To make the statement

\[
\|Ax\| \approx \|A'x\|
\]

precise, observe the following result which is adapted from the proof of Theorem 14 of [2] via Markov's Inequality. If we have a sketch size \(\text{sketch\_size}=k\) which is at least

\[
k \geq \frac{2}{\epsilon^2 \delta}
\]

Then for any fixed vector \(x\),

\[
\|Ax\| = (1 \pm \epsilon)\|A'x\|
\]

with probability at least one minus delta.

This implementation takes advantage of sparsity: computing a sketch takes time proportional to \(A.n\text{nz}\). Data \(A\) which is in \texttt{scipy.sparse.csc\_matrix} format gives the quickest computation time for sparse input.

```python
>>> from scipy import linalg
>>> from scipy import sparse
>>> n_rows, n_columns, density, sketch_n_rows = 15000, 100, 0.01, 200
>>> A = sparse.rand(n_rows, n_columns, density=density, format='csc')
>>> B = sparse.rand(n_rows, n_columns, density=density, format='csr')
>>> C = sparse.rand(n_rows, n_columns, density=density, format='coo')
>>> D = np.random.randn(n_rows, n_columns)
>>> SA = linalg.clarkson_woodruff_transform(A, sketch_n_rows) # fastest
>>> SB = linalg.clarkson_woodruff_transform(B, sketch_n_rows) # fast
>>> SC = linalg.clarkson_woodruff_transform(C, sketch_n_rows) # slower
>>> SD = linalg.clarkson_woodruff_transform(D, sketch_n_rows) # slowest
```

That said, this method does perform well on dense inputs, just slower on a relative scale.
References

[1], [2]

Examples

Given a big dense matrix $A$:

```python
>>> from scipy import linalg
>>> n_rows, n_columns, sketch_n_rows = 15000, 100, 200
>>> A = np.random.randn(n_rows, n_columns)
>>> sketch = linalg.clarkson_woodruff_transform(A, sketch_n_rows)
>>> sketch.shape
(200, 100)
>>> norm_A = np.linalg.norm(A)
>>> norm_sketch = np.linalg.norm(sketch)
```

Now with high probability, the true norm $\text{norm}_A$ is close to the sketched norm $\text{norm}_\text{sketch}$ in absolute value.

Similarly, applying our sketch preserves the solution to a linear regression of $\min \|Ax - b\|$.

```python
>>> from scipy import linalg
>>> n_rows, n_columns, sketch_n_rows = 15000, 100, 200
>>> A = np.random.randn(n_rows, n_columns)
>>> b = np.random.randn(n_rows)
>>> x = np.linalg.lstsq(A, b, rcond=None)
>>> Ab = np.hstack((A, b.reshape(-1, 1)))
>>> SAb = linalg.clarkson_woodruff_transform(Ab, sketch_n_rows)
>>> SA, Sb = SAb[:, :-1], SAb[:, -1]
>>> x_sketch = np.linalg.lstsq(SA, Sb, rcond=None)
```

As with the matrix norm example, $\text{np.linalg.norm}(A @ x - b)$ is close to $\text{np.linalg.norm}(A @ x_{\text{sketch}} - b)$ with high probability.

6.10.7 Special Matrices

- `block_diag(*args)`: Create a block diagonal matrix from provided arrays.
- `circulant(c)`: Construct a circulant matrix.
- `companion(a)`: Create a companion matrix.
- `convolution_matrix(a, n[, mode])`: Construct a convolution matrix.
- `dft(n[, scale])`: Discrete Fourier transform matrix.
- `fiedler(a)`: Returns a symmetric Fiedler matrix.
- `fiedler_companion(a)`: Returns a Fiedler companion matrix.
- `hadamard(n[, dtype])`: Construct an Hadamard matrix.
- `hankel(c[, r])`: Construct a Hankel matrix.
- `helmert(n)`: Create a Helmert matrix of order $n$.
- `hilbert(n)`: Create a Hilbert matrix of order $n$.
- `invhilbert(n[, exact])`: Compute the inverse of the Hilbert matrix of order $n$.
- `leslie(f, s)`: Create a Leslie matrix.
- `pascal(n[, kind, exact])`: Returns the n x n Pascal matrix.
- `invpascal(n[, kind, exact])`: Returns the inverse of the n x n Pascal matrix.
Table 96 – continued from previous page

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>toeplitz(c[, r])</code></td>
<td>Construct a Toeplitz matrix.</td>
</tr>
<tr>
<td><code>tri(N[, M, k, dtype])</code></td>
<td>Construct (N, M) matrix filled with ones at and below the kth diagonal.</td>
</tr>
</tbody>
</table>

**scipy.linalg.block_diag**

`scipy.linalg.block_diag(*arrs)`

Create a block diagonal matrix from provided arrays.

Given the inputs `A`, `B` and `C`, the output will have these arrays arranged on the diagonal:

```
[[A, 0, 0],
 [0, B, 0],
 [0, 0, C]]
```

**Parameters**

- `A, B, C, ...`
  [array_like, up to 2-D] Input arrays. A 1-D array or array_like sequence of length `n` is treated as a 2-D array with shape `(1, n)`.

**Returns**

- `D` [ndarray] Array with `A, B, C, ...` on the diagonal. `D` has the same dtype as `A`.

**Notes**

If all the input arrays are square, the output is known as a block diagonal matrix.

Empty sequences (i.e., array-likes of zero size) will not be ignored. Noteworthy, both `[]` and `[[ ]]` are treated as matrices with shape `(1, 0)`.

**Examples**

```python
>>> from scipy.linalg import block_diag
>>> A = [[1, 0],
... [0, 1]]
>>> B = [[3, 4, 5],
... [6, 7, 8]]
>>> C = [[7]]
>>> P = np.zeros((2, 0), dtype='int32')
>>> block_diag(A, B, C)
array([[1, 0, 0, 0, 0],
       [0, 1, 0, 0, 0],
       [0, 0, 3, 4, 5],
       [0, 0, 6, 7, 8],
       [0, 0, 0, 0, 7]])
>>> block_diag(A, P, B, C)
array([[1, 0, 0, 0, 0],
       [0, 1, 0, 0, 0],
       [0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0]])
```

(continues on next page)
```python
>>> block_diag([1.0, [2, 3], [[4, 5], [6, 7]])
array([[ 1.,  0.,  0.,  0.,  0.],
       [ 0.,  2.,  3.,  0.,  0.],
       [ 0.,  0.,  4.,  5.,  0.],
       [ 0.,  0.,  6.,  7.,  0.]])
```

### `scipy.linalg.circulant`

`scipy.linalg.circulant(c)`

Construct a circulant matrix.

**Parameters**

- `c` : (N, array_like) 1-D array, the first column of the matrix.

**Returns**

- `A` : (N, N) ndarray A circulant matrix whose first column is `c`.

**See also:**

- `toeplitz`

  Toeplitz matrix

- `hankel`

  Hankel matrix

- `solve_circulant`

  Solve a circulant system.

**Notes**

New in version 0.8.0.

**Examples**

```python
>>> from scipy.linalg import circulant
>>> circulant([1, 2, 3])
array([[1, 3, 2],
       [2, 1, 3],
       [3, 2, 1]])
```
scipy.linalg.companion

`scipy.linalg.companion(a)`

Create a companion matrix.

Create the companion matrix [1] associated with the polynomial whose coefficients are given in `a`.

**Parameters**

- `a`  
  [(N,) array_like] 1-D array of polynomial coefficients. The length of `a` must be at least two, and `a[0]` must not be zero.

**Returns**

- `c`  
  [N-1, N-1] ndarray The first row of `c` is `-a[1:] / a[0]`, and the first sub-diagonal is all ones. The data-type of the array is the same as the data-type of `1.0 * a[0]`.

**Raises**

`ValueError`

If any of the following are true: a) `a.ndim != 1`; b) `a.size < 2`; c) `a[0] == 0`.

**Notes**

New in version 0.8.0.

**References**

[1]

**Examples**

```python
>>> from scipy.linalg import companion
>>> companion([1, -10, 31, -30])
array([[ 10., -31., 30.],
       [  1.,  0.,  0.],
       [  0.,  1.,  0.]])
```

scipy.linalg.convolution_matrix

`scipy.linalg.convolution_matrix(a, n, mode='full')`

Construct a convolution matrix.

Constructs the Toeplitz matrix representing one-dimensional convolution [1]. See the notes below for details.

**Parameters**

- `a`  
  [(m,) array_like] The 1-D array to convolve.

- `n`  
  [int] The number of columns in the resulting matrix. It gives the length of the input to be convolved with `a`. This is analogous to the length of `v` in `numpy.convolve(a, v)`.

- `mode`  
  [str] This is analogous to `mode` in `numpy.convolve(v, a, mode)`. It must be one of (`full`, `valid`, `same`). See below for how `mode` determines the shape of the result.

**Returns**

- `A`  
  [(k, n) ndarray] The convolution matrix whose row count `k` depends on `mode`.
The code:

\[
A = \text{convolution\_matrix}(a, n, \text{mode})
\]

creates a Toeplitz matrix \( A \) such that \( A \odot v \) is equivalent to using \( \text{convolve}(a, v, \text{mode}) \). The returned array always has \( n \) columns. The number of rows depends on the specified \( \text{mode} \), as explained above.

In the default ‘full’ mode, the entries of \( A \) are given by:

\[
A[i, j] = (a[i-j] \text{ if } (0 <= (i-j) < m) \text{ else } 0)
\]

where \( m = \text{len}(a) \). Suppose, for example, the input array is \([x, y, z] \). The convolution matrix has the form:

\[
\begin{align*}
[x, 0, 0, \ldots, 0, 0] \\
[y, x, 0, \ldots, 0, 0] \\
[z, y, x, \ldots, 0, 0] \\
\vdots \\
[0, 0, 0, \ldots, x, 0] \\
[0, 0, 0, \ldots, y, x] \\
[0, 0, 0, \ldots, z, y] \\
[0, 0, 0, \ldots, 0, z]
\end{align*}
\]

In ‘valid’ mode, the entries of \( A \) are given by:

\[
A[i, j] = (a[i-j+m-1] \text{ if } (0 <= (i-j+m-1) < m) \text{ else } 0)
\]

This corresponds to a matrix whose rows are the subset of those from the ‘full’ case where all the coefficients in \( a \) are contained in the row. For input \([x, y, z] \), this array looks like:

\[
\begin{align*}
[z, y, x, 0, 0, \ldots, 0, 0, 0] \\
[0, z, y, x, 0, \ldots, 0, 0, 0] \\
[0, 0, z, y, x, \ldots, 0, 0, 0] \\
\vdots \\
[0, 0, 0, 0, 0, \ldots, x, 0, 0] \\
[0, 0, 0, 0, 0, \ldots, y, x, 0] \\
[0, 0, 0, 0, 0, \ldots, z, y, x]
\end{align*}
\]

In the ‘same’ mode, the entries of \( A \) are given by:
```
d = (m - 1) // 2
A[i, j] = (a[i-j+d] if 0 <= (i-j+d) < m) else 0
```

The typical application of the 'same' mode is when one has a signal of length \( n \) (with \( n \) greater than \( \text{len}(a) \)), and the desired output is a filtered signal that is still of length \( n \).

For input \([x, y, z]\), this array looks like:

\[
\begin{align*}
[y, x, 0, 0, ..., 0, 0, 0] \\
[z, y, x, 0, ..., 0, 0, 0] \\
[0, z, y, x, ..., 0, 0, 0] \\
[0, 0, z, y, ..., 0, 0, 0] \\
... \\
[0, 0, 0, 0, ..., y, x, 0] \\
[0, 0, 0, 0, ..., z, y, x] \\
[0, 0, 0, 0, ..., 0, z, y]
\end{align*}
\]

New in version 1.5.0.

**References**

[1]

**Examples**

```
>>> from scipy.linalg import convolution_matrix
>>> A = convolution_matrix([-1, 4, -2], 5, mode='same')
>>> A
array([[ 4, -1,  0,  0,  0],
       [-2,  4, -1,  0,  0],
       [ 0, -2,  4, -1,  0],
       [ 0,  0, -2,  4, -1],
       [ 0,  0,  0, -2,  4]])
```

Compare multiplication by \( A \) with the use of `numpy.convolve`.

```
>>> x = np.array([1, 2, 0, -3, 0.5])
>>> A @ x
array([ 2. ,  6. , -1. , -12.5,  8. ])
```

Verify that \( A @ x \) produced the same result as applying the convolution function.

```
>>> np.convolve([-1, 4, -2], x, mode='same')
array([ 2. ,  6. , -1. , -12.5,  8. ])
```

For comparison to the case mode='same' shown above, here are the matrices produced by mode='full' and mode='valid' for the same coefficients and size.

```
>>> convolution_matrix([-1, 4, -2], 5, mode='full')
array([[-1,  0,  0,  0,  0],
       [ 4, -1,  0,  0,  0],
       [-2,  4, -1,  0,  0],
       [ 0, -2,  4, -1,  0],
       [ 0,  0, -2,  4, -1]])
```
(continues on next page)
[ 0, -2, 4, -1, 0],
[ 0, 0, -2, 4, -1],
[ 0, 0, 0, -2, 4],
[ 0, 0, 0, 0, -2]]

>>> convolution_matrix([-1, 4, -2], 5, mode='valid')
array([[ 0, -2, 4, -1, 0],
[ 0, 0, -2, 4, -1],
[ 0, 0, 0, -2, 4]])

scipy.linalg.dft

scipy.linalg.dft(n, scale=None)
Discrete Fourier transform matrix.

Create the matrix that computes the discrete Fourier transform of a sequence [1]. The nth primitive root of unity used to generate the matrix is \( \exp(-2\pi i/n) \), where \( i = \sqrt{-1} \).

Parameters

- **n** [int] Size the matrix to create.
- **scale** [str, optional] Must be None, ‘sqrtn’, or ‘n’. If scale is ‘sqrtn’, the matrix is divided by \( \sqrt{n} \). If scale is ‘n’, the matrix is divided by \( n \). If scale is None (the default), the matrix is not normalized, and the return value is simply the Vandermonde matrix of the roots of unity.

Returns

- **m** [(n, n) ndarray] The DFT matrix.

Notes

When scale is None, multiplying a vector by the matrix returned by dft is mathematically equivalent to (but much less efficient than) the calculation performed by scipy.fft.fft.

New in version 0.14.0.

References

[1]

Examples

```python
>>> from scipy.linalg import dft
>>> np.set_printoptions(precision=2, suppress=True)  # for compact output
>>> m = dft(5)
>>> m
array([[ 1. +0.j , 1. +0.j , 1. +0.j , 1. +0.j , 1. +0.j ],
       [ 1. +0.j , 0.31-0.95j, -0.81-0.59j, -0.81+0.59j, 0.31+0.95j],
       [ 1. +0.j , -0.81-0.59j, 0.31+0.95j, 0.31-0.95j, -0.81+0.59j],
       [ 1. +0.j , -0.81+0.59j, 0.31-0.95j, 0.31+0.95j, -0.81-0.59j],
       [ 1. +0.j , 0.31+0.95j, -0.81+0.59j, -0.81-0.59j, 0.31-0.95j]])
```
>>> x = np.array([1, 2, 3, 0, 3])
>>> m @ x  # Compute the DFT of x
array([ 9. +0.j , 0.12-0.81j, -2.12+3.44j, -2.12-3.44j, 0.12+0.81j])

Verify that m @ x is the same as fft(x).

```python
>>> from scipy.fft import fft
>>> fft(x)  # Same result as m @ x
array([ 9. +0.j , 0.12-0.81j, -2.12+3.44j, -2.12-3.44j, 0.12+0.81j])
```

**scipy.linalg.fiedler**

documented

**scipy.linalg.fiedler(a)**

Returns a symmetric Fiedler matrix

Given an sequence of numbers a, Fiedler matrices have the structure \( F[i, j] = \text{np.abs}(a[i] - a[j]) \), and hence zero diagonals and nonnegative entries. A Fiedler matrix has a dominant positive eigenvalue and other eigenvalues are negative. Although not valid generally, for certain inputs, the inverse and the determinant can be derived explicitly as given in [1].

**Parameters**

- **a** : [n] array_like, coefficient array

**Returns**

- **F** : [(n, n)] ndarray

**Notes**

New in version 1.3.0.

**References**

[1]

**Examples**

```python
>>> from scipy.linalg import det, inv, fiedler
>>> a = [1, 4, 12, 45, 77]
>>> n = len(a)
>>> A = fiedler(a)
>>> A
array([ [ 0,  3, 11, 44, 76],
        [ 3,  0,  8, 41, 73],
        [11,  8,  0, 33, 65],
        [44, 41, 33,  0, 32],
        [76, 73, 65, 32,  0]])
```
The explicit formulas for determinant and inverse seem to hold only for monotonically increasing/decreasing arrays. Note the tridiagonal structure and the corners.

```python
>>> Ai = inv(A)
>>> Ai[np.abs(Ai) < 1e-12] = 0. # cleanup the numerical noise for display
>>> Ai
array([[-0.16008772, 0.16666667, 0. , 0. , 0.00657895],
       [ 0.16666667, -0.22916667, 0.0625 , 0. , 0. ],
       [ 0. , 0.0625 , -0.07765152, 0.01515152, 0. ],
       [ 0. , 0. , 0.01515152, -0.03077652, 0.015625 ],
       [ 0.00657895, 0. , 0. , 0.015625 , -0.00904605]])
```

```python
>>> det(A)
15409151.999999998
>>> (-1)**(n-1) * 2**(n-2) * np.diff(a).prod() * (a[-1] - a[0])
15409152
```

scipy.linalg.fiedler_companion

Scipy.linalg.fiedler_companion(a)

Returns a Fiedler companion matrix.

Given a polynomial coefficient array a, this function forms a pentadiagonal matrix with a special structure whose eigenvalues coincides with the roots of a.

**Parameters**

- **a**
  - [(N,) array_like] 1-D array of polynomial coefficients in descending order with a nonzero leading coefficient. For N < 2, an empty array is returned.

**Returns**

- **c**
  - [(N-1, N-1) ndarray] Resulting companion matrix

**See also:**

- companion

**Notes**

Similar to companion the leading coefficient should be nonzero. In the case the leading coefficient is not 1, other coefficients are rescaled before the array generation. To avoid numerical issues, it is best to provide a monic polynomial.

New in version 1.3.0.

**References**

[1]
Examples

```python
>>> from scipy.linalg import fiedler_companion, eigvals
>>> p = np.poly(np.arange(1, 9, 2))  # [1., -16., 86., -176., 105.]
>>> fc = fiedler_companion(p)
>>> fc
array([[ 16., -86.,  1.,  0.],
       [  1.,  0.,  0.,  0.],
       [  0., 176.,  0., -105.],
       [  0.,  1.,  0.,  0.]])
>>> eigvals(fc)
array([7.+0.j, 5.+0.j, 3.+0.j, 1.+0.j])
```

**scipy.linalg.hadamard**

Construct an Hadamard matrix.

Constructs an n-by-n Hadamard matrix, using Sylvester’s construction. `n` must be a power of 2.

**Parameters**

- `n` [int] The order of the matrix. `n` must be a power of 2.
- `dtype` [dtype, optional] The data type of the array to be constructed.

**Returns**

**Notes**

New in version 0.8.0.

**Examples**

```python
>>> from scipy.linalg import hadamard
>>> hadamard(2, dtype=complex)
array([[ 1.+0.j,  1.+0.j],
       [ 1.+0.j, -1.-0.j]])
>>> hadamard(4)
array([[ 1,  1,  1,  1],
       [ 1, -1,  1, -1],
       [ 1,  1, -1, -1],
       [ 1, -1, -1,  1]])
```
**scipy.linalg.hankel**

**scipy.linalg.hankel(c, r=None)**

Construct a Hankel matrix.

The Hankel matrix has constant anti-diagonals, with `c` as its first column and `r` as its last row. If `r` is not given, then `r = zeros_like(c)` is assumed.

**Parameters**

- `c`  
  [array_like] First column of the matrix. Whatever the actual shape of `c`, it will be converted to a 1-D array.

- `r`  
  [array_like, optional] Last row of the matrix. If None, `r = zeros_like(c)` is assumed. `r[0]` is ignored; the last row of the returned matrix is `c[-1], r[1:]`. Whatever the actual shape of `r`, it will be converted to a 1-D array.

**Returns**

- `A`  
  [(len(c), len(r)) ndarray] The Hankel matrix. Dtype is the same as `(c[0] + r[0])`. `dtype`.

**See also:**

- `toeplitz`
  Toeplitz matrix

- `circulant`
  circulant matrix

**Examples**

```python
>>> from scipy.linalg import hankel
>>> hankel([1, 17, 99])
array([[ 1, 17, 99],
       [17, 99,  0],
       [99,  0,  0]])
>>> hankel([1,2,3,4], [4,7,7,8,9])
array([[1, 2, 3, 4, 7],
       [2, 3, 4, 7, 7],
       [3, 4, 7, 7, 8],
       [4, 7, 7, 8, 9]])
```

**scipy.linalg.helmert**

**scipy.linalg.helmert(n, full=False)**

Create an Helmert matrix of order `n`.

This has applications in statistics, compositional or simplicial analysis, and in Aitchison geometry.

**Parameters**

- `n`  
  [int] The size of the array to create.

- `full`  
  [bool, optional] If True the (n, n) ndarray will be returned. Otherwise the submatrix that does not include the first row will be returned. Default: False.

**Returns**
M [ndarray] The Helmert matrix. The shape is (n, n) or (n-1, n) depending on the full argument.

Examples

```python
>>> from scipy.linalg import helmert
>>> helmert(5, full=True)
array([[ 0.4472136 , 0.4472136 , 0.4472136 , 0.4472136 , 0.4472136 ],
       [ 0.70710678, -0.70710678, 0. , 0. , 0. ],
       [ 0.40824829, 0.40824829, -0.81649658, 0. , 0. ],
       [ 0.28867513, 0.28867513, 0.28867513, -0.8660254 , 0. ],
       [ 0.2236068 , 0.2236068 , 0.2236068 , 0.2236068 , -0.89442719]])
```

scipy.linalg.hilbert

scipy.linalg.hilbert(n)

Create a Hilbert matrix of order n.

Returns the n by n array with entries $h[i,j] = 1 / (i + j + 1)$.

Parameters

- n [int] The size of the array to create.

Returns

- h [(n, n) ndarray] The Hilbert matrix.

See also:

invhilbert

Compute the inverse of a Hilbert matrix.

Notes

New in version 0.10.0.

Examples

```python
>>> from scipy.linalg import hilbert
>>> hilbert(3)
array([[ 1. , 0.5 , 0.33333333],
       [ 0.5 , 0.33333333, 0.25 ],
       [ 0.33333333, 0.25 , 0.2 ]])
```
scipy.linalg.invhilbert

scipy.linalg.invhilbert \((n, exact=False)\)

Compute the inverse of the Hilbert matrix of order \(n\).

The entries in the inverse of a Hilbert matrix are integers. When \(n\) is greater than 14, some entries in the inverse exceed the upper limit of 64 bit integers. The \(exact\) argument provides two options for dealing with these large integers.

Parameters

- **n** [int] The order of the Hilbert matrix.
- **exact** [bool, optional] If False, the data type of the array that is returned is np.float64, and the array is an approximation of the inverse. If True, the array is the exact integer inverse array. To represent the exact inverse when \(n > 14\), the returned array is an object array of long integers. For \(n \leq 14\), the exact inverse is returned as an array with data type np.int64.

Returns

- **invh** [(n, n) ndarray] The data type of the array is np.float64 if \(exact\) is False. If \(exact\) is True, the data type is either np.int64 (for \(n \leq 14\)) or object (for \(n > 14\)). In the latter case, the objects in the array will be long integers.

See also:

hilbert

Create a Hilbert matrix.

Notes

New in version 0.10.0.

Examples

```python
given code
```
scipy.linalg.leslie

scipy.linalg.leslie(f, s)

Create a Leslie matrix.

Given the length \( n \) array of fecundity coefficients \( f \) and the length \( n-1 \) array of survival coefficients \( s \), return the associated Leslie matrix.

**Parameters**

- \( f \) [(N,) array_like] The “fecundity” coefficients.
- \( s \) [(N-1,) array_like] The “survival” coefficients, has to be 1-D. The length of \( s \) must be one less than the length of \( f \), and it must be at least 1.

**Returns**

- \( L \) [(N, N) ndarray] The array is zero except for the first row, which is \( f \), and the first sub-diagonal, which is \( s \). The data-type of the array will be the data-type of \( f[0]+s[0] \).

**Notes**

New in version 0.8.0.

The Leslie matrix is used to model discrete-time, age-structured population growth [1] [2]. In a population with \( n \) age classes, two sets of parameters define a Leslie matrix: the \( n \) “fecundity coefficients”, which give the number of offspring per-capita produced by each age class, and the \( n - 1 \) “survival coefficients”, which give the per-capita survival rate of each age class.

**References**

[1], [2]

**Examples**

```python
>>> from scipy.linalg import leslie
>>> leslie([0.1, 2.0, 1.0, 0.1], [0.2, 0.8, 0.7])
array([[ 0.1, 2. , 1. , 0.1],
       [ 0.2, 0. , 0. , 0. ],
       [ 0. , 0.8, 0. , 0. ],
       [ 0. , 0. , 0.7, 0. ]])
```

scipy.linalg.pascal

scipy.linalg.pascal(n, kind='symmetric', exact=True)

Returns the \( n \times n \) Pascal matrix.

The Pascal matrix is a matrix containing the binomial coefficients as its elements.

**Parameters**

- \( n \) [int] The size of the matrix to create; that is, the result is an \( n \times n \) matrix.
- \( \text{kind} \) [str, optional] Must be one of ‘symmetric’, ‘lower’, or ‘upper’. Default is ‘symmetric’.
exact [bool, optional] If exact is True, the result is either an array of type numpy.uint64 (if n < 35) or an object array of Python long integers. If exact is False, the coefficients in the matrix are computed using scipy.special.comb with exact=False. The result will be a floating point array, and the values in the array will not be the exact coefficients, but this version is much faster than exact=True.

Returns

p [(n, n) ndarray] The Pascal matrix.

See also:

invpascal

Notes

See https://en.wikipedia.org/wiki/Pascal_matrix for more information about Pascal matrices.

New in version 0.11.0.

Examples

```python
>>> from scipy.linalg import pascal
>>> pascal(4)
array([[ 1,  1,  1,  1],
       [ 1,  2,  3,  4],
       [ 1,  3,  6, 10],
       [ 1,  4, 10, 20]], dtype=uint64)
>>> pascal(4, kind='lower')
array([[1, 0, 0, 0],
       [1, 1, 0, 0],
       [1, 2, 1, 0],
       [1, 3, 3, 1]], dtype=uint64)
>>> pascal(50)[-1, -1]
25477612258980856902730428600
>>> from scipy.special import comb
>>> comb(98, 49, exact=True)
25477612258980856902730428600
```

scipy.linalg.invpascal

scipy.linalg.invpascal (n, kind='symmetric', exact=True)

Returns the inverse of the n x n Pascal matrix.

The Pascal matrix is a matrix containing the binomial coefficients as its elements.

Parameters

n [int] The size of the matrix to create; that is, the result is an n x n matrix.

kind [str, optional] Must be one of ‘symmetric’, ‘lower’, or ‘upper’. Default is ‘symmetric’.

exact [bool, optional] If exact is True, the result is either an array of type numpy.int64 (if n <= 35) or an object array of Python integers. If exact is False, the coefficients in the matrix are computed using scipy.special.comb with exact=False. The result will be a floating point array, and for large n, the values in the array will not be the exact coefficients.
Returns

invp  [(n, n) ndarray] The inverse of the Pascal matrix.

See also:

pascal

Notes

New in version 0.16.0.

References

[1], [2]

Examples

```python
>>> from scipy.linalg import invpascal, pascal
>>> invp = invpascal(5)
>>> invp
array([[  5,  -10,   10,  - 5,   1],
       [-10,   30,  -35,   19,  - 4],
       [ 10,  -35,   46,  -27,   6],
       [- 5,   19,  -27,   17,  - 4],
       [  1,   -4,    6,  - 4,   1]])
```

```python
>>> p = pascal(5)
>>> p.dot(invp)
array([[ 1.,  0.,  0.,  0.,  0.],
       [ 0.,  1.,  0.,  0.,  0.],
       [ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  0.,  0.,  1.,  0.],
       [ 0.,  0.,  0.,  0.,  1.]])
```

An example of the use of `kind` and `exact`:

```python
>>> invpascal(5, kind='lower', exact=False)
array([[  1.,   0.,  -0.,   0.,   0.],
       [ -1.,   1.,  -0.,   0.,   0.],
       [  1.,  -2.,   1.,  -0.,   0.],
       [ -1.,   3.,  -3.,   1.,  -0.],
       [  1.,  -4.,   6.,  -4.,   1.]])
```
scipy.linalg.toeplitz

scipy.linalg.toeplitz(c, r=None)

Construct a Toeplitz matrix.

The Toeplitz matrix has constant diagonals, with c as its first column and r as its first row. If r is not given, r == conjugate(c) is assumed.

Parameters

- `c` : array_like
  First column of the matrix. Whatever the actual shape of c, it will be converted to a 1-D array.

- `r` : array_like, optional
  First row of the matrix. If None, r = conjugate(c) is assumed; in this case, if c[0] is real, the result is a Hermitian matrix. r[0] is ignored; the first row of the returned matrix is [c[0], r[1:]]. Whatever the actual shape of r, it will be converted to a 1-D array.

Returns

- `A` : (len(c), len(r)) ndarray
  The Toeplitz matrix. Dtype is the same as (c[0] + r[0]).

See also:

circulant
  circulant matrix

hankel
  Hankel matrix

solve_toeplitz
  Solve a Toeplitz system.

Notes

The behavior when c or r is a scalar, or when c is complex and r is None, was changed in version 0.8.0. The behavior in previous versions was undocumented and is no longer supported.

Examples

```python
>>> from scipy.linalg import toeplitz
>>> toeplitz([1,2,3], [1,4,5,6])
array([[1, 4, 5, 6],
       [2, 1, 4, 5],
       [3, 2, 1, 4]])
>>> toeplitz([1.0, 2+3j, 4-1j])
array([[ 1.+0.j,  2.-3.j,  4.+1.j],
       [ 2.+3.j,  1.+0.j,  2.-3.j],
       [ 4.-1.j,  2.+3.j,  1.+0.j]])
```
scipy.linalg.tri

scipy.linalg.tri(N, M=None, k=0, dtype=None)

Construct (N, M) matrix filled with ones at and below the kth diagonal.

The matrix has $A[i,j] == 1$ for $i <= j + k$

Parameters

- **N** [int] The size of the first dimension of the matrix.
- **M** [int or None, optional] The size of the second dimension of the matrix. If M is None, $M = N$ is assumed.
- **k** [int, optional] Number of subdiagonal below which matrix is filled with ones. $k = 0$ is the main diagonal, $k < 0$ subdiagonal and $k > 0$ superdiagonal.
- **dtype** [dtype, optional] Data type of the matrix.

Returns

- **tri** [ndarray] Tri matrix.

Examples

```python
>>> from scipy.linalg import tri
>>> tri(3, 5, 2, dtype=int)
array([[1, 1, 1, 0, 0],
       [1, 1, 1, 1, 0],
       [1, 1, 1, 1, 1]])
>>> tri(3, 5, -1, dtype=int)
array([[0, 0, 0, 0, 0],
       [1, 0, 0, 0, 0],
       [1, 1, 0, 0, 0]])
```

6.10.8 Low-level routines

- **get_blas_funcs** (names[, arrays, dtype, ilp64]) Return available BLAS function objects from names. Arrays are used to determine the optimal prefix of BLAS routines.
- **get_lapack_funcs** (names[, arrays, dtype, ilp64]) Return available LAPACK function objects from names.
- **find_best_blas_type** ([arrays, dtype]) Find best-matching BLAS/LAPACK type.

**scipy.linalg.get_blas_funcs**

scipy.linalg.get_blas_funcs(names[, arrays, dtype, ilp64]) Return available BLAS function objects from names. Arrays are used to determine the optimal prefix of BLAS routines.

Parameters

- **names** [str or sequence of str] Name(s) of BLAS functions without type prefix.
- **arrays** [sequence of ndarrays, optional] Arrays can be given to determine optimal prefix of BLAS routines. If not given, double-precision routines will be used, otherwise the most generic type in arrays will be used.
- **dtype** [str or dtype, optional] Data-type specifier. Not used if **arrays** is non-empty.
ilp64  

[[True, False, ‘preferred’], optional] Whether to return ILP64 routine variant. Choosing 'preferred' returns ILP64 routine if available, and otherwise the 32-bit routine. Default: False

Returns

funcs  

[list] List containing the found function(s).

Notes

This routine automatically chooses between Fortran/C interfaces. Fortran code is used whenever possible for arrays with column major order. In all other cases, C code is preferred.

In BLAS, the naming convention is that all functions start with a type prefix, which depends on the type of the principal matrix. These can be one of {'s', 'd', 'c', 'z'} for the NumPy types {float32, float64, complex64, complex128} respectively. The code and the dtype are stored in attributes typecode and dtype of the returned functions.

Examples

```python
>>> import scipy.linalg as LA
>>> a = np.random.rand(3,2)
>>> x_gemv = LA.get_blas_funcs('gemv', (a,))
>>> x_gemv.typecode
'd'
>>> x_gemv = LA.get_blas_funcs('gemv', (a*1j,))
>>> x_gemv.typecode
'z'
```

scipy.linalg.get_lapack_funcs

scipy.linalg.get_lapack_funcs(names, arrays=(), dtype=None, ilp64=False)

Return available LAPACK function objects from names.

Arrays are used to determine the optimal prefix of LAPACK routines.

Parameters

- names  
  [str or sequence of str] Name(s) of LAPACK functions without type prefix.
- arrays  
  [sequence of ndarrays, optional] Arrays can be given to determine optimal prefix of LAPACK routines. If not given, double-precision routines will be used, otherwise the most generic type in arrays will be used.
- dtype  
  [str or dtype, optional] Data-type specifier. Not used if arrays is non-empty.
- ilp64  
  [{'True, False, 'preferred'}, optional] Whether to return ILP64 routine variant. Choosing 'preferred' returns ILP64 routine if available, and otherwise the 32-bit routine. Default: False

Returns

funcs  

[list] List containing the found function(s).
Notes

This routine automatically chooses between Fortran/C interfaces. Fortran code is used whenever possible for arrays with column major order. In all other cases, C code is preferred.

In LAPACK, the naming convention is that all functions start with a type prefix, which depends on the type of the principal matrix. These can be one of {'s', 'd', 'c', 'z'} for the NumPy types {float32, float64, complex64, complex128} respectively, and are stored in attribute `typecode` of the returned functions.

Examples

Suppose we would like to use ‘?lange’ routine which computes the selected norm of an array. We pass our array in order to get the correct ‘lange’ flavor.

```python
>>> import scipy.linalg as LA
>>> a = np.random.rand(3,2)
>>> x_lange = LA.get_lapack_funcs('lange', (a,))
>>> x_lange.typecode
'd'
>>> x_lange = LA.get_lapack_funcs('lange', (a*1j,))
>>> x_lange.typecode
'z'
```

Several LAPACK routines work best when its internal WORK array has the optimal size (big enough for fast computation and small enough to avoid waste of memory). This size is determined also by a dedicated query to the function which is often wrapped as a standalone function and commonly denoted as `###_lwork`. Below is an example for `zsysv`.

```python
>>> import scipy.linalg as LA
>>> a = np.random.rand(1000,1000)
>>> b = np.random.rand(1000,1)*1j
>>> # We pick up zsysv and zsysv_lwork due to b array
... xsysv, xlwork = LA.get_lapack_funcs(('sysv', 'sysv_lwork'), (a, b))
>>> opt_lwork, _ = xlwork(a.shape[0]) # returns a complex for 'z' prefix
>>> udut, ipiv, x, info = xsysv(a, b, lwork=int(opt_lwork.real))
```

`scipy.linalg.find_best_blas_type`

`scipy.linalg.find_best_blas_type(arrays=(), dtype=None)`

Find best-matching BLAS/LAPACK type.

Arrays are used to determine the optimal prefix of BLAS routines.

Parameters

- **arrays** [sequence of ndarrays, optional] Arrays can be given to determine optimal prefix of BLAS routines. If not given, double-precision routines will be used, otherwise the most generic type in arrays will be used.

- **dtype** [str or dtype, optional] Data-type specifier. Not used if `arrays` is non-empty.

Returns

- **prefix** [str] BLAS/LAPACK prefix character.
- **dtype** [dtype] Inferred Numpy data type.
prefer_fortran

[bool] Whether to prefer Fortran order routines over C order.

Examples

```python
>>> import scipy.linalg.blas as bla
>>> a = np.random.rand(10,15)
>>> b = np.asfortranarray(a)  # Change the memory layout order
>>> bla.find_best_blas_type((a,))
('d', dtype('float64'), False)
>>> bla.find_best_blas_type((a*1j,))
('z', dtype('complex128'), False)
>>> bla.find_best_blas_type((b,))
('d', dtype('float64'), True)
```

- `scipy.linalg.cython_lapack` – Low-level LAPACK functions for Cython

6.11 Low-level BLAS functions (`scipy.linalg.blas`)

This module contains low-level functions from the BLAS library.
New in version 0.12.0.

**Note:** The common `overwrite_<>` option in many routines, allows the input arrays to be overwritten to avoid extra memory allocation. However this requires the array to satisfy two conditions which are memory order and the data type to match exactly the order and the type expected by the routine.

As an example, if you pass a double precision float array to any `S...` routine which expects single precision arguments, `f2py` will create an intermediate array to match the argument types and overwriting will be performed on that intermediate array.

Similarly, if a C-contiguous array is passed, `f2py` will pass a FORTRAN-contiguous array internally. Please make sure that these details are satisfied. More information can be found in the `f2py` documentation.

**Warning:** These functions do little to no error checking. It is possible to cause crashes by mis-using them, so prefer using the higher-level routines in `scipy.linalg`.

</tr>
</tbody>
</table>

**scipy.linalg.blas.get_blas_funcs**

Return available BLAS function objects from names.

Parameters:

- **names**: [str or sequence of str] Name(s) of BLAS functions without type prefix.
- **arrays**: [sequence of ndarrays, optional] Arrays can be given to determine optimal prefix of BLAS routines. If not given, double-precision routines will be used, otherwise the most generic type in arrays will be used.
- **dtype**: [str or dtype, optional] Data-type specifier. Not used if **arrays** is non-empty.
- **ilp64**: [{'True, False, 'preferred'}, optional] Whether to return ILP64 routine variant. Choosing 'preferred' returns ILP64 routine if available, and otherwise the 32-bit routine. Default: False

Returns:

- **funcs**: [list] List containing the found function(s).

Notes:

This routine automatically chooses between Fortran/C interfaces. Fortran code is used whenever possible for arrays with column major order. In all other cases, C code is preferred.

In BLAS, the naming convention is that all functions start with a type prefix, which depends on the type of the principal matrix. These can be one of {'s', 'd', 'c', 'z'} for the NumPy types {float32, float64, complex64, complex128} respectively. The code and the dtype are stored in attributes **typecode** and **dtype** of the returned functions.

Examples:

```python
>>> import scipy.linalg as LA
>>> a = np.random.rand(3,2)
>>> x_gemv = LA.get_blas_funcs('gemv', (a,))
>>> x_gemv.typecode
'd'
>>> x_gemv = LA.get_blas_funcs('gemv',(a*1j,))
>>> x_gemv.typecode
'z'
```
scipy.linalg.blas.find_best_blas_type

**scipy.linalg.blas.find_best_blas_type(arrays=(), dtype=None)**

Find best-matching BLAS/LAPACK type.

Arrays are used to determine the optimal prefix of BLAS routines.

**Parameters**

arrays [sequence of ndarrays, optional] Arrays can be given to determine optimal prefix of BLAS routines. If not given, double-precision routines will be used, otherwise the most generic type in arrays will be used.

dtype [str or dtype, optional] Data-type specifier. Not used if arrays is non-empty.

**Returns**

prefix [str] BLAS/LAPACK prefix character.
dtype [dtype] Inferred Numpy data type.
prefer_fortran [bool] Whether to prefer Fortran order routines over C order.

**Examples**

```python
>>> import scipy.linalg.blas as bla
>>> a = np.random.rand(10,15)
>>> b = np.asfortranarray(a)  # Change the memory layout order
>>> bla.find_best_blas_type((a,))
('d', dtype('float64'), False)
>>> bla.find_best_blas_type((a*1j,))
('z', dtype('complex128'), False)
>>> bla.find_best_blas_type((b,))
('d', dtype('float64'), True)
```

scipy.linalg.blas.caxpy

scipy.linalg.blas.caxpy(x, [n, a, offx, incx, offy, incy]) = <fortran object>
Wrapper for caxpy.

Parameters

- x [input rank-1 array('F') with bounds (*)]
- y [input rank-1 array('F') with bounds (*)]

Returns

- z [rank-1 array('F') with bounds (*) and y storage]

Other Parameters

- n [input int, optional] Default: (len(x)-offx)/abs(incx)
- a [input complex, optional] Default: (1.0, 0.0)
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offy [input int, optional] Default: 0
```python
scipy.linalg.blas.ccopy

scipy.linalg.blas.ccopy(x[, n, offx, incx, offy, incy]) = <fortran object>

Wrapper for ccopy.

Parameters
- x [input rank-1 array('F') with bounds (*)]
- y [input rank-1 array('F') with bounds (*)]

Returns
- y [rank-1 array('F') with bounds (*)]

Other Parameters
- n [input int, optional] Default: (len(x)-offx)/abs(incx)
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offy [input int, optional] Default: 0
- incy [input int, optional] Default: 1

scipy.linalg.blas.cdotc

scipy.linalg.blas.cdotc(x[, n, offx, incx, offy, incy]) = <fortran cdotc>

Wrapper for cdotc.

Parameters
- x [input rank-1 array('F') with bounds (*)]
- y [input rank-1 array('F') with bounds (*)]

Returns
- xy [complex]

Other Parameters
- n [input int, optional] Default: (len(x)-offx)/abs(incx)
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offy [input int, optional] Default: 0
- incy [input int, optional] Default: 1

scipy.linalg.blas.cdotu

scipy.linalg.blas.cdotu(x[, n, offx, incx, offy, incy]) = <fortran cdotu>

Wrapper for cdotu.

Parameters
- x [input rank-1 array('F') with bounds (*)]
- y [input rank-1 array('F') with bounds (*)]

Returns
- xy [complex]
```
Other Parameters

- **n** [input int, optional] Default: \((\text{len}(x)-\text{offx})/\text{abs}(\text{incx})\)
- **offx** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1
- **offy** [input int, optional] Default: 0
- **incy** [input int, optional] Default: 1

**scipy.linalg.blas.crotg**

\[
\text{scipy.linalg.blas.crotg}(a, b) = \text{<fortran object>}
\]

Wrapper for \texttt{crotg}.

**Parameters**

- **a** [input complex]
- **b** [input complex]

**Returns**

- **c** [complex]
- **s** [complex]

**scipy.linalg.blas.cscal**

\[
\text{scipy.linalg.blas.cscal}(a, x[, n, offx, incx]) = \text{<fortran object>}
\]

Wrapper for \texttt{cscal}.

**Parameters**

- **a** [input complex]
- **x** [input rank-1 array('F') with bounds (*)]

**Returns**

- **x** [rank-1 array('F') with bounds (*)]

**Other Parameters**

- **n** [input int, optional] Default: \((\text{len}(x)-\text{offx})/\text{abs}(\text{incx})\)
- **offx** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1

**scipy.linalg.blas.csrot**

\[
\text{scipy.linalg.blas.csrot}(x, y, c[, s, n, offx, incx, offy, incy, overwrite_x, overwrite_y]) = \text{<fortran object>}
\]

Wrapper for \texttt{csrot}.

**Parameters**

- **x** [input rank-1 array('F') with bounds (*)]
- **y** [input rank-1 array('F') with bounds (*)]
- **c** [input float]
- **s** [input float]

**Returns**

- **x** [rank-1 array('F') with bounds (*)]
Other Parameters

- **n** [input int, optional] Default: \((\text{len}(x) - \text{off}_x) / \text{abs}(\text{inc}_x) + 1\)
- **overwrite_x** [input int, optional] Default: 0
- **off_x** [input int, optional] Default: 0
- **inc_x** [input int, optional] Default: 1
- **overwrite_y** [input int, optional] Default: 0
- **off_y** [input int, optional] Default: 0
- **inc_y** [input int, optional] Default: 1

**scipy.linalg.blas.csscal**

```python
scipy.linalg.blas.csscal(a, x[, n, offx, incx, overwrite_x]) = <fortran object>
```

Wrapper for csscal.

**Parameters**

- **a** [input float]
- **x** [input rank-1 array('F') with bounds (*)]

**Returns**

- **x** [rank-1 array('F') with bounds (*)]

Other Parameters

- **n** [input int, optional] Default: \((\text{len}(x) - \text{off}_x) / \text{abs}(\text{inc}_x)\)
- **overwrite_x** [input int, optional] Default: 0
- **off_x** [input int, optional] Default: 0
- **inc_x** [input int, optional] Default: 1

**scipy.linalg.blas.cswap**

```python
scipy.linalg.blas.cswap(x, y[, n, offx, incx, offy, incy]) = <fortran object>
```

Wrapper for cswap.

**Parameters**

- **x** [input rank-1 array('F') with bounds (*)]
- **y** [input rank-1 array('F') with bounds (*)]

**Returns**

- **x** [rank-1 array('F') with bounds (*)]
- **y** [rank-1 array('F') with bounds (*)]

Other Parameters

- **n** [input int, optional] Default: \((\text{len}(x) - \text{off}_x) / \text{abs}(\text{inc}_x)\)
- **off_x** [input int, optional] Default: 0
- **inc_x** [input int, optional] Default: 1
- **off_y** [input int, optional] Default: 0
- **inc_y** [input int, optional] Default: 1
scipy.linalg.blas.dasum

scipy.linalg.blas.dasum(x[, n, offx, incx]) = <fortran dasum>
Wrapper for dasum.

Parameters
- x [input rank-1 array('d') with bounds (*)]

Returns
- s [float]

Other Parameters
- n [input int, optional] Default: (len(x)-offx)/abs(incx)
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1

scipy.linalg.blas.daxpy

scipy.linalg.blas.daxpy(x, y[, n, a, offx, incx, offy, incy]) = <fortran object>
Wrapper for daxpy.

Parameters
- x [input rank-1 array('d') with bounds (*)]
- y [input rank-1 array('d') with bounds (*)]

Returns
- z [rank-1 array('d') with bounds (*) and y storage]

Other Parameters
- n [input int, optional] Default: (len(x)-offx)/abs(incx)
- a [input float, optional] Default: 1.0
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offy [input int, optional] Default: 0
- incy [input int, optional] Default: 1

scipy.linalg.blas.dcopy

scipy.linalg.blas.dcopy(x, y[, n, offx, incx, offy, incy]) = <fortran object>
Wrapper for dcopy.

Parameters
- x [input rank-1 array('d') with bounds (*)]
- y [input rank-1 array('d') with bounds (*)]

Returns
- y [rank-1 array('d') with bounds (*)]

Other Parameters
- n [input int, optional] Default: (len(x)-offx)/abs(incx)
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1
**scipy.linalg.blas.ddot**

```python
scipy.linalg.blas.ddot(x, y[, n, offx, incx, offy, incy]) = <fortran ddot>
```

Wrapper for `ddot`.

**Parameters**

- `x` [input rank-1 array('d') with bounds (*)]
- `y` [input rank-1 array('d') with bounds (*)]

**Returns**

- `xy` [float]

**Other Parameters**

- `n` [input int, optional] Default: `(len(x)-offx)/abs(incx)`
- `offx` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
- `offy` [input int, optional] Default: 0
- `incy` [input int, optional] Default: 1

**scipy.linalg.blas.dnrm2**

```python
scipy.linalg.blas.dnrm2(x[, n, offx, incx]) = <fortran dnrm2>
```

Wrapper for `dnrm2`.

**Parameters**

- `x` [input rank-1 array('d') with bounds (*)]

**Returns**

- `n2` [float]

**Other Parameters**

- `n` [input int, optional] Default: `(len(x)-offx)/abs(incx)`
- `offx` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1

**scipy.linalg.blas.drot**

```python
scipy.linalg.blas.drot(x, y, c[, n, offx, incx, offy, incy, overwrite_x, overwrite_y]) = <fortran drot object>
```

Wrapper for `drot`.

**Parameters**

- `x` [input rank-1 array('d') with bounds (*)]
- `y` [input rank-1 array('d') with bounds (*)]
- `c` [input float]
- `s` [input float]

**Returns**
x [rank-1 array('d') with bounds (*)]
y [rank-1 array('d') with bounds (*)]

Other Parameters

n [input int, optional] Default: (len(x)-offx)/abs(incx)+1
overwrite_x [input int, optional] Default: 0
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1
overwrite_y [input int, optional] Default: 0
offy [input int, optional] Default: 0
incy [input int, optional] Default: 1

scipy.linalg.blas.drotg

scipy.linalg.blas.drotg(a, b) = <fortran object>
Wrapper for drotg.
Parameters
a [input float]
b [input float]

Returns
c [float]
s [float]

scipy.linalg.blas.drotm

scipy.linalg.blas.drotm(x, y, param[, n, offx, incx, offy, incy, overwrite_x, overwrite_y]) = <fortran object>
Wrapper for drotm.
Parameters
x [input rank-1 array('d') with bounds (*)]
y [input rank-1 array('d') with bounds (*)]
param [input rank-1 array('d') with bounds (5)]

Returns
x [rank-1 array('d') with bounds (*)]
y [rank-1 array('d') with bounds (*)]

Other Parameters
n [input int, optional] Default: (len(x)-offx)/abs(incx)
overwrite_x [input int, optional] Default: 0
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1
overwrite_y [input int, optional] Default: 0
offy [input int, optional] Default: 0
incy [input int, optional] Default: 1
scipy.linalg.blas.drotmg

scipy.linalg.blas.drotmg(d1, d2, x1, y1) = <fortran object>
Wrapper for drotmg.

Parameters
- d1 [input float]
- d2 [input float]
- x1 [input float]
- y1 [input float]

Returns
- param [rank-1 array('d') with bounds (5)]

scipy.linalg.blas.dscal

scipy.linalg.blas.dscal(a, x[, n, offx, incx]) = <fortran object>
Wrapper for dscal.

Parameters
- a [input float]
- x [input rank-1 array('d') with bounds (*)]

Returns
- x [rank-1 array('d') with bounds (*)]

Other Parameters
- n [input int, optional] Default: (len(x)-offx)/abs(incx)
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1

scipy.linalg.blas.dswap

scipy.linalg.blas.dswap(x, y[, n, offx, incx, offy, incy]) = <fortran object>
Wrapper for dswap.

Parameters
- x [input rank-1 array('d') with bounds (*)]
- y [input rank-1 array('d') with bounds (*)]

Returns
- x [rank-1 array('d') with bounds (*)]
- y [rank-1 array('d') with bounds (*)]

Other Parameters
- n [input int, optional] Default: (len(x)-offx)/abs(incx)
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offy [input int, optional] Default: 0
- incy [input int, optional] Default: 1
scipy.linalg.blas.dzasum

scipy.linalg.blas.dzasum(x[, n, offx, incx]) = <fortran dzasum>

Wrapper for dzasum.

Parameters
- x [input rank-1 array('D') with bounds (*)]

Returns
- s [float]

Other Parameters
- n [input int, optional] Default: (len(x)-offx)/abs(incx)
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1

scipy.linalg.blas.dznrm2

scipy.linalg.blas.dznrm2(x[, n, offx, incx]) = <fortran dznrm2>

Wrapper for dznrm2.

Parameters
- x [input rank-1 array('D') with bounds (*)]

Returns
- n2 [float]

Other Parameters
- n [input int, optional] Default: (len(x)-offx)/abs(incx)
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1

scipy.linalg.blas.icamax

scipy.linalg.blas.icamax(x[, n, offx, incx]) = <fortran object>

Wrapper for icamax.

Parameters
- x [input rank-1 array('F') with bounds (*)]

Returns
- k [int]

Other Parameters
- n [input int, optional] Default: (len(x)-offx)/abs(incx)
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1
scipy.linalg.blas.idamax

\[
\text{scipy.linalg.blas.idamax}(x[, n, offx, incx]) = \text{<fortran object>}
\]
Wrapper for idamax.

**Parameters**
- \(x\) [input rank-1 array('d') with bounds (*)]

**Returns**
- \(k\) [int]

**Other Parameters**
- \(n\) [input int, optional] Default: (len(x)-offx)/abs(incx)
- \(offx\) [input int, optional] Default: 0
- \(incx\) [input int, optional] Default: 1

scipy.linalg.blas.isamax

\[
\text{scipy.linalg.blas.isamax}(x[, n, offx, incx]) = \text{<fortran object>}
\]
Wrapper for isamax.

**Parameters**
- \(x\) [input rank-1 array('f') with bounds (*)]

**Returns**
- \(k\) [int]

**Other Parameters**
- \(n\) [input int, optional] Default: (len(x)-offx)/abs(incx)
- \(offx\) [input int, optional] Default: 0
- \(incx\) [input int, optional] Default: 1

scipy.linalg.blas.izamax

\[
\text{scipy.linalg.blas.izamax}(x[, n, offx, incx]) = \text{<fortran object>}
\]
Wrapper for izamax.

**Parameters**
- \(x\) [input rank-1 array('D') with bounds (*)]

**Returns**
- \(k\) [int]

**Other Parameters**
- \(n\) [input int, optional] Default: (len(x)-offx)/abs(incx)
- \(offx\) [input int, optional] Default: 0
- \(incx\) [input int, optional] Default: 1
scipy.linalg.blas.sasum

scipy.linalg.blas.sasum($x[, n, offx, incx]$) = <fortran sasum>

Wrapper for sasum.

Parameters

- $x$ [input rank-1 array('f') with bounds (*)]

Returns

- $s$ [float]

Other Parameters

- $n$ [input int, optional] Default: (len(x)-offx)/abs(incx)
- $offx$ [input int, optional] Default: 0
- $incx$ [input int, optional] Default: 1

scipy.linalg.blas.saxpy

scipy.linalg.blas.saxpy($x[, y, n, a, offx, incx, offy, incy]$) = <fortran object>

Wrapper for saxpy.

Parameters

- $x$ [input rank-1 array('f') with bounds (*)]
- $y$ [input rank-1 array('f') with bounds (*)]

Returns

- $z$ [rank-1 array('f') with bounds (*) and y storage]

Other Parameters

- $n$ [input int, optional] Default: (len(x)-offx)/abs(incx)
- $a$ [input float, optional] Default: 1.0
- $offx$ [input int, optional] Default: 0
- $incx$ [input int, optional] Default: 1
- $offy$ [input int, optional] Default: 0
- $incy$ [input int, optional] Default: 1

scipy.linalg.blas.scasum

scipy.linalg.blas.scasum($x[, n, offx, incx]$) = <fortran scasum>

Wrapper for scasum.

Parameters

- $x$ [input rank-1 array('F') with bounds (*)]

Returns

- $s$ [float]

Other Parameters

- $n$ [input int, optional] Default: (len(x)-offx)/abs(incx)
- $offx$ [input int, optional] Default: 0
- $incx$ [input int, optional] Default: 1
scipy.linalg.blas.scnrm2

**scipy.linalg.blas.scnrm2**\( (x[, n, offx, incx]) = \texttt{<fortran scnrm2>} \)

Wrapper for scnnrm2.

**Parameters**

- **x** [input rank-1 array('F') with bounds (*)]

**Returns**

- **n2** [float]

**Other Parameters**

- **n** [input int, optional] Default: \((\text{len(x)}-\text{offx})/\text{abs(incx)}\)
- **offx** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1

scipy.linalg.blas.scopy

**scipy.linalg.blas.scopy**\( (x[, y[, n, offx, incx, offy, incy]]) = \texttt{<fortran object>} \)

Wrapper for scopy.

**Parameters**

- **x** [input rank-1 array('F') with bounds (*)]
- **y** [input rank-1 array('F') with bounds (*)]

**Returns**

- **y** [rank-1 array('F') with bounds (*)]

**Other Parameters**

- **n** [input int, optional] Default: \((\text{len(x)}-\text{offx})/\text{abs(incx)}\)
- **offx** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1
- **offy** [input int, optional] Default: 0
- **incy** [input int, optional] Default: 1

scipy.linalg.blas.sdot

**scipy.linalg.blas.sdot**\( (x[, y[, n, offx, incx, offy, incy]]) = \texttt{<fortran sdot>} \)

Wrapper for sdot.

**Parameters**

- **x** [input rank-1 array('F') with bounds (*)]
- **y** [input rank-1 array('F') with bounds (*)]

**Returns**

- **xy** [float]

**Other Parameters**

- **n** [input int, optional] Default: \((\text{len(x)}-\text{offx})/\text{abs(incx)}\)
- **offx** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1
- **offy** [input int, optional] Default: 0
- **incy** [input int, optional] Default: 1
scipy.linalg.blas.snrm2

scipy.linalg.blas.snrm2 (x[\[n, offx, incx\]] ) = <fortran snrm2>
Wrapper for snrm2.

Parameters

\(x\)  [input rank-1 array(\‘f\’) with bounds (*)]

Returns

\(n2\)  [float]

Other Parameters

\(n\)  [input int, optional] Default: (len(x)-offx)/abs(incx)
\(offx\)  [input int, optional] Default: 0
\(incx\)  [input int, optional] Default: 1

scipy.linalg.blas.srot

scipy.linalg.blas.srot (x, y, c, s[\[n, offx, incx, offy, incy, overwrite_x, overwrite_y\]] ) = <fortran srot
object>
Wrapper for srot.

Parameters

\(x\)  [input rank-1 array(\‘f\’) with bounds (*)]
\(y\)  [input rank-1 array(\‘f\’) with bounds (*)]
\(c\)  [input float]
\(s\)  [input float]

Returns

\(x\)  [rank-1 array(\‘f\’) with bounds (*)]
\(y\)  [rank-1 array(\‘f\’) with bounds (*)]

Other Parameters

\(n\)  [input int, optional] Default: (len(x)-1-offx)/abs(incx)+1
\(overwrite_x\)  [input int, optional] Default: 0
\(offx\)  [input int, optional] Default: 0
\(incx\)  [input int, optional] Default: 1
\(overwrite_y\)  [input int, optional] Default: 0
\(offy\)  [input int, optional] Default: 0
\(incy\)  [input int, optional] Default: 1
**scipy.linalg.blas.srotg**

scipy.linalg.blas.srotg(a, b) = <fortran object>

Wrapper for srotg.

**Parameters**

- **a** [input float]
- **b** [input float]

**Returns**

- **c** [float]
- **s** [float]

**scipy.linalg.blas.srotm**

scipy.linalg.blas.srotm(x, y, param[, n, offx, incx, offy, incy, overwrite_x, overwrite_y]) = <fortran object>

Wrapper for srotm.

**Parameters**

- **x** [input rank-1 array('f') with bounds (*)]
- **y** [input rank-1 array('f') with bounds (*)]
- **param** [input rank-1 array('f') with bounds (5)]

**Returns**

- **x** [rank-1 array('f') with bounds (*)]
- **y** [rank-1 array('f') with bounds (*)]

**Other Parameters**

- **n** [input int, optional] Default: (len(x)-offx)/abs/incx
- **overwrite_x** [input int, optional] Default: 0
- **offx** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1
- **overwrite_y** [input int, optional] Default: 0
- **offy** [input int, optional] Default: 0
- **incy** [input int, optional] Default: 1

**scipy.linalg.blas.srotmg**

scipy.linalg.blas.srotmg(d1, d2, x1, y1) = <fortran object>

Wrapper for srotmg.

**Parameters**

- **d1** [input float]
- **d2** [input float]
- **x1** [input float]
- **y1** [input float]

**Returns**

- **param** [rank-1 array('f') with bounds (5)]
**scipy.linalg.blas.sscal**

```python
scipy.linalg.blas.sscal(a, x[, n, offx, incx]) = <fortran object>
```

Wrapper for `sscal`.

**Parameters**
- `a` [input float]
- `x` [input rank-1 array('f') with bounds (*)]

**Returns**
- `x` [rank-1 array('f') with bounds (*)]

**Other Parameters**
- `n` [input int, optional] Default: `(len(x)-offx)/abs(incx)`
- `offx` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1

**scipy.linalg.blas.sswap**

```python
scipy.linalg.blas.sswap(x, y[, n, offx, incx, offy, incy]) = <fortran object>
```

Wrapper for `sswap`.

**Parameters**
- `x` [input rank-1 array('f') with bounds (*)]
- `y` [input rank-1 array('f') with bounds (*)]

**Returns**
- `x` [rank-1 array('f') with bounds (*)]
- `y` [rank-1 array('f') with bounds (*)]

**Other Parameters**
- `n` [input int, optional] Default: `(len(x)-offx)/abs(incx)`
- `offx` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
- `offy` [input int, optional] Default: 0
- `incy` [input int, optional] Default: 1

**scipy.linalg.blas.zaxpy**

```python
scipy.linalg.blas.zaxpy(x, y[, n, a, offx, incx, offy, incy]) = <fortran object>
```

Wrapper for `zaxpy`.

**Parameters**
- `x` [input rank-1 array('D') with bounds (*)]
- `y` [input rank-1 array('D') with bounds (*)]

**Returns**
- `z` [rank-1 array('D') with bounds (*) and y storage]

**Other Parameters**
- `n` [input int, optional] Default: `(len(x)-offx)/abs(incx)`
- `a` [input complex, optional] Default: (1.0, 0.0)
6.11. Low-level BLAS functions

**scipy.linalg.blas.zcopy**

```python
scipy.linalg.blas.zcopy(x, y[, n, offx, incx, offy, incy]) = <fortran object>
```

Wrapper for `zcopy`.

**Parameters**

- `x` [input rank-1 array('D') with bounds (*)]
- `y` [input rank-1 array('D') with bounds (*)]

**Returns**

- `y` [rank-1 array('D') with bounds (*)]

**Other Parameters**

- `n` [input int, optional] Default: (len(x)-offx)/abs(incx)
- `offx` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
- `offy` [input int, optional] Default: 0
- `incy` [input int, optional] Default: 1

**scipy.linalg.blas.zdotc**

```python
scipy.linalg.blas.zdotc(x, y[, n, offx, incx, offy, incy]) = <fortran zdotc>
```

Wrapper for `zdotc`.

**Parameters**

- `x` [input rank-1 array('D') with bounds (*)]
- `y` [input rank-1 array('D') with bounds (*)]

**Returns**

- `xy` [complex]

**Other Parameters**

- `n` [input int, optional] Default: (len(x)-offx)/abs(incx)
- `offx` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
- `offy` [input int, optional] Default: 0
- `incy` [input int, optional] Default: 1
scipy.linalg.blas.zdotu

**scipy.linalg.blas.zdotu (x, y[, n, offx, incx, offy, incy]) = <fortran zdotu>**

Wrapper for zdotu.

**Parameters**

- **x**
  - [input rank-1 array(‘D’) with bounds (*)]

- **y**
  - [input rank-1 array(‘D’) with bounds (*)]

**Returns**

- **xy**
  - [complex]

**Other Parameters**

- **n**
  - [input int, optional] Default: (len(x)-offx)/abs(incx)
- **offx**
  - [input int, optional] Default: 0
- **incx**
  - [input int, optional] Default: 1
- **offy**
  - [input int, optional] Default: 0
- **incy**
  - [input int, optional] Default: 1

scipy.linalg.blas.zdrot

**scipy.linalg.blas.zdrot (x, y, c[, s, n, offx, incx, offy, incy, overwrite_x, overwrite_y]) = <fortran object>**

Wrapper for zdrot.

**Parameters**

- **x**
  - [input rank-1 array(‘D’) with bounds (*)]
- **y**
  - [input rank-1 array(‘D’) with bounds (*)]
- **c**
  - [input float]
- **s**
  - [input float]

**Returns**

- **x**
  - [rank-1 array(‘D’) with bounds (*)]
- **y**
  - [rank-1 array(‘D’) with bounds (*)]

**Other Parameters**

- **n**
  - [input int, optional] Default: (len(x)-1-offx)/abs(incx)+1
- **overwrite_x**
  - [input int, optional] Default: 0
- **offx**
  - [input int, optional] Default: 0
- **incx**
  - [input int, optional] Default: 1
- **overwrite_y**
  - [input int, optional] Default: 0
- **offy**
  - [input int, optional] Default: 0
- **incy**
  - [input int, optional] Default: 1
scipy.linalg.blas.zdscal

`scipy.linalg.blas.zdscal(a, x[, n, offx, incx, overwrite_x]) = <fortran object>`

Wrapper for zdscal.

**Parameters**
- `a` [input float]
- `x` [input rank-1 array('D') with bounds (*)]

**Returns**
- `x` [rank-1 array('D') with bounds (*)]

**Other Parameters**
- `n` [input int, optional] Default: (len(x)-offx)/abs(incx)
- `overwrite_x` [input int, optional] Default: 0
- `offx` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1

scipy.linalg.blas.zrotg

`scipy.linalg.blas.zrotg(a, b) = <fortran object>`

Wrapper for zrotg.

**Parameters**
- `a` [input complex]
- `b` [input complex]

**Returns**
- `c` [complex]
- `s` [complex]

scipy.linalg.blas.zscal

`scipy.linalg.blas.zscal(a, x[, n, offx, incx]) = <fortran object>`

Wrapper for zscal.

**Parameters**
- `a` [input complex]
- `x` [input rank-1 array('D') with bounds (*)]

**Returns**
- `x` [rank-1 array('D') with bounds (*)]

**Other Parameters**
- `n` [input int, optional] Default: (len(x)-offx)/abs(incx)
- `offx` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
scipy.linalg.blas.zswap

scipy.linalg.blas.zswap(x, y[, n, offx, incx, offy, incy]) = <fortran object>
Wrapper for zswap.

Parameters

x  [input rank-1 array('D') with bounds (*)]
y  [input rank-1 array('D') with bounds (*)]

Returns

x  [rank-1 array('D') with bounds (*)]
y  [rank-1 array('D') with bounds (*)]

Other Parameters

n  [input int, optional] Default: (len(x)-offx)/abs(incx)
offx  [input int, optional] Default: 0
incx  [input int, optional] Default: 1
offy  [input int, optional] Default: 0
incy  [input int, optional] Default: 1

### scipy.linalg.blas.sgbmv

Wrapper for sgbmv.

**Parameters**

- m [input int]
- n [input int]
- kl [input int]
- ku [input int]
- alpha [input float]
- a [input rank-2 array('f') with bounds (lda,n)]
- x [input rank-1 array('f') with bounds (*)]

**Returns**

- yout [rank-1 array('f') with bounds (ly) and y storage]
### Other Parameters

- **incx** [input int, optional] Default: 1
- **offx** [input int, optional] Default: 0
- **beta** [input float, optional] Default: 0.0
- **y** [input rank-1 array('f') with bounds (ly)]
- **overwrite_y** [input int, optional] Default: 0
- **incy** [input int, optional] Default: 1
- **offy** [input int, optional] Default: 0
- **trans** [input int, optional] Default: 0

#### scipy.linalg.blas.sgemv

```python
def scipy.linalg.blas.sgemv(alpha, a, x, beta, y, offx, incx, offy, incy, trans, overwrite_y):
    return <fortran object>
```

Wrapper for `sgemv`.

**Parameters**

- **alpha** [input float]
- **a** [input rank-2 array('f') with bounds (m,n)]
- **x** [input rank-1 array('f') with bounds (*)]

**Returns**

- **y** [rank-1 array('f') with bounds (ly)]

#### Other Parameters

- **beta** [input float, optional] Default: 0.0
- **y** [input rank-1 array('f') with bounds (ly)]
- **overwrite_y** [input int, optional] Default: 0
- **offx** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1
- **offy** [input int, optional] Default: 0
- **incy** [input int, optional] Default: 1
- **trans** [input int, optional] Default: 0

#### scipy.linalg.blas.sger

```python
def scipy.linalg.blas.sger(alpha, x, y, incx, incy, a, overwrite_x, overwrite_y, overwrite_a):
    return <fortran object>
```

Wrapper for `sger`.

**Parameters**

- **alpha** [input float]
- **x** [input rank-1 array('f') with bounds (m)]
- **y** [input rank-1 array('f') with bounds (n)]

**Returns**

- **a** [rank-2 array('f') with bounds (m,n)]

#### Other Parameters
overwrite_x  [input int, optional] Default: 1
incx  [input int, optional] Default: 1
overwrite_y  [input int, optional] Default: 1
incy  [input int, optional] Default: 1
a  [input rank-2 array('f') with bounds (m,n), optional] Default: 0.0
overwrite_a  [input int, optional] Default: 0

scipy.linalg.blas.ssbmv

scipy.linalg.blas.ssbmv (k, alpha, a[incx, offx, beta, y, incy, offy, lower, overwrite_y]) = <fortran object>
Wrapper for ssbmv.

Parameters
- k  [input int]
- alpha  [input float]
- a  [input rank-2 array('f') with bounds (lda,n)]
- x  [input rank-1 array('f') with bounds (*)]

Returns
- yout  [rank-1 array('f') with bounds (ly) and y storage]

Other Parameters
- incx  [input int, optional] Default: 1
- offx  [input int, optional] Default: 0
- beta  [input float, optional] Default: 0.0
- y  [input rank-1 array('f') with bounds (ly)]
- overwrite_y  [input int, optional] Default: 0
- incy  [input int, optional] Default: 1
- offy  [input int, optional] Default: 0
- lower  [input int, optional] Default: 0

scipy.linalg.blas.sspr

scipy.linalg.blas.sspr (n, alpha, x, ap[incx, offx, lower, overwrite_ap]) = <fortran object>
Wrapper for sspr.

Parameters
- n  [input int]
- alpha  [input float]
- x  [input rank-1 array('f') with bounds (*)]
- ap  [input rank-1 array('f') with bounds (*)]

Returns
- apu  [rank-1 array('f') with bounds (*) and ap storage]

Other Parameters
- incx  [input int, optional] Default: 1

```python

scipy.linalg.blas.sspr2

scipy.linalg.blas.sspr2(n, alpha, x, y, ap[, incx, offx, incy, offy, lower, overwrite_ap]) =
<fortran object>

Wrapper for ssp2.

Parameters

n  [input int]
alpha  [input float]
x  [input rank-1 array('f') with bounds (*)]
y  [input rank-1 array('f') with bounds (*)]
ap  [input rank-1 array('f') with bounds (*)]

Returns

apu  [rank-1 array('f') with bounds (*) and ap storage]

Other Parameters

incx  [input int, optional] Default: 1
offx  [input int, optional] Default: 0
incy  [input int, optional] Default: 1
offy  [input int, optional] Default: 0
overwrite_ap  [input int, optional] Default: 0
lower  [input int, optional] Default: 0

scipy.linalg.blas.ssyr2

scipy.linalg.blas.ssyr2(alpha, a, x[, beta, y, offx, incx, offy, incy, lower, overwrite_y]) =
<fortran object>

Wrapper for ssyr2.

Parameters

alpha  [input float]
a  [input rank-2 array('f') with bounds (n,n)]
x  [input rank-1 array('f') with bounds (*)]

Returns

y  [rank-1 array('f') with bounds (ly)]

Other Parameters

beta  [input float, optional] Default: 0.0
y  [input rank-1 array('f') with bounds (ly)]
overwrite_y  [input int, optional] Default: 0
offx  [input int, optional] Default: 0
incx  [input int, optional] Default: 1
offy  [input int, optional] Default: 0
```

6.11. Low-level BLAS functions ($\texttt{scipy.linalg.blas}$)

\texttt{scipy.linalg.blas.syr}

\texttt{scipy.linalg.blas.syr}($\alpha$, \texttt{x}, \texttt{lower}, \texttt{incx}, \texttt{offx}, \texttt{n}, \texttt{a}, \texttt{overwrite_a}) = <fortran object>

Wrapper for \texttt{syr}.

Parameters

- \texttt{alpha} [input float]
- \texttt{x} [input rank-1 array('f') with bounds (*)]

Returns

- \texttt{a} [rank-2 array('f') with bounds (n,n)]

Other Parameters

- \texttt{lower} [input int, optional] Default: 0
- \texttt{incx} [input int, optional] Default: 1
- \texttt{offx} [input int, optional] Default: 0
- \texttt{n} [input int, optional] Default: (\text{len(x)}-1-offx)/abs(incx)+1
- \texttt{a} [input rank-2 array('f') with bounds (n,n)]
- \texttt{overwrite_a} [input int, optional] Default: 0

\texttt{scipy.linalg.blas.syr2}

\texttt{scipy.linalg.blas.syr2}($\alpha$, \texttt{x, y}, \texttt{lower}, \texttt{incx}, \texttt{offx}, \texttt{incy}, \texttt{offy}, \texttt{n}, \texttt{a}, \texttt{overwrite_a}) = <fortran object>

Wrapper for \texttt{syr2}.

Parameters

- \texttt{alpha} [input float]
- \texttt{x} [input rank-1 array('f') with bounds (*)]
- \texttt{y} [input rank-1 array('f') with bounds (*)]

Returns

- \texttt{a} [rank-2 array('f') with bounds (n,n)]

Other Parameters

- \texttt{lower} [input int, optional] Default: 0
- \texttt{incx} [input int, optional] Default: 1
- \texttt{offx} [input int, optional] Default: 0
- \texttt{incy} [input int, optional] Default: 1
- \texttt{offy} [input int, optional] Default: 0
- \texttt{n} [input int, optional] Default: ((\text{len(x)}-1-offx)/abs(incx)+1 <=(\text{len(y)}-1-offy)/abs(incy)+1
  ?(\text{len(x)}-1-offx)/abs(incx)+1 ;(\text{len(y)}-1-offy)/abs(incy)+1)
- \texttt{a} [input rank-2 array('f') with bounds (n,n)]
- \texttt{overwrite_a} [input int, optional] Default: 0
scipy.linalg.blas.stbmv

scipy.linalg.blas.stbmv (k, a, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>

Wrapper for stbmv.

Parameters

- k [input int]
- a [input rank-2 array('f') with bounds (lda,n)]
- x [input rank-1 array('f') with bounds (*)]

Returns

- xout [rank-1 array('f') with bounds (*) and x storage]

Other Parameters

- overwrite_x [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offx [input int, optional] Default: 0
- lower [input int, optional] Default: 0
- trans [input int, optional] Default: 0
- diag [input int, optional] Default: 0

scipy.linalg.blas.stpsv

scipy.linalg.blas.stpsv (n, ap, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>

Wrapper for stpsv.

Parameters

- n [input int]
- ap [input rank-1 array('f') with bounds (*)]
- x [input rank-1 array('f') with bounds (*)]

Returns

- xout [rank-1 array('f') with bounds (*) and x storage]

Other Parameters

- overwrite_x [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offx [input int, optional] Default: 0
- lower [input int, optional] Default: 0
- trans [input int, optional] Default: 0
- diag [input int, optional] Default: 0
scipy.linalg.blas.strmv

scipy.linalg.blas.strmv(a, x[, offx, incx, lower, trans, diag, overwrite_x]) = <fortran object>

Wrapper for strmv.

Parameters
a [input rank-2 array('f') with bounds (n,n)]
x [input rank-1 array('f') with bounds (*)]

Returns
x [rank-1 array('f') with bounds (*)]

Other Parameters
overwrite_x [input int, optional] Default: 0
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1
lower [input int, optional] Default: 0
trans [input int, optional] Default: 0
diag [input int, optional] Default: 0

scipy.linalg.blas.strsv

scipy.linalg.blas.strsv(a, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>

Wrapper for strsv.

Parameters
a [input rank-2 array('f') with bounds (n,n)]
x [input rank-1 array('f') with bounds (*)]

Returns
xout [rank-1 array('f') with bounds (*) and x storage]

Other Parameters
overwrite_x [input int, optional] Default: 0
incx [input int, optional] Default: 1
offx [input int, optional] Default: 0
lower [input int, optional] Default: 0
trans [input int, optional] Default: 0
diag [input int, optional] Default: 0

scipy.linalg.blas.dgbmv

scipy.linalg.blas.dgbmv(m, n, kl, ku, alpha, a, x[, incy, offx, beta, y, incx, offy, trans, overwrite_y]) = <fortran object>

Wrapper for dgbmv.

Parameters
m [input int]
n [input int]
kl [input int]
\textbf{SciPy Reference Guide, Release 1.6.3}

\begin{verbatim}
ku [input int]
alpha [input float]
a [input rank-2 array(‘d’) with bounds (lda,n)]
x [input rank-1 array(‘d’) with bounds (*)]

\textit{Returns}

yout [rank-1 array(‘d’) with bounds (ly) and y storage]

\textit{Other Parameters}

\begin{itemize}
  \item incx [input int, optional] Default: 1
  \item offx [input int, optional] Default: 0
  \item beta [input float, optional] Default: 0.0
  \item y [input rank-1 array(‘d’) with bounds (ly)]
  \item overwrite_y [input int, optional] Default: 0
  \item incy [input int, optional] Default: 1
  \item offy [input int, optional] Default: 0
  \item trans [input int, optional] Default: 0
\end{itemize}

\texttt{scipy.linalg.blas.dgemv}

\texttt{scipy.linalg.blas.dgemv(alpha, a, x[, beta, y, offx, incx, offy, incy, trans, overwrite_y]) =
<fortran object>}

Wrapper for \texttt{dgemv}.

\textit{Parameters}

\begin{itemize}
  \item alpha [input float]
  \item a [input rank-2 array(‘d’) with bounds (m,n)]
  \item x [input rank-1 array(‘d’) with bounds (*)]
\end{itemize}

\textit{Returns}

\begin{itemize}
  \item y [rank-1 array(‘d’) with bounds (ly)]
\end{itemize}

\textit{Other Parameters}

\begin{itemize}
  \item beta [input float, optional] Default: 0.0
  \item y [input rank-1 array(‘d’) with bounds (ly)]
  \item overwrite_y [input int, optional] Default: 0
  \item offx [input int, optional] Default: 0
  \item incx [input int, optional] Default: 1
  \item offy [input int, optional] Default: 0
  \item incy [input int, optional] Default: 1
  \item trans [input int, optional] Default: 0
\end{itemize}
\end{verbatim}
scipy.linalg.blas.dger

scipy.linalg.blas.dger(alpha, x[, incx, incy, a, overwrite_x, overwrite_y, overwrite_a]) = <fortran object>

Wrapper for dger.

Parameters

alpha [input float]
x [input rank-1 array('d') with bounds (m)]
y [input rank-1 array('d') with bounds (n)]

Returns

a [rank-2 array('d') with bounds (m,n)]

Other Parameters

overwrite_x [input int, optional] Default: 1
incx [input int, optional] Default: 1
overwrite_y [input int, optional] Default: 1
incy [input int, optional] Default: 1
a [input rank-2 array('d') with bounds (m,n), optional] Default: 0.0
overwrite_a [input int, optional] Default: 0

scipy.linalg.blas.dsbmv

scipy.linalg.blas.dsbmv(k, alpha, a[, incx, offx, beta, y, incy, offy, lower, overwrite_y]) = <fortran object>

Wrapper for dsbmv.

Parameters

k [input int]
alpha [input float]
a [input rank-2 array('d') with bounds (lda,n)]
x [input rank-1 array('d') with bounds (*)]

Returns

yout [rank-1 array('d') with bounds (ly) and y storage]

Other Parameters

incx [input int, optional] Default: 1
offx [input int, optional] Default: 0
beta [input float, optional] Default: 0.0
y [input rank-1 array('d') with bounds (ly)]
overwrite_y [input int, optional] Default: 0
incy [input int, optional] Default: 0
offy [input int, optional] Default: 0
lower [input int, optional] Default: 0
scipy.linalg.blas.dspr

scipy.linalg.blas.dspr(n, alpha, x, ap[, incx, offx, lower, overwrite_ap]) = <fortran object>

Wrapper for dspr.

Parameters

- n [input int]
- alpha [input float]
- x [input rank-1 array('d') with bounds (*)]
- ap [input rank-1 array('d') with bounds (*)]

Returns

- apu [rank-1 array('d') with bounds (*) and ap storage]

Other Parameters

- incx [input int, optional] Default: 1
- offx [input int, optional] Default: 0
- overwrite_ap [input int, optional] Default: 0
- lower [input int, optional] Default: 0

scipy.linalg.blas.dspr2

scipy.linalg.blas.dspr2(n, alpha, x, y, ap[, incx, offx, incy, offy, lower, overwrite_ap]) = <fortran object>

Wrapper for dspr2.

Parameters

- n [input int]
- alpha [input float]
- x [input rank-1 array('d') with bounds (*)]
- y [input rank-1 array('d') with bounds (*)]
- ap [input rank-1 array('d') with bounds (*)]

Returns

- apu [rank-1 array('d') with bounds (*) and ap storage]

Other Parameters

- incx [input int, optional] Default: 1
- offx [input int, optional] Default: 0
- incy [input int, optional] Default: 1
- offy [input int, optional] Default: 0
- overwrite_ap [input int, optional] Default: 0
- lower [input int, optional] Default: 0
scipy.linalg.blas.dsymv

scipy.linalg.blas.dsymv(\(\alpha, a, x[, \beta, y, \text{offx, incx, offy, incy, lower, overwrite}_y]\)) = <fortran object>

Wrapper for dsymv.

Parameters

\(\alpha\) [input float]  
\(a\) [input rank-2 array('d') with bounds (n,n)]  
\(x\) [input rank-1 array('d') with bounds (*)]

Returns

\(y\) [rank-1 array('d') with bounds (ly)]

Other Parameters

\(\beta\) [input float, optional] Default: 0.0  
\(y\) [input rank-1 array('d') with bounds (ly)]  
\text{overwrite}_y [input int, optional] Default: 0  
\text{offx} [input int, optional] Default: 0  
\text{incx} [input int, optional] Default: 1  
\text{offy} [input int, optional] Default: 0  
\text{incy} [input int, optional] Default: 1  
\text{lower} [input int, optional] Default: 0

scipy.linalg.blas.dsyr

scipy.linalg.blas.dsyr(\(\alpha, x[, \text{lower, incx, offx, n, a, overwrite}_a]\)) = <fortran object>

Wrapper for dsyr.

Parameters

\(\alpha\) [input float]  
\(x\) [input rank-1 array('d') with bounds (*)]

Returns

\(a\) [rank-2 array('d') with bounds (n,n)]

Other Parameters

\(\text{lower}\) [input int, optional] Default: 0  
\(\text{incx}\) [input int, optional] Default: 1  
\text{offx} [input int, optional] Default: 0  
\(n\) [input int, optional] Default: (len(x)-1-offx)/abs(incx)+1  
\(a\) [input rank-2 array('d') with bounds (n,n)]  
\text{overwrite}_a [input int, optional] Default: 0
scipy.linalg.blas.dsy2

Wrapper for dsyr2.

Parameters

- **alpha**: [input float]
- **x**: [input rank-1 array('d') with bounds (*)]
- **y**: [input rank-1 array('d') with bounds (*)]

Returns

- **a**: [rank-2 array('d') with bounds (n,n)]

Other Parameters

- **lower**: [input int, optional] Default: 0
- **incx**: [input int, optional] Default: 1
- **offx**: [input int, optional] Default: 0
- **incy**: [input int, optional] Default: 1
- **offy**: [input int, optional] Default: 0
- **n**: [input int, optional] Default: 
  \[(\text{len}(x)-1-\text{offx})/\text{abs}(\text{incx})+1 \leq (\text{len}(y)-1-\text{offy})/\text{abs}(\text{incy})+1 \? (\text{len}(y)-1-\text{offy})/\text{abs}(\text{incy})+1 \):(\text{len}(y)-1-\text{offy})/\text{abs}(\text{incy})+1\]
- **a**: [input rank-2 array('d') with bounds (n,n)]
- **overwrite_a**: [input int, optional] Default: 0

scipy.linalg.blas.dtbmv

Wrapper for dtbmv.

Parameters

- **k**: [input int]
- **a**: [input rank-2 array('d') with bounds (lda,n)]
- **x**: [input rank-1 array('d') with bounds (*)]

Returns

- **xout**: [rank-1 array('d') with bounds (*) and x storage]

Other Parameters

- **overwrite_x**: [input int, optional] Default: 0
- **incx**: [input int, optional] Default: 1
- **offx**: [input int, optional] Default: 0
- **lower**: [input int, optional] Default: 0
- **trans**: [input int, optional] Default: 0
- **diag**: [input int, optional] Default: 0
scipy.linalg.blas.dtpsv

scipy.linalg.blas.dtpsv (n, ap, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>

Wrapper for dtpsv.

Parameters

- n [input int]
- ap [input rank-1 array('d') with bounds (*)]
- x [input rank-1 array('d') with bounds (*)]

Returns

- xout [rank-1 array('d') with bounds (*) and x storage]

Other Parameters

- overwrite_x [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offx [input int, optional] Default: 0
- lower [input int, optional] Default: 0
- trans [input int, optional] Default: 0
- diag [input int, optional] Default: 0

scipy.linalg.blas.dtrmv

scipy.linalg.blas.dtrmv (a, x[, offx, incx, lower, trans, diag, overwrite_x]) = <fortran object>

Wrapper for dtrmv.

Parameters

- a [input rank-2 array('d') with bounds (n,n)]
- x [input rank-1 array('d') with bounds (*)]

Returns

- x [rank-1 array('d') with bounds (*)]

Other Parameters

- overwrite_x [input int, optional] Default: 0
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- lower [input int, optional] Default: 0
- trans [input int, optional] Default: 0
- diag [input int, optional] Default: 0
scipy.linalg.blas.dtrsv

Wrapper for dtrsv.

Parameters

- `a` [input rank-2 array('d') with bounds (n,n)]
- `x` [input rank-1 array('d') with bounds (*)]

Returns

- `xout` [rank-1 array('d') with bounds (*) and x storage]

Other Parameters

- `overwrite_x` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
- `offx` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
- `trans` [input int, optional] Default: 0
- `diag` [input int, optional] Default: 0

scipy.linalg.blas.cgbmv

Wrapper for cgbmv.

Parameters

- `m` [input int]
- `n` [input int]
- `kl` [input int]
- `ku` [input int]
- `alpha` [input complex]
- `a` [input rank-2 array('F') with bounds (lda,n)]
- `x` [input rank-1 array('F') with bounds (*)]

Returns

- `yout` [rank-1 array('F') with bounds (ly) and y storage]

Other Parameters

- `incx` [input int, optional] Default: 1
- `offx` [input int, optional] Default: 0
- `beta` [input complex, optional] Default: (0.0, 0.0)
- `y` [input rank-1 array('F') with bounds (ly)]
- `overwrite_y` [input int, optional] Default: 0
- `incy` [input int, optional] Default: 1
- `offy` [input int, optional] Default: 0
- `trans` [input int, optional] Default: 0
scipy.linalg.blas.cgemv

scipy.linalg.blas.cgemv(\(alpha, a, x[, beta, y, \text{offx, incx, offy, incy, trans, overwrite_y}]\)) =

Wrapper for cgemv.

Parameters

- \(alpha\) [input complex]
- \(a\) [input rank-2 array('F') with bounds (m,n)]
- \(x\) [input rank-1 array('F') with bounds (*)]

Returns

- \(y\) [rank-1 array('F') with bounds (ly)]

Other Parameters

- \(beta\) [input complex, optional] Default: (0.0, 0.0)
- \(y\) [input rank-1 array('F') with bounds (ly)]
- overwrite_y [input int, optional] Default: 0
- \(\text{offx}\) [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- \(\text{offy}\) [input int, optional] Default: 0
- incy [input int, optional] Default: 1
- trans [input int, optional] Default: 0

scipy.linalg.blas.cgerc

scipy.linalg.blas.cgerc(\(alpha, x[, y, incx, incy, a, overwrite_x, overwrite_y, overwrite_a}\)) =

Wrapper for cgerc.

Parameters

- \(alpha\) [input complex]
- \(x\) [input rank-1 array('F') with bounds (m)]
- \(y\) [input rank-1 array('F') with bounds (n)]

Returns

- \(a\) [rank-2 array('F') with bounds (m,n)]

Other Parameters

- overwrite_x [input int, optional] Default: 1
- incx [input int, optional] Default: 1
- overwrite_y [input int, optional] Default: 1
- incy [input int, optional] Default: 1
- \(a\) [input rank-2 array('F') with bounds (m,n), optional] Default: (0,0,0,0)
- overwrite_a [input int, optional] Default: 0
**SciPy Reference Guide, Release 1.6.3**

**scipy.linalg.blas.cgeru**

```
scipy.linalg.blas.cgeru(alpha, x, y[, incx, incy, a, overwrite_x, overwrite_y, overwrite_a]) =
<fortran object>
```

Wrapper for cgeru.

**Parameters**

- **alpha** [input complex]
- **x** [input rank-1 array('F') with bounds (m)]
- **y** [input rank-1 array('F') with bounds (n)]

**Returns**

- **a** [rank-2 array('F') with bounds (m,n)]

**Other Parameters**

- **overwrite_x** [input int, optional] Default: 1
- **incx** [input int, optional] Default: 1
- **overwrite_y** [input int, optional] Default: 1
- **incy** [input int, optional] Default: 1
- **a** [input rank-2 array('F') with bounds (m,n), optional] Default: (0.0,0.0)
- **overwrite_a** [input int, optional] Default: 0

**scipy.linalg.blas.chbmv**

```
scipy.linalg.blas.chbmv(k, alpha, a, x[, incx, offx, beta, y, incy, offy, lower, overwrite_y]) =
<fortran object>
```

Wrapper for chbmv.

**Parameters**

- **k** [input int]
- **alpha** [input complex]
- **a** [input rank-2 array('F') with bounds (lda,n)]
- **x** [input rank-1 array('F') with bounds (*)]

**Returns**

- **yout** [rank-1 array('F') with bounds (ly) and y storage]

**Other Parameters**

- **incx** [input int, optional] Default: 1
- **offx** [input int, optional] Default: 0
- **beta** [input complex, optional] Default: (0.0, 0.0)
- **incy** [input int, optional] Default: 1
- **offy** [input int, optional] Default: 0
- **lower** [input int, optional] Default: 0
scipy.linalg.blas.chemv

```
scipy.linalg.blas.chemv(alpha, a, x[, beta, y, offx, incx, offy, incy, lower, overwrite_y]) = <fortran object>
```

Wrapper for chemv.

**Parameters**

- **alpha**: [input complex]
- **a**: [input rank-2 array('F') with bounds (n,n)]
- **x**: [input rank-1 array('F') with bounds (*)]

**Returns**

- **y**: [rank-1 array('F') with bounds (ly)]

**Other Parameters**

- **beta**: [input complex, optional] Default: (0.0, 0.0)
- **y**: [input rank-1 array('F') with bounds (ly)]
- **overwrite_y**: [input int, optional] Default: 0
- **offx**: [input int, optional] Default: 0
- **incx**: [input int, optional] Default: 1
- **offy**: [input int, optional] Default: 0
- **incy**: [input int, optional] Default: 1
- **lower**: [input int, optional] Default: 0

scipy.linalg.blas.cher

```
scipy.linalg.blas.cher(alpha, x[, lower, incx, offx, n, a, overwrite_a]) = <fortran object>
```

Wrapper for cher.

**Parameters**

- **alpha**: [input complex]
- **x**: [input rank-1 array('F') with bounds (*)]

**Returns**

- **a**: [rank-2 array('F') with bounds (n,n)]

**Other Parameters**

- **lower**: [input int, optional] Default: 0
- **incx**: [input int, optional] Default: 1
- **offx**: [input int, optional] Default: 0
- **n**: [input int, optional] Default: (len(x)-1-offx)/abs(incx)+1
- **a**: [input rank-2 array('F') with bounds (n,n)]
- **overwrite_a**: [input int, optional] Default: 0
**scipy.linalg.blas.cher2**

`scipy.linalg.blas.cher2(alpha, x, y[, lower, incx, offx, incy, offy, n, a, overwrite_a]) = <fortran object>`

Wrapper for `cher2`.

**Parameters**
- `alpha` [input complex]
- `x` [input rank-1 array('F') with bounds (*)]
- `y` [input rank-1 array('F') with bounds (*)]

**Returns**
- `a` [rank-2 array('F') with bounds (n,n)]

**Other Parameters**
- `lower` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
- `offx` [input int, optional] Default: 0
- `incy` [input int, optional] Default: 1
- `offy` [input int, optional] Default: 0
- `n` [input int, optional] Default: ((len(x)-1-offx)/abs(incx)+1 <=(len(y)-1-offy)/abs(incy)+1 ?(len(x)-1-offx)/abs(incx)+1 :len(y)-1-offy)/abs(incy)+1)
- `a` [input rank-2 array('F') with bounds (n,n)]
- `overwrite_a` [input int, optional] Default: 0

**scipy.linalg.blas.chpmv**

`scipy.linalg.blas.chpmv(n, alpha, ap, x[, incx, offx, beta, y, incy, offy, lower, overwrite_y]) = <fortran object>`

Wrapper for `chpmv`.

**Parameters**
- `n` [input int]
- `alpha` [input complex]
- `ap` [input rank-1 array('F') with bounds (*)]
- `x` [input rank-1 array('F') with bounds (*)]

**Returns**
- `yout` [rank-1 array('F') with bounds (ly) and y storage]

**Other Parameters**
- `incx` [input int, optional] Default: 1
- `offx` [input int, optional] Default: 0
- `beta` [input complex, optional] Default: (0.0, 0.0)
- `y` [input rank-1 array('F') with bounds (ly)]
- `overwrite_y` [input int, optional] Default: 0
- `incy` [input int, optional] Default: 1
- `offy` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
**scipy.linalg.blas.chpr**

**scipy.linalg.blas.chpr** \((n, \alpha, x, ap[, \text{incx}, \text{offx}, \text{lower}, \text{overwrite}_ap])\) = <fortran object>

Wrapper for chpr.

**Parameters**

- \(n\) [input int]
- \(\alpha\) [input float]
- \(x\) [input rank-1 array('F') with bounds (*)]
- \(ap\) [input rank-1 array('F') with bounds (*)]

**Returns**

- \(ap\) [rank-1 array('F') with bounds (*) and ap storage]

**Other Parameters**

- \(\text{incx}\) [input int, optional] Default: 1
- \(\text{offx}\) [input int, optional] Default: 0
- \(\text{overwrite}_ap\) [input int, optional] Default: 0
- \(\text{lower}\) [input int, optional] Default: 0

**scipy.linalg.blas.chpr2**

**scipy.linalg.blas.chpr2** \((n, \alpha, x, y, ap[, \text{incx}, \text{offx}, \text{incy}, \text{offy}, \text{lower}, \text{overwrite}_ap])\) = <fortran object>

Wrapper for chpr2.

**Parameters**

- \(n\) [input int]
- \(\alpha\) [input complex]
- \(x\) [input rank-1 array('F') with bounds (*)]
- \(y\) [input rank-1 array('F') with bounds (*)]
- \(ap\) [input rank-1 array('F') with bounds (*)]

**Returns**

- \(ap\) [rank-1 array('F') with bounds (*) and ap storage]

**Other Parameters**

- \(\text{incx}\) [input int, optional] Default: 1
- \(\text{offx}\) [input int, optional] Default: 0
- \(\text{incy}\) [input int, optional] Default: 1
- \(\text{offy}\) [input int, optional] Default: 0
- \(\text{overwrite}_ap\) [input int, optional] Default: 0
- \(\text{lower}\) [input int, optional] Default: 0
scipy.linalg.blas.ctbmv

scipy.linalg.blas.ctbmv(k, a, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>

Wrapper for ctbmv.

Parameters

k [input int]
a [input rank-2 array('F') with bounds (lda,n)]
x [input rank-1 array('F') with bounds (*)]

Returns

xout [rank-1 array('F') with bounds (*) and x storage]

Other Parameters

overwrite_x [input int, optional] Default: 0
incx [input int, optional] Default: 1
offx [input int, optional] Default: 0
lower [input int, optional] Default: 0
trans [input int, optional] Default: 0
diag [input int, optional] Default: 0

scipy.linalg.blas.ctbsv

scipy.linalg.blas.ctbsv(k, a, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>

Wrapper for ctbsv.

Parameters

k [input int]
a [input rank-2 array('F') with bounds (lda,n)]
x [input rank-1 array('F') with bounds (*)]

Returns

xout [rank-1 array('F') with bounds (*) and x storage]

Other Parameters

overwrite_x [input int, optional] Default: 0
incx [input int, optional] Default: 1
offx [input int, optional] Default: 0
lower [input int, optional] Default: 0
trans [input int, optional] Default: 0
diag [input int, optional] Default: 0
scipy.linalg.blas.ctpmv

**scipy.linalg.blas.ctpmv** *(n, ap, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>*

Wrapper for `ctpmv`.

**Parameters**
- `n` [input int]
- `ap` [input rank-1 array('F') with bounds (*)]
- `x` [input rank-1 array('F') with bounds (*)]

**Returns**
- `xout` [rank-1 array('F') with bounds (*) and x storage]

**Other Parameters**
- `overwrite_x` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
- `offx` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
- `trans` [input int, optional] Default: 0
- `diag` [input int, optional] Default: 0

scipy.linalg.blas.ctpsv

**scipy.linalg.blas.ctpsv** *(n, ap, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>*

Wrapper for `ctpsv`.

**Parameters**
- `n` [input int]
- `ap` [input rank-1 array('F') with bounds (*)]
- `x` [input rank-1 array('F') with bounds (*)]

**Returns**
- `xout` [rank-1 array('F') with bounds (*) and x storage]

**Other Parameters**
- `overwrite_x` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
- `offx` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
- `trans` [input int, optional] Default: 0
- `diag` [input int, optional] Default: 0
scipy.linalg.blas.ctrmv

\[ \text{scipy.linalg.blas.ctrmv}(a, x[, \text{offx}, \text{incx}, \text{lower}, \text{trans}, \text{diag}, \text{overwrite}_x]) = \text{<fortran object>} \]

Wrapper for ctrmv.

Parameters

- \( a \) [input rank-2 array('F') with bounds (n,n)]
- \( x \) [input rank-1 array('F') with bounds (*)]

Returns

- \( x \) [rank-1 array('F') with bounds (*)]

Other Parameters

- \( \text{overwrite}_x \) [input int, optional] Default: 0
- \( \text{offx} \) [input int, optional] Default: 0
- \( \text{incx} \) [input int, optional] Default: 1
- \( \text{lower} \) [input int, optional] Default: 0
- \( \text{trans} \) [input int, optional] Default: 0
- \( \text{diag} \) [input int, optional] Default: 0

scipy.linalg.blas.ctrs

\[ \text{scipy.linalg.blas.ctrsv}(a, x[, \text{incx}, \text{offx}, \text{lower}, \text{trans}, \text{diag}, \text{overwrite}_x]) = \text{<fortran object>} \]

Wrapper for ctrsv.

Parameters

- \( a \) [input rank-2 array('F') with bounds (n,n)]
- \( x \) [input rank-1 array('F') with bounds (*)]

Returns

- \( xout \) [rank-1 array('F') with bounds (*) and x storage]

Other Parameters

- \( \text{overwrite}_x \) [input int, optional] Default: 0
- \( \text{incx} \) [input int, optional] Default: 1
- \( \text{offx} \) [input int, optional] Default: 0
- \( \text{lower} \) [input int, optional] Default: 0
- \( \text{trans} \) [input int, optional] Default: 0
- \( \text{diag} \) [input int, optional] Default: 0

scipy.linalg.blas.csyr

\[ \text{scipy.linalg.blas.csyr}(\alpha, x[, \text{lower}, \text{incx}, \text{offx}, n, \text{overwrite}_a]) = \text{<fortran object>} \]

Wrapper for csyr.

Parameters

- \( \alpha \) [input complex]
- \( x \) [input rank-1 array('F') with bounds (*)]

Returns
a (rank-2 array('F') with bounds (n,n))

Other Parameters

lower [input int, optional] Default: 0
incx [input int, optional] Default: 1
offx [input int, optional] Default: 0
n [input int, optional] Default: (len(x)-1-offx)/abs(incx)+1
a [input rank-2 array('F') with bounds (n,n)]
overwrite_a [input int, optional] Default: 0

scipy.linalg.blas.zgbmv

scipy.linalg.blas.zgbmv (m, n, kl, ku, alpha, a, x, incx, offx, beta, y, incy, offy, trans, overwrite_y) = <fortran object>

Wrapper for zgbmv.

Parameters

m [input int]
n [input int]
kl [input int]
ku [input int]
alpha [input complex]
a [input rank-2 array('D') with bounds (lda,n)]
x [input rank-1 array('D') with bounds (*)]

Returns

yout [rank-1 array('D') with bounds (ly) and y storage]

Other Parameters

incx [input int, optional] Default: 1
offx [input int, optional] Default: 0
beta [input complex, optional] Default: (0.0, 0.0)
y [input rank-1 array('D') with bounds (ly)]
overwrite_y [input int, optional] Default: 0
incy [input int, optional] Default: 1
offy [input int, optional] Default: 0
trans [input int, optional] Default: 0

scipy.linalg.blas.zgemv

scipy.linalg.blas.zgemv (alpha, a, x, beta, y, offx, incx, offy, incy, trans, overwrite_y) = <fortran object>

Wrapper for zgemv.

Parameters

alpha [input complex]
a [input rank-2 array('D') with bounds (m,n)]
x [input rank-1 array('D') with bounds (*)]

Returns
**y** [rank-1 array('D') with bounds (ly)]

**Other Parameters**

**beta** [input complex, optional] Default: (0.0, 0.0)

**y** [input rank-1 array('D') with bounds (ly)]

**overwrite_y** [input int, optional] Default: 0

**offx** [input int, optional] Default: 0

**incx** [input int, optional] Default: 1

**offy** [input int, optional] Default: 0

**incy** [input int, optional] Default: 1

**trans** [input int, optional] Default: 0

### scipy.linalg.blas.zgerc

```python
scipy.linalg.blas.zgerc(alpha, x, y, incx, incy, a, overwrite_x, overwrite_y, overwrite_a) =
<fortran object>
```

**Wrapper for zgerc.**

**Parameters**

**alpha** [input complex]

**x** [input rank-1 array('D') with bounds (m)]

**y** [input rank-1 array('D') with bounds (n)]

**Returns**

**a** [rank-2 array('D') with bounds (m,n)]

**Other Parameters**

**overwrite_x** [input int, optional] Default: 1

**incx** [input int, optional] Default: 1

**overwrite_y** [input int, optional] Default: 1

**incy** [input int, optional] Default: 1

**a** [input rank-2 array('D') with bounds (m,n), optional] Default: (0,0,0,0)

**overwrite_a** [input int, optional] Default: 0

### scipy.linalg.blas.zgeru

```python
scipy.linalg.blas.zgeru(alpha, x, y, incx, incy, a, overwrite_x, overwrite_y, overwrite_a) =
<fortran object>
```

**Wrapper for zgeru.**

**Parameters**

**alpha** [input complex]

**x** [input rank-1 array('D') with bounds (m)]

**y** [input rank-1 array('D') with bounds (n)]

**Returns**

**a** [rank-2 array('D') with bounds (m,n)]

**Other Parameters**
overwrite_x
[input int, optional] Default: 1

incx
[input int, optional] Default: 1

overwrite_y
[input int, optional] Default: 1

incy
[input int, optional] Default: 1

a
[input rank-2 array('D') with bounds (m,n), optional] Default: (0.0,0.0)

overwrite_a
[input int, optional] Default: 0

scipy.linalg.blas.zhbmv

scipy.linalg.blas.zhbmv(k, alpha, a, x[, incx, offx, beta, y, incy, offy, lower, overwrite_y]) =
<fortran object>

Wrapper for zhbmv.

Parameters

k [input int]

alpha [input complex]

a [input rank-2 array('D') with bounds (lda,n)]

x [input rank-1 array('D') with bounds (*)]

Returns

yout [rank-1 array('D') with bounds (ly) and y storage]

Other Parameters

incx [input int, optional] Default: 1

offx [input int, optional] Default: 0

beta [input complex, optional] Default: (0.0, 0.0)

y [input rank-1 array('D') with bounds (ly)]

overwrite_y [input int, optional] Default: 0

incy [input int, optional] Default: 1

offy [input int, optional] Default: 0

lower [input int, optional] Default: 0

scipy.linalg.blas.zhemv

scipy.linalg.blas.zhemv(alpha, a, x[, beta, y, offx, incx, offy, incy, lower, overwrite_y]) =
<fortran object>

Wrapper for zhemv.

Parameters

alpha [input complex]

a [input rank-2 array('D') with bounds (n,n)]

x [input rank-1 array('D') with bounds (*)]

Returns

y [rank-1 array('D') with bounds (ly)]

Other Parameters

beta [input complex, optional] Default: (0.0, 0.0)
scipy.linalg.blas.zher

**scipy.linalg.blas.zher** \((alpha, x[, lower, incx, offx, n, a, overwrite_a])\) = <fortran object>

Wrapper for zher.

**Parameters**
- **alpha** [input complex]
- **x** [input rank-1 array('D') with bounds (*)]

**Returns**
- **a** [rank-2 array('D') with bounds (n,n)]

**Other Parameters**
- **lower** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1
- **offx** [input int, optional] Default: 0
- **n** [input int, optional] Default: \((\text{len}(x)-1-\text{offx})/\text{abs}(\text{incx})+1\)
- **a** [input rank-2 array('D') with bounds (n,n)]
- **overwrite_a** [input int, optional] Default: 0

scipy.linalg.blas.zher2

**scipy.linalg.blas.zher2** \((alpha, x, y[, lower, incx, offx, incy, offy, n, a, overwrite_a])\) = <fortran object>

Wrapper for zher2.

**Parameters**
- **alpha** [input complex]
- **x** [input rank-1 array('D') with bounds (*)]
- **y** [input rank-1 array('D') with bounds (*)]

**Returns**
- **a** [rank-2 array('D') with bounds (n,n)]

**Other Parameters**
- **lower** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1
- **offx** [input int, optional] Default: 0
- **incy** [input int, optional] Default: 1
- **offy** [input int, optional] Default: 0
- **n** [input int, optional] Default: \(((\text{len}(x)-1-\text{offx})/\text{abs}(\text{incx})+1 \leq (\text{len}(y)-1-\text{offy})/\text{abs}(\text{incy})+1)\)

```
a                      [input rank-2 array('D') with bounds (n,n)]
overwrite_a
                      [input int, optional] Default: 0

scipy.linalg.blas.zhpmv

scipy.linalg.blas.zhpmv(n, alpha, ap, x[, incx, offx, beta, y, incy, offy, lower, overwrite_y]) = <fortran object>
Wrapper for zhpmv.

Parameters

  n              [input int]
  alpha          [input complex]
  ap             [input rank-1 array('D') with bounds (*)]
  x              [input rank-1 array('D') with bounds (*)]

Returns

  yout           [rank-1 array('D') with bounds (ly) and y storage]

Other Parameters

  incx           [input int, optional] Default: 1
  offx           [input int, optional] Default: 0
  beta           [input complex, optional] Default: (0.0, 0.0)
  y              [input rank-1 array('D') with bounds (ly)]
  overwrite_y
                      [input int, optional] Default: 0
  incy           [input int, optional] Default: 1
  offy           [input int, optional] Default: 0
  lower          [input int, optional] Default: 0

scipy.linalg.blas.zhpr

scipy.linalg.blas.zhpr(n, alpha, x, ap[, incx, offx, lower, overwrite_ap]) = <fortran object>
Wrapper for zhpr.

Parameters

  n              [input int]
  alpha          [input float]
  x              [input rank-1 array('D') with bounds (*)]
  ap             [input rank-1 array('D') with bounds (*)]

Returns

  apu            [rank-1 array('D') with bounds (*) and ap storage]

Other Parameters

  incx           [input int, optional] Default: 1
  offx           [input int, optional] Default: 0
  overwrite_ap   [input int, optional] Default: 0
  lower          [input int, optional] Default: 0

6.11. Low-level BLAS functions (scipy.linalg.blas) 1143
scipy.linalg.blas.zhpr2

scipy.linalg.blas.zhpr2(n, alpha, x, y, ap[, incx, offx, incy, offy, lower, overwrite_ap]) = <fortran object>
Wrapper for zhpr2.

Parameters
- n [input int]
- alpha [input complex]
- x [input rank-1 array('D') with bounds (*)]
- y [input rank-1 array('D') with bounds (*)]
- ap [input rank-1 array('D') with bounds (*)]

Returns
- apu [rank-1 array('D') with bounds (*) and ap storage]

Other Parameters
- incx [input int, optional] Default: 1
- offx [input int, optional] Default: 0
- incy [input int, optional] Default: 1
- offy [input int, optional] Default: 0
- overwrite_ap [input int, optional] Default: 0
- lower [input int, optional] Default: 0

scipy.linalg.blas.ztbmv

scipy.linalg.blas.ztbmv(k, a[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>
Wrapper for ztbmv.

Parameters
- k [input int]
- a [input rank-2 array('D') with bounds (lda,n)]
- x [input rank-1 array('D') with bounds (*)]

Returns
- xout [rank-1 array('D') with bounds (*) and x storage]

Other Parameters
- overwrite_x [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offx [input int, optional] Default: 0
- lower [input int, optional] Default: 0
- trans [input int, optional] Default: 0
- diag [input int, optional] Default: 0

1144 Chapter 6. API Reference
**scipy.linalg.blas.ztbsv**

```python
scipy.linalg.blas.ztbsv(k, a, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>
```

Wrapper for ztbsv.

**Parameters**

- **k** [input int]
- **a** [input rank-2 array('D') with bounds (lda,n)]
- **x** [input rank-1 array('D') with bounds (*)]

**Returns**

- **xout** [rank-1 array('D') with bounds (*) and x storage]

**Other Parameters**

- **overwrite_x** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1
- **offx** [input int, optional] Default: 0
- **lower** [input int, optional] Default: 0
- **trans** [input int, optional] Default: 0
- **diag** [input int, optional] Default: 0

---

**scipy.linalg.blas.ztpmv**

```python
scipy.linalg.blas.ztpmv(n, ap, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>
```

Wrapper for ztpmv.

**Parameters**

- **n** [input int]
- **ap** [input rank-1 array('D') with bounds (*)]
- **x** [input rank-1 array('D') with bounds (*)]

**Returns**

- **xout** [rank-1 array('D') with bounds (*) and x storage]

**Other Parameters**

- **overwrite_x** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1
- **offx** [input int, optional] Default: 0
- **lower** [input int, optional] Default: 0
- **trans** [input int, optional] Default: 0
- **diag** [input int, optional] Default: 0
scipy.linalg.blas.ztrmv

scipy.linalg.blas.ztrmv(a, x[, offx, incx, lower, trans, diag, overwrite_x]) = <fortran object>
Wrapper for ztrmv.

Parameters

a    [input rank-2 array('D') with bounds (n,n)]
x    [input rank-1 array('D') with bounds (*)]

Returns

x    [rank-1 array('D') with bounds (*)]

Other Parameters

overwrite_x
    [input int, optional] Default: 0
offx    [input int, optional] Default: 0
incx    [input int, optional] Default: 1
lower    [input int, optional] Default: 0
trans    [input int, optional] Default: 0
diag    [input int, optional] Default: 0

scipy.linalg.blas.ztrsv

scipy.linalg.blas.ztrsv(a, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>
Wrapper for ztrsv.

Parameters

a    [input rank-2 array('D') with bounds (n,n)]
x    [input rank-1 array('D') with bounds (*)]

Returns

xout    [rank-1 array('D') with bounds (*) and x storage]

Other Parameters

overwrite_x
    [input int, optional] Default: 0
incx    [input int, optional] Default: 1
offx    [input int, optional] Default: 0
lower    [input int, optional] Default: 0
trans    [input int, optional] Default: 0
diag    [input int, optional] Default: 0

scipy.linalg.blas.zsyr

scipy.linalg.blas.zsyr(alpha, x[, lower, incx, offx, n, a, overwrite_a]) = <fortran object>
Wrapper for zsyr.

Parameters

alpha    [input complex]
x    [input rank-1 array('D') with bounds (*)]

Returns

a [rank-2 array('D') with bounds (n,n)]

Other Parameters
lower [input int, optional] Default: 0
incx [input int, optional] Default: 1
offx [input int, optional] Default: 0
n [input int, optional] Default: (len(x)-1-offx)/abs(incx)+1
a [input rank-2 array('D') with bounds (n,n)]
overwrite_a [input int, optional] Default: 0

</table>
**scipy.linalg.blas.sgemm**

`scipy.linalg.blas.sgemm(alpha, a, b[, beta, c, trans_a, trans_b, overwrite_c]) = <fortran object>`

Wrapper for *[®gemm]*.

**Parameters**

- **alpha**: [input float]
- **a**: [input rank-2 array('f') with bounds (lda,ka)]
- **b**: [input rank-2 array('f') with bounds (ldb,kb)]

**Returns**

- **c**: [rank-2 array('f') with bounds (m,n)]

**Other Parameters**

- **beta**: [input float, optional] Default: 0.0
- **c**: [input rank-2 array('f') with bounds (m,n)]
- **overwrite_c**: [input int, optional] Default: 0
- **trans_a**: [input int, optional] Default: 0
- **trans_b**: [input int, optional] Default: 0

**scipy.linalg.blas.ssymm**

`scipy.linalg.blas.ssymm(alpha, a, b[, beta, c, side, lower, overwrite_c]) = <fortran object>`

Wrapper for *[®symm]*.

**Parameters**

- **alpha**: [input float]
- **a**: [input rank-2 array('f') with bounds (lda,ka)]
- **b**: [input rank-2 array('f') with bounds (ldb,kb)]

**Returns**

- **c**: [rank-2 array('f') with bounds (m,n)]

**Other Parameters**

- **beta**: [input float, optional] Default: 0.0
- **c**: [input rank-2 array('f') with bounds (m,n)]
- **overwrite_c**: [input int, optional] Default: 0
- **side**: [input int, optional] Default: 0
- **lower**: [input int, optional] Default: 0
scipy.linalg.blas.syr2k

`scipy.linalg.blas.syr2k(alpha, a, beta, b, trans, lower, overwrite_c) = <fortran object>`

Wrapper for `syr2k`.

**Parameters**

- **alpha**: [input float]
- **a**: [input rank-2 array('f') with bounds (lda,ka)]
- **b**: [input rank-2 array('f') with bounds (ldb,kb)]

**Returns**

- **c**: [rank-2 array('f') with bounds (n,n)]

**Other Parameters**

- **beta**: [input float, optional] Default: 0.0
- **c**: [input rank-2 array('f') with bounds (n,n)]
- **overwrite_c**: [input int, optional] Default: 0
- **trans**: [input int, optional] Default: 0
- **lower**: [input int, optional] Default: 0

scipy.linalg.blas.syrk

`scipy.linalg.blas.syrk(alpha, a, beta, c, trans, lower, overwrite_c) = <fortran object>`

Wrapper for `syrk`.

**Parameters**

- **alpha**: [input float]
- **a**: [input rank-2 array('f') with bounds (lda,ka)]

**Returns**

- **c**: [rank-2 array('f') with bounds (n,n)]

**Other Parameters**

- **beta**: [input float, optional] Default: 0.0
- **c**: [input rank-2 array('f') with bounds (n,n)]
- **overwrite_c**: [input int, optional] Default: 0
- **trans**: [input int, optional] Default: 0
- **lower**: [input int, optional] Default: 0

scipy.linalg.blas.strmm

`scipy.linalg.blas.strmm(alpha, a, b, side, lower, trans_a, diag, overwrite_b) = <fortran object>`

Wrapper for `strmm`.

**Parameters**

- **alpha**: [input float]
- **a**: [input rank-2 array('f') with bounds (lda,k)]
- **b**: [input rank-2 array('f') with bounds (ldb,n)]

6.11. Low-level BLAS functions (scipy.linalg.blas)
**Returns**

- \( b \) [rank-2 array(‘f’) with bounds (ldb,n)]

**Other Parameters**

- `overwrite_b` [input int, optional] Default: 0
- `side` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
- `trans_a` [input int, optional] Default: 0
- `diag` [input int, optional] Default: 0

**scipy.linalg.blas.strsm**

```python
scipy.linalg.blas.strsm(alpha, a, b[, side, lower, trans_a, diag, overwrite_b]) = <fortran object>
```

Wrapper for `strsm`.

**Parameters**

- `alpha` [input float]
- `a` [input rank-2 array(‘f’) with bounds (lda,*)]
- `b` [input rank-2 array(‘f’) with bounds (ldb,n)]

**Returns**

- \( x \) [rank-2 array(‘f’) with bounds (ldb,n) and b storage]

**Other Parameters**

- `overwrite_b` [input int, optional] Default: 0
- `side` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
- `trans_a` [input int, optional] Default: 0
- `diag` [input int, optional] Default: 0

**scipy.linalg.blas.dgemm**

```python
scipy.linalg.blas.dgemm(alpha, a, b[, beta, c, trans_a, trans_b, overwrite_c]) = <fortran object>
```

Wrapper for `dgemm`.

**Parameters**

- `alpha` [input float]
- `a` [input rank-2 array(‘d’) with bounds (lda,ka)]
- `b` [input rank-2 array(‘d’) with bounds (ldb,kb)]

**Returns**

- \( c \) [rank-2 array(‘d’) with bounds (m,n)]

**Other Parameters**

- `beta` [input float, optional] Default: 0.0
- `c` [input rank-2 array(‘d’) with bounds (m,n)]
- `overwrite_c` [input int, optional] Default: 0
trans_a  [input int, optional] Default: 0
trans_b  [input int, optional] Default: 0

scipy.linalg.blas.dsymm

scipy.linalg.blas.dsymm (alpha, a, b[, beta, c, side, lower, overwrite_c]) = <fortran object>
Wrapper for dsymm.

Parameters

alpha    [input float]
a         [input rank-2 array('d') with bounds (lda,ka)]
b         [input rank-2 array('d') with bounds (ldb,kb)]

Returns

c         [rank-2 array('d') with bounds (m,n)]

Other Parameters

beta    [input float, optional] Default: 0.0
c         [input rank-2 array('d') with bounds (m,n)]
overwrite_c    [input int, optional] Default: 0
side    [input int, optional] Default: 0
lower    [input int, optional] Default: 0

scipy.linalg.blas dsyr2k

scipy.linalg.blas.dsyrk (alpha, a, b[, beta, c, trans, lower, overwrite_c]) = <fortran object>
Wrapper for dsyr2k.

Parameters

alpha    [input float]
a         [input rank-2 array('d') with bounds (lda,ka)]
b         [input rank-2 array('d') with bounds (ldb,kb)]

Returns

c         [rank-2 array('d') with bounds (n,n)]

Other Parameters

beta    [input float, optional] Default: 0.0
c         [input rank-2 array('d') with bounds (n,n)]
overwrite_c    [input int, optional] Default: 0
trans    [input int, optional] Default: 0
lower    [input int, optional] Default: 0
**scipy.linalg.blas.dsysr**

**scipy.linalg.blas.dsysr** (alpha, a[, beta, c, trans, lower, overwrite_c]) = <fortran object>

Wrapper for dsysrk.

**Parameters**

- alpha [input float]
- a [input rank-2 array('d') with bounds (lda,ka)]

**Returns**

- c [rank-2 array('d') with bounds (n,n)]

**Other Parameters**

- beta [input float, optional] Default: 0.0
- c [input rank-2 array('d') with bounds (n,n)]
- overwrite_c [input int, optional] Default: 0
- trans [input int, optional] Default: 0
- lower [input int, optional] Default: 0

**scipy.linalg.blas.dtrmm**

**scipy.linalg.blas.dtrmm** (alpha, a, b[, side, lower, trans_a, diag, overwrite_b]) = <fortran object>

Wrapper for dtrmm.

**Parameters**

- alpha [input float]
- a [input rank-2 array('d') with bounds (lda,k)]
- b [input rank-2 array('d') with bounds (ldb,n)]

**Returns**

- b [rank-2 array('d') with bounds (ldb,n)]

**Other Parameters**

- overwrite_b [input int, optional] Default: 0
- side [input int, optional] Default: 0
- lower [input int, optional] Default: 0
- trans_a [input int, optional] Default: 0
- diag [input int, optional] Default: 0

**scipy.linalg.blas.dtrsm**

**scipy.linalg.blas.dtrsm** (alpha, a, b[, side, lower, trans_a, diag, overwrite_b]) = <fortran object>

Wrapper for dtrsm.

**Parameters**

- alpha [input float]
- a [input rank-2 array('d') with bounds (lda,* )]
- b [input rank-2 array('d') with bounds (ldb,n) ]
Returns

\[ x \] [rank-2 array('d') with bounds (ldb,n) and b storage]

Other Parameters

overwrite_b

[ input int, optional] Default: 0
side

[ input int, optional] Default: 0
lower

[ input int, optional] Default: 0
trans_a

[ input int, optional] Default: 0
diag

[ input int, optional] Default: 0

\textbf{scipy.linalg.blas.cgemm}

\textbf{scipy.linalg.blas.cgemm} (alpha, a, \textbf{b}, beta, trans_a, trans_b, overwrite_c \textbf{)} = <fortran object>

Wrapper for \texttt{cgemm}.

Parameters

\textbf{alpha} [input complex]
a

[ input rank-2 array('F') with bounds (lda,ka)]
b

[ input rank-2 array('F') with bounds (ldb,kb)]

Returns

c [rank-2 array('F') with bounds (m,n)]

Other Parameters

\textbf{beta} [input complex, optional] Default: (0.0, 0.0)
c

[ input rank-2 array('F') with bounds (m,n)]
overwrite_c

[ input int, optional] Default: 0
trans_a

[ input int, optional] Default: 0
trans_b

[ input int, optional] Default: 0

\textbf{scipy.linalg.blas.chemm}

\textbf{scipy.linalg.blas.chemm} (alpha, a, \textbf{b}, beta, \textbf{c}, side, lower, overwrite_c \textbf{)} = <fortran object>

Wrapper for \texttt{chemm}.

Parameters

\textbf{alpha} [input complex]
a

[ input rank-2 array('F') with bounds (lda,ka)]
b

[ input rank-2 array('F') with bounds (ldb,kb)]

Returns

c [rank-2 array('F') with bounds (m,n)]

Other Parameters

\textbf{beta} [input complex, optional] Default: (0.0, 0.0)
c

[ input rank-2 array('F') with bounds (m,n)]
overwrite_c

[ input int, optional] Default: 0
side

[ input int, optional] Default: 0

lower [input int, optional] Default: 0

scipy.linalg.blas.cher2k

scipy.linalg.blas.cher2k(alpha, a, b[, beta, c, trans, lower, overwrite_c]) = <fortran object>
Wrapper for cher2k.

Parameters

alpha [input complex]
a [input rank-2 array('F') with bounds (lda,ka)]
b [input rank-2 array('F') with bounds (ldb,kb)]

Returns
c [rank-2 array('F') with bounds (n,n)]

Other Parameters

beta [input complex, optional] Default: (0.0, 0.0)
c [input rank-2 array('F') with bounds (n,n)]
overwrite_c [input int, optional] Default: 0
trans [input int, optional] Default: 0
lower [input int, optional] Default: 0

scipy.linalg.blas.cherk

scipy.linalg.blas.cherk(alpha, a[, beta, c, trans, lower, overwrite_c]) = <fortran object>
Wrapper for cherk.

Parameters

alpha [input complex]
a [input rank-2 array('F') with bounds (lda,ka)]

Returns
c [rank-2 array('F') with bounds (n,n)]

Other Parameters

beta [input complex, optional] Default: (0.0, 0.0)
c [input rank-2 array('F') with bounds (n,n)]
overwrite_c [input int, optional] Default: 0
trans [input int, optional] Default: 0
lower [input int, optional] Default: 0
scipy.linalg.blas.csymm

`scipy.linalg.blas.csymm(alpha, a, b[, beta, c, side, lower, overwrite_c]) = <fortran object>`

Wrapper for `csymm`.

**Parameters**

- `alpha` [input complex]
- `a` [input rank-2 array('F') with bounds (lda,ka)]
- `b` [input rank-2 array('F') with bounds (ldb,kb)]

**Returns**

- `c` [rank-2 array('F') with bounds (m,n)]

**Other Parameters**

- `beta` [input complex, optional] Default: (0.0, 0.0)
- `c` [input rank-2 array('F') with bounds (m,n)]
- `overwrite_c` [input int, optional] Default: 0
- `side` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0

scipy.linalg.blas.csyr2k

`scipy.linalg.blas.csyr2k(alpha, a, b[, beta, c, trans, lower, overwrite_c]) = <fortran object>`

Wrapper for `csyr2k`.

**Parameters**

- `alpha` [input complex]
- `a` [input rank-2 array('F') with bounds (lda,ka)]
- `b` [input rank-2 array('F') with bounds (ldb,kb)]

**Returns**

- `c` [rank-2 array('F') with bounds (n,n)]

**Other Parameters**

- `beta` [input complex, optional] Default: (0.0, 0.0)
- `c` [input rank-2 array('F') with bounds (n,n)]
- `overwrite_c` [input int, optional] Default: 0
- `trans` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0

scipy.linalg.blas.csyrk

`scipy.linalg.blas.csyrk(alpha, a[, beta, c, trans, lower, overwrite_c]) = <fortran object>`

Wrapper for `csyrk`.

**Parameters**

- `alpha` [input complex]
- `a` [input rank-2 array('F') with bounds (lda,ka)]

**Returns**
c | [rank-2 array('F') with bounds (n,n)]

Other Parameters

beta | [input complex, optional] Default: (0.0, 0.0)
c | [input rank-2 array('F') with bounds (n,n)]
overwrite_c | [input int, optional] Default: 0
trans | [input int, optional] Default: 0
lower | [input int, optional] Default: 0

**scipy.linalg.blas.ctrm**

scipy.linalg.blas.ctrm \((alpha, a, b[, side, lower, trans_a, diag, overwrite_b])\) = <fortran object>

Wrapper for ctrmm.

Parameters

alpha | [input complex]
a | [input rank-2 array('F') with bounds (lda,k)]
b | [input rank-2 array('F') with bounds (ldb,n)]

Returns

b | [rank-2 array('F') with bounds (ldb,n)]

Other Parameters

overwrite_b | [input int, optional] Default: 0
side | [input int, optional] Default: 0
lower | [input int, optional] Default: 0
trans_a | [input int, optional] Default: 0
diag | [input int, optional] Default: 0

**scipy.linalg.blas.ctrm**

scipy.linalg.blas.ctrm \((alpha, a, b[, side, lower, trans_a, diag, overwrite_b])\) = <fortran object>

Wrapper for ctrsm.

Parameters

alpha | [input complex]
a | [input rank-2 array('F') with bounds (lda,*)]
b | [input rank-2 array('F') with bounds (ldb,n)]

Returns

x | [rank-2 array('F') with bounds (ldb,n) and b storage]

Other Parameters

overwrite_b | [input int, optional] Default: 0
side | [input int, optional] Default: 0
lower | [input int, optional] Default: 0
trans_a | [input int, optional] Default: 0
diag [input int, optional] Default: 0

**scipy.linalg.blas.zgemm**

scipy.linalg.blas.zgemm (alpha, a[, beta, c, trans_a, trans_b, overwrite_c]) = <fortran object>

Wrapper for zgemm.

**Parameters**

alpha [input complex]
a [input rank-2 array('D') with bounds (lda,ka)]
b [input rank-2 array('D') with bounds (ldb,kb)]

**Returns**

c [rank-2 array('D') with bounds (m,n)]

**Other Parameters**

beta [input complex, optional] Default: (0.0, 0.0)
c [input rank-2 array('D') with bounds (m,n)]
overwrite_c [input int, optional] Default: 0
trans_a [input int, optional] Default: 0
trans_b [input int, optional] Default: 0

**scipy.linalg.blas.zhemm**

scipy.linalg.blas.zhemm (alpha, a, b[, beta, c, side, lower, overwrite_c]) = <fortran object>

Wrapper for zhemm.

**Parameters**

alpha [input complex]
a [input rank-2 array('D') with bounds (lda,ka)]
b [input rank-2 array('D') with bounds (ldb,kb)]

**Returns**

c [rank-2 array('D') with bounds (m,n)]

**Other Parameters**

beta [input complex, optional] Default: (0.0, 0.0)
c [input rank-2 array('D') with bounds (m,n)]
overwrite_c [input int, optional] Default: 0
side [input int, optional] Default: 0
lower [input int, optional] Default: 0
scipy.linalg.blas.zher2k

\[ \text{scipy.linalg.blas.zher2k}(\alpha, a, b[, \beta, c, \text{trans}, \text{lower}, \text{overwrite}_c]) = \text{<fortran object>} \]

Wrapper for zher2k.

**Parameters**

- \( \alpha \) [input complex]
- \( a \) [input rank-2 array(\‘D\’) with bounds (lda,ka)]
- \( b \) [input rank-2 array(\‘D\’) with bounds (ldb,kb)]

**Returns**

- \( c \) [rank-2 array(\‘D\’) with bounds (n,n)]

**Other Parameters**

- \( \beta \) [input complex, optional] Default: (0.0, 0.0)
- \( c \) [input rank-2 array(\‘D\’) with bounds (n,n)]
- \( \text{overwrite}_c \) [input int, optional] Default: 0
- \( \text{trans} \) [input int, optional] Default: 0
- \( \text{lower} \) [input int, optional] Default: 0

scipy.linalg.blas.zherk

\[ \text{scipy.linalg.blas.zherk}(\alpha, a[, \beta, c, \text{trans}, \text{lower}, \text{overwrite}_c]) = \text{<fortran object>} \]

Wrapper for zherk.

**Parameters**

- \( \alpha \) [input complex]
- \( a \) [input rank-2 array(\‘D\’) with bounds (lda,ka)]

**Returns**

- \( c \) [rank-2 array(\‘D\’) with bounds (n,n)]

**Other Parameters**

- \( \beta \) [input complex, optional] Default: (0.0, 0.0)
- \( c \) [input rank-2 array(\‘D\’) with bounds (n,n)]
- \( \text{overwrite}_c \) [input int, optional] Default: 0
- \( \text{trans} \) [input int, optional] Default: 0
- \( \text{lower} \) [input int, optional] Default: 0

scipy.linalg.blas.zsymm

\[ \text{scipy.linalg.blas.zsymm}(\alpha, a, b[, \beta, c, \text{side}, \text{lower}, \text{overwrite}_c]) = \text{<fortran object>} \]

Wrapper for zsymm.

**Parameters**

- \( \alpha \) [input complex]
- \( a \) [input rank-2 array(\‘D\’) with bounds (lda,ka)]
- \( b \) [input rank-2 array(\‘D\’) with bounds (ldb,kb)]

**Returns**

6.11. Low-level BLAS functions (scipy.linalg.blas) 1159

\[ c \text{ [rank-2 array(}\text{D}\text{) with bounds (m,n)]} \]

**Other Parameters**

- **beta** [input complex, optional] Default: (0.0, 0.0)
- **c** [input rank-2 array(\text{D}) with bounds (m,n)]
- **overwrite_c** [input int, optional] Default: 0
- **side** [input int, optional] Default: 0
- **lower** [input int, optional] Default: 0

**scipy.linalg.blas.zsyr2k**

\[
\text{scipy.linalg.blas.zsyr2k} (\alpha, \beta, a, c, trans, lower, overwrite_c) = \text{<fortran object>}
\]

**Wrapper for zsyr2k.**

**Parameters**

- **alpha** [input complex]
- **a** [input rank-2 array(\text{D}) with bounds (lda,ka)]
- **b** [input rank-2 array(\text{D}) with bounds (ldb,kb)]

**Returns**

- **c** [rank-2 array(\text{D}) with bounds (n,n)]

**Other Parameters**

- **beta** [input complex, optional] Default: (0.0, 0.0)
- **c** [input rank-2 array(\text{D}) with bounds (n,n)]
- **overwrite_c** [input int, optional] Default: 0
- **trans** [input int, optional] Default: 0
- **lower** [input int, optional] Default: 0

**scipy.linalg.blas.zsyrk**

\[
\text{scipy.linalg.blas.zsyrk} (\alpha, a, c, trans, lower, overwrite_c) = \text{<fortran object>}
\]

**Wrapper for zsyrk.**

**Parameters**

- **alpha** [input complex]
- **a** [input rank-2 array(\text{D}) with bounds (lda,ka)]

**Returns**

- **c** [rank-2 array(\text{D}) with bounds (n,n)]

**Other Parameters**

- **beta** [input complex, optional] Default: (0.0, 0.0)
- **c** [input rank-2 array(\text{D}) with bounds (n,n)]
- **overwrite_c** [input int, optional] Default: 0
- **trans** [input int, optional] Default: 0
- **lower** [input int, optional] Default: 0
**scipy.linalg.blas.ztrmm**

```python
scipy.linalg.blas.ztrmm(alpha, a, b[, side, lower, trans_a, diag, overwrite_b]) = <fortran object>
```

Wrapper for `ztrmm`.

**Parameters**

- `alpha` [input complex]
- `a` [input rank-2 array('D') with bounds (lda,k)]
- `b` [input rank-2 array('D') with bounds (ldb,n)]

**Returns**

- `b` [rank-2 array('D') with bounds (ldb,n)]

**Other Parameters**

- `overwrite_b` [input int, optional] Default: 0
- `side` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
- `trans_a` [input int, optional] Default: 0
- `diag` [input int, optional] Default: 0

**scipy.linalg.blas.ztrsm**

```python
scipy.linalg.blas.ztrsm(alpha, a, b[, side, lower, trans_a, diag, overwrite_b]) = <fortran object>
```

Wrapper for `ztrsm`.

**Parameters**

- `alpha` [input complex]
- `a` [input rank-2 array('D') with bounds (lda,*)]
- `b` [input rank-2 array('D') with bounds (ldb,n)]

**Returns**

- `x` [rank-2 array('D') with bounds (ldb,n) and b storage]

**Other Parameters**

- `overwrite_b` [input int, optional] Default: 0
- `side` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
- `trans_a` [input int, optional] Default: 0
- `diag` [input int, optional] Default: 0
6.12 Low-level LAPACK functions (scipy.linalg.lapack)

This module contains low-level functions from the LAPACK library.

The \texttt{*gegv} family of routines have been removed from LAPACK 3.6.0 and have been deprecated in SciPy 0.17.0. They will be removed in a future release.

New in version 0.12.0.

\begin{quote}
\textbf{Note:} The common \texttt{overwrite_<>} option in many routines, allows the input arrays to be overwritten to avoid extra memory allocation. However this requires the array to satisfy two conditions which are memory order and the data type to match exactly the order and the type expected by the routine.

As an example, if you pass a double precision float array to any \texttt{S....} routine which expects single precision arguments, \texttt{f2py} will create an intermediate array to match the argument types and overwriting will be performed on that intermediate array.

Similarly, if a C-contiguous array is passed, \texttt{f2py} will pass a FORTRAN-contiguous array internally. Please make sure that these details are satisfied. More information can be found in the \texttt{f2py} documentation.
\end{quote}

\begin{quote}
\textbf{Warning:} These functions do little to no error checking. It is possible to cause crashes by mis-using them, so prefer using the higher-level routines in \texttt{scipy.linalg}.
\end{quote}

6.12.1 Finding functions

\texttt{get_lapack_funcs(names[, arrays, dtype, ilp64])} Return available LAPACK function objects from names.

\texttt{scipy.linalg.lapack.get_lapack_funcs(names[, arrays, dtype, ilp64])} Return available LAPACK function objects from names.

Arrays are used to determine the optimal prefix of LAPACK routines.

\begin{description}
\item \texttt{names} [str or sequence of str] Name(s) of LAPACK functions without type prefix.
\item \texttt{arrays} [sequence of ndarrays, optional] Arrays can be given to determine optimal prefix of LAPACK routines. If not given, double-precision routines will be used, otherwise the most generic type in arrays will be used.
\item \texttt{dtype} [str or dtype, optional] Data-type specifier. Not used if \texttt{arrays} is non-empty.
\item \texttt{ilp64} [‘True, False, ‘preferred’], optional] Whether to return ILP64 routine variant. Choosing ‘preferred’ returns ILP64 routine if available, and otherwise the 32-bit routine. Default: False
\end{description}

\begin{description}
\item \texttt{funcs} [list] List containing the found function(s).
\end{description}
Notes

This routine automatically chooses between Fortran/C interfaces. Fortran code is used whenever possible for arrays with column major order. In all other cases, C code is preferred.

In LAPACK, the naming convention is that all functions start with a type prefix, which depends on the type of the principal matrix. These can be one of {'s', 'd', 'c', 'z'} for the NumPy types {float32, float64, complex64, complex128} respectively, and are stored in attribute `typecode` of the returned functions.

Examples

Suppose we would like to use ‘?lange’ routine which computes the selected norm of an array. We pass our array in order to get the correct ‘lange’ flavor.

```python
>>> import scipy.linalg as LA
>>> a = np.random.rand(3,2)
>>> x_lange = LA.get_lapack_funcs('lange', (a,))
>>> x_lange.typecode
'd'
>>> x_lange = LA.get_lapack_funcs('lange', (a*1j,))
>>> x_lange.typecode
'z'
```

Several LAPACK routines work best when its internal WORK array has the optimal size (big enough for fast computation and small enough to avoid waste of memory). This size is determined also by a dedicated query to the function which is often wrapped as a standalone function and commonly denoted as `##_lwork`. Below is an example for `?sysv`.

```python
>>> import scipy.linalg as LA
>>> a = np.random.rand(1000,1000)
>>> b = np.random.rand(1000,1)*1j
>>> # We pick up zsylv and zsylv_lwork due to b array
... xsylv, xlwork = LA.get_lapack_funcs(('sysv', 'sysv_lwork'), (a, b))
>>> opt_lwork, _ = xlwork(a.shape[0])  # returns a complex for 'z' prefix
>>> udut, ipiv, x, info = xsylv(a, b, lwork=int(opt_lwork.real))
```

6.12.2 All functions

- `sgbsv(kl,ku,ab,[overwrite_ab,overwrite_b])`  Wrapper for `sgbsv`
- `dgbsv(kl,ku,ab,[overwrite_ab,overwrite_b])`  Wrapper for `dgbsv`
- `cgbsv(kl,ku,ab,[overwrite_ab,overwrite_b])`  Wrapper for `cgbsv`
- `zgbsv(kl,ku,ab,[overwrite_ab,overwrite_b])`  Wrapper for `zgbsv`
- `sgbtrf(ab,kl,ku,[m,n,ldab,overwrite_ab])`  Wrapper for `sgbtrf`
- `dgbtrf(ab,kl,ku,[m,n,ldab,overwrite_ab])`  Wrapper for `dgbtrf`
- `cgbtrf(ab,kl,ku,[m,n,ldab,overwrite_ab])`  Wrapper for `cgbtrf`
- `zgbtrf(ab,kl,ku,[m,n,ldab,overwrite_ab])`  Wrapper for `zgbtrf`
- `sgbtrs(...)`  Wrapper for `sgbtrs`
- `dgbtrs(...)`  Wrapper for `dgbtrs`
- `cgbtrs(...)`  Wrapper for `cgbtrs`
- `zgbtrs(...)`  Wrapper for `zgbtrs`

**scipy.linalg.lapack.sgsbv**

scipy.linalg.lapack.sgsbv(kl, ku, ab[, overwrite_ab, overwrite_b]) = <fortran object>
Wrapper for sgsbv.

**Parameters**

- **kl** [input int]
- **ku** [input int]
- **ab** [input rank-2 array('f') with bounds (2*kl+ku+1,n)]
- **b** [input rank-2 array('f') with bounds (n,nrhs)]

**Returns**

- **lub** [rank-2 array('f') with bounds (2*kl+ku+1,n) and ab storage]
- **piv** [rank-1 array('i') with bounds (n)]
- **x** [rank-2 array('f') with bounds (n,nrhs) and b storage]
- **info** [int]

**Other Parameters**

- **overwrite_ab** [input int, optional] Default: 0
- **overwrite_b** [input int, optional] Default: 0

**scipy.linalg.lapack.dgsbv**

scipy.linalg.lapack.dgsbv(kl, ku, ab[, overwrite_ab, overwrite_b]) = <fortran object>
Wrapper for dgsbv.

**Parameters**

- **kl** [input int]
- **ku** [input int]
- **ab** [input rank-2 array('d') with bounds (2*kl+ku+1,n)]
- **b** [input rank-2 array('d') with bounds (n,nrhs)]
Returns

- `lub` [rank-2 array('d') with bounds (2*kl+ku+1,n) and ab storage]
- `piv` [rank-1 array('i') with bounds (n)]
- `x` [rank-2 array('d') with bounds (n,nrhs) and b storage]
- `info` [int]

Other Parameters

- `overwrite_ab` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0

scipy.linalg.lapack.cgbsv

scipy.linalg.lapack.cgbsv(\(kl, ku, ab[, overwrite_ab, overwrite_b]\)) = <fortran object>

Wrapper for cgbsv.

Parameters

- `kl` [input int]
- `ku` [input int]
- `ab` [input rank-2 array('F') with bounds (2*kl+ku+1,n)]
- `b` [input rank-2 array('F') with bounds (n,nrhs)]

Returns

- `lub` [rank-2 array('F') with bounds (2*kl+ku+1,n) and ab storage]
- `piv` [rank-1 array('i') with bounds (n)]
- `x` [rank-2 array('F') with bounds (n,nrhs) and b storage]
- `info` [int]

Other Parameters

- `overwrite_ab` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0

scipy.linalg.lapack.zgbsv

scipy.linalg.lapack.zgbsv(\(kl, ku, ab[, overwrite_ab, overwrite_b]\)) = <fortran object>

Wrapper for zgbsv.

Parameters

- `kl` [input int]
- `ku` [input int]
- `ab` [input rank-2 array('D') with bounds (2*kl+ku+1,n)]
- `b` [input rank-2 array('D') with bounds (n,nrhs)]

Returns

- `lub` [rank-2 array('D') with bounds (2*kl+ku+1,n) and ab storage]
- `piv` [rank-1 array('i') with bounds (n)]
- `x` [rank-2 array('D') with bounds (n,nrhs) and b storage]
- `info` [int]
**Other Parameters**

overwrite_ab
[input int, optional] Default: 0

overwrite_b
[input int, optional] Default: 0

**scipy.linalg.lapack.sgbtrf**

```python
scipy.linalg.lapack.sgbtrf(ab, kl[, m, n, ldab, overwrite_ab]) = <fortran object>
```

Wrapper for sgbtrf.

**Parameters**

- ab  [input rank-2 array('f') with bounds (ldab,n)]
- kl  [input int]
- ku  [input int]

**Returns**

- lu  [rank-2 array('f') with bounds (ldab,n) and ab storage]
- ipiv [rank-1 array('i') with bounds (MIN(m,n))]
- info [int]

**Other Parameters**

- m  [input int, optional] Default: shape(ab,1)
- n  [input int, optional] Default: shape(ab,1)
- overwrite_ab  [input int, optional] Default: 0
- ldab  [input int, optional] Default: max(shape(ab,0),1)

**scipy.linalg.lapack.dgbtrf**

```python
scipy.linalg.lapack.dgbtrf(ab, kl[, m, n, ldab, overwrite_ab]) = <fortran object>
```

Wrapper for dgbtrf.

**Parameters**

- ab  [input rank-2 array('d') with bounds (ldab,n)]
- kl  [input int]
- ku  [input int]

**Returns**

- lu  [rank-2 array('d') with bounds (ldab,n) and ab storage]
- ipiv [rank-1 array('i') with bounds (MIN(m,n))]
- info [int]

**Other Parameters**

- m  [input int, optional] Default: shape(ab,1)
- n  [input int, optional] Default: shape(ab,1)
- overwrite_ab  [input int, optional] Default: 0
- ldab  [input int, optional] Default: max(shape(ab,0),1)
scipy.linalg.lapack.cgbtrf

Wrapper for cgbtrf.

Parameters

- ab [input rank-2 array('F') with bounds (ldab,n)]
- kl [input int]
- ku [input int]

Returns

- lu [rank-2 array('F') with bounds (ldab,n) and ab storage]
- ipiv [rank-1 array('i') with bounds (MIN(m,n))]
- info [int]

Other Parameters

- m [input int, optional] Default: shape(ab,1)
- n [input int, optional] Default: shape(ab,1)
- overwrite_ab [input int, optional] Default: 0
- ldab [input int, optional] Default: max(shape(ab,0),1)

scipy.linalg.lapack.zgbtrf

Wrapper for zgbtrf.

Parameters

- ab [input rank-2 array('D') with bounds (ldab,n)]
- kl [input int]
- ku [input int]

Returns

- lu [rank-2 array('D') with bounds (ldab,n) and ab storage]
- ipiv [rank-1 array('i') with bounds (MIN(m,n))]
- info [int]

Other Parameters

- m [input int, optional] Default: shape(ab,1)
- n [input int, optional] Default: shape(ab,1)
- overwrite_ab [input int, optional] Default: 0
- ldab [input int, optional] Default: max(shape(ab,0),1)
**scipy.linalg.lapack.sgbtrs**

Wrapper for `sgbtrs`.

### Parameters
- **ab** [input rank-2 array('f') with bounds (ldab,n)]
- **kl** [input int]
- **ku** [input int]
- **b** [input rank-2 array('f') with bounds (ldb,nrhs)]
- **ipiv** [input rank-1 array('i') with bounds (n)]

### Returns
- **x** [rank-2 array('f') with bounds (ldb,nrhs) and b storage]
- **info** [int]

### Other Parameters
- **overwrite_b** [input int, optional] Default: 0
- **trans** [input int, optional] Default: 0
- **n** [input int, optional] Default: shape(ab,1)
- **ldab** [input int, optional] Default: shape(ab,0)
- **ldb** [input int, optional] Default: shape(b,0)

**scipy.linalg.lapack.dgbtrs**

Wrapper for `dgbtrs`.

### Parameters
- **ab** [input rank-2 array('d') with bounds (ldab,n)]
- **kl** [input int]
- **ku** [input int]
- **b** [input rank-2 array('d') with bounds (ldb,nrhs)]
- **ipiv** [input rank-1 array('i') with bounds (n)]

### Returns
- **x** [rank-2 array('d') with bounds (ldb,nrhs) and b storage]
- **info** [int]

### Other Parameters
- **overwrite_b** [input int, optional] Default: 0
- **trans** [input int, optional] Default: 0
- **n** [input int, optional] Default: shape(ab,1)
- **ldab** [input int, optional] Default: shape(ab,0)
- **ldb** [input int, optional] Default: shape(b,0)
### scipy.linalg.lapack.cgbtrs

**scipy.linalg.lapack.cgbtrs**

- **Parameters**
  - `ab` [input rank-2 array('F') with bounds (ldab,n)]
  - `kl` [input int]
  - `ku` [input int]
  - `b` [input rank-2 array('F') with bounds (ldb,nrhs)]
  - `ipiv` [input rank-1 array('i') with bounds (n)]

- **Returns**
  - `x` [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
  - `info` [int]

- **Other Parameters**
  - `overwrite_b` [input int, optional] Default: 0
  - `trans` [input int, optional] Default: 0
  - `n` [input int, optional] Default: shape(ab,1)
  - `ldab` [input int, optional] Default: shape(ab,0)
  - `ldb` [input int, optional] Default: shape(b,0)

---

### scipy.linalg.lapack.zgbtrs

- **Parameters**
  - `ab` [input rank-2 array('D') with bounds (ldab,n)]
  - `kl` [input int]
  - `ku` [input int]
  - `b` [input rank-2 array('D') with bounds (ldb,nrhs)]
  - `ipiv` [input rank-1 array('i') with bounds (n)]

- **Returns**
  - `x` [rank-2 array('D') with bounds (ldb,nrhs) and b storage]
  - `info` [int]

- **Other Parameters**
  - `overwrite_b` [input int, optional] Default: 0
  - `trans` [input int, optional] Default: 0
  - `n` [input int, optional] Default: shape(ab,1)
  - `ldab` [input int, optional] Default: shape(ab,0)
  - `ldb` [input int, optional] Default: shape(b,0)
scipy.linalg.lapack.sgebal

`scipy.linalg.lapack.sgebal(a[, scale, permute, overwrite_a]) = <fortran object>`

Wrapper for sgebal.

**Parameters**

`a`  
[input rank-2 array('f') with bounds (m,n)]

**Returns**

`ba`  
[rank-2 array('f') with bounds (m,n) and a storage]

`lo`  
[int]

`hi`  
[int]

`pivscale`  
[rank-1 array('f') with bounds (n)]

`info`  
[int]

**Other Parameters**

`scale`  
[input int, optional] Default: 0

`permute`  
[input int, optional] Default: 0

`overwrite_a`  
[input int, optional] Default: 0

---

scipy.linalg.lapack.dgebal

`scipy.linalg.lapack.dgebal(a[, scale, permute, overwrite_a]) = <fortran object>`

Wrapper for dgebal.

**Parameters**

`a`  
[input rank-2 array('d') with bounds (m,n)]

**Returns**

`ba`  
[rank-2 array('d') with bounds (m,n) and a storage]

`lo`  
[int]

`hi`  
[int]

`pivscale`  
[rank-1 array('d') with bounds (n)]

`info`  
[int]

**Other Parameters**

`scale`  
[input int, optional] Default: 0

`permute`  
[input int, optional] Default: 0

`overwrite_a`  
[input int, optional] Default: 0

---

scipy.linalg.lapack.cgebal

`scipy.linalg.lapack.cgebal(a[, scale, permute, overwrite_a]) = <fortran object>`

Wrapper for cgebal.

**Parameters**

`a`  
[input rank-2 array('F') with bounds (m,n)]

**Returns**

`ba`  
[rank-2 array('F') with bounds (m,n) and a storage]
scipy.linalg.lapack.zgebal

scipy.linalg.lapack.zgebal(a[, scale, permute, overwrite_a]) = <fortran object>

Wrapper for zgebal.

Parameters
a [input rank-2 array('D') with bounds (m,n)]

Returns
ba [rank-2 array('D') with bounds (m,n) and a storage]
lo [int]
hi [int]
pivscale [rank-1 array('d') with bounds (n)]
info [int]

Other Parameters
scale [input int, optional] Default: 0
permute [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0

scipy.linalg.lapack.sgecon

scipy.linalg.lapack.sgecon(a, anorm[, norm]) = <fortran object>

Wrapper for sgecon.

Parameters
a [input rank-2 array('F') with bounds (n,n)]
anorm [input float]

Returns
rcond [float]
info [int]

Other Parameters
norm [input string(len=1), optional] Default: ‘1’
scipy.linalg.lapack.dgecon

```python
scipy.linalg.lapack.dgecon(a, anorm[, norm]) = <fortran object>
```

Wrapper for dgecon.

**Parameters**
- `a` [input rank-2 array('d') with bounds (n,n)]
- `anorm` [input float]

**Returns**
- `rcond` [float]
- `info` [int]

**Other Parameters**
- `norm` [input string(len=1), optional] Default: ‘l’

scipy.linalg.lapack.cgecon

```python
scipy.linalg.lapack.cgecon(a, anorm[, norm]) = <fortran object>
```

Wrapper for cgecon.

**Parameters**
- `a` [input rank-2 array('F') with bounds (n,n)]
- `anorm` [input float]

**Returns**
- `rcond` [float]
- `info` [int]

**Other Parameters**
- `norm` [input string(len=1), optional] Default: ‘l’

scipy.linalg.lapack.zgecon

```python
scipy.linalg.lapack.zgecon(a, anorm[, norm]) = <fortran object>
```

Wrapper for zgecon.

**Parameters**
- `a` [input rank-2 array('D') with bounds (n,n)]
- `anorm` [input float]

**Returns**
- `rcond` [float]
- `info` [int]

**Other Parameters**
- `norm` [input string(len=1), optional] Default: ‘l’
scipy.linalg.lapack.sgeequ

\texttt{scipy.linalg.lapack.sgeequ}(a) = <fortran object>
\textit{Wrapper for sgeequ.}

\textbf{Parameters}

\begin{itemize}
  \item \texttt{a} [input rank-2 array('f') with bounds (m,n)]
\end{itemize}

\textbf{Returns}

\begin{itemize}
  \item \texttt{r} [rank-1 array('f') with bounds (m)]
  \item \texttt{c} [rank-1 array('f') with bounds (n)]
  \item \texttt{rowcnd} [float]
  \item \texttt{colcnd} [float]
  \item \texttt{amax} [float]
  \item \texttt{info} [int]
\end{itemize}

scipy.linalg.lapack.dgeequ

\texttt{scipy.linalg.lapack.dgeequ}(a) = <fortran object>
\textit{Wrapper for dgeequ.}

\textbf{Parameters}

\begin{itemize}
  \item \texttt{a} [input rank-2 array('d') with bounds (m,n)]
\end{itemize}

\textbf{Returns}

\begin{itemize}
  \item \texttt{r} [rank-1 array('d') with bounds (m)]
  \item \texttt{c} [rank-1 array('d') with bounds (n)]
  \item \texttt{rowcnd} [float]
  \item \texttt{colcnd} [float]
  \item \texttt{amax} [float]
  \item \texttt{info} [int]
\end{itemize}

scipy.linalg.lapack.cgeequ

\texttt{scipy.linalg.lapack.cgeequ}(a) = <fortran object>
\textit{Wrapper for cgeequ.}

\textbf{Parameters}

\begin{itemize}
  \item \texttt{a} [input rank-2 array('F') with bounds (m,n)]
\end{itemize}

\textbf{Returns}

\begin{itemize}
  \item \texttt{r} [rank-1 array('f') with bounds (m)]
  \item \texttt{c} [rank-1 array('f') with bounds (n)]
  \item \texttt{rowcnd} [float]
  \item \texttt{colcnd} [float]
  \item \texttt{amax} [float]
  \item \texttt{info} [int]
\end{itemize}
scipy.linalg.lapack.zgeequ

scipy.linalg.lapack.zgeequ(a) = <fortran object>
Wrapper for zgeequ.

Parameters
    a [input rank-2 array('D') with bounds (m,n)]

Returns
    r [rank-1 array('d') with bounds (m)]
    c [rank-1 array('d') with bounds (n)]
    rowcnd [float]
    colcnd [float]
    amax [float]
    info [int]

scipy.linalg.lapack.sgeequb

scipy.linalg.lapack.sgeequb(a) = <fortran object>
Wrapper for sgeequb.

Parameters
    a [input rank-2 array('f') with bounds (m,n)]

Returns
    r [rank-1 array('f') with bounds (m)]
    c [rank-1 array('f') with bounds (n)]
    rowcnd [float]
    colcnd [float]
    amax [float]
    info [int]

scipy.linalg.lapack.dgeequb

scipy.linalg.lapack.dgeequb(a) = <fortran object>
Wrapper for dgeequb.

Parameters
    a [input rank-2 array('d') with bounds (m,n)]

Returns
    r [rank-1 array('d') with bounds (m)]
    c [rank-1 array('d') with bounds (n)]
    rowcnd [float]
    colcnd [float]
    amax [float]
    info [int]
scipy.linalg.lapack.cgeequb

scipy.linalg.lapack.cgeequb(a) = <fortran object>

Wrapper for cgeequb.

Parameters

a [input rank-2 array('F') with bounds (m,n)]

Returns

r [rank-1 array('f') with bounds (m)]
c [rank-1 array('f') with bounds (n)]
rowcnd [float]
colcnd [float]
amax [float]
info [int]

scipy.linalg.lapack.zgeequb

scipy.linalg.lapack.zgeequb(a) = <fortran object>

Wrapper for zgeequb.

Parameters

a [input rank-2 array('D') with bounds (m,n)]

Returns

r [rank-1 array('d') with bounds (m)]
c [rank-1 array('d') with bounds (n)]
rowcnd [float]
colcnd [float]
amax [float]
info [int]

scipy.linalg.lapack.sgees

scipy.linalg.lapack.sgees (sselect, a[, compute_v, sort_t, lwork, sselect_extra_args, overwrite_a]) = <fortran object>

Wrapper for sgees.

Parameters

sselect [call-back function]
a [input rank-2 array('f') with bounds (n,n)]

Returns

t [rank-2 array('f') with bounds (n,n) and a storage]
sdim [int]
wr [rank-1 array('f') with bounds (n)]
wi [rank-1 array('f') with bounds (n)]
vs [rank-2 array('f') with bounds (ldvs,n)]
work [rank-1 array('f') with bounds (MAX(lwork,1))]
info [int]

Other Parameters
compute_v  
[input int, optional] Default: 1

sort_t  
[input int, optional] Default: 0

dselect_extra_args  
[input tuple, optional] Default: ()

overwrite_a  
[input int, optional] Default: 0

lwork  
[input int, optional] Default: max(3*n,1)

Notes

Call-back functions:

```python
def sselect(arg1, arg2):
    return sselect
```

Required arguments:
- arg1: input float
- arg2: input float

Return objects:
- sselect: int

scipy.linalg.lapack.dgees

```python
scipy.linalg.lapack.dgees(dselect, a[, compute_v, sort_t, lwork, dselect_extra_args, overwrite_a]) =
<fortran object>
```

Wrapper for dgees.

**Parameters**

- dselect  
  [call-back function]
- a  
  [input rank-2 array('d') with bounds (n,n)]

**Returns**

- t  
  [rank-2 array('d') with bounds (n,n) and a storage]
- sdim  
  [int]
- wr  
  [rank-1 array('d') with bounds (n)]
- wi  
  [rank-1 array('d') with bounds (n)]
- vs  
  [rank-2 array('d') with bounds (ldvs,n)]
- work  
  [rank-1 array('d') with bounds (MAX(lwork,1))]
- info  
  [int]

**Other Parameters**

- compute_v  
  [input int, optional] Default: 1
- sort_t  
  [input int, optional] Default: 0
- dselect_extra_args  
  [input tuple, optional] Default: ()
- overwrite_a  
  [input int, optional] Default: 0
- lwork  
  [input int, optional] Default: max(3*n,1)
Notes

Call-back functions:

```python
def dselect(arg1,arg2): return dselect
Required arguments:
  arg1 : input float
  arg2 : input float
Return objects:
  dselect : int
```

scipy.linalg.lapack.cgees

scipy.linalg.lapack.cgees(cselect, a[, compute_v, sort_t, hwork, cselect_extra_args, overwrite_a]) =
<fortran object>

Wrapper for cgees.

Parameters

- cselect [call-back function]
- a [input rank-2 array('F') with bounds (n,n)]

Returns

- t [rank-2 array('F') with bounds (n,n) and a storage]
- sdim [int]
- w [rank-1 array('F') with bounds (n)]
- vs [rank-2 array('F') with bounds (ldvs,n)]
- work [rank-1 array('F') with bounds (MAX(lwork,1))]
- info [int]

Other Parameters

- compute_v [input int, optional] Default: 1
- sort_t [input int, optional] Default: 0
- cselect_extra_args [input tuple, optional] Default: ()
- overwrite_a [input int, optional] Default: 0
- lwork [input int, optional] Default: max(3*n,1)

Notes

Call-back functions:

```python
def cselect(arg): return cselect
Required arguments:
  arg : input complex
Return objects:
  cselect : int
```
scipy.linalg.lapack.zgees

scipy.linalg.lapack.zgees(zselect, a[, compute_v, sort_t, lwork, zselect_extra_args, overwrite_a]) =<fortran object>

Wrapper for zgees.

Parameters

zselect [call-back function]
a [input rank-2 array('D') with bounds (n,n)]

Returns

t [rank-2 array('D') with bounds (n,n) and a storage]
sdim [int]
w [rank-1 array('D') with bounds (n)]
vs [rank-2 array('D') with bounds (ldvs,n)]
work [rank-1 array('D') with bounds (MAX(lwork,1))]
info [int]

Other Parameters

compute_v [input int, optional] Default: 1
sort_t [input int, optional] Default: 0
zselect_extra_args [input tuple, optional] Default: ()
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)

Notes

Call-back functions:

def zselect(arg): return zselect
Required arguments:
   arg : input complex
Return objects:
   zselect : int

scipy.linalg.lapack.sgeev

scipy.linalg.lapack.sgeev(a[, compute_vl, compute_vr, lwork, overwrite_a]) = <fortran object>

Wrapper for sgeev.

Parameters

a [input rank-2 array('f') with bounds (n,n)]

Returns

wr [rank-1 array('f') with bounds (n)]
wi [rank-1 array('f') with bounds (n)]
vl [rank-2 array('f') with bounds (ldvl,n)]
vr [rank-2 array('f') with bounds (ldvr,n)]
Other Parameters

- `compute_vl`: [input int, optional] Default: 1
- `compute_vr`: [input int, optional] Default: 1
- `overwrite_a`: [input int, optional] Default: 0
- `lwork`: [input int, optional] Default: max(4*n,1)

scipy.linalg.lapack.dgeev

scipy.linalg.lapack.dgeev(a[, compute_vl, compute_vr, lwork, overwrite_a]) = <fortran object>

Wrapper for dgeev.

Parameters

- `a`: [input rank-2 array('d') with bounds (n,n)]

Returns

- `wr`: [rank-1 array('d') with bounds (n)]
- `wi`: [rank-1 array('d') with bounds (n)]
- `vl`: [rank-2 array('d') with bounds (ldvl,n)]
- `vr`: [rank-2 array('d') with bounds (ldvr,n)]
- `info`: [int]

Other Parameters

- `compute_vl`: [input int, optional] Default: 1
- `compute_vr`: [input int, optional] Default: 1
- `overwrite_a`: [input int, optional] Default: 0
- `lwork`: [input int, optional] Default: max(4*n,1)

scipy.linalg.lapack.cgeev

scipy.linalg.lapack.cgeev(a[, compute_vl, compute_vr, lwork, overwrite_a]) = <fortran object>

Wrapper for cgeev.

Parameters

- `a`: [input rank-2 array('F') with bounds (n,n)]

Returns

- `w`: [rank-1 array('F') with bounds (n)]
- `vl`: [rank-2 array('F') with bounds (ldvl,n)]
- `vr`: [rank-2 array('F') with bounds (ldvr,n)]
- `info`: [int]

Other Parameters
compute_vl
   [input int, optional] Default: 1
compute_vr
   [input int, optional] Default: 1
overwrite_a
   [input int, optional] Default: 0
lwork
   [input int, optional] Default: max(2*n,1)

scipy.linalg.lapack.zgeev

scipy.linalg.lapack.zgeev(a[, compute_vl, compute_vr, lwork, overwrite_a]) = <fortran object>
Wrapper for zgeev.

Parameters
   a
   [input rank-2 array('D') with bounds (n,n)]

Returns
   w
   [rank-1 array('D') with bounds (n)]
   vl
   [rank-2 array('D') with bounds (ldvl,n)]
   vr
   [rank-2 array('D') with bounds (ldvr,n)]
   info
   [int]

Other Parameters
   compute_vl
   [input int, optional] Default: 1
   compute_vr
   [input int, optional] Default: 1
   overwrite_a
   [input int, optional] Default: 0
   lwork
   [input int, optional] Default: max(2*n,1)

scipy.linalg.lapack.sgeev_lwork

scipy.linalg.lapack.sgeev_lwork(n[, compute_vl, compute_vr]) = <fortran object>
Wrapper for sgeev_lwork.

Parameters
   n
   [input int]

Returns
   work
   [float]
   info
   [int]

Other Parameters
   compute_vl
   [input int, optional] Default: 1
   compute_vr
   [input int, optional] Default: 1
scipy.linalg.lapack.dgeev_lwork

scipy.linalg.lapack.dgeev_lwork(n[, compute_vl, compute_vr]) = <fortran object>

Wrapper for dgeev_lwork.

Parameters
n [input int]

Returns
work [float]
info [int]

Other Parameters
compute_vl [input int, optional] Default: 1
compute_vr [input int, optional] Default: 1

scipy.linalg.lapack.cgeev_lwork

scipy.linalg.lapack.cgeev_lwork(n[, compute_vl, compute_vr]) = <fortran object>

Wrapper for cgeev_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

Other Parameters
compute_vl [input int, optional] Default: 1
compute_vr [input int, optional] Default: 1

scipy.linalg.lapack.zgeev_lwork

scipy.linalg.lapack.zgeev_lwork(n[, compute_vl, compute_vr]) = <fortran object>

Wrapper for zgeev_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

Other Parameters
compute_vl [input int, optional] Default: 1

6.12. Low-level LAPACK functions (scipy.linalg.lapack)
**compute_vr**
[input int, optional] Default: 1

**scipy.linalg.lapack.sgegv**

scipy.linalg.lapack.sgegv(*args, **kwds)
sgegv is deprecated! The *gegv family of routines has been deprecated in LAPACK 3.6.0 in favor of the *ggev family of routines. The corresponding wrappers will be removed from SciPy in a future release.

alphar,alphai,beta,vl,vr,info = sgegv(a,b,[compute_vl,compute_vr,lwork,overwrite_a,overwrite_b])

Wrapper for sgegv.

**Parameters**

- **a** [input rank-2 array('f') with bounds (n,n)]
- **b** [input rank-2 array('f') with bounds (n,n)]

**Returns**

- **alphar** [rank-1 array('f') with bounds (n)]
- **alphai** [rank-1 array('f') with bounds (n)]
- **beta** [rank-1 array('f') with bounds (n)]
- **vl** [rank-2 array('f') with bounds (ldvl,n)]
- **vr** [rank-2 array('f') with bounds (ldvr,n)]
- **info** [int]

**Other Parameters**

- **compute_vl** [input int, optional] Default: 1
- **compute_vr** [input int, optional] Default: 1
- **overwrite_a** [input int, optional] Default: 0
- **overwrite_b** [input int, optional] Default: 0
- **lwork** [input int, optional] Default: max(8*n,1)

**scipy.linalg.lapack.dgegv**

scipy.linalg.lapack.dgegv(*args, **kwds)
dgegv is deprecated! The *gegv family of routines has been deprecated in LAPACK 3.6.0 in favor of the *ggev family of routines. The corresponding wrappers will be removed from SciPy in a future release.

alphar,alphai,beta,vl,vr,info = dgegv(a,b,[compute_vl,compute_vr,lwork,overwrite_a,overwrite_b])

Wrapper for dgegv.

**Parameters**

- **a** [input rank-2 array('d') with bounds (n,n)]
- **b** [input rank-2 array('d') with bounds (n,n)]

**Returns**

- **alphar** [rank-1 array('d') with bounds (n)]
- **alphai** [rank-1 array('d') with bounds (n)]
- **beta** [rank-1 array('d') with bounds (n)]
scipy.linalg.lapack.cggev

scipy.linalg.lapack.cggev(*args, **kwds)

cggev is deprecated! The *ggev family of routines has been deprecated in LAPACK 3.6.0 in favor of the *gegv family of routines. The corresponding wrappers will be removed from SciPy in a future release.

alpha, beta, vl, vr, info = cggev(a, b, [compute_vl, compute_vr, lwork, overwrite_a, overwrite_b])

Wrapper for cggev.

Parameters

\( a \) [input rank-2 array('F') with bounds (n,n)]
\( b \) [input rank-2 array('F') with bounds (n,n)]

Returns

\( \alpha \) [rank-1 array('F') with bounds (n)]
\( \beta \) [rank-1 array('F') with bounds (n)]
\( vl \) [rank-2 array('F') with bounds (ldvl,n)]
\( vr \) [rank-2 array('F') with bounds (ldvr,n)]
\( \text{info} \) [int]

Other Parameters

\( \text{compute}_v\lambda \) [input int, optional] Default: 1
\( \text{compute}_v\gamma \) [input int, optional] Default: 1
\( \text{overwrite}_a \) [input int, optional] Default: 0
\( \text{overwrite}_b \) [input int, optional] Default: 0
\( l\text{work} \) [input int, optional] Default: max(2*n,1)
scipy.linalg.lapack.zgegv

scipy.linalg.lapack.zgegv (*args, **kwds)
zgegv is deprecated! The *ggev family of routines has been deprecated in LAPACK 3.6.0 in favor of the *ggev family of routines. The corresponding wrappers will be removed from SciPy in a future release.

alpha, beta, vl, vr, info = zgegv(a, b, [compute_vl, compute_vr, lwork, overwrite_a, overwrite_b])

Wrapper for zgegv.

Parameters
  a [input rank-2 array(‘D’) with bounds (n,n)]
  b [input rank-2 array(‘D’) with bounds (n,n)]

Returns
  alpha [rank-1 array(‘D’) with bounds (n)]
  beta [rank-1 array(‘D’) with bounds (n)]
  vl [rank-2 array(‘D’) with bounds (ldvl,n)]
  vr [rank-2 array(‘D’) with bounds (ldvr,n)]
  info [int]

Other Parameters
  compute_vl [input int, optional] Default: 1
  compute_vr [input int, optional] Default: 1
  overwrite_a [input int, optional] Default: 0
  overwrite_b [input int, optional] Default: 0
  lwork [input int, optional] Default: max(2*n,1)

scipy.linalg.lapack.sgehrd

scipy.linalg.lapack.sgehrd(a[, lo, hi, lwork, overwrite_a]) = <fortran object>

Wrapper for sgehrd.

Parameters
  a [input rank-2 array(‘f’) with bounds (n,n)]

Returns
  ht [rank-2 array(‘f’) with bounds (n,n) and a storage]
  tau [rank-1 array(‘f’) with bounds (n - 1)]
  info [int]

Other Parameters
  lo [input int, optional] Default: 0
  hi [input int, optional] Default: n-1
  overwrite_a [input int, optional] Default: 0
  lwork [input int, optional] Default: MAX(n,1)
6.12. Low-level LAPACK functions (scipy.linalg.lapack)

**scipy.linalg.lapack.dgehrd**

```python
scipy.linalg.lapack.dgehrd(a[, lo, hi, lwork, overwrite_a]) = <fortran object>
```

Wrapper for `dgehrd`.

**Parameters**

- `a` [input rank-2 array('d') with bounds (n,n)]

**Returns**

- `ht` [rank-2 array('d') with bounds (n,n) and a storage]
- `tau` [rank-1 array('d') with bounds (n - 1)]
- `info` [int]

**Other Parameters**

- `lo` [input int, optional] Default: 0
- `hi` [input int, optional] Default: n-1
- `overwrite_a` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: MAX(n,1)

**scipy.linalg.lapack.cgehrd**

```python
scipy.linalg.lapack.cgehrd(a[, lo, hi, lwork, overwrite_a]) = <fortran object>
```

Wrapper for `cgehrd`.

**Parameters**

- `a` [input rank-2 array('F') with bounds (n,n)]

**Returns**

- `ht` [rank-2 array('F') with bounds (n,n) and a storage]
- `tau` [rank-1 array('F') with bounds (n - 1)]
- `info` [int]

**Other Parameters**

- `lo` [input int, optional] Default: 0
- `hi` [input int, optional] Default: n-1
- `overwrite_a` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: MAX(n,1)

**scipy.linalg.lapack.zgehrd**

```python
scipy.linalg.lapack.zgehrd(a[, lo, hi, lwork, overwrite_a]) = <fortran object>
```

Wrapper for `zgehrd`.

**Parameters**

- `a` [input rank-2 array('D') with bounds (n,n)]

**Returns**

- `ht` [rank-2 array('D') with bounds (n,n) and a storage]
- `tau` [rank-1 array('D') with bounds (n - 1)]
- `info` [int]
**Other Parameters**

- `lo` [input int, optional] Default: 0
- `hi` [input int, optional] Default: n-1
- `overwrite_a` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: MAX(n,1)

```python
scipy.linalg.lapack.sgehrd_lwork

scipy.linalg.lapack.sgehrd_lwork(n[, lo, hi]) = <fortran object>
Wrapper for sgehrd_lwork.

Parameters
- `n` [input int]

Returns
- `work` [float]
- `info` [int]

Other Parameters
- `lo` [input int, optional] Default: 0
- `hi` [input int, optional] Default: n-1

scipy.linalg.lapack.dgehrd_lwork

scipy.linalg.lapack.dgehrd_lwork(n[, lo, hi]) = <fortran object>
Wrapper for dgehrd_lwork.

Parameters
- `n` [input int]

Returns
- `work` [float]
- `info` [int]

Other Parameters
- `lo` [input int, optional] Default: 0
- `hi` [input int, optional] Default: n-1

scipy.linalg.lapack.cgehrd_lwork

scipy.linalg.lapack.cgehrd_lwork(n[, lo, hi]) = <fortran object>
Wrapper for cgehrd_lwork.

Parameters
- `n` [input int]

Returns
- `work` [complex]
- `info` [int]
**Other Parameters**

- *lo*  [input int, optional] Default: 0
- *hi*  [input int, optional] Default: n-1

**scipy.linalg.lapack.zgehrd_lwork**

`scipy.linalg.lapack.zgehrd_lwork(n[,lo,hi]) = <fortran object>`

Wrapper for `zgehrd_lwork`.

**Parameters**

- *n*  [input int]

**Returns**

- *work*  [complex]
- *info*  [int]

**Other Parameters**

- *lo*  [input int, optional] Default: 0
- *hi*  [input int, optional] Default: n-1

**scipy.linalg.lapack.sgejsv**

`scipy.linalg.lapack.sgejsv(a[,joba,jobu,jobv,jobr,jobt,jobp,lwork,overwrite_a]) = <fortran object>`

Wrapper for `sgejsv`.

**Parameters**

- *a*  [input rank-2 array('f') with bounds (lda,n)]

**Returns**

- *sva*  [rank-1 array('f') with bounds (n)]
- *u*  [rank-2 array('f') with bounds (((jobt == 0)\&\&(jobu == 3)?0:m),((jobt == 0)\&\&(jobu == 3)?0:(jobu == 1?m:n)))]
- *v*  [rank-2 array('f') with bounds (((jobt == 0)\&\&(jobv == 3)?0:ldv),((jobt == 0)\&\&(jobv == 3)?0:n))]
- *workout*  [rank-1 array('f') with bounds (7)]
- *iworkout*  [rank-1 array('i') with bounds (3)]
- *info*  [int]

**Other Parameters**

- *joba*  [input int, optional] Default: 4
- *jobu*  [input int, optional] Default: 0
- *jobv*  [input int, optional] Default: 0
- *jobr*  [input int, optional] Default: 1
- *jobt*  [input int, optional] Default: 0
- *jobp*  [input int, optional] Default: 1
- *overwrite_a*  [input int, optional] Default: 0
- *lwork*  [input int, optional] Default: \(\max(6*n+2*n*n,\max(2*m+n,\max(4*n+n*n,\max(2*n+n*n+6, 7))))\)
scipy.linalg.lapack.dgejsv

**scipy.linalg.lapack.dgejsv** *(array, joba, jobu, jobv, jobr, jobt, jobp, lwork, overwrite_a) = <fortran object>*

Wrapper for dgejsv.

**Parameters**
- *a* [input rank-2 array('d') with bounds (lda,n)]
- *joba* [input int, optional] Default: 4
- *jobu* [input int, optional] Default: 0
- *jobv* [input int, optional] Default: 0
- *jobr* [input int, optional] Default: 1
- *jobt* [input int, optional] Default: 0
- *jobp* [input int, optional] Default: 1
- *overwrite_a* [input int, optional] Default: 0
- *lwork* [input int, optional] Default: max(6*n+2*n*n, max(2*m+n, max(4*n+n*n, max(2*n+n*n+6, 7))))

**Returns**
- *sva* [rank-1 array('d') with bounds (n)]
- *u* [rank-2 array('d') with bounds ((jobt == 0)&(jobu == 3)?0:m,((jobt == 0)&(jobu == 3)?0:(jobu == 1)?m:n))]
- *v* [rank-2 array('d') with bounds ((jobt == 0)&(jobv == 3)?0:ldv,((jobt == 0)&(jobv == 3)?0:n))]
- *workout* [rank-1 array('d') with bounds (7)]
- *iworkout* [rank-1 array('i') with bounds (3)]
- *info* [int]

**Other Parameters**
- *trans* [input string(len=1), optional] Default: ‘N’
- *overwrite_a* [input int, optional] Default: 0
- *overwrite_b* [input int, optional] Default: 0
- *lwork* [input int, optional] Default: MAX(MIN(m,n)+MAX(MIN(m,n),nrhs),1)

scipy.linalg.lapack.sgels

**scipy.linalg.lapack.sgels** *(a, b[, trans, lwork, overwrite_a, overwrite_b]) = <fortran object>*

Wrapper for sgels.

**Parameters**
- *a* [input rank-2 array('f') with bounds (m,n)]
- *b* [input rank-2 array('f') with bounds (MAX(m,n),nrhs)]
- *trans* [input string(len=1), optional] Default: ‘N’
- *overwrite_a* [input int, optional] Default: 0
- *overwrite_b* [input int, optional] Default: 0
- *lwork* [input int, optional] Default: MAX(MIN(m,n)+MAX(MIN(m,n),nrhs),1)
scipy.linalg.lapack.dgels

scipy.linalg.lapack.dgels(a, b, [trans, lwork, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for dgels.

Parameters
a [input rank-2 array('d') with bounds (m,n)]
b [input rank-2 array('d') with bounds (MAX(m,n),nrhs)]

Returns
lqr [rank-2 array('d') with bounds (m,n) and a storage]
x [rank-2 array('d') with bounds (MAX(m,n),nrhs) and b storage]
info [int]

Other Parameters
trans [input string(len=1), optional] Default: 'N'
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
lwork [input int, optional] Default: MAX(MIN(m,n)+MAX(MIN(m,n),nrhs),1)

scipy.linalg.lapack.cgels

scipy.linalg.lapack.cgels(a, b, [trans, lwork, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for cgels.

Parameters
a [input rank-2 array('F') with bounds (m,n)]
b [input rank-2 array('F') with bounds (MAX(m,n),nrhs)]

Returns
lqr [rank-2 array('F') with bounds (m,n) and a storage]
x [rank-2 array('F') with bounds (MAX(m,n),nrhs) and b storage]
info [int]

Other Parameters
trans [input string(len=1), optional] Default: 'N'
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
lwork [input int, optional] Default: MAX(MIN(m,n)+MAX(MIN(m,n),nrhs),1)
scipy.linalg.lapack.zgels

scipy.linalg.lapack.zgels(a, b[, trans, lwork, overwrite_a, overwrite_b]) = <fortran object>
Wrapper for zgels.

Parameters
a [input rank-2 array('D') with bounds (m,n)]
b [input rank-2 array('D') with bounds (MAX(m,n),nrhs)]

Returns
lqr [rank-2 array('D') with bounds (m,n) and a storage]
x [rank-2 array('D') with bounds (MAX(m,n),nrhs) and b storage]
info [int]

Other Parameters
trans [input string(len=1), optional] Default: ‘N’
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
lwork [input int, optional] Default: MAX(MIN(m,n)+MAX(MIN(m,n),nrhs),1)

scipy.linalg.lapack.sgels_lwork

scipy.linalg.lapack.sgels_lwork(m, n, nrhs[, trans]) = <fortran object>
Wrapper for sgels_lwork.

Parameters
m [input int]
n [input int]
nrhs [input int]

Returns
work [float]
info [int]

Other Parameters
trans [input string(len=1), optional] Default: ‘N’

scipy.linalg.lapack.dgels_lwork

scipy.linalg.lapack.dgels_lwork(m, n, nrhs[, trans]) = <fortran object>
Wrapper for dgels_lwork.

Parameters
m [input int]
n [input int]
nrhs [input int]

Returns
work [float]
info [int]

**Other Parameters**

trans [input string(len=1), optional] Default: ‘N’

**scipy.linalg.lapack.cgels_lwork**

```python
scipy.linalg.lapack.cgels_lwork(m, n, nrhs[, trans]) = <fortran object>
```

Wrapper for cgels_lwork.

**Parameters**

- m [input int]
- n [input int]
- nrhs [input int]

**Returns**

- work [complex]
- info [int]

**Other Parameters**

trans [input string(len=1), optional] Default: ‘N’

**scipy.linalg.lapack.zgels_lwork**

```python
scipy.linalg.lapack.zgels_lwork(m, n, nrhs[, trans]) = <fortran object>
```

Wrapper for zgels_lwork.

**Parameters**

- m [input int]
- n [input int]
- nrhs [input int]

**Returns**

- work [complex]
- info [int]

**Other Parameters**

trans [input string(len=1), optional] Default: ‘N’

**scipy.linalg.lapack.sgelsd**

```python
scipy.linalg.lapack.sgelsd(a, b, lwork, size_iwork[, cond, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for sgelsd.

**Parameters**

- a [input rank-2 array('f') with bounds (m,n)]
- b [input rank-2 array('f') with bounds (maxmn,nrhs)]
- lwork [input int]
- size_iwork [input int]

**Returns**

6.12. Low-level LAPACK functions (**scipy.linalg.lapack**)

\[
\begin{align*}
x & \quad \text{[rank-2 array('f') with bounds (maxmn,nrhs) and b storage]} \\
s & \quad \text{[rank-1 array('f') with bounds (minmn)]} \\
\text{rank} & \quad \text{[int]} \\
\text{info} & \quad \text{[int]}
\end{align*}
\]

**Other Parameters**

- \(\text{overwrite}_a\)
  - [input int, optional] Default: 0
- \(\text{overwrite}_b\)
  - [input int, optional] Default: 0
- \(\text{cond}\)
  - [input float, optional] Default: -1.0

**scipy.linalg.lapack.dgelsd**

```
scipy.linalg.lapack.dgelsd(a, b, lwork, size_iwork[, cond, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for \texttt{dgelsd}.

**Parameters**

- \(a\)
  - [input rank-2 array('d') with bounds (m,n)]
- \(b\)
  - [input rank-2 array('d') with bounds (maxmn,nrhs)]
- \(lwork\)
  - [input int]
- \(size\_iwork\)
  - [input int]

**Returns**

- \(x\)
  - [rank-2 array('d') with bounds (maxmn,nrhs) and b storage]
- \(s\)
  - [rank-1 array('d') with bounds (minmn)]
- \(\text{rank}\)
  - [int]
- \(\text{info}\)
  - [int]

**Other Parameters**

- \(\text{overwrite}_a\)
  - [input int, optional] Default: 0
- \(\text{overwrite}_b\)
  - [input int, optional] Default: 0
- \(\text{cond}\)
  - [input float, optional] Default: -1.0

**scipy.linalg.lapack.cgelsd**

```
scipy.linalg.lapack.cgelsd(a, b, lwork, size_rwork, size_iwork[, cond, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for \texttt{cgelsd}.

**Parameters**

- \(a\)
  - [input rank-2 array('F') with bounds (m,n)]
- \(b\)
  - [input rank-2 array('F') with bounds (maxmn,nrhs)]
- \(lwork\)
  - [input int]
- \(size\_rwork\)
  - [input int]
- \(size\_iwork\)
  - [input int]

**Returns**

- \(x\)
  - [rank-2 array('F') with bounds (maxmn,nrhs) and b storage]
- \(s\)
  - [rank-1 array('F') with bounds (minmn)]
- \(\text{rank}\)
  - [int]
- \(\text{info}\)
  - [int]

x [rank-2 array('F') with bounds (maxmn,nrhs) and b storage]
s [rank-1 array('f') with bounds (minmn)]
rank [int]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
cond [input float, optional] Default: -1.0

scipy.linalg.lapack.zgelsd

scipy.linalg.lapack.zgelsd(a, b, lwork, size_rwork, size_iwork[, cond, overwrite_a, overwrite_b])
= <fortran object>
Wrapper for zgelsd.

Parameters
a [input rank-2 array('D') with bounds (m,n)]
b [input rank-2 array('D') with bounds (maxmn,nrhs)]
lwork [input int]
size_rwork [input int]
size_iwork [input int]

Returns
x [rank-2 array('D') with bounds (maxmn,nrhs) and b storage]
s [rank-1 array('d') with bounds (minmn)]
rank [int]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
cond [input float, optional] Default: -1.0

scipy.linalg.lapack.sgelsd_lwork

scipy.linalg.lapack.sgelsd_lwork(m, n, nrhs[, cond, lwork]) = <fortran object>
Wrapper for sgelsd_lwork.

Parameters
m [input int]
n [input int]
nrhs [input int]

Returns
work [float]
iwork [int]
info [int]

Other Parameters
cond [input float, optional] Default: -1.0
lwork [input int, optional] Default: -1

scipy.linalg.lapack.dgelsd_lwork

scipy.linalg.lapack.dgelsd_lwork (m, n, nrhs[, cond, lwork]) = <fortran object>
Wrapper for dgelsd_lwork.

Parameters
m [input int]
n [input int]
nrhs [input int]

Returns
work [float]
iwork [int]
info [int]

Other Parameters
cond [input float, optional] Default: -1.0
lwork [input int, optional] Default: -1

scipy.linalg.lapack.cgelsd_lwork

scipy.linalg.lapack.cgelsd_lwork (m, n, nrhs[, cond, lwork]) = <fortran object>
Wrapper for cgelsd_lwork.

Parameters
m [input int]
n [input int]
nrhs [input int]

Returns
work [complex]
rwork [float]
iwork [int]
info [int]

Other Parameters
cond [input float, optional] Default: -1.0
lwork [input int, optional] Default: -1
scipy.linalg.lapack.zgelsd_lwork

\[ \text{scipy.linalg.lapack.zgelsd_lwork}(m, n, nrhs[, cond, lwork]) = \text{<fortran object>} \]

Wrapper for zgelsd_lwork.

**Parameters**

- \( m \) [input int]
- \( n \) [input int]
- \( nrhs \) [input int]

**Returns**

- \( \text{work} \) [complex]
- \( \text{rwork} \) [float]
- \( \text{iwork} \) [int]
- \( \text{info} \) [int]

**Other Parameters**

- \( \text{cond} \) [input float, optional] Default: -1.0
- \( \text{lwork} \) [input int, optional] Default: -1

scipy.linalg.lapack.sgelss

\[ \text{scipy.linalg.lapack.sgelss}(a, b[, cond, lwork, overwrite_a, overwrite_b]) = \text{<fortran object>} \]

Wrapper for sgelss.

**Parameters**

- \( a \) [input rank-2 array('f') with bounds (m,n)]
- \( b \) [input rank-2 array('f') with bounds (maxmn,nrhs)]

**Returns**

- \( \text{v} \) [rank-2 array('f') with bounds (m,n) and a storage]
- \( \text{x} \) [rank-2 array('f') with bounds (maxmn,nrhs) and b storage]
- \( \text{s} \) [rank-1 array('f') with bounds (minmn)]
- \( \text{rank} \) [int]
- \( \text{work} \) [rank-1 array('f') with bounds (MAX(lwork,1))]
- \( \text{info} \) [int]

**Other Parameters**

- \( \text{overwrite_a} \) [input int, optional] Default: 0
- \( \text{overwrite_b} \) [input int, optional] Default: 0
- \( \text{cond} \) [input float, optional] Default: -1.0
- \( \text{lwork} \) [input int, optional] Default: max(3*minmn+MAX(2*minmn,MAX(maxmn,nrhs)),1)
scipy.linalg.lapack.dgelss

```python
scipy.linalg.lapack.dgelss(a, b[, cond, lwork, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for dgelss.

**Parameters**

- `a`: [input rank-2 array('d') with bounds (m,n)]
- `b`: [input rank-2 array('d') with bounds (maxmn,nrhs)]

**Returns**

- `v`: [rank-2 array('d') with bounds (m,n) and a storage]
- `x`: [rank-2 array('d') with bounds (maxmn,nrhs) and b storage]
- `s`: [rank-1 array('d') with bounds (minmn)]
- `rank`: [int]
- `work`: [rank-1 array('d') with bounds (MAX(lwork,1))]  
- `info`: [int]

**Other Parameters**

- `overwrite_a`: [input int, optional] Default: 0
- `overwrite_b`: [input int, optional] Default: 0
- `cond`: [input float, optional] Default: -1.0
- `lwork`: [input int, optional] Default: max(3*minmn+MAX(2*minmn,MAX(maxmn,nrhs)),1)

scipy.linalg.lapack.cgelss

```python
scipy.linalg.lapack.cgelss(a, b[, cond, lwork, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for cgelss.

**Parameters**

- `a`: [input rank-2 array('F') with bounds (m,n)]
- `b`: [input rank-2 array('F') with bounds (maxmn,nrhs)]

**Returns**

- `v`: [rank-2 array('F') with bounds (m,n) and a storage]
- `x`: [rank-2 array('F') with bounds (maxmn,nrhs) and b storage]
- `s`: [rank-1 array('f') with bounds (minmn)]
- `rank`: [int]
- `work`: [rank-1 array('F') with bounds (MAX(lwork,1))]  
- `info`: [int]

**Other Parameters**

- `overwrite_a`: [input int, optional] Default: 0
- `overwrite_b`: [input int, optional] Default: 0
- `cond`: [input float, optional] Default: -1.0
- `lwork`: [input int, optional] Default: max(2*minmn+MAX(maxmn,nrhs),1)
scipy.linalg.lapack.zgelss

`scipy.linalg.lapack.zgelss(a, b[, cond, lwork, overwrite_a, overwrite_b]) = <fortran object>`

Wrapper for zgelss.

**Parameters**

- `a` [input rank-2 array(‘D’) with bounds (m,n)]
- `b` [input rank-2 array(‘D’) with bounds (maxmn,nrhs)]

**Returns**

- `v` [rank-2 array(‘D’) with bounds (m,n) and a storage]
- `x` [rank-2 array(‘D’) with bounds (maxmn,nrhs) and b storage]
- `s` [rank-1 array(‘d’) with bounds (minmn)]
- `rank` [int]
- `work` [rank-1 array(‘D’) with bounds (MAX(lwork,1))]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0
- `cond` [input float, optional] Default: -1.0
- `lwork` [input int, optional] Default: max(2*minmn+MAX(maxmn,nrhs),1)

scipy.linalg.lapack.sgelss_lwork

`scipy.linalg.lapack.sgelss_lwork (m, n, nrhs[, cond, lwork]) = <fortran object>`

Wrapper for sgelss_lwork.

**Parameters**

- `m` [input int]
- `n` [input int]
- `nrhs` [input int]

**Returns**

- `work` [float]
- `info` [int]

**Other Parameters**

- `cond` [input float, optional] Default: -1.0
- `lwork` [input int, optional] Default: -1
scipy.linalg.lapack.dgelss_lwork

scipy.linalg.lapack.dgelss_lwork(m, n, nrhs[, cond, lwork]) = <fortran object>
Wrapper for dgelss_lwork.

Parameters
m [input int]
n [input int]
nrhs [input int]

Returns
work [float]
info [int]

Other Parameters
cond [input float, optional] Default: -1.0
lwork [input int, optional] Default: -1

scipy.linalg.lapack.cgelss_lwork

scipy.linalg.lapack.cgelss_lwork(m, n, nrhs[, cond, lwork]) = <fortran object>
Wrapper for cgelss_lwork.

Parameters
m [input int]
n [input int]
nrhs [input int]

Returns
work [complex]
info [int]

Other Parameters
cond [input float, optional] Default: -1.0
lwork [input int, optional] Default: -1

scipy.linalg.lapack.zgelss_lwork

scipy.linalg.lapack.zgelss_lwork(m, n, nrhs[, cond, lwork]) = <fortran object>
Wrapper for zgelss_lwork.

Parameters
m [input int]
n [input int]
nrhs [input int]

Returns
work [complex]
info [int]

Other Parameters
cond [input float, optional] Default: -1.0
lwork  [input int, optional] Default: -1

scipy.linalg.lapack.sgelsy

scipy.linalg.lapack.sgelsy(a, b, jptv, cond, lwork[, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for sgelsy.

Parameters

a  [input rank-2 array('f') with bounds (m,n)]
b  [input rank-2 array('f') with bounds (maxmn,nrhs)]
jptv  [input rank-1 array('i') with bounds (n)]
cond  [input float]
lwork  [input int]

Returns

v  [rank-2 array('f') with bounds (m,n) and a storage]
x  [rank-2 array('f') with bounds (maxmn,nrhs) and b storage]
j  [rank-1 array('i') with bounds (n) and jptv storage]
rank  [int]
info  [int]

Other Parameters

overwrite_a  [input int, optional] Default: 0
overwrite_b  [input int, optional] Default: 0

scipy.linalg.lapack.dgelsy

scipy.linalg.lapack.dgelsy(a, b, jptv, cond, lwork[, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for dgelsy.

Parameters

a  [input rank-2 array('d') with bounds (m,n)]
b  [input rank-2 array('d') with bounds (maxmn,nrhs)]
jptv  [input rank-1 array('i') with bounds (n)]
cond  [input float]
lwork  [input int]

Returns

v  [rank-2 array('d') with bounds (m,n) and a storage]
x  [rank-2 array('d') with bounds (maxmn,nrhs) and b storage]
j  [rank-1 array('i') with bounds (n) and jptv storage]
rank  [int]
info  [int]

Other Parameters

overwrite_a  [input int, optional] Default: 0
overwrite_b
    [input int, optional] Default: 0

scipy.linalg.lapack.cgelsy

scipy.linalg.lapack.cgelsy(a, b, jptv, cond, lwork[, overwrite_a, overwrite_b]) = <fortran object>
Wrapper for cgelsy.

Parameters
    a
        [input rank-2 array('F') with bounds (m,n)]
    b
        [input rank-2 array('F') with bounds (maxmn,nrhs)]
    jptv
        [input rank-1 array('i') with bounds (n)]
    cond
        [input float]
    lwork
        [input int]

Returns
    v
        [rank-2 array('F') with bounds (m,n) and a storage]
    x
        [rank-2 array('F') with bounds (maxmn,nrhs) and b storage]
    j
        [rank-1 array('i') with bounds (n) and jptv storage]
    rank
        [int]
    info
        [int]

Other Parameters
    overwrite_a
        [input int, optional] Default: 0
    overwrite_b
        [input int, optional] Default: 0

scipy.linalg.lapack.zgelsy

scipy.linalg.lapack.zgelsy(a, b, jptv, cond, lwork[, overwrite_a, overwrite_b]) = <fortran object>
Wrapper for zgelsy.

Parameters
    a
        [input rank-2 array('D') with bounds (m,n)]
    b
        [input rank-2 array('D') with bounds (maxmn,nrhs)]
    jptv
        [input rank-1 array('i') with bounds (n)]
    cond
        [input float]
    lwork
        [input int]

Returns
    v
        [rank-2 array('D') with bounds (m,n) and a storage]
    x
        [rank-2 array('D') with bounds (maxmn,nrhs) and b storage]
    j
        [rank-1 array('i') with bounds (n) and jptv storage]
    rank
        [int]
    info
        [int]

Other Parameters
    overwrite_a
        [input int, optional] Default: 0
overwrite_b
    [input int, optional] Default: 0

**sdgsy_lwork**

```python
scipy.linalg.lapack.sgelsy_lwork(m, n, nrhs, cond[, lwork]) = <fortran object>
```

Wrapper for `sgelsy_lwork`.

**Parameters**

- m [input int]
- n [input int]
- nrhs [input int]
- cond [input float]

**Returns**

- work [float]
- info [int]

**Other Parameters**

- lwork [input int, optional] Default: -1

**dgsy_lwork**

```python
scipy.linalg.lapack.dgelsy_lwork(m, n, nrhs, cond[, lwork]) = <fortran object>
```

Wrapper for `dgelsy_lwork`.

**Parameters**

- m [input int]
- n [input int]
- nrhs [input int]
- cond [input float]

**Returns**

- work [float]
- info [int]

**Other Parameters**

- lwork [input int, optional] Default: -1

**cgelsy_lwork**

```python
scipy.linalg.lapack.cgelsy_lwork(m, n, nrhs, cond[, lwork]) = <fortran object>
```

Wrapper for `cgelsy_lwork`.

**Parameters**

- m [input int]
- n [input int]
- nrhs [input int]
- cond [input float]

**Returns**
work [complex]
info [int]

Other Parameters
lwork [input int, optional] Default: -1

scipy.linalg.lapack.zgelsy_lwork

scipy.linalg.lapack.zgelsy_lwork(m, n, nrhs, cond[, lwork]) = <fortran object>
Wrapper for zgelsy_lwork.

Parameters
m [input int]
n [input int]
nrhs [input int]
cond [input float]

Returns
work [complex]
info [int]

Other Parameters
lwork [input int, optional] Default: -1

scipy.linalg.lapack.sgeqp3

scipy.linalg.lapack.sgeqp3(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for sgeqp3.

Parameters
a [input rank-2 array('f') with bounds (m,n)]

Returns
qr [rank-2 array('f') with bounds (m,n) and a storage]
jpvt [rank-1 array('i') with bounds (n)]
tau [rank-1 array('f') with bounds (MIN(m,n))]
work [rank-1 array('f') with bounds (MAX(lwork,1))]
info [int]

Other Parameters
overwrite_a
    [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*(n+1),1)
scipy.linalg.lapack.dgeqp3

scipy.linalg.lapack.dgeqp3 \(\text{\texttt{a}, lwork, overwrite\_a} \) = <fortran object>  
Wrapper for dgeqp3.

Parameters

\(a\)  
[input rank-2 array('d') with bounds (m,n)]

Returns

\(qr\)  
[rank-2 array('d') with bounds (m,n) and a storage]
\(jpvt\)  
[rank-1 array('i') with bounds (n)]
\(tau\)  
[rank-1 array('d') with bounds (MIN(m,n))]
\(work\)  
[rank-1 array('d') with bounds (MAX(lwork,1))]
\(info\)  
[int]

Other Parameters

\(\text{overwrite\_a}\)  
[input int, optional] Default: 0
\(lwork\)  
[input int, optional] Default: max(3*(n+1),1)

scipy.linalg.lapack.cgeqp3

scipy.linalg.lapack.cgeqp3 \(\text{\texttt{a}, lwork, overwrite\_a} \) = <fortran object>  
Wrapper for cgeqp3.

Parameters

\(a\)  
[input rank-2 array('F') with bounds (m,n)]

Returns

\(qr\)  
[rank-2 array('F') with bounds (m,n) and a storage]
\(jpvt\)  
[rank-1 array('i') with bounds (n)]
\(tau\)  
[rank-1 array('F') with bounds (MIN(m,n))]
\(work\)  
[rank-1 array('F') with bounds (MAX(lwork,1))]
\(info\)  
[int]

Other Parameters

\(\text{overwrite\_a}\)  
[input int, optional] Default: 0
\(lwork\)  
[input int, optional] Default: max(3*(n+1),1)

scipy.linalg.lapack.zgeqp3

scipy.linalg.lapack.zgeqp3 \(\text{\texttt{a}, lwork, overwrite\_a} \) = <fortran object>  
Wrapper for zgeqp3.

Parameters

\(a\)  
[input rank-2 array('D') with bounds (m,n)]

Returns

\(qr\)  
[rank-2 array('D') with bounds (m,n) and a storage]
\(jpvt\)  
[rank-1 array('i') with bounds (n)]
\(tau\)  
[rank-1 array('D') with bounds (MIN(m,n))]

6.12. Low-level LAPACK functions (scipy.linalg.lapack)
```
work [rank-1 array('D') with bounds (MAX(lwork,1))]
info [int]

Other Parameters

overwrite_a
   [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*(n+1),1)

scipy.linalg.lapack.sgeqrf

scipy.linalg.lapack.sgeqrf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for sgeqrf.

Parameters

a [input rank-2 array('f') with bounds (m,n)]

Returns

qr [rank-2 array('f') with bounds (m,n) and a storage]
tau [rank-1 array('f') with bounds (MIN(m,n))]
work [rank-1 array('f') with bounds (MAX(lwork,1))]
info [int]

Other Parameters

overwrite_a
   [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.dgeqrf

scipy.linalg.lapack.dgeqrf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for dgeqrf.

Parameters

a [input rank-2 array('d') with bounds (m,n)]

Returns

qr [rank-2 array('d') with bounds (m,n) and a storage]
tau [rank-1 array('d') with bounds (MIN(m,n))]
work [rank-1 array('d') with bounds (MAX(lwork,1))]
info [int]

Other Parameters

overwrite_a
   [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)
```
scipy.linalg.lapack.cgeqrf

scipy.linalg.lapack.cgeqrf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for cgeqrf.

Parameters

a [input rank-2 array('F') with bounds (m,n)]

Returns

qr [rank-2 array('F') with bounds (m,n) and a storage]
tau [rank-1 array('F') with bounds (MIN(m,n))]
work [rank-1 array('F') with bounds (MAX(lwork,1))]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.zgeqrf

scipy.linalg.lapack.zgeqrf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for zgeqrf.

Parameters

a [input rank-2 array('D') with bounds (m,n)]

Returns

qr [rank-2 array('D') with bounds (m,n) and a storage]
tau [rank-1 array('D') with bounds (MIN(m,n))]
work [rank-1 array('D') with bounds (MAX(lwork,1))]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.sgeqrf_lwork

scipy.linalg.lapack.sgeqrf_lwork(m, n) = <fortran object>
Wrapper for sgeqrf_lwork.

Parameters

m [input int]
n [input int]

Returns

work [float]
info [int]
scipy.linalg.lapack.dgeqrf_lwork

scipy.linalg.lapack.dgeqrf_lwork(m, n) = <fortran object>
Wrapper for dgeqrf_lwork.

Parameters
m [input int]
n [input int]

Returns
work [float]
info [int]

scipy.linalg.lapack.cgeqrf_lwork

scipy.linalg.lapack.cgeqrf_lwork(m, n) = <fortran object>
Wrapper for cgeqrf_lwork.

Parameters
m [input int]
n [input int]

Returns
work [complex]
info [int]

scipy.linalg.lapack.zgeqrf_lwork

scipy.linalg.lapack.zgeqrf_lwork(m, n) = <fortran object>
Wrapper for zgeqrf_lwork.

Parameters
m [input int]
n [input int]

Returns
work [complex]
info [int]

scipy.linalg.lapack.sgeqrfp

scipy.linalg.lapack.sgeqrfp(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for sgeqrfp.

Parameters
a [input rank-2 array('f') with bounds (m,n)]

Returns
qr [rank-2 array('f') with bounds (m,n) and a storage]
tau [rank-1 array('f') with bounds (MIN(m,n))]
info [int]
Other Parameters

overwrite_a
[input int, optional] Default: 0
lwork [input int, optional] Default: MAX(1, n)

scipy.linalg.lapack.dgeqrfp

scipy.linalg.lapack.dgeqrfp(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for dgeqrfp.

Parameters

a [input rank-2 array('d') with bounds (m,n)]

Returns

qr [rank-2 array('d') with bounds (m,n) and a storage]
tau [rank-1 array('d') with bounds (MIN(m,n))]
info [int]

Other Parameters

overwrite_a
[input int, optional] Default: 0
lwork [input int, optional] Default: MAX(1, n)

scipy.linalg.lapack.cgeqrfp

scipy.linalg.lapack.cgeqrfp(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for cgeqrfp.

Parameters

a [input rank-2 array('F') with bounds (m,n)]

Returns

qr [rank-2 array('F') with bounds (m,n) and a storage]
tau [rank-1 array('F') with bounds (MIN(m,n))]
info [int]

Other Parameters

overwrite_a
[input int, optional] Default: 0
lwork [input int, optional] Default: MAX(1, n)

scipy.linalg.lapack.zgeqrfp

scipy.linalg.lapack.zgeqrfp(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for zgeqrfp.

Parameters

a    [input rank-2 array('D') with bounds (m,n)]

Returns

qr   [rank-2 array('D') with bounds (m,n) and a storage]
tau  [rank-1 array('D') with bounds (MIN(m,n))]
info  [int]

Other Parameters

overwrite_a
    [input int, optional] Default: 0
lwork  [input int, optional] Default: MAX(1, n)

scipy.linalg.lapack.sgeqrfp_lwork

scipy.linalg.lapack.sgeqrfp_lwork(m, n) = <fortran object>
Wrapper for sgeqrfp_lwork.

Parameters

m    [input int]
n    [input int]

Returns

work  [float]
info  [int]

scipy.linalg.lapack.dgeqrfp_lwork

scipy.linalg.lapack.dgeqrfp_lwork(m, n) = <fortran object>
Wrapper for dgeqrfp_lwork.

Parameters

m    [input int]
n    [input int]

Returns

work  [float]
info  [int]
scipy.linalg.lapack.cgeqrfp_lwork

scipy.linalg.lapack.cgeqrfp_lwork(m, n) = <fortran object>
Wrapper for cgeqrfp_lwork.

Parameters
m [input int]
n [input int]

Returns
work [complex]
info [int]

scipy.linalg.lapack.zgeqrfp_lwork

scipy.linalg.lapack.zgeqrfp_lwork(m, n) = <fortran object>
Wrapper for zgeqrfp_lwork.

Parameters
m [input int]
n [input int]

Returns
work [complex]
info [int]

scipy.linalg.lapack.sgerqf

scipy.linalg.lapack.sgerqf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for sgerqf.

Parameters
a [input rank-2 array('f') with bounds (m,n)]

Returns
qr [rank-2 array('f') with bounds (m,n) and a storage]
tau [rank-1 array('f') with bounds (MIN(m,n))]
work [rank-1 array('f') with bounds (MAX(lwork,1))]
info [int]

Other Parameters
overwrite_a

[optional] Default: 0
lwork [input int, optional] Default: max(3*m,1)
scipy.linalg.lapack.dgerqf

scipy.linalg.lapack.dgerqf(a[, lwork, overwrite_a]) = <fortran object>

Wrapper for dgerqf.

Parameters
   a       [input rank-2 array('d') with bounds (m,n)]

Returns
   qr      [rank-2 array('d') with bounds (m,n) and a storage]
   tau     [rank-1 array('d') with bounds (MIN(m,n))]
   work    [rank-1 array('d') with bounds (MAX(lwork,1))]
   info    [int]

Other Parameters
   overwrite_a
     [input int, optional] Default: 0
   lwork    [input int, optional] Default: max(3*m,1)

scipy.linalg.lapack.cgerqf

scipy.linalg.lapack.cgerqf(a[, lwork, overwrite_a]) = <fortran object>

Wrapper for cgerqf.

Parameters
   a       [input rank-2 array('F') with bounds (m,n)]

Returns
   qr      [rank-2 array('F') with bounds (m,n) and a storage]
   tau     [rank-1 array('F') with bounds (MIN(m,n))]
   work    [rank-1 array('F') with bounds (MAX(lwork,1))]
   info    [int]

Other Parameters
   overwrite_a
     [input int, optional] Default: 0
   lwork    [input int, optional] Default: max(3*m,1)

scipy.linalg.lapack.zgerqf

scipy.linalg.lapack.zgerqf(a[, lwork, overwrite_a]) = <fortran object>

Wrapper for zgerqf.

Parameters
   a       [input rank-2 array('D') with bounds (m,n)]

Returns
   qr      [rank-2 array('D') with bounds (m,n) and a storage]
   tau     [rank-1 array('D') with bounds (MIN(m,n))]
   work    [rank-1 array('D') with bounds (MAX(lwork,1))]
   info    [int]
6.12. Low-level LAPACK functions (scipy.linalg.lapack)

Other Parameters

overwrite_a
[input int, optional] Default: 0
lwork [input int, optional] Default: max(3*m,1)

scipy.linalg.lapack.sgesdd

scipy.linalg.lapack.sgesdd(a[, compute_uv, full_matrices, lwork, overwrite_a]) = <fortran object>

Wrapper for sgesdd.

Parameters

a [input rank-2 array('f') with bounds (m,n)]

Returns

u [rank-2 array('f') with bounds (u0,u1)]
s [rank-1 array('f') with bounds (minmn)]
vt [rank-2 array('f') with bounds (vt0,vt1)]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
compute_uv [input int, optional] Default: 1
full_matrices [input int, optional] Default: 1
lwork [input int, optional] Default: max((compute_uv?4*minmn*minmn+MAX(m,n)+9*minmn:MAX(14*minmn+4,10*minmn+2+25*(25+8))+MAX(m,n)),1)

scipy.linalg.lapack.dgesdd

scipy.linalg.lapack.dgesdd(a[, compute_uv, full_matrices, lwork, overwrite_a]) = <fortran object>

Wrapper for dgesdd.

Parameters

a [input rank-2 array('d') with bounds (m,n)]

Returns

u [rank-2 array('d') with bounds (u0,u1)]
s [rank-1 array('d') with bounds (minmn)]
vt [rank-2 array('d') with bounds (vt0,vt1)]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
compute_uv [input int, optional] Default: 1
full_matrices [input int, optional] Default: 1
lwork [input int, optional] Default: max((compute_uv?4*minmn*minmn+MAX(m,n)+9*minmn:MAX(14*minmn+4,10*minmn+2+25*(25+8))+MAX(m,n)),1)
scipy.linalg.lapack.cgesdd

scipy.linalg.lapack.cgesdd(a[:, compute_uv, full_matrices, lwork, overwrite_a]) = <fortran object>
Wrapper for cgesdd.

Parameters
a [input rank-2 array('F') with bounds (m,n)]

Returns
u [rank-2 array('F') with bounds (u0,u1)]
s [rank-1 array('f') with bounds (minmn)]
vt [rank-2 array('F') with bounds (vt0,vt1)]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
compute_uv [input int, optional] Default: 1
full_matrices [input int, optional] Default: 1
lwork [input int, optional] Default: max((compute_uv?2*minmn*minmn+MAX(m,n)+2*minmn:2*minmn+MAX(m,n)),1)

scipy.linalg.lapack.zgesdd

scipy.linalg.lapack.zgesdd(a[:, compute_uv, full_matrices, lwork, overwrite_a]) = <fortran object>
Wrapper for zgesdd.

Parameters
a [input rank-2 array('D') with bounds (m,n)]

Returns
u [rank-2 array('D') with bounds (u0,u1)]
s [rank-1 array('d') with bounds (minmn)]
vt [rank-2 array('D') with bounds (vt0,vt1)]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
compute_uv [input int, optional] Default: 1
full_matrices [input int, optional] Default: 1
lwork [input int, optional] Default: max((compute_uv?2*minmn*minmn+MAX(m,n)+2*minmn:2*minmn+MAX(m,n)),1)
scipy.linalg.lapack.sgesdd_lwork

Wrapper for sgesdd_lwork.

Parameters
- \( m \) [input int]
- \( n \) [input int]

Returns
- \( \text{work} \) [float]
- \( \text{info} \) [int]

Other Parameters
- \( \text{compute}_\text{uv} \) [input int, optional] Default: 1
- \( \text{full}_\text{matrices} \) [input int, optional] Default: 1

scipy.linalg.lapack.dgesdd_lwork

Wrapper for dgesdd_lwork.

Parameters
- \( m \) [input int]
- \( n \) [input int]

Returns
- \( \text{work} \) [float]
- \( \text{info} \) [int]

Other Parameters
- \( \text{compute}_\text{uv} \) [input int, optional] Default: 1
- \( \text{full}_\text{matrices} \) [input int, optional] Default: 1

scipy.linalg.lapack.cgesdd_lwork

Wrapper for cgesdd_lwork.

Parameters
- \( m \) [input int]
- \( n \) [input int]

Returns
- \( \text{work} \) [complex]
info [int]

Other Parameters

compute_uv [input int, optional] Default: 1
full_matrices [input int, optional] Default: 1

scipy.linalg.lapack.zgesdd_lwork

scipy.linalg.lapack.zgesdd_lwork(m, n[, compute_uv, full_matrices]) = <fortran object>
Wrapper for zgesdd_lwork.

Parameters

m [input int]
n [input int]

Returns

work [complex]
info [int]

Other Parameters

compute_uv [input int, optional] Default: 1
full_matrices [input int, optional] Default: 1

scipy.linalg.lapack.sgesv

scipy.linalg.lapack.sgesv(a, b[, overwrite_a, overwrite_b]) = <fortran object>
Wrapper for sgesv.

Parameters

a [input rank-2 array('f') with bounds (n,n)]
b [input rank-2 array('f') with bounds (n,nrhs)]

Returns

lu [rank-2 array('f') with bounds (n,n) and a storage]
piv [rank-1 array('i') with bounds (n)]
x [rank-2 array('f') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
scipy.linalg.lapack.dgesv

```python
scipy.linalg.lapack.dgesv(a, b[, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for dgesv.

**Parameters**

- `a` [input rank-2 array('d') with bounds (n,n)]
- `b` [input rank-2 array('d') with bounds (n, nrhs)]

**Returns**

- `lu` [rank-2 array('d') with bounds (n,n) and a storage]
- `piv` [rank-1 array('i') with bounds (n)]
- `x` [rank-2 array('d') with bounds (n, nrhs) and b storage]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0

scipy.linalg.lapack.cgesv

```python
scipy.linalg.lapack.cgesv(a, b[, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for cgesv.

**Parameters**

- `a` [input rank-2 array('F') with bounds (n,n)]
- `b` [input rank-2 array('F') with bounds (n, nrhs)]

**Returns**

- `lu` [rank-2 array('F') with bounds (n,n) and a storage]
- `piv` [rank-1 array('i') with bounds (n)]
- `x` [rank-2 array('F') with bounds (n, nrhs) and b storage]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0

scipy.linalg.lapack.zgesv

```python
scipy.linalg.lapack.zgesv(a, b[, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for zgesv.

**Parameters**

- `a` [input rank-2 array('D') with bounds (n,n)]
- `b` [input rank-2 array('D') with bounds (n, nrhs)]

**Returns**

- `lu` [rank-2 array('D') with bounds (n,n) and a storage]
- `piv` [rank-1 array('i') with bounds (n)]
- `x` [rank-2 array('D') with bounds (n, nrhs) and b storage]
- `info` [int]

lu [rank-2 array('D') with bounds (n,n) and a storage]
piv [rank-1 array('i') with bounds (n)]
x [rank-2 array('D') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.sgesvd

scipy.linalg.lapack.sgesvd(a[, compute_uv, full_matrices, lwork, overwrite_a]) = <fortran object>

Wrapper for sgesvd.

Parameters

a [input rank-2 array('f') with bounds (m,n)]

Returns

u [rank-2 array('f') with bounds (u0,u1)]
s [rank-1 array('f') with bounds (minmn)]
vt [rank-2 array('f') with bounds (vt0,vt1)]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
compute_uv [input int, optional] Default: 1
full_matrices [input int, optional] Default: 1
lwork [input int, optional] Default: max(MAX(3*minmn+MAX(m,n),5*minmn),1)

scipy.linalg.lapack.dgesvd

scipy.linalg.lapack.dgesvd(a[, compute_uv, full_matrices, lwork, overwrite_a]) = <fortran object>

Wrapper for dgesvd.

Parameters

a [input rank-2 array('d') with bounds (m,n)]

Returns

u [rank-2 array('d') with bounds (u0,u1)]
s [rank-1 array('d') with bounds (minmn)]
vt [rank-2 array('d') with bounds (vt0,vt1)]
info [int]

Other Parameters
overwrite_a
    [input int, optional] Default: 0
compute_uv
    [input int, optional] Default: 1
full_matrices
    [input int, optional] Default: 1
lwork
    [input int, optional] Default: max(MAX(3*minmn+MAX(m,n),5*minmn),1)

**scipy.linalg.lapack.cgesvd**

```python
scipy.linalg.lapack.cgesvd(a[, compute_uv, full_matrices, lwork, overwrite_a]) = <fortran object>
```

Wrapper for cgesvd.

**Parameters**

- **a** [input rank-2 array('F') with bounds (m,n)]

**Returns**

- **u** [rank-2 array('F') with bounds (u0,u1)]
- **s** [rank-1 array('f') with bounds (minmn)]
- **vt** [rank-2 array('F') with bounds (vt0,vt1)]
- **info** [int]

**Other Parameters**

- overwrite_a [input int, optional] Default: 0
- compute_uv [input int, optional] Default: 1
- full_matrices [input int, optional] Default: 1
- lwork [input int, optional] Default: MAX(2*minmn+MAX(m,n),1)

**scipy.linalg.lapack.zgesvd**

```python
scipy.linalg.lapack.zgesvd(a[, compute_uv, full_matrices, lwork, overwrite_a]) = <fortran object>
```

Wrapper for zgesvd.

**Parameters**

- **a** [input rank-2 array('D') with bounds (m,n)]

**Returns**

- **u** [rank-2 array('D') with bounds (u0,u1)]
- **s** [rank-1 array('d') with bounds (minmn)]
- **vt** [rank-2 array('D') with bounds (vt0,vt1)]
- **info** [int]

**Other Parameters**

- overwrite_a [input int, optional] Default: 0
- compute_uv [input int, optional] Default: 1
full_matrices
  [input int, optional] Default: 1
lwork
  [input int, optional] Default: MAX(2*minmn+MAX(m,n),1)

scipy.linalg.lapack.sgesvd_lwork

scipy.linalg.lapack.sgesvd_lwork(m, n[, compute_uv, full_matrices]) = <fortran object>
Wrapper for sgesvd_lwork.

Parameters
  m [input int]
  n [input int]

Returns
  work [float]
  info [int]

Other Parameters
  compute_uv
    [input int, optional] Default: 1
  full_matrices
    [input int, optional] Default: 1

scipy.linalg.lapack.dgesvd_lwork

scipy.linalg.lapack.dgesvd_lwork(m, n[, compute_uv, full_matrices]) = <fortran object>
Wrapper for dgesvd_lwork.

Parameters
  m [input int]
  n [input int]

Returns
  work [float]
  info [int]

Other Parameters
  compute_uv
    [input int, optional] Default: 1
  full_matrices
    [input int, optional] Default: 1
scipy.linalg.lapack.cgesvd_lwork

scipy.linalg.lapack.cgesvd_lwork(m, n[, compute_uv, full_matrices]) = <fortran object>
Wrapper for cgesvd_lwork.

Parameters

m [input int]
n [input int]

Returns

work [complex]
info [int]

Other Parameters

compute_uv [input int, optional] Default: 1
full_matrices [input int, optional] Default: 1

scipy.linalg.lapack.zgesvd_lwork

scipy.linalg.lapack.zgesvd_lwork(m, n[, compute_uv, full_matrices]) = <fortran object>
Wrapper for zgesvd_lwork.

Parameters

m [input int]
n [input int]

Returns

work [complex]
info [int]

Other Parameters

compute_uv [input int, optional] Default: 1
full_matrices [input int, optional] Default: 1

scipy.linalg.lapack.sgesvx

scipy.linalg.lapack.sgesvx(a, b[, fact, trans, af, ipiv, equed, r, c, overwrite_a, overwrite_b]) = <fortran object>
Wrapper for sgesvx.

Parameters

a [input rank-2 array('f') with bounds (n,n)]
b [input rank-2 array('f') with bounds (n,nrhs)]

Returns

as [rank-2 array('f') with bounds (n,n) and a storage]
### scipy.linalg.lapack.dgesvx

```python
scipy.linalg.lapack.dgesvx(a, b[, fact, trans, af, ipiv, equed, r, c, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for dgesvx.

#### Parameters

- **a**: [input rank-2 array('d') with bounds (n,n)]
- **b**: [input rank-2 array('d') with bounds (n, nrhs)]

#### Returns

- **as**: [rank-2 array('d') with bounds (n,n) and a storage]
- **lu**: [rank-2 array('d') with bounds (n,n) and af storage]
- **ipiv**: [rank-1 array('i') with bounds (n)]
- **equed**: [string(len=1)]
- **rs**: [rank-1 array('d') with bounds (n) and r storage]
- **cs**: [rank-1 array('d') with bounds (n) and c storage]
- **bs**: [rank-2 array('d') with bounds (n,nrhs) and b storage]
- **x**: [rank-2 array('d') with bounds (n,nrhs)]
- **rcond**: [float]
- **ferr**: [rank-1 array('d') with bounds (nrhs)]
- **berr**: [rank-1 array('d') with bounds (nrhs)]
- **info**: [int]

#### Other Parameters

- **fact** [input string(len=1), optional] Default: ‘E’
- **trans** [input string(len=1), optional] Default: ‘N’
- **overwrite_a** [input int, optional] Default: 0
- **af** [input rank-2 array('d') with bounds (n,n)]
- **ipiv** [input rank-1 array('i') with bounds (n)]
- **equed** [input string(len=1), optional] Default: ‘B’
- **r** [input rank-1 array('d') with bounds (n)]
- **c** [input rank-1 array('d') with bounds (n)]
- **overwrite_b** [input int, optional] Default: 0
overwrite_a
    [input int, optional] Default: 0
af
    [input rank-2 array('d') with bounds (n,n)]
ipiv
    [input rank-1 array('i') with bounds (n)]
equed
    [input string(len=1), optional] Default: ‘B’
r
    [input rank-1 array('d') with bounds (n)]
c
    [input rank-1 array('d') with bounds (n)]
overwrite_b
    [input int, optional] Default: 0

scipy.linalg.lapack.cgesvx

scipy.linalg.lapack.cgesvx(a, b[, fact, trans, af, ipiv, equed, r, c, overwrite_a, overwrite_b]) =
<fortran object>
Wrapper for cgesvx.

Parameters

a
    [input rank-2 array('F') with bounds (n,n)]
b
    [input rank-2 array('F') with bounds (n,nrhs)]

Returns

as
    [rank-2 array('F') with bounds (n,n) and a storage]
lu
    [rank-2 array('F') with bounds (n,n) and af storage]
ipiv
    [rank-1 array('i') with bounds (n)]
equed
    [string(len=1)]
rs
    [rank-1 array('f') with bounds (n) and r storage]
cs
    [rank-1 array('f') with bounds (n) and c storage]
bs
    [rank-2 array('F') with bounds (n,nrhs) and b storage]
x
    [rank-2 array('F') with bounds (n,nrhs)]
rcnd
    [float]
ferr
    [rank-1 array('f') with bounds (nrhs)]
berr
    [rank-1 array('f') with bounds (nrhs)]
info
    [int]

Other Parameters

fact
    [input string(len=1), optional] Default: ‘E’
trans
    [input string(len=1), optional] Default: ‘N’
overwrite_a
    [input int, optional] Default: 0
af
    [input rank-2 array('F') with bounds (n,n)]
ipiv
    [input rank-1 array('i') with bounds (n)]
equed
    [input string(len=1), optional] Default: ‘B’
r
    [input rank-1 array('f') with bounds (n)]
c
    [input rank-1 array('f') with bounds (n)]
overwrite_b
    [input int, optional] Default: 0

6.12. Low-level LAPACK functions (scipy.linalg.lapack)
scipy.linalg.lapack.zgesvx

scipy.linalg.lapack.zgesvx(a, b[, fact, trans, af, ipiv, equed, r, c, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for zgesvx.

Parameters

a [input rank-2 array('D') with bounds (n,n)]
b [input rank-2 array('D') with bounds (n,nrhs)]

Returns

as [rank-2 array('D') with bounds (n,n) and a storage]
lu [rank-2 array('D') with bounds (n,n) and af storage]
ipiv [rank-1 array('i') with bounds (n)]
equed [string(len=1)]
rs [rank-1 array('d') with bounds (n) and r storage]
cs [rank-1 array('d') with bounds (n) and c storage]
bs [rank-2 array('D') with bounds (n,nrhs) and b storage]
x [rank-2 array('D') with bounds (n,nrhs)]
rcnd [float]
ferr [rank-1 array('d') with bounds (nrhs)]
berr [rank-1 array('d') with bounds (nrhs)]
info [int]

Other Parameters

fact [input string(len=1), optional] Default: 'E'
trans [input string(len=1), optional] Default: 'N'
overwrite_a [input int, optional] Default: 0
af [input rank-2 array('D') with bounds (n,n)]
ipiv [input rank-1 array('i') with bounds (n)]
equed [input string(len=1), optional] Default: 'B'
r [input rank-1 array('d') with bounds (n)]
c [input rank-1 array('d') with bounds (n)]
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.sgetrf

scipy.linalg.lapack.sgetrf(a[, overwrite_a]) = <fortran object>

Wrapper for sgetrf.

Parameters

a [input rank-2 array('f') with bounds (m,n)]

Returns

lu [rank-2 array('f') with bounds (m,n) and a storage]
piv [rank-1 array('i') with bounds (MIN(m,n))] info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
scipy.linalg.lapack.dgetrf

```python
scipy.linalg.lapack.dgetrf(a[, overwrite_a]) = <fortran object>
```

Wrapper for dgetrf.

**Parameters**

- `a` [input rank-2 array('d') with bounds (m,n)]

**Returns**

- `lu` [rank-2 array('d') with bounds (m,n) and a storage]
- `piv` [rank-1 array('i') with bounds (MIN(m,n))]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0

scipy.linalg.lapack.cgetrf

```python
scipy.linalg.lapack.cgetrf(a[, overwrite_a]) = <fortran object>
```

Wrapper for cgetrf.

**Parameters**

- `a` [input rank-2 array('F') with bounds (m,n)]

**Returns**

- `lu` [rank-2 array('F') with bounds (m,n) and a storage]
- `piv` [rank-1 array('i') with bounds (MIN(m,n))]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0

scipy.linalg.lapack.zgetrf

```python
scipy.linalg.lapack.zgetrf(a[, overwrite_a]) = <fortran object>
```

Wrapper for zgetrf.

**Parameters**

- `a` [input rank-2 array('D') with bounds (m,n)]

**Returns**

- `lu` [rank-2 array('D') with bounds (m,n) and a storage]
- `piv` [rank-1 array('i') with bounds (MIN(m,n))]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0
scipy.linalg.lapack.sgetc2

`scipy.linalg.lapack.sgetc2(a[, overwrite_a]) = <fortran object>`
Wrapper for sgetc2.

**Parameters**

- `a` [input rank-2 array('f') with bounds (n,n)]

**Returns**

- `lu` [rank-2 array('f') with bounds (n,n) and a storage]
- `ipiv` [rank-1 array('i') with bounds (n)]
- `jpiv` [rank-1 array('i') with bounds (n)]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0

scipy.linalg.lapack.dgetc2

`scipy.linalg.lapack.dgetc2(a[, overwrite_a]) = <fortran object>`
Wrapper for dgetc2.

**Parameters**

- `a` [input rank-2 array('d') with bounds (n,n)]

**Returns**

- `lu` [rank-2 array('d') with bounds (n,n) and a storage]
- `ipiv` [rank-1 array('i') with bounds (n)]
- `jpiv` [rank-1 array('i') with bounds (n)]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0

scipy.linalg.lapack.cgetc2

`scipy.linalg.lapack.cgetc2(a[, overwrite_a]) = <fortran object>`
Wrapper for cgetc2.

**Parameters**

- `a` [input rank-2 array('F') with bounds (n,n)]

**Returns**

- `lu` [rank-2 array('F') with bounds (n,n) and a storage]
- `ipiv` [rank-1 array('i') with bounds (n)]
- `jpiv` [rank-1 array('i') with bounds (n)]
- `info` [int]

**Other Parameters**
overwrite_a
    [input int, optional] Default: 0

scipy.linalg.lapack.zgetc2

scipy.linalg.lapack.zgetc2(a[, overwrite_a]) = <fortran object>
Wrapper for zgetc2.

Parameters
    a       [input rank-2 array('D') with bounds (n,n)]
    overwrite_a
        [input int, optional] Default: 0

Returns
    lu     [rank-2 array('D') with bounds (n,n) and a storage]
    ipiv   [rank-1 array('i') with bounds (n)]
    jpiv   [rank-1 array('i') with bounds (n)]
    info   [int]

Other Parameters
    overwrite_a
        [input int, optional] Default: 0

scipy.linalg.lapack.sgetri

scipy.linalg.lapack.sgetri(lu, piv[, bwork, overwrite_lu]) = <fortran object>
Wrapper for sgetri.

Parameters
    lu      [input rank-2 array('f') with bounds (n,n)]
    piv     [input rank-1 array('i') with bounds (n)]
    overwrite_lu
        [input int, optional] Default: 0
    bwork   [input int, optional] Default: max(3*n,1)

Returns
    inv_a   [rank-2 array('f') with bounds (n,n) and lu storage]
    info    [int]

Other Parameters
    overwrite_lu
        [input int, optional] Default: 0

scipy.linalg.lapack.dgetri

scipy.linalg.lapack.dgetri(lu, piv[, bwork, overwrite_lu]) = <fortran object>
Wrapper for dgetri.

Parameters
    lu      [input rank-2 array('d') with bounds (n,n)]
    piv     [input rank-1 array('i') with bounds (n)]
    overwrite_lu
        [input int, optional] Default: 0
    bwork   [input int, optional] Default: max(3*n,1)

Returns
    inv_a   [rank-2 array('d') with bounds (n,n) and lu storage]
    info    [int]
Other Parameters

overwrite_lu
[input int, optional] Default: 0

lwork
[input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.cgetri

scipy.linalg.lapack.cgetri(\(lu, piv[, lwork, overwrite_lu]\)) = <fortran object>
Wrapper for cgetri.

Parameters

lu
[input rank-2 array('F') with bounds (n,n)]
piv
[input rank-1 array('i') with bounds (n)]

Returns

inv_a
[rank-2 array('F') with bounds (n,n) and lu storage]
info
[int]

Other Parameters

overwrite_lu
[input int, optional] Default: 0

lwork
[input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.zgetri

scipy.linalg.lapack.zgetri(\(lu, piv[, lwork, overwrite_lu]\)) = <fortran object>
Wrapper for zgetri.

Parameters

lu
[input rank-2 array('D') with bounds (n,n)]
piv
[input rank-1 array('i') with bounds (n)]

Returns

inv_a
[rank-2 array('D') with bounds (n,n) and lu storage]
info
[int]

Other Parameters

overwrite_lu
[input int, optional] Default: 0

lwork
[input int, optional] Default: max(3*n,1)
scipy.linalg.lapack.sgetri_lwork

scipy.linalg.lapack.sgetri_lwork(n) = <fortran object>
Wrapper for sgetri_lwork.

Parameters
n [input int]

Returns
work [float]
info [int]

scipy.linalg.lapack.dgetri_lwork

scipy.linalg.lapack.dgetri_lwork(n) = <fortran object>
Wrapper for dgetri_lwork.

Parameters
n [input int]

Returns
work [float]
info [int]

scipy.linalg.lapack.cgetri_lwork

scipy.linalg.lapack.cgetri_lwork(n) = <fortran object>
Wrapper for cgetri_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

scipy.linalg.lapack.zgetri_lwork

scipy.linalg.lapack.zgetri_lwork(n) = <fortran object>
Wrapper for zgetri_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]
### scipy.linalg.lapack.sgetrs

**scipy.linalg.lapack.sgetrs**

Wrapper for sgetrs.

**Parameters**

- `lu` [input rank-2 array('f') with bounds (n,n)]
- `piv` [input rank-1 array('i') with bounds (n)]
- `b` [input rank-2 array('f') with bounds (n,nrhs)]

**Returns**

- `x` [rank-2 array('f') with bounds (n,nrhs) and b storage]
- `info` [int]

**Other Parameters**

- `overwrite_b` [input int, optional] Default: 0
- `trans` [input int, optional] Default: 0

### scipy.linalg.lapack.dgetrs

**scipy.linalg.lapack.dgetrs**

Wrapper for dgetrs.

**Parameters**

- `lu` [input rank-2 array('d') with bounds (n,n)]
- `piv` [input rank-1 array('i') with bounds (n)]
- `b` [input rank-2 array('d') with bounds (n,nrhs)]

**Returns**

- `x` [rank-2 array('d') with bounds (n,nrhs) and b storage]
- `info` [int]

**Other Parameters**

- `overwrite_b` [input int, optional] Default: 0
- `trans` [input int, optional] Default: 0

### scipy.linalg.lapack.cgetrs

**scipy.linalg.lapack.cgetrs**

Wrapper for cgetrs.

**Parameters**

- `lu` [input rank-2 array('F') with bounds (n,n)]
- `piv` [input rank-1 array('i') with bounds (n)]
- `b` [input rank-2 array('F') with bounds (n,nrhs)]

**Returns**

- `x` [rank-2 array('F') with bounds (n,nrhs) and b storage]
- `info` [int]
### Other Parameters

- **overwrite_b**
  - [input int, optional] Default: 0
- **trans**
  - [input int, optional] Default: 0

#### scipy.linalg.lapack.zgetrs

```python
scipy.linalg.lapack.zgetrs (lu, piv[, trans, overwrite_b])
```

Wrapper for zgetrs.

**Parameters**

- **lu**
  - [input rank-2 array('D') with bounds (n,n)]
- **piv**
  - [input rank-1 array('i') with bounds (n)]
- **b**
  - [input rank-2 array('D') with bounds (n,nrhs)]

**Returns**

- **x**
  - [rank-2 array('D') with bounds (n,nrhs) and b storage]
- **info**
  - [int]

### Other Parameters

- **overwrite_b**
  - [input int, optional] Default: 0
- **trans**
  - [input int, optional] Default: 0

#### scipy.linalg.lapack.sgetrs

```python
scipy.linalg.lapack.sgetrs (lu, rhs[, ipiv, j piv, overwrite_rhs])
```

Wrapper for sgetrs.

**Parameters**

- **lu**
  - [input rank-2 array('f') with bounds (n,n)]
- **rhs**
  - [input rank-1 array('f') with bounds (n)]
- **ipiv**
  - [input rank-1 array('i') with bounds (n)]
- **jpiv**
  - [input rank-1 array('i') with bounds (n)]

**Returns**

- **x**
  - [rank-1 array('f') with bounds (n) and rhs storage]
- **scale**
  - [float]

### Other Parameters

- **overwrite_rhs**
  - [input int, optional] Default: 0
scipy.linalg.lapack.dgesc2

scipy.linalg.lapack.dgesc2(lu, rhs, ipiv[, overwrite_rhs]) = <fortran object>

Wrapper for dgesc2.

Parameters

- lu [input rank-2 array('d') with bounds (n,n)]
- rhs [input rank-1 array('d') with bounds (n)]
- ipiv [input rank-1 array('i') with bounds (n)]
- jpiv [input rank-1 array('i') with bounds (n)]

Returns

- x [rank-1 array('d') with bounds (n) and rhs storage]
- scale [float]

Other Parameters

- overwrite_rhs [input int, optional] Default: 0

scipy.linalg.lapack.cgesc2

scipy.linalg.lapack.cgesc2(lu, rhs, ipiv[, overwrite_rhs]) = <fortran object>

Wrapper for cgesc2.

Parameters

- lu [input rank-2 array('F') with bounds (n,n)]
- rhs [input rank-1 array('F') with bounds (n)]
- ipiv [input rank-1 array('i') with bounds (n)]
- jpiv [input rank-1 array('i') with bounds (n)]

Returns

- x [rank-1 array('F') with bounds (n) and rhs storage]
- scale [float]

Other Parameters

- overwrite_rhs [input int, optional] Default: 0

scipy.linalg.lapack.zgesc2

scipy.linalg.lapack.zgesc2(lu, rhs, ipiv[, overwrite_rhs]) = <fortran object>

Wrapper for zgesc2.

Parameters

- lu [input rank-2 array('D') with bounds (n,n)]
- rhs [input rank-1 array('D') with bounds (n)]
- ipiv [input rank-1 array('i') with bounds (n)]
- jpiv [input rank-1 array('i') with bounds (n)]

Returns

- x [rank-1 array('D') with bounds (n) and rhs storage]
- scale [float]
Other Parameters

overwrite_rhs
[input int, optional] Default: 0

scipy.linalg.lapack.sgges

scipy.linalg.lapack.sgges (sselect, a, b[, jobvsl, jobvsr, sort_t, ldvsl, ldvsr, lwork, sselect_extra_args, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for sgges.

Parameters

sselect [call-back function]
a [input rank-2 array('f') with bounds (lda,n)]
b [input rank-2 array('f') with bounds (ldb,n)]

Returns

a [rank-2 array('f') with bounds (lda,n)]
b [rank-2 array('f') with bounds (ldb,n)]
sdim [int]
alphar [rank-1 array('f') with bounds (n)]
alphai [rank-1 array('f') with bounds (n)]
beta [rank-1 array('f') with bounds (n)]
vsl [rank-2 array('f') with bounds (ldvsl,n)]
vsr [rank-2 array('f') with bounds (ldvsr,n)]
work [rank-1 array('f') with bounds (MAX(lwork,1))]info [int]

Other Parameters

jobvsl [input int, optional] Default: 1
jobvsr [input int, optional] Default: 1
sort_t [input int, optional] Default: 0
sselect_extra_args [input tuple, optional] Default: ()
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
ldvsl [input int, optional] Default: ((jobvsl==1)?n:1)
ldvsr [input int, optional] Default: ((jobvsr==1)?n:1)
lwork [input int, optional] Default: max(8*n+16,1)

Notes

Call-back functions:

def sselect (alphar, alphai, beta): return sselect
Required arguments:
    alphar : input float
    alphai : input float
    beta : input float
Return objects:
    sselect : int
scipy.linalg.lapack.dgges

Wrapper for dgges.

Parameters

- **dselect** [call-back function]
- **a** [input rank-2 array of 'd' with bounds (lda,n)]
- **b** [input rank-2 array of 'd' with bounds (ldb,n)]

Returns

- **a** [rank-2 array of 'd' with bounds (lda,n)]
- **b** [rank-2 array of 'd' with bounds (ldb,n)]
- **sdim** [int]
- **alphar** [rank-1 array of 'd' with bounds (n)]
- **alphai** [rank-1 array of 'd' with bounds (n)]
- **beta** [rank-1 array of 'd' with bounds (n)]
- **vsl** [rank-2 array of 'd' with bounds (ldvsl,n)]
- **vsr** [rank-2 array of 'd' with bounds (ldvsr,n)]
- **work** [rank-1 array of 'd' with bounds (MAX(lwork,1))]  
- **info** [int]

Other Parameters

- **jobvsl** [input int, optional] Default: 1
- **jobvsr** [input int, optional] Default: 1
- **sort_t** [input int, optional] Default: 0
- **dselect_extra_args** [input tuple, optional] Default: ()
- **overwrite_a** [input int, optional] Default: 0
- **overwrite_b** [input int, optional] Default: 0
- **ldvsl** [input int, optional] Default: ((jobvsl==1)?n:1)
- **ldvsr** [input int, optional] Default: ((jobvsr==1)?n:1)
- **lwork** [input int, optional] Default: max(8*n+16,1)

Notes

Call-back functions:

```python
def dselect(alphar, alphai, beta):  
    return dselect
```

Required arguments:
- **alphar** : input float
- **alphai** : input float
- **beta** : input float

Return objects:
- **dselect** : int
scipy.linalg.lapack.cgges

scipy.linalg.lapack.cgges (cselect, a, b, jobvsl, jobvsr, sort_t, ldvsl, ldvsr, lwork, cselect_extra_args, overwrite_a, overwrite_b) = <fortran object>

Wrapper for cgges.

Parameters

- **cselect** [call-back function]
- **a** [input rank-2 array('F') with bounds (lda,n)]
- **b** [input rank-2 array('F') with bounds (ldb,n)]

Returns

- **a** [rank-2 array('F') with bounds (lda,n)]
- **b** [rank-2 array('F') with bounds (ldb,n)]
- **sdim** [int]
- **alpha** [rank-1 array('F') with bounds (n)]
- **beta** [rank-1 array('F') with bounds (n)]
- **vsl** [rank-2 array('F') with bounds (ldvsl,n)]
- **vsr** [rank-2 array('F') with bounds (ldvsr,n)]
- **work** [rank-1 array('F') with bounds (MAX(lwork,1))]
- **info** [int]

Other Parameters

- **jobvsl** [input int, optional] Default: 1
- **jobvsr** [input int, optional] Default: 1
- **sort_t** [input int, optional] Default: 0
- **cselect_extra_args** [input tuple, optional] Default: ()
- **overwrite_a** [input int, optional] Default: 0
- **overwrite_b** [input int, optional] Default: 0
- **ldvsl** [input int, optional] Default: ((jobvsl==1)?n:1)
- **ldvsr** [input int, optional] Default: ((jobvsr==1)?n:1)
- **lwork** [input int, optional] Default: max(2*n,1)

Notes

Call-back functions:

```python
def cselect (alpha,beta): return cselect
```

Required arguments:

- **alpha** : input complex
- **beta** : input complex

Return objects:

- **cselect** : int

**scipy.linalg.lapack.zgges**

Wrapper for zgges.

### Parameters

- **zselect** [call-back function]
- **a** [input rank-2 array(‘D’) with bounds (lda,n)]
- **b** [input rank-2 array(‘D’) with bounds (ldb,n)]

### Returns

- **a** [rank-2 array(‘D’) with bounds (lda,n)]
- **b** [rank-2 array(‘D’) with bounds (ldb,n)]
- **sdim** [int]
- **alpha** [rank-1 array(‘D’) with bounds (n)]
- **beta** [rank-1 array(‘D’) with bounds (n)]
- **vsl** [rank-2 array(‘D’) with bounds (ldvsl,n)]
- **vsr** [rank-2 array(‘D’) with bounds (ldvsr,n)]
- **work** [rank-1 array(‘D’) with bounds (MAX(lwork,1))]
- **info** [int]

### Other Parameters

- **jobvsl** [input int, optional] Default: 1
- **jobvsr** [input int, optional] Default: 1
- **sort_t** [input int, optional] Default: 0
- **zselect_extra_args** [input tuple, optional] Default: ()
- **overwrite_a** [input int, optional] Default: 0
- **overwrite_b** [input int, optional] Default: 0
- **ldvsl** [input int, optional] Default: ((jobvsl==1)?n:1)
- **ldvsr** [input int, optional] Default: ((jobvsr==1)?n:1)
- **lwork** [input int, optional] Default: max(2*n,1)

### Notes

Call-back functions:

```python
def zselect(alpha, beta): return zselect
```

Required arguments:

- **alpha** : input complex
- **beta** : input complex

Return objects:

- **zselect** : int
scipy.linalg.lapack.sgev

scipy.linalg.lapack.sgev(a, b[, compute_vl, compute_vr, lwork, overwrite_a, overwrite_b]) =
<fortran object>

Wrapper for sgeev.

Parameters

a [input rank-2 array('f') with bounds (n,n)]
b [input rank-2 array('f') with bounds (n,n)]

Returns

alphar [rank-1 array('f') with bounds (n)]
alphei [rank-1 array('f') with bounds (n)]
beta [rank-1 array('f') with bounds (n)]
vl [rank-2 array('f') with bounds (ldvl,n)]
vr [rank-2 array('f') with bounds (ldvr,n)]
work [rank-1 array('f') with bounds (MAX(lwork,1))] info [int]

Other Parameters

compute_vl [input int, optional] Default: 1
compute_vr [input int, optional] Default: 1
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
lwork [input int, optional] Default: max(8*n,1)

scipy.linalg.lapack.dgev

scipy.linalg.lapack.dgev(a, b[, compute_vl, compute_vr, lwork, overwrite_a, overwrite_b]) =
<fortran object>

Wrapper for dgeev.

Parameters

a [input rank-2 array('d') with bounds (n,n)]
b [input rank-2 array('d') with bounds (n,n)]

Returns

alphar [rank-1 array('d') with bounds (n)]
alphei [rank-1 array('d') with bounds (n)]
beta [rank-1 array('d') with bounds (n)]
vl [rank-2 array('d') with bounds (ldvl,n)]
vr [rank-2 array('d') with bounds (ldvr,n)]
work [rank-1 array('d') with bounds (MAX(lwork,1))] info [int]

Other Parameters

compute_vl [input int, optional] Default: 1
```python
compute_vr
    [input int, optional] Default: 1
overwrite_a
    [input int, optional] Default: 0
overwrite_b
    [input int, optional] Default: 0
lwork
    [input int, optional] Default: max(8*n,1)

scipy.linalg.lapack.cggev

scipy.linalg.lapack.cggev(a, b[, compute_vl, compute_vr, lwork, overwrite_a, overwrite_b]) =
    <fortran object>
Wrapper for cggev.

Parameters
a
    [input rank-2 array('F') with bounds (n,n)]
b
    [input rank-2 array('F') with bounds (n,n)]

Returns
alpha
    [rank-1 array('F') with bounds (n)]
beta
    [rank-1 array('F') with bounds (n)]
vl
    [rank-2 array('F') with bounds (ldvl,n)]
vr
    [rank-2 array('F') with bounds (ldvr,n)]
work
    [rank-1 array('F') with bounds (MAX(lwork,1))]
info
    [int]

Other Parameters
compute_vl
    [input int, optional] Default: 1
compute_vr
    [input int, optional] Default: 1
overwrite_a
    [input int, optional] Default: 0
overwrite_b
    [input int, optional] Default: 0
lwork
    [input int, optional] Default: max(2*n,1)

scipy.linalg.lapack.zggev

scipy.linalg.lapack.zggev(a, b[, compute_vl, compute_vr, lwork, overwrite_a, overwrite_b]) =
    <fortran object>
Wrapper for zggev.

Parameters
a
    [input rank-2 array('D') with bounds (n,n)]
b
    [input rank-2 array('D') with bounds (n,n)]

Returns
alpha
    [rank-1 array('D') with bounds (n)]
beta
    [rank-1 array('D') with bounds (n)]
vl
    [rank-2 array('D') with bounds (ldvl,n)]
vr
    [rank-2 array('D') with bounds (ldvr,n)]
```

**work**  
(rank-1 array('D') with bounds (MAX(lwork,1))]

**info**  
[int]

*Other Parameters*

- **compute_vl**  
[input int, optional] Default: 1
- **compute_vr**  
[input int, optional] Default: 1
- **overwrite_a**  
[input int, optional] Default: 0
- **overwrite_b**  
[input int, optional] Default: 0
- **lwork**  
[input int, optional] Default: max(2*n,1)

**scipy.linalg.lapack.sgglse**

```python
scipy.linalg.lapack.sgglse(a, b, c, d[, lwork, overwrite_a, overwrite_b, overwrite_c, overwrite_d])
```

*Wrapper for sglse.*

**Parameters**

- **a**  
(input rank-2 array('f') with bounds (m,n])
- **b**  
(input rank-2 array('f') with bounds (p,n])
- **c**  
(input rank-1 array('f') with bounds (m])
- **d**  
(input rank-1 array('f') with bounds (p])

**Returns**

- **t**  
(rank-2 array('f') with bounds (m,n) and a storage]
- **r**  
(rank-2 array('f') with bounds (p,n) and b storage]
- **res**  
(rank-1 array('f') with bounds (m) and c storage]
- **x**  
(rank-1 array('f') with bounds (n])
- **info**  
[int]

*Other Parameters*

- **overwrite_a**  
[input int, optional] Default: 0
- **overwrite_b**  
[input int, optional] Default: 0
- **overwrite_c**  
[input int, optional] Default: 0
- **overwrite_d**  
[input int, optional] Default: 0
- **lwork**  
[input int, optional] Default: max(m+n+p,1)
scipy.linalg.lapack.dgglse

scipy.linalg.lapack.dgglse(a, b, c, d[, lwork, overwrite_a, overwrite_b, overwrite_c, overwrite_d])

= <fortran object>

Wrapper for dgglse.

Parameters

a [input rank-2 array('d') with bounds (m,n)]
b [input rank-2 array('d') with bounds (p,n)]
c [input rank-1 array('d') with bounds (m)]
d [input rank-1 array('d') with bounds (p)]

Returns

t [rank-2 array('d') with bounds (m,n) and a storage]
r [rank-2 array('d') with bounds (p,n) and b storage]
res [rank-1 array('d') with bounds (m) and c storage]
x [rank-1 array('d') with bounds (n)]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
overwrite_c [input int, optional] Default: 0
overwrite_d [input int, optional] Default: 0
lwork [input int, optional] Default: max(m+n+p,1)

scipy.linalg.lapack.cgglse

scipy.linalg.lapack.cgglse(a, b, c, d[, lwork, overwrite_a, overwrite_b, overwrite_c, overwrite_d])

= <fortran object>

Wrapper for cgglse.

Parameters

a [input rank-2 array('F') with bounds (m,n)]
b [input rank-2 array('F') with bounds (p,n)]
c [input rank-1 array('F') with bounds (m)]
d [input rank-1 array('F') with bounds (p)]

Returns

t [rank-2 array('F') with bounds (m,n) and a storage]
r [rank-2 array('F') with bounds (p,n) and b storage]
res [rank-1 array('F') with bounds (m) and c storage]
x [rank-1 array('F') with bounds (n)]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0

6.12. Low-level LAPACK functions (scipy.linalg.lapack)

```python
overwrite_b
    [input int, optional] Default: 0
overwrite_c
    [input int, optional] Default: 0
overwrite_d
    [input int, optional] Default: 0
lwork
    [input int, optional] Default: max(m+n+p,1)
```

**scipy.linalg.lapack.zgglse**

```python
scipy.linalg.lapack.zgglse(a, b, c, d[, lwork, overwrite_a, overwrite_b, overwrite_c, overwrite_d]) = <fortran object>
```

Wrapper for zgglse.

**Parameters**
- **a** [input rank-2 array('D') with bounds (m,n)]
- **b** [input rank-2 array('D') with bounds (p,n)]
- **c** [input rank-1 array('D') with bounds (m)]
- **d** [input rank-1 array('D') with bounds (p)]

**Returns**
- **t** [rank-2 array('D') with bounds (m,n) and a storage]
- **r** [rank-2 array('D') with bounds (p,n) and b storage]
- **res** [rank-1 array('D') with bounds (m) and c storage]
- **x** [rank-1 array('D') with bounds (n)]
- **info** [int]

**Other Parameters**
- **overwrite_a**
  [input int, optional] Default: 0
- **overwrite_b**
  [input int, optional] Default: 0
- **overwrite_c**
  [input int, optional] Default: 0
- **overwrite_d**
  [input int, optional] Default: 0
- **lwork**
  [input int, optional] Default: max(m+n+p,1)

**scipy.linalg.lapack.sgglse_lwork**

```python
scipy.linalg.lapack.sgglse_lwork(m, n, p) = <fortran object>
```

Wrapper for sgglse_lwork.

**Parameters**
- **m** [input int]
- **n** [input int]
- **p** [input int]

**Returns**
- **work** [float]
- **info** [int]
scipy.linalg.lapack.dgglse_lwork

scipy.linalg.lapack.dgglse_lwork \( m, n, p \) = <fortran object>

Wrapper for dgglse_lwork.

**Parameters**

- m [input int]
- n [input int]
- p [input int]

**Returns**

- work [float]
- info [int]

scipy.linalg.lapack.cgglse_lwork

scipy.linalg.lapack.cgglse_lwork \( m, n, p \) = <fortran object>

Wrapper for cgglse_lwork.

**Parameters**

- m [input int]
- n [input int]
- p [input int]

**Returns**

- work [complex]
- info [int]

scipy.linalg.lapack.zgglse_lwork

scipy.linalg.lapack.zgglse_lwork \( m, n, p \) = <fortran object>

Wrapper for zgglse_lwork.

**Parameters**

- m [input int]
- n [input int]
- p [input int]

**Returns**

- work [complex]
- info [int]
scipy.linalg.lapack.sgtsv

scipy.linalg.lapack.\texttt{sgtsv}(dl, d, du, b[, overwrite_dl, overwrite_d, overwrite_du, overwrite_b]) = <fortran object>

Wrapper for \texttt{sgtsv}.

\textbf{Parameters}

- \texttt{dl} [input rank-1 array('f') with bounds (n - 1)]
- \texttt{d} [input rank-1 array('f') with bounds (n)]
- \texttt{du} [input rank-1 array('f') with bounds (n - 1)]
- \texttt{b} [input rank-2 array('f') with bounds (n,nrhs)]

\textbf{Returns}

- \texttt{du2} [rank-1 array('f') with bounds (n - 1) and dl storage]
- \texttt{d} [rank-1 array('f') with bounds (n)]
- \texttt{du} [rank-1 array('f') with bounds (n - 1)]
- \texttt{x} [rank-2 array('f') with bounds (n,nrhs) and b storage]
- \texttt{info} [int]

\textbf{Other Parameters}

- \texttt{overwrite_dl} [input int, optional] Default: 0
- \texttt{overwrite_d} [input int, optional] Default: 0
- \texttt{overwrite_du} [input int, optional] Default: 0
- \texttt{overwrite_b} [input int, optional] Default: 0

scipy.linalg.lapack.dgtsv

scipy.linalg.lapack.\texttt{dgtsv}(dl, d, du, b[, overwrite_dl, overwrite_d, overwrite_du, overwrite_b]) = <fortran object>

Wrapper for \texttt{dgtsv}.

\textbf{Parameters}

- \texttt{dl} [input rank-1 array('d') with bounds (n - 1)]
- \texttt{d} [input rank-1 array('d') with bounds (n)]
- \texttt{du} [input rank-1 array('d') with bounds (n - 1)]
- \texttt{b} [input rank-2 array('d') with bounds (n,nrhs)]

\textbf{Returns}

- \texttt{du2} [rank-1 array('d') with bounds (n - 1) and dl storage]
- \texttt{d} [rank-1 array('d') with bounds (n)]
- \texttt{du} [rank-1 array('d') with bounds (n - 1)]
- \texttt{x} [rank-2 array('d') with bounds (n,nrhs) and b storage]
- \texttt{info} [int]

\textbf{Other Parameters}

- \texttt{overwrite_dl} [input int, optional] Default: 0
- \texttt{overwrite_d} [input int, optional] Default: 0
overwrite_du
   [input int, optional] Default: 0
overwrite_b
   [input int, optional] Default: 0

scipy.linalg.lapack.cgtsv

scipy.linalg.lapack.cgtsv(dl, d, du, b[, overwrite_dl, overwrite_d, overwrite_du, overwrite_b]) =
<fortran object>

Wrapper for cgtsv.

Parameters

dl  [input rank-1 array('F') with bounds (n - 1)]
d   [input rank-1 array('F') with bounds (n)]
du  [input rank-1 array('F') with bounds (n - 1)]
b   [input rank-2 array('F') with bounds (n,nrhs)]

Returns

du2  [rank-1 array('F') with bounds (n - 1) and dl storage]
d   [rank-1 array('F') with bounds (n)]
du  [rank-1 array('F') with bounds (n - 1)]
x   [rank-2 array('F') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters

overwrite_dl
   [input int, optional] Default: 0
overwrite_d
   [input int, optional] Default: 0
overwrite_du
   [input int, optional] Default: 0
overwrite_b
   [input int, optional] Default: 0

scipy.linalg.lapack.zgtsv

scipy.linalg.lapack.zgtsv(dl, d, du, b[, overwrite_dl, overwrite_d, overwrite_du, overwrite_b]) =
<fortran object>

Wrapper for zgtsv.

Parameters

dl  [input rank-1 array('D') with bounds (n - 1)]
d   [input rank-1 array('D') with bounds (n)]
du  [input rank-1 array('D') with bounds (n - 1)]
b   [input rank-2 array('D') with bounds (n,nrhs)]

Returns

du2  [rank-1 array('D') with bounds (n - 1) and dl storage]
d   [rank-1 array('D') with bounds (n)]
du  [rank-1 array('D') with bounds (n - 1)]
x   [rank-2 array('D') with bounds (n,nrhs) and b storage]
info [int]
**Other Parameters**

- **overwrite_dl**
  
  [input int, optional] Default: 0

- **overwrite_d**
  
  [input int, optional] Default: 0

- **overwrite_du**
  
  [input int, optional] Default: 0

- **overwrite_b**
  
  [input int, optional] Default: 0

---

**scipy.linalg.lapack.sgtsvx**

*scipy.linalg.lapack.sgtsvx*(dl, d, du[, fact, trans, dlf, df, duf, du2, ipiv]) = <fortran object>

Wrapper for *sgtsvx*.

**Parameters**

- **dl**
  
  [input rank-1 array('f') with bounds (MAX(0, n-1))]

- **d**
  
  [input rank-1 array('f') with bounds (n)]

- **du**
  
  [input rank-1 array('f') with bounds (MAX(0, n-1))]

- **b**
  
  [input rank-2 array('f') with bounds (ldb,nrhs)]

**Returns**

- **dlf**
  
  [rank-1 array('f') with bounds (MAX(0,n-1))]

- **df**
  
  [rank-1 array('f') with bounds (n)]

- **duf**
  
  [rank-1 array('f') with bounds (MAX(0,n-1))]

- **du2**
  
  [rank-1 array('f') with bounds (MAX(0,n-2))]

- **ipiv**
  
  [rank-1 array('i') with bounds (n)]

- **x**
  
  [rank-2 array('f') with bounds (ldx,nrhs)]

- **rcond**
  
  [float]

- **ferr**
  
  [rank-1 array('f') with bounds (nrhs)]

- **berr**
  
  [rank-1 array('f') with bounds (nrhs)]

- **info**
  
  [int]

**Other Parameters**

- **fact**
  
  [input string(len=1), optional] Default: ‘N’

- **trans**
  
  [input string(len=1), optional] Default: ‘N’

- **dlf**
  
  [input rank-1 array('f') with bounds (MAX(0,n-1))]

- **df**
  
  [input rank-1 array('f') with bounds (n)]

- **duf**
  
  [input rank-1 array('f') with bounds (MAX(0,n-1))]

- **du2**
  
  [input rank-1 array('f') with bounds (MAX(0,n-2))]

- **ipiv**
  
  [input rank-1 array('i') with bounds (n)]
scipy.linalg.lapack.dgtsvx

\[
\text{scipy.linalg.lapack.dgtsvx}(\text{dl}, d, \text{du}, b[, \text{fact}, \text{trans}, \text{dlf}, \text{df}, \text{duf}, \text{du2}, \text{ipiv}]) = \text{<fortran object>}
\]

Wrapper for \text{dgtsvx}.

\textbf{Parameters}

- \text{dl} [input rank-1 array('d') with bounds (MAX(0, n-1))]
- \text{d} [input rank-1 array('d') with bounds (n)]
- \text{du} [input rank-1 array('d') with bounds (MAX(0, n-1))]
- \text{b} [input rank-2 array('d') with bounds (ldb,nrhs)]

\textbf{Returns}

- \text{dlf} [rank-1 array('d') with bounds (MAX(0,n-1))]
- \text{df} [rank-1 array('d') with bounds (n)]
- \text{duf} [rank-1 array('d') with bounds (MAX(0,n-1))]
- \text{du2} [rank-1 array('d') with bounds (MAX(0,n-2))]
- \text{ipiv} [rank-1 array('i') with bounds (n)]
- \text{x} [rank-2 array('d') with bounds (ldx,nrhs)]
- \text{rcond} [float]
- \text{ferr} [rank-1 array('d') with bounds (nrhs)]
- \text{berr} [rank-1 array('d') with bounds (nrhs)]
- \text{info} [int]

\textbf{Other Parameters}

- \text{fact} [input string(len=1), optional] Default: 'N'
- \text{trans} [input string(len=1), optional] Default: 'N'
- \text{dlf} [input rank-1 array('d') with bounds (MAX(0,n-1))]
- \text{df} [input rank-1 array('d') with bounds (n)]
- \text{duf} [input rank-1 array('d') with bounds (MAX(0,n-1))]
- \text{du2} [input rank-1 array('d') with bounds (MAX(0,n-2))]
- \text{ipiv} [input rank-1 array('i') with bounds (n)]

scipy.linalg.lapack.cgtsvx

\[
\text{scipy.linalg.lapack.cgtsvx}(\text{dl}, d, \text{du}, b[, \text{fact}, \text{trans}, \text{dlf}, \text{df}, \text{duf}, \text{du2}, \text{ipiv}]) = \text{<fortran object>}
\]

Wrapper for \text{cgtsvx}.

\textbf{Parameters}

- \text{dl} [input rank-1 array('F') with bounds (MAX(0, n-1))]
- \text{d} [input rank-1 array('F') with bounds (n)]
- \text{du} [input rank-1 array('F') with bounds (MAX(0, n-1))]
- \text{b} [input rank-2 array('F') with bounds (ldb,nrhs)]

\textbf{Returns}

- \text{dlf} [rank-1 array('F') with bounds (MAX(0,n-1))]
- \text{df} [rank-1 array('F') with bounds (n)]
- \text{duf} [rank-1 array('F') with bounds (MAX(0,n-1))]
- \text{du2} [rank-1 array('F') with bounds (MAX(0,n-2))]
- \text{ipiv} [rank-1 array('i') with bounds (n)]
- \text{x} [rank-2 array('F') with bounds (ldx,nrhs)]
- \text{rcond} [float]
ferr [rank-1 array('f') with bounds (nrhs)]
berr [rank-1 array('f') with bounds (nrhs)]
info [int]

**Other Parameters**

fact [input string(len=1), optional] Default: 'N'
trans [input string(len=1), optional] Default: 'N'
dlf [input rank-1 array('F') with bounds (MAX(0,n-1))]
df [input rank-1 array('F') with bounds (n)]
duf [input rank-1 array('F') with bounds (MAX(0,n-1))]
du2 [input rank-1 array('F') with bounds (MAX(0,n-2))]
ipiv [input rank-1 array('i') with bounds (n)]

`scipy.linalg.lapack.zgtsvx`  
`scipy.linalg.lapack.zgtsvx(dl, d, du, b[, fact, trans, dlf, df, duf, du2, ipiv]) = <fortran object>`

Wrapper for zgtsvx.

**Parameters**

dl [input rank-1 array('D') with bounds (MAX(0, n-1))]
d [input rank-1 array('D') with bounds (n)]
du [input rank-1 array('D') with bounds (MAX(0, n-1))]
b [input rank-2 array('D') with bounds (ldb,nrhs)]

**Returns**

dlf [rank-1 array('D') with bounds (MAX(0, n-1))]
df [rank-1 array('D') with bounds (n)]
duf [rank-1 array('D') with bounds (MAX(0, n-1))]
du2 [rank-1 array('D') with bounds (MAX(0, n-2))]
ipiv [rank-1 array('i') with bounds (n)]
x [rank-2 array('D') with bounds (ldx,nrhs)]
rcond [float]
ferr [rank-1 array('d') with bounds (nrhs)]
berr [rank-1 array('d') with bounds (nrhs)]
info [int]

**Other Parameters**

fact [input string(len=1), optional] Default: 'N'
trans [input string(len=1), optional] Default: 'N'
dlf [input rank-1 array('D') with bounds (MAX(0, n-1))]
df [input rank-1 array('D') with bounds (n)]
duf [input rank-1 array('D') with bounds (MAX(0, n-1))]
du2 [input rank-1 array('D') with bounds (MAX(0, n-2))]
ipiv [input rank-1 array('i') with bounds (n)]
scipy.linalg.lapack.chbevd

```python
scipy.linalg.lapack.chbevd(ab[, compute_v, lower, ldab, lrwork, liwork, overwrite_ab]) =
<fortran object>
```

Wrapper for chbevd.

### Parameters
- `ab` [input rank-2 array('F') with bounds (ldab,n)]

### Returns
- `w` [rank-1 array('f') with bounds (n)]
- `z` [rank-2 array('F') with bounds (ldz,ldz)]
- `info` [int]

### Other Parameters
- `overwrite_ab` [input int, optional] Default: 1
- `compute_v` [input int, optional] Default: 1
- `lower` [input int, optional] Default: 0
- `ldab` [input int, optional] Default: shape(ab,0)
- `lrwork` [input int, optional] Default: (compute_v?1+5*n+2*n*n:n)
- `liwork` [input int, optional] Default: (compute_v?3+5*n:1)

scipy.linalg.lapack.zhbevd

```python
scipy.linalg.lapack.zhbevd(ab[, compute_v, lower, ldab, lrwork, liwork, overwrite_ab]) =
<fortran object>
```

Wrapper for zhbevd.

### Parameters
- `ab` [input rank-2 array('D') with bounds (ldab,n)]

### Returns
- `w` [rank-1 array('d') with bounds (n)]
- `z` [rank-2 array('D') with bounds (ldz,ldz)]
- `info` [int]

### Other Parameters
- `overwrite_ab` [input int, optional] Default: 1
- `compute_v` [input int, optional] Default: 1
- `lower` [input int, optional] Default: 0
- `ldab` [input int, optional] Default: shape(ab,0)
- `lrwork` [input int, optional] Default: (compute_v?1+5*n+2*n*n:n)
- `liwork` [input int, optional] Default: (compute_v?3+5*n:1)
**scipy.linalg.lapack.chbevx**

Wrapper for `chbevx`.

### Parameters
- **ab** [input rank-2 array('F') with bounds (ldab,n)]
- **vl** [input float]
- **vu** [input float]
- **il** [input int]
- **iu** [input int]

### Returns
- **w** [rank-1 array('f') with bounds (n)]
- **z** [rank-2 array('F') with bounds (ldz,mmax)]
- **m** [int]
- **ifail** [rank-1 array('i') with bounds ((compute_v?n:1))] (compute_v?n:1)]
- **info** [int]

### Other Parameters
- **overwrite_ab** [input int, optional] Default: 1
- **ldab** [input int, optional] Default: shape(ab,0)
- **compute_v** [input int, optional] Default: 1
- **range** [input int, optional] Default: 0
- **lower** [input int, optional] Default: 0
- **abstol** [input float, optional] Default: 0.0
- **mmax** [input int, optional] Default: (compute_v?(range==2?(iu-il+1):n):1)

**scipy.linalg.lapack.zhbevx**

Wrapper for `zhbevx`.

### Parameters
- **ab** [input rank-2 array('D') with bounds (ldab,n)]
- **vl** [input float]
- **vu** [input float]
- **il** [input int]
- **iu** [input int]

### Returns
- **w** [rank-1 array('d') with bounds (n)]
- **z** [rank-2 array('D') with bounds (ldz,mmax)]
- **m** [int]
- **ifail** [rank-1 array('i') with bounds ((compute_v?n:1))] (compute_v?n:1)]
- **info** [int]

### Other Parameters
overwrite_ab
  [input int, optional] Default: 1
ldab
  [input int, optional] Default: shape(ab,0)
compute_v
  [input int, optional] Default: 1
range
  [input int, optional] Default: 0
lower
  [input int, optional] Default: 0
abstol
  [input float, optional] Default: 0.0
mmax
  [input int, optional] Default: (compute_v?(range==2?(iu-il+1):n):1)

scipy.linalg.lapack.checon

scipy.linalg.lapack.checon(a, ipiv, anorm[, lower]) = <fortran object>
Wrapper for checon.

Parameters
  a     [input rank-2 array(F) with bounds (n,n)]
  ipiv  [input rank-1 array(i) with bounds (n)]
  anorm [input float]

Returns
  rcond  [float]
  info   [int]

Other Parameters
  lower  [input int, optional] Default: 0

scipy.linalg.lapack.zhecon

scipy.linalg.lapack.zhecon(a, ipiv, anorm[, lower]) = <fortran object>
Wrapper for zhecon.

Parameters
  a     [input rank-2 array(D) with bounds (n,n)]
  ipiv  [input rank-1 array(i) with bounds (n)]
  anorm [input float]

Returns
  rcond  [float]
  info   [int]

Other Parameters
  lower  [input int, optional] Default: 0
scipy.linalg.lapack.cheequb

scipy.linalg.lapack.cheequb(a[, lower]) = <fortran object>
Wrapper for cheequb.

Parameters
a [input rank-2 array('F') with bounds (lda,n)]

Returns
s [rank-1 array('f') with bounds (n)]
scond [float]
amax [float]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.zheequb

scipy.linalg.lapack.zheequb(a[, lower]) = <fortran object>
Wrapper for zheequb.

Parameters
a [input rank-2 array('D') with bounds (lda,n)]

Returns
s [rank-1 array('d') with bounds (n)]
scond [float]
amax [float]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.cheev

scipy.linalg.lapack.cheev(a[, compute_v, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for cheev.

Parameters
a [input rank-2 array('F') with bounds (n,n)]

Returns
w [rank-1 array('f') with bounds (n)]
v [rank-2 array('F') with bounds (n,n) and a storage]
info [int]

Other Parameters
compute_v [input int, optional] Default: 1
lower [input int, optional] Default: 0
overwrite_a
    [input int, optional] Default: 0
lwork     [input int, optional] Default: max(2*n-1,1)

scipy.linalg.lapack.zheev

scipy.linalg.lapack.zheev(a[, compute_v, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for zheev.

Parameters
a     [input rank-2 array('D') with bounds (n,n)]

Returns
w     [rank-1 array('d') with bounds (n)]
v     [rank-2 array('D') with bounds (n,n) and a storage]
info   [int]

Other Parameters
compute_v     [input int, optional] Default: 1
lower     [input int, optional] Default: 0
overwrite_a     [input int, optional] Default: 0
lwork     [input int, optional] Default: max(2*n-1,1)

scipy.linalg.lapack.cheev_lwork

scipy.linalg.lapack.cheev_lwork(n[, lower]) = <fortran object>
Wrapper for cheev_lwork.

Parameters
n     [input int]

Returns
work   [complex]
info    [int]

Other Parameters
lower     [input int, optional] Default: 0

scipy.linalg.lapack.zheev_lwork

scipy.linalg.lapack.zheev_lwork(n[, lower]) = <fortran object>
Wrapper for zheev_lwork.

Parameters
n     [input int]

Returns
work   [complex]
info    [int]
Other Parameters

*lower*  [input int, optional] Default: 0

scipy.linalg.lapack.cheevd

`scipy.linalg.lapack.cheevd(a[, compute_v, lower, lwork, liwork, lrwork, overwrite_a]) = <fortran object>`

Wrapper for cheevd.

Parameters

*a*  [input rank-2 array(`F`) with bounds (n,n)]

Returns

*w*  [rank-1 array(`f`) with bounds (n)]

*v*  [rank-2 array(`F`) with bounds (n,n) and a storage]

*info*  [int]

Other Parameters

*compute_v*  [input int, optional] Default: 1

*lower*  [input int, optional] Default: 0

*overwrite_a*  [input int, optional] Default: 0

*lwork*  [input int, optional] Default: max((compute_v?2*n+n*n:n+1),1)

*liwork*  [input int, optional] Default: (compute_v?3+5*n:1)

*lrwork*  [input int, optional] Default: (compute_v?1+5*n+2*n*n:n)

scipy.linalg.lapack.zheevd

`scipy.linalg.lapack.zheevd(a[, compute_v, lower, lwork, liwork, lrwork, overwrite_a]) = <fortran object>`

Wrapper for zheevd.

Parameters

*a*  [input rank-2 array(`D`) with bounds (n,n)]

Returns

*w*  [rank-1 array(`d`) with bounds (n)]

*v*  [rank-2 array(`D`) with bounds (n,n) and a storage]

*info*  [int]

Other Parameters

*compute_v*  [input int, optional] Default: 1

*lower*  [input int, optional] Default: 0

*overwrite_a*  [input int, optional] Default: 0

*lwork*  [input int, optional] Default: max((compute_v?2*n+n*n:n+1),1)

*liwork*  [input int, optional] Default: (compute_v?3+5*n:1)

*lrwork*  [input int, optional] Default: (compute_v?1+5*n+2*n*n:n)
scipy.linalg.lapack.cheevd_lwork

Wrapper for cheevd_lwork.

Parameters
- \( n \) [input int]

Returns
- work [complex]
- iwork [int]
- rwork [float]
- info [int]

Other Parameters
- compute_v [input int, optional] Default: 1
- lower [input int, optional] Default: 0

scipy.linalg.lapack.zheevd_lwork

Wrapper for zheevd_lwork.

Parameters
- \( n \) [input int]

Returns
- work [complex]
- iwork [int]
- rwork [float]
- info [int]

Other Parameters
- compute_v [input int, optional] Default: 1
- lower [input int, optional] Default: 0

scipy.linalg.lapack.cheevr

Wrapper for cheevr.

Parameters
- \( a \) [input rank-2 array('F') with bounds (n,n)]

Returns
- \( w \) [rank-1 array('f') with bounds (n)]
- \( z \) [rank-2 array('F') with bounds ((compute_v?MAX(0,n):0),(compute_v?(*range=='I'?iu-il+1:MAX(1,n)):0))]
- \( m \) [int]
isuppz [rank-1 array('i') with bounds (2*max(1,n))]  
info [int]

Other Parameters

compute_v  
[input int, optional] Default 1
range  
[input string(len=1), optional] Default 'A'
lower  
[input int, optional] Default 0
overwrite_a  
[input int, optional] Default 0
vl  
[input float, optional] Default 0.0
vu  
[input float, optional] Default 1.0
il  
[input int, optional] Default 1
iu  
[input int, optional] Default n
abstol  
[input float, optional] Default 0.0
lwork  
[input int, optional] Default max(2*n,1)
lrwork  
[input int, optional] Default max(24*n,1)
lworkspace  
[input int, optional] Default max(1,10*n)

scipy.linalg.lapack.zheevr

scipy.linalg.lapack.zheevr(a, compute_v, range, lower, vl, vu, il, iu, abstol, lwork, lrwork, lworkspace, overwrite_a) = <fortran object>

Wrapper for zheevr.

Parameters

a  
[input rank-2 array('D') with bounds (n,n)]

Returns

w  
[rank-1 array('d') with bounds (n)]
z  
[rank-2 array('D') with bounds {{compute_v?MAX(0,n):0},{compute_v? (*range=='I'?il-il+1:MAX(1,n)):0}}]
m  
[int]
isuppz [rank-1 array('i') with bounds (2*max(1,n))]
info [int]

Other Parameters

compute_v  
[input int, optional] Default 1
range  
[input string(len=1), optional] Default 'A'
lower  
[input int, optional] Default 0
overwrite_a  
[input int, optional] Default 0
vl  
[input float, optional] Default 0.0
vu  
[input float, optional] Default 1.0
il  
[input int, optional] Default 1
iu  
[input int, optional] Default n
abstol  
[input float, optional] Default 0.0
lwork  
[input int, optional] Default max(2*n,1)
lrwork  
[input int, optional] Default max(24*n,1)
lworkspace  
[input int, optional] Default max(1,10*n)
scipy.linalg.lapack.cheevr_lwork

Wrapper for cheevr_lwork.

Parameters
- n [input int]

Returns
- work [complex]
- rwork [float]
- iwork [int]
- info [int]

Other Parameters
- lower [input int, optional] Default: 0

scipy.linalg.lapack.zheevr_lwork

Wrapper for zheevr_lwork.

Parameters
- n [input int]

Returns
- work [complex]
- rwork [float]
- iwork [int]
- info [int]

Other Parameters
- lower [input int, optional] Default: 0

scipy.linalg.lapack.cheevx

Wrapper for cheevx.

Parameters
- a [input rank-2 array('F') with bounds (n,n)]

Returns
- w [rank-1 array('f') with bounds (n)]
- z [rank-2 array('F') with bounds ((compute_v*n), (compute_v?(*range=='I'?iu-il+1:MAX(1,n)):0))]
- m [int]
- ifail [rank-1 array('i') with bounds (compute_v*n)]
- info [int]

Other Parameters
**compute_v**
[input int, optional] Default 1

**range**
[input string(len=1), optional] Default 'A'

**lower**
[input int, optional] Default 0

**overwrite_a**
[input int, optional] Default 0

**vl**
[input float, optional] Default 0.0

**vu**
[input float, optional] Default 1.0

**il**
[input int, optional] Default 1

**iu**
[input int, optional] Default n

**abstol**
[input float, optional] Default 0.0

**lwork**
[input int, optional] Default max(2*n,1)

---

**scipy.linalg.lapack.zheevx**

`scipy.linalg.lapack.zheevx(a[, compute_v, range, lower, vl, vu, il, iu, abstol, lwork, overwrite_a])`

= <fortran object>

Wrapper for zheevx.

**Parameters**

**a**
[input rank-2 array('D') with bounds (n,n)]

**Returns**

**w**
[rank-1 array('d') with bounds (n)]

**z**
[rank-2 array('D') with bounds ((compute_v*n), (compute_v?(*range=='I'? iu-il+1:MAX(1,n)):0))]

**m**
[int]

**ifail**
[rank-1 array('i') with bounds (compute_v*n)]

**info**
[int]

**Other Parameters**

**compute_v**
[input int, optional] Default 1

**range**
[input string(len=1), optional] Default 'A'

**lower**
[input int, optional] Default 0

**overwrite_a**
[input int, optional] Default 0

**vl**
[input float, optional] Default 0.0

**vu**
[input float, optional] Default 1.0

**il**
[input int, optional] Default 1

**iu**
[input int, optional] Default n

**abstol**
[input float, optional] Default 0.0

**lwork**
[input int, optional] Default max(2*n,1)
scipy.linalg.lapack.cheevx_lwork

Scipy Reference Guide, Release 1.6.3

scipy.linalg.lapack.cheevx_lwork (n[, lower]) = <fortran object>
Wrapper for cheevx_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.zheevx_lwork

scipy.linalg.lapack.zheevx_lwork (n[, lower]) = <fortran object>
Wrapper for zheevx_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.chegst

scipy.linalg.lapack.chegst (a, b[, itype, lower, overwrite_a]) = <fortran object>
Wrapper for chegst.

Parameters
a [input rank-2 array('F') with bounds (n,n)]
b [input rank-2 array('F') with bounds (n,n)]

d Returns
c [rank-2 array('F') with bounds (n,n) and a storage]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
itype [input int, optional] Default: 1
lower [input int, optional] Default: 0
scipy.linalg.lapack.zhegst

scipy.linalg.lapack.zhegst(a, b[, itype, lower, overwrite_a]) = <fortran object>

Wrapper for zhegst.

Parameters

- a [input rank-2 array('D') with bounds (n,n)]
- b [input rank-2 array('D') with bounds (n,n)]

Returns

- c [rank-2 array('D') with bounds (n,n) and a storage]
- info [int]

Other Parameters

- overwrite_a [input int, optional] Default: 0
- itype [input int, optional] Default: 1
- lower [input int, optional] Default: 0

scipy.linalg.lapack.chegv

scipy.linalg.lapack.chegv(a, b[, itype, jobz, uplo, lwork, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for chegv.

Parameters

- a [input rank-2 array('F') with bounds (n,n)]
- b [input rank-2 array('F') with bounds (n,n)]

Returns

- w [rank-1 array('f') with bounds (n)]
- v [rank-2 array('F') with bounds (n,n) and a storage]
- info [int]

Other Parameters

- itype [input int, optional] Default: 1
- jobz [input string(len=1), optional] Default: ‘V’
- uplo [input string(len=1), optional] Default: ‘L’
- overwrite_a [input int, optional] Default: 0
- overwrite_b [input int, optional] Default: 0
- lwork [input int, optional] Default: max(2*n-1,1)

6.12. Low-level LAPACK functions (scipy.linalg.lapack)
### scipy.linalg.lapack.zhegv

**Description**
Wrapper for zhegv.

**Parameters**
- **a** [input rank-2 array('D') with bounds (n,n)]
- **b** [input rank-2 array('D') with bounds (n,n)]

**Returns**
- **w** [rank-1 array('d') with bounds (n)]
- **v** [rank-2 array('D') with bounds (n,n) and a storage]
- **info** [int]

**Other Parameters**
- **itype** [input int, optional] Default: 1
- **jobz** [input string(len=1), optional] Default: 'V'
- **uplo** [input string(len=1), optional] Default: 'L'
- **overwrite_a** [input int, optional] Default: 0
- **overwrite_b** [input int, optional] Default: 0
- **lwork** [input int, optional] Default: max(2*n-1,1)

### scipy.linalg.lapack.chegv_lwork

**Description**
Wrapper for chegvlwork.

**Parameters**
- **n** [input int]

**Returns**
- **work** [complex]
- **info** [int]

**Other Parameters**
- **uplo** [input string(len=1), optional] Default: ‘L’

### scipy.linalg.lapack.zhegv_lwork

**Description**
Wrapper for zhegv_lwork.

**Parameters**
- **n** [input int]

**Returns**
- **work** [complex]
- **info** [int]
**Other Parameters**

`uplo` [input string(len=1), optional] Default: 'L'

`scipy.linalg.lapack.chegvd`

`scipy.linalg.lapack.chegvd(a, b[, itype, jobz, uplo, lwork, lrwork, liwork, overwrite_a, overwrite_b]) = <fortran object>`

Wrapper for `chegvd`.

**Parameters**

- `a` [input rank-2 array('F') with bounds (n,n)]
- `b` [input rank-2 array('F') with bounds (n,n)]

**Returns**

- `w` [rank-1 array('f') with bounds (n)]
- `v` [rank-2 array('F') with bounds (n,n) with a storage]
- `info` [int]

**Other Parameters**

- `itype` [input int, optional] Default 1
- `jobz` [input string(len=1), optional] Default 'V'
- `uplo` [input string(len=1), optional] Default 'L'
- `overwrite_a` [input int, optional] Default 0
- `overwrite_b` [input int, optional] Default 0
- `lwork` [input int, optional] Default (*jobz=='N'?n+1:n*(n+2))
- `lrwork` [input int, optional] Default max((*jobz=='N'?n:2*n*n+5*n+1),1)
- `liwork` [input int, optional] Default (*jobz=='N'?1:5*n+3)

`scipy.linalg.lapack.zhegvd`

`scipy.linalg.lapack.zhegvd(a, b[, itype, jobz, uplo, lwork, lrwork, liwork, overwrite_a, overwrite_b]) = <fortran object>`

Wrapper for `zhegvd`.

**Parameters**

- `a` [input rank-2 array('D') with bounds (n,n)]
- `b` [input rank-2 array('D') with bounds (n,n)]

**Returns**

- `w` [rank-1 array('d') with bounds (n)]
- `v` [rank-2 array('D') with bounds (n,n) with a storage]
- `info` [int]

**Other Parameters**

- `itype` [input int, optional] Default 1
- `jobz` [input string(len=1), optional] Default 'V'
- `uplo` [input string(len=1), optional] Default 'L'
- `overwrite_a` [input int, optional] Default 0

```python
overwrite_b
    [input int, optional] Default 0
lwork
    [input int, optional] Default (*jobz=='N'?n+1:n*(n+2))
lrwork
    [input int, optional] Default max((*jobz=='N'?n:2*n*n+5*n+1),1)
liwork
    [input int, optional] Default (*jobz=='N'?1:5*n+3)

scipy.linalg.lapack.chegvx

scipy.linalg.lapack.chegvx(a, b, itype, jobz, range, uplo, vl, vu, il, iu, abstol, lwork, overwrite_a, overwrite_b) = <fortran object>
Wrapper for chegvx.

Parameters

a
    [input rank-2 array('F') with bounds (n,n)]
b
    [input rank-2 array('F') with bounds (n,n)]

Returns

w
    [rank-1 array('f') with bounds (n)]
z
    [rank-2 array('F') with bounds ((jobz[0]=='V'?MAX(0,n):0),
            (jobz[0]=='V'?(range[0]=='I'?iu-il+1:MAX(1,n)):0))]
m
    [int]
ifail
    [rank-1 array('i') with bounds ((jobz[0]=='N'?0:n))]
info
    [int]

Other Parameters

itype
    [input int, optional] Default: 1
jobz
    [input string(len=1), optional] Default: ‘V’
range
    [input string(len=1), optional] Default: ‘A’
uplo
    [input string(len=1), optional] Default: ‘L’
overwrite_a
    [input int, optional] Default: 0
overwrite_b
    [input int, optional] Default: 0
vl
    [input float, optional] Default: 0.0
vu
    [input float, optional] Default: 1.0
il
    [input int, optional] Default: 1
iu
    [input int, optional] Default: n
abstol
    [input float, optional] Default: 0.0
lwork
    [input int, optional] Default: max(2*n,1)

scipy.linalg.lapack.zhegvx

scipy.linalg.lapack.zhegvx(a, b, itype, jobz, range, uplo, vl, vu, il, iu, abstol, lwork, overwrite_a, overwrite_b) = <fortran object>
Wrapper for zhegvx.

Parameters

a
    [input rank-2 array('D') with bounds (n,n)]
b
    [input rank-2 array('D') with bounds (n,n)]

Returns

w
    [rank-1 array('d') with bounds (n)]
```

Chapter 6. API Reference

\[ z \] [rank-2 array('D') with bounds ((jobz[0]=='V'?MAX(0,n):0),(jobz[0]=='V'?range[0]=='I'?iul+1:MAX(1,n)):0))]
\[ m \] [int]
\[ ifail \] [rank-1 array('i') with bounds ((jobz[0]=='N'?0:n))]
\[ info \] [int]

Other Parameters

\[ itype \] [input int, optional] Default: 1
\[ jobz \] [input string(len=1), optional] Default: ‘V’
\[ range \] [input string(len=1), optional] Default: ‘A’
\[ uplo \] [input string(len=1), optional] Default: ‘L’
\[ overwrite_a \] [input int, optional] Default: 0
\[ overwrite_b \] [input int, optional] Default: 0
\[ vl \] [input float, optional] Default: 0.0
\[ vu \] [input float, optional] Default: 1.0
\[ il \] [input int, optional] Default: 1
\[ iu \] [input int, optional] Default: n
\[ abstol \] [input float, optional] Default: 0.0
\[ lwork \] [input int, optional] Default: max(2*n,1)

\texttt{scipy.linalg.lapack.chegvx_lwork}

\texttt{scipy.linalg.lapack.chegvx_lwork}(n[, uplo]) = <fortran object>

Wrapper for \texttt{chegvx_lwork}.

\textbf{Parameters}

\[ n \] [input int]

\textbf{Returns}

\textbf{work} [complex]
\textbf{info} [int]

\textbf{Other Parameters}

\[ uplo \] [input string(len=1), optional] Default: ‘L’

\texttt{scipy.linalg.lapack.zhegvx_lwork}

\texttt{scipy.linalg.lapack.zhegvx_lwork}(n[, uplo]) = <fortran object>

Wrapper for \texttt{zhegvx_lwork}.

\textbf{Parameters}

\[ n \] [input int]

\textbf{Returns}

\textbf{work} [complex]
\textbf{info} [int]

\textbf{Other Parameters}

\[ uplo \] [input string(len=1), optional] Default: ‘L’

scipy.linalg.lapack.chesv

scipy.linalg.lapack.chesv (a, b[, lwork, lower, overwrite_a, overwrite_b]) = <fortran object>
Wrapper for chesv.

Parameters

a [input rank-2 array('F') with bounds (n,n)]
b [input rank-2 array('F') with bounds (n,nrhs)]

Returns

uduh [rank-2 array('F') with bounds (n,n) and a storage]
ipiv [rank-1 array('i') with bounds (n)]
x [rank-2 array('F') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
lwork [input int, optional] Default: max(n,1)
lower [input int, optional] Default: 0

scipy.linalg.lapack.zhesv

scipy.linalg.lapack.zhesv (a, b[, lwork, lower, overwrite_a, overwrite_b]) = <fortran object>
Wrapper for zhesv.

Parameters

a [input rank-2 array('D') with bounds (n,n)]
b [input rank-2 array('D') with bounds (n,nrhs)]

Returns

uduh [rank-2 array('D') with bounds (n,n) and a storage]
ipiv [rank-1 array('i') with bounds (n)]
x [rank-2 array('D') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
lwork [input int, optional] Default: max(n,1)
lower [input int, optional] Default: 0

scipy.linalg.lapack.chesv_lwork

scipy.linalg.lapack.chesv_lwork(n[, lower]) = <fortran object>
Wrapper for chesv_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.zhesv_lwork

scipy.linalg.lapack.zhesv_lwork(n[, lower]) = <fortran object>
Wrapper for zhesv_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.chesvx

scipy.linalg.lapack.chesvx(a, b[, af, ipiv, lwork, factored, lower, overwrite_a, overwrite_b]) = <fortran object>
Wrapper for chesvx.

Parameters
a [input rank-2 array('F') with bounds (n,n)]
b [input rank-2 array('F') with bounds (n,nrhs)]

Returns
uduh [rank-2 array('F') with bounds (n,n) and af storage]
ipiv [rank-1 array('i') with bounds (n)]
x [rank-2 array('F') with bounds (n,nrhs)]
rcond [float]
ferr [rank-1 array('f') with bounds (nrhs)]
berr [rank-1 array('f') with bounds (nrhs)]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0

6.12. Low-level LAPACK functions (scipy.linalg.lapack) 1273
### scipy.linalg.lapack.zhesvx

**scipy.linalg.lapack.zhesvx**

`scipy.linalg.lapack.zhesvx(a, b[, af, ipiv, lwork, factored, lower, overwrite_a, overwrite_b]) = <fortran object>`

Wrapper for zhesvx.

#### Parameters

- **a** [input rank-2 array('D') with bounds (n,n)]
- **b** [input rank-2 array('D') with bounds (n,nrhs)]

#### Returns

- **uduh** [rank-2 array('D') with bounds (n,n) and af storage]
- **ipiv** [rank-1 array('i') with bounds (n)]
- **x** [rank-2 array('D') with bounds (n,nrhs)]
- **rcond** [float]
- **ferr** [rank-1 array('d') with bounds (nrhs)]
- **berr** [rank-1 array('d') with bounds (nrhs)]
- **info** [int]

#### Other Parameters

- **overwrite_a**
  - [input int, optional] Default: 0
- **af** [input rank-2 array('D') with bounds (n,n)]
- **ipiv** [input rank-1 array('i') with bounds (n)]
- **overwrite_b**
  - [input int, optional] Default: 0
- **lwork** [input int, optional] Default: max(2*n,1)
- **factored** [input int, optional] Default: 0
- **lower** [input int, optional] Default: 0

### scipy.linalg.lapack.chesvx_lwork

**scipy.linalg.lapack.chesvx_lwork**

`scipy.linalg.lapack.chesvx_lwork(n[, lower]) = <fortran object>`

Wrapper for chesvx_lwork.

#### Parameters

- **n** [input int]

#### Returns

- **work** [complex]
- **info** [int]

#### Other Parameters

- **lower**
  - [input int, optional] Default: 0
scipy.linalg.lapack.zhesvx_lwork

scipy.linalg.lapack.zhesvx_lwork(n[, lower]) = <fortran object>
Wrapper for zhesvx_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.chetrd

scipy.linalg.lapack.chetrd(a[, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for chetrd.

Parameters
a [input rank-2 array('F') with bounds (lda,n)]

Returns
c [rank-2 array('F') with bounds (lda,n) and a storage]
d [rank-1 array('f') with bounds (n)]
e [rank-1 array('f') with bounds (n - 1)]
tau [rank-1 array('F') with bounds (n - 1)]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: MAX(n,1)

scipy.linalg.lapack.zhetrd

scipy.linalg.lapack.zhetrd(a[, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for zhetrd.

Parameters
a [input rank-2 array('D') with bounds (lda,n)]

Returns
c [rank-2 array('D') with bounds (lda,n) and a storage]
d [rank-1 array('d') with bounds (n)]
e [rank-1 array('d') with bounds (n - 1)]
tau [rank-1 array('D') with bounds (n - 1)]
info [int]

Other Parameters

lower [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: MAX(n,1)

scipy.linalg.lapack.chetrd_lwork

scipy.linalg.lapack.chetrd_lwork(n[, lower]) = <fortran object>
Wrapper for chetrd_lwork.

Parameters

n [input int]

Returns

work [complex]
info [int]

Other Parameters

lower [input int, optional] Default: 0

scipy.linalg.lapack.zhetrd_lwork

scipy.linalg.lapack.zhetrd_lwork(n[, lower]) = <fortran object>
Wrapper for zhetrd_lwork.

Parameters

n [input int]

Returns

work [complex]
info [int]

Other Parameters

lower [input int, optional] Default: 0

scipy.linalg.lapack.chetrf

scipy.linalg.lapack.chetrf(a[, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for chetrf.

Parameters

a [input rank-2 array('F') with bounds (n,n)]

Returns

ldu [rank-2 array('F') with bounds (n,n) and a storage]
ipiv [rank-1 array('i') with bounds (n)]
info [int]

Other Parameters

lower [input int, optional] Default: 0
overwrite_a
  [input int, optional] Default: 0
lwork
  [input int, optional] Default: max(n,1)

scipy.linalg.lapack.zhetrf

scipy.linalg.lapack.zhetrf(a[, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for zhetrf.

Parameters
  a
    [input rank-2 array('D') with bounds (n,n)]

Returns
  ldu
    [rank-2 array('D') with bounds (n,n) and a storage]
ipiv
    [rank-1 array('i') with bounds (n)]
info
    [int]

Other Parameters
  lower
    [input int, optional] Default: 0
  overwrite_a
    [input int, optional] Default: 0
  lwork
    [input int, optional] Default: max(n,1)

scipy.linalg.lapack.chetrf_lwork

scipy.linalg.lapack.chetrf_lwork(n[, lower]) = <fortran object>
Wrapper for chetrf_lwork.

Parameters
  n
    [input int]

Returns
  work
    [complex]
info
    [int]

Other Parameters
  lower
    [input int, optional] Default: 0

scipy.linalg.lapack.zhetrf_lwork

scipy.linalg.lapack.zhetrf_lwork(n[, lower]) = <fortran object>
Wrapper for zhetrf_lwork.

Parameters
  n
    [input int]

Returns
  work
    [complex]
info
    [int]

Other Parameters

6.12. Low-level LAPACK functions (scipy.linalg.lapack)
**SciPy Reference Guide, Release 1.6.3**

lower  [input int, optional] Default: 0

**scipy.linalg.lapack.chfrk**

`scipy.linalg.lapack.chfrk(n, k, alpha, a[, transr, uplo, trans, overwrite_c]) = <fortran object>`

Wrapper for chfrk.

*Parameters*

- `n` [input int]
- `k` [input int]
- `alpha` [input float]
- `a` [input rank-2 array('F') with bounds (lda,ka)]
- `beta` [input float]
- `c` [input rank-1 array('F') with bounds (nt)]

*Returns*

- `cout` [rank-1 array('F') with bounds (nt) and c storage]

*Other Parameters*

- `transr` [input string(len=1), optional] Default: ‘N’
- `uplo` [input string(len=1), optional] Default: ‘U’
- `trans` [input string(len=1), optional] Default: ‘N’
- `overwrite_c` [input int, optional] Default: 0

**scipy.linalg.lapack.zhfrk**

`scipy.linalg.lapack.zhfrk(n, k, alpha, a, beta, c[, transr, uplo, trans, overwrite_c]) = <fortran object>`

Wrapper for zhfrk.

*Parameters*

- `n` [input int]
- `k` [input int]
- `alpha` [input float]
- `a` [input rank-2 array('D') with bounds (lda,ka)]
- `beta` [input float]
- `c` [input rank-1 array('D') with bounds (nt)]

*Returns*

- `cout` [rank-1 array('D') with bounds (nt) and c storage]

*Other Parameters*

- `transr` [input string(len=1), optional] Default: ‘N’
- `uplo` [input string(len=1), optional] Default: ‘U’
- `trans` [input string(len=1), optional] Default: ‘N’
- `overwrite_c` [input int, optional] Default: 0
scipy.linalg.lapack.slamch

**scipy.linalg.lapack.slamch** = `<fortran slamch`  
Wrapper for slamch.

**Parameters**

- **cmach**: [input string(len=1)]

**Returns**

- **slamch**: [float]

dtypes: (cmach = string, slamch = float)

---

scipy.linalg.lapack.dlamch

**scipy.linalg.lapack.dlamch** = `<fortran dlamch`  
Wrapper for dlamch.

**Parameters**

- **cmach**: [input string(len=1)]

**Returns**

- **dlamch**: [float]

dtypes: (cmach = string, dlamch = float)

---

scipy.linalg.lapack.slange

**scipy.linalg.lapack.slange** = `<fortran slange`  
Wrapper for slange.

**Parameters**

- **norm**: [input string(len=1)]
- **a**: [input rank-2 array('f') with bounds (m,n)]

**Returns**

- **n2**: [float]

dtypes: (norm = string, a = array(‘f’, ndim=2, shape=(m,n)), n2 = float)

---

scipy.linalg.lapack.dlange

**scipy.linalg.lapack.dlange** = `<fortran dlange`  
Wrapper for dlange.

**Parameters**

- **norm**: [input string(len=1)]
- **a**: [input rank-2 array('d') with bounds (m,n)]

**Returns**

- **n2**: [float]

dtypes: (norm = string, a = array(‘d’, ndim=2, shape=(m,n)), n2 = float)
**scipy.linalg.lapack.clange**

scipy.linalg.lapack.clange(norm, a) = <fortran clange>

Wrapper for clange.

**Parameters**

- **norm** [input string(len=1)]
- **a** [input rank-2 array('F') with bounds (m,n)]

**Returns**

- **n2** [float]

---

**scipy.linalg.lapack.zlange**

scipy.linalg.lapack.zlange(norm, a) = <fortran zlange>

Wrapper for zlange.

**Parameters**

- **norm** [input string(len=1)]
- **a** [input rank-2 array('D') with bounds (m,n)]

**Returns**

- **n2** [float]

---

**scipy.linalg.lapack.slarf**

scipy.linalg.lapack.slarf(v, tau, c, work[, side, incv, overwrite_c]) = <fortran object>

Wrapper for slarf.

**Parameters**

- **v** [input rank-1 array('f') with bounds ((side[0]=='L'?(1 + (m-1)*abs(incv)):(1 + (n-1)*abs(incv)))]]
- **tau** [input float]
- **c** [input rank-2 array('F') with bounds (m,n)]
- **work** [input rank-1 array('F') with bounds (lwork)]

**Returns**

- **c** [rank-2 array('F') with bounds (m,n)]

**Other Parameters**

- **side** [input string(len=1), optional] Default: ‘L’
- **incv** [input int, optional] Default: 1
- **overwrite_c** [input int, optional] Default: 0
scipy.linalg.lapack.dlarf

scipy.linalg.lapack.dlarf(v, tau, c[, side, incv, overwrite_c]) = <fortran object>

Wrapper for dlarf.

Parameters

v [input rank-1 array('d') with bounds ((side[0]=='L'?(1 + (m-1)*abs(incv)):(1 + (n-1)*abs(incv)))]

tau [input float]

c [input rank-2 array('d') with bounds (m,n)]

work [input rank-1 array('d') with bounds (lwork)]

Returns

c [rank-2 array('d') with bounds (m,n)]

Other Parameters

side [input string(len=1), optional] Default: 'L'

incv [input int, optional] Default: 1

overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.clarf

scipy.linalg.lapack.clarf(v, tau, c[, side, incv, overwrite_c]) = <fortran object>

Wrapper for clarf.

Parameters

v [input rank-1 array('F') with bounds ((side[0]=='L'?(1 + (m-1)*abs(incv)):(1 + (n-1)*abs(incv)))]

tau [input complex]

c [input rank-2 array('F') with bounds (m,n)]

work [input rank-1 array('F') with bounds (lwork)]

Returns

c [rank-2 array('F') with bounds (m,n)]

Other Parameters

side [input string(len=1), optional] Default: 'L'

incv [input int, optional] Default: 1

overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.zlarf

scipy.linalg.lapack.zlarf(v, tau, c[, side, incv, overwrite_c]) = <fortran object>

Wrapper for zlarf.

Parameters

v [input rank-1 array('D') with bounds ((side[0]=='L'?(1 + (m-1)*abs(incv)):(1 + (n-1)*abs(incv)))]

tau [input complex]

c [input rank-2 array('D') with bounds (m,n)]
work  [input rank-1 array('D') with bounds (lwork)]

Returns

c  [rank-2 array('D') with bounds (m,n)]

Other Parameters

side  [input string(len=1), optional] Default: 'L'
incv  [input int, optional] Default: 1
overwrite_c  [input int, optional] Default: 0

scipy.linalg.lapack.slarfg

scipy.linalg.lapack.slarfg(n, alpha, x[, incx, overwrite_x]) = <fortran object>
Wrapper for slarfg.

Parameters

n  [input int]
alpha  [input float]
x  [input rank-1 array('f') with bounds (lx)]

Returns

alpha  [float]
x  [rank-1 array('f') with bounds (lx)]
tau  [float]

Other Parameters

overwrite_x  [input int, optional] Default: 0
incx  [input int, optional] Default: 1

scipy.linalg.lapack.dlarfg

scipy.linalg.lapack.dlarfg(n, alpha, x[, incx, overwrite_x]) = <fortran object>
Wrapper for dlarfg.

Parameters

n  [input int]
alpha  [input float]
x  [input rank-1 array('d') with bounds (lx)]

Returns

alpha  [float]
x  [rank-1 array('d') with bounds (lx)]
tau  [float]

Other Parameters

overwrite_x  [input int, optional] Default: 0
incx  [input int, optional] Default: 1
scipy.linalg.lapack.clarfg

scipy.linalg.lapack.clarfg(n, alpha, x[, incx, overwrite_x]) = <fortran object>
Wrapper for clarfg.

Parameters
- n [input int]
- alpha [input complex]
- x [input rank-1 array('F') with bounds (lx)]

Returns
- alpha [complex]
- x [rank-1 array('F') with bounds (lx)]
- tau [complex]

Other Parameters
- overwrite_x [input int, optional] Default: 0
- incx [input int, optional] Default: 1

scipy.linalg.lapack.zlarfg

scipy.linalg.lapack.zlarfg(n, alpha, x[, incx, overwrite_x]) = <fortran object>
Wrapper for zlarfg.

Parameters
- n [input int]
- alpha [input complex]
- x [input rank-1 array('D') with bounds (lx)]

Returns
- alpha [complex]
- x [rank-1 array('D') with bounds (lx)]
- tau [complex]

Other Parameters
- overwrite_x [input int, optional] Default: 0
- incx [input int, optional] Default: 1

scipy.linalg.lapack.slartg

scipy.linalg.lapack.slartg(f, g) = <fortran object>
Wrapper for slartg.

Parameters
- f [input float]
- g [input float]

Returns
- cs [float]
- sn [float]
scipy.linalg.lapack.dlartg

`scipy.linalg.lapack.dlartg(f, g) = <fortran object>`
Wrapper for `dlartg`.

**Parameters**
- `f` [input float]
- `g` [input float]

**Returns**
- `cs` [float]
- `sn` [float]
- `r` [float]

scipy.linalg.lapack.clartg

`scipy.linalg.lapack.clartg(f, g) = <fortran object>`
Wrapper for `clartg`.

**Parameters**
- `f` [input complex]
- `g` [input complex]

**Returns**
- `cs` [float]
- `sn` [complex]
- `r` [complex]

scipy.linalg.lapack.zlartg

`scipy.linalg.lapack.zlartg(f, g) = <fortran object>`
Wrapper for `zlartg`.

**Parameters**
- `f` [input complex]
- `g` [input complex]

**Returns**
- `cs` [float]
- `sn` [complex]
- `r` [complex]
scipy.linalg.lapack.slasd4

scipy.linalg.lapack.slasd4(i, d[, z, rho]) = <fortran object>
Wrapper for slasd4.

Parameters
i [input int]
d [input rank-1 array('f') with bounds (n)]
z [input rank-1 array('f') with bounds (n)]

Returns
delta [rank-1 array('f') with bounds (n)]
sigma [float]
work [rank-1 array('f') with bounds (n)]
info [int]

Other Parameters
rho [input float, optional] Default: 1.0

scipy.linalg.lapack.dlasd4

scipy.linalg.lapack.dlasd4(i, d[, z, rho]) = <fortran object>
Wrapper for dlasd4.

Parameters
i [input int]
d [input rank-1 array('d') with bounds (n)]
z [input rank-1 array('d') with bounds (n)]

Returns
delta [rank-1 array('d') with bounds (n)]
sigma [float]
work [rank-1 array('d') with bounds (n)]
info [int]

Other Parameters
rho [input float, optional] Default: 1.0

scipy.linalg.lapack.slaswp

scipy.linalg.lapack.slaswp(a, piv[, k1, k2, off, inc, overwrite_a]) = <fortran object>
Wrapper for slaswp.

Parameters
a [input rank-2 array('f') with bounds (nrows,n)]
piv [input rank-1 array('i') with bounds (npiv)]

Returns
a [rank-2 array('f') with bounds (nrows,n)]

Other Parameters
`scipy.linalg.lapack.dlaswp`

scipy.linalg.lapack.dlaswp \((a, piv[, k1, k2, off, inc, overwrite_a]) = <fortran object>\)

Wrapper for dlaswp.

**Parameters**

- a: [input rank-2 array('d') with bounds (nrows,n)]
- piv: [input rank-1 array('i') with bounds (npiv)]

**Returns**

- a: [rank-2 array('d') with bounds (nrows,n)]

**Other Parameters**

- overwrite_a: [input int, optional] Default: 0
- k1: [input int, optional] Default: 0
- k2: [input int, optional] Default: npiv-1
- off: [input int, optional] Default: 0
- inc: [input int, optional] Default: 1

`scipy.linalg.lapack.claswp`

scipy.linalg.lapack.claswp \((a, piv[, k1, k2, off, inc, overwrite_a]) = <fortran object>\)

Wrapper for claswp.

**Parameters**

- a: [input rank-2 array('F') with bounds (nrows,n)]
- piv: [input rank-1 array('i') with bounds (npiv)]

**Returns**

- a: [rank-2 array('F') with bounds (nrows,n)]

**Other Parameters**

- overwrite_a: [input int, optional] Default: 0
- k1: [input int, optional] Default: 0
- k2: [input int, optional] Default: npiv-1
- off: [input int, optional] Default: 0
- inc: [input int, optional] Default: 1
scipy.linalg.lapack.zlaswp

scipy.linalg.lapack.zlaswp(a, piv[, k1, k2, off, inc, overwrite_a]) = <fortran object>
Wrapper for zlaswp.

Parameters
- **a** [input rank-2 array('D') with bounds (nrows,n)]
- **piv** [input rank-1 array('i') with bounds (npiv)]

Returns
- **a** [rank-2 array('D') with bounds (nrows,n)]

Other Parameters
- **overwrite_a** [input int, optional] Default: 0
- **k1** [input int, optional] Default: 0
- **k2** [input int, optional] Default: npiv-1
- **off** [input int, optional] Default: 0
- **inc** [input int, optional] Default: 1

scipy.linalg.lapack.slauum

scipy.linalg.lapack.slauum(c[, lower, overwrite_c]) = <fortran object>
Wrapper for slauum.

Parameters
- **c** [input rank-2 array('f') with bounds (n,n)]

Returns
- **a** [rank-2 array('f') with bounds (n,n) and c storage]
- **info** [int]

Other Parameters
- **overwrite_c** [input int, optional] Default: 0
- **lower** [input int, optional] Default: 0

scipy.linalg.lapack.dlauum

scipy.linalg.lapack.dlauum(c[, lower, overwrite_c]) = <fortran object>
Wrapper for dlauum.

Parameters
- **c** [input rank-2 array('d') with bounds (n,n)]

Returns
- **a** [rank-2 array('d') with bounds (n,n) and c storage]
- **info** [int]

Other Parameters
- **overwrite_c** [input int, optional] Default: 0
lower [input int, optional] Default: 0

scipy.linalg.lapack.clauum

scipy.linalg.lapack.clauum(c[, lower, overwrite_c]) = <fortran object>
Wrapper for clauum.

Parameters
c [input rank-2 array('F') with bounds (n,n)]

Returns
a [rank-2 array('F') with bounds (n,n) and c storage]
info [int]

Other Parameters
overwrite_c [input int, optional] Default: 0
lower [input int, optional] Default: 0

scipy.linalg.lapack.zlauum

scipy.linalg.lapack.zlauum(c[, lower, overwrite_c]) = <fortran object>
Wrapper for zlauum.

Parameters
c [input rank-2 array('D') with bounds (n,n)]

Returns
a [rank-2 array('D') with bounds (n,n) and c storage]
info [int]

Other Parameters
overwrite_c [input int, optional] Default: 0
lower [input int, optional] Default: 0

scipy.linalg.lapack.sorcsd

scipy.linalg.lapack.sorcsd(x11, x12, x21, x22[, compute_u1, compute_u2, compute_v1t, compute_v2t, trans, signs, overwrite_x11, overwrite_x12, overwrite_x21, overwrite_x22]) = <fortran object>
Wrapper for sorcsd.

Parameters
x11 [input rank-2 array('f') with bounds (p,q)]
x12 [input rank-2 array('f') with bounds (p,mmq)]
x21 [input rank-2 array('f') with bounds (mmp,q)]
x22 [input rank-2 array('f') with bounds (mmp,mmq)]

Returns
cs11 [rank-2 array('f') with bounds (p,q) and x11 storage]

6.12. Low-level LAPACK functions (scipy.linalg.lapack)

\[ \text{cs12} \quad \text{[rank-2 array('f') with bounds (p,mmq) and x12 storage]} \]
\[ \text{cs21} \quad \text{[rank-2 array('f') with bounds (mmp,q) and x21 storage]} \]
\[ \text{cs22} \quad \text{[rank-2 array('f') with bounds (mmp,mmq) and x22 storage]} \]
\[ \text{theta} \quad \text{[rank-1 array('f') with bounds (min(min(p,mmp),min(q,mmq)))]} \]
\[ \text{u1} \quad \text{[rank-2 array('f') with bounds ((compute_u1?p:0),(compute_u1?p:0))]} \]
\[ \text{u2} \quad \text{[rank-2 array('f') with bounds ((compute_u2?mmp:0),(compute_u2?mmp:0))]} \]
\[ \text{v1t} \quad \text{[rank-2 array('f') with bounds ((compute_v1t?q:0),(compute_v1t?q:0))]} \]
\[ \text{v2t} \quad \text{[rank-2 array('f') with bounds ((compute_v2t?mmq:0),(compute_v2t?mmq:0))]} \]
\[ \text{info} \quad \text{[int]} \]

**Other Parameters**

`compute_u1`
- [input int, optional] Default: 1

`compute_u2`
- [input int, optional] Default: 1

`compute_v1t`
- [input int, optional] Default: 1

`compute_v2t`
- [input int, optional] Default: 1

`trans`
- [input int, optional] Default: 0

`signs`
- [input int, optional] Default: 0

`overwrite_x11`
- [input int, optional] Default: 0

`overwrite_x12`
- [input int, optional] Default: 0

`overwrite_x21`
- [input int, optional] Default: 0

`overwrite_x22`
- [input int, optional] Default: 0

`lwork`
- [input int, optional] Default: 2+2*m+5*MAX(1,q-1)+4*MAX(1,q)+8*q

**scipy.linalg.lapack.dorcsd**

\[ \text{scipy.linalg.lapack.dorcsd}(x11, x12, x21, x22[, compute_u1, compute_u2, compute_v1t, compute_v2t, trans, signs, lwork, overwrite_x11, overwrite_x12, overwrite_x21, overwrite_x22]) = <fortran object> \]

Wrapper for `dorcsd`.

**Parameters**

- `x11` [input rank-2 array('d') with bounds (p,q)]
- `x12` [input rank-2 array('d') with bounds (p,mmq)]
- `x21` [input rank-2 array('d') with bounds (mmp,q)]
- `x22` [input rank-2 array('d') with bounds (mmp,mmq)]

**Returns**

- `cs11` [rank-2 array('d') with bounds (p,q) and x11 storage]
- `cs12` [rank-2 array('d') with bounds (p,mmq) and x12 storage]
- `cs21` [rank-2 array('d') with bounds (mmp,q) and x21 storage]
- `cs22` [rank-2 array('d') with bounds (mmp,mmq) and x22 storage]
- `theta` [rank-1 array('d') with bounds (min(min(p,mmp),min(q,mmq)))]
- `u1` [rank-2 array('d') with bounds ((compute_u1?p:0),(compute_u1?p:0))]
- `u2` [rank-2 array('d') with bounds ((compute_u2?mmp:0),(compute_u2?mmp:0))]
- `v1t` [rank-2 array('d') with bounds ((compute_v1t?q:0),(compute_v1t?q:0))]
- `v2t` [rank-2 array('d') with bounds ((compute_v2t?mmq:0),(compute_v2t?mmq:0))]

Other Parameters

- `compute_u1`
- [input int, optional] Default: 1
- `compute_u2`
- [input int, optional] Default: 1
- `compute_v1t`
- [input int, optional] Default: 1
- `compute_v2t`
- [input int, optional] Default: 1
- `trans`
- [input int, optional] Default: 0
- `signs`
- [input int, optional] Default: 0
- `overwrite_x11`
- [input int, optional] Default: 0
- `overwrite_x12`
- [input int, optional] Default: 0
- `overwrite_x21`
- [input int, optional] Default: 0
- `overwrite_x22`
- [input int, optional] Default: 0
- `lwork`
- [input int, optional] Default: 2+2*m+5*MAX(1,q-1)+4*MAX(1,q)+8*q

scipy.linalg.lapack.dorcsd

scipy.linalg.lapack.dorcsd(x11, x12, x21, x22[, compute_u1, compute_u2, compute_v1t, compute_v2t, trans, signs, lwork, overwrite_x11, overwrite_x12, overwrite_x21, overwrite_x22]) = <fortran object>

Wrapper for dorcsd.

Parameters

- `x11` [input rank-2 array('d') with bounds (p,q)]
- `x12` [input rank-2 array('d') with bounds (p,mmq)]
- `x21` [input rank-2 array('d') with bounds (mmp,q)]
- `x22` [input rank-2 array('d') with bounds (mmp,mmq)]

Returns

- `cs11` [rank-2 array('d') with bounds (p,q) and x11 storage]
- `cs12` [rank-2 array('d') with bounds (p,mmq) and x12 storage]
- `cs21` [rank-2 array('d') with bounds (mmp,q) and x21 storage]
- `cs22` [rank-2 array('d') with bounds (mmp,mmq) and x22 storage]
- `theta` [rank-1 array('d') with bounds (min(min(p,mmp),min(q,mmq)))]
- `u1` [rank-2 array('d') with bounds ((compute_u1?p:0),(compute_u1?p:0))]
- `u2` [rank-2 array('d') with bounds ((compute_u2?mmp:0),(compute_u2?mmp:0))]
- `v1t` [rank-2 array('d') with bounds ((compute_v1t?q:0),(compute_v1t?q:0))]
- `v2t` [rank-2 array('d') with bounds ((compute_v2t?mmq:0),(compute_v2t?mmq:0))]
v2t  [rank-2 array('d') with bounds ((compute_v2t?mmq:0),(compute_v2t?mmq:0))]
info  [int]

Other Parameters

compute_u1  [input int, optional] Default: 1
compute_u2  [input int, optional] Default: 1
compute_v1t  [input int, optional] Default: 1
compute_v2t  [input int, optional] Default: 1
trans  [input int, optional] Default: 0
signs  [input int, optional] Default: 0
overwrite_x11  [input int, optional] Default: 0
overwrite_x12  [input int, optional] Default: 0
overwrite_x21  [input int, optional] Default: 0
overwrite_x22  [input int, optional] Default: 0
lwork  [input int, optional] Default: 2+2*m+5*MAX(1,q-1)+4*MAX(1,q)+8*q

scipy.linalg.lapack.sorcsd_lwork

scipy.linalg.lapack.sorcsd_lwork(m, p, q) = <fortran object>
Wrapper for sorcsd_lwork.

Parameters

m  [input int]
p  [input int]
q  [input int]

Returns

work  [float]
info  [int]

scipy.linalg.lapack.dorcsd_lwork

scipy.linalg.lapack.dorcsd_lwork(m, p, q) = <fortran object>
Wrapper for dorcsd_lwork.

Parameters

m  [input int]
p  [input int]
q  [input int]

Returns

work  [float]
info  [int]
scipy.linalg.lapack.sorghr

scipy.linalg.lapack.sorghr(a, tau[, lo, hi, lwork, overwrite_a]) = <fortran object>
Wrapper for sorghr.

Parameters
a [input rank-2('F') with bounds (n,n)]
tau [input rank-1('F') with bounds (n - 1)]

Returns
ht [rank-2('F') with bounds (n,n) and a storage]
info [int]

Other Parameters
lo [input int, optional] Default: 0
hi [input int, optional] Default: n-1
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(hi-lo,1)

scipy.linalg.lapack.dorghr

scipy.linalg.lapack.dorghr(a, tau[, lo, hi, lwork, overwrite_a]) = <fortran object>
Wrapper for dorghr.

Parameters
a [input rank-2('D') with bounds (n,n)]
tau [input rank-1('D') with bounds (n - 1)]

Returns
ht [rank-2('D') with bounds (n,n) and a storage]
info [int]

Other Parameters
lo [input int, optional] Default: 0
hi [input int, optional] Default: n-1
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(hi-lo,1)

scipy.linalg.lapack.sorghr_lwork

scipy.linalg.lapack.sorghr_lwork(n[, lo, hi]) = <fortran object>
Wrapper for sorghr_lwork.

Parameters
n [input int]

Returns
work [float]
info [int]
Other Parameters

lo  [input int, optional] Default: 0
hi  [input int, optional] Default: n-1

scipy.linalg.lapack.dorghr_lwork

scipy.linalg.lapack.dorghr_lwork(n[,lo,hi]) = <fortran object>
Wrapper for dorghr_lwork.

Parameters

n   [input int]

Returns

work [float]
info [int]

Other Parameters

lo  [input int, optional] Default: 0
hi  [input int, optional] Default: n-1

scipy.linalg.lapack.sorgqr

scipy.linalg.lapack.sorgqr(a,tau[,lwork,overwrite_a]) = <fortran object>
Wrapper for sorgqr.

Parameters

a   [input rank-2 array('f') with bounds (m,n)]
tau [input rank-1 array('f') with bounds (k)]

Returns

q   [rank-2 array('f') with bounds (m,n) and a storage]
work [rank-1 array('f') with bounds (MAX(lwork,1))]
info [int]

Other Parameters

overwrite_a

[lwork, overwrite_a]
   [input int, optional] Default: 0
   [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.dorgqr

scipy.linalg.lapack.dorgqr(a,tau[,lwork,overwrite_a]) = <fortran object>
Wrapper for dorgqr.

Parameters

a   [input rank-2 array('d') with bounds (m,n)]
tau [input rank-1 array('d') with bounds (k)]

Returns

q   [rank-2 array('d') with bounds (m,n) and a storage]
work [rank-1 array('d') with bounds (MAX(lwork,1))]

1292 Chapter 6. API Reference
```python
info [int]

Other Parameters

overwrite_a
[input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.sorgrq

scipy.linalg.lapack.sorgrq (a, tau[, lwork, overwrite_a]) = <fortran object>
Wrapper for sorgrq.

Parameters

a [input rank-2 array('f') with bounds (m,n)]
tau [input rank-1 array('f') with bounds (k)]

Returns

q [rank-2 array('f') with bounds (m,n) and a storage]
work [rank-1 array('f') with bounds (MAX(lwork,1))] info [int]

Other Parameters

overwrite_a
[input int, optional] Default: 0
lwork [input int, optional] Default: max(3*m,1)

scipy.linalg.lapack.dorgrq

scipy.linalg.lapack.dorgrq (a, tau[, lwork, overwrite_a]) = <fortran object>
Wrapper for dorgrq.

Parameters

a [input rank-2 array('d') with bounds (m,n)]
tau [input rank-1 array('d') with bounds (k)]

Returns

q [rank-2 array('d') with bounds (m,n) and a storage]
work [rank-1 array('d') with bounds (MAX(lwork,1))] info [int]

Other Parameters

overwrite_a
[input int, optional] Default: 0
lwork [input int, optional] Default: max(3*m,1)
```

6.12. Low-level LAPACK functions (scipy.linalg.lapack)
scipy.linalg.lapack.sormqr

scipy.linalg.lapack.sormqr(side, trans, a, tau, c, lwork[, overwrite_c]) = <fortran object>
Wrapper for sormqr.

Parameters

side [input string(len=1)]
trans [input string(len=1)]
a [input rank-2 array('f') with bounds (lda,k)]
tau [input rank-1 array('f') with bounds (k)]
c [input rank-2 array('f') with bounds (ldc,n)]
lwork [input int]

Returns

cq [rank-2 array('f') with bounds (ldc,n) and c storage]
work [rank-1 array('f') with bounds (MAX(lwork,1))]
info [int]

Other Parameters

overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.dormqr

scipy.linalg.lapack.dormqr(side, trans, a, tau, c, lwork[, overwrite_c]) = <fortran object>
Wrapper for dormqr.

Parameters

side [input string(len=1)]
trans [input string(len=1)]
a [input rank-2 array('d') with bounds (lda,k)]
tau [input rank-1 array('d') with bounds (k)]
c [input rank-2 array('d') with bounds (ldc,n)]
lwork [input int]

Returns

cq [rank-2 array('d') with bounds (ldc,n) and c storage]
work [rank-1 array('d') with bounds (MAX(lwork,1))]
info [int]

Other Parameters

overwrite_c [input int, optional] Default: 0
### scipy.linalg.lapack.sormrz

**Wrapper for** `sormrz`.

**Parameters**
- `a` [input rank-2 array('f') with bounds (k,nt)]
- `tau` [input rank-1 array('f') with bounds (k)]
- `c` [input rank-2 array('f') with bounds (m,n)]

**Returns**
- `cq` [rank-2 array('f') with bounds (m,n) and c storage]
- `info` [int]

**Other Parameters**
- `side` [input string(len=1), optional] Default: ‘L’
- `trans` [input string(len=1), optional] Default: ‘N’
- `overwrite_c` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: MAX((side[0]=='L'?n:m),1)

### scipy.linalg.lapack.dormrz

**Wrapper for** `dormrz`.

**Parameters**
- `a` [input rank-2 array('d') with bounds (k,nt)]
- `tau` [input rank-1 array('d') with bounds (k)]
- `c` [input rank-2 array('d') with bounds (m,n)]

**Returns**
- `cq` [rank-2 array('d') with bounds (m,n) and c storage]
- `info` [int]

**Other Parameters**
- `side` [input string(len=1), optional] Default: ‘L’
- `trans` [input string(len=1), optional] Default: ‘N’
- `overwrite_c` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: MAX((side[0]=='L'?n:m),1)

### scipy.linalg.lapack.sormrz_lwork

**Wrapper for** `sormrz_lwork`.

**Parameters**
- `m` [input int]
- `n` [input int]

**Returns**

---

6.12. Low-level LAPACK functions *(scipy.linalg.lapack)*
work [float]
info [int]

Other Parameters
side [input string(len=1), optional] Default: ‘L’
trans [input string(len=1), optional] Default: ‘N’

scipy.linalg.lapack.dormrz_lwork

scipy.linalg.lapack.dormrz_lwork(m, n[, side, trans]) = <fortran object>
Wrapper for dormrz_lwork.

Parameters
m [input int]
n [input int]

Returns
work [float]
info [int]

Other Parameters
side [input string(len=1), optional] Default: ‘L’
trans [input string(len=1), optional] Default: ‘N’

scipy.linalg.lapack.spbsv

scipy.linalg.lapack.spbsv(ab, b[, lower, ldab, overwrite_ab, overwrite_b]) = <fortran object>
Wrapper for spbsv.

Parameters
ab [input rank-2 array('f') with bounds (ldab,n)]
b [input rank-2 array('f') with bounds (ldb,nrhs)]

Returns
c [rank-2 array('f') with bounds (ldab,n) and ab storage]
x [rank-2 array('f') with bounds (ldb,nrhs) and b storage]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_ab [input int, optional] Default: 0
ldab [input int, optional] Default: shape(ab,0)
overwrite_b [input int, optional] Default: 0
scipy.linalg.lapack.dpbsv

scipy.linalg.lapack.dpbsv(ab, b[, lower, ldab, overwrite_ab, overwrite_b]) = <fortran object>

Wrapper for dpbsv.

Parameters

ab [input rank-2 array('d') with bounds (ldab,n)]
b [input rank-2 array('d') with bounds (ldb,nrhs)]

Returns

c [rank-2 array('d') with bounds (ldab,n) and ab storage]
x [rank-2 array('d') with bounds (ldb,nrhs) and b storage]
info [int]

Other Parameters

lower [input int, optional] Default: 0
overwrite_ab [input int, optional] Default: 0
ldab [input int, optional] Default: shape(ab,0)
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.cpbsv

scipy.linalg.lapack.cpbsv(ab, b[, lower, ldab, overwrite_ab, overwrite_b]) = <fortran object>

Wrapper for cpbsv.

Parameters

ab [input rank-2 array('F') with bounds (ldab,n)]
b [input rank-2 array('F') with bounds (ldb,nrhs)]

Returns

c [rank-2 array('F') with bounds (ldab,n) and ab storage]
x [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
info [int]

Other Parameters

lower [input int, optional] Default: 0
overwrite_ab [input int, optional] Default: 0
ldab [input int, optional] Default: shape(ab,0)
overwrite_b [input int, optional] Default: 0
scipy.linalg.lapack.zpbsv

scipy.linalg.lapack.zpbsv(ab[, lower, ldab, overwrite_ab, overwrite_b]) = <fortran object>

Wrapper for zpbsv.

Parameters

ab [input rank-2 array('D') with bounds (ldab,n)]
b [input rank-2 array('D') with bounds (ldb,nrhs)]

Returns

c [rank-2 array('D') with bounds (ldab,n) and ab storage]
x [rank-2 array('D') with bounds (ldb,nrhs) and b storage]
info [int]

Other Parameters

lower [input int, optional] Default: 0
overwrite_ab [input int, optional] Default: 0
ldab [input int, optional] Default: shape(ab,0)
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.spbtrf

scipy.linalg.lapack.spbtrf(ab[, lower, ldab, overwrite_ab]) = <fortran object>

Wrapper for spbtrf.

Parameters

ab [input rank-2 array('f') with bounds (ldab,n)]

Returns

c [rank-2 array('f') with bounds (ldab,n) and ab storage]
info [int]

Other Parameters

lower [input int, optional] Default: 0
overwrite_ab [input int, optional] Default: 0
ldab [input int, optional] Default: shape(ab,0)

scipy.linalg.lapack.dpbtrf

scipy.linalg.lapack.dpbtrf(ab[, lower, ldab, overwrite_ab]) = <fortran object>

Wrapper for dpbtrf.

Parameters

ab [input rank-2 array('d') with bounds (ldab,n)]

Returns

c [rank-2 array('d') with bounds (ldab,n) and ab storage]
info [int]
**Other Parameters**

- `lower` [input int, optional] Default: 0
- `overwrite_ab` [input int, optional] Default: 0
- `ldab` [input int, optional] Default: shape(ab,0)

**scipy.linalg.lapack.cpbtrf**

```python
scipy.linalg.lapack.cpbtrf(ab[, lower, ldab, overwrite_ab]) = <fortran object>
```

Wrapper for `cpbtrf`.

**Parameters**

- `ab` [input rank-2 array('F') with bounds (ldab,n)]

**Returns**

- `c` [rank-2 array('F') with bounds (ldab,n) and ab storage]
- `info` [int]

**Other Parameters**

- `lower` [input int, optional] Default: 0
- `overwrite_ab` [input int, optional] Default: 0
- `ldab` [input int, optional] Default: shape(ab,0)

**scipy.linalg.lapack.zpbtrf**

```python
scipy.linalg.lapack.zpbtrf(ab[, lower, ldab, overwrite_ab]) = <fortran object>
```

Wrapper for `zpbtrf`.

**Parameters**

- `ab` [input rank-2 array('D') with bounds (ldab,n)]

**Returns**

- `c` [rank-2 array('D') with bounds (ldab,n) and ab storage]
- `info` [int]

**Other Parameters**

- `lower` [input int, optional] Default: 0
- `overwrite_ab` [input int, optional] Default: 0
- `ldab` [input int, optional] Default: shape(ab,0)
scipy.linalg.lapack.spbtrs

Wrapper for spbtrs.

Parameters

| ab          | [input rank-2 array('f') with bounds (ldab,n)] |
| b           | [input rank-2 array('f') with bounds (ldb,nrhs)] |

Returns

| x           | [rank-2 array('f') with bounds (ldb,nrhs) and b storage] |
| info        | [int] |

Other Parameters

| lower   | [input int, optional] Default: 0 |
| ldab    | [input int, optional] Default: shape(ab,0) |
| overwrite_b | [input int, optional] Default: 0 |

scipy.linalg.lapack.dpbtrs

Wrapper for dpbtrs.

Parameters

| ab          | [input rank-2 array('d') with bounds (ldab,n)] |
| b           | [input rank-2 array('d') with bounds (ldb,nrhs)] |

Returns

| x           | [rank-2 array('d') with bounds (ldb,nrhs) and b storage] |
| info        | [int] |

Other Parameters

| lower   | [input int, optional] Default: 0 |
| ldab    | [input int, optional] Default: shape(ab,0) |
| overwrite_b | [input int, optional] Default: 0 |

scipy.linalg.lapack.cpbtrs

Wrapper for cpbtrs.

Parameters

| ab          | [input rank-2 array('F') with bounds (ldab,n)] |
| b           | [input rank-2 array('F') with bounds (ldb,nrhs)] |

Returns

| x           | [rank-2 array('F') with bounds (ldb,nrhs) and b storage] |
| info        | [int] |

Other Parameters
lower [input int, optional] Default: 0
ldab [input int, optional] Default: shape(ab,0)
overwrite_b
    [input int, optional] Default: 0

scipy.linalg.lapack.zpbtrs

scipy.linalg.lapack.zpbtrs(ab, b[, lower, ldab, overwrite_b]) = <fortran object>
Wrapper for zpbtrs.

Parameters
ab [input rank-2 array('D') with bounds (ldab,n)]
b [input rank-2 array('D') with bounds (ldb,nrhs)]

Returns
x [rank-2 array('D') with bounds (ldb,nrhs) and b storage]
info [int]

Other Parameters
lower [input int, optional] Default: 0
ldab [input int, optional] Default: shape(ab,0)
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.spftrf

scipy.linalg.lapack.spftrf(n, a[, transr, uplo, overwrite_a]) = <fortran object>
Wrapper for spftrf.

Parameters
n [input int]
a [input rank-1 array('f') with bounds (nt)]

Returns
achol [rank-1 array('f') with bounds (nt) and a storage]
info [int]

Other Parameters
transr [input string(len=1), optional] Default: 'N'
uplo [input string(len=1), optional] Default: 'U'
overwrite_a [input int, optional] Default: 0
scipy.linalg.lapack.dpftrf

scipy.linalg.lapack.dpftrf(n, a[, transr, uplo, overwrite_a]) = <fortran object>

Wrapper for dpftrf.

Parameters

n [input int]
a [input rank-1 array('d') with bounds (nt)]

Returns

achol [rank-1 array('d') with bounds (nt) and a storage]
info [int]

Other Parameters

transr [input string(len=1), optional] Default: ‘N’
uplo [input string(len=1), optional] Default: ‘U’
overwrite_a [input int, optional] Default: 0

scipy.linalg.lapack.cpftrf

scipy.linalg.lapack.cpftrf(n, a[, transr, uplo, overwrite_a]) = <fortran object>

Wrapper for cpftrf.

Parameters

n [input int]
a [input rank-1 array('F') with bounds (nt)]

Returns

achol [rank-1 array('F') with bounds (nt) and a storage]
info [int]

Other Parameters

transr [input string(len=1), optional] Default: ‘N’
uplo [input string(len=1), optional] Default: ‘U’
overwrite_a [input int, optional] Default: 0

scipy.linalg.lapack.zpftrf

scipy.linalg.lapack.zpftrf(n, a[, transr, uplo, overwrite_a]) = <fortran object>

Wrapper for zpftrf.

Parameters

n [input int]
a [input rank-1 array('D') with bounds (nt)]

Returns

achol [rank-1 array('D') with bounds (nt) and a storage]
info [int]

Other Parameters
transr  [input string(len=1), optional] Default: ‘N’
uplo  [input string(len=1), optional] Default: ‘U’
overwrite_a  [input int, optional] Default: 0

scipy.linalg.lapack.spftri

scipy.linalg.lapack.spftri(n, a[, transr, uplo, overwrite_a]) = <fortran object>
Wrapper for spftri.

Parameters
n  [input int]
a  [input rank-1 array('f') with bounds (nt)]

Returns
ainv  [rank-1 array('f') with bounds (nt) and a storage]
info  [int]

Other Parameters
transr  [input string(len=1), optional] Default: ‘N’
uplo  [input string(len=1), optional] Default: ‘U’
overwrite_a  [input int, optional] Default: 0

scipy.linalg.lapack.dpftri

scipy.linalg.lapack.dpftri(n, a[, transr, uplo, overwrite_a]) = <fortran object>
Wrapper for dpftri.

Parameters
n  [input int]
a  [input rank-1 array('d') with bounds (nt)]

Returns
ainv  [rank-1 array('d') with bounds (nt) and a storage]
info  [int]

Other Parameters
transr  [input string(len=1), optional] Default: ‘N’
uplo  [input string(len=1), optional] Default: ‘U’
overwrite_a  [input int, optional] Default: 0

scipy.linalg.lapack.cpftri

scipy.linalg.lapack.cpftri(n, a[, transr, uplo, overwrite_a]) = <fortran object>
Wrapper for cpftri.

Parameters
n [input int]
a [input rank-1 array('F') with bounds (nt)]

Returns
ainv [rank-1 array('F') with bounds (nt) and a storage]
info [int]

Other Parameters
transr [input string(len=1), optional] Default: 'N'
uplo [input string(len=1), optional] Default: 'U'
overwrite_a [input int, optional] Default: 0

scipy.linalg.lapack.zpftri

scipy.linalg.lapack.zpftri(n, a[, transr, uplo, overwrite_a]) = <fortran object>
Wrapper for zpftri.

Parameters
n [input int]
a [input rank-1 array('D') with bounds (nt)]

Returns
ainv [rank-1 array('D') with bounds (nt) and a storage]
info [int]

Other Parameters
transr [input string(len=1), optional] Default: 'N'
uplo [input string(len=1), optional] Default: 'U'
overwrite_a [input int, optional] Default: 0

scipy.linalg.lapack.spftrs

scipy.linalg.lapack.spftrs(n, a, b[, transr, uplo, overwrite_b]) = <fortran object>
Wrapper for spftrs.

Parameters
n [input int]
a [input rank-1 array('f') with bounds (nt)]
b [input rank-2 array('f') with bounds (ldb,nhrs)]

Returns
x [rank-2 array('f') with bounds (ldb,nhrs) and b storage]
info [int]
Other Parameters

- \texttt{transr} [input string(len=1), optional] Default: 'N'
- \texttt{uplo} [input string(len=1), optional] Default: 'U'
- \texttt{overwrite_b} [input int, optional] Default: 0

\texttt{scipy.linalg.lapack.dpftrs}

\texttt{scipy.linalg.lapack.dpftrs(n, a, b[, transr, uplo, overwrite_b])} = <fortran object>

Wrapper for \texttt{dpftrs}.

Parameters

- \texttt{n} [input int]
- \texttt{a} [input rank-1 array('d') with bounds (nt)]
- \texttt{b} [input rank-2 array('d') with bounds (ldb,nhrs)]

Returns

- \texttt{x} [rank-2 array('d') with bounds (ldb,nhrs) and b storage]
- \texttt{info} [int]

Other Parameters

- \texttt{transr} [input string(len=1), optional] Default: 'N'
- \texttt{uplo} [input string(len=1), optional] Default: 'U'
- \texttt{overwrite_b} [input int, optional] Default: 0

\texttt{scipy.linalg.lapack.cpftrs}

\texttt{scipy.linalg.lapack.cpftrs(n, a, b[, transr, uplo, overwrite_b])} = <fortran object>

Wrapper for \texttt{cpftrs}.

Parameters

- \texttt{n} [input int]
- \texttt{a} [input rank-1 array('F') with bounds (nt)]
- \texttt{b} [input rank-2 array('F') with bounds (ldb,nhrs)]

Returns

- \texttt{x} [rank-2 array('F') with bounds (ldb,nhrs) and b storage]
- \texttt{info} [int]

Other Parameters

- \texttt{transr} [input string(len=1), optional] Default: 'N'
- \texttt{uplo} [input string(len=1), optional] Default: 'U'
- \texttt{overwrite_b} [input int, optional] Default: 0
scipy.linalg.lapack.zpftrs

scipy.linalg.lapack.zpftrs(n, a, b[, transr, uplo, overwrite_b]) = <fortran object>
Wrapper for zpftrs.

Parameters

- n  [input int]
- a  [input rank-1 array('D') with bounds (nt)]
- b  [input rank-2 array('D') with bounds (ldb, nhrs)]

Returns

- x  [rank-2 array('D') with bounds (ldb, nhrs) and b storage]
- info  [int]

Other Parameters

- transr  [input string(len=1), optional] Default: ‘N’
- uplo  [input string(len=1), optional] Default: ‘U’
- overwrite_b  [input int, optional] Default: 0

scipy.linalg.lapack.spocon

scipy.linalg.lapack.spocon(a, anorm[, uplo]) = <fortran object>
Wrapper for spocon.

Parameters

- a  [input rank-2 array('f') with bounds (n,n)]
- anorm  [input float]

Returns

- rcond  [float]
- info  [int]

Other Parameters

- uplo  [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.dpocon

scipy.linalg.lapack.dpocon(a, anorm[, uplo]) = <fortran object>
Wrapper for dpocon.

Parameters

- a  [input rank-2 array('d') with bounds (n,n)]
- anorm  [input float]

Returns

- rcond  [float]
- info  [int]

Other Parameters

- uplo  [input string(len=1), optional] Default: ‘U’
scipy.linalg.lapack.cpocon

scipy.linalg.lapack.cpocon(a, anorm[, uplo]) = <fortran object>

Wrapper for cpocon.

Parameters

- a [input rank-2 array('F') with bounds (n,n)]
- anorm [input float]

Returns

- rcond [float]
- info [int]

Other Parameters

- uplo [input string(len=1), optional] Default: 'U'

scipy.linalg.lapack.zpocon

scipy.linalg.lapack.zpocon(a, anorm[, uplo]) = <fortran object>

Wrapper for zpocon.

Parameters

- a [input rank-2 array('D') with bounds (n,n)]
- anorm [input float]

Returns

- rcond [float]
- info [int]

Other Parameters

- uplo [input string(len=1), optional] Default: 'U'

scipy.linalg.lapack.spstrf

scipy.linalg.lapack.spstrf(a[, tol, lower, overwrite_a]) = <fortran object>

Wrapper for spstrf.

Parameters

- a [input rank-2 array('f') with bounds (n,n)]

Returns

- c [rank-2 array('f') with bounds (n,n) and a storage]
- piv [rank-1 array('i') with bounds (n)]
- rank_c [int]
- info [int]

Other Parameters

- overwrite_a [input int, optional] Default: 0
- tol [input float, optional] Default: -1.0
- lower [input int, optional] Default: 0
scipy.linalg.lapack.dpstrf

`scipy.linalg.lapack.dpstrf(a[, tol, lower, overwrite_a]) = <fortran object>`

Wrapper for dpstrf.

**Parameters**

- `a` [input rank-2 array('d') with bounds (n,n)]

**Returns**

- `c` [rank-2 array('d') with bounds (n,n) and a storage]
- `piv` [rank-1 array('i') with bounds (n)]
- `rank_c` [int]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0
- `tol` [input float, optional] Default: -1.0
- `lower` [input int, optional] Default: 0

scipy.linalg.lapack.cpstrf

`scipy.linalg.lapack.cpstrf(a[, tol, lower, overwrite_a]) = <fortran object>`

Wrapper for cpstrf.

**Parameters**

- `a` [input rank-2 array('F') with bounds (n,n)]

**Returns**

- `c` [rank-2 array('F') with bounds (n,n) and a storage]
- `piv` [rank-1 array('i') with bounds (n)]
- `rank_c` [int]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0
- `tol` [input float, optional] Default: -1.0
- `lower` [input int, optional] Default: 0

scipy.linalg.lapack.zpstrf

`scipy.linalg.lapack.zpstrf(a[, tol, lower, overwrite_a]) = <fortran object>`

Wrapper for zpstrf.

**Parameters**

- `a` [input rank-2 array('D') with bounds (n,n)]

**Returns**

- `c` [rank-2 array('D') with bounds (n,n) and a storage]
- `piv` [rank-1 array('i') with bounds (n)]
- `rank_c` [int]
info  [int]

Other Parameters

overwrite_a  [input int, optional] Default: 0
tol  [input float, optional] Default: -1.0
lower  [input int, optional] Default: 0

scipy.linalg.lapack.spstf2

scipy.linalg.lapack.spstf2(a[, tol, lower, overwrite_a]) = <fortran object>
Wrapper for spstf2.

Parameters

a  [input rank-2 array('f') with bounds (n,n)]

Returns

c  [rank-2 array('f') with bounds (n,n) and a storage]
piv  [rank-1 array('i') with bounds (n)]
rank_c  [int]
info  [int]

Other Parameters

overwrite_a  [input int, optional] Default: 0
tol  [input float, optional] Default: -1.0
lower  [input int, optional] Default: 0

scipy.linalg.lapack.dpstf2

scipy.linalg.lapack.dpstf2(a[, tol, lower, overwrite_a]) = <fortran object>
Wrapper for dpstf2.

Parameters

a  [input rank-2 array('d') with bounds (n,n)]

Returns

c  [rank-2 array('d') with bounds (n,n) and a storage]
piv  [rank-1 array('i') with bounds (n)]
rank_c  [int]
info  [int]

Other Parameters

overwrite_a  [input int, optional] Default: 0
tol  [input float, optional] Default: -1.0
lower  [input int, optional] Default: 0
**scipy.linalg.lapack.cpstf2**

```
scipy.linalg.lapack.cpstf2(a[, tol, lower, overwrite_a]) = <fortran object>
```

Wrapper for `cpstf2`.

**Parameters**
- `a` [input rank-2 array('F') with bounds (n,n)]

**Returns**
- `c` [rank-2 array('F') with bounds (n,n) and a storage]
- `piv` [rank-1 array('i') with bounds (n)]
- `rank_c` [int]
- `info` [int]

**Other Parameters**
- `overwrite_a` [input int, optional] Default: 0
- `tol` [input float, optional] Default: -1.0
- `lower` [input int, optional] Default: 0

**scipy.linalg.lapack.zpstf2**

```
scipy.linalg.lapack.zpstf2(a[, tol, lower, overwrite_a]) = <fortran object>
```

Wrapper for `zpstf2`.

**Parameters**
- `a` [input rank-2 array('D') with bounds (n,n)]

**Returns**
- `c` [rank-2 array('D') with bounds (n,n) and a storage]
- `piv` [rank-1 array('i') with bounds (n)]
- `rank_c` [int]
- `info` [int]

**Other Parameters**
- `overwrite_a` [input int, optional] Default: 0
- `tol` [input float, optional] Default: -1.0
- `lower` [input int, optional] Default: 0

**scipy.linalg.lapack.sposv**

```
scipy.linalg.lapack.sposv(a, b[, lower, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for `sposv`.

**Parameters**
- `a` [input rank-2 array('f') with bounds (n,n)]
- `b` [input rank-2 array('f') with bounds (n,nrhs)]

**Returns**
- `c` [rank-2 array('f') with bounds (n,n) and a storage]
- `x` [rank-2 array('f') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters
- overwrite_a
  [input int, optional] Default: 0
- overwrite_b
  [input int, optional] Default: 0
- lower
  [input int, optional] Default: 0

scipy.linalg.lapack.dposv

scipy.linalg.lapack.dposv(a, b[, lower, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for dposv.

Parameters
- a [input rank-2 array('d') with bounds (n,n)]
- b [input rank-2 array('d') with bounds (n,nrhs)]

Returns
- c [rank-2 array('d') with bounds (n,n) and a storage]
- x [rank-2 array('d') with bounds (n,nrhs) and b storage]
- info [int]

Other Parameters
- overwrite_a
  [input int, optional] Default: 0
- overwrite_b
  [input int, optional] Default: 0
- lower
  [input int, optional] Default: 0

scipy.linalg.lapack.cposv

scipy.linalg.lapack.cposv(a, b[, lower, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for cposv.

Parameters
- a [input rank-2 array('F') with bounds (n,n)]
- b [input rank-2 array('F') with bounds (n,nrhs)]

Returns
- c [rank-2 array('F') with bounds (n,n) and a storage]
- x [rank-2 array('F') with bounds (n,nrhs) and b storage]
- info [int]

Other Parameters
- overwrite_a
  [input int, optional] Default: 0
- overwrite_b
  [input int, optional] Default: 0
- lower
  [input int, optional] Default: 0
scipy.linalg.lapack.zposv

**scipy.linalg.lapack.zposv** (*a*, *b*, *lower*, *overwrite_a*, *overwrite_b*) = *<fortran object>*

Wrapper for zposv.

**Parameters**

- **a** [input rank-2 array('D') with bounds (n,n)]
- **b** [input rank-2 array('D') with bounds (n,nrhs)]

**Returns**

- **c** [rank-2 array('D') with bounds (n,n) and a storage]
- **x** [rank-2 array('D') with bounds (n,nrhs) and b storage]
- **info** [int]

**Other Parameters**

- **overwrite_a** [input int, optional] Default: 0
- **overwrite_b** [input int, optional] Default: 0
- **lower** [input int, optional] Default: 0

scipy.linalg.lapack.sposvx

**scipy.linalg.lapack.sposvx** (*a*, *b*, *fact*, *af*, *equed*, *s*, *lower*, *overwrite_a*, *overwrite_b*) = *<fortran object>*

Wrapper for sposvx.

**Parameters**

- **a** [input rank-2 array('f') with bounds (n,n)]
- **b** [input rank-2 array('f') with bounds (n,nrhs)]

**Returns**

- **a_s** [rank-2 array('f') with bounds (n,n) and a storage]
- **lu** [rank-2 array('f') with bounds (n,n) and af storage]
- **equed** [string(len=1)]
- **s** [rank-1 array('f') with bounds (n)]
- **b_s** [rank-2 array('f') with bounds (n,nrhs) and b storage]
- **x** [rank-2 array('f') with bounds (n,nrhs)]
- **rcond** [float]
- **ferr** [rank-1 array('f') with bounds (nrhs)]
- **berr** [rank-1 array('f') with bounds (nrhs)]
- **info** [int]

**Other Parameters**

- **fact** [input string(len=1), optional] Default: ‘E’
- **overwrite_a** [input int, optional] Default: 0
- **af** [input rank-2 array('f') with bounds (n,n)]
- **equed** [input string(len=1), optional] Default: ‘Y’
- **s** [input rank-1 array('f') with bounds (n)]
- **overwrite_b** [input int, optional] Default: 0
- **lower** [input int, optional] Default: 0
scipy.linalg.lapack.dposvx

\[ \text{scipy.linalg.lapack.dposvx}(a, b[, \ \text{fact}, \ \text{af}, \ \text{equed}, \ s, \ \text{lower}, \ \text{overwrite}_a, \ \text{overwrite}_b]) = \begin{array}{c} \text{<fortran object>} \end{array} \]

Wrapper for \text{dposvx}.

**Parameters**

- **\text{a}** [input rank-2 array ('d') with bounds (n,n)]
- **\text{b}** [input rank-2 array ('d') with bounds (n,nrhs)]

**Returns**

- **\text{a_s}** [rank-2 array ('d') with bounds (n,n) and a storage]
- **\text{lu}** [rank-2 array ('d') with bounds (n,n) and af storage]
- **\text{equed}** [string (len=1)]
- **\text{s}** [rank-1 array ('d') with bounds (n)]
- **\text{b_s}** [rank-2 array ('d') with bounds (n,nrhs) and b storage]
- **\text{x}** [rank-2 array ('d') with bounds (n,nrhs)]
- **\text{rcond}** [float]
- **\text{ferr}** [rank-1 array ('d') with bounds (nrhs)]
- **\text{berr}** [rank-1 array ('d') with bounds (nrhs)]
- **\text{info}** [int]

**Other Parameters**

- **\text{fact}** [input string (len=1), optional] Default: 'E'
- **\text{overwrite}_a** [input int, optional] Default: 0
- **\text{af}** [input rank-2 array ('d') with bounds (n,n)]
- **\text{equed}** [input string (len=1), optional] Default: 'Y'
- **\text{s}** [input rank-1 array ('d') with bounds (n)]
- **\text{overwrite}_b** [input int, optional] Default: 0
- **\text{lower}** [input int, optional] Default: 0

scipy.linalg.lapack.cposvx

\[ \text{scipy.linalg.lapack.cposvx}(a, b[, \ \text{fact}, \ \text{af}, \ \text{equed}, \ s, \ \text{lower}, \ \text{overwrite}_a, \ \text{overwrite}_b]) = \begin{array}{c} \text{<fortran object>} \end{array} \]

Wrapper for \text{cposvx}.

**Parameters**

- **\text{a}** [input rank-2 array ('F') with bounds (n,n)]
- **\text{b}** [input rank-2 array ('F') with bounds (n,nrhs)]

**Returns**

- **\text{a_s}** [rank-2 array ('F') with bounds (n,n) and a storage]
- **\text{lu}** [rank-2 array ('F') with bounds (n,n) and af storage]
- **\text{equed}** [string (len=1)]
- **\text{s}** [rank-1 array ('f') with bounds (n)]
- **\text{b_s}** [rank-2 array ('F') with bounds (n,nrhs) and b storage]
- **\text{x}** [rank-2 array ('F') with bounds (n,nrhs)]
- **\text{rcond}** [float]
- **\text{ferr}** [rank-1 array ('f') with bounds (nrhs)]
- **\text{berr}** [rank-1 array ('f') with bounds (nrhs)]

6.12. Low-level LAPACK functions (scipy.linalg.lapack)

```python
c scipy.linalg.lapack.zposvx
scipy.linalg.lapack.zposvx(a, b[, fact, af, equed, s, lower, overwrite_a, overwrite_b]) =
<fortran object>

Wrapper for zposvx.

Parameters
a [input rank-2 array('D') with bounds (n,n)]
b [input rank-2 array('D') with bounds (n,nrhs)]

Returns
a_s [rank-2 array('D') with bounds (n,n) and a storage]
lu [rank-2 array('D') with bounds (n,n) and af storage]
equed [string(len=1)]
s [rank-1 array('d') with bounds (n)]
b_s [rank-2 array('D') with bounds (n,nrhs) and b storage]
x [rank-2 array('D') with bounds (n,nrhs)]
rcond [float]
ferr [rank-1 array('d') with bounds (nrhs)]
berr [rank-1 array('d') with bounds (nrhs)]
info [int]

Other Parameters
fact [input string(len=1), optional] Default: ‘E’
overwrite_a [input int, optional] Default: 0
af [input rank-2 array('D') with bounds (n,n)]
equed [input string(len=1), optional] Default: ‘Y’
s [input rank-1 array('d') with bounds (n)]
overwrite_b [input int, optional] Default: 0
lower [input int, optional] Default: 0
```

Other Parameters

- `info` [int]
- `fact` [input string(len=1), optional] Default: ‘E’
- `overwrite_a` [input int, optional] Default: 0
- `af` [input rank-2 array('F') with bounds (n,n)]
- `equed` [input string(len=1), optional] Default: ‘Y’
- `s` [input rank-1 array('f') with bounds (n)]
- `overwrite_b` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
scipy.linalg.lapack.spotrf

scipy.linalg.lapack.spotrf(a[:, lower, clean, overwrite_a]) = <fortran object>
Wrapper for spotrf.

Parameters
  a [input rank-2 array('f') with bounds (n,n)]

Returns
  c [rank-2 array('f') with bounds (n,n) and a storage]
  info [int]

Other Parameters
  overwrite_a [input int, optional] Default: 0
  lower [input int, optional] Default: 0
  clean [input int, optional] Default: 1

scipy.linalg.lapack.dpotrf

scipy.linalg.lapack.dpotrf(a[:, lower, clean, overwrite_a]) = <fortran object>
Wrapper for dpotrf.

Parameters
  a [input rank-2 array('d') with bounds (n,n)]

Returns
  c [rank-2 array('d') with bounds (n,n) and a storage]
  info [int]

Other Parameters
  overwrite_a [input int, optional] Default: 0
  lower [input int, optional] Default: 0
  clean [input int, optional] Default: 1

scipy.linalg.lapack.cpotrf

scipy.linalg.lapack.cpotrf(a[:, lower, clean, overwrite_a]) = <fortran object>
Wrapper for cpotrf.

Parameters
  a [input rank-2 array('F') with bounds (n,n)]

Returns
  c [rank-2 array('F') with bounds (n,n) and a storage]
  info [int]

Other Parameters
  overwrite_a [input int, optional] Default: 0
  lower [input int, optional] Default: 0
clean  [input int, optional] Default: 1

**scipy.linalg.lapack.zpotrf**

```python
scipy.linalg.lapack.zpotrf(a[, lower, clean, overwrite_a]) = <fortran object>
```
Wrapper for zpotrf.

**Parameters**

- **a**  [input rank-2 array('D') with bounds (n,n)]

**Returns**

- **c**  [rank-2 array('D') with bounds (n,n) and a storage]
- **info**  [int]

**Other Parameters**

- **overwrite_a**  [input int, optional] Default: 0
- **lower**  [input int, optional] Default: 0
- **clean**  [input int, optional] Default: 1

**scipy.linalg.lapack.spotri**

```python
scipy.linalg.lapack.spotri(c[, lower, overwrite_c]) = <fortran object>
```
Wrapper for spotri.

**Parameters**

- **c**  [input rank-2 array('f') with bounds (n,n)]

**Returns**

- **inv_a**  [rank-2 array('f') with bounds (n,n) and c storage]
- **info**  [int]

**Other Parameters**

- **overwrite_c**  [input int, optional] Default: 0
- **lower**  [input int, optional] Default: 0

**scipy.linalg.lapack.dpotri**

```python
scipy.linalg.lapack.dpotri(c[, lower, overwrite_c]) = <fortran object>
```
Wrapper for dpotri.

**Parameters**

- **c**  [input rank-2 array('d') with bounds (n,n)]

**Returns**

- **inv_a**  [rank-2 array('d') with bounds (n,n) and c storage]
- **info**  [int]

**Other Parameters**
6.12. Low-level LAPACK functions (scipy.linalg.lapack)

scipy.linalg.lapack.cpotri

```
overwrite_c
   [input int, optional] Default: 0
lower
   [input int, optional] Default: 0
```

scipy.linalg.lapack.cpotri

```
scipy.linalg.lapack.cpotri(c[, lower, overwrite_c]) = <fortran object>
Wrapper for cpotri.

Parameters
  c
      [input rank-2 array('F') with bounds (n,n)]

Returns
  inv_a
      [rank-2 array('F') with bounds (n,n) and c storage]
  info
      [int]

Other Parameters
  overwrite_c
      [input int, optional] Default: 0
  lower
      [input int, optional] Default: 0
```

scipy.linalg.lapack.zpotri

```
scipy.linalg.lapack.zpotri(c[, lower, overwrite_c]) = <fortran object>
Wrapper for zpotri.

Parameters
  c
      [input rank-2 array('D') with bounds (n,n)]

Returns
  inv_a
      [rank-2 array('D') with bounds (n,n) and c storage]
  info
      [int]

Other Parameters
  overwrite_c
      [input int, optional] Default: 0
  lower
      [input int, optional] Default: 0
```

scipy.linalg.lapack.spotrs

```
scipy.linalg.lapack.spotrs(c, b[, lower, overwrite_b]) = <fortran object>
Wrapper for spotrs.

Parameters
  c
      [input rank-2 array('f') with bounds (n,n)]
  b
      [input rank-2 array('f') with bounds (n,nrhs)]

Returns
  x
      [rank-2 array('f') with bounds (n,nrhs) and b storage]
  info
      [int]

Other Parameters
```
overwrite_b  [input int, optional] Default: 0
lower  [input int, optional] Default: 0

scipy.linalg.lapack.dpotrs

scipy.linalg.lapack.dpotrs(c, b[, lower, overwrite_b]) = <fortran object>
Wrapper for dpotrs.

Parameters

c  [input rank-2 array('d') with bounds (n,n)]
b  [input rank-2 array('d') with bounds (n,nrhs)]

Returns

x  [rank-2 array('d') with bounds (n,nrhs) and b storage]
info  [int]

Other Parameters

overwrite_b  [input int, optional] Default: 0
lower  [input int, optional] Default: 0

scipy.linalg.lapack.cpotrs

scipy.linalg.lapack.cpotrs(c, b[, lower, overwrite_b]) = <fortran object>
Wrapper for cpotrs.

Parameters

c  [input rank-2 array('F') with bounds (n,n)]
b  [input rank-2 array('F') with bounds (n,nrhs)]

Returns

x  [rank-2 array('F') with bounds (n,nrhs) and b storage]
info  [int]

Other Parameters

overwrite_b  [input int, optional] Default: 0
lower  [input int, optional] Default: 0

scipy.linalg.lapack.zpotrs

scipy.linalg.lapack.zpotrs(c, b[, lower, overwrite_b]) = <fortran object>
Wrapper for zpotrs.

Parameters

c  [input rank-2 array('D') with bounds (n,n)]
b  [input rank-2 array('D') with bounds (n,nrhs)]

Returns

x  [rank-2 array('D') with bounds (n,nrhs) and b storage]
info          [int]

**Other Parameters**

overwrite_b      [input int, optional] Default: 0
lower           [input int, optional] Default: 0

**scipy.linalg.lapack.sppcon**

`scipy.linalg.lapack.sppcon(n, ap, anorm[, lower]) = <fortran object>`

Wrapper for `sppcon`.

**Parameters**

- `n` [input int]
- `ap` [input rank-1 array('f') with bounds (L)]
- `anorm` [input float]

**Returns**

- `rcond` [float]
- `info` [int]

**Other Parameters**

- `lower` [input int, optional] Default: 0

**scipy.linalg.lapack.dppcon**

`scipy.linalg.lapack.dppcon(n, ap, anorm[, lower]) = <fortran object>`

Wrapper for `dppcon`.

**Parameters**

- `n` [input int]
- `ap` [input rank-1 array('d') with bounds (L)]
- `anorm` [input float]

**Returns**

- `rcond` [float]
- `info` [int]

**Other Parameters**

- `lower` [input int, optional] Default: 0

**scipy.linalg.lapack.cppcon**

`scipy.linalg.lapack.cppcon(n, ap, anorm[, lower]) = <fortran object>`

Wrapper for `cppcon`.

**Parameters**

- `n` [input int]
- `ap` [input rank-1 array('F') with bounds (L)]
- `anorm` [input float]

**Returns**

- `rcond` [float]
- `info` [int]

...rcond  [float]
info   [int]

Other Parameters
lower    [input int, optional] Default: 0

scipy.linalg.lapack.zppcon

scipy.linalg.lapack.zppcon(n, ap, anorm[, lower]) = <fortran object>
Wrapper for zppcon.

Parameters
n       [input int]
ap     [input rank-1 array('D') with bounds (L)]
anorm   [input float]

Returns
rcond   [float]
info    [int]

Other Parameters
lower    [input int, optional] Default: 0

scipy.linalg.lapack.sppsv

scipy.linalg.lapack.sppsv(n, ap, b[, lower, overwrite_b]) = <fortran object>
Wrapper for sppsv.

Parameters
n       [input int]
ap     [input rank-1 array('F') with bounds (L)]
b       [input rank-2 array('F') with bounds (ldb,nrhs)]

Returns
x       [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
info    [int]

Other Parameters
lower    [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
scipy.linalg.lapack.dppsv

scipy.linalg.lapack.dppsv(n, ap, b[, lower, overwrite_b]) = <fortran object>
Wrapper for dppsv.

Parameters
  n [input int]
  ap [input rank-1 array('d') with bounds (L)]
  b [input rank-2 array('d') with bounds (ldb,nrhs)]

Returns
  x [rank-2 array('d') with bounds (ldb,nrhs) and b storage]
  info [int]

Other Parameters
  lower [input int, optional] Default: 0
  overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.cppsv

scipy.linalg.lapack.cppsv(n, ap, b[, lower, overwrite_b]) = <fortran object>
Wrapper for cppsv.

Parameters
  n [input int]
  ap [input rank-1 array('F') with bounds (L)]
  b [input rank-2 array('F') with bounds (ldb,nrhs)]

Returns
  x [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
  info [int]

Other Parameters
  lower [input int, optional] Default: 0
  overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.zppsv

scipy.linalg.lapack.zppsv(n, ap, b[, lower, overwrite_b]) = <fortran object>
Wrapper for zppsv.

Parameters
  n [input int]
  ap [input rank-1 array('D') with bounds (L)]
  b [input rank-2 array('D') with bounds (ldb,nrhs)]

Returns
  x [rank-2 array('D') with bounds (ldb,nrhs) and b storage]
  info [int]
Other Parameters

- lower  [input int, optional] Default: 0
- overwrite_b  [input int, optional] Default: 0

scipy.linalg.lapack.spptrf

scipy.linalg.lapack.spptrf(n, ap[, lower, overwrite_ap]) = <fortran object>
Wrapper for spptrf.

Parameters

- n  [input int]
- ap  [input rank-1 array('f') with bounds (L)]

Returns

- ul  [rank-1 array('f') with bounds (L) and ap storage]
- info  [int]

Other Parameters

- lower  [input int, optional] Default: 0
- overwrite_ap  [input int, optional] Default: 0

scipy.linalg.lapack.dpptrf

scipy.linalg.lapack.dpptrf(n, ap[, lower, overwrite_ap]) = <fortran object>
Wrapper for dpptrf.

Parameters

- n  [input int]
- ap  [input rank-1 array('d') with bounds (L)]

Returns

- ul  [rank-1 array('d') with bounds (L) and ap storage]
- info  [int]

Other Parameters

- lower  [input int, optional] Default: 0
- overwrite_ap  [input int, optional] Default: 0

scipy.linalg.lapack.cpptrf

```python
scipy.linalg.lapack.cpptrf(n, ap[, lower, overwrite_ap]) = <fortran object>
Wrapper for cpptrf.

Parameters
n [input int]
ap [input rank-1 array('F') with bounds (L)]

Returns
ul [rank-1 array('F') with bounds (L) and ap storage]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_ap [input int, optional] Default: 0
```

scipy.linalg.lapack.zpptrf

```python
scipy.linalg.lapack.zpptrf(n, ap[, lower, overwrite_ap]) = <fortran object>
Wrapper for zpptrf.

Parameters
n [input int]
ap [input rank-1 array('D') with bounds (L)]

Returns
ul [rank-1 array('D') with bounds (L) and ap storage]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_ap [input int, optional] Default: 0
```

scipy.linalg.lapack.spptri

```python
scipy.linalg.lapack.spptri(n, ap[, lower, overwrite_ap]) = <fortran object>
Wrapper for spptri.

Parameters
n [input int]
ap [input rank-1 array('f') with bounds (L)]

Returns
uli [rank-1 array('f') with bounds (L) and ap storage]
info [int]

Other Parameters
lower [input int, optional] Default: 0
```
overwrite_ap
    [input int, optional] Default: 0

scipy.linalg.lapack.dpptri

scipy.linalg.lapack.dpptri(n, ap[, lower, overwrite_ap]) = <fortran object>
Wrapper for dpptri.

Parameters
    n      [input int]
    ap     [input rank-1 array('d') with bounds (L)]

Returns
    uli    [rank-1 array('d') with bounds (L) and ap storage]
    info   [int]

Other Parameters
    lower   [input int, optional] Default: 0
    overwrite_ap  [input int, optional] Default: 0

scipy.linalg.lapack.cpptri

scipy.linalg.lapack.cpptri(n, ap[, lower, overwrite_ap]) = <fortran object>
Wrapper for cpptri.

Parameters
    n      [input int]
    ap     [input rank-1 array('F') with bounds (L)]

Returns
    uli    [rank-1 array('F') with bounds (L) and ap storage]
    info   [int]

Other Parameters
    lower   [input int, optional] Default: 0
    overwrite_ap  [input int, optional] Default: 0

scipy.linalg.lapack.zpptri

scipy.linalg.lapack.zpptri(n, ap[, lower, overwrite_ap]) = <fortran object>
Wrapper for zpptri.

Parameters
    n      [input int]
    ap     [input rank-1 array('D') with bounds (L)]

Returns
    uli    [rank-1 array('D') with bounds (L) and ap storage]
    info   [int]
Other Parameters

- `lower` [input int, optional] Default: 0
- `overwrite_ap` [input int, optional] Default: 0

**scipy.linalg.lapack.spptrs**

`scipy.linalg.lapack.spptrs(n, ap[, lower, overwrite_b]) = <fortran object>`

Wrapper for `spptrs`.

**Parameters**

- `n` [input int]
- `ap` [input rank-1 array('f') with bounds (L)]
- `b` [input rank-2 array('f') with bounds (ldb,nrhs)]

**Returns**

- `x` [rank-2 array('f') with bounds (ldb,nrhs) and b storage]
- `info` [int]

Other Parameters

- `lower` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0

**scipy.linalg.lapack.dpptrs**

`scipy.linalg.lapack.dpptrs(n, ap[, lower, overwrite_b]) = <fortran object>`

Wrapper for `dpptrs`.

**Parameters**

- `n` [input int]
- `ap` [input rank-1 array('d') with bounds (L)]
- `b` [input rank-2 array('d') with bounds (ldb,nrhs)]

**Returns**

- `x` [rank-2 array('d') with bounds (ldb,nrhs) and b storage]
- `info` [int]

Other Parameters

- `lower` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0
scipy.linalg.lapack.cpptrs

scipy.linalg.lapack.cpptrs(n, ap[, lower, overwrite_b]) = <fortran object>
Wrapper for cpptrs.

Parameters
  n [input int]
  ap [input rank-1 array('F') with bounds (L)]
  b [input rank-2 array('F') with bounds (ldb,nrhs)]

Returns
  x [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
  info [int]

Other Parameters
  lower [input int, optional] Default: 0
  overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.zpptrs

scipy.linalg.lapack.zpptrs(n, ap[, lower, overwrite_b]) = <fortran object>
Wrapper for zpptrs.

Parameters
  n [input int]
  ap [input rank-1 array('D') with bounds (L)]
  b [input rank-2 array('D') with bounds (ldb,nrhs)]

Returns
  x [rank-2 array('D') with bounds (ldb,nrhs) and b storage]
  info [int]

Other Parameters
  lower [input int, optional] Default: 0
  overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.sptsv

scipy.linalg.lapack.sptsv(d, e, b[, overwrite_d, overwrite_e, overwrite_b]) = <fortran object>
Wrapper for sptsv.

Parameters
  d [input rank-1 array('f') with bounds (n)]
  e [input rank-1 array('f') with bounds (n - 1)]
  b [input rank-2 array('f') with bounds (n,nrhs)]

Returns
  d [rank-1 array('f') with bounds (n)]
  du [rank-1 array('f') with bounds (n - 1) and e storage]
x     [rank-2 array('f') with bounds (n,nrhs) and b storage]
info  [int]

Other Parameters

overwrite_d
  [input int, optional] Default: 0
overwrite_e
  [input int, optional] Default: 0
overwrite_b
  [input int, optional] Default: 0

scipy.linalg.lapack.dptsv

scipy.linalg.lapack.dptsv(d, e, b[, overwrite_d, overwrite_e, overwrite_b]) = <fortran object>

Wrapper for dptsv.

Parameters

d     [input rank-1 array('d') with bounds (n)]
e     [input rank-1 array('d') with bounds (n - 1)]
b     [input rank-2 array('d') with bounds (n,nrhs)]

Returns

d     [rank-1 array('d') with bounds (n)]
du    [rank-1 array('d') with bounds (n - 1) and e storage]
x     [rank-2 array('d') with bounds (n,nrhs) and b storage]
info  [int]

Other Parameters

overwrite_d
  [input int, optional] Default: 0
overwrite_e
  [input int, optional] Default: 0
overwrite_b
  [input int, optional] Default: 0

scipy.linalg.lapack.cptsv

scipy.linalg.lapack.cptsv(d, e, b[, overwrite_d, overwrite_e, overwrite_b]) = <fortran object>

Wrapper for cptsv.

Parameters

d     [input rank-1 array('f') with bounds (n)]
e     [input rank-1 array('F') with bounds (n - 1)]
b     [input rank-2 array('F') with bounds (n,nrhs)]

Returns

d     [rank-1 array('f') with bounds (n)]
du    [rank-1 array('F') with bounds (n - 1) and e storage]
x     [rank-2 array('F') with bounds (n,nrhs) and b storage]
info  [int]
Other Parameters

overwrite_d
[input int, optional] Default: 0

overwrite_e
[input int, optional] Default: 0

overwrite_b
[input int, optional] Default: 0

scipy.linalg.lapack.zptsv

scipy.linalg.lapack.zptsv(d, e, b[, overwrite_d, overwrite_e, overwrite_b]) = <fortran object>
Wrapper for zptsv.

Parameters

d [input rank-1 array('d') with bounds (n)]
e [input rank-1 array('D') with bounds (n - 1)]
b [input rank-2 array('D') with bounds (n,nrhs)]

Returns

d [rank-1 array('d') with bounds (n)]

du [rank-1 array('D') with bounds (n - 1) and e storage]
x [rank-2 array('D') with bounds (n,nrhs) and b storage]

info [int]

Other Parameters

overwrite_d
[input int, optional] Default: 0

overwrite_e
[input int, optional] Default: 0

overwrite_b
[input int, optional] Default: 0

scipy.linalg.lapack.sptsvx

scipy.linalg.lapack.sptsvx(d, e, b[, fact, df, ef]) = <fortran object>
Wrapper for sptsvx.

Parameters

d [input rank-1 array('f') with bounds (n)]
e [input rank-1 array('f') with bounds (max(0, n-1))]
b [input rank-2 array('f') with bounds (ldb,nrhs)]

Returns

df [rank-1 array('f') with bounds (n)]
ef [rank-1 array('f') with bounds (max(0, n-1))]
x [rank-2 array('f') with bounds (ldx,nrhs)]

rcond [float]
ferr [rank-1 array('f') with bounds (nrhs)]
berr [rank-1 array('f') with bounds (nrhs)]

info [int]
Other Parameters

- `fact` [input string(len=1), optional] Default: 'N'
- `df` [input rank-1 array('f') with bounds (n)]
- `ef` [input rank-1 array('f') with bounds (max(0, n-1))]

**scipy.linalg.lapack.dptsvx**

\[
\text{scipy.linalg.lapack.dptsvx}(d, e, b[, \text{fact}, \text{df}, \text{ef}]) = \text{<fortran object>}
\]

Wrapper for **dptsvx**.

Parameters

- `d` [input rank-1 array('d') with bounds (n)]
- `e` [input rank-1 array('d') with bounds (max(0, n-1))]
- `b` [input rank-2 array('d') with bounds (ldb,nrhs)]

Returns

- `df` [rank-1 array('d') with bounds (n)]
- `ef` [rank-1 array('d') with bounds (max(0, n-1))]
- `x` [rank-2 array('d') with bounds (ldx,nrhs)]
- `rcond` [float]
- `ferr` [rank-1 array('d') with bounds (nrhs)]
- `berr` [rank-1 array('d') with bounds (nrhs)]
- `info` [int]

Other Parameters

- `fact` [input string(len=1), optional] Default: 'N'
- `df` [input rank-1 array('f') with bounds (n)]
- `ef` [input rank-1 array('f') with bounds (max(0, n-1))]

**scipy.linalg.lapack.cptsvx**

\[
\text{scipy.linalg.lapack.cptsvx}(d, e, b[, \text{fact}, \text{df}, \text{ef}]) = \text{<fortran object>}
\]

Wrapper for **cptsvx**.

Parameters

- `d` [input rank-1 array('f') with bounds (n)]
- `e` [input rank-1 array('F') with bounds (max(0, n-1))]
- `b` [input rank-2 array('F') with bounds (ldb,nrhs)]

Returns

- `df` [rank-1 array('f') with bounds (n)]
- `ef` [rank-1 array('F') with bounds (max(0, n-1))]
- `x` [rank-2 array('F') with bounds (ldx,nrhs)]
- `rcond` [float]
- `ferr` [rank-1 array('f') with bounds (nrhs)]
- `berr` [rank-1 array('f') with bounds (nrhs)]
- `info` [int]

Other Parameters

- `fact` [input string(len=1), optional] Default: 'N'
- `df` [input rank-1 array('f') with bounds (n)]
**scipy.linalg.lapack.zptsvx**

**scipy.linalg.lapack.zptsvx** *(d, e, b[, fact, df, ef]) = <fortran object>*

Wrapper for zptsvx.

**Parameters**

- **d** [input rank-1 array('d') with bounds (n)]
- **e** [input rank-1 array('D') with bounds (max(0, n-1))]
- **b** [input rank-2 array('D') with bounds (ldb,nrhs)]

**Returns**

- **df** [rank-1 array('d') with bounds (n)]
- **ef** [rank-1 array('D') with bounds (max(0, n-1))]
- **x** [rank-2 array('D') with bounds (ldx,nrhs)]
- **rcond** [float]
- **ferr** [rank-1 array('d') with bounds (nrhs)]
- **berr** [rank-1 array('d') with bounds (nrhs)]
- **info** [int]

**Other Parameters**

- **fact** [input string(len=1), optional] Default: 'N'
- **df** [input rank-1 array('d') with bounds (n)]
- **ef** [input rank-1 array('D') with bounds (max(0, n-1))]

**scipy.linalg.lapack.spttrf**

**scipy.linalg.lapack.spttrf** *(d, e[, overwrite_d, overwrite_e]) = <fortran object>*

Wrapper for spttrf.

**Parameters**

- **d** [input rank-1 array('f') with bounds (n)]
- **e** [input rank-1 array('f') with bounds ((n>0?n-1:0))]

**Returns**

- **d** [rank-1 array('f') with bounds (n)]
- **e** [rank-1 array('f') with bounds ((n>0?n-1:0))]
- **info** [int]

**Other Parameters**

- **overwrite_d** [input int, optional] Default: 0
- **overwrite_e** [input int, optional] Default: 0
scipy.linalg.lapack.dtptrf

scipy.linalg.lapack.dtptrf(d, e[, overwrite_d, overwrite_e]) = <fortran object>

Wrapper for dpttrf.

Parameters

- **d**: [input rank-1 array('d') with bounds (n)]
- **e**: [input rank-1 array('d') with bounds ((n>0?n-1:0))]

Returns

- **d**: [rank-1 array('d') with bounds (n)]
- **e**: [rank-1 array('d') with bounds ((n>0?n-1:0))]
- **info**: [int]

Other Parameters

- **overwrite_d**: [input int, optional] Default: 0
- **overwrite_e**: [input int, optional] Default: 0

scipy.linalg.lapack.cpttrf

scipy.linalg.lapack.cpttrf(d, e[, overwrite_d, overwrite_e]) = <fortran object>

Wrapper for cpttrf.

Parameters

- **d**: [input rank-1 array('f') with bounds (n)]
- **e**: [input rank-1 array('F') with bounds ((n>0?n-1:0))]

Returns

- **d**: [rank-1 array('f') with bounds (n)]
- **e**: [rank-1 array('F') with bounds ((n>0?n-1:0))]
- **info**: [int]

Other Parameters

- **overwrite_d**: [input int, optional] Default: 0
- **overwrite_e**: [input int, optional] Default: 0

scipy.linalg.lapack.zpttrf

scipy.linalg.lapack.zpttrf(d, e[, overwrite_d, overwrite_e]) = <fortran object>

Wrapper for zpttrf.

Parameters

- **d**: [input rank-1 array('d') with bounds (n)]
- **e**: [input rank-1 array('D') with bounds ((n>0?n-1:0))]

Returns

- **d**: [rank-1 array('d') with bounds (n)]
- **e**: [rank-1 array('D') with bounds ((n>0?n-1:0))]

6.12. Low-level LAPACK functions (scipy.linalg.lapack)
info [int]

Other Parameters
overwrite_d
    [input int, optional] Default: 0
overwrite_e
    [input int, optional] Default: 0

scipy.linalg.lapack.spttrs

scipy.linalg.lapack.spttrs(d, e, b[, overwrite_b]) = <fortran object>
Wrapper for spttrs.

Parameters
    d [input rank-1 array('f') with bounds (n)]
    e [input rank-1 array('f') with bounds ((n>0?n-1:0))]
    b [input rank-2 array('f') with bounds (ldb,nrhs)]

Returns
    x [rank-2 array('f') with bounds (ldb,nrhs) and b storage]
    info [int]

Other Parameters
overwrite_b
    [input int, optional] Default: 0

scipy.linalg.lapack.dpttrs

scipy.linalg.lapack.dpttrs(d, e, b[, overwrite_b]) = <fortran object>
Wrapper for dpttrs.

Parameters
    d [input rank-1 array('d') with bounds (n)]
    e [input rank-1 array('d') with bounds ((n>0?n-1:0))]
    b [input rank-2 array('d') with bounds (ldb,nrhs)]

Returns
    x [rank-2 array('d') with bounds (ldb,nrhs) and b storage]
    info [int]

Other Parameters
overwrite_b
    [input int, optional] Default: 0
scipy.linalg.lapack.cpttrs

scipy.linalg.lapack.cpttrs(d, e, b[, lower, overwrite_b]) = <fortran object>

Wrapper for cpttrs.

Parameters

- d [input rank-1 array('F') with bounds (n)]
- e [input rank-1 array('F') with bounds ((n>0?n-1:0))]
- b [input rank-2 array('F') with bounds (ldb,nrhs)]

Returns

- x [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
- info [int]

Other Parameters

- lower [input int, optional] Default: 0
- overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.zpttrs

scipy.linalg.lapack.zpttrs(d, e, b[, lower, overwrite_b]) = <fortran object>

Wrapper for zpttrs.

Parameters

- d [input rank-1 array('D') with bounds (n)]
- e [input rank-1 array('D') with bounds ((n>0?n-1:0))]
- b [input rank-2 array('D') with bounds (ldb,nrhs)]

Returns

- x [rank-2 array('D') with bounds (ldb,nrhs) and b storage]
- info [int]

Other Parameters

- lower [input int, optional] Default: 0
- overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.spteqr

scipy.linalg.lapack.spteqr(d, e, z[, compute_z, overwrite_d, overwrite_e, overwrite_z]) = <fortran object>

Wrapper for spteqr.

Parameters

- d [input rank-1 array('F') with bounds (n)]
- e [input rank-1 array('F') with bounds ((n>0?n-1:0))]
- z [input rank-2 array('F') with bounds ((compute_z==0?shape(z, 0):max(1,n)),(compute_z==0?shape(z, 1):n))]

Returns

- d [rank-1 array('F') with bounds (n)]

Other Parameters

compute_z
[input int, optional] Default: 0
overwrite_d
[input int, optional] Default: 0
overwrite_e
[input int, optional] Default: 0
overwrite_z
[input int, optional] Default: 0

scipy.linalg.lapack.dpteqr

scipy.linalg.lapack.dpteqr(d, e, z[, compute_z, overwrite_d, overwrite_e, overwrite_z]) =
<fortran object>
Wrapper for dpteqr.

Parameters

d [input rank-1 array('d') with bounds (n)]
e [input rank-1 array('d') with bounds ((n>0?n-1:0)])
z [input rank-2 array('d') with bounds ((compute_z==0?shape(z, 0):max(1,n)),(compute_z==0?shape(z, 1):n))]

info [int]

Other Parameters

compute_z
[input int, optional] Default: 0
overwrite_d
[input int, optional] Default: 0
overwrite_e
[input int, optional] Default: 0
overwrite_z
[input int, optional] Default: 0

scipy.linalg.lapack.cpteqr

```
scipy.linalg.lapack.cpteqr(d, e, z[, compute_z, overwrite_d, overwrite_e, overwrite_z]) =
<fortran object>
```
Wrapper for `cpteqr`.

**Parameters**

- `d` [input rank-1 array('f') with bounds (n)]
- `e` [input rank-1 array('f') with bounds ((n>0?n-1:0))]
- `z` [input rank-2 array('F') with bounds ((compute_z==0?shape(z, 0):max(1,n)),(compute_z==0?shape(z, 1):n))]

**Returns**

- `d` [rank-1 array('f') with bounds (n)]
- `e` [rank-1 array('f') with bounds ((n>0?n-1:0))]
- `z` [rank-2 array('F') with bounds ((compute_z==0?shape(z, 0):max(1,n)),(compute_z==0?shape(z, 1):n))]
- `info` [int]

**Other Parameters**

- `compute_z` [input int, optional] Default: 0
- `overwrite_d` [input int, optional] Default: 0
- `overwrite_e` [input int, optional] Default: 0
- `overwrite_z` [input int, optional] Default: 0

scipy.linalg.lapack.zpteqr

```
scipy.linalg.lapack.zpteqr(d, e, z[, compute_z, overwrite_d, overwrite_e, overwrite_z]) =
<fortran object>
```
Wrapper for `zpteqr`.

**Parameters**

- `d` [input rank-1 array('d') with bounds (n)]
- `e` [input rank-1 array('d') with bounds ((n>0?n-1:0))]
- `z` [input rank-2 array('D') with bounds ((compute_z==0?shape(z, 0):max(1,n)),(compute_z==0?shape(z, 1):n))]

**Returns**

- `d` [rank-1 array('d') with bounds (n)]
- `e` [rank-1 array('d') with bounds ((n>0?n-1:0))]
- `z` [rank-2 array('D') with bounds ((compute_z==0?shape(z, 0):max(1,n)),(compute_z==0?shape(z, 1):n))]
- `info` [int]

**Other Parameters**

- `compute_z` [input int, optional] Default: 0
- `overwrite_d` [input int, optional] Default: 0
overwrite_e
    [input int, optional] Default: 0
overwrite_z
    [input int, optional] Default: 0

scipy.linalg.lapack.crot

scipy.linalg.lapack.crot(x, y, c[, n, offx, incx, offy, incy, overwrite_x, overwrite_y]) =
<fortran object>

Wrapper for crot.

Parameters

x [input rank-1 array('F') with bounds (lx)]
y [input rank-1 array('F') with bounds (ly)]
c [input float]
s [input complex]

Returns

x [rank-1 array('F') with bounds (lx)]
y [rank-1 array('F') with bounds (ly)]

Other Parameters

n [input int, optional] Default: (lx-1-offx)/abs(incx)+1
overwrite_x [input int, optional] Default: 0
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1
overwrite_y [input int, optional] Default: 0
offy [input int, optional] Default: 0
incy [input int, optional] Default: 1

scipy.linalg.lapack.zrot

scipy.linalg.lapack.zrot(x, y, c[, n, offx, incx, offy, incy, overwrite_x, overwrite_y]) =
<fortran object>

Wrapper for zrot.

Parameters

x [input rank-1 array('D') with bounds (lx)]
y [input rank-1 array('D') with bounds (ly)]
c [input float]
s [input complex]

Returns

x [rank-1 array('D') with bounds (lx)]
y [rank-1 array('D') with bounds (ly)]

Other Parameters

n [input int, optional] Default: (lx-1-offx)/abs(incx)+1
overwrite_x [input int, optional] Default: 0
scipy.linalg.lapack.ssbev

scipy.linalg.lapack.ssbev(ab[, compute_v, lower, ldab, overwrite_ab]) = <fortran object>
Wrapper for ssbev.

Parameters

**ab**  [input rank-2 array('f') with bounds (ldab,n)]

Returns

**w**  [rank-1 array('f') with bounds (n)]
**z**  [rank-2 array('f') with bounds (ldz,ldz)]
**info**  [int]

Other Parameters

**overwrite_ab**  [input int, optional] Default: 1
**compute_v**  [input int, optional] Default: 1
**lower**  [input int, optional] Default: 0
**ldab**  [input int, optional] Default: shape(ab,0)

scipy.linalg.lapack.dsbev

scipy.linalg.lapack.dsbev(ab[, compute_v, lower, ldab, overwrite_ab]) = <fortran object>
Wrapper for dsbev.

Parameters

**ab**  [input rank-2 array('d') with bounds (ldab,n)]

Returns

**w**  [rank-1 array('d') with bounds (n)]
**z**  [rank-2 array('d') with bounds (ldz,ldz)]
**info**  [int]

Other Parameters

**overwrite_ab**  [input int, optional] Default: 1
**compute_v**  [input int, optional] Default: 1
**lower**  [input int, optional] Default: 0
**ldab**  [input int, optional] Default: shape(ab,0)
scipy.linalg.lapack.ssbevd

scipy.linalg.lapack.ssbevd(ab[, compute_v, lower, ldab, liwork, overwrite_ab]) = <fortran object>

Wrapper for ssbevd.

Parameters

ab [input rank-2 array('f') with bounds (ldab,n)]

Returns

w [rank-1 array('f') with bounds (n)]
z [rank-2 array('f') with bounds (ldz,ldz)]
info [int]

Other Parameters

overwrite_ab [input int, optional] Default: 1
compute_v [input int, optional] Default: 1
lower [input int, optional] Default: 0
ldab [input int, optional] Default: shape(ab,0)
liwork [input int, optional] Default: (compute_v?3+5*n:1)

scipy.linalg.lapack.dsbevd

scipy.linalg.lapack.dsbevd(ab[, compute_v, lower, ldab, liwork, overwrite_ab]) = <fortran object>

Wrapper for dsbevd.

Parameters

ab [input rank-2 array('d') with bounds (ldab,n)]

Returns

w [rank-1 array('d') with bounds (n)]
z [rank-2 array('d') with bounds (ldz,ldz)]
info [int]

Other Parameters

overwrite_ab [input int, optional] Default: 1
compute_v [input int, optional] Default: 1
lower [input int, optional] Default: 0
ldab [input int, optional] Default: shape(ab,0)
liwork [input int, optional] Default: (compute_v?3+5*n:1)
scipy.linalg.lapack.ssbevx

Wrapper for ssbevx.

Parameters:
- ab: [input rank-2 array('f') with bounds (ldab,n)]
- vl: [input float]
- vu: [input float]
- il: [input int]
- iu: [input int]

Returns:
- w: [rank-1 array('f') with bounds (n)]
- z: [rank-2 array('f') with bounds (ldz,mmax)]
- m: [int]
- ifail: [rank-1 array('i') with bounds ((compute_v?n:1))]
- info: [int]

Other Parameters:
- overwrite_ab: [input int, optional] Default: 1
- ldab: [input int, optional] Default: shape(ab,0)
- compute_v: [input int, optional] Default: 1
- range: [input int, optional] Default: 0
- lower: [input int, optional] Default: 0
- abstol: [input float, optional] Default: 0.0
- mmax: [input int, optional] Default: (compute_v?(range==2?(iu-il+1):n):1)

scipy.linalg.lapack.dsbevx

Wrapper for dsbevx.

Parameters:
- ab: [input rank-2 array('d') with bounds (ldab,n)]
- vl: [input float]
- vu: [input float]
- il: [input int]
- iu: [input int]

Returns:
- w: [rank-1 array('d') with bounds (n)]
- z: [rank-2 array('d') with bounds (ldz,mmax)]
- m: [int]
- ifail: [rank-1 array('i') with bounds ((compute_v?n:1))]
- info: [int]

Other Parameters
overwrite_ab
    [input int, optional] Default: 1
ldab
    [input int, optional] Default: shape(ab,0)
compute_v
    [input int, optional] Default: 1
range
    [input int, optional] Default: 0
lower
    [input int, optional] Default: 0
abstol
    [input float, optional] Default: 0.0
mmax
    [input int, optional] Default: (compute_v?(range==2?(iu-il+1):n):1)

scipy.linalg.lapack.ssfrk

scipy.linalg.lapack.ssfrk(n, k, alpha, a, beta, c[, transr, uplo, trans, overwrite_c]) = <fortran object>

Wrapper for ssfrk.

Parameters

n     [input int]
k     [input int]
alpha [input float]
a     [input rank-2 array('f') with bounds (lda,ka)]
beta [input float]
c     [input rank-1 array('f') with bounds (nt)]

Returns

cout  [rank-1 array('f') with bounds (nt) and c storage]

Other Parameters

transr [input string(len=1), optional] Default: ‘N’
uplo   [input string(len=1), optional] Default: ‘U’
trans  [input string(len=1), optional] Default: ‘N’
overwrite_c
    [input int, optional] Default: 0

scipy.linalg.lapack.dsfrk

scipy.linalg.lapack.dsfrk(n, k, alpha, a, beta, c[, transr, uplo, trans, overwrite_c]) = <fortran object>

Wrapper for dsfrk.

Parameters

n     [input int]
k     [input int]
alpha [input float]
a     [input rank-2 array('d') with bounds (lda,ka)]
beta [input float]
c     [input rank-1 array('d') with bounds (nt)]

Returns

cout  [rank-1 array('d') with bounds (nt) and c storage]

Other Parameters
transr  [input string(len=1), optional] Default: ‘N’
uplo   [input string(len=1), optional] Default: ‘U’
trans  [input string(len=1), optional] Default: ‘N’
overwrite_c  [input int, optional] Default: 0

scipy.linalg.lapack.sstebz

scipy.linalg.lapack.sstebz (d, e, range, vl, vu, il, iu, tol, order) = <fortran object>
Wrapper for sstebz.

Parameters

- d    [input rank-1 array('f') with bounds (n)]
- e    [input rank-1 array('f') with bounds (n - 1)]
- range [input int]
- vl   [input float]
- vu   [input float]
- il   [input int]
- iu   [input int]
- tol  [input float]
- order [input string(len=1)]

Returns

- m    [int]
- w    [rank-1 array('f') with bounds (n)]
- iblock [rank-1 array('i') with bounds (n)]
- isplit [rank-1 array('i') with bounds (n)]
- info [int]

scipy.linalg.lapack.dstebz

scipy.linalg.lapack.dstebz (d, e, range, vl, vu, il, iu, tol, order) = <fortran object>
Wrapper for dstebz.

Parameters

- d    [input rank-1 array('d') with bounds (n)]
- e    [input rank-1 array('d') with bounds (n - 1)]
- range [input int]
- vl   [input float]
- vu   [input float]
- il   [input int]
- iu   [input int]
- tol  [input float]
- order [input string(len=1)]

Returns

- m    [int]
- w    [rank-1 array('d') with bounds (n)]
- iblock [rank-1 array('i') with bounds (n)]
- isplit [rank-1 array('i') with bounds (n)]
- info [int]
scipy.linalg.lapack.sstein

scipy.linalg.lapack.sstein\((d, e, w, iblock, isplit)\) = <fortran object>

Wrapper for sstein.

Parameters

\- d [input rank-1 array('f') with bounds (n)]
\- e [input rank-1 array('f') with bounds (n - 1)]
\- w [input rank-1 array('f') with bounds (m)]
\- iblock [input rank-1 array('i') with bounds (n)]
\- isplit [input rank-1 array('i') with bounds (n)]

Returns

\- z [rank-2 array('f') with bounds (ldz,m)]
\- info [int]

scipy.linalg.lapack.dstein

scipy.linalg.lapack.dstein\((d, e, w, iblock, isplit)\) = <fortran object>

Wrapper for dstein.

Parameters

\- d [input rank-1 array('d') with bounds (n)]
\- e [input rank-1 array('d') with bounds (n - 1)]
\- w [input rank-1 array('d') with bounds (m)]
\- iblock [input rank-1 array('i') with bounds (n)]
\- isplit [input rank-1 array('i') with bounds (n)]

Returns

\- z [rank-2 array('d') with bounds (ldz,m)]
\- info [int]

scipy.linalg.lapack.sstemr

scipy.linalg.lapack.sstemr\((d, e, range, vl, vu, il, iu[, compute_v, lwork, liwork, overwrite_d])\) = <fortran object>

Wrapper for sstemr.

Parameters

\- d [input rank-1 array('f') with bounds (n)]
\- e [input rank-1 array('f') with bounds (n)]
\- range [input int]
\- vl [input float]
\- vu [input float]
\- il [input int]
\- iu [input int]

Returns

\- m [int]
\- w [rank-1 array('f') with bounds (n)]
\- z [rank-2 array('f') with bounds (n,n)]
\- info [int]
**Other Parameters**

- **overwrite_d**
  
  [input int, optional] Default: 0

- **compute_v**
  
  [input int, optional] Default: 1

- **lwork**
  
  [input int, optional] Default: max((compute_v?18*n:12*n),1)

- **liwork**
  
  [input int, optional] Default: (compute_v?10*n:8*n)

---

dstemr

**scipy.linalg.lapack.dstemr**

```python
scipy.linalg.lapack.dstemr(d, e, range, vl, vu, il, iu[, compute_v, lwork, liwork, overwrite_d]) = <fortran object>
```

Wrapper for dstemr.

**Parameters**

- **d**
  
  [input rank-1 array('d') with bounds (n)]

- **e**
  
  [input rank-1 array('d') with bounds (n)]

- **range**
  
  [input int]

- **vl**
  
  [input float]

- **vu**
  
  [input float]

- **il**
  
  [input int]

- **iu**
  
  [input int]

**Returns**

- **m**
  
  [int]

- **w**
  
  [rank-1 array('d') with bounds (n)]

- **z**
  
  [rank-2 array('d') with bounds (n,n)]

- **info**
  
  [int]

**Other Parameters**

- **overwrite_d**
  
  [input int, optional] Default: 0

- **compute_v**
  
  [input int, optional] Default: 1

- **lwork**
  
  [input int, optional] Default: max((compute_v?18*n:12*n),1)

- **liwork**
  
  [input int, optional] Default: (compute_v?10*n:8*n)

---

sstemr_lwork

**scipy.linalg.lapack.sstemr_lwork**

```python
scipy.linalg.lapack.sstemr_lwork(d, e, range, vl, vu, il, iu[, compute_v, overwrite_d, overwrite_e]) = <fortran object>
```

Wrapper for sstemr_lwork.

**Parameters**

- **d**
  
  [input rank-1 array('f') with bounds (n)]

- **e**
  
  [input rank-1 array('f') with bounds (n)]

- **range**
  
  [input int]

- **vl**
  
  [input float]

- **vu**
  
  [input float]

- **il**
  
  [input int]

- **iu**
  
  [input int]
Returns

work [float]
iwork [int]
info [int]

Other Parameters

overwrite_d
[input int, optional] Default: 0
overwrite_e
[input int, optional] Default: 0
compute_v
[input int, optional] Default: 1

scipy.linalg.lapack.dstemr_lwork

scipy.linalg.lapack.dstemr_lwork (d, e, range, vl, vu, il, iu[, compute_v, overwrite_d, overwrite_e]) = <fortran object>
Wrapper for dstemr_lwork.

Parameters

d [input rank-1 array('d') with bounds (n)]
e [input rank-1 array('d') with bounds (n)]
r
[put int]
vl [input float]
vu [input float]
il [input int]
iu [input int]

Returns

work [float]
iwork [int]
info [int]

Other Parameters

overwrite_d
[input int, optional] Default: 0
overwrite_e
[input int, optional] Default: 0
compute_v
[input int, optional] Default: 1

scipy.linalg.lapack.ssterf

scipy.linalg.lapack.ssterf (d[, overwrite_d, overwrite_e]) = <fortran object>
Wrapper for ssterf.

Parameters

d [input rank-1 array('f') with bounds (n)]
e [input rank-1 array('f') with bounds (n - 1)]

Returns

vals [rank-1 array('f') with bounds (n) and d storage]
info [int]

Other Parameters

overwrite_d
  [input int, optional] Default: 0
overwrite_e
  [input int, optional] Default: 0

scipy.linalg.lapack.dsterf

scipy.linalg.lapack.dsterf(d, e, overwrite_d, overwrite_e) = <fortran object>
Wrapper for dsterf.

Parameters

d [input rank-1 array('d') with bounds (n)]
e [input rank-1 array('d') with bounds (n - 1)]

Returns

vals [rank-1 array('d') with bounds (n) and d storage]
info [int]

Other Parameters

overwrite_d
  [input int, optional] Default: 0
overwrite_e
  [input int, optional] Default: 0

scipy.linalg.lapack.sstev

scipy.linalg.lapack.sstev(d, e, compute_v, overwrite_d, overwrite_e) = <fortran object>
Wrapper for sstev.

Parameters

d [input rank-1 array('f') with bounds (n)]
e [input rank-1 array('f') with bounds (MAX(n-1,1))]

Returns

vals [rank-1 array('f') with bounds (n) and d storage]
z [rank-2 array('f') with bounds (ldz,(compute_v?n:1))]
info [int]

Other Parameters

overwrite_d
  [input int, optional] Default: 0
overwrite_e
  [input int, optional] Default: 0
compute_v
  [input int, optional] Default: 1
scipy.linalg.lapack.dstev

scipy.linalg.lapack.dstev(d, e[, compute_v, overwrite_d, overwrite_e]) = <fortran object>

Wrapper for dstev.

Parameters

d   [input rank-1 array('d') with bounds (n)]
e   [input rank-1 array('d') with bounds (MAX(n-1,1))]

Returns

vals   [rank-1 array('d') with bounds (n) and d storage]
z   [rank-2 array('d') with bounds (ldz,(compute_v?n:1))]
info   [int]

Other Parameters

overwrite_d   [input int, optional] Default: 0
overwrite_e   [input int, optional] Default: 0
compute_v   [input int, optional] Default: 1

scipy.linalg.lapack.ssycon

scipy.linalg.lapack.ssycon(a, ipiv, anorm[, lower]) = <fortran object>

Wrapper for ssycon.

Parameters

a   [input rank-2 array('f') with bounds (n,n)]

ipiv   [input rank-1 array('i') with bounds (n)]
anorm   [input float]

Returns

rcond   [float]
info   [int]

Other Parameters

lower   [input int, optional] Default: 0

scipy.linalg.lapack.dsycon

scipy.linalg.lapack.dsycon(a, ipiv, anorm[, lower]) = <fortran object>

Wrapper for dsycon.

Parameters

a   [input rank-2 array('d') with bounds (n,n)]

ipiv   [input rank-1 array('i') with bounds (n)]
anorm   [input float]

Returns

rcond   [float]
info   [int]
Other Parameters

lower [input int, optional] Default: 0

scipy.linalg.lapack.csycon

scipy.linalg.lapack.csycon(a, ipiv, anorm[, lower]) = <fortran object>
Wrapper for csycon.

Parameters

a [input rank-2 array('F') with bounds (n,n)]
ipiv [input rank-1 array('i') with bounds (n)]
anorm [input float]

Returns

rcond [float]
info [int]

Other Parameters

lower [input int, optional] Default: 0

scipy.linalg.lapack.zsycon

scipy.linalg.lapack.zsycon(a, ipiv, anorm[, lower]) = <fortran object>
Wrapper for zsycon.

Parameters

a [input rank-2 array('D') with bounds (n,n)]
ipiv [input rank-1 array('i') with bounds (n)]
anorm [input float]

Returns

rcond [float]
info [int]

Other Parameters

lower [input int, optional] Default: 0

scipy.linalg.lapack.ssyconv

scipy.linalg.lapack.ssyconv(a, ipiv[, lower, way, overwrite_a]) = <fortran object>
Wrapper for ssyconv.

Parameters

a [input rank-2 array('f') with bounds (n,n)]
ipiv [input rank-1 array('i') with bounds (n)]

Returns

a [rank-2 array('f') with bounds (n,n)]
e [rank-1 array('f') with bounds (n)]
info [int]
Other Parameters

lower [input int, optional] Default: 0
way [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0

scipy.linalg.lapack.dsyconv

scipy.linalg.lapack.dsyconv(a, ipiv[, lower, way, overwrite_a]) = <fortran object>
Wrapper for dsyconv.

Parameters

a [input rank-2 array('d') with bounds (n,n)]
ipiv [input rank-1 array('i') with bounds (n)]

Returns

a [rank-2 array('d') with bounds (n,n)]
e [rank-1 array('d') with bounds (n)]
info [int]

Other Parameters

lower [input int, optional] Default: 0
way [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0

scipy.linalg.lapack.csyconv

scipy.linalg.lapack.csyconv(a, ipiv[, lower, way, overwrite_a]) = <fortran object>
Wrapper for csyconv.

Parameters

a [input rank-2 array('F') with bounds (n,n)]
ipiv [input rank-1 array('i') with bounds (n)]

Returns

a [rank-2 array('F') with bounds (n,n)]
e [rank-1 array('F') with bounds (n)]
info [int]

Other Parameters

lower [input int, optional] Default: 0
way [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0
scipy.linalg.lapack.zsyconv

```python
scipy.linalg.lapack.zsyconv(a, ipiv[, lower, way, overwrite_a]) = <fortran object>
Wrapper for zsyconv.

Parameters
    a : [input rank-2 array('D') with bounds (n,n)]
    ipiv : [input rank-1 array('i') with bounds (n)]

Returns
    a : [rank-2 array('D') with bounds (n,n)]
    e : [rank-1 array('D') with bounds (n)]
    info : [int]

Other Parameters
    lower : [input int, optional] Default: 0
    way : [input int, optional] Default: 0
    overwrite_a : [input int, optional] Default: 0
```

scipy.linalg.lapack.ssyequb

```python
scipy.linalg.lapack.ssyequb(a[, lower]) = <fortran object>
Wrapper for ssyequb.

Parameters
    a : [input rank-2 array('f') with bounds (lda,n)]

Returns
    s : [rank-1 array('f') with bounds (n)]
    scond : [float]
    amax : [float]
    info : [int]

Other Parameters
    lower : [input int, optional] Default: 0
```

scipy.linalg.lapack.dsyequb

```python
scipy.linalg.lapack.dsyequb(a[, lower]) = <fortran object>
Wrapper for dsyequb.

Parameters
    a : [input rank-2 array('d') with bounds (lda,n)]

Returns
    s : [rank-1 array('d') with bounds (n)]
    scond : [float]
    amax : [float]
    info : [int]

Other Parameters
```
lower [input int, optional] Default: 0

**scipy.linalg.lapack.csyequb**

```python
scipy.linalg.lapack.csyequb(a[, lower]) = <fortran object>
```

Wrapper for csyequb.

**Parameters**

- **a** [input rank-2 array('F') with bounds (lda,n)]

**Returns**

- **s** [rank-1 array('f') with bounds (n)]
- **scond** [float]
- **amax** [float]
- **info** [int]

**Other Parameters**

- **lower** [input int, optional] Default: 0

**scipy.linalg.lapack.zsyequb**

```python
scipy.linalg.lapack.zsyequb(a[, lower]) = <fortran object>
```

Wrapper for zsyequb.

**Parameters**

- **a** [input rank-2 array('D') with bounds (lda,n)]

**Returns**

- **s** [rank-1 array('d') with bounds (n)]
- **scond** [float]
- **amax** [float]
- **info** [int]

**Other Parameters**

- **lower** [input int, optional] Default: 0

**scipy.linalg.lapack.ssyev**

```python
scipy.linalg.lapack.ssyev(a[, compute_v, lower, lwork, overwrite_a]) = <fortran object>
```

Wrapper for ssyev.

**Parameters**

- **a** [input rank-2 array('f') with bounds (n,n)]

**Returns**

- **w** [rank-1 array('f') with bounds (n)]
- **v** [rank-2 array('f') with bounds (n,n) and a storage]
- **info** [int]

**Other Parameters**
compute_v  [input int, optional] Default: 1
lower   [input int, optional] Default: 0
overwrite_a  [input int, optional] Default: 0
lwork  [input int, optional] Default: max(3*n-1,1)

scipy.linalg.lapack.dsyev

scipy.linalg.lapack.dsyev(a[, compute_v, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for dsyev.

Parameters
  a  [input rank-2 array('d') with bounds (n,n)]

Returns
  w  [rank-1 array('d') with bounds (n)]
  v  [rank-2 array('d') with bounds (n,n) and a storage]
  info  [int]

Other Parameters
  compute_v  [input int, optional] Default: 1
  lower   [input int, optional] Default: 0
  overwrite_a  [input int, optional] Default: 0
  lwork  [input int, optional] Default: max(3*n-1,1)

scipy.linalg.lapack.ssyev_lwork

scipy.linalg.lapack.ssyev_lwork(n[, lower]) = <fortran object>
Wrapper for ssyev_lwork.

Parameters
  n  [input int]

Returns
  work  [float]
  info  [int]

Other Parameters
  lower  [input int, optional] Default: 0
scipy.linalg.lapack.dsyev_lwork

Wrapper for dsyev_lwork.

Parameters

- `n` [input int]

Returns

- `work` [float]
- `info` [int]

Other Parameters

- `lower` [input int, optional] Default: 0

scipy.linalg.lapack.ssyevd

Wrapper for ssyevd.

Parameters

- `a` [input rank-2 array('f') with bounds (n,n)]

Returns

- `w` [rank-1 array('f') with bounds (n)]
- `v` [rank-2 array('f') with bounds (n,n) and a storage]
- `info` [int]

Other Parameters

- `compute_v` [input int, optional] Default: 1
- `lower` [input int, optional] Default: 0
- `overwrite_a` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: max((compute_v?1+6*n+2*n*n:2*n+1),1)
- `liwork` [input int, optional] Default: (compute_v?3+5*n:1)

scipy.linalg.lapack.dsyevd

Wrapper for dsyevd.

Parameters

- `a` [input rank-2 array('d') with bounds (n,n)]

Returns

- `w` [rank-1 array('d') with bounds (n)]
- `v` [rank-2 array('d') with bounds (n,n) and a storage]
- `info` [int]

Other Parameters
compute_v  
    [input int, optional] Default: 1
lower  
    [input int, optional] Default: 0
overwrite_a  
    [input int, optional] Default: 0
lwork  
    [input int, optional] Default: max((compute_v?1+6*n+2*n*n:2*n+1),1)
ilwork  
    [input int, optional] Default: (compute_v?3+5*n:1)

scipy.linalg.lapack.ssyevd_lwork

scipy.linalg.lapack.ssyevd_lwork(n[, compute_v, lower]) = <fortran object>
Wrapper for ssyevd_lwork.

Parameters
n  [input int]

Returns
work  [float]
iwork  [int]
info  [int]

Other Parameters
compute_v  
    [input int, optional] Default: 1
lower  
    [input int, optional] Default: 0

scipy.linalg.lapack.dsyevd_lwork

scipy.linalg.lapack.dsyevd_lwork(n[, compute_v, lower]) = <fortran object>
Wrapper for dsyevd_lwork.

Parameters
n  [input int]

Returns
work  [float]
iwork  [int]
info  [int]

Other Parameters
compute_v  
    [input int, optional] Default: 1
lower  
    [input int, optional] Default: 0
scipy.linalg.lapack.ssyevr

scipy.linalg.lapack.ssyevr(a[, compute_v, range, lower, vl, il, iu, abstol, lwork, liwork, overwrite_a]) = <fortran object>

Wrapper for ssyevr.

Parameters

a [input rank-2 array('f') with bounds (n,n)]

Returns

w [rank-1 array('f') with bounds (n)]

z [rank-2 array('f') with bounds ((compute_v?MAX(0,n):0),(compute_v?(*range=='I'?iu-il+1:MAX(1,n)):0))]

m [int]

isuppz [rank-1 array('i') with bounds ((compute_v?(2*(range=='A'||range=='I'&&iu-il+1==n)?n:0)):0)]

info [int]

Other Parameters

compute_v [input int, optional] Default 1
range [input string(len=1), optional] Default 'A'
lower [input int, optional] Default 0
overwrite_a [input int, optional] Default 0
vl [input float, optional] Default 0.0
vu [input float, optional] Default 1.0
il [input int, optional] Default 1
iu [input int, optional] Default n
abstol [input float, optional] Default 0.0
lwork [input int, optional] Default max(26*n,1)
liwork [input int, optional] Default max(1,10*n)

scipy.linalg.lapack.dsyevr

scipy.linalg.lapack.dsyevr(a[, compute_v, range, lower, vl, il, iu, abstol, lwork, liwork, overwrite_a]) = <fortran object>

Wrapper for dsyevr.

Parameters

a [input rank-2 array('d') with bounds (n,n)]

Returns

w [rank-1 array('d') with bounds (n)]

z [rank-2 array('d') with bounds ((compute_v?MAX(0,n):0),(compute_v?(*range=='I'?iu-il+1:MAX(1,n)):0))]

m [int]

isuppz [rank-1 array('i') with bounds ((compute_v?(2*(range=='A'||range=='I'&&iu-il+1==n)?n:0)):0)]

info [int]

Other Parameters
compute_v
  [input int, optional] Default 1
range  [input string(len=1), optional] Default 'A'
lower [input int, optional] Default 0
overwrite_a
  [input int, optional] Default 0
vl  [input float, optional] Default 0.0
vu  [input float, optional] Default 1.0
il  [input int, optional] Default 1
iu  [input int, optional] Default n
abstol [input float, optional] Default 0.0
lwork [input int, optional] Default max(26*n,1)
liwork [input int, optional] Default max(1,10*n)

scipy.linalg.lapack.ssyevr_lwork

scipy.linalg.lapack.ssyevr_lwork(n[, lower]) = <fortran object>
Wrapper for ssyevr_lwork.

Parameters
n  [input int]

Returns
work  [float]
iwork  [int]
info  [int]

Other Parameters
lower  [input int, optional] Default: 0

scipy.linalg.lapack.dsyevr_lwork

scipy.linalg.lapack.dsyevr_lwork(n[, lower]) = <fortran object>
Wrapper for dsyevr_lwork.

Parameters
n  [input int]

Returns
work  [float]
iwork  [int]
info  [int]

Other Parameters
lower  [input int, optional] Default: 0
scipy.linalg.lapack.ssyevx

scipy.linalg.lapack.ssyevx(a[, compute_v, range, lower, vl, vu, il, iu, abstol, lwork, overwrite_a])

Wrapper for ssyevx.

Parameters

- **a** [input rank-2 array('f') with bounds (n,n)]

Returns

- **w** [rank-1 array('f') with bounds (n)]
- **z** [rank-2 array('f') with bounds ((compute_v?MAX(0,n):0),(compute_v?(*range=='I'?iu-il+1:MAX(1,n)):0))]
- **m** [int]
- **ifail** [rank-1 array('i') with bounds ((compute_v?n:0))]
- **info** [int]

Other Parameters

- **compute_v** [input int, optional] Default 1
- **range** [input string(len=1), optional] Default 'A'
- **lower** [input int, optional] Default 0
- **overwrite_a** [input int, optional] Default 0
- **vl** [input float, optional] Default 0.0
- **vu** [input float, optional] Default 1.0
- **il** [input int, optional] Default 1
- **iu** [input int, optional] Default n
- **abstol** [input float, optional] Default 0.0
- **lwork** [input int, optional] Default max(8*n,1)

scipy.linalg.lapack.dsyevx

scipy.linalg.lapack.dsyevx(a[, compute_v, range, lower, vl, vu, il, iu, abstol, lwork, overwrite_a])

Wrapper for dsyevx.

Parameters

- **a** [input rank-2 array('d') with bounds (n,n)]

Returns

- **w** [rank-1 array('d') with bounds (n)]
- **z** [rank-2 array('d') with bounds ((compute_v?MAX(0,n):0),(compute_v?(*range=='I'?iu-il+1:MAX(1,n)):0))]
- **m** [int]
- **ifail** [rank-1 array('i') with bounds ((compute_v?n:0))]
- **info** [int]

Other Parameters

- **compute_v** [input int, optional] Default 1
- **range** [input string(len=1), optional] Default 'A'
- **lower** [input int, optional] Default 0
overwrite_a
  [input int, optional] Default 0
vl
  [input float, optional] Default 0.0
vu
  [input float, optional] Default 1.0
il
  [input int, optional] Default 1
iu
  [input int, optional] Default n
abstol
  [input float, optional] Default 0.0
lwork
  [input int, optional] Default max(8*n, 1)

**scipy.linalg.lapack.ssyevx_lwork**

```
sipy.linalg.lapack.ssyevx_lwork (n[, lower]) = <fortran object>
```

Wrapper for ssyevx_lwork.

**Parameters**

- n [input int]

**Returns**

- work [float]
- info [int]

**Other Parameters**

- lower [input int, optional] Default: 0

**scipy.linalg.lapack.dsyevx_lwork**

```
sipy.linalg.lapack.dsyevx_lwork (n[, lower]) = <fortran object>
```

Wrapper for dsyevx_lwork.

**Parameters**

- n [input int]

**Returns**

- work [float]
- info [int]

**Other Parameters**

- lower [input int, optional] Default: 0

**scipy.linalg.lapack.ssygst**

```
sipy.linalg.lapack.ssygst (a, b[, itype, lower, overwrite_a]) = <fortran object>
```

Wrapper for ssygst.

**Parameters**

- a [input rank-2 array('f') with bounds (n,n)]
- b [input rank-2 array('f') with bounds (n,n)]

**Returns**

- c [rank-2 array('f') with bounds (n,n) and a storage]
- info [int]
Other Parameters

overwrite_a
[input int, optional] Default: 0
itype
[input int, optional] Default: 1
lower
[input int, optional] Default: 0

scipy.linalg.lapack.dsygst

scipy.linalg.lapack.dsygst(a, b[, itype, lower, overwrite_a]) = <fortran object>
Wrapper for dsygst.

Parameters
a [input rank-2 array('d') with bounds (n,n)]
b [input rank-2 array('d') with bounds (n,n)]

Returns
c [rank-2 array('d') with bounds (n,n) and a storage]
info [int]

Other Parameters
overwrite_a
[input int, optional] Default: 0
itype
[input int, optional] Default: 1
lower
[input int, optional] Default: 0

scipy.linalg.lapack.ssygv

scipy.linalg.lapack.ssygv(a, b[, itype, jobz, uplo, lwork, overwrite_a, overwrite_b]) = <fortran object>
Wrapper for ssygv.

Parameters
a [input rank-2 array('f') with bounds (n,n)]
b [input rank-2 array('f') with bounds (n,n)]

Returns
w [rank-1 array('f') with bounds (n)]
v [rank-2 array('f') with bounds (n,n) and a storage]
info [int]

Other Parameters
itype [input int, optional] Default: 1
jobz [input string(len=1), optional] Default: ‘V’
uplo [input string(len=1), optional] Default: ‘L’
overwrite_a
[input int, optional] Default: 0
overwrite_b
[input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n-1,1)
scipy.linalg.lapack.dsygv

scipy.linalg.lapack.dsygv (a, b[, itype, jobz, uplo, lwork, overwrite_a, overwrite_b]) = <fortran object>
Wrapper for dsygv.

Parameters

a [input rank-2 array('d') with bounds (n,n)]
b [input rank-2 array('d') with bounds (n,n)]

Returns

w [rank-1 array('d') with bounds (n)]
v [rank-2 array('d') with bounds (n,n) and a storage]
info [int]

Other Parameters

itype [input int, optional] Default: 1
jobz [input string(len=1), optional] Default: ‘V’
uplo [input string(len=1), optional] Default: ‘L’
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n-1,1)

scipy.linalg.lapack.ssygv_lwork

scipy.linalg.lapack.ssygv_lwork (n[, uplo]) = <fortran object>
Wrapper for ssygv_lwork.

Parameters

n [input int]

Returns

work [float]
info [int]

Other Parameters

uplo [input string(len=1), optional] Default: ‘L’

scipy.linalg.lapack.dsygv_lwork

scipy.linalg.lapack.dsygv_lwork (n[, uplo]) = <fortran object>
Wrapper for dsygv_lwork.

Parameters

n [input int]

Returns

work [float]
info [int]
Other Parameters

uplo [input string(len=1), optional] Default: ‘L’

scipy.linalg.lapack.ssygvd

scipy.linalg.lapack.ssygvd(a, b[, itype, jobz, uplo, lwork, liwork, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for ssygvd.

Parameters

a [input rank-2 array('f') with bounds (n,n)]
b [input rank-2 array('f') with bounds (n,n)]

Returns

w [rank-1 array('f') with bounds (n)]
v [rank-2 array('f') with bounds (n,n) with a storage]
info [int]

Other Parameters

itype [input int, optional] Default 1
jobz [input string(len=1), optional] Default 'V'
uplo [input string(len=1), optional] Default 'L'
overwrite_a [input int, optional] Default 0
overwrite_b [input int, optional] Default 0
lwork [input int, optional] Default (*jobz=='N'?2*n+1:1+6*n+2*n*n)
liwork [input int, optional] Default (*jobz=='N'?1:5*n+3)

scipy.linalg.lapack.dsygvd

scipy.linalg.lapack.dsygvd(a, b[, itype, jobz, uplo, lwork, liwork, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for dsygvd.

Parameters

a [input rank-2 array('d') with bounds (n,n)]
b [input rank-2 array('d') with bounds (n,n)]

Returns

w [rank-1 array('d') with bounds (n)]
v [rank-2 array('d') with bounds (n,n) with a storage]
info [int]

Other Parameters

itype [input int, optional] Default 1
jobz [input string(len=1), optional] Default 'V'
uplo [input string(len=1), optional] Default 'L'
overwrite_a [input int, optional] Default 0
overwrite_b [input int, optional] Default 0
**Parameters**

- `a` ([input rank-2 array('f') with bounds (n,n)]
- `b` ([input rank-2 array('f') with bounds (n,n)]

**Returns**

- `w` ([rank-1 array('f') with bounds (n)]
- `z` ([rank-2 array('f') with bounds ((jobz[0]=='V'?MAX(0,n):0),(jobz[0]=='V'?(range[0]=='I'?iu-il+1:MAX(1,n)):0))]
- `m` [int]
- `ifail` ([rank-1 array('i') with bounds ((jobz[0]=='N'?0:n))]
- `info` [int]

**Other Parameters**

- `itype` [input int, optional] Default: 1
- `jobz` [input string(len=1), optional] Default: 'V'
- `range` [input string(len=1), optional] Default: 'A'
- `uplo` [input string(len=1), optional] Default: 'L'
- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0
- `vl` [input float, optional] Default: 0.0
- `vu` [input float, optional] Default: 1.0
- `il` [input int, optional] Default: 1
- `iu` [input int, optional] Default: n
- `abstol` [input float, optional] Default: 0.0
- `lwork` [input int, optional] Default: max(8*n,1)
ifail [rank-1 array('i') with bounds((jobz[0]=='N'?0:n))]
info [int]

Other Parameters
itype [input int, optional] Default: 1
jobz [input string(len=1), optional] Default: 'V'
range [input string(len=1), optional] Default: 'A'
uplo [input string(len=1), optional] Default: 'L'
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
vl [input float, optional] Default: 0.0
vu [input float, optional] Default: 1.0
il [input int, optional] Default: 1
iu [input int, optional] Default: n
abstol [input float, optional] Default: 0.0
lwork [input int, optional] Default: max(8*n,1)

scipy.linalg.lapack.ssygvx_lwork

scipy.linalg.lapack.ssygvx_lwork(n[, uplo]) = <fortran object>
Wrapper for ssygvx_lwork.

Parameters
n [input int]

Returns
work [float]
info [int]

Other Parameters
uplo [input string(len=1), optional] Default: 'L'

scipy.linalg.lapack.dsygvx_lwork

scipy.linalg.lapack.dsygvx_lwork(n[, uplo]) = <fortran object>
Wrapper for dsygvx_lwork.

Parameters
n [input int]

Returns
work [float]
info [int]

Other Parameters
uplo [input string(len=1), optional] Default: 'L'
scipy.linalg.lapack.ssysv

scipy.linalg.lapack.ssysv(a, b[, lwork, lower, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for ssyev.

Parameters

- a [input rank-2 array('f') with bounds (n,n)]
- b [input rank-2 array('f') with bounds (n,nrhs)]

Returns

- udut [rank-2 array('f') with bounds (n,n) and a storage]
- ipiv [rank-1 array('i') with bounds (n)]
- x [rank-2 array('f') with bounds (n,nrhs) and b storage]
- info [int]

Other Parameters

- overwrite_a [input int, optional] Default: 0
- overwrite_b [input int, optional] Default: 0
- lwork [input int, optional] Default: max(n,1)
- lower [input int, optional] Default: 0

scipy.linalg.lapack.dsysv

scipy.linalg.lapack.dsysv(a, b[, lwork, lower, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for dsyev.

Parameters

- a [input rank-2 array('d') with bounds (n,n)]
- b [input rank-2 array('d') with bounds (n,nrhs)]

Returns

- udut [rank-2 array('d') with bounds (n,n) and a storage]
- ipiv [rank-1 array('i') with bounds (n)]
- x [rank-2 array('d') with bounds (n,nrhs) and b storage]
- info [int]

Other Parameters

- overwrite_a [input int, optional] Default: 0
- overwrite_b [input int, optional] Default: 0
- lwork [input int, optional] Default: max(n,1)
- lower [input int, optional] Default: 0
```python
scipy.linalg.lapack.csysv

scipy.linalg.lapack.csysv(a, b[, lwork, lower, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for csysv.

Parameters
a [input rank-2 array('F') with bounds (n,n)]
b [input rank-2 array('F') with bounds (n,nrhs)]

Returns
udut [rank-2 array('F') with bounds (n,n) and a storage]
ipiv [rank-1 array('i') with bounds (n)]
x [rank-2 array('F') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
lwork [input int, optional] Default: max(n,1)
lower [input int, optional] Default: 0

scipy.linalg.lapack.zsysv

scipy.linalg.lapack.zsysv(a, b[, lwork, lower, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for zsysv.

Parameters
a [input rank-2 array('D') with bounds (n,n)]
b [input rank-2 array('D') with bounds (n,nrhs)]

Returns
udut [rank-2 array('D') with bounds (n,n) and a storage]
ipiv [rank-1 array('i') with bounds (n)]
x [rank-2 array('D') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
lwork [input int, optional] Default: max(n,1)
lower [input int, optional] Default: 0
```
scipy.linalg.lapack.ssysv_lwork

scipy.linalg.lapack.ssysv_lwork(n[, lower]) = <fortran object>
Wrapper for ssysv_lwork.

Parameters
n [input int]

Returns
work [float]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.dsysv_lwork

scipy.linalg.lapack.dsysv_lwork(n[, lower]) = <fortran object>
Wrapper for dsysv_lwork.

Parameters
n [input int]

Returns
work [float]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.csysv_lwork

scipy.linalg.lapack.csysv_lwork(n[, lower]) = <fortran object>
Wrapper for csysv_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

Other Parameters
lower [input int, optional] Default: 0

6.12. Low-level LAPACK functions (scipy.linalg.lapack)
scipy.linalg.lapack.zsysv_lwork

scipy.linalg.lapack.zsysv_lwork($n[, lower ]$) = <fortran object>
Wrapper for zsysv_lwork.

Parameters

- $n$ [input int]

Returns

- work [complex]
- info [int]

Other Parameters

- lower [input int, optional] Default: 0

scipy.linalg.lapack.ssysvx

scipy.linalg.lapack.ssysvx($a, b[, af, ipiv, lwork, factored, lower, overwrite_a, overwrite_b ]$) = <fortran object>
Wrapper for ssyevx.

Parameters

- $a$ [input rank-2 array('f') with bounds (n,n)]
- $b$ [input rank-2 array('f') with bounds (n,nrhs)]

Returns

- $a_s$ [rank-2 array('f') with bounds (n,n) and a storage]
- $udut$ [rank-2 array('f') with bounds (n,n) and af storage]
- $ipiv$ [rank-1 array('i') with bounds (n)]
- $b_s$ [rank-2 array('f') with bounds (n,nrhs) and b storage]
- $x$ [rank-2 array('f') with bounds (n,nrhs)]
- $rcond$ [float]
- $ferr$ [rank-1 array('f') with bounds (nrhs)]
- $berr$ [rank-1 array('f') with bounds (nrhs)]
- $info$ [int]

Other Parameters

- overwrite_a [input int, optional] Default: 0
- af [input rank-2 array('f') with bounds (n,n)]
- ipiv [input rank-1 array('i') with bounds (n)]
- overwrite_b [input int, optional] Default: 0
- lwork [input int, optional] Default: max(3*n,1)
- factored [input int, optional] Default: 0
- lower [input int, optional] Default: 0
scipy.linalg.lapack.dsysvx

\[
\text{scipy.linalg.lapack.dsysvx}(a, b[, \text{af, ipiv, lwork, factored, lower, overwrite_a, overwrite_b}]) = <\text{fortran object}>
\]

Wrapper for dsysvx.

**Parameters**

- \(a\) [input rank-2 array('d') with bounds (n,n)]
- \(b\) [input rank-2 array('d') with bounds (n,nrhs)]

**Returns**

- \(a_s\) [rank-2 array('d') with bounds (n,n) and a storage]
- \(udut\) [rank-2 array('d') with bounds (n,n) and af storage]
- \(ipiv\) [rank-1 array('i') with bounds (n)]
- \(b_s\) [rank-2 array('d') with bounds (n,nrhs) and b storage]
- \(x\) [rank-2 array('d') with bounds (n,nrhs)]
- \(rcond\) [float]
- \(ferr\) [rank-1 array('d') with bounds (nrhs)]
- \(berr\) [rank-1 array('d') with bounds (nrhs)]
- \(info\) [int]

**Other Parameters**

- \(\text{overwrite_a}\) [input int, optional] Default: 0
- \(af\) [input rank-2 array('d') with bounds (n,n)]
- \(\text{ipiv}\) [input rank-1 array('i') with bounds (n)]
- \(\text{overwrite_b}\) [input int, optional] Default: 0
- \(lwork\) [input int, optional] Default: max(3*n,1)
- \(\text{factored}\) [input int, optional] Default: 0
- \(\text{lower}\) [input int, optional] Default: 0

scipy.linalg.lapack.csysvx

\[
\text{scipy.linalg.lapack.csysvx}(a, b[, \text{af, ipiv, lwork, factored, lower, overwrite_a, overwrite_b}]) = <\text{fortran object}>
\]

Wrapper for csyvx.

**Parameters**

- \(a\) [input rank-2 array('F') with bounds (n,n)]
- \(b\) [input rank-2 array('F') with bounds (n,nrhs)]

**Returns**

- \(a_s\) [rank-2 array('F') with bounds (n,n) and a storage]
- \(udut\) [rank-2 array('F') with bounds (n,n) and af storage]
- \(ipiv\) [rank-1 array('i') with bounds (n)]
- \(b_s\) [rank-2 array('F') with bounds (n,nrhs) and b storage]
- \(x\) [rank-2 array('F') with bounds (n,nrhs)]
- \(rcond\) [float]
- \(ferr\) [rank-1 array('f') with bounds (nrhs)]
- \(berr\) [rank-1 array('f') with bounds (nrhs)]
- \(info\) [int]

**Other Parameters**

- \(\text{overwrite_a}\) [input int, optional] Default: 0
- \(af\) [input rank-2 array('F') with bounds (n,n)]
- \(\text{ipiv}\) [input rank-1 array('i') with bounds (n)]
- \(\text{overwrite_b}\) [input int, optional] Default: 0
- \(lwork\) [input int, optional] Default: max(3*n,1)
- \(\text{factored}\) [input int, optional] Default: 0
- \(\text{lower}\) [input int, optional] Default: 0
overwrite_a
   [input int, optional] Default: 0
af
   [input rank-2 array('F') with bounds (n,n)]
ipiv
   [input rank-1 array('i') with bounds (n)]
overwrite_b
   [input int, optional] Default: 0
lwork
   [input int, optional] Default: max(3*n,1)
factored
   [input int, optional] Default: 0
lower
   [input int, optional] Default: 0

scipy.linalg.lapack.zsysvx

scipy.linalg.lapack.zsysvx(a, b[, af, ipiv, lwork, factored, lower, overwrite_a, overwrite_b]) =
<fortran object>
Wrapper for zsysvx.

Parameters
   a
   [input rank-2 array('D') with bounds (n,n)]
   b
   [input rank-2 array('D') with bounds (n,nrhs)]

Returns
   a_s
   [rank-2 array('D') with bounds (n,n) and a storage]
   udut
   [rank-2 array('D') with bounds (n,n) and af storage]
   ipiv
   [rank-1 array('i') with bounds (n)]
   b_s
   [rank-2 array('D') with bounds (n,nrhs) and b storage]
   x
   [rank-2 array('D') with bounds (n,nrhs)]
   rcond
   [float]
   ferr
   [rank-1 array('d') with bounds (nrhs)]
   berr
   [rank-1 array('d') with bounds (nrhs)]
   info
   [int]

Other Parameters

overwrite_a
   [input int, optional] Default: 0
af
   [input rank-2 array('D') with bounds (n,n)]
ipiv
   [input rank-1 array('i') with bounds (n)]
overwrite_b
   [input int, optional] Default: 0
lwork
   [input int, optional] Default: max(3*n,1)
factored
   [input int, optional] Default: 0
lower
   [input int, optional] Default: 0

scipy.linalg.lapack.ssysvx_lwork

scipy.linalg.lapack.ssysvx_lwork(n[, lower]) = <fortran object>
Wrapper for ssyevx_lwork.

Parameters
   n
   [input int]

Returns
   work
   [float]
info  [int]

Other Parameters
lower  [input int, optional] Default: 0

scipy.linalg.lapack.dsysvx_lwork

scipy.linalg.lapack.dsysvx_lwork(n[, lower]) = <fortran object>
Wrapper for dsyevx_lwork.

Parameters
n  [input int]

Returns
work  [float]
info  [int]

Other Parameters
lower  [input int, optional] Default: 0

scipy.linalg.lapack.csysvx_lwork

scipy.linalg.lapack.csysvx_lwork(n[, lower]) = <fortran object>
Wrapper for csysvx_lwork.

Parameters
n  [input int]

Returns
work  [complex]
info  [int]

Other Parameters
lower  [input int, optional] Default: 0

scipy.linalg.lapack.zsysvx_lwork

scipy.linalg.lapack.zsysvx_lwork(n[, lower]) = <fortran object>
Wrapper for zsysvx_lwork.

Parameters
n  [input int]

Returns
work  [complex]
info  [int]

Other Parameters
lower  [input int, optional] Default: 0
scipy.linalg.lapack.ssytf2

scipy.linalg.lapack.ssytf2(a[, lower, overwrite_a]) = <fortran object>

Wrapper for ssytf2.

Parameters
a [input rank-2 array('f') with bounds (n,n)]

Returns
ldu [rank-2 array('f') with bounds (n,n) and a storage]
ipiv [rank-1 array('i') with bounds (n)]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0

scipy.linalg.lapack.dsytf2

scipy.linalg.lapack.dsytf2(a[, lower, overwrite_a]) = <fortran object>

Wrapper for dsytf2.

Parameters
a [input rank-2 array('d') with bounds (n,n)]

Returns
ldu [rank-2 array('d') with bounds (n,n) and a storage]
ipiv [rank-1 array('i') with bounds (n)]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0

scipy.linalg.lapack.csytf2

scipy.linalg.lapack.csytf2(a[, lower, overwrite_a]) = <fortran object>

Wrapper for csytf2.

Parameters
a [input rank-2 array('F') with bounds (n,n)]

Returns
ldu [rank-2 array('F') with bounds (n,n) and a storage]
ipiv [rank-1 array('i') with bounds (n)]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_a
   [input int, optional] Default: 0

scipy.linalg.lapack.zsytf2

scipy.linalg.lapack.zsytf2(a[, lower, overwrite_a]) = <fortran object>
Wrapper for zsytf2.

Parameters
   a            [input rank-2 array('D') with bounds (n,n)]

Returns
   ldu [rank-2 array('D') with bounds (n,n) and a storage]
   ipiv [rank-1 array('i') with bounds (n)]
   info [int]

Other Parameters
   lower [input int, optional] Default: 0
   overwrite_a [input int, optional] Default: 0

scipy.linalg.lapack.ssytrd

scipy.linalg.lapack.ssytrd(a[, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for ssytrd.

Parameters
   a            [input rank-2 array('f') with bounds (lda,n)]

Returns
   c [rank-2 array('f') with bounds (lda,n) and a storage]
   d [rank-1 array('f') with bounds (n)]
   e [rank-1 array('f') with bounds (n - 1)]
   tau [rank-1 array('f') with bounds (n - 1)]
   info [int]

Other Parameters
   lower [input int, optional] Default: 0
   overwrite_a [input int, optional] Default: 0
   lwork [input int, optional] Default: MAX(n,1)

**scipy.linalg.lapack.dsytrd**

`scipy.linalg.lapack.dsytrd(a[, lower, lwork, overwrite_a]) = <fortran object>`

Wrapper for dsytrd.

**Parameters**

- `a` [input rank-2 array('d') with bounds (lda,n)]

**Returns**

- `c` [rank-2 array('d') with bounds (lda,n) and a storage]
- `d` [rank-1 array('d') with bounds (n)]
- `e` [rank-1 array('d') with bounds (n - 1)]
- `tau` [rank-1 array('d') with bounds (n - 1)]
- `info` [int]

**Other Parameters**

- `lower` [input int, optional] Default: 0
- `overwrite_a` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: MAX(n,1)

**scipy.linalg.lapack.ssytrd_lwork**

`scipy.linalg.lapack.ssytrd_lwork(n[, lower]) = <fortran object>`

Wrapper for ssytrd_lwork.

**Parameters**

- `n` [input int]

**Returns**

- `work` [float]
- `info` [int]

**Other Parameters**

- `lower` [input int, optional] Default: 0

**scipy.linalg.lapack.dsytrd_lwork**

`scipy.linalg.lapack.dsytrd_lwork(n[, lower]) = <fortran object>`

Wrapper for dsytrd_lwork.

**Parameters**

- `n` [input int]

**Returns**

- `work` [float]
- `info` [int]

**Other Parameters**

- `lower` [input int, optional] Default: 0
scipy.linalg.lapack.ssytrf

scipy.linalg.lapack.ssytrf(a[, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for ssytrf.

Parameters
a [input rank-2 array('f') with bounds (n,n)]

Returns
ldu [rank-2 array('f') with bounds (n,n) and a storage]
ipiv [rank-1 array('i') with bounds (n)]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(n,1)

scipy.linalg.lapack.dsytrf

scipy.linalg.lapack.dsytrf(a[, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for dsytrf.

Parameters
a [input rank-2 array('d') with bounds (n,n)]

Returns
ldu [rank-2 array('d') with bounds (n,n) and a storage]
ipiv [rank-1 array('i') with bounds (n)]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(n,1)

scipy.linalg.lapack.csytrf

scipy.linalg.lapack.csytrf(a[, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for csytrf.

Parameters
a [input rank-2 array('F') with bounds (n,n)]

Returns
ldu [rank-2 array('F') with bounds (n,n) and a storage]
ipiv [rank-1 array('i') with bounds (n)]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_a  [input int, optional] Default: 0
lwork    [input int, optional] Default: max(n,1)

scipy.linalg.lapack.zsytrf

scipy.linalg.lapack.zsytrf(a [lower, lwork, overwrite_a]) = <fortran object>
Wrapper for zsytrf.
Parameters
a [input rank-2 array('D') with bounds (n,n)]

Returns
ldu [rank-2 array('D') with bounds (n,n) and a storage]
ipiv [rank-1 array('I') with bounds (n)]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(n,1)

scipy.linalg.lapack.ssytrf_lwork

scipy.linalg.lapack.ssytrf_lwork(n [lower]) = <fortran object>
Wrapper for ssytrf_lwork.
Parameters
n [input int]

Returns
work [float]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.dsytrf_lwork

scipy.linalg.lapack.dsytrf_lwork(n [lower]) = <fortran object>
Wrapper for dsytrf_lwork.
Parameters
n [input int]

Returns
work [float]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.csytrf_lwork

scipy.linalg.lapack.csytrf_lwork(n[, lower]) = <fortran object>
Wrapper for csytrf_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.zsytrf_lwork

scipy.linalg.lapack.zsytrf_lwork(n[, lower]) = <fortran object>
Wrapper for zsytrf_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.stbtrs

scipy.linalg.lapack.stbtrs(ab, b[, uplo, trans, diag, overwrite_b]) = <fortran object>
Wrapper for stbtrs.

Parameters
ab [input rank-2 array('f') with bounds (ldab,n)]
b [input rank-2 array('f') with bounds (ldb,nrhs)]

Returns
x [rank-2 array('f') with bounds (ldb,nrhs) and b storage]
info [int]

Other Parameters
uplo [input string(len=1), optional] Default: 'U'
trans [input string(len=1), optional] Default: 'N'
diag [input string(len=1), optional] Default: 'N'
overwrite_b [input int, optional] Default: 0
scipy.linalg.lapack.dtbtrs

**scipy.linalg.lapack.dtbtrs** *(ab, b[, uplo, trans, diag, overwrite_b]) = <fortran object>*

Wrapper for dtbtrs.

**Parameters**
- **ab** [input rank-2 array('d') with bounds (ldab,n)]
- **b** [input rank-2 array('d') with bounds (ldb,nrhs)]

**Returns**
- **x** [rank-2 array('d') with bounds (ldb,nrhs) and b storage]
- **info** [int]

**Other Parameters**
- **uplo** [input string(len=1), optional] Default: ‘U’
- **trans** [input string(len=1), optional] Default: ‘N’
- **diag** [input string(len=1), optional] Default: ‘N’
- **overwrite_b** [input int, optional] Default: 0

scipy.linalg.lapack.ctbtrs

**scipy.linalg.lapack.ctbtrs** *(ab, b[, uplo, trans, diag, overwrite_b]) = <fortran object>*

Wrapper for ctbtrs.

**Parameters**
- **ab** [input rank-2 array('F') with bounds (ldab,n)]
- **b** [input rank-2 array('F') with bounds (ldb,nrhs)]

**Returns**
- **x** [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
- **info** [int]

**Other Parameters**
- **uplo** [input string(len=1), optional] Default: ‘U’
- **trans** [input string(len=1), optional] Default: ‘N’
- **diag** [input string(len=1), optional] Default: ‘N’
- **overwrite_b** [input int, optional] Default: 0

scipy.linalg.lapack.ztbtrs

**scipy.linalg.lapack.ztbtrs** *(ab, b[, uplo, trans, diag, overwrite_b]) = <fortran object>*

Wrapper for ztbtrs.

**Parameters**
- **ab** [input rank-2 array('D') with bounds (ldab,n)]
- **b** [input rank-2 array('D') with bounds (ldb,nrhs)]

**Returns**
- **x** [rank-2 array('D') with bounds (ldb,nrhs) and b storage]
- **info** [int]
**Other Parameters**

- `uplo` [input string(len=1), optional] Default: ‘U’
- `trans` [input string(len=1), optional] Default: ‘N’
- `diag` [input string(len=1), optional] Default: ‘N’
- `overwrite_b` [input int, optional] Default: 0

### scipy.linalg.lapack.stfsm

scipy.linalg.lapack.stfsm(`alpha`, `a`, `b`, `transr`, `side`, `uplo`, `trans`, `diag`, `overwrite_b`) = <fortran object>

Wrapper for stfsm.

**Parameters**

- `alpha` [input float]
- `a` [input rank-1 array('f') with bounds (nt)]
- `b` [input rank-2 array('f') with bounds (m,n)]

**Returns**

- `x` [rank-2 array('f') with bounds (m,n) and b storage]

**Other Parameters**

- `transr` [input string(len=1), optional] Default: ‘N’
- `side` [input string(len=1), optional] Default: ‘L’
- `uplo` [input string(len=1), optional] Default: ‘U’
- `trans` [input string(len=1), optional] Default: ‘N’
- `diag` [input string(len=1), optional] Default: ‘N’
- `overwrite_b` [input int, optional] Default: 0

### scipy.linalg.lapack.dtfsm

scipy.linalg.lapack.dtfsm(`alpha`, `a`, `b`, `transr`, `side`, `uplo`, `trans`, `diag`, `overwrite_b`) = <fortran object>

Wrapper for dtfsm.

**Parameters**

- `alpha` [input float]
- `a` [input rank-1 array('d') with bounds (nt)]
- `b` [input rank-2 array('d') with bounds (m,n)]

**Returns**

- `x` [rank-2 array('d') with bounds (m,n) and b storage]

**Other Parameters**

- `transr` [input string(len=1), optional] Default: ‘N’
- `side` [input string(len=1), optional] Default: ‘L’
- `uplo` [input string(len=1), optional] Default: ‘U’
- `trans` [input string(len=1), optional] Default: ‘N’
- `diag` [input string(len=1), optional] Default: ‘N’
- `overwrite_b` [input int, optional] Default: 0

---

6.12. Low-level LAPACK functions (scipy.linalg.lapack)
scipy.linalg.lapack.ctfsm

\[ \texttt{scipy.linalg.lapack.ctfsm}(\texttt{alpha}, \texttt{a}, \texttt{b}[, \texttt{transr}, \texttt{side}, \texttt{uplo}, \texttt{trans}, \texttt{diag}, \texttt{overwrite\_b}]) = \texttt{<fortran object>} \]

Wrapper for ctfsm.

**Parameters**

- \texttt{alpha} [input complex]
- \texttt{a} [input rank-1 array('F') with bounds (nt)]
- \texttt{b} [input rank-2 array('F') with bounds (m,n)]

**Returns**

- \texttt{x} [rank-2 array('F') with bounds (m,n) and b storage]

**Other Parameters**

- \texttt{transr} [input string(len=1), optional] Default: 'N'
- \texttt{side} [input string(len=1), optional] Default: 'L'
- \texttt{uplo} [input string(len=1), optional] Default: 'U'
- \texttt{trans} [input string(len=1), optional] Default: 'N'
- \texttt{diag} [input string(len=1), optional] Default: 'N'
- \texttt{overwrite\_b} [input int, optional] Default: 0

scipy.linalg.lapack.ztfsm

\[ \texttt{scipy.linalg.lapack.ztfsm}(\texttt{alpha}, \texttt{a}, \texttt{b}[, \texttt{transr}, \texttt{side}, \texttt{uplo}, \texttt{trans}, \texttt{diag}, \texttt{overwrite\_b}]) = \texttt{<fortran object>} \]

Wrapper for ztfsm.

**Parameters**

- \texttt{alpha} [input complex]
- \texttt{a} [input rank-1 array('D') with bounds (nt)]
- \texttt{b} [input rank-2 array('D') with bounds (m,n)]

**Returns**

- \texttt{x} [rank-2 array('D') with bounds (m,n) and b storage]

**Other Parameters**

- \texttt{transr} [input string(len=1), optional] Default: 'N'
- \texttt{side} [input string(len=1), optional] Default: 'L'
- \texttt{uplo} [input string(len=1), optional] Default: 'U'
- \texttt{trans} [input string(len=1), optional] Default: 'N'
- \texttt{diag} [input string(len=1), optional] Default: 'N'
- \texttt{overwrite\_b} [input int, optional] Default: 0
scipy.linalg.lapack.stfttp

scipy.linalg.lapack.stfttp(n, arf[, transr, uplo]) = <fortran object>

Wrapper for stfttp.

Parameters

- n [input int]
- arf [input rank-1 array('f') with bounds (nt)]

Returns

- ap [rank-1 array('f') with bounds (nt)]
- info [int]

Other Parameters

- transr [input string(len=1), optional] Default: ‘N’
- uplo [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.dtfttp

scipy.linalg.lapack.dtfttp(n, arf[, transr, uplo]) = <fortran object>

Wrapper for dtfttp.

Parameters

- n [input int]
- arf [input rank-1 array('d') with bounds (nt)]

Returns

- ap [rank-1 array('d') with bounds (nt)]
- info [int]

Other Parameters

- transr [input string(len=1), optional] Default: ‘N’
- uplo [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.ctfttp

scipy.linalg.lapack.ctfttp(n, arf[, transr, uplo]) = <fortran object>

Wrapper for ctfttp.

Parameters

- n [input int]
- arf [input rank-1 array('F') with bounds (nt)]

Returns

- ap [rank-1 array('F') with bounds (nt)]
- info [int]

Other Parameters

- transr [input string(len=1), optional] Default: ‘N’
- uplo [input string(len=1), optional] Default: ‘U’

6.12. Low-level LAPACK functions (scipy.linalg.lapack)
scipy.linalg.lapack.ztfttp

scipy.linalg.lapack.ztfttp(n, arf[, transr, uplo]) = <fortran object>
Wrapper for ztfttp.

Parameters

n    [input int]
arf  [input rank-1 array('D') with bounds (nt)]

Returns

ap    [rank-1 array('D') with bounds (nt)]
info  [int]

Other Parameters

transr [input string(len=1), optional] Default: ‘N’
uplo   [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.stfttr

scipy.linalg.lapack.stfttr(n, arf[, transr, uplo]) = <fortran object>
Wrapper for stfttr.

Parameters

n    [input int]
arf  [input rank-1 array('f') with bounds (nt)]

Returns

a    [rank-2 array('f') with bounds (lda,n)]
info  [int]

Other Parameters

transr [input string(len=1), optional] Default: ‘N’
uplo   [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.dtfttr

scipy.linalg.lapack.dtfttr(n, arf[, transr, uplo]) = <fortran object>
Wrapper for dtfttr.

Parameters

n    [input int]
arf  [input rank-1 array('d') with bounds (nt)]

Returns

a    [rank-2 array('d') with bounds (lda,n)]
info  [int]

Other Parameters

transr [input string(len=1), optional] Default: ‘N’
uplo   [input string(len=1), optional] Default: ‘U’
**scipy.linalg.lapack.ctfttr**

Wrapper for `ctfttr`.

**Parameters**
- `n` [input int]
- `arf` [input rank-1 array('F') with bounds (nt)]

**Returns**
- `a` [rank-2 array('F') with bounds (lda,n)]
- `info` [int]

**Other Parameters**
- `transr` [input string(len=1), optional] Default: ‘N’
- `uplo` [input string(len=1), optional] Default: ‘U’

**scipy.linalg.lapack.ztfttr**

Wrapper for `ztfttr`.

**Parameters**
- `n` [input int]
- `arf` [input rank-1 array('D') with bounds (nt)]

**Returns**
- `a` [rank-2 array('D') with bounds (lda,n)]
- `info` [int]

**Other Parameters**
- `transr` [input string(len=1), optional] Default: ‘N’
- `uplo` [input string(len=1), optional] Default: ‘U’

**scipy.linalg.lapack.stgsen**

Wrapper for `stgsen`.

**Parameters**
- `select` [input rank-1 array('i') with bounds (n)]
- `a` [input rank-2 array('f') with bounds (lda,n)]
- `b` [input rank-2 array('f') with bounds (ldb,n)]
- `q` [input rank-2 array('f') with bounds (ldq,n)]
- `z` [input rank-2 array('f') with bounds (ldz,n)]

**Returns**
- `a` [rank-2 array('f') with bounds (lda,n)]
- `b` [rank-2 array('f') with bounds (ldb,n)]
- `alphar` [rank-1 array('f') with bounds (n)]
- `alphai` [rank-1 array('f') with bounds (n)]

---

**6.12. Low-level LAPACK functions (scipy.linalg.lapack)**

1381
\[
\begin{align*}
\text{beta} & \quad \text{[rank-1 array('f') with bounds (n)]} \\

\]

Other Parameters

- \text{overwrite_a} [input int, optional] Default: 0
- \text{overwrite_b} [input int, optional] Default: 0
- \text{overwrite_q} [input int, optional] Default: 0
- \text{overwrite_z} [input int, optional] Default: 0
- \text{lwork} [input int, optional] Default: max(MAX(4*n+16,2*m*(n-m)),1)
- \text{liwork} [input int, optional] Default: n+6

\text{scipy.linalg.lapack.dtgsen}

\begin{verbatim}
scipy.linalg.lapack.dtgsen (select, a, b, q[, lwork, liwork, overwrite_a, overwrite_b, overwrite_q, overwrite_z]) = <fortran object>
\end{verbatim}

Wrapper for dtgsen.

Parameters

- \text{select} [input rank-1 array('i') with bounds (n)]
- \text{a} [input rank-2 array('d') with bounds (lda,n)]
- \text{b} [input rank-2 array('d') with bounds (ldb,n)]
- \text{q} [input rank-2 array('d') with bounds (ldq,n)]
- \text{z} [input rank-2 array('d') with bounds (ldz,n)]

Returns

- \text{a} [rank-2 array('d') with bounds (lda,n)]
- \text{b} [rank-2 array('d') with bounds (ldb,n)]
- \text{alphar} [rank-1 array('d') with bounds (n)]
- \text{alphai} [rank-1 array('d') with bounds (n)]
- \text{beta} [rank-1 array('d') with bounds (n)]
- \text{q} [rank-2 array('d') with bounds (ldq,n)]
- \text{z} [rank-2 array('d') with bounds (ldz,n)]
- \text{m} [int]
- \text{pl} [float]

- \text{dif} [rank-1 array('d') with bounds (2)]
- \text{work} [rank-1 array('d') with bounds (MAX(lwork,1))]
- \text{iwork} [rank-1 array('i') with bounds (MAX(1,liwork))]
- \text{info} [int]

Other Parameters
\texttt{SciPyReferenceGuide, Release 1.6.3}

\texttt{overwrite_a}

[input int, optional] Default: 0

\texttt{overwrite_b}

[input int, optional] Default: 0

\texttt{overwrite_q}

[input int, optional] Default: 0

\texttt{overwrite_z}

[input int, optional] Default: 0

\texttt{lwork}

[input int, optional] Default: max(MAX(4*n+16,2*m*(n-m)),1)

\texttt{liwork}

[input int, optional] Default: n+6

\texttt{scipy.linalg.lapack.ctgsen}

\texttt{scipy.linalg.lapack.ctgsen (select, a, b, q, z[, lwork, liwork, overwrite_a, overwrite_b, overwrite_q, overwrite_z])} = \texttt{<fortran object>}

\texttt{Wrapper for ctgsen.}

\texttt{Parameters}

\texttt{select} [input rank-1 array('i') with bounds (n)]

\texttt{a} [input rank-2 array('F') with bounds (lda,n)]

\texttt{b} [input rank-2 array('F') with bounds (ldb,n)]

\texttt{q} [input rank-2 array('F') with bounds (ldq,n)]

\texttt{z} [input rank-2 array('F') with bounds (ldz,n)]

\texttt{Returns}

\texttt{a} [rank-2 array('F') with bounds (lda,n)]

\texttt{b} [rank-2 array('F') with bounds (ldb,n)]

\texttt{alpha} [rank-1 array('F') with bounds (n)]

\texttt{beta} [rank-1 array('F') with bounds (n)]

\texttt{q} [rank-2 array('F') with bounds (ldq,n)]

\texttt{z} [rank-2 array('F') with bounds (ldz,n)]

\texttt{m} [int]

\texttt{pl} [float]

\texttt{pr} [float]

\texttt{dif} [rank-1 array('f') with bounds (2)]

\texttt{work} [rank-1 array('F') with bounds (MAX(lwork,1))]

\texttt{iwork} [rank-1 array('i') with bounds (MAX(1,liwork))]

\texttt{info} [int]

\texttt{Other Parameters}

\texttt{overwrite_a}

[input int, optional] Default: 0

\texttt{overwrite_b}

[input int, optional] Default: 0

\texttt{overwrite_q}

[input int, optional] Default: 0

\texttt{overwrite_z}

[input int, optional] Default: 0

\texttt{lwork}

[input int, optional] Default: max(2*m*(n-m),1)

\texttt{liwork}

[input int, optional] Default: n+2

\textbf{6.12. Low-level LAPACK functions (\texttt{scipy.linalg.lapack})}
scipy.linalg.lapack.ztgsen

scipy.linalg.lapack.ztgsen (select, a, b, q[, lwork, liwork, overwrite_a, overwrite_b, overwrite_q, overwrite_z]) = <fortran object>

Wrapper for ztgsen.

Parameters

select [input rank-1 array(‘i’) with bounds (n)]
a [input rank-2 array(‘D’) with bounds (lda,n)]
b [input rank-2 array(‘D’) with bounds (ldb,n)]
q [input rank-2 array(‘D’) with bounds (ldq,n)]
z [input rank-2 array(‘D’) with bounds (ldz,n)]

Returns

a [rank-2 array(‘D’) with bounds (lda,n)]
b [rank-2 array(‘D’) with bounds (ldb,n)]
alpha [rank-1 array(‘D’) with bounds (n)]
beta [rank-1 array(‘D’) with bounds (n)]
q [rank-2 array(‘D’) with bounds (ldq,n)]
z [rank-2 array(‘D’) with bounds (ldz,n)]
m [int]
pl [float]
pr [float]
dif [rank-1 array(‘d’) with bounds (2)]
work [rank-1 array(‘D’) with bounds (MAX(lwork,1))]
iwork [rank-1 array(‘i’) with bounds (MAX(1,liwork))]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
overwrite_q [input int, optional] Default: 0
overwrite_z [input int, optional] Default: 0
lwork [input int, optional] Default: max(2*m*(n-m),1)
liwork [input int, optional] Default: n+2

scipy.linalg.lapack.stpttf

scipy.linalg.lapack.stpttf (n, ap[, transr, uplo]) = <fortran object>

Wrapper for stpttf.

Parameters

n [input int]
ap [input rank-1 array(‘F’) with bounds (nt)]

Returns

arf [rank-1 array(‘F’) with bounds (nt)]
info [int]
Other Parameters

transr  [input string(len=1), optional] Default: 'N'
uplo    [input string(len=1), optional] Default: 'U'

scipy.linalg.lapack.dtpttf

scipy.linalg.lapack.dtpttf(n, ap[, transr, uplo]) = <fortran object>
Wrapper for dtpttf.

Parameters
n [input int]
ap [input rank-1 array('d') with bounds (nt)]

Returns
arf [rank-1 array('d') with bounds (nt)]
info [int]

Other Parameters
transr  [input string(len=1), optional] Default: 'N'
uplo    [input string(len=1), optional] Default: 'U'

scipy.linalg.lapack.ctpttf

scipy.linalg.lapack.ctpttf(n, ap[, transr, uplo]) = <fortran object>
Wrapper for ctpttf.

Parameters
n [input int]
ap [input rank-1 array('F') with bounds (nt)]

Returns
arf [rank-1 array('F') with bounds (nt)]
info [int]

Other Parameters
transr  [input string(len=1), optional] Default: 'N'
uplo    [input string(len=1), optional] Default: 'U'

scipy.linalg.lapack.ztpttf

scipy.linalg.lapack.ztpttf(n, ap[, transr, uplo]) = <fortran object>
Wrapper for ztpttf.

Parameters
n [input int]
ap [input rank-1 array('D') with bounds (nt)]

Returns
arf [rank-1 array('D') with bounds (nt)]
info [int]
Other Parameters

`transr`  [input string(len=1), optional] Default: ‘N’
`uplo`    [input string(len=1), optional] Default: ‘U’

**scipy.linalg.lapack.stptr**

```python
scipy.linalg.lapack.stptr(n, ap[, uplo]) = <fortran object>
```

Wrapper for `stptr`.

Parameters

- `n` [input int]
- `ap` [input rank-1 array('f') with bounds (nt)]

Returns

- `a` [rank-2 array('f') with bounds (n,n)]
- `info` [int]

Other Parameters

- `uplo` [input string(len=1), optional] Default: ‘U’

**scipy.linalg.lapack.dtpttr**

```python
scipy.linalg.lapack.dtpttr(n, ap[, uplo]) = <fortran object>
```

Wrapper for `dtpttr`.

Parameters

- `n` [input int]
- `ap` [input rank-1 array('d') with bounds (nt)]

Returns

- `a` [rank-2 array('d') with bounds (n,n)]
- `info` [int]

Other Parameters

- `uplo` [input string(len=1), optional] Default: ‘U’

**scipy.linalg.lapack.ctpttr**

```python
scipy.linalg.lapack.ctpttr(n, ap[, uplo]) = <fortran object>
```

Wrapper for `ctpttr`.

Parameters

- `n` [input int]
- `ap` [input rank-1 array('F') with bounds (nt)]

Returns

- `a` [rank-2 array('F') with bounds (n,n)]
- `info` [int]

Other Parameters

- `uplo` [input string(len=1), optional] Default: ‘U’
scipy.linalg.lapack.ztptr

```python
scipy.linalg.lapack.ztptr(n, ap[, uplo]) = <fortran object>
```

Wrapper for ztptr.

**Parameters**

- `n` [input int]
- `ap` [input rank-1 array('D') with bounds (nt)]

**Returns**

- `a` [rank-2 array('D') with bounds (n,n)]
- `info` [int]

**Other Parameters**

- `uplo` [input string(len=1), optional] Default: 'U'

scipy.linalg.lapack.strsyl

```python
scipy.linalg.lapack.strsyl(a, b, c[, trana, tranb, isgn, overwrite_c]) = <fortran object>
```

Wrapper for strsyl.

**Parameters**

- `a` [input rank-2 array('f') with bounds (m,m)]
- `b` [input rank-2 array('f') with bounds (n,n)]
- `c` [input rank-2 array('f') with bounds (m,n)]

**Returns**

- `x` [rank-2 array('f') with bounds (m,n) and c storage]
- `scale` [float]
- `info` [int]

**Other Parameters**

- `trana` [input string(len=1), optional] Default: 'N'
- `tranb` [input string(len=1), optional] Default: 'N'
- `isgn` [input int, optional] Default: 1
- `overwrite_c` [input int, optional] Default: 0

scipy.linalg.lapack.dtrsyl

```python
scipy.linalg.lapack.dtrsyl(a, b, c[, trana, tranb, isgn, overwrite_c]) = <fortran object>
```

Wrapper for dtrsyl.

**Parameters**

- `a` [input rank-2 array('d') with bounds (m,m)]
- `b` [input rank-2 array('d') with bounds (n,n)]
- `c` [input rank-2 array('d') with bounds (m,n)]

**Returns**

- `x` [rank-2 array('d') with bounds (m,n) and c storage]
- `scale` [float]
- `info` [int]
Other Parameters

- `trana` [input string(len=1), optional] Default: 'N'
- `tranb` [input string(len=1), optional] Default: 'N'
- `isgn` [input int, optional] Default: 1
- `overwrite_c` [input int, optional] Default: 0

`scipy.linalg.lapack.ctrsyl`

Wrapper for `ctrsyl`.

Parameters

- `a` [input rank-2 array('F') with bounds (m,m)]
- `b` [input rank-2 array('F') with bounds (n,n)]
- `c` [input rank-2 array('F') with bounds (m,n)]

Returns

- `x` [rank-2 array('F') with bounds (m,n) and c storage]
- `scale` [float]
- `info` [int]

Other Parameters

- `trana` [input string(len=1), optional] Default: 'N'
- `tranb` [input string(len=1), optional] Default: 'N'
- `isgn` [input int, optional] Default: 1
- `overwrite_c` [input int, optional] Default: 0

`scipy.linalg.lapack.ztrsyl`

Wrapper for `ztrsyl`.

Parameters

- `a` [input rank-2 array('D') with bounds (m,m)]
- `b` [input rank-2 array('D') with bounds (n,n)]
- `c` [input rank-2 array('D') with bounds (m,n)]

Returns

- `x` [rank-2 array('D') with bounds (m,n) and c storage]
- `scale` [float]
- `info` [int]

Other Parameters

- `trana` [input string(len=1), optional] Default: 'N'
- `tranb` [input string(len=1), optional] Default: 'N'
- `isgn` [input int, optional] Default: 1
- `overwrite_c` [input int, optional] Default: 0
**scipy.linalg.lapack.strtri**

```python
scipy.linalg.lapack.strtri(c[, lower, unitdiag, overwrite_c]) = <fortran object>
```
Wrapper for `strtri`.

**Parameters**

- `c` [input rank-2 array('f') with bounds (n,n)]

**Returns**

- `inv_c` [rank-2 array('f') with bounds (n,n) and c storage]
- `info` [int]

**Other Parameters**

- `overwrite_c` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
- `unitdiag` [input int, optional] Default: 0

---

**scipy.linalg.lapack.dtrtri**

```python
scipy.linalg.lapack.dtrtri(c[, lower, unitdiag, overwrite_c]) = <fortran object>
```
Wrapper for `dtrtri`.

**Parameters**

- `c` [input rank-2 array('d') with bounds (n,n)]

**Returns**

- `inv_c` [rank-2 array('d') with bounds (n,n) and c storage]
- `info` [int]

**Other Parameters**

- `overwrite_c` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
- `unitdiag` [input int, optional] Default: 0

---

**scipy.linalg.lapack.ctrtri**

```python
scipy.linalg.lapack.ctrtri(c[, lower, unitdiag, overwrite_c]) = <fortran object>
```
Wrapper for `ctrtri`.

**Parameters**

- `c` [input rank-2 array('F') with bounds (n,n)]

**Returns**

- `inv_c` [rank-2 array('F') with bounds (n,n) and c storage]
- `info` [int]

**Other Parameters**

- `overwrite_c` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
unitdiag  [input int, optional] Default: 0

scipy.linalg.lapack.ztrtri

scipy.linalg.lapack.ztrtri(c[, lower, unitdiag, overwrite_c]) = <fortran object>
Wrapper for ztrtri.

Parameters
  c  [input rank-2 array('D') with bounds (n,n)]

Returns
  inv_c  [rank-2 array('D') with bounds (n,n) and c storage]
  info  [int]

Other Parameters
  overwrite_c  [input int, optional] Default: 0
  lower  [input int, optional] Default: 0
  unitdiag  [input int, optional] Default: 0

scipy.linalg.lapack.strtrs

scipy.linalg.lapack.strtrs(a, b[, lower, trans, unitdiag, lda, overwrite_b]) = <fortran object>
Wrapper for strtrs.

Parameters
  a  [input rank-2 array('f') with bounds (lda,n)]
  b  [input rank-2 array('f') with bounds (ldb,nrhs)]

Returns
  x  [rank-2 array('f') with bounds (ldb,nrhs) and b storage]
  info  [int]

Other Parameters
  lower  [input int, optional] Default: 0
  trans  [input int, optional] Default: 0
  unitdiag  [input int, optional] Default: 0
  lda  [input int, optional] Default: shape(a,0)
  overwrite_b  [input int, optional] Default: 0
**scipy.linalg.lapack.dtrtrs**

Wrapper for dtrtrs.

Parameters

- `a` [input rank-2 array('d') with bounds (lda,n)]
- `b` [input rank-2 array('d') with bounds (ldb,nrhs)]

Returns

- `x` [rank-2 array('d') with bounds (ldb,nrhs) and b storage]
- `info` [int]

Other Parameters

- `lower` [input int, optional] Default: 0
- `trans` [input int, optional] Default: 0
- `unitdiag` [input int, optional] Default: 0
- `lda` [input int, optional] Default: shape(a,0)
- `overwrite_b` [input int, optional] Default: 0

**scipy.linalg.lapack.ctrtrs**

Wrapper for ctrtrs.

Parameters

- `a` [input rank-2 array('F') with bounds (lda,n)]
- `b` [input rank-2 array('F') with bounds (ldb,nrhs)]

Returns

- `x` [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
- `info` [int]

Other Parameters

- `lower` [input int, optional] Default: 0
- `trans` [input int, optional] Default: 0
- `unitdiag` [input int, optional] Default: 0
- `lda` [input int, optional] Default: shape(a,0)
- `overwrite_b` [input int, optional] Default: 0
scipy.linalg.lapack.ztrtrs

Wrapper for ztrtrs.

Parameters

a [input rank-2 array('D') with bounds (lda,n)]
b [input rank-2 array('D') with bounds (ldb, nrhs)]

Returns

x [rank-2 array('D') with bounds (ldb, nrhs) and b storage]
info [int]

Other Parameters

lower [input int, optional] Default: 0
trans [input int, optional] Default: 0
unitdiag [input int, optional] Default: 0
lda [input int, optional] Default: shape(a,0)
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.strttf

Wrapper for strttf.

Parameters

a [input rank-2 array('f') with bounds (lda, n)]

Returns

arf [rank-1 array('f') with bounds (n*(n+1)/2)]
info [int]

Other Parameters

transr [input string(len=1), optional] Default: ‘N’
uplo [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.dtrttf

Wrapper for dtrttf.

Parameters

a [input rank-2 array('d') with bounds (lda, n)]

Returns

arf [rank-1 array('d') with bounds (n*(n+1)/2)]
info [int]

Other Parameters

transr [input string(len=1), optional] Default: ‘N’
**uplo**  [input string(len=1), optional] Default: ‘U’

**scipy.linalg.lapack.ctrttf**

`scipy.linalg.lapack.ctrttf(a[, transr, uplo]) = <fortran object>`

Wrapper for `ctrfft`.

**Parameters**

- **a**  [input rank-2 array('F') with bounds (lda,n)]

**Returns**

- **arf**  [rank-1 array('F') with bounds (n*(n+1)/2)]
- **info**  [int]

**Other Parameters**

- **transr**  [input string(len=1), optional] Default: ‘N’
- **uplo**  [input string(len=1), optional] Default: ‘U’

**scipy.linalg.lapack.ztrttf**

`scipy.linalg.lapack.ztrttf(a[, transr, uplo]) = <fortran object>`

Wrapper for `ztrttf`.

**Parameters**

- **a**  [input rank-2 array('D') with bounds (lda,n)]

**Returns**

- **arf**  [rank-1 array('D') with bounds (n*(n+1)/2)]
- **info**  [int]

**Other Parameters**

- **transr**  [input string(len=1), optional] Default: ‘N’
- **uplo**  [input string(len=1), optional] Default: ‘U’

**scipy.linalg.lapack.strttp**

`scipy.linalg.lapack.strttp(a[, uplo]) = <fortran object>`

Wrapper for `strttp`.

**Parameters**

- **a**  [input rank-2 array('f') with bounds (lda,n)]

**Returns**

- **ap**  [rank-1 array('f') with bounds (n*(n+1)/2)]
- **info**  [int]

**Other Parameters**

- **uplo**  [input string(len=1), optional] Default: ‘U’
scipy.linalg.lapack.dtrttp

Wrapper for dtrttp.

Parameters

- a [input rank-2 array('d') with bounds (lda,n)]

Returns

- ap [rank-1 array('d') with bounds (n*(n+1)/2)]
- info [int]

Other Parameters

- uplo [input string(len=1), optional] Default: 'U'

scipy.linalg.lapack.ctrttp

Wrapper for ctrttp.

Parameters

- a [input rank-2 array('F') with bounds (lda,n)]

Returns

- ap [rank-1 array('F') with bounds (n*(n+1)/2)]
- info [int]

Other Parameters

- uplo [input string(len=1), optional] Default: 'U'

scipy.linalg.lapack.ztrttp

Wrapper for ztrttp.

Parameters

- a [input rank-2 array('D') with bounds (lda,n)]

Returns

- ap [rank-1 array('D') with bounds (n*(n+1)/2)]
- info [int]

Other Parameters

- uplo [input string(len=1), optional] Default: 'U'
scipy.linalg.lapack.stzrzf

scipy.linalg.lapack.stzrzf(a[, lwork, overwrite_a]) = <fortran object>

Wrapper for stzrzf.

Parameters
a [input rank-2 array('f') with bounds (m,n)]

Returns
rz [rank-2 array('f') with bounds (m,n) and a storage]
tau [rank-1 array('f') with bounds (m)]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: MAX(m,1)

scipy.linalg.lapack.dtzrzf

scipy.linalg.lapack.dtzrzf(a[, lwork, overwrite_a]) = <fortran object>

Wrapper for dtzrzf.

Parameters
a [input rank-2 array('d') with bounds (m,n)]

Returns
rz [rank-2 array('d') with bounds (m,n) and a storage]
tau [rank-1 array('d') with bounds (m)]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: MAX(m,1)

scipy.linalg.lapack.ctzrzf

scipy.linalg.lapack.ctzrzf(a[, lwork, overwrite_a]) = <fortran object>

Wrapper for ctzrzf.

Parameters
a [input rank-2 array('F') with bounds (m,n)]

Returns
rz [rank-2 array('F') with bounds (m,n) and a storage]
tau [rank-1 array('F') with bounds (m)]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: MAX(m,1)

scipy.linalg.lapack.ztzrzf

scipy.linalg.lapack.ztzrzf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for ztzrzf.

Parameters
    a [input rank-2 array('D') with bounds (m,n)]

Returns
    rz [rank-2 array('D') with bounds (m,n) and a storage]
    tau [rank-1 array('D') with bounds (m)]
    info [int]

Other Parameters
    overwrite_a [input int, optional] Default: 0
    lwork [input int, optional] Default: MAX(m,1)

scipy.linalg.lapack.stzrzf_lwork

scipy.linalg.lapack.stzrzf_lwork(m, n) = <fortran object>
Wrapper for stzrzf_lwork.

Parameters
    m [input int]
    n [input int]

Returns
    work [float]
    info [int]

scipy.linalg.lapack.dtzrzf_lwork

scipy.linalg.lapack.dtzrzf_lwork(m, n) = <fortran object>
Wrapper for dtzrzf_lwork.

Parameters
    m [input int]
    n [input int]

Returns
    work [float]
    info [int]
6.12. Low-level LAPACK functions (scipy.linalg.lapack)
scipy.linalg.lapack.zunghr

Wrapper for zunghr.

Parameters

- `a` [input rank-2 array('D') with bounds (n,n)]
- `tau` [input rank-1 array('D') with bounds (n - 1)]

Returns

- `ht` [rank-2 array('D') with bounds (n,n) and a storage]
- `info` [int]

Other Parameters

- `lo` [input int, optional] Default: 0
- `hi` [input int, optional] Default: n-1
- `overwrite_a` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: max(hi-lo,1)

scipy.linalg.lapack.cunghr_lwork

Wrapper for cunghr_lwork.

Parameters

- `n` [input int]

Returns

- `work` [complex]
- `info` [int]

Other Parameters

- `lo` [input int, optional] Default: 0
- `hi` [input int, optional] Default: n-1

scipy.linalg.lapack.zunghr_lwork

Wrapper for zunghr_lwork.

Parameters

- `n` [input int]

Returns

- `work` [complex]
- `info` [int]

Other Parameters

- `lo` [input int, optional] Default: 0
- `hi` [input int, optional] Default: n-1
scipy.linalg.lapack.cungqr

scipy.linalg.lapack.cungqr (a, tau[, lwork, overwrite_a]) = <fortran object>

Wrapper for cungqr.

Parameters

- a [input rank-2 array('F') with bounds (m,n)]
- tau [input rank-1 array('F') with bounds (k)]

Returns

- q [rank-2 array('F') with bounds (m,n) and a storage]
- work [rank-1 array('F') with bounds (MAX(lwork,1))]
- info [int]

Other Parameters

- overwrite_a [input int, optional] Default: 0
- lwork [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.zungqr

scipy.linalg.lapack.zungqr (a, tau[, lwork, overwrite_a]) = <fortran object>

Wrapper for zungqr.

Parameters

- a [input rank-2 array('D') with bounds (m,n)]
- tau [input rank-1 array('D') with bounds (k)]

Returns

- q [rank-2 array('D') with bounds (m,n) and a storage]
- work [rank-1 array('D') with bounds (MAX(lwork,1))]
- info [int]

Other Parameters

- overwrite_a [input int, optional] Default: 0
- lwork [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.cungrq

scipy.linalg.lapack.cungrq (a, tau[, lwork, overwrite_a]) = <fortran object>

Wrapper for cungrq.

Parameters

- a [input rank-2 array('F') with bounds (m,n)]
- tau [input rank-1 array('F') with bounds (k)]

Returns

- q [rank-2 array('F') with bounds (m,n) and a storage]
- work [rank-1 array('F') with bounds (MAX(lwork,1))]
- info [int]
Other Parameters

overwrite_a 
[input int, optional] Default: 0
lwork [input int, optional] Default: max(3*m,1)

scipy.linalg.lapack.zungrq

scipy.linalg.lapack.zungrq(a, tau[, lwork, overwrite_a]) = <fortran object>
Wrapper for zungrq.

Parameters

a [input rank-2 array('D') with bounds (m,n)]
tau [input rank-1 array('D') with bounds (k)]

Returns

q [rank-2 array('D') with bounds (m,n) and a storage]
work [rank-1 array('D') with bounds (MAX(lwork,1))]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*m,1)

scipy.linalg.lapack.cunmqr

scipy.linalg.lapack.cunmqr(side, trans, a, tau[, c work[, overwrite_c]]) = <fortran object>
Wrapper for cunmqr.

Parameters

side [input string(len=1)]
trans [input string(len=1)]
a [input rank-2 array('F') with bounds (lda,k)]
tau [input rank-1 array('F') with bounds (k)]
c [input rank-2 array('F') with bounds (ldc,n)]
lwork [input int]

Returns

cq [rank-2 array('F') with bounds (ldc,n) and c storage]
work [rank-1 array('F') with bounds (MAX(lwork,1))]
info [int]

Other Parameters

overwrite_c [input int, optional] Default: 0
scipy.linalg.lapack.zunmqr

```python
scipy.linalg.lapack.zunmqr(side, trans, a, tau, c, lwork[, overwrite_c]) = <fortran object>
```

Wrapper for `zunmqr`.

**Parameters**

- **side** [input string(len=1)]
- **trans** [input string(len=1)]
- **a** [input rank-2 array('D') with bounds (lda,k)]
- **tau** [input rank-1 array('D') with bounds (k)]
- **c** [input rank-2 array('D') with bounds (ldc,n)]
- **lwork** [input int]

**Returns**

- **cq** [rank-2 array('D') with bounds (ldc,n) and c storage]
- **work** [rank-1 array('D') with bounds (MAX(lwork,1))]
- **info** [int]

**Other Parameters**

- **overwrite_c** [input int, optional] Default: 0

scipy.linalg.lapack.sgeqrt

```python
scipy.linalg.lapack.sgeqrt(nb, a[, overwrite_a]) = <fortran object>
```

Wrapper for `sgeqrt`.

**Parameters**

- **nb** [input int]
- **a** [input rank-2 array('f') with bounds (m,n)]

**Returns**

- **a** [rank-2 array('f') with bounds (m,n)]
- **t** [rank-2 array('f') with bounds (nb,MIN(m,n))]
- **info** [int]

**Other Parameters**

- **overwrite_a** [input int, optional] Default: 0

scipy.linalg.lapack.dgeqrt

```python
scipy.linalg.lapack.dgeqrt(nb, a[, overwrite_a]) = <fortran object>
```

Wrapper for `dgeqrt`.

**Parameters**

- **nb** [input int]
- **a** [input rank-2 array('d') with bounds (m,n)]

**Returns**

- **a** [rank-2 array('d') with bounds (m,n)]
- **t** [rank-2 array('d') with bounds (nb,MIN(m,n))]

6.12. Low-level LAPACK functions (scipy.linalg.lapack)
info [int]

**Other Parameters**

overwrite_a

[input int, optional] Default: 0

**scipy.linalg.lapack.cgeqrt**

scipy.linalg.lapack.cgeqrt(nb, a[, overwrite_a]) = <fortran object>

Wrapper for cgeqrt.

**Parameters**

nb [input int]

a [input rank-2 array('F') with bounds (m,n)]

**Returns**

a [rank-2 array('F') with bounds (m,n)]

t [rank-2 array('F') with bounds (nb,MIN(m,n))]

info [int]

**Other Parameters**

overwrite_a

[input int, optional] Default: 0

**scipy.linalg.lapack.zgeqrt**

scipy.linalg.lapack.zgeqrt(nb, a[, overwrite_a]) = <fortran object>

Wrapper for zgeqrt.

**Parameters**

nb [input int]

a [input rank-2 array('D') with bounds (m,n)]

**Returns**

a [rank-2 array('D') with bounds (m,n)]

t [rank-2 array('D') with bounds (nb,MIN(m,n))]

info [int]

**Other Parameters**

overwrite_a

[input int, optional] Default: 0
scipy.linalg.lapack.sgemqrt

scipy.linalg.lapack.sgemqrt(v, t, c[, side, trans, overwrite_c]) = <fortran object>

Wrapper for sgemqrt.

Parameters
v [input rank-2 array('f') with bounds ((side[0]=='L'?m:n),k)]
t [input rank-2 array('f') with bounds (nb,k)]
c [input rank-2 array('f') with bounds (m,n)]

Returns
c [rank-2 array('f') with bounds (m,n)]
info [int]

Other Parameters
side [input string(len=1), optional] Default: 'L'
trans [input string(len=1), optional] Default: 'N'
overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.dgemqrt

scipy.linalg.lapack.dgemqrt(v, t, c[, side, trans, overwrite_c]) = <fortran object>

Wrapper for dgemqrt.

Parameters
v [input rank-2 array('d') with bounds ((side[0]=='L'?m:n),k)]
t [input rank-2 array('d') with bounds (nb,k)]
c [input rank-2 array('d') with bounds (m,n)]

Returns
c [rank-2 array('d') with bounds (m,n)]
info [int]

Other Parameters
side [input string(len=1), optional] Default: 'L'
trans [input string(len=1), optional] Default: 'N'
overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.cgemqrt

scipy.linalg.lapack.cgemqrt(v, t, c[, side, trans, overwrite_c]) = <fortran object>

Wrapper for cgemqrt.

Parameters
v [input rank-2 array('F') with bounds ((side[0]=='L'?m:n),k)]
t [input rank-2 array('F') with bounds (nb,k)]
c [input rank-2 array('F') with bounds (m,n)]

Returns
c [rank-2 array('F') with bounds (m,n)]
info [int]

Other Parameters
side [input string(len=1), optional] Default: 'L'
trans [input string(len=1), optional] Default: 'N'
overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.zgemqrt

scipy.linalg.lapack.zgemqrt(v, t, c[, side, trans, overwrite_c]) = <fortran object>
Wrapper for zgemqrt.

Parameters
v [input rank-2 array('D') with bounds ((side[0]=='L'?m:n),k)]
t [input rank-2 array('D') with bounds (nb,k)]
c [input rank-2 array('D') with bounds (m,n)]

Returns
c [rank-2 array('D') with bounds (m,n)]
info [int]

Other Parameters
side [input string(len=1), optional] Default: 'L'
trans [input string(len=1), optional] Default: 'N'
overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.sgttrf

scipy.linalg.lapack.sgttrf(dl, d, du[, overwrite_dl, overwrite_d, overwrite_du]) = <fortran object>
Wrapper for sgttrf.

Parameters
dl [input rank-1 array('f') with bounds (n-1)]
d [input rank-1 array('f') with bounds (n)]
du [input rank-1 array('f') with bounds (n-1)]

Returns
dl [rank-1 array('f') with bounds (n-1)]
d [rank-1 array('f') with bounds (n)]
du [rank-1 array('f') with bounds (n-1)]
du2 [rank-1 array('f') with bounds (n-2)]
ipiv [rank-1 array('i') with bounds (n)]
info [int]

Other Parameters
overwrite_dl [input int, optional] Default: 0
overwrite_d [input int, optional] Default: 0
overwrite_du
[input int, optional] Default: 0

scipy.linalg.lapack.dgttrf

scipy.linalg.lapack.dgttrf (dl, d, du[, overwrite_dl, overwrite_d, overwrite_du]) = <fortran object>

Wrapper for dgttrf.

Parameters

- dl  [input rank-1 array('d') with bounds (n - 1)]
- d   [input rank-1 array('d') with bounds (n)]
- du  [input rank-1 array('d') with bounds (n - 1)]

Returns

- dl  [rank-1 array('d') with bounds (n - 1)]
- d   [rank-1 array('d') with bounds (n)]
- du  [rank-1 array('d') with bounds (n - 1)]
- du2 [rank-1 array('d') with bounds (n - 2)]
- ipiv [rank-1 array('i') with bounds (n)]
- info [int]

Other Parameters

- overwrite_dl [input int, optional] Default: 0
- overwrite_d [input int, optional] Default: 0
- overwrite_du [input int, optional] Default: 0

scipy.linalg.lapack.cgttrf

scipy.linalg.lapack.cgttrf (dl, d, du[, overwrite_dl, overwrite_d, overwrite_du]) = <fortran object>

Wrapper for cgttrf.

Parameters

- dl  [input rank-1 array('F') with bounds (n - 1)]
- d   [input rank-1 array('F') with bounds (n)]
- du  [input rank-1 array('F') with bounds (n - 1)]

Returns

- dl  [rank-1 array('F') with bounds (n - 1)]
- d   [rank-1 array('F') with bounds (n)]
- du  [rank-1 array('F') with bounds (n - 1)]
- du2 [rank-1 array('F') with bounds (n - 2)]
- ipiv [rank-1 array('i') with bounds (n)]
- info [int]

Other Parameters

- overwrite_dl [input int, optional] Default: 0
overwrite_d
   [input int, optional] Default: 0
overwrite_du
   [input int, optional] Default: 0

scipy.linalg.lapack.zgttrf

scipy.linalg.lapack.zgttrf (dl, d, du[, overwrite_dl, overwrite_d, overwrite_du]) = <fortran object>
Wrapper for zgttrf.

Parameters
   dl   [input rank-1 array('D') with bounds (n - 1)]
   d    [input rank-1 array('D') with bounds (n)]
   du   [input rank-1 array('D') with bounds (n - 1)]

Returns
   dl   [rank-1 array('D') with bounds (n - 1)]
   d    [rank-1 array('D') with bounds (n)]
   du   [rank-1 array('D') with bounds (n - 1)]
   du2  [rank-1 array('D') with bounds (n - 2)]
   ipiv [rank-1 array('i') with bounds (n)]
   info [int]

Other Parameters
   overwrite_dl
      [input int, optional] Default: 0
   overwrite_d
      [input int, optional] Default: 0
   overwrite_du
      [input int, optional] Default: 0

scipy.linalg.lapack.sgttrs

scipy.linalg.lapack.sgttrs (dl, d, du, du2, ipiv, b[, trans, overwrite_b]) = <fortran object>
Wrapper for sgttrs.

Parameters
   dl   [input rank-1 array('f') with bounds (n - 1)]
   d    [input rank-1 array('f') with bounds (n)]
   du   [input rank-1 array('f') with bounds (n - 1)]
   du2  [input rank-1 array('f') with bounds (n - 2)]
   ipiv [input rank-1 array('i') with bounds (n)]
   b    [input rank-2 array('f') with bounds (ldb,nrhs)]

Returns
   x    [rank-2 array('f') with bounds (ldb,nrhs) and b storage]
   info [int]

Other Parameters
   trans  [input string(len=1), optional] Default: ‘N’
overwrite_b
[input int, optional] Default: 0

scipy.linalg.lapack.dgttrs

scipy.linalg.lapack.dgttrs (dl, d, du, du2, ipiv, b[, trans, overwrite_b]) = <fortran object>  
Wrapper for dgttrs.

Parameters

- dl [input rank-1 array('d') with bounds (n - 1)]
- d [input rank-1 array('d') with bounds (n)]
- du [input rank-1 array('d') with bounds (n - 1)]
- du2 [input rank-1 array('d') with bounds (n - 2)]
- ipiv [input rank-1 array('i') with bounds (n)]
- b [input rank-2 array('d') with bounds (ldb,nrhs)]

Returns

- x [rank-2 array('d') with bounds (ldb,nrhs) and b storage]
- info [int]

Other Parameters

- trans [input string(len=1), optional] Default: ‘N’
- overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.cgttrs

scipy.linalg.lapack.cgttrs (dl, d, du, du2, ipiv, b[, trans, overwrite_b]) = <fortran object>  
Wrapper for cgttrs.

Parameters

- dl [input rank-1 array('F') with bounds (n - 1)]
- d [input rank-1 array('F') with bounds (n)]
- du [input rank-1 array('F') with bounds (n - 1)]
- du2 [input rank-1 array('F') with bounds (n - 2)]
- ipiv [input rank-1 array('i') with bounds (n)]
- b [input rank-2 array('F') with bounds (ldb,nrhs)]

Returns

- x [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
- info [int]

Other Parameters

- trans [input string(len=1), optional] Default: ‘N’
- overwrite_b [input int, optional] Default: 0
scipy.linalg.lapack.zgttrs

scipy.linalg.lapack.zgttrs(dl, d, du, du2, ipiv, b[, trans, overwrite_b]) = <fortran object>

Wrapper for zgttrs.

Parameters
- dl [input rank-1 array('D') with bounds (n - 1)]
- d [input rank-1 array('D') with bounds (n)]
- du [input rank-1 array('D') with bounds (n - 1)]
- du2 [input rank-1 array('D') with bounds (n - 2)]
- ipiv [input rank-1 array('i') with bounds (n)]
- b [input rank-2 array('D') with bounds (ldb,nrhs)]

Returns
- x [rank-2 array('D') with bounds (ldb,nrhs) and b storage]
- info [int]

Other Parameters
- trans [input string(len=1), optional] Default: ‘N’
- overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.stpqrt

scipy.linalg.lapack.stpqrt(l, nb, a[, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for stpqrt.

Parameters
- l [input int]
- nb [input int]
- a [input rank-2 array('f') with bounds (n,n)]
- b [input rank-2 array('f') with bounds (m,n)]

Returns
- a [rank-2 array('f') with bounds (n,n)]
- b [rank-2 array('f') with bounds (m,n)]
- t [rank-2 array('f') with bounds (nb,n)]
- info [int]

Other Parameters
- overwrite_a [input int, optional] Default: 0
- overwrite_b [input int, optional] Default: 0
scipy.linalg.lapack.dtpqrt

Wrapper for dtpqrt.

Parameters

- `l` [input int]
- `nb` [input int]
- `a` [input rank-2 array('d') with bounds (n,n)]
- `b` [input rank-2 array('d') with bounds (m,n)]

Returns

- `a` [rank-2 array('d') with bounds (n,n)]
- `b` [rank-2 array('d') with bounds (m,n)]
- `t` [rank-2 array('d') with bounds (nb,n)]
- `info` [int]

Other Parameters

- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0

scipy.linalg.lapack.ctpqrt

Wrapper for ctpqrt.

Parameters

- `l` [input int]
- `nb` [input int]
- `a` [input rank-2 array('F') with bounds (n,n)]
- `b` [input rank-2 array('F') with bounds (m,n)]

Returns

- `a` [rank-2 array('F') with bounds (n,n)]
- `b` [rank-2 array('F') with bounds (m,n)]
- `t` [rank-2 array('F') with bounds (nb,n)]
- `info` [int]

Other Parameters

- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0
### scipy.linalg.lapack.ztpqrt

**scipy.linalg.lapack.ztpqrt**(l, nb, a[, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for ztpqrt.

**Parameters**

- **l** [input int]
- **nb** [input int]
- **a** [input rank-2 array('D') with bounds (n,n)]
- **b** [input rank-2 array('D') with bounds (m,n)]

**Returns**

- **a** [rank-2 array('D') with bounds (n,n)]
- **b** [rank-2 array('D') with bounds (m,n)]
- **t** [rank-2 array('D') with bounds (nb,n)]
- **info** [int]

**Other Parameters**

- **overwrite_a** [input int, optional] Default: 0
- **overwrite_b** [input int, optional] Default: 0

### scipy.linalg.lapack.stpmqrt

**scipy.linalg.lapack.stpmqrt**(l, v, t, a[, side, trans, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for stpmqrt.

**Parameters**

- **l** [input int]
- **v** [input rank-2 array('f') with bounds ((side[0]=='L'?m:n),k)]
- **t** [input rank-2 array('f') with bounds (nb,k)]
- **a** [input rank-2 array('f') with bounds ((side[0]=='L'?k:m),(side[0]=='L'?n:k))] 
- **b** [input rank-2 array('f') with bounds (m,n)]

**Returns**

- **a** [rank-2 array('f') with bounds ((side[0]=='L'?k:m),(side[0]=='L'?n:k))] 
- **b** [rank-2 array('f') with bounds (m,n)]
- **info** [int]

**Other Parameters**

- **side** [input string(len=1), optional] Default: ‘L’
- **trans** [input string(len=1), optional] Default: ‘N’
- **overwrite_a** [input int, optional] Default: 0
- **overwrite_b** [input int, optional] Default: 0

scipy.linalg.lapack.dtpmqrt

(scipy.linalg.lapack.dtpmqrt(l, v, t, a, b[, side, trans, overwrite_a, overwrite_b]) = <fortran object>)
Wrapper for dtpmqrt.

Parameters
l [input int]
v [input rank-2 array('d') with bounds ((side[0]=='L'?m:n),k)]
t [input rank-2 array('d') with bounds (nb,k)]
a [input rank-2 array('d') with bounds ((side[0]=='L'?k:m),(side[0]=='L'?n:k))]]
b [input rank-2 array('d') with bounds (m,n)]

Returns
a [rank-2 array('d') with bounds ((side[0]=='L'?k:m),(side[0]=='L'?n:k))]]
b [rank-2 array('d') with bounds (m,n)]
info [int]

Other Parameters
side [input string(len=1), optional] Default: 'L'
trans [input string(len=1), optional] Default: 'N'
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.ctpmqrt

(scipy.linalg.lapack.ctpmqrt(l, v, t, a, b[, side, trans, overwrite_a, overwrite_b]) = <fortran object>)
Wrapper for ctpmqrt.

Parameters
l [input int]
v [input rank-2 array('F') with bounds ((side[0]=='L'?m:n),k)]
t [input rank-2 array('F') with bounds (nb,k)]
a [input rank-2 array('F') with bounds ((side[0]=='L'?k:m),(side[0]=='L'?n:k))]]
b [input rank-2 array('F') with bounds (m,n)]

Returns
a [rank-2 array('F') with bounds ((side[0]=='L'?k:m),(side[0]=='L'?n:k))]]
b [rank-2 array('F') with bounds (m,n)]
info [int]

Other Parameters
side [input string(len=1), optional] Default: 'L'
trans [input string(len=1), optional] Default: 'N'
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
scipy.linalg.lapack.ztpmqrt

scipy.linalg.lapack.ztpmqrt(l, v, t, a[, side, trans, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for ztpmqrt.

Parameters

- `l` [input int]
- `v` [input rank-2 array('D') with bounds ((side[0]=='L'?m:n),k)]
- `t` [input rank-2 array('D') with bounds (nb,k)]
- `a` [input rank-2 array('D') with bounds ((side[0]=='L'?k:m),(side[0]=='L'?n:k))]  
- `b` [input rank-2 array('D') with bounds (m,n)]

Returns

- `a` [rank-2 array('D') with bounds ((side[0]=='L'?k:m),(side[0]=='L'?n:k))]  
- `b` [rank-2 array('D') with bounds (m,n)]
- `info` [int]

Other Parameters

- `side` [input string(len=1), optional] Default: ‘L’
- `trans` [input string(len=1), optional] Default: ‘N’
- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0

scipy.linalg.lapack.cuncsd

scipy.linalg.lapack.cuncsd(x11, x12, x21, x22[, compute_u1, compute_u2, compute_v1t, compute_v2t, trans, signs, lwork, lrwork, overwrite_x11, overwrite_x12, overwrite_x21, overwrite_x22]) = <fortran object>

Wrapper for cuncsd.

Parameters

- `x11` [input rank-2 array('F') with bounds (p,q)]
- `x12` [input rank-2 array('F') with bounds (p,mmq)]
- `x21` [input rank-2 array('F') with bounds (mmp,q)]
- `x22` [input rank-2 array('F') with bounds (mmp,mmq)]

Returns

- `cs11` [rank-2 array('F') with bounds (p,q) and x11 storage]
- `cs12` [rank-2 array('F') with bounds (p,mmq) and x12 storage]
- `cs21` [rank-2 array('F') with bounds (mmp,q) and x21 storage]
- `cs22` [rank-2 array('F') with bounds (mmp,mmq) and x22 storage]
- `theta` [rank-1 array('f') with bounds (min(min(p,mmp),min(q,mmq)))]
- `u1` [rank-1 array('f') with bounds ((compute_u1?p:0),(compute_u1?p:0))]
- `u2` [rank-2 array('F') with bounds ((compute_u2?mmp:0),(compute_u2?mmp:0))]
- `v1t` [rank-2 array('F') with bounds ((compute_v1t?q:0),(compute_v1t?q:0))]
- `v2t` [rank-2 array('F') with bounds ((compute_v2t?mmq:0),(compute_v2t?mmq:0))]
- `info` [int]

Other Parameters

compute_u1
[input int, optional] Default: 1

compute_u2
[input int, optional] Default: 1

compute_v1t
[input int, optional] Default: 1

compute_v2t
[input int, optional] Default: 1

trans
[input int, optional] Default: 1

signs
[input int, optional] Default: 0

overwrite_x11
[input int, optional] Default: 0

overwrite_x12
[input int, optional] Default: 0

overwrite_x21
[input int, optional] Default: 0

overwrite_x22
[input int, optional] Default: 0

lwork
[input int, optional] Default: \(2*m+\max(1,\max(mmp,mmq))+1\)

lrwork
[input int, optional] Default: \(5*\max(1,q-1)+4*\max(1,q)+8*q+1\)

scipy.linalg.lapack.zuncsd

scipy.linalg.lapack.zuncsd(x11, x12, x21, x22[, compute_u1, compute_u2, compute_v1t, compute_v2t, trans, signs, lwork, lrwork, overwrite_x11, overwrite_x12, overwrite_x21, overwrite_x22]) = <fortran object>

Wrapper for zuncsd.

Parameters

- x11  : [input rank-2 array('D') with bounds (p,q)]
- x12  : [input rank-2 array('D') with bounds (p,mmq)]
- x21  : [input rank-2 array('D') with bounds (mmp,q)]
- x22  : [input rank-2 array('D') with bounds (mmp,mmq)]

Returns

- cs11 : [rank-2 array('D') with bounds (p,q) and x11 storage]
- cs12 : [rank-2 array('D') with bounds (p,mmq) and x12 storage]
- cs21 : [rank-2 array('D') with bounds (mmp,q) and x21 storage]
- cs22 : [rank-2 array('D') with bounds (mmp,mmq) and x22 storage]
- theta : [rank-1 array('d') with bounds (min(min(p,mmp),min(q,mmq)))]
- u1   : [rank-2 array('D') with bounds ((compute_u1?p:0),(compute_u1?p:0))]
- u2   : [rank-2 array('D') with bounds ((compute_u2?mmp:0),(compute_u2?mmp:0))]
- v1t  : [rank-2 array('D') with bounds ((compute_v1t?q:0),(compute_v1t?q:0))]
- v2t  : [rank-2 array('D') with bounds ((compute_v2t?mmq:0),(compute_v2t?mmq:0))]
- info : [int]

Other Parameters

- compute_u1
  [input int, optional] Default: 1
- compute_u2
  [input int, optional] Default: 1
- compute_v1t
  [input int, optional] Default: 1

6.12. Low-level LAPACK functions (scipy.linalg.lapack) 1413
compute_v2t
    [input int, optional] Default: 1
trans  [input int, optional] Default: 0
signs  [input int, optional] Default: 0
overwrite_x11
    [input int, optional] Default: 0
overwrite_x12
    [input int, optional] Default: 0
overwrite_x21
    [input int, optional] Default: 0
overwrite_x22
    [input int, optional] Default: 0
lwork  [input int, optional] Default: 2*m+MAX(1,MAX(mmp,mmq))+1
lrwork  [input int, optional] Default: 5*MAX(1,q-1)+4*MAX(1,q)+8*q+1

scipy.linalg.lapack.cuncsd_lwork

scipy.linalg.lapack.cuncsd_lwork(m, p, q) = <fortran object>
Wrapper for cuncsd_lwork.

Parameters
m  [input int]
p  [input int]
q  [input int]

Returns
work  [complex]
rwork  [float]
info  [int]

scipy.linalg.lapack.zuncsd_lwork

scipy.linalg.lapack.zuncsd_lwork(m, p, q) = <fortran object>
Wrapper for zuncsd_lwork.

Parameters
m  [input int]
p  [input int]
q  [input int]

Returns
work  [complex]
rwork  [float]
info  [int]
**scipy.linalg.lapack.cunmrz**

Wrapper for `cunmrz`.

**Parameters**
- `a` [input rank-2 array('F') with bounds (k,nt)]
- `tau` [input rank-1 array('F') with bounds (k)]
- `c` [input rank-2 array('F') with bounds (m,n)]

**Returns**
- `cq` [rank-2 array('F') with bounds (m,n) and c storage]
- `info` [int]

**Other Parameters**
- `side` [input string(len=1), optional] Default: ‘L’
- `trans` [input string(len=1), optional] Default: ‘N’
- `overwrite_c` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: MAX((side[0]=='L'?n:m),1)

**scipy.linalg.lapack.zunmrz**

Wrapper for `zunmrz`.

**Parameters**
- `a` [input rank-2 array('D') with bounds (k,nt)]
- `tau` [input rank-1 array('D') with bounds (k)]
- `c` [input rank-2 array('D') with bounds (m,n)]

**Returns**
- `cq` [rank-2 array('D') with bounds (m,n) and c storage]
- `info` [int]

**Other Parameters**
- `side` [input string(len=1), optional] Default: ‘L’
- `trans` [input string(len=1), optional] Default: ‘N’
- `overwrite_c` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: MAX((side[0]=='L'?n:m),1)

**scipy.linalg.lapack.cunmrz_lwork**

Wrapper for `cunmrz_lwork`.

**Parameters**
- `m` [input int]
- `n` [input int]

**Returns**
- `lwork` [input int]
work [complex]
info [int]

Other Parameters
side [input string(len=1), optional] Default: ‘L’
trans [input string(len=1), optional] Default: ‘N’

scipy.linalg.lapack.zunmrz_lwork

scipy.linalg.lapack.zunmrz_lwork(m, n[, side, trans]) = <fortran object>
Wrapper for zunmrz_lwork.

Parameters
m [input int]
n [input int]

Returns
work [complex]
info [int]

Other Parameters
side [input string(len=1), optional] Default: ‘L’
trans [input string(len=1), optional] Default: ‘N’

scipy.linalg.lapack.ilaver

scipy.linalg.lapack.ilaver = <fortran object>
Wrapper for ilaver.

Returns
major [int]
minor [int]
patch [int]

6.13 BLAS Functions for Cython

Usable from Cython via:
cimport scipy.linalg.cython_blas

These wrappers do not check for alignment of arrays. Alignment should be checked before these wrappers are used. Raw function pointers (Fortran-style pointer arguments):

- caxpy
- ccopy
- cdotc
- cdotu
- cgbmv
• cgemm
• cgemv
• cgerc

6.14 LAPACK functions for Cython

Usable from Cython via:

```
cimport scipy.linalg.cython_lapack
```

This module provides Cython-level wrappers for all primary routines included in LAPACK 3.4.0 except for \texttt{zcgesv} since its interface is not consistent from LAPACK 3.4.0 to 3.6.0. It also provides some of the fixed-api auxiliary routines. These wrappers do not check for alignment of arrays. Alignment should be checked before these wrappers are used.

Raw function pointers (Fortran-style pointer arguments):

- \texttt{cbbcsd}
- \texttt{cbdsqr}
- \texttt{cbbrd}
- \texttt{cgbcon}
- \texttt{cgequ}
- \texttt{cgequb}
- \texttt{cgbtrfs}

6.15 Interpolative matrix decomposition (scipy.linalg.interpolative)

New in version 0.13.

An interpolative decomposition (ID) of a matrix $A \in \mathbb{C}^{m \times n}$ of rank $k \leq \min\{m, n\}$ is a factorization

$$A \Pi = \begin{bmatrix} A \Pi_1 & A \Pi_2 \end{bmatrix} = A \Pi_1 \begin{bmatrix} I & T \end{bmatrix},$$
where $\Pi = [\Pi_1, \Pi_2]$ is a permutation matrix with $\Pi_1 \in \{0, 1\}^{n \times k}$, i.e., $A\Pi_2 = A\Pi_1 T$. This can equivalently be written as $A = BP$, where $B = A\Pi_1$ and $P = [I, T]\Pi^T$ are the skeleton and interpolation matrices, respectively.

If $A$ does not have exact rank $k$, then there exists an approximation in the form of an ID such that $A = BP + E$, where $\|E\| \sim \sigma_{k+1}$ is on the order of the $(k + 1)$-th largest singular value of $A$. Note that $\sigma_{k+1}$ is the best possible error for a rank-$k$ approximation and, in fact, is achieved by the singular value decomposition (SVD) $A \approx USV^*$, where $U \in \mathbb{C}^{m \times k}$ and $V \in \mathbb{C}^{n \times k}$ have orthonormal columns and $S = \text{diag}(\sigma_i) \in \mathbb{C}^{k \times k}$ is diagonal with nonnegative entries.

The principal advantages of using an ID over an SVD are that:

- it is cheaper to construct;
- it preserves the structure of $A$; and
- it is more efficient to compute with in light of the identity submatrix of $P$.

### 6.15.1 Routines

Main functionality:

```python
interp_decomp(A, eps_or_k[, rand])  # Compute ID of a matrix.
reconstruct_matrix_from_id(B, idx, proj)  # Reconstruct matrix from its ID.
reconstruct_interp_matrix(idx, proj)  # Reconstruct interpolation matrix from ID.
reconstruct_skel_matrix(A, k, idx)  # Reconstruct skeleton matrix from ID.
id_to_svd(B, idx, proj)  # Convert ID to SVD.
svd(A, eps_or_k[, rand])  # Compute SVD of a matrix via an ID.
estimate_spectral_norm(A[, its])  # Estimate spectral norm of a matrix by the randomized power method.
estimate_spectral_norm_diff(A, B[, its])  # Estimate spectral norm of the difference of two matrices by the randomized power method.
estimate_rank(A, eps)  # Estimate matrix rank to a specified relative precision using randomized methods.
```

**scipy.linalg.interpolative.interp_decomp**

`scipy.linalg.interpolative.interp_decomp(A, eps_or_k, rand=True)`  
Compute ID of a matrix.

An ID of a matrix $A$ is a factorization defined by a rank $k$, a column index array $idx$, and interpolation coefficients $proj$ such that:

```python
numpy.dot(A[:,idx[:k]], proj) = A[:,idx[k:]]
```

The original matrix can then be reconstructed as:

```python
numpy.hstack([A[:,idx[:k]],
              numpy.dot(A[:,idx[:k]], proj)])[:,numpy.argsort(idx)]
```

or via the routine `reconstruct_matrix_from_id`. This can equivalently be written as:

```python
numpy.dot(A[:,idx[1k]],
          numpy.hstack([numpy.eye(k), proj])[:,np.argsort(idx)]
```

in terms of the skeleton and interpolation matrices.

\[ B = A[:, \text{idx}[:k]] \]

and:

\[ P = \text{numpy.hstack([numpy.eye(k), proj])[:, np.argsort(idx)} \]

respectively. See also `reconstruct_interp_matrix` and `reconstruct_skel_matrix`.

The ID can be computed to any relative precision or rank (depending on the value of `eps_or_k`). If a precision is specified (`eps_or_k < 1`), then this function has the output signature:

\[ k, \text{idx}, \text{proj} = \text{interp_decomp}(A, \text{eps_or_k}) \]

Otherwise, if a rank is specified (`eps_or_k >= 1`), then the output signature is:

\[ \text{idx}, \text{proj} = \text{interp_decomp}(A, \text{eps_or_k}) \]

**Parameters**

- **A** [numpy.ndarray or scipy.sparse.linalg.LinearOperator with `rmatvec`]
  Matrix to be factored
- **eps_or_k** [float or int]
  Relative error (if `eps_or_k < 1`) or rank (if `eps_or_k >= 1`) of approximation.
- **rand** [bool, optional]
  Whether to use random sampling if `A` is of type `numpy.ndarray` (randomized algorithms are always used if `A` is of type `scipy.sparse.linalg.LinearOperator`).

**Returns**

- **k** [int]
  Rank required to achieve specified relative precision if `eps_or_k < 1`.
- **idx** [numpy.ndarray]
  Column index array.
- **proj** [numpy.ndarray]
  Interpolation coefficients.

**scipy.linalg.interpolative.reconstruct_matrix_from_id**

`scipy.linalg.interpolative.reconstruct_matrix_from_id(B, idx, proj)`

Reconstruct matrix from its ID.

A matrix `A` with skeleton matrix `B` and ID indices and coefficients `idx` and `proj`, respectively, can be reconstructed as:

\[ \text{numpy.hstack([B, \text{numpy.dot(B, proj)]})[:, \text{numpy.argsort(idx)}] \]

See also `reconstruct_interp_matrix` and `reconstruct_skel_matrix`.

**Parameters**

- **B** [numpy.ndarray]
  Skeleton matrix.
- **idx** [numpy.ndarray]
  Column index array.
- **proj** [numpy.ndarray]
  Interpolation coefficients.

**Returns**

- **numpy.ndarray**
  Reconstructed matrix.
scipy.linalg.interpolative.reconstruct_interp_matrix

**scipy.linalg.interpolative.reconstruct_interp_matrix(idx, proj)**

Reconstruct interpolation matrix from ID.

The interpolation matrix can be reconstructed from the ID indices and coefficients idx and proj, respectively, as:

\[ P = \text{numpy.hstack}([\text{numpy.eye}(	ext{proj.shape}[0]), \text{proj}][:,\text{numpy.argsort(idx)}]) \]

The original matrix can then be reconstructed from its skeleton matrix B via:

\[ \text{numpy.dot}(B, P) \]

See also `reconstruct_matrix_from_id` and `reconstruct_skel_matrix`.

**Parameters**

- **idx** [numpy.ndarray] Column index array.
- **proj** [numpy.ndarray] Interpolation coefficients.

**Returns**

- **numpy.ndarray** Interpolation matrix.

scipy.linalg.interpolative.reconstruct_skel_matrix

**scipy.linalg.interpolative.reconstruct_skel_matrix(A, k, idx)**

Reconstruct skeleton matrix from ID.

The skeleton matrix can be reconstructed from the original matrix A and its ID rank and indices k and idx, respectively, as:

\[ B = A[:, \text{idx}[:k]] \]

The original matrix can then be reconstructed via:

\[ \text{numpy.hstack}([B, \text{numpy.dot}(B, \text{proj})][:,\text{numpy.argsort(idx)}]) \]

See also `reconstruct_matrix_from_id` and `reconstruct_interp_matrix`.

**Parameters**

- **A** [numpy.ndarray] Original matrix.
- **k** [int] Rank of ID.
- **idx** [numpy.ndarray] Column index array.

**Returns**

- **numpy.ndarray** Skeleton matrix.
**scipy.linalg.interpolative.id_to_svd**

**scipy.linalg.interpolative.id_to_svd**($B$, $idx$, $proj$)

Convert ID to SVD.

The SVD reconstruction of a matrix with skeleton matrix $B$ and ID indices and coefficients $idx$ and $proj$, respectively, is:

$$U, S, V = \text{id_to_svd}(B, idx, proj)$$

$$A = \text{numpy.dot}(U, \text{numpy.dot}(\text{numpy.diag}(S), V.conj().T))$$

See also `svd`.

**Parameters**

- $idx$ [numpy.ndarray] Column index array.
- $proj$ [numpy.ndarray] Interpolation coefficients.

**Returns**

- $U$ [numpy.ndarray] Left singular vectors.
- $S$ [numpy.ndarray] Singular values.
- $V$ [numpy.ndarray] Right singular vectors.

**scipy.linalg.interpolative.svd**

**scipy.linalg.interpolative.svd**($A$, $eps_or_k$, $rand=True$)

Compute SVD of a matrix via an ID.

An SVD of a matrix $A$ is a factorization:

$$A = \text{numpy.dot}(U, \text{numpy.dot}(\text{numpy.diag}(S), V.conj().T))$$

where $U$ and $V$ have orthonormal columns and $S$ is nonnegative.

The SVD can be computed to any relative precision or rank (depending on the value of $eps_or_k$).

See also `interp_decomp` and `id_to_svd`.

**Parameters**

- $A$ [numpy.ndarray or scipy.sparse.linalg.LinearOperator] Matrix to be factored, given as either a numpy.ndarray or a scipy.sparse.linalg.LinearOperator with the `matvec` and `rmatvec` methods (to apply the matrix and its adjoint).
- $eps_or_k$ [float or int] Relative error (if $eps_or_k < 1$) or rank (if $eps_or_k >= 1$) of approximation.
- $rand$ [bool, optional] Whether to use random sampling if $A$ is of type numpy.ndarray (randomized algorithms are always used if $A$ is of type scipy.sparse.linalg.LinearOperator).

**Returns**

- $U$ [numpy.ndarray] Left singular vectors.
- $S$ [numpy.ndarray] Singular values.
- $V$ [numpy.ndarray] Right singular vectors.
**scipy.linalg.interpolative.estimate_spectral_norm**

*scipy.linalg.interpolative.estimate_spectral_norm*(\(A, \text{its}=20\))

Estimate spectral norm of a matrix by the randomized power method.

**Parameters**

\(-A\)  
[scipy.sparse.linalg.LinearOperator] Matrix given as a scipy.sparse.linalg.LinearOperator with the matvec and rmatvec methods (to apply the matrix and its adjoint).

\(-\text{its}\)  
[int, optional] Number of power method iterations.

**Returns**

\(-\text{float}\)  
Spectral norm estimate.

**scipy.linalg.interpolative.estimate_spectral_norm_diff**

*scipy.linalg.interpolative.estimate_spectral_norm_diff*(\(A, B, \text{its}=20\))

Estimate spectral norm of the difference of two matrices by the randomized power method.

**Parameters**

\(-A\)  
[scipy.sparse.linalg.LinearOperator] First matrix given as a scipy.sparse.linalg.LinearOperator with the matvec and rmatvec methods (to apply the matrix and its adjoint).

\(-B\)  
[scipy.sparse.linalg.LinearOperator] Second matrix given as a scipy.sparse.linalg.LinearOperator with the matvec and rmatvec methods (to apply the matrix and its adjoint).

\(-\text{its}\)  
[int, optional] Number of power method iterations.

**Returns**

\(-\text{float}\)  
Spectral norm estimate of matrix difference.

**scipy.linalg.interpolative.estimate_rank**

*scipy.linalg.interpolative.estimate_rank*(\(A, \text{eps}\))

Estimate matrix rank to a specified relative precision using randomized methods.

The matrix \(A\) can be given as either a numpy.ndarray or a scipy.sparse.linalg.LinearOperator, with different algorithms used for each case. If \(A\) is of type numpy.ndarray, then the output rank is typically about 8 higher than the actual numerical rank.

**Parameters**

\(-A\)  
[numpy.ndarray or scipy.sparse.linalg.LinearOperator] Matrix whose rank is to be estimated, given as either a numpy.ndarray or a scipy.sparse.linalg.LinearOperator with the rmatvec method (to apply the matrix adjoint).

\(-\text{eps}\)  
[float] Relative error for numerical rank definition.

**Returns**

\(-\text{int}\)  
Estimated matrix rank.

**scipy.linalg.interpolative.seed**

scipy.linalg.interpolative.seed(seed=None)

Seed the internal random number generator used in this ID package.

The generator is a lagged Fibonacci method with 55-element internal state.

**Parameters**

- `seed` [int, sequence, `default`, optional] If `default`, the random seed is reset to a default value.
- If `seed` is a sequence containing 55 floating-point numbers in range [0, 1], these are used to set the internal state of the generator.
- If the value is an integer, the internal state is obtained from `numpy.random.RandomState` (MT19937) with the integer used as the initial seed.
- If `seed` is omitted (None), `numpy.random.rand` is used to initialize the generator.

**scipy.linalg.interpolative.rand**

scipy.linalg.interpolative.rand(*shape)

Generate standard uniform pseudorandom numbers via a very efficient lagged Fibonacci method.

This routine is used for all random number generation in this package and can affect ID and SVD results.

**Parameters**

- `shape` Shape of output array

### 6.15.2 References

This module uses the ID software package [R5a82238cdab4-1] by Martinsson, Rokhlin, Shkolnisky, and Tygert, which is a Fortran library for computing IDs using various algorithms, including the rank-revealing QR approach of [R5a82238cdab4-2] and the more recent randomized methods described in [R5a82238cdab4-3], [R5a82238cdab4-4], and [R5a82238cdab4-5]. This module exposes its functionality in a way convenient for Python users. Note that this module does not add any functionality beyond that of organizing a simpler and more consistent interface.

We advise the user to consult also the documentation for the ID package.

### 6.15.3 Tutorial

**Initializing**

The first step is to import `scipy.linalg.interpolative` by issuing the command:

```python
>>> import scipy.linalg.interpolative as sli
```

Now let's build a matrix. For this, we consider a Hilbert matrix, which is well known to have low rank:
We can also do this explicitly via:

```python
>>> import numpy as np
>>> n = 1000
>>> A = np.empty((n, n), order='F')
>>> for j in range(n):
...     for i in range(n):
...         A[i, j] = 1. / (i + j + 1)
```

Note the use of the flag `order='F'` in `numpy.empty`. This instantiates the matrix in Fortran-contiguous order and is important for avoiding data copying when passing to the backend.

We then define multiplication routines for the matrix by regarding it as a `scipy.sparse.linalg.LinearOperator`:

```python
>>> from scipy.sparse.linalg import aslinearoperator
>>> L = aslinearoperator(A)
```

This automatically sets up methods describing the action of the matrix and its adjoint on a vector.

### Computing an ID

We have several choices of algorithm to compute an ID. These fall largely according to two dichotomies:

1. how the matrix is represented, i.e., via its entries or via its action on a vector; and
2. whether to approximate it to a fixed relative precision or to a fixed rank.

We step through each choice in turn below.

In all cases, the ID is represented by three parameters:

1. a rank \( k \);  
2. an index array \( \text{idx} \); and  
3. interpolation coefficients \( \text{proj} \). 

The ID is specified by the relation \( \text{np.dot}(A[:, \text{idx[:k]}], \text{proj}) == A[:, \text{idx[k:]}] \). 

### From matrix entries

We first consider a matrix given in terms of its entries.

To compute an ID to a fixed precision, type:

```python
>>> k, idx, proj = sli.interp_decomp(A, eps)
```

where \( \text{eps} < 1 \) is the desired precision.

To compute an ID to a fixed rank, use:

```python
>>> idx, proj = sli.interp_decomp(A, k)
```
where \( k \geq 1 \) is the desired rank.

Both algorithms use random sampling and are usually faster than the corresponding older, deterministic algorithms, which can be accessed via the commands:

```python
>>> k, idx, proj = sli.interp_decomp(A, eps, rand=False)
```

and:

```python
>>> idx, proj = sli.interp_decomp(A, k, rand=False)
```

respectively.

**From matrix action**

Now consider a matrix given in terms of its action on a vector as a `scipy.sparse.linalg.LinearOperator`. To compute an ID to a fixed precision, type:

```python
>>> k, idx, proj = sli.interp_decomp(L, eps)
```

To compute an ID to a fixed rank, use:

```python
>>> idx, proj = sli.interp_decomp(L, k)
```

These algorithms are randomized.

**Reconstructing an ID**

The ID routines above do not output the skeleton and interpolation matrices explicitly but instead return the relevant information in a more compact (and sometimes more useful) form. To build these matrices, write:

```python
>>> B = sli.reconstruct_skel_matrix(A, k, idx)
```

for the skeleton matrix and:

```python
>>> P = sli.reconstruct_interp_matrix(idx, proj)
```

for the interpolation matrix. The ID approximation can then be computed as:

```python
>>> C = np.dot(B, P)
```

This can also be constructed directly using:

```python
>>> C = sli.reconstruct_matrix_from_id(B, idx, proj)
```

without having to first compute \( P \).

Alternatively, this can be done explicitly as well using:

```python
>>> B = A[:,idx[:k]]
>>> P = np.hstack([np.eye(k), proj])[:,np.argsort(idx)]
>>> C = np.dot(B, P)
```
Computing an SVD

An ID can be converted to an SVD via the command:

```python
>>> U, S, V = sli.id_to_svd(B, idx, proj)
```

The SVD approximation is then:

```python
>>> C = np.dot(U, np.dot(np.diag(S), np.dot(V.conj().T)))
```

The SVD can also be computed “fresh” by combining both the ID and conversion steps into one command. Following the various ID algorithms above, there are correspondingly various SVD algorithms that one can employ.

From matrix entries

We consider first SVD algorithms for a matrix given in terms of its entries.

To compute an SVD to a fixed precision, type:

```python
>>> U, S, V = sli.svd(A, eps)
```

To compute an SVD to a fixed rank, use:

```python
>>> U, S, V = sli.svd(A, k)
```

Both algorithms use random sampling; for the deterministic versions, issue the keyword `rand=False` as above.

From matrix action

Now consider a matrix given in terms of its action on a vector.

To compute an SVD to a fixed precision, type:

```python
>>> U, S, V = sli.svd(L, eps)
```

To compute an SVD to a fixed rank, use:

```python
>>> U, S, V = sli.svd(L, k)
```

Utility routines

Several utility routines are also available.

To estimate the spectral norm of a matrix, use:

```python
>>> snorm = sli.estimate_spectral_norm(A)
```

This algorithm is based on the randomized power method and thus requires only matrix-vector products. The number of iterations to take can be set using the keyword `its` (default: `its=20`). The matrix is interpreted as a `scipy.sparse.linalg.LinearOperator`, but it is also valid to supply it as a `numpy.ndarray`, in which case it is trivially converted using `scipy.sparse.linalg.aslinearoperator`.

The same algorithm can also estimate the spectral norm of the difference of two matrices $A_1$ and $A_2$ as follows:

```python
>>> diff = sli.estimate_spectral_norm_diff(A1, A2)
```
This is often useful for checking the accuracy of a matrix approximation.

Some routines in `scipy.linalg.interpolative` require estimating the rank of a matrix as well. This can be done with either:

```python
>>> k = sli.estimate_rank(A, eps)
```

or:

```python
>>> k = sli.estimate_rank(L, eps)
```

depending on the representation. The parameter `eps` controls the definition of the numerical rank.

Finally, the random number generation required for all randomized routines can be controlled via `scipy.linalg.interpolative.seed`. To reset the seed values to their original values, use:

```python
>>> sli.seed('default')
```

To specify the seed values, use:

```python
>>> sli.seed(s)
```

where `s` must be an integer or array of 55 floats. If an integer, the array of floats is obtained by using `numpy.random.rand` with the given integer seed.

To simply generate some random numbers, type:

```python
>>> sli.rand(n)
```

where `n` is the number of random numbers to generate.

**Remarks**

The above functions all automatically detect the appropriate interface and work with both real and complex data types, passing input arguments to the proper backend routine.

### 6.16 Miscellaneous routines (`scipy.misc`)

Various utilities that don’t have another home.

- `ascent()` Get an 8-bit grayscale bit-depth, 512 x 512 derived image for easy use in demos
- `central_diff_weights(Np[, ndiv])` Return weights for an Np-point central derivative.
- `derivative(func, x0[, dx, n, args, order])` Find the nth derivative of a function at a point.
- `face([gray])` Get a 1024 x 768, color image of a raccoon face.
- `electrocardiogram()` Load an electrocardiogram as an example for a 1-D signal.
6.16.1 scipy.misc.ascent

scipy.misc.ascent()
Get an 8-bit grayscale bit-depth, 512 x 512 derived image for easy use in demos
The image is derived from accent-to-the-top.jpg at http://www.public-domain-image.com/
people-public-domain-images-pictures/

Parameters
None

Returns
ascent [ndarray] convenient image to use for testing and demonstration

Examples

```python
>>> import scipy.misc
>>> ascent = scipy.misc.ascent()
>>> ascent.shape
(512, 512)
>>> ascent.max()
255
```

```python
>>> import matplotlib.pyplot as plt
>>> plt.gray()
>>> plt.imshow(ascent)
>>> plt.show()
```

![Image of ascent](http://www.public-domain-image.com/people-public-domain-images-pictures/accent-to-the-top.jpg)
6.16.2 scipy.misc.central_diff_weights

scipy.misc.central_diff_weights(Np, ndiv=1)
Return weights for an Np-point central derivative.
Assumes equally-spaced function points.
If weights are in the vector w, then derivative is w[0] * f(x-h0*dx) + ... + w[-1] * f(x+h0*dx)

Parameters
- Np [int] Number of points for the central derivative.
- ndiv [int, optional] Number of divisions. Default is 1.

Returns

Notes
Can be inaccurate for a large number of points.

References
[1]

Examples
We can calculate a derivative value of a function.

```python
>>> from scipy.misc import central_diff_weights
>>> def f(x):
...     return 2 * x**2 + 3
>>> x = 3.0 # derivative point
>>> h = 0.1 # differential step
>>> Np = 3 # point number for central derivative
>>> weights = central_diff_weights(Np) # weights for first derivative
>>> vals = [f(x + (i - Np/2) * h) for i in range(Np)]
>>> sum(w * v for (w, v) in zip(weights, vals))/h
11.799999999999978
```

This value is close to the analytical solution: f'(x) = 4x, so f'(3) = 12

6.16.3 scipy.misc.derivative

scipy.misc.derivative(func, x0, dx=1.0, n=1, args=(), order=3)
Find the nth derivative of a function at a point.
Given a function, use a central difference formula with spacing dx to compute the nth derivative at x0.

Parameters
- func [function] Input function.
- x0 [float] The point at which the nth derivative is found.
- dx [float, optional] Spacing.
n        [int, optional] Order of the derivative. Default is 1.
args    [tuple, optional] Arguments
order   [int, optional] Number of points to use, must be odd.

Notes

Decreasing the step size too small can result in round-off error.

Examples

```python
>>> from scipy.misc import derivative
>>> def f(x):
...     return x**3 + x**2
>>> derivative(f, 1.0, dx=1e-6)
4.9999999999217337
```

6.16.4 scipy.misc.face

scipy.misc.face(gray=False)

Get a 1024 x 768, color image of a racoon face.

raccoon-procyon-lotor.jpg at http://www.public-domain-image.com

Parameters

gray       [bool, optional] If True return 8-bit grey-scale image, otherwise return a color image

Returns

face       [ndarray] image of a racoon face

Examples

```python
>>> import scipy.misc
>>> face = scipy.misc.face()
>>> face.shape
(768, 1024, 3)
>>> face.max()
255
>>> face.dtype
dtype('uint8')

>>> import matplotlib.pyplot as plt
>>> plt.gray()
>>> plt.imshow(face)
>>> plt.show()
```
6.16.5 scipy.misc.electrocardiogram

scipy.misc.electrocardiogram()

Load an electrocardiogram as an example for a 1-D signal.

The returned signal is a 5 minute long electrocardiogram (ECG), a medical recording of the heart’s electrical activity, sampled at 360 Hz.

Returns

ecg [ndarray] The electrocardiogram in millivolt (mV) sampled at 360 Hz.

Notes

The provided signal is an excerpt (19:35 to 24:35) from the record 208 (lead MLII) provided by the MIT-BIH Arrhythmia Database [1] on PhysioNet [2]. The excerpt includes noise induced artifacts, typical heartbeats as well as pathological changes.

New in version 1.1.0.

References

[1], [2]

Examples

```python
>>> from scipy.misc import electrocardiogram
>>> ecg = electrocardiogram()
>>> ecg
array([-0.245, -0.215, -0.185, ..., -0.405, -0.395, -0.385])
>>> ecg.shape, ecg.mean(), ecg.std()
((108000,), -0.16510875, 0.5992473991177294)
```
As stated the signal features several areas with a different morphology. E.g., the first few seconds show the electrical activity of a heart in normal sinus rhythm as seen below.

```python
>>> import matplotlib.pyplot as plt
>>> fs = 360
>>> time = np.arange(ecg.size) / fs
>>> plt.plot(time, ecg)
>>> plt.xlabel("time in s")
>>> plt.ylabel("ECG in mV")
>>> plt.xlim(9, 10.2)
>>> plt.ylim(-1, 1.5)
>>> plt.show()
```

After second 16, however, the first premature ventricular contractions, also called extrasystoles, appear. These have a different morphology compared to typical heartbeats. The difference can easily be observed in the following plot.

```python
>>> plt.plot(time, ecg)
>>> plt.xlabel("time in s")
>>> plt.ylabel("ECG in mV")
>>> plt.xlim(46.5, 50)
>>> plt.ylim(-2, 1.5)
>>> plt.show()
```

At several points large artifacts disturb the recording, e.g.:

```python
>>> plt.plot(time, ecg)
>>> plt.xlabel("time in s")
>>> plt.ylabel("ECG in mV")
>>> plt.xlim(207, 215)
>>> plt.ylim(-2, 3.5)
>>> plt.show()
```

Finally, examining the power spectrum reveals that most of the biosignal is made up of lower frequencies. At 60 Hz the noise induced by the mains electricity can be clearly observed.
6.17 Multidimensional image processing (scipy.ndimage)

This package contains various functions for multidimensional image processing.

6.17.1 Filters

```python
def convolve(input, weights[, output, mode,...])
    Multidimensional convolution.
def convolve1d(input, weights[, axis, output,...])
    Calculate a 1-D convolution along the given axis.
def correlate(input, weights[, output, mode,...])
    Multidimensional correlation.
def correlate1d(input, weights[, axis, output,...])
    Calculate a 1-D correlation along the given axis.
def gaussian_filter(input, sigma[, order,...])
    Multidimensional Gaussian filter.
def gaussian_filter1d(input, sigma[, axis,...])
    1-D Gaussian filter.
def gaussian_gradient_magnitude(input, sigma[, ...])
    Multidimensional gradient magnitude using Gaussian derivatives.
def gaussian_laplace(input, sigma[, output,...])
    Multidimensional Laplace filter using Gaussian second derivatives.
def generic_filter(input, function[, size,...])
    Calculate a multidimensional filter using the given function.
def generic_filter1d(input, function, filter_size)
    Calculate a 1-D filter along the given axis.
def generic_gradient_magnitude(input, derivative)
    Gradient magnitude using a provided gradient function.
```

scipy.ndimage.convolve

`scipy.ndimage.convolve` (input, weights, output=None, mode='reflect', cval=0.0, origin=0)

Multidimensional convolution.

The array is convolved with the given kernel.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input</td>
<td>array_like</td>
</tr>
<tr>

</tr>
</tbody>
</table>

- **input**: The input array.
- **weights**: Array of weights, same number of dimensions as input.
- **output**: The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode**: The `mode` parameter determines how the input array is extended beyond its boundaries. Default is 'reflect'. Behavior for each valid value is as follows:
  - ‘reflect’ (d c b a | a b c d | d c b a)
    - The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - ‘constant’ (k k k k | a b c d | k k k k)
    - The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
  - ‘nearest’ (a a a a | a b c d | d d d d)
    - The input is extended by replicating the last pixel.
  - ‘mirror’ (d c b a | a b c d | c b a)
    - The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - ‘wrap’ (a b c d | a b c d | a b c d)
    - The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

- ‘grid-mirror’
  - This is a synonym for ‘reflect’.
- ‘grid-constant’
  - This is a synonym for ‘constant’.
- ‘grid-wrap’
  - This is a synonym for ‘wrap’.
- **cval**: Value to fill past edges of input if `mode` is 'constant'. Default is 0.0
origin [int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

Returns

result [ndarray] The result of convolution of input with weights.

See also:
correlate

Correlate an image with a kernel.

Notes

Each value in result is \( C_i = \sum_j I_{i+k-j} W_j \), where \( W \) is the weights kernel, \( j \) is the N-D spatial index over \( W \), \( I \) is the input and \( k \) is the coordinate of the center of \( W \), specified by origin in the input parameters.

Examples

Perhaps the simplest case to understand is mode='constant', cval=0.0, because in this case borders (i.e., where the weights kernel, centered on any one value, extends beyond an edge of input) are treated as zeros.

```python
>>> a = np.array([[1, 2, 0, 0],
    ... [5, 3, 0, 4],
    ... [0, 0, 0, 7],
    ... [9, 3, 0, 0]])
>>> k = np.array([[1, 1, 1],
    ... [1, 1, 0],
    ... [1, 0, 0]])
>>> from scipy import ndimage
>>> ndimage.convolve(a, k, mode='constant', cval=0.0)
array([[11, 10, 7, 4],
    [10, 3, 11, 11],
    [15, 12, 14, 7],
    [12, 3, 7, 0]])
```

Setting cval=1.0 is equivalent to padding the outer edge of input with 1.0's (and then extracting only the original region of the result).

```python
>>> ndimage.convolve(a, k, mode='constant', cval=1.0)
array([[13, 11, 8, 7],
    [11, 3, 11, 14],
    [16, 12, 14, 10],
    [15, 6, 10, 5]])
```

With mode='reflect' (the default), outer values are reflected at the edge of input to fill in missing values.

```python
>>> b = np.array([[2, 0, 0],
    ... [1, 0, 0],
    ... [0, 0, 0]])
>>> k = np.array([[0,1,0],
    ... [0,1,0],
    ... [0,1,0]])
>>> ndimage.convolve(b, k, mode='reflect')
(continues on next page)
This includes diagonally at the corners.

```python
>>> k = np.array([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
>>> ndimage.convolve(b, k)
array([[4, 2, 0],
       [3, 2, 0],
       [1, 1, 0]])
```

With `mode='nearest'`, the single nearest value in to an edge in `input` is repeated as many times as needed to match the overlapping `weights`.

```python
>>> c = np.array([[2, 0, 1],
                 ... [1, 0, 0],
                 ... [0, 0, 0]])
>>> k = np.array([[0, 1, 0],
                 ... [0, 1, 0],
                 ... [0, 1, 0],
                 ... [0, 1, 0]])
>>> ndimage.convolve(c, k, mode='nearest')
array([[7, 0, 3],
       [5, 0, 2],
       [3, 0, 1]])
```

**scipy.ndimage.convolve1d**

`scipy.ndimage.convolve1d(input, weights, axis=-1, output=None, mode='reflect', cval=0.0, origin=0)`

Calculate a 1-D convolution along the given axis.

The lines of the array along the given axis are convolved with the given weights.

**Parameters**

- `input` ([array_like]) The input array.
- `weights` ([ndarray]) 1-D sequence of numbers.
- `axis` ([int, optional]) The axis of `input` along which to calculate. Default is -1.
- `output` ([array or dtype, optional]) The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- `mode` ([{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional]) The `mode` parameter determines how the input array is extended beyond its boundaries. Default is 'reflect'. Behavior for each valid value is as follows:
  - **reflect** (`d c b a \ a b c d \ d c b a`)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - **constant** (`k k k k \ a b c d \ k k k k`)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
  - **nearest** (`a a a a \ a b c d \ d d d d`)
    The input is extended by replicating the last pixel.
`mirror` \((d \ c \ b \ \mid a \ b \ c \ d \ \mid c \ b \ a)\)

The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

`wrap` \((a \ b \ c \ d \ \mid a \ b \ c \ d \ \mid a \ b \ c \ d)\)

The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

`grid-mirror`

This is a synonym for ‘reflect’.

`grid-constant`

This is a synonym for ‘constant’.

`grid-wrap`

This is a synonym for ‘wrap’.

cval

[scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0.

origin

[int, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right.

Returns

`convolve1d`

[ndarray] Convolved array with same shape as input

Examples

```python
>>> from scipy.ndimage import convolve1d
>>> convolve1d([2, 8, 0, 4, 1, 9, 9, 0], weights=[1, 3])
array([14, 24, 4, 13, 12, 36, 27, 0])
```

`scipy.ndimage.correlate`

`scipy.ndimage.correlate` \((input, weights, output=None, mode='reflect', cval=0.0, origin=0)\)

Multidimensional correlation.

The array is correlated with the given kernel.

Parameters

- input
  - [array_like] The input array.
- weights
  - [ndarray] array of weights, same number of dimensions as input
- output
  - [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- mode
  - [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The `mode` parameter determines how the input array is extended beyond its boundaries. Default is ‘reflect’. Behavior for each valid value is as follows:
    - `reflect` \((d \ c \ b \ a \ \mid a \ b \ c \ d \ \mid d \ c \ b \ a)\)
      - The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
    - `constant` \((k \ k \ k \ k \ \mid a \ b \ c \ d \ \mid k \ k \ k \ k)\)
      - The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
    - `nearest` \((a \ a \ a \ a \ \mid a \ b \ c \ d \ \mid d \ d \ d \ d)\)
      - The input is extended by replicating the last pixel.
The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

‘wrap’ (a b c d | a b c d | a b c d)

The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

‘grid-mirror’

This is a synonym for ‘reflect’.

‘grid-constant’

This is a synonym for ‘constant’.

‘grid-wrap’

This is a synonym for ‘wrap’.

cval [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

origin [int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

Returns

result [ndarray] The result of correlation of input with weights.

See also:

convolve

Convolve an image with a kernel.

Examples

Correlation is the process of moving a filter mask often referred to as kernel over the image and computing the sum of products at each location.

```python
>>> from scipy.ndimage import correlate
>>> input_img = np.arange(25).reshape(5,5)
>>> print(input_img)
[[ 0  1  2  3  4]
 [ 5  6  7  8  9]
 [10 11 12 13 14]
 [15 16 17 18 19]
 [20 21 22 23 24]]
```

Define a kernel (weights) for correlation. In this example, it is for sum of center and up, down, left and right next elements.

```python
>>> weights = [[0, 1, 0],
... [1, 1, 1],
... [0, 1, 0]]
```

We can calculate a correlation result: For example, element [2,2] is 7 + 11 + 12 + 13 + 17 = 60.

```python
>>> correlate(input_img, weights)
array([[ 6, 10, 15, 20, 24],
 [26, 30, 35, 40, 44],
[46, 50, 55, 60, 64],
[66, 70, 75, 80, 84],
[86, 90, 95, 100, 104]])
```
Calculate a 1-D correlation along the given axis.

The lines of the array along the given axis are correlated with the given weights.

Parameters

- **input**: [array_like] The input array.
- **weights**: [array] 1-D sequence of numbers.
- **axis**: [int, optional] The axis of input along which to calculate. Default is -1.
- **output**: [array or dtypes, optional] The array in which to place the output, or the dtypes of the returned array. By default an array of the same dtype as input will be created.
- **mode**: [{’reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘reflect’. Behavior for each valid value is as follows:
  - **reflect** (d c b a | a b c d | d c b a)
    - The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - **constant** (k k k k | a b c d | k k k k)
    - The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - **nearest** (a a a a | a b c d | d d d d)
    - The input is extended by replicating the last pixel.
  - **mirror** (d c b | a b c d | c b a)
    - The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - **wrap** (a b c d | a b c d | a b c d)
    - The input is extended by wrapping around to the opposite edge.
- **cval**: [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.
- **origin**: [int, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right.
Examples

```python
>>> from scipy.ndimage import correlate1d
>>> correlate1d([2, 8, 0, 4, 1, 9, 9, 0], weights=[1, 3])
array([ 8, 26,  8, 12,  7, 28, 36,  9])
```

**scipy.ndimage.gaussian_filter**

`scipy.ndimage.gaussian_filter(input, sigma, order=0, output=None, mode='reflect', cval=0.0, truncate=4.0)`

Multidimensional Gaussian filter.

**Parameters**

- `input` [array_like] The input array.
- `sigma` [scalar or sequence of scalars] Standard deviation for Gaussian kernel. The standard deviations of the Gaussian filter are given for each axis as a sequence, or as a single number, in which case it is equal for all axes.
- `order` [int or sequence of ints, optional] The order of the filter along each axis is given as a sequence of integers, or as a single number. An order of 0 corresponds to convolution with a Gaussian kernel. A positive order corresponds to convolution with that derivative of a Gaussian.
- `output` [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- `mode` [str or sequence, optional] The `mode` parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:
  - `reflect' (d c b a | a b c d | d c b a)`
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - `constant' (k k k k | a b c d | k k k k)`
    The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
  - `nearest' (a a a a | a b c d | d d d d)`
    The input is extended by replicating the last pixel.
  - `mirror' (d c b | a b c d | c b a)`
    The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - `wrap' (a b c d | a b c d | a b c d)`
    The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:
- `grid-constant'` This is a synonym for 'constant'.
- `grid-mirror'` This is a synonym for 'reflect'.
- `grid-wrap'` This is a synonym for 'wrap'.

- `cval` [scalar, optional] Value to fill past edges of input if `mode` is 'constant'. Default is 0.0.
- `truncate` [float] Truncate the filter at this many standard deviations. Default is 4.0.

**Returns**

- `gaussian_filter` [ndarray] Returned array of same shape as `input`. 
Notes

The multidimensional filter is implemented as a sequence of 1-D convolution filters. The intermediate arrays are stored in the same data type as the output. Therefore, for output types with a limited precision, the results may be imprecise because intermediate results may be stored with insufficient precision.

Examples

```python
>>> from scipy.ndimage import gaussian_filter
>>> a = np.arange(50, step=2).reshape((5,5))
>>> a
array([[ 0,  2,  4,  6,  8],
       [10, 12, 14, 16, 18],
       [20, 22, 24, 26, 28],
       [30, 32, 34, 36, 38],
       [40, 42, 44, 46, 48]])
>>> gaussian_filter(a, sigma=1)
array([[ 4,  6,  8,  9, 11],
       [10, 12, 14, 15, 17],
       [20, 22, 24, 25, 27],
       [29, 31, 33, 34, 36],
       [35, 37, 39, 40, 42]])
```

```python
>>> from scipy import misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = gaussian_filter(ascent, sigma=5)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```

**scipy.ndimage.gaussian_filter1d**

`scipy.ndimage.gaussian_filter1d(input, sigma, axis=-1, order=0, output=None, mode='reflect', cval=0.0, truncate=4.0)`

1-D Gaussian filter.

**Parameters**

- **input** [array_like] The input array.
- **sigma** [scalar] Standard deviation for Gaussian kernel.
- **axis** [int, optional] The axis of `input` along which to calculate. Default is -1.
- **order** [int, optional] An order of 0 corresponds to convolution with a Gaussian kernel. A positive order corresponds to convolution with that derivative of a Gaussian.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘reflect’. Behavior for each valid value is as follows:
'reflect' (d c b a | a b c d | d c b a)
   The input is extended by reflecting about the edge of the last pixel. This mode
   is also sometimes referred to as half-sample symmetric.

'constant' (k k k k | a b c d | k k k k)
   The input is extended by filling all values beyond the edge with the same constant
   value, defined by the cval parameter.

'nearest' (a a a a | a b c d | d d d d)
   The input is extended by replicating the last pixel.

'mirror' (d c b | a b c d | c b a)
   The input is extended by reflecting about the center of the last pixel. This mode
   is also sometimes referred to as whole-sample symmetric.

'wrap' (a b c d | a b c d | a b c d)
   The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

'grid-mirror'
   This is a synonym for 'reflect'.

'grid-constant'
   This is a synonym for 'constant'.

'grid-wrap'
   This is a synonym for 'wrap'.

cval [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
trunc [float, optional] Truncate the filter at this many standard deviations. Default is 4.0.

Returns

gaussian_filter1d
   [ndarray]
**Examples**

```python
>>> from scipy.ndimage import gaussian_filter1d
>>> gaussian_filter1d([1.0, 2.0, 3.0, 4.0, 5.0], 1)
array([ 1.42704095, 2.06782203, 3., 3.93217797, 4.57295905])
>>> gaussian_filter1d([1.0, 2.0, 3.0, 4.0, 5.0], 4)
array([ 2.91948343, 2.95023502, 3., 3.04976498, 3.08051657])
>>> import matplotlib.pyplot as plt
>>> np.random.seed(280490)
>>> x = np.random.randn(101).cumsum()
>>> y3 = gaussian_filter1d(x, 3)
>>> y6 = gaussian_filter1d(x, 6)
>>> plt.plot(x, 'k', label='original data')
>>> plt.plot(y3, '--', label='filtered, sigma=3')
>>> plt.plot(y6, ':', label='filtered, sigma=6')
>>> plt.legend()
>>> plt.grid()
>>> plt.show()
```

**scipy.ndimage.gaussian_gradient_magnitude**

`scipy.ndimage.gaussian_gradient_magnitude(input, sigma, output=None, mode='reflect', cval=0.0, **kwargs)`

Multidimensional gradient magnitude using Gaussian derivatives.

**Parameters**

- **input** [array_like] The input array.
- **sigma** [scalar or sequence of scalars] The standard deviations of the Gaussian filter are given for each axis as a sequence, or as a single number, in which case it is equal for all axes.
- **output** [array or dtypes, optional] The array in which to place the output, or the dtypes of the returned array. By default an array of the same dtype as input will be created.
- **mode** [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the
number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:

- **‘reflect’** *(d c b a | a b c d | d c b a)*
  
The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

- **‘constant’** *(k k k k | a b c d | k k k k)*
  
The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.

- **‘nearest’** *(a a a a | a b c d | d d d d)*
  
The input is extended by replicating the last pixel.

- **‘mirror’** *(d c b | a b c d | c b a)*
  
The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

- **‘wrap’** *(a b c d | a b c d | a b c d)*
  
The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

- **‘grid-constant’**
  
  This is a synonym for ‘constant’.

- **‘grid-mirror’**
  
  This is a synonym for ‘reflect’.

- **‘grid-wrap’**
  
  This is a synonym for ‘wrap’.

**cval** [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

Extra keyword arguments will be passed to `gaussian_filter()`.

**Returns**

- **`gaussian_gradient_magnitude`**
  
  [ndarray] Filtered array. Has the same shape as `input`.

**Examples**

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.gaussian_gradient_magnitude(ascent, sigma=5)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```
scipy.ndimage.gaussian_laplace

scipy.ndimage.gaussian_laplace (input, sigma, output=None, mode='reflect', cval=0.0, **kwargs)

Multidimensional Laplace filter using Gaussian second derivatives.

Parameters

input [array_like] The input array.
sigma [scalar or sequence of scalars] The standard deviations of the Gaussian filter are given for each axis as a sequence, or as a single number, in which case it is equal for all axes.
output [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
mode [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:
‘reflect’ (d c b a | a b c d | d c b a)
The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
‘constant’ (k k k k | a b c d | k k k k)
The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
‘nearest’ (a a a a | a b c d | d d d d)
The input is extended by replicating the last pixel.
‘mirror’ (d c b | a b c d | c b a)
The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
‘wrap’ (a b c d | a b c d | a b c d)
The input is extended by wrapping around to the opposite edge.
For consistency with the interpolation functions, the following mode names can also be used:
‘grid-constant’
This is a synonym for ‘constant’.
‘grid-mirror’
This is a synonym for ‘reflect’.
'grid-wrap'

This is a synonym for 'wrap'.

cval [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.

Extra keyword arguments will be passed to gaussian_filter().

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> ascent = misc.ascent()

>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side

>>> result = ndimage.gaussian_laplace(ascent, sigma=1)
>>> ax1.imshow(result)

>>> result = ndimage.gaussian_laplace(ascent, sigma=3)
>>> ax2.imshow(result)
>>> plt.show()
```
scipy.ndimage.generic_filter

**scipy.ndimage.generic_filter** *(input, function, size=None, footprint=None, output=None, mode='reflect', cval=0.0, origin=0, extra_arguments=(), extra_keywords=None)*

Calculate a multidimensional filter using the given function.

At each element the provided function is called. The input values within the filter footprint at that element are passed to the function as a 1-D array of double values.

**Parameters**

- **input** [array_like] The input array.
- **function** [{callable, scipy.LowLevelCallable}] Function to apply at each element.
- **size** [scalar or tuple, optional] See footprint, below. Ignored if footprint is given.
- **footprint** [array, optional] Either size or footprint must be defined. size gives the shape that is taken from the input array, at every element position, to define the input to the filter function. footprint is a boolean array that specifies (implicitly) a shape, but also which of the elements within this shape will get passed to the filter function. Thus size=(n,m) is equivalent to footprint=np.ones((n,m)). We adjust size to the number of dimensions of the input array, so that, if the input array is shape (10,10,10), and size is 2, then the actual size used is (2,2,2). When footprint is given, size is ignored.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [{‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘reflect’. Behavior for each valid value is as follows:
  - ‘reflect’ *(d c b a | a b c d | d c b a)*
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - ‘constant’ *(k k k k | a b c d | k k k k)*
    The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - ‘nearest’ *(a a a a | a b c d | d d d d)*
    The input is extended by replicating the last pixel.
  - ‘mirror’ *(d c b | a b c d | c b a)*
    The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - ‘wrap’ *(a b c d | a b c d | a b c d)*
    The input is extended by wrapping around to the opposite edge. For consistency with the interpolation functions, the following mode names can also be used:
    - ‘grid-mirror’
      This is a synonym for ‘reflect’.
    - ‘grid-constant’
      This is a synonym for ‘constant’.
    - ‘grid-wrap’
      This is a synonym for ‘wrap’.
- **cval** [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.
- **origin** [int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.
- **extra_arguments** [sequence, optional] Sequence of extra positional arguments to pass to passed function.
**extra_keywords**

[dict, optional] dict of extra keyword arguments to pass to passed function.

**Notes**

This function also accepts low-level callback functions with one of the following signatures and wrapped in `scipy.LowLevelCallable`:

```python
int callback(double *buffer, npy_intp filter_size,
             double *return_value, void *user_data)
int callback(double *buffer, intptr_t filter_size,
             double *return_value, void *user_data)
```

The calling function iterates over the elements of the input and output arrays, calling the callback function at each element. The elements within the footprint of the filter at the current element are passed through the `buffer` parameter, and the number of elements within the footprint through `filter_size`. The calculated value is returned in `return_value`. `user_data` is the data pointer provided to `scipy.LowLevelCallable` as-is.

The callback function must return an integer error status that is zero if something went wrong and one otherwise. If an error occurs, you should normally set the python error status with an informative message before returning, otherwise a default error message is set by the calling function.

In addition, some other low-level function pointer specifications are accepted, but these are for backward compatibility only and should not be used in new code.

**scipy.ndimage.generic_filter1d**

`scipy.ndimage.generic_filter1d (input, function, filter_size, axis=-1, output=None, mode='reflect', cval=0.0, origin=0, extra_arguments=(), extra_keywords=None)`

Calculate a 1-D filter along the given axis.

`generic_filter1d` iterates over the lines of the array, calling the given function at each line. The arguments of the line are the input line, and the output line. The input and output lines are 1-D double arrays. The input line is extended appropriately according to the filter size and origin. The output line must be modified in-place with the result.

**Parameters**

- **input** [array_like] The input array.
- **function** [[callable, scipy.LowLevelCallable]] Function to apply along given axis.
- **filter_size** [scalar] Length of the filter.
- **axis** [int, optional] The axis of `input` along which to calculate. Default is -1.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The `mode` parameter determines how the input array is extended beyond its boundaries. Default is ‘reflect’. Behavior for each valid value is as follows:
  - **‘reflect’** (`d c b a | a b c d | d c b a`) The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - **‘constant’** (`k k k k | a b c d | k k k k`) The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
`nearest` (a a a a | a b c d | d d d d)  
The input is extended by replicating the last pixel.

`mirror` (d c b | a b c d | c b a)  
The input is extended by reflecting about the center of the last pixel. This mode  
is also sometimes referred to as whole-sample symmetric.

`wrap` (a b c d | a b c d | a b c d)  
The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

`grid-mirror`  
This is a synonym for ‘reflect’.

`grid-constant`  
This is a synonym for ‘constant’.

`grid-wrap`  
This is a synonym for ‘wrap’.

cval [scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0.

origin [int, optional] Controls the placement of the filter on the input array’s pixels. A value of 0  
(the default) centers the filter over the pixel, with positive values shifting the filter to the left,  
and negative ones to the right.

extra_arguments [sequence, optional] Sequence of extra positional arguments to pass to passed function.

extra_keywords [dict, optional] dict of extra keyword arguments to pass to passed function.

Notes

This function also accepts low-level callback functions with one of the following signatures and wrapped in `scipy.LowLevelCallable`:

```c
int function(double *input_line, npy_intp input_length,  
               double *output_line, npy_intp output_length,  
               void *user_data)
```

The calling function iterates over the lines of the input and output arrays, calling the callback function at each line. The current line is extended according to the border conditions set by the calling function, and the result is copied into the array that is passed through `input_line`. The length of the input line (after extension) is passed through `input_length`. The callback function should apply the filter and store the result in the array passed through `output_line`. The length of the output line is passed through `output_length`. `user_data` is the data pointer provided to `scipy.LowLevelCallable` as-is.

The callback function must return an integer error status that is zero if something went wrong and one otherwise. If an error occurs, you should normally set the python error status with an informative message before returning, otherwise a default error message is set by the calling function.

In addition, some other low-level function pointer specifications are accepted, but these are for backward compatibility only and should not be used in new code.
scipy.ndimage.generic_gradient_magnitude

Gradient magnitude using a provided gradient function.

Parameters

- **input** [array_like] The input array.
- **derivative** [callable] Callable with the following signature:

  ```python
derivative(input, axis, output, mode, cval,
  *extra_arguments, **extra_keywords)
  ```

  See *extra_arguments*, *extra_keywords* below. *derivative* can assume that *input* and *output* are ndarrays. Note that the output from *derivative* is modified inplace; be careful to copy important inputs before returning them.

- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

- **mode** [str or sequence, optional] The *mode* parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:
  - **reflect** ([d c b a | a b c d | d c b a])
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - **constant** ([k k k k | a b c d | k k k k])
    The input is extended by filling all values beyond the edge with the same constant value, defined by the *cval* parameter.
  - **nearest** ([a a a a | a b c d | d d d d])
    The input is extended by replicating the last pixel.
  - **mirror** ([d c b | a b c d | c b a])
    The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - **wrap** ([a b c d | a b c d | a b c d])
    The input is extended by wrapping around to the opposite edge.

  For consistency with the interpolation functions, the following mode names can also be used:
  - **grid-constant**
    This is a synonym for 'constant'.
  - **grid-mirror**
    This is a synonym for 'reflect'.
  - **grid-wrap**
    This is a synonym for 'wrap'.

- **cval** [scalar, optional] Value to fill past edges of input if *mode* is 'constant'. Default is 0.0.
- **extra_keywords** [dict, optional] dict of extra keyword arguments to pass to passed function.
- **extra_arguments** [sequence, optional] Sequence of extra positional arguments to pass to passed function.
scipy.ndimage.generic_laplace

scipy.ndimage.generic_laplace(input, derivative2, output=None, mode='reflect', cval=0.0, extra_arguments=(), extra_keywords=None)

N-D Laplace filter using a provided second derivative function.

Parameters

input [array_like] The input array.

derivative2 [callable] Callable with the following signature:

    derivative2(input, axis, output, mode, cval, *extra_arguments, **extra_keywords)

See extra_arguments, extra_keywords below.

output [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

mode [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behaviour is as follows:

    'reflect' (d c b a | a b c d | d c b a)
        The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

    'constant' (k k k k | a b c d | k k k k)
        The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.

    'nearest' (a a a a | a b c d | d d d d)
        The input is extended by replicating the last pixel.

    'mirror' (d c b | a b c d | c b a)
        The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

    'wrap' (a b c d | a b c d | a b c d)
        The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

    'grid-constant'
        This is a synonym for 'constant'.

    'grid-mirror'
        This is a synonym for 'reflect'.

    'grid-wrap'
        This is a synonym for 'wrap'.

cval [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.

extra_keywords [dict, optional] Dict of extra keyword arguments to pass to passed function.

extra_arguments [sequence, optional] Sequence of extra positional arguments to pass to passed function.
scipy.ndimage.laplace

scipy.ndimage.laplace(input, output=None, mode='reflect', cval=0.0)

N-D Laplace filter based on approximate second derivatives.

Parameters

input [array_like] The input array.
output [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
mode [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:
- ‘reflect’ (d c b a | a b c d | d c b a)
  The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
- ‘constant’ (k k k k | a b c d | k k k k)
  The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
- ‘nearest’ (a a a a | a b c d | d d d d)
  The input is extended by replicating the last pixel.
- ‘mirror’ (d c b | a b c d | c b a)
  The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
- ‘wrap’ (a b c d | a b c d | a b c d)
  The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:
- ‘grid-constant’
  This is a synonym for ‘constant’.
- ‘grid-mirror’
  This is a synonym for ‘reflect’.
- ‘grid-wrap’
  This is a synonym for ‘wrap’.

cval [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.laplace(ascent)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```
scipy.ndimage.maximum_filter

scipy.ndimage.maximum_filter(input, size=None, footprint=None, output=None, mode='reflect', cval=0.0, origin=0)

Calculate a multidimensional maximum filter.

Parameters

- **input** [array_like] The input array.
- **size** [scalar or tuple, optional] See footprint, below. Ignored if footprint is given.
- **footprint** [array, optional] Either size or footprint must be defined. size gives the shape that is taken from the input array, at every element position, to define the input to the filter function. footprint is a boolean array that specifies (implicitly) a shape, but also which of the elements within this shape will get passed to the filter function. Thus size=(n,m) is equivalent to footprint=np.ones((n,m)). We adjust size to the number of dimensions of the input array, so that, if the input array is shape (10,10,10), and size is 2, then the actual size used is (2,2,2). When footprint is given, size is ignored.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:
  - 'reflect' (d c b a | a b c d | d c b a)
    - The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - 'constant' (k k k k | a b c d | k k k k)
    - The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - 'nearest' (a a a a | a b c d | d d d d)
    - The input is extended by replicating the last pixel.
  - 'mirror' (d c b | a b c d | c b a)
    - The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - 'wrap' (a b c d | a b c d | a b c d)
The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

- **'grid-constant'**
  This is a synonym for ‘constant’.
- **'grid-mirror'**
  This is a synonym for ‘reflect’.
- **'grid-wrap'**
  This is a synonym for ‘wrap’.

**cval**
[scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

**origin**
[int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

**Returns**

- **maximum_filter**
  [ndarray] Filtered array. Has the same shape as input.

**Notes**

A sequence of modes (one per axis) is only supported when the footprint is separable. Otherwise, a single mode string must be provided.

**Examples**

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.maximum_filter(ascent, size=20)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```

**scipy.ndimage.maximum_filter1d**

*scipy.ndimage.maximum_filter1d*(*input*, *size*, *axis=-1*, *output=None*, *mode='reflect'*, *cval=0.0*, *origin=0*)

Calculate a 1-D maximum filter along the given axis.

The lines of the array along the given axis are filtered with a maximum filter of given size.

**Parameters**

- **input**
  [array_like] The input array.
- **size**
  [int] Length along which to calculate the 1-D maximum.
- **axis**
  [int, optional] The axis of input along which to calculate. Default is -1.
- **output**
  [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
mode  

[[‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘reflect’. Behavior for each valid value is as follows:

‘reflect’ (d c b a | a b c d | d c b a)

The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

‘constant’ (k k k k | a b c d | k k k k)

The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.

‘nearest’ (a a a a | a b c d | d d d d)

The input is extended by replicating the last pixel.

‘mirror’ (d c b | a b c d | c b a)

The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

‘wrap’ (a b c d | a b c d | a b c d)

The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

‘grid-mirror’

This is a synonym for ‘reflect’.

‘grid-constant’

This is a synonym for ‘constant’.

‘grid-wrap’

This is a synonym for ‘wrap’.

cval  [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

origin  [int, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right.

**Returns**

maximum1d  [ndarray, None] Maximum-filtered array with same shape as input. None if output is not None
Notes

This function implements the MAXLIST algorithm [1], as described by Richard Harter [2], and has a guaranteed O(n) performance, n being the input length, regardless of filter size.

References

[1], [2]

Examples

```python
>>> from scipy.ndimage import maximum_filter1d
>>> maximum_filter1d([2, 8, 0, 4, 1, 9, 9, 0], size=3)
array([8, 8, 8, 4, 9, 9, 9, 9])
```

scipy.ndimage.median_filter

scipy.ndimage.median_filter(input, size=None, footprint=None, output=None, mode='reflect', cval=0.0, origin=0)

Calculate a multidimensional median filter.

Parameters

- **input** [array_like] The input array.
- **size** [scalar or tuple, optional] See footprint, below. Ignored if footprint is given.
- **footprint** [array, optional] Either size or footprint must be defined. size gives the shape that is taken from the input array, at every element position, to define the input to the filter function. footprint is a boolean array that specifies (implicitly) a shape, but also which of the elements within this shape will get passed to the filter function. Thus size=(n,m) is equivalent to footprint=np.ones((n,m)). We adjust size to the number of dimensions of the input array, so that, if the input array is shape (10,10,10), and size is 2, then the actual size used is (2,2,2). When footprint is given, size is ignored.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is 'reflect'. Behavior for each valid value is as follows:
  - **reflect** (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - **constant** (k k k k | a b c d | k k k k)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - **nearest** (a a a a | a b c d | d d d d)
    The input is extended by replicating the last pixel.
  - **mirror** (d c b | a b c d | c b a)
    The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - **wrap** (a b c d | a b c d | a b c d)
    The input is extended by wrapping around to the opposite edge. For consistency with the interpolation functions, the following mode names can also be used:
'grid-mirror'
   This is a synonym for 'reflect'.
'grid-constant'
   This is a synonym for 'constant'.
'grid-wrap'
   This is a synonym for 'wrap'.

cval
   [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
origin
   [int or sequence, optional] Controls the placement of the filter on the input array's pixels. A
   value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter
   to the left, and negative ones to the right. By passing a sequence of origins with length equal
   to the number of dimensions of the input array, different shifts can be specified along each
   axis.

Returns

median_filter
   [ndarray] Filtered array. Has the same shape as input.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()   # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)   # left side
>>> ax2 = fig.add_subplot(122)   # right side
>>> ascent = misc.ascent()
>>> result = ndimage.median_filter(ascent, size=20)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```
scipy.ndimage.minimum_filter

scipy.ndimage.minimum_filter(input, size=None, footprint=None, output=None, mode='reflect', cval=0.0, origin=0)

Calculate a multidimensional minimum filter.

Parameters

- **input** [array_like] The input array.
- **size** [scalar or tuple, optional] See footprint, below. Ignored if footprint is given.
- **footprint** [array, optional] Either size or footprint must be defined. size gives the shape that is taken from the input array, at every element position, to define the input to the filter function. footprint is a boolean array that specifies (implicitly) a shape, but also which of the elements within this shape will get passed to the filter function. Thus size=(n,m) is equivalent to footprint=np.ones((n,m)). We adjust size to the number of dimensions of the input array, so that, if the input array is shape (10,10,10), and size is 2, then the actual size used is (2,2,2). When footprint is given, size is ignored.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:
  - 'reflect' (d c b a | a b c d | b c d a)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - 'constant' (k k k k | a b c d | k k k k)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - 'nearest' (a a a a | a b c d | d d d d)
    The input is extended by replicating the last pixel.
  - 'mirror' (d c b | a b c d | c b a)
    The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - 'wrap' (a b c d | a b c d | a b c d)
    The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:
  - 'grid-constant'
    This is a synonym for 'constant'.
  - 'grid-mirror'
    This is a synonym for 'reflect'.
  - 'grid-wrap'
    This is a synonym for 'wrap'.
- **cval** [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
- **origin** [int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the right, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

Returns

- **minimum_filter** [ndarray] Filtered array. Has the same shape as input.
Notes

A sequence of modes (one per axis) is only supported when the footprint is separable. Otherwise, a single mode string must be provided.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.minimum_filter(ascent, size=20)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```

`scipy.ndimage.minimum_filter1d`

`scipy.ndimage.minimum_filter1d(input, size=-1, output=None, mode='reflect', cval=0.0, origin=0)`

Calculate a 1-D minimum filter along the given axis.

The lines of the array along the given axis are filtered with a minimum filter of given size.

Parameters

- **input**: [array_like] The input array.
- **size**: [int] length along which to calculate 1D minimum
- **axis**: [int, optional] The axis of input along which to calculate. Default is -1.
- **output**: [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
**mode**  
\[\{'reflect', 'constant', 'nearest', 'mirror', 'wrap', \}\]  
The **mode** parameter determines how the input array is extended beyond its boundaries. Default is 'reflect'. Behavior for each valid value is as follows:

- **'reflect'**  
  \[d c b a | a b c d | d c b a\]  
The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

- **'constant'**  
  \[k k k k | a b c d | k k k k\]  
The input is extended by filling all values beyond the edge with the same constant value, defined by the **cval** parameter.

- **'nearest'**  
  \[a a a a | a b c d | d d d d\]  
The input is extended by replicating the last pixel.

- **'mirror'**  
  \[d c b | a b c d | c b a\]  
The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

- **'wrap'**  
  \[a b c d | a b c d | a b c d\]  
The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

- **'grid-mirror'**  
  This is a synonym for 'reflect'.

- **'grid-constant'**  
  This is a synonym for 'constant'.

- **'grid-wrap'**  
  This is a synonym for 'wrap'.

**cval**  
[scalar, optional] Value to fill past edges of input if **mode** is 'constant'. Default is 0.0.

**origin**  
[int, optional] Controls the placement of the filter on the input array's pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right.

**Notes**

This function implements the MINLIST algorithm [1], as described by Richard Harter [2], and has a guaranteed O(n) performance, n being the input length, regardless of filter size.

**References**

[1], [2]

**Examples**

```python
>>> from scipy.ndimage import minimum_filter1d
>>> minimum_filter1d([2, 8, 0, 4, 1, 9, 9, 0], size=3)
array([2, 0, 0, 0, 1, 1, 0, 0])
```
scipy.ndimage.percentile_filter

Calculate a multidimensional percentile filter.

**Parameters**

- **input** [array_like] The input array.
- **percentile** [scalar] The percentile parameter may be less than zero, i.e., percentile = -20 equals percentile = 80.
- **size** [scalar or tuple, optional] Either size or footprint must be defined. size gives the shape that is taken from the input array, at every element position, to define the input to the filter function. footprint is a boolean array that specifies (implicitly) a shape, but also which of the elements within this shape will get passed to the filter function. Thus size=(2,2) is equivalent to footprint=np.ones((2,2)). We adjust size to the number of dimensions of the input array, so that, if the input array is shape (10,10,10), and size is 2, then the actual size used is (2,2,2). When footprint is given, size is ignored.
- **footprint** [array, optional] Either size or footprint must be defined. footprint is a boolean array that specifies (implicitly) a shape, but also which of the elements within this shape will get passed to the filter function. Thus size=(2,2) is equivalent to footprint=np.ones((2,2)). We adjust size to the number of dimensions of the input array, so that, if the input array is shape (10,10,10), and size is 2, then the actual size used is (2,2,2). When footprint is given, size is ignored.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is 'reflect'. Behavior for each valid value is as follows:
  - **reflect** (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - **constant** (k k k k | a b c d | k k k k)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - **nearest** (a a a a | a b c d | d d d d)
    The input is extended by replicating the last pixel.
  - **mirror** (d c b | a b c d | c b a)
    The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - **wrap** (a b c d | a b c d | a b c d)
    The input is extended by wrapping around to the opposite edge. For consistency with the interpolation functions, the following mode names can also be used:
  - **grid-mirror**
    This is a synonym for 'reflect'.
  - **grid-constant**
    This is a synonym for 'constant'.
  - **grid-wrap**
    This is a synonym for 'wrap'.
- **cval** [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
- **origin** [int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

**Returns**

- **percentile_filter** [ndarray] Filtered array. Has the same shape as input.
Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.percentile_filter(ascent, percentile=20, size=20)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```

scipy.ndimage.prewitt

scipy.ndimage.prewitt(input, axis=-1, output=None, mode='reflect', cval=0.0)

Calculate a Prewitt filter.

**Parameters**

- `input` [array_like] The input array.
- `axis` [int, optional] The axis of `input` along which to calculate. Default is -1.
- `output` [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- `mode` [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:
  - ‘reflect’ (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - ‘constant’ (k k k k | a b c d | k k k k)
The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.

- **nearest** \((a\ a\ a\ |\ a\ b\ c\ d\ |\ d\ d\ d\ d\)\)
  The input is extended by replicating the last pixel.

- **mirror** \((d\ c\ b\ |\ a\ b\ c\ d\ |\ c\ b\ a\)\)
  The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

- **wrap** \((a\ b\ c\ d\ |\ a\ b\ c\ d\ |\ a\ b\ c\ d\)\)
  The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

- **grid-constant**
  This is a synonym for ‘constant’.

- **grid-mirror**
  This is a synonym for ‘reflect’.

- **grid-wrap**
  This is a synonym for ‘wrap’.

`cval` [scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0.

### Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.prewitt(ascent)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```
scipy.ndimage.rank_filter

scipy.ndimage.rank_filter(input, rank, size=None, footprint=None, output=None, mode='reflect', cval=0.0, origin=0)

Calculate a multidimensional rank filter.

Parameters

input [array_like] The input array.
rank [int] The rank parameter may be less than zero, i.e., rank = -1 indicates the largest element.
size [scalar or tuple, optional] See footprint, below. Ignored if footprint is given.
footprint [array, optional] Either size or footprint must be defined. size gives the shape that is taken from the input array, at every element position, to define the input to the filter function. footprint is a boolean array that specifies (implicitly) a shape, but also which of the elements within this shape will get passed to the filter function. Thus size=(n,m) is equivalent to footprint=np.ones((n,m)). We adjust size to the number of dimensions of the input array, so that, if the input array is shape (10,10,10), and size is 2, then the actual size used is (2,2,2). When footprint is given, size is ignored.
output [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
mode [['reflect', 'constant', 'nearest', 'mirror', 'wrap'], optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘reflect’. Behavior for each valid value is as follows:
‘reflect’ (d c b a | a b c d | d c b a)
   The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
‘constant’ (k k k k | a b c d | k k k k)
   The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
‘nearest’ (a a a a | a b c d | d d d d)
   The input is extended by replicating the last pixel.
‘mirror’ (d c b | a b c d | c b a)
   The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
‘wrap’ (a b c d | a b c d | a b c d)
   The input is extended by wrapping around to the opposite edge. For consistency with the interpolation functions, the following mode names can also be used:
‘grid-mirror’
   This is a synonym for ‘reflect’.
‘grid-constant’
   This is a synonym for ‘constant’.
‘grid-wrap’
   This is a synonym for ‘wrap’.
cval [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.
origin [int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

Returns

rank_filter [ndarray] Filtered array. Has the same shape as input.
Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.rank_filter(ascent, rank=42, size=20)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```

`scipy.ndimage.sobel`

`scipy.ndimage.sobel(input, axis=-1, output=None, mode='reflect', cval=0.0)`

Calculate a Sobel filter.

**Parameters**

- **input** : [array_like] The input array.
- **axis** : [int, optional] The axis of `input` along which to calculate. Default is -1.
- **output** : [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** : [str or sequence, optional] The `mode` parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:
  - ‘reflect’ (*d c b a* | *a b c d* | *d c b a*)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - ‘constant’ (*k k k k* | *a b c d* | *k k k k*)
The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.

- **nearest** (`a a a a | a b c d | d d d d`)
  - The input is extended by replicating the last pixel.

- **mirror** (`d c b | a b c d | c b a`)
  - The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

- **wrap** (`a b c d | a b c d | a b c d`)
  - The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

- **grid-constant**
  - This is a synonym for ‘constant’.

- **grid-mirror**
  - This is a synonym for ‘reflect’.

- **grid-wrap**
  - This is a synonym for ‘wrap’.

**cval** [scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0.

### Examples

```python
globot
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.sobel(ascent)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```

![Example Image](image-url)
scipy.ndimage.uniform_filter

scipy.ndimage.uniform_filter (input, size=3, output=None, mode='reflect', cval=0.0, origin=0)

Multidimensional uniform filter.

Parameters

- **input** [array_like] The input array.
- **size** [int or sequence of ints, optional] The sizes of the uniform filter are given for each axis as a sequence, or as a single number, in which case the size is equal for all axes.
- **output** [array or dttype, optional] The array in which to place the output, or the dttype of the returned array. By default an array of the same dttype as input will be created.
- **mode** [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:
  - 'reflect' (d c b a | a b c d | d c b a)
    - The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - 'constant' (k k k k | a b c d | k k k k)
    - The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - 'nearest' (a a a a | a b c d | d d d d)
    - The input is extended by replicating the last pixel.
  - 'mirror' (d c b | a b c d | c b a)
    - The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - 'wrap' (a b c d | a b c d | a b c d)
    - The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:
- 'grid-constant'
  - This is a synonym for 'constant'.
- 'grid-mirror'
  - This is a synonym for 'reflect'.
- 'grid-wrap'
  - This is a synonym for 'wrap'.
- **cval** [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
- **origin** [int or sequence, optional] Controls the placement of the filter on the input array's pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

Returns

uniform_filter

[ndarray] Filtered array. Has the same shape as input.
Notes

The multidimensional filter is implemented as a sequence of 1-D uniform filters. The intermediate arrays are stored in the same data type as the output. Therefore, for output types with a limited precision, the results may be imprecise because intermediate results may be stored with insufficient precision.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.uniform_filter(ascent, size=20)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```

```
scipy.ndimage.uniform_filter1d

scipy.ndimage.uniform_filter1d(input, size=-1, output=None, mode='reflect', cval=0.0, origin=0)

Calculate a 1-D uniform filter along the given axis.

The lines of the array along the given axis are filtered with a uniform filter of given size.

Parameters

input [array_like] The input array.
size [int] length of uniform filter
axis [int, optional] The axis of input along which to calculate. Default is -1.
```
output [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

mode [['reflect', 'constant', 'nearest', 'mirror', 'wrap'], optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘reflect’. Behavior for each valid value is as follows:

‘reflect’ (d c b a | a b c d | d c b a)
The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

‘constant’ (k k k k | a b c d | k k k k)
The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.

‘nearest’ (a a a a | a b c d | d d d d)
The input is extended by replicating the last pixel.

‘mirror’ (d c b a | a b c d | c b a)
The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

‘wrap’ (a b c d | a b c d | a b c d)
The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

‘grid-mirror’
This is a synonym for ‘reflect’.

‘grid-constant’
This is a synonym for ‘constant’.

‘grid-wrap’
This is a synonym for ‘wrap’.

cval [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

origin [int, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right.

Examples

```python
>>> from scipy.ndimage import uniform_filter1d
>>> uniform_filter1d([2, 8, 0, 4, 1, 9, 9, 0], size=3)
array([4, 3, 4, 1, 4, 6, 6, 3])
```

6.17.2 Fourier filters

- `fourier_ellipsoid(input, size[, n, axis, output])` Multidimensional ellipsoid Fourier filter.
- `fourier_gaussian(input, sigma[, n, axis, output])` Multidimensional Gaussian fourier filter.
- `fourier_shift(input, shift[, n, axis, output])` Multidimensional Fourier shift filter.
- `fourier_uniform(input, size[, n, axis, output])` Multidimensional uniform fourier filter.
scipy.ndimage.fourier_ellipsoid

The array is multiplied with the fourier transform of a ellipsoid of given sizes.

Parameters

- input [array_like] The input array.
- size [float or sequence] The size of the box used for filtering. If a float, size is the same for all axes. If a sequence, size has to contain one value for each axis.
- n [int, optional] If n is negative (default), then the input is assumed to be the result of a complex fft. If n is larger than or equal to zero, the input is assumed to be the result of a real fft, and n gives the length of the array before transformation along the real transform direction.
- axis [int, optional] The axis of the real transform.
- output [ndarray, optional] If given, the result of filtering the input is placed in this array. None is returned in this case.

Returns

- fourier_ellipsoid [ndarray] The filtered input.

Notes

This function is implemented for arrays of rank 1, 2, or 3.

Examples

```python
>>> from scipy import ndimage, misc
>>> import numpy.fft
>>> import matplotlib.pyplot as plt
>>> fig, (ax1, ax2) = plt.subplots(1, 2)
>>> plt.gray() # show the filtered result in grayscale
>>> ascent = misc.ascent()
>>> input_ = numpy.fft.fft2(ascent)
>>> result = ndimage.fourier_ellipsoid(input_, size=20)
>>> result = numpy.fft.ifft2(result)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result.real) # the imaginary part is an artifact
>>> plt.show()
```
n [int, optional] If $n$ is negative (default), then the input is assumed to be the result of a complex
fft. If $n$ is larger than or equal to zero, the input is assumed to be the result of a real fft, and
$n$ gives the length of the array before transformation along the real transform direction.

axis [int, optional] The axis of the real transform.

output [ndarray, optional] If given, the result of filtering the input is placed in this array. None is
returned in this case.

Returns

fourier_gaussian [ndarray] The filtered input.

Examples

```python
>>> from scipy import ndimage, misc
>>> import numpy.fft
>>> import matplotlib.pyplot as plt
>>> fig, (ax1, ax2) = plt.subplots(1, 2)
>>> plt.gray()  # show the filtered result in grayscale
>>> ascent = misc.ascent()
>>> input_ = numpy.fft.fft2(ascent)
>>> result = ndimage.fourier_gaussian(input_, sigma=4)
>>> result = numpy.fft.ifft2(result)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result.real)  # the imaginary part is an artifact
>>> plt.show()
```
scipy.ndimage.fourier_shift

scipy.ndimage.fourier_shift(input, shift=-1, axis=-1, output=None)

Multidimensional Fourier shift filter.

The array is multiplied with the Fourier transform of a shift operation.

**Parameters**

- **input** [array_like] The input array.
- **shift** [float or sequence] The size of the box used for filtering. If a float, `shift` is the same for all axes. If a sequence, `shift` has to contain one value for each axis.
- **n** [int, optional] If `n` is negative (default), then the input is assumed to be the result of a complex fft. If `n` is larger than or equal to zero, the input is assumed to be the result of a real fft, and `n` gives the length of the array before transformation along the real transform direction.
- **axis** [int, optional] The axis of the real transform.
- **output** [ndarray, optional] If given, the result of shifting the input is placed in this array. None is returned in this case.

**Returns**

- **fourier_shift**[ndarray] The shifted input.

**Examples**

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> import numpy.fft
>>> fig, (ax1, ax2) = plt.subplots(1, 2)
>>> plt.gray()  # show the filtered result in grayscale
>>> ascent = misc.ascent()
>>> input_ = numpy.fft.fft2(ascent)
>>> result = ndimage.fourier_shift(input_, shift=200)
>>> result = numpy.fft.ifft2(result)
```

(continues on next page)
```python
>>> ax1.imshow(ascent)
>>> ax2.imshow(result.real) # the imaginary part is an artifact
>>> plt.show()
```

**scipy.ndimage.fourier_uniform**

`scipy.ndimage.fourier_uniform(input, size, n=-1, axis=-1, output=None)`

Multidimensional uniform Fourier filter.

The array is multiplied with the Fourier transform of a box of given size.

**Parameters**

- `input` [array_like] The input array.
- `size` [float or sequence] The size of the box used for filtering. If a float, `size` is the same for all axes. If a sequence, `size` has to contain one value for each axis.
- `n` [int, optional] If `n` is negative (default), then the input is assumed to be the result of a complex fft. If `n` is larger than or equal to zero, the input is assumed to be the result of a real fft, and `n` gives the length of the array before transformation along the real transform direction.
- `axis` [int, optional] The axis of the real transform.
- `output` [ndarray, optional] If given, the result of filtering the input is placed in this array. None is returned in this case.

**Returns**

- `fourier_uniform` [ndarray] The filtered input.
Examples

```python
>>> from scipy import ndimage, misc
>>> import numpy.fft
>>> import matplotlib.pyplot as plt
>>> fig, (ax1, ax2) = plt.subplots(1, 2)
>>> plt.gray()  # show the filtered result in grayscale
>>> ascent = misc.ascent()
>>> input_ = numpy.fft.fft2(ascent)
>>> result = ndimage.fourier_uniform(input_, size=20)
>>> result = numpy.fft.ifft2(result)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result.real)  # the imaginary part is an artifact
>>> plt.show()
```

6.17.3 Interpolation

<td>Zoom an array.</td>
</tr>
</tbody>
</table>
Apply an affine transformation.

Given an output image pixel index vector \( \mathbf{o} \), the pixel value is determined from the input image at position \( \text{np}. \text{dot}(\text{matrix}, \mathbf{o}) + \text{offset} \).

This does ‘pull’ (or ‘backward’) resampling, transforming the output space to the input to locate data. Affine transformations are often described in the ‘push’ (or ‘forward’) direction, transforming input to output. If you have a matrix for the ‘push’ transformation, use its inverse (\text{numpy.linalg.inv}) in this function.

**Parameters**

- **input** [array_like] The input array.
- **matrix** [ndarray] The inverse coordinate transformation matrix, mapping output coordinates to input coordinates. If \( \text{ndim} \) is the number of dimensions of \( \text{input} \), the given matrix must have one of the following shapes:
  - \((\text{ndim}, \text{ndim})\): the linear transformation matrix for each output coordinate.
  - \((\text{ndim},)\): assume that the 2-D transformation matrix is diagonal, with the diagonal specified by the given value. A more efficient algorithm is then used that exploits the separability of the problem.
  - \((\text{ndim} + 1, \text{ndim} + 1)\): assume that the transformation is specified using homogeneous coordinates [1]. In this case, any value passed to \( \text{offset} \) is ignored.
  - \((\text{ndim}, \text{ndim} + 1)\): as above, but the bottom row of a homogeneous transformation matrix is always \([0, 0, \ldots, 1]\), and may be omitted.
- **offset** [float or sequence, optional] The offset into the array where the transform is applied. If a float, \( \text{offset} \) is the same for each axis. If a sequence, \( \text{offset} \) should contain one value for each axis.
- **output_shape** [tuple of ints, optional] Shape tuple.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **order** [int, optional] The order of the spline interpolation, default is 3. The order has to be in the range 0-5.
- **mode** [{‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’}, optional] The \( \text{mode} \) parameter determines how the input array is extended beyond its boundaries. Default is ‘constant’. Behavior for each valid value is as follows (see additional plots and details on boundary modes):
  - ‘reflect’ (\( d \ldots c b a | a b c d | d \ldots c b a \))
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - ‘constant’ (\( k \ldots k k | a b c d | k k k \ k k k \))
    The input is extended by filling all values beyond the edge with the same constant value, defined by the \( \text{cval} \) parameter. No interpolation is performed beyond the edges of the input.
  - ‘grid-constant’ (\( k \ldots k k | a b c d | k k k \ k k k \))
    The input is extended by filling all values beyond the edge with the same constant value, defined by the \( \text{cval} \) parameter. Interpolation occurs for samples outside the input’s extent as well.
  - ‘nearest’ (\( a \ldots a a | a b c d | d d d \ d d d \))
    The input is extended by replicating the last pixel.
'mirror' \((d \ c \ b \ | \ a \ b \ c \ d \ | \ c \ b \ a)\) 

The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

'grid-wrap' \((a \ b \ c \ d \ | \ a \ b \ c \ d \ | \ a \ b \ c \ d)\) 

The input is extended by wrapping around to the opposite edge.

'wrap' \((d \ b \ c \ d \ | \ a \ b \ c \ d \ | \ b \ c \ a \ b)\) 

The input is extended by wrapping around to the opposite edge, but in a way such that the last point and initial point exactly overlap. In this case it is not well defined which sample will be chosen at the point of overlap.

cval [scalar, optional] Value to fill past edges of input if \texttt{mode} is 'constant'. Default is 0.0.
prefilter [bool, optional] Determines if the input array is prefiltered with \texttt{spline_filter} before interpolation. The default is True, which will create a temporary float64 array of filtered values if \texttt{order > 1}. If setting this to False, the output will be slightly blurred if \texttt{order > 1}, unless the input is prefiltered, i.e. it is the result of calling \texttt{spline_filter} on the original input.

Returns 

affine_transform [ndarray] The transformed input.

Notes

The given matrix and offset are used to find for each point in the output the corresponding coordinates in the input by an affine transformation. The value of the input at those coordinates is determined by spline interpolation of the requested order. Points outside the boundaries of the input are filled according to the given mode.

Changed in version 0.18.0: Previously, the exact interpretation of the affine transformation depended on whether the matrix was supplied as a 1-D or a 2-D array. If a 1-D array was supplied to the matrix parameter, the output pixel value at index \(o\) was determined from the input image at position \(\text{matrix} \cdot (o + \text{offset})\).

For complex-valued \texttt{input}, this function transforms the real and imaginary components independently.

New in version 1.6.0: Complex-valued support added.

References

[1]

scipy.ndimage.geometric_transform

scipy.ndimage.geometric_transform (input, mapping, output_shape=None, output=None, order=3, mode='constant', cval=0.0, prefilter=True, extra_arguments=(), extra_keywords={})

Apply an arbitrary geometric transform.

The given mapping function is used to find, for each point in the output, the corresponding coordinates in the input. The value of the input at those coordinates is determined by spline interpolation of the requested order.

Parameters

input [array_like] The input array.
mapping [callable, scipy.LowLevelCallable] A callable object that accepts a tuple of length equal to the output array rank, and returns the corresponding input coordinates as a tuple of length equal to the input array rank.
output_shape
[tuple of ints, optional] Shape tuple.

output [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

order [int, optional] The order of the spline interpolation, default is 3. The order has to be in the range 0-5.

mode [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘constant’. Behavior for each valid value is as follows (see additional plots and details on boundary modes):

‘reflect’ (d c b a | a b c d | d c b a)
The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

‘grid-mirror’
This is a synonym for ‘reflect’.

‘constant’ (k k k k | a b c d | k k k k)
The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter. No interpolation is performed beyond the edges of the input.

‘grid-constant’ (k k k k | a b c d | k k k k)
The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter. Interpolation occurs for samples outside the input’s extent as well.

‘nearest’ (a a a a | a b c d | d d d d)
The input is extended by replicating the last pixel.

‘mirror’ (d c b a | a b c d | c b a)
The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

‘grid-wrap’ (a b c d | a b c d | a b c d)
The input is extended by wrapping around to the opposite edge.

‘wrap’ (d b c d | a b c d | b c a b)
The input is extended by wrapping around to the opposite edge, but in a way such that the last point and initial point exactly overlap. In this case it is not well defined which sample will be chosen at the point of overlap.

cval [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

prefilter [bool, optional] Determines if the input array is prefiltered with spline_filter before interpolation. The default is True, which will create a temporary float64 array of filtered values if order > 1. If setting this to False, the output will be slightly blurred if order > 1, unless the input is prefiltered, i.e. it is the result of calling spline_filter on the original input.

extra_arguments [tuple, optional] Extra arguments passed to mapping.

extra_keywords [dict, optional] Extra keywords passed to mapping.

Returns

output [ndarray] The filtered input.

See also:

map_coordinates, affine_transform, spline_filter1d
Notes

This function also accepts low-level callback functions with one of the following signatures and wrapped in `scipy.LowLevelCallable`:

```python
int mapping(npy_intp *output_coordinates, double *input_coordinates, int output_rank, int input_rank, void *user_data)
int mapping(intptr_t *output_coordinates, double *input_coordinates, int output_rank, int input_rank, void *user_data)
```

The calling function iterates over the elements of the output array, calling the callback function at each element. The coordinates of the current output element are passed through `output_coordinates`. The callback function must return the coordinates at which the input must be interpolated in `input_coordinates`. The rank of the input and output arrays are given by `input_rank` and `output_rank` respectively. `user_data` is the data pointer provided to `scipy.LowLevelCallable` as-is.

The callback function must return an integer error status that is zero if something went wrong and one otherwise. If an error occurs, you should normally set the Python error status with an informative message before returning, otherwise a default error message is set by the calling function.

In addition, some other low-level function pointer specifications are accepted, but these are for backward compatibility only and should not be used in new code.

For complex-valued input, this function transforms the real and imaginary components independently.

New in version 1.6.0: Complex-valued support added.

Examples

```python
>>> import numpy as np
>>> from scipy.ndimage import geometric_transform
>>> a = np.arange(12.).reshape((4, 3))
>>> def shift_func(output_coords):
...     return (output_coords[0] - 0.5, output_coords[1] - 0.5)
...
>>> geometric_transform(a, shift_func)
array([[ 0. , 0. , 0. ],
       [ 1.362, 2.738],
       [ 4.812, 6.187],
       [ 8.263, 9.637]])
```

```python
>>> b = [1, 2, 3, 4, 5]
>>> def shift_func(output_coords):
...     return (output_coords[0] - 3,)
...
>>> geometric_transform(b, shift_func, mode='constant')
array([0, 0, 0, 1, 2])
>>> geometric_transform(b, shift_func, mode='nearest')
array([1, 1, 1, 1, 2])
>>> geometric_transform(b, shift_func, mode='reflect')
array([3, 2, 1, 1, 2])
>>> geometric_transform(b, shift_func, mode='wrap')
array([2, 3, 4, 1, 2])
```
**scipy.ndimage.map_coordinates**

The `map_coordinates` function allows you to map the input array to new coordinates by interpolation. The array of coordinates is used to find, for each point in the output, the corresponding coordinates in the input. The value of the input at those coordinates is determined by spline interpolation of the requested order. The shape of the output is derived from that of the coordinate array by dropping the first axis. The values of the array along the first axis are the coordinates in the input array at which the output value is found.

**Parameters**

- **input** [array_like] The input array.
- **coordinates** [array_like] The coordinates at which `input` is evaluated.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **order** [int, optional] The order of the spline interpolation, default is 3. The order has to be in the range 0-5.
- **mode** [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is 'constant'. Behavior for each valid value is as follows (see additional plots and details on boundary modes):
  - **reflect** (d c b a | a b c d | d c b a)
  - The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - **grid-mirror** This is a synonym for 'reflect'.
  - **constant** (k k k k | a b c d | k k k k)
  - The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter. No interpolation is performed beyond the edges of the input.
  - **grid-constant** (k k k k | a b c d | k k k k)
  - The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter. Interpolation occurs for samples outside the input's extent as well.
  - **nearest** (a a a a | a b c d | d d d d)
  - The input is extended by replicating the last pixel.
  - **mirror** (d c b | a b c d | c b a)
  - The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - **grid-wrap** (a b c d | a b c d | a b c d)
  - The input is extended by wrapping around to the opposite edge.
  - **wrap** (d b c d | a b c d | b c a b)
  - The input is extended by wrapping around to the opposite edge, but in a way such that the last point and initial point exactly overlap. In this case it is not well defined which sample will be chosen at the point of overlap.
- **cval** [scalar, optional] Value to fill past edges of input if `mode` is 'constant'. Default is 0.0.
- **prefilter** [bool, optional] Determines if the input array is prefiltered with `spline_filter` before interpolation. The default is True, which will create a temporary `float64` array of filtered values if `order > 1`. If setting this to False, the output will be slightly blurred if `order > 1`, unless the input is prefiltered, i.e. it is the result of calling `spline_filter` on the original input.

**Returns**
map_coordinates

```
[ndarray] The result of transforming the input. The shape of the output is derived from that of coordinates by dropping the first axis.
```

See also:

`spline_filter`, `geometric_transform`, `scipy.interpolate`

Notes

For complex-valued input, this function maps the real and imaginary components independently.

New in version 1.6.0: Complex-valued support added.

Examples

```python
>>> from scipy import ndimage
>>> a = np.arange(12.).reshape((4, 3))
>>> a
array([[ 0.,  1.,  2.],
       [ 3.,  4.,  5.],
       [ 6.,  7.,  8.],
       [ 9., 10., 11.]])
>>> ndimage.map_coordinates(a, [[0.5, 2], [0.5, 1]], order=1)
array([ 2.,  7.])
```

Above, the interpolated value of a[0.5, 0.5] gives output[0], while a[2, 1] is output[1].

```python
>>> inds = np.array([[0.5, 2], [0.5, 4]])
>>> ndimage.map_coordinates(a, inds, order=1, cval=-33.3)
array([ 2. , -33.3])
>>> ndimage.map_coordinates(a, inds, order=1, mode='nearest')
array([ 2. ,  8.])
>>> ndimage.map_coordinates(a, inds, order=1, cval=0, output=bool)
array([ True, False], dtype=bool)
```

scipy.ndimage.rotate

```
scipy.ndimage.rotate(input, angle, axes=1, 0, reshape=True, output=None, order=3, mode='constant', cval=0.0, prefilter=True)
```

Rotate an array.

The array is rotated in the plane defined by the two axes given by the axes parameter using spline interpolation of the requested order.

Parameters

- **input**: [array_like] The input array.
- **angle**: [float] The rotation angle in degrees.
- **axes**: [tuple of 2 ints, optional] The two axes that define the plane of rotation. Default is the first two axes.
- **reshape**: [bool, optional] If reshape is true, the output shape is adapted so that the input array is contained completely in the output. Default is True.
output  [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

order  [int, optional] The order of the spline interpolation, default is 3. The order has to be in the range 0-5.

mode  [(‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’), optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘constant’. Behavior for each valid value is as follows (see additional plots and details on boundary modes):

- **reflect** (d c b a | a b c d | d c b a)
  The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

- **grid-mirror**
  This is a synonym for ‘reflect’.

- **constant** (k k k k | a b c d | k k k k)
  The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter. No interpolation is performed beyond the edges of the input.

- **grid-constant** (k k k k | a b c d | k k k k)
  The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter. Interpolation occurs for samples outside the input's extent as well.

- **nearest** (a a a a | a b c d | d d d d)
  The input is extended by replicating the last pixel.

- **mirror** (d c b | a b c d | c b a)
  The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

- **grid-wrap** (a b c d | a b c d | a b c d)
  The input is extended by wrapping around to the opposite edge.

- **wrap** (d b c d | a b c d | b c a b)
  The input is extended by wrapping around to the opposite edge, but in a way such that the last point and initial point exactly overlap. In this case it is not well defined which sample will be chosen at the point of overlap.

- **cval** [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

- **prefilter** [bool, optional] Determines if the input array is prefiltered with spline_filter before interpolation. The default is True, which will create a temporary float64 array of filtered values if order > 1. If setting this to False, the output will be slightly blurred if order > 1, unless the input is prefiltered, i.e. it is the result of calling spline_filter on the original input.

Returns

- **rotate** [ndarray] The rotated input.

Notes

For complex-valued input, this function rotates the real and imaginary components independently.

New in version 1.6.0: Complex-valued support added.
Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure(figsize=(10, 3))
>>> ax1, ax2, ax3 = fig.subplots(1, 3)
>>> img = misc.ascent()
>>> img_45 = ndimage.rotate(img, 45, reshape=False)
>>> full_img_45 = ndimage.rotate(img, 45, reshape=True)
>>> ax1.imshow(img, cmap='gray')
>>> ax1.set_axis_off()
>>> ax2.imshow(img_45, cmap='gray')
>>> ax2.set_axis_off()
>>> ax3.imshow(full_img_45, cmap='gray')
>>> ax3.set_axis_off()
>>> fig.set_tight_layout(True)
>>> plt.show()
```

```python
>>> print(img.shape)
(512, 512)
>>> print(img_45.shape)
(512, 512)
>>> print(full_img_45.shape)
(724, 724)
```

**scipy.ndimage.shift**

The array is shifted using spline interpolation of the requested order. Points outside the boundaries of the input are filled according to the given mode.

**Parameters**

- `input` [array_like] The input array.
- `shift` [float or sequence] The shift along the axes. If a float, `shift` is the same for each axis. If a sequence, `shift` should contain one value for each axis.
- `output` [array or dtypes, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
order: int, optional] The order of the spline interpolation, default is 3. The order has to be in the range 0-5.

mode: ['reflect', 'constant', 'nearest', 'mirror', 'wrap'], optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is 'constant'. Behavior for each valid value is as follows (see additional plots and details on boundary modes):

- 'reflect' (d c b a | a b c d | d c b a)
  The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

- 'grid-mirror' This is a synonym for 'reflect'.

- 'constant' (k k k k | a b c d | k k k k)
  The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter. No interpolation is performed beyond the edges of the input.

- 'grid-constant' (k k k k | a b c d | k k k k)
  The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter. Interpolation occurs for samples outside the input's extent as well.

- 'nearest' (a a a a | a b c d | d d d d)
  The input is extended by replicating the last pixel.

- 'mirror' (d c b | a b c d | c b a)
  The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

- 'grid-wrap' (a b c d | a b c d | a b c d)
  The input is extended by wrapping around to the opposite edge.

- 'wrap' (d b c d | a b c d | b c a b)
  The input is extended by wrapping around to the opposite edge, but in a way such that the last point and initial point exactly overlap. In this case it is not well defined which sample will be chosen at the point of overlap.

cval: scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
prefilter: bool, optional] Determines if the input array is prefiltered with spline_filter before interpolation. The default is True, which will create a temporary float64 array of filtered values if order > 1. If setting this to False, the output will be slightly blurred if order > 1, unless the input is prefiltered, i.e. it is the result of calling spline_filter on the original input.

Returns

Notes

For complex-valued input, this function shifts the real and imaginary components independently.

New in version 1.6.0: Complex-valued support added.
scipy.ndimage.spline_filter

scipy.ndimage.spline_filter(input, order=3, output=<class 'numpy.float64'>, mode='mirror')

Multidimensional spline filter.

For more details, see spline_filter1d.

See also:

spline_filter1d

Calculate a 1-D spline filter along the given axis.

Notes

The multidimensional filter is implemented as a sequence of 1-D spline filters. The intermediate arrays are stored in the same data type as the output. Therefore, for output types with a limited precision, the results may be imprecise because intermediate results may be stored with insufficient precision.

For complex-valued input, this function processes the real and imaginary components independently.

New in version 1.6.0: Complex-valued support added.

Examples

We can filter an image using multidimensional splines:

```python
>>> from scipy.ndimage import spline_filter
>>> import matplotlib.pyplot as plt
>>> orig_img = np.eye(20)  # create an image
>>> orig_img[10, :] = 1.0
>>> sp_filter = spline_filter(orig_img, order=3)
>>> f, ax = plt.subplots(1, 2, sharex=True)
>>> for ind, data in enumerate([orig_img, "original image"],
...                            [sp_filter, "spline filter"]):
...    ax[ind].imshow(data[0], cmap='gray_r')
...    ax[ind].set_title(data[1])
>>> plt.tight_layout()
>>> plt.show()
```

scipy.ndimage.spline_filter1d

scipy.ndimage.spline_filter1d(input, order=3, axis=-1, output=<class 'numpy.float64'>, mode='mirror')

Calculate a 1-D spline filter along the given axis.

The lines of the array along the given axis are filtered by a spline filter. The order of the spline must be >= 2 and <= 5.

Parameters

- **input** [array_like] The input array.
- **order** [int, optional] The order of the spline, default is 3.
- **axis** [int, optional] The axis along which the spline filter is applied. Default is the last axis.
- **output** [ndarray or dtype, optional] The array in which to place the output, or the dtype of the returned array. Default is numpy.float64.
mode

[['reflect', 'constant', 'nearest', 'mirror', 'wrap'], optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is 'mirror'. Behavior for each valid value is as follows (see additional plots and details on boundary modes):

- **reflect** *(d c b a | a b c d | d c b a)*
  The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

- **grid-mirror**
  This is a synonym for 'reflect'.

- **constant** *(k k k k | a b c d | k k k k)*
  The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter. No interpolation is performed beyond the edges of the input.

- **grid-constant** *(k k k k | a b c d | k k k k)*
  The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter. Interpolation occurs for samples outside the input's extent as well.

- **nearest** *(a a a a | a b c d | d d d d)*
  The input is extended by replicating the last pixel.

- **mirror** *(d c b | a b c d | c b a)*
  The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

- **grid-wrap** *(a b c d | a b c d | a b c d)*
  The input is extended by wrapping around to the opposite edge.

- **wrap** *(d b c d | a b c d | b c a b)*
  The input is extended by wrapping around to the opposite edge, but in a way such that the last point and initial point exactly overlap. In this case it is not well defined which sample will be chosen at the point of overlap.

**Returns**

- **spline_filter1d** [ndarray] The filtered input.

See also:

- **spline_filter**
Multidimensional spline filter.

Notes

All functions in `ndimage.interpolation` do spline interpolation of the input image. If using B-splines of order > 1, the input image values have to be converted to B-spline coefficients first, which is done by applying this 1-D filter sequentially along all axes of the input. All functions that require B-spline coefficients will automatically filter their inputs, a behavior controllable with the `prefilter` keyword argument. For functions that accept a `mode` parameter, the result will only be correct if it matches the `mode` used when filtering.

For complex-valued input, this function processes the real and imaginary components independently.

New in version 1.6.0: Complex-valued support added.

Examples

We can filter an image using 1-D spline along the given axis:

```python
>>> from scipy.ndimage import spline_filter1d
>>> import matplotlib.pyplot as plt
>>> orig_img = np.eye(20)  # create an image
>>> orig_img[10, :] = 1.0
>>> sp_filter_axis_0 = spline_filter1d(orig_img, axis=0)
>>> sp_filter_axis_1 = spline_filter1d(orig_img, axis=1)
>>> f, ax = plt.subplots(1, 3, sharex=True)
>>> for ind, data in enumerate([[orig_img, "original image"],
...                             [sp_filter_axis_0, "spline filter (axis=0)"],
...                             [sp_filter_axis_1, "spline filter (axis=1)"]):
...     ax[ind].imshow(data[0], cmap='gray_r')
...     ax[ind].set_title(data[1])
>>> plt.tight_layout()
>>> plt.show()
```
scipy.ndimage.zoom

**scipy.ndimage.zoom** *(input, zoom, output=None, order=3, mode='constant', cval=0.0, prefilter=True, *, grid_mode=False)*

Zoom an array.

The array is zoomed using spline interpolation of the requested order.

**Parameters**

- **input** [array_like] The input array.
- **zoom** [float or sequence] The zoom factor along the axes. If a float, `zoom` is the same for each axis. If a sequence, `zoom` should contain one value for each axis.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **order** [int, optional] The order of the spline interpolation, default is 3. The order has to be in the range 0-5.
- **mode** [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The `mode` parameter determines how the input array is extended beyond its boundaries. Default is 'constant'. Behavior for each valid value is as follows (see additional plots and details on boundary modes):
  - **'reflect'** `(d c b a | a b c d | d c b a)`
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - **'grid-mirror'**
    This is a synonym for 'reflect'.
  - **'constant'** `(k k k k | a b c d | k k k k)`
    The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter. No interpolation is performed beyond the edges of the input.
  - **'grid-constant'** `(k k k k | a b c d | k k k k)`
    The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter. Interpolation occurs for samples outside the input's extent as well.
  - **'nearest'** `(a a a a | a b c d | d d d d)`
    The input is extended by replicating the last pixel.
  - **'mirror'** `(d c b | a b c d | c b a)`
    The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - **'grid-wrap'** `(a b c d | a b c d | a b c d)`
    The input is extended by wrapping around to the opposite edge.
  - **'wrap'** `(d b c d | a b c d | b c a b)`
    The input is extended by wrapping around to the opposite edge, but in a way such that the last point and initial point exactly overlap. In this case it is not well defined which sample will be chosen at the point of overlap.
- **cval** [scalar, optional] Value to fill past edges of input if `mode` is 'constant'. Default is 0.0.
- **prefilter** [bool, optional] Determines if the input array is prefiltered with `spline_filter` before interpolation. The default is True, which will create a temporary `float64` array of filtered values if `order > 1`. If setting this to False, the output will be slightly blurred if `order > 1`, unless the input is prefiltered, i.e. it is the result of calling `spline_filter` on the original input.
- **grid_mode** [bool, optional] If False, the distance from the pixel centers is zoomed. Otherwise, the distance including the full pixel extent is used. For example, a 1d signal of length 5 is considered to have length 4 when `grid_mode` is False, but length 5 when `grid_mode` is True. See the following visual illustration:
The starting point of the arrow in the diagram above corresponds to coordinate location 0 in each mode.

**Returns**

- `zoom` [ndarray] The zoomed input.

**Notes**

For complex-valued `input`, this function zooms the real and imaginary components independently.

New in version 1.6.0: Complex-valued support added.

**Examples**

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt

>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(211)  # left side
>>> ax2 = fig.add_subplot(212)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.zoom(ascent, 3.0)
>>> ax1.imshow(ascent, vmin=0, vmax=255)
>>> ax2.imshow(result, vmin=0, vmax=255)
>>> plt.show()
```

**scipy.ndimage.center_of_mass**

Calculate the center of mass of the values of an array at labels.

**Parameters**

- **input** ([ndarray]) Data from which to calculate center-of-mass. The masses can either be positive or negative.
- **labels** ([ndarray, optional]) Labels for objects in input, as generated by `ndimage.label`. Only used with `index`. Dimensions must be the same as `input`.
- **index** ([int or sequence of ints, optional]) Labels for which to calculate centers-of-mass. If not specified, all labels greater than zero are used. Only used with `labels`. 

6.17. Multidimensional image processing (scipy.ndimage) 1535
Returns

center_of_mass
[tuple, or list of tuples] Coordinates of centers-of-mass.

Examples

```python
center_of_mass
```

Calculation of multiple objects in an image

```python
center_of_mass
```

Negative masses are also accepted, which can occur for example when bias is removed from measured data due to random noise.

```python
center_of_mass
```

If there are division by zero issues, the function does not raise an error but rather issues a RuntimeWarning before returning inf and/or NaN.

```python
center_of_mass
```

scipy.ndimage.extrema

```python
center_of_mass
```

Calculate the minimums and maximums of the values of an array at labels, along with their positions.

Parameters

- `input` [ndarray] N-D image data to process.
- `labels` [ndarray, optional] Labels of features in input. If not None, must be same shape as `input`.
- `index` [int or sequence of ints, optional] Labels to include in output. If None (default), all values where non-zero labels are used.
Returns

minimums, maximums
[int or ndarray] Values of minimums and maximums in each feature.

min_positions, max_positions
[tuple or list of tuples] Each tuple gives the N-D coordinates of the corresponding minimum or maximum.

See also:
maximum, minimum, maximum_position, minimum_position, center_of_mass

Examples

```python
>>> a = np.array([[1, 2, 0, 0],
...                [5, 3, 0, 4],
...                [0, 0, 0, 7],
...                [9, 3, 0, 0]])
>>> from scipy import ndimage
>>> ndimage.extrema(a)
(0, 9, (0, 0), (3, 0))
```

Features to process can be specified using labels and index:

```python
>>> lbl, nlbl = ndimage.label(a)
>>> ndimage.extrema(a, lbl, index=np.arange(1, nlbl+1))
(array([1, 4, 3]),
 array([5, 7, 9]),
 [(0, 0), (1, 3), (3, 1)],
 [(1, 0), (2, 3), (3, 0)])
```

If no index is given, non-zero labels are processed:

```python
>>> ndimage.extrema(a, lbl)
(1, 9, (0, 0), (3, 0))
```

scipy.ndimage.find_objects

scipy.ndimage.find_objects (input, max_label=0)
Find objects in a labeled array.

Parameters

- input [ndarray of ints] Array containing objects defined by different labels. Labels with value 0 are ignored.
- max_label [int, optional] Maximum label to be searched for in input. If max_label is not given, the positions of all objects are returned.

Returns

- object_slices [list of tuples] A list of tuples, with each tuple containing N slices (with N the dimension of the input array). Slices correspond to the minimal parallelepiped that contains the object. If a number is missing, None is returned instead of a slice.
See also:

`label, center_of_mass`

Notes

This function is very useful for isolating a volume of interest inside a 3-D array, that cannot be “seen through”.

Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((6, 6), dtype=int)
>>> a[2:4, 2:4] = 1
>>> a[4, 4] = 1
>>> a[:, 2, :3] = 2
>>> a[0, 5] = 3
>>> a
array([[2, 2, 2, 0, 0, 3],
       [2, 2, 2, 0, 0, 0],
       [0, 0, 1, 1, 0, 0],
       [0, 0, 1, 1, 0, 0],
       [0, 0, 0, 0, 1, 0],
       [0, 0, 0, 0, 0, 0]])
>>> ndimage.find_objects(a)
[(slice(2, 5, None), slice(2, 5, None)), (slice(0, 2, None), slice(0, 3, None)), (slice(0, 1, None), slice(5, 6, None))]
>>> ndimage.find_objects(a, max_label=2)
[(slice(2, 5, None), slice(2, 5, None)), (slice(0, 2, None), slice(0, 3, None))]
>>> ndimage.find_objects(a == 1, max_label=2)
[(slice(2, 5, None), slice(2, 5, None)), None]
>>> loc = ndimage.find_objects(a)[0]
>>> a[loc]
array([[1, 1, 0],
       [1, 1, 0],
       [0, 0, 1]])
```

`scipy.ndimage.histogram`

`scipy.ndimage.histogram` *(input, min, max, bins=None, labels=None, index=None)*

Calculate the histogram of the values of an array, optionally at labels.

Histogram calculates the frequency of values in an array within bins determined by *min*, *max*, and *bins*. The *labels* and *index* keywords can limit the scope of the histogram to specified sub-regions within the array.

**Parameters**

- **input** *(array_like)*: Data for which to calculate histogram.
- **min, max** *(int)*: Minimum and maximum values of range of histogram bins.
- **bins** *(int)*: Number of bins.
- **labels** *(array_like, optional)*: Labels for objects in *input*. If not None, must be same shape as *input*. 

index  [int or sequence of ints, optional] Label or labels for which to calculate histogram. If None, all values where label is greater than zero are used

Returns

hist  [ndarray] Histogram counts.

Examples

```python
>>> a = np.array([[ 0. , 0.2146, 0.5962, 0. ],
    ...                [ 0. , 0.7778, 0. , 0. ],
    ...                [ 0. , 0. , 0. , 0. ],
    ...                [ 0. , 0. , 0.7181, 0.2787],
    ...                [ 0. , 0. , 0.6573, 0.3094]])
```
```python
from scipy import ndimage
```n
dimage.measurements.histogram(a, 0, 1, 10)
array([13, 0, 2, 1, 0, 1, 1, 2, 0, 0])

With labels and no indices, non-zero elements are counted:

```python
>>>lbl, nlbl = ndimage.label(a)
>>> ndimage.measurements.histogram(a, 0, 1, 10, lbl)
array([0, 0, 2, 1, 0, 1, 1, 2, 0, 0])
```

Indices can be used to count only certain objects:

```python
>>> ndimage.measurements.histogram(a, 0, 1, 10, lbl, 2)
array([0, 0, 1, 1, 0, 0, 1, 1, 0, 0])
```

scipy.ndimage.label

scipy.ndimage.label(input, structure=None, output=None)
Label features in an array.

Parameters

input  [array_like] An array-like object to be labeled. Any non-zero values in input are counted as features and zero values are considered the background.
structure  [array_like, optional] A structuring element that defines feature connections. structure must be centrosymmetric (see Notes). If no structuring element is provided, one is automatically generated with a squared connectivity equal to one. That is, for a 2-D input array, the default structuring element is:

```python
[[[0,1,0],
  [1,1,1],
  [0,1,0]]
```

output  [(None, data-type, array_like), optional] If output is a data type, it specifies the type of the resulting labeled feature array. If output is an array-like object, then output will be updated with the labeled features from this function. This function can operate in-place, by passing output=input. Note that the output must be able to store the largest label, or this function will raise an Exception.

Returns
label  [ndarray or int] An integer ndarray where each unique feature in input has a unique label in the returned array.

num_features  [int] How many objects were found.
If output is None, this function returns a tuple of (labeled_array, num_features).
If output is a ndarray, then it will be updated with values in labeled_array and only num_features will be returned by this function.

See also:

find_objects

generate a list of slices for the labeled features (or objects); useful for finding features’ position or dimensions

Notes

A centrosymmetric matrix is a matrix that is symmetric about the center. See [1] for more information.
The structure matrix must be centrosymmetric to ensure two-way connections. For instance, if the structure matrix is not centrosymmetric and is defined as:

\[
\begin{bmatrix}
0 ,1, 0, \\
1,1,0, \\
0,0,0
\end{bmatrix}
\]

and the input is:

\[
\begin{bmatrix}
1,2, \\
0,3
\end{bmatrix}
\]

then the structure matrix would indicate the entry 2 in the input is connected to 1, but 1 is not connected to 2.

References

[1]

Examples

Create an image with some features, then label it using the default (cross-shaped) structuring element:

```python
>>> from scipy.ndimage import label, generate_binary_structure
>>> a = np.array([[0,0,1,1,0],
... [0,0,0,1,0,0],
... [1,1,0,0,1,0],
... [0,0,0,1,0,0]])
>>> labeled_array, num_features = label(a)
```

Each of the 4 features are labeled with a different integer:

```python
>>> num_features
4
>>> labeled_array
array([[0, 0, 1, 1, 0, 0],
... [0, 0, 0, 1, 0, 0],
... [1, 1, 0, 0, 1, 0],
... [0, 0, 0, 1, 0, 0]])
```
Generate a structuring element that will consider features connected even if they touch diagonally:

```python
>>> s = generate_binary_structure(2, 2)
```

or,

```python
>>> s = [[1, 1, 1],
...      [1, 1, 1],
...      [1, 1, 1]]
```

Label the image using the new structuring element:

```python
>>> labeled_array, num_features = label(a, structure=s)
```

Show the 2 labeled features (note that features 1, 3, and 4 from above are now considered a single feature):

```python
>>> num_features
2
>>> labeled_array
array([[0, 0, 1, 1, 0, 0],
       [0, 0, 0, 1, 0, 0],
       [2, 2, 0, 0, 1, 0],
       [0, 0, 0, 1, 0, 0]])
```

**scipy.ndimage.labeled_comprehension**

`scipy.ndimage.labeled_comprehension(input, labels, index, func, out_dtype, default, pass_positions=False)`

Roughly equivalent to `[func(input[labels == i]) for i in index]`.

Sequentially applies an arbitrary function (that works on array_like input) to subsets of an N-D image array specified by `labels` and `index`. The option exists to provide the function with positional parameters as the second argument.

**Parameters**

- `input` [array_like] Data from which to select `labels` to process.
- `labels` [array_like or None] Labels to objects in `input`. If not None, array must be same shape as `input`. If None, `func` is applied to raveled `input`.
- `index` [int, sequence of ints or None] Subset of `labels` to which to apply `func`. If a scalar, a single value is returned. If None, `func` is applied to all non-zero values of `labels`.
- `func` [callable] Python function to apply to `labels` from `input`.
- `out_dtype` [dtype] Dtype to use for `result`.
- `default` [int, float or None] Default return value when a element of `index` does not exist in `labels`.
- `pass_positions` [bool, optional] If True, pass linear indices to `func` as a second argument. Default is False.

**Returns**

- `result` [ndarray] Result of applying `func` to each of `labels` to `input` in `index`. 

---

6.17. Multidimensional image processing (scipy.ndimage) 1541
Examples

```python
>>> a = np.array([[1, 2, 0, 0],
                ... [5, 3, 0, 4],
                ... [0, 0, 0, 7],
                ... [9, 3, 0, 0]])
>>> from scipy import ndimage
>>> lbl, nlbl = ndimage.label(a)
>>> lbls = np.arange(1, nlbl+1)
>>> ndimage.labeled_comprehension(a, lbl, lbls, np.mean, float, 0)
array([ 2.75, 5.5 , 6. ])
Falling back to default:

```python
>>> lbls = np.arange(1, nlbl+2)
>>> ndimage.labeled_comprehension(a, lbl, lbls, np.mean, float, -1)
array([ 2.75, 5.5 , 6. , -1. ])

Passing positions:

```python
>>> def fn(val, pos):
...     print("fn says: \$s : \$s" % (val, pos))
...     return (val.sum()) if (pos.sum() % 2 == 0) else (-val.sum())
... 
>>> ndimage.labeled_comprehension(a, lbl, lbls, fn, float, 0, True)
fn says: [1 2 5 3] : [0 1 4 5]
fn says: [4 7] : [ 7 11]
fn says: [9 3] : [12 13]
array([ 11., 11., -12., 0.])
```

scipy.ndimage.maximum

scipy.ndimage.maximum(input, labels=None, index=None)

Calculate the maximum of the values of an array over labeled regions.

Parameters:

- **input**: array_like
  Array_like of values. For each region specified by labels, the maximal values of input over the region is computed.

- **labels**: array_like, optional
  An array of integers marking different regions over which the maximum value of input is to be computed. labels must have the same shape as input. If labels is not specified, the maximum over the whole array is returned.

- **index**: array_like, optional
  A list of region labels that are taken into account for computing the maxima. If index is None, the maximum over all elements where labels is non-zero is returned.

Returns:

- **output**: [float or list of floats]
  List of maxima of input over the regions determined by labels and whose index is in index. If index or labels are not specified, a float is returned: the maximal value of input if labels is None, and the maximal value of elements where labels is greater than zero if index is None.

See also:
label, minimum, median, maximum_position, extrema, sum, mean, variance, standard_deviation

Notes

The function returns a Python list and not a NumPy array, use np.array to convert the list to an array.

Examples

```python
>>> a = np.arange(16).reshape((4, 4))
>>> a

array([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11],
        [12, 13, 14, 15]])
>>> labels = np.zeros_like(a)
>>> labels[:2,:2] = 1
>>> labels[2:, 1:3] = 2
>>> labels

array([[1, 1, 0, 0],
        [1, 1, 0, 2],
        [0, 2, 2, 0],
        [0, 2, 2, 0]])
>>> from scipy import ndimage
>>> ndimage.maximum(a)

15.0
>>> ndimage.maximum(a, labels=labels, index=[1, 2])

[5.0, 14.0]
>>> ndimage.maximum(a, labels=labels)

14.0

>>> b = np.array([[1, 2, 0, 0],
        ... [5, 3, 0, 4],
        ... [0, 0, 0, 7],
        ... [9, 3, 0, 0]])
>>> labels, labels_nb = ndimage.label(b)
>>> labels

array([[1, 1, 0, 0],
        [1, 1, 0, 2],
        [0, 0, 0, 2],
        [3, 3, 0, 0]])
>>> ndimage.maximum(b, labels=labels, index=np.arange(1, labels_nb + 1))

[5.0, 7.0, 9.0]
```
scipy.ndimage.maximum_position

scipy.ndimage\_maximum\_position(input, labels=None, index=None)

Find the positions of the maximums of the values of an array at labels.

For each region specified by labels, the position of the maximum value of input within the region is returned.

**Parameters**

- **input** [array_like] Array_like of values.
- **labels** [array_like, optional] An array of integers marking different regions over which the position of the maximum value of input is to be computed. labels must have the same shape as input. If labels is not specified, the location of the first maximum over the whole array is returned. The labels argument only works when index is specified.
- **index** [array_like, optional] A list of region labels that are taken into account for finding the location of the maxima. If index is None, the first maximum over all elements where labels is non-zero is returned. The index argument only works when labels is specified.

**Returns**

- **output** [list of tuples of ints] List of tuples of ints that specify the location of maxima of input over the regions determined by labels and whose index is in index. If index or labels are not specified, a tuple of ints is returned specifying the location of the first maximal value of input.

**See also:**

label, minimum, median, maximum\_position, extrema, sum, mean, variance, standard\_deviation

**Examples**

```python
>>> from scipy import ndimage
>>> a = np.array([[1, 2, 0, 0],
...                [5, 3, 0, 4],
...                [0, 0, 0, 7],
...                [9, 3, 0, 0]])
>>> ndimage.maximum_position(a)
(3, 0)
```

Features to process can be specified using labels and index:

```python
>>> lbl = np.array([[0, 1, 2, 3],
...                 [0, 1, 2, 3],
...                 [0, 1, 2, 3],
...                 [0, 1, 2, 3]])
>>> ndimage.maximum_position(a, lbl, 1)
(1, 1)
```

If no index is given, non-zero labels are processed:

```python
>>> ndimage.maximum_position(a, lbl)
(2, 3)
```

If there are no maxima, the position of the first element is returned:
scipy.ndimage.mean

scipy.ndimage.mean(input, labels=None, index=None)

Calculate the mean of the values of an array at labels.

Parameters

- **input** : array_like
  Array on which to compute the mean of elements over distinct regions.

- **labels** : array_like, optional
  Array of labels of same shape, or broadcastable to the same shape as input. All elements sharing the same label form one region over which the mean of the elements is computed.

- **index** : int or sequence of ints, optional
  Labels of the objects over which the mean is to be computed. Default is None, in which case the mean for all values where label is greater than 0 is calculated.

Returns

- **out** : list
  Sequence of same length as index, with the mean of the different regions labeled by the labels in index.

See also:

- variance, standard_deviation, minimum, maximum, sum, label

Examples

```python
>>> from scipy import ndimage
>>> a = np.arange(25).reshape((5,5))
>>> labels = np.zeros_like(a)
>>> labels[3:5,3:5] = 1
>>> index = np.unique(labels)
>>> labels
array([[0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0],
       [0, 0, 0, 1, 1],
       [0, 0, 0, 1, 1]])
>>> index
array([0, 1])
>>> ndimage.mean(a, labels=labels, index=index)
[10.285714285714286, 21.0]
```
scipy.ndimage.median

scipy.ndimage.median(input, labels=None, index=None)

Calculate the median of the values of an array over labeled regions.

Parameters

- **input** [array_like] Array_like of values. For each region specified by labels, the median value of input over the region is computed.
- **labels** [array_like, optional] An array_like of integers marking different regions over which the median value of input is to be computed. labels must have the same shape as input. If labels is not specified, the median over the whole array is returned.
- **index** [array_like, optional] A list of region labels that are taken into account for computing the medians. If index is None, the median over all elements where labels is non-zero is returned.

Returns

- **median** [float or list of floats] List of medians of input over the regions determined by labels and whose index is in index. If index or labels are not specified, a float is returned: the median value of input if labels is None, and the median value of elements where labels is greater than zero if index is None.

See also:

- label, minimum, maximum, extrema, sum, mean, variance, standard_deviation

Notes

The function returns a Python list and not a NumPy array, use np.array to convert the list to an array.

Examples

```python
>>> from scipy import ndimage
>>> a = np.array([[1, 2, 0, 1],
...               [5, 3, 0, 4],
...               [0, 0, 0, 7],
...               [9, 3, 0, 0]])
>>> labels, labels_nb = ndimage.label(a)
>>> labels
array([[1, 1, 0, 2],
       [1, 1, 0, 2],
       [0, 0, 0, 2],
       [3, 3, 0, 0]])
>>> ndimage.median(a, labels=labels, index=np.arange(1, labels_nb + 1))
[2.5, 4.0, 6.0]
>>> ndimage.median(a)
1.0
>>> ndimage.median(a, labels=labels)
3.0
```
scipy.ndimage.minimum

scipy.ndimage.minimum(input, labels=None, index=None)

Calculate the minimum of the values of an array over labeled regions.

Parameters

input : array_like
    Array_like of values. For each region specified by labels, the minimal values of input over the region is computed.

labels : array_like, optional
    An array_like of integers marking different regions over which the minimum value of input is to be computed. labels must have the same shape as input. If labels is not specified, the minimum over the whole array is returned.

index : array_like, optional
    A list of region labels that are taken into account for computing the minima. If index is None, the minimum over all elements where labels is non-zero is returned.

Returns

minimum : float or list of floats
    List of minima of input over the regions determined by labels and whose index is in index. If index or labels are not specified, a float is returned: the minimal value of input if labels is None, and the minimal value of elements where labels is greater than zero if index is None.

See also:

label, maximum, median, minimum_position, extrema, sum, mean, variance, standard_deviation

Notes

The function returns a Python list and not a NumPy array, use np.array to convert the list to an array.

Examples

```python
>>> from scipy import ndimage
>>> a = np.array([[[1, 2, 0, 0],
...                [5, 3, 0, 4]],
...                [[0, 0, 0, 7],
...                [9, 3, 0, 0]]])
>>> labels, labels_nb = ndimage.label(a)
>>> labels
array([[1, 1, 0, 0],
       [1, 0, 0, 2],
       [3, 3, 0, 0]])
>>> ndimage.minimum(a, labels=labels, index=np.arange(1, labels_nb + 1))
[1.0, 4.0, 3.0]
>>> ndimage.minimum(a)
0.0
>>> ndimage.minimum(a, labels=labels)
1.0
```
scipy.ndimage.minimum_position

**scipy.ndimage.minimum_position**(*input, labels=None, index=None*)

Find the positions of the minimums of the values of an array at labels.

**Parameters**

- **input** ([array_like]) Array_like of values.
- **labels** ([array_like, optional]) An array of integers marking different regions over which the position of the minimum value of *input* is to be computed. *labels* must have the same shape as *input*. If *labels* is not specified, the location of the first minimum over the whole array is returned. The *labels* argument only works when *index* is specified.
- **index** ([array_like, optional]) A list of region labels that are taken into account for finding the location of the minima. If *index* is None, the first minimum over all elements where *labels* is non-zero is returned. The *index* argument only works when *labels* is specified.

**Returns**

- **output** ([list of tuples of ints]) Tuple of ints or list of tuples of ints that specify the location of minima of *input* over the regions determined by *labels* and whose index is in *index*. If *index* or *labels* are not specified, a tuple of ints is returned specifying the location of the first minimal value of *input*.

See also:

- label, minimum, median, maximum_position, extrema, sum, mean, variance
- standard_deviation

**Examples**

```python
>>> a = np.array([[10, 20, 30],
...                [40, 80, 100],
...                [1, 100, 200]])
>>> b = np.array([[1, 2, 0, 1],
...                [5, 3, 0, 4],
...                [0, 0, 0, 7],
...                [9, 3, 0, 0]])
```

```python
>>> from scipy import ndimage

>>> ndimage.minimum_position(a)
(2, 0)
>>> ndimage.minimum_position(b)
(0, 2)
```

Features to process can be specified using *labels* and *index*:

```python
>>> label, pos = ndimage.label(a)
>>> ndimage.minimum_position(a, label, index=np.arange(1, pos+1))
[(2, 0)]
```
```python
>>> label, pos = ndimage.label(b)
>>> ndimage.minimum_position(b, label, index=np.arange(1, pos+1))
[(0, 0), (0, 3), (3, 1)]
```

**scipy.ndimage.standard_deviation**

`scipy.ndimage.standard_deviation` (input, labels=None, index=None)

Calculate the standard deviation of the values of an N-D image array, optionally at specified sub-regions.

**Parameters**

- **input** [array_like] N-D image data to process.
- **labels** [array_like, optional] Labels to identify sub-regions in `input`. If not None, must be same shape as `input`.
- **index** [int or sequence of ints, optional] `labels` to include in output. If None (default), all values where `labels` is non-zero are used.

**Returns**

- **standard_deviation** [float or ndarray] Values of standard deviation, for each sub-region if `labels` and `index` are specified.

See also:

- `label`, `variance`, `maximum`, `minimum`, `extrema`

**Examples**

```python
>>> a = np.array([[1, 2, 0, 0],
...                [5, 3, 0, 4],
...                [0, 0, 0, 7],
...                [9, 3, 0, 0]])
>>> from scipy import ndimage
>>> ndimage.standard_deviation(a)
2.7585095613392387
```

Features to process can be specified using `labels` and `index`:

```python
>>> lbl, nlbl = ndimage.label(a)
>>> ndimage.standard_deviation(a, lbl, index=np.arange(1, nlbl+1))
array([ 1.479, 1.5, 3. ])
```

If no index is given, non-zero `labels` are processed:

```python
>>> ndimage.standard_deviation(a, lbl)
2.4874685927665499
```
scipy.ndimage.sum_labels

scipy.ndimage.sum_labels(input, labels=None, index=None)

Calculate the sum of the values of the array.

Parameters

- **input** [array_like] Values of input inside the regions defined by labels are summed together.
- **labels** [array_like of ints, optional] Assign labels to the values of the array. Has to have the same shape as input.
- **index** [array_like, optional] A single label number or a sequence of label numbers of the objects to be measured.

Returns

- **sum** [ndarray or scalar] An array of the sums of values of input inside the regions defined by labels with the same shape as index. If ‘index’ is None or scalar, a scalar is returned.

See also:

- mean, median

Examples

```python
>>> from scipy import ndimage
>>> input = [0,1,2,3]
>>> labels = [1,1,2,2]
>>> ndimage.sum(input, labels, index=[1,2])
[1.0, 5.0]
>>> ndimage.sum(input, labels, index=1)
1
>>> ndimage.sum(input, labels)
6
```
Examples

```python
>>> a = np.array([[1, 2, 0, 0],
...                [5, 3, 0, 4],
...                [0, 0, 0, 7],
...                [9, 3, 0, 0]])
>>> from scipy import ndimage
>>> ndimage.variance(a)
7.609375
```

Features to process can be specified using `labels` and `index`:

```python
>>> lbl, nlbl = ndimage.label(a)
>>> ndimage.variance(a, lbl, index=np.arange(1, nlbl+1))
array([ 2.1875, 2.25, 9.])
```

If no index is given, all non-zero `labels` are processed:

```python
>>> ndimage.variance(a, lbl)
6.1875
```

### scipy.ndimage.watershed_ift

`scipy.ndimage.watershed_ift` *(input, markers, structure=None, output=None)*

Apply watershed from markers using image foresting transform algorithm.

**Parameters**

- `input` *[array_like]*: Input.
- `markers` *[array_like]*: Markers are points within each watershed that form the beginning of the process. Negative markers are considered background markers which are processed after the other markers.
- `structure` *[structure element, optional]*: A structuring element defining the connectivity of the object can be provided. If None, an element is generated with a squared connectivity equal to one.
- `output` *[ndarray, optional]*: An output array can optionally be provided. The same shape as input.

**Returns**

- `watershed_ift` *[ndarray]*: Output. Same shape as `input`.

**References**

6.17.5 Morphology

**binary_closing**(input[, structure, …])  Multidimensional binary closing with the given structuring element.

**binary_dilation**(input[, structure, …])  Multidimensional binary dilation with the given structuring element.

**binary_erosion**(input[, structure, …])  Multidimensional binary erosion with a given structuring element.

**binary_fill_holes**(input[, structure, …])  Fill the holes in binary objects.

**binary_hit_or_miss**(input[, structure1, …])  Multidimensional binary hit-or-miss transform.

**binary_opening**(input[, structure, …])  Multidimensional binary opening with the given structuring element.

**binary_propagation**(input[, structure, mask, …])  Multidimensional binary propagation with the given structuring element.

**black_tophat**(input[, size, footprint, …])  Multidimensional black tophat filter.

**distance_transform_bf**(input[, metric, …])  Distance transform function by a brute force algorithm.

**distance_transform_cdt**(input[, metric, …])  Distance transform for chamfer type of transforms.

**distance_transform_edt**(input[, sampling, …])  Exact Euclidean distance transform.

**generate_binary_structure**(rank, connectivity)  Generate a binary structure for binary morphological operations.

**grey_closing**(input[, size, footprint, …])  Multidimensional grayscale closing.

**grey_dilation**(input[, size, footprint, …])  Calculate a greyscale dilation, using either a structuring element, or a footprint corresponding to a flat structuring element.

**grey_erosion**(input[, size, footprint, …])  Calculate a greyscale erosion, using either a structuring element, or a footprint corresponding to a flat structuring element.

**grey_opening**(input[, size, footprint, …])  Multidimensional grayscale opening.

**iterate_structure**(structure, iterations[, …])  Iterate a structure by dilating it with itself.

**morphological_gradient**(input[, size, …])  Multidimensional morphological gradient.

**morphological_laplace**(input[, size, …])  Multidimensional morphological laplace.

**white_tophat**(input[, size, footprint, …])  Multidimensional white tophat filter.

---

**scipy.ndimage.binary_closing**

scipy.ndimage.binary_closing(input, structure=None, iterations=1, output=None, origin=0, mask=None, border_value=0, brute_force=False)

Multidimensional binary closing with the given structuring element.

The closing of an input image by a structuring element is the erosion of the dilation of the image by the structuring element.

**Parameters**

- **input**  [array_like] Binary array_like to be closed. Non-zero (True) elements form the subset to be closed.
- **structure**  [array_like, optional] Structuring element used for the closing. Non-zero elements are considered True. If no structuring element is provided an element is generated with a square connectivity equal to one (i.e., only nearest neighbors are connected to the center, diagonally-connected elements are not considered neighbors).
- **iterations**  [int, optional] The dilation step of the closing, then the erosion step are each repeated iterations times (one, by default). If iterations is less than 1, each operations is repeated until the result does not change anymore. Only an integer of iterations is accepted.
output [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.

origin [int or tuple of ints, optional] Placement of the filter, by default 0.

mask [array_like, optional] If a mask is given, only those elements with a True value at the corresponding mask element are modified at each iteration.

border_value [int (cast to 0 or 1), optional] Value at the border in the output array.

brute_force [boolean, optional] Memory condition: if False, only the pixels whose value was changed in the last iteration are tracked as candidates to be updated in the current iteration; if true all pixels are considered as candidates for update, regardless of what happened in the previous iteration. False by default.

Returns

binary_closing [ndarray of bools] Closing of the input by the structuring element.

See also:

grey_closing, binary_opening, binary_dilation, binary_erosion
generate_binary_structure

Notes

Closing [1] is a mathematical morphology operation [2] that consists in the succession of a dilation and an erosion of the input with the same structuring element. Closing therefore fills holes smaller than the structuring element.

Together with opening (binary_opening), closing can be used for noise removal.

Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((5,5), dtype=int)
>>> a[1:-1, 1:-1] = 1; a[2,2] = 0
>>> a
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
>>> # Closing removes small holes
>>> ndimage.binary_closing(a).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
```
>>> # Closing is the erosion of the dilation of the input
>>> ndimage.binary_dilation(a).astype(int)
array([[0, 1, 1, 1, 0],
       [1, 1, 1, 1, 1],
       [1, 1, 1, 1, 1],
       [1, 1, 1, 1, 1],
       [0, 1, 1, 1, 0]])

>>> ndimage.binary_erosion(ndimage.binary_dilation(a)).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])

>>> a = np.zeros((7, 7), dtype=int)
>>> a[1:6, 2:5] = 1; a[1:3, 3] = 0
>>> a
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 0, 1, 0, 0],
       [0, 0, 1, 0, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])

>>> # In addition to removing holes, closing can also
>>> # coarsen boundaries with fine hollows.
>>> ndimage.binary_closing(a).astype(int)
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])

>>> ndimage.binary_closing(a, structure=np.ones((2, 2))).astype(int)
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
scipy.ndimage.binary_dilation

scipy.ndimage.binary_dilation(input, structure=None, iterations=1, mask=None, output=None, border_value=0, origin=0, brute_force=False)

Multidimensional binary dilation with the given structuring element.

Parameters

input [array_like] Binary array_like to be dilated. Non-zero (True) elements form the subset to be dilated.
structure [array_like, optional] Structuring element used for the dilation. Non-zero elements are considered True. If no structuring element is provided an element is generated with a square connectivity equal to one.
iterations [int, optional] The dilation is repeated iterations times (one, by default). If iterations is less than 1, the dilation is repeated until the result does not change anymore. Only an integer of iterations is accepted.
mask [array_like, optional] If a mask is given, only those elements with a True value at the corresponding mask element are modified at each iteration.
output [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.
border_value [int (cast to 0 or 1), optional] Value at the border in the output array.
origin [int or tuple of ints, optional] Placement of the filter, by default 0.
brute_force [boolean, optional] Memory condition: if False, only the pixels whose value was changed in the last iteration are tracked as candidates to be updated (dilated) in the current iteration; if True all pixels are considered as candidates for dilation, regardless of what happened in the previous iteration. False by default.

Returns

binary_dilation [ndarray of bools] Dilation of the input by the structuring element.

See also:
grey_dilation, binary_erosion, binary_closing, binary_opening
generate_binary_structure

Notes

Dilation [1] is a mathematical morphology operation [2] that uses a structuring element for expanding the shapes in an image. The binary dilation of an image by a structuring element is the locus of the points covered by the structuring element, when its center lies within the non-zero points of the image.

(continues on next page)
scipy.ndimage.binary_erosion

scipy.ndimage.binary_erosion(input, structure=None, iterations=1, mask=None, output=None, border_value=0, origin=0, brute_force=False)

Multidimensional binary erosion with a given structuring element.

Binary erosion is a mathematical morphology operation used for image processing.

Parameters

- **input**: [array_like] Binary image to be eroded. Non-zero (True) elements form the subset to be eroded.
- **structure**: [array_like, optional] Structuring element used for the erosion. Non-zero elements are considered True. If no structuring element is provided, an element is generated with a square connectivity equal to one.
- **iterations**: [int, optional] The erosion is repeated *iterations* times (one, by default). If iterations is less than 1, the erosion is repeated until the result does not change anymore.
- **mask**: [array_like, optional] If a mask is given, only those elements with a True value at the corresponding mask element are modified at each iteration.
- **output**: [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.
- **border_value**: [int (cast to 0 or 1), optional] Value at the border in the output array.
- **origin**: [int or tuple of ints, optional] Placement of the filter, by default 0.
- **brute_force**: [boolean, optional] Memory condition: if False, only the pixels whose value was changed in the last iteration are tracked as candidates to be updated (eroded) in the current iteration; if True all pixels are considered as candidates for erosion, regardless of what happened in the previous iteration. False by default.

Returns

- **binary_erosion**: [ndarray of bools] Erosion of the input by the structuring element.

grey_erosion, binary_dilation, binary_closing, binary_opening

generate_binary_structure
Notes

Erosion [1] is a mathematical morphology operation [2] that uses a structuring element for shrinking the shapes in an image. The binary erosion of an image by a structuring element is the locus of the points where a superimposition of the structuring element centered on the point is entirely contained in the set of non-zero elements of the image.

Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((7,7), dtype=int)
>>> a[1:6, 2:5] = 1
>>> a
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
>>> ndimage.binary_erosion(a).astype(a.dtype)
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 1, 0, 0, 0],
       [0, 0, 0, 1, 0, 0, 0],
       [0, 0, 0, 1, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
>>> # Erosion removes objects smaller than the structure
>>> ndimage.binary_erosion(a, structure=np.ones((5,5))).astype(a.dtype)
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
```

**scipy.ndimage.binary_fill_holes**

The function `scipy.ndimage.binary_fill_holes` fills the holes in binary objects.

**Parameters**

- **input** [array_like] N-D binary array with holes to be filled
- **structure** [array_like, optional] Structuring element used in the computation; large-size elements make computations faster but may miss holes separated from the background by thin regions. The
default element (with a square connectivity equal to one) yields the intuitive result where all holes in the input have been filled.

**output** [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.

**origin** [int, tuple of ints, optional] Position of the structuring element.

**Returns**

**out** [ndarray] Transformation of the initial image *input* where holes have been filled.

See also:

*binary_dilation*, *binary_propagation*, *label*

**Notes**

The algorithm used in this function consists in invading the complementary of the shapes in *input* from the outer boundary of the image, using binary dilations. Holes are not connected to the boundary and are therefore not invaded. The result is the complementary subset of the invaded region.

**Examples**

```python
>>> from scipy import ndimage
>>> a = np.zeros((5, 5), dtype=int)
>>> a[1:4, 1:4] = 1
>>> a[2,2] = 0
>>> a
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 0, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
>>> ndimage.binary_fill_holes(a).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
>>> # Too big structuring element
>>> ndimage.binary_fill_holes(a, structure=np.ones((5,5))).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 0, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
```
scipy.ndimage.binary_hit_or_miss

scipy.ndimage.binary_hit_or_miss(input, structure1=None, structure2=None, output=None, origin1=0, origin2=None)

Multidimensional binary hit-or-miss transform.

The hit-or-miss transform finds the locations of a given pattern inside the input image.

**Parameters**

- **input** [array_like (cast to booleans)] Binary image where a pattern is to be detected.
- **structure1** [array_like (cast to booleans), optional] Part of the structuring element to be fitted to the foreground (non-zero elements) of input. If no value is provided, a structure of square connectivity 1 is chosen.
- **structure2** [array_like (cast to booleans), optional] Second part of the structuring element that has to miss completely the foreground. If no value is provided, the complementary of structure1 is taken.
- **output** [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.
- **origin1** [int or tuple of ints, optional] Placement of the first part of the structuring element structure1, by default 0 for a centered structure.
- **origin2** [int or tuple of ints, optional] Placement of the second part of the structuring element structure2, by default 0 for a centered structure. If a value is provided for origin1 and not for origin2, then origin2 is set to origin1.

**Returns**

- **binary_hit_or_miss** [ndarray] Hit-or-miss transform of input with the given structuring element (structure1, structure2).

       [0, 0, 0, 0, 0, 0, 0]])

scipy.ndimage.binary_opening

`scipy.ndimage.binary_opening(input, structure=None, iterations=1, output=None, origin=0, mask=None, border_value=0, brute_force=False)`

Multidimensional binary opening with the given structuring element.

The opening of an input image by a structuring element is the dilation of the erosion of the image by the structuring element.

**Parameters**

- `input` [array_like] Binary array_like to be opened. Non-zero (True) elements form the subset to be opened.
- `structure` [array_like, optional] Structuring element used for the opening. Non-zero elements are considered True. If no structuring element is provided an element is generated with a square connectivity equal to one (i.e., only nearest neighbors are connected to the center, diagonally-connected elements are not considered neighbors).
- `iterations` [int, optional] The erosion step of the opening, then the dilation step are each repeated `iterations` times (one, by default). If `iterations` is less than 1, each operation is repeated until the result does not change anymore. Only an integer of iterations is accepted.
- `output` [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.
- `origin` [int or tuple of ints, optional] Placement of the filter, by default 0.
- `mask` [array_like, optional] If a mask is given, only those elements with a True value at the corresponding mask element are modified at each iteration. New in version 1.1.0.
- `border_value` [int (cast to 0 or 1), optional] Value at the border in the output array. New in version 1.1.0.
brute_force

[boolean, optional] Memory condition: if False, only the pixels whose value was changed in the last iteration are tracked as candidates to be updated in the current iteration; if true all pixels are considered as candidates for update, regardless of what happened in the previous iteration. False by default.
New in version 1.1.0.

Returns

binary_opening

[ndarray of bools] Opening of the input by the structuring element.

See also:

grey_opening, binary_closing, binary_erosion, binary_dilation
generate_binary_structure

Notes

Opening [1] is a mathematical morphology operation [2] that consists in the succession of an erosion and a dilation of the input with the same structuring element. Opening, therefore, removes objects smaller than the structuring element.
Together with closing (binary_closing), opening can be used for noise removal.

Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((5,5), dtype=int)
>>> a[1:4, 1:4] = 1; a[4, 4] = 1
>>> a
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 1]])
>>> # Opening removes small objects
>>> ndimage.binary_opening(a, structure=np.ones((3,3))).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
>>> # Opening can also smooth corners
>>> ndimage.binary_opening(a).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0]]))
```
>>> # Opening is the dilation of the erosion of the input
>>> ndimage.binary_erosion(a).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0],
       [0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0]])

>>> ndimage.binary_dilation(ndimage.binary_erosion(a)).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 1, 0, 0],
       [0, 0, 0, 0, 0]])

scipy.ndimage.binary_propagation

scipy.ndimage.binary_propagation(input, structure=None, mask=None, output=None, border_value=0, origin=0)

Multidimensional binary propagation with the given structuring element.

Parameters

- **input** [array_like] Binary image to be propagated inside mask.
- **structure** [array_like, optional] Structuring element used in the successive dilations. The output may depend on the structuring element, especially if mask has several connex components. If no structuring element is provided, an element is generated with a squared connectivity equal to one.
- **mask** [array_like, optional] Binary mask defining the region into which input is allowed to propagate.
- **output** [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.
- **border_value** [int (cast to 0 or 1), optional] Value at the border in the output array.
- **origin** [int or tuple of ints, optional] Placement of the filter, by default 0.

Returns

- **binary_propagation** [ndarray] Binary propagation of input inside mask.

Notes

This function is functionally equivalent to calling binary_dilation with the number of iterations less than one: iterative dilation until the result does not change anymore.

The succession of an erosion and propagation inside the original image can be used instead of an opening for deleting small objects while keeping the contours of larger objects untouched.

Examples

```python
>>> from scipy import ndimage
>>> input = np.zeros((8, 8), dtype=int)
>>> input[2, 2] = 1
>>> mask = np.zeros((8, 8), dtype=int)
>>> input
array([[0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0]])
>>> mask
array([[0, 0, 0, 0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 0, 0, 0, 1, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 1, 1],
       [0, 0, 0, 0, 0, 0, 1, 1]])
>>> ndimage.binary_propagation(input, mask=mask).astype(int)
array([[0, 0, 0, 0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 0, 0, 0, 1, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 1, 1],
       [0, 0, 0, 0, 0, 0, 1, 1]])
>>> ndimage.binary_propagation(input, mask=mask, ... structure=np.ones((3, 3))).astype(int)
array([[0, 0, 0, 0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 0, 0, 0, 1, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 1, 1],
       [0, 0, 0, 0, 0, 0, 1, 1]])
>>> # Comparison between opening and erosion+propagation
>>> a = np.zeros((6, 6), dtype=int)
>>> a[2:5, 2:5] = 1; a[0, 0] = 1; a[5, 5] = 1
(continues on next page)
scipy.ndimage.black_tophat

scipy.ndimage.black_tophat (input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)

Multidimensional black tophat filter.

Parameters

- **input** [array_like] Input.
- **size** [tuple of ints, optional] Shape of a flat and full structuring element used for the filter. Optional if footprint or structure is provided.
- **footprint** [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the black tophat filter.
- **structure** [array of ints, optional] Structuring element used for the filter. structure may be a non-flat structuring element.
- **output** [array, optional] An array used for storing the output of the filter may be provided.
- **mode** [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The mode parameter determines how the array borders are handled, where cval is the value when mode is equal to ‘constant’. Default is ‘reflect’
- **cval** [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.
- **origin** [scalar, optional] The origin parameter controls the placement of the filter. Default 0

```python
>>> a
array([[1, 0, 0, 0, 0, 0],
        [0, 0, 0, 0, 0, 0],
        [0, 0, 1, 1, 1, 0],
        [0, 0, 1, 1, 1, 0],
        [0, 0, 1, 1, 1, 0],
        [0, 0, 0, 0, 0, 1]])
>>> ndimage.binary_opening(a).astype(int)
array([[0, 0, 0, 0, 0, 0],
        [0, 0, 0, 0, 0, 0],
        [0, 0, 0, 1, 0, 0],
        [0, 0, 1, 1, 1, 0],
        [0, 0, 0, 1, 0, 0],
        [0, 0, 0, 0, 0, 0]])
>>> b = ndimage.binary_erosion(a)
>>> b.astype(int)
array([[0, 0, 0, 0, 0, 0],
        [0, 0, 0, 0, 0, 0],
        [0, 0, 1, 0, 0, 0],
        [0, 0, 0, 0, 0, 0],
        [0, 0, 0, 0, 0, 0],
        [0, 0, 0, 0, 0, 0]])
>>> ndimage.binary_propagation(b, mask=a).astype(int)
array([[0, 0, 0, 0, 0, 0],
        [0, 0, 0, 1, 1, 1],
        [0, 0, 1, 1, 1, 0],
        [0, 0, 0, 0, 0, 0],
        [0, 0, 0, 0, 0, 0],
        [0, 0, 0, 0, 0, 0]])
```
black_tophat

[ndarray] Result of the filter of input with structure.

white_tophat, grey_opening, grey_closing

**scipy.ndimage.distance_transform_bf**

<table>
<thead>
<tr>
<th>Function:</th>
<th>scipy.ndimage.distance_transform_bf(input, metric='euclidean', sampling=None, return_distances=True, return_indices=False, distances=None, indices=None)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description:</td>
<td>Distance transform function by a brute force algorithm. This function calculates the distance transform of the input, by replacing each foreground (non-zero) element, with its shortest distance to the background (any zero-valued element). In addition to the distance transform, the feature transform can be calculated. In this case the index of the closest background element to each foreground element is returned in a separate array.</td>
</tr>
</tbody>
</table>

**Parameters**

- **input** [array_like] Input
- **metric** ['euclidean', 'taxicab', 'chessboard'], optional] 'cityblock' and 'manhattan' are also valid, and map to 'taxicab'. The default is 'euclidean'.
- **sampling** [float, or sequence of float, optional] This parameter is only used when metric is 'euclidean'. Spacing of elements along each dimension. If a sequence, must be of length equal to the input rank; if a single number, this is used for all axes. If not specified, a grid spacing of unity is implied.
- **return_distances** [bool, optional] Whether to calculate the distance transform. Default is True.
- **return_indices** [bool, optional] Whether to calculate the feature transform. Default is False.
- **distances** [ndarray, optional] An output array to store the calculated distance transform, instead of returning it. This parameter is only used when return_distances is True. It must be the same shape as input, and of type float64 if metric is 'euclidean', uint32 otherwise.
- **indices** [int32 ndarray, optional] An output array to store the calculated feature transform, instead of returning it. Its shape must be (input.ndim,) + input.shape.

**Returns**

- **distances** [ndarray, optional] The calculated distance transform. Returned only when return_distances is True and distances is not supplied. It will have the same shape as the input array.
- **indices** [int32 ndarray, optional] The calculated feature transform. It has an input-shaped array for each dimension of the input. See distance_transform_edt documentation for an example. Returned only when return_indices is True and indices is not supplied.
**Notes**

This function employs a slow brute force algorithm, see also the function `distance_transform_cdt` for more efficient taxicab and chessboard algorithms.

```python
scipy.ndimage.distance_transform_cdt
```

Distance transform for chamfer type of transforms.

In addition to the distance transform, the feature transform can be calculated. In this case the index of the closest background element to each foreground element is returned in a separate array.

**Parameters**

- `input` [array_like] Input
- `metric` [{'chessboard', 'taxicab'} or array_like, optional] The metric determines the type of chamfering that is done. If the metric is equal to 'taxicab' a structure is generated using `generate_binary_structure` with a squared distance equal to 1. If the metric is equal to 'chessboard', a metric is generated using `generate_binary_structure` with a squared distance equal to the dimensionality of the array. These choices correspond to the common interpretations of the 'taxicab' and the 'chessboard' distance metrics in two dimensions. A custom metric may be provided, in the form of a matrix where each dimension has a length of three. 'cityblock' and 'manhattan' are also valid, and map to 'taxicab'. The default is 'chessboard'.
- `return_distances` [bool, optional] Whether to calculate the distance transform. Default is True.
- `return_indices` [bool, optional] Whether to calculate the feature transform. Default is False.
- `distances` [int32 ndarray, optional] An output array to store the calculated distance transform, instead of returning it. This parameter is only used when `return_distances` is True. It must be the same shape as `input`.
- `indices` [int32 ndarray, optional] An output array to store the calculated feature transform, instead of returning it. Its shape must be `(input.ndim,) + input.shape`.

**Returns**

- `distances` [int32 ndarray, optional] The calculated distance transform. Returned only when `return_distances` is True, and `distances` is not supplied. It will have the same shape as the input array.
- `indices` [int32 ndarray, optional] The calculated feature transform. It has an input-shaped array for each dimension of the input. See `distance_transform_edt` documentation for an example. Returned only when `return_indices` is True, and `indices` is not supplied.

```python
scipy.ndimage.distance_transform_edt
```

Exact Euclidean distance transform.

In addition to the distance transform, the feature transform can be calculated. In this case the index of the closest background element to each foreground element is returned in a separate array.

**Parameters**

- `input` [array_like] Input data to transform. Can be any type but will be converted into binary: 1 wherever input equates to True, 0 elsewhere.
**Sampling** [float, or sequence of float, optional] Spacing of elements along each dimension. If a sequence, must be of length equal to the input rank; if a single number, this is used for all axes. If not specified, a grid spacing of unity is implied.

**Return_distances** [bool, optional] Whether to calculate the distance transform. Default is True.

**Return_indices** [bool, optional] Whether to calculate the feature transform. Default is False.

**Distances** [float64 ndarray, optional] An output array to store the calculated distance transform, instead of returning it. This parameter is only used when *return_distances* is True. It must be the same shape as *input*.

**Indices** [int32 ndarray, optional] An output array to store the calculated feature transform, instead of returning it. Its shape must be *(input.ndim,) + input.shape*. 

**Returns**

**Distances** [float64 ndarray, optional] The calculated distance transform. Returned only when *return_distances* is True and *distances* is not supplied. It will have the same shape as the input array.

**Indices** [int32 ndarray, optional] The calculated feature transform. It has an input-shaped array for each dimension of the input. See example below. Returned only when *return_indices* is True and *indices* is not supplied.

**Notes**

The Euclidean distance transform gives values of the Euclidean distance:

\[
y_i = \sqrt{\sum_{i} (x[i] - b[i])^2}
\]

where b[i] is the background point (value 0) with the smallest Euclidean distance to input points x[i], and n is the number of dimensions.

**Examples**

```python
>>> from scipy import ndimage
>>> a = np.array([[[0, 1, 1, 1, 1],
                 [0, 0, 1, 1, 1],
                 [0, 1, 1, 1, 1],
                 [0, 1, 1, 1, 1],
                 [0, 1, 1, 1, 0]],
                ...
               ])
>>> ndimage.distance_transform_edt(a)
array([[ 0. , 1. , 1.4142, 2.2361, 3. ],
       [ 0. , 0. , 1. , 2. , 2. ],
       [ 0. , 1. , 1.4142, 1.4142, 1. ],
       [ 0. , 1. , 1.4142, 1. , 0. ],
       [ 0. , 1. , 1. , 0. , 0. ]])
```

With a sampling of 2 units along x, 1 along y:

```python
>>> ndimage.distance_transform_edt(a, sampling=[2, 1])
array([[ 0. , 1. , 2. , 2.8284, 3.6056],
       [ 0. , 0. , 1. , 2. , 3. ]],
      (continues on next page)
```
Asking for indices as well:

```python
>>> edt, inds = ndimage.distance_transform_edt(a, return_indices=True)
>>> inds
array([[[0, 0, 1, 1, 3],
        [1, 1, 1, 1, 3],
        [2, 2, 1, 3, 3],
        [3, 3, 4, 4, 3],
        [4, 4, 4, 4, 4]],
       [[0, 0, 1, 1, 4],
        [0, 1, 1, 1, 4],
        [0, 0, 1, 4, 4],
        [0, 0, 3, 3, 4],
        [0, 0, 3, 3, 4]]])
```

With arrays provided for inplace outputs:

```python
>>> indices = np.zeros((np.ndim(a),) + a.shape, dtype=np.int32)
>>> ndimage.distance_transform_edt(a, return_indices=True, indices=indices)
array([[ 0. , 1. , 1.4142, 2.2361, 3. ],
       [ 0. , 0. , 1. , 2. , 2. ],
       [ 0. , 1. , 1.4142, 1.4142, 1. ],
       [ 0. , 1. , 1.4142, 1. , 0. ],
       [ 0. , 1. , 1. , 0. , 0. ]])
>>> indices
array([[[0, 0, 1, 1, 3],
        [1, 1, 1, 1, 3],
        [2, 2, 1, 3, 3],
        [3, 3, 4, 4, 3],
        [4, 4, 4, 4, 4]],
       [[0, 0, 1, 1, 4],
        [0, 1, 1, 1, 4],
        [0, 0, 1, 4, 4],
        [0, 0, 3, 3, 4],
        [0, 0, 3, 3, 4]]])
```

### scipy.ndimage.generate_binary_structure

**scipy.ndimage.generate_binary_structure** *(rank, connectivity)*

Generate a binary structure for binary morphological operations.

**Parameters**

- **rank** [int] Number of dimensions of the array to which the structuring element will be applied, as returned by `np.ndim`.
- **connectivity** [int] `connectivity` determines which elements of the output array belong to the structure, i.e., are considered as neighbors of the central element. Elements up to a squared distance of
connectivity from the center are considered neighbors. connectivity may range from 1 (no diagonal elements are neighbors) to rank (all elements are neighbors).

Returns

**output** [ndarray of bools] Structuring element which may be used for binary morphological operations, with rank dimensions and all dimensions equal to 3.

See also:

iterate_structure, binary_dilation, binary_erosion

Notes

generate_binary_structure can only create structuring elements with dimensions equal to 3, i.e., minimal dimensions. For larger structuring elements, that are useful e.g., for eroding large objects, one may either use iterate_structure, or create directly custom arrays with numpy functions such as numpy.ones.

Examples

```python
>>> from scipy import ndimage
>>> struct = ndimage.generate_binary_structure(2, 1)
>>> struct
array([[False,  True, False],
       [ True,  True,  True],
       [False,  True, False]], dtype=bool)
>>> a = np.zeros((5,5))
>>> a[2, 2] = 1
>>> a
array([[ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.]], dtype=bool)
>>> b = ndimage.binary_dilation(a, structure=struct).astype(a.dtype)
>>> b
array([[ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  1.,  1.,  1.,  0.],
       [ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.]], dtype=bool)
>>> ndimage.binary_dilation(b, structure=struct).astype(a.dtype)
array([[ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  1.,  1.,  1.,  0.],
       [ 1.,  1.,  1.,  1.,  1.],
       [ 0.,  1.,  1.,  1.,  0.],
       [ 0.,  0.,  1.,  0.,  0.]], dtype=bool)
>>> struct = ndimage.generate_binary_structure(2, 2)
>>> struct
array([[ True,  True,  True],
       [ True,  True,  True],
       [ True,  True,  True]], dtype=bool)
>>> struct = ndimage.generate_binary_structure(3, 1)
```
>>> struct # no diagonal elements
array([[False, False, False],
[False, True, False],
[False, False, False],
[[False, True, False],
[True, True, True],
[False, True, False],
[False, False, False],
[False, True, False],
[False, False, False]], dtype=bool)

scipy.ndimage.grey_closing

scipy.ndimage.grey_closing(input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)

Multidimensional grayscale closing.

A grayscale closing consists in the succession of a grayscale dilation, and a grayscale erosion.

Parameters

- **input**: [array_like] Array over which the grayscale closing is to be computed.
- **size**: [tuple of ints] Shape of a flat and full structuring element used for the grayscale closing. Optional if footprint or structure is provided.
- **footprint**: [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the grayscale closing.
- **structure**: [array of ints, optional] Structuring element used for the grayscale closing. structure may be a non-flat structuring element.
- **output**: [array, optional] An array used for storing the output of the closing may be provided.
- **mode**: [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The mode parameter determines how the array borders are handled, where cval is the value when mode is equal to ‘constant’. Default is ‘reflect’
- **cval**: [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.
- **origin**: [scalar, optional] The origin parameter controls the placement of the filter. Default 0

Returns

- **grey_closing**: [ndarray] Result of the grayscale closing of input with structure.

See also:

- **binary_closing**, **grey_dilation**, **grey_erosion**, **grey_opening**
- **generate_binary_structure**
Notes

The action of a grayscale closing with a flat structuring element amounts to smoothen deep local minima, whereas binary closing fills small holes.

Examples

```python
>>> from scipy import ndimage
>>> a = np.arange(36).reshape((6, 6))
>>> a[3, 3] = 0
>>> a
array([[ 0,  1,  2,  3,  4,  5],
       [ 6,  7,  8,  9, 10, 11],
       [12, 13, 14, 15, 16, 17],
       [18, 19,  20,  22,  23],
       [24, 25,  26,  28,  29],
       [30, 31, 32, 33, 34, 35]])
>>> ndimage.grey_closing(a, size=(3, 3))
array([[ 7,  7,  8,  9, 10, 11],
       [ 7,  7,  8,  9, 10, 11],
       [13, 13, 14, 15, 16, 17],
       [19, 19,  20,  22,  23],
       [25, 25,  26,  28,  29],
       [31, 31, 32, 33, 34, 35]])
>>> # Note that the local minimum a[3,3] has disappeared
```

scipy.ndimage.grey_dilation

`scipy.ndimage.grey_dilation(input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)`

Calculate a greyscale dilation, using either a structuring element, or a footprint corresponding to a flat structuring element.

Grayscale dilation is a mathematical morphology operation. For the simple case of a full and flat structuring element, it can be viewed as a maximum filter over a sliding window.

Parameters

- **input** [array_like] Array over which the greyscale dilation is to be computed.
- **size** [tuple of ints] Shape of a flat and full structuring element used for the greyscale dilation. Optional if `footprint` or `structure` is provided.
- **footprint** [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the greyscale dilation. Non-zero values give the set of neighbors of the center over which the maximum is chosen.
- **structure** [array of ints, optional] Structuring element used for the greyscale dilation. `structure` may be a non-flat structuring element.
- **output** [array, optional] An array used for storing the output of the dilation may be provided.
mode      [{'reflect','constant','nearest','mirror','wrap'},optional] The mode parameter determines how the array borders are handled, where val is the value when mode is equal to 'constant'. Default is 'reflect'
cval      [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
origin    [scalar, optional] The origin parameter controls the placement of the filter. Default 0

Returns

grey_dilation
    [ndarray] Grayscale dilation of input.

binary_dilation, grey_erosion, grey_closing, grey_opening

generate_binary_structure, maximum_filter

Notes

The grayscale dilation of an image input by a structuring element s defined over a domain E is given by:

\[(\text{input}+s)(x) = \max\{\text{input}(y) + s(x-y), \text{for } y \in E\}\]

In particular, for structuring elements defined as s(y) = 0 for y in E, the grayscale dilation computes the maximum of the input image inside a sliding window defined by E.

Grayscale dilation [1] is a mathematical morphology operation [2].

Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((7,7), dtype=int)
>>> a[2:5, 2:5] = 1
>>> a[4,4] = 2; a[2,3] = 3
>>> a
array([[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 1, 3, 1, 0, 0],
[0, 0, 1, 1, 1, 0, 0],
[0, 0, 1, 1, 2, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0]])
>>> ndimage.grey_dilation(a, size=(3,3))
array([[0, 0, 0, 0, 0, 0, 0],
[0, 1, 3, 3, 3, 1, 0],
[0, 1, 3, 3, 3, 1, 0],
[0, 1, 3, 3, 2, 0, 0],
[0, 1, 1, 2, 2, 2, 0],
[0, 1, 1, 2, 2, 2, 0],
[0, 0, 0, 0, 0, 0, 0]])
```

(continues on next page)
>>> ndimage.grey_dilation(a, footprint=np.ones((3,3)))
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 1, 3, 3, 3, 1, 0],

       [0, 1, 1, 2, 2, 0],
       [0, 0, 0, 0, 0, 0]])

>>> s = ndimage.generate_binary_structure(2,1)

>>> s
array([[False,  True, False],
       [ True,  True,  True],
       [False,  True, False]], dtype=bool)

>>> ndimage.grey_dilation(a, footprint=s)
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 3, 1, 0, 0],
       [0, 1, 3, 3, 3, 1, 0],
       [0, 1, 1, 3, 2, 1, 0],
       [0, 1, 1, 2, 2, 2, 0],
       [0, 0, 1, 1, 2, 0, 0],
       [0, 0, 0, 0, 0, 0]])

>>> ndimage.grey_dilation(a, size=(3,3), structure=np.ones((3,3)))
array([[1, 1, 1, 1, 1, 1, 1],
       [1, 2, 4, 4, 4, 2, 1],
       [1, 2, 4, 4, 4, 2, 1],
       [1, 2, 4, 4, 4, 3, 1],
       [1, 2, 2, 3, 3, 3, 1],
       [1, 2, 2, 3, 3, 3, 1],
       [1, 1, 1, 1, 1, 1, 1]])

scipy.ndimage.grey_erosion

Calculate a greyscale erosion, using either a structuring element, or a footprint corresponding to a flat structuring element.

Grayscale erosion is a mathematical morphology operation. For the simple case of a full and flat structuring element, it can be viewed as a minimum filter over a sliding window.

**Parameters**

- **input** [array_like] Array over which the grayscale erosion is to be computed.
- **size** [tuple of ints] Shape of a flat and full structuring element used for the grayscale erosion. Optional if `footprint` or `structure` is provided.
- **footprint** [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the grayscale erosion. Non-zero values give the set of neighbors of the center over which the minimum is chosen.
- **structure** [array of ints, optional] Structuring element used for the grayscale erosion. `structure` may be a non-flat structuring element.
- **output** [array, optional] An array used for storing the output of the erosion may be provided.
- **mode** [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The `mode` parameter determines how the array borders are handled, where `cval` is the value when mode is equal to ‘constant’. 
- **cval** [0.0, optional] Value to fill past edges of input if `mode` is equal to ‘constant’.
Default is ‘reflect’

**cval**
[scalar, optional] Value to fill past edges of input if  mode is ‘constant’. Default is 0.0.

**origin**
[scalar, optional] The origin parameter controls the placement of the filter. Default 0

**Returns**

**output**
[ndarray] Grayscale erosion of  input.

See also:

- `binary_erosion`
- `grey_dilation`
- `grey_opening`
- `grey_closing`
- `generate_binary_structure`
- `minimum_filter`

**Notes**

The grayscale erosion of an image input by a structuring element  defined over a domain  is given by:

\[(input + s)(x) = \min\{input(y) - s(x-y), \text{for } y \in E\}\]

In particular, for structuring elements defined as  for  in , the grayscale erosion computes the minimum of the input image inside a sliding window defined by .

Grayscale erosion [1] is a mathematical morphology operation [2].

**Examples**

```python
>>> from scipy import ndimage
>>> a = np.zeros((7,7), dtype=int)
>>> a[1:6, 1:6] = 3
>>> a[4,4] = 2; a[2,3] = 1
>>> a
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 3, 3, 3, 3, 3, 0],
       [0, 3, 3, 1, 3, 3, 0],
       [0, 3, 3, 3, 3, 3, 0],
       [0, 3, 3, 3, 2, 3, 0],
       [0, 3, 3, 3, 3, 3, 0],
       [0, 0, 0, 0, 0, 0, 0]])
>>> ndimage.grey_erosion(a, size=(3,3))
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 3, 2, 2, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
>>> footprint = ndimage.generate_binary_structure(2, 1)
>>> footprint
array([[False,  True, False],
       [False,  True, False]])
```
```python
>>> [[True, True, True],
     [False, True, False]], dtype=bool

>>> # Diagonally-connected elements are not considered neighbors
>>> ndimage.grey_erosion(a, size=(3,3), footprint=footprint)
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 3, 1, 2, 0, 0],
       [0, 0, 3, 2, 2, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
```

**scipy.ndimage.grey_opening**

`scipy.ndimage.grey_opening(input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)`

Multidimensional grayscale opening.

A grayscale opening consists in the succession of a grayscale erosion, and a grayscale dilation.

**Parameters**

- **input** [array_like] Array over which the grayscale opening is to be computed.
- **size** [tuple of ints] Shape of a flat and full structuring element used for the grayscale opening. Optional if `footprint` or `structure` is provided.
- **footprint** [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the grayscale opening.
- **structure** [array of ints, optional] Structuring element used for the grayscale opening. `structure` may be a non-flat structuring element.
- **output** [array, optional] An array used for storing the output of the opening may be provided.
- **mode** [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The `mode` parameter determines how the array borders are handled, where `cval` is the value when mode is equal to ‘constant’. Default is ‘reflect’.
- **cval** [scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0.
- **origin** [scalar, optional] The `origin` parameter controls the placement of the filter. Default 0

**Returns**

- **grey_opening** [ndarray] Result of the grayscale opening of `input` with `structure`.

**See also:**

- `binary_opening`, `grey_dilation`, `grey_erosion`, `grey_closing`
- `generate_binary_structure`
Notes

The action of a grayscale opening with a flat structuring element amounts to smoothen high local maxima, whereas binary opening erases small objects.

Examples

```python
>>> from scipy import ndimage
>>> a = np.arange(36).reshape((6, 6))
>>> a[3, 3] = 50
>>> a
array([[ 0,  1,  2,  3,  4,  5],
       [ 6,  7,  8,  9, 10, 11],
       [12, 13, 14, 15, 16, 17],
       [18, 19, 20, 21, 22, 23],
       [24, 25, 26, 27, 28, 29],
       [30, 31, 32, 33, 34, 35]])
>>> ndimage.grey_opening(a, size=(3, 3))
array([[ 0,  1,  2,  3,  4,  4],
       [ 6,  7,  8,  9, 10, 10],
       [12, 13, 14, 15, 16, 16],
       [18, 19, 20, 21, 22, 22],
       [24, 25, 26, 27, 28, 28],
       [24, 25, 26, 27, 28, 28]])
>>> # Note that the local maximum a[3,3] has disappeared
```

scipy.ndimage.iterate_structure

scipy.ndimage.iterate_structure(structure, iterations, origin=None)

Iterate a structure by dilating it with itself.

Parameters

structure  [array_like] Structuring element (an array of bools, for example), to be dilated with itself.
iterations  [int] number of dilations performed on the structure with itself
origin      [optional] If origin is None, only the iterated structure is returned. If not, a tuple of the iterated structure and the modified origin is returned.

Returns

iterate_structure  [ndarray of bools] A new structuring element obtained by dilating structure (iterations - 1) times with itself.

See also:

generate_binary_structure
Examples

```python
>>> from scipy import ndimage
>>> struct = ndimage.generate_binary_structure(2, 1)
>>> struct.astype(int)
array([[0, 1, 0],
       [1, 1, 1],
       [0, 1, 0]])
>>> ndimage.iterate_structure(struct, 2).astype(int)
array([[0, 0, 1, 0, 0],
       [0, 1, 1, 1, 0],
       [1, 1, 1, 1, 1],
       [0, 1, 1, 1, 0],
       [0, 0, 1, 0, 0]])
>>> ndimage.iterate_structure(struct, 3).astype(int)
array([[0, 0, 0, 1, 0, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 1, 1, 1, 1, 1, 0],
       [1, 1, 1, 1, 1, 1, 1],
       [0, 1, 1, 1, 1, 1, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 0, 1, 0, 0, 0]])
```

scipy.ndimage.morphological_gradient

scipy.ndimage.morphological_gradient (input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)

Multidimensional morphological gradient.

The morphological gradient is calculated as the difference between a dilation and an erosion of the input with a given structuring element.

Parameters

- **input** [array_like] Array over which to compute the morphological gradient.
- **size** [tuple of ints] Shape of a flat and full structuring element used for the mathematical morphology operations. Optional if footprint or structure is provided. A larger size yields a more blurred gradient.
- **footprint** [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the morphology operations. Larger footprints give a more blurred morphological gradient.
- **structure** [array of ints, optional] Structuring element used for the morphology operations. structure may be a non-flat structuring element.
- **output** [array, optional] An array used for storing the output of the morphological gradient may be provided.
- **mode** [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional The mode parameter determines how the array borders are handled, where cval is the value when mode is equal to ‘constant’. Default is ‘reflect’
- **cval** [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.
- **origin** [scalar, optional] The origin parameter controls the placement of the filter. Default 0

Returns

- **morphological_gradient** [ndarray] Morphological gradient of input.
See also:

grey_dilation, grey_erosion, gaussian_gradient_magnitude

Notes

For a flat structuring element, the morphological gradient computed at a given point corresponds to the maximal difference between elements of the input among the elements covered by the structuring element centered on the point.

Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((7, 7), dtype=int)
>>> a[2:5, 2:5] = 1
>>> ndimage.morphological_gradient(a, size=(3,3))
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 1, 1, 1, 1, 1, 0],
       [0, 1, 1, 1, 1, 1, 0],
       [0, 1, 1, 0, 1, 1, 0],
       [0, 1, 1, 1, 1, 1, 0],
       [0, 1, 1, 1, 1, 1, 0],
       [0, 0, 0, 0, 0, 0, 0]])
>>> # The morphological gradient is computed as the difference
>>> # between a dilation and an erosion
>>> ndimage.grey_dilation(a, size=(3,3)) -
... ndimage.grey_erosion(a, size=(3,3))
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 1, 1, 1, 1, 1, 0],
       [0, 1, 1, 1, 1, 1, 0],
       [0, 1, 1, 0, 1, 1, 0],
       [0, 1, 1, 1, 1, 1, 0],
       [0, 1, 1, 1, 1, 1, 0],
       [0, 0, 0, 0, 0, 0, 0]])
>>> a = np.zeros((7, 7), dtype=int)
>>> a[2:5, 2:5] = 1
>>> a[4,4] = 2; a[2,3] = 3
>>> a
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 3, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 2, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
>>> ndimage.morphological_gradient(a, size=(3,3))
```

(continues on next page)
scipy.ndimage.morphological_laplace

scipy.ndimage.morphological_laplace(input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)

Multidimensional morphological laplace.

Parameters

- **input**: [array_like] Input.
- **size** [int or sequence of ints, optional] See structure.
- **footprint** [bool or ndarray, optional] See structure.
- **structure** [structure, optional] Either size, footprint, or the structure must be provided.
- **output** [ndarray, optional] An output array can optionally be provided.
- **mode** [['reflect', 'constant', 'nearest', 'mirror', 'wrap'], optional] The mode parameter determines how the array borders are handled. For 'constant' mode, values beyond borders are set to be cval. Default is 'reflect'.
- **cval** [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0
- **origin** [origin, optional] The origin parameter controls the placement of the filter.

Returns

**morphological_laplace**

[ndarray] Output

scipy.ndimage.white_tophat

scipy.ndimage.white_tophat(input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)

Multidimensional white tophat filter.

Parameters

- **input** [array_like] Input.
- **size** [tuple of ints] Shape of a flat and full structuring element used for the filter. Optional if footprint or structure is provided.
- **footprint** [array of ints, optional] Positions of elements of a flat structuring element used for the white tophat filter.
- **structure** [array of ints, optional] Structuring element used for the filter. structure may be a non-flat structuring element.
- **output** [array, optional] An array used for storing the output of the filter may be provided.
- **mode** [['reflect', 'constant', 'nearest', 'mirror', 'wrap'], optional] The mode parameter determines how the array borders are handled, where cval is the value when mode is equal to 'constant'. Default is 'reflect'.
- **cval** [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
- **origin** [scalar, optional] The origin parameter controls the placement of the filter. Default is 0.
Returns

output  [ndarray] Result of the filter of input with structure.

**scipy.odr.Data**

```python
class scipy.odr.Data (x, y=None, we=None, wd=None, fix=None, meta={})
```

The data to fit.

**Parameters**

- `x` [array_like] Observed data for the independent variable of the regression
- `y` [array_like, optional] If array-like, observed data for the dependent variable of the regression. A scalar input implies that the model to be used on the data is implicit.
- `we` [array_like, optional] If `we` is a scalar, then that value is used for all data points (and all dimensions of the response variable). If `we` is a rank-1 array of length q (the dimensionality of the response variable), then this vector is the diagonal of the covariant weighting matrix for all data points. If `we` is a rank-1 array of length n (the number of data points), then the i'th element is the weight for the i'th response variable observation (single-dimensional only). If `we` is a rank-2 array of shape (q, q), then this is the full covariant weighting matrix broadcast to each observation. If `we` is a rank-2 array of shape (q, n), then `we[:,i]` is the diagonal of the covariant weighting matrix for the i'th observation. If `we` is a rank-3 array of shape (q, q, n),
then \( we[:,:,i] \) is the full specification of the covariant weighting matrix for each observation. If the fit is implicit, then only a positive scalar value is used.

**wd**

[array_like, optional] If \( wd \) is a scalar, then that value is used for all data points (and all dimensions of the input variable). If \( wd = 0 \), then the covariant weighting matrix for each observation is set to the identity matrix (so each dimension of each observation has the same weight). If \( wd \) is a rank-1 array of length \( m \) (the dimensionality of the input variable), then this vector is the diagonal of the covariant weighting matrix for all data points. If \( wd \) is a rank-1 array of length \( n \) (the number of data points), then the \( i \)’th element is the weight for the \( i \)th input variable observation (single-dimensional only). If \( wd \) is a rank-2 array of shape \((m, m)\), then this is the full covariant weighting matrix broadcast to each observation. If \( wd \) is a rank-2 array of shape \((m, n)\), then \( wd[:,:,i] \) is the diagonal of the covariant weighting matrix for the \( i \)th observation. If \( wd \) is a rank-3 array of shape \((m, m, n)\), then \( wd[:,:,i] \) is the full specification of the covariant weighting matrix for each observation.

**fix**

[array_like of ints, optional] The \( fix \) argument is the same as \( ifixx \) in the class ODR. It is an array of integers with the same shape as \( data.x \) that determines which input observations are treated as fixed. One can use a sequence of length \( m \) (the dimensionality of the input observations) to fix some dimensions for all observations. A value of 0 fixes the observation, a value \( > 0 \) makes it free.

**meta**

---

**Notes**

Each argument is attached to the member of the instance of the same name. The structures of \( x \) and \( y \) are described in the Model class docstring. If \( y \) is an integer, then the Data instance can only be used to fit with implicit models where the dimensionality of the response is equal to the specified value of \( y \).

The \( we \) argument weights the effect a deviation in the response variable has on the fit. The \( wd \) argument weights the effect a deviation in the input variable has on the fit. To handle multidimensional inputs and responses easily, the structure of these arguments has the \( n \)'th dimensional axis first. These arguments heavily use the structured arguments feature of ODRPACK to conveniently and flexibly support all options. See the ODRPACK User's Guide for a full explanation of how these weights are used in the algorithm. Basically, a higher value of the weight for a particular data point makes a deviation at that point more detrimental to the fit.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>set_meta</code>&lt;sup&gt;self,<strong>kwds</strong>&lt;/sup&gt;</td>
<td>Update the metadata dictionary with the keywords and data provided by keywords.</td>
</tr>
</tbody>
</table>

**scipy.odr.Data.set_meta**

Data.set_meta (self,**kwds)

Update the metadata dictionary with the keywords and data provided by keywords.
Examples

```python
data.set_meta(lab="Ph 7; Lab 26", title="Ag110 + Ag108 Decay")
```

**scipy.odr.RealData**

```python
class scipy.odr.RealData(x, y=None, sx=None, sy=None, covx=None, covy=None, fix=None, meta={})
```

The data, with weightings as actual standard deviations and/or covariances.

**Parameters**

- **x**  
  
  [array_like] Observed data for the independent variable of the regression

- **y**  
  
  [array_like, optional] If array-like, observed data for the dependent variable of the regression. A scalar input implies that the model to be used on the data is implicit.

- **sx**  
  
  [array_like, optional] Standard deviations of $x$. $sx$ are standard deviations of $x$ and are converted to weights by dividing 1.0 by their squares.

- **sy**  
  
  [array_like, optional] Standard deviations of $y$. $sy$ are standard deviations of $y$ and are converted to weights by dividing 1.0 by their squares.

- **covx**  
  
  [array_like, optional] Covariance of $x$. $covx$ is an array of covariance matrices of $x$ and are converted to weights by performing a matrix inversion on each observation’s covariance matrix.

- **covy**  
  
  [array_like, optional] Covariance of $y$. $covy$ is an array of covariance matrices and are converted to weights by performing a matrix inversion on each observation’s covariance matrix.

- **fix**  
  
  [array_like, optional] The argument and member fix is the same as Data.fix and ODR.ifixx: It is an array of integers with the same shape as $x$ that determines which input observations are treated as fixed. One can use a sequence of length m (the dimensionality of the input observations) to fix some dimensions for all observations. A value of 0 fixes the observation, a value > 0 makes it free.

- **meta**  
  

**Notes**

The weights $wd$ and $we$ are computed from provided values as follows:

- $sx$ and $sy$ are converted to weights by dividing 1.0 by their squares. For example, $wd = 1./\text{numpy.power(sx, 2)}$.

- $covx$ and $covy$ are arrays of covariance matrices and are converted to weights by performing a matrix inversion on each observation’s covariance matrix. For example, $we[i] = \text{numpy.linalg.inv(covy[i])}$.

These arguments follow the same structured argument conventions as wd and we only restricted by their natures: $sx$ and $sy$ can’t be rank-3, but $covx$ and $covy$ can be.

Only set either $sx$ or $covx$ (not both). Setting both will raise an exception. Same with $sy$ and $covy$. 
Methods

```
set_meta(self, **kwds)  Update the metadata dictionary with the keywords and
data provided by keywords.
```

**scipy.odr.RealData.set_meta**

RealData.set_meta(self, **kwds)

Update the metadata dictionary with the keywords and data provided by keywords.

**Examples**

```
data.set_meta(lab="Ph 7; Lab 26", title="Ag110 + Ag108 Decay")
```

**scipy.odr.Model**

```
class scipy.odr.Model(fcn, fjacb=None, fjacd=None, extra_args=None, estimate=None, implicit=0, meta=None)
```

The Model class stores information about the function you wish to fit.

It stores the function itself, at the least, and optionally stores functions which compute the Jacobians used during fitting. Also, one can provide a function that will provide reasonable starting values for the fit parameters possibly given the set of data.

**Parameters**

- **fcn** [function] fcn(beta, x) \(\rightarrow\) y
- **fjacb** [function] Jacobian of fcn wrt the fit parameters beta.
  fjacb(beta, x) \(\rightarrow\) @f_i(x,B)/@B_j
- **fjacd** [function] Jacobian of fcn wrt the (possibly multidimensional) input variable.
  fjacd(beta, x) \(\rightarrow\) @f_i(x,B)/@x_j
- **extra_args** [tuple, optional] If specified, extra_args should be a tuple of extra arguments to pass to fcn, fjacb, and fjacd. Each will be called by apply(fcn, (beta, x) + extra_args)
- **estimate** [array_like of rank-1] Provides estimates of the fit parameters from the data
  estimate(data) \(\rightarrow\) estbeta
- **implicit** [boolean] If TRUE, specifies that the model is implicit; i.e fcn(beta, x) \(~=\) 0 and there is no y data to fit against
- **meta** [dict, optional] freeform dictionary of metadata for the model

**Notes**

Note that the fcn, fjacb, and fjacd operate on NumPy arrays and return a NumPy array. The estimate object takes an instance of the Data class.

Here are the rules for the shapes of the argument and return arrays of the callback functions:

- **x** if the input data is single-dimensional, then x is rank-1 array; i.e., x = array([1, 2, 3, ...]); x.shape = (n,)
  If the input data is multi-dimensional, then x is a rank-2 array; i.e., x = array([[1, 2, ...], [2, 4, ...]]); x.shape = (m, n). In all cases, it has the same shape as the input data array passed to odr. m is the dimensionality of the input data, n is the number of observations.
if the response variable is single-dimensional, then \( y \) is a rank-1 array, i.e., \( y = \text{array}([2, 4, \ldots]) \); \( y.\text{shape} = (n,) \). If the response variable is multi-dimensional, then \( y \) is a rank-2 array, i.e., \( y = \text{array}([[[2, 4, \ldots]], [[3, 6, \ldots]]]) \); \( y.\text{shape} = (q, n) \) where \( q \) is the dimensionality of the response variable.

**beta**

rank-1 array of length \( p \) where \( p \) is the number of parameters; i.e. \( \text{beta} = \text{array}([B_1, B_2, \ldots, B_p]) \)

**fjacb**

if the response variable is multi-dimensional, then the return array's shape is \((q, p, n)\) such that \( \text{fjacb}(x, \text{beta})[l,k,i] = d f_l(X,B)/d B_k \) evaluated at the \( i \)th data point. If \( q == 1 \), then the return array is only rank-2 and with shape \((p, n)\).

**fjacd**

as with fjacb, only the return array's shape is \((q, m, n)\) such that \( \text{fjacd}(x, \text{beta})[l,j,i] = d f_l(X,B)/d X_j \) at the \( i \)th data point. If \( q == 1 \), then the return array's shape is \((m, n)\). If \( m == 1 \), the shape is \((q, n)\). If \( m == q == 1 \), the shape is \((n,)\).

**Methods**

```python
set_meta(self, **kwds)
```

Update the metadata dictionary with the keywords and data provided here.

**scipy.odr.Model.set_meta**

```python
Model.set_meta(self, **kwds)
```

Update the metadata dictionary with the keywords and data provided here.

**Examples**

```python
set_meta(name="Exponential", equation="y = a \exp(b x) + c")
```

**scipy.odr.ODR**

```python
class scipy.odr.ODR(data, model, beta0=None, delta0=None, ifxb=None, ifx0=None, job=None, iprint=None, errfile=None, rptfile=None, ndigit=None, taufac=None, sstol=None, partol=None, maxit=None, stpb=None, stpd=None, sclb=None, scld=None, work=None, iwork=None, overwrite=False)
```

The ODR class gathers all information and coordinates the running of the main fitting routine.

Members of instances of the ODR class have the same names as the arguments to the initialization routine.

**Parameters**

- **data** [Data class instance] instance of the Data class
- **model** [Model class instance] instance of the Model class

**Other Parameters**

- **beta0** [array_like of rank-1] a rank-1 sequence of initial parameter values. Optional if model provides an “estimate” function to estimate these values.
- **delta0** [array_like of floats of rank-1, optional] a (double-precision) float array to hold the initial values of the errors in the input variables. Must be same shape as data.x
ifixb  
[array_like of ints of rank-1, optional]  sequence of integers with the same length as beta0 that determines which parameters are held fixed. A value of 0 fixes the parameter, a value > 0 makes the parameter free.

ifixx  
[array_like of ints with same shape as data.x, optional] an array of integers with the same shape as data.x that determines which input observations are treated as fixed. One can use a sequence of length m (the dimensionality of the input observations) to fix some dimensions for all observations. A value of 0 fixes the observation, a value > 0 makes it free.

job  
[int, optional] an integer telling ODRPACK what tasks to perform. See p. 31 of the ODRPACK User's Guide if you absolutely must set the value here. Use the method set_job post-initialization for a more readable interface.

iprint  

erfile  
[str, optional] string with the filename to print ODRPACK errors to. If the file already exists, an error will be thrown. The overwrite argument can be used to prevent this. Do Not Open This File Yourself!

rptfile  
[str, optional] string with the filename to print ODRPACK summaries to. If the file already exists, an error will be thrown. The overwrite argument can be used to prevent this. Do Not Open This File Yourself!

ndigit  
[int, optional] integer specifying the number of reliable digits in the computation of the function.

taufac  
[float, optional] float specifying the initial trust region. The default value is 1. The initial trust region is equal to taufac times the length of the first computed Gauss-Newton step. taufac must be less than 1.

sstol  
[float, optional] float specifying the tolerance for convergence based on the relative change in the sum-of-squares. The default value is eps**(1/2) where eps is the smallest value such that 1 + eps > 1 for double precision computation on the machine. sstol must be less than 1.

partol  
[float, optional] float specifying the tolerance for convergence based on the relative change in the estimated parameters. The default value is eps**(2/3) for explicit models and eps**(1/3) for implicit models. partol must be less than 1.

maxit  
[int, optional] integer specifying the maximum number of iterations to perform. For first runs, maxit is the total number of iterations performed and defaults to 50. For restarts, maxit is the number of additional iterations to perform and defaults to 10.

stpb  
[array_like, optional] sequence (len(stpb) == len(beta0)) of relative step sizes to compute finite difference derivatives wrt the parameters.

stpd  
[optional] array (stpd.shape == data.x.shape or stpd.shape == (m,)) of relative step sizes to compute finite difference derivatives wrt the input variable errors. If stpd is a rank-1 array with length m (the dimensionality of the input variable), then the values are broadcast to all observations.

sclb  
[array_like, optional] sequence (len(stpb) == len(beta0)) of scaling factors for the parameters. The purpose of these scaling factors are to scale all of the parameters to around unity. Normally appropriate scaling factors are computed if this argument is not specified. Specify them yourself if the automatic procedure goes awry.

scld  
[array_like, optional] array (scld.shape == data.x.shape or scld.shape == (m,)) of scaling factors for the errors in the input variables. Again, these factors are automatically computed if you do not provide them. If scld.shape == (m,), then the scaling factors are broadcast to all observations.

work  
[nndarray, optional] array to hold the double-valued working data for ODRPACK. When restarting, takes the value of self.output.work.

iwork  
[nndarray, optional] array to hold the integer-valued working data for ODRPACK. When restarting, takes the value of self.output.iwork.

overwrite  
[bool, optional] If it is True, output files defined by errfile and rptfile are overwritten. The default is False.
**Attributes**

- **data**  
  [Data] The data for this fit

- **model**  
  [Model] The model used in fit

- **output**  
  [Output] An instance if the Output class containing all of the returned data from an invocation of ODR.run() or ODR.restart()

**Methods**

- **restart**(self[, iter])  
  Restarts the run with iter more iterations.

- **run**(self)  
  Run the fitting routine with all of the information given and with full_output=1.

- **set_iprint**(self[, init, so_init, iter, …])  
  Set the iprint parameter for the printing of computation reports.

- **set_job**(self[, fit_type, deriv, var_calc, …])  
  Sets the “job” parameter is a hopefully comprehensible way.

**scipy.odr.ODR.restart**

```python
ODR.restart (self, iter=None)
```

Restarts the run with iter more iterations.

**Parameters**

- **iter**  
  [int, optional] ODRPACK’s default for the number of new iterations is 10.

**Returns**

- **output**  
  [Output instance] This object is also assigned to the attribute .output .

**scipy.odr.ODR.run**

```python
ODR.run (self)
```

Run the fitting routine with all of the information given and with full_output=1.

**Returns**

- **output**  
  [Output instance] This object is also assigned to the attribute .output .

**scipy.odr.ODR.set_iprint**

```python
ODR.set_iprint (self, init=None, so_init=None, iter=None, so_iter=None, iter_step=None, final=None, so_final=None)
```

Set the iprint parameter for the printing of computation reports.

If any of the arguments are specified here, then they are set in the iprint member. If iprint is not set manually or with this method, then ODRPACK defaults to no printing. If no filename is specified with the member rptfile, then ODRPACK prints to stdout. One can tell ODRPACK to print to stdout in addition to the specified filename by setting the so_* arguments to this function, but one cannot specify to print to stdout but not a file since one can do that by not specifying a rptfile filename.

There are three reports: initialization, iteration, and final reports. They are represented by the arguments init, iter, and final respectively. The permissible values are 0, 1, and 2 representing “no report”, “short report”, and “long report” respectively.

The argument iter_step (0 <= iter_step <= 9) specifies how often to make the iteration report; the report will be made for every iter_step'th iteration starting with iteration one. If iter_step == 0, then no iteration report is made, regardless of the other arguments.

### 6.18. Orthogonal distance regression (scipy.odr)

1587
If the rptfile is None, then any so_* arguments supplied will raise an exception.

**scipy.odr.ODR.set_job**

```python
ODR.set_job (self, fit_type=None, deriv=None, var_calc=None, del_init=None, restart=None)
```

Sets the “job” parameter in a hopefully comprehensible way.

If an argument is not specified, then the value is left as is. The default value from class initialization is for all of these options set to 0.

**Parameters**

- **fit_type**
  - [0, 1, 2] int
  - 0 -> explicit ODR
  - 1 -> implicit ODR
  - 2 -> ordinary least-squares

- **deriv**
  - [0, 1, 2, 3] int
  - 0 -> forward finite differences
  - 1 -> central finite differences
  - 2 -> user-supplied derivatives (Jacobians) with results checked by ODRPACK
  - 3 -> user-supplied derivatives, no checking

- **var_calc**
  - [0, 1, 2] int
  - 0 -> calculate asymptotic covariance matrix and fit parameter uncertainties (V_B, s_B) using derivatives recomputed at the final solution
  - 1 -> calculate V_B and s_B using derivatives from last iteration
  - 2 -> do not calculate V_B and s_B

- **del_init**
  - [0, 1] int
  - 0 -> initial input variable offsets set to 0
  - 1 -> initial offsets provided by user in variable “work”

- **restart**
  - [0, 1] int
  - 0 -> fit is not a restart
  - 1 -> fit is a restart

**Notes**

The permissible values are different from those given on pg. 31 of the ODRPACK User’s Guide only in that one cannot specify numbers greater than the last value for each variable.

If one does not supply functions to compute the Jacobians, the fitting procedure will change deriv to 0, finite differences, as a default. To initialize the input variable offsets by yourself, set del_init to 1 and put the offsets into the “work” variable correctly.

**scipy.odr.Output**

```python
class scipy.odr.Output (output)
```

The Output class stores the output of an ODR run.
Notes

Takes one argument for initialization, the return value from the function `odr`. The attributes listed as “optional” above are only present if `odr` was run with `full_output=1`.

Attributes

- **beta** [ndarray] Estimated parameter values, of shape (q,).
- **sd_beta** [ndarray] Standard deviations of the estimated parameters, of shape (p,).
- **cov_beta** [ndarray] Covariance matrix of the estimated parameters, of shape (p,p).
- **delta** [ndarray, optional] Array of estimated errors in input variables, of same shape as x.
- **eps** [ndarray, optional] Array of estimated errors in response variables, of same shape as y.
- **xplus** [ndarray, optional] Array of x + delta.
- **y** [ndarray, optional] Array y = fcn(x + delta).
- **res_var** [float, optional] Residual variance.
- **sum_square** [float, optional] Sum of squares error.
- **sum_square_delta** [float, optional] Sum of squares of delta error.
- **sum_square_eps** [float, optional] Sum of squares of eps error.
- **inv_condnum** [float, optional] Inverse condition number (cf. ODRPACK UG p. 77).
- **rel_error** [float, optional] Relative error in function values computed within fcn.
- **work** [ndarray, optional] Final work array.
- **work_ind** [dict, optional] Indices into work for drawing out values (cf. ODRPACK UG p. 83).
- **info** [int, optional] Reason for returning, as output by ODRPACK (cf. ODRPACK UG p. 38).
- **stopreason** [list of str, optional] info interpreted into English.

Methods

```
pprint(self) Pretty-print important results.
```

`scipy.odr.Output.pprint`

```
Output.pprint(self) Pretty-print important results.
```

`scipy.odr.odr`

```
scipy.odr.odr (fcn, beta0, y, x, we=None, wd=None, fjacb=None, fjacd=None, extra_args=None, ifixx=None, ifxlb=None, job=0, iprint=0, errfile=None, rptfile=None, ndigit=0, taufac=0.0, sstol=- 1.0, partol=- 1.0, maxit=- 1, stpb=None, stpd=None, sclb=None, scld=None, work=None, iwork=None, full_output=0)
```

Low-level function for ODR.

See also:

ODR

The ODR class gathers all information and coordinates the running of the main fitting routine.

Model

6.18. Orthogonal distance regression (`scipy.odr`) 1589
The Model class stores information about the function you wish to fit.

**Data**

The data to fit.

**RealData**

Data with weights as actual std. dev.s and/or covariances.

**Notes**

This is a function performing the same operation as the *ODR, Model, and Data* classes together. The parameters of this function are explained in the class documentation.

**scipy.odr.OdrWarning**

```
exception scipy.odr.OdrWarning

Warning indicating that the data passed into ODR will cause problems when passed into `odr` that the user should be aware of.

with_traceback()
    Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

**scipy.odr.OdrError**

```
exception scipy.odr.OdrError

Exception indicating an error in fitting.

This is raised by `odr` if an error occurs during fitting.

with_traceback()
    Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

**scipy.odr.OdrStop**

```
exception scipy.odr.OdrStop

Exception stopping fitting.

You can raise this exception in your objective function to tell `odr` to stop fitting.

with_traceback()
    Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

**scipy.odr.polynomial**

```
scipy.odr.polynomial(order)

Factory function for a general polynomial model.

Parameters

order [int or sequence] If an integer, it becomes the order of the polynomial to fit. If a sequence of numbers, then these are the explicit powers in the polynomial. A constant term (power 0) is always included, so don’t include 0. Thus, polynomial(n) is equivalent to polynomial(range(1, n+1)).
```
Returns

polynomial

Examples

We can fit an input data using orthogonal distance regression (ODR) with a polynomial model:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy import odr
>>> x = np.linspace(0.0, 5.0)
>>> y = np.sin(x)
>>> poly_model = odr.polynomial(3)  # using third order polynomial model
>>> data = odr.Data(x, y)
>>> odr_obj = odr.ODR(data, poly_model)
>>> output = odr_obj.run()  # running ODR fitting
>>> poly = np.poly1d(output.beta[::-1])
>>> poly_y = poly(x)
>>> plt.plot(x, y, label="input data")
>>> plt.plot(x, poly_y, label="polynomial ODR")
>>> plt.legend()
>>> plt.show()
```
scipy.odr.exponential

scipy.odr.exponential = <scipy.odr.models._ExponentialModel object>

Exponential model

This model is defined by $y = \beta_0 + e^{\beta_1 x}$

Examples

We can calculate orthogonal distance regression with an exponential model:

```python
>>> from scipy import odr
>>> x = np.linspace(0.0, 5.0)
>>> y = -10.0 + np.exp(0.5*x)
>>> data = odr.Data(x, y)
>>> odr_obj = odr.ODR(data, odr.exponential)
>>> output = odr_obj.run()
>>> print(output.beta)
[-10.  0.5]
```

scipy.odr.multilinear

scipy.odr.multilinear = <scipy.odr.models._MultilinearModel object>

Arbitrary-dimensional linear model

This model is defined by $y = \beta_0 + \sum_{i=1}^{m} \beta_i x_i$

Examples

We can calculate orthogonal distance regression with an arbitrary dimensional linear model:

```python
>>> from scipy import odr
>>> x = np.linspace(0.0, 5.0)
>>> y = 10.0 + 5.0 * x
>>> data = odr.Data(x, y)
>>> odr_obj = odr.ODR(data, odr.multilinear)
>>> output = odr_obj.run()
>>> print(output.beta)
[10.  5.]
```

scipy.odr.unilinear

scipy.odr.unilinear = <scipy.odr.models._UnilinearModel object>

Univariate linear model

This model is defined by $y = \beta_0 x + \beta_1$
Examples

We can calculate orthogonal distance regression with an unilinear model:

```python
>>> from scipy import odr
>>> x = np.linspace(0.0, 5.0)
>>> y = 1.0 * x + 2.0
>>> data = odr.Data(x, y)
>>> odr_obj = odr.ODR(data, odr.unilinear)
>>> output = odr_obj.run()
>>> print(output.beta)
[1. 2.]
```

**scipy.odr.quadratic**

```python
scipy.odr.quadratic = <scipy.odr.models._QuadraticModel object>
```

Quadratic model

This model is defined by \( y = \beta_0 x^2 + \beta_1 x + \beta_2 \)

Examples

We can calculate orthogonal distance regression with a quadratic model:

```python
>>> from scipy import odr
>>> x = np.linspace(0.0, 5.0)
>>> y = 1.0 * x ** 2 + 2.0 * x + 3.0
>>> data = odr.Data(x, y)
>>> odr_obj = odr.ODR(data, odr.quadratic)
>>> output = odr_obj.run()
>>> print(output.beta)
[1. 2. 3.]
```

6.18.2 Usage information

Introduction

Why Orthogonal Distance Regression (ODR)? Sometimes one has measurement errors in the explanatory (a.k.a., “independent”) variable(s), not just the response (a.k.a., “dependent”) variable(s). Ordinary Least Squares (OLS) fitting procedures treat the data for explanatory variables as fixed, i.e., not subject to error of any kind. Furthermore, OLS procedures require that the response variables be an explicit function of the explanatory variables; sometimes making the equation explicit is impractical and/or introduces errors. ODR can handle both of these cases with ease, and can even reduce to the OLS case if that is sufficient for the problem.

ODRPACK is a FORTRAN-77 library for performing ODR with possibly non-linear fitting functions. It uses a modified trust-region Levenberg-Marquardt-type algorithm [1] to estimate the function parameters. The fitting functions are provided by Python functions operating on NumPy arrays. The required derivatives may be provided by Python functions as well, or may be estimated numerically. ODRPACK can do explicit or implicit ODR fits, or it can do OLS. Input and output variables may be multidimensional. Weights can be provided to account for different variances of the observations, and even covariances between dimensions of the variables.

The `scipy.odr` package offers an object-oriented interface to ODRPACK, in addition to the low-level `odr` function.
Additional background information about ODRPACK can be found in the ODRPACK User's Guide, reading which is recommended.

**Basic usage**

1. Define the function you want to fit against:

   ```python
def f(B, x):
       '''Linear function y = m*x + b'''
       # B is a vector of the parameters.
       # x is an array of the current x values.
       # x is in the same format as the x passed to Data or RealData.
       # Return an array in the same format as y passed to Data or RealData.
       return B[0]*x + B[1]
   ```

2. Create a Model:

   ```python
   linear = Model(f)
   ```

3. Create a Data or RealData instance:

   ```python
   mydata = Data(x, y, wd=1./power(sx, 2), we=1./power(sy, 2))
   ```

   or, when the actual covariances are known:

   ```python
   mydata = RealData(x, y, sx=sx, sy=sy)
   ```

4. Instantiate ODR with your data, model and initial parameter estimate:

   ```python
   myodr = ODR(mydata, linear, beta0=[1., 2.])
   ```

5. Run the fit:

   ```python
   myoutput = myodr.run()
   ```

6. Examine output:

   ```python
   myoutput.pprint()
   ```

**References**

### 6.19 Optimization and root finding (**scipy.optimize**)

SciPy optimize provides functions for minimizing (or maximizing) objective functions, possibly subject to constraints. It includes solvers for nonlinear problems (with support for both local and global optimization algorithms), linear programming, constrained and nonlinear least-squares, root finding, and curve fitting.

Common functions and objects, shared across different solvers, are:

show_options([solver, method, disp])

Show documentation for additional options of optimization solvers.

OptimizeResult

Represents the optimization result.

OptimizeWarning

6.19.1 scipy.optimize.show_options

scipy.optimize.show_options(solver=None, method=None, disp=True)

Show documentation for additional options of optimization solvers.

These are method-specific options that can be supplied through the options dict.

Parameters

- **solver** [str] Type of optimization solver. One of 'minimize', 'minimize_scalar', 'root', 'root_scalar', 'linprog', or 'quadratic_assignment'.
- **method** [str, optional] If not given, shows all methods of the specified solver. Otherwise, show only the options for the specified method. Valid values corresponds to methods' names of respective solver (e.g., 'BFGS' for 'minimize').
- **disp** [bool, optional] Whether to print the result rather than returning it.

Returns

- **text** Either None (for disp=True) or the text string (disp=False)

Notes

The solver-specific methods are:

- Nelder-Mead
- Powell
- CG
- BFGS
- Newton-CG
- L-BFGS-B
- TNC
- COBYLA
- SLSQP
- dogleg
- trust-ncg

scipy.optimize.root

- hybr
- lm
- broyden1
- broyden2

Examples

We can print documentations of a solver in stdout:

```python
>>> from scipy.optimize import show_options
>>> show_options(solver="minimize")
...
```

Specifying a method is possible:

```python
>>> show_options(solver="minimize", method="Nelder-Mead")
...
```

We can also get the documentations as a string:

```python
>>> show_options(solver="minimize", method="Nelder-Mead", disp=False)
Minimization of scalar function of one or more variables using the ...
```

6.19.2 scipy.optimize.OptimizeResult

class scipy.optimize.OptimizeResult

Represents the optimization result.

Notes

There may be additional attributes not listed above depending of the specific solver. Since this class is essentially a subclass of dict with attribute accessors, one can see which attributes are available using the `keys()` method.

Attributes

- `x` [ndarray] The solution of the optimization.
- `success` [bool] Whether or not the optimizer exited successfully.
- `status` [int] Termination status of the optimizer. Its value depends on the underlying solver. Refer to `message` for details.
- `message` [str] Description of the cause of the termination.
- `fun, jac, hess`: [ndarray] Values of objective function, its Jacobian and its Hessian (if available). The Hessians may be approximations, see the documentation of the function in question.
- `hess_inv` [object] Inverse of the objective function’s Hessian; may be an approximation. Not available for all solvers. The type of this attribute may be either np.ndarray or scipy.sparse.linalg.LinearOperator.
- `nfev, njev, nhev` [int] Number of evaluations of the objective functions and of its Jacobian and Hessian.
- `nit` [int] Number of iterations performed by the optimizer.
- `maxcv` [float] The maximum constraint violation.

### scipy.optimize.OptimizeResult.__getitem__

OptimizeResult.__getitem__

\[ x.__getitem__(y) \Rightarrow x[y] \]

### scipy.optimize.OptimizeResult.__len__

OptimizeResult.__len__ (self, /)

Return \( \text{len}(self) \).
**scipy.optimize.OptimizeResult.fromkeys**

OptimizeResult.fromkeys(iterable, value=None)

Create a new dictionary with keys from iterable and values set to value.

**scipy.optimize.OptimizeResult.get**

OptimizeResult.get(self, key, default=None)

Return the value for key if key is in the dictionary, else default.

**scipy.optimize.OptimizeResult.items**

OptimizeResult.items()

**scipy.optimize.OptimizeResult.keys**

OptimizeResult.keys()

**scipy.optimize.OptimizeResult.pop**

OptimizeResult.pop()

If key is not found, d is returned if given, otherwise KeyError is raised

**scipy.optimize.OptimizeResult.popitem**

OptimizeResult.popitem()

2-tuple; but raise KeyError if D is empty.

**scipy.optimize.OptimizeResult.setdefault**

OptimizeResult.setdefault(self, key, default=None)

Insert key with a value of default if key is not in the dictionary.

Return the value for key if key is in the dictionary, else default.

**scipy.optimize.OptimizeResult.update**

OptimizeResult.update()

If E is present and has a .keys() method, then does: for k in E: D[k] = E[k] If E is present and lacks a .keys() method, then does: for k, v in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]
scipy.optimize.OptimizeResult.values

OptimizeResult.values()

6.19.3 scipy.optimize.OptimizeWarning

exception scipy.optimize.OptimizeWarning

with_traceback()
    Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

6.19.4 Optimization

Scalar functions optimization

minimize_scalar(fun[, bracket, bounds, ...]) Minimization of scalar function of one variable.

scipy.optimize.minimize_scalar

scipy.optimize.minimize_scalar(fun, bracket=None, bounds=None, args=(), method='brent', tol=None, options=None)
    Minimization of scalar function of one variable.

Parameters

fun [callable] Objective function. Scalar function, must return a scalar.

bracket [sequence, optional] For methods 'brent' and 'golden', bracket defines the bracketing interval and can either have three items (a, b, c) so that a < b < c and \( \text{fun}(b) < \text{fun}(a), \text{fun}(c) \) or two items a and c which are assumed to be a starting interval for a downhill bracket search (see bracket); it doesn’t always mean that the obtained solution will satisfy a <= x <= c.

bounds [sequence, optional] For method ‘bounded’, bounds is mandatory and must have two items corresponding to the optimization bounds.

args [tuple, optional] Extra arguments passed to the objective function.

method [str or callable, optional] Type of solver. Should be one of:
    • ‘Brent’ (see here)
    • ‘Bounded’ (see here)
    • ‘Golden’ (see here)
    • custom - a callable object (added in version 0.14.0), see below

tol [float, optional] Tolerance for termination. For detailed control, use solver-specific options.

    maxiter [int] Maximum number of iterations to perform.
    disp [bool] Set to True to print convergence messages.

See show_options for solver-specific options.

Returns

res [OptimizeResult] The optimization result represented as an OptimizeResult object. Important attributes are: x the solution array, success a Boolean flag indicating if the optimizer exited successfully and message which describes the cause of the termination. See OptimizeResult for a description of other attributes.

See also:
minimize

Interface to minimization algorithms for scalar multivariate functions

show_options

Additional options accepted by the solvers

Notes

This section describes the available solvers that can be selected by the ‘method’ parameter. The default method is Brent.

Method Brent uses Brent’s algorithm to find a local minimum. The algorithm uses inverse parabolic interpolation when possible to speed up convergence of the golden section method.

Method Golden uses the golden section search technique. It uses analog of the bisection method to decrease the bracketed interval. It is usually preferable to use the Brent method.

Method Bounded can perform bounded minimization. It uses the Brent method to find a local minimum in the interval $x_1 < x_{\text{opt}} < x_2$.

Custom minimizers

It may be useful to pass a custom minimization method, for example when using some library frontend to minimize_scalar. You can simply pass a callable as the method parameter.

The callable is called as method(fun, args, **kwargs, **options) where kwargs corresponds to any other parameters passed to minimize(such as bracket, tol, etc.), except the options dict, which has its contents also passed as method parameters pair by pair. The method shall return an OptimizeResult object.

The provided method callable must be able to accept (and possibly ignore) arbitrary parameters; the set of parameters accepted by minimize may expand in future versions and then these parameters will be passed to the method. You can find an example in the scipy.optimize tutorial.

New in version 0.11.0.

Examples

Consider the problem of minimizing the following function.

```python
>>> def f(x):
...     return (x - 2) * x * (x + 2)**2
```

Using the Brent method, we find the local minimum as:

```python
>>> from scipy.optimize import minimize_scalar
>>> res = minimize_scalar(f)
>>> res.x
1.28077640403
```

Using the Bounded method, we find a local minimum with specified bounds as:

```python
>>> res = minimize_scalar(f, bounds=(-3, -1), method='bounded')
>>> res.x
-2.00000002026
```

The minimize_scalar function supports the following methods:
minimize_scalar(method='brent')

scipy.optimize.minimize_scalar(func, args=(), method='brent', tol=None, options={'func': None, 'brack': None, 'xtol': 1.48e-08, 'maxiter': 500})

See also:

For documentation for the rest of the parameters, see scipy.optimize.minimize_scalar

Options

maxiter [int] Maximum number of iterations to perform.
xtol [float] Relative error in solution xopt acceptable for convergence.

Notes

Uses inverse parabolic interpolation when possible to speed up convergence of golden section method.

minimize_scalar(method='bounded')

scipy.optimize.minimize_scalar(func, bounds=None, args=(), method='bounded', tol=None, options={'func': None, 'xatol': 1e-05, 'maxiter': 500, 'disp': 0})

See also:

For documentation for the rest of the parameters, see scipy.optimize.minimize_scalar

Options

maxiter [int] Maximum number of iterations to perform.
disp: int, optional

If non-zero, print messages.

0 : no message printing. 1 : non-convergence notification messages only. 2 :
print a message on convergence too. 3 : print iteration results.

xatol [float] Absolute error in solution xopt acceptable for convergence.

minimize_scalar(method='golden')

scipy.optimize.minimize_scalar(func, args=(), method='golden', tol=None, options={'func': None, 'brack': None, 'xtol': 1.4901161193847656e-08, 'maxiter': 5000})

See also:

For documentation for the rest of the parameters, see scipy.optimize.minimize_scalar

Options

maxiter [int] Maximum number of iterations to perform.
xtol [float] Relative error in solution xopt acceptable for convergence.
Local (multivariate) optimization

<table>
<thead>
<tr>
<th>minimize(fun, x0[, args, method, jac, hess, ...])</th>
<th>Minimization of scalar function of one or more variables.</th>
</tr>
</thead>
</table>

**scipy.optimize.minimize**

`scipy.optimize.minimize(fun, x0, args=(), method=None, jac=None, hess=None, hessp=None, bounds=None, constraints=(), tol=None, callback=None, options=None)`

Minimization of scalar function of one or more variables.

**Parameters**

- **fun** [callable] The objective function to be minimized.
  
  \[
  \text{fun}(x, \text{args}) \rightarrow \text{float}
  \]
  
  where \(x\) is an 1-D array with shape \((n,)\) and \(\text{args}\) is a tuple of the fixed parameters needed to completely specify the function.

- **x0** [ndarray, shape \((n,)\)] Initial guess. Array of real elements of size \((n,)\), where ‘n’ is the number of independent variables.

- **args** [tuple, optional] Extra arguments passed to the objective function and its derivatives (\(\text{fun}, \text{jac}\) and \(\text{hess}\) functions).

- **method** [str or callable, optional] Type of solver. Should be one of
  
  - ‘Nelder-Mead’ (see here)
  - ‘Powell’ (see here)
  - ‘CG’ (see here)
  - ‘BFGS’ (see here)
  - ‘Newton-CG’ (see here)
  - ‘L-BFGS-B’ (see here)
  - ‘TNC’ (see here)
  - ‘COBYLA’ (see here)
  - ‘SLSQP’ (see here)
  - ‘trust-constr’ (see here)
  - ‘dogleg’ (see here)
  - ‘trust-ng’ (see here)
  - ‘trust-exact’ (see here)
  - ‘trust-krylov’ (see here)
  - custom - a callable object (added in version 0.14.0), see below for description.

  If not given, chosen to be one of BFGS, L-BFGS-B, SLSQP, depending if the problem has constraints or bounds.

- **jac** [{callable, ‘2-point’, ‘3-point’, ‘cs’, bool}, optional] Method for computing the gradient vector. Only for CG, BFGS, Newton-CG, L-BFGS-B, TNC, SLSQP, dogleg, trust-ng, trust-krylov, trust-exact and trust-constr. If it is a callable, it should be a function that returns the gradient vector:

  \[
  \text{jac}(x, \text{args}) \rightarrow \text{array_like, shape \((n,)\)}
  \]

  where \(x\) is an array with shape \((n,)\) and \(\text{args}\) is a tuple with the fixed parameters. If \(\text{jac}\) is a Boolean and is True, \(\text{fun}\) is assumed to return and objective and gradient as an \((\ell, \text{g})\) tuple. Methods ‘Newton-CG’, ‘trust-ng’, ‘dogleg’, ‘trust-exact’, and ‘trust-krylov’ require that either a callable be supplied, or that \(\text{fun}\) return the objective and gradient. If None or False, the gradient will be estimated using 2-point finite difference estimation with an absolute step size. Alternatively, the keywords \{'2-point', '3-point', 'cs'\} can be used to select a finite difference scheme for numerical estimation of the gradient with a relative step size. These finite difference schemes obey any specified \(\text{bounds}\).

hess(x, *args) -> {LinearOperator, spmatrix, array}, (n, n)
where x is a (n,) ndarray and args is a tuple with the fixed parameters. LinearOperator and
sparse matrix returns are allowed only for ‘trust-constr’ method. Alternatively, the keywords
{‘2-point’, ‘3-point’, ‘cs’} select a finite difference scheme for numerical estimation. Or,
objects implementing HessianUpdateStrategy interface can be used to approximate
the Hessian. Available quasi-Newton methods implementing this interface are:
• BFGS;
• SR1.
Whenever the gradient is estimated via finite-differences, the Hessian cannot be estimated
with options {‘2-point’, ‘3-point’, ‘cs’} and needs to be estimated using one of the quasi-
Newton strategies. Finite-difference options {‘2-point’, ‘3-point’, ‘cs’} and HessianUp-
dateStrategy are available only for ‘trust-constr’ method.

hessp
[callable, optional] Hessian of objective function times an arbitrary vector p. Only for
Newton-CG, trust-negc, trust-krylov, trust-constr. Only one of hess or hessp needs to be
given. If hess is provided, then hessp will be ignored. hessp must compute the Hessian times
an arbitrary vector:
\[
hessp(x, p, *args) -> \text{narray shape (n,)}
\]
where x is a (n,) ndarray, p is an arbitrary vector with dimension (n,) and args is a tuple with
the fixed parameters.

bounds
[sequence or Bounds, optional] Bounds on variables for L-BFGS-B, TNC, SLSQP, Powell,
and trust-constr methods. There are two ways to specify the bounds:
1. Instance of Bounds class.
2. Sequence of (min, max) pairs for each element in x. None is used to specify no bound.

constraints
[Constraint, dict] or List of {Constraint, dict}, optional] Constraints definition (only for
COBYLA, SLSQP and trust-constr).
Constraints for ‘trust-constr’ are defined as a single object or a list of objects specifying con-
straints to the optimization problem. Available constraints are:
• LinearConstraint
• NonlinearConstraint
Constraints for COBYLA, SLSQP are defined as a list of dictionaries. Each dictionary with
fields:
\[
fun [callable] The function defining the constraint.
jac [callable, optional] The Jacobian of fun (only for SLSQP).
args [sequence, optional] Extra arguments to be passed to the function and Jacob-
ian.
\]
Equality constraint means that the constraint function result is to be zero whereas inequality
means that it is to be non-negative. Note that COBYLA only supports inequality constraints.
tol
[float, optional] Tolerance for termination. For detailed control, use solver-specific options.

options
[dict, optional] A dictionary of solver options. All methods accept the following generic
options:
\[
maxiter [int] Maximum number of iterations to perform. Depending on the method
each iteration may use several function evaluations.
disp [bool] Set to True to print convergence messages.
\]
For method-specific options, see show_options.

callback
[callable, optional] Called after each iteration. For ‘trust-constr’ it is a callable with the sig-
nature:
\[
callback(xk, OptimizeResult state) -> bool
\]
where xk is the current parameter vector and state is an OptimizeResult object,
with the same fields as the ones from the return. If callback returns True the algorithm
execution is terminated. For all the other methods, the signature is:
\[
callback(xk)
\]
where xk is the current parameter vector.
Returns

res [OptimizeResult] The optimization result represented as a OptimizeResult object. Important attributes are: x the solution array, success a Boolean flag indicating if the optimizer exited successfully and message which describes the cause of the termination. See OptimizeResult for a description of other attributes.

See also:

minimize_scalar

Interface to minimization algorithms for scalar univariate functions

show_options

Additional options accepted by the solvers

Notes

This section describes the available solvers that can be selected by the ‘method’ parameter. The default method is BFGS.

Unconstrained minimization

Method Nelder-Mead uses the Simplex algorithm [1], [2]. This algorithm is robust in many applications. However, if numerical computation of derivative can be trusted, other algorithms using the first and/or second derivatives information might be preferred for their better performance in general.

Method CG uses a nonlinear conjugate gradient algorithm by Polak and Ribiere, a variant of the Fletcher-Reeves method described in [5] pp.120-122. Only the first derivatives are used.

Method BFGS uses the quasi-Newton method of Broyden, Fletcher, Goldfarb, and Shanno (BFGS) [5] pp. 136. It uses the first derivatives only. BFGS has proven good performance even for non-smooth optimizations. This method also returns an approximation of the Hessian inverse, stored as hess_inv in the OptimizeResult object.

Method Newton-CG uses a Newton-CG algorithm [5] pp. 168 (also known as the truncated Newton method). It uses a CG method to compute the search direction. See also TNC method for a box-constrained minimization with a similar algorithm. Suitable for large-scale problems.

Method dogleg uses the dog-leg trust-region algorithm [5] for unconstrained minimization. This algorithm requires the gradient and Hessian; furthermore the Hessian is required to be positive definite.

Method trust-ncg uses the Newton conjugate gradient trust-region algorithm [5] for unconstrained minimization. This algorithm requires the gradient and either the Hessian or a function that computes the product of the Hessian with a given vector. Suitable for large-scale problems.

Method trust-krylov uses the Newton GLTR trust-region algorithm [14], [15] for unconstrained minimization. This algorithm requires the gradient and either the Hessian or a function that computes the product of the Hessian with a given vector. Suitable for large-scale problems. On indefinite problems it requires usually less iterations than the trust-ncg method and is recommended for medium and large-scale problems.

Method trust-exact is a trust-region method for unconstrained minimization in which quadratic subproblems are solved almost exactly [13]. This algorithm requires the gradient and the Hessian (which is not required to be positive definite). It is, in many situations, the Newton method to converge in fewer iterations and the most recommended for small and medium-size problems.

Bound-Constrained minimization

Method Powell is a modification of Powell’s method [3], [4] which is a conjugate direction method. It performs sequential one-dimensional minimizations along each vector of the directions set (direc field in options and info),
which is updated at each iteration of the main minimization loop. The function need not be differentiable, and no derivatives are taken. If bounds are not provided, then an unbounded line search will be used. If bounds are provided and the initial guess is within the bounds, then every function evaluation throughout the minimization procedure will be within the bounds. If bounds are provided, the initial guess is outside the bounds, and direc is full rank (default has full rank), then some function evaluations during the first iteration may be outside the bounds, but every function evaluation after the first iteration will be within the bounds. If direc is not full rank, then some parameters may not be optimized and the solution is not guaranteed to be within the bounds.

Method **TNC** uses a truncated Newton algorithm [5], [8] to minimize a function with variables subject to bounds. This algorithm uses gradient information; it is also called Newton Conjugate-Gradient. It differs from the Newton-CG method described above as it wraps a C implementation and allows each variable to be given upper and lower bounds.

**Constrained Minimization**

Method **COBYLA** uses the Constrained Optimization BY Linear Approximation (COBYLA) method [9], [10], [11]. The algorithm is based on linear approximations to the objective function and each constraint. The method wraps a FORTRAN implementation of the algorithm. The constraints functions ‘fun’ may return either a single number or an array or list of numbers.

Method **SLSQP** uses Sequential Least SQuares Programming to minimize a function of several variables with any combination of bounds, equality and inequality constraints. The method wraps the SLSQP Optimization subroutine originally implemented by Dieter Kraft [12]. Note that the wrapper handles infinite values in bounds by converting them into large floating values.

Method **trust-constr** is a trust-region algorithm for constrained optimization. It switches between two implementations depending on the problem definition. It is the most versatile constrained minimization algorithm implemented in SciPy and the most appropriate for large-scale problems. For equality constrained problems it is an implementation of Byrd-Omojokun Trust-Region SQP method described in [17] and in [5], p. 549. When inequality constraints are imposed as well, it switches to the trust-region interior point method described in [16]. This interior point algorithm, in turn, solves inequality constraints by introducing slack variables and solving a sequence of equality-constrained barrier problems for progressively smaller values of the barrier parameter. The previously described equality constrained SQP method is used to solve the subproblems with increasing levels of accuracy as the iterate gets closer to a solution.

**Finite-Difference Options**

For Method **trust-constr** the gradient and the Hessian may be approximated using three finite-difference schemes: (‘2-point’, ‘3-point’, ‘cs’). The scheme ‘cs’ is, potentially, the most accurate but it requires the function to correctly handles complex inputs and to be differentiable in the complex plane. The scheme ‘3-point’ is more accurate than ‘2-point’ but requires twice as many operations.

**Custom minimizers**

It may be useful to pass a custom minimization method, for example when using a frontend to this method such as scipy.optimize.basinhopping or a different library. You can simply pass a callable as the method parameter.

The callable is called as method(fun, x0, args, **kwags, **options) where kwags corresponds to any other parameters passed to minimize (such as callback, hess, etc.), except the options dict, which has its contents also passed as method parameters pair by pair. Also, if jac has been passed as a bool type, jac and fun are mangled so that fun returns just the function values and jac is converted to a function returning the Jacobian. The method shall return an OptimizeResult object.

The provided method callable must be able to accept (and possibly ignore) arbitrary parameters; the set of parameters accepted by minimize may expand in future versions and then these parameters will be passed to the method. You can find an example in the scipy.optimize tutorial.

New in version 0.11.0.
Examples

Let us consider the problem of minimizing the Rosenbrock function. This function (and its respective derivatives) is implemented in `rosen` (resp. `rosen_der`, `rosen_hess`) in the `scipy.optimize`.

```python
>>> from scipy.optimize import minimize, rosen, rosen_der
```

A simple application of the *Nelder-Mead* method is:

```python
>>> x0 = [1.3, 0.7, 0.8, 1.9, 1.2]
>>> res = minimize(rosen, x0, method='Nelder-Mead', tol=1e-6)
>>> res.x
array([ 1., 1., 1., 1., 1.])
```

Now using the *BFGS* algorithm, using the first derivative and a few options:

```python
>>> res = minimize(rosen, x0, method='BFGS', jac=rosen_der,
...                options={'gtol': 1e-6, 'disp': True})
Optimization terminated successfully.
Current function value: 0.000000
Iterations: 26
Function evaluations: 31
Gradient evaluations: 31
>>> res.x
array([ 1., 1., 1., 1., 1.])
>>> print(res.message)
Optimization terminated successfully.
>>> res.hess_inv
array([[ 0.00749589, 0.01255155, 0.02396251, 0.04750988, 0.09495377],
       [ 0.01255155, 0.02510441, 0.04794055, 0.09502834, 0.18996269],
       [ 0.02396251, 0.04794055, 0.09631614, 0.19092151, 0.38165151],
       [ 0.04750988, 0.09502834, 0.19092151, 0.38341252, 0.7664427 ],
       [ 0.09495377, 0.18996269, 0.38165151, 0.7664427, 1.53713523]])
```

Next, consider a minimization problem with several constraints (namely Example 16.4 from [5]). The objective function is:

```python
>>> fun = lambda x: (x[0] - 1)**2 + (x[1] - 2.5)**2
```

There are three constraints defined as:

```python
>>> cons = ([{'type': 'ineq', 'fun': lambda x: x[0] - 2 * x[1] + 2},
...           {'type': 'ineq', 'fun': lambda x: -x[0] - 2 * x[1] + 6},
...           {'type': 'ineq', 'fun': lambda x: -x[0] + 2 * x[1] + 2})
```

And variables must be positive, hence the following bounds:

```python
>>> bnds = ((0, None), (0, None))
```
The optimization problem is solved using the SLSQP method as:

```
>>> res = minimize(fun, (2, 0), method='SLSQP', bounds=bnds,
                 constraints=cons)
```

It should converge to the theoretical solution (1.4, 1.7).

The `minimize` function supports the following methods:

```
minimize(method='Nelder-Mead')
```

```
scipy.optimize.minimize (fun, x0, args=(), method='Nelder-Mead', tol=None, callback=None,
                         options={'func': None, 'maxiter': None, 'maxfev': None, 'disp': False, 'return_all': False, 'initial_simplex': None, 'xatol': 0.0001, 'fatol': 0.0001, 'adaptive': False})
```

Minimization of scalar function of one or more variables using the Nelder-Mead algorithm.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

```
Options
disp [bool] Set to True to print convergence messages.
maxiter, maxfev
        [int] Maximum allowed number of iterations and function evaluations. Will default to N*200, where N is the number of variables, if neither maxiter or maxfev is set. If both maxiter and maxfev are set, minimization will stop at the first reached.
return_all [bool, optional] Set to True to return a list of the best solution at each of the iterations.
initial_simplex
        [array_like of shape (N + 1, N)] Initial simplex. If given, overrides x0. initial_simplex[j,:] should contain the coordinates of the jth vertex of the N+1 vertices in the simplex, where N is the dimension.
xatol [float, optional] Absolute error in xopt between iterations that is acceptable for convergence.
fatol [number, optional] Absolute error in func(xopt) between iterations that is acceptable for convergence.
```

```
Options
disp [bool] Set to True to print convergence messages.
xtol [float] Relative error in solution xopt acceptable for convergence.
```
**SciPy Reference Guide, Release 1.6.3**

**ftol**  
[float] Relative error in \( \text{fun}(x_{\text{opt}}) \) acceptable for convergence.

**maxiter, maxfev**  
[int] Maximum allowed number of iterations and function evaluations. Will default to \( N\times1000 \), where \( N \) is the number of variables, if neither \( \text{maxiter} \) or \( \text{maxfev} \) is set. If both \( \text{maxiter} \) and \( \text{maxfev} \) are set, minimization will stop at the first reached.

**direc**  
[ndarray] Initial set of direction vectors for the Powell method.

**return_all**  
[bool, optional] Set to True to return a list of the best solution at each of the iterations.

**bounds**  
[Bounds] If bounds are not provided, then an unbounded line search will be used. If bounds are provided and the initial guess is within the bounds, then every function evaluation throughout the minimization procedure will be within the bounds. If bounds are provided, the initial guess is outside the bounds, and \( \text{direc} \) is full rank (or left to default), then some function evaluations during the first iteration may be outside the bounds, but every function evaluation after the first iteration will be within the bounds. If \( \text{direc} \) is not full rank, then some parameters may not be optimized and the solution is not guaranteed to be within the bounds.

**return_all**  
[bool, optional] Set to True to return a list of the best solution at each of the iterations.

**minimize(method='CG')**

scipy.optimize.minimize (fun, x0, args=(), method='CG', jac=None, tol=None, callback=None, options={'gtol': 1e-05, 'norm': inf, 'eps': 1.4901161193847656e-08, 'maxiter': None, 'disp': False, 'return_all': False, 'finite_diff_rel_step': None})

Minimization of scalar function of one or more variables using the conjugate gradient algorithm.

**See also:**

For documentation for the rest of the parameters, see scipy.optimize.minimize

**Options**

**disp**  
[bool] Set to True to print convergence messages.

**maxiter**  
[int] Maximum number of iterations to perform.

**gtol**  
[float] Gradient norm must be less than \( \text{gtol} \) before successful termination.

**norm**  
[float] Order of norm (Inf is max, -Inf is min).

**eps**  
[float or ndarray] If \( \text{jac} \) is None the absolute step size used for numerical approximation of the jacobian via forward differences.

**return_all**  
[bool, optional] Set to True to return a list of the best solution at each of the iterations.

**finite_diff_rel_step**  
[None or array_like, optional] If \( \text{jac} \) in ['2-point', '3-point', 'cs'] the relative step size to use for numerical approximation of the jacobian. The absolute step size is computed as \( h = \text{rel_step} \times \text{sign}(x0) \times \max(1, \text{abs}(x0)) \), possibly adjusted to fit into the bounds. For method='3-point' the sign of \( h \) is ignored. If None (default) then step is selected automatically.

**minimize(method='BFGS')**

scipy.optimize.minimize (fun, x0, args=(), method='BFGS', jac=None, tol=None, callback=None, options={'gtol': 1e-05, 'norm': inf, 'eps': 1.4901161193847656e-08, 'maxiter': None, 'disp': False, 'return_all': False, 'finite_diff_rel_step': None})

Minimization of scalar function of one or more variables using the BFGS algorithm.

**See also:**

For documentation for the rest of the parameters, see scipy.optimize.minimize

**Options**

**disp**  
[bool] Set to True to print convergence messages.
**maxiter**  [int] Maximum number of iterations to perform.

**gtol**  [float] Gradient norm must be less than gtol before successful termination.

**norm**  [float] Order of norm (Inf is max, -Inf is min).

**eps**  [float or ndarray] If jac is None the absolute step size used for numerical approximation of the jacobian via forward differences.

**return_all**  [bool, optional] Set to True to return a list of the best solution at each of the iterations.

**finite_diff_rel_step**  [None or array_like, optional] If jac in ['2-point', '3-point', 'cs'] the relative step size to use for numerical approximation of the jacobian. The absolute step size is computed as h = rel_step * sign(x0) * max(1, abs(x0)), possibly adjusted to fit into the bounds. For method='3-point' the sign of h is ignored. If None (default) then step is selected automatically.

**minimize(method='Newton-CG')**

```python
scipy.optimize.minimize(fun, x0, args=(), method='Newton-CG', jac=None, hess=None, hessp=None, tol=None, callback=None, options={'xtol': 1e-05, 'eps': 1.4901161193847656e-08, 'maxiter': None, 'disp': False, 'return_all': False})
```

Minimization of scalar function of one or more variables using the Newton-CG algorithm.

Note that the jac parameter (Jacobian) is required.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

**Options**

- **disp**  [bool] Set to True to print convergence messages.
- **xtol**  [float] Average relative error in solution xopt acceptable for convergence.
- **maxiter**  [int] Maximum number of iterations to perform.
- **eps**  [float or ndarray] If hessp is approximated, use this value for the step size.
- **return_all**  [bool, optional] Set to True to return a list of the best solution at each of the iterations.

**minimize(method='L-BFGS-B')**

```python
scipy.optimize.minimize(fun, x0, args=(), method='L-BFGS-B', jac=None, bounds=None, tol=None, callback=None, options={'disp': None, 'maxcor': 10, 'ftol': 2.220446049250313e-09, 'gtol': 1e-05, 'eps': 1e-08, 'maxfun': 15000, 'maxiter': 15000, 'iprint': -1, 'maxls': 20, 'finite_diff_rel_step': None})
```

Minimize a scalar function of one or more variables using the L-BFGS-B algorithm.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

**Options**

- **disp**  [None or int] If disp is None (the default), then the supplied version of iprint is used. If disp is not None, then it overrides the supplied version of iprint with the behaviour you outlined.
- **maxcor**  [int] The maximum number of variable metric corrections used to define the limited memory matrix. (The limited memory BFGS method does not store the full hessian but uses this many terms in an approximation to it.)
- **ftol**  [float] The iteration stops when (f^k - f^{k+1}) / max{|f^k|,|f^{k+1}|,1} <= ftol.
- **gtol**  [float] The iteration will stop when max{|proj g_i | i = 1, ..., n) <= gtol where pg_i is the i-th component of the projected gradient.

6.19. Optimization and root finding (scipy.optimize)

</tbody>
</table>

Notes

The option `ftol` is exposed via the `scipy.optimize.minimize` interface, but calling `scipy.optimize.fmin_l_bfgs_b` directly exposes `factr`. The relationship between the two is `ftol = factr * numpy.finfo(float).eps`. I.e., `factr` multiplies the default machine floating-point precision to arrive at `ftol`.

`minimize(method='TNC')`

`scipy.optimize.minimize` (fun, x0, args=(), method='TNC', jac=None, bounds=None, tol=None, callback=None, options={'eps': 1e-08, 'scale': None, 'offset': None, 'mesg_num': None, 'maxCGit': -1, 'maxiter': None, 'eta': -1, 'stepmx': 0, 'accuracy': 0, 'minfev': 0, 'ftol': -1, 'xtol': -1, 'gtol': -1, 'rescale': -1, 'disp': False, 'finite_diff_rel_step': None, 'maxfun': None})

Minimize a scalar function of one or more variables using a truncated Newton (TNC) algorithm.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize`
accuracy [float] Relative precision for finite difference calculations. If <= machine_precision, set to \sqrt{\text{machine\_precision}}. Defaults to 0.

minfev [float] Minimum function value estimate. Defaults to 0.

ftol [float] Precision goal for the value of f in the stopping criterion. If ftol < 0.0, ftol is set to 0.0 defaults to -1.

xtol [float] Precision goal for the value of x in the stopping criterion (after applying x scaling factors). If xtol < 0.0, xtol is set to \sqrt{\text{machine\_precision}}. Defaults to -1.

gtol [float] Precision goal for the value of the projected gradient in the stopping criterion (after applying x scaling factors). If gtol < 0.0, gtol is set to 1e-2 * \sqrt{\text{accuracy}}. Setting it to 0.0 is not recommended. Defaults to -1.

rescale [float] Scaling factor (in log10) used to trigger f value rescaling. If 0, rescale at each iteration. If a large value, never rescale. If < 0, rescale is set to 1.3.

finite_diff_rel_step

[None or array_like, optional] If \text{jac in \{2-point, 3-point, cs\}} the relative step size to use for numerical approximation of the jacobian. The absolute step size is computed as \( h = \text{rel\_step} \times \text{sign}(x0) \times \max(1, \abs{x0}) \), possibly adjusted to fit into the bounds. For method='3-point' the sign of \( h \) is ignored. If None (default) then step is selected automatically.

maxfun [int] Maximum number of function evaluations. If None, maxfun is set to max(100, 10*len(x0)). Defaults to None.

minimize(method='COBYLA')

\text{scipy.optimize.minimize}(\text{fun, x0, args=(), method='COBYLA', constraints=(), tol=None, callback=None, options={'rhobeg': 1.0, 'maxiter': 1000, 'disp': False, 'catol': 0.0002})

Minimize a scalar function of one or more variables using the Constrained Optimization BY Linear Approximation (COBYLA) algorithm.

See also:

For documentation for the rest of the parameters, see \text{scipy.optimize.minimize}

\textbf{Options}

rhobeg [float] Reasonable initial changes to the variables.

tol [float] Final accuracy in the optimization (not precisely guaranteed). This is a lower bound on the size of the trust region.

disp [bool] Set to True to print convergence messages. If False, \text{verbosity} is ignored as set to 0.

maxiter [int] Maximum number of function evaluations.

catol [float] Tolerance (absolute) for constraint violations

minimize(method='SLSQP')

\text{scipy.optimize.minimize}(\text{fun, x0, args=(), method='SLSQP', jac=None, bounds=None, constraints=(), tol=None, callback=None, options={'func': None, 'maxiter': 100, 'ftol': 1e-06, 'iprint': 1, 'disp': False, 'eps': 1.4901161193847656e-08, 'finite_diff_rel_step': None})

Minimize a scalar function of one or more variables using Sequential Least Squares Programming (SLSQP).

See also:

For documentation for the rest of the parameters, see \text{scipy.optimize.minimize}

\textbf{Options}

ftol [float] Precision goal for the value of f in the stopping criterion.

eps [float] Step size used for numerical approximation of the Jacobian.

disp [bool] Set to True to print convergence messages. If False, verbosity is ignored and set to 0.

maxiter [int] Maximum number of iterations.

finite_diff_rel_step

[None or array_like, optional] If jac in ['2-point', '3-point', 'cs'] the relative step size to use for numerical approximation of jac. The absolute step size is computed as h = rel_step * sign(x0) * max(1, abs(x0)), possibly adjusted to fit into the bounds. For method='3-point' the sign of h is ignored. If None (default) then step is selected automatically.

minimize(method='trust-constr')

scipy.optimize.minimize (fun, x0, args=(), method='trust-constr', hess=None, hessp=None, bounds=None, constraints=(), tol=None, callback=None, options={'grad': None, 'xtol': 1e-08, 'gtol': 1e-08, 'barrier_tol': 1e-08, 'sparse_jacobian': None, 'maxiter': 1000, 'verbose': 0, 'finite_diff_rel_step': None, 'initial_constr_penalty': 1.0, 'initial_tr_radius': 1.0, 'initial_barrier_parameter': 0.1, 'initial_barrier_tolerance': 0.1, 'factorization_method': None, 'disp': False})

Minimize a scalar function subject to constraints.

Parameters

gtol [float, optional] Tolerance for termination by the norm of the Lagrangian gradient. The algorithm will terminate when both the infinity norm (i.e., max abs value) of the Lagrangian gradient and the constraint violation are smaller than gtol. Default is 1e-8.

xtol [float, optional] Tolerance for termination by the change of the independent variable. The algorithm will terminate when tr_radius < xtol, where tr_radius is the radius of the trust region used in the algorithm. Default is 1e-8.

barrier_tol [float, optional] Threshold on the barrier parameter for the algorithm termination. When inequality constraints are present, the algorithm will terminate only when the barrier parameter is less than barrier_tol. Default is 1e-8.

sparse_jacobian [[bool, None], optional] Determines how to represent Jacobians of the constraints. If bool, then Jacobians of all the constraints will be converted to the corresponding format. If None (default), then Jacobians won’t be converted, but the algorithm can proceed only if they all have the same format.

initial_tr_radius: float, optional

Initial trust radius. The trust radius gives the maximum distance between solution points in consecutive iterations. It reflects the trust the algorithm puts in the local approximation of the optimization problem. For an accurate local approximation the trust-region should be large and for an approximation valid only close to the current point it should be a small one. The trust radius is automatically updated throughout the optimization process, with initial_tr_radius being its initial value. Default is 1 (recommended in [1], p. 19).

initial_constr_penalty [float, optional] Initial constraints penalty parameter. The penalty parameter is used for balancing the requirements of decreasing the objective function and satisfying the constraints. It is used for defining the merit function: merit_function(x) = fun(x) + constr_penalty * constr_norm_l2(x), where constr_norm_l2(x) is the l2 norm of a vector containing all the constraints. The merit function is used for accepting or rejecting trial points and constr_penalty weights the two conflicting goals of reducing objective function and constraints. The penalty is automatically updated throughout the optimization process, with initial_constr_penalty being its initial value. Default is 1 (recommended in [1], p 19).

initial_barrier_parameter, initial_barrier_tolerance: float, optional

6.19. Optimization and root finding (scipy.optimize)
Initial barrier parameter and initial tolerance for the barrier subproblem. Both are used only when inequality constraints are present. For dealing with optimization problems \( \min_x f(x) \) subject to inequality constraints \( c(x) \leq 0 \) the algorithm introduces slack variables, solving the problem \( \min_{(x,s)} f(x) + \text{barrier\_parameter} \cdot \sum \ln(s) \) subject to the equality constraints \( c(x) + s = 0 \) instead of the original problem. This sub-problem is solved for decreasing values of \text{barrier\_parameter} and with decreasing tolerances for the termination, starting with \text{initial\_barrier\_parameter} for the barrier parameter and \text{initial\_barrier\_tolerance} for the barrier tolerance. Default is 0.1 for both values (recommended in [1] p. 19). Also note that \text{barrier\_parameter} and \text{barrier\_tolerance} are updated with the same prefactor.

\textbf{factorization\_method}

[string or None, optional] Method to factorize the Jacobian of the constraints. Use None (default) for the auto selection or one of:

• ‘NormalEquation’ (requires scikit-sparse)
• ‘AugmentedSystem’
• ‘QRFactorization’
• ‘SVDFactorization’

The methods ‘NormalEquation’ and ‘AugmentedSystem’ can be used only with sparse constraints. The projections required by the algorithm will be computed using, respectively, the normal equation and the augmented system approaches explained in [1]. ‘NormalEquation’ computes the Cholesky factorization of \( A^T A \) and ‘AugmentedSystem’ performs the LU factorization of an augmented system. They usually provide similar results. ‘AugmentedSystem’ is used by default for sparse matrices.

The methods ‘QRFactorization’ and ‘SVDFactorization’ can be used only with dense constraints. They compute the required projections using, respectively, QR and SVD factorizations. The ‘SVDFactorization’ method can cope with Jacobian matrices with deficient row rank and will be used whenever other factorization methods fail (which may imply the conversion of sparse matrices to a dense format when required). By default, ‘QRFactorization’ is used for dense matrices.

\textbf{finite\_diff\_rel\_step}

[None or array_like, optional] Relative step size for the finite difference approximation.

\textbf{maxiter}

[int, optional] Maximum number of algorithm iterations. Default is 1000.

\textbf{verbose}

[[0, 1, 2], optional] Level of algorithm’s verbosity:

• 0 (default): work silently.
• 1: display a termination report.
• 2: display progress during iterations.
• 3: display progress during iterations (more complete report).

\textbf{disp}

[bool, optional] If True (default), then verbose will be set to 1 if it was 0.

\textbf{Returns}

\texttt{OptimizeResult} with the fields documented below. Note the following:

1. All values corresponding to the constraints are ordered as they were passed to the solver. And values corresponding to \texttt{bounds} constraints are put after other constraints.
2. All numbers of function, Jacobian or Hessian evaluations correspond to numbers of actual Python function calls. It means, for example, that if a Jacobian is estimated by finite differences, then the number of Jacobian evaluations will be zero and the number of function evaluations will be incremented by all calls during the finite difference estimation.

\textbf{x}

[ndarray, shape (n,)] Solution found.

\textbf{optimality}

[float] Infinity norm of the Lagrangian gradient at the solution.

\textbf{constr\_violation}

[float] Maximum constraint violation at the solution.

\textbf{fun}

[float] Objective function at the solution.

\textbf{grad}

[ndarray, shape (n,)] Gradient of the objective function at the solution.
**lagrangian_grad**

[ndarray, shape (n,)] Gradient of the Lagrangian function at the solution.

**nit**

[int] Total number of iterations.

**nfev**

[integer] Number of the objective function evaluations.

**njev**

[integer] Number of the objective function gradient evaluations.

**nhev**

[integer] Number of the objective function Hessian evaluations.

**cg_niter**

[int] Total number of the conjugate gradient method iterations.

**method**

[{'equality_constrained_sqp', 'tr_interior_point'}] Optimization method used.

**constr**

[list of ndarray] List of constraint values at the solution.

**jac**

[list of {ndarray, sparse matrix}] List of the Jacobian matrices of the constraints at the solution.

**v**

[list of ndarray] List of the Lagrange multipliers for the constraints at the solution. For an inequality constraint a positive multiplier means that the upper bound is active, a negative multiplier means that the lower bound is active and if a multiplier is zero it means the constraint is not active.

**constr_nfev**

[list of int] Number of constraint evaluations for each of the constraints.

**constr_njev**

[list of int] Number of Jacobian matrix evaluations for each of the constraints.

**constr_nhev**

[list of int] Number of Hessian evaluations for each of the constraints.

**tr_radius**

[float] Radius of the trust region at the last iteration.

**constr_penalty**

[float] Penalty parameter at the last iteration, see *initial_constr_penalty*.

**barrier_tolerance**

[float] Tolerance for the barrier subproblem at the last iteration. Only for problems with inequality constraints.

**barrier_parameter**

[float] Barrier parameter at the last iteration. Only for problems with inequality constraints.

**execution_time**

[float] Total execution time.

**message**

[st] Termination message.

**status**

[0, 1, 2, 3] Termination status:

• 0: The maximum number of function evaluations is exceeded.
• 1: *gtol* termination condition is satisfied.
• 2: *xtol* termination condition is satisfied.
• 3: *callback* function requested termination.

**cg_stop_cond**

[int] Reason for CG subproblem termination at the last iteration:

• 0: CG subproblem not evaluated.
• 1: Iteration limit was reached.
• 2: Reached the trust-region boundary.
• 3: Negative curvature detected.
• 4: Tolerance was satisfied.

`minimize(method='trust-krylov')`

```python
scipy.optimize.minimize (fun, x0, args=(), method='trust-krylov', jac=None, hess=None, hessp=None, tol=None, callback=None, options={'inexact': True})
```

Minimization of a scalar function of one or more variables using a nearly exact trust-region algorithm that only requires matrix vector products with the hessian matrix.

New in version 1.0.0.

See also:
For documentation for the rest of the parameters, see `scipy.optimize.minimize`

**Options**
inexact [bool, optional] Accuracy to solve subproblems. If True requires less nonlinear iterations, but more vector products.

minimize(method='trust-exact')

scipy.optimize.minimize (fun, x0, args=(), method='trust-exact', jac=None, hess=None, tol=None, callback=None, options={})

Minimization of scalar function of one or more variables using an exact trust-region algorithm.

See also:

For documentation for the rest of the parameters, see scipy.optimize.minimize

Options

initial_tr_radius [float] Initial trust-region radius.

max_tr_radius [float] Maximum value of the trust-region radius. No steps that are longer than this value will be proposed.

eta [float] Trust region related acceptance stringency for proposed steps.

gtol [float] Gradient norm must be less than gtol before successful termination.

Constraints are passed to minimize function as a single object or as a list of objects from the following classes:

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NonlinearConstraint</td>
<td>Nonlinear constraint on the variables.</td>
</tr>
<tr>
<td>LinearConstraint</td>
<td>Linear constraint on the variables.</td>
</tr>
</tbody>
</table>

scipy.optimize.NonlinearConstraint

class scipy.optimize.NonlinearConstraint (fun, lb, ub[, jac, ...])

Nonlinear constraint on the variables.

The constraint has the general inequality form:

```
lb <= fun(x) <= ub
```

Here the vector of independent variables x is passed as ndarray of shape (n,) and fun returns a vector with m components.

It is possible to use equal bounds to represent an equality constraint or infinite bounds to represent a one-sided constraint.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fun</td>
<td>[callable] The function defining the constraint. The signature is fun(x) -&gt; array_like, shape (m,).</td>
</tr>
<tr>
<td>lb, ub</td>
<td>[array_like] Lower and upper bounds on the constraint. Each array must have the shape (m,) or be a scalar, in the latter case a bound will be the same for all components of the constraint. Use np.inf with an appropriate sign to specify a one-sided constraint. Set components of lb and ub equal to represent an equality constraint. Note that you can mix constraints of different types: interval, one-sided or equality, by setting different components of lb and ub as necessary.</td>
</tr>
</tbody>
</table>
jac  [{callable, '2-point', '3-point', 'cs'}, optional] Method of computing the Jacobian matrix (an
m-by-n matrix, where element (i, j) is the partial derivative of f[i] with respect to x[j]).
The keywords {'2-point', '3-point', 'cs'} select a finite difference scheme for the numerical
estimation. A callable must have the following signature: `jac(x) -> {ndarray, sparse matrix}, shape (m, n)`. Default is '2-point'.

computing the Hessian matrix. The keywords {'2-point', '3-point', 'cs'} select a finite differ-
ence scheme for numerical estimation. Alternatively, objects implementing HessianUp-
dateStrategy interface can be used to approximate the Hessian. Currently available
implementations are:
- BFGS (default option)
- SR1
A callable must return the Hessian matrix of `dot(fun, v)` and must have the fol-
lowing signature: `hess(x, v) -> {LinearOperator, sparse matrix, array_like}, shape (n, n)`. Here `v` is ndarray with shape (m,) containing La-
grange multipliers.

keep_feasible  [array_like of bool, optional] Whether to keep the constraint components feasible throughout
iterations. A single value set this property for all components. Default is False. Has no effect
for equality constraints.

finite_diff_rel_step: None or array_like, optional
Relative step size for the finite difference approximation. Default is None, which will select
a reasonable value automatically depending on a finite difference scheme.

finite_diff_jac_sparsity: {None, array_like, sparse matrix}, optional
Defines the sparsity structure of the Jacobian matrix for finite difference estimation, its shape
must be (m, n). If the Jacobian has only few non-zero elements in each row, providing
the sparsity structure will greatly speed up the computations. A zero entry means that a
Corresponding element in the Jacobian is identically zero. If provided, forces the use of
'lsqr' trust-region solver. If None (default) then dense differencing will be used.

Notes

Finite difference schemes {'2-point', '3-point', 'cs'} may be used for approximating either the Jacobian or the Hes-
sian. We, however, do not allow its use for approximating both simultaneously. Hence whenever the Jacobian is
estimated via finite-differences, we require the Hessian to be estimated using one of the quasi-Newton strategies.

The scheme 'cs' is potentially the most accurate, but requires the function to correctly handles complex inputs and
be analytically continuable to the complex plane. The scheme '3-point' is more accurate than '2-point' but requires
twice as many operations.

Examples

Constrain `x[0] < sin(x[1]) + 1.9`

```python
>>> from scipy.optimize import NonlinearConstraint
>>> con = lambda x: x[0] - np.sin(x[1])
>>> nlc = NonlinearConstraint(con, -np.inf, 1.9)
```
scipy.optimize.LinearConstraint

class scipy.optimize.LinearConstraint (A, lb, ub, keep_feasible=False)

Linear constraint on the variables.

The constraint has the general inequality form:

\[ \text{lb} \leq A \cdot \text{x} \leq \text{ub} \]

Here the vector of independent variables \( \text{x} \) is passed as ndarray of shape (n,) and the matrix A has shape (m, n).

It is possible to use equal bounds to represent an equality constraint or infinite bounds to represent a one-sided constraint.

**Parameters**

- **A**
  - [array_like, sparse matrix], shape (m, n) Matrix defining the constraint.

- **lb, ub**
  - [array_like] Lower and upper bounds on the constraint. Each array must have the shape (m,) or be a scalar, in the latter case a bound will be the same for all components of the constraint. Use np.inf with an appropriate sign to specify a one-sided constraint. Set components of \( \text{lb} \) and \( \text{ub} \) equal to represent an equality constraint. Note that you can mix constraints of different types: interval, one-sided or equality, by setting different components of \( \text{lb} \) and \( \text{ub} \) as necessary.

- **keep_feasible**
  - [array_like of bool, optional] Whether to keep the constraint components feasible throughout iterations. A single value set this property for all components. Default is False. Has no effect for equality constraints.

Simple bound constraints are handled separately and there is a special class for them:

**Bounds**(lb, ub[, keep_feasible])

Bounds constraint on the variables.

scipy.optimize.Bounds

class scipy.optimize.Bounds (lb, ub, keep_feasible=False)

Bounds constraint on the variables.

The constraint has the general inequality form:

\[ \text{lb} \leq \text{x} \leq \text{ub} \]

It is possible to use equal bounds to represent an equality constraint or infinite bounds to represent a one-sided constraint.

**Parameters**

- **lb, ub**
  - [array_like, optional] Lower and upper bounds on independent variables. Each array must have the same size as \( \text{x} \) or be a scalar, in which case a bound will be the same for all the variables. Set components of \( \text{lb} \) and \( \text{ub} \) equal to fix a variable. Use np.inf with an appropriate sign to disable bounds on all or some variables. Note that you can mix constraints of different types: interval, one-sided or equality, by setting different components of \( \text{lb} \) and \( \text{ub} \) as necessary.

- **keep_feasible**
  - [array_like of bool, optional] Whether to keep the constraint components feasible throughout iterations. A single value set this property for all components. Default is False. Has no effect for equality constraints.

Quasi-Newton strategies implementing HessianUpdateStrategy interface can be used to approximate the Hessian in minimize function (available only for the ‘trust-constr’ method). Available quasi-Newton methods implementing this
interface are:

<table>
<thead>
<tr>
<th>BFGS([exception_strategy, min_curvature, ...])</th>
<th>Broyden-Fletcher-Goldfarb-Shanno (BFGS) Hessian update strategy.</th>
</tr>
</thead>
<tbody>
<tr>
<td>SR1([min_denominator, init_scale])</td>
<td>Symmetric-rank-1 Hessian update strategy.</td>
</tr>
</tbody>
</table>

`scipy.optimize.BFGS`

class `scipy.optimize.BFGS`(exception_strategy='skip_update', min_curvature=None, init_scale='auto')

Broyden-Fletcher-Goldfarb-Shanno (BFGS) Hessian update strategy.

**Parameters**

- **exception_strategy**
  [[‘skip_update’, ‘damp_update’], optional] Define how to proceed when the curvature condition is violated. Set it to ‘skip_update’ to just skip the update. Or, alternatively, set it to ‘damp_update’ to interpolate between the actual BFGS result and the unmodified matrix. Both exceptions strategies are explained in [1], p.536-537.

- **min_curvature**
  [float] This number, scaled by a normalization factor, defines the minimum curvature `\text{dot}(\text{delta}_\text{grad}, \text{delta}_\text{x})` allowed to go unaffected by the exception strategy. By default is equal to `1e-8` when `exception_strategy = ‘skip_update’` and equal to `0.2` when `exception_strategy = ‘damp_update’`.

- **init_scale**
  [[float, ‘auto’]] Matrix scale at first iteration. At the first iteration the Hessian matrix or its inverse will be initialized with `\text{init_scale} \times \text{np.eye(n)}`, where `n` is the problem dimension. Set it to ‘auto’ in order to use an automatic heuristic for choosing the initial scale. The heuristic is described in [1], p.143. By default uses ‘auto’.

**Notes**

The update is based on the description in [1], p.140.

**References**

[1]

**Methods**

- **dot(self, p)** Compute the product of the internal matrix with the given vector.
- **get_matrix(self)** Return the current internal matrix.
- **initialize(self, n, approx_type)** Initialize internal matrix.
- **update(self, delta_x, delta_grad)** Update internal matrix.
**scipy.optimize.BFGS.dot**

```
BFGS.dot(self, p)
```

Computethe product of the internal matrix with the given vector.

**Parameters**

- `p` : [array_like] 1-D array representing a vector.

**Returns**

- `Hp` : [array] 1-D represents the result of multiplying the approximation matrix by vector `p`.

**scipy.optimize.BFGS.get_matrix**

```
BFGS.get_matrix(self)
```

Returnthecurrentinternal matrix.

**Returns**

- `M` : [ndarray, shape (n, n)] Dense matrix containing either the Hessian or its inverse (depending on how `approx_type` was defined).

**scipy.optimize.BFGS.initialize**

```
BFGS.initialize(self, n, approx_type)
```

Initializeinternalmatrix.

Allocate internal memory for storing and updating the Hessian or its inverse.

**Parameters**

- `n` : [int] Problem dimension.
- `approx_type` : [\{'hess', 'inv_hess'\}] Selects either the Hessian or the inverse Hessian. When set to 'hess' the Hessian will be stored and updated. When set to 'inv_hess' its inverse will be used instead.

**scipy.optimize.BFGS.update**

```
BFGS.update(self, delta_x, delta_grad)
```

Updatetheinnermatrix.

Update Hessian matrix or its inverse (depending on how `approx_type` is defined) using information about the last evaluated points.

**Parameters**

- `delta_x` : [ndarray] The difference between two points the gradient function have been evaluated at: `delta_x = x2 - x1`.
- `delta_grad` : [ndarray] The difference between the gradients: `delta_grad = grad(x2) - grad(x1)`.
scipy.optimize.SR1

class scipy.optimize.SR1(min_denominator=1e-08, init_scale='auto')
Symmetric-rank-1 Hessian update strategy.

Parameters

min_denominator [float] This number, scaled by a normalization factor, defines the minimum denominator magnitude allowed in the update. When the condition is violated we skip the update. By default uses $1e^{-8}$.

init_scale [float, 'auto'], optional] Matrix scale at first iteration. At the first iteration the Hessian matrix or its inverse will be initialized with init_scale*np.eye(n), where n is the problem dimension. Set it to 'auto' in order to use an automatic heuristic for choosing the initial scale. The heuristic is described in [1], p.143. By default uses 'auto'.

Notes
The update is based on the description in [1], p.144-146.

Methods

dot(self, p) Compute the product of the internal matrix with the given vector.

get_matrix(self) Return the current internal matrix.

initialize(self, n, approx_type) Initialize internal matrix.

update(self, delta_x, delta_grad) Update internal matrix.

scipy.optimize.SR1.dot

SR1.dot (self, p)
Compute the product of the internal matrix with the given vector.

Parameters

p [array_like] 1-D array representing a vector.

Returns

Hp [array] 1-D represents the result of multiplying the approximation matrix by vector p.
**scipy.optimize.SR1.get_matrix**

SR1.get_matrix(self)

Return the current internal matrix.

**Returns**

M : ndarray, shape (n, n)
    Dense matrix containing either the Hessian or its inverse (depending on how approx_type was defined).

**scipy.optimize.SR1.initialize**

SR1.initialize(self, n, approx_type)

Initialize internal matrix.

Allocate internal memory for storing and updating the Hessian or its inverse.

**Parameters**

n : int
    Problem dimension.

approx_type : {‘hess’, ‘inv_hess’}
    Selects either the Hessian or the inverse Hessian. When set to ‘hess’ the Hessian will be stored and updated. When set to ‘inv_hess’ its inverse will be used instead.

**scipy.optimize.SR1.update**

SR1.update(self, delta_x, delta_grad)

Update internal matrix.

Update Hessian matrix or its inverse (depending on how ‘approx_type’ is defined) using information about the last evaluated points.

**Parameters**

delta_x : ndarray
    The difference between two points the gradient function have been evaluated at: \( \Delta x = x_2 - x_1 \).

delta_grad : ndarray
    The difference between the gradients: \( \Delta \text{grad} = \text{grad}(x_2) - \text{grad}(x_1) \).

scipy.optimize.basinhopping

scipy.optimize.basinhopping(func, x0, niter=100, T=1.0, stepsize=0.5, minimizer_kwargs=None, take_step=None, accept_test=None, callback=None, interval=50, disp=False, niter_success=None, seed=None)

Find the global minimum of a function using the basin-hopping algorithm

Basin-hopping is a two-phase method that combines a global stepping algorithm with local minimization at each step. Designed to mimic the natural process of energy minimization of clusters of atoms, it works well for similar problems with “funnel-like, but rugged” energy landscapes [5].

As the step-taking, step acceptance, and minimization methods are all customizable, this function can also be used to implement other two-phase methods.

Parameters

- **func**: [callable f(x, *args)] Function to be optimized. args can be passed as an optional item in the dict minimizer_kwargs
- **x0**: [array_like] Initial guess.
- **niter**: [integer, optional] The number of basin-hopping iterations. There will be a total of niter + 1 runs of the local minimizer.
- **T**: [float, optional] The “temperature” parameter for the accept or reject criterion. Higher “temperatures” mean that larger jumps in function value will be accepted. For best results T should be comparable to the separation (in function value) between local minima.
- **minimizer_kwargs**: [dict, optional] Extra keyword arguments to be passed to the local minimizer scipy.optimize.minimize() Some important options could be:
  - **method** [str] The minimization method (e.g. "L-BFGS-B")
  - **args** [tuple] Extra arguments passed to the objective function (func) and its derivatives (Jacobian, Hessian).
- **take_step**: [callable take_step(x), optional] Replace the default step-taking routine with this routine. The default step-taking routine is a random displacement of the coordinates, but other step-taking algorithms may be better for some systems. take_step can optionally have the attribute take_step.stepsize. If this attribute exists, then basinhopping will adjust take_step.stepsize in order to try to optimize the global minimum search.
- **accept_test**: [callable, accept_test(f_new=f_new, x_new=x_new, f_old=fold, x_old=x_old), optional] Define a test which will be used to judge whether or not to accept the step. This will be used in addition to the Metropolis test based on “temperature” T. The acceptable return values are True, False, or "force accept". If any of the tests return False then the step is rejected. If the latter, then this will override any other tests in order to accept the step. This can be used, for example, to forcefully escape from a local minimum that basinhopping is trapped in.
- **callback**: [callable, callback(x, f, accept), optional] A callback function which will be called for all minima found. x and f are the coordinates and function value of the trial minimum, and accept is whether or not that minimum was accepted. This can be used, for example, to save the lowest N minima found. Also, callback can be used to specify a user defined stop criterion by optionally returning True to stop the basinhopping routine.
- **interval**: [integer, optional] interval for how often to update the stepsize
- **disp**: [bool, optional] Set to True to print status messages
- **niter_success**: [integer, optional] Stop the run if the global minimum candidate remains the same for this number of iterations.
- **seed**: [{int, RandomState, Generator}, optional] If seed is not specified the RandomState singleton is used. If seed is an int, a new RandomState instance is used, seeded with seed. If seed is already a RandomState or Generator instance, then that object is used. Specify seed
for repeatable minimizations. The random numbers generated with this seed only affect the
default Metropolis accept-test and the default take-step. If you supply your own take-step
and accept-test, and these functions use random number generation, then those functions are
responsible for the state of their random number generator.

**Returns**

`res` [OptimizeResult] The optimization result represented as a `OptimizeResult` object. Im-
portant attributes are: `x` the solution array, `fun` the value of the function at the solution, and
`message` which describes the cause of the termination. The `OptimizeResult` object
returned by the selected minimizer at the lowest minimum is also contained within this ob-
ject and can be accessed through the `lowest_optimization_result` attribute. See
`OptimizeResult` for a description of other attributes.

**See also:**

minimize

The local minimization function called once for each basinhopping step. `minimizer_kwargs` is passed to
this routine.

**Notes**

Basin-hopping is a stochastic algorithm which attempts to find the global minimum of a smooth scalar function of
one or more variables [1] [2] [3] [4]. The algorithm in its current form was described by David Wales and Jonathan

The algorithm is iterative with each cycle composed of the following features

1) random perturbation of the coordinates
2) local minimization
3) accept or reject the new coordinates based on the minimized function value

The acceptance test used here is the Metropolis criterion of standard Monte Carlo algorithms, although there are
many other possibilities [3].

This global minimization method has been shown to be extremely efficient for a wide variety of problems in physics
and chemistry. It is particularly useful when the function has many minima separated by large barriers. See the
Cambridge Cluster Database http://www-wales.ch.cam.ac.uk/CCD.html for databases of molecular systems that
have been optimized primarily using basin-hopping. This database includes minimization problems exceeding 300
degrees of freedom.

See the free software program GMIN (http://www-wales.ch.cam.ac.uk/GMIN) for a Fortran implementation of
basin-hopping. This implementation has many different variations of the procedure described above, including
more advanced step taking algorithms and alternate acceptance criterion.

For stochastic global optimization there is no way to determine if the true global minimum has actually been
found. Instead, as a consistency check, the algorithm can be run from a number of different random starting points
to ensure the lowest minimum found in each example has converged to the global minimum. For this reason,
`basinhopping` will by default simply run for the number of iterations `niter` and return the lowest minimum
found. It is left to the user to ensure that this is in fact the global minimum.

**Choosing stepsize**: This is a crucial parameter in `basinhopping` and depends on the problem being solved.
The step is chosen uniformly in the region from `x0-stepsize` to `x0+stepsize`, in each dimension. Ideally, it should be
comparable to the typical separation (in argument values) between local minima of the function being optimized.
`basinhopping` will, by default, adjust `stepsize` to find an optimal value, but this may take many iterations.
You will get quicker results if you set a sensible initial value for `stepsize`. 
Choosing T: The parameter T is the “temperature” used in the Metropolis criterion. Basin hopping steps are always accepted if \( \text{func}(x_{\text{new}}) < \text{func}(x_{\text{old}}) \). Otherwise, they are accepted with probability:

\[
\exp\left( -\frac{\text{func}(x_{\text{new}}) - \text{func}(x_{\text{old}})}{T} \right)
\]

So, for best results, T should be comparable to the typical difference (in function values) between local minima. (The height of “walls” between local minima is irrelevant.)

If T is 0, the algorithm becomes Monotonic Basin-Hopping, in which all steps that increase energy are rejected.

New in version 0.12.0.

References

[1], [2], [3], [4], [5]

Examples

The following example is a 1-D minimization problem, with many local minima superimposed on a parabola.

```python
>>> from scipy.optimize import basinhopping
>>> func = lambda x: np.cos(14.5 * x - 0.3) + (x + 0.2) * x
>>> x0=[1.]
```

Basinhopping, internally, uses a local minimization algorithm. We will use the parameter `minimizer_kwargs` to tell basinhopping which algorithm to use and how to set up that minimizer. This parameter will be passed to `scipy.optimize.minimize()`.

```python
>>> minimizer_kwargs = {"method": "BFGS"}
>>> ret = basinhopping(func, x0, minimizer_kwargs=minimizer_kwargs,
...     niter=200)
>>> print("global minimum: x = %.4f, f(x0) = %.4f" % (ret.x, ret.fun))
global minimum: x = -0.1951, f(x0) = -1.0009
```

Next consider a 2-D minimization problem. Also, this time, we will use gradient information to significantly speed up the search.

```python
>>> def func2d(x):
...     f = np.cos(14.5 * x[0] - 0.3) + (x[1] + 0.2) * x[1] + (x[0] +
...         0.2) * x[0]
...     df = np.zeros(2)
...     df[0] = -14.5 * np.sin(14.5 * x[0] - 0.3) + 2. * x[0] + 0.2
...     df[1] = 2. * x[1] + 0.2
...     return f, df
```

We'll also use a different local minimization algorithm. Also, we must tell the minimizer that our function returns both energy and gradient (Jacobian).

```python
>>> minimizer_kwargs = {"method":"L-BFGS-B", "jac":True}
>>> x0 = [1.0, 1.0]
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...     niter=200)
>>> print("global minimum: x = [%.4f, %.4f], f(x0) = %.4f" % (ret.x[0],
...     ret.x[1],
```

(continues on next page)
Here is an example using a custom step-taking routine. Imagine you want the first coordinate to take larger steps than the rest of the coordinates. This can be implemented like so:

```python
>>> class MyTakeStep(object):
...     def __init__(self, stepsize=0.5):
...         self.stepsize = stepsize
...     def __call__(self, x):
...         s = self.stepsize
...         x[0] += np.random.uniform(-2.*s, 2.*s)
...         x[1:] += np.random.uniform(-s, s, x[1:].shape)
...         return x
```

Since `MyTakeStep.stepsize` exists, basinhopping will adjust the magnitude of `stepsize` to optimize the search. We'll use the same 2-D function as before:

```python
>>> mytakestep = MyTakeStep()
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...                    niter=200, take_step=mynakestep)
```

Now, let's do an example using a custom callback function which prints the value of every minimum found:

```python
>>> def print_fun(x, f, accepted):
...     print("at minimum %.4f accepted %d" % (f, int(accepted)))
```

We'll run it for only 10 basinhopping steps this time:

```python
>>> np.random.seed(1)
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...                    niter=10, callback=print_fun)
```

The minimum at -1.0109 is actually the global minimum, found already on the 8th iteration.

Now let's implement bounds on the problem using a custom accept_test:

```python
>>> class MyBounds(object):
...     def __init__(self, xmax=[1.1, 1.1], xmin=[-1.1, -1.1]):
```

(continues on next page)
... self.xmax = np.array(xmax)
... self.xmin = np.array(xmin)
... def __call__(self, **kwargs):
...     x = kwargs['x_new']
...     tmax = bool(np.all(x <= self.xmax))
...     tmin = bool(np.all(x >= self.xmin))
...     return tmax and tmin

>>> mybounds = MyBounds()
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...                     niter=10, accept_test=mybounds)

scipy.optimize.brute

scipy.optimize.brute(func, ranges, args=(), Ns=20, full_output=0, finish=<function fmin at 0x7f068c640e60>, disp=False, workers=1)

Minimize a function over a given range by brute force.

Uses the “brute force” method, i.e., computes the function’s value at each point of a multidimensional grid of points, to find the global minimum of the function.

The function is evaluated everywhere in the range with the datatype of the first call to the function, as enforced by the vectorize NumPy function. The value and type of the function evaluation returned when full_output=True are affected in addition by the finish argument (see Notes).

The brute force approach is inefficient because the number of grid points increases exponentially - the number of grid points to evaluate is \( Ns^{\text{len}(x)} \). Consequently, even with coarse grid spacing, even moderately sized problems can take a long time to run, and/or run into memory limitations.

**Parameters**

- **func** [callable] The objective function to be minimized. Must be in the form \( f(x, *\text{args}) \), where \( x \) is the argument in the form of a 1-D array and \( \text{args} \) is a tuple of any additional fixed parameters needed to completely specify the function.
- **ranges** [tuple] Each component of the ranges tuple must be either a “slice object” or a range tuple of the form \((\text{low}, \text{high})\). The program uses these to create the grid of points on which the objective function will be computed. See Note 2 for more detail.
- **args** [tuple, optional] Any additional fixed parameters needed to completely specify the function.
- **Ns** [int, optional] Number of grid points along the axes, if not otherwise specified. See Note 2.
- **full_output** [bool, optional] If True, return the evaluation grid and the objective function’s values on it.
- **finish** [callable, optional] An optimization function that is called with the result of brute force minimization as initial guess. finish should take func and the initial guess as positional arguments, and take args as keyword arguments. It may additionally take full_output and/or disp as keyword arguments. Use None if no “polishing” function is to be used. See Notes for more details.
- **disp** [bool, optional] Set to True to print convergence messages from the finish callable.
- **workers** [int or map-like callable, optional] If workers is an int the grid is subdivided into workers sections and evaluated in parallel (uses multiprocessing.Pool). Supply -1 to use all cores available to the Process. Alternatively supply a map-like callable, such as multiprocessing.Pool.map for evaluating the grid in parallel. This evaluation is carried out as workers(func, iterable). Requires that func be pickleable. New in version 1.3.0.

**Returns**

x0  [ndarray] A 1-D array containing the coordinates of a point at which the objective function had its minimum value. (See Note 1 for which point is returned.)
fvval  [float] Function value at the point x0. (Returned when full_output is True.)
ggrid  [tuple] Representation of the evaluation grid. It has the same length as x0. (Returned when full_output is True.)
Jout  [ndarray] Function values at each point of the evaluation grid, i.e., Jout = func(*grid). (Returned when full_output is True.)

See also:
basinhopping, differential_evolution

Notes

Note 1: The program finds the gridpoint at which the lowest value of the objective function occurs. If finish is None, that is the point returned. When the global minimum occurs within (or not very far outside) the grid’s boundaries, and the grid is fine enough, that point will be in the neighborhood of the global minimum.

However, users often employ some other optimization program to “polish” the gridpoint values, i.e., to seek a more precise (local) minimum near brute’s best gridpoint. The brute function’s finish option provides a convenient way to do that. Any polishing program used must take brute’s output as its initial guess as a positional argument, and take brute’s input values for args as keyword arguments, otherwise an error will be raised. It may additionally take full_output and/or disp as keyword arguments.

brute assumes that the finish function returns either an OptimizeResult object or a tuple in the form: (xmin, Jmin, ..., statuscode), where xmin is the minimizing value of the argument, Jmin is the minimum value of the objective function, “...” may be some other returned values (which are not used by brute), and statuscode is the status code of the finish program.

Note that when finish is not None, the values returned are those of the finish program, not the gridpoint ones. Consequently, while brute confines its search to the input grid points, the finish program’s results usually will not coincide with any gridpoint, and may fall outside the grid’s boundary. Thus, if a minimum only needs to be found over the provided grid points, make sure to pass in finish=None.

Note 2: The grid of points is a numpy.mgrid object. For brute the ranges and Ns inputs have the following effect. Each component of the ranges tuple can be either a slice object or a two-tuple giving a range of values, such as (0, 5). If the component is a slice object, brute uses it directly. If the component is a two-tuple range, brute internally converts it to a slice object that interpolates Ns points from its low-value to its high-value, inclusive.

Examples

We illustrate the use of brute to seek the global minimum of a function of two variables that is given as the sum of a positive-definite quadratic and two deep “Gaussian-shaped” craters. Specifically, define the objective function f as the sum of three other functions, f = f1 + f2 + f3. We suppose each of these has a signature (z, *params), where z = (x, y), and params and the functions are as defined below.

```python
>>> params = (2, 3, 7, 8, 9, 10, 44, -1, 2, 26, 1, -2, 0.5)
>>> def f1(z, *params):
...     x, y = z
...     a, b, c, d, e, f, g, h, i, j, k, l, scale = params
...     return (a * x**2 + b * x * y + c * y**2 + d*x + e*y + f)
```
Thus, the objective function may have local minima near the minimum of each of the three functions of which it is composed. To use `fmin` to polish its gridpoint result, we may then continue as follows:

```python
g1 = lambda x: a * np.exp(- ((x-h)**2 + (y-l)**2) / scale)
g2 = lambda x: b * np.exp(- ((x-h)**2 + (y-l)**2) / scale)
g3 = lambda x: c * np.exp(- ((x-k)**2 + (y-l)**2) / scale)
```

```python
f = lambda x: g1(x) + g2(x) + g3(x)
```

```
>> rranges = (slice(-4, 4, 0.25), slice(-4, 4, 0.25))
>>> from scipy import optimize
>>> resbrute = optimize.brute(f, rranges, args=params, full_output=True, ...   finish=optimize.fmin)
>>> resbrute[0]  # global minimum
array([-1.05665192, 1.80834843])
>>> resbrute[1]  # function value at global minimum
-3.4085818767
```

Note that if `finish` had been set to None, we would have gotten the gridpoint [-1.0 1.75] where the rounded function value is -2.892.

**scipy.optimize.differential_evolution**

`scipy.optimize.differential_evolution(func, bounds, args=(), strategy='best1bin', maxiter=1000, popsize=15, tol=0.01, mutation=0.5, recombination=0.7, seed=None, callback=None, disp=False, polish=True, init='latinhypercube', atol=0, updating='immediate', workers=1, constraints=())`

Finds the global minimum of a multivariate function.

Differential Evolution is stochastic in nature (does not use gradient methods) to find the minimum, and can search large areas of candidate space, but often requires larger numbers of function evaluations than conventional gradient-based techniques.

The algorithm is due to Storn and Price [1].

**Parameters**

- `func` [callable] The objective function to be minimized. Must be in the form `f(x, *args)`, where `x` is the argument in the form of a 1-D array and `args` is a tuple of any additional fixed parameters needed to completely specify the function.
- `bounds` [sequence or `Bounds`, optional] Bounds for variables. There are two ways to specify the bounds: 1. Instance of `Bounds` class. 2. `(min, max)` pairs for each element in `x`, defining the finite lower and upper bounds for the optimizing argument of `func`. It is required to have `len(bounds) == len(x)`. `len(bounds)` is used to determine the number of parameters in `x`.
- `args` [tuple, optional] Any additional fixed parameters needed to completely specify the objective function.
- `strategy` [str, optional] The differential evolution strategy to use. Should be one of:
maxiter [int, optional] The maximum number of generations over which the entire population is evolved. The maximum number of function evaluations (with no polishing) is: 
\[(\text{maxiter} + 1) \times \text{popsize} \times \text{len}(x)\]

popsize [int, optional] A multiplier for setting the total population size. The population has \(\text{popsize} \times \text{len}(x)\) individuals (unless the initial population is supplied via the \text{init} keyword).

tol [float, optional] Relative tolerance for convergence, the solving stops when 
\[\text{np.std(pop)} \leq \text{atol} + \text{tol} \times \text{np.abs(np.mean(population_energies))}\]

mutation [float or tuple(float, float), optional] The mutation constant. In the literature this is also known as differential weight, being denoted by F. If specified as a float it should be in the range [0, 2]. If specified as a tuple \((\text{min}, \text{max})\) dithering is employed. Dithering randomly changes the mutation constant on a generation by generation basis. The mutation constant for that generation is taken from \(U[\text{min}, \text{max})\). Dithering can help speed convergence significantly. Increasing the mutation constant increases the search radius, but will slow down convergence.

recombination [float, optional] The recombination constant, should be in the range [0, 1]. In the literature this is also known as the crossover probability, being denoted by CR. Increasing this value allows a larger number of mutants to progress into the next generation, but at the risk of population stability.

seed [{int, RandomState, Generator}, optional] If \text{seed} is not specified the RandomState singleton is used. If \text{seed} is an int, a new RandomState instance is used, seeded with \text{seed}. If \text{seed} is already a RandomState or a Generator instance, then that object is used. Specify \text{seed} for repeatable minimizations.

disp [bool, optional] Prints the evaluated \text{func} at every iteration.

callback [callable, \text{callback}(\text{xk}, \text{convergence}=\text{val}), optional] A function to follow the progress of the minimization. \text{xk} is the current value of \text{x0}. \text{val} represents the fractional value of the population convergence. When \text{val} is greater than one the function halts. If \text{callback} returns \text{True}, then the minimization is halted (any polishing is still carried out).

polish [bool, optional] If True (default), then \text{scipy.optimize.minimize} with the \text{L-BFGS-B} method is used to polish the best population member at the end, which can improve the minimization slightly. If a constrained problem is being studied then the \text{trust-constr} method is used instead.

init [str or array-like, optional] Specify which type of population initialization is performed. Should be one of:
- 'latinhypercube'
- 'random'
- array specifying the initial population. The array should have shape \((M, \text{len}(x))\), where \(M\) is the total population size and \text{len}(x) is the number of parameters. \text{init} is clipped to bounds before use.
The default is 'latinhypercube'. Latin Hypercube sampling tries to maximize coverage of the available parameter space. 'random' initializes the population randomly - this has the drawback that clustering can occur, preventing the whole of parameter space being covered. Use of an array to specify a population subset could be used, for example, to create a tight bunch of initial guesses in an location where the solution is known to exist, thereby reducing time for convergence.

**atol**

[float, optional] Absolute tolerance for convergence, the solving stops when np.std(pop) <= atol + tol * np.abs(np.mean(population_energies)), where and atol and tol are the absolute and relative tolerance respectively.

**updating**

[('immediate', 'deferred'), optional] If 'immediate', the best solution vector is continuously updated within a single generation [4]. This can lead to faster convergence as trial vectors can take advantage of continuous improvements in the best solution. With 'deferred', the best solution vector is updated once per generation. Only 'deferred' is compatible with parallelization, and the workers keyword can over-ride this option.

New in version 1.2.0.

**workers**

[int or map-like callable, optional] If workers is an int the population is subdivided into workers sections and evaluated in parallel (uses multiprocessing.Pool). Supply -1 to use all available CPU cores. Alternatively supply a map-like callable, such as multiprocessing.Pool.map for evaluating the population in parallel. This evaluation is carried out as workers(func, iterable). This option will override the updating keyword to updating='deferred' if workers != 1. Requires that func be pickleable.

New in version 1.2.0.

**constraints**

[[NonLinearConstraint, LinearConstraint, Bounds]] Constraints on the solver, over and above those applied by the bounds kwd. Uses the approach by Lampinen [5]. New in version 1.4.0.

**Returns**

[OptimizeResult] The optimization result represented as a OptimizeResult object. Important attributes are: x the solution array, success a Boolean flag indicating if the optimizer exited successfully and message which describes the cause of the termination. See OptimizeResult for a description of other attributes. If polish was employed, and a lower minimum was obtained by the polishing, then OptimizeResult also contains the jac attribute. If the eventual solution does not satisfy the applied constraints success will be False.

**Notes**

Differential evolution is a stochastic population based method that is useful for global optimization problems. At each pass through the population the algorithm mutates each candidate solution by mixing with other candidate solutions to create a trial candidate. There are several strategies [2] for creating trial candidates, which suit some problems more than others. The 'best1bin' strategy is a good starting point for many systems. In this strategy two members of the population are randomly chosen. Their difference is used to mutate the best member (the 'best' in 'best1bin'), b₀, so far:

\[ b' = b_0 + mutation \times (population[rand0] - population[rand1]) \]

A trial vector is then constructed. Starting with a randomly chosen ith parameter the trial is sequentially filled (in modulo) with parameters from b' or the original candidate. The choice of whether to use b' or the original candidate is made with a binomial distribution (the 'bin' in 'best1bin') - a random number in [0, 1) is generated. If this number is less than the recombination constant then the parameter is loaded from b', otherwise it is loaded from the original candidate. The final parameter is always loaded from b'. Once the trial candidate is built its fitness is assessed. If the trial is better than the original candidate then it takes its place. If it is also better than the
best overall candidate it also replaces that. To improve your chances of finding a global minimum use higher `popsize` values, with higher `mutation` and (dithering), but lower `recombination` values. This has the effect of widening the search radius, but slowing convergence. By default the best solution vector is updated continuously within a single iteration (`updating='immediate'`). This is a modification [4] of the original differential evolution algorithm which can lead to faster convergence as trial vectors can immediately benefit from improved solutions. To use the original Storn and Price behaviour, updating the best solution once per iteration, set `updating='deferred'`. New in version 0.15.0.

**Examples**

Let us consider the problem of minimizing the Rosenbrock function. This function is implemented in `rosen` in `scipy.optimize`.

```python
>>> from scipy.optimize import rosen, differential_evolution
>>> bounds = [(0, 2), (0, 2), (0, 2), (0, 2), (0, 2)]
>>> result = differential_evolution(rosen, bounds)
>>> result.x, result.fun
(array([1., 1., 1., 1., 1.]), 1.9216496320061384e-19)
```

Now repeat, but with parallelization.

```python
>>> bounds = [(0, 2), (0, 2), (0, 2), (0, 2), (0, 2)]
>>> result = differential_evolution(rosen, bounds, updating='deferred',
... workers=2)
>>> result.x, result.fun
(array([1., 1., 1., 1., 1.]), 1.9216496320061384e-19)
```

Let’s try and do a constrained minimization

```python
>>> from scipy.optimize import NonlinearConstraint, Bounds
>>> def constr_f(x):
...     return np.array(x[0] + x[1])
>>> nlc = NonlinearConstraint(constr_f, -np.inf, 1.9)
>>> bounds = Bounds([0., 0.], [2., 2.])
>>> result = differential_evolution(rosen, bounds, constraints=(nlc),
... seed=1)
>>> result.x, result.fun
(array([0.96633867, 0.93363577]), 0.0011361355854792312)
```

Next find the minimum of the Ackley function (https://en.wikipedia.org/wiki/Test_functions_for_optimization).

```python
>>> from scipy.optimize import differential_evolution
>>> import numpy as np
>>> def ackley(x):
...     arg1 = -0.2 * np.sqrt(0.5 * (x[0] ** 2 + x[1] ** 2))
(continues on next page)```

(continued from previous page)

```python
...    arg2 = 0.5 * (np.cos(2. * np.pi * x[0]) + np.cos(2. * np.pi * -x[1]))
...    return -20. * np.exp(arg1) - np.exp(arg2) + 20. + np.e
```

```python
>>> bounds = [(-5, 5), (-5, 5)]
>>> result = differential_evolution(ackley, bounds)
>>> result.x, result.fun
(array([ 0., 0.]), 4.4408920985006262e-16)
```

scipy.optimize.shgo

`scipy.optimize.shgo(func, bounds, args=(), constraints=None, n=100, iters=1, callback=None, minimize_kwargs=None, options=None, sampling_method='simplicial')`

Finds the global minimum of a function using SHG optimization.

SHGO stands for “simplicial homology global optimization”.

**Parameters**

- `func` [callable] The objective function to be minimized. Must be in the form `f(x, *args)`, where `x` is the argument in the form of a 1-D array and `args` is a tuple of any additional fixed parameters needed to completely specify the function.

- `bounds` [sequence] Bounds for variables. `(min, max)` pairs for each element in `x`, defining the lower and upper bounds for the optimizing argument of `func`. It is required to have `len(bounds) == len(x)`. `len(bounds)` is used to determine the number of parameters in `x`. Use `None` for one of `min` or `max` when there is no bound in that direction. By default bounds are `(None, None)`.

- `args` [tuple, optional] Any additional fixed parameters needed to completely specify the objective function.

- `constraints` [dict or sequence of dict, optional] Constraints definition. Function(s) $\mathbb{R}^n \rightarrow \mathbb{R}^m$ in the form:

  ```
  g(x) >= 0 applied as g : \mathbb{R}^n \rightarrow \mathbb{R}^m
  h(x) == 0 applied as h : \mathbb{R}^n \rightarrow \mathbb{R}^p
  ```

  Each constraint is defined in a dictionary with fields:

  - `fun` [callable] The function defining the constraint.
  - `jac` [callable, optional] The Jacobian of `fun` (only for SLSQP).
  - `args` [sequence, optional] Extra arguments to be passed to the function and Jacobian.

  Equality constraint means that the constraint function result is to be zero whereas inequality means that it is to be non-negative. Note that COBYLA only supports inequality constraints.

**Note:** Only the COBYLA and SLSQP local minimize methods currently support constraint arguments. If the `constraints` sequence used in the local optimization problem is not defined in `minimizer_kwargs` and a constrained method is used then the global constraints will be used. (Defining a `constraints` sequence in `minimizer_kwargs` means that constraints will not be added so if equality constraints and so forth need to be added then the inequality functions in `constraints` need to be added to `minimizer_kwargs` too).

- `n` [int, optional] Number of sampling points used in the construction of the simplicial complex. Note that this argument is only used for sobol and other arbitrary sampling methods.

- `iters` [int, optional] Number of iterations used in the construction of the simplicial complex.
callback [callable, optional] Called after each iteration, as callback(xk), where xk is the current parameter vector.

minimizer_kwargs [dict, optional] Extra keyword arguments to be passed to the minimizer scipy.optimize.minimize Some important options could be:
- method [str] The minimization method (e.g. SLSQP).
- args [tuple] Extra arguments passed to the objective function (func) and its derivatives (Jacobian, Hessian).
- options [dict, optional] Note that by default the tolerance is specified as {ftol: 1e-12}

options [dict, optional] A dictionary of solver options. Many of the options specified for the global routine are also passed to the scipy.optimize.minimize routine. The options that are also passed to the local routine are marked with “(L)”.

Stopping criteria, the algorithm will terminate if any of the specified criteria are met. However, the default algorithm does not require any to be specified:
- maxfev [int (L)] Maximum number of function evaluations in the feasible domain. (Note only methods that support this option will terminate the routine at precisely exact specified value. Otherwise the criterion will only terminate during a global iteration)
- f_min Specify the minimum objective function value, if it is known.
- f_tol [float] Precision goal for the value of f in the stopping criterion. Note that the global routine will also terminate if a sampling point in the global routine is within this tolerance.
- maxiter [int] Maximum number of iterations to perform.
- maxev [int] Maximum number of sampling evaluations to perform (includes searching in infeasible points).
- maxtime [float] Maximum processing runtime allowed
- minhgrad [int] Minimum homology group rank differential. The homology group of the objective function is calculated (approximately) during every iteration. The rank of this group has a one-to-one correspondence with the number of locally convex subdomains in the objective function (after adequate sampling points each of these subdomains contain a unique global minimum). If the difference in the hgr is 0 between iterations for maxhgrad specified iterations the algorithm will terminate.

Objective function knowledge:
- symmetry [bool] Specify True if the objective function contains symmetric variables. The search space (and therefore performance) is decreased by O(n!).
- jac [bool or callable, optional] Jacobian (gradient) of objective function. Only for CG, BFGS, Newton-CG, L-BFGS-B, TNC, SLSQP, dogleg, trust-ncg. If jac is a boolean and is True, fun is assumed to return the gradient along with the objective function. If False, the gradient will be estimated numerically. jac can also be a callable returning the gradient of the objective. In this case, it must accept the same arguments as fun. (Passed to scipy.optimize.minimize automatically)
- hess, hessp [callable, optional] Hessian (matrix of second-order derivatives) of objective function or Hessian of objective function times an arbitrary vector p. Only for Newton-CG, dogleg, trust-ncg. Only one of hessp or hess needs to be given. If hess is provided, then hessp will be ignored. If neither hess nor hessp is provided, then the Hessian product will be approximated using finite differences on jac. hessp must compute the Hessian times an arbitrary vector. (Passed to scipy.optimize.minimize automatically)

Algorithm settings:
- minimize_every_iter
If True then promising global sampling points will be passed to a local
minimization routine every iteration. If False then only the final minimizer
pool will be run. Defaults to False.

• **local_iter**

  [int] Only evaluate a few of the best minimizer pool candidates every itera-
tion. If False all potential points are passed to the local minimization routine.

• **infty_constraints**

  [bool]

  If True then any sampling points generated which are outside will the feasi-
ble domain will be saved and given an objective function value of \( \infty \). If
False then these points will be discarded. Using this functionality could lead
to higher performance with respect to function evaluations before the global
minimum is found, specifying False will use less memory at the cost of a
slight decrease in performance. Defaults to True.

Feedback:

• **disp**

  [bool (L)] Set to True to print convergence messages.

**sampling_method**

[str or function, optional]

Current built in sampling method options are `sobol` and `simplicial`. The default `simplicial` uses less memory and provides the theoretical guar-
antee of convergence to the global minimum in finite time. The `sobol` method is faster in
terms of sampling point generation at the cost of higher memory resources and the loss of
guaranteed convergence. It is more appropriate for most “easier” problems where the con-
vergence is relatively fast. User defined sampling functions must accept two arguments of
\( n \) sampling points of dimension \( \text{dim} \) per call and output an array of sampling points with
shape \( n \times \text{dim} \).

**Returns**

[res]

[OptimizeResult] The optimization result represented as a `OptimizeResult` object. Im-
portant attributes are: \( x \) the solution array corresponding to the global minimum, \( \text{fun} \) the
function output at the global solution, \( \text{xl} \) an ordered list of local minima solutions, \( \text{funl} \)
the function output at the corresponding local solutions, \( \text{success} \) a Boolean flag indicating
if the optimizer exited successfully, \( \text{message} \) which describes the cause of the termina-
tion, \( \text{nfev} \) the total number of objective function evaluations including the sampling calls,
\( \text{nlfev} \) the total number of objective function evaluations culminating from all local search
optimizations, \( \text{nit} \) number of iterations performed by the global routine.

**Notes**

Global optimization using simplicial homology global optimization [1]. Appropriate for solving general purpose
NLP and blackbox optimization problems to global optimality (low-dimensional problems).

In general, the optimization problems are of the form:

```
minimize f(x) subject to

\[
\begin{align*}
g_i(x) & \geq 0, \quad i = 1, \ldots, m \\
h_j(x) & = 0, \quad j = 1, \ldots, p
\end{align*}
\]
```

where \( x \) is a vector of one or more variables. \( f(x) \) is the objective function \( \mathbb{R}^n \rightarrow \mathbb{R} \), \( g_i(x) \) are the inequality
constraints, and \( h_j(x) \) are the equality constraints.

Optionally, the lower and upper bounds for each element in \( x \) can also be specified using the `bounds` argument.

While most of the theoretical advantages of SHGO are only proven for when \( f(x) \) is a Lipschitz smooth function,
the algorithm is also proven to converge to the global optimum for the more general case where \( f(x) \) is non-con-
tinuous, non-convex and non-smooth, if the default sampling method is used [1].
The local search method may be specified using the `minimizer_kwargs` parameter which is passed on to `scipy.optimize.minimize`. By default, the SLSQP method is used. In general, it is recommended to use the SLSQP or COBYLA local minimization if inequality constraints are defined for the problem since the other methods do not use constraints.

The `sobol` method points are generated using the Sobol (1967) sequence. The primitive polynomials and various sets of initial direction numbers for generating Sobol sequences is provided by [3] by Frances Kuo and Stephen Joe. The original program `sobol.cc` (MIT) is available and described at https://web.maths.unsw.edu.au/~fkuo/sobol/ translated to Python 3 by Carl Sandrock 2016-03-31.

**References**

[1], [2], [3], [4], [5]

**Examples**

First consider the problem of minimizing the Rosenbrock function, `rosen`:

```python
>>> from scipy.optimize import rosen, shgo
>>> bounds = [(0,2), (0, 2), (0, 2), (0, 2), (0, 2)]
>>> result = shgo(rosen, bounds)
>>> result.x, result.fun
(array([ 1., 1., 1., 1., 1.]), 2.9203923741900809e-18)
```

Note that `bounds` determine the dimensionality of the objective function and is therefore a required input, however you can specify empty bounds using `None` or objects like `np.inf` which will be converted to large float numbers.

```python
>>> bounds = [(None, None), ]*4
>>> result = shgo(rosen, bounds)
>>> result.x
array([ 0.99999851, 0.99999704, 0.99999411, 0.9999882 ])
```

Next, we consider the Eggholder function, a problem with several local minima and one global minimum. We will demonstrate the use of arguments and the capabilities of `shgo`. (https://en.wikipedia.org/wiki/Test_functions_for_optimization)

```python
>>> def eggholder(x):
...     return -(x[1] + 47.0)
...             * np.sin(np.sqrt(abs(x[0]/2.0 + (x[1] + 47.0))))
...             - x[0] * np.sin(np.sqrt(abs(x[0] - (x[1] + 47.0))))
...         
... bounds = [(-512, 512), (-512, 512)]
```

`shgo` has two built-in low discrepancy sampling sequences. First, we will input 30 initial sampling points of the Sobol sequence:

```python
>>> result = shgo(eggholder, bounds, n=30, sampling_method='sobol')
>>> result.x, result.fun
(array([ 512., 404.23180542]), -959.64066272085051)
```

`shgo` also has a return for any other local minima that was found, these can be called using:
These results are useful in applications where there are many global minima and the values of other global minima are desired or where the local minima can provide insight into the system (for example morphologies in physical chemistry [5]).

If we want to find a larger number of local minima, we can increase the number of sampling points or the number of iterations. We'll increase the number of sampling points to 60 and the number of iterations from the default of 1 to 5. This gives us 60 x 5 = 300 initial sampling points.

Note the difference between, e.g., n=180, iters=1 and n=60, iters=3. In the first case the promising points contained in the minimiser pool is processed only once. In the latter case it is processed every 60 sampling points for a total of 3 times.

To demonstrate solving problems with non-linear constraints consider the following example from Hock and Schittkowski problem 73 (cattle-feed) [4]:

The approximate answer given in [4] is:

f([0.6355216, −0.12e−11, 0.3127019, 0.0517765]) = 29.894378

>>> def f(x):  # (cattle-feed)
...

>>> def g1(x):
...    return 2.3*x[0] + 5.6*x[1] + 11.1*x[2] + 1.3*x[3] - 5  # >=0
...

>>> def g2(x):
...    return (12*x[0] + 11.9*x[1] + 41.8*x[2] + 52.1*x[3] - 21 - 1.645 * np.sqrt(0.28*x[0]**2 + 0.19*x[1]**2 + 20.5*x[2]**2 + 0.62*x[3]**2))  # >=0
...

>>> def h1(x):
...

>>> cons = [('type': 'ineq', 'fun': g1),  # <=0
...         ('type': 'ineq', 'fun': g2),
...         ('type': 'eq', 'fun': h1)]

>>> bounds = [(0, 1.0),]*4

>>> res = shgo(f, bounds, iters=3, constraints=cons)

>>> res
    fun: 29.894378159142136
    funl: array([29.89437816])
    message: 'Optimization terminated successfully.'
    nfev: 114
    nit: 3
    nlfev: 35

scipy.optimize.dual_annealing

scipy.optimize.dual_annealing (func, bounds, args=(), maxiter=1000, local_search_options={}, initial_temp=5230.0, restart_temp_ratio=2e-05, visit=2.62, accept=-5.0, maxfun=10000000.0, seed=None, no_local_search=False, callback=None, x0=None)

Find the global minimum of a function using Dual Annealing.

Parameters

func [callable] The objective function to be minimized. Must be in the form f(x, *args), where x is the argument in the form of a 1-D array and args is a tuple of any additional fixed parameters needed to completely specify the function.

6.19. Optimization and root finding (scipy.optimize) 1639
bounds  [sequence, shape (n, 2)] Bounds for variables. (min, max) pairs for each element in x, defining bounds for the objective function parameter.

args    [tuple, optional] Any additional fixed parameters needed to completely specify the objective function.

maxiter [int, optional] The maximum number of global search iterations. Default value is 1000.

local_search_options
          [dict, optional] Extra keyword arguments to be passed to the local minimizer (minimize). Some important options could be: method for the minimizer method to use and args for objective function additional arguments.

initial_temp
          [float, optional] The initial temperature, use higher values to facilitates a wider search of the energy landscape, allowing dual annealing to escape local minima that it is trapped in. Default value is 5230. Range is (0.01, 5.e4).

restart_temp_ratio
          [float, optional] During the annealing process, temperature is decreasing, when it reaches initial_temp * restart_temp_ratio, the reannealing process is triggered. Default value of the ratio is 2e-5. Range is (0, 1).

visit   [float, optional] Parameter for visiting distribution. Default value is 2.62. Higher values give the visiting distribution a heavier tail, this makes the algorithm jump to a more distant region. The value range is (0, 3).

accept [float, optional] Parameter for acceptance distribution. It is used to control the probability of acceptance. The lower the acceptance parameter, the smaller the probability of acceptance. Default value is -5.0 with a range (-1e4, -5).

maxfun [int, optional] Soft limit for the number of objective function calls. If the algorithm is in the middle of a local search, this number will be exceeded, the algorithm will stop just after the local search is done. Default value is 1e7.

seed  [[int, RandomState, Generator], optional] If seed is not specified the RandomState singleton is used. If seed is an int, a new RandomState instance is used, seeded with seed. If seed is already a RandomState or Generator instance, then that instance is used. Specify seed for repeatable minimizations. The random numbers generated with this seed only affect the visiting distribution function and new coordinates generation.

no_local_search
          [bool, optional] If no_local_search is set to True, a traditional Generalized Simulated Annealing will be performed with no local search strategy applied.

callback [callable, optional] A callback function with signature callback(x, f, context), which will be called for all minima found. x and f are the coordinates and function value of the latest minimum found, and context has value in [0, 1, 2], with the following meaning:
• 0: minimum detected in the annealing process.
• 1: detection occurred in the local search process.
• 2: detection done in the dual annealing process.

If the callback implementation returns True, the algorithm will stop.

x0  [ndarray, shape(n,), optional] Coordinates of a single N-D starting point.

Returns

res  [OptimizeResult] The optimization result represented as a OptimizeResult object. Important attributes are: x the solution array, fun the value of the function at the solution, and message which describes the cause of the termination. See OptimizeResult for a description of other attributes.
Notes

This function implements the Dual Annealing optimization. This stochastic approach derived from [3] combines the generalization of CSA (Classical Simulated Annealing) and FSA (Fast Simulated Annealing) [1] [2] coupled to a strategy for applying a local search on accepted locations [4]. An alternative implementation of this same algorithm is described in [5] and benchmarks are presented in [6]. This approach introduces an advanced method to refine the solution found by the generalized annealing process. This algorithm uses a distorted Cauchy-Lorentz visiting distribution, with its shape controlled by the parameter $q_v$

$$g_{qv}(\Delta x(t)) \propto \frac{[T_{qv}(t)]^{-\frac{D}{q_v}}}{1 + (q_v - 1) \left(\frac{(\Delta x(t))^2}{[T_{qv}(t)]^{\frac{2}{q_v}}}\right)^{\frac{1}{q_v - 2}}}$$

Where $t$ is the artificial time. This visiting distribution is used to generate a trial jump distance $\Delta x(t)$ of variable $x(t)$ under artificial temperature $T_{qv}(t)$.

From the starting point, after calling the visiting distribution function, the acceptance probability is computed as follows:

$$p_{qa} = \min\{1, [1 - (1 - q_a) \beta \Delta E]^{\frac{1}{1 - q_a}}\}$$

Where $q_a$ is a acceptance parameter. For $q_a < 1$, zero acceptance probability is assigned to the cases where

$$[1 - (1 - q_a) \beta \Delta E] < 0$$

The artificial temperature $T_{qv}(t)$ is decreased according to

$$T_{qv}(t) = T_{qv}(1) \frac{2q_v^{-1} - 1}{(1 + t)^{2q_v^{-1}}}$$

Where $q_v$ is the visiting parameter.

New in version 1.2.0.

Examples

The following example is a 10-D problem, with many local minima. The function involved is called Rastrigin (https://en.wikipedia.org/wiki/Rastrigin_function)

```python
>>> from scipy.optimize import dual_annealing
>>> func = lambda x: np.sum(x*x - 10*np.cos(2*np.pi*x)) + 10*np.size(x)
>>> lw = [-5.12] * 10
>>> up = [5.12] * 10
>>> ret = dual_annealing(func, bounds=list(zip(lw, up)), seed=1234)
>>> ret.x
array([-4.26437714e-09, -3.91699361e-09, -1.86149218e-09, -3.97165720e-09,
       -6.29151648e-09, -6.53145322e-09, -3.93616815e-09, -6.55623025e-09,
       -6.05775280e-09, -5.00668935e-09]) # may vary
>>> ret.fun
0.000000
```

6.19. Optimization and root finding (scipy.optimize) 1641
6.19.5 Least-squares and curve fitting

Nonlinear least-squares

```python
least_squares(fun, x0[, jac, bounds, ...])
```
Solve a nonlinear least-squares problem with bounds on the variables.

```python
scipy.optimize.least_squares
```

Solve a nonlinear least-squares problem with bounds on the variables.

Given the residuals \( f(x) \) (an \( m \)-D real function of \( n \) real variables) and the loss function \( \rho(s) \) (a scalar function), \( \text{least_squares} \) finds a local minimum of the cost function \( F(x) \):

\[
\minimize F(x) = 0.5 \sum (\rho(f_i(x) \times 2), i = 0, \ldots, m - 1)
\]

subject to \( lb \leq x \leq ub \)

The purpose of the loss function \( \rho(s) \) is to reduce the influence of outliers on the solution.

**Parameters**

- **fun**
  - [callable] Function which computes the vector of residuals, with the signature \( \text{fun}(x, *\text{args}, **\text{kwargs}) \), i.e., the minimization proceeds with respect to its first argument. The argument \( x \) passed to this function is an ndarray of shape \((n,)\) (never a scalar, even for \( n=1 \)). It must allocate and return a 1-D array_like of shape \((m,)\) or as a scalar. If the argument \( x \) is complex or the function \( \text{fun} \) returns complex residuals, it must be wrapped in a real function of real arguments, as shown at the end of the Examples section.

- **x0**
  - [array_like with shape \((n,)\) or float] Initial guess on independent variables. If float, it will be treated as a 1-D array with one element.

- **jac**
  - [‘2-point’, ‘3-point’, ‘cs’, callable, optional] Method of computing the Jacobian matrix (an \( m \)-by-\( n \) matrix, where element \((i, j)\) is the partial derivative of \( f[i] \) with respect to \( x[j] \)). The keywords select a finite difference scheme for numerical estimation. The scheme ‘3-point’ is more accurate, but requires twice as many operations as ‘2-point’ (default). The scheme ‘cs’ uses complex steps, and while potentially the most accurate, it is applicable only when \( \text{fun} \) correctly handles complex inputs and can be analytically continued to the complex plane. Method ‘lm’ always uses the ‘2-point’ scheme. If callable, it is used as \( \text{jac}(x, *\text{args}, **\text{kwargs}) \) and should return a good approximation (or the exact value) for the Jacobian as an array_like (np.atleast_2d is applied), a sparse matrix (csr_matrix preferred for performance) or a \text{scipy.sparse.linalg.LinearOperator}.

- **bounds**
  - [2-tuple of array_like, optional] Lower and upper bounds on independent variables. Defaults to no bounds. Each array must match the size of \( x0 \) or be a scalar, in the latter case a bound will be the same for all variables. Use \text{np.inf} with an appropriate sign to disable bounds on all or some variables.

- **method**
    - ‘trf’ : Trust Region Reflective algorithm, particularly suitable for large sparse problems with bounds. Generally robust method.
    - ‘dogbox’ : dogleg algorithm with rectangular trust regions, typical use case is small problems with bounds. Not recommended for problems with rank-deficient Jacobian.
    - ‘lm’ : Levenberg-Marquardt algorithm as implemented in MINPACK. Doesn't handle bounds and sparse Jacobians. Usually the most efficient method for small unconstrained problems.
Default is ‘trf’. See Notes for more information.

ftol
[Float or None, optional] Tolerance for termination by the change of the cost function. Default is 1e-8. The optimization process is stopped when \( \frac{dF}{F} < \text{ftol} \times F \), and there was an adequate agreement between a local quadratic model and the true model in the last step. If None and ‘method’ is not ‘lm’, the termination by this condition is disabled. If ‘method’ is ‘lm’, this tolerance must be higher than machine epsilon.

xtol
[Float or None, optional] Tolerance for termination by the change of the independent variables. Default is 1e-8. The exact condition depends on the method used:
- For ‘trf’ and ‘dogbox’: \( \text{norm}(\text{dx}) < \text{xtol} \times (\text{xtol} + \text{norm}(x)) \).
- For ‘lm’: \( \text{Delta} < \text{xtol} \times \text{norm}(\text{xs}) \), where Delta is a trust-region radius and xs is the value of x scaled according to x_scale parameter (see below).
If None and ‘method’ is not ‘lm’, the termination by this condition is disabled. If ‘method’ is ‘lm’, this tolerance must be higher than machine epsilon.

gtol
[Float or None, optional] Tolerance for termination by the norm of the gradient. Default is 1e-8. The exact condition depends on a method used:
- For ‘trf’: \( \text{norm}(g_{\text{scaled}}, \text{ord} = \infty) < \text{gtol} \), where g_scaled is the value of the gradient scaled to account for the presence of the bounds [STIR].
- For ‘dogbox’: \( \text{norm}(g_{\text{free}}, \text{ord} = \infty) < \text{gtol} \), where g_free is the gradient with respect to the variables which are not in the optimal state on the boundary.
- For ‘lm’: the maximum absolute value of the cosine of angles between columns of the Jacobian and the residual vector is less than gtol, or the residual vector is zero.
If None and ‘method’ is not ‘lm’, the termination by this condition is disabled. If ‘method’ is ‘lm’, this tolerance must be higher than machine epsilon.

x_scale
[array_like or ‘jac’, optional] Characteristic scale of each variable. Setting x_scale is equivalent to reformulating the problem in scaled variables \( x_{s} = \frac{x}{x_{\text{scale}}} \). An alternative view is that the size of a trust region along jth dimension is proportional to \( x_{\text{scale}}[j] \). Improved convergence may be achieved by setting x_scale such that a step of a given size along all of the scaled variables has a similar effect on the cost function. If set to ‘jac’, the scale is iteratively updated using the inverse norms of the columns of the Jacobian matrix (as described in [JJMore]).

loss
[str or callable, optional] Determines the loss function. The following keyword values are allowed:
- ‘linear’ (default): \( \rho(z) = z \). Gives a standard least-squares problem.
- ‘soft_L1’: \( \rho(z) = 2 \times ((1 + z)^{0.5} - 1) \). The smooth approximation of L1 (absolute value) loss. Usually a good choice for robust least squares.
- ‘huber’: \( \rho(z) = z \text{ if } z \leq 1 \text{ else } 2z^{0.5} - 1 \). Works similarly to ‘soft_L1’.
- ‘cauchy’: \( \rho(z) = \ln(1 + z) \). Severely weakens outliers influence, but may cause difficulties in optimization process.
- ‘arctan’: \( \rho(z) = \arctan(z) \). Limits a maximum loss on a single residual, has properties similar to ‘cauchy’.
If callable, it must take a 1-D ndarray \( z = f**2 \) and return an array_like with shape (3, m) where row 0 contains function values, row 1 contains first derivatives and row 2 contains second derivatives. Method ‘lm’ supports only ‘linear’ loss.

f_scale
[float, optional] Value of soft margin between inlier and outlier residuals, default is 1.0. The loss function is evaluated as follows: \( \rho_{\text{in}}(f**2) = C**2 \times \rho(f**2 / C**2) \), where C is f_scale, and rho is determined by loss parameter. This parameter has no effect with loss=’linear’, but for other loss values it is of crucial importance.

max_nfev
[None or int, optional] Maximum number of function evaluations before the termination. If None (default), the value is chosen automatically:
- For ‘trf’ and ‘dogbox’: 100 * n.
- For ‘lm’: 100 * n if jac is callable and 100 * n * (n + 1) otherwise (because ‘lm’ counts function calls in Jacobian estimation).
**diff_step** [None or array_like, optional] Determines the relative step size for the finite difference approximation of the Jacobian. The actual step is computed as $x \times \text{diff_step}$. If None (default), then diff_step is taken to be a conventional “optimal” power of machine epsilon for the finite difference scheme used [NR].

- ‘exact’ is suitable for not very large problems with dense Jacobian matrices. The computational complexity per iteration is comparable to a singular value decomposition of the Jacobian matrix.
- ‘lsmr’ is suitable for problems with sparse and large Jacobian matrices. It uses the iterative procedure `scipy.sparse.linalg.lsmr` for finding a solution of a linear least-squares problem and only requires matrix-vector product evaluations.

If None (default), the solver is chosen based on the type of Jacobian returned on the first iteration.

**tr_options** [dict, optional] Keyword options passed to trust-region solver.
- **tr_solver='exact'**: tr_options are ignored.
- **tr_solver='lsmr'**: options for `scipy.sparse.linalg.lsmr`. Additionally, method='trf' supports ‘regularize’ option (bool, default is True), which adds a regularization term to the normal equation, which improves convergence if the Jacobian is rank-deficient [Byrd] (eq. 3.4).

**jac_sparsity** [{None, array_like, sparse matrix}, optional] Defines the sparsity structure of the Jacobian matrix for finite difference estimation, its shape must be (m, n). If the Jacobian has only few non-zero elements in each row, providing the sparsity structure will greatly speed up the computations [Curtis]. A zero entry means that a corresponding element in the Jacobian is identically zero. If provided, forces the use of ‘lsmr’ trust-region solver. If None (default), then dense differencing will be used. Has no effect for ‘lm’ method.

**verbose** [{0, 1, 2}, optional] Level of algorithm’s verbosity:
- 0 (default): work silently.
- 1: display a termination report.
- 2: display progress during iterations (not supported by ‘lm’ method).

**args, kwargs** [tuple and dict, optional] Additional arguments passed to fun and jac. Both empty by default. The calling signature is fun(x, *args, **kwargs) and the same for jac.

**Returns**

**result** [OptimizeResult] OptimizeResult with the following fields defined:
- **x** [ndarray, shape (n,)] Solution found.
- **cost** [float] Value of the cost function at the solution.
- **fun** [ndarray, shape (m,)] Vector of residuals at the solution.
- **jac** [ndarray, sparse matrix or LinearOperator, shape (m, n)] Modified Jacobian matrix at the solution, in the sense that $J^T J$ is a Gauss-Newton approximation of the Hessian of the cost function. The type is the same as the one used by the algorithm.
- **grad** [ndarray, shape (m,)] Gradient of the cost function at the solution.
- **optimality** [float] First-order optimality measure. In unconstrained problems, it is always the uniform norm of the gradient. In constrained problems, it is the quantity which was compared with gtol during iterations.
- **active_mask** [ndarray of int, shape (n,)] Each component shows whether a corresponding constraint is active (that is, whether a variable is at the bound):
  - 0: a constraint is not active.
  - -1: a lower bound is active.
  - 1: an upper bound is active.
Might be somewhat arbitrary for ‘trf’ method as it generates a sequence of strictly feasible iterates and active_mask is determined within a tolerance threshold.

**nfev**
[int] Number of function evaluations done. Methods ‘trf’ and ‘dogbox’ do not count function calls for numerical Jacobian approximation, as opposed to ‘lm’ method.

**njev**
[int or None] Number of Jacobian evaluations done. If numerical Jacobian approximation is used in ‘lm’ method, it is set to None.

**status**
[int] The reason for algorithm termination:
• -1: improper input parameters status returned from MINPACK.
• 0: the maximum number of function evaluations is exceeded.
• 1: gtol termination condition is satisfied.
• 2: ftol termination condition is satisfied.
• 3: xtol termination condition is satisfied.
• 4: Both ftol and xtol termination conditions are satisfied.

**message**
[str] Verbal description of the termination reason.

**success**
[bool] True if one of the convergence criteria is satisfied (status > 0).

See also:

**leastsq**
A legacy wrapper for the MINPACK implementation of the Levenberg-Marquadt algorithm.

**curve_fit**
Least-squares minimization applied to a curve-fitting problem.

**Notes**

Method ‘lm’ (Levenberg-Marquardt) calls a wrapper over least-squares algorithms implemented in MINPACK (lmder, lmdif). It runs the Levenberg-Marquardt algorithm formulated as a trust-region type algorithm. The implementation is based on paper [JIM], it is very robust and efficient with a lot of smart tricks. It should be your first choice for unconstrained problems. Note that it doesn’t support bounds. Also, it doesn’t work when m < n.

Method ‘trf’ (Trust Region Reflective) is motivated by the process of solving a system of equations, which constitute the first-order optimality condition for a bound-constrained minimization problem as formulated in [STIR]. The algorithm iteratively solves trust-region subproblems augmented by a special diagonal quadratic term and with trust-region shape determined by the distance from the bounds and the direction of the gradient. This enhancements help to avoid making steps directly into bounds and efficiently explore the whole space of variables. To further improve convergence, the algorithm considers search directions reflected from the bounds. To obey theoretical requirements, the algorithm keeps iterates strictly feasible. With dense Jacobians trust-region subproblems are solved by an exact method very similar to the one described in [JIM] (and implemented in MINPACK). The difference from the MINPACK implementation is that a singular value decomposition of a Jacobian matrix is done once per iteration, instead of a QR decomposition and series of Givens rotation eliminations. For large sparse Jacobians a 2-D subspace approach of solving trust-region subproblems is used [STIR], [Byrd]. The subspace is spanned by a scaled gradient and an approximate Gauss-Newton solution delivered by scipy.sparse.linalg.lsmr. When no constraints are imposed the algorithm is very similar to MINPACK and has generally comparable performance. The algorithm works quite robust in unbounded and bounded problems, thus it is chosen as a default algorithm.

Method ‘dogbox’ operates in a trust-region framework, but considers rectangular trust regions as opposed to conventional ellipsoids [Vogl]. The intersection of a current trust region and initial bounds is again rectangular, so on each iteration a quadratic minimization problem subject to bound constraints is solved approximately by Powell’s dogleg method [NumOpt]. The required Gauss-Newton step can be computed exactly for dense Jacobians or approximately by scipy.sparse.linalg.lsmr for large sparse Jacobians. The algorithm is likely to exhibit
The algorithm often outperforms ‘trf’ in bounded problems with a small number of variables.

Robust loss functions are implemented as described in [BA]. The idea is to modify a residual vector and a Jacobian matrix on each iteration such that computed gradient and Gauss-Newton Hessian approximation match the true gradient and Hessian approximation of the cost function. Then the algorithm proceeds in a normal way, i.e., robust loss functions are implemented as a simple wrapper over standard least-squares algorithms.

References

[STIR], [NR], [Byrd], [Curtis], [JJMore], [Voglis], [NumOpt], [BA]

Examples

In this example we find a minimum of the Rosenbrock function without bounds on independent variables.

```
>>> def fun_rosenbrock(x):
...    return np.array([10 * (x[1] - x[0])**2, (1 - x[0])])
```

Notice that we only provide the vector of the residuals. The algorithm constructs the cost function as a sum of squares of the residuals, which gives the Rosenbrock function. The exact minimum is at \( x = [1.0, 1.0] \).

```
>>> from scipy.optimize import least_squares
>>> x0_rosenbrock = np.array([2, 2])
>>> res_1 = least_squares(fun_rosenbrock, x0_rosenbrock)
>>> res_1.x
array([ 1.,  1.])
>>> res_1.cost
9.8669242910846867e-30
>>> res_1.optimality
8.8928864934219529e-14
```

We now constrain the variables, in such a way that the previous solution becomes infeasible. Specifically, we require that \( x[1] \geq 1.5 \), and \( x[0] \) left unconstrained. To this end, we specify the `bounds` parameter to `least_squares` in the form `bounds=([-np.inf, 1.5], np.inf)`.

```
>>> def jac_rosenbrock(x):
...    return np.array([
...        [-20 * x[0], 10],
...        [-1, 0]])
```

Putting this all together, we see that the new solution lies on the bound:

```
>>> res_2 = least_squares(fun_rosenbrock, x0_rosenbrock, jac_rosenbrock,
...    bounds=([-np.inf, 1.5], np.inf))
>>> res_2.x
array([ 1.22437075,  1.5])
>>> res_2.cost
0.02521309349329585
```
Now we solve a system of equations (i.e., the cost function should be zero at a minimum) for a Broyden tridiagonal vector-valued function of 100000 variables:

```python
>>> def fun_broyden(x):
...    f = (3 - x) * x + 1
...    f[1:] -= x[:-1]
...    f[1:] -= 2 * x[1:]
...    return f
```

The corresponding Jacobian matrix is sparse. We tell the algorithm to estimate it by finite differences and provide the sparsity structure of Jacobian to significantly speed up this process.

```python
>>> from scipy.sparse import lil_matrix
>>> def sparsity_broyden(n):
...    sparsity = lil_matrix((n, n), dtype=int)
...    i = np.arange(n)
...    sparsity[i, i] = 1
...    i = np.arange(i, n)
...    sparsity[i, i - 1] = 1
...    i = np.arange(n - 1)
...    sparsity[i, i + 1] = 1
...    return sparsity
```

```python
>>> n = 100000
>>> x0_broyden = -np.ones(n)
... >>> res_3 = least_squares(fun_broyden, x0_broyden,
...     jac_sparsity=sparsity_broyden(n))
```

Let’s also solve a curve fitting problem using robust loss function to take care of outliers in the data. Define the model function as \( y = a + b \times \exp(c \times t) \), where \( t \) is a predictor variable, \( y \) is an observation and \( a, b, c \) are parameters to estimate.

First, define the function which generates the data with noise and outliers, define the model parameters, and generate data:

```python
>>> def gen_data(t, a, b, c, noise=0, n_outliers=0, random_state=0):
...    y = a + b * np.exp(t * c)
...    rnd = np.random.RandomState(random_state)
...    error = noise * rnd.randn(t.size)
...    outliers = rnd.randint(0, t.size, n_outliers)
...    error[outliers] *= 10
...    return y + error
```
Define function for computing residuals and initial estimate of parameters.

```python
>>> def fun(x, t, y):
...     return x[0] + x[1] * np.exp(x[2] * t) - y
... >>> x0 = np.array([1.0, 1.0, 0.0])
```

Compute a standard least-squares solution:

```python
>>> res_lsq = least_squares(fun, x0, args=(t_train, y_train))
```

Now compute two solutions with two different robust loss functions. The parameter `f_scale` is set to 0.1, meaning that inlier residuals should not significantly exceed 0.1 (the noise level used).

```python
>>> res_soft_l1 = least_squares(fun, x0, loss='soft_l1', f_scale=0.1,
...                               args=(t_train, y_train))
>>> res_log = least_squares(fun, x0, loss='cauchy', f_scale=0.1,
...                          args=(t_train, y_train))
```

And, finally, plot all the curves. We see that by selecting an appropriate `loss` we can get estimates close to optimal even in the presence of strong outliers. But keep in mind that generally it is recommended to try 'soft_l1' or 'huber' losses first (if at all necessary) as the other two options may cause difficulties in optimization process.

```python
>>> t_test = np.linspace(t_min, t_max, n_points * 10)
>>> y_true = gen_data(t_test, a, b, c)
>>> y_lsq = gen_data(t_test, *res_lsq.x)
>>> y_soft_l1 = gen_data(t_test, *res_soft_l1.x)
>>> y_log = gen_data(t_test, *res_log.x)
... >>> import matplotlib.pyplot as plt
... >>> plt.plot(t_train, y_train, 'o')
... >>> plt.plot(t_test, y_true, 'k', linewidth=2, label='true')
... >>> plt.plot(t_test, y_lsq, label='linear loss')
... >>> plt.plot(t_test, y_soft_l1, label='soft_l1 loss')
... >>> plt.plot(t_test, y_log, label='cauchy loss')
... >>> plt.xlabel("t")
... >>> plt.ylabel("y")
... >>> plt.legend()
... >>> plt.show()
```

In the next example, we show how complex-valued residual functions of complex variables can be optimized with `least_squares()`. Consider the following function:
>>> def f(z):
...     return z - (0.5 + 0.5j)

We wrap it into a function of real variables that returns real residuals by simply handling the real and imaginary parts as independent variables:

>>> def f_wrap(x):
...     fx = f(x[0] + 1j*x[1])
...     return np.array([fx.real, fx.imag])

Thus, instead of the original m-D complex function of n complex variables we optimize a 2m-D real function of 2n real variables:

>>> from scipy.optimize import least_squares
>>> res_wrapped = least_squares(f_wrap, (0.1, 0.1), bounds=([0, 0], [1, -1]))
>>> z = res_wrapped.x[0] + res_wrapped.x[1]*1j
>>> z
(0.49999999999925893+0.49999999999925893j)

**scipy.optimize.nnls**

`scipy.optimize.nnls (A, b, maxiter=None)`

Solve $\arg\min_x \| A x - b \| _2$ for $x \geq 0$. This is a wrapper for a FORTRAN non-negative least squares solver.

**Parameters**

- **A** : [ndarray] Matrix $A$ as shown above.
- **b** : [ndarray] Right-hand side vector.
- **maxiter** : int, optional
  Maximum number of iterations, optional. Default is $3 * A$.shape[1].

**Returns**

- **x** : [ndarray] Solution vector.
- **rnorm** : float
  Residual, $\| A x - b \| _2$. 

6.19. Optimization and root finding (scipy.optimize)
Notes

The FORTRAN code was published in the book below. The algorithm is an active set method. It solves the KKT (Karush-Kuhn-Tucker) conditions for the non-negative least squares problem.

scipy.optimize.lsq_linear

scipy.optimize.lsq_linear(A, b, bounds=\(-\infty, \infty\), method='trf', tol=1e-10, lsq_solver=None, lsmr_tol=None, max_iter=None, verbose=0)

Solve a linear least-squares problem with bounds on the variables.

Given a m-by-n design matrix A and a target vector b with m elements, lsq_linear solves the following optimization problem:

\[
\text{minimize } 0.5 \| Ax - b \|_2^2 \\
\text{subject to } lb \leq x \leq ub
\]

This optimization problem is convex, hence a found minimum (if iterations have converged) is guaranteed to be global.

Parameters

- **A**: [array_like, sparse matrix of LinearOperator, shape (m, n)] Design matrix. Can be scipy.sparse.linalg.LinearOperator.
- **b**: [array_like, shape (m,)] Target vector.
- **bounds**: [2-tuple of array_like, optional] Lower and upper bounds on independent variables. Defaults to no bounds. Each array must have shape (n,) or be a scalar, in the latter case a bound will be the same for all variables. Use np.inf with an appropriate sign to disable bounds on all or some variables.
  - ‘trf’: Trust Region Reflective algorithm adapted for a linear least-squares problem. This is an interior-point-like method and the required number of iterations is weakly correlated with the number of variables.
  - ‘bvls’: Bounded-variable least-squares algorithm. This is an active set method, which requires the number of iterations comparable to the number of variables. Can’t be used when A is sparse or LinearOperator. Default is ‘trf’.
tol  [float, optional] Tolerance parameter. The algorithm terminates if a relative change of the cost function is less than tol on the last iteration. Additionally, the first-order optimality measure is considered:
• method='trf' terminates if the uniform norm of the gradient, scaled to account for the presence of the bounds, is less than tol.
• method='bvls' terminates if Karush-Kuhn-Tucker conditions are satisfied within tol tolerance.

lsq_solver  [(None, ‘exact’, ‘lsmr’), optional] Method of solving unbounded least-squares problems throughout iterations:
• ‘exact’: Use dense QR or SVD decomposition approach. Can't be used when A is sparse or LinearOperator.
• ‘lsmr’: Use scipy.sparse.linalg.lsmr iterative procedure which requires only matrix-vector product evaluations. Can't be used with method='bvls'.
If None (default), the solver is chosen based on type of A.

lsmr_tol  [None, float or ‘auto’, optional] Tolerance parameters ‘atol’ and ‘btol’ for scipy.sparse.linalg.lsmr. If None (default), it is set to 1e-2 * tol. If ‘auto’, the tolerance will be adjusted based on the optimality of the current iterate, which can speed up the optimization process, but is not always reliable.

max_iter  [None or int, optional] Maximum number of iterations before termination. If None (default), it is set to 100 for method='trf' or to the number of variables for method='bvls' (not counting iterations for ‘bvls’ initialization).

verbose  [(0, 1, 2), optional] Level of algorithm’s verbosity:
• 0: works silently (default).
• 1: display a termination report.
• 2: display progress during iterations.

Returns

OptimizeResult with the following fields defined:
x  [ndarray, shape (n,)] Solution found.
cost  [float] Value of the cost function at the solution.
fun  [ndarray, shape (m,)] Vector of residuals at the solution.
optimality  [float] First-order optimality measure. The exact meaning depends on method, refer to the description of tol parameter.
active_mask  [ndarray of int, shape (n,)] Each component shows whether a corresponding constraint is active (that is, whether a variable is at the bound):
• 0: a constraint is not active.
• -1: a lower bound is active.
• 1: an upper bound is active.
Might be somewhat arbitrary for the trf method as it generates a sequence of strictly feasible iterates and active_mask is determined within a tolerance threshold.

nit  [int] Number of iterations. Zero if the unconstrained solution is optimal.
status  [int] Reason for algorithm termination:
• -1: the algorithm was not able to make progress on the last iteration.
• 0: the maximum number of iterations is exceeded.
• 1: the first-order optimality measure is less than tol.
• 2: the relative change of the cost function is less than tol.
• 3: the unconstrained solution is optimal.
message  [str] Verbal description of the termination reason.
success  [bool] True if one of the convergence criteria is satisfied (status > 0).

See also:
nnls
Linear least squares with non-negativity constraint.

**least_squares**

Nonlinear least squares with bounds on the variables.

**Notes**

The algorithm first computes the unconstrained least-squares solution by `numpy.linalg.lstsq` or `scipy.sparse.linalg.lsmr` depending on `lsq_solver`. This solution is returned as optimal if it lies within the bounds.

Method ‘trf’ runs the adaptation of the algorithm described in [STIR] for a linear least-squares problem. The iterations are essentially the same as in the nonlinear least-squares algorithm, but as the quadratic function model is always accurate, we don’t need to track or modify the radius of a trust region. The line search (backtracking) is used as a safety net when a selected step does not decrease the cost function. Read more detailed description of the algorithm in `scipy.optimize.least_squares`.

Method ‘bvls’ runs a Python implementation of the algorithm described in [BVLS]. The algorithm maintains active and free sets of variables, on each iteration chooses a new variable to move from the active set to the free set and then solves the unconstrained least-squares problem on free variables. This algorithm is guaranteed to give an accurate solution eventually, but may require up to n iterations for a problem with n variables. Additionally, an ad-hoc initialization procedure is implemented, that determines which variables to set free or active initially. It takes some number of iterations before actual BVLS starts, but can significantly reduce the number of further iterations.

**References**

[STIR], [BVLS]

**Examples**

In this example, a problem with a large sparse matrix and bounds on the variables is solved.

```python
>>> from scipy.sparse import rand
>>> from scipy.optimize import lsq_linear
...
>>> np.random.seed(0)
...
>>> m = 20000
>>> n = 10000
...
>>> A = rand(m, n, density=1e-4)
>>> b = np.random.randn(m)
...
>>> lb = np.random.randn(n)
>>> ub = lb + 1
...
>>> res = lsq_linear(A, b, bounds=(lb, ub), lsmr_tol='auto', verbose=1)
# may vary
The relative change of the cost function is less than `tol`.
Number of iterations 16, initial cost 1.5039e+04, final cost 1.1112e+04, first-order optimality 4.66e-08.
```
Curve fitting

\[ \text{curve_fit}(f, \text{xdata}, \text{ydata}[\text{, p0, sigma, ...}]) \]

Use non-linear least squares to fit a function, \( f \), to data.

**scipy.optimize.curve_fit**

\[ \text{scipy.optimize.curve_fit}(f, \text{xdata}, \text{ydata}, \text{p0=None, sigma=None, absolute_sigma=False,} \]

\[ \text{check_finite=True, bounds=-(inf, inf, method=None, jac=None, **kwargs)} \]

Use non-linear least squares to fit a function, \( f \), to data.

Assumes \( ydata = f(xdata, \text{*params}) + \text{eps} \).

**Parameters**

- \( f \) [callable] The model function, \( f(x, ...) \). It must take the independent variable as the first argument and the parameters to fit as separate remaining arguments.

- \( xdata \) [array_like or object] The independent variable where the data is measured. Should usually be an M-length sequence or an (k,M)-shaped array for functions with k predictors, but can actually be any object.

- \( ydata \) [array_like] The dependent data, a length M array - nominally \( f(xdata, ...) \).

- \( p0 \) [array_like, optional] Initial guess for the parameters (length N). If None, then the initial values will all be 1 (if the number of parameters for the function can be determined using introspection, otherwise a ValueError is raised).

- \( sigma \) [None or M-length sequence or MxM array, optional] Determines the uncertainty in \( ydata \). If we define residuals as \( r = ydata - f(xdata, \text{*popt}) \), then the interpretation of \( sigma \) depends on its number of dimensions:
  - A 1-D \( sigma \) should contain values of standard deviations of errors in \( ydata \). In this case, the optimized function is \( \text{chisq} = \text{sum}((r / \text{sigma}) ** 2) \).
  - A 2-D \( sigma \) should contain the covariance matrix of errors in \( ydata \). In this case, the optimized function is \( \text{chisq} = r.T @ \text{inv}(\text{sigma}) @ r \).

- \( \text{absolute_sigma} \) [bool, optional] If True, \( sigma \) is used in an absolute sense and the estimated parameter covariance \( \text{pcov} \) reflects these absolute values.

- \( \text{check_finite} \) [bool, optional] If True, check that the input arrays do not contain nans of infs, and raise a ValueError if they do. Setting this parameter to False may silently produce nonsensical results if the input arrays do contain nans. Default is True.

- \( \text{bounds} \) [2-tuple of array_like, optional] Lower and upper bounds on parameters. Defaults to no bounds. Each element of the tuple must be either an array with the length equal to the number of parameters, or a scalar (in which case the bound is taken to be the same for all parameters). Use \( \text{np.inf} \) with an appropriate sign to disable bounds on all or some parameters.

- \( \text{method} \) ['lm', 'trf', 'dogbox'], optional] Method to use for optimization. See \textit{least_squares} for more details. Default is 'lm' for unconstrained problems and 'trf' if \( \text{bounds} \) are provided.
The method 'lm' won’t work when the number of observations is less than the number of variables, use ‘trf’ or ‘dogbox’ in this case.

New in version 0.17.

**jac**
[callable, string or None, optional] Function with signature `jac(x, ...)` which computes the Jacobian matrix of the model function with respect to parameters as a dense array_like structure. It will be scaled according to provided `sigma`. If None (default), the Jacobian will be estimated numerically. String keywords for ‘trf’ and ‘dogbox’ methods can be used to select a finite difference scheme, see `least_squares`.

New in version 0.18.

**kwargs**
Keyword arguments passed to `leastsq` for method='lm' or `least_squares` otherwise.

**Returns**

**popt**
[array] Optimal values for the parameters so that the sum of the squared residuals of \( f(xdata, \star popt) - ydata \) is minimized.

**pcov**
[2-D array] The estimated covariance of popt. The diagonals provide the variance of the parameter estimate. To compute one standard deviation errors on the parameters use `perr = np.sqrt(np.diag(pcov))`.

How the `sigma` parameter affects the estimated covariance depends on `absolute_sigma` argument, as described above.

If the Jacobian matrix at the solution doesn’t have a full rank, then ‘lm’ method returns a matrix filled with `np.inf`, on the other hand ‘trf’ and ‘dogbox’ methods use Moore-Penrose pseudoinverse to compute the covariance matrix.

**Raises**

**ValueError**
if either `ydata` or `xdata` contain NaNs, or if incompatible options are used.

**RuntimeError**
if the least-squares minimization fails.

**OptimizeWarning**
if covariance of the parameters can not be estimated.

See also:

**least_squares**
Minimize the sum of squares of nonlinear functions.

**scipy.stats.linregress**
Calculate a linear least squares regression for two sets of measurements.

**Notes**

With `method='lm'`, the algorithm uses the Levenberg-Marquardt algorithm through `leastsq`. Note that this algorithm can only deal with unconstrained problems.

Box constraints can be handled by methods ‘trf’ and ‘dogbox’. Refer to the docstring of `least_squares` for more information.
Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.optimize import curve_fit

>>> def func(x, a, b, c):
...     return a * np.exp(-b * x) + c

Define the data to be fit with some noise:
```
>>> xdata = np.linspace(0, 4, 50)
>>> y = func(xdata, 2.5, 1.3, 0.5)
>>> np.random.seed(1729)
>>> y_noise = 0.2 * np.random.normal(size=xdata.size)
>>> ydata = y + y_noise
>>> plt.plot(xdata, ydata, 'b-', label='data')
```

Fit for the parameters a, b, c of the function `func`:
```
>>> popt, pcov = curve_fit(func, xdata, ydata)
>>> popt
array([ 2.55423706, 1.35190947, 0.47450618])
>>> popt.plot(xdata, func(xdata, *popt), 'r-',
...            label='fit: a=%5.3f, b=%5.3f, c=%5.3f' % tuple(popt))
```

Constrain the optimization to the region of 0 <= a <= 3, 0 <= b <= 1 and 0 <= c <= 0.5:
```
>>> popt, pcov = curve_fit(func, xdata, ydata, bounds=(0, [3., 1., 0.5]))
>>> popt
array([ 2.43708906, 1. , 0.35015434])
>>> popt.plot(xdata, func(xdata, *popt), 'g--',
...            label='fit: a=%5.3f, b=%5.3f, c=%5.3f' % tuple(popt))
```
```
>>> plt.xlabel('x')
>>> plt.ylabel('y')
>>> plt.legend()
>>> plt.show()
```

### 6.19.6 Root finding

**Scalar functions**

- `root_scalar`(`f, args, method, bracket, ...`) Find a root of a scalar function.
- `brentq`(`f, a, b, args,xtol, rtol, maxiter, ...`) Find a root of a function in a bracketing interval using Brent's method.
- `brenth`(`f, a, b, args,xtol, rtol, maxiter, ...`) Find a root of a function in a bracketing interval using Brent’s method with hyperbolic extrapolation.
- `ridder`(`f, a, b, args,xtol, rtol, maxiter, ...`) Find a root of a function in an interval using Ridder’s method.
- `bisect`(`f, a, b, args,xtol, rtol, maxiter, ...`) Find root of a function within an interval using bisection.

**scipy.optimize.root_scalar**

Find a root of a scalar function.

*Parameters*

- **f** [callable] A function to find a root of.
- **args** [tuple, optional] Extra arguments passed to the objective function and its derivative(s).
- **method** [str, optional] Type of solver. Should be one of
  - ‘bisect’ (see here)
  - ‘brentq’ (see here)
  - ‘brent’ (see here)
  - ‘ridder’ (see here)
  - ‘toms748’ (see here)
  - ‘newton’ (see here)
  - ‘secant’ (see here)
  - ‘halley’ (see here)
- **bracket**: A sequence of 2 floats, optional
  - An interval bracketing a root. \( f(x, \ast args) \) must have different signs at the two endpoints.
- **x0** [float, optional] Initial guess.
- **x1** [float, optional] A second guess.
- **fprime** [bool or callable, optional] If \( fprime \) is a boolean and is True, \( f \) is assumed to return the value of the objective function and of the derivative. \( fprime \) can also be a callable returning the derivative of \( f \). In this case, it must accept the same arguments as \( f \).
- **fprime2** [bool or callable, optional] If \( fprime2 \) is a boolean and is True, \( f \) is assumed to return the value of the objective function and of the first and second derivatives. \( fprime2 \) can also be a callable returning the second derivative of \( f \). In this case, it must accept the same arguments as \( f \).
- **xtol** [float, optional] Tolerance (absolute) for termination.
- **rtol** [float, optional] Tolerance (relative) for termination.
- **maxiter** [int, optional] Maximum number of iterations.
- **options** [dict, optional] A dictionary of solver options. E.g., \( k \), see `show_options()` for details.

*Returns*

- **sol** [RootResults] The solution represented as a `RootResults` object. Important attributes are: `root` the solution, `converged` a boolean indicating if the algorithm exited successfully and `flag` which describes the cause of the termination. See `RootResults` for a description of other attributes.

**See also:**

- `show_options`
  - Additional options accepted by the solvers
- `root`
  - Find a root of a vector function.
Notes

This section describes the available solvers that can be selected by the 'method' parameter.

The default is to use the best method available for the situation presented. If a bracket is provided, it may use one of the bracketing methods. If a derivative and an initial value are specified, it may select one of the derivative-based methods. If no method is judged applicable, it will raise an Exception.

Examples

Find the root of a simple cubic

```python
>>> from scipy import optimize
>>> def f(x):
...     return (x**3 - 1)  # only one real root at x = 1
```

```python
>>> def fprime(x):
...     return 3*x**2
```

The `brentq` method takes as input a bracket

```python
>>> sol = optimize.root_scalar(f, bracket=[0, 3], method='brentq')
```

The `newton` method takes as input a single point and uses the derivative(s)

```python
>>> sol = optimize.root_scalar(f, x0=0.2, fprime=fprime, method='newton')
```

The function can provide the value and derivative(s) in a single call.
```python
>>> def f_p_pp(x):
...     return (x**3 - 1), 3*x**2, 6*x

>>> sol = optimize.root_scalar(f_p_pp, x0=0.2, fprime=True, method='newton', fprime2=True, method='halley')
>>> sol.root, sol.iterations, sol.function_calls
(1.0, 7, 8)
```

### scipy.optimize.brentq

The function `scipy.optimize.brentq` finds a root of a function in a bracketing interval using Brent’s method.

Uses the classic Brent’s method to find a zero of the function `f` on the sign changing interval `[a, b]`. Generally considered the best of the rootfinding routines here. It is a safe version of the secant method that uses inverse quadratic extrapolation. Brent’s method combines root bracketing, interval bisection, and inverse quadratic interpolation. It is sometimes known as the van Wijngaarden-Dekker-Brent method. Brent (1973) claims convergence is guaranteed for functions computable within `[a, b]`

[Brent1973] provides the classic description of the algorithm. Another description can be found in a recent edition of Numerical Recipes, including [PressEtal1992]. A third description is at [http://mathworld.wolfram.com/BrentsMethod.html](http://mathworld.wolfram.com/BrentsMethod.html). It should be easy to understand the algorithm just by reading our code. Our code diverges a bit from standard presentations: we choose a different formula for the extrapolation step.

### Parameters

- **f** [function] Python function returning a number. The function `f` must be continuous, and `f(a)` and `f(b)` must have opposite signs.
- **a** [scalar] One end of the bracketing interval `[a, b]`.
- **b** [scalar] The other end of the bracketing interval `[a, b]`.
- **xtol** [number, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root. The parameter must be nonnegative. For nice functions, Brent’s method will often satisfy the above condition with `xtol/2` and `rtol/2`. [Brent1973]
- **rtol** [number, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root. The parameter cannot be smaller than its default value of `4*np.finfo(float).eps`. For nice functions, Brent’s method will often satisfy the above condition with `xtol/2` and `rtol/2`. [Brent1973]
- **maxiter** [int, optional] If convergence is not achieved in `maxiter` iterations, an error is raised. Must be `> 0`.
- **args** [tuple, optional] Containing extra arguments for the function `f`. `f` is called by `apply(f, (x) + args)`.
- **full_output** [bool, optional] If `full_output` is False, the root is returned. If `full_output` is True, the return value is `(x, r)`, where `x` is the root, and `r` is a `RootResults` object.
- **disp** [bool, optional] If True, raise `RuntimeError` if the algorithm didn’t converge. Otherwise, the convergence status is recorded in any `RootResults` return object.

### Returns

- **x** The root found.
- **r** A `RootResults` object containing additional information.

---

1658 Chapter 6. API Reference

x0  [float] Zero of \( f \) between \( a \) and \( b \).

r  [RootResults (present if \texttt{full_output} = \texttt{True})] Object containing information about the convergence. In particular, \( r.converged \) is True if the routine converged.

Notes

\( f \) must be continuous. \( f(a) \) and \( f(b) \) must have opposite signs.

Examples

```python
>>> def f(x):
...     return (x**2 - 1)

>>> from scipy import optimize

>>> root = optimize.brentq(f, -2, 0)
>>> root
-1.0
```
>>> root = optimize.brentq(f, 0, 2)
>>> root
1.0

**scipy.optimize.brent**

**scipy.optimize.brent** *(f, a, b, args=(), xtol=2e-12, rtol=8.881784197001252e-16, maxiter=100, full_output=False, disp=True)*

Find a root of a function in a bracketing interval using Brent's method with hyperbolic extrapolation.

A variation on the classic Brent routine to find a zero of the function f between the arguments a and b that uses hyperbolic extrapolation instead of inverse quadratic extrapolation. There was a paper back in the 1980's ... f(a) and f(b) cannot have the same signs. Generally, on a par with the brent routine, but not as heavily tested. It is a safe version of the secant method that uses hyperbolic extrapolation. The version here is by Chuck Harris.

**Parameters**

- **f**
  [function] Python function returning a number. f must be continuous, and f(a) and f(b) must have opposite signs.

- **a**
  [scalar] One end of the bracketing interval [a,b].

- **b**
  [scalar] The other end of the bracketing interval [a,b].

- **xtol**
  [number, optional] The computed root x0 will satisfy np.allclose(x, x0, atol=xtol, rtol=rtol), where x is the exact root. The parameter must be nonnegative. As with brentq, for nice functions the method will often satisfy the above condition with xtol/2 and rtol/2.

- **rtol**
  [number, optional] The computed root x0 will satisfy np.allclose(x, x0, atol=xtol, rtol=rtol), where x is the exact root. The parameter cannot be smaller than its default value of 4*np.finfo(float).eps. As with brentq, for nice functions the method will often satisfy the above condition with xtol/2 and rtol/2.

- **maxiter**
  [int, optional] If convergence is not achieved in maxiter iterations, an error is raised. Must be >= 0.

- **args**
  [tuple, optional] Containing extra arguments for the function f. f is called by apply(f, (x)+args).

- **full_output**
  [bool, optional] If full_output is False, the root is returned. If full_output is True, the return value is (x, r), where x is the root, and r is a RootResults object.

- **disp**
  [bool, optional] If True, raise RuntimeError if the algorithm didn't converge. Otherwise, the convergence status is recorded in any RootResults return object.

**Returns**

- **x0**
  [float] Zero of f between a and b.

- **r**
  [RootResults (present if full_output = True)] Object containing information about the convergence. In particular, r.converged is True if the routine converged.

  constrained multivariate optimizers
**Examples**

```python
>>> def f(x):
...     return (x**2 - 1)
```

```python
>>> from scipy import optimize
```

```python
>>> root = optimize.brent(f, -2, 0)
>>> root
-1.0
```

```python
>>> root = optimize.brent(f, 0, 2)
>>> root
1.0
```

**scipy.optimize.ridder**

scipy.optimize.ridder(f, a, b, args=(), xtol=2e-12, rtol=8.881784197001252e-16, maxiter=100, full_output=False, disp=True)

Find a root of a function in an interval using Ridder’s method.

**Parameters**

- **f** [function] Python function returning a number. f must be continuous, and f(a) and f(b) must have opposite signs.
- **a** [scalar] One end of the bracketing interval [a,b].
- **b** [scalar] The other end of the bracketing interval [a,b].
- **xtol** [number, optional] The computed root x0 will satisfy np.allclose(x, x0, atol=xtol, rtol=rtol), where x is the exact root. The parameter must be non-negative.
- **rtol** [number, optional] The computed root x0 will satisfy np.allclose(x, x0, atol=xtol, rtol=rtol), where x is the exact root. The parameter cannot be smaller than its default value of 4*np.finfo(float).eps.
- **maxiter** [int, optional] If convergence is not achieved in maxiter iterations, an error is raised. Must be >= 0.
- **args** [tuple, optional] Containing extra arguments for the function f. f is called by apply(f, (x)+args).
full_output

[bool, optional] If full_output is False, the root is returned. If full_output is True, the return value is \((x, r)\), where \(x\) is the root, and \(r\) is a RootResults object.

disp

[bool, optional] If True, raise RuntimeError if the algorithm didn’t converge. Otherwise, the convergence status is recorded in any RootResults return object.

Returns

x0 [float] Zero of \(f\) between \(a\) and \(b\).

r [RootResults (present if full_output = True)] Object containing information about the convergence. In particular, \(r.converged\) is True if the routine converged.

1-D root-finding

fixed_point

scalar fixed-point finder

Notes

Uses [Ridders1979] method to find a zero of the function \(f\) between the arguments \(a\) and \(b\). Ridders’ method is faster than bisection, but not generally as fast as the Brent routines. [Ridders1979] provides the classic description and source of the algorithm. A description can also be found in any recent edition of Numerical Recipes.

The routine used here diverges slightly from standard presentations in order to be a bit more careful of tolerance.

References

[Ridders1979]

Examples

```python
>>> def f(x):
...     return (x**2 - 1)

>>> from scipy import optimize

>>> root = optimize.ridder(f, 0, 2)

1.0

>>> root = optimize.ridder(f, -2, 0)

-1.0
```
scipy.optimize.bisect

scipy.optimize.bisect(f, a, b, args=(), xtol=2e-12, rtol=8.881784197001252e-16, maxiter=100,
                     full_output=False, disp=True)

Find root of a function within an interval using bisection.

Basic bisection routine to find a zero of the function \( f \) between the arguments \( a \) and \( b \). \( f(a) \) and \( f(b) \) cannot have the same signs. Slow but sure.

**Parameters**

- **f** [function] Python function returning a number. \( f \) must be continuous, and \( f(a) \) and \( f(b) \) must have opposite signs.
- **a** [scalar] One end of the bracketing interval \([a,b]\).
- **b** [scalar] The other end of the bracketing interval \([a,b]\).
- **xtol** [number, optional] The computed root \( x_0 \) will satisfy
  \[
  \text{np.allclose}(x, x_0, \text{atol}=\text{xtol}, \text{rtol}=\text{rtol})
  \]
  where \( x \) is the exact root. The parameter must be non-negative.
- **rtol** [number, optional] The computed root \( x_0 \) will satisfy
  \[
  \text{np.allclose}(x, x_0, \text{atol}=\text{xtol}, \text{rtol}=\text{rtol})
  \]
  where \( x \) is the exact root. The parameter cannot be smaller than its default value of \( 4 \times \text{np.finfo(float).eps} \).
- **maxiter** [int, optional] If convergence is not achieved in **maxiter** iterations, an error is raised. Must be \( \geq 0 \).
- **args** [tuple, optional] Containing extra arguments for the function \( f \). \( f \) is called by
  \[
  \text{apply}(f, (x)+\text{args})
  \]
- **full_output** [bool, optional] If **full_output** is False, the root is returned. If **full_output** is True, the return value is \((x, r)\), where \( x \) is the root, and \( r \) is a \texttt{RootResults} object.
- **disp** [bool, optional] If True, raise RuntimeError if the algorithm didn’t converge. Otherwise, the convergence status is recorded in a \texttt{RootResults} return object.

**Returns**

- **x0** [float] Zero of \( f \) between \( a \) and \( b \).
- **r** [\texttt{RootResults} (present if **full_output** = True)] Object containing information about the convergence. In particular, \( r.converged \) is True if the routine converged.

Examples

```python
def f(x):
    ...  return (x**2 - 1)
```  

```python
from scipy import optimize

>>> root = optimize.bisect(f, 0, 2)
>>> root
1.0

>>> root = optimize.bisect(f, -2, 0)
>>> root
-1.0
```

**scipy.optimize.newton**

Find a zero of a real or complex function using the Newton-Raphson (or secant or Halley’s) method.

If `x0` is a sequence with more than one item, then `newton` returns an array, and `func` must be vectorized and return a sequence or array of the same shape as its first argument. If `fprime` or `fprime2` is given, then its return must also have the same shape.

**Parameters**

- **func** : callable The function whose zero is wanted. It must be a function of a single variable of the form $f(x, a, b, c, ...)$, where $a, b, c, ...$ are extra arguments that can be passed in the `args` parameter.
- **x0** : float, sequence, or ndarray An initial estimate of the zero that should be somewhere near the actual zero. If not scalar, then `func` must be vectorized and return a sequence or array of the same shape as its first argument.
- **fprime** : callable, optional The derivative of the function when available and convenient. If it is None (default), then the secant method is used.
- **args** : tuple, optional Extra arguments to be used in the function call.
- **tol** : float, optional The allowable error of the zero value. If `func` is complex-valued, a larger `tol` is recommended as both the real and imaginary parts of $x$ contribute to $|x - x0|$.
- **maxiter** : int, optional Maximum number of iterations.
- **fprime2** : callable, optional The second order derivative of the function when available and convenient. If it is None (default), then the normal Newton-Raphson or the secant method is used. If it is not None, then Halley’s method is used.
- **x1** : float, optional Another estimate of the zero that should be somewhere near the actual zero. Used if `fprime` is not provided.
- **rtol** : float, optional Tolerance (relative) for termination.
- **full_output** : bool, optional If `full_output` is False (default), the root is returned. If True and `x0` is scalar, the return value is $(x, r)$, where $x$ is the root and $r$ is a `RootResults` object. If True and `x0` is non-scalar, the return value is $(x, converged, zero_der)` (see Returns section for details).
disp  [bool, optional] If True, raise a RuntimeError if the algorithm didn’t converge, with the error message containing the number of iterations and current function value. Otherwise, the convergence status is recorded in a \texttt{RootResults} return object. Ignored if \texttt{x0} is not scalar. \textit{Note: this has little to do with displaying, however, the ‘disp’ keyword cannot be renamed for backwards compatibility.}

\textbf{Returns}

\begin{itemize}
  \item \texttt{root}  [float, sequence, or \texttt{ndarray}] Estimated location where function is zero.
  \item \texttt{r}  [\texttt{RootResults}, optional] Present if \texttt{full_output=True} and \texttt{x0} is scalar. Object containing information about the convergence. In particular, \texttt{r.converged} is True if the routine converged.
  \item \texttt{converged}  [ndarray of bool, optional] Present if \texttt{full_output=True} and \texttt{x0} is non-scalar. For vector functions, indicates which elements converged successfully.
  \item \texttt{zero_der}  [ndarray of bool, optional] Present if \texttt{full_output=True} and \texttt{x0} is non-scalar. For vector functions, indicates which elements had a zero derivative.
\end{itemize}

\textbf{See also:}

\texttt{brentq, brent, ridder, bisect}

\texttt{fsolve}

find zeros in N dimensions.

\textbf{Notes}

The convergence rate of the Newton-Raphson method is quadratic, the Halley method is cubic, and the secant method is sub-quadratic. This means that if the function is well-behaved the actual error in the estimated zero after the \textit{n}th iteration is approximately the square (cube for Halley) of the error after the (n-1)th step. However, the stopping criterion used here is the step size and there is no guarantee that a zero has been found. Consequently, the result should be verified. Safer algorithms are \texttt{brentq}, \texttt{brent}, \texttt{ridder}, and \texttt{bisect}, but they all require that the root first be bracketed in an interval where the function changes sign. The \texttt{brentq} algorithm is recommended for general use in one dimensional problems when such an interval has been found.

When \texttt{newton} is used with arrays, it is best suited for the following types of problems:

\begin{itemize}
  \item The initial guesses, \texttt{x0}, are all relatively the same distance from the roots.
  \item Some or all of the extra arguments, \texttt{args}, are also arrays so that a class of similar problems can be solved together.
  \item The size of the initial guesses, \texttt{x0}, is larger than O(100) elements. Otherwise, a naive loop may perform as well or better than a vector.
\end{itemize}

\textbf{Examples}

```python
>>> from scipy import optimize
>>> import matplotlib.pyplot as plt

>>> def f(x):
...    return (x**3 - 1)  # only one real root at x = 1

def fprime is not provided, use the secant method:
```
```python
>>> root = optimize.newton(f, 1.5)
>>> root
1.0000000000000016
>>> root = optimize.newton(f, 1.5, fprime2=lambda x: 6 * x)
>>> root
1.0000000000000016
```

Only `fprime` is provided, use the Newton-Raphson method:

```python
>>> root = optimize.newton(f, 1.5, fprime=lambda x: 3 * x**2)
>>> root
1.0
```

Both `fprime2` and `fprime` are provided, use Halley's method:

```python
>>> root = optimize.newton(f, 1.5, fprime=lambda x: 3 * x**2,
...                         fprime2=lambda x: 6 * x)
>>> root
1.0
```

When we want to find zeros for a set of related starting values and/or function parameters, we can provide both of those as an array of inputs:

```python
>>> f = lambda x, a: x**3 - a
>>> fder = lambda x, a: 3 * x**2
>>> np.random.seed(4321)
>>> x = np.random.randn(100)
>>> a = np.arange(-50, 50)
>>> vec_res = optimize.newton(f, x, fprime=fder, args=(a, ))
```

The above is the equivalent of solving for each value in `(x, a)` separately in a for-loop, just faster:

```python
>>> loop_res = [optimize.newton(f, x0, fprime=fder, args=(a0,))
... for x0, a0 in zip(x, a)]
>>> np.allclose(vec_res, loop_res)
True
```

Plot the results found for all values of `a`:

```python
>>> analytical_result = np.sign(a) * np.abs(a)**(1/3)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(a, analytical_result, 'o')
>>> ax.plot(a, vec_res, '.')
>>> ax.set_xlabel('$a$')
>>> ax.set_ylabel('$x$ where $f(x, a)=0$')
>>> plt.show()
```

科学优化工具包

该方法实现Alefeld、Potro和Shi的算法748，用于在区间\([a, b]\)内找到函数\(f\)的零点，其中\(f(a)\)和\(f(b)\)具有相反的符号。

它使用了逆三次插值和“牛顿-二次”步骤的混合方法。

**Parameters**

- \(f\) [function] Python函数返回一个标量。函数\(f\)必须连续，且\(f(a)\)和\(f(b)\)具有相反的符号。
- \(a\) [scalar] 搜索区间下界
- \(b\) [scalar] 搜索区间上界
- \(args\) [tuple, optional] 包含额外参数的元组，用于函数\(f\)。函数\(f\)被调用为\(f(x, \ast args)\)。
- \(k\) [int, optional] 每个迭代需要执行的牛顿-二次步骤的数目。\(k\geq 1\)。
- \(xtol\) [scalar, optional] 计算得到的根\(x_0\)将满足\(\text{np.allclose}(x, x_0, \text{atol}=\text{xtol}, \text{rtol}=\text{rtol})\)，其中\(x\)是精确的根。该参数必须非负。
- \(rtol\) [scalar, optional] 计算得到的根\(x_0\)将满足\(\text{np.allclose}(x, x_0, \text{atol}=\text{xtol}, \text{rtol}=\text{rtol})\)，其中\(x\)是精确的根。
- \(maxiter\) [int, optional] 如果在\(maxiter\)次迭代中未达到收敛，则引发错误。必须\(\geq 0\)。
- \(full_output\) [bool, optional] 如果\(full_output\)为False，则返回根。如果\(full_output\)为True，则返回值为\((x, r)\)，其中\(x\)是根，\(r\)是\(\text{RootResults}\)对象。
- \(disp\) [bool, optional] 如果为True，则在算法未收敛时引发RuntimeError。否则，收敛状况记录在\(\text{RootResults}\)返回对象中。

**Returns**

- \(x_0\) [float] \(f\)的近似零点
- \(r\) [\(\text{RootResults}\) (present if \(\text{full_output} = \text{True}\))] 包含关于收敛情况的信息。特别是，\(r.converged\)为True，表示该函数收敛了。

fsolve

find zeroes in N dimensions.

Notes

f must be continuous. Algorithm 748 with \( k=2 \) is asymptotically the most efficient algorithm known for finding roots of a four times continuously differentiable function. In contrast with Brent's algorithm, which may only decrease the length of the enclosing bracket on the last step, Algorithm 748 decreases it each iteration with the same asymptotic efficiency as it finds the root.

For easy statement of efficiency indices, assume that \( f \) has 4 continuous derivatives. For \( k=1 \), the convergence order is at least 2.7, and with about asymptotically 2 function evaluations per iteration, the efficiency index is approximately 1.65. For \( k=2 \), the order is about 4.6 with asymptotically 3 function evaluations per iteration, and the efficiency index 1.66. For higher values of \( k \), the efficiency index approaches the \( k \)th root of \( (3k-2) \), hence \( k=1 \) or \( k=2 \) are usually appropriate.

Examples

```python
>>> def f(x):
...     return (x**3 - 1) # only one real root at x = 1

>>> from scipy import optimize
>>> root, results = optimize.toms748(f, 0, 2, full_output=True)
>>> root
1.0
>>> results
    converged: True
    flag: 'converged'
    function_calls: 11
    iterations: 5
    root: 1.0
```

scipy.optimize.RootResults

```python
class scipy.optimize.RootResults(root, iterations, function_calls, flag)
```

Represents the root finding result.

Attributes

- **root** [float] Estimated root location.
- **iterations** [int] Number of iterations needed to find the root.
- **function_calls** [int] Number of times the function was called.
- **converged** [bool] True if the routine converged.
- **flag** [str] Description of the cause of termination.
The `root_scalar` function supports the following methods:

### root_scalar(method='brentq')

```python
scipy.optimize.root_scalar (args=(), method='brentq', x0=None, options={})
```

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.root_scalar`

**Options**

- **args** [tuple, optional]: Extra arguments passed to the objective function.
- **xtol** [float, optional]: Tolerance (absolute) for termination.
- **rtol** [float, optional]: Tolerance (relative) for termination.
- **maxiter** [int, optional]: Maximum number of iterations.
- **options**: dict, optional
  - Specifies any method-specific options not covered above

### root_scalar(method='brenth')

```python
scipy.optimize.root_scalar (args=(), method='brenth', x0=None, options={})
```

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.root_scalar`

**Options**

- **args** [tuple, optional]: Extra arguments passed to the objective function.
- **xtol** [float, optional]: Tolerance (absolute) for termination.
- **rtol** [float, optional]: Tolerance (relative) for termination.
- **maxiter** [int, optional]: Maximum number of iterations.
- **options**: dict, optional
  - Specifies any method-specific options not covered above.

### root_scalar(method='bisect')

```python
scipy.optimize.root_scalar (args=(), method='bisect', x0=None, options={})
```

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.root_scalar`

**Options**

- **args** [tuple, optional]: Extra arguments passed to the objective function.
- **xtol** [float, optional]: Tolerance (absolute) for termination.
- **rtol** [float, optional]: Tolerance (relative) for termination.
- **maxiter** [int, optional]: Maximum number of iterations.
- **options**: dict, optional
  - Specifies any method-specific options not covered above.
root_scalar(method='ridder')

```
scipy.optimize.root_scalar (args=(), method='ridder', x0=None, options={})
```

See also:

For documentation for the rest of the parameters, see `scipy.optimize.root_scalar`

Options

- **args**: [tuple, optional] Extra arguments passed to the objective function.
- **xtol**: [float, optional] Tolerance (absolute) for termination.
- **rtol**: [float, optional] Tolerance (relative) for termination.
- **maxiter**: [int, optional] Maximum number of iterations.
- **options**: dict, optional

  Specifies any method-specific options not covered above.

root_scalar(method='newton')

```
scipy.optimize.root_scalar (args=(), method='newton', x0=None, options={})
```

See also:

For documentation for the rest of the parameters, see `scipy.optimize.root_scalar`

Options

- **args**: [tuple, optional] Extra arguments passed to the objective function and its derivative.
- **xtol**: [float, optional] Tolerance (absolute) for termination.
- **rtol**: [float, optional] Tolerance (relative) for termination.
- **maxiter**: [int, optional] Maximum number of iterations.
- **x0**: [float, required] Initial guess.
- **fprime**: [bool or callable, optional] If `fprime` is a boolean and is True, `f` is assumed to return the value of derivative along with the objective function. `fprime` can also be a callable returning the derivative of `f`. In this case, it must accept the same arguments as `f`.
- **options**: dict, optional

  Specifies any method-specific options not covered above.

root_scalar(method='toms748')

```
scipy.optimize.root_scalar (args=(), method='toms748', x0=None, options={})
```

The table below lists situations and appropriate methods, along with asymptotic convergence rates per iteration (and per function evaluation) for successful convergence to a simple root(*). Bisection is the slowest of them all, adding one bit of accuracy for each function evaluation, but is guaranteed to converge. The other bracketing methods all (eventually) increase the number of accurate bits by about 50% for every function evaluation. The derivative-based methods, all built on newton, can converge quite quickly if the initial value is close to the root. They can also be applied to functions defined on (a subset of) the complex plane.
See also:

**scipy.optimize.cython_optimize** – Typed Cython versions of zeros functions

Fixed point finding:

```python
fixed_point(func, x0[, args, xtol, maxiter, ...])    Find a fixed point of the function.
```

**scipy.optimize.fixed_point**

```python
scipy.optimize.fixed_point(func, x0, args=(), xtol=1e-08, maxiter=500, method='del2')
```

Find a fixed point of the function.

Given a function of one or more variables and a starting point, find a fixed point of the function: i.e., where \( \text{func}(x0) = x0 \).

**Parameters**

- **func** [function] Function to evaluate.
- **x0** [array_like] Fixed point of function.
- **args** [tuple, optional] Extra arguments to `func`.
- **xtol** [float, optional] Convergence tolerance, defaults to 1e-08.
- **maxiter** [int, optional] Maximum number of iterations, defaults to 500.
- **method** [{'del2', 'iteration'}, optional] Method of finding the fixed-point, defaults to “del2”, which uses Steffensen’s Method with Aitken’s Del^2 convergence acceleration [1]. The “iteration” method simply iterates the function until convergence is detected, without attempting to accelerate the convergence.
References

[1]

Examples

```python
>>> from scipy import optimize
>>> def func(x, c1, c2):
...    return np.sqrt(c1/(x+c2))
>>> c1 = np.array([10, 12.])
>>> c2 = np.array([3, 5.])
>>> optimize.fixed_point(func, [1.2, 1.3], args=(c1,c2))
array([ 1.4920333 , 1.37228132])
```

Multidimensional

```python
root(fun, x0[, args, method, jac, tol, ...]) Find a root of a vector function.
```

`scipy.optimize.root`

`scipy.optimize.root(fun, x0[, args, method='hybr', jac=None, tol=None, callback=None, options=None])`

Find a root of a vector function.

**Parameters**

- `fun` [callable] A vector function to find a root of.
- `x0` [ndarray] Initial guess.
- `args` [tuple, optional] Extra arguments passed to the objective function and its Jacobian.
- `method` [str, optional] Type of solver. Should be one of
  - `hybr` *(see here)*
  - `lm` *(see here)*
  - `broyden1` *(see here)*
  - `broyden2` *(see here)*
  - `anderson` *(see here)*
  - `linearmixing` *(see here)*
  - `diagbroyden` *(see here)*
  - `excitingmixing` *(see here)*
  - `krylov` *(see here)*
  - `df-sane` *(see here)*
- `jac` [bool or callable, optional] If `jac` is a Boolean and is True, `fun` is assumed to return the value of Jacobian along with the objective function. If False, the Jacobian will be estimated numerically. `jac` can also be a callable returning the Jacobian of `fun`. In this case, it must accept the same arguments as `fun`.
- `tol` [float, optional] Tolerance for termination. For detailed control, use solver-specific options.
- `callback` [function, optional] Optional callback function. It is called on every iteration as `callback(x, f)` where `x` is the current solution and `f` the corresponding residual. For all methods but ‘hybr’ and ‘lm’.
- `options` [dict, optional] A dictionary of solver options. E.g., `xtol` or `maxiter`, see `show_options()` for details.

**Returns**
sol  [OptimizeResult] The solution represented as an OptimizeResult object. Important attributes are: x the solution array, success a Boolean flag indicating if the algorithm exited successfully and message which describes the cause of the termination. See OptimizeResult for a description of other attributes.

See also:

show_options

Additional options accepted by the solvers

Notes

This section describes the available solvers that can be selected by the ‘method’ parameter. The default method is hybr.

Method hybr uses a modification of the Powell hybrid method as implemented in MINPACK [1].

Method lm solves the system of nonlinear equations in a least squares sense using a modification of the Levenberg-Marquardt algorithm as implemented in MINPACK [1].

Method df-sane is a derivative-free spectral method. [3]

Methods broyden1, broyden2, anderson, linearmixing, diagbroyden, excitingmixing, krylov are inexact Newton methods, with backtracking or full line searches [2]. Each method corresponds to a particular Jacobian approximations. See nonlin for details.

• Method broyden1 uses Broyden’s first Jacobian approximation, it is known as Broyden’s good method.
• Method broyden2 uses Broyden’s second Jacobian approximation, it is known as Broyden’s bad method.
• Method anderson uses (extended) Anderson mixing.
• Method Krylov uses Krylov approximation for inverse Jacobian. It is suitable for large-scale problem.
• Method diagbroyden uses diagonal Broyden Jacobian approximation.
• Method linearmixing uses a scalar Jacobian approximation.
• Method excitingmixing uses a tuned diagonal Jacobian approximation.

Warning: The algorithms implemented for methods diagbroyden, linearmixing and excitingmixing may be useful for specific problems, but whether they will work may depend strongly on the problem.

New in version 0.11.0.

References

[1], [2], [3]
Examples

The following functions define a system of nonlinear equations and its jacobian.

```python
>>> def fun(x):
...     return [x[0] + 0.5 * (x[0] - x[1])**3 - 1.0,
...             0.5 * (x[1] - x[0])**3 + x[1]]
```

```python
>>> def jac(x):
...     return np.array([[1 + 1.5 * (x[0] - x[1])**2,
...                       -1.5 * (x[0] - x[1])**2,
...                       -1.5 * (x[1] - x[0])**2,
...                       1 + 1.5 * (x[1] - x[0])**2]])
```

A solution can be obtained as follows.

```python
>>> from scipy import optimize
>>> sol = optimize.root(fun, [0, 0], jac=jac, method='hybr')
>>> sol.x
array([ 0.84116389, 0.15883611])
```

The `root` function supports the following methods:

**root(method='hybr')**

`scipy.optimize.root` (fun, x0, args=(), method='hybr', jac=None, tol=None, callback=None, options={})

Find the roots of a multivariate function using MINPACK's hybrd and hybrj routines (modified Powell method).

For documentation for the rest of the parameters, see `scipy.optimize.root`

**Options**

- `col_deriv` [bool] Specify whether the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).
- `xtol` [float] The calculation will terminate if the relative error between two consecutive iterates is at most `xtol`.
- `maxfev` [int] The maximum number of calls to the function. If zero, then `100*(N+1)` is the maximum where N is the number of elements in `x0`.
- `band` [tuple] If set to a two-sequence containing the number of sub- and super-diagonals within the band of the Jacobi matrix, the Jacobi matrix is considered banded (only for `fprime=None`).
- `eps` [float] A suitable step length for the forward-difference approximation of the Jacobian (for `fprime=None`). If `eps` is less than the machine precision, it is assumed that the relative errors in the functions are of the order of the machine precision.
- `factor` [float] A parameter determining the initial step bound (`factor * || diag * x||`). Should be in the interval (0.1, 100).
- `diag` [sequence] N positive entries that serve as a scale factors for the variables.
root(method='lm')

scipy.optimize.root (fun, x0, args=(), method='lm', jac=None, tol=None, callback=None, options={'col_deriv': 0, 'xtol': 1.49012e-08, 'ftol': 1.49012e-08, 'gtol': 0.0, 'maxiter': 0, 'eps': 0.0, 'factor': 100, 'diag': None})

Solve for least squares with Levenberg-Marquardt

See also:
For documentation for the rest of the parameters, see scipy.optimize.root

Options

- col_deriv [bool] non-zero to specify that the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).
- ftol [float] Relative error desired in the sum of squares.
- xtol [float] Relative error desired in the approximate solution.
- gtol [float] Orthogonality desired between the function vector and the columns of the Jacobian.
- maxiter [int] The maximum number of calls to the function. If zero, then 100*(N+1) is the maximum where N is the number of elements in x0.
- epsfcn [float] A suitable step length for the forward-difference approximation of the Jacobian (for Dfun=None). If epsfcn is less than the machine precision, it is assumed that the relative errors in the functions are of the order of the machine precision.
- factor [float] A parameter determining the initial step bound (factor * || diag * x||). Should be in interval (0.1, 100).
- diag [sequence] N positive entries that serve as a scale factors for the variables.

root(method='broyden1')

scipy.optimize.root (fun, x0, args=(), method='broyden1', tol=None, callback=None, options={})

See also:
For documentation for the rest of the parameters, see scipy.optimize.root

Options

- nit [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- disp [bool, optional] Print status to stdout on every iteration.
- maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, NoConvergence is raised.
- ftol [float, optional] Relative tolerance for the residual. If omitted, not used.
- fatol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- xtol [float, optional] Relative minimum step size. If omitted, not used.
- xatol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
- line_search [None, ‘armijo’ (default), ‘wolfe’], optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.
- jac_options [dict, optional]
  Options for the respective Jacobian approximation.

**alpha** [float, optional] Initial guess for the Jacobian is (-1/alpha).

**reduction_method**
[std or tuple, optional] Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form (method, param1, param2, ...) that gives the name of the method and values for additional parameters.

Methods available:
- **restart** Drop all matrix columns. Has no extra parameters.
- **simple** Drop oldest matrix column. Has no extra parameters.
- **svd** Keep only the most significant SVD components.

Extra parameters:
- **to_retain** Number of SVD components to retain when rank reduction is done. Default is max_rank - 2.

**max_rank** [int, optional] Maximum rank for the Broyden matrix. Default is infinity (i.e., no rank reduction).

**root(method='broyden2')**

```python
scipy.optimize.root (fun, x0, args=(), method='broyden2', tol=None, callback=None, options={})
```

For documentation for the rest of the parameters, see `scipy.optimize.root`

**Options**

- **nit** [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- **disp** [bool, optional] Print status to stdout on every iteration.
- **maxiter** [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.
- **ftol** [float, optional] Relative tolerance for the residual. If omitted, not used.
- **fatol** [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- **xtol** [float, optional] Relative minimum step size. If omitted, not used.
- **xatol** [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- **tol_norm** [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
- **line_search** [{None, ‘armijo’ (default), ‘wolfe’}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.
- **jac_options** [dict, optional] Options for the respective Jacobian approximation.
- **alpha** [float, optional] Initial guess for the Jacobian is (-1/alpha).
- **reduction_method** [std or tuple, optional] Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form (method, param1, param2, ...) that gives the name of the method and values for additional parameters.
Methods available:

- **restart**  
  Drop all matrix columns. Has no extra parameters.

- **simple**  
  Drop oldest matrix column. Has no extra parameters.

- **svd**  
  Keep only the most significant SVD components.

Extra parameters:

- **to_retain**  
  Number of SVD components to retain when rank reduction is done. Default is \( \max_{\text{rank}} - 2 \).

- **max_rank**  
  [int, optional] Maximum rank for the Broyden matrix. Default is infinity (i.e., no rank reduction).

**root(method='anderson')**

```python
scipy.optimize.root(fun, x0, args=(), method='anderson', tol=None, callback=None, options={})
```

See also:

For documentation for the rest of the parameters, see `scipy.optimize.root`

**Options**

- **nit**  
  [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

- **disp**  
  [bool, optional] Print status to stdout on every iteration.

- **maxiter**  
  [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, **NoConvergence** is raised.

- **ftol**  
  [float, optional] Relative tolerance for the residual. If omitted, not used.

- **fatol**  
  [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

- **xtol**  
  [float, optional] Relative minimum step size. If omitted, not used.

- **xatol**  
  [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

- **tol_norm**  
  [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

- **line_search**  
  [['None', 'armijo' (default), 'wolfe'], optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

- **jac_options**  
  [dict, optional] Options for the respective Jacobian approximation.

- **alpha**  
  [float, optional] Initial guess for the Jacobian is \((-1/\alpha)\).

- **M**  
  [float, optional] Number of previous vectors to retain. Defaults to 5.

- **w0**  
  [float, optional] Regularization parameter for numerical stability. Compared to unity, good values of the order of 0.01.
root(method='linearmixing')

```python
scipy.optimize.root(fun, x0, args=(), method='linearmixing', tol=None, callback=None, options={})
```

**Options**

- `nit` [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- `disp` [bool, optional] Print status to stdout on every iteration.
- `maxiter` [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.
- `ftol` [float, optional] Relative tolerance for the residual. If omitted, not used.
- `fatol` [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is $6 \times 10^{-6}$.
- `xtol` [float, optional] Relative minimum step size. If omitted, not used.
- `xatol` [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- `tol_norm` [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
- `line_search` [{None, ‘armijo’ (default), ‘wolfe’}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.
- `jac_options` [dict, optional] Options for the respective Jacobian approximation.
- `alpha` [float, optional] Initial guess for the jacobian is $(-1/\alpha)$.

root(method='diagbroyden')

```python
scipy.optimize.root(fun, x0, args=(), method='diagbroyden', tol=None, callback=None, options={})
```

See also:
For documentation for the rest of the parameters, see `scipy.optimize.root`.

**Options**

- `nit` [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- `disp` [bool, optional] Print status to stdout on every iteration.
- `maxiter` [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.
- `ftol` [float, optional] Relative tolerance for the residual. If omitted, not used.
- `fatol` [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is $6 \times 10^{-6}$.
- `xtol` [float, optional] Relative minimum step size. If omitted, not used.
- `xatol` [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- `tol_norm` [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search

{None, 'armijo' (default), 'wolfe'}, optional Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.

jac_options

{dict, optional} Options for the respective Jacobian approximation.

alpha [float, optional] Initial guess for the Jacobian is (-1/alpha).

root(method='excitingmixing')

scipy.optimize.root (fun, x0, args=(), method='excitingmixing', tol=None, callback=None, options={})

See also:

For documentation for the rest of the parameters, see scipy.optimize.root

Options

nit [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

disp [bool, optional] Print status to stdout on every iteration.

maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, NoConvergence is raised.

ftol [float, optional] Relative tolerance for the residual. If omitted, not used.

fatol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

xtol [float, optional] Relative minimum step size. If omitted, not used.

xatol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search

{None, 'armijo' (default), 'wolfe'}, optional Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.

jac_options

{dict, optional} Options for the respective Jacobian approximation.

alpha [float, optional] Initial Jacobian approximation is (-1/alpha).

alphamax [float, optional] The entries of the diagonal Jacobian are kept in the range [alpha, alphamax].

root(method='krylov')

scipy.optimize.root (fun, x0, args=(), method='krylov', tol=None, callback=None, options={})

See also:

For documentation for the rest of the parameters, see scipy.optimize.root

Options

nit [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

disp [bool, optional] Print status to stdout on every iteration.

maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, NoConvergence is raised.

ftol [float, optional] Relative tolerance for the residual. If omitted, not used.

fatol  [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
xtol  [float, optional] Relative minimum step size. If omitted, not used.
xatol  [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
tol_norm  [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
line_search  [[None, ‘armijo’ (default), ‘wolfe’], optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.
jac_options  [dict, optional] Options for the respective Jacobian approximation.
rdiff  [float, optional] Relative step size to use in numerical differentiation.
method  [['lgmres', 'gmres', 'bicgstab', 'cgs', 'minres'] or function] Krylov method to use to approximate the Jacobian. Can be a string, or a function implementing the same interface as the iterative solvers in scipy.sparse.linalg. The default is scipy.sparse.linalg.lgmres.
inner_M  [LinearOperator or InverseJacobian] Preconditioner for the inner Krylov iteration. Note that you can use also inverse Jacobians as (adaptive) preconditioners. For example,

```python
>>> jac = BroydenFirst()
>>> kjac = KrylovJacobian(inner_M=jac.inverse).
```
If the preconditioner has a method named ‘update’, it will be called as update(x, f) after each nonlinear step, with x giving the current point, and f the current function value.

inner_tol, inner_maxiter, ...
Parameters to pass on to the “inner” Krylov solver. See scipy.sparse.linalg.gmres for details.
outer_k  [int, optional] Size of the subspace kept across LGMRES nonlinear iterations. See scipy.sparse.linalg.lgmres for details.

root(method=’df-sane’)
scipy.optimize.root(func, x0, args=(), method=’df-sane’, tol=None, callback=None, options={‘func’: None, ‘ftol’: 1e-08, ‘fatol’: 1e-300, ‘maxfev’: 1000, ‘fnorm’: None, ‘disp’: False, ‘M’: 10, ‘eta_strategy’: None, ‘sigma_eps’: 1e-10, ‘sigma_0’: 1.0, ‘line_search’: ‘cruc’})
Solve nonlinear equation with the DF-SANE method

See also:
For documentation for the rest of the parameters, see scipy.optimize.root

Options

ftol  [float, optional] Relative norm tolerance.
fatol  [float, optional] Absolute norm tolerance. Algorithm terminates when ||func(x)|| < fatol + ftol ||func(x_0)||.
fnorm  [callable, optional] Norm to use in the convergence check. If None, 2-norm is used.
maxfev  [int, optional] Maximum number of function evaluations.
disp  [bool, optional] Whether to print convergence process to stdout.
eta_strategy  [callable, optional] Choice of the eta_k parameter, which gives slack for growth of ||F||^**2. Called as eta_k = eta_strategy(k, x, F) with k the iteration

6.19. Optimization and root finding (scipy.optimize) 1681
number, \( x \) the current iterate and \( F \) the current residual. Should satisfy \( \eta_k > 0 \) and 
\[ \sum(\eta_k, k=0..\infty) < \infty. \] Default: \( \|F\|^2 / (1 + k)^2 \).

**sigma_\text{eps}** [float, optional] The spectral coefficient is constrained to \( \sigma_\text{eps} < \sigma < 1/\sigma_\text{eps} \). Default: \( 1e-10 \)

**sigma_\text{0}** [float, optional] Initial spectral coefficient. Default: 1.0

**M** [int, optional] Number of iterates to include in the nonmonotonic line search. Default: 10

**line_search** [{'cruz', 'cheng'}] Type of line search to employ. ‘cruz’ is the original one defined in [Martínez & Raydan. Math. Comp. 75, 1429 (2006)], ‘cheng’ is a modified search defined in [Cheng & Li. IMA J. Numer. Anal. 29, 814 (2009)]. Default: ‘cruz’

### 6.19.7 Linear programming

**linprog**([c, A_ub, b_ub, A_eq, b_eq, bounds, …]) Linear programming: minimize a linear objective function subject to linear equality and inequality constraints.

**scipy.optimize.linprog**

scipy.optimize.linprog(c, A_ub=None, b_ub=None, A_eq=None, b_eq=None, bounds=None, method='interior-point', callback=None, options=None, x0=None)

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints.

Linear programming solves problems of the following form:

\[
\begin{align*}
\min \quad & c^Tx \\
\text{such that} \quad & A_{ub}x \leq b_{ub}, \\
& A_{eq}x = b_{eq}, \\
& l \leq x \leq u,
\end{align*}
\]

where \( x \) is a vector of decision variables; \( c, b_{ub}, b_{eq}, l, \) and \( u \) are vectors; and \( A_{ub} \) and \( A_{eq} \) are matrices.

Alternatively, that’s:

minimize:

\[
c @ x
\]

such that:

\[
A_{ub} @ x \leq b_{ub} \\
A_{eq} @ x == b_{eq} \\
lb <= x <= ub
\]

Note that by default \( lb = 0 \) and \( ub = None \) unless specified with \( \text{bounds} \).

**Parameters**

\[
c \quad \text{[1-D array]} \quad \text{The coefficients of the linear objective function to be minimized.}
\]

b_ub [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of A_ub @ x.

b_eq [1-D array, optional] The equality constraint vector. Each element of A_eq @ x must equal the corresponding element of b_eq.

bounds [sequence, optional] A sequence of (min, max) pairs for each element in x, defining the minimum and maximum values of that decision variable. Use None to indicate that there is no bound. By default, bounds are (0, None) (all decision variables are non-negative). If a single tuple (min, max) is provided, then min and max will serve as bounds for all decision variables.

method [str, optional] The algorithm used to solve the standard form problem. 'highs-ds', 'highs-ipm', 'highs', 'interior-point' (default), 'revised simplex', and 'simplex' (legacy) are supported.

callback [callable, optional] If a callback function is provided, it will be called at least once per iteration of the algorithm. The callback function must accept a single scipy.optimize.OptimizeResult consisting of the following fields:

x [1-D array] The current solution vector.

fun [float] The current value of the objective function c @ x.

success [bool] True when the algorithm has completed successfully.

slack [1-D array] The (nominally positive) values of the slack, b_ub - A_ub @ x.

con [1-D array] The (nominally zero) residuals of the equality constraints, b_eq - A_eq @ x.

phase [int] The phase of the algorithm being executed.

status [int] An integer representing the status of the algorithm.

0 : Optimization proceeding nominally.
1 : Iteration limit reached.
2 : Problem appears to be infeasible.
3 : Problem appears to be unbounded.
4 : Numerical difficulties encountered.

nit [int] The current iteration number.

Callback functions are not currently supported by the HiGHS methods.

options [dict, optional] A dictionary of solver options. All methods accept the following options:

disp [bool] Set to True to print convergence messages. Default: False.

presolve [bool] Set to False to disable automatic presolve. Default: True.

All methods except the HiGHS solvers also accept:

tol [float] A tolerance which determines when a residual is “close enough” to zero to be considered exactly zero.

autoscale [bool] Set to True to automatically perform equilibration. Consider using this option if the numerical values in the constraints are separated by several orders of magnitude. Default: False.

rr_method [string] Method used to identify and remove redundant rows from the equality constraint matrix after presolve. For problems with dense input, the available methods for redundancy removal are:

“SVD”: Repeatedly performs singular value decomposition on the matrix, detecting redundant rows based on nonzeros in the left singular
vectors that correspond with zero singular values. May be fast when
the matrix is nearly full rank.

“ID”: Uses a randomized interpolative decomposition. Identifies
columns of the matrix transpose not used in a full-rank interpolative
decomposition of the matrix.

None: Uses “svd” if the matrix is nearly full rank, that is, the difference
between the matrix rank and the number of rows is less than five. If
not, uses “pivot”. The behavior of this default is subject to change
without prior notice.

Default: None. For problems with sparse input, this option is ignored, and the
pivot-based algorithm presented in [5] is used.

For method-specific options, see show_options('linprog').

x0
[1-D array, optional] Guess values of the decision variables, which will be refined by the
optimization algorithm. This argument is currently used only by the ‘revised simplex’ method,
and can only be used if x0 represents a basic feasible solution.

Returns

res [OptimizeResult] A scipy.optimize.OptimizeResult consisting of the fields:
x [1-D array] The values of the decision variables that minimizes the objective
function while satisfying the constraints.
fun [float] The optimal value of the objective function c @ x.
slack [1-D array] The (nominally positive) values of the slack variables, b_ub -
A_ub @ x.
con [1-D array] The (nominally zero) residuals of the equality constraints, b_eq -
A_eq @ x.
success [bool] True when the algorithm succeeds in finding an optimal solution.
status [int] An integer representing the exit status of the algorithm.
  0 : Optimization terminated successfully.
  1 : Iteration limit reached.
  2 : Problem appears to be infeasible.
  3 : Problem appears to be unbounded.
  4 : Numerical difficulties encountered.
nit [int] The total number of iterations performed in all phases.

See also:

show_options

Additional options accepted by the solvers.

Notes

This section describes the available solvers that can be selected by the ‘method’ parameter.

’higs-ds’ and ’higs-ipm’ are interfaces to the HiGHS simplex and interior-point method solvers [13], respectively.
’higs’ chooses between the two automatically. These are the fastest linear programming solvers in SciPy, especially
for large, sparse problems; which of these two is faster is problem-dependent. ’interior-point’ is the default as it
was the fastest and most robust method before the recent addition of the HiGHS solvers. ’revised simplex’ is more
accurate than interior-point for the problems it solves. ’simplex’ is the legacy method and is included for backwards
compatibility and educational purposes.

Method highs-ds is a wrapper of the C++ high performance dual revised simplex implementation (HSOL) [13],
[14]. Method highs-ipm is a wrapper of a C++ implementation of an interior-point method [13]; it features a
crossover routine, so it is as accurate as a simplex solver. Method *highs* chooses between the two automatically. For new code involving *linprog*, we recommend explicitly choosing one of these three method values.

New in version 1.5.0.

Method *interior-point* uses the primal-dual path following algorithm as outlined in [4]. This algorithm supports sparse constraint matrices and is typically faster than the simplex methods, especially for large, sparse problems. Note, however, that the solution returned may be slightly less accurate than those of the simplex methods and will not, in general, correspond with a vertex of the polytope defined by the constraints.

New in version 1.0.0.

Method *revised simplex* uses the revised simplex method as described in [9], except that a factorization [11] of the basis matrix, rather than its inverse, is efficiently maintained and used to solve the linear systems at each iteration of the algorithm.

New in version 1.3.0.

Method *simplex* uses a traditional, full-tableau implementation of Dantzig's simplex algorithm [1], [2] (not the Nelder-Mead simplex). This algorithm is included for backwards compatibility and educational purposes.

New in version 0.15.0.

Before applying *interior-point*, *revised simplex*, or *simplex*, a presolve procedure based on [8] attempts to identify trivial infeasibilities, trivial unboundedness, and potential problem simplifications. Specifically, it checks for:

- rows of zeros in $A_{eq}$ or $A_{ub}$, representing trivial constraints;
- columns of zeros in $A_{eq}$ and $A_{ub}$, representing unconstrained variables;
- column singletons in $A_{eq}$, representing fixed variables; and
- column singletons in $A_{ub}$, representing simple bounds.

If presolve reveals that the problem is unbounded (e.g., an unconstrained and unbounded variable has negative cost) or infeasible (e.g., a row of zeros in $A_{eq}$ corresponds with a nonzero in $b_{eq}$), the solver terminates with the appropriate status code. Note that presolve terminates as soon as any sign of unboundedness is detected; consequently, a problem may be reported as unbounded when in reality the problem is infeasible (but infeasibility has not been detected yet). Therefore, if it is important to know whether the problem is actually infeasible, solve the problem again with option *presolve=False*.

If neither infeasibility nor unboundedness are detected in a single pass of the presolve, bounds are tightened where possible and fixed variables are removed from the problem. Then, linearly dependent rows of the $A_{eq}$ matrix are removed, (unless they represent an infeasibility) to avoid numerical difficulties in the primary solve routine. Note that rows that are nearly linearly dependent (within a prescribed tolerance) may also be removed, which can change the optimal solution in rare cases. If this is a concern, eliminate redundancy from your problem formulation and run with option *rr=False* or *presolve=False*.

Several potential improvements can be made here: additional presolve checks outlined in [8] should be implemented, the presolve routine should be run multiple times (until no further simplifications can be made), and more of the efficiency improvements from [5] should be implemented in the redundancy removal routines.

After presolve, the problem is transformed to standard form by converting the (tightened) simple bounds to upper bound constraints, introducing non-negative slack variables for inequality constraints, and expressing unbounded variables as the difference between two non-negative variables. Optionally, the problem is automatically scaled via equilibration [12]. The selected algorithm solves the standard form problem, and a postprocessing routine converts the result to a solution to the original problem.

6.19. Optimization and root finding (*scipy.optimize*) 1685
References

[1], [2], [3], [4], [5], [6], [7], [8], [9], [10], [11], [12], [13], [14]

Examples

Consider the following problem:

\[
\begin{align*}
\min_{x_0, x_1} & \quad -x_0 + 4x_1 \\
\text{such that} & \quad -3x_0 + x_1 \leq 6, \\
& \quad -x_0 - 2x_1 \geq -4, \\
& \quad x_1 \geq -3.
\end{align*}
\]

The problem is not presented in the form accepted by `linprog`. This is easily remedied by converting the “greater than” inequality constraint to a “less than” inequality constraint by multiplying both sides by a factor of \(-1\). Note also that the last constraint is really the simple bound \(-3 \leq x_1 \leq \infty\). Finally, since there are no bounds on \(x_0\), we must explicitly specify the bounds \(-\infty \leq x_0 \leq \infty\), as the default is for variables to be non-negative. After collecting coefficients into arrays and tuples, the input for this problem is:

```python
>>> c = [-1, 4]
>>> A = [[-3, 1], [1, 2]]
>>> b = [6, 4]
>>> x0_bounds = (None, None)
>>> x1_bounds = (-3, None)
>>> from scipy.optimize import linprog
>>> res = linprog(c, A_ub=A, b_ub=b, bounds=[x0_bounds, x1_bounds])
```

Note that the default method for `linprog` is ‘interior-point’, which is approximate by nature.

```python
>>> print(res)
con: array([], dtype=float64)
fun: -21.99999984082494 # may vary
message: 'Optimization terminated successfully.'
nit: 6 # may vary
slack: array([3.89999997e+01, 8.46872439e-08]) # may vary
status: 0
success: True
x: array([ 9.99999989, -2.99999999]) # may vary
```

If you need greater accuracy, try ‘revised simplex’.

```python
>>> res = linprog(c, A_ub=A, b_ub=b, bounds=[x0_bounds, x1_bounds],
                method='revised simplex')
>>> print(res)
con: array([], dtype=float64)
fun: -22.0 # may vary
message: 'Optimization terminated successfully.'
nit: 1 # may vary
slack: array([39., 0.]) # may vary
status: 0
success: True
x: array([ 10., -3.]) # may vary
```

The `linprog` function supports the following methods:
linprog(method='simplex')

scipy.optimize.linprog(c, A_ub=None, b_ub=None, A_eq=None, b_eq=None, bounds=None, method='simplex', callback=None, options={'maxiter': 5000, 'disp': False, 'presolve': True, 'tol': 1e-12, 'autoscale': False, 'rr': True, 'bland': False}, x0=None)

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using the tableau-based simplex method.

Linear programming solves problems of the following form:

\[
\min_x \ c^T x \\
\text{such that } A_{ub} x \leq b_{ub}, \\
A_{eq} x = b_{eq}, \\
l \leq x \leq u,
\]

where \( x \) is a vector of decision variables; \( c, b_{ub}, b_{eq}, l, \) and \( u \) are vectors; and \( A_{ub} \) and \( A_{eq} \) are matrices.

Alternatively, that’s:

\[
\begin{align*}
\text{minimize:} & \quad c @ x \\
\text{such that:} & \\
A_{ub} @ x & \leq b_{ub} \\
A_{eq} @ x & = b_{eq} \\
lb & \leq x \leq ub
\end{align*}
\]

Note that by default \( lb = 0 \) and \( ub = None\) unless specified with \( \text{bounds}\).

**Parameters**

- **c** [1-D array] The coefficients of the linear objective function to be minimized.
- **A_ub** [2-D array, optional] The inequality constraint matrix. Each row of \( A_{ub} \) specifies the coefficients of a linear inequality constraint on \( x \).
- **b_ub** [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of \( A_{ub} @ x \).
- **A_eq** [2-D array, optional] The equality constraint matrix. Each row of \( A_{eq} \) specifies the coefficients of a linear equality constraint on \( x \).
- **b_eq** [1-D array, optional] The equality constraint vector. Each element of \( A_{eq} @ x \) must equal the corresponding element of \( b_{eq} \).
- **bounds** [sequence, optional] A sequence of \((\text{min}, \text{max})\) pairs for each element in \( x \), defining the minimum and maximum values of that decision variable. Use \( None \) to indicate that there is no bound. By default, bounds are \((0, None)\) (all decision variables are non-negative). If a single tuple \((\text{min}, \text{max})\) is provided, then \( \text{min} \) and \( \text{max} \) will serve as bounds for all decision variables.
- **method** [str] This is the method-specific documentation for \('\text{simplex}', '\text{highs}', '\text{highs-ds}', '\text{highs-ipm}', '\text{interior-point}' (default), and \'\text{revised simplex}' are also available.
- **callback** [callable, optional] Callback function to be executed once per iteration.

**Returns**

- **res** [OptimizeResult] A \( \text{scipy.optimize.OptimizeResult} \) consisting of the fields:
  - **x** [1-D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.
  - **fun** [float] The optimal value of the objective function \( c @ x \).
slack [1-D array] The (nominally positive) values of the slack variables, \( b_{ub} - A_{ub} @ x \).

con [1-D array] The (nominally zero) residuals of the equality constraints, \( b_{eq} - A_{eq} @ x \).

success [bool] True when the algorithm succeeds in finding an optimal solution.

status [int] An integer representing the exit status of the algorithm.
0 : Optimization terminated successfully.
1 : Iteration limit reached.
2 : Problem appears to be infeasible.
3 : Problem appears to be unbounded.
4 : Numerical difficulties encountered.

nit [int] The total number of iterations performed in all phases.

See also:
For documentation for the rest of the parameters, see \texttt{scipy.optimize.linprog}

\textbf{Options}

maxiter [int (default: 5000)] The maximum number of iterations to perform in either phase.
disp [bool (default: False)] Set to True if indicators of optimization status are to be printed to the console each iteration.
presolve [bool (default: True)] Presolve attempts to identify trivial infeasibilities, identify trivial unboundedness, and simplify the problem before sending it to the main solver. It is generally recommended to keep the default setting True; set to False if presolve is to be disabled.
tol [float (default: 1e-12)] The tolerance which determines when a solution is “close enough” to zero in Phase 1 to be considered a basic feasible solution or close enough to positive to serve as an optimal solution.
autoscale [bool (default: False)] Set to True to automatically perform equilibration. Consider using this option if the numerical values in the constraints are separated by several orders of magnitude.
rr [bool (default: True)] Set to False to disable automatic redundancy removal.
bland [bool] If True, use Bland’s anti-cycling rule \cite{3} to choose pivots to prevent cycling. If False, choose pivots which should lead to a converged solution more quickly. The latter method is subject to cycling (non-convergence) in rare instances.

\textbf{unknown_options}
[dict] Optional arguments not used by this particular solver. If unknown_options is non-empty a warning is issued listing all unused options.

\textbf{References}

\cite{1}, \cite{2}, \cite{3}

\texttt{linprog(method=’interior-point’)}

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using the interior-point method of \cite{4}. 

1688 Chapter 6. API Reference
Linear programming solves problems of the following form:

\[
\begin{align*}
\min \quad & c^T x \\
\text{subject to} \quad & A_{ub} x \leq b_{ub}, \\
& A_{eq} x = b_{eq}, \\
& l \leq x \leq u,
\end{align*}
\]

where \(x\) is a vector of decision variables; \(c, b_{ub}, b_{eq}, l,\) and \(u\) are vectors; and \(A_{ub}\) and \(A_{eq}\) are matrices.

Alternatively, that’s:

minimize:

\[
c \odot x
\]

such that:

\[
A_{ub} \odot x \leq b_{ub} \\
A_{eq} \odot x = b_{eq} \\
lb \leq x \leq ub
\]

Note that by default \(lb = 0\) and \(ub = \text{None}\) unless specified with \texttt{bounds}.

### Parameters

- **c** [1-D array] The coefficients of the linear objective function to be minimized.
- **A_ub** [2-D array, optional] The inequality constraint matrix. Each row of \(A_{ub}\) specifies the coefficients of a linear inequality constraint on \(x\).
- **b_ub** [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of \(A_{ub} \odot x\).
- **A_eq** [2-D array, optional] The equality constraint matrix. Each row of \(A_{eq}\) specifies the coefficients of a linear equality constraint on \(x\).
- **b_eq** [1-D array, optional] The equality constraint vector. Each element of \(A_{eq} \odot x\) must equal the corresponding element of \(b_{eq}\).
- **bounds** [sequence, optional] A sequence of \((\min, \max)\) pairs for each element in \(x\), defining the minimum and maximum values of that decision variable. Use \texttt{None} to indicate that there is no bound. By default, bounds are \((0, \text{None})\) (all decision variables are non-negative). If a single tuple \((\min, \max)\) is provided, then \(\min\) and \(\max\) will serve as bounds for all decision variables.
- **method** [str] This is the method-specific documentation for ‘interior-point’.  ‘highs’, ‘highs-ds’, ‘highs-ipm’, ‘revised simplex’, and ‘simplex’ (legacy) are also available.
- **callback** [callable, optional] Callback function to be executed once per iteration.

### Returns

- **res** [scipy.optimize.OptimizeResult] A \texttt{scipy.optimize.OptimizeResult} consisting of the fields:
  - **x** [1-D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.
  - **fun** [float] The optimal value of the objective function \(c \odot x\).
  - **slack** [1-D array] The (nominally positive) values of the slack variables, \(b_{ub} - A_{ub} \odot x\).
  - **con** [1-D array] The (nominally zero) residuals of the equality constraints, \(b_{eq} - A_{eq} \odot x\).
  - **success** [bool] True when the algorithm succeeds in finding an optimal solution.
  - **status** [int] An integer representing the exit status of the algorithm.
    - 0: Optimization terminated successfully.
    - 1: Iteration limit reached.
2: Problem appears to be infeasible.
3: Problem appears to be unbounded.
4: Numerical difficulties encountered.

nit [int] The total number of iterations performed in all phases.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.linprog`

**Options**

maxiter [int (default: 1000)] The maximum number of iterations of the algorithm.
disp [bool (default: False)] Set to True if indicators of optimization status are to be printed to the console each iteration.
presolve [bool (default: True)] Presolve attempts to identify trivial infeasibilities, identify trivial unboundedness, and simplify the problem before sending it to the main solver. It is generally recommended to keep the default setting True; set to False if presolve is to be disabled.
tol [float (default: 1e-8)] Termination tolerance to be used for all termination criteria; see Section 4.5.
autoscale [bool (default: False)] Set to True to automatically perform equilibration. Consider using this option if the numerical values in the constraints are separated by several orders of magnitude.
rr [bool (default: True)] Set to False to disable automatic redundancy removal.
alpha0 [float (default: 0.99995)] The maximal step size for Mehrota’s predictor-corrector search direction; see $\beta_3$ of Table 8.1.
beta [float (default: 0.1)] The desired reduction of the path parameter $\mu$ (see [6]) when Mehrota’s predictor-corrector is not in use (uncommon).
sparse [bool (default: False)] Set to True if the problem is to be treated as sparse after presolve. If either $A_{eq}$ or $A_{ub}$ is a sparse matrix, this option will automatically be set True, and the problem will be treated as sparse even during presolve. If your constraint matrices contain mostly zeros and the problem is not very small (less than about 100 constraints or variables), consider setting True or providing $A_{eq}$ and $A_{ub}$ as sparse matrices.
lstsq [bool (default: False)] Set to True if the problem is expected to be very poorly conditioned. This should always be left False unless severe numerical difficulties are encountered. Leave this at the default unless you receive a warning message suggesting otherwise.
sym_pos [bool (default: True)] Leave True if the problem is expected to yield a well conditioned symmetric positive definite normal equation matrix (almost always). Leave this at the default unless you receive a warning message suggesting otherwise.
cholesky [bool (default: True)] Set to True if the normal equations are to be solved by explicit Cholesky decomposition followed by explicit forward/backward substitution. This is typically faster for problems that are numerically well-behaved.
pc [bool (default: True)] Leave True if the predictor-corrector method of Mehrota is to be used. This is almost always (if not always) beneficial.
ip [bool (default: False)] Set to True if the improved initial point suggestion due to Section 4.3 is desired. Whether this is beneficial or not depends on the problem.
permc_spec [str (default: ‘MMD_AT_PLUS_A’)] (Has effect only with sparse = True, lstsq = False, sym_pos = True, and no SuiteSparse.) A matrix is factorized in each iteration of the algorithm. This option specifies how to permute the columns of the matrix for sparsity preservation. Acceptable values are:
- NATURAL: natural ordering.
- MMD_ATA: minimum degree ordering on the structure of $A^{T}A$.
- MMD_AT_PLUS_A: minimum degree ordering on the structure of $A^{T}+A$.
- COLAMD: approximate minimum degree column ordering.
This option can impact the convergence of the interior point algorithm; test different values to determine which performs best for your problem. For more information, refer to scipy.sparse.linalg.splu.

**unknown_options**

[dict] Optional arguments not used by this particular solver. If `unknown_options` is non-empty a warning is issued listing all unused options.

**Notes**

This method implements the algorithm outlined in [4] with ideas from [8] and a structure inspired by the simpler methods of [6].

The primal-dual path following method begins with initial ‘guesses’ of the primal and dual variables of the standard form problem and iteratively attempts to solve the (nonlinear) Karush-Kuhn-Tucker conditions for the problem with a gradually reduced logarithmic barrier term added to the objective. This particular implementation uses a homogeneous self-dual formulation, which provides certificates of infeasibility or unboundedness where applicable.

The default initial point for the primal and dual variables is that defined in [4] Section 4.4 Equation 8.22. Optionally (by setting initial point option `ip=True`), an alternate (potentially improved) starting point can be calculated according to the additional recommendations of [4] Section 4.4.

A search direction is calculated using the predictor-corrector method (single correction) proposed by Mehrota and detailed in [4] Section 4.1. (A potential improvement would be to implement the method of multiple corrections described in [4] Section 4.2.) In practice, this is accomplished by solving the normal equations, [4] Section 5.1 Equations 8.31 and 8.32, derived from the Newton equations [4] Section 5 Equations 8.25 (compare to [4] Section 4 Equations 8.6-8.8). The advantage of solving the normal equations rather than 8.25 directly is that the matrices involved are symmetric positive definite, so Cholesky decomposition can be used rather than the more expensive LU factorization.

With default options, the solver used to perform the factorization depends on third-party software availability and the conditioning of the problem.

For dense problems, solvers are tried in the following order:

1. `scipy.linalg.cho_factor`
2. `scipy.linalg.solve with option sym_pos=True`
3. `scipy.linalg.solve with option sym_pos=False`
4. `scipy.linalg.lstsq`

For sparse problems:

1. `sksparse.cholmod.cholesky` (if scikit-sparse and SuiteSparse are installed)
2. `scipy.sparse.linalg.factorized` (if scikit-umfpack and SuiteSparse are installed)
3. `scipy.sparse.linalg.splu` (which uses SuperLU distributed with SciPy)
4. `scipy.sparse.linalg.lsqr`

If the solver fails for any reason, successively more robust (but slower) solvers are attempted in the order indicated. Attempting, failing, and re-starting factorization can be time consuming, so if the problem is numerically challenging, options can be set to bypass solvers that are failing. Setting `cholesky=False` skips to solver 2, `sym_pos=False` skips to solver 3, and `lstsq=True` skips to solver 4 for both sparse and dense problems.

Potential improvements for combatting issues associated with dense columns in otherwise sparse problems are outlined in [4] Section 5.3 and [10] Section 4.1-4.2; the latter also discusses the alleviation of accuracy issues associated with the substitution approach to free variables.
After calculating the search direction, the maximum possible step size that does not activate the non-negativity constraints is calculated, and the smaller of this step size and unity is applied (as in [4] Section 4.1.) [4] Section 4.3 suggests improvements for choosing the step size.

The new point is tested according to the termination conditions of [4] Section 4.5. The same tolerance, which can be set using the tol option, is used for all checks. (A potential improvement would be to expose the different tolerances to be set independently.) If optimality, unboundedness, or infeasibility is detected, the solve procedure terminates; otherwise it repeats.

Whereas the top level linprog module expects a problem of form:

Minimize:

\[ c \mathrel{\@} x \]

Subject to:

\[
\begin{align*}
A_{ub} \mathrel{\@} x & \leq b_{ub} \\
A_{eq} \mathrel{\@} x &= b_{eq} \\
lb & \leq x \leq ub 
\end{align*}
\]

where \( lb = 0 \) and \( ub = None \) unless set in bounds. The problem is automatically converted to the form:

Minimize:

\[ c \mathrel{\@} x \]

Subject to:

\[
\begin{align*}
A \mathrel{\@} x &= b \\
x & \geq 0 
\end{align*}
\]

for solution. That is, the original problem contains equality, upper-bound and variable constraints whereas the method specific solver requires equality constraints and variable non-negativity. linprog converts the original problem to standard form by converting the simple bounds to upper bound constraints, introducing non-negative slack variables for inequality constraints, and expressing unbounded variables as the difference between two non-negative variables. The problem is converted back to the original form before results are reported.

References

[4], [6], [8], [9], [10]

**linprog**(method='revised simplex')

`scipy.optimize.linprog(c, A_ub=None, b_ub=None, A_eq=None, b_eq=None, bounds=None, method='revised_simplex', callback=None, options={'maxiter': 5000, 'disp': False, 'presolve': True, 'tol': 1e-12, 'autoscale': False, 'rr': True, 'maxupdate': 10, 'mast': False, 'pivot': 'mrc'}, x0=None)

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using the revised simplex method.
Linear programming solves problems of the following form:

$$\min_{x} \quad c^T x$$

such that $A_{ub} x \leq b_{ub}$,

$$A_{eq} x = b_{eq},$$

$l \leq x \leq u,$

where $x$ is a vector of decision variables; $c$, $b_{ub}$, $b_{eq}$, $l$, and $u$ are vectors; and $A_{ub}$ and $A_{eq}$ are matrices.

Alternatively, that’s:

minimize:

$$c @ x$$

such that:

$$A_{ub} @ x \leq b_{ub}$$
$$A_{eq} @ x == b_{eq}$$
$$lb \leq x \leq ub$$

Note that by default $lb = 0$ and $ub = None$ unless specified with `bounds`.

**Parameters**

- **c** [1-D array] The coefficients of the linear objective function to be minimized.
- **A_ub** [2-D array, optional] The inequality constraint matrix. Each row of $A_{ub}$ specifies the coefficients of a linear inequality constraint on $x$.
- **b_ub** [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of $A_{ub} @ x$.
- **A_eq** [2-D array, optional] The equality constraint matrix. Each row of $A_{eq}$ specifies the coefficients of a linear equality constraint on $x$.
- **b_eq** [1-D array, optional] The equality constraint vector. Each element of $A_{eq} @ x$ must equal the corresponding element of $b_{eq}$.
- **bounds** [sequence, optional] A sequence of $(min, max)$ pairs for each element in $x$, defining the minimum and maximum values of that decision variable. Use None to indicate that there is no bound. By default, bounds are $(0, None)$ (all decision variables are non-negative). If a single tuple $(min, max)$ is provided, then $min$ and $max$ will serve as bounds for all decision variables.
- **method** [str] This is the method-specific documentation for ‘revised simplex’. ‘highs’, ‘highs-ds’, ‘highs-ipm’, ‘interior-point’ (default), and ‘simplex’ (legacy) are also available.
- **callback** [callable, optional] Callback function to be executed once per iteration.
- **x0** [1-D array, optional] Guess values of the decision variables, which will be refined by the optimization algorithm. This argument is currently used only by the ‘revised simplex’ method, and can only be used if $x0$ represents a basic feasible solution.

**Returns**

- **res** [OptimizeResult] A `scipy.optimize.OptimizeResult` consisting of the fields:
  - **x** [1-D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.
  - **fun** [float] The optimal value of the objective function $c @ x$.
  - **slack** [1-D array] The (nominally positive) values of the slack variables, $b_{ub} - A_{ub} @ x$.
  - **con** [1-D array] The (nominally zero) residuals of the equality constraints, $b_{eq} - A_{eq} @ x$.
  - **success** [bool] True when the algorithm succeeds in finding an optimal solution.

status [int] An integer representing the exit status of the algorithm.
        0: Optimization terminated successfully.
        1: Iteration limit reached.
        2: Problem appears to be infeasible.
        3: Problem appears to be unbounded.
        4: Numerical difficulties encountered.
        5: Problem has no constraints; turn presolve on.
        6: Invalid guess provided.

nit [int] The total number of iterations performed in all phases.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.linprog`

Options

maxiter [int (default: 5000)] The maximum number of iterations to perform in either phase.
disp [bool (default: False)] Set to True if indicators of optimization status are to be printed to
    the console each iteration.
presolve [bool (default: True)] Presolve attempts to identify trivial infeasibilities, identify trivial un-
    boundedness, and simplify the problem before sending it to the main solver. It is generally
    recommended to keep the default setting True; set to False if presolve is to be disabled.
tol [float (default: 1e-12)] The tolerance which determines when a solution is “close enough” to
    zero in Phase 1 to be considered a basic feasible solution or close enough to positive to serve
    as an optimal solution.
autoscale [bool (default: False)] Set to True to automatically perform equilibration. Consider
    using this option if the numerical values in the constraints are separated by several orders of
    magnitude.
rr [bool (default: True)] Set to False to disable automatic redundancy removal.
maxupdate [int (default: 10)] The maximum number of updates performed on the LU factorization.
    After this many updates are reached, the basis matrix is factorized from scratch.
mast [bool (default: False)] Minimize Amortized Solve Time. If enabled, the average time to
    solve a linear system using the basis factorization is measured. Typically, the average solve
    time will decrease with each successive solve after initial factorization, as factorization takes
    much more time than the solve operation (and updates). Eventually, however, the updated
    factorization becomes sufficiently complex that the average solve time begins to increase.
    When this is detected, the basis is refactorized from scratch. Enable this option to maximize
    speed at the risk of nondeterministic behavior. Ignored if maxupdate is 0.
pivot [“mrc” or “bland” (default: “mrc”)] Pivot rule: Minimum Reduced Cost (“mrc”) or Bland’s
    rule (“bland”). Choose Bland’s rule if iteration limit is reached and cycling is suspected.
unknown_options [dict] Optional arguments not used by this particular solver. If unknown_options is non-
    empty a warning is issued listing all unused options.
Notes

Method revised simplex uses the revised simplex method as described in [9], except that a factorization [11] of the basis matrix, rather than its inverse, is efficiently maintained and used to solve the linear systems at each iteration of the algorithm.

References

```
linprog(method='highs-ipm')
```

`scipy.optimize.linprog(c, A_ub=None, b_ub=None, A_eq=None, b_eq=None, bounds=None, method='highs-ipm', callback=None, options={}, x0=None)`

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using the HiGHS interior point solver.

Linear programming solves problems of the following form:

\[
\begin{align*}
\text{min} & \quad c^T x \\
\text{such that} & \quad A_{ub} x \leq b_{ub}, \\
& \quad A_{eq} x = b_{eq}, \\
& \quad l \leq x \leq u,
\end{align*}
\]

where \( x \) is a vector of decision variables; \( c, b_{ub}, b_{eq}, l, \) and \( u \) are vectors; and \( A_{ub} \) and \( A_{eq} \) are matrices.

Alternatively, that's:

```
minimize:
c @ x
```

such that:

```
A_ub @ x <= b_ub
A_eq @ x == b_eq
lb <= x <= ub
```

Note that by default \( \text{lb} = 0 \) and \( \text{ub} = \text{None} \) unless specified with \( \text{bounds} \).

**Parameters**

- **c** [1-D array] The coefficients of the linear objective function to be minimized.
- **A_ub** [2-D array, optional] The inequality constraint matrix. Each row of \( A_{ub} \) specifies the coefficients of a linear inequality constraint on \( x \).
- **b_ub** [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of \( A_{ub} \) @ \( x \).
- **A_eq** [2-D array, optional] The equality constraint matrix. Each row of \( A_{eq} \) specifies the coefficients of a linear equality constraint on \( x \).
- **b_eq** [1-D array, optional] The equality constraint vector. Each element of \( A_{eq} \) @ \( x \) must equal the corresponding element of \( b_{eq} \).
bounds  [sequence, optional] A sequence of (min, max) pairs for each element in x, defining the minimum and maximum values of that decision variable. Use None to indicate that there is no bound. By default, bounds are (0, None) (all decision variables are non-negative). If a single tuple (min, max) is provided, then min and max will serve as bounds for all decision variables.

method  [str] This is the method-specific documentation for ‘highs-ipm’. ‘highs-ipm’, ‘highs-ds’, ‘interior-point’ (default), ‘revised simplex’, and ‘simplex’ (legacy) are also available.

Returns  
res  [OptimizeResult] A scipy.optimize.OptimizeResult consisting of the fields:
x  [1D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.
fun  [float] The optimal value of the objective function c @ x.
slack  [1D array] The (nominally positive) values of the slack, b_ub - A_ub @ x.
con  [1D array] The (nominally zero) residuals of the equality constraints, b_eq - A_eq @ x.
success  [bool] True when the algorithm succeeds in finding an optimal solution.
status  [int] An integer representing the exit status of the algorithm.
0 : Optimization terminated successfully.
1 : Iteration or time limit reached.
2 : Problem appears to be infeasible.
3 : Problem appears to be unbounded.
4 : The HiGHS solver ran into a problem.
nit  [int] The total number of iterations performed. For the HiGHS interior-point method, this does not include crossover iterations.
crossover_nit  [int] The number of primal/dual pushes performed during the crossover routine for the HiGHS interior-point method.

See also:
For documentation for the rest of the parameters, see scipy.optimize.linprog

Options
maxiter  [int] The maximum number of iterations to perform in either phase. For ‘highs-ipm’, this does not include the number of crossover iterations. Default is the largest possible value for an int on the platform.
disp  [bool (default: False)] Set to True if indicators of optimization status are to be printed to the console during optimization.
presolve  [bool (default: True)] Presolve attempts to identify trivial infeasibilities, identify trivial unboundedness, and simplify the problem before sending it to the main solver. It is generally recommended to keep the default setting True; set to False if presolve is to be disabled.
time_limit  [float] The maximum time in seconds allotted to solve the problem; default is the largest possible value for a double on the platform.
dual_feasibility_tolerance  [double (default: 1e-07)] The minimum of this and primal_feasibility_tolerance is used for the feasibility tolerance of ‘highs-ipm’.
primal_feasibility_tolerance  [double (default: 1e-07)] The minimum of this and dual_feasibility_tolerance is used for the feasibility tolerance of ‘highs-ipm’.
ipm_optimality_tolerance  [double (default: 1e-08)] Optimality tolerance for ‘highs-ipm’. Minimum allowable value is 1e-12.
unknown_options
  {dict} Optional arguments not used by this particular solver. If unknown_options is non-empty, a warning is issued listing all unused options.

Notes

Method ‘highs-ipm’ is a wrapper of a C++ implementation of an interior-point method [13]; it features a crossover routine, so it is as accurate as a simplex solver. Method ‘highs-ds’ is a wrapper of the C++ high performance dual revised simplex implementation (HSOL) [13], [14]. Method ‘highs’ chooses between the two automatically. For new code involving linprog, we recommend explicitly choosing one of these three method values instead of ‘interior-point’ (default), ‘revised simplex’, and ‘simplex’ (legacy).

[13], [14]

linprog(method='highs-ds')

scipy.optimize.linprog(c, A_ub=None, b_ub=None, A_eq=None, b_eq=None, bounds=None, method='highs-ds', callback=None, options={'maxiter': None, 'disp': False, 'presolve': True, 'time_limit': None, 'dual_feasibility_tolerance': None, 'primal_feasibility_tolerance': None, 'simplex_dual_edge_weight_strategy': None}, x0=None)

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using the HiGHS dual simplex solver.

Linear programming solves problems of the following form:

\[
\begin{align*}
\min_{x} & \quad c^T x \\
\text{subject to} & \quad A_{ub} x \leq b_{ub} , \\
& \quad A_{eq} x = b_{eq} , \\
& \quad l \leq x \leq u ,
\end{align*}
\]

where \( x \) is a vector of decision variables; \( c, b_{ub}, b_{eq}, l, \) and \( u \) are vectors; and \( A_{ub} \) and \( A_{eq} \) are matrices.

Alternatively, that's:

minimize:

\[
\begin{align*}
& c \odot x \\
\text{subject to} & \quad A_{ub} \odot x \leq b_{ub} \\
& \quad A_{eq} \odot x = b_{eq} \\
& \quad l \leq x \leq ub
\end{align*}
\]

Note that by default \( lb = 0 \) and \( ub = None \) unless specified with bounds.

Parameters

| \( c \) | [1-D array] The coefficients of the linear objective function to be minimized. |
| \( A_{ub} \) | [2-D array, optional] The inequality constraint matrix. Each row of \( A_{ub} \) specifies the coefficients of a linear inequality constraint on \( x \). |
b_ub [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of \( A_{ub} @ x \).

A_eq [2-D array, optional] The equality constraint matrix. Each row of \( A_{eq} \) specifies the coefficients of a linear equality constraint on \( x \).

b_eq [1-D array, optional] The equality constraint vector. Each element of \( A_{eq} @ x \) must equal the corresponding element of \( b_{eq} \).

bounds [sequence, optional] A sequence of \((\min, \max)\) pairs for each element in \( x \), defining the minimum and maximum values of that decision variable. Use None to indicate that there is no bound. By default, bounds are \((0, \text{None})\) (all decision variables are non-negative). If a single tuple \((\min, \max)\) is provided, then \( \min \) and \( \max \) will serve as bounds for all decision variables.

method [str] This is the method-specific documentation for 'highs-ds'. 'highs', 'highs-ipm', 'interior-point' (default), 'revised simplex', and 'simplex' (legacy) are also available.

Returns [OptimizeResult] A scipy.optimize.OptimizeResult consisting of the fields:

x [1D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.

fun [float] The optimal value of the objective function \( c @ x \).

slack [1D array] The (nominally positive) values of the slack, \( b_{ub} - A_{ub} @ x \).

con [1D array] The (nominally zero) residuals of the equality constraints, \( b_{eq} - A_{eq} @ x \).

success [bool] True when the algorithm succeeds in finding an optimal solution.

status [int] An integer representing the exit status of the algorithm.

0 : Optimization terminated successfully.
1 : Iteration or time limit reached.
2 : Problem appears to be infeasible.
3 : Problem appears to be unbounded.
4 : The HiGHS solver ran into a problem.

nit [int] The total number of iterations performed. This includes iterations in all phases.

crossover_nit [int] This is always 0 for the HiGHS simplex method. For the HiGHS interior-point method, this is the number of primal/dual pushes performed during the crossover routine.

See also:

For documentation for the rest of the parameters, see scipy.optimize.linprog

Options

maxiter [int] The maximum number of iterations to perform in either phase. Default is the largest possible value for an int on the platform.

disp [bool (default: False)] Set to True if indicators of optimization status are to be printed to the console during optimization.

presolve [bool (default: True)] Presolve attempts to identify trivial infeasibilities, identify trivial unboundedness, and simplify the problem before sending it to the main solver. It is generally recommended to keep the default setting True; set to False if presolve is to be disabled.

time_limit [float] The maximum time in seconds allotted to solve the problem; default is the largest possible value for a double on the platform.

dual_feasibility_tolerance [double (default: 1e-07)] Dual feasibility tolerance for 'highs-ds'.

primal_feasibility_tolerance
[double (default: 1e-07)] Primal feasibility tolerance for 'highs-ds'.

simplex_dual_edge_weight_strategy
[str (default: None)] Strategy for simplex dual edge weights. The default, None, automatically selects one of the following.
'dantzig' uses Dantzig's original strategy of choosing the most negative reduced cost.
'devex' uses the strategy described in [15].
'steepest' uses the exact steepest edge strategy as described in [16].
'steepest-devex' begins with the exact steepest edge strategy until the computation is too costly or inexact and then switches to the devex method. Currently, None always selects 'steepest-devex', but this may change as new options become available.

unknown_options
[dict] Optional arguments not used by this particular solver. If unknown_options is non-empty, a warning is issued listing all unused options.

Notes

Method 'highs-ds' is a wrapper of the C++ high performance dual revised simplex implementation (HSOL) [13], [14]. Method 'highs-ipm' is a wrapper of a C++ implementation of an interior-point method [13]; it features a crossover routine, so it is as accurate as a simplex solver. Method 'highs' chooses between the two automatically. For new code involving linprog, we recommend explicitly choosing one of these three method values instead of 'interior-point' (default), 'revised simplex', and 'simplex' (legacy).

References

[13], [14], [15], [16]

linprog(method='highs')

scipy.optimize.linprog(c, A_ub=None, b_ub=None, A_eq=None, b_eq=None, bounds=None, method='highs', callback=None, options={'maxiter': None, 'disp': False, 'pre-solve': True, 'time_limit': None, 'dual_feasibility_tolerance': None, 'primal_feasibility_tolerance': None, 'ipm_optimality_tolerance': None, 'simplex_dual_edge_weight_strategy': None}, x0=None)

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using one of the HiGHS solvers.

Linear programming solves problems of the following form:

$$\min_{x} \mathbf{c}^T \mathbf{x}$$

such that $A_{ub} \mathbf{x} \leq b_{ub}$,

$A_{eq} \mathbf{x} = b_{eq}$,

$l \leq \mathbf{x} \leq u$,

where $\mathbf{x}$ is a vector of decision variables; $\mathbf{c}$, $b_{ub}$, $b_{eq}$, $l$, and $u$ are vectors; and $A_{ub}$ and $A_{eq}$ are matrices.

Alternatively, that’s:

```
minimize:

\sum_{i} c_i x_i
```
such that:

\[
\begin{align*}
A_{ub} \times & \leq b_{ub} \\
A_{eq} \times & = b_{eq} \\
lb & \leq x \leq ub
\end{align*}
\]

Note that by default \(lb = 0\) and \(ub = None\) unless specified with bounds.

**Parameters**

- **c** [1-D array] The coefficients of the linear objective function to be minimized.
- **A\_ub** [2-D array, optional] The inequality constraint matrix. Each row of \(A_{ub}\) specifies the coefficients of a linear inequality constraint on \(x\).
- **b\_ub** [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of \(A_{ub} \times \).
- **A\_eq** [2-D array, optional] The equality constraint matrix. Each row of \(A_{eq}\) specifies the coefficients of a linear equality constraint on \(x\).
- **b\_eq** [1-D array, optional] The equality constraint vector. Each element of \(A_{eq} \times \) must equal the corresponding element of \(b_{eq}\).
- **bounds** [sequence, optional] A sequence of \((min, max)\) pairs for each element in \(x\), defining the minimum and maximum values of that decision variable. Use None to indicate that there is no bound. By default, bounds are \((0, None)\) (all decision variables are non-negative). If a single tuple \((min, max)\) is provided, then \(min\) and \(max\) will serve as bounds for all decision variables.
- **method** [str] This is the method-specific documentation for 'highs', which chooses automatically between 'highs-ds' and 'highs-ipm'. 'interior-point' (default), 'revised simplex', and 'simplex' (legacy) are also available.

**Returns**

- **res** [OptimizeResult] A scipy.optimize.OptimizeResult consisting of the fields:
  - **x** [1D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.
  - **fun** [float] The optimal value of the objective function \(c \times \).
  - **slack** [1D array] The (nominally positive) values of the slack, \(b_{ub} - A_{ub} \times \).
  - **con** [1D array] The (nominally zero) residuals of the equality constraints, \(b_{eq} - A_{eq} \times \).
  - **success** [bool] True when the algorithm succeeds in finding an optimal solution.
  - **status** [int] An integer representing the exit status of the algorithm.
    - 0: Optimization terminated successfully.
    - 1: Iteration or time limit reached.
    - 2: Problem appears to be infeasible.
    - 3: Problem appears to be unbounded.
    - 4: The HiGHS solver ran into a problem.
  - **message** [str] A string descriptor of the exit status of the algorithm.
  - **nit** [int] The total number of iterations performed. For the HiGHS simplex method, this includes iterations in all phases. For the HiGHS interior-point method, this does not include crossover iterations.
  - **crossover\_nit** [int] The number of primal/dual pushes performed during the crossover routine for the HiGHS interior-point method. This is 0 for the HiGHS simplex method.

**See also:**

For documentation for the rest of the parameters, see scipy.optimize.linprog

**Options**
maxiter  [int]  The maximum number of iterations to perform in either phase. For 'highs-ipm', this does not include the number of crossover iterations. Default is the largest possible value for an int on the platform.

disp  [bool (default: False)] Set to True if indicators of optimization status are to be printed to the console during optimization.

presolve  [bool (default: True)] Presolve attempts to identify trivial infeasibilities, identify trivial unboundedness, and simplify the problem before sending it to the main solver. It is generally recommended to keep the default setting True; set to False if presolve is to be disabled.

time_limit  [float]  The maximum time in seconds allotted to solve the problem; default is the largest possible value for a double on the platform.

dual_feasibility_tolerance  [double (default: 1e-07)]  Dual feasibility tolerance for 'highs-ds'. The minimum of this and primal_feasibility_tolerance is used for the feasibility tolerance of 'highs-ipm'.

primal_feasibility_tolerance  [double (default: 1e-07)]  Primal feasibility tolerance for 'highs-ds'. The minimum of this and dual_feasibility_tolerance is used for the feasibility tolerance of 'highs-ipm'.

ipm_optimality_tolerance  [double (default: 1e-08)]  Optimality tolerance for 'highs-ipm'. Minimum allowable value is 1e-12.

simplex_dual_edge_weight_strategy  [str (default: None)]  Strategy for simplex dual edge weights. The default, None, automatically selects one of the following.
'dantzig' uses Dantzig's original strategy of choosing the most negative reduced cost.
'devex' uses the strategy described in [15].
'steepest' uses the exact steepest edge strategy as described in [16].
'steepest-devex' begins with the exact steepest edge strategy until the computation is too costly or inexact and then switches to the devex method. Currently, None always selects 'steepest-devex', but this may change as new options become available.

unknown_options  [dict]  Optional arguments not used by this particular solver. If unknown_options is non-empty, a warning is issued listing all unused options.

Notes

Method 'highs-ds' is a wrapper of the C++ high performance dual revised simplex implementation (HSOL) [13], [14]. Method 'highs-ipm' is a wrapper of a C++ implementation of an interior-point method [13]; it features a crossover routine, so it is as accurate as a simplex solver. Method 'highs' chooses between the two automatically.

For new code involving linprog, we recommend explicitly choosing one of these three method values instead of 'interior-point' (default), 'revised simplex', and 'simplex' (legacy).

References

[13], [14], [15], [16]

The simplex, interior-point, and revised simplex methods support callback functions, such as:

| linprog_verbose_callback(res) | A sample callback function demonstrating the linprog callback interface. |
scipy.optimize.linprog_verbose_callback

scipy.optimize.linprog_verbose_callback(res)

A sample callback function demonstrating the linprog callback interface. This callback produces detailed output to sys.stdout before each iteration and after the final iteration of the simplex algorithm.

**Parameters**

res  
[A scipy.optimize.OptimizeResult consisting of the following fields:]

x  
[1-D array] The independent variable vector which optimizes the linear programming problem.

fun  
[float] Value of the objective function.

success  
[bool] True if the algorithm succeeded in finding an optimal solution.

slack  
[1-D array] The values of the slack variables. Each slack variable corresponds to an inequality constraint. If the slack is zero, then the corresponding constraint is active.

con  
[1-D array] The (nominally zero) residuals of the equality constraints, that is, \( b - A_{eq} \times x \)

phase  
[int] The phase of the optimization being executed. In phase 1 a basic feasible solution is sought and the T has an additional row representing an alternate objective function.

status  
[int] An integer representing the exit status of the optimization:

<table>
<thead>
<tr>
<th>Status Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Optimization terminated successfully</td>
</tr>
<tr>
<td>1</td>
<td>Iteration limit reached</td>
</tr>
<tr>

<td>Problem appears to be infeasible</td>
</tr>
<tr>
<td>3</td>
<td>Problem appears to be unbounded</td>
</tr>
<tr>
<td>4</td>
<td>Serious numerical difficulties encountered</td>
</tr>
</tbody>
</table>

nit  
[int] The number of iterations performed.

message  
[str] A string descriptor of the exit status of the optimization.

6.19.8 Assignment problems

<table>
<thead>
<tr>
<th>linear_sum_assignment(cost_matrix[, maximize])</th>
<th>Solve the linear sum assignment problem.</th>

scipy.optimize.linear_sum_assignment

scipy.optimize.linear_sum_assignment(cost_matrix, maximize=False)

Solve the linear sum assignment problem.

The linear sum assignment problem is also known as minimum weight matching in bipartite graphs. A problem instance is described by a matrix \( C \), where each \( C[i,j] \) is the cost of matching vertex i of the first partite set (a “worker”) and vertex j of the second set (a “job”). The goal is to find a complete assignment of workers to jobs of minimal cost.

Formally, let \( X \) be a boolean matrix where \( X[i,j] = 1 \) iff row i is assigned to column j. Then the optimal assignment has cost

\[
\min \sum_i \sum_j C_{i,j} X_{i,j}
\]
where, in the case where the matrix X is square, each row is assigned to exactly one column, and each column to exactly one row.

This function can also solve a generalization of the classic assignment problem where the cost matrix is rectangular. If it has more rows than columns, then not every row needs to be assigned to a column, and vice versa.

The problem is also solved for sparse inputs in scipy.sparse.csgraph.

Parameters

- **cost_matrix**: [array] The cost matrix of the bipartite graph.
- **maximize**: [bool (default: False)] Calculates a maximum weight matching if true.

Returns

- **row_ind, col_ind**: [array] An array of row indices and one of corresponding column indices giving the optimal assignment. The cost of the assignment can be computed as cost_matrix[row_ind, col_ind].sum(). The row indices will be sorted; in the case of a square cost matrix they will be equal to numpy.arange(cost_matrix.shape[0]).

Notes

New in version 0.17.0.

References

Examples

```python
>>> cost = np.array([[4, 1, 3], [2, 0, 5], [3, 2, 2]])
>>> from scipy.optimize import linear_sum_assignment
>>> row_ind, col_ind = linear_sum_assignment(cost)
>>> col_ind
array([1, 0, 2])
>>> cost[row_ind, col_ind].sum()
5
```
scipy.optimize.quadratic_assignment

scipy.optimize.quadratic_assignment(A, B, method='faq', options=None)

Approximates solution to the quadratic assignment problem and the graph matching problem.

Quadratic assignment solves problems of the following form:

$$\min_P \text{trace}(A^T P B P^T)$$

subject to $P \in \mathcal{P}$

where $\mathcal{P}$ is the set of all permutation matrices, and $A$ and $B$ are square matrices.

Graph matching tries to maximize the same objective function. This algorithm can be thought of as finding the alignment of the nodes of two graphs that minimizes the number of induced edge disagreements, or, in the case of weighted graphs, the sum of squared edge weight differences.

Note that the quadratic assignment problem is NP-hard. The results given here are approximations and are not guaranteed to be optimal.

**Parameters**

- **A** [2-D array, square] The square matrix $A$ in the objective function above.
- **B** [2-D array, square] The square matrix $B$ in the objective function above.
- **method** [str in {‘faq’, ‘2opt’} (default: ‘faq’)] The algorithm used to solve the problem. ‘faq’ (default) and ‘2opt’ are available.
- **options** [dict, optional] A dictionary of solver options. All solvers support the following:
  - **maximize** [bool (default: False)] Maximizes the objective function if True.
  - **partial_match** [2-D array of integers, optional (default: None)] Fixes part of the matching. Also known as a “seed” [2].
    - Each row of `partial_match` specifies a pair of matched nodes: node `partial_match[i, 0]` of $A$ is matched to node `partial_match[i, 1]` of $B$. The array has shape $(m, 2)$, where $m$ is not greater than the number of nodes, $n$.
- **rng** [int, RandomState, Generator or None, optional (default: None)] Accepts an integer as a seed for the random generator or a RandomState or Generator object. If None (default), uses global numpy.random random state.

For method-specific options, see `show_options('quadratic_assignment')`.

**Returns**

- **res** [OptimizeResult] OptimizeResult containing the following fields.
  - **col_ind** [1-D array] Column indices corresponding to the best permutation found of the nodes of $B$.
  - **fun** [float] The objective value of the solution.
  - **nit** [int] The number of iterations performed during optimization.

**Notes**

The default method ‘faq’ uses the Fast Approximate QAP algorithm [1]; it typically offers the best combination of speed and accuracy. Method ‘2opt’ can be computationally expensive, but may be a useful alternative, or it can be used to refine the solution returned by another method.
References

[1], [2], [3]

Examples

```python
>>> import numpy as np
>>> from scipy.optimize import quadratic_assignment
>>> A = np.array([[0, 80, 150, 170], [80, 0, 130, 100],
                ... [150, 130, 0, 120], [170, 100, 120, 0]])
>>> B = np.array([[0, 5, 2, 7], [0, 0, 3, 8],
                ... [0, 0, 0, 3], [0, 0, 0, 0]])
>>> res = quadratic_assignment(A, B)
>>> print(res)
   col_ind: array([0, 3, 2, 1])
   fun: 3260
   nit: 9

The see the relationship between the returned col_ind and fun, use col_ind to form the best permutation matrix found, then evaluate the objective function $f(P) = \text{trace}(A^T P B P^T)$.

```python
>>> perm = res['col_ind']
>>> P = np.eye(len(A), dtype=int)[perm]
>>> fun = np.trace(A.T @ P @ B @ P.T)
>>> print(fun)
3260
```

Alternatively, to avoid constructing the permutation matrix explicitly, directly permute the rows and columns of the distance matrix.

```python
>>> fun = np.trace(A.T @ B[perm][:, perm])
>>> print(fun)
3260
```

Although not guaranteed in general, quadratic_assignment happens to have found the globally optimal solution.

```python
>>> from itertools import permutations
>>> perm_opt, fun_opt = None, np.inf
>>> for perm in permutations([0, 1, 2, 3]):
...    perm = np.array(perm)
...    fun = np.trace(A.T @ B[perm][:, perm])
...    if fun < fun_opt:
...        fun_opt, perm_opt = fun, perm
>>> print(np.array_equal(perm_opt, res['col_ind']))
True
```

Here is an example for which the default method, ‘faq’, does not find the global optimum.

```python
>>> A = np.array([[0, 5, 8, 6], [5, 0, 5, 1],
                ... [8, 5, 0, 2], [6, 1, 2, 0]])
>>> B = np.array([[0, 1, 8, 4], [1, 0, 5, 2],
                ... [8, 5, 0, 5], [4, 2, 5, 0]])
```

(continues on next page)
The `quadratic_assignment` function supports the following methods:

**quadratic_assignment(method='faq')**

scipy.optimize.quadratic_assignment (A, B, method='faq', options= {'maximize': False, 'partial_match': None, 'rng': None, 'P0': 'barycenter', 'shuffle_input': False, 'maxiter': 30, 'tol': 0.03})

Solve the quadratic assignment problem (approximately).

This function solves the Quadratic Assignment Problem (QAP) and the Graph Matching Problem (GMP) using the Fast Approximate QAP Algorithm (FAQ) [1].

Quadratic assignment solves problems of the following form:

\[
\min_{P} \text{trace}(A^T P B P^T)
\]

s.t. \( P \in \mathcal{P} \)

where \( \mathcal{P} \) is the set of all permutation matrices, and \( A \) and \( B \) are square matrices.

Graph matching tries to maximize the same objective function. This algorithm can be thought of as finding the alignment of the nodes of two graphs that minimizes the number of induced edge disagreements, or, in the case of weighted graphs, the sum of squared edge weight differences.

Note that the quadratic assignment problem is NP-hard. The results given here are approximations and are not guaranteed to be optimal.

**Parameters**

- **A** [2-D array, square] The square matrix \( A \) in the objective function above.
- **B** [2-D array, square] The square matrix \( B \) in the objective function above.
- **method** [str in {'faq', '2opt'} (default: 'faq')] The algorithm used to solve the problem. This is the method-specific documentation for ‘faq’. ‘2opt’ is also available.

**Returns**

- **res** [OptimizeResult] OptimizeResult containing the following fields.
  - col_ind [1-D array] Column indices corresponding to the best permutation found of the nodes of \( B \).
  - fun [float] The objective value of the solution.
  - nit [int] The number of Frank-Wolfe iterations performed.
See also:

For documentation for the rest of the parameters, see \texttt{scipy.optimize.quadratic_assignment}

\textbf{Options}

\texttt{maximize} \ [bool (default: False)] Maximizes the objective function if \texttt{True}.

\texttt{partial_match} \ [2-D array of integers, optional (default: None)] Fixes part of the matching. Also known as a “seed” [2].

Each row of \texttt{partial_match} specifies a pair of matched nodes: node \texttt{partial_match[i, 0]} of \texttt{A} is matched to node \texttt{partial_match[i, 1]} of \texttt{B}. The array has shape \((m, 2)\), where \(m\) is not greater than the number of nodes, \(n\).

\texttt{rng} \ [int, \texttt{RandomState}, \texttt{Generator} or None, optional (default: None)] Accepts an integer as a seed for the random generator or a \texttt{RandomState} or \texttt{Generator} object. If None (default), uses global \texttt{numpy.random} random state.

\texttt{P0} \ [2-D array, “barycenter”, or “randomized” (default: “barycenter”)] Initial position. Must be a doubly-stochastic matrix [3].

If the initial position is an array, it must be a doubly stochastic matrix of size \(m' \times m'\) where \(m' = n - m\).

If “barycenter” (default), the initial position is the barycenter of the Birkhoff polytope (the space of doubly stochastic matrices). This is a \(m' \times m'\) matrix with all entries equal to \(1/m'\).

If “randomized” the initial search position is \(P_0 = (J + K)/2\), where \(J\) is the barycenter and \(K\) is a random doubly stochastic matrix.

\texttt{shuffle_input} \ [bool (default: False)] Set to \texttt{True} to resolve degenerate gradients randomly. For non-degenerate gradients this option has no effect.

\texttt{maxiter} \ [int, positive (default: 30)] Integer specifying the max number of Frank-Wolfe iterations performed.

\texttt{tol} \ [float (default: 0.03)] Tolerance for termination. Frank-Wolfe iteration terminates when \(\frac{\|P_i - P_{i+1}\|_F}{\sqrt{m'}} \leq tol\), where \(i\) is the iteration number.

\textbf{Notes}

The algorithm may be sensitive to the initial permutation matrix (or search “position”) due to the possibility of several local minima within the feasible region. A barycenter initialization is more likely to result in a better solution than a single random initialization. However, calling \texttt{quadratic_assignment} several times with different random initializations may result in a better optimum at the cost of longer total execution time.

\textbf{References}

[1], [2], [3]
Examples

As mentioned above, a barycenter initialization often results in a better solution than a single random initialization.

```python
>>> np.random.seed(0)
>>> n = 15
>>> A = np.random.rand(n, n)
>>> B = np.random.rand(n, n)
>>> res = quadratic_assignment(A, B)  # FAQ is default method
>>> print(res.fun)
46.871483385480545

>>> options = {"P0": "randomized"}  # use randomized initialization
>>> res = quadratic_assignment(A, B, options=options)
>>> print(res.fun)
47.224831071310625  # may vary

However, consider running from several randomized initializations and keeping the best result.

```python
>>> res = min([quadratic_assignment(A, B, options=options)
...             for i in range(30)], key=lambda x: x.fun)
>>> print(res.fun)
46.671852533681516  # may vary
```

The ‘2-opt’ method can be used to further refine the results.

```python
>>> options = {"partial_guess": np.array([np.arange(n), res.col_ind]).T}
>>> res = quadratic_assignment(A, B, method="2opt", options=options)
>>> print(res.fun)
46.47160735721583  # may vary
```

### quadratic_assignment(method='2opt')

scipy.optimize.quadratic_assignment \((A, B, method='2opt', options=\{'maximize': False, 'rng': None, 'partial_match': None, 'partial_guess': None\})\)

Solve the quadratic assignment problem (approximately).

This function solves the Quadratic Assignment Problem (QAP) and the Graph Matching Problem (GMP) using the 2-opt algorithm [1].

Quadratic assignment solves problems of the following form:

\[
\min_P \text{trace}(A^T P BP^T) \\
\text{subject to } P \in \mathcal{P}
\]

where \(\mathcal{P}\) is the set of all permutation matrices, and \(A\) and \(B\) are square matrices.

Graph matching tries to maximize the same objective function. This algorithm can be thought of as finding the alignment of the nodes of two graphs that minimizes the number of induced edge disagreements, or, in the case of weighted graphs, the sum of squared edge weight differences.

Note that the quadratic assignment problem is NP-hard. The results given here are approximations and are not guaranteed to be optimal.

**Parameters**

B [2-D array, square] The square matrix $B$ in the objective function above.

method [str in {'faq', '2opt'} (default: 'faq')] The algorithm used to solve the problem. This is the method-specific documentation for '2opt'. 'faq' is also available.

Returns

res [OptimizeResult] OptimizeResult containing the following fields.

col_ind [1-D array] Column indices corresponding to the best permutation found of the nodes of $B$.

fun [float] The objective value of the solution.

nit [int] The number of iterations performed during optimization.

See also:

For documentation for the rest of the parameters, see scipy.optimize.quadratic_assignment

Options

maximize [bool (default: False)] Maximizes the objective function if True.

rng [int, RandomState, Generator or None, optional (default: None)] Accepts an integer as a seed for the random generator or a RandomState or Generator object. If None (default), uses global numpy.random random state.

partial_match [2-D array of integers, optional (default: None)] Fixes part of the matching. Also known as a “seed” [2].

Each row of partial_match specifies a pair of matched nodes: node partial_match[i, 0] of $A$ is matched to node partial_match[i, 1] of $B$. The array has shape (m, 2), where m is not greater than the number of nodes, n.

partial_guess [2-D array of integers, optional (default: None)] A guess for the matching between the two matrices. Unlike partial_match, partial_guess does not fix the indices; they are still free to be optimized.

Each row of partial_guess specifies a pair of matched nodes: node partial_guess[i, 0] of $A$ is matched to node partial_guess[i, 1] of $B$. The array has shape (m, 2), where m is not greater than the number of nodes, n.

Notes

This is a greedy algorithm that works similarly to bubble sort: beginning with an initial permutation, it iteratively swaps pairs of indices to improve the objective function until no such improvements are possible.

### 6.19.9 Utilities

#### Finite-difference approximation

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>approx_fprime(xk, f, epsilon, *args)</code></td>
<td>Finite-difference approximation of the gradient of a scalar function.</td>
</tr>
<tr>
<td><code>check_grad(func, grad, x0, *args, **kwargs)</code></td>
<td>Check the correctness of a gradient function by comparing it against a (forward) finite-difference approximation of the gradient.</td>
</tr>
</tbody>
</table>

The `approx_fprime` function is defined as:

\[
f'(i) = \frac{f(xk[i] + \text{epsilon}[i]) - f(xk[i])}{\text{epsilon}[i]}
\]

where `f` is the function of which to determine the gradient (partial derivatives), `xk` is the coordinate vector at which to determine the gradient of `f`, and `epsilon` is the increment to `xk` to use for determining the function gradient.

The main use of `approx_fprime` is in scalar function optimizers like `fmin_bfgs`, to determine numerically the Jacobian of a function.
Examples

```python
>>> from scipy import optimize
>>> def func(x, c0, c1):
...     "Coordinate vector `x` should be an array of size two."
...     return c0 * x[0]**2 + c1*x[1]**2

>>> x = np.ones(2)
>>> c0, c1 = (1, 200)
>>> eps = np.sqrt(np.finfo(float).eps)
>>> optimize.approx_fprime(x, func, [eps, np.sqrt(200) * eps], c0, c1)
array([ 2. , 400.00004198])
```

**scipy.optimize.check_grad**

`scipy.optimize.check_grad(func, grad, x0, *args, **kwargs)`

Check the correctness of a gradient function by comparing it against a (forward) finite-difference approximation of the gradient.

**Parameters**

- `func` [callable func(x0, *args)]: Function whose derivative is to be checked.
- `grad` [callable grad(x0, *args)]: Gradient of `func`.
- `x0` [ndarray]: Points to check `grad` against forward difference approximation of `grad` using `func`.
- `args` [*args, optional]: Extra arguments passed to `func` and `grad`.
- `epsilon` [float, optional]: Step size used for the finite difference approximation. It defaults to `sqrt(np.finfo(float).eps)`, which is approximately 1.49e-08.

**Returns**

- `err` [float]: The square root of the sum of squares (i.e., the 2-norm) of the difference between `grad(x0, *args)` and the finite difference approximation of `grad` using `func` at the points `x0`.

See also:

`approx_fprime`

**Examples**

```python
>>> def func(x):
...     return x[0]**2 - 0.5 * x[1]**3
>>> def grad(x):
...     return [2 * x[0], -1.5 * x[1]**2]
>>> from scipy.optimize import check_grad
>>> check_grad(func, grad, [1.5, -1.5])
2.9802322387695312e-08
```
### Line search

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bracket(func[, xa, xb, args, grow_limit, ...])</code></td>
<td>Bracket the minimum of the function.</td>
</tr>
<tr>
<td><code>line_search(f, myfprime, xk, pk[, gfk, ...])</code></td>
<td>Find alpha that satisfies strong Wolfe conditions.</td>
</tr>
</tbody>
</table>

#### scipy.optimize.bracket

- **Function**
  
  ```python
  scipy.optimize.bracket (func, xa=0.0, xb=1.0, args=(), grow_limit=110.0, maxiter=1000)
  ```

- **Description**
  
  Bracket the minimum of the function.

- **Parameters**
  
  - `func` ([callable `f(x,*args)`]) Objective function to minimize.
  - `xa, xb` ([float, optional]) Bracketing interval. Defaults `xa` to 0.0, and `xb` to 1.0.
  - `args` ([tuple, optional]) Additional arguments (if present), passed to `func`.
  - `grow_limit` ([float, optional]) Maximum grow limit. Defaults to 110.0
  - `maxiter` ([int, optional]) Maximum number of iterations to perform. Defaults to 1000.

- **Returns**
  
  - `xa, xb, xc` ([float]) Bracket.
  - `fa, fb, fc` ([float]) Objective function values in bracket.
  - `funcalls` ([int]) Number of function evaluations made.

#### Examples

This function can find a downward convex region of a function:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.optimize import bracket
>>> def f(x):
...     return 10*x**2 + 3*x + 5
>>> x = np.linspace(-2, 2)
>>> y = f(x)
>>> init_xa, init_xb = 0, 1
>>> xa, xb, xc, fa, fb, fc, funcalls = bracket(f, xa=init_xa, xb=init_xb)
>>> plt.axvline(x=init_xa, color="k", linestyle="--")
>>> plt.axvline(x=init_xb, color="k", linestyle="--")
>>> plt.plot(x, y, "-k")
>>> plt.plot(xa, fa, "bx")
>>> plt.plot(xb, fb, "rx")
>>> plt.plot(xc, fc, "bx")
>>> plt.show()
```
scipy.optimize.line_search

Find alpha that satisfies strong Wolfe conditions.

Parameters

- `f` [callable f(x,*args)] Objective function.
- `myfprime` [callable f’(x,*args)] Objective function gradient.
- `xk` [ndarray] Starting point.
- `pk` [ndarray] Search direction.
- `gfk` [ndarray, optional] Gradient value for x=xk (xk being the current parameter estimate). Will be recomputed if omitted.
- `old_fval` [float, optional] Function value for x=xk. Will be recomputed if omitted.
- `old_old_fval` [float, optional] Function value for the point preceding x=xk.
- `args` [tuple, optional] Additional arguments passed to objective function.
- `c1` [float, optional] Parameter for Armijo condition rule.
- `c2` [float, optional] Parameter for curvature condition rule.
- `amax` [float, optional] Maximum step size
- `extra_condition` [callable, optional] A callable of the form `extra_condition(alpha, x, f, g)` returning a boolean. Arguments are the proposed step alpha and the corresponding x, f and g values. The line search accepts the value of alpha only if this callable returns True. If the callable returns False for the step length, the algorithm will continue with new iterates. The callable is only called for iterates satisfying the strong Wolfe conditions.
- `maxiter` [int, optional] Maximum number of iterations to perform.

Returns

- `alpha` [float or None] Alpha for which \( x_{\text{new}} = x_0 + \alpha \cdot pk \), or None if the line search algorithm did not converge.
- `fc` [int] Number of function evaluations made.
- `gc` [int] Number of gradient evaluations made.
**new_fval** [float or None] New function value \( f(x_{\text{new}}) = f(x_0 + \alpha \cdot p_k) \), or None if the line search algorithm did not converge.

**old_fval** [float] Old function value \( f(x_0) \).

**new_slope** [float or None] The local slope along the search direction at the new value \( \langle myfprime(x_{\text{new}}), p_k \rangle \), or None if the line search algorithm did not converge.

**Notes**

**Examples**

```python
>>> from scipy.optimize import line_search
```

A objective function and its gradient are defined.

```python
>>> def obj_func(x):
...     return (x[0])**2 + (x[1])**2
>>> def obj_grad(x):
...     return [2*x[0], 2*x[1]]
```

We can find alpha that satisfies strong Wolfe conditions.

```python
>>> start_point = np.array([1.8, 1.7])
>>> search_gradient = np.array([-1.0, -1.0])
>>> line_search(obj_func, obj_grad, start_point, search_gradient)
(1.0, 2, 1, 1.1300000000000001, 6.13, [1.6, 1.4])
```

**Hessian approximation**

- **LbfgsInvHessProduct**(*args, **kwargs*) Linear operator for the L-BFGS approximate inverse Hessian.
- **HessianUpdateStrategy**() Interface for implementing Hessian update strategies.

**scipy.optimize.LbfgsInvHessProduct**

**class scipy.optimize.LbfgsInvHessProduct**(*args, **kwargs*)

Linear operator for the L-BFGS approximate inverse Hessian.

This operator computes the product of a vector with the approximate inverse of the Hessian of the objective function, using the L-BFGS limited memory approximation to the inverse Hessian, accumulated during the optimization.

Objects of this class implement the **scipy.sparse.linalg.LinearOperator** interface.

**Parameters**

- **sk** [array_like, shape=(n_corr, n)] Array of \( n_{corr} \) most recent updates to the solution vector. (See [1]).
- **yk** [array_like, shape=(n_corr, n)] Array of \( n_{corr} \) most recent updates to the gradient. (See [1]).
References

[1]

Attributes

H    Hermitian adjoint.
T    Transpose this linear operator.

Methods

__call__(self, x)  Call self as a function.
adjoint(self)    Hermitian adjoint.
dot(self, x)      Matrix-matrix or matrix-vector multiplication.
matmat(self, X)   Matrix-matrix multiplication.
matvec(self, x)   Matrix-vector multiplication.
rmatmat(self, X)  Adjoint matrix-matrix multiplication.
rmatvec(self, x)  Adjoint matrix-vector multiplication.
todense(self)     Return a dense array representation of this operator.
transpose(self)   Transpose this linear operator.

scipy.optimize.LbfgsInvHessProduct.__call__

LbfgsInvHessProduct.__call__(self, x)
Call self as a function.

scipy.optimize.LbfgsInvHessProduct.adjoint

LbfgsInvHessProduct.adjoint(self)
Hermitian adjoint.

Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.

Can be abbreviated self.H instead of self.adjoint().

Returns

scipy.optimize.LbfgsInvHessProduct.dot

LbfgsInvHessProduct.dot(self, x)
Matrix-matrix or matrix-vector multiplication.

Parameters

x  [array_like] 1-d or 2-d array, representing a vector or matrix.

Returns

Ax  [array] 1-d or 2-d array (depending on the shape of x) that represents the result of applying this linear operator on x.
scipy.optimize.LbfgsInvHessProduct.matmat

LbfgsInvHessProduct\matmat(self, X)

Matrix-matrix multiplication.

Performs the operation y=A*X where A is an MxN linear operator and X dense N*K matrix or ndarray.

Parameters

X \quad \{[\text{matrix, ndarray}] \} \text{An array with shape (N,K).}

Returns

Y \quad \{[\text{matrix, ndarray}] \} \text{A matrix or ndarray with shape (M,K) depending on the type of the X argument.}

Notes

This matmat wraps any user-specified matmat routine or overridden \_matmat method to ensure that y has the correct type.

scipy.optimize.LbfgsInvHessProduct.matvec

LbfgsInvHessProduct\matvec(self, x)

Matrix-vector multiplication.

Performs the operation y=A*x where A is an MxN linear operator and x is a column vector or 1-d array.

Parameters

x \quad \{[\text{matrix, ndarray}] \} \text{An array with shape (N,) or (N,1).}

Returns

y \quad \{[\text{matrix, ndarray}] \} \text{A matrix or ndarray with shape (M,) or (M,1) depending on the type and shape of the x argument.}

Notes

This matvec wraps the user-specified matvec routine or overridden \_matvec method to ensure that y has the correct shape and type.

scipy.optimize.LbfgsInvHessProduct.rmatmat

LbfgsInvHessProduct\rmatmat(self, X)

Adjoint matrix-matrix multiplication.

Performs the operation y = A^H * x where A is an MxN linear operator and x is a column vector or 1-d array, or 2-d array. The default implementation defers to the adjoint.

Parameters

X \quad \{[\text{matrix, ndarray}] \} \text{A matrix or 2D array.}

Returns

Y \quad \{[\text{matrix, ndarray}] \} \text{A matrix or 2D array depending on the type of the input.}
Notes

This rmatmat wraps the user-specified rmatmat routine.

**scipy.optimize.LbfgsInvHessProduct.rmatvec**

```
LbfgsInvHessProduct.rmatvec(self, x)
```

Adjoint matrix-vector multiplication.

Performs the operation \( y = A^H \times x \) where \( A \) is an \( M \times N \) linear operator and \( x \) is a column vector or 1-d array.

**Parameters**

- **x**
  - \([\text{matrix, ndarray}]\)
  - An array with shape \((M,)\) or \((M, 1)\).

**Returns**

- **y**
  - \([\text{matrix, ndarray}]\)
  - A matrix or ndarray with shape \((N,)\) or \((N, 1)\) depending on the type and shape of the \( x \) argument.

Notes

This rmatvec wraps the user-specified rmatvec routine or overridden _rmatvec method to ensure that \( y \) has the correct shape and type.

**scipy.optimize.LbfgsInvHessProduct.todense**

```
LbfgsInvHessProduct.todense(self)
```

Return a dense array representation of this operator.

**Returns**

- **arr**
  - \([\text{ndarray}, \text{shape}=(n, n)]\)
  - An array with the same shape and containing the same data represented by this *LinearOperator*.

**scipy.optimize.LbfgsInvHessProduct.transpose**

```
LbfgsInvHessProduct.transpose(self)
```

Transpose this linear operator.

Returns a *LinearOperator* that represents the transpose of this one. Can be abbreviated \( \text{self}.T \) instead of \( \text{self}.\text{transpose}() \).

```
__mul__
```
scipy.optimize.HessianUpdateStrategy

class scipy.optimize.HessianUpdateStrategy

Interface for implementing Hessian update strategies.

Many optimization methods make use of Hessian (or inverse Hessian) approximations, such as the quasi-Newton methods BFGS, SR1, L-BFGS. Some of these approximations, however, do not actually need to store the entire matrix or can compute the internal matrix product with a given vector in a very efficiently manner. This class serves as an abstract interface between the optimization algorithm and the quasi-Newton update strategies, giving freedom of implementation to store and update the internal matrix as efficiently as possible. Different choices of initialization and update procedure will result in different quasi-Newton strategies.

Four methods should be implemented in derived classes: initialize, update, dot and get_matrix.

Notes

Any instance of a class that implements this interface, can be accepted by the method minimize and used by the compatible solvers to approximate the Hessian (or inverse Hessian) used by the optimization algorithms.

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dot(self, p)</td>
<td>Compute the product of the internal matrix with the given vector.</td>
</tr>
<tr>
<td>get_matrix(self)</td>
<td>Return current internal matrix.</td>
</tr>
<tr>
<td>initialize(self, n, approx_type)</td>
<td>Initialize internal matrix.</td>
</tr>
<tr>
<td>update(self, delta_x, delta_grad)</td>
<td>Update internal matrix.</td>
</tr>
</tbody>
</table>

scipy.optimize.HessianUpdateStrategy.dot

HessianUpdateStrategy.dot (self, p)

Compute the product of the internal matrix with the given vector.

Parameters

- p: [array_like] 1-D array representing a vector.

Returns

- Hp: [array] 1-D represents the result of multiplying the approximation matrix by vector p.

scipy.optimize.HessianUpdateStrategy.get_matrix

HessianUpdateStrategy.get_matrix (self)

Return current internal matrix.

Returns

- H: [ndarray, shape (n, n)] Dense matrix containing either the Hessian or its inverse (depending on how ‘approx_type’ is defined).
scipy.optimize.HessianUpdateStrategy.initialize

HessianUpdateStrategy.initialize(self, n, approx_type)

Initialize internal matrix.
Allocate internal memory for storing and updating the Hessian or its inverse.

Parameters

n [int] Problem dimension.
approx_type [{'hess', 'inv_hess'}] Selects either the Hessian or the inverse Hessian. When set to 'hess' the Hessian will be stored and updated. When set to 'inv_hess' its inverse will be used instead.

scipy.optimize.HessianUpdateStrategy.update

HessianUpdateStrategy.update(self, delta_x, delta_grad)

Update internal matrix.
Update Hessian matrix or its inverse (depending on how 'approx_type' is defined) using information about the last evaluated points.

Parameters

delta_x [ndarray] The difference between two points the gradient function have been evaluated at: delta_x = x2 - x1.
delta_grad [ndarray] The difference between the gradients: delta_grad = grad(x2) - grad(x1).

Benchmark problems

<table>
<thead>

<tr>
<td>rosen_hess_prod(x, p)</td>
<td>Product of the Hessian matrix of the Rosenbrock function with a vector.</td>
</tr>
</tbody>
</table>

scipy.optimize.rosen

scipy.optimize.rosen(x)
The Rosenbrock function.
The function computed is:

\[
\text{sum}(100.0^*(x[1:] - x[-1]**2.0)**2.0 + (1 - x[-1])**2.0)
\]

Parameters

x [array_like] 1-D array of points at which the Rosenbrock function is to be computed.

Returns

f [float] The value of the Rosenbrock function.
See also:

rosen_der, rosen_hess, rosen_hess_prod

Examples

```python
>>> from scipy.optimize import rosen
>>> X = 0.1 * np.arange(10)
>>> rosen(X)
76.56
```

For higher-dimensional input rosen broadcasts. In the following example, we use this to plot a 2D landscape. Note that rosen_hess does not broadcast in this manner.

```python
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.mplot3d import Axes3D
>>> x = np.linspace(-1, 1, 50)
>>> X, Y = np.meshgrid(x, x)
>>> ax = plt.subplot(111, projection='3d')
>>> ax.plot_surface(X, Y, rosen([X, Y]))
>>> plt.show()
```

**scipy.optimize.rosen_der**

scipy.optimize.rosen_der(x)

The derivative (i.e. gradient) of the Rosenbrock function.

*Parameters*

- **x**
  
  [array_like] 1-D array of points at which the derivative is to be computed.

*Returns*

- **rosen_der**
  
  [(N,) ndarray] The gradient of the Rosenbrock function at x.

See also:
rosen, rosen_hess, rosen_hess_prod

Examples

```python
>>> from scipy.optimize import rosen_der
>>> X = 0.1 * np.arange(9)
>>> rosen_der(X)
array([-2., 10.6, 15.6, 13.4, 6.4, -3., -12.4, -19.4, 62.])
```

scipy.optimize.rosen_hess

scipy.optimize.**rosen_hess**(x)

The Hessian matrix of the Rosenbrock function.

**Parameters**

- **x**
  
  [array_like] 1-D array of points at which the Hessian matrix is to be computed.

**Returns**

- **rosen_hess**
  
  [ndarray] The Hessian matrix of the Rosenbrock function at x.

See also:

rosen, rosen_der, rosen_hess_prod

Examples

```python
>>> from scipy.optimize import rosen_hess
>>> X = 0.1 * np.arange(4)
>>> rosen_hess(X)
array([[-38.,  0.,  0.,  0.],
       [ 0., 134., -40.,  0.],
       [ 0., -40., 130., -80.],
       [ 0., 0., -80., 200.]])
```

scipy.optimize.rosen_hess_prod

scipy.optimize.**rosen_hess_prod**(x, p)

Product of the Hessian matrix of the Rosenbrock function with a vector.

**Parameters**

- **x**
  
  [array_like] 1-D array of points at which the Hessian matrix is to be computed.

- **p**
  
  [array_like] 1-D array, the vector to be multiplied by the Hessian matrix.

**Returns**

- **rosen_hess_prod**
  
  [ndarray] The Hessian matrix of the Rosenbrock function at x multiplied by the vector p.

See also:

rosen, rosen_der, rosen_hess
Examples

```python
>>> from scipy.optimize import rosen_hess_prod
>>> X = 0.1 * np.arange(9)
>>> p = 0.5 * np.arange(9)
>>> rosen_hess_prod(X, p)
array([-0.,  27., -10., -95., -192., -265., -278., -195., -180.])
```

### scipy.optimize.fmin

```python
scipy.optimize.fmin(func, x0, args=(), xtol=0.0001, ftol=0.0001, maxiter=None, maxfun=None, full_output=0, disp=1, retall=0, callback=None, initial_simplex=None)
```

Minimize a function using the downhill simplex algorithm.

This algorithm only uses function values, not derivatives or second derivatives.

**Parameters**

- `func` ([callable func(x,*args)]): The objective function to be minimized.
- `x0` ([ndarray]): Initial guess.
- `args` ([tuple, optional]): Extra arguments passed to func, i.e., `f(x,*args)`.  
- `xtol` ([float, optional]): Absolute error in xopt between iterations that is acceptable for convergence.
- `ftol` ([number, optional]): Absolute error in func(xopt) between iterations that is acceptable for convergence.
- `maxiter` ([int, optional]): Maximum number of iterations to perform.
- `maxfun` ([number, optional]): Maximum number of function evaluations to make.
- `full_output` ([bool, optional]): Set to True if fopt and warnflag outputs are desired.
- `disp` ([bool, optional]): Set to True to print convergence messages.
- `retall` ([bool, optional]): Set to True to return list of solutions at each iteration.
- `callback` ([callable, optional]): Called after each iteration, as callback(xk), where xk is the current parameter vector.
- `initial_simplex`
[array_like of shape (N + 1, N), optional] Initial simplex. If given, overrides $x_0$.
initial_simplex[j,:] should contain the coordinates of the jth vertex of the N+1
vertices in the simplex, where N is the dimension.

**Returns**

- xopt: [ndarray] Parameter that minimizes function.
- fopt: [float] Value of function at minimum: $f_{opt} = \text{func}(x_{opt})$.
- iter: [int] Number of iterations performed.
- funcalls: [int] Number of function calls made.
- warnflag: [int] 1: Maximum number of function evaluations made. 2: Maximum number of iterations reached.
- allvecs: [list] Solution at each iteration.

**See also:**

- **minimize**
  Interface to minimization algorithms for multivariate functions. See the ‘Nelder-Mead’ method in particular.

**Notes**

Uses a Nelder-Mead simplex algorithm to find the minimum of function of one or more variables.

This algorithm has a long history of successful use in applications. But it will usually be slower than an algorithm
that uses first or second derivative information. In practice, it can have poor performance in high-dimensional
problems and is not robust to minimizing complicated functions. Additionally, there currently is no complete
theory describing when the algorithm will successfully converge to the minimum, or how fast it will if it does. Both
the ftol and xtol criteria must be met for convergence.

**References**

[1], [2]

**Examples**

```python
>>> def f(x):
...     return x**2

>>> from scipy import optimize

>>> minimum = optimize.fmin(f, 1)
Optimization terminated successfully.
    Current function value: 0.000000
    Iterations: 17
    Function evaluations: 34
>>> minimum[0]
-8.8817841970012523e-16
```
scipy.optimize.fmin_powell

`scipy.optimize.fmin_powell(func, x0, args=(), xtol=0.0001, ftol=0.0001, maxiter=None, maxfun=None, full_output=0, disp=1, retall=0, callback=None, direc=None)`

Minimize a function using modified Powell’s method.

This method only uses function values, not derivatives.

**Parameters**

- **func** [callable f(x,*args)] Objective function to be minimized.
- **x0** [ndarray] Initial guess.
- **args** [tuple, optional] Extra arguments passed to func.
- **xtol** [float, optional] Line-search error tolerance.
- **ftol** [float, optional] Relative error in \( \text{func}(x_{opt}) \) acceptable for convergence.
- **maxiter** [int, optional] Maximum number of iterations to perform.
- **maxfun** [int, optional] Maximum number of function evaluations to make.
- **full_output** [bool, optional] If True, \( f_{opt}, x_i, \text{direc}, \text{iter}, \text{funcalls} \), and \text{warnflag} are returned.
- **disp** [bool, optional] If True, print convergence messages.
- **retall** [bool, optional] If True, return a list of the solution at each iteration.
- **callback** [callable, optional] An optional user-supplied function, called after each iteration. Called as \( \text{callback}(x_k) \), where \( x_k \) is the current parameter vector.
- **direc** [ndarray, optional] Initial fitting step and parameter order set as an \((N, N)\) array, where \( N \) is the number of fitting parameters in \( x_0 \). Defaults to step size 1.0 fitting all parameters simultaneously \((\text{np.ones}\((N, N)\))\). To prevent initial consideration of values in a step or to change initial step size, set to 0 or desired step size in the \( J \)th position in the \( M \)th block, where \( J \) is the position in \( x_0 \) and \( M \) is the desired evaluation step, with steps being evaluated in index order. Step size and ordering will change freely as minimization proceeds.

**Returns**

- **xopt** [ndarray] Parameter which minimizes \( \text{func} \).
- **fopt** [number] Value of function at minimum: \( f_{opt} = \text{func}(x_{opt}) \).
- **direc** [ndarray] Current direction set.
- **iter** [int] Number of iterations.
- **funcalls** [int] Number of function calls made.
- **warnflag** [int] **Integer warning flag:**
  - 1 : Maximum number of function evaluations.
  - 2 : Maximum number of iterations.
  - 3 : NaN result encountered.
  - 4 : The result is out of the provided bounds.
- **allvecs** [list] List of solutions at each iteration.

**See also:**

- **minimize**

Interface to unconstrained minimization algorithms for multivariate functions. See the ‘Powell’ method in particular.
Notes

Uses a modification of Powell’s method to find the minimum of a function of N variables. Powell’s method is a conjugate direction method.

The algorithm has two loops. The outer loop merely iterates over the inner loop. The inner loop minimizes over each current direction in the direction set. At the end of the inner loop, if certain conditions are met, the direction that gave the largest decrease is dropped and replaced with the difference between the current estimated x and the estimated x from the beginning of the inner-loop.

The technical conditions for replacing the direction of greatest increase amount to checking that

1. No further gain can be made along the direction of greatest increase from that iteration.
2. The direction of greatest increase accounted for a large sufficient fraction of the decrease in the function value from that iteration of the inner loop.

Examples

```python
>>> def f(x):
...   return x**2

>>> from scipy import optimize

>>> minimum = optimize.fmin_powell(f, -1)
Optimization terminated successfully.
Current function value: 0.000000
Iterations: 2
Function evaluations: 18

>>> minimum
array(0.0)
```

scipy.optimize.fmin_cg

scipy.optimize.fmin_cg(f, x0, fprime=None, args=(), gtol=1e-05, norm=inf, epsilon=1.4901161193847656e-08, maxiter=None, full_output=0, disp=1, retall=0, callback=None)

Minimize a function using a nonlinear conjugate gradient algorithm.

Parameters

- `f` ([callable, f(x, *args)]) Objective function to be minimized. Here x must be a 1-D array of the variables that are to be changed in the search for a minimum, and `args` are the other (fixed) parameters of `f`.
- `x0` ([ndarray]) A user-supplied initial estimate of `xopt`, the optimal value of `x`. It must be a 1-D array of values.
### fprime

[callable, fprime(x, *args), optional] A function that returns the gradient of f at x. Here x and args are as described above for f. The returned value must be a 1-D array. Defaults to None, in which case the gradient is approximated numerically (see epsilon, below).

### args

[tuple, optional] Parameter values passed to f and fprime. Must be supplied whenever additional fixed parameters are needed to completely specify the functions f and fprime.

### gtol

[float, optional] Stop when the norm of the gradient is less than gtol.

### norm

[float, optional] Order to use for the norm of the gradient (-np.inf is min, np.inf is max).

### epsilon

[float or ndarray, optional] Step size(s) to use when fprime is approximated numerically. Can be a scalar or a 1-D array. Defaults to sqrt(eps), with eps the floating point machine precision. Usually sqrt(eps) is about 1.5e-8.

### maxiter

[int, optional] Maximum number of iterations to perform. Default is 200 * len(x0).

### full_output

[bool, optional] If True, return fopt, func_calls, grad_calls, and warnflag in addition to xopt. See the Returns section below for additional information on optional return values.

### disp

[bool, optional] If True, return a convergence message, followed by xopt.

### retall

[bool, optional] If True, add to the returned values the results of each iteration.

### callback

[callable, optional] An optional user-supplied function, called after each iteration. Called as callback(xk), where xk is the current value of x0.

### Returns

- **xopt** [ndarray] Parameters which minimize f, i.e., f(xopt) == fopt.
- **fopt** [float, optional] Minimum value found, f(xopt). Only returned if full_output is True.
- **func_calls** [int, optional] The number of function calls made. Only returned if full_output is True.
- **grad_calls** [int, optional] The number of gradient calls made. Only returned if full_output is True.
- **warnflag** [int, optional] Integer value with warning status, only returned if full_output is True.
  0 : Success.
  1 : The maximum number of iterations was exceeded.
  2 : [Gradient and/or function calls were not changing. May indicate] that precision was lost, i.e., the routine did not converge.
  3 : NaN result encountered.
- **allvecs** [list of ndarray, optional] List of arrays, containing the results at each iteration. Only returned if retall is True.

### See also:

- **minimize**

  common interface to all scipy.optimize algorithms for unconstrained and constrained minimization of multivariate functions. It provides an alternative way to call fmin_cg, by specifying method='CG'.

### Notes

This conjugate gradient algorithm is based on that of Polak and Ribiere [1]. Conjugate gradient methods tend to work better when:

1. f has a unique global minimizing point, and no local minima or other stationary points,
2. f is, at least locally, reasonably well approximated by a quadratic function of the variables,
3. f is continuous and has a continuous gradient,
4. fprime is not too large, e.g., has a norm less than 1000,
5. The initial guess, x0, is reasonably close to f’s global minimizing point, xopt.
References

[1]

Examples

Example 1: seek the minimum value of the expression \( a\cdot u^2 + b\cdot u\cdot v + c\cdot v^2 + d\cdot u + e\cdot v + f \) for given values of the parameters and an initial guess \((u, v) = (0, 0)\).

```python
>>> args = (2, 3, 7, 8, 9, 10)  # parameter values
>>> def f(x, *args):
...     u, v = x
...     a, b, c, d, e, f = args
...     return a*u**2 + b*u*v + c*v**2 + d*u + e*v + f

>>> def gradf(x, *args):
...     u, v = x
...     a, b, c, d, e, f = args
...     gu = 2*a*u + b*v + d  # u-component of the gradient
...     gv = b*u + 2*c*v + e  # v-component of the gradient
...     return np.asarray((gu, gv))

>>> x0 = np.asarray((0, 0))  # Initial guess.
>>> from scipy import optimize

>>> res1 = optimize.fmin_cg(f, x0, fprime=gradf, args=args)
Optimization terminated successfully.
Current function value: 1.617021
Iterations: 4
Function evaluations: 8
Gradient evaluations: 8
>>> res1
array([-1.80851064, -0.25531915])
```

Example 2: solve the same problem using the `minimize` function. (This `myopts` dictionary shows all of the available options, although in practice only non-default values would be needed. The returned value will be a dictionary.)

```python
>>> opts = {'maxiter': None,  # default value.
...         'disp': True,  # non-default value.
...         'gtol': 1e-5,  # default value.
...         'norm': np.inf,  # default value.
...         'eps': 1.4901161193847656e-08}  # default value.
>>> res2 = optimize.minimize(f, x0, jac=gradf, args=args,
...                           method='CG', options=opts)
Optimization terminated successfully.
Current function value: 1.617021
Iterations: 4
Function evaluations: 8
Gradient evaluations: 8
>>> res2.x  # minimum found
array([-1.80851064, -0.25531915])
```
**scipy.optimize.fmin_bfgs**

Minimize a function using the BFGS algorithm.

Parameters

- **f** [callable f(x,*args)] Objective function to be minimized.
- **x0** [ndarray] Initial guess.
- **fprime** [callable f'(x,*args), optional] Gradient of f.
- **args** [tuple, optional] Extra arguments passed to f and fprime.
- **gtol** [float, optional] Gradient norm must be less than gtol before successful termination.
- **norm** [float, optional] Order of norm (Inf is max, -Inf is min)
- **epsilon** [int or ndarray, optional] If fprime is approximated, use this value for the step size.
- **callback** [callable, optional] An optional user-supplied function to call after each iteration. Called as callback(xk), where xk is the current parameter vector.
- **maxiter** [int, optional] Maximum number of iterations to perform.
- **full_output** [bool, optional] If True, return fopt, func_calls, grad_calls, and warnflag in addition to xopt.
- **disp** [bool, optional] Print convergence message if True.
- **retall** [bool, optional] Return a list of results at each iteration if True.

Returns

- **xopt** [ndarray] Parameters which minimize f, i.e., f(xopt) == fopt.
- **fopt** [float] Minimum value.
- **gopt** [ndarray] Value of gradient at minimum, f'(xopt), which should be near 0.
- **Bopt** [ndarray] Value of 1/f''(xopt), i.e., the inverse Hessian matrix.
- **func_calls** [int] Number of function calls made.
- **grad_calls** [int] Number of gradient calls made.
- **warnflag** [integer] 1 : Maximum number of iterations exceeded. 2 : Gradient and/or function calls not changing. 3 : NaN result encountered.
- **allvecs** [list] The value of xopt at each iteration. Only returned if retall is True.

See also:

- **minimize**

  Interface to minimization algorithms for multivariate functions. See the ‘BFGS’ method in particular.

Notes

Optimize the function, f, whose gradient is given by fprime using the quasi-Newton method of Broyden, Fletcher, Goldfarb, and Shanno (BFGS)
References

scipy.optimize.fmin_ncg

Unconstrained minimization of a function using the Newton-CG method.

Parameters

- **f** [callable f(x, *args)] Objective function to be minimized.
- **x0** [ndarray] Initial guess.
- **fprime** [callable f'(x, *args)] Gradient of f.
- **fhess_p** [callable fhess_p(x, p, *args), optional] Function which computes the Hessian of f times an arbitrary vector, p.
- **fhess** [callable fhess(x, *args), optional] Function to compute the Hessian matrix of f.
- **args** [tuple, optional] Extra arguments passed to f, fprime, fhess_p, and fhess (the same set of extra arguments is supplied to all of these functions).
- **epsilon** [float or ndarray, optional] If fhess is approximated, use this value for the step size.
- **callback** [callable, optional] An optional user-supplied function which is called after each iteration. Called as callback(xk), where xk is the current parameter vector.
- **avextol** [float, optional] Convergence is assumed when the average relative error in the minimizer falls below this amount.
- **maxiter** [int, optional] Maximum number of iterations to perform.
- **full_output** [bool, optional] If True, return the optional outputs.
- **disp** [bool, optional] If True, print convergence message.
- **retall** [bool, optional] If True, return a list of results at each iteration.

Returns

- **xopt** [ndarray] Parameters which minimize f, i.e., f(xopt) == fopt.
- **fopt** [float] Value of the function at xopt, i.e., fopt = f(xopt).
- **fcalls** [int] Number of function calls made.
- **gcalls** [int] Number of gradient calls made.
- **hcalls** [int] Number of Hessian calls made.
- **allvecs** [list] The result at each iteration, if retall is True (see below).

See also:

minimize

Interface to minimization algorithms for multivariate functions. See the ‘Newton-CG’ method in particular.
Notes

Only one of \( fhess_p \) or \( fhess \) need to be given. If \( fhess \) is provided, then \( fhess_p \) will be ignored. If neither \( fhess \) nor \( fhess_p \) is provided, then the hessian product will be approximated using finite differences on \( fprime \). \( fhess_p \) must compute the hessian times an arbitrary vector. If it is not given, finite-differences on \( fprime \) are used to compute it.

Newton-CG methods are also called truncated Newton methods. This function differs from scipy.optimize.min_tnc because

1. \texttt{scipy.optimize.fmin_ncg} is written purely in Python using NumPy

   and scipy while scipy.optimize.min_tnc calls a C function.

2. \texttt{scipy.optimize.fmin_ncg} is only for unconstrained minimization

   while scipy.optimize.min_tnc is for unconstrained minimization or box constrained minimization. (Box constraints give lower and upper bounds for each variable separately.)

\texttt{scipy.optimize.fmin_l_bfgs_b}

\texttt{scipy.optimize.fmin_l_bfgs_b(func, x0, fprime=None, args=(), approx_grad=0, bounds=None, m=10, factr=10000000.0, pgtol=1e-05, epsilon=1e-08, iprint=-1, maxfun=15000, maxiter=15000, disp=None, callback=None, maxls=20)}

Minimize a function func using the L-BFGS-B algorithm.

Parameters

- \texttt{func} \[callable f(x,*args)\] Function to minimize.
- \texttt{x0} \[ndarray\] Initial guess.
- \texttt{fprime} \[callable fprime(x,*args), optional\] The gradient of \texttt{func}. If None, then \texttt{func} returns the function value and the gradient (\( f, g = \text{func}(x, *\text{args}) \)), unless \texttt{approx_grad} is True in which case \texttt{func} returns only \( f \).
- \texttt{args} \[sequence, optional\] Arguments to pass to \texttt{func} and \texttt{fprime}.
- \texttt{approx_grad} \[bool, optional\] Whether to approximate the gradient numerically (in which case \texttt{func} returns only the function value).
- \texttt{bounds} \[list, optional\] (\( \text{min, max} \)) pairs for each element in \( x \), defining the bounds on that parameter. Use None or +/-inf for one of \texttt{min} or \texttt{max} when there is no bound in that direction.
- \texttt{m} \[int, optional\] The maximum number of variable metric corrections used to define the limited memory matrix. (The limited memory BFGS method does not store the full hessian but uses this many terms in an approximation to it.)
factr [float, optional] The iteration stops when \( (f^k - f^{(k+1)}) / \max\{|f^k|, |f^{(k+1)}|, 1\} \leq \text{factr} \times \text{eps} \), where eps is the machine precision, which is automatically generated by the code. Typical values for factr are: 1e12 for low accuracy; 1e7 for moderate accuracy; 10.0 for extremely high accuracy. See Notes for relationship to ftol, which is exposed (instead of factr) by the scipy.optimize.minimize interface to L-BFGS-B.

pgtol [float, optional] The iteration will stop when \( \max(|\text{proj } g_i |, i = 1, \ldots, n) \leq \text{pgtol} \) where pg_i is the i-th component of the projected gradient.

epsilon [float, optional] Step size used when approx_grad is True, for numerically calculating the gradient.

iprint [int, optional] Controls the frequency of output. iprint < 0 means no output; iprint = 0 print only one line at the last iteration; 0 < iprint < 99 print also f and |proj g| every iprint iterations; iprint = 99 print details of every iteration except n-vectors; iprint = 100 print also the changes of active set and final x; iprint > 100 print details of every iteration including x and g.

disp [int, optional] If zero, then no output. If a positive number, then this over-rides iprint (i.e., iprint gets the value of disp).

maxfun [int, optional] Maximum number of function evaluations.

maxiter [int, optional] Maximum number of iterations.

callback [callable, optional] Called after each iteration, as callback(xk), where xk is the current parameter vector.

maxls [int, optional] Maximum number of line search steps (per iteration). Default is 20.

Returns

x [array_like] Estimated position of the minimum.

f [float] Value of func at the minimum.

d [dict] Information dictionary.

• d['warnflag'] is
  – 0 if converged,
  – 1 if too many function evaluations or too many iterations,
  – 2 if stopped for another reason, given in d['task']

• d['grad'] is the gradient at the minimum (should be 0 ish)

• d['funcalls'] is the number of function calls made.

• d['nit'] is the number of iterations.

scipy.optimize.fmin_tnc

def scipy.optimize.fmin_tnc(func, x0, fprime=None, args=(), approx_grad=0, bounds=None, epsilon=1e-8, scale=None, offset=None, messages=15, maxCGit=-1, maxfun=None, eta=-1, stepmx=0, accuracy=0, fmin=0, ftol=-1, xtol=-1, pgtol=-1, rescale=-1, disp=None, callback=None)

Minimize a function with variables subject to bounds, using gradient information in a truncated Newton algorithm. This method wraps a C implementation of the algorithm.

Parameters

- func [callable func(x, *args)] Function to minimize. Must do one of:
  1. Return f and g, where f is the value of the function and g its gradient (a list of floats).
  2. Return the function value but supply gradient function separately as fprime.
  3. Return the function value and set approx_grad=True. If the function returns None, the minimization is aborted.

- x0 [array_like] Initial estimate of minimum.

- fprime [callable fprime(x, *args), optional] Gradient of func. If None, then either func must return the function value and the gradient (f, g = func(x, *args)) or approx_grad must be True.

- args [tuple, optional] Arguments to pass to function.

- approx_grad [bool, optional] If true, approximate the gradient numerically.

- bounds [list, optional] (min, max) pairs for each element in x0, defining the bounds on that parameter. Use None or +/-inf for one of min or max when there is no bound in that direction.

- epsilon [float, optional] Used if approx_grad is True. The stepsize in a finite difference approximation for fprime.

- scale [array_like, optional] Scaling factors to apply to each variable. If None, the factors are upper for interval bounded variables and 1+|x| for the others. Defaults to None.

- offset [array_like, optional] Value to subtract from each variable. If None, the offsets are (up+low)/2 for interval bounded variables and x for the others.

- messages [int, optional] Bit mask used to select messages display during minimization values defined in the MSGS dict. Defaults to MSGS_ALL.

- disp [int, optional] Integer interface to messages. 0 = no message, 5 = all messages

- maxCGit [int, optional] Maximum number of hessian*vector evaluations per main iteration. If maxCGit == 0, the direction chosen is -gradient if maxCGit < 0, maxCGit is set to max(1,min(50,n/2)). Defaults to -1.

- maxfun [int, optional] Maximum number of function evaluation. If None, maxfun is set to max(100, 10*len(x0)). Defaults to None.

- eta [float, optional] Severity of the line search. If < 0 or > 1, set to 0.25. Defaults to -1.

- stepmx [float, optional] Maximum step for the line search. May be increased during call. If too small, it will be set to 10.0. Defaults to 0.

- accuracy [float, optional] Relative precision for finite difference calculations. If <= machine_precision, set to sqrt(machine_precision). Defaults to 0.

fmin  [float, optional] Minimum function value estimate. Defaults to 0.
ftol  [float, optional] Precision goal for the value of f in the stopping criterion. If ftol < 0.0, ftol is set to 0.0 defaults to -1.
xtol  [float, optional] Precision goal for the value of x in the stopping criterion (after applying x scaling factors). If xtol < 0.0, xtol is set to sqrt(machine_precision). Defaults to -1.
pgtol  [float, optional] Precision goal for the value of the projected gradient in the stopping criterion (after applying x scaling factors). If pgtol < 0.0, pgtol is set to 1e-2 * sqrt(accuracy). Setting it to 0.0 is not recommended. Defaults to -1.
rescale  [float, optional] Scaling factor (in log10) used to trigger f value rescaling. If 0, rescale at each iteration. If a large value, never rescale. If < 0, rescale is set to 1.3.
callback  [callable, optional] Called after each iteration, as callback(xk), where xk is the current parameter vector.

Returns

x  [ndarray] The solution.
nfeval  [int] The number of function evaluations.
rc  [int] Return code, see below

See also:

minimize

Interface to minimization algorithms for multivariate functions. See the ‘TNC’ method in particular.

Notes

The underlying algorithm is truncated Newton, also called Newton Conjugate-Gradient. This method differs from scipy.optimize.fmin_ncg in that

1. it wraps a C implementation of the algorithm
2. it allows each variable to be given an upper and lower bound.

The algorithm incorporates the bound constraints by determining the descent direction as in an unconstrained truncated Newton, but never taking a step-size large enough to leave the space of feasible x's. The algorithm keeps track of a set of currently active constraints, and ignores them when computing the minimum allowable step size. (The x's associated with the active constraint are kept fixed.) If the maximum allowable step size is zero then a new constraint is added. At the end of each iteration one of the constraints may be deemed no longer active and removed. A constraint is considered no longer active if it is currently active but the gradient for that variable points inward from the constraint. The specific constraint removed is the one associated with the variable of largest index whose constraint is no longer active.

Return codes are defined as follows:

-1 : Infeasible (lower bound > upper bound)
 0 : Local minimum reached (|pg| ~ 0)
 1 : Converged (|f_n-f_(n-1)| ~ 0)
 2 : Converged (|x_n-x_(n-1)| ~ 0)
 3 : Max. number of function evaluations reached
 4 : Linear search failed
 5 : All lower bounds are equal to the upper bounds
 6 : Unable to progress
 7 : User requested end of minimization

6.19. Optimization and root finding (scipy.optimize) 1733
References

Wright S., Nocedal J. (2006), ‘Numerical Optimization’

scipy.optimize.fmin_cobyla

scipy.optimize.fmin_cobyla(func, x0, cons, args=(), consargs=None, rhobeg=1.0, rhoend=0.0001, maxfun=1000, disp=None, catol=0.0002)

Minimize a function using the Constrained Optimization By Linear Approximation (COBYLA) method. This method wraps a FORTRAN implementation of the algorithm.

Parameters

func [callable] Function to minimize. In the form func(x, *args).
x0 [ndarray] Initial guess.
cons [sequence] Constraint functions; must all be >=0 (a single function if only 1 constraint). Each function takes the parameters x as its first argument, and it can return either a single number or an array or list of numbers.
args [tuple, optional] Extra arguments to pass to function.
consargs [tuple, optional] Extra arguments to pass to constraint functions (default of None means use same extra arguments as those passed to func). Use () for no extra arguments.
rhobeg [float, optional] Reasonable initial changes to the variables.
rhoend [float, optional] Final accuracy in the optimization (not precisely guaranteed). This is a lower bound on the size of the trust region.
disp [{0, 1, 2, 3}, optional] Controls the frequency of output; 0 implies no output.
maxfun [int, optional] Maximum number of function evaluations.
catol [float, optional] Absolute tolerance for constraint violations.

Returns

x [ndarray] The argument that minimises f.

See also:

minimize

Interface to minimization algorithms for multivariate functions. See the ‘COBYLA’ method in particular.

Notes

This algorithm is based on linear approximations to the objective function and each constraint. We briefly describe the algorithm.

Suppose the function is being minimized over k variables. At the jth iteration the algorithm has k+1 points v_1, ..., v_(k+1), an approximate solution x_j, and a radius RHO_j. (i.e., linear plus a constant) approximations to the objective function and constraint functions such that their function values agree with the linear approximation on the k+1 points v_1, ..., v_(k+1). This gives a linear program to solve (where the linear approximations of the constraint functions are constrained to be non-negative).

However, the linear approximations are likely only good approximations near the current simplex, so the linear program is given the further requirement that the solution, which will become x_(j+1), must be within RHO_j from x_j. RHO_j only decreases, never increases. The initial RHO_j is rhobeg and the final RHO_j is rhoend. In this way COBYLA’s iterations behave like a trust region algorithm.
Additionally, the linear program may be inconsistent, or the approximation may give poor improvement. For details about how these issues are resolved, as well as how the points \( v_i \) are updated, refer to the source code or the references below.

References

Examples

Minimize the objective function \( f(x, y) = x \cdot y \) subject to the constraints \( x^2 + y^2 < 1 \) and \( y > 0 \):

```python
>>> def objective(x):
...     return x[0]*x[1]
...
>>> def constr1(x):
...     return 1 - (x[0]**2 + x[1]**2)
...
>>> def constr2(x):
...     return x[1]
...
>>> from scipy.optimize import fmin_cobyla
>>> fmin_cobyla(objective, [0.0, 0.1], [constr1, constr2], rhoend=1e-7)
array([-0.70710685, 0.70710671])
```

The exact solution is \((-\sqrt{2})/2, \sqrt{2}/2\).

**scipy.optimize.fmin_slsqp**

Python interface function for the SLSQP Optimization subroutine originally implemented by Dieter Kraft.

```
scipy.optimize.fmin_slsqp(func, x0, eqcons=(), f_eqcons=None, ieqcons=(), f_ieqcons=None, 
                         bounds=(), fprime=None, fprime_eqcons=None, fprime_ieqcons=None, 
                         args=(), iter=100, acc=1e-06, iprint=1, disp=None, full_output=0, 
                         epsilon=1.4901161193847656e-08, callback=None)
```

Minimize a function using Sequential Least Squares Programming

**Parameters**

- **func** [callable \( f(x,*args) \)] Objective function. Must return a scalar.
- **x0** [1-D ndarray of float] Initial guess for the independent variable(s).
- **eqcons** [list, optional] A list of functions of length \( n \) such that \( eqcons[j](x,*args) = 0.0 \) in a successfully optimized problem.
- **f_eqcons** [callable \( f(x,*args) \), optional] Returns a 1-D array in which each element must equal 0.0 in a successfully optimized problem. If \( f_{eqcons} \) is specified, \( eqcons \) is ignored.
- **ieqcons** [list, optional] A list of functions of length \( n \) such that \( ieqcons[j](x,*args) \geq 0.0 \) in a successfully optimized problem.
**f_ieqcons**  [callable f(x,*args), optional] Returns a 1-D ndarray in which each element must be greater or equal to 0.0 in a successfully optimized problem. If f_ieqcons is specified, ieqcons is ignored.

**bounds**  [list, optional] A list of tuples specifying the lower and upper bound for each independent variable [(xl0, xu0),(xl1, xu1),...] Infinite values will be interpreted as large floating values.

**fprime**  [callable f(x,*args), optional] A function that evaluates the partial derivatives of func.

**fprime_eqcons**  [callable f(x,*args), optional] A function of the form f(x, *args) that returns the m by n array of equality constraint normals. If not provided, the normals will be approximated. The array returned by fprime_eqcons should be sized as (len(eqcons), len(x0)).

**fprime_ieqcons**  [callable f(x,*args), optional] A function of the form f(x, *args) that returns the m by n array of inequality constraint normals. If not provided, the normals will be approximated. The array returned by fprime_ieqcons should be sized as (len(ieqcons), len(x0)).

**args**  [sequence, optional] Additional arguments passed to func and fprime.

**iter**  [int, optional] The maximum number of iterations.

**acc**  [float, optional] Requested accuracy.

**iprint**  [int, optional] The verbosity of fmin_slsqp:

- iprint <= 0: Silent operation
- iprint == 1: Print summary upon completion (default)
- iprint >= 2: Print status of each iterate and summary

**disp**  [int, optional] Overrides the iprint interface (preferred).

**full_output**  [bool, optional] If False, return only the minimizer of func (default). Otherwise, output final objective function and summary information.

**epsilon**  [float, optional] The step size for finite-difference derivative estimates.

**callback**  [callable, optional] Called after each iteration, as callback(x), where x is the current parameter vector.

**Returns**

- **out**  [ndarray of float] The final minimizer of func.
- **fx**  [ndarray of float, if full_output is true] The final value of the objective function.
- **its**  [int, if full_output is true] The number of iterations.
- **imode**  [int, if full_output is true] The exit mode from the optimizer (see below).
- **smode**  [string, if full_output is true] Message describing the exit mode from the optimizer.

**See also:**

- **minimize**

  Interface to minimization algorithms for multivariate functions. See the ‘SLSQP’ method in particular.

**Notes**

Exit modes are defined as follows:

```
-1 : Gradient evaluation required (g & a)
 0 : Optimization terminated successfully
 1 : Function evaluation required (f & c)
 2 : More equality constraints than independent variables
 3 : More than 3*n iterations in LSQ subproblem
 4 : Inequality constraints incompatible
 5 : Singular matrix E in LSQ subproblem
 6 : Singular matrix C in LSQ subproblem
```

(continues on next page)
Examples

Examples are given in the tutorial.

**scipy.optimize.fminbound**

`scipy.optimize.fminbound(func, x1, x2, args=(), xtol=1e-05, maxfun=500, full_output=0, disp=1)`

Bounded minimization for scalar functions.

**Parameters**

- `func [callable f(x,*args)]`: Objective function to be minimized (must accept and return scalars).
- `x1, x2 [float or array scalar]`: The optimization bounds.
- `args [tuple, optional]`: Extra arguments passed to function.
- `maxfun [int, optional]`: Maximum number of function evaluations allowed.
- `full_output [bool, optional]`: If True, return optional outputs.
- `disp [int, optional]`: If non-zero, print messages.
  - 0: no message printing. 1: non-convergence notification messages only. 2: print a message on convergence too. 3: print iteration results.

**Returns**

- `xopt [ndarray]`: Parameters (over given interval) which minimize the objective function.
- `fval [number]`: The function value at the minimum point.
- ` ierr [int]`: An error flag (0 if converged, 1 if maximum number of function calls reached).
- `numfunc [int]`: The number of function calls made.

See also:

**minimize_scalar**

Interface to minimization algorithms for scalar univariate functions. See the ‘Bounded’ method in particular.
Notes

Finds a local minimizer of the scalar function `func` in the interval x1 < xopt < x2 using Brent’s method. (See `brent` for auto-bracketing.)

Examples

`fminbound` finds the minimum of the function in the given range. The following examples illustrate the same

```python
>>> def f(x):
...     return x**2

>>> from scipy import optimize

>>> minimum = optimize.fminbound(f, -1, 2)
>>> minimum
0.0

>>> minimum = optimize.fminbound(f, 1, 2)
>>> minimum
1.0000059608609866
```

**scipy.optimize.brent**

`scipy.optimize.brent (func, args=(), brack=None, tol=1.48e-08, full_output=0, maxiter=500)`

Given a function of one variable and a possible bracket, return the local minimum of the function isolated to a fractional precision of tol.

**Parameters**

- `func` [callable f(x,*args)] Objective function.
- `args` [tuple, optional] Additional arguments (if present).
- `brack` [tuple, optional] Either a triple (xa,xb,xc) where xa<xb<xc and func(xb) < func(xa), func(xc) or a pair (xa,xb) which are used as a starting interval for a downhill bracket search (see `bracket`). Providing the pair (xa,xb) does not always mean the obtained solution will satisfy xa<==x<=xb.
- `tol` [float, optional] Stop if between iteration change is less than tol.
- `full_output` [bool, optional] If True, return all output args (xmin, fval, iter, funcalls).
- `maxiter` [int, optional] Maximum number of iterations in solution.

**Returns**

- `xmin` [ndarray] Optimum point.
- `fval` [float] Optimum value.
- `iter` [int] Number of iterations.
- `funcalls` [int] Number of objective function evaluations made.

See also:

**minimize_scalar**

Interface to minimization algorithms for scalar univariate functions. See the ‘Brent’ method in particular.
Notes

Uses inverse parabolic interpolation when possible to speed up convergence of golden section method. Does not ensure that the minimum lies in the range specified by `brack`. See `fminbound`.

Examples

We illustrate the behaviour of the function when `brack` is of size 2 and 3 respectively. In the case where `brack` is of the form `(xa,xb)`, we can see for the given values, the output need not necessarily lie in the range `(xa,xb)`.

```python
>>> def f(x):
...     return x**2

>>> from scipy import optimize

>>> minimum = optimize.brent(f, brack=(1, 2))
>>> minimum
0.0

>>> minimum = optimize.brent(f, brack=(-1, 0.5, 2))
>>> minimum
-2.7755575615628914e-17
```

`scipy.optimize.golden`

`scipy.optimize.golden(func, args=(), brack=None, tol=1.4901161193847656e-08, full_output=0, maxiter=5000)`

Return the minimum of a function of one variable using golden section method.

Given a function of one variable and a possible bracketing interval, return the minimum of the function isolated to a fractional precision of `tol`.

**Parameters**

- `func` [callable func(x,*args)] Objective function to minimize.
- `args` [tuple, optional] Additional arguments (if present), passed to func.
- `brack` [tuple, optional] Triple `(a,b,c)`, where `(a<b<c)` and `func(b) < func(a),func(c)`. If bracket consists of two numbers `(a,c)`, then they are assumed to be a starting interval for a downhill bracket search (see `bracket`); it doesn’t always mean that obtained solution will satisfy `a<=x<=c`.
- `tol` [float, optional] x tolerance stop criterion
- `full_output` [bool, optional] If True, return optional outputs.
- `maxiter` [int] Maximum number of iterations to perform.

See also:

`minimize_scalar`

Interface to minimization algorithms for scalar univariate functions. See the ‘Golden’ method in particular.
Notes

Uses analog of bisection method to decrease the bracketed interval.

Examples

We illustrate the behaviour of the function when `brack` is of size 2 and 3, respectively. In the case where `brack` is of the form `(xa, xb)`, we can see for the given values, the output need not necessarily lie in the range `(xa, xb)`.

```python
>>> def f(x):
...    return x**2

>>> from scipy import optimize

>>> minimum = optimize.golden(f, brack=(1, 2))
>>> minimum
1.5717777884887342e-16
>>> minimum = optimize.golden(f, brack=(-1, 0.5, 2))
>>> minimum
-1.5717777884887342e-16
```

Least-squares

`leastsq(func, x0[, args, Dfun, full_output, ...])` Minimize the sum of squares of a set of equations.

```python
scipy.optimize.leastsq
```

Minimize the sum of squares of a set of equations.

```python
x = arg min(sum(func(y)**2, axis=0))
      y
```

Parameters

- `func` [callable] Should take at least one (possibly length N vector) argument and returns M floating point numbers. It must not return NaNs or fitting might fail.
- `x0` [ndarray] The starting estimate for the minimization.
- `args` [tuple, optional] Any extra arguments to func are placed in this tuple.
- `Dfun` [callable, optional] A function or method to compute the Jacobian of func with derivatives across the rows. If this is None, the Jacobian will be estimated.
- `full_output` [bool, optional] non-zero to return all optional outputs.
- `col_deriv` [bool, optional] non-zero to specify that the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).
- `ftol` [float, optional] Relative error desired in the sum of squares.
- `xtol` [float, optional] Relative error desired in the approximate solution.
- `gtol` [float, optional] Orthogonality desired between the function vector and the columns of the Jacobian.
maxfev  [int, optional] The maximum number of calls to the function. If Dfun is provided, then
the default maxfev is 100*(N+1) where N is the number of elements in x0, otherwise the default
maxfev is 200*(N+1).

dfun  [float, optional] A variable used in determining a suitable step length for the forward-differ-
ence approximation of the Jacobian (for Dfun=None). Normally the actual step length will
be \sqrt{\text{epsfcn}} * x If epsfcn is less than the machine precision, it is assumed that the relative
errors are of the order of the machine precision.

diag  [sequence, optional] N positive entries that serve as a scale factors for the variables.

Returns

x  [ndarray] The solution (or the result of the last iteration for an unsuccessful call).
cov_x  [ndarray] The inverse of the Hessian. fjac and ipvt are used to construct an estimate of
the Hessian. A value of None indicates a singular matrix, which means the curvature in
parameters x is numerically flat. To obtain the covariance matrix of the parameters x, cov_x
must be multiplied by the variance of the residuals – see curve_fit.

infodict  [dict] a dictionary of optional outputs with the keys:
nfev  The number of function calls
fvec  The function evaluated at the output
fjac  A permutation of the R matrix of a QR factorization of the final approximate
Jacobian matrix, stored column wise. Together with ipvt, the covariance of the
estimate can be approximated.

ipvt  An integer array of length N which defines a permutation matrix, p, such that
fjac*p = q*r, where r is upper triangular with diagonal elements of nonincreas-
ing magnitude. Column j of p is column ipvt(j) of the identity matrix.

qtf  The vector (transpose(q) * fvec).

mesg  [str] A string message giving information about the cause of failure.

ier  [int] An integer flag. If it is equal to 1, 2, 3 or 4, the solution was found. Otherwise, the
solution was not found. In either case, the optional output variable ‘mesg’ gives more infor-
mation.

See also:

least_squares

Newer interface to solve nonlinear least-squares problems with bounds on the variables. See method=='lm'
in particular.

Notes

“leastsq” is a wrapper around MINPACK’s lmdif and lmder algorithms.

cov_x is a Jacobian approximation to the Hessian of the least squares objective function. This approximation
assumes that the objective function is based on the difference between some observed target data (ydata) and a
(non-linear) function of the parameters f(xdata, params)

func(params) = ydata - f(xdata, params)

so that the objective function is

\[
\min_{\text{params}} \sum (ydata - f(xdata, params))^2, \text{ axis=0}
\]

The solution, x, is always a 1-D array, regardless of the shape of x0, or whether x0 is a scalar.
Examples

```python
>>> from scipy.optimize import leastsq
>>> def func(x):
...     return 2*(x-3)**2+1
>>> leastsq(func, 0)
(array([2.99999999]), 1)
```

### Root finding

General nonlinear solvers:

<table>
<thead>

#### `scipy.optimize.fsolve`:

```
scipy.optimize.fsolve (func, x0[, args=(), fprime=None, full_output=0, col_deriv=0, xtol=1.49012e-08, maxfev=0, band=None, epsfcn=None, factor=100, diag=None])
```

Find the roots of a function. Return the roots of the (non-linear) equations defined by \( \text{func(x)} = 0 \) given a starting estimate.

**Parameters**

- `func` : callable \( f(x, \ *\ args) \) A function that takes at least one (possibly vector) argument, and returns a value of the same length.
- `x0` : ndarray The starting estimate for the roots of \( \text{func(x)} = 0 \).
- `args` : tuple, optional Any extra arguments to `func`.
- `fprime` : callable \( f(x, \ *\ args) \), optional A function to compute the Jacobian of `func` with derivatives across the rows. By default, the Jacobian will be estimated.
- `full_output` : bool, optional If True, return optional outputs.
- `col_deriv` : bool, optional Specify whether the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).
- `xtol` : float, optional The calculation will terminate if the relative error between two consecutive iterates is at most `xtol`.
- `maxfev` : int, optional The maximum number of calls to the function. If zero, then \( 100 \times (N+1) \) is the maximum where \( N \) is the number of elements in `x0`.
- `band` : tuple, optional If set to a two-sequence containing the number of sub- and super-diagonals within the band of the Jacobi matrix, the Jacobi matrix is considered banded (only for \( \text{fprime=None} \)).
- `epsfcn` : float, optional A suitable step length for the forward-difference approximation of the Jacobian (for \( \text{fprime=None} \)). If `epsfcn` is less than the machine precision, it is assumed that the relative errors in the functions are of the order of the machine precision.
- `factor` : float, optional A parameter determining the initial step bound (\( \text{factor} \times || diag \times x || \)). Should be in the interval \((0.1, 100)\).
- `diag` : sequence, optional \( N \) positive entries that serve as a scale factors for the variables.

**Returns**

- `x` : ndarray The solution (or the result of the last iteration for an unsuccessful call).
infodict [dict] A dictionary of optional outputs with the keys:
- nfrev number of function calls
- njev number of Jacobian calls
- fvec function evaluated at the output
- fjac the orthogonal matrix, q, produced by the QR factorization of the final approximate Jacobian matrix, stored column wise
- r upper triangular matrix produced by QR factorization of the same matrix
- qtf the vector (transpose(q) * fvec)
- ier [int] An integer flag. Set to 1 if a solution was found, otherwise refer to mesg for more information.
- mesg [str] If no solution is found, mesg details the cause of failure.

See also:

root

Interface to root finding algorithms for multivariate functions. See the method='hybr' in particular.

Notes

fsolve is a wrapper around MINPACK’s hybrd and hybrj algorithms.

Examples

Find a solution to the system of equations: \(x_0 \cos(x_1) = 4, x_1 x_0 - x_1 = 5\).

```python
>>> from scipy.optimize import fsolve
>>> def func(x):
...     return [x[0] * np.cos(x[1]) - 4,
...             x[1] * x[0] - x[1] - 5]
>>> root = fsolve(func, [1, 1])
>>> root
array([6.50409711, 0.90841421])
>>> np.isclose(func(root), [0.0, 0.0]) # func(root) should be almost 0.0.
array([ True, True])
```

scipy.optimize.broyden1

scipy.optimize.broyden1 \((F, xin, iter=None, alpha=None, reduction_method='restart', max_rank=None, verbose=False, maxiter=None, f_tol=None, f_rtol=None, x_tol=None, x_rtol=None, tol_norm=None, line_search='armijo', callback=None, **kw)\)

Find a root of a function, using Broyden’s first Jacobian approximation.

This method is also known as "Broyden’s good method".

Parameters

- **F** [function(x) -> f] Function whose root to find; should take and return an array-like object.
- **xin** [array_like] Initial guess for the solution.
- **alpha** [float, optional] Initial guess for the Jacobian is \((-1/alpha)\).
- **reduction_method** [str or tuple, optional] Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form (method, param1, param2, ...) that gives the name of the method and values for additional parameters.
Methods available:
• `restart`: drop all matrix columns. Has no extra parameters.
• `simple`: drop oldest matrix column. Has no extra parameters.
• `svd`: keep only the most significant SVD components. Takes an extra parameter, `to_retain`, which determines the number of SVD components to retain when rank reduction is done. Default is \( \text{max\_rank} - 2 \).

`max_rank` [int, optional] Maximum rank for the Broyden matrix. Default is infinity (i.e., no rank reduction).

`iter` [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

`verbose` [bool, optional] Print status to stdout on every iteration.

`maxiter` [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.

`f_tol` [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

`f_rtol` [float, optional] Relative tolerance for the residual. If omitted, not used.

`x_tol` [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

`x_rtol` [float, optional] Relative minimum step size. If omitted, not used.

`tol_norm` [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

`line_search` [{None, ‘armijo’ (default), ‘wolfe’}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

`callback` [function, optional] Optional callback function. It is called on every iteration as `callback(x, f)` where `x` is the current solution and `f` the corresponding residual.

**Returns**

`sol` [ndarray] An array (of similar array type as `x0`) containing the final solution.

**Raises**

`NoConvergence` When a solution was not found.

**See also:**

`root`

Interface to root finding algorithms for multivariate functions. See `method='broyden1'` in particular.

**Notes**

This algorithm implements the inverse Jacobian Quasi-Newton update

\[
H_+ = H + (dx - H df)dx^T H / (dx^T H df)
\]

which corresponds to Broyden’s first Jacobian update

\[
J_+ = J + (df - J dx)dx^T / dx^T dx
\]
References

[1]

Examples

The following functions define a system of nonlinear equations

```python
>>> def fun(x):
...     return [x[0] + 0.5 * (x[0] - x[1])**3 - 1.0,
...             0.5 * (x[1] - x[0])**3 + x[1]]
```

A solution can be obtained as follows.

```python
>>> from scipy import optimize
>>> sol = optimize.broyden1(fun, [0, 0])
>>> sol
array([0.84116396, 0.15883641])
```

`scipy.optimize.broyden2`

`scipy.optimize.broyden2` (*F*, *xin*, *iter=None*, *alpha=None*, *reduction_method='restart'*, *max_rank=None*, *verbose=False*, *maxiter=None*, *f_tol=None*, *f_rtol=None*, *x_tol=None*, *x_rtol=None*, *tol_norm=None*, *line_search='armijo'*, *callback=None*, **kw)

Find a root of a function, using Broyden’s second Jacobian approximation.

This method is also known as “Broyden’s bad method”.

**Parameters**

- **F** *(function(x) -> f)* Function whose root to find; should take and return an array-like object.
- **xin** *(array_like)* Initial guess for the solution
- **alpha** *(float, optional)* Initial guess for the Jacobian is 

  \((-1/\text{alpha})\).
- **reduction_method** *(str or tuple, optional)* Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form (method, param1, param2, ...) that gives the name of the method and values for additional parameters. Methods available:
  - **restart**: drop all matrix columns. Has no extra parameters.
  - **simple**: drop oldest matrix column. Has no extra parameters.
  - **svd**: keep only the most significant SVD components. Takes an extra parameter, `to_retain`, which determines the number of SVD components to retain when rank reduction is done. Default is `max_rank - 2`.
- **max_rank** *(int, optional)* Maximum rank for the Broyden matrix. Default is infinity (i.e., no rank reduction).
- **iter** *(int, optional)* Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- **verbose** *(bool, optional)* Print status to stdout on every iteration.
- **maxiter** *(int, optional)* Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.
- **f_tol** *(float, optional)* Absolute tolerance (in max-norm) for the residual. If omitted, default is `6e-6`.
- **f_rtol** *(float, optional)* Relative tolerance for the residual. If omitted, not used.

x_tol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

x_dtol [float, optional] Relative minimum step size. If omitted, not used.

tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search [{None, ‘armijo’ (default), ‘wolfe’}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

callback [function, optional] Optional callback function. It is called on every iteration as callback(x, f) where x is the current solution and f the corresponding residual.

Returns

sol [ndarray] An array (of similar array type as x0) containing the final solution.

Raises

NoConvergence When a solution was not found.

See also:

root

Interface to root finding algorithms for multivariate functions. See method='broyden2' in particular.

Notes

This algorithm implements the inverse Jacobian Quasi-Newton update

\[ H_+ = H + (dx - H df) df^T / (df^T df) \]

corresponding to Broyden’s second method.

References

[1]

Examples

The following functions define a system of nonlinear equations

```python
>>> def fun(x):
...    return [x[0] + 0.5 * (x[0] - x[1])**3 - 1.0,
...           0.5 * (x[1] - x[0])**3 + x[1]]
```

A solution can be obtained as follows.

```python
>>> from scipy import optimize
>>> sol = optimize.broyden2(fun, [0, 0])
>>> sol
array([0.84116365, 0.15883529])
```

Large-scale nonlinear solvers:
newton_krylov(F, xin[, iter, rdiff, method, …]) Find a root of a function, using Krylov approximation for inverse Jacobian.

anderson(F, xin[, iter, alpha, w0, M, …]) Find a root of a function, using (extended) Anderson mixing.

scipy.optimize.newton_krylov

scipy.optimize.newton_krylov (F, xin, iter=None, rdiff=None, method='lgmres', inner_maxiter=20, inner_M=None, outer_k=10, verbose=False, maxiter=None, f_tol=None, f_rtol=None, x_tol=None, x_rtol=None, tol_norm=None, line_search='armijo', callback=None, **kw)

Find a root of a function, using Krylov approximation for inverse Jacobian.

This method is suitable for solving large-scale problems.

Parameters

- **F**: [function(x) -> f] Function whose root to find; should take and return an array-like object.
- **xin**: [array_like] Initial guess for the solution.
- **rdiff**: [float, optional] Relative step size to use in numerical differentiation.
- **method**: ['lgmres', 'gmres', 'bicgstab', 'cgs', 'minres'] or function Krylov method to use to approximate the Jacobian. Can be a string, or a function implementing the same interface as the iterative solvers in scipy.sparse.linalg. The default is scipy.sparse.linalg.lgmres.
- **inner_maxiter**: [int, optional] Parameter to pass to the “inner” Krylov solver: maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **inner_M**: [LinearOperator or InverseJacobian] Preconditioner for the inner Krylov iteration. Note that you can use also inverse Jacobians as (adaptive) preconditioners. For example,

```python
>>> from scipy.optimize.nonlin import BroydenFirst, ...
   KrylovJacobian
>>> from scipy.optimize.nonlin import InverseJacobian
>>> jac = BroydenFirst()
>>> kjac = KrylovJacobian(inner_M=InverseJacobian(jac))
```

If the preconditioner has a method named ‘update’, it will be called as update(x, f) after each nonlinear step, with x giving the current point, and f the current function value.

- **outer_k**: [int, optional] Size of the subspace kept across LGMRES nonlinear iterations. See scipy.sparse.linalg.lgmres for details.
- **inner_kwargs**: [kwargs] Keyword parameters for the “inner” Krylov solver (defined with method). Parameter names must start with the inner_ prefix which will be stripped before passing on the inner method. See, e.g., scipy.sparse.linalg.gmres for details.
- **iter**: [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- **verbose**: [bool, optional] Print status to stdout on every iteration.
- **maxiter**: [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, NoConvergence is raised.
- **f_tol**: [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- **f_rtol**: [float, optional] Relative tolerance for the residual. If omitted, not used.
- **x_tol**: [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- **x_rtol**: [float, optional] Relative minimum step size. If omitted, not used.
**tol_norm** [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

**line_search** [{None, ‘armijo’ (default), ‘wolfe’}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

**callback** [function, optional] Optional callback function. It is called on every iteration as `callback(x, f)` where x is the current solution and f the corresponding residual.

**Returns**

**sol** [ndarray] An array (of similar array type as `x0`) containing the final solution.

**Raises**

**NoConvergence** When a solution was not found.

See also:

**root**

Interface to root finding algorithms for multivariate functions. See `method='krylov'` in particular.

**scipy.sparse.linalg.gmres**

**scipy.sparse.linalg.lgmres**

**Notes**

This function implements a Newton-Krylov solver. The basic idea is to compute the inverse of the Jacobian with an iterative Krylov method. These methods require only evaluating the Jacobian-vector products, which are conveniently approximated by a finite difference:

\[ Jv \approx (f(x + \omega * v/|v|) - f(x))/\omega \]

Due to the use of iterative matrix inverses, these methods can deal with large nonlinear problems.

SciPy’s `scipy.sparse.linalg` module offers a selection of Krylov solvers to choose from. The default here is `lgmres`, which is a variant of restarted GMRES iteration that reuses some of the information obtained in the previous Newton steps to invert Jacobians in subsequent steps.

For a review on Newton-Krylov methods, see for example [1], and for the LGMRES sparse inverse method, see [2].

Examples

The following functions define a system of nonlinear equations

```python
>>> def fun(x):
...     return [x[0] + 0.5 * x[1] - 1.0,
...             0.5 * (x[1] - x[0]) ** 2]
```

A solution can be obtained as follows.

```python
>>> from scipy import optimize
>>> sol = optimize.newton_krylov(fun, [0, 0])
>>> sol
array([0.66731771, 0.66536458])
```

scipy.optimize.anderson

The Jacobian is formed by for a ‘best’ solution in the space spanned by last $M$ vectors. As a result, only a $M \times M$ matrix inversions and $M \times N$ multiplications are required. [Ey]

Parameters

- **F** [function(x) -> f] Function whose root to find; should take and return an array-like object.
- **xin** [array_like] Initial guess for the solution
- **alpha** [float, optional] Initial guess for the Jacobian is (-1/alpha).
- **M** [float, optional] Number of previous vectors to retain. Defaults to 5.
- **w0** [float, optional] Regularization parameter for numerical stability. Compared to unity, good values of the order of 0.01.
- **iter** [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- **verbose** [bool, optional] Print status to stdout on every iteration.
- **maxiter** [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, NoConvergence is raised.
- **f_tol** [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- **f_rtol** [float, optional] Relative tolerance for the residual. If omitted, not used.
- **x_tol** [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- **x_rtol** [float, optional] Relative minimum step size. If omitted, not used.
- **tol_norm** [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
- **line_search** [{None, ‘armijo’ (default), ‘wolfe’}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.
- **callback** [function, optional] Optional callback function. It is called on every iteration as `callback(x, f)` where `x` is the current solution and `f` the corresponding residual.

Returns

- **sol** [ndarray] An array (of similar array type as x0) containing the final solution.

Raises
NoConvergence
When a solution was not found.

Examples

The following functions define a system of nonlinear equations

```python
>>> def fun(x):
    ...     return [x[0] + 0.5 * (x[0] - x[1])**3 - 1.0,
    ...               0.5 * (x[1] - x[0])**3 + x[1]]
```

A solution can be obtained as follows.

```python
>>> from scipy import optimize
>>> sol = optimize.anderson(fun, [0, 0])
>>> sol
array([0.84116588, 0.15883789])
```

Simple iteration solvers:

- `excitingmixing(F, xin[, iter, alpha, ...])`: Find a root of a function, using a tuned diagonal Jacobian approximation. The Jacobian matrix is diagonal and is tuned on each iteration.
- `linearmixing(F, xin[, iter, alpha, verbose, ...])`: Find a root of a function, using a scalar Jacobian approximation.
- `diagbroyden(F, xin[, iter, alpha, verbose, ...])`: Find a root of a function, using diagonal Broyden Jacobian approximation.

`scipy.optimize.excitingmixing`

`scipy.optimize.excitingmixing` accepts:

- `F`: Function whose root to find; should take and return an array-like object.
- `xin`: Initial guess for the root.
- `iter`: Maximum number of iterations.
- `alpha`: Tolerance for the change in the Jacobian.
- `alphamax`: Maximum value of `alpha`.
- `verbose`: Print status messages.
- `maxiter`: Maximum number of iterations.
- `f_tol`: Tolerance for the absolute value of the function.
- `f_rtol`: Tolerance for the relative change in the function.
- `x_tol`: Tolerance for the absolute value of the root.
- `x_rtol`: Tolerance for the relative change in the root.
- `tol_norm`: Tolerance for the norm of the Jacobian.
- `line_search`: Line search method.
- `callback`: Callable that is called after each iteration.

Warning: This algorithm may be useful for specific problems, but whether it will work may depend strongly on the problem.
In [array_like] Initial guess for the solution.
alpha [float, optional] Initial Jacobian approximation is (-1/alpha).
alphamax [float, optional] The entries of the diagonal Jacobian are kept in the range [alpha, alphamax].
iter [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
verbose [bool, optional] Print status to stdout on every iteration.
maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, NoConvergence is raised.
f_tol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
f_rtol [float, optional] Relative tolerance for the residual. If omitted, not used.
x_tol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
x_rtol [float, optional] Relative minimum step size. If omitted, not used.
tol_norm [function(vector)->scalar, optional] Norm to use in convergence check. Default is the maximum norm.
line_search [{None, 'armijo' (default), 'wolfe'}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.
callback [function, optional] Optional callback function. It is called on every iteration as callback(x, f) where x is the current solution and f the corresponding residual.

Returns

sol [ndarray] An array (of similar array type as x0) containing the final solution.

Raises

NoConvergence
When a solution was not found.

See also:

root

Interface to root finding algorithms for multivariate functions. See method='excitingmixing' in particular.

scipy.optimize.linearmixing

Parameters

F [function(x) -> f] Function whose root to find; should take and return an array-like object.
xin [array_like] Initial guess for the solution.
alpha [float, optional] The Jacobian approximation is (-1/alpha).
iter [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

verbose [bool, optional] Print status to stdout on every iteration.

maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, NoConvergence is raised.

f_tol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is $6e^{-6}$.

f_rtol [float, optional] Relative tolerance for the residual. If omitted, not used.

x_tol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

x_rtol [float, optional] Relative minimum step size. If omitted, not used.

tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search [[None, ‘armijo’ (default), ‘wolfe’], optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

callback [function, optional] Optional callback function. It is called on every iteration as callback(x, f) where x is the current solution and f the corresponding residual.

Returns

sol [ndarray] An array (of similar array type as x0) containing the final solution.

Raises

NoConvergence When a solution was not found.

scipy.optimize.diagbroyden

scipy.optimize.diagbroyden(F, xin, iter=None, alpha=None, verbose=False, maxiter=None,
                        f_tol=None, f_rtol=None, x_tol=None, x_rtol=None, tol_norm=None,
                        line_search=’armijo’, callback=None, **kw)

Find a root of a function, using diagonal Broyden Jacobian approximation.

The Jacobian approximation is derived from previous iterations, by retaining only the diagonal of Broyden matrices.

**Warning:** This algorithm may be useful for specific problems, but whether it will work may depend strongly on the problem.

Parameters

F [function(x) -> f] Function whose root to find; should take and return an array-like object.

xin [array_like] Initial guess for the solution

alpha [float, optional] Initial guess for the Jacobian is (-1/alpha).

iter [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

verbose [bool, optional] Print status to stdout on every iteration.
maxiter: \[\text{int, optional}\] Maximum number of iterations to make. If more are needed to meet convergence, \texttt{NoConvergence} is raised.

f_tol: \[\text{float, optional}\] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

f_rtol: \[\text{float, optional}\] Relative tolerance for the residual. If omitted, not used.

x_tol: \[\text{float, optional}\] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

x_rtol: \[\text{float, optional}\] Relative minimum step size. If omitted, not used.

tol_norm: \[\text{function(vector -> scalar, optional)}\] Norm to use in convergence check. Default is the maximum norm.

diagbroyden \[\{\text{None, 'armijo', 'wolfe'}, \text{optional}\}\] Which type of line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.

callback: \[\text{function, optional}\] Optional callback function. It is called on every iteration as \texttt{callback(x, f)} where \texttt{x} is the current solution and \texttt{f} the corresponding residual.

Returns:

- \texttt{sol}: \[\text{ndarray}\] An array (of similar array type as \texttt{x0}) containing the final solution.

Raises:

- \texttt{NoConvergence}: When a solution was not found.

See also:

- \texttt{root}  
  Interface to root finding algorithms for multivariate functions. See \texttt{method='diagbroyden'} in particular.

Examples

The following functions define a system of nonlinear equations

```python
>>> def fun(x):
...     return [x[0] + 0.5 * (x[0] - x[1])**3 - 1.0,
...             0.5 * (x[1] - x[0])**3 + x[1]]
```

A solution can be obtained as follows.

```python
>>> from scipy import optimize
>>> sol = optimize.diagbroyden(fun, [0, 0])
>>> sol
array([0.84116403, 0.15883597])
```

Additional information on the nonlinear solvers
This is a collection of general-purpose nonlinear multidimensional solvers. These solvers find $x$ for which $F(x) = 0$. Both $x$ and $F$ can be multidimensional.

### 6.20.2 Examples

#### Small problem

```python
def F(x):
    ...  return np.cos(x) + x[::-1] - [1, 2, 3, 4]
```

```python
import scipy.optimize
>>> x = scipy.optimize.broyden1(F, [1,1,1,1], f_tol=1e-14)
>>> x
array([4.04674914, 3.91158389, 2.71791677, 1.61756251])
```

#### Large problem

Suppose that we needed to solve the following integrodifferential equation on the square $[0, 1] \times [0, 1]$:

$$
\nabla^2 P = 10 \left( \int_0^1 \int_0^1 \cosh(P) \, dx \, dy \right)^2
$$

with $P(x, 1) = 1$ and $P = 0$ elsewhere on the boundary of the square.
The solution can be found using the `newton_krylov` solver:

```python
import numpy as np
from scipy.optimize import newton_krylov
from numpy import cosh, zeros_like, mgrid, zeros

# parameters
nx, ny = 75, 75
hx, hy = 1. / (nx-1), 1. / (ny-1)

P_left, P_right = 0, 0
P_top, P_bottom = 1, 0

def residual(P):
    d2x = zeros_like(P)
    d2y = zeros_like(P)

    d2x[0] = (P[1] - 2*P[0] + P_left)/hx/hx
    d2x[-1] = (P_right - 2*P[::1] + P[::2])/hx/hx

    d2y[:,1:-1] = (P[:,2] - 2*P[:,1:-1] + P[:,:2])/hy/hy
    d2y[:,0] = (P[:,1] - 2*P[:,0] + P_bottom)/hy/hy
    d2y[:,-1] = (P_top - 2*P[:,::1] + P[:,::2])/hy/hy

    return d2x + d2y - 10*cosh(P).mean()**2

# solve
guess = zeros((nx, ny), float)
sol = newton_krylov(residual, guess, method='lgmres', verbose=1)
print('Residual: %g' % abs(residual(sol)).max())

# visualize
import matplotlib.pyplot as plt
x, y = mgrid[0:1:(nx+1j), 0:1:(ny+1j)]
plt.pcolormesh(x, y, sol, shading='gouraud')
plt.colorbar()
plt.show()
```

### 6.21 Cython optimize zeros API

The underlying C functions for the following root finders can be accessed directly using Cython:

- `bisect`
- `ridder`
- `brenth`
- `brentq`

The Cython API for the zeros functions is similar except there is no `disp` argument. Import the zeros functions using `cimport from scipy.optimize.cython_optimize`. 
6.21.1 Callback signature

The zeros functions in cython_optimize expect a callback that takes a double for the scalar independent variable as the 1st argument and a user defined struct with any extra parameters as the 2nd argument.

```c
double (*callback_type)(double, void*)
```

6.21.2 Examples

Usage of cython_optimize requires Cython to write callbacks that are compiled into C. For more information on compiling Cython, see the Cython Documentation.

These are the basic steps:

1. Create a Cython .pyx file, for example: myexample.pyx.
2. Import the desired root finder from cython_optimize.
3. Write the callback function, and call the selected zeros function passing the callback, any extra arguments, and the other solver parameters.

```python
def callback(x, _):  # example callback
    return some_function(x, _)

from scipy.optimize.cython_optimize cimport brentq
from libc cimport math
myargs = {'C0': 1.0, 'C1': 0.7}  # a dictionary of extra arguments
XLO, XHI = 0.5, 1.0  # lower and upper search boundaries
XTOL, RTOL, MITR = 1e-3, 1e-3, 10  # other solver parameters
```

(continues on next page)
# user-defined struct for extra parameters
ctypedef struct test_params:
    double C0
double C1

# user-defined callback
cdef double f(double x, void *args):
    cdef test_params *myargs = <test_params *> args
    return myargs.C0 - math.exp(-(x - myargs.C1))

# Cython wrapper function
cdef double brentq_wrapper_example(dict args, double xa, double xb,
    double xtol, double rtol, int mitr):
    # Cython automatically casts dictionary to struct
cdef test_params myargs = args
    return brentq(f, xa, xb, <test_params *> &myargs, xtol, rtol, mitr, NULL)

# Python function
def brentq_example(args=myargs, xa=XLO, xb=XHI, xtol=XTOL, rtol=RTOL,
    mitr=MTR):
    '''Calls Cython wrapper from Python.''
    return brentq_wrapper_example(args, xa, xb, xtol, rtol, mitr)

4. If you want to call your function from Python, create a Cython wrapper, and a Python function that calls the wrapper, or use cpdef. Then, in Python, you can import and run the example.

   
      from myexample import brentq_example
      x = brentq_example()
      # 0.6999942848231314

5. Create a Cython .pxd file if you need to export any Cython functions.

6.21.3 Full output

The functions in cython_optimize can also copy the full output from the solver to a C struct that is passed as its last argument. If you don’t want the full output, just pass NULL. The full output struct must be type zeros_full_output, which is defined in scipy.optimize.cython_optimize with the following fields:

- int funcalls: number of function calls
- int iterations: number of iterations
- int error_num: error number
- double root: root of function

The root is copied by cython_optimize to the full output struct. An error number of -1 means a sign error, -2 means a convergence error, and 0 means the solver converged. Continuing from the previous example:
```python
from scipy.optimize.cython_optimize cimport zeros_full_output

cdef brentfull_output brent_full_output_example(
bdict args, double xa, double xb, double xtol, double rtol,
int mitr):
    cdef test_params myargs = args
cdef zeros_full_output my_full_output
    # use my_full_output instead of NULL
    brentq(f, xa, xb, &myargs, xtol, rtol, mitr, &my_full_output)
    return my_full_output

# Python function
def brent_full_output_example(args=myargs, xa=XLO, xb=XHI, xtol=XTOL,
rtol=RTOL, mitr=MITR):
    '''Returns full output'''
    return brentq_full_output_wrapper_example(args, xa, xb, xtol, rtol,
mitr)

result = brent_full_output_example()
# {'error_num': 0,
# 'funcalls': 6,
# 'iterations': 5,
# 'root': 0.699942848231314}
```

**scipy.signal.convolve**

*scipy.signal.convolve*(in1, in2, mode='full', method='auto')

Convolves two N-dimensional arrays.

Convolves in1 and in2, with the output size determined by the mode argument.

**Parameters**

- **in1** [array_like] First input. Should have the same number of dimensions as in1.
- **in2** [array_like] Second input. Should have the same number of dimensions as in1.
- **mode** [str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:
  - **full** The output is the full discrete linear convolution of the inputs. (Default)
  - **valid** The output consists only of those elements that do not rely on the zero-padding. In 'valid' mode, either in1 or in2 must be at least as large as the other in every dimension.
  - **same** The output is the same size as in1, centered with respect to the ‘full’ output.
- **method** [str {'auto', 'direct', 'fft'}, optional] A string indicating which method to use to calculate the convolution.
  - **direct** The convolution is determined directly from sums, the definition of convolution.
  - **fft** The Fourier Transform is used to perform the convolution by calling *fftconvolve*.
  - **auto** Automatically chooses direct or Fourier method based on an estimate of which is faster (default). See Notes for more detail. New in version 0.19.0.

**Returns**

- **convolve** [array] An N-dimensional array containing a subset of the discrete linear convolution of in1 with in2.

**See also:**

- **numpy.polymul**
  - Performs polynomial multiplication (same operation, but also accepts *poly1d* objects)
- **choose_conv_method**
  - Chooses the fastest appropriate convolution method
- **fftconvolve**
  - Always uses the FFT method.
- **oaconvolve**
  - Uses the overlap-add method to do convolution, which is generally faster when the input arrays are large and significantly different in size.
Notes

By default, `convolve` and `correlate` use `method='auto'`, which calls `choose_conv_method` to choose the fastest method using pre-computed values (`choose_conv_method` can also measure real-world timing with a keyword argument). Because `fftconvolve` relies on floating point numbers, there are certain constraints that may force `method=direct` (more detail in `choose_conv_method` docstring).

Examples

Smooth a square pulse using a Hann window:

```python
>>> from scipy import signal
>>> sig = np.repeat([0., 1., 0.], 100)
>>> win = signal.windows.hann(50)
>>> filtered = signal.convolve(sig, win, mode='same') / sum(win)

>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_win, ax_filt) = plt.subplots(3, 1, sharex=True)
>>> ax_orig.plot(sig)
>>> ax_orig.set_title('Original pulse')
>>> ax_orig.margins(0, 0.1)
>>> ax_win.plot(win)
>>> ax_win.set_title('Filter impulse response')
>>> ax_win.margins(0, 0.1)
>>> ax_filt.plot(filtered)
>>> ax_filt.set_title('Filtered signal')
>>> ax_filt.margins(0, 0.1)
>>> fig.tight_layout()
>>> fig.show()
```
scipy.signal.correlate

\texttt{scipy.signal.correlate(in1, in2, mode='full', method='auto')}  
Cross-correlate two N-dimensional arrays.

Cross-correlate \texttt{in1} and \texttt{in2}, with the output size determined by the \texttt{mode} argument.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{in1} [array_like] First input.
  \item \texttt{in2} [array_like] Second input. Should have the same number of dimensions as \texttt{in1}.
  \item \texttt{mode} [str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:
    \begin{itemize}
      \item \texttt{full} The output is the full discrete linear cross-correlation of the inputs. (Default)
      \item \texttt{valid} The output consists only of those elements that do not rely on the zero-padding. In ‘valid’ mode, either \texttt{in1} or \texttt{in2} must be at least as large as the other in every dimension.
      \item \texttt{same} The output is the same size as \texttt{in1}, centered with respect to the ‘full’ output.
    \end{itemize}
  \item \texttt{method} [str {'auto', 'direct', 'fft'}, optional] A string indicating which method to use to calculate the correlation.
    \begin{itemize}
      \item \texttt{direct} The correlation is determined directly from sums, the definition of correlation.
      \item \texttt{fft} The Fast Fourier Transform is used to perform the correlation more quickly (only available for numerical arrays.)
      \item \texttt{auto} Automatically chooses direct or Fourier method based on an estimate of which is faster (default). See \texttt{convolve} Notes for more detail. New in version 0.19.0.
    \end{itemize}
\end{itemize}

\textbf{Returns}

\texttt{correlate} [array] An N-dimensional array containing a subset of the discrete linear cross-correlation of \texttt{in1} with \texttt{in2}.

\textbf{See also:}

\begin{itemize}
  \item \texttt{choose_conv_method}
  \item \texttt{correlation_lags}
\end{itemize}

\begin{itemize}
  \item \texttt{choose_conv_method} contains more documentation on \texttt{method}.
  \item \texttt{correlation_lags} calculates the lag / displacement indices array for 1D cross-correlation.
\end{itemize}

\textbf{Notes}

The correlation \( z \) of two d-dimensional arrays \( x \) and \( y \) is defined as:

\[
  z[\ldots,k,\ldots] = \sum[\ldots, i_1, \ldots] x[\ldots, i_1, \ldots] \ast \text{conj}(y[\ldots, i_1 - k, \ldots])
\]

This way, if \( x \) and \( y \) are 1-D arrays and \( z = \text{correlate}(x, y, 'full') \) then

\[
  z[k] = (x \ast y)(k - N + 1) = \sum_{l=0}^{||x||-1} x_l y_{l-k+N-1}
\]

for \( k = 0, 1, \ldots, ||x|| + ||y|| - 2 \)

where \( ||x|| \) is the length of \( x \), \( N = \max(||x||, ||y||) \), and \( y_m \) is 0 when \( m \) is outside the range of \( y \).

\texttt{method='fft'} only works for numerical arrays as it relies on \texttt{fftconvolve}. In certain cases (i.e., arrays of objects or when rounding integers can lose precision), \texttt{method='direct'} is always used.
When using “same” mode with even-length inputs, the outputs of \texttt{correlate} and \texttt{correlate2d} differ: There is a 1-index offset between them.

\section*{Examples}

Implement a matched filter using cross-correlation, to recover a signal that has passed through a noisy channel.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> sig = np.repeat([0., 1., 1., 0., 1., 0., 1.], 128)
>>> sig_noise = sig + np.random.randn(len(sig))
>>> corr = signal.correlate(sig_noise, np.ones(128), mode='same') / 128

>>> clock = np.arange(64, len(sig), 128)
>>> fig, (ax_orig, ax_noise, ax_corr) = plt.subplots(3, 1, sharex=True)
>>> ax_orig.plot(sig)
>>> ax_orig.plot(clock, sig[clock], 'ro')
>>> ax_orig.set_title('Original signal')
>>> ax_noise.plot(sig_noise)
>>> ax_noise.set_title('Signal with noise')
>>> ax_corr.plot(corr)
>>> ax_corr.plot(clock, corr[clock], 'ro')
>>> ax_corr.axhline(0.5, ls=':')
>>> ax_corr.set_title('Cross-correlated with rectangular pulse')
>>> ax_orig.margins(0, 0.1)
>>> fig.tight_layout()
>>> plt.show()
```

Compute the cross-correlation of a noisy signal with the original signal.

```python
>>> x = np.arange(128) / 128
>>> sig = np.sin(2 * np.pi * x)
```

(continues on next page)
```python
>>> sig_noise = sig + np.random.randn(len(sig))
>>> corr = signal.correlate(sig_noise, sig)
>>> lags = signal.correlation_lags(len(sig), len(sig_noise))
>>> corr /= np.max(corr)

>>> fig, (ax_orig, ax_noise, ax_corr) = plt.subplots(3, 1, figsize=(4.8, 4.8))
>>> ax_orig.plot(sig)
>>> ax_orig.set_title('Original signal')
>>> ax_noise.plot(sig_noise)
>>> ax_noise.set_title('Signal with noise')
>>> ax_corr.plot(lags, corr)
>>> ax_corr.set_title('Cross-correlated signal')
>>> ax_corr.set_xlabel('Lag')
>>> ax_orig.margins(0, 0.1)
>>> ax_noise.margins(0, 0.1)
>>> ax_corr.margins(0, 0.1)
>>> fig.tight_layout()
>>> plt.show()
```

6.22. Signal processing (scipy.signal)
**scipy.signal.fftconvolve**

scipy.signal.fftconvolve(in1, in2, mode='full', axes=None)

Convolve two N-dimensional arrays using FFT.

Convolve `in1` and `in2` using the fast Fourier transform method, with the output size determined by the `mode` argument.

This is generally much faster than `convolve` for large arrays (n > ~500), but can be slower when only a few output values are needed, and can only output float arrays (int or object array inputs will be cast to float).

As of v0.19, `convolve` automatically chooses this method or the direct method based on an estimation of which is faster.

**Parameters**

- **in1** [array_like] First input.
- **in2** [array_like] Second input. Should have the same number of dimensions as `in1`.
- **mode** [str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:
  - `full` The output is the full discrete linear convolution of the inputs. (Default)
  - `valid` The output consists only of those elements that do not rely on the zero-padding.
    In ‘valid’ mode, either `in1` or `in2` must be at least as large as the other in every dimension.
  - `same` The output is the same size as `in1`, centered with respect to the ‘full’ output.
- **axes** [int or array_like of ints or None, optional] Axes over which to compute the convolution.
  The default is over all axes.

**Returns**

- **out** [array] An N-dimensional array containing a subset of the discrete linear convolution of `in1` with `in2`.

**See also:**

- `convolve`
  Uses the direct convolution or FFT convolution algorithm depending on which is faster.

- `oaconvolve`
  Uses the overlap-add method to do convolution, which is generally faster when the input arrays are large and significantly different in size.

**Examples**

Autocorrelation of white noise is an impulse.

```python
>>> from scipy import signal
>>> sig = np.random.randn(1000)
>>> autocorr = signal.fftconvolve(sig, sig[::-1], mode='full')
```

```python
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_mag) = plt.subplots(2, 1)
>>> ax_orig.plot(sig)
>>> ax_orig.set_title('White noise')
>>> ax_mag.plot(np.arange(-len(sig)+1, len(sig)), autocorr)
>>> ax_mag.set_title('Autocorrelation')
```

(continues on next page)
Gaussian blur implemented using FFT convolution. Notice the dark borders around the image, due to the zero-padding beyond its boundaries. The `convolve2d` function allows for other types of image boundaries, but is far slower.

```
>>> from scipy import misc
>>> face = misc.face(gray=True)
>>> kernel = np.outer(signal.windows.gaussian(70, 8), signal.windows.gaussian(70, 8))
>>> blurred = signal.fftconvolve(face, kernel, mode='same')
```
**scipy.signal.oaconvolve**

`scipy.signal.oaconvolve(in1, in2, mode='full', axes=None)`  
Convolves two N-dimensional arrays using the overlap-add method.

- **in1** [array_like] First input.
- **in2** [array_like] Second input. Should have the same number of dimensions as `in1`.
- **mode** [str {‘full’, ‘valid’, ‘same’}, optional] A string indicating the size of the output:
  - **full** The output is the full discrete linear convolution of the inputs. (Default)
  - **valid** The output consists only of those elements that do not rely on the zero-padding. In ‘valid’ mode, either `in1` or `in2` must be at least as large as the other in every dimension.
  - **same** The output is the same size as `in1`, centered with respect to the ‘full’ output.
- **axes** [int or array_like of ints or None, optional] Axes over which to compute the convolution. The default is over all axes.

**Returns**

- **out** [array] An N-dimensional array containing a subset of the discrete linear convolution of `in1` with `in2`.

**See also:**

- **convolve**
  - Uses the direct convolution or FFT convolution algorithm depending on which is faster.
- **fftconvolve**
  - An implementation of convolution using FFT.

**Notes**

New in version 1.4.0.

**References**

[1], [2]
Examples

Convolve a 100,000 sample signal with a 512-sample filter.

```python
>>> from scipy import signal
>>> sig = np.random.randn(100000)
>>> filt = signal.firwin(512, 0.01)
>>> fsig = signal oaconvolve(sig, filt)

>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_mag) = plt.subplots(2, 1)
>>> ax_orig.plot(sig)
>>> ax_orig.set_title('White noise')
>>> ax_mag.plot(fsig)
>>> ax_mag.set_title('Filtered noise')
>>> fig.tight_layout()
>>> fig.show()
```

```
White noise
```

```
Filtered noise
```

`sipy.signal.convolve2d`

`sipy.signal.convolve2d` (*in1*, *in2*, *mode*='full', *boundary*='fill', *fillvalue*=0)

Convolves two 2-dimensional arrays.

Convolve *in1* and *in2* with output size determined by *mode*, and boundary conditions determined by *boundary* and *fillvalue*.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>in1</em></td>
<td>[array_like] First input.</td>
</tr>
<tr>
<td><em>in2</em></td>
<td>[array_like] Second input. Should have the same number of dimensions as <em>in1</em>.</td>
</tr>
<tr>
<td><em>mode</em></td>
<td>[str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:</td>
</tr>
<tr>
<td></td>
<td><strong>full</strong> The output is the full discrete linear convolution of the inputs. (Default)</td>
</tr>
<tr>
<td></td>
<td><strong>valid</strong> The output consists only of those elements that do not rely on the zero-padding.</td>
</tr>
<tr>
<td></td>
<td>In ‘valid’ mode, either <em>in1</em> or <em>in2</em> must be at least as large as the other in every dimension.</td>
</tr>
<tr>
<td><em>boundary</em></td>
<td>[str {'fill', 'wrap', 'symm'}, optional] The boundary condition for the convolution.</td>
</tr>
<tr>
<td><em>fillvalue</em></td>
<td>[float, optional] The value used in case of <em>wrap</em> or <em>symm</em> boundary condition.</td>
</tr>
</tbody>
</table>
same The output is the same size as \textit{in1}, centered with respect to the ‘full’ output.

\textbf{boundary} \texttt{[str{‘fill’, ‘wrap’, ‘symm’}, optional]} A flag indicating how to handle boundaries:
- \texttt{fill} pad input arrays with \texttt{fillvalue}. (default)
- \texttt{wrap} circular boundary conditions.
- \texttt{symm} symmetrical boundary conditions.

\textbf{fillvalue} \texttt{[scalar, optional]} Value to fill pad input arrays with. Default is 0.

\textbf{Returns}

\textbf{out} \texttt{[ndarray]} A 2-dimensional array containing a subset of the discrete linear convolution of \textit{in1} with \textit{in2}.

\textbf{Examples}

Compute the gradient of an image by 2D convolution with a complex Scharr operator. (Horizontal operator is real, vertical is imaginary.) Use symmetric boundary condition to avoid creating edges at the image boundaries.

```python
>>> from scipy import signal
>>> from scipy import misc
>>> ascent = misc.ascent()
>>> scharr = np.array([[-3-3j, 0-10j, 3-3j],
                         [-10+0j, 0+0j, +10+0j],
                         [ 3+3j, 0+10j, 3+3j]]) # Gx + j*Gy
>>> grad = signal.convolve2d(ascent, scharr, boundary='symm', mode='same')
```

```python
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_mag, ax_ang) = plt.subplots(3, 1, figsize=(6, 15))
>>> ax_orig.imshow(ascent, cmap='gray')
>>> ax_orig.set_title('Original')
>>> ax_orig.set_axis_off()
>>> ax_mag.imshow(np.abs(grad), cmap='gray')
>>> ax_mag.set_title('Gradient magnitude')
>>> ax_mag.set_axis_off()
>>> ax_ang.imshow(np.angle(grad), cmap='hsv') # hsv is cyclic, like angles
>>> ax_ang.set_title('Gradient orientation')
>>> ax_ang.set_axis_off()
>>> fig.show()
```

\textbf{scipy.signal.correlate2d}

\texttt{scipy.signal.correlate2d(in1, in2, mode='full', boundary='fill', fillvalue=0)}

Cross-correlate two 2-dimensional arrays.

Cross correlate \textit{in1} and \textit{in2} with output size determined by \textit{mode}, and boundary conditions determined by \textit{boundary} and \textit{fillvalue}.

\textbf{Parameters}

\begin{itemize}
  \item \textbf{in1} \texttt{[array_like]} First input.
  \item \textbf{in2} \texttt{[array_like]} Second input. Should have the same number of dimensions as \textit{in1}.
  \item \textbf{mode} \texttt{[str{‘full’, ‘valid’, ‘same’}, optional]} A string indicating the size of the output:
    \begin{itemize}
      \item \texttt{full} The output is the full discrete linear cross-correlation of the inputs. (Default)
      \item \texttt{valid} No output if inputs do not overlap and result of convolution would be larger than \textit{in1}.
      \item \texttt{same} The output is the same size as \textit{in1}, centered with respect to the ‘full’ output.
    \end{itemize}
  \item \textbf{boundary} \texttt{[str{‘fill’, ‘wrap’, ‘symm’}, optional]} A flag indicating how to handle boundaries:
    \begin{itemize}
      \item \texttt{fill} pad input arrays with \texttt{fillvalue}. (default)
      \item \texttt{wrap} circular boundary conditions.
      \item \texttt{symm} symmetrical boundary conditions.
    \end{itemize}
  \item \textbf{fillvalue} \texttt{[scalar, optional]} Value to fill pad input arrays with. Default is 0.
\end{itemize}
Original

Gradient magnitude

Gradient orientation
**valid**  The output consists only of those elements that do not rely on the zero-padding. In ‘valid’ mode, either \( in1 \) or \( in2 \) must be at least as large as the other in every dimension.

**same**  The output is the same size as \( in1 \), centered with respect to the ‘full’ output.

**boundary**  [str {‘fill’, ‘wrap’, ‘symm’}, optional] A flag indicating how to handle boundaries:
- **fill**  pad input arrays with fill value. (default)
- **wrap**  circular boundary conditions.
- **symm**  symmetrical boundary conditions.

**fillvalue**  [scalar, optional] Value to fill pad input arrays with. Default is 0.

**Returns**

**correlate2d**

[ndarray] A 2-dimensional array containing a subset of the discrete linear cross-correlation of \( in1 \) with \( in2 \).

**Notes**

When using “same” mode with even-length inputs, the outputs of `correlate` and `correlate2d` differ: There is a 1-index offset between them.

**Examples**

Use 2D cross-correlation to find the location of a template in a noisy image:

```python
>>> from scipy import signal
>>> from scipy import misc
>>> face = misc.face(gray=True) - misc.face(gray=True).mean()
>>> template = np.copy(face[300:365, 670:750])  # right eye
>>> template -= template.mean()
>>> face = face + np.random.randn(*face.shape) * 50  # add noise
>>> corr = signal.correlate2d(face, template, boundary='symm', mode='same')
>>> y, x = np.unravel_index(np.argmax(corr), corr.shape)  # find the match

>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_template, ax_corr) = plt.subplots(3, 1, figsize=(6, 15))
>>> ax_orig.imshow(face, cmap='gray')
>>> ax_orig.set_title('Original')
>>> ax_orig.set_axis_off()
>>> ax_template.imshow(template, cmap='gray')
>>> ax_template.set_title('Template')
>>> ax_template.set_axis_off()
>>> ax_corr.imshow(corr, cmap='gray')
>>> ax_corr.set_title('Cross-correlation')
>>> ax_corr.set_axis_off()
>>> ax_orig.plot(x, y, 'ro')
>>> fig.show()
```
Original

Template

Cross-correlation
scipy.signal.sepfir2d

**scipy.signal.sepfir2d(input, hrow, hcol)**

Convolves with a 2-D separable FIR filter.

Convolves the rank-2 input array with the separable filter defined by the rank-1 arrays hrow, and hcol. Mirror symmetric boundary conditions are assumed. This function can be used to find an image given its B-spline representation.

**Parameters**

- **input** [ndarray] The input signal. Must be a rank-2 array.
- **hrow** [ndarray] A rank-1 array defining the row direction of the filter. Must be odd-length
- **hcol** [ndarray] A rank-1 array defining the column direction of the filter. Must be odd-length

**Returns**

- **output** [ndarray] The filtered signal.

**Examples**

Examples are given in the tutorial.

scipy.signal.choose_conv_method

**scipy.signal.choose_conv_method(in1, in2, mode='full', measure=False)**

Find the fastest convolution/correlation method.

This primarily exists to be called during the method='auto' option in convolve and correlate. It can also be used to determine the value of method for many different convolutions of the same dtype/shape. In addition, it supports timing the convolution to adapt the value of method to a particular set of inputs and/or hardware.

**Parameters**

- **in1** [array_like] The first argument passed into the convolution function.
- **in2** [array_like] The second argument passed into the convolution function.
- **mode** [str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:
  - **full** The output is the full discrete linear convolution of the inputs. (Default)
  - **valid** The output consists only of those elements that do not rely on the zero-padding.
  - **same** The output is the same size as in1, centered with respect to the ‘full’ output.
- **measure** [bool, optional] If True, run and time the convolution of in1 and in2 with both methods and return the fastest. If False (default), predict the fastest method using precomputed values.

**Returns**

- **method** [str] A string indicating which convolution method is fastest, either ‘direct’ or ‘fft’
- **times** [dict, optional] A dictionary containing the times (in seconds) needed for each method. This value is only returned if measure=True.

See also:

- convolve
- correlate

### 6.22. Signal processing (scipy.signal)
Notes

Generally, this method is 99% accurate for 2D signals and 85% accurate for 1D signals for randomly chosen input sizes. For precision, use `measure=True` to find the fastest method by timing the convolution. This can be used to avoid the minimal overhead of finding the fastest method later, or to adapt the value of `method` to a particular set of inputs.

Experiments were run on an Amazon EC2 r5a.2xlarge machine to test this function. These experiments measured the ratio between the time required when using `method='auto'` and the time required for the fastest method (i.e., \( \text{ratio} = \text{time}_{\text{auto}} / \min(\text{time}_{\text{fft}}, \text{time}_{\text{direct}}) \)). In these experiments, we found:

- There is a 95% chance of this ratio being less than 1.5 for 1D signals and a 99% chance of being less than 2.5 for 2D signals.
- The ratio was always less than 2.5/5 for 1D/2D signals respectively.
- This function is most inaccurate for 1D convolutions that take between 1 and 10 milliseconds with `method='direct'`. A good proxy for this (at least in our experiments) is \( 1e6 \leq \text{in1.size} * \text{in2.size} \leq 1e7 \).

The 2D results almost certainly generalize to 3D/4D/etc because the implementation is the same (the 1D implementation is different).

All the numbers above are specific to the EC2 machine. However, we did find that this function generalizes fairly decently across hardware. The speed tests were of similar quality (and even slightly better) than the same tests performed on the machine to tune this function's numbers (a mid-2014 15-inch MacBook Pro with 16GB RAM and a 2.5GHz Intel i7 processor).

There are cases when `fftconvolve` supports the inputs but this function returns `direct` (e.g., to protect against floating point integer precision).

New in version 0.19.

Examples

Estimate the fastest method for a given input:

```python
>>> from scipy import signal
>>> img = np.random.rand(32, 32)
>>> filter = np.random.rand(8, 8)
>>> method = signal.choose_conv_method(img, filter, mode='same')
>>> method
'fft'
```

This can then be applied to other arrays of the same dtype and shape:

```python
>>> img2 = np.random.rand(32, 32)
>>> filter2 = np.random.rand(8, 8)
>>> corr2 = signal.correlate(img2, filter2, mode='same', method=method)
>>> conv2 = signal.convolve(img2, filter2, mode='same', method=method)
```

The output of this function (method) works with `correlate` and `convolve`. 
scipy.signal.correlation_lags

scipy.signal.correlation_lags(in1_len, in2_len, mode='full')
Calculates the lag / displacement indices array for 1D cross-correlation.

Parameters

in1_size [int] First input size.
in2_size [int] Second input size.
mode [str {‘full’, ‘valid’, ‘same’}, optional] A string indicating the size of the output. See the document-
tation correlate for more information.

Returns

lags [array] Returns an array containing cross-correlation lag/displacement indices. Indices can
be indexed with the np.argmax of the correlation to return the lag/displacement.

See also:
correlate
Compute the N-dimensional cross-correlation.

Notes

Cross-correlation for continuous functions $f$ and $g$ is defined as:

$$(f * g)(\tau) \triangleq \int_{t_0}^{t_0+T} f(t) g(t + \tau) \, dt$$

Where $\tau$ is defined as the displacement, also known as the lag.

Cross correlation for discrete functions $f$ and $g$ is defined as:

$$(f * g)[n] \triangleq \sum_{-\infty}^{\infty} f[m] g[m + n]$$

Where $n$ is the lag.

Examples

Cross-correlation of a signal with its time-delayed self.

```python
>>> from scipy import signal
>>> rng = np.random.RandomState(0)
>>> x = rng.standard_normal(1000)
>>> y = np.concatenate([rng.standard_normal(100), x])
>>> correlation = signal.correlate(x, y, mode="full")
>>> lags = signal.correlation_lags(x.size, y.size, mode="full")
>>> lag = lags[np.argmax(correlation)]
```

**scipy.signal.bspline**

`scipy.signal.bspline(x, n)`

B-spline basis function of order n.

**Parameters**

- `x` [array like] a knot vector
- `n` [int] The order of the spline. Must be non-negative, i.e., `n >= 0`

**Returns**

- `res` [ndarray] B-spline basis function values

**See also:**

- `cubic`
  A cubic B-spline.
- `quadratic`
  A quadratic B-spline.

**Notes**

Uses `numpy.piecewise` and automatic function-generator.

**Examples**

We can calculate B-Spline basis function of several orders:

```python
>>> from scipy.signal import bspline, cubic, quadratic
>>> bspline(0.0, 1)
1

>>> knots = [-1.0, 0.0, -1.0]
>>> bspline(knots, 2)
array([0.125, 0.75, 0.125])
```
scipy.signal.cubic

`scipy.signal.cubic(x)`

A cubic B-spline.

This is a special case of `bspline`, and equivalent to `bspline(x, 3)`.

**Parameters**

- `x` : [array like] a knot vector

**Returns**

- `res` : [ndarray] Cubic B-spline basis function values

**See also:**

- `bspline`

  B-spline basis function of order n

- `quadratic`

  A quadratic B-spline.

**Examples**

We can calculate B-Spline basis function of several orders:

```python
>>> from scipy.signal import bspline, cubic, quadratic
>>> bspline(0.0, 1)
1
```

```python
>>> knots = [-1.0, 0.0, -1.0]
>>> bspline(knots, 2)
array([0.125, 0.75, 0.125])
```

```python
>>> np.array_equal(bspline(knots, 2), quadratic(knots))
True
```

```python
>>> np.array_equal(bspline(knots, 3), cubic(knots))
True
```
**scipy.signal.quadratic**

`scipy.signal.quadratic(x)`

A quadratic B-spline.

This is a special case of `bspline`, and equivalent to `bspline(x, 2)`.

**Parameters**

- `x` [array like] a knot vector

**Returns**

- `res` [ndarray] Quadratic B-spline basis function values

**See also:**

`bspline`

B-spline basis function of order n

`cubic`

A cubic B-spline.

**Examples**

We can calculate B-Spline basis function of several orders:

```python
>>> from scipy.signal import bspline, cubic, quadratic
>>> bspline(0.0, 1)
1

>>> knots = [-1.0, 0.0, -1.0]
>>> bspline(knots, 2)
array([0.125, 0.75, 0.125])

>>> np.array_equal(bspline(knots, 2), quadratic(knots))
True

>>> np.array_equal(bspline(knots, 3), cubic(knots))
True
```

**scipy.signal.gauss_spline**

`scipy.signal.gauss_spline(x, n)`

Gaussian approximation to B-spline basis function of order n.

**Parameters**

- `x` [array] a knot vector
- `n` [int] The order of the spline. Must be non-negative, i.e., `n >= 0`

**Returns**

- `res` [ndarray] B-spline basis function values approximated by a zero-mean Gaussian function.
Notes

The B-spline basis function can be approximated well by a zero-mean Gaussian function with standard-deviation equal to \( \sigma = (n + 1)/12 \) for large \( n \):

\[
\frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{x^2}{2\sigma^2}\right)
\]

References

[1], [2]

Examples

We can calculate B-Spline basis functions approximated by a gaussian distribution:

```python
>>> from scipy.signal import gauss_spline, bspline
>>> knots = np.array([-1.0, 0.0, -1.0])
>>> gauss_spline(knots, 3)
array([0.15418033, 0.6909883, 0.15418033]) # may vary
```

```python
>>> bspline(knots, 3)
array([0.16666667, 0.66666667, 0.16666667]) # may vary
```

scipy.signal.cspline1d

*scipy.signal.cspline1d*(signal, lamb=0.0)

Compute cubic spline coefficients for rank-1 array.

Find the cubic spline coefficients for a 1-D signal assuming mirror-symmetric boundary conditions. To obtain the signal back from the spline representation mirror-symmetric-convolve these coefficients with a length 3 FIR window \([1.0, 4.0, 1.0]/6.0\).

**Parameters**

- `signal` : [ndarray] A rank-1 array representing samples of a signal.
- `lamb` : [float, optional] Smoothing coefficient, default is 0.0.

**Returns**

- `c` : [ndarray] Cubic spline coefficients.

See also:

`cspline1d_eval`

Evaluate a cubic spline at the new set of points.
Examples

We can filter a signal to reduce and smooth out high-frequency noise with a cubic spline:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import cspline1d, cspline1d_eval
>>> sig = np.repeat([0., 1., 0.], 100)
>>> sig += np.random.randn(len(sig))*0.05  # add noise
>>> time = np.linspace(0, len(sig))
>>> filtered = cspline1d_eval(cspline1d(sig), time)
>>> plt.plot(sig, label="signal")
>>> plt.plot(time, filtered, label="filtered")
>>> plt.legend()
>>> plt.show()
```

scipy.signal.cspline1d

scipy.signal.cspline1d(signal, lamb=0.0)
Compute cubic spline coefficients for rank-1 array.

Parameters

- signal [ndarray] A rank-1 array representing samples of a signal.
- lamb [float, optional] Smoothing coefficient (must be zero for now).

Returns

- c [ndarray] Cubic spline coefficients.

See also:

- cspline1d_eval
  Evaluate a cubic spline at the new set of points.
Notes

Find the quadratic spline coefficients for a 1-D signal assuming mirror-symmetric boundary conditions. To obtain the signal back from the spline representation mirror-symmetric-convolve these coefficients with a length 3 FIR window [1.0, 6.0, 1.0]/8.0.

Examples

We can filter a signal to reduce and smooth out high-frequency noise with a quadratic spline:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import qspline1d, qspline1d_eval
>>> sig = np.repeat([0., 1., 0.], 100)
>>> sig += np.random.randn(len(sig))*0.05  # add noise
>>> time = np.linspace(0, len(sig))
>>> filtered = qspline1d_eval(qspline1d(sig), time)
>>> plt.plot(sig, label="signal")
>>> plt.plot(time, filtered, label="filtered")
>>> plt.legend()
>>> plt.show()
```

```
0 50 100 150 200 250 300
0.2
0.0
0.2
0.4
0.6
0.8
1.0
```

`scipy.signal.cspline2d`

`scipy.signal.cspline2d(input, lambda=0.0, precision=-1.0)`

Coefficients for 2-D cubic (3rd order) B-spline.

Return the third-order B-spline coefficients over a regularly spaced input grid for the two-dimensional input image.

Parameters

- `input` [ndarray] The input signal.
- `lambda` [float] Specifies the amount of smoothing in the transfer function.
- `precision` [float] Specifies the precision for computing the infinite sum needed to apply mirror-symmetric boundary conditions.
Returns

output  [ndarray] The filtered signal.

Examples

Examples are given in the tutorial.

scipy.signal.qspline2d

scipy.signal.qspline2d (input, lambda=0.0, precision=-1.0)

Coefficients for 2-D quadratic (2nd order) B-spline:

Return the second-order B-spline coefficients over a regularly spaced input grid for the two-dimensional input image.

Parameters

input  [ndarray] The input signal.
lambda  [float] Specifies the amount of smoothing in the transfer function.
precision  [float] Specifies the precision for computing the infinite sum needed to apply mirror-symmetric boundary conditions.

Returns

output  [ndarray] The filtered signal.

Examples

Examples are given in the tutorial.

scipy.signal.cspline1d_eval

scipy.signal.cspline1d_eval (cj, newx, dx=1.0, x0=0)

Evaluate a cubic spline at the new set of points.

dx is the old sample-spacing while x0 was the old origin. In other-words the old-sample points (knot-points) for which the cj represent spline coefficients were at equally-spaced points of:

oldx = x0 + j*dx j=0…N-1, with N=len(cj)

Edges are handled using mirror-symmetric boundary conditions.

Parameters

cj  [ndarray] cubic spline coefficients
newx  [ndarray] New set of points.
dx  [float, optional] Old sample-spacing, the default value is 1.0.
x0  [int, optional] Old origin, the default value is 0.

Returns

res  [ndarray] Evaluated a cubic spline points.

See also:

cspline1d

Compute cubic spline coefficients for rank-1 array.
Examples

We can filter a signal to reduce and smooth out high-frequency noise with a cubic spline:

\[
\begin{align*}
\text{import matplotlib.pyplot as plt} \\
\text{from scipy.signal import cspline1d, cspline1d_eval} \\
\text{sig = np.repeat([0., 1., 0.], 100)} \\
\text{sig += np.random.randn(len(sig))*0.05 \quad \# add noise} \\
\text{time = np.linspace(0, len(sig))} \\
\text{filtered = cspline1d_eval(cspline1d(sig), time)} \\
\text{plt.plot(sig, label="signal"}) \\
\text{plt.plot(time, filtered, label="filtered")} \\
\text{plt.legend()} \\
\text{plt.show()}
\end{align*}
\]

scipy.signal.qspline1d_eval

\[\text{scipy.signal.qspline1d_eval}(cj, newx, dx=1.0, x0=0)\]

Evaluate a quadratic spline at the new set of points.

Parameters

- \(cj\): [ndarray] Quadratic spline coefficients.
- \(newx\): [ndarray] New set of points.
- \(dx\): [float, optional] Old sample-spacing, the default value is 1.0.
- \(x0\): [int, optional] Old origin, the default value is 0.

Returns

- \(res\): [ndarray] Evaluated a quadratic spline points.

See also:

qspline1d

Compute quadratic spline coefficients for rank-1 array.
Notes

dx is the old sample-spacing while x0 was the old origin. In other-words the old-sample points (knot-points) for which the \( c_j \) represent spline coefficients were at equally-spaced points of:

\[
\text{oldx} = x_0 + j \times dx \quad j=0\ldots N-1, \quad \text{with} \quad N = \text{len}(c_j)
\]

Edges are handled using mirror-symmetric boundary conditions.

Examples

We can filter a signal to reduce and smooth out high-frequency noise with a quadratic spline:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import qspline1d, qspline1d_eval
>>> sig = np.repeat([0., 1., 0.], 100)
>>> sig += np.random.randn(len(sig)) * 0.05  # add noise
>>> time = np.linspace(0, len(sig))
>>> filtered = qspline1d_eval(qspline1d(sig), time)
>>> plt.plot(sig, label="signal")
>>> plt.plot(time, filtered, label="filtered")
>>> plt.legend()
>>> plt.show()
```
**scipy.signal.spline_filter**

`scipy.signal.spline_filter(Iin, lmbda=5.0)`  
Smoothing spline (cubic) filtering of a rank-2 array.

Filter an input data set, `Iin`, using a (cubic) smoothing spline of fall-off `lmbda`.

**Parameters**

- `Iin`: [array like] input data set
- `lmbda`: [float, optional] spline smoothing fall-off value, default is 5.0.

**Returns**

- `res`: [ndarray] filtered input data

**Examples**

We can filter an multi dimensional signal (ex: 2D image) using cubic B-spline filter:

```python
>>> from scipy.signal import spline_filter
>>> import matplotlib.pyplot as plt
>>> orig_img = np.eye(20)  # create an image
>>> orig_img[10, :] = 1.0
>>> sp_filter = spline_filter(orig_img, lmbda=0.1)
>>> f, ax = plt.subplots(1, 2, sharex=True)
>>> for ind, data in enumerate([[orig_img, "original image"], ...
... [sp_filter, "spline filter"])]:
... ax[ind].imshow(data[0], cmap='gray_r')
... ax[ind].set_title(data[1])
>>> plt.tight_layout()
>>> plt.show()
```

**scipy.signal.order_filter**

- `scipy.signal.order_filter(a, domain, rank)`
  - Perform an order filter on an N-D array.

  Perform an order filter on the array in. The domain argument acts as a mask centered over each pixel. The non-zero elements of domain are used to select elements surrounding each input pixel which are placed in a list. The list is sorted, and the output for that pixel is the element corresponding to rank in the sorted list.

  **Parameters**

  - `a` [ndarray] The N-dimensional input array.
  - `domain` [array_like] A mask array with the same number of dimensions as `a`. Each dimension should have an odd number of elements.
  - `rank` [int] A non-negative integer which selects the element from the sorted list (0 corresponds to the smallest element, 1 is the next smallest element, etc.).
Returns

```
out [ndarray] The results of the order filter in an array with the same shape as a.
```

Examples

```python
>>> from scipy import signal
>>> x = np.arange(25).reshape(5, 5)
>>> domain = np.identity(3)
>>> x
array([[0, 1, 2, 3, 4],
       [5, 6, 7, 8, 9],
       [10, 11, 12, 13, 14],
       [15, 16, 17, 18, 19],
       [20, 21, 22, 23, 24]])
>>> signal.order_filter(x, domain, 0)
array([[0., 0., 0., 0., 0.],
       [0., 0., 1., 2., 0.],
       [0., 5., 6., 7., 0.],
       [0., 10., 11., 12., 0.],
       [0., 0., 0., 0., 0.]])
>>> signal.order_filter(x, domain, 2)
array([[6., 7., 8., 9., 4.],
       [16., 17., 18., 19., 14.],
       [21., 22., 23., 24., 19.],
       [20., 21., 22., 23., 24.]])
```

`scipy.signal.medfilt`

`scipy.signal.medfilt(volume, kernel_size=None)`

Perform a median filter on an N-dimensional array.

Apply a median filter to the input array using a local window-size given by `kernel_size`. The array will automatically be zero-padded.

Parameters

```
volume [array_like] An N-dimensional input array.
kernel_size [array_like, optional] A scalar or an N-length list giving the size of the median filter window in each dimension. Elements of `kernel_size` should be odd. If `kernel_size` is a scalar, then this scalar is used as the size in each dimension. Default size is 3 for each dimension.
```

Returns

```
out [ndarray] An array the same size as input containing the median filtered result.
```

Warns

```
UserWarning
If array size is smaller than kernel size along any dimension
```

See also:

`scipy.ndimage.median_filter`
Notes

The more general function `scipy.ndimage.median_filter` has a more efficient implementation of a median filter and therefore runs much faster.

`scipy.signal.medfilt2d`

`scipy.signal.medfilt2d(input, kernel_size=3)`

Median filter a 2-dimensional array.

Apply a median filter to the `input` array using a local window-size given by `kernel_size` (must be odd). The array is zero-padded automatically.

Parameters

- `input` [array_like] A 2-dimensional input array.
- `kernel_size` [array_like, optional] A scalar or a list of length 2, giving the size of the median filter window in each dimension. Elements of `kernel_size` should be odd. If `kernel_size` is a scalar, then this scalar is used as the size in each dimension. Default is a kernel of size `(3, 3)`.

Returns

- `out` [ndarray] An array the same size as input containing the median filtered result.

See also:

`scipy.ndimage.median_filter`

Notes

The more general function `scipy.ndimage.median_filter` has a more efficient implementation of a median filter and therefore runs much faster.

`scipy.signal.wiener`

`scipy.signal.wiener(im, mysize=None, noise=None)`

Perform a Wiener filter on an N-dimensional array.

Apply a Wiener filter to the N-dimensional array `im`.

Parameters

- `mysize` [int or array_like, optional] A scalar or an N-length list giving the size of the Wiener filter window in each dimension. Elements of mysize should be odd. If mysize is a scalar, then this scalar is used as the size in each dimension.
- `noise` [float, optional] The noise-power to use. If None, then noise is estimated as the average of the local variance of the input.

Returns

- `out` [ndarray] Wiener filtered result with the same shape as `im`. 
Notes

This implementation is similar to wiener2 in Matlab/Octave. For more details see [1]

References

[1]

Examples

```python
>>> from scipy.misc import face
>>> from scipy.signal.signaltools import wiener
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> img = np.random.random((40, 40)) #Create a random image
>>> filtered_img = wiener(img, (5, 5)) #Filter the image
>>> f, (plot1, plot2) = plt.subplots(1, 2)
>>> plot1.imshow(img)
>>> plot2.imshow(filtered_img)
>>> plt.show()
```

scipy.signal.symiirorder1

scipy.signal.symiirorder1(input, c0, z1, precision=-1.0)

Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of first-order sections. The second section uses a reversed sequence. This implements a system with the following transfer function and mirror-symmetric boundary conditions:

\[
H(z) = \frac{c_0}{(1-z1/z)(1 - z1/z)}
\]
The resulting signal will have mirror symmetric boundary conditions as well.

**Parameters**

- **input** ([ndarray]) The input signal.
- **c0, z1** ([scalar]) Parameters in the transfer function.
- **precision** Specifies the precision for calculating initial conditions of the recursive filter based on mirror-symmetric input.

**Returns**

- **output** ([ndarray]) The filtered signal.

**scipy.signal.symiirorder2**

**scipy.signal.symiirorder2** (*input, r, omega, precision=-1.0*)

Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of second-order sections. The second section uses a reversed sequence. This implements the following transfer function:

\[
H(z) = \frac{cs^2}{(1 - a2/z - a3/z^2)(1 - a2z - a3z^2)}
\]

where:

- \(a2 = (2r \cos \omega)\)
- \(a3 = -r^2\)
- \(cs = 1 - 2r \cos \omega + r^2\)

**Parameters**

- **input** ([ndarray]) The input signal.
- **r, omega** ([float]) Parameters in the transfer function.
- **precision** [float] Specifies the precision for calculating initial conditions of the recursive filter based on mirror-symmetric input.

**Returns**

- **output** ([ndarray]) The filtered signal.

**scipy.signal.lfilter**

**scipy.signal.lfilter** (*b, a, x, axis=-1, zi=None*)

Filter data along one-dimension with an IIR or FIR filter.

Filter a data sequence, \(x\), using a digital filter. This works for many fundamental data types (including Object type). The filter is a direct form II transposed implementation of the standard difference equation (see Notes).

The function `sosfilt` (and filter design using `output='sos'`) should be preferred over `lfilter` for most filtering tasks, as second-order sections have fewer numerical problems.

**Parameters**

- **b** ([array_like]) The numerator coefficient vector in a 1-D sequence.
- **a** ([array_like]) The denominator coefficient vector in a 1-D sequence. If \(a[0]\) is not 1, then both \(a\) and \(b\) are normalized by \(a[0]\).
- **x** ([array_like]) An N-dimensional input array.
axis [int, optional] The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.

zi [array_like, optional] Initial conditions for the filter delays. It is a vector (or array of vectors for an N-dimensional input) of length max(len(a), len(b)) - 1. If zi is None or is not given then initial rest is assumed. See lfiltic for more information.

Returns

y [array] The output of the digital filter.

zf [array, optional] If zi is None, this is not returned, otherwise, zf holds the final filter delay values.

See also:
lfiltic
    Construct initial conditions for lfilter.
lfilter_zi
    Compute initial state (steady state of step response) for lfilter.

filtfilt
    A forward-backward filter, to obtain a filter with linear phase.
savgol_filter
    A Savitzky-Golay filter.
sosfilt
    Filter data using cascaded second-order sections.
sosfiltfilt
    A forward-backward filter using second-order sections.

Notes

The filter function is implemented as a direct II transposed structure. This means that the filter implements:

\[
\begin{align*}
a[0]^*y[n] &= b[0]^*x[n] + b[1]^*x[n-1] + \ldots + b[M]^*x[n-M] \\
&\quad - a[1]^*y[n-1] - \ldots - a[N]^*y[n-N] \\
\end{align*}
\]

where \( M \) is the degree of the numerator, \( N \) is the degree of the denominator, and \( n \) is the sample number. It is implemented using the following difference equations (assuming \( M = N \)):

\[
\begin{align*}
a[0]^*y[n] &= b[0]^*x[n] + d[0][n-1] \\
\quad \ldots \\
d[N-1][n] &= b[N]^*x[n] - a[N]^*y[n] \\
\end{align*}
\]

where \( d \) are the state variables.

The rational transfer function describing this filter in the z-transform domain is:
\[ Y(z) = - \frac{b[0] + b[1]z + \ldots + b[M] z}{a[0] + a[1]z + \ldots + a[N] z} \]

**Examples**

Generate a noisy signal to be filtered:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(-1, 1, 201)
>>> x = (np.sin(2*np.pi*0.75*t*(1-t) + 2.1) +
      ... 0.1*np.sin(2*np.pi*1.25*t + 1) +
      ... 0.18*np.cos(2*np.pi*3.85*t))
>>> xn = x + np.random.randn(len(t)) * 0.08
```

Create an order 3 lowpass butterworth filter:

```python
>>> b, a = signal.butter(3, 0.05)
```

Apply the filter to \( x \). Use \texttt{lfilter\_zi} to choose the initial condition of the filter:

```python
>>> zi = signal.lfilter\_zi(b, a)
>>> z, _ = signal.lfilter(b, a, xn, zi=zi*xn[0])
```

Apply the filter again, to have a result filtered at an order the same as \texttt{filtfilt}:

```python
>>> z2, _ = signal.lfilter(b, a, z, zi=zi*z[0])
```

Use \texttt{filtfilt} to apply the filter:

```python
>>> y = signal.filtfilt(b, a, xn)
```

Plot the original signal and the various filtered versions:

```python
>>> plt.figure
>>> plt.plot(t, xn, 'b', alpha=0.75)
>>> plt.plot(t, z, 'r--', t, z2, 'r', t, y, 'k')
>>> plt.legend(('noisy signal', 'lfilter, once', 'lfilter, twice',
              'filtfilt'), loc='best')
>>> plt.grid(True)
>>> plt.show()
```
scipy.signal.lfiltic

scipy.signal.lfiltic(b, a, y, x=None)

Construct initial conditions for lfilter given input and output vectors.

Given a linear filter (b, a) and initial conditions on the output y and the input x, return the initial conditions on the state vector zi which is used by lfilter to generate the output given the input.

Parameters

- b [array_like] Linear filter term.
- a [array_like] Linear filter term.
- y [array_like] Initial conditions.
  - If N = len(a) - 1, then y = {y[-1], y[-2], ..., y[-N]}.
  - If y is too short, it is padded with zeros.
- x [array_like, optional] Initial conditions.
  - If M = len(b) - 1, then x = {x[-1], x[-2], ..., x[-M]}.
  - If x is not given, its initial conditions are assumed zero.
  - If x is too short, it is padded with zeros.

Returns

- zi [ndarray] The state vector $zi = \{z_0[-1], z_1[-1], ..., z_{K-1}[\cdot]\}$, where $K = \max(M, N)$.

See also:

lfilter, lfilter_zi
**scipy.signal.lfilter_zi**

`scipy.signal.lfilter_zi(b, a)`

Construct initial conditions for `lfilter` for step response steady-state.

Compute an initial state \( z_i \) for the `lfilter` function that corresponds to the steady state of the step response.

A typical use of this function is to set the initial state so that the output of the filter starts at the same value as the first element of the signal to be filtered.

**Parameters**

- **b**, **a**
  - `[array_like (1-D)]` The IIR filter coefficients. See `lfilter` for more information.

**Returns**

- **zi**
  - `[1-D ndarray]` The initial state for the filter.

**See also:**

`lfilter`, `lfiltic`, `filtfilt`

**Notes**

A linear filter with order \( m \) has a state space representation \((A, B, C, D)\), for which the output \( y \) of the filter can be expressed as:

\[
\begin{align*}
  z(n+1) &= A \ast z(n) + B \ast x(n) \\
  y(n) &= C \ast z(n) + D \ast x(n)
\end{align*}
\]

where \( z(n) \) is a vector of length \( m \), \( A \) has shape \((m, m)\), \( B \) has shape \((m, 1)\), \( C \) has shape \((1, m)\) and \( D \) has shape \((1, 1)\) (assuming \( x(n) \) is a scalar). `lfilter_zi` solves:

\[
  z_i = A \ast z_i + B
\]

In other words, it finds the initial condition for which the response to an input of all ones is a constant.

Given the filter coefficients \( a \) and \( b \), the state space matrices for the transposed direct form II implementation of the linear filter, which is the implementation used by `scipy.signal.lfilter`, are:

\[
\begin{align*}
  A &= \text{scipy.linalg.companion}(a).T \\
  B &= b[1:] - a[1:] \ast b[0]
\end{align*}
\]

assuming \( a[0] \) is 1.0; if \( a[0] \) is not 1, \( a \) and \( b \) are first divided by \( a[0] \).

**Examples**

The following code creates a lowpass Butterworth filter. Then it applies that filter to an array whose values are all 1.0; the output is also all 1.0, as expected for a lowpass filter. If the \( z_i \) argument of `lfilter` had not been given, the output would have shown the transient signal.

```python
>>> from numpy import array, ones
>>> from scipy.signal import lfilter, lfilter_zi, butter
>>> b, a = butter(5, 0.25)
>>> zi = lfilter_zi(b, a)
>>> y, zo = lfilter(b, a, ones(10), zi=zi)
```

(continues on next page)
Another example:

```python
>>> x = np.array([0.5, 0.5, 0.5, 0.0, 0.0, 0.0, 0.0])
>>> y, zf = scipy.signal.lfilter(b, a, x, zi=zi*x[0])
>>> y
array([ 0.5 , 0.5 , 0.5 , 0.49836039, 0.48610528, 0.44399389, 0.35505241])
```

Note that the `zi` argument to `lfilter` was computed using `lfilter_zi` and scaled by `x[0]`. Then the output `y` has no transient until the input drops from 0.5 to 0.0.

### scipy.signal.filtfilt

**scipy.signal.filtfilt**  
`scipy.signal.filtfilt(b, a, x, axis=-1, padtype='odd', padlen=None, method='pad', irlen=None)`  
Apply a digital filter forward and backward to a signal.

- **Parameters**
  - `b` ([N.], array_like): The numerator coefficient vector of the filter.
  - `a` ([N.], array_like): The denominator coefficient vector of the filter. If `a[0]` is not 1, then both `a` and `b` are normalized by `a[0].`
  - `x` ([array_like]): The array of data to be filtered.
  - `axis` ([int, optional]): The axis of `x` to which the filter is applied. Default is `-1`.
  - `padtype` ([str or None, optional]): Must be `'odd'`, `'even'`, `'constant'`, or None. This determines the type of extension to use for the padded signal to which the filter is applied. If `padtype` is None, no padding is used. The default is `'odd'`.
  - `padlen` ([int or None, optional]): The number of elements by which to extend `x` at both ends of `axis` before applying the filter. This value must be less than `x.shape[axis] - 1`. `padlen=0` implies no padding. The default value is `3 * max(len(a), len(b))`.
  - `method` ([str, optional]): Determines the method for handling the edges of the signal, either “pad” or “gust”. When `method` is “pad”, the signal is padded; the type of padding is determined by `padtype` and `padlen`, and `irlen` is ignored. When `method` is “gust”, Gustafsson's method is used, and `padtype` and `padlen` are ignored.
  - `irlen` ([int or None, optional]): When `method` is “gust”, `irlen` specifies the length of the impulse response of the filter. If `irlen` is None, no part of the impulse response is ignored. For a long signal, specifying `irlen` can significantly improve the performance of the filter.

- **Returns**
  - `y` ([ndarray]): The filtered output with the same shape as `x`.

**See also:**

- `sosfiltfilt`
- `lfilter_zi`
- `lfilter`
- `lfiltic`
- `savgol_filter`
- `sosfilt`

6.22. Signal processing (scipy.signal)
Notes

When method is “pad”, the function pads the data along the given axis in one of three ways: odd, even or constant. The odd and even extensions have the corresponding symmetry about the end point of the data. The constant extension extends the data with the values at the end points. On both the forward and backward passes, the initial condition of the filter is found by using \texttt{lfilt\_zi} and scaling it by the end point of the extended data.

When method is “gust”, Gustafsson’s method \cite{1} is used. Initial conditions are chosen for the forward and backward passes so that the forward-backward filter gives the same result as the backward-forward filter.

The option to use Gustafsson’s method was added in scipy version 0.16.0.

References

\cite{1}

Examples

The examples will use several functions from \textit{scipy.signal}.

generate a one second signal that is the sum of two pure sine waves, with frequencies 5 Hz and 250 Hz, sampled at 2000 Hz.

\begin{verbatim}
>>> t = np.linspace(0, 1.0, 2001)
>>> xlow = np.sin(2 * np.pi * 5 * t)
>>> xhigh = np.sin(2 * np.pi * 250 * t)
>>> x = xlow + xhigh
\end{verbatim}

Now create a lowpass Butterworth filter with a cutoff of 0.125 times the Nyquist frequency, or 125 Hz, and apply it to \texttt{x} with \texttt{filt\_filt}. The result should be approximately \texttt{xlow}, with no phase shift.

\begin{verbatim}
>>> b, a = signal.butter(8, 0.125)
>>> y = signal.filt\_filt(b, a, x, padlen=150)
>>> np.abs(y - xlow).max()
0.1086182074789912e-06
\end{verbatim}

We get a fairly clean result for this artificial example because the odd extension is exact, and with the moderately long padding, the filter’s transients have dissipated by the time the actual data is reached. In general, transient effects at the edges are unavoidable.

The following example demonstrates the option method=“gust”.

First, create a filter.

\begin{verbatim}
>>> b, a = signal.ellip(4, 0.01, 120, 0.125) # Filter to be applied.
>>> np.random.seed(123456)
\end{verbatim}

\texttt{sig} is a random input signal to be filtered.

\begin{verbatim}
>>> n = 60
>>> sig = np.random.randn(n)**3 + 3*np.random.randn(n).cumsum()
\end{verbatim}
Apply `filtfilt` to `sig`, once using the Gustafsson method, and once using padding, and plot the results for comparison.

```python
>>> fgust = signal.filtfilt(b, a, sig, method="gust")
>>> fpad = signal.filtfilt(b, a, sig, padlen=50)
>>> plt.plot(sig, 'k-', label='input')
>>> plt.plot(fgust, 'b-', linewidth=4, label='gust')
>>> plt.plot(fpad, 'c-', linewidth=1.5, label='pad')
>>> plt.legend(loc='best')
>>> plt.show()
```

The `irlen` argument can be used to improve the performance of Gustafsson's method.

Estimate the impulse response length of the filter.

```python
>>> z, p, k = signal.tf2zpk(b, a)
>>> eps = 1e-9
>>> r = np.max(np.abs(p))
>>> approx_impulse_len = int(np.ceil(np.log(eps) / np.log(r)))
>>> approx_impulse_len
137
```

Apply the filter to a longer signal, with and without the `irlen` argument. The difference between `y1` and `y2` is small. For long signals, using `irlen` gives a significant performance improvement.

```python
>>> x = np.random.randn(5000)
>>> y1 = signal.filtfilt(b, a, x, method='gust')
>>> y2 = signal.filtfilt(b, a, x, method='gust', irlen=approx_impulse_len)
>>> print(np.max(np.abs(y1 - y2)))
1.80056858312e-10
```
scipy.signal.savgol_filter

scipy.signal.savgol_filter(x, window_length, polyorder, deriv=0, delta=1.0, axis=-1, mode='interp', cval=0.0)

Apply a Savitzky-Golay filter to an array.

This is a 1-D filter. If x has dimension greater than 1, axis determines the axis along which the filter is applied.

Parameters

x [array_like] The data to be filtered. If x is not a single or double precision floating point array, it will be converted to type numpy.float64 before filtering.

window_length [int] The length of the filter window (i.e., the number of coefficients). window_length must be a positive odd integer. If mode is 'interp', window_length must be less than or equal to the size of x.

polyorder [int] The order of the polynomial used to fit the samples. polyorder must be less than window_length.

deriv [int, optional] The order of the derivative to compute. This must be a nonnegative integer. The default is 0, which means to filter the data without differentiating.

delta [float, optional] The spacing of the samples to which the filter will be applied. This is only used if deriv > 0. Default is 1.0.

axis [int, optional] The axis of the array x along which the filter is to be applied. Default is -1.

mode [str, optional] Must be 'mirror', 'constant', 'nearest', 'wrap' or 'interp'. This determines the type of extension to use for the padded signal to which the filter is applied. When mode is 'constant', the padding value is given by cval. See the Notes for more details on 'mirror', 'constant', 'wrap', and 'nearest'. When the 'interp' mode is selected (the default), no extension is used. Instead, a degree polyorder polynomial is fit to the last window_length values of the edges, and this polynomial is used to evaluate the last window_length // 2 output values.

cval [scalar, optional] Value to fill past the edges of the input if mode is 'constant'. Default is 0.0.

Returns

y [ndarray, same shape as x] The filtered data.

See also:

savgol_coeffs

Notes

Details on the mode options:

'mirror':
  Repeats the values at the edges in reverse order. The value closest to the edge is not included.

'nearest':
  The extension contains the nearest input value.

'constant':
  The extension contains the value given by the cval argument.

'wrap':
  The extension contains the values from the other end of the array.

For example, if the input is [1, 2, 3, 4, 5, 6, 7, 8], and window_length is 7, the following shows the extended data for the various mode options (assuming cval is 0):
New in version 0.14.0.

**Examples**

```python
>>> from scipy.signal import savgol_filter
>>> np.set_printoptions(precision=2)  # For compact display.
>>> x = np.array([2, 2, 5, 2, 1, 0, 1, 4, 9])
Filter with a window length of 5 and a degree 2 polynomial. Use the defaults for all other parameters.
```
```
>>> savgol_filter(x, 5, 2)
array([1.66, 3.17, 3.54, 2.86, 0.66, 0.17, 1.0 , 4.0 , 9.0])
Note that the last five values in x are samples of a parabola, so when mode='interp' (the default) is used with polyorder=2, the last three values are unchanged. Compare that to, for example, mode='nearest':
```
```
>>> savgol_filter(x, 5, 2, mode='nearest')
array([1.74, 3.03, 3.54, 2.86, 0.66, 0.17, 1.0 , 4.6 , 7.97])
```

**scipy.signal.deconvolve**

**scipy.signal.deconvolve**(signal, divisor)

Deconvolves divisor out of signal using inverse filtering.

Returns the quotient and remainder such that signal = convolve(divisor, quotient) + remainder

**Parameters**

- signal [array_like] Signal data, typically a recorded signal
- divisor [array_like] Divisor data, typically an impulse response or filter that was applied to the original signal

**Returns**

- quotient [ndarray] Quotient, typically the recovered original signal
- remainder [ndarray] Remainder

**See also:**

**numpy.polydiv**

performs polynomial division (same operation, but also accepts poly1d objects)
Examples

Deconvolve a signal that’s been filtered:

```python
>>> from scipy import signal
>>> original = [0, 1, 0, 0, 1, 0, 0]
>>> impulse_response = [2, 1]
>>> recorded = signal.convolve(impulse_response, original)
array([0, 2, 1, 0, 2, 3, 1, 0, 0])
>>> recovered, remainder = signal.deconvolve(recorded, impulse_response)
array([ 0., 1., 0., 0., 1., 1., 0., 0.])
```

`sosfilt`

Filter data along one dimension using cascaded second-order sections.

Filter a data sequence, `x`, using a digital IIR filter defined by `sos`.

**Parameters**

- `sos` : array_like
  Array of second-order filter coefficients, must have shape (n_sections, 6). Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.

- `x` : array_like
  An N-dimensional input array.

- `axis` : int, optional
  The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.

- `zi` : array_like, optional
  Initial conditions for the cascaded filter delays. It is a (at least 2D) vector of shape (n_sections, ..., 2, ...), where ..., 2, ... denotes the shape of x, but with x.shape[axis] replaced by 2. If zi is None or is not given then initial rest (i.e., all zeros) is assumed. Note that these initial conditions are not the same as the initial conditions given by `lfiltic` or `lfilter_zi`.

**Returns**

- `y` : ndarray
  The output of the digital filter.

- `zf` : ndarray, optional
  If zi is None, this is not returned, otherwise, zf holds the final filter delay values.

See also:

- `zpk2sos`, `sos2zpk`, `sosfilt_zi`, `sosfiltfilt`, `sosfreqz`

**Notes**

The filter function is implemented as a series of second-order filters with direct-form II transposed structure. It is designed to minimize numerical precision errors for high-order filters.

New in version 0.16.0.
Examples

Plot a 13th-order filter's impulse response using both `lfilter` and `sosfilt`, showing the instability that results from trying to do a 13th-order filter in a single stage (the numerical error pushes some poles outside of the unit circle):

```python
>>> import matplotlib.pyplot as plt
>>> from scipy import signal
>>> b, a = signal.ellip(13, 0.009, 80, 0.05, output='ba')
>>> sos = signal.ellip(13, 0.009, 80, 0.05, output='sos')
>>> x = signal.unit_impulse(700)
>>> y_tf = signal.lfilter(b, a, x)
>>> y_sos = signal.sosfilt(sos, x)
>>> plt.plot(y_tf, 'r', label='TF')
>>> plt.plot(y_sos, 'k', label='SOS')
>>> plt.legend(loc='best')
>>> plt.show()
```

`scipy.signal.sosfilt_zi`

`scipy.signal.sosfilt_zi(sos)`

Construct initial conditions for sosfilt for step response steady-state.

Compute an initial state \( z_i \) for the `sosfilt` function that corresponds to the steady state of the step response.

A typical use of this function is to set the initial state so that the output of the filter starts at the same value as the first element of the signal to be filtered.

**Parameters**

- `sos` [array_like] Array of second-order filter coefficients, must have shape \((n_{sections}, 6)\). See `sosfilt` for the SOS filter format specification.

**Returns**

- `zi` [ndarray] Initial conditions suitable for use with `sosfilt.shape` \((n_{sections}, 2)\).
See also:

`sosfilt`, `zpk2sos`

Notes

New in version 0.16.0.

Examples

Filter a rectangular pulse that begins at time 0, with and without the use of the `zi` argument of `scipy.signal.sosfilt`.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> sos = signal.butter(9, 0.125, output='sos')
>>> zi = signal.sosfilt_zi(sos)
>>> x = (np.arange(250) < 100).astype(int)
>>> f1 = signal.sosfilt(sos, x)
>>> f2, zo = signal.sosfilt(sos, x, zi=zi)

>>> plt.plot(x, 'k--', label='x')
>>> plt.plot(f1, 'b', alpha=0.5, linewidth=2, label='filtered')
>>> plt.plot(f2, 'g', alpha=0.25, linewidth=4, label='filtered with zi')
>>> plt.legend(loc='best')
>>> plt.show()
```

![Plot of rectangular pulse filtered and filtered with initial conditions](image)
scipy.signal.sosfiltfilt

scipy.signal.sosfiltfilt (sos, x, axis=-1, padtype='odd', padlen=None)

A forward-backward digital filter using cascaded second-order sections.

See filtfilt for more complete information about this method.

Parameters

- **sos** [array_like] Array of second-order filter coefficients, must have shape \((n\_sections, 6)\). Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.
- **x** [array_like] The array of data to be filtered.
- **axis** [int, optional] The axis of \(x\) to which the filter is applied. Default is -1.
- **padtype** [str or None, optional] Must be 'odd', 'even', 'constant', or None. This determines the type of extension to use for the padded signal to which the filter is applied. If padtype is None, no padding is used. The default is 'odd'.
- **padlen** [int or None, optional] The number of elements by which to extend \(x\) at both ends of \(axis\) before applying the filter. This value must be less than \(x\_shape[axis] - 1\). padlen=0 implies no padding. The default value is:

\[
3 \times (2 \times \text{len}(sos) + 1 - \min((\text{sos}[:, 2] == 0).\text{sum}(), (\text{sos}[:, 5] == 0).\text{sum}()))
\]

The extra subtraction at the end attempts to compensate for poles and zeros at the origin (e.g. for odd-order filters) to yield equivalent estimates of padlen to those of filtfilt for second-order section filters built with scipy.signal functions.

Returns

- **y** [ndarray] The filtered output with the same shape as \(x\).

See also:

filtfilt, sosfilt, sosfilt_zi, sosfreqz

Notes

New in version 0.18.0.

Examples

```python
>>> from scipy.signal import sosfiltfilt, butter
>>> import matplotlib.pyplot as plt
```

Create an interesting signal to filter.

```python
>>> n = 201
>>> t = np.linspace(0, 1, n)
>>> np.random.seed(123)
>>> x = 1 + (t < 0.5) - 0.25*t**2 + 0.05*np.random.randn(n)
```

Create a lowpass Butterworth filter, and use it to filter \(x\).

```python
>>> sos = butter(4, 0.125, output='sos')
>>> y = sosfiltfilt(sos, x)
```
For comparison, apply an 8th order filter using `sosfilt`. The filter is initialized using the mean of the first four values of $x$.

```python
>>> from scipy.signal import sosfilt, sosfilt_zi
>>> sos8 = butter(8, 0.125, output='sos')
>>> zi = x[:4].mean() * sosfilt_zi(sos8)
>>> y2, zo = sosfilt(sos8, x, zi=zi)
```

Plot the results. Note that the phase of $y$ matches the input, while $y2$ has a significant phase delay.

```python
>>> plt.plot(t, x, alpha=0.5, label='x(t)')
>>> plt.plot(t, y, label='y(t)')
>>> plt.plot(t, y2, label='y2(t)')
>>> plt.legend(framealpha=1, shadow=True)
>>> plt.grid(alpha=0.25)
>>> plt.xlabel('t')
>>> plt.show()
```

**scipy.signal.hilbert**

`scipy.signal.hilbert(x, N=None, axis=-1)`

Compute the analytic signal, using the Hilbert transform.

The transformation is done along the last axis by default.

**Parameters**

- `x` : [array_like] Signal data. Must be real.
- `N` : [int, optional] Number of Fourier components. Default: `x.shape[axis]`
- `axis` : [int, optional] Axis along which to do the transformation. Default: -1.

**Returns**

- `xa` : [ndarray] Analytic signal of $x$, of each 1-D array along `axis`
Notes

The analytic signal $x_a(t)$ of signal $x(t)$ is:

$$x_a = F^{-1}(F(x)2U) = x + iy$$

where $F$ is the Fourier transform, $U$ the unit step function, and $y$ the Hilbert transform of $x$. [1]

In other words, the negative half of the frequency spectrum is zeroed out, turning the real-valued signal into a complex signal. The Hilbert transformed signal can be obtained from `np.imag(hilbert(x))`, and the original signal from `np.real(hilbert(x))`.

References

[1], [2], [3]

Examples

In this example we use the Hilbert transform to determine the amplitude envelope and instantaneous frequency of an amplitude-modulated signal.

```python
>>> import numpy as np
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import hilbert, chirp

>>> duration = 1.0
>>> fs = 400.0
>>> samples = int(fs*duration)
>>> t = np.arange(samples) / fs

We create a chirp of which the frequency increases from 20 Hz to 100 Hz and apply an amplitude modulation.

```python
>>> signal = chirp(t, 20.0, t[-1], 100.0)
>>> signal *= (1.0 + 0.5 * np.sin(2.0*np.pi*3.0*t) )
```  

The amplitude envelope is given by magnitude of the analytic signal. The instantaneous frequency can be obtained by differentiating the instantaneous phase in respect to time. The instantaneous phase corresponds to the phase angle of the analytic signal.

```python
>>> analytic_signal = hilbert(signal)
>>> amplitude_envelope = np.abs(analytic_signal)
>>> instantaneous_phase = np.unwrap(np.angle(analytic_signal))
>>> instantaneous_frequency = (np.diff(instantaneous_phase) / ...
... (2.0*np.pi) * fs)
```

```python
>>> fig = plt.figure()
>>> ax0 = fig.add_subplot(211)
>>> ax0.plot(t, signal, label='signal')
>>> ax0.plot(t, amplitude_envelope, label='envelope')
>>> ax0.set_xlabel("time in seconds")
>>> ax0.legend()
>>> ax1 = fig.add_subplot(212)
```  

(continues on next page)
scipy.signal.hilbert2

scipy.signal.hilbert2(x, N=None)

Compute the ‘2-D’ analytic signal of x

Parameters

- x : array_like
  2-D signal data.
- N : int or tuple of two ints, optional
  Number of Fourier components. Default is x.shape

Returns

- xa : ndarray
  Analytic signal of x taken along axes (0,1).

References

[1]

scipy.signal.decimate

scipy.signal.decimate(x, q, n=None, ftype='iir', axis=-1, zero_phase=True)

Downsample the signal after applying an anti-aliasing filter.

By default, an order 8 Chebyshev type I filter is used. A 30 point FIR filter with Hamming window is used if ftype is 'fir'.

Parameters

- x : array_like
  The signal to be downsampled, as an N-dimensional array.
.. _decimate:

.. literalinclude:: decimate

.. _zero_phase:

.. literalinclude:: zero_phase

.. _resample:

.. literalinclude:: resample

.. _resample_poly:

.. literalinclude:: resample_poly

.. _detrend:

.. literalinclude:: detrend

6.22. Signal processing (scipy.signal)
Examples

```python
>>> from scipy import signal
>>> randgen = np.random.RandomState(9)
>>> npoints = 1000
>>> noise = randgen.randn(npoints)
>>> x = 3 + 2*np.linspace(0, 1, npoints) + noise
>>> (signal.detrend(x) - noise).max() < 0.01
True
```

**scipy.signal.resample**

`scipy.signal.resample(x, num, t=None, axis=0, window=None, domain='time')`

Resample `x` to `num` samples using Fourier method along the given axis.

The resampled signal starts at the same value as `x` but is sampled with a spacing of \( \frac{\text{len}(x)}{\text{num}} \times (\text{spacing of } x) \). Because a Fourier method is used, the signal is assumed to be periodic.

**Parameters**

- `x` [array_like] The data to be resampled.
- `num` [int] The number of samples in the resampled signal.
- `t` [array_like, optional] If `t` is given, it is assumed to be the equally spaced sample positions associated with the signal data in `x`.
- `axis` [int, optional] The axis of `x` that is resampled. Default is 0.
- `window` [array_like, callable, string, float, or tuple, optional] Specifies the window applied to the signal in the Fourier domain. See below for details.
- `domain` [string, optional] A string indicating the domain of the input `x`: `time` Consider the input `x` as time-domain (Default), `freq` Consider the input `x` as frequency-domain.

**Returns**

- `resampled_x` or `(resampled_x, resampled_t)`
  Either the resampled array, or, if `t` was given, a tuple containing the resampled array and the corresponding resampled positions.

**See also:**

- `decimate`
  Downsample the signal after applying an FIR or IIR filter.
- `resample_poly`
  Resample using polyphase filtering and an FIR filter.

**Notes**

The argument `window` controls a Fourier-domain window that tapers the Fourier spectrum before zero-padding to alleviate ringing in the resampled values for sampled signals you didn't intend to be interpreted as band-limited.

If `window` is a function, then it is called with a vector of inputs indicating the frequency bins (i.e. \( \text{fftfreq}(\text{x.shape}[\text{axis}]) \)).

If `window` is an array of the same length as \( x.\text{shape}[\text{axis}] \) it is assumed to be the window to be applied directly in the Fourier domain (with dc and low-frequency first).
For any other type of window, the function `scipy.signal.get_window` is called to generate the window.

The first sample of the returned vector is the same as the first sample of the input vector. The spacing between samples is changed from $dx$ to $dx \times \frac{\text{len}(x)}{\text{num}}$.

If $t$ is not None, then it is used solely to calculate the resampled positions $\text{resampled}_t$.

As noted, `resample` uses FFT transformations, which can be very slow if the number of input or output samples is large and prime; see `scipy.fft.fft`.

**Examples**

Note that the end of the resampled data rises to meet the first sample of the next cycle:

```python
>>> from scipy import signal

>>> x = np.linspace(0, 10, 20, endpoint=False)
>>> y = np.cos(-x**2/6.0)
>>> f = signal.resample(y, 100)
>>> xnew = np.linspace(0, 10, 100, endpoint=False)

>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'go-', xnew, f, '.-', 10, y[0], 'ro')
>>> plt.legend(["data", "resampled"], loc='best')
>>> plt.show()
```

![Graph showing data and resampled signals](image)
scipy.signal.resample_poly

scipy.signal.resample_poly(x, up, down, axis=0, window='kaiser', 5.0, padtype='constant', 
cval=None)

Resample x along the given axis using polyphase filtering.

The signal x is upsampled by the factor up, a zero-phase low-pass FIR filter is applied, and then it is downsampled by the factor down. The resulting sample rate is \( \text{up} / \text{down} \) times the original sample rate. By default, values beyond the boundary of the signal are assumed to be zero during the filtering step.

Parameters

- x [array_like] The data to be resampled.
- up [int] The upsampling factor.
- down [int] The downsampling factor.
- axis [int, optional] The axis of x that is resampled. Default is 0.
- window [string, tuple, or array_like, optional] Desired window to use to design the low-pass filter, or the FIR filter coefficients to employ. See below for details.
- padtype [string, optional] constant, line, mean, median, maximum, minimum or any of the other signal extension modes supported by scipy.signal.upfirdn. Changes assumptions on values beyond the boundary. If constant, assumed to be cval (default zero). If line assumed to continue a linear trend defined by the first and last points. mean, median, maximum and minimum work as in np.pad and assume that the values beyond the boundary are the mean, median, maximum or minimum respectively of the array along the axis.
- cval [float, optional] Value to use if padtype='constant'. Default is zero.

Returns

- resampled_x [array] The resampled array.

See also:

deicimate

Downsample the signal after applying an FIR or IIR filter.

resample

Resample up or down using the FFT method.

Notes

This polyphase method will likely be faster than the Fourier method in scipy.signal.resample when the number of samples is large and prime, or when the number of samples is large and up and down share a large greatest common denominator. The length of the FIR filter used will depend on \( \text{max}(\text{up, down}) / / \text{gcd(}\text{up, down}) \). The number of operations during polyphase filtering will depend on the filter length and down (see scipy.signal.upfirdn for details).

The argument window specifies the FIR low-pass filter design.

If window is an array_like it is assumed to be the FIR filter coefficients. Note that the FIR filter is applied after the upsampling step, so it should be designed to operate on a signal at a sampling frequency higher than the original by a factor of \( \text{up}/\text{gcd(up, down)} \). This function’s output will be centered with respect to this array, so it is best to pass a symmetric filter with an odd number of samples if, as is usually the case, a zero-phase filter is desired.
For any other type of window, the functions `scipy.signal.get_window` and `scipy.signal.firwin` are called to generate the appropriate filter coefficients.

The first sample of the returned vector is the same as the first sample of the input vector. The spacing between samples is changed from $dx$ to $dx \times \frac{\text{down}}{\text{up}}$.

**Examples**

By default, the end of the resampled data rises to meet the first sample of the next cycle for the FFT method, and gets closer to zero for the polyphase method:

```python
>>> from scipy import signal

>>> x = np.linspace(0, 10, 20, endpoint=False)
>>> y = np.cos(-x**2/6.0)
>>> f_fft = signal.resample(y, 100)
>>> f_poly = signal.resample_poly(y, 100, 20)
>>> xnew = np.linspace(0, 10, 100, endpoint=False)

>>> import matplotlib.pyplot as plt
>>> plt.plot(xnew, f_fft, 'b.-', xnew, f_poly, 'r.-')
>>> plt.plot(10, y[0], 'bo', 10, 0., 'ro')  # boundaries
>>> plt.legend(["resample", 'resamp_poly', 'data'], loc='best')
>>> plt.show()
```

This default behaviour can be changed by using the `padtype` option:

```python
>>> import numpy as np
>>> from scipy import signal

>>> N = 5
>>> x = np.linspace(0, 1, N, endpoint=False)
```
```python
>>> y = 2 + x**2 - 1.7*np.sin(x) + .2*np.cos(11*x)
>>> y2 = 1 + x**3 + 0.1*np.sin(x) + 1*np.cos(11*x)
>>> Y = np.stack([y, y2], axis=-1)
>>> up = 4
>>> xr = np.linspace(0, 1, N*up, endpoint=False)

>>> y2 = signal.resample_poly(Y, up, 1, padtype='constant')
>>> y3 = signal.resample_poly(Y, up, 1, padtype='mean')
>>> y4 = signal.resample_poly(Y, up, 1, padtype='line')

>>> import matplotlib.pyplot as plt
>>> for i in [0,1]:
...    plt.figure()
...    plt.plot(xr, y4[:,i], 'g.', label='line')
...    plt.plot(xr, y3[:,i], 'y.', label='mean')
...    plt.plot(xr, y2[:,i], 'r.', label='constant')
...    plt.plot(x, Y[:,i], 'k-')
...    plt.legend()
>>> plt.show()
```

**scipy.signal.upfirdn**

`scipy.signal.upfirdn(h, x, up=1, down=1, axis=-1, mode='constant', cval=0)`

Upsample, FIR filter, and downsample.

**Parameters**

- `h` [array_like] 1-D FIR (finite-impulse response) filter coefficients.
- `x` [array_like] Input signal array.
- `up` [int, optional] Upsampling rate. Default is 1.
- `down` [int, optional] Downsampling rate. Default is 1.
- `axis` [int, optional] The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.
**mode** [str, optional] The signal extension mode to use. The set {"constant", "symmetric", "reflect", "edge", "wrap") correspond to modes provided by numpy.pad. "smooth" implements a smooth extension by extending based on the slope of the last 2 points at each end of the array. "antireflect" and "antisymmetric" are anti-symmetric versions of "reflect" and "symmetric". The mode "line" extends the signal based on a linear trend defined by the first and last points along the axis.

New in version 1.4.0.

**cval** [float, optional] The constant value to use when mode == "constant".

New in version 1.4.0.

**Returns**

**y** [ndarray] The output signal array. Dimensions will be the same as x except for along axis, which will change size according to the h, up, and down parameters.

**Notes**

The algorithm is an implementation of the block diagram shown on page 129 of the Vaidyanathan text [1] (Figure 4.3-8d).

The direct approach of upsampling by factor of P with zero insertion, FIR filtering of length h, and downsampling by factor of Q is O(N*Q) per output sample. The polyphase implementation used here is O(N/P).

New in version 0.18.

[1]

Examples

Simple operations:

```python
>>> from scipy.signal import upfirdn
>>> upfirdn([1, 1, 1], [1, 1, 1])  # FIR filter
array([1., 2., 3., 2., 1.])
>>> upfirdn([1], [1, 2, 3], 3)  # upsampling with zeros insertion
array([1., 0., 2., 0., 3., 0., 0.])
>>> upfirdn([1, 1, 1], [1, 2, 3], 3)  # upsampling with sample-and-hold
array([1., 1., 2., 2., 3., 3., 3.])
>>> upfirdn([.5, 1, .5], [1, 1, 1], 2)  # linear interpolation
array([0.5, 1., 1., 1., 1., 1., 1., 0.5, 0.])
>>> upfirdn([1], np.arange(10), 1, 3)  # decimation by 3
array([0., 3., 6., 9.])
>>> upfirdn([.5, 1, .5], np.arange(10), 2, 3)  # linear interp, rate 2/3
array([0., 1., 2.5, 4., 5.5, 7., 8.5, 0.])
```

Apply a single filter to multiple signals:

```python
>>> x = np.reshape(np.arange(8), (4, 2))
>>> x
array([[0, 1],
        [2, 3],
        [4, 5],
        [6, 7]])
```

Apply along the last dimension of `x`:

```python
>>> h = [1, 1]
>>> upfirdn(h, x, 2)
array([[0., 0., 1., 1.],
       [2., 2., 3., 3.],
       [4., 4., 5., 5.],
       [6., 6., 7., 7.]])
```

Apply along the 0th dimension of `x`:

```python
>>> upfirdn(h, x, 2, axis=0)
array([[0., 1.],
       [0., 1.],
       [2., 3.],
       [2., 3.],
       [4., 5.],
       [4., 5.],
       [6., 7.],
       [6., 7.]])
```

**scipy.signal.bilinear**

`scipy.signal.bilinear(b, a, fs=1.0)`

Return a digital IIR filter from an analog one using a bilinear transform.

Transform a set of poles and zeros from the analog s-plane to the digital z-plane using Tustin’s method, which substitutes \((z-1) / (z+1)\) for \(s\), maintaining the shape of the frequency response.

**Parameters**

- **b**
  - [array_like] Numerator of the analog filter transfer function.
**scipy.signal.bilinear_zpk**

Return a digital IIR filter from an analog one using a bilinear transform.

Transform a set of poles and zeros from the analog s-plane to the digital z-plane using Tustin's method, which substitutes \((z-1) / (z+1)\) for \(s\), maintaining the shape of the frequency response.

**Parameters**

- **z**: [array_like] Zeros of the analog filter transfer function.
- **p**: [array_like] Poles of the analog filter transfer function.
- **k**: [float] System gain of the analog filter transfer function.
- **fs**: [float] Sample rate, as ordinary frequency (e.g., hertz). No prewarping is done in this function.

**Returns**

- **z**: [ndarray] Numerator of the transformed digital filter transfer function.
- **p**: [ndarray] Denominator of the transformed digital filter transfer function.
z [ndarray] Zeros of the transformed digital filter transfer function.

p [ndarray] Poles of the transformed digital filter transfer function.

k [float] System gain of the transformed digital filter.

bilinear

Notes

New in version 1.1.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> fs = 100
>>> bf = 2 * np.pi * np.array([7, 13])
>>> filts = signal.lti(*signal.butter(4, bf, btype='bandpass',
                        analog=True,
                        output='zpk'))
>>> filtz = signal.lti(*signal.bilinear_zpk(filts.zeros, filts.poles,
                                           filts.gain, fs))
>>> wz, hz = signal.freqz_zpk(filtz.zeros, filtz.poles, filtz.gain)
>>> ws, hs = signal.freqs_zpk(filts.zeros, filts.poles, filts.gain,
                             worN=fs*wz)
>>> plt.semilogx(wz*fs/(2*np.pi), 20*np.log10(np.abs(hz).clip(1e-15)),
               label=r'$|H_z(e^{j \omega})|$')
>>> plt.semilogx(wz*fs/(2*np.pi), 20*np.log10(np.abs(hs).clip(1e-15)),
               color='r')
```

(continues on next page)
... label=r'$|H(j \omega)|$'
>>> plt.legend()
>>> plt.xlabel('Frequency [Hz]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.grid()

scipy.signal.findfreqs

scipy.signal.findfreqs(num, den, N, kind='ba')

Find array of frequencies for computing the response of an analog filter.

Parameters

- **num, den** [array_like, 1-D] The polynomial coefficients of the numerator and denominator of the transfer function of the filter or LTI system, where the coefficients are ordered from highest to lowest degree. Or, the roots of the transfer function numerator and denominator (i.e., zeroes and poles).
- **N** [int] The length of the array to be computed.
- **kind** [str {'ba', 'zp'}, optional] Specifies whether the numerator and denominator are specified by their polynomial coefficients ('ba'), or their roots ('zp').

Returns

Examples

Find a set of nine frequencies that span the “interesting part” of the frequency response for the filter with the transfer function

\[
H(s) = \frac{s}{s^2 + 8s + 25}
\]

```python
>>> from scipy import signal
>>> signal.findfreqs([1, 0], [1, 8, 25], N=9)
array([ 1.00000000e-02, 3.16227766e-02, 1.00000000e-01,
        3.16227766e-01, 1.00000000e+00, 3.16227766e+00,
        1.00000000e+01, 3.16227766e+01, 1.00000000e+02])
```

scipy.signal.firls

**scipy.signal.firls** (numtaps, bands, desired, weight=None, nyq=None, fs=None)

FIR filter design using least-squares error minimization.

Calculate the filter coefficients for the linear-phase finite impulse response (FIR) filter which has the best approximation to the desired frequency response described by `bands` and `desired` in the least squares sense (i.e., the integral of the weighted mean-squared error within the specified bands is minimized).

**Parameters**

- **numtaps** [int] The number of taps in the FIR filter. `numtaps` must be odd.
- **bands** [array_like] A monotonic nondecreasing sequence containing the band edges in Hz. All elements must be non-negative and less than or equal to the Nyquist frequency given by `nyq`.
- **desired** [array_like] A sequence the same size as `bands` containing the desired gain at the start and end point of each band.
- **weight** [array_like, optional] A relative weighting to give to each band region when solving the least squares problem. `weight` has to be half the size of `bands`.
- **nyq** [float, optional] Deprecated. Use `fs` instead. Nyquist frequency. Each frequency in `bands` must be between 0 and `nyq` (inclusive). Default is 1.
- **fs** [float, optional] The sampling frequency of the signal. Each frequency in `bands` must be between 0 and `fs/2` (inclusive). Default is 2.

**Returns**

- **coeffs** [ndarray] Coefficients of the optimal (in a least squares sense) FIR filter.

See also:

- firwin
- firwin2
- minimum_phase
- remez
Notes

This implementation follows the algorithm given in [1]. As noted there, least squares design has multiple advantages:

1. Optimal in a least-squares sense.
2. Simple, non-iterative method.
3. The general solution can obtained by solving a linear system of equations.
4. Allows the use of a frequency dependent weighting function.

This function constructs a Type I linear phase FIR filter, which contains an odd number of `coeffs` satisfying for \( n < \text{numtaps} \):

\[
\text{coeffs}(n) = \text{coeffs}(\text{numtaps} - 1 - n)
\]

The odd number of coefficients and filter symmetry avoid boundary conditions that could otherwise occur at the Nyquist and 0 frequencies (e.g., for Type II, III, or IV variants).

New in version 0.18.

References

[1]

Examples

We want to construct a band-pass filter. Note that the behavior in the frequency ranges between our stop bands and pass bands is unspecified, and thus may overshoot depending on the parameters of our filter:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> fig, axs = plt.subplots(2)
>>> fs = 10.0  # Hz
>>> desired = (0, 0, 1, 1, 0, 0)
>>> for bi, bands in enumerate(((0, 1, 2, 3, 4, 5), (0, 1, 2, 4, 4.5, -5))):
...     fir_firls = signal.firls(73, bands, desired, fs=fs)
...     fir_remez = signal.remez(73, bands, desired[:2], fs=fs)
...     fir_firwin2 = signal.firwin2(73, bands, desired, fs=fs)
...     hs = list()
...     ax = axs[bi]
...     for fir in (fir_firls, fir_remez, fir_firwin2):
...         freq, response = signal.freqz(fir)
...         hs.append(ax.semilogy(0.5*fs*freq/np.pi, np.abs(response))[0])
...     for band, gains in zip(zip(bands[:2], bands[1:2]),
...                            zip(desired[::2], desired[1:2])):
...         ax.semilogy(band, np.maximum(gains, 1e-7), 'k--', linewidth=2)
...     if bi == 0:
...         ax.legend(hs, ('firls', 'remez', 'firwin2'),
...                   loc='lower center', frameon=False)
...     else:
...         ax.set_xlabel('Frequency (Hz)')
...     ax.grid(True)
```
scipy.signal.firwin

scipy.signal.firwin(numtaps, cutoff, width=None, window='hamming', pass_zero=True, scale=True, nyq=None, fs=None)

FIR filter design using the window method.

This function computes the coefficients of a finite impulse response filter. The filter will have linear phase; it will be Type I if numtaps is odd and Type II if numtaps is even.

Type II filters always have zero response at the Nyquist frequency, so a ValueError exception is raised if firwin is called with numtaps even and having a passband whose right end is at the Nyquist frequency.

Parameters

- **numtaps** [int] Length of the filter (number of coefficients, i.e. the filter order + 1). numtaps must be odd if a passband includes the Nyquist frequency.
- **cutoff** [float or 1-D array_like] Cutoff frequency of filter (expressed in the same units as fs) OR an array of cutoff frequencies (that is, band edges). In the latter case, the frequencies in cutoff should be positive and monotonically increasing between 0 and fs/2. The values 0 and fs/2 must not be included in cutoff.
- **width** [float or None, optional] If width is not None, then assume it is the approximate width of the transition region (expressed in the same units as fs) for use in Kaiser FIR filter design. In this case, the window argument is ignored.
- **window** [string or tuple of string and parameter values, optional] Desired window to use. See scipy.signal.get_window for a list of windows and required parameters.
- **pass_zero** [{'True, False, ‘bandpass’, ‘lowpass’, ‘highpass’, ‘bandstop’}, optional] If True, the gain at the frequency 0 (i.e., the “DC gain”) is 1. If False, the DC gain is 0. Can also be a string argument for the desired filter type (equivalent to btype in IIR design functions).
scale [bool, optional] Set to True to scale the coefficients so that the frequency response is exactly unity at a certain frequency. That frequency is either:

- 0 (DC) if the first passband starts at 0 (i.e. pass_zero is True)
- fs/2 (the Nyquist frequency) if the first passband ends at fs/2 (i.e the filter is a single band highpass filter); center of first passband otherwise

nyq [float, optional] Deprecated. Use `fs` instead. This is the Nyquist frequency. Each frequency in `cutoff` must be between 0 and nyq. Default is 1.

fs [float, optional] The sampling frequency of the signal. Each frequency in `cutoff` must be between 0 and fs/2. Default is 2.

Returns

h [(numtaps,) ndarray] Coefficients of length numtaps FIR filter.

Raises

ValueError

If any value in `cutoff` is less than or equal to 0 or greater than or equal to fs/2, if the values in `cutoff` are not strictly monotonically increasing, or if numtaps is even but a passband includes the Nyquist frequency.

remez

Examples

Low-pass from 0 to f:

```python
>>> from scipy import signal
>>> numtaps = 3
>>> f = 0.1
>>> signal.firwin(numtaps, f)
array([ 0.06799017, 0.86401967, 0.06799017])
```

Use a specific window function:

```python
>>> signal.firwin(numtaps, f, window='nuttall')
array([ 3.56607041e-04, 9.99286786e-01, 3.56607041e-04])
```

High-pass ('stop' from 0 to f):

```python
>>> signal.firwin(numtaps, f, pass_zero=False)
array([-0.00859313, 0.98281375, -0.00859313])
```

Band-pass:

```python
>>> f1, f2 = 0.1, 0.2
>>> signal.firwin(numtaps, [f1, f2], pass_zero=False)
array([0.06301614, 0.88770441, 0.06301614])
```
Band-stop:

```python
>>> signal.firwin(numtaps, [f1, f2])
array([-0.00801395, 1.0160279 , -0.00801395])
```

Multi-band (passbands are \([0, f_1]\), \([f_2, f_3]\) and \([f_4, 1]\)):

```python
>>> f3, f4 = 0.3, 0.4
>>> signal.firwin(numtaps, [f1, f2, f3, f4])
array([-0.01376344, 1.02752689, -0.01376344])
```

Multi-band (passbands are \([f_1, f_2]\) and \([f_3, f_4]\)):

```python
>>> signal.firwin(numtaps, [f1, f2, f3, f4], pass_zero=False)
array([ 0.04890915, 0.91284326, 0.04890915])
```

### scipy.signal.firwin2

**scipy.signal.firwin2**

FIR filter design using the window method.

From the given frequencies `freq` and corresponding gains `gain`, this function constructs an FIR filter with linear phase and (approximately) the given frequency response.

**Parameters**

- **numtaps** [int] The number of taps in the FIR filter. `numtaps` must be less than `nfreqs`.
- **freq** [array_like, 1-D] The frequency sampling points. Typically 0.0 to 1.0 with 1.0 being Nyquist. The Nyquist frequency is half `fs`. The values in `freq` must be nondecreasing. A value can be repeated once to implement a discontinuity. The first value in `freq` must be 0, and the last value must be `fs/2`. Values 0 and `fs/2` must not be repeated.
- **gain** [array_like] The filter gains at the frequency sampling points. Certain constraints to gain values, depending on the filter type, are applied, see Notes for details.
- **nfreqs** [int, optional] The size of the interpolation mesh used to construct the filter. For most efficient behavior, this should be a power of 2 plus 1 (e.g., 129, 257, etc). The default is one more than the smallest power of 2 that is not less than `numtaps`. `nfreqs` must be greater than `numtaps`.
- **window** [string or (string, float) or float, or None, optional] Window function to use. Default is “hamming”. See `scipy.signal.get_window` for the complete list of possible values. If None, no window function is applied.
- **nyq** [float, optional] Deprecated. Use ‘fs’ instead. This is the Nyquist frequency. Each frequency in `freq` must be between 0 and `nyq`. Default is 1.
- **antisymmetric** [bool, optional] Whether resulting impulse response is symmetric/antisymmetric. See Notes for more details.
- **fs** [float, optional] The sampling frequency of the signal. Each frequency in `cutoff` must be between 0 and `fs/2`. Default is 2.

**Returns**

- **taps** [ndarray] The filter coefficients of the FIR filter, as a 1-D array of length `numtaps`.

See also:

- **firls**
- **firwin**
minimum_phase
remez

Notes

From the given set of frequencies and gains, the desired response is constructed in the frequency domain. The inverse FFT is applied to the desired response to create the associated convolution kernel, and the first numtaps coefficients of this kernel, scaled by window, are returned.

The FIR filter will have linear phase. The type of filter is determined by the value of ‘numtaps’ and antisymmetric flag. There are four possible combinations:

- odd numtaps, antisymmetric is False, type I filter is produced
- even numtaps, antisymmetric is False, type II filter is produced
- odd numtaps, antisymmetric is True, type III filter is produced
- even numtaps, antisymmetric is True, type IV filter is produced

Magnitude response of all but type I filters are subject to following constraints:

- type II – zero at the Nyquist frequency
- type III – zero at zero and Nyquist frequencies
- type IV – zero at zero frequency

New in version 0.9.0.

References

[1], [2]

Examples

A lowpass FIR filter with a response that is 1 on [0.0, 0.5], and that decreases linearly on [0.5, 1.0] from 1 to 0:

```python
>>> from scipy import signal
>>> taps = signal.firwin2(150, [0.0, 0.5, 1.0], [1.0, 1.0, 0.0])
>>> print(taps[72:78])
[-0.02286961 -0.06362756 0.57310236 0.57310236 -0.06362756 -0.02286961]
```

scipy.signal.freqs

scipy.signal.freqs(b, a, worN=200, plot=None)

Compute frequency response of analog filter.

Given the M-order numerator b and N-order denominator a of an analog filter, compute its frequency response:

$$H(w) = \frac{b[0] * (jw)^M + b[1] * (jw)^{M-1} + \ldots + b[M]}{a[0] * (jw)^N + a[1] * (jw)^{N-1} + \ldots + a[N]}$$

Parameters

**SciPy Reference Guide, Release 1.6.3**

b  [array_like] Numerator of a linear filter.
a  [array_like] Denominator of a linear filter.
worN  [{None, int, array_like}, optional] If None, then compute at 200 frequencies around the interesting parts of the response curve (determined by pole-zero locations). If a single integer, then compute at that many frequencies. Otherwise, compute the response at the angular frequencies (e.g., rad/s) given in worN.
plot  [callable, optional] A callable that takes two arguments. If given, the return parameters w and h are passed to plot. Useful for plotting the frequency response inside freqs.

**Returns**

w  [ndarray] The angular frequencies at which h was computed.
h  [ndarray] The frequency response.

**See also:**

freqz

Compute the frequency response of a digital filter.

**Notes**

Using Matplotlib’s “plot” function as the callable for plot produces unexpected results, this plots the real part of the complex transfer function, not the magnitude. Try lambda w, h: plot(w, abs(h)).

**Examples**

```python
>>> from scipy.signal import freqs, iirfilter

>>> b, a = iirfilter(4, [1, 10], 1, 60, analog=True, ftype='cheby1')

>>> w, h = freqs(b, a, worN=np.logspace(-1, 2, 1000))

>>> import matplotlib.pyplot as plt
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.xlabel('Frequency')
>>> plt.ylabel('Amplitude response [dB]')
>>> plt.grid()
>>> plt.show()
```

**scipy.signal.freqs_zpk**

`scipy.signal.freqs_zpk(z, p, k, worN=200)`

Compute frequency response of analog filter.

Given the zeros z, poles p, and gain k of a filter, compute its frequency response:

\[
H(j\omega) = k \frac{(j\omega - z[0]) \times (j\omega - z[1]) \times \ldots \times (j\omega - z[-1])}{(j\omega - p[0]) \times (j\omega - p[1]) \times \ldots \times (j\omega - p[-1])}
\]

**Parameters**
z  [array_like] zeroes of a linear filter
p  [array_like] poles of a linear filter
k  [scalar] gain of a linear filter

worN  [{None, int, array_like}, optional] If None, then compute at 200 frequencies around the interesting parts of the response curve (determined by pole-zero locations). If a single integer, then compute at that many frequencies. Otherwise, compute the response at the angular frequencies (e.g., rad/s) given in worN.

Returns

w  [ndarray] the angular frequencies at which h was computed.
h  [ndarray] the frequency response.

See also:

freqs
Compute the frequency response of an analog filter in TF form

freqz
Compute the frequency response of a digital filter in TF form

freqz_zpk
Compute the frequency response of a digital filter in ZPK form
Notes

New in version 0.19.0.

Examples

```python
>>> from scipy.signal import freqs_zpk, iirfilter

>>> z, p, k = iirfilter(4, [1, 10], 1, 60, analog=True, ftype='cheby1',
                      output='zpk')

>>> w, h = freqs_zpk(z, p, k, worN=np.logspace(-1, 2, 1000))

>>> import matplotlib.pyplot as plt
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.xlabel('Frequency')
>>> plt.ylabel('Amplitude response [dB]')
>>> plt.grid()
>>> plt.show()
```

scipy.signal.freqz

Given the M-order numerator \(b\) and N-order denominator \(a\) of a digital filter, compute its frequency response:

\[
H(e^{j\omega}) = \frac{b[0] + b[1]e^{-j\omega} + \ldots + b[M]e^{-jWM}}{1 - e^{-j\omega} + e^{-2j\omega} + \ldots + e^{-Nj\omega}}
\]
A(e) = a[0] + a[1]e + ... + a[N]e

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
</tr>
<tr>
<td>a</td>
</tr>
</tbody>
</table>
| worN      | [[None, int, array_like], optional] If a single integer, then compute at that many frequencies (default is N=512). This is a convenient alternative to:

```python
np.linspace(0, fs if whole else fs/2, N, endpoint=include_nyquist)
```

Using a number that is fast for FFT computations can result in faster computations (see Notes).

If an array_like, compute the response at the frequencies given. These are in the same units as fs.

| whole     | [bool, optional] Normally, frequencies are computed from 0 to the Nyquist frequency, fs/2 (upper-half of unit-circle). If whole is True, compute frequencies from 0 to fs. Ignored if worN is array_like. |
| plot      | [callable] A callable that takes two arguments. If given, the return parameters w and h are passed to plot. Useful for plotting the frequency response inside freqz. |
| fs        | [float, optional] The sampling frequency of the digital system. Defaults to 2*pi radians/sample (so w is from 0 to pi). New in version 1.2.0. |

| include_nyquist | [bool, optional] If whole is False and worN is an integer, setting include_nyquist to True will include the last frequency (Nyquist frequency) and is otherwise ignored. New in version 1.5.0. |

Notes

Using Matplotlib’s `matplotlib.pyplot.plot` function as the callable for `plot` produces unexpected results, as this plots the real part of the complex transfer function, not the magnitude. Try `lambda w, h: plot(w, np.abs(h))`.

A direct computation via (R)FFT is used to compute the frequency response when the following conditions are met:

1. An integer value is given for `worN`.
2. `worN` is fast to compute via FFT (i.e., `next_fast_len(worN)` equals `worN`).
3. The denominator coefficients are a single value (`a.shape[0] == 1`).
4. `worN` is at least as long as the numerator coefficients (`worN >= b.shape[0]`).
5. If `b.ndim > 1`, then `b.shape[-1] == 1`.

For long FIR filters, the FFT approach can have lower error and be much faster than the equivalent direct polynomial calculation.

Examples

```python
>>> from scipy import signal
>>> b = signal.firwin(80, 0.5, window='kaiser', 8)
>>> w, h = signal.freqz(b)
```

```python
>>> import matplotlib.pyplot as plt
>>> fig, ax1 = plt.subplots()
>>> ax1.set_title('Digital filter frequency response')
```

```python
>>> ax1.plot(w, 20 * np.log10(abs(h)), 'b')
>>> ax1.set_ylabel('Amplitude [dB]', color='b')
>>> ax1.set_xlabel('Frequency [rad/sample]')
```

```python
>>> ax2 = ax1.twinx()
>>> angles = np.unwrap(np.angle(h))
>>> ax2.plot(w, angles, 'g')
>>> ax2.set_ylabel('Angle (radians)', color='g')
>>> ax2.grid()
>>> ax2.axis('tight')
>>> plt.show()
```

Broadcasting Examples

Suppose we have two FIR filters whose coefficients are stored in the rows of an array with shape (2, 25). For this demonstration, we’ll use random data:

```python
>>> np.random.seed(42)
>>> b = np.random.rand(2, 25)
```

To compute the frequency response for these two filters with one call to `freqz`, we must pass in `b.T`, because `freqz` expects the first axis to hold the coefficients. We must then extend the shape with a trivial dimension of length 1 to allow broadcasting with the array of frequencies. That is, we pass in `b.T[... , np.newaxis]`, which has shape (25, 2, 1):
Now, suppose we have two transfer functions, with the same numerator coefficients \( b = [0.5, 0.5] \). The coefficients for the two denominators are stored in the first dimension of the 2-D array \( a \):

\[
\begin{bmatrix}
1 & 1 \\
-0.25 & -0.5
\end{bmatrix}
\]

```python
>>> b = np.array([0.5, 0.5])
>>> a = np.array([[1, 1], [-0.25, -0.5]])
```

Only \( a \) is more than 1-D. To make it compatible for broadcasting with the frequencies, we extend it with a trivial dimension in the call to `freqz`:

```python
>>> w, h = signal.freqz(b, a..., np.newaxis), worN=1024)
>>> w.shape
(1024,)
>>> h.shape
(2, 1024)
```
scipy.signal.freqz_zpk

`scipy.signal.freqz_zpk(z, p, k, worN=512, whole=False, fs=6.283185307179586)`

Compute the frequency response of a digital filter in ZPK form.

Given the Zeros, Poles and Gain of a digital filter, compute its frequency response:

\[ H(z) = k \prod_i (z - Z[i]) / \prod_j (z - P[j]) \]

where \(k\) is the gain, \(Z\) are the zeros and \(P\) are the poles.

**Parameters**

- `z` [array_like] Zeros of a linear filter
- `p` [array_like] Poles of a linear filter
- `k` [scalar] Gain of a linear filter
- `worN` [[None, int, array_like], optional] If a single integer, then compute at that many frequencies (default is N=512).
  If an array_like, compute the response at the frequencies given. These are in the same units as `fs`.
- `whole` [bool, optional] Normally, frequencies are computed from 0 to the Nyquist frequency, `fs/2` (upper-half of unit-circle). If `whole` is True, compute frequencies from 0 to `fs`. Ignored if `w` is array_like.
- `fs` [float, optional] The sampling frequency of the digital system. Defaults to `2*pi` radians/sample (so `w` is from 0 to pi).
  New in version 1.2.0.

**Returns**

- `w` [ndarray] The frequencies at which \(h\) was computed, in the same units as `fs`. By default, `w` is normalized to the range \([0, \pi)\) (radians/sample).
- `h` [ndarray] The frequency response, as complex numbers.

**See also:**

- `freqs`
  Compute the frequency response of an analog filter in TF form
- `freqs_zpk`
  Compute the frequency response of an analog filter in ZPK form
- `freqz`
  Compute the frequency response of a digital filter in TF form

**Notes**

New in version 0.19.0.
Examples

Design a 4th-order digital Butterworth filter with cut-off of 100 Hz in a system with sample rate of 1000 Hz, and plot the frequency response:

```python
>>> from scipy import signal
>>> z, p, k = signal.butter(4, 100, output='zpk', fs=1000)
>>> w, h = signal.freqz_zpk(z, p, k, fs=1000)

>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(1, 1, 1)
>>> ax1.set_title('Digital filter frequency response')

>>> ax1.plot(w, 20 * np.log10(abs(h)), 'b')
>>> ax1.set_ylabel('Amplitude [dB]', color='b')
>>> ax1.set_xlabel('Frequency [Hz]')
>>> ax1.grid()

>>> ax2 = ax1.twinx()
>>> angles = np.unwrap(np.angle(h))
>>> ax2.plot(w, angles, 'g')
>>> ax2.set_ylabel('Angle [radians]', color='g')

>>> plt.axis('tight')
>>> plt.show()
```
**scipy.signal.sosfreqz**

```python
scipy.signal.sosfreqz (sos, worN=512, whole=False, fs=6.283185307179586)
```

Compute the frequency response of a digital filter in SOS format.

Given `sos`, an array with shape (n, 6) of second order sections of a digital filter, compute the frequency response of the system function:

\[
H(z) = \frac{B_0(z) \cdot B_1(z) \cdot \ldots \cdot B_{n-1}(z)}{A_0(z) \cdot A_1(z) \cdot \ldots \cdot A_{n-1}(z)}
\]

for \( z = \exp(\omega \cdot \text{j}) \), where \( B_k(z) \) and \( A_k(z) \) are numerator and denominator of the transfer function of the \( k \)-th second order section.

**Parameters**

- `sos` [array_like] Array of second-order filter coefficients, must have shape \((n\_sections, 6)\). Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.
- `worN` [[None, int, array_like], optional] If a single integer, then compute at that many frequencies (default is \( N=512 \)). Using a number that is fast for FFT computations can result in faster computations (see Notes of `freqz`). If an array_like, compute the response at the frequencies given (must be 1-D). These are in the same units as `fs`.
- `whole` [bool, optional] Normally, frequencies are computed from 0 to the Nyquist frequency, \( fs/2 \) (upper-half of unit-circle). If `whole` is True, compute frequencies from 0 to \( fs \).
- `fs` [float, optional] The sampling frequency of the digital system. Defaults to 2*\( \pi \) radians/sample (so \( w \) is from 0 to \( \pi \)). New in version 1.2.0.

**Returns**

- `w` [ndarray] The frequencies at which \( h \) was computed, in the same units as `fs`. By default, \( w \) is normalized to the range \([0, \pi)\) (radians/sample).
- `h` [ndarray] The frequency response, as complex numbers.

**See also:**

`freqz`, `sosfilt`

**Notes**

New in version 0.19.0.

**Examples**

Design a 15th-order bandpass filter in SOS format.

```python
>>> from scipy import signal
>>> sos = signal.ellip (15, 0.5, 60, (0.2, 0.4), btype='bandpass',
                      output='sos')
```

Compute the frequency response at 1500 points from DC to Nyquist.
```python
>>> w, h = signal.sosfreqz(sos, worN=1500)
```

Plot the response.

```python
>>> import matplotlib.pyplot as plt
>>> plt.subplot(2, 1, 1)
>>> db = 20*np.log10(np.maximum(np.abs(h), 1e-5))
>>> plt.plot(w/np.pi, db)
>>> plt.ylim(-75, 5)
>>> plt.grid(True)
>>> plt.yticks([0, -20, -40, -60])
>>> plt.ylabel('Gain [dB]')
>>> plt.title('Frequency Response')
>>> plt.subplot(2, 1, 2)
>>> plt.plot(w/np.pi, np.angle(h))
>>> plt.grid(True)
>>> plt.yticks([-np.pi, -0.5*np.pi, 0, 0.5*np.pi, np.pi],
            [r'$-\pi$', r'$-\pi/2$', '0', r'$\pi/2$', r'$\pi$'])
>>> plt.ylabel('Phase [rad]')
>>> plt.xlabel('Normalized frequency (1.0 = Nyquist)')
>>> plt.show()
```

If the same filter is implemented as a single transfer function, numerical error corrupts the frequency response:

```python
>>> b, a = signal.ellip(15, 0.5, 60, (0.2, 0.4), btype='bandpass',
                      output='ba')
>>> w, h = signal.freqz(b, a, worN=1500)
>>> plt.subplot(2, 1, 1)
>>> db = 20*np.log10(np.maximum(np.abs(h), 1e-5))
>>> plt.plot(w/np.pi, db)
>>> plt.ylim(-75, 5)
>>> plt.grid(True)
>>> plt.yticks([0, -20, -40, -60])
>>> plt.ylabel('Gain [dB]')
```

(continues on next page)
scipy.signal.gammatone

**scipy.signal.gammatone** *(freq, ftype, order=None, numtaps=None, fs=None)*

Gammatone filter design.

This function computes the coefficients of an FIR or IIR gammatone digital filter [1].

**Parameters**

- **freq** ([float] Center frequency of the filter (expressed in the same units as fs).
- **ftype** ([{'fir', 'iir'}]) The type of filter the function generates. If 'fir', the function will generate an Nth order FIR gammatone filter. If 'iir', the function will generate an 8th order digital IIR filter, modeled as an 4th order gammatone filter.
- **order** ([int, optional]) The order of the filter. Only used when ftype='fir'. Default is 4 to model the human auditory system. Must be between 0 and 24.
- **numtaps** ([int, optional]) Length of the filter. Only used when ftype='fir'. Default is fs*0.015 if fs is greater than 1000, 15 if fs is less than or equal to 1000.
- **fs** ([float, optional]) The sampling frequency of the signal. freq must be between 0 and fs/2. Default is 2.

**Returns**

- **b, a** ([ndarray, ndarray]) Numerator (b) and denominator (a) polynomials of the filter.

**Raises**

6.22. Signal processing (scipy.signal) 1835
ValueError

If \( freq \) is less than or equal to 0 or greater than or equal to \( fs/2 \), if \( ftype \) is not ‘fir’ or ‘iir’, if \( order \) is less than or equal to 0 or greater than 24 when \( ftype='fir' \)

Examples

16-sample 4th order FIR Gammatone filter centered at 440 Hz

```python
>>> from scipy import signal
>>> signal.gammatone(440, 'fir', numtaps=16, fs=16000)
(array([ 0.00000000e+00, 2.22196719e-07, 1.64942101e-06, 4.99298227e-06,
      1.01993969e-05, 1.63125770e-05, 2.14648940e-05, 2.29947263e-05,
      1.76776931e-05, 2.04980537e-06, -2.72062858e-05, -7.28455299e-05,
      -1.36651076e-04, -2.19066855e-04, -3.18905076e-04, -4.33156712e-04]), [1.0])
```

IIR Gammatone filter centered at 440 Hz

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.gammatone(440, 'iir', fs=16000)
>>> w, h = signal.freqz(b, a)
>>> plt.plot(w / ((2 * np.pi) / 16000), 20 * np.log10(abs(h)))
>>> plt.xscale('log')
>>> plt.title('Gammatone filter frequency response')
>>> plt.xlabel('Frequency')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(440, color='green') # cutoff frequency
>>> plt.show()
```
scipy.signal.group_delay

scipy.signal.group_delay(system, w=512, whole=False, fs=6.283185307179586)

Compute the group delay of a digital filter.

The group delay measures by how many samples amplitude envelopes of various spectral components of a signal are delayed by a filter. It is formally defined as the derivative of continuous (unwrapped) phase:

\[
D(w) = - \frac{\text{arg } H(e^{jw})}{dw}
\]

Parameters

- **system** [tuple of array_like (b, a)] Numerator and denominator coefficients of a filter transfer function.
- **w** [{None, int, array_like}, optional] If a single integer, then compute at that many frequencies (default is N=512). If an array_like, compute the delay at the frequencies given. These are in the same units as fs.
- **whole** [bool, optional] Normally, frequencies are computed from 0 to the Nyquist frequency, fs/2 (upper-half of unit-circle). If whole is True, compute frequencies from 0 to fs. Ignored if w is array_like.
- **fs** [float, optional] The sampling frequency of the digital system. Defaults to 2*pi radians/sample (so w is from 0 to pi). New in version 1.2.0.

Returns

- **w** [ndarray] The frequencies at which group delay was computed, in the same units as fs. By default, w is normalized to the range [0, pi) (radians/sample).
- **gd** [ndarray] The group delay.

See also:

- freqz
Frequency response of a digital filter

**Notes**

The similar function in MATLAB is called *grpdelay*.

If the transfer function $H(z)$ has zeros or poles on the unit circle, the group delay at corresponding frequencies is undefined. When such a case arises the warning is raised and the group delay is set to 0 at those frequencies.

For the details of numerical computation of the group delay refer to [1].

New in version 0.16.0.

**References**

[1]

**Examples**

```python
>>> from scipy import signal
>>> b, a = signal.iirdesign(0.1, 0.3, 5, 50, ftype='cheby1')
>>> w, gd = signal.group_delay((b, a))

>>> import matplotlib.pyplot as plt
>>> plt.title('Digital filter group delay')
>>> plt.plot(w, gd)
>>> plt.ylabel('Group delay [samples]')
>>> plt.xlabel('Frequency [rad/sample]')
>>> plt.show()
```

Digital filter group delay
scipy.signal.iirdesign

scipy.signal.iirdesign(wp, ws, gpass, gstop, analog=False, ftype='ellip', output='ba', fs=None)
Complete IIR digital and analog filter design.

Given passband and stopband frequencies and gains, construct an analog or digital IIR filter of minimum order for a given basic type. Return the output in numerator, denominator ('ba'), pole-zero ('zpk') or second order sections ('sos') form.

Parameters

wp, ws  [float or array like, shape (2,)] Passband and stopband edge frequencies. Possible values are scalars (for lowpass and highpass filters) or ranges (for bandpass and bandstop filters). For digital filters, these are in the same units as fs. By default, fs is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. For example:
  • Lowpass: wp = 0.2, ws = 0.3
  • Highpass: wp = 0.3, ws = 0.2
  • Bandpass: wp = [0.2, 0.5], ws = [0.1, 0.6]
  • Bandstop: wp = [0.1, 0.6], ws = [0.2, 0.5]
For analog filters, wp and ws are angular frequencies (e.g., rad/s). Note, that for bandpass and bandstop filters passband must lie strictly inside stopband or vice versa.

gpass  [float] The maximum loss in the passband (dB).
gstop  [float] The minimum attenuation in the stopband (dB).
analog  [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.
ftype  [str, optional] The type of IIR filter to design:
  • Butterworth: ‘butter’
  • Chebyshev I: ‘cheby1’
  • Chebyshev II: ‘cheby2’
  • Cauer/elliptic: ‘ellip’
  • Bessel/Thomson: ‘bessel’
output  [{'ba', 'zpk', 'sos'}, optional] Filter form of the output:
  • second-order sections (recommended): ‘sos’
  • numerator/denominator (default): ‘ba’
  • pole-zero: ‘zpk’
In general the second-order sections ('sos') form is recommended because inferring the coefficients for the numerator/denominator form ('ba') suffers from numerical instabilities. For reasons of backward compatibility the default form is the numerator/denominator form ('ba'), where the 'b' and the 'a' in 'ba' refer to the commonly used names of the coefficients used. Note: Using the second-order sections form ('sos') is sometimes associated with additional computational costs: for data-intense use cases it is therefore recommended to also investigate the numerator/denominator form ('ba').

fs  [float, optional] The sampling frequency of the digital system.
New in version 1.2.0.

Returns

b, a  [ndarray, ndarray] Numerator (b) and denominator (a) polynomials of the IIR filter. Only returned if output='ba'.
z, p, k  [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if output='zpk'.
sos  [ndarray] Second-order sections representation of the IIR filter. Only returned if output=='sos'.

iirfilter

General filter design using order and critical frequencies

Notes

The 'sos' output parameter was added in 0.16.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> import matplotlib.ticker

>>> wp = 0.2
>>> ws = 0.3
>>> gpass = 1
>>> gstop = 40

>>> system = signal.iirdesign(wp, ws, gpass, gstop)
>>> w, h = signal.freqz(system)

>>> fig, ax1 = plt.subplots()
>>> ax1.set_title('Digital filter frequency response')
>>> ax1.plot(w, 20 * np.log10(abs(h)), 'b')
>>> ax1.set_ylabel('Amplitude [dB]', color='b')
>>> ax1.set_xlabel('Frequency [rad/sample]')
>>> ax1.grid()
>>> ax1.set_yscale('log')
>>> ax2 = ax1.twinx()
>>> angles = np.unwrap(np.angle(h))
>>> ax2.plot(w, angles, 'g')
>>> ax2.set_ylabel('Angle (radians)', color='g')
>>> ax2.grid()
>>> ax2.axis('tight')
>>> ax2.set_yscale('linear')
>>> nticks = 8
>>> ax1.yaxis.set_major_locator(matplotlib.ticker.LinearLocator(nticks))
>>> ax2.yaxis.set_major_locator(matplotlib.ticker.LinearLocator(nticks))
```
scipy.signal.iirfilter

Parameters

N : int
   The order of the filter.

Wn : array_like
    A scalar or length-2 sequence giving the critical frequencies.
    For digital filters, Wn are in the same units as fs. By default, fs is 2 half-cycles/sample, so
    these are normalized from 0 to 1, where 1 is the Nyquist frequency. (Wn is thus in half-cycles
    / sample.)
    For analog filters, Wn is an angular frequency (e.g., rad/s).

rp : float, optional
    For Chebyshev and elliptic filters, provides the maximum ripple in the pass-
    band. (dB)

rs : float, optional
    For Chebyshev and elliptic filters, provides the minimum attenuation in the
    stop band. (dB)

btype : {'bandpass', 'lowpass', 'highpass', 'bandstop'}, optional
    The type of filter. Default is 'band-
    pass'.

analog : bool, optional
    When True, return an analog filter, otherwise a digital filter is returned.

ftype : str, optional
    The type of IIR filter to design:
    - Butterworth: 'butter'
    - Chebyshev I: 'cheby1'
    - Chebyshev II: 'cheby2'
    - Cauer/elliptic: 'ellip'
    - Bessel/Thomson: 'bessel'

output : {'ba', 'zpk', 'sos'}, optional
    Filter form of the output:
    - second-order sections (recommended): 'sos'
    - numerator/denominator (default): 'ba'
    - pole-zero: 'zpk'

In general the second-order sections ('sos') form is recommended because inferring the coef-

Design an Nth-order digital or analog filter and return the filter coefficients.
reasons of backward compatibility the default form is the numerator/denominator form ('ba'), where the 'b' and the 'a' in 'ba' refer to the commonly used names of the coefficients used. Note: Using the second-order sections form ('sos') is sometimes associated with additional computational costs: for data-intense use cases it is therefore recommended to also investigate the numerator/denominator form ('ba').

\textit{fs} 
[\texttt{float, optional}] The sampling frequency of the digital system. New in version 1.2.0.

\textit{Returns} 
\texttt{b, a} 
[\texttt{ndarray, ndarray}] Numerator (\textit{b}) and denominator (\textit{a}) polynomials of the IIR filter. Only returned if \texttt{output='ba'}. 
\texttt{z, p, k} 
[\texttt{ndarray, ndarray, float}] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if \texttt{output='zpk'}. 
\texttt{sos} 
[\texttt{ndarray}] Second-order sections representation of the IIR filter. Only returned if \texttt{output='sos'}. 

\textbf{See also:} 
\texttt{butter}  
Filter design using order and critical points 
\texttt{cheby1, cheby2, ellip, bessel}  
\texttt{buttord}  
Find order and critical points from passband and stopband spec 
\texttt{cheb1ord, cheb2ord, ellipord} 
\texttt{iirdesign}  
General filter design using passband and stopband spec 

\textbf{Notes} 
The 'sos' output parameter was added in 0.16.0.

\textbf{Examples} 
Generate a 17th-order Chebyshev II analog bandpass filter from 50 Hz to 200 Hz and plot the frequency response:

\begin{verbatim}
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.iirfilter(17, [2*np.pi*50, 2*np.pi*200], rs=60,
...                           btype='band', analog=True, ftype='cheby2')
>>> w, h = signal.freqs(b, a, 1000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1, 1, 1)
>>> ax.semilogx(w / (2*np.pi), 20 * np.log10(np.maximum(abs(h), 1e-5)))
>>> ax.set_title('Chebyshev Type II bandpass frequency response')
>>> ax.set_xlabel('Frequency [Hz]')
>>> ax.set_ylabel('Amplitude [dB]')
>>> ax.axis([10, 1000, -100, 10])
\end{verbatim}
Create a digital filter with the same properties, in a system with sampling rate of 2000 Hz, and plot the frequency response. (Second-order sections implementation is required to ensure stability of a filter of this order):

```python
>>> sos = signal.iirfilter(17, [50, 200], rs=60, btype='band', analog=False, ftype='cheby2', fs=2000, output='sos')
>>> w, h = signal.sosfreqz(sos, 2000, fs=2000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1, 1, 1)
>>> ax.semilogx(w, 20 * np.log10(np.maximum(abs(h), 1e-5)))
>>> ax.set_title('Chebyshev Type II bandpass frequency response')
>>> ax.set_xlabel('Frequency [Hz]')
>>> ax.set_ylabel('Amplitude [dB]')
>>> ax.axis((10, 1000, -100, 10))
>>> ax.grid(which='both', axis='both')
>>> plt.show()
```

**scipy.signal.kaiser_atten**

`scipy.signal.kaiser_atten(numtaps, width)`

Compute the attenuation of a Kaiser FIR filter.

Given the number of taps \( N \) and the transition width \( width \), compute the attenuation \( a \) in dB, given by Kaiser's formula:

\[
a = 2.285 \times (N - 1) \times \pi \times width + 7.95
\]

**Parameters**

- `numtaps` : [int] The number of taps in the FIR filter.
**Chebyshev Type II bandpass frequency response**

width

[float] The desired width of the transition region between passband and stopband (or, in general, at any discontinuity) for the filter, expressed as a fraction of the Nyquist frequency.

Returns

a

[float] The attenuation of the ripple, in dB.

See also:

kaiserord, kaiser_beta

Examples

Suppose we want to design a FIR filter using the Kaiser window method that will have 211 taps and a transition width of 9 Hz for a signal that is sampled at 480 Hz. Expressed as a fraction of the Nyquist frequency, the width is $9/(0.5*480) = 0.0375$. The approximate attenuation (in dB) is computed as follows:

```python
>>> from scipy.signal import kaiser_atten
>>> kaiser_atten(211, 0.0375)
64.48099630593983
```

**scipy.signal.kaiser_beta**

`scipy.signal.kaiser_beta(a)`

Compute the Kaiser parameter $\beta$, given the attenuation $a$.

Parameters

a

[float] The desired attenuation in the stopband and maximum ripple in the passband, in dB. This should be a **positive** number.

Returns

beta

[float] The $\beta$ parameter to be used in the formula for a Kaiser window.
References

Examples

Suppose we want to design a lowpass filter, with 65 dB attenuation in the stop band. The Kaiser window parameter to be used in the window method is computed by $kaiser\_beta(65)$:

```python
>>> from scipy.signal import kaiser_beta
>>> kaiser_beta(65)
6.20426
```

`scipy.signal.kaiserord`

`scipy.signal.kaiserord(ripple, width)`

Determine the filter window parameters for the Kaiser window method.

The parameters returned by this function are generally used to create a finite impulse response filter using the window method, with either `firwin` or `firwin2`.

**Parameters**

- `ripple` [float] Upper bound for the deviation (in dB) of the magnitude of the filter’s frequency response from that of the desired filter (not including frequencies in any transition intervals). That is, if $w$ is the frequency expressed as a fraction of the Nyquist frequency, $A(w)$ is the actual frequency response of the filter and $D(w)$ is the desired frequency response, the design requirement is that:

  \[
  \text{abs}(A(w) - D(w)) < 10^{-\text{ripple}/20}
  \]

  for $0 \leq w \leq 1$ and $w$ not in a transition interval.

- `width` [float] Width of transition region, normalized so that 1 corresponds to pi radians / sample. That is, the frequency is expressed as a fraction of the Nyquist frequency.

**Returns**

- `numtaps` [int] The length of the Kaiser window.
- `beta` [float] The beta parameter for the Kaiser window.

See also:

`kaiser\_beta`, `kaiser\_atten`

**Notes**

There are several ways to obtain the Kaiser window:

- `signal.windows.kaiser(numtaps, beta, sym=True)`
- `signal.get_window(beta, numtaps)`
- `signal.get_window(('kaiser', beta), numtaps)`

The empirical equations discovered by Kaiser are used.
References

Examples

We will use the Kaiser window method to design a lowpass FIR filter for a signal that is sampled at 1000 Hz.

We want at least 65 dB rejection in the stop band, and in the pass band the gain should vary no more than 0.5%.

We want a cutoff frequency of 175 Hz, with a transition between the pass band and the stop band of 24 Hz. That is, in the band [0, 163], the gain varies no more than 0.5%, and in the band [187, 500], the signal is attenuated by at least 65 dB.

```python
>>> from scipy.signal import kaiserord, firwin, freqz
>>> import matplotlib.pyplot as plt
>>> fs = 1000.0
>>> cutoff = 175
>>> width = 24
```

The Kaiser method accepts just a single parameter to control the pass band ripple and the stop band rejection, so we use the more restrictive of the two. In this case, the pass band ripple is 0.005, or 46.02 dB, so we will use 65 dB as the design parameter.

Use `kaiserord` to determine the length of the filter and the parameter for the Kaiser window.

```python
>>> numtaps, beta = kaiserord(65, width/(0.5*fs))
>>> numtaps
167
>>> beta
6.20426
```

Use `firwin` to create the FIR filter.

```python
>>> taps = firwin(numtaps, cutoff, window=('kaiser', beta),
...                scale=False, nyq=0.5*fs)
```

Compute the frequency response of the filter. \( w \) is the array of frequencies, and \( h \) is the corresponding complex array of frequency responses.

```python
>>> w, h = freqz(taps, worN=8000)
>>> w *= 0.5*fs/np.pi  # Convert w to Hz.
```

Compute the deviation of the magnitude of the filter's response from that of the ideal lowpass filter. Values in the transition region are set to `nan`, so they won't appear in the plot.

```python
>>> ideal = w < cutoff  # The "ideal" frequency response.
>>> deviation = np.abs(np.abs(h) - ideal)
>>> deviation[(w > cutoff - 0.5*width) & (w < cutoff + 0.5*width)] = np.nan
```

Plot the deviation. A close look at the left end of the stop band shows that the requirement for 65 dB attenuation is violated in the first lobe by about 0.125 dB. This is not unusual for the Kaiser window method.
```python
>>> plt.plot(w, 20*np.log10(np.abs(deviation)))
>>> plt.xlim(0, 0.5*fs)
>>> plt.ylim(-90, -60)
>>> plt.grid(alpha=0.25)
>>> plt.axhline(-65, color='r', ls='--', alpha=0.3)
>>> plt.xlabel('Frequency (Hz)')
>>> plt.ylabel('Deviation from ideal (dB)')
>>> plt.title('Lowpass Filter Frequency Response')
>>> plt.show()
```

**scipy.signal.minimum_phase**

`scipy.signal.minimum_phase(h, method='homomorphic', n_fft=None)`

Convert a linear-phase FIR filter to minimum phase

**Parameters**

- **h** [array] Linear-phase FIR filter coefficients.
- **method** [{'hilbert', 'homomorphic'}] The method to use:
  - **'homomorphic' (default)**
    - This method [4] [5] works best with filters with an odd number of taps, and the resulting minimum phase filter will have a magnitude response that approximates the square root of the original filter’s magnitude response.
  - **'hilbert'**
    - This method [1] is designed to be used with equiripple filters (e.g., from `remez`) with unity or zero gain regions.
- **n_fft** [int] The number of points to use for the FFT. Should be at least a few times larger than the signal length (see Notes).

**Returns**

- **h_minimum** [array] The minimum-phase version of the filter, with length `length(h) + 1) // 2`. 

**See also:**

6.22. Signal processing (scipy.signal) 1847

In the case of the Hilbert method, the deviation from the ideal spectrum $\text{epsilon}$ is related to the number of stopband zeros $n_{\text{stop}}$ and FFT length $n_{\text{fft}}$ as:

$$\text{epsilon} = 2. * \frac{n_{\text{stop}}}{n_{\text{fft}}}$$

For example, with 100 stopband zeros and a FFT length of 2048, $\text{epsilon} = 0.0976$. If we conservatively assume that the number of stopband zeros is one less than the filter length, we can take the FFT length to be the next power of 2 that satisfies $\text{epsilon}=0.01$ as:

$$n_{\text{fft}} = 2 ** \text{int} (\text{np.ceil}(\text{np.log2}(2 * (\text{len}(h) - 1) / 0.01)))$$

This gives reasonable results for both the Hilbert and homomorphic methods, and gives the value used when $n_{\text{fft}}$=None.

Alternative implementations exist for creating minimum-phase filters, including zero inversion [2] and spectral factorization [3] [4]. For more information, see:

http://dspguru.com/dsp/howtos/how-to-design-minimum-phase-fir-filters

References

[1], [2], [3], [4], [5]

Examples

Create an optimal linear-phase filter, then convert it to minimum phase:

```python
>>> from scipy.signal import remez, minimum_phase, freqz, group_delay
>>> import matplotlib.pyplot as plt
>>> freq = [0, 0.2, 0.3, 1.0]
>>> desired = [1, 0]
>>> h_linear = remez(151, freq, desired, Hz=2.)
```

Convert it to minimum phase:

```python
>>> h_min_hom = minimum_phase(h_linear, method='homomorphic')
>>> h_min_hil = minimum_phase(h_linear, method='hilbert')
```

Compare the three filters:

```python
>>> fig, axs = plt.subplots(4, figsize=(4, 8))
>>> for h, style, color in zip((h_linear, h_min_hom, h_min_hil),
... ( '-', '-', '--' ), ('k', 'r', 'c')):
...     (continues on next page)```

... w, H = freqz(h)
... w, gd = group_delay((h, 1))
... w /= np.pi
... axs[0].plot(h, color=color, linestyle=style)
... axs[1].plot(w, np.abs(H), color=color, linestyle=style)
... axs[2].plot(w, 20 * np.log10(np.abs(H)), color=color,...
  linestyle=style)
... axs[3].plot(w, gd, color=color, linestyle=style)

... for ax in axs:
  ... ax.grid(True, color='0.5')
  ... ax.fill_between(freq[1:3], *ax.get_ylim(), color='#ffeeaa',...
  zorder=1)
... axs[0].set(xlim=[0, len(h_linear) - 1], ylabel='Amplitude', xlabel=...
  'Samples')
... axs[1].legend(['Linear', 'Min-Hom', 'Min-Hil'], title='Phase')
... for ax, ylim in zip(axs[1:], ([0, 1.1], [-150, 10], [-60, 60])):
  ... ax.set(xlim=[0, 1], ylim=ylim, xlabel='Frequency')
... axs[1].set(ylimlabel='Magnitude')
... axs[2].set(ylimlabel='Magnitude (dB)')
... axs[3].set(ylimlabel='Group delay')
... plt.tight_layout()

scipy.signal.savgol_coeffs

scipy.signal.savgol_coeffs(window_length, polyorder, deriv=0, delta=1.0, pos=None, use='conv')

Compute the coefficients for a 1-D Savitzky-Golay FIR filter.

Parameters

window_length
  [int] The length of the filter window (i.e., the number of coefficients). window_length must be an odd positive integer.

polyorder
  [int] The order of the polynomial used to fit the samples. polyorder must be less than window_length.

deriv
  [int, optional] The order of the derivative to compute. This must be a nonnegative integer. The default is 0, which means to filter the data without differentiating.

delta
  [float, optional] The spacing of the samples to which the filter will be applied. This is only used if deriv > 0.

pos
  [int or None, optional] If pos is not None, it specifies evaluation position within the window. The default is the middle of the window.

use
  [str, optional] Either ‘conv’ or ‘dot’. This argument chooses the order of the coefficients. The default is ‘conv’, which means that the coefficients are ordered to be used in a convolution. With use=’dot’, the order is reversed, so the filter is applied by dotting the coefficients with the data set.

Returns

coeffs
  [1-D ndarray] The filter coefficients.

savgol_filter
Notes

New in version 0.14.0.

References

Examples

```python
>>> from scipy.signal import savgol_coeffs
>>> savgol_coeffs(5, 2)
array([-0.08571429, 0.34285714, 0.48571429, 0.34285714, -0.08571429])
>>> savgol_coeffs(5, 2, deriv=1)
array([2.00000000e-01, 1.00000000e-01, 2.07548111e-16, -1.00000000e-01,
            -2.00000000e-01])
Not that use='dot' simply reverses the coefficients.
```

```
>>> savgol_coeffs(5, 2, pos=3)
array([0.25714286, 0.37142857, 0.34285714, 0.17142857, -0.14285714])
>>> savgol_coeffs(5, 2, pos=3, use='dot')
array([-0.14285714, 0.17142857, 0.34285714, 0.37142857, 0.25714286])
```

x contains data from the parabola \(x = t^2\), sampled at \(t = -1, 0, 1, 2, 3\). c holds the coefficients that will compute the derivative at the last position. When dotted with x the result should be 6.

```python
>>> x = np.array([1, 0, 1, 4, 9])
>>> c = savgol_coeffs(5, 2, pos=4, deriv=1, use='dot')
>>> c.dot(x)
6.0
```

`scipy.signal.remez`

`scipy.signal.remez` *(numtaps, bands, desired, weight=None, Hz=None, type='bandpass', maxiter=25, grid_density=16, fs=None)*

Calculate the minimax optimal filter using the Remez exchange algorithm.

Calculate the filter-coefficients for the finite impulse response (FIR) filter whose transfer function minimizes the maximum error between the desired gain and the realized gain in the specified frequency bands using the Remez exchange algorithm.

**Parameters**

- **numtaps**  
  [int] The desired number of taps in the filter. The number of taps is the number of terms in the filter, or the filter order plus one.

- **bands**  
  [array_like] A monotonic sequence containing the band edges. All elements must be non-negative and less than half the sampling frequency as given by `fs`.

- **desired**  
  [array_like] A sequence half the size of bands containing the desired gain in each of the specified bands.

- **weight**  
  [array_like, optional] A relative weighting to give to each band region. The length of `weight` has to be half the length of `bands`.

6.22. Signal processing (`scipy.signal`) 1851
Hz [scalar, optional] Deprecated. Use `fs` instead. The sampling frequency in Hz. Default is 1.

type ['bandpass', 'differentiator', 'hilbert'], optional] The type of filter:
• ‘bandpass’: flat response in bands. This is the default.
• ‘differentiator’: frequency proportional response in bands.
• ‘hilbert’ [filter with odd symmetry, that is, type III] (for even order) or type IV (for odd order) linear phase filters.

maxiter [int, optional] Maximum number of iterations of the algorithm. Default is 25.

grid_density [int, optional] Grid density. The dense grid used in `remez` is of size `(numtaps + 1) * grid_density`. Default is 16.

fs [float, optional] The sampling frequency of the signal. Default is 1.

Returns

out [ndarray] A rank-1 array containing the coefficients of the optimal (in a minimax sense) filter.

firwin
firwin2
minimum_phase

References

[1], [2]

Examples

In these examples `remez` gets used creating a bandpass, bandstop, lowpass and highpass filter. The used parameters are the filter order, an array with according frequency boundaries, the desired attenuation values and the sampling frequency. Using `freqz` the corresponding frequency response gets calculated and plotted.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> def plot_response(fs, w, h, title):
...    "Utility function to plot response functions"
...    fig = plt.figure()
...    ax = fig.add_subplot(111)
...    ax.plot(0.5*fs*np.pi, 20*np.log10(np.abs(h)))
...    ax.set_ymargin(-40, 5)
...    ax.set_title('Frequency (Hz)')
...    ax.set_xlabel('Frequency (Hz)')
...    ax.set_ylabel('Gain (dB)')
...    ax.set_title(title)
```

This example shows a steep low pass transition according to the small transition width and high filter order:
This example shows a high pass filter:

```python
>>> fs = 22050.0  # Sample rate, Hz
>>> cutoff = 2000.0  # Desired cutoff frequency, Hz
>>> trans_width = 250  # Width of transition from pass band to stop band, Hz
>>> numtaps = 125  # Size of the FIR filter.
>>> taps = signal.remez(numtaps, [0, cutoff - trans_width, cutoff, 0.], [0, 1], Hz=fs)
>>> w, h = signal.freqz(taps, [1], worN=2000)
>>> plot_response(fs, w, h, "High-pass Filter")
```

For a signal sampled with 22 kHz a bandpass filter with a pass band of 2-5 kHz gets calculated using the Remez algorithm. The transition width is 260 Hz and the filter order 10:

```python
>>> fs = 22000.0  # Sample rate, Hz
>>> band = [6000, 8000]  # Desired pass band, Hz
>>> trans_width = 200  # Width of transition from pass band to stop band, Hz
>>> numtaps = 10  # Size of the FIR filter.
>>> edges = [0, band[0] - trans_width, band[0], band[1], band[1] + trans_width, 0.5*fs]
>>> taps = signal.remez(numtaps, edges, [0, 1, 0], Hz=fs)
>>> w, h = signal.freqz(taps, [1], worN=2000)
>>> plot_response(fs, w, h, "Band-pass Filter")
```

It can be seen that for this bandpass filter, the low order leads to higher ripple and less steep transitions. There is very low attenuation in the stop band and little overshoot in the pass band. Of course the desired gain can be better approximated with a higher filter order.

The next example shows a bandstop filter. Because of the high filter order the transition is quite steep:

```python
>>> fs = 20000.0  # Sample rate, Hz
>>> band = [6000, 8000]  # Desired stop band, Hz
>>> trans_width = 200  # Width of transition from pass band to stop band, Hz
>>> numtaps = 175  # Size of the FIR filter.
>>> edges = [0, band[0] - trans_width, band[0], band[1], band[1] + trans_width, 0.5*fs]
>>> taps = signal.remez(numtaps, edges, [1, 0, 1], Hz=fs)
>>> w, h = signal.freqz(taps, [1], worN=2000)
>>> plot_response(fs, w, h, "Band-stop Filter")
```
>>> plt.show()

```
scipy.signal.unique_roots

scipy.signal.unique_roots(p, tol=0.001, rtype='min')
Determine unique roots and their multiplicities from a list of roots.

Parameters

- p : [array_like] The list of roots.
- tol : [float, optional] The tolerance for two roots to be considered equal in terms of the distance between them. Default is 1e-3. Refer to Notes about the details on roots grouping.
- rtype : [{'max', 'maximum', 'min', 'minimum', 'avg', 'mean'}, optional] How to determine the returned root if multiple roots are within tol of each other.
```
Band-pass Filter

Gain (dB) vs. Frequency (Hz)

Band-stop Filter

Gain (dB) vs. Frequency (Hz)
• 'max', 'maximum': pick the maximum of those roots
• 'min', 'minimum': pick the minimum of those roots
• 'avg', 'mean': take the average of those roots

When finding minimum or maximum among complex roots they are compared first by the real part and then by the imaginary part.

**Returns**

- `unique` [ndarray] The list of unique roots.
- `multiplicity` [ndarray] The multiplicity of each root.

**Notes**

If we have 3 roots \(a, b\) and \(c\), such that \(a\) is close to \(b\) and \(b\) is close to \(c\) (distance is less than \(tol\)), then it doesn’t necessarily mean that \(a\) is close to \(c\). It means that roots grouping is not unique. In this function we use “greedy” grouping going through the roots in the order they are given in the input \(p\).

This utility function is not specific to roots but can be used for any sequence of values for which uniqueness and multiplicity has to be determined. For a more general routine, see `numpy.unique`.

**Examples**

```python
>>> from scipy import signal
>>> vals = [0, 1.3, 1.31, 2.8, 1.25, 2.2, 10.3]
>>> uniq, mult = signal.unique_roots(vals, tol=2e-2, rtype='avg')
```

Check which roots have multiplicity larger than 1:

```python
>>> uniq[mult > 1]
array([ 1.305])
```

**scipy.signal.residue**

`scipy.signal.residue(b, a, tol=0.001, rtype='avg')`

Compute partial-fraction expansion of \(b(s) / a(s)\).

If \(M\) is the degree of numerator \(b\) and \(N\) the degree of denominator \(a\):

\[
H(s) = \frac{b(s)}{a(s)} = \frac{b[0] \ s**(M) + b[1] \ s**(M-1) + \ldots + b[M]}{a[0] \ s**+(N) + a[1] \ s**(N-1) + \ldots + a[N]}
\]

then the partial-fraction expansion \(H(s)\) is defined as:

\[
\begin{align*}
\frac{r[0]}{(s-p[0])} & \quad \frac{r[1]}{(s-p[1])} & \quad \frac{r[-1]}{(s-p[-1])} \\
\end{align*}
\]

If there are any repeated roots (closer together than \(tol\)), then \(H(s)\) has terms like:
This function is used for polynomials in positive powers of \( s \) or \( z \), such as analog filters or digital filters in controls engineering. For negative powers of \( z \) (typical for digital filters in DSP), use \texttt{residuez}. See Notes for details about the algorithm.

### Parameters

- \( b \)  
  - [array_like] Numerator polynomial coefficients.

- \( a \)  
  - [array_like] Denominator polynomial coefficients.

- \( \texttt{tol} \)  
  - [float, optional] The tolerance for two roots to be considered equal in terms of the distance between them. Default is 1e-3. See \texttt{unique_roots} for further details.

- \( \texttt{rtype} \)  
  - [{'avg', 'min', 'max'}, optional] Method for computing a root to represent a group of identical roots. Default is 'avg'. See \texttt{unique_roots} for further details.

### Returns

- \( r \)  
  - [ndarray] Residues corresponding to the poles. For repeated poles, the residues are ordered to correspond to ascending by power fractions.

- \( p \)  
  - [ndarray] Poles ordered by magnitude in ascending order.

- \( k \)  
  - [ndarray] Coefficients of the direct polynomial term.

See also:

- \texttt{invres}, \texttt{residuez}, \texttt{numpy.poly}, \texttt{unique_roots}

### Notes

The “deflation through subtraction” algorithm is used for computations — method 6 in [1].

The form of partial fraction expansion depends on poles multiplicity in the exact mathematical sense. However there is no way to exactly determine multiplicity of roots of a polynomial in numerical computing. Thus you should think of the result of \texttt{residue} with given \( \texttt{tol} \) as partial fraction expansion computed for the denominator composed of the computed poles with empirically determined multiplicity. The choice of \( \texttt{tol} \) can drastically change the result if there are close poles.

### References

[1]

scipy.signal.residuez

scipy.signal\.residuez\( b, a, \texttt{tol}=0.001, \texttt{rtype}='\texttt{avg}'\)

Compute partial-fraction expansion of \( b(z) / a(z) \).

If \( M \) is the degree of numerator \( b \) and \( N \) the degree of denominator \( a \):

\[
\begin{align*}
\frac{b(z)}{a(z)} &= \frac{b[0] + b[1] z**(-1) + \ldots + b[M] z**(-M)}{a[0] + a[1] z**(-1) + \ldots + a[N] z**(-N)}
\end{align*}
\]

then the partial-fraction expansion \( H(z) \) is defined as:
```latex
\begin{align*}
  r[0] &\quad r[-1] \\
  = &\quad \frac{-\ldots-\frac{k[0]}{(1-p[0]z^*(-1))}}{\frac{k[1]}{(1-p[-1]z^*(-1))}} + \ldots + k[0] + k[1]z^*(1) \ldots
\end{align*}
```

If there are any repeated roots (closer than \( \text{tol} \)), then the partial fraction expansion has terms like:

```latex
\begin{align*}
  r[i] &\quad r[i+1] &\quad r[i+n-1] \\
  \frac{-\ldots-\frac{r[i]}{(1-p[i]z^*(-1))}}{\frac{r[i+1]}{(1-p[i]z^*(-1))}**2} &\quad \frac{r[i+n-1]}{(1-p[i]z^*(-1))**n}
\end{align*}
```

This function is used for polynomials in negative powers of \( z \), such as digital filters in DSP. For positive powers, use \texttt{residue}.

See Notes of \texttt{residue} for details about the algorithm.

**Parameters**

- \texttt{b} [array_like]: Numerator polynomial coefficients.
- \texttt{a} [array_like]: Denominator polynomial coefficients.
- \texttt{tol} [float, optional]: The tolerance for two roots to be considered equal in terms of the distance between them. Default is 1e-3. See \texttt{unique_roots} for further details.
- \texttt{rtype} [['avg', 'min', 'max'], optional]: Method for computing a root to represent a group of identical roots. Default is 'avg'. See \texttt{unique_roots} for further details.

**Returns**

- \texttt{r} [ndarray]: Residues corresponding to the poles. For repeated poles, the residues are ordered to correspond to ascending by power fractions.
- \texttt{p} [ndarray]: Poles ordered by magnitude in ascending order.
- \texttt{k} [ndarray]: Coefficients of the direct polynomial term.

See also:

- \texttt{invresz}, \texttt{residue}, \texttt{unique_roots}

**scipy.signal.invres**

\texttt{scipy.signal.invres} \((r, p, k, \text{tol}=0.001, \text{rtype}='\text{avg}')\)

Compute \( b(s) \) and \( a(s) \) from partial fraction expansion.

If \( M \) is the degree of numerator \( b \) and \( N \) the degree of denominator \( a \):

\[
H(s) = \frac{b(s)}{a(s)} = \frac{b[0] s^*(M) + b[1] s^*(M-1) + \ldots + b[M]}{a[0] s^*(N) + a[1] s^*(N-1) + \ldots + a[N]}
\]

then the partial-fraction expansion \( H(s) \) is defined as:

\[
\begin{align*}
  r[0] &\quad r[1] &\quad r[-1] \\
  = &\quad \frac{-\ldots-\frac{r[0]}{(s-p[0])}}{\frac{r[1]}{(s-p[1])}} + \frac{-\ldots-\frac{r[-1]}{(s-p[-1])}}{\frac{k(s)}{(s-p[-1])}} + k(s)
\end{align*}
\]

If there are any repeated roots (closer together than \( \text{tol} \)), then \( H(s) \) has terms like:

\[
\begin{align*}
  r[i] &\quad r[i+1] &\quad r[i+n-1] \\
  \frac{-\ldots-\frac{r[i]}{(s-p[i])}}{\frac{r[i+1]}{(s-p[i])}**2} &\quad \frac{r[i+n-1]}{(s-p[i])**n}
\end{align*}
\]
This function is used for polynomials in positive powers of s or z, such as analog filters or digital filters in controls engineering. For negative powers of z (typical for digital filters in DSP), use `invresz`.

**Parameters**

- **r** [array_like] Residues corresponding to the poles. For repeated poles, the residues must be ordered to correspond to ascending by power fractions.
- **p** [array_like] Poles. Equal poles must be adjacent.
- **k** [array_like] Coefficients of the direct polynomial term.
- **tol** [float, optional] The tolerance for two roots to be considered equal in terms of the distance between them. Default is 1e-3. See `unique_roots` for further details.
- **rtype** [{'avg', 'min', 'max'}, optional] Method for computing a root to represent a group of identical roots. Default is 'avg'. See `unique_roots` for further details.

**Returns**

- **b** [ndarray] Numerator polynomial coefficients.
- **a** [ndarray] Denominator polynomial coefficients.

See also:

`residue`, `invresz`, `unique_roots`

### scipy.signal.invresz

scipy.signal.invresz(r, p, k, tol=0.001, rtype='avg')

Compute b(z) and a(z) from partial fraction expansion.

If $M$ is the degree of numerator $b$ and $N$ the degree of denominator $a$:

\[
H(z) = \frac{b(z)}{a(z)} = \frac{b[0] + b[1] z**(-1) + \ldots + b[M] z**(-M)}{a[0] + a[1] z**(-1) + \ldots + a[N] z**(-N)}
\]

then the partial-fraction expansion $H(z)$ is defined as:

\[
\frac{r[0]}{(1-p[0]z**(-1))} + \frac{r[1]}{(1-p[-1]z**(-1))} + \ldots
\]

If there are any repeated roots (closer than `tol`), then the partial fraction expansion has terms like:

\[
\frac{r[i]}{(1-p[i]z**(-1))} + \frac{r[i+1]}{(1-p[i]z**(-1))^2} + \ldots + \frac{r[i+n-1]}{(1-p[i]z**(-1))^n}
\]

This function is used for polynomials in negative powers of z, such as digital filters in DSP. For positive powers, use `invres`.

**Parameters**

- **r** [array_like] Residues corresponding to the poles. For repeated poles, the residues must be ordered to correspond to ascending by power fractions.
- **p** [array_like] Poles. Equal poles must be adjacent.
- **k** [array_like] Coefficients of the direct polynomial term.
- **tol** [float, optional] The tolerance for two roots to be considered equal in terms of the distance between them. Default is 1e-3. See `unique_roots` for further details.
**rtype**

[{'avg', 'min', 'max'}, optional] Method for computing a root to represent a group of identical roots. Default is 'avg'. See `unique_roots` for further details.

**Returns**

- `b` [ndarray] Numerator polynomial coefficients.
- `a` [ndarray] Denominator polynomial coefficients.

**See also:**

`residuez`, `unique_roots`, `invres`

**scipy.signal.abcd_normalize**

**scipy.signal.abcd_normalize**(A=None, B=None, C=None, D=None)

Check state-space matrices and ensure they are 2-D.

If enough information on the system is provided, that is, enough properly-shaped arrays are passed to the function, the missing ones are built from this information, ensuring the correct number of rows and columns. Otherwise a ValueError is raised.

**Parameters**

- **A, B, C, D** [array_like, optional] State-space matrices. All of them are None (missing) by default. See `ss2tf` for format.

**Returns**

- **A, B, C, D** [array] Properly shaped state-space matrices.

**Raises**

- **ValueError**

  If not enough information on the system was provided.

**scipy.signal.band_stop_obj**

**scipy.signal.band_stop_obj**(wp, ind, passb, stopb, gpass, gstop, type)

Band Stop Objective Function for order minimization.

Returns the non-integer order for an analog band stop filter.

**Parameters**

- **wp** [scalar] Edge of passband `passb`.
- **ind** [int, {0, 1}] Index specifying which `passb` edge to vary (0 or 1).
- **passb** [ndarray] Two element sequence of fixed passband edges.
- **stopb** [ndarray] Two element sequence of fixed stopband edges.
- **gstop** [float] Amount of attenuation in stopband in dB.
- **gpass** [float] Amount of ripple in the passband in dB.
- **type** [{'butter', 'cheby', 'ellip'}] Type of filter.

**Returns**

- **n** [scalar] Filter order (possibly non-integer).

**scipy.signal.besselap**

**scipy.signal.besselap**(N, norm='phase')

Return (z,p,k) for analog prototype of an Nth-order Bessel filter.

**Parameters**

- **N** [int] The order of the filter.
- **norm** [{'phase', 'delay', 'mag'}, optional] Frequency normalization:
  - **phase**
    - The filter is normalized such that the phase response reaches its midpoint at an angular (e.g., rad/s) cutoff frequency of 1. This happens for both low-pass and high-pass filters, so this is the “phase-matched” case. [6]
    - The magnitude response asymptotes are the same as a Butterworth filter of the same order with a cutoff of \( Wn \).
    - This is the default, and matches MATLAB’s implementation.

---

6.22. Signal processing (`scipy.signal`)
delay  The filter is normalized such that the group delay in the passband is 1 (e.g., 1 second). This is the “natural” type obtained by solving Bessel polynomials

mag  The filter is normalized such that the gain magnitude is -3 dB at angular frequency 1. This is called “frequency normalization” by Bond. [1]

New in version 0.18.0.

Returns

- z  [ndarray] Zeros of the transfer function. Is always an empty array.
- p  [ndarray] Poles of the transfer function.
- k  [scalar] Gain of the transfer function. For phase-normalized, this is always 1.

See also:

bessel

Filter design function using this prototype

Notes

To find the pole locations, approximate starting points are generated [2] for the zeros of the ordinary Bessel polynomial [3], then the Aberth-Ehrlich method [4] [5] is used on the Kv(x) Bessel function to calculate more accurate zeros, and these locations are then inverted about the unit circle.

References

[1], [2], [3], [4], [5], [6]

`scipy.signal.buttap`

`scipy.signal.buttap(N)`

Return (z,p,k) for analog prototype of Nth-order Butterworth filter. The filter will have an angular (e.g., rad/s) cutoff frequency of 1.

See also:

butter

Filter design function using this prototype

`scipy.signal.cheb1ap`

`scipy.signal.cheb1ap(N, rp)`

Return (z,p,k) for Nth-order Chebyshev type I analog lowpass filter. The returned filter prototype has rp decibels of ripple in the passband.

The filter’s angular (e.g. rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first drops below −rp.

See also:

cheby1

Filter design function using this prototype
scipy.signal.cheb2ap

scipy.signal.cheb2ap(N, rs)
Return (z,p,k) for Nth-order Chebyshev type I analog lowpass filter.
The returned filter prototype has rs decibels of ripple in the stopband.
The filter's angular (e.g., rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first reaches -rs.

See also:

cheby2
Filter design function using this prototype

scipy.signal.cmplx_sort

scipy.signal.cmplx_sort(p)
Sort roots based on magnitude.

Parameters

p
[array_like] The roots to sort, as a 1-D array.

Returns

indx [ndarray] Array of indices needed to sort the input p.

Examples

```python
>>> from scipy import signal
>>> vals = [1, 4, 1+1.j, 3]
>>> p_sorted, indx = signal.cmplx_sort(vals)
>>> p_sorted
array([1.+0.j, 1.+1.j, 3.+0.j, 4.+0.j])
>>> indx
array([0, 2, 3, 1])
```

scipy.signal.ellipap

scipy.signal.ellipap(N, rp, rs)
Return (z,p,k) of Nth-order elliptic analog lowpass filter.
The filter is a normalized prototype that has rp decibels of ripple in the passband and a stopband rs decibels down.
The filter's angular (e.g., rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first drops below -rp.

[1]

scipy.signal.lp2bp

scipy.signal.lp2bp(b, a, wo=1.0, bw=1.0)

Transform a lowpass filter prototype to a bandpass filter.

Return an analog band-pass filter with center frequency wo and bandwidth bw from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

Parameters

b [array_like] Numerator polynomial coefficients.
a [array_like] Denominator polynomial coefficients.
wo [float] Desired passband center, as angular frequency (e.g., rad/s). Defaults to no change.
bw [float] Desired passband width, as angular frequency (e.g., rad/s). Defaults to 1.

Returns

b [array_like] Numerator polynomial coefficients of the transformed band-pass filter.
a [array_like] Denominator polynomial coefficients of the transformed band-pass filter.

See also:

lp2lp, lp2hp, lp2bs, bilinear

lp2bp_zpk

Notes

This is derived from the s-plane substitution

\[ s \rightarrow \frac{s^2 + \omega_0^2}{s \cdot BW} \]

This is the “wideband” transformation, producing a passband with geometric (log frequency) symmetry about wo.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> lp = signal.lti([1.0], [1.0, 1.0])
>>> bp = signal.lti(*signal.lp2bp(lp.num, lp.den))
>>> w, mag_lp, p_lp = lp.bode()
>>> w, mag_bp, p_bp = bp.bode(w)

>>> plt.plot(w, mag_lp, label='Lowpass')
>>> plt.plot(w, mag_bp, label='Bandpass')
>>> plt.semilogx()
>>> plt.grid()
>>> plt.xlabel('Frequency [rad/s]')
```
>> plt.ylabel('Magnitude [dB]')
>> plt.legend()

```

Frequency [rad/s]

---

**scipy.signal.lp2bp_zpk**

*scipy.signal.lp2bp_zpk*(z, p, k, wo=1.0, bw=1.0)  
Transform a lowpass filter prototype to a bandpass filter.

Return an analog band-pass filter with center frequency *wo* and bandwidth *bw* from an analog low-pass filter prototype with unity cutoff frequency, using zeros, poles, and gain ('zpk') representation.

**Parameters**

- *z* [array_like] Zeros of the analog filter transfer function.
- *p* [array_like] Poles of the analog filter transfer function.
- *k* [float] System gain of the analog filter transfer function.
- *wo* [float] Desired passband center, as angular frequency (e.g., rad/s). Defaults to no change.
- *bw* [float] Desired passband width, as angular frequency (e.g., rad/s). Defaults to 1.

**Returns**

- *z* [ndarray] Zeros of the transformed band-pass filter transfer function.
- *p* [ndarray] Poles of the transformed band-pass filter transfer function.
- *k* [float] System gain of the transformed band-pass filter.

**See also:**

- *lp2bp*

---

6.22. Signal processing (scipy.signal) 1865
Notes

This is derived from the s-plane substitution

\[ s \rightarrow \frac{s^2 + \omega_0^2}{s \cdot BW} \]

This is the “wideband” transformation, producing a passband with geometric (log frequency) symmetry about \( \omega_0 \).

New in version 1.1.0.

**scipy.signal.lp2bs**

**scipy.signal.lp2bs\( \{b, a, wo=1.0, bw=1.0\} \)**

Transform a lowpass filter prototype to a bandstop filter.

Return an analog band-stop filter with center frequency \( \omega_0 \) and bandwidth \( bw \) from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

**Parameters**

- \( b \)  
  [array_like] Numerator polynomial coefficients.
- \( a \)  
  [array_like] Denominator polynomial coefficients.
- \( wo \)  
  [float] Desired stopband center, as angular frequency (e.g., rad/s). Defaults to no change.
- \( bw \)  
  [float] Desired stopband width, as angular frequency (e.g., rad/s). Defaults to 1.

**Returns**

- \( b \)  
  [array_like] Numerator polynomial coefficients of the transformed band-stop filter.
- \( a \)  
  [array_like] Denominator polynomial coefficients of the transformed band-stop filter.

See also:

- \( lp2lp \), \( lp2hp \), \( lp2bp \), \( bilinear \)
- \( lp2bs\_zpk \)

**Notes**

This is derived from the s-plane substitution

\[ s \rightarrow \frac{s \cdot BW}{s^2 + \omega_0^2} \]

This is the “wideband” transformation, producing a stopband with geometric (log frequency) symmetry about \( \omega_0 \).

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> lp = signal.lti([1.0], [1.0, 1.5])
>>> bs = signal.lti(*signal.lp2bs(lp.num, lp.den))
>>> w, mag_lp, p_lp = lp.bode()
>>> w, mag_bs, p_bs = bs.bode(w)
>>> plt.plot(w, mag_lp, label='Lowpass')
```
```python
>>> plt.plot(w, mag_bs, label='Bandstop')
>>> plt.semilogx()
>>> plt.grid()
>>> plt.xlabel('Frequency [rad/s]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.legend()
```

![Magnitude vs Frequency](image)

### scipy.signal.lp2bs_zpk

**scipy.signal.lp2bs_zpk** *(z, p, k, wo=1.0, bw=1.0)*

Transform a lowpass filter prototype to a bandstop filter.

Return an analog band-stop filter with center frequency *wo* and stopband width *bw* from an analog low-pass filter prototype with unity cutoff frequency, using zeros, poles, and gain (`zpk`) representation.

**Parameters**

- **z** *(array_like)* Zeros of the analog filter transfer function.
- **p** *(array_like)* Poles of the analog filter transfer function.
- **k** *(float)* System gain of the analog filter transfer function.
- **wo** *(float)* Desired stopband center, as angular frequency (e.g., rad/s). Defaults to no change.
- **bw** *(float)* Desired stopband width, as angular frequency (e.g., rad/s). Defaults to 1.

**Returns**

- **z** *(ndarray)* Zeros of the transformed band-stop filter transfer function.
- **p** *(ndarray)* Poles of the transformed band-stop filter transfer function.
- **k** *(float)* System gain of the transformed band-stop filter.

**See also:**

- `lp2lp_zpk`, `lp2hp_zpk`, `lp2bp_zpk`, `bilinear`
- `lp2bs`
**Notes**

This is derived from the s-plane substitution

\[ s \rightarrow \frac{s \cdot BW}{s^2 + \omega_0^2} \]

This is the “wideband” transformation, producing a stopband with geometric (log frequency) symmetry about \( \omega_0 \).

New in version 1.1.0.

**scipy.signal.lp2hp**

**scipy.signal.lp2hp \((b, a, \omega_0=1.0)\)**

Transform a lowpass filter prototype to a highpass filter.

Return an analog high-pass filter with cutoff frequency \( \omega_0 \) from an analog low-pass filter prototype with unity cutoff frequency, in transfer function (‘ba’) representation.

**Parameters**

- **b** [array_like] Numerator polynomial coefficients.
- **a** [array_like] Denominator polynomial coefficients.
- **\( \omega_0 \)** [float] Desired cutoff, as angular frequency (e.g., rad/s). Defaults to no change.

**Returns**

- **b** [array_like] Numerator polynomial coefficients of the transformed high-pass filter.
- **a** [array_like] Denominator polynomial coefficients of the transformed high-pass filter.

**See also:**

- `lp2lp`, `lp2bp`, `lp2bs`, `bilinear`
- `lp2hp_zpk`

**Notes**

This is derived from the s-plane substitution

\[ s \rightarrow \frac{\omega_0}{s} \]

This maintains symmetry of the lowpass and highpass responses on a logarithmic scale.

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> lp = signal.lti([1.0], [1.0, 1.0])
>>> hp = signal.lti(signal.lp2hp(lp.num, lp.den))
>>> w, mag_lp, p_lp = lp.bode()
>>> w, mag_hp, p_hp = hp.bode(w)
```
```python
>>> plt.plot(w, mag_lp, label='Lowpass')
>>> plt.plot(w, mag_hp, label='Highpass')
>>> plt.semilogx()
>>> plt.grid()
>>> plt.xlabel('Frequency [rad/s]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.legend()
```

![Plot of Lowpass and Highpass transfer functions](image)

```python
scipy.signal.lp2hp_zpk
```

`scipy.signal.lp2hp_zpk(z, p, k, wo=1.0)`

Transform a lowpass filter prototype to a highpass filter.

Return an analog high-pass filter with cutoff frequency `wo` from an analog low-pass filter prototype with unity cutoff frequency, using zeros, poles, and gain ('zpk') representation.

**Parameters**

- `z` [array_like] Zeros of the analog filter transfer function.
- `p` [array_like] Poles of the analog filter transfer function.
- `k` [float] System gain of the analog filter transfer function.
- `wo` [float] Desired cutoff, as angular frequency (e.g., rad/s). Defaults to no change.

**Returns**

- `z` [ndarray] Zeros of the transformed high-pass filter transfer function.
- `p` [ndarray] Poles of the transformed high-pass filter transfer function.
- `k` [float] System gain of the transformed high-pass filter.

**See also:**

- `lp2lp_zpk`, `lp2bp_zpk`, `lp2bs_zpk`, `bilinear`
- `lp2hp`
Notes

This is derived from the s-plane substitution

\[ s \rightarrow \frac{\omega_0}{s} \]

This maintains symmetry of the lowpass and highpass responses on a logarithmic scale.

New in version 1.1.0.

scipy.signal.lp2lp

scipy.signal.lp2lp(b, a, wo=1.0)
Transform a lowpass filter prototype to a different frequency.

Return an analog low-pass filter with cutoff frequency \( \omega_0 \) from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

Parameters

- b [array_like] Numerator polynomial coefficients.
- a [array_like] Denominator polynomial coefficients.
- wo [float] Desired cutoff, as angular frequency (e.g. rad/s). Defaults to no change.

Returns

- b [array_like] Numerator polynomial coefficients of the transformed low-pass filter.
- a [array_like] Denominator polynomial coefficients of the transformed low-pass filter.

See also:

lp2hp, lp2bp, lp2bs, bilinear

lp2lp_zpk

Notes

This is derived from the s-plane substitution

\[ s \rightarrow \frac{s}{\omega_0} \]

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> lp = signal.lti([1.0], [1.0, 1.0])
>>> lp2 = signal.lti(*signal.lp2lp(lp.num, lp.den, 2))
>>> w, mag_lp, p_lp = lp.bode()
>>> w, mag_lp2, p_lp2 = lp2.bode(w)
```
```python
>>> plt.plot(w, mag_lp, label='Lowpass')
>>> plt.plot(w, mag_lp2, label='Transformed Lowpass')
>>> plt.semilogx()
>>> plt.grid()
>>> plt.xlabel('Frequency [rad/s]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.legend()
```

```python
scipy.signal.lp2lp_zpk
```

`scipy.signal.lp2lp_zpk(z, p, k, wo=1.0)`

Transform a lowpass filter prototype to a different frequency.

Return an analog low-pass filter with cutoff frequency \( wo \) from an analog low-pass filter prototype with unity cutoff frequency, using zeros, poles, and gain ('zpk') representation.

**Parameters**

- **z** [array_like] Zeros of the analog filter transfer function.
- **p** [array_like] Poles of the analog filter transfer function.
- **k** [float] System gain of the analog filter transfer function.
- **wo** [float] Desired cutoff, as angular frequency (e.g., rad/s). Defaults to no change.

**Returns**

- **z** [ndarray] Zeros of the transformed low-pass filter transfer function.
- **p** [ndarray] Poles of the transformed low-pass filter transfer function.
- **k** [float] System gain of the transformed low-pass filter.

**See also:**

- `lp2hp_zpk`, `lp2bp_zpk`, `lp2bs_zpk`, `bilinear`
- `lp2lp`
Notes

This is derived from the s-plane substitution

\[ s \rightarrow \frac{s}{\omega_0} \]

New in version 1.1.0.

scipy.signal.normalize

\texttt{scipy.signal.normalize}(b, a)

Normalize numerator/denominator of a continuous-time transfer function.

If values of \( b \) are too close to 0, they are removed. In that case, a BadCoefficients warning is emitted.

Parameters

- \( b: \text{array_like} \)
  - Numerator of the transfer function. Can be a 2-D array to normalize multiple transfer functions.

- \( a: \text{array_like} \)
  - Denominator of the transfer function. At most 1-D.

Returns

- \( \text{num: array} \)
  - The numerator of the normalized transfer function. At least a 1-D array. A 2-D array if the input \( \text{num} \) is a 2-D array.

- \( \text{den: 1-D array} \)
  - The denominator of the normalized transfer function.

Notes

Coefficients for both the numerator and denominator should be specified in descending exponent order (e.g., \( s^2 + 3s + 5 \) would be represented as \([1, 3, 5]\)).

scipy.signal.butter

scipy.signal.butter(\(N, \text{Wn}, \text{btype}='\text{low}', \text{analog}=\text{False}, \text{output}='\text{ba}', \text{fs}=\text{None}\))

Butterworth digital and analog filter design.

Design an Nth-order digital or analog Butterworth filter and return the filter coefficients.

**Parameters**

- **N** [int] The order of the filter.
- **Wn** [array_like] The critical frequency or frequencies. For lowpass and highpass filters, \(Wn\) is a scalar; for bandpass and bandstop filters, \(Wn\) is a length-2 sequence.
  For a Butterworth filter, this is the point at which the gain drops to \(1/\sqrt{2}\) that of the passband (the "-3 dB point").
  For digital filters, \(Wn\) are in the same units as \(fs\). By default, \(fs\) is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (\(Wn\) is thus in half-cycles/sample.)
  For analog filters, \(Wn\) is an angular frequency (e.g. rad/s).
- **btype** [{'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional] The type of filter. Default is 'low-pass'.
- **analog** [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.
- **output** [{'ba', 'zpk', 'sos'}, optional] Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba' for backwards compatibility, but 'sos' should be used for general-purpose filtering.
- **fs** [float, optional] The sampling frequency of the digital system.

**Returns**

- **b, a** [ndarray, ndarray] Numerator \((b)\) and denominator \((a)\) polynomials of the IIR filter. Only returned if \(output='ba'\).
- **z, p, k** [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if \(output='zpk'\).
- **sos** [ndarray] Second-order sections representation of the IIR filter. Only returned if \(output=='sos'\).

See also:

- buttord, buttap

**Notes**

The Butterworth filter has maximally flat frequency response in the passband.

The 'sos' output parameter was added in 0.16.0.

If the transfer function form \([b, a]\) is requested, numerical problems can occur since the conversion between roots and the polynomial coefficients is a numerically sensitive operation, even for \(N \geq 4\). It is recommended to work with the SOS representation.
Examples

Design an analog filter and plot its frequency response, showing the critical points:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.butter(4, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Butterworth filter frequency response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green')  # cutoff frequency
>>> plt.show()
```

![Butterworth filter frequency response](image)

Generate a signal made up of 10 Hz and 20 Hz, sampled at 1 kHz

```python
>>> t = np.linspace(0, 1, 1000, False)  # 1 second
>>> sig = np.sin(2*np.pi*10*t) + np.sin(2*np.pi*20*t)
>>> fig, (ax1, ax2) = plt.subplots(2, 1, sharex=True)
>>> ax1.plot(t, sig)
>>> ax1.set_title('10 Hz and 20 Hz sinusoids')
>>> ax1.axis([0, 1, -2, 2])
```

Design a digital high-pass filter at 15 Hz to remove the 10 Hz tone, and apply it to the signal. (It’s recommended to use second-order sections format when filtering, to avoid numerical error with transfer function (ba) format):

```python
>>> sos = signal.butter(10, 15, 'hp', fs=1000, output='sos')
>>> filtered = signal.sosfilt(sos, sig)
>>> ax2.plot(t, filtered)
>>> ax2.set_title('After 15 Hz high-pass filter')
```

(continues on next page)
```python
>>> ax2.axis([0, 1, -2, 2])
>>> ax2.set_xlabel('Time [seconds]')
>>> plt.tight_layout()
>>> plt.show()
```

![Graph showing 10 Hz and 20 Hz sinusoids](image)

![Graph showing After 15 Hz high-pass filter](image)

**scipy.signal.buttord**

*scipy.signal.buttord(wp, ws, gpass, gstop, analog=False, fs=None)*

Butterworth filter order selection.

Return the order of the lowest order digital or analog Butterworth filter that loses no more than *gpass* dB in the passband and has at least *gstop* dB attenuation in the stopband.

**Parameters**

- **wp, ws** [float] Passband and stopband edge frequencies. For digital filters, these are in the same units as *fs*. By default, *fs* is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (*wp* and *ws* are thus in half-cycles/sample.) For example:
  - Lowpass: *wp* = 0.2, *ws* = 0.3
  - Highpass: *wp* = 0.3, *ws* = 0.2
  - Bandpass: *wp* = [0.2, 0.5], *ws* = [0.1, 0.6]
  - Bandstop: *wp* = [0.1, 0.6], *ws* = [0.2, 0.5]
  For analog filters, *wp* and *ws* are angular frequencies (e.g., rad/s).
- **gpass** [float] The maximum loss in the passband (dB).
- **gstop** [float] The minimum attenuation in the stopband (dB).
- **analog** [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.
- **fs** [float, optional] The sampling frequency of the digital system.
  New in version 1.2.0.

**Returns**

- **ord** [int] The lowest order for a Butterworth filter which meets specs.

wn [ndarray or float] The Butterworth natural frequency (i.e. the “3dB frequency”). Should be used with _butter_ to give filter results. If _fs_ is specified, this is in the same units, and _fs_ must also be passed to _butter_.

General filter design using order and critical frequencies

*iirdesign*

General filter design using passband and stopband spec

**Examples**

Design an analog bandpass filter with passband within 3 dB from 20 to 50 rad/s, while rejecting at least -40 dB below 14 and above 60 rad/s. Plot its frequency response, showing the passband and stopband constraints in gray.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> N, Wn = signal.buttord([20, 50], [14, 60], 3, 40, True)
>>> b, a = signal.butter(N, Wn, 'band', True)
>>> w, h = signal.freqs(b, a, np.logspace(1, 2, 500))
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Butterworth bandpass filter fit to constraints')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([1, 14, 14, 1], [-40, -40, 99, 99], '0.9', lw=0) # stop
>>> plt.fill([20, 20, 50, 50], [-99, -3, -3, -99], '0.9', lw=0) # pass
>>> plt.fill([60, 60, 1e9, 1e9], [99, -40, -40, 99], '0.9', lw=0) # stop
>>> plt.axis([10, 100, -60, 3])
>>> plt.show()
```

**scipy.signal.cheby1**

*scipy.signal.cheby1* (*N, rp, Wn, btype='low', analog=False, output='ba', fs=None*)

Chebyshev type I digital and analog filter design.

Design an Nth-order digital or analog Chebyshev type I filter and return the filter coefficients.

**Parameters**

*N* [int] The order of the filter.

*rp* [float] The maximum ripple allowed below unity gain in the passband. Specified in decibels, as a positive number.
Wn | [array_like] A scalar or length-2 sequence giving the critical frequencies. For Type I filters, this is the point in the transition band at which the gain first drops below \(-\)Rp. For digital filters, \(Wn\) are in the same units as \(fs\). By default, \(fs\) is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (\(Wn\) is thus in half-cycles/sample.) For analog filters, \(Wn\) is an angular frequency (e.g., rad/s).

analog | [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

output | [{‘ba’, ‘zpk’, ‘sos’}, optional] Type of output: numerator/denominator (‘ba’), pole-zero (‘zpk’), or second-order sections (‘sos’). Default is ‘ba’ for backwards compatibility, but ‘sos’ should be used for general-purpose filtering.

Returns

b, a | [ndarray, ndarray] Numerator (\(b\)) and denominator (\(a\)) polynomials of the IIR filter. Only returned if \(output='ba'\).

z, p, k | [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if \(output='zpk'\).

sos | [ndarray] Second-order sections representation of the IIR filter. Only returned if \(output='sos'\).

See also:

chebord, chebap
Notes

The Chebyshev type I filter maximizes the rate of cutoff between the frequency response’s passband and stopband, at the expense of ripple in the passband and increased ringing in the step response.

Type I filters roll off faster than Type II (cheby2), but Type II filters do not have any ripple in the passband. The equiripple passband has N maxima or minima (for example, a 5th-order filter has 3 maxima and 2 minima). Consequently, the DC gain is unity for odd-order filters, or -rp dB for even-order filters.

The 'sos' output parameter was added in 0.16.0.

Examples

Design an analog filter and plot its frequency response, showing the critical points:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.cheby1(4, 5, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev Type I frequency response (rp=5)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.axhline(-5, color='green') # rp
>>> plt.show()
```

Generate a signal made up of 10 Hz and 20 Hz, sampled at 1 kHz
Design a digital high-pass filter at 15 Hz to remove the 10 Hz tone, and apply it to the signal. (It’s recommended to use second-order sections format when filtering, to avoid numerical error with transfer function (ba) format):

```python
>>> sos = signal.cheby1(10, 1, 15, 'hp', fs=1000, output='sos')
>>> filtered = signal.sosfilt(sos, sig)
>>> ax2.plot(t, filtered)
>>> ax2.set_title('After 15 Hz high-pass filter')
>>> ax2.axis([0, 1, -2, 2])
```
• Highpass: $wp = 0.3$, $ws = 0.2$
• Bandpass: $wp = [0.2, 0.5]$, $ws = [0.1, 0.6]$
• Bandstop: $wp = [0.1, 0.6]$, $ws = [0.2, 0.5]$

For analog filters, $wp$ and $ws$ are angular frequencies (e.g., rad/s).

**gpass**
[float] The maximum loss in the passband (dB).

**gstop**
[float] The minimum attenuation in the stopband (dB).

**analog**
[bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

**fs**
[float, optional] The sampling frequency of the digital system.

New in version 1.2.0.

**Returns**

**ord**
[int] The lowest order for a Chebyshev type I filter that meets specs.

**wn**
[ndarray or float] The Chebyshev natural frequency (the “3dB frequency”) for use with cheby1 to give filter results. If $fs$ is specified, this is in the same units, and $fs$ must also be passed to cheby1.

See also:

General filter design using order and critical frequencies

**iirdesign**
General filter design using passband and stopband spec

**Examples**

Design a digital lowpass filter such that the passband is within 3 dB up to 0.2*(fs/2), while rejecting at least -40 dB above 0.3*(fs/2). Plot its frequency response, showing the passband and stopband constraints in gray.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> N, Wn = signal.cheb1ord(0.2, 0.3, 3, 40)
>>> b, a = signal.cheby1(N, 3, Wn, 'low')
>>> w, h = signal.freqz(b, a)
>>> plt.semilogx(w / np.pi, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev I lowpass filter fit to constraints')
>>> plt.xlabel('Normalized frequency')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([.01, 0.2, 0.2, .01], [-3, -3, -99, -99], '0.9', lw=0) # stop
>>> plt.fill([0.3, 0.3, 2, 2], [9, -40, -40, 9], '0.9', lw=0) # pass
>>> plt.axis([0.08, 1, -60, 3])
>>> plt.show()
```
scipy.signal.cheby2

scipy.signal.cheby2 $(N, rs, Wn, btype='low', analog=False, output='ba', fs=None)$

Chebyshev type II digital and analog filter design.

Design an Nth-order digital or analog Chebyshev type II filter and return the filter coefficients.

**Parameters**

- $N$ [int] The order of the filter.
- $rs$ [float] The minimum attenuation required in the stop band. Specified in decibels, as a positive number.
- $Wn$ [array_like] A scalar or length-2 sequence giving the critical frequencies. For Type II filters, this is the point in the transition band at which the gain first reaches $-rs$. For digital filters, $Wn$ are in the same units as $fs$. By default, $fs$ is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. ($Wn$ is thus in half-cycles / sample.) For analog filters, $Wn$ is an angular frequency (e.g., rad/s).
- analog [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.
- output [‘ba’, ‘zpk’, ‘sos’], optional] Type of output: numerator/denominator (‘ba’), pole-zero (‘zpk’), or second-order sections (‘sos’). Default is ‘ba’ for backwards compatibility, but ‘sos’ should be used for general-purpose filtering.

**Returns**

- $b, a$ [ndarray, ndarray] Numerator ($b$) and denominator ($a$) polynomials of the IIR filter. Only returned if output='ba'.
- $z, p, k$ [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if output='zpk'.
- sos [ndarray] Second-order sections representation of the IIR filter. Only returned if output='sos'.

**See also:**

6.22. Signal processing (scipy.signal)
cheb2ord, cheb2ap

Notes

The Chebyshev type II filter maximizes the rate of cutoff between the frequency response’s passband and stopband, at the expense of ripple in the stopband and increased ringing in the step response.

Type II filters do not roll off as fast as Type I (cheby1).

The ‘sos’ output parameter was added in 0.16.0.

Examples

Design an analog filter and plot its frequency response, showing the critical points:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.cheby2(4, 40, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev Type II frequency response (rs=40)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green')  # cutoff frequency
>>> plt.axhline(-40, color='green')  # rs
>>> plt.show()
```

Generate a signal made up of 10 Hz and 20 Hz, sampled at 1 kHz.
```python
>>> t = np.linspace(0, 1, 1000, False)  # 1 second
>>> sig = np.sin(2*np.pi*10*t) + np.sin(2*np.pi*20*t)
>>> fig, (ax1, ax2) = plt.subplots(2, 1, sharex=True)
>>> ax1.plot(t, sig)
>>> ax1.set_title('10 Hz and 20 Hz sinusoids')
>>> ax1.axis([0, 1, -2, 2])
Design a digital high-pass filter at 17 Hz to remove the 10 Hz tone, and apply it to the signal. (It’s recommended to use second-order sections format when filtering, to avoid numerical error with transfer function (ba) format):

```python
>>> sos = signal.cheby2(12, 20, 17, 'hp', fs=1000, output='sos')
>>> filtered = signal.sosfilt(sos, sig)
>>> ax2.plot(t, filtered)
>>> ax2.set_title('After 17 Hz high-pass filter')
>>> ax2.axis([0, 1, -2, 2])
>>> ax2.set_xlabel('Time [seconds]')
>>> plt.show()
```
• Bandpass: \(wp = [0.2, 0.5], ws = [0.1, 0.6]\)
• Bandstop: \(wp = [0.1, 0.6], ws = [0.2, 0.5]\)

For analog filters, \(wp\) and \(ws\) are angular frequencies (e.g., rad/s).

\[g_{\text{pass}}\] [float] The maximum loss in the passband (dB).

\[g_{\text{stop}}\] [float] The minimum attenuation in the stopband (dB).

\[\text{analog}\] [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

\[fs\] [float, optional] The sampling frequency of the digital system.

New in version 1.2.0.

Returns

\[\text{ord}\] [int] The lowest order for a Chebyshev type II filter that meets specs.

\[\text{wn}\] [ndarray or float] The Chebyshev natural frequency (the “3dB frequency”) for use with \(\text{cheby2}\) to give filter results. If \(fs\) is specified, this is in the same units, and \(fs\) must also be passed to \(\text{cheby2}\).

General filter design using order and critical frequencies

\(\text{iirdesign}\)
General filter design using passband and stopband spec

Examples

Design a digital bandstop filter which rejects -60 dB from 0.2*(fs/2) to 0.5*(fs/2), while staying within 3 dB below 0.1*(fs/2) or above 0.6*(fs/2). Plot its frequency response, showing the passband and stopband constraints in gray.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> N, Wn = signal.cheb2ord([0.1, 0.6], [0.2, 0.5], 3, 60)
>>> b, a = signal.cheby2(N, 60, Wn, 'stop')
>>> w, h = signal.freqz(b, a)
>>> plt.semilogx(w / np.pi, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev II bandstop filter fit to constraints')
>>> plt.xlabel('Normalized frequency')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([.01, .1, .1, .01], [-3, -3, -99, -99], '0.9', lw=0) # stop
>>> plt.fill([.2, .2, .5, .5], [9, -60, -60, 9], '0.9', lw=0) # pass
>>> plt.fill([.6, .6, 2, 2], [-99, -3, -3, -99], '0.9', lw=0) # stop
>>> plt.axis([0.06, 1, -80, 3])
>>> plt.show()
```
**scipy.signal.ellip**

The function `scipy.signal.ellip(N, rp, rs, Wn, btype='low', analog=False, output='ba', fs=None)`

Elliptic (Cauer) digital and analog filter design.

Design an Nth-order digital or analog elliptic filter and return the filter coefficients.

**Parameters**

- **N** [int] The order of the filter.
- **rp** [float] The maximum ripple allowed below unity gain in the passband. Specified in decibels, as a positive number.
- **rs** [float] The minimum attenuation required in the stop band. Specified in decibels, as a positive number.
- **Wn** [array_like] A scalar or length-2 sequence giving the critical frequencies. For elliptic filters, this is the point in the transition band at which the gain first drops below -rp. For digital filters, Wn are in the same units as fs. By default, fs is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (Wn is thus in half-cycles / sample.) For analog filters, Wn is an angular frequency (e.g., rad/s).
- **btype** [{'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional] The type of filter. Default is 'lowpass'.
- **analog** [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.
- **output** [{'ba', 'zpk', 'sos'}, optional] Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba' for backwards compatibility, but 'sos' should be used for general-purpose filtering.
- **fs** [float, optional] The sampling frequency of the digital system. New in version 1.2.0.

**Returns**

- **b, a** [ndarray, ndarray] Numerator (b) and denominator (a) polynomials of the IIR filter. Only returned if output='ba'.
- **z, p, k** [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if output='zpk'.
- **sos** [ndarray] Second-order sections representation of the IIR filter. Only returned if output=='sos'.

6.22. Signal processing (scipy.signal)
See also: ellipord, ellipap

Notes

Also known as Cauer or Zolotarev filters, the elliptical filter maximizes the rate of transition between the frequency response's passband and stopband, at the expense of ripple in both, and increased ringing in the step response.

As \( rp \) approaches 0, the elliptical filter becomes a Chebyshev type II filter (cheby2). As \( rs \) approaches 0, it becomes a Chebyshev type I filter (cheby1). As both approach 0, it becomes a Butterworth filter (butter).

The equiripple passband has \( N \) maxima or minima (for example, a 5th-order filter has 3 maxima and 2 minima). Consequently, the DC gain is unity for odd-order filters, or \( -rp \) dB for even-order filters.

The 'sos' output parameter was added in 0.16.0.

Examples

Design an analog filter and plot its frequency response, showing the critical points:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> b, a = signal.ellip(4, 5, 40, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20*np.log10(abs(h)))
>>> plt.title('Elliptic filter frequency response (rp=5, rs=40)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both') # cutoff frequency
>>> plt.axvline(100, color='green') # rs
>>> plt.axhline(-5, color='green') # rp
>>> plt.show()
```

Generate a signal made up of 10 Hz and 20 Hz, sampled at 1 kHz

```python
>>> t = np.linspace(0, 1, 1000, False)  # 1 second
>>> sig = np.sin(2*np.pi*10*t) + np.sin(2*np.pi*20*t)
>>> fig, (ax1, ax2) = plt.subplots(2, 1, sharex=True)
>>> ax1.plot(t, sig)
>>> ax1.set_title('10 Hz and 20 Hz sinuosids')
>>> ax1.axis([0, 1, -2, 2])
```

Design a digital high-pass filter at 17 Hz to remove the 10 Hz tone, and apply it to the signal. (It's recommended to use second-order sections format when filtering, to avoid numerical error with transfer function (ba) format):

```python
>>> sos = signal.ellip(8, 1, 100, 17, 'hp', fs=1000, output='sos')
>>> filtered = signal.sosfilt(sos, sig)
>>> ax2.plot(t, filtered)
>>> ax2.set_title('After 17 Hz high-pass filter')
```
Elliptic filter frequency response (rp=5, rs=40)

>>> ax2.axis([0, 1, -2, 2])
>>> ax2.set_xlabel('Time [seconds]
>>> plt.tight_layout()
>>> plt.show()
**scipy.signal.ellipord**

`scipy.signal.ellipord(wp, ws, gpass, gstop, analog=False, fs=None)`

Elliptic (Cauer) filter order selection.

Return the order of the lowest order digital or analog elliptic filter that loses no more than `gpass` dB in the passband and has at least `gstop` dB attenuation in the stopband.

**Parameters**

- `wp, ws` [float] Passband and stopband edge frequencies. For digital filters, these are in the same units as `fs`. By default, `fs` is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (wp and ws are thus in half-cycles / sample.) For example:
  - Lowpass: wp = 0.2, ws = 0.3
  - Highpass: wp = 0.3, ws = 0.2
  - Bandpass: wp = [0.2, 0.5], ws = [0.1, 0.6]
  - Bandstop: wp = [0.1, 0.6], ws = [0.2, 0.5]
  For analog filters, `wp` and `ws` are angular frequencies (e.g., rad/s).

- `gpass` [float] The maximum loss in the passband (dB).

- `gstop` [float] The minimum attenuation in the stopband (dB).

- `analog` [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

- `fs` [float, optional] The sampling frequency of the digital system.

New in version 1.2.0.

**Returns**

- `ord` [int] The lowest order for an Elliptic (Cauer) filter that meets specs.

- `wn` [ndarray or float] The Chebyshev natural frequency (the “3dB frequency”) for use with `ellip` to give filter results. If `fs` is specified, this is in the same units, and `fs` must also be passed to `ellip`.

**See also:**

- `ellip` Filter design using order and critical points

- `buttord` Find order and critical points from passband and stopband spec

- `cheb1ord, cheb2ord` iirfilter

  General filter design using order and critical frequencies

- `iirdesign` iirfilter

  General filter design using passband and stopband spec
Examples

Design an analog highpass filter such that the passband is within 3 dB above 30 rad/s, while rejecting -60 dB at 10 rad/s. Plot its frequency response, showing the passband and stopband constraints in gray.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> N, Wn = signal.ellipord(30, 10, 3, 60, True)
>>> b, a = signal.ellip(N, 3, 60, Wn, 'high', True)
>>> w, h = signal.freqs(b, a, np.logspace(0, 3, 500))
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Elliptical highpass filter fit to constraints')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([.1, 10, 10, .1], [1e4, 1e4, -60, -60], '0.9', lw=0) # stop
>>> plt.fill([30, 30, 1e9, 1e9], [-99, -3, -3, -99], '0.9', lw=0) # pass
>>> plt.axis([1, 300, -80, 3])
>>> plt.show()
```

![Elliptical highpass filter fit to constraints](image)

**scipy.signal.bessel**

`scipy.signal.bessel(N, Wn, btype='low', analog=False, output='ba', norm='phase', fs=None)`

Bessel/Thomson digital and analog filter design.

Design an Nth-order digital or analog Bessel filter and return the filter coefficients.

**Parameters**

- **N** [int] The order of the filter.
- **Wn** [array_like] A scalar or length-2 sequence giving the critical frequencies (defined by the `norm` parameter). For analog filters, `Wn` is an angular frequency (e.g., rad/s).
For digital filters, \( Wn \) are in the same units as \( fs \). By default, \( fs \) is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. \( Wn \) is thus in half-cycles / sample.

**btype**

[{'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional] The type of filter. Default is 'low-pass'.

**analog**

[bool, optional] When True, return an analog filter, otherwise a digital filter is returned. (See Notes.)

**output**

[{'ba', 'zpk', 'sos'}, optional] Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

**norm**

[{'phase', 'delay', 'mag'}, optional] Critical frequency normalization:

- **phase**
  The filter is normalized such that the phase response reaches its midpoint at angular (e.g. rad/s) frequency \( Wn \). This happens for both low-pass and high-pass filters, so this is the "phase-matched" case. The magnitude response asymptotes are the same as a Butterworth filter of the same order with a cutoff of \( Wn \). This is the default, and matches MATLAB’s implementation.

- **delay**
  The filter is normalized such that the group delay in the passband is \( 1/Wn \) (e.g., seconds). This is the "natural" type obtained by solving Bessel polynomials.

- **mag**
  The filter is normalized such that the gain magnitude is -3 dB at angular frequency \( Wn \).

  New in version 0.18.0.

**fs**

[float, optional] The sampling frequency of the digital system.

  New in version 1.2.0.

**Returns**

- **b, a**
  [ndarray, ndarray] Numerator (\( b \)) and denominator (\( a \)) polynomials of the IIR filter. Only returned if output='ba'.

- **z, p, k**
  [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if output='zpk'.

- **sos**
  [ndarray] Second-order sections representation of the IIR filter. Only returned if output=='sos'.

**Notes**

Also known as a Thomson filter, the analog Bessel filter has maximally flat group delay and maximally linear phase response, with very little ringing in the step response. [1]

The Bessel is inherently an analog filter. This function generates digital Bessel filters using the bilinear transform, which does not preserve the phase response of the analog filter. As such, it is only approximately correct at frequencies below about \( fs/4 \). To get maximally-flat group delay at higher frequencies, the analog Bessel filter must be transformed using phase-preserving techniques.

See `besselap` for implementation details and references.

The 'sos' output parameter was added in 0.16.0.
References

[1]

Examples

Plot the phase-normalized frequency response, showing the relationship to the Butterworth’s cutoff frequency (green):

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.butter(4, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)), color='silver', ls='dashed')
>>> b, a = signal.bessel(4, 100, 'low', analog=True, norm='phase')
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)))

>>> plt.title('Bessel filter magnitude response (with Butterworth)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green')  # cutoff frequency
>>> plt.show()
```

![Bessel filter magnitude response (with Butterworth)](image)

and the phase midpoint:

```python
>>> plt.figure()
>>> plt.semilogx(w, np.unwrap(np.angle(h)))
>>> plt.axvline(100, color='green')  # cutoff frequency
>>> plt.axhline(-np.pi, color='red')  # phase midpoint
>>> plt.title('Bessel filter phase response')
```

(continues on next page)
Plot the magnitude-normalized frequency response, showing the -3 dB cutoff:

```python
>>> b, a = signal.bessel(3, 10, 'low', analog=True, norm='mag')
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)))
>>> plt.axhline(-3, color='red')  # -3 dB magnitude
>>> plt.title('Magnitude-normalized Bessel filter frequency response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()
```

Plot the delay-normalized filter, showing the maximally-flat group delay at 0.1 seconds:

```python
>>> b, a = signal.bessel(5, 1/0.1, 'low', analog=True, norm='delay')
>>> w, h = signal.freqs(b, a)
>>> plt.figure()
>>> plt.semilogx(w[1:], -np.diff(np.unwrap(np.angle(h)))/np.diff(w))
>>> plt.axhline(0.1, color='red')  # 0.1 seconds group delay
>>> plt.title('Bessel filter group delay')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Group delay [seconds]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()
```
**6.22. Signal processing** (*scipy.signal*)

Magnitude-normalized Bessel filter frequency response

- Amplitude [dB]
- Frequency [radians / second]

Bessel filter group delay

- Group delay [seconds]
- Frequency [radians / second]
scipy.signal.iirnotch

scipy.signal.iirnotch(w0, Q, fs=2.0)

Design second-order IIR notch digital filter.

A notch filter is a band-stop filter with a narrow bandwidth (high quality factor). It rejects a narrow frequency band and leaves the rest of the spectrum little changed.

**Parameters**

- **w0** [float] Frequency to remove from a signal. If *fs* is specified, this is in the same units as *fs*. By default, it is a normalized scalar that must satisfy 0 < w0 < 1, with w0 = 1 corresponding to half of the sampling frequency.
- **Q** [float] Quality factor. Dimensionless parameter that characterizes notch filter -3 dB bandwidth bw relative to its center frequency, $Q = \frac{w0}{bw}$.
- **fs** [float, optional] The sampling frequency of the digital system. New in version 1.2.0.

**Returns**

- **b, a** [ndarray, ndarray] Numerator (b) and denominator (a) polynomials of the IIR filter.

**See also:**

iirpeak

**Notes**

New in version 0.19.0.

**References**

[1]

**Examples**

Design and plot filter to remove the 60 Hz component from a signal sampled at 200 Hz, using a quality factor $Q = 30$

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> fs = 200.0  # Sample frequency (Hz)
>>> f0 = 60.0   # Frequency to be removed from signal (Hz)
>>> Q = 30.0   # Quality factor
>>> # Design notch filter
>>> b, a = signal.iirnotch(f0, Q, fs)

>>> # Frequency response
>>> freq, h = signal.freqz(b, a, fs=fs)
>>> # Plot
>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20*np.log10(abs(h)), color='blue')
```

(continues on next page)
>>> ax[0].set_title("Frequency Response")
>>> ax[0].set_ylabel("Amplitude (dB)", color='blue')
>>> ax[0].set_xlim([0, 100])
>>> ax[0].set_ylim([-25, 10])
>>> ax[0].grid()
>>> ax[1].plot(freq, np.unwrap(np.angle(h))*180/np.pi, color='green')
>>> ax[1].set_ylabel("Angle (degrees)", color='green')
>>> ax[1].set_xlabel("Frequency (Hz)"")
>>> ax[1].set_xlim([0, 100])
>>> ax[1].set_xticks([-90, -60, -30, 0, 30, 60, 90])
>>> ax[1].set_yticks([-90, 90])
>>> ax[1].grid()
>>> plt.show()
scipy.signal.iirpeak

scipy.signal.iirpeak(w0, Q, fs=2.0)
    Design second-order IIR peak (resonant) digital filter.
    A peak filter is a band-pass filter with a narrow bandwidth (high quality factor). It rejects components outside a
    narrow frequency band.

    Parameters
    w0 [float] Frequency to be retained in a signal. If fs is specified, this is in the same units as
    fs. By default, it is a normalized scalar that must satisfy 0 < w0 < 1, with w0 = 1
    corresponding to half of the sampling frequency.
    Q [float] Quality factor. Dimensionless parameter that characterizes peak filter -3 dB bandwidth
    bw relative to its center frequency, Q = w0/bw.
    fs [float, optional] The sampling frequency of the digital system.
    New in version 1.2.0.

    Returns
    b, a [ndarray, ndarray] Numerator (b) and denominator (a) polynomials of the IIR filter.

    See also:
    iirnotch

    Notes
    New in version 0.19.0.

    References
    [1]

    Examples
    Design and plot filter to remove the frequencies other than the 300 Hz component from a signal sampled at 1000
    Hz, using a quality factor Q = 30

    >>> from scipy import signal
    >>> import matplotlib.pyplot as plt

    >>> fs = 1000.0  # Sample frequency (Hz)
    >>> f0 = 300.0  # Frequency to be retained (Hz)
    >>> Q = 30.0  # Quality factor
    >>> # Design peak filter
    >>> b, a = signal.iirpeak(f0, Q, fs)

    >>> # Frequency response
    >>> freq, h = signal.freqz(b, a, fs=fs)
    >>> # Plot
    >>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
    >>> ax[0].plot(freq, 20*np.log10(np.maximum(abs(h), 1e-5)), color='blue')

    (continues on next page)
>>> ax[0].set_title("Frequency Response")
>>> ax[0].set_ylabel("Amplitude (dB)", color='blue')
>>> ax[0].set_xlim([0, 500])
>>> ax[0].set_ylim([-50, 10])
>>> ax[0].grid()
>>> ax[1].plot(freq, np.unwrap(np.angle(h))*180/np.pi, color='green')
>>> ax[1].set_ylabel("Angle (degrees)", color='green')
>>> ax[1].set_xlabel("Frequency (Hz)")
>>> ax[1].set_xlim([0, 500])
>>> ax[1].set_ylim([-90, 90])
>>> ax[1].grid()
>>> plt.show()
scipy.signal.iircomb

scipy.signal.iircomb(w0, Q, ftype='notch', fs=2.0)

Design IIR notching or peaking digital comb filter.

A notching comb filter is a band-stop filter with a narrow bandwidth (high quality factor). It rejects a narrow frequency band and leaves the rest of the spectrum little changed.

A peaking comb filter is a band-pass filter with a narrow bandwidth (high quality factor). It rejects components outside a narrow frequency band.

Parameters

- **w0** [float] Frequency to attenuate (notching) or boost (peaking). If `fs` is specified, this is in the same units as `fs`. By default, it is a normalized scalar that must satisfy `0 < w0 < 1`, with `w0 = 1` corresponding to half of the sampling frequency.

- **Q** [float] Quality factor. Dimensionless parameter that characterizes notch filter -3 dB bandwidth \( bw \) relative to its center frequency, \( Q = \frac{w0}{bw} \).

- **ftype** [{'notch', 'peak'}] The type of comb filter generated by the function. If ‘notch’, then it returns a filter with notches at frequencies \( 0, w0, 2 * w0, \) etc. If ‘peak’, then it returns a filter with peaks at frequencies \( 0.5 * w0, 1.5 * w0, 2.5 * w0 \), etc. Default is ‘notch’.

- **fs** [float, optional] The sampling frequency of the signal. Default is 2.0.

Returns

- **b, a** [ndarray, ndarray] Numerator (\( b \)) and denominator (\( a \)) polynomials of the IIR filter.

Raises

ValueError

If \( w0 \) is less than or equal to 0 or greater than or equal to \( fs / 2 \), if \( fs \) is not divisible by \( w0 \), if \( ftype \) is not ‘notch’ or ‘peak’

See also:

- iirnotch
- iirpeak

Notes

For implementation details, see [1]. The TF implementation of the comb filter is numerically stable even at higher orders due to the use of a single repeated pole, which won’t suffer from precision loss.

[1]
Examples

Design and plot notching comb filter at 20 Hz for a signal sampled at 200 Hz, using quality factor Q = 30

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> fs = 200.0  # Sample frequency (Hz)
>>> f0 = 20.0  # Frequency to be removed from signal (Hz)
>>> Q = 30.0  # Quality factor

# Design notching comb filter
>>> b, a = signal.iircomb(f0, Q, ftype='notch', fs=fs)

# Frequency response
>>> freq, h = signal.freqz(b, a, fs=fs)
>>> response = abs(h)

# To avoid divide by zero when graphing
>>> response[response == 0] = 1e-20

# Plot
>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20 * np.log10(np.maximum(abs(h), 1e-5)), color='blue')
>>> ax[0].set_title('Frequency Response')
>>> ax[0].set_ylabel('Amplitude (dB)', color='blue')
>>> ax[0].set_xlim([0, 100])
>>> ax[0].set_ylim([-30, 10])
>>> ax[0].grid()

>>> ax[1].plot(freq, np.unwrap(np.angle(h)) * 180 / np.pi, color='green')
>>> ax[1].set_xlabel('Frequency (Hz)')
>>> ax[1].set_ylabel('Angle (degrees)', color='green')
>>> ax[1].set_xlim([0, 100])
>>> ax[1].set_ylim([-90, 90])
>>> ax[1].set_yticks([-90, -60, -30, 0, 30, 60, 90])
>>> ax[1].set_ylim([-90, 90])
>>> ax[1].grid()
>>> plt.show()
```

Design and plot peaking comb filter at 250 Hz for a signal sampled at 1000 Hz, using quality factor Q = 30

```python
>>> fs = 1000.0  # Sample frequency (Hz)
>>> f0 = 250.0  # Frequency to be retained (Hz)
>>> Q = 30.0  # Quality factor

# Design peaking filter
>>> b, a = signal.iircomb(f0, Q, ftype='peak', fs=fs)

# Frequency response
>>> freq, h = signal.freqz(b, a, fs=fs)
>>> response = abs(h)

# To avoid divide by zero when graphing
>>> response[response == 0] = 1e-20

# Plot
>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20 * np.log10(np.maximum(abs(h), 1e-5)), color='blue')
>>> ax[0].set_title('Frequency Response')
>>> ax[0].set_ylabel('Amplitude (dB)', color='blue')
```

(continues on next page)
```python
>>> ax[0].set_xlim([0, 500])
>>> ax[0].set_ylim([-80, 10])
>>> ax[0].grid()
>>> ax[1].plot(freq, np.unwrap(np.angle(h)) * 180 / np.pi, color='green')
>>> ax[1].set_ylabel("Angle (degrees)", color='green')
>>> ax[1].set_xlabel("Frequency (Hz)"")
>>> ax[1].set_xlim([0, 500])
>>> ax[1].set_yticks([-90, -60, -30, 0, 30, 60, 90])
>>> ax[1].set_ylim([-90, 90])
>>> ax[1].grid()
>>> plt.show()

**scipy.signal.lti**

```python
class scipy.signal.lti(*system)
```

Continuous-time linear time invariant system base class.

**Parameters**

*system [arguments] The `lti` class can be instantiated with either 2, 3 or 4 arguments. The following gives the number of arguments and the corresponding continuous-time subclass that is created:

- 2: `TransferFunction`: (numerator, denominator)
- 3: `ZerosPolesGain`: (zeros, poles, gain)
- 4: `StateSpace`: (A, B, C, D)

Each argument can be an array or a sequence.

**See also:**

`ZerosPolesGain, StateSpace, TransferFunction, dlti`

**Notes**

`lti` instances do not exist directly. Instead, `lti` creates an instance of one of its subclasses: `StateSpace`, `TransferFunction` or `ZerosPolesGain`.

If (numerator, denominator) is passed in for `*system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g., \(s^2 + 3s + 5\) would be represented as \([1, 3, 5]\)).

Changing the value of properties that are not directly part of the current system representation (such as the zeros of a `StateSpace` system) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.
Examples

```python
>>> from scipy import signal

>>> signal.lti(1, 2, 3, 4)
StateSpaceContinuous(
    array([[1]]),
    array([[2]]),
    array([[3]]),
    array([[4]]),
    dt: None
)

>>> signal.lti([1, 2], [3, 4], 5)
ZerosPolesGainContinuous(
    array([1, 2]),
    array([3, 4]),
    5,
    dt: None
)

>>> signal.lti([3, 4], [1, 2])
TransferFunctionContinuous(
    array([3., 4.]),
    array([1., 2.]),
    dt: None
)
```

Attributes

- **dt**: Return the sampling time of the system, `None` for `lti` systems.
- **poles**: Poles of the system.
- **zeros**: Zeros of the system.

Methods

- `bode(self, w, n)`: Calculate Bode magnitude and phase data of a continuous-time system.
- `freqresp(self, w, n)`: Calculate the frequency response of a continuous-time system.
- `impulse(self, X0, T, N)`: Return the impulse response of a continuous-time system.
- `output(self, U, T, X0)`: Return the response of a continuous-time system to input `U`.
- `step(self, X0, T, N)`: Return the step response of a continuous-time system.
- `to_discrete(self, dt, method, alpha)`: Return a discretized version of the current system.
scipy.signal.lti.bode

```python
lti.bode(self, w=None, n=100)
```
Calculate Bode magnitude and phase data of a continuous-time system.

Returns a 3-tuple containing arrays of frequencies [rad/s], magnitude [dB] and phase [deg]. See `bode` for details.

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> sys = signal.TransferFunction([1], [1, 1])

>>> w, mag, phase = sys.bode()

>>> plt.figure()
>>> plt.semilogx(w, mag)  # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()
```

scipy.signal.lti.freqresp

```python
lti.freqresp(self, w=None, n=10000)
```
Calculate the frequency response of a continuous-time system.

Returns a 2-tuple containing arrays of frequencies [rad/s] and complex magnitude. See `freqresp` for details.
scipy.signal.lti.impulse

lti.impulse (self, X0=None, T=None, N=None)

Return the impulse response of a continuous-time system. See impulse for details.

scipy.signal.lti.output

lti.output (self, U, T, X0=None)

Return the response of a continuous-time system to input $U$. See lsim for details.

scipy.signal.lti.step

lti.step (self, X0=None, T=None, N=None)

Return the step response of a continuous-time system. See step for details.

scipy.signal.lti.to_discrete

lti.to_discrete (self, dt, method='zoh', alpha=None)

Return a discretized version of the current system.

Parameters: See cont2discrete for details.

Returns

sys: instance of dlti

scipy.signal.StateSpace

class scipy.signal.StateSpace (*system, **kwargs)

Linear Time Invariant system in state-space form.

Represents the system as the continuous-time, first order differential equation $\dot{x} = Ax + Bu$ or the discrete-time difference equation $x[k+1] = Ax[k] + Bu[k]$. StateSpace systems inherit additional functionality from the lti, respectively the dlti classes, depending on which system representation is used.

Parameters

*system: arguments
The `StateSpace` class can be instantiated with 1 or 4 arguments. The following gives the number of input arguments and their interpretation:

- **1:** `lti` or `dlti` system: `(StateSpace, TransferFunction or ZerosPolesGain)`
- **4:** array_like: `(A, B, C, D)`

**dt:** float, optional

Sampling time [s] of the discrete-time systems. Defaults to `None` (continuous-time). Must be specified as a keyword argument, for example, `dt=0.1`.

**See also:**

`TransferFunction`, `ZerosPolesGain`, `lti`, `dlti`

`ss2zpk`, `ss2tf`, `zpk2sos`

**Notes**

Changing the value of properties that are not part of the `StateSpace` system representation (such as `zeros` or `poles`) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.

**Examples**

```python
>>> from scipy import signal

>>> a = np.array([[0, 1], [0, 0]])
>>> b = np.array([[0], [1]])
>>> c = np.array([[1, 0]])
>>> d = np.array([[0]])

>>> sys = signal.StateSpace(a, b, c, d)
>>> print(sys)
StateSpaceContinuous(
array([[0, 1],
       [0, 0]]),
array([[0],
       [1]]),
array([[1, 0]]),
array([[0]]),
dt: None)

>>> sys.to_discrete(0.1)
StateSpaceDiscrete(
array([[1. , 0.1],
       [0. , 1. ]]),
array([[0.005],
       [0.1 ]]),
array([[1, 0]]),
array([[0]]),
```

(continues on next page)
dt: 0.1

```python
>>> a = np.array([[1, 0.1], [0, 1]])
>>> b = np.array([[0.005], [0.1]])

>>> signal.StateSpace(a, b, c, d, dt=0.1)
StateSpaceDiscrete(
    array([[1. , 0.1],
            [0. , 1. ]]),
    array([[0.005],
            [0.1 ]]),
    array([[1, 0]]),
    array([[0]]),
    dt: 0.1)
```

### Attributes

- **A**: State matrix of the `StateSpace` system.
- **B**: Input matrix of the `StateSpace` system.
- **C**: Output matrix of the `StateSpace` system.
- **D**: Feedthrough matrix of the `StateSpace` system.
- **dt**: Return the sampling time of the system, `None` for `lti` systems.
- **poles**: Poles of the system.
- **zeros**: Zeros of the system.

### Methods

- `__mul__(self, other)` Post-multiply another system or a scalar
- `to_ss(self)` Return a copy of the current `StateSpace` system.
- `to_tf(self, **kwargs)` Convert system representation to `TransferFunction`.
- `to_zpk(self, **kwargs)` Convert system representation to `ZerosPolesGain`.

#### scipy.signal.StateSpace.__mul__

`StateSpace.__mul__(self, other)` Post-multiply another system or a scalar

Handles multiplication of systems in the sense of a frequency domain multiplication. That means, given two systems $E_1(s)$ and $E_2(s)$, their multiplication, $H(s) = E_1(s) * E_2(s)$, means that applying $H(s)$ to $U(s)$ is equivalent to first applying $E_2(s)$, and then $E_1(s)$. 

Notes

For SISO systems the order of system application does not matter. However, for MIMO systems, where the two systems are matrices, the order above ensures standard Matrix multiplication rules apply.

**scipy.signal.StateSpace.to_ss**

StateSpace.to_ss(self)

Return a copy of the current StateSpace system.

**Returns**

sys [instance of StateSpace] The current system (copy)

**scipy.signal.StateSpace.to_tf**

StateSpace.to_tf(self, **kwargs)

Convert system representation to TransferFunction.

**Parameters**

kwargs [dict, optional] Additional keywords passed to ss2zpk

**Returns**

sys [instance of TransferFunction] Transfer function of the current system

**scipy.signal.StateSpace.to_zpk**

StateSpace.to_zpk(self, **kwargs)

Convert system representation to ZerosPolesGain.

**Parameters**

kwargs [dict, optional] Additional keywords passed to ss2zpk

**Returns**

sys [instance of ZerosPolesGain] Zeros, poles, gain representation of the current system

**scipy.signal.TransferFunction**

class scipy.signal.TransferFunction(*system, **kwargs)

Linear Time Invariant system class in transfer function form.

Represents the system as the continuous-time transfer function $H(s) = \sum_{i=0}^{N} b[N - i]s^i / \sum_{j=0}^{M} a[M - j]s^j$ or the discrete-time transfer function $H(z) = \sum_{i=0}^{N} b[N - i]z^i / \sum_{j=0}^{M} a[M - j]z^j$, where $b$ are elements of the numerator num, $a$ are elements of the denominator den, and $N = \text{len}(b) - 1, M = \text{len}(a) - 1$. TransferFunction systems inherit additional functionality from the lti, respectively the dlti classes, depending on which system representation is used.

**Parameters**

*system: arguments

The TransferFunction class can be instantiated with 1 or 2 arguments. The following gives the number of input arguments and their interpretation:

- 1: lti or dlti system: (StateSpace, TransferFunction or ZerosPolesGain)
- 2: array_like: (numerator, denominator)
**dt**: float, optional

Sampling time [s] of the discrete-time systems. Defaults to *None* (continuous-time). Must be specified as a keyword argument, for example, `dt=0.1`.

**See also:**

*ZerosPolesGain*, *StateSpace*, *lti*, *dlti*

*tf2ss*, *tf2zpk*, *tf2sos*

**Notes**

Changing the value of properties that are not part of the *TransferFunction* system representation (such as the *A*, *B*, *C*, *D* state-space matrices) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_ss()` before accessing/changing the *A*, *B*, *C*, *D* system matrices.

If (numerator, denominator) is passed in for *system*, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. `s^2 + 3s + 5` or `z^2 + 3z + 5` would be represented as `[1, 3, 5]`)

**Examples**

Construct the transfer function:

\[ H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1} \]

```python
>>> from scipy import signal

>>> num = [1, 3, 3]
>>> den = [1, 2, 1]

>>> signal.TransferFunction(num, den)
TransferFunctionContinuous(
    array([1., 3., 3.]),
    array([1., 2., 1.]),
    dt: None
)
```

Construct the transfer function with a sampling time of 0.1 seconds:

\[ H(z) = \frac{z^2 + 3z + 3}{z^2 + 2z + 1} \]

```python
>>> signal.TransferFunction(num, den, dt=0.1)
TransferFunctionDiscrete(
    array([1., 3., 3.]),
    array([1., 2., 1.]),
    dt: 0.1
)
```
**Methods**

<table>
<thead>
<tr>

</tbody>
</table>

**scipy.signal.TransferFunction.to_ss**

`TransferFunction.to_ss(self)`

Convert system representation to StateSpace.

**Returns**

- `sys` [instance of StateSpace] State space model of the current system

**scipy.signal.TransferFunction.to_tf**

`TransferFunction.to_tf(self)`

Return a copy of the current TransferFunction system.

**Returns**

- `sys` [instance of TransferFunction] The current system (copy)

**scipy.signal.TransferFunction.to_zpk**

`TransferFunction.to_zpk(self)`

Convert system representation to ZerosPolesGain.

**Returns**

- `sys` [instance of ZerosPolesGain] Zeros, poles, gain representation of the current system

**scipy.signal.ZerosPolesGain**

class scipy.signal.ZerosPolesGain(*system, **kwargs)

Linear Time Invariant system class in zeros, poles, gain form.

Represents the system as the continuous- or discrete-time transfer function \( H(s) = k \prod_i (s - z[i]) / \prod_j (s - p[j]) \), where \( k \) is the gain, \( z \) are the zeros and \( p \) are the poles. ZerosPolesGain systems inherit additional functionality from the \( lti \), respectively the \( dlti \) classes, depending on which system representation is used.

**Parameters**

- `*system` [arguments] The ZerosPolesGain class can be instantiated with 1 or 3 arguments. The following gives the number of input arguments and their interpretation:
  - 1: \( lti \) or \( dlti \) system: \((StateSpace, TransferFunction or ZerosPolesGain)\)
• 3: array_like: (zeros, poles, gain)

dt: float, optional
Sampling time [s] of the discrete-time systems. Defaults to None (continuous-time). Must be specified as a keyword argument, for example, dt=0.1.

See also:

TransferFunction, StateSpace, lti, dlti
zpk2ss, zpk2tf, zpk2sos

Notes

Changing the value of properties that are not part of the ZerosPolesGain system representation (such as the A, B, C, D state-space matrices) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call sys = sys.to_ss() before accessing/changing the A, B, C, D system matrices.

Examples

```python
>>> from scipy import signal

Transfer function: H(s) = 5(s - 1)(s - 2) / (s - 3)(s - 4)

>>> signal.ZerosPolesGain([[1, 2], [3, 4]], 5)
ZerosPolesGainContinuous(
    array([[1, 2]],
    array([[3, 4]],
    5,
    dt: None
)

Transfer function: H(z) = 5(z - 1)(z - 2) / (z - 3)(z - 4)

>>> signal.ZerosPolesGain([[1, 2], [3, 4]], 5, dt=0.1)
ZerosPolesGainDiscrete(
    array([[1, 2]],
    array([[3, 4]],
    5,
    dt: 0.1
)

Attributes

dt Return the sampling time of the system, None for lti systems.
gain Gain of the ZerosPolesGain system.
poles Poles of the ZerosPolesGain system.
zeros Zeros of the ZerosPolesGain system.

</tr>
<tr>
<td><code>to_zpk(self)</code></td>
<td>Return a copy of the current 'ZerosPolesGain' system.</td>
</tr>
</tbody>
</table>

**scipy.signal.ZerosPolesGain.to_ss**

ZerosPolesGain.to_ss(self)  
Convert system representation to `StateSpace`.

*Returns*

- `sys` [instance of `StateSpace`] State space model of the current system

**scipy.signal.ZerosPolesGain.to_tf**

ZerosPolesGain.to_tf(self)  
Convert system representation to `TransferFunction`.

*Returns*

- `sys` [instance of `TransferFunction`] Transfer function of the current system

**scipy.signal.ZerosPolesGain.to_zpk**

ZerosPolesGain.to_zpk(self)  
Return a copy of the current 'ZerosPolesGain' system.

*Returns*

- `sys` [instance of `ZerosPolesGain`] The current system (copy)

**scipy.signal.lsim**

scipy.signal.lsim(system, U, T, X0=None, interp=True)  
Simulate output of a continuous-time linear system.

*Parameters*

- `system` [an instance of the LTI class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
  - 1: (instance of `lti`)
  - 2: (num, den)
  - 3: (zeros, poles, gain)
  - 4: (A, B, C, D)

- `U` [array_like] An input array describing the input at each time `T` (interpolation is assumed between given times). If there are multiple inputs, then each column of the rank-2 array represents an input. If `U = 0` or `None`, a zero input is used.

- `T` [array_like] The time steps at which the input is defined and at which the output is desired. Must be nonnegative, increasing, and equally spaced.

- `X0` [array_like, optional] The initial conditions on the state vector (zero by default).

- `interp` [bool, optional] Whether to use linear (True, the default) or zero-order-hold (False) interpolation for the input array.

*Returns*

- `T` [1D ndarray] Time values for the output.

yout [1D ndarray] System response.

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \( s^2 + 3s + 5 \) would be represented as \([1, 3, 5]\)).

Examples

We’ll use \texttt{lsim} to simulate an analog Bessel filter applied to a signal.

```python
>>> from scipy.signal import bessel, lsim
>>> import matplotlib.pyplot as plt
```

Create a low-pass Bessel filter with a cutoff of 12 Hz.

```python
>>> b, a = bessel(N=5, Wn=2*np.pi*12, btype='lowpass', analog=True)
```

Generate data to which the filter is applied.

```python
>>> t = np.linspace(0, 1.25, 500, endpoint=False)
```

The input signal is the sum of three sinusoidal curves, with frequencies 4 Hz, 40 Hz, and 80 Hz. The filter should mostly eliminate the 40 Hz and 80 Hz components, leaving just the 4 Hz signal.

```python
>>> u = (np.cos(2*np.pi*4*t) + 0.6*np.sin(2*np.pi*40*t) +
... 0.5*np.cos(2*np.pi*80*t))
```

Simulate the filter with \texttt{lsim}.

```python
>>> tout, yout, xout = lsim((b, a), u, T=t)
```

Plot the result.

```python
>>> plt.plot(t, u, 'r', alpha=0.5, linewidth=1, label='input')
>>> plt.plot(tout, yout, 'k', linewidth=1.5, label='output')
>>> plt.legend(loc='best', shadow=True, framealpha=1)
>>> plt.grid(alpha=0.3)
>>> plt.xlabel('t')
>>> plt.show()
```

In a second example, we simulate a double integrator \( y'' = u \), with a constant input \( u = 1 \). We’ll use the state space representation of the integrator.

```python
>>> from scipy.signal import lti
>>> A = np.array([[0.0, 1.0], [0.0, 0.0]])
>>> B = np.array([[0.0], [1.0]])
>>> C = np.array([[1.0, 0.0]])
>>> D = 0.0
>>> system = lti(A, B, C, D)
```

\( t \) and \( u \) define the time and input signal for the system to be simulated.
Compute the simulation, and then plot $y$. As expected, the plot shows the curve $y = 0.5t^2$.

```python
>>> t = np.linspace(0, 5, num=50)
>>> u = np.ones_like(t)

```
**scipy.signal.lsim2**

`scipy.signal.lsim2(system, U=None, T=None, X0=None, **kwargs)`

Simulate output of a continuous-time linear system, by using the ODE solver `scipy.integrate.odeint`.

**Parameters**

- **system** [an instance of the `lti` class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
  - 1: (instance of `lti`)
  - 2: (num, den)
  - 3: (zeros, poles, gain)
  - 4: (A, B, C, D)
- **U** [array_like (1D or 2D), optional] An input array describing the input at each time T. Linear interpolation is used between given times. If there are multiple inputs, then each column of the rank-2 array represents an input. If U is not given, the input is assumed to be zero.
- **T** [array_like (1D or 2D), optional] The time steps at which the input is defined and at which the output is desired. The default is 101 evenly spaced points on the interval [0,10.0].
- **X0** [array_like (1D), optional] The initial condition of the state vector. If X0 is not given, the initial conditions are assumed to be 0.
- **kwargs** [dict] Additional keyword arguments are passed on to the function `odeint`. See the notes below for more details.

**Returns**

- **T** [1D ndarray] The time values for the output.
- **yout** [ndarray] The response of the system.
- **xout** [ndarray] The time-evolution of the state-vector.

See also:

- `lsim`

**Notes**

This function uses `scipy.integrate.odeint` to solve the system’s differential equations. Additional keyword arguments given to `lsim2` are passed on to `odeint`. See the documentation for `scipy.integrate.odeint` for the full list of arguments.

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. `s^2 + 3s + 5` would be represented as `[1, 3, 5]`).

**Examples**

We’ll use `lsim2` to simulate an analog Bessel filter applied to a signal.

```python
>>> from scipy.signal import bessel, lsim2
>>> import matplotlib.pyplot as plt
```

Create a low-pass Bessel filter with a cutoff of 12 Hz.

```python
>>> b, a = bessel(N=5, Wn=2*np.pi*12, btype='lowpass', analog=True)
```

Generate data to which the filter is applied.
The input signal is the sum of three sinusoidal curves, with frequencies 4 Hz, 40 Hz, and 80 Hz. The filter should mostly eliminate the 40 Hz and 80 Hz components, leaving just the 4 Hz signal.

Simulate the filter with `lsim2`.

Plot the result.

In a second example, we simulate a double integrator $y'' = u$, with a constant input $u = 1$. We’ll use the state space representation of the integrator.
Compute the simulation, and then plot $y$. As expected, the plot shows the curve $y = 0.5t^2$.

```python
>>> tout, y, x = lsim2(system, u, t)
>>> plt.plot(t, y)
>>> plt.grid(alpha=0.3)
>>> plt.xlabel('t')
>>> plt.show()
```

**scipy.signal.impulse**

`scipy.signal.impulse(system, X0=None, T=None, N=None)`

Impulse response of continuous-time system.

**Parameters**

- **system** [an instance of the LTI class or a tuple of array_like] describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of `lti`)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
- **X0** [array_like, optional] Initial state-vector. Defaults to zero.
- **T** [array_like, optional] Time points. Computed if not given.
- **N** [int, optional] The number of time points to compute (if $T$ is not given).

**Returns**

- **T** [ndarray] A 1-D array of time points.
- **yout** [ndarray] A 1-D array containing the impulse response of the system (except for singularities at zero).
Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \( s^2 + 3s + 5 \) would be represented as \([1, 3, 5]\)).

Examples

Compute the impulse response of a second order system with a repeated root: \( x''(t) + 2x'(t) + x(t) = u(t) \)

```python
>>> from scipy import signal
>>> system = ([1.0], [1.0, 2.0, 1.0])
>>> t, y = signal.impulse(system)
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, y)
```

```
scipy.signal.impulse2
```

**scipy.signal.impulse2** (*system, X0=None, T=None, N=None, **kwargs*)

Impulse response of a single-input, continuous-time linear system.

**Parameters**

- **system** [an instance of the LTI class or a tuple of array_like] describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of \lild\)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
- **X0** [1-D array_like, optional] The initial condition of the state vector. Default: 0 (the zero vector).
- **T** [1-D array_like, optional] The time steps at which the input is defined and at which the output is desired. If T is not given, the function will generate a set of time samples automatically.
- **N** [int, optional] Number of time points to compute. Default: 100.
**kwargs**
[Various types] Additional keyword arguments are passed on to the function `scipy.signal.lsim2`, which in turn passes them on to `scipy.integrate.odeint`; see the latter’s documentation for information about these arguments.

**Returns**

- **T** [ndarray] The time values for the output.
- **yout** [ndarray] The output response of the system.

See also:

- `impulse`, `lsim2`, `scipy.integrate.odeint`

**Notes**

The solution is generated by calling `scipy.signal.lsim2`, which uses the differential equation solver `scipy.integrate.odeint`.

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \( s^2 + 3s + 5 \) would be represented as \([1, 3, 5]\)).

New in version 0.8.0.

**Examples**

Compute the impulse response of a second order system with a repeated root: \( x''(t) + 2x'(t) + x(t) = u(t) \)

```python
>>> from scipy import signal
>>> system = ([1.0], [1.0, 2.0, 1.0])
>>> t, y = signal.impulse2(system)
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, y)
```

![Graph](image_url)
scipy.signal.step

scipy.signal.step (system, X0=None, T=None, N=None)

Step response of continuous-time system.

Parameters

- **system** [an instance of the LTI class or a tuple of array_like] describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of lti)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)

- **X0** [array_like, optional] Initial state-vector (default is zero).
- **T** [array_like, optional] Time points (computed if not given).
- **N** [int, optional] Number of time points to compute if T is not given.

Returns

- **T** [1D ndarray] Output time points.
- **yout** [1D ndarray] Step response of system.

See also:

scipy.signal.step2

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \( s^2 + 3s + 5 \) would be represented as [1, 3, 5]).

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> lti = signal.lti([1.0], [1.0, 1.0])
>>> t, y = signal.step(lti)
>>> plt.plot(t, y)
>>> plt.xlabel('Time [s]')
>>> plt.ylabel('Amplitude')
>>> plt.title('Step response for 1. Order Lowpass')
>>> plt.grid()
```

scipy.signal.step2

scipy.signal.step2 (system, X0=None, T=None, N=None, **kwargs)

Step response of continuous-time system.

This function is functionally the same as scipy.signal.step, but it uses the function scipy.signal.lsim2 to compute the step response.

Parameters

- **system** [an instance of the LTI class or a tuple of array_like] describing the system. The following gives the number of elements in the tuple and the interpretation:
Step response for 1. Order Lowpass

- 1 (instance of lti)
- 2 (num, den)
- 3 (zeros, poles, gain)
- 4 (A, B, C, D)

X0 [array_like, optional] Initial state-vector (default is zero).
T [array_like, optional] Time points (computed if not given).
N [int, optional] Number of time points to compute if T is not given.
kwargs [various types] Additional keyword arguments are passed on the function scipy.signal.lsim2, which in turn passes them on to scipy.integrate.odeint. See the documentation for scipy.integrate.odeint for information about these arguments.

Returns:
- T [1D ndarray] Output time points.
- yout [1D ndarray] Step response of system.

See also:

scipy.signal.step

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \( s^2 + 3s + 5 \) would be represented as \([1, 3, 5]\)).

New in version 0.8.0.
Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> lti = signal.lti([1.0], [1.0, 1.0])
>>> t, y = signal.step2(lti)
>>> plt.plot(t, y)
>>> plt.xlabel('Time [s]')
>>> plt.ylabel('Amplitude')
>>> plt.title('Step response for 1. Order Lowpass')
>>> plt.grid()
```

![Step response for 1. Order Lowpass](image)

**scipy.signal.freqresp**

Calculate the frequency response of a continuous-time system.

**Parameters**

- `system` [an instance of the `lti` class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of `lti`)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)

- `w` [array_like, optional] Array of frequencies (in rad/s). Magnitude and phase data is calculated for every value in this array. If not given, a reasonable set will be calculated.

- `n` [int, optional] Number of frequency points to compute if `w` is not given. The `n` frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

**Returns**

- `w` [1D ndarray] Frequency array [rad/s]
- `H` [1D ndarray] Array of complex magnitude values
Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \( s^2 + 3s + 5 \) would be represented as \([1, 3, 5]\)).

Examples

Generating the Nyquist plot of a transfer function

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Transfer function: \( H(s) = \frac{5}{(s-1)^3} \)

```  
```python
>>> s1 = signal.ZerosPolesGain([], [1, 1, 1], [5])

```  
```python
>>> w, H = signal.freqresp(s1)

```  
```python
>>> plt.figure()
>>> plt.plot(H.real, H.imag, "b")
>>> plt.plot(H.real, -H.imag, "r")
>>> plt.show()
```
scipy.signal.bode

scipy.signal.bode(system, w=None, n=100)

Calculate Bode magnitude and phase data of a continuous-time system.

Parameters

- **system** [an instance of the LTI class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of LTI)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)

- **w** [array_like, optional] Array of frequencies (in rad/s). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.

- **n** [int, optional] Number of frequency points to compute if w is not given. The n frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

Returns

- **w** [1D ndarray] Frequency array [rad/s]
- **mag** [1D ndarray] Magnitude array [dB]
- **phase** [1D ndarray] Phase array [deg]

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \( s^2 + 3s + 5 \) would be represented as \([1, 3, 5]\)).

New in version 0.11.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> sys = signal.TransferFunction([1], [1, 1])
>>> w, mag, phase = signal.bode(sys)

>>> plt.figure()
>>> plt.semilogx(w, mag)  # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()
```

**scipy.signal.dlti**

```python
class scipy.signal.dlti(*system, **kwargs)
```
Discrete-time linear time invariant system base class.

**Parameters**

*system: arguments

The `dlti` class can be instantiated with either 2, 3 or 4 arguments. The following gives the number of arguments and the corresponding discrete-time subclass that is created:

- 2: `TransferFunction`: (numerator, denominator)
- 3: `ZerosPolesGain`: (zeros, poles, gain)
- 4: `StateSpace`: (A, B, C, D)

Each argument can be an array or a sequence.

dt: float, optional

Sampling time [s] of the discrete-time systems. Defaults to True (unspecified sampling time). Must be specified as a keyword argument, for example, `dt=0.1`.

**See also:**

`ZerosPolesGain, StateSpace, TransferFunction, lti`

**Notes**

`dlti` instances do not exist directly. Instead, `dlti` creates an instance of one of its subclasses: `StateSpace`, `TransferFunction` or `ZerosPolesGain`.

Changing the value of properties that are not directly part of the current system representation (such as the zeros of a `StateSpace` system) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.

If (numerator, denominator) is passed in for *system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g., \( z^2 + 3z + 5 \) would be represented as \([1, 3, 5]\)).

New in version 0.18.0.
Examples

```python
>>> from scipy import signal

>>> signal.dlti(1, 2, 3, 4)
StateSpaceDiscrete(
    array([[1]]),
    array([[2]]),
    array([[3]]),
    array([[4]]),
    dt: True
)

>>> signal.dlti(1, 2, 3, 4, dt=0.1)
StateSpaceDiscrete(
    array([[1]]),
    array([[2]]),
    array([[3]]),
    array([[4]]),
    dt: 0.1
)

>>> signal.dlti([1, 2], [3, 4], 5, dt=0.1)
ZerosPolesGainDiscrete(
    array([1, 2]),
    array([3, 4]),
    5,
    dt: 0.1
)

>>> signal.dlti([3, 4], [1, 2], dt=0.1)
TransferFunctionDiscrete(
    array([3., 4.]),
    array([1., 2.]),
    dt: 0.1
)
```

Attributes

- `dt` Return the sampling time of the system.
- `poles` Poles of the system.
- `zeros` Zeros of the system.
Methods

```
bode(self[, w, n])          Calculate Bode magnitude and phase data of a
discrete-time system.

freqresp(self[, w, n, whole]) Calculate the frequency response of a discrete-time
system.

impulse(self[, x0, t, n])    Return the impulse response of the discrete-time
dlti system.

output(self, u, t[, x0])     Return the response of the discrete-time system to in-
put u.

step(self[, x0, t, n])       Return the step response of the discrete-time dlti
system.
```

**scipy.signal.dlti.bode**

`dlti.bode (self, w=None, n=100)`  
Calculate Bode magnitude and phase data of a discrete-time system.  

Returns a 3-tuple containing arrays of frequencies [rad/s], magnitude [dB] and phase [deg]. See `dbode` for details.

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Transfer function: \( H(z) = \frac{1}{z^2 + 2z + 3} \) with sampling time 0.5s

```python
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.5)
```

Equivalent: `signal.dbode(sys)`

```python
>>> w, mag, phase = sys.bode()
```

```python
>>> plt.figure()
>>> plt.semilogx(w, mag)  # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()
```

**scipy.signal.dlti.freqresp**

`dlti.freqresp (self, w=None, n=10000, whole=False)`  
Calculate the frequency response of a discrete-time system.  

Returns a 2-tuple containing arrays of frequencies [rad/s] and complex magnitude. See `dfreqresp` for details.
6.22. Signal processing (scipy.signal)
**scipy.signal.dlti.impulse**

dlti.impulse(self, x0=None, t=None, n=None)

Return the impulse response of the discrete-time dlti system. See dimpulse for details.

**scipy.signal.dlti.output**

dlti.output(self, u, t, x0=None)

Return the response of the discrete-time system to input u. See dlsim for details.

**scipy.signal.dlti.step**

dlti.step(self, x0=None, t=None, n=None)

Return the step response of the discrete-time dlti system. See dstep for details.

**scipy.signal.dlsim**

scipy.signal.dlsim(system, u, t=None, x0=None)

Simulate output of a discrete-time linear system.

**Parameters**

- **system** [tuple of array_like or instance of dlti] A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1: (instance of dlti)
  - 3: (num, den, dt)
  - 4: (zeros, poles, gain, dt)
  - 5: (A, B, C, D, dt)

- **u** [array_like] An input array describing the input at each time t (interpolation is assumed between given times). If there are multiple inputs, then each column of the rank-2 array represents an input.

- **t** [array_like, optional] The time steps at which the input is defined. If t is given, it must be the same length as u, and the final value in t determines the number of steps returned in the output.

- **x0** [array_like, optional] The initial conditions on the state vector (zero by default).

**Returns**

- **tout** [ndarray] Time values for the output, as a 1-D array.
- **yout** [ndarray] System response, as a 1-D array.
- **xout** [ndarray, optional] Time-evolution of the state-vector. Only generated if the input is a StateSpace system.

See also:

- lsim, dstep, dimpulse, cont2discrete
Examples

A simple integrator transfer function with a discrete time step of 1.0 could be implemented as:

```python
>>> from scipy import signal
>>> tf = ([1.0,], [1.0, -1.0], 1.0)
>>> t_in = [0.0, 1.0, 2.0, 3.0]
>>> u = np.asarray([0.0, 0.0, 1.0, 1.0])
>>> t_out, y = signal.dlsim(tf, u, t=t_in)
>>> y.T
array([[ 0., 0., 0., 1.]])
```

**scipy.signal.dimpulse**

`scipy.signal.dimpulse(system, x0=None, t=None, n=None)`

Impulse response of discrete-time system.

**Parameters**

- `system` [tuple of array_like or instance of `dlti`] A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1: (instance of `dlti`)
  - 3: (num, den, dt)
  - 4: (zeros, poles, gain, dt)
  - 5: (A, B, C, D, dt)
- `x0` [array_like, optional] Initial state-vector. Defaults to zero.
- `t` [array_like, optional] Timepoints. Computed if not given.
- `n` [int, optional] The number of time points to compute (if `t` is not given).

**Returns**

- `tout` [ndarray] Time values for the output, as a 1-D array.
- `yout` [tuple of ndarray] Impulse response of system. Each element of the tuple represents the output of the system based on an impulse in each input.

**See also:**

`impulse, dstep, dlsim, cont2discrete`

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> butter = signal.dlti(*signal.butter(3, 0.5))
>>> t, y = signal.dimpulse(butter, n=25)
>>> plt.step(t, np.squeeze(y))
>>> plt.grid()
>>> plt.xlabel('n [samples]')
>>> plt.ylabel('Amplitude')
```
**scipy.signal.dstep**

`scipy.signal.dstep(system, x0=None, t=None, n=None)`

Step response of discrete-time system.

**Parameters**

- **system** ([tuple of array_like]) A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1: (instance of \( \text{dti} \))
  - 3: (num, den, dt)
  - 4: (zeros, poles, gain, dt)
  - 5: (A, B, C, D, dt)
- **x0** ([array_like, optional]) Initial state-vector. Defaults to zero.
- **t** ([array_like, optional]) Time points. Computed if not given.
- **n** ([int, optional]) The number of time points to compute (if \( t \) is not given).

**Returns**

- **tout** ([ndarray]) Output time points, as a 1-D array.
- **yout** ([tuple of ndarray]) Step response of system. Each element of the tuple represents the output of the system based on a step response to each input.

**See also:**

`step, dimpulse, dlsim, cont2discrete`
Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> butter = signal.dlti(*signal.butter(3, 0.5))
>>> t, y = signal.dstep(butter, n=25)
>>> plt.step(t, np.squeeze(y))
>>> plt.grid()
>>> plt.xlabel('n [samples]')
>>> plt.ylabel('Amplitude')
```

![Step response example]

**scipy.signal.dfreqresp**

`scipy.signal.dfreqresp(system, w=None, n=10000, whole=False)`

Calculate the frequency response of a discrete-time system.

**Parameters**

- **system**  
  [an instance of the `dlti` class or a tuple describing the system.]. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of `dlti`)
  - 2 (numerator, denominator, dt)
  - 3 (zeros, poles, gain, dt)
  - 4 (A, B, C, D, dt)

- **w**  
  [array_like, optional] Array of frequencies (in radians/sample). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.

- **n**  
  [int, optional] Number of frequency points to compute if `w` is not given. The `n` frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

- **whole**  
  [bool, optional] Normally, if `w` is not given, frequencies are computed from 0 to the Nyquist frequency, `pi` radians/sample (upper-half of unit-circle). If `whole` is True, compute frequencies from 0 to `2*pi` radians/sample.
**Returns**

- \(w\) [1D ndarray] Frequency array [radians/sample]
- \(H\) [1D ndarray] Array of complex magnitude values

**Notes**

If \((\text{num}, \text{den})\) is passed in for \texttt{system}, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \(z^2 + 3z + 5\) would be represented as \([1, 3, 5]\)).

New in version 0.18.0.

**Examples**

Generating the Nyquist plot of a transfer function

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Transfer function: \(H(z) = \frac{1}{z^2 + 2z + 3}\)

```python
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.05)
```python

```python
>>> w, H = signal.dfreqresp(sys)
```python

```python
>>> plt.figure()
>>> plt.plot(H.real, H.imag, "b")
>>> plt.plot(H.real, -H.imag, "r")
```

```python
>>> plt.show()
```
scipy.signal.dbode

scipy.signal.dbode(system, w=None, n=100)
Calculate Bode magnitude and phase data of a discrete-time system.

Parameters

- **system** [an instance of the LTI class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of dlti)
  - 2 (num, den, dt)
  - 3 (zeros, poles, gain, dt)
  - 4 (A, B, C, D, dt)

- **w** [array_like, optional] Array of frequencies (in radians/sample). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.

- **n** [int, optional] Number of frequency points to compute if w is not given. The n frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

Returns

- **w** [1D ndarray] Frequency array [rad/time_unit]
- **mag** [1D ndarray] Magnitude array [dB]
- **phase** [1D ndarray] Phase array [deg]

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \(z^2 + 3z + 5\) would be represented as [1, 3, 5]).

New in version 0.18.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Transfer function: \(H(z) = 1 / (z^2 + 2z + 3)\)

```python
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.05)

Equivalent: sys.bode()
```python

```python
>>> w, mag, phase = signal.dbode(sys)

```python
```python
>>> plt.figure()
>>> plt.semilogx(w, mag)  # Bode magnitude plot
```python
```python
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
```
```python
>>> plt.show()
```

### scipy.signal.tf2zpk

`scipy.signal.tf2zpk(b, a)`

Return zero, pole, gain (z, p, k) representation from a numerator, denominator representation of a linear filter.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
<td>[array_like] Numerator polynomial coefficients.</td>
</tr>
<tr>
<td>a</td>
<td>[array_like] Denominator polynomial coefficients.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>z</td>
<td>[ndarray] Zeros of the transfer function.</td>
</tr>
<tr>
<td>p</td>
<td>[ndarray] Poles of the transfer function.</td>
</tr>
<tr>
<td>k</td>
<td>[float] System gain.</td>
</tr>
</tbody>
</table>

**Notes**

If some values of `b` are too close to 0, they are removed. In that case, a BadCoefficients warning is emitted.

The `b` and `a` arrays are interpreted as coefficients for positive, descending powers of the transfer function variable. So the inputs `b = [b_0, b_1, ..., b_M]` and `a = [a_0, a_1, ..., a_N]` can represent an analog filter of the form:

\[
H(s) = \frac{b_0 s^M + b_1 s^{(M-1)} + \cdots + b_M}{a_0 s^N + a_1 s^{(N-1)} + \cdots + a_N}
\]

or a discrete-time filter of the form:

\[
H(z) = \frac{b_0 z^M + b_1 z^{(M-1)} + \cdots + b_M}{a_0 z^N + a_1 z^{(N-1)} + \cdots + a_N}
\]
This “positive powers” form is found more commonly in controls engineering. If \( M \) and \( N \) are equal (which is true for all filters generated by the bilinear transform), then this happens to be equivalent to the “negative powers” discrete-time form preferred in DSP:

\[
H(z) = \frac{b_0 + b_1 z^{-1} + \cdots + b_M z^{-M}}{a_0 + a_1 z^{-1} + \cdots + a_N z^{-N}}
\]

Although this is true for common filters, remember that this is not true in the general case. If \( M \) and \( N \) are not equal, the discrete-time transfer function coefficients must first be converted to the “positive powers” form before finding the poles and zeros.

**scipy.signal.tf2sos**

**scipy.signal.tf2sos**\((b, a, pairing='nearest')\)

Return second-order sections from transfer function representation

**Parameters**

- **b**  
  [array_like] Numerator polynomial coefficients.

- **a**  
  [array_like] Denominator polynomial coefficients.

- **pairing**  
  [{'nearest', 'keep_odd'}, optional] The method to use to combine pairs of poles and zeros into sections. See `zpk2sos`.

**Returns**

- **sos**  
  [ndarray] Array of second-order filter coefficients, with shape \((n_sections, 6)\). See `sosfilt` for the SOS filter format specification.

**See also:**

- `zpk2sos`, `sosfilt`

**Notes**

It is generally discouraged to convert from TF to SOS format, since doing so usually will not improve numerical precision errors. Instead, consider designing filters in ZPK format and converting directly to SOS. TF is converted to SOS by first converting to ZPK format, then converting ZPK to SOS.

New in version 0.16.0.

**scipy.signal.tf2ss**

**scipy.signal.tf2ss**\((num, den)\)

Transfer function to state-space representation.

**Parameters**

- **num, den**  
  [array_like] Sequences representing the coefficients of the numerator and denominator polynomials, in order of descending degree. The denominator needs to be at least as long as the numerator.

**Returns**

- **A, B, C, D**  
  [ndarray] State space representation of the system, in controller canonical form.
Examples

Convert the transfer function:

\[ H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1} \]

```python
>>> num = [1, 3, 3]
>>> den = [1, 2, 1]
```

to the state-space representation:

\[
\dot{x}(t) = \begin{bmatrix}
-2 & -1 \\
1 & 0
\end{bmatrix} x(t) + \begin{bmatrix}
1 \\
0
\end{bmatrix} u(t)
\]

\[
y(t) = \begin{bmatrix}
1 & 2
\end{bmatrix} x(t) + \begin{bmatrix}
1
\end{bmatrix} u(t)
\]

```python
>>> from scipy.signal import tf2ss
>>> A, B, C, D = tf2ss(num, den)
>>> A
array([[-2., -1.],
       [ 1.,  0.]])
>>> B
array([[ 1.],
       [ 0.]])
>>> C
array([[ 1.,  2.]])
>>> D
array([[ 1.]])
```

**scipy.signal.zpk2tf**

scipy.signal.zpk2tf(z, p, k)

Return polynomial transfer function representation from zeros and poles

**Parameters**

- **z** [array_like] Zeros of the transfer function.
- **p** [array_like] Poles of the transfer function.
- **k** [float] System gain.

**Returns**

- **b** [ndarray] Numerator polynomial coefficients.
- **a** [ndarray] Denominator polynomial coefficients.
scipy.signal.zpk2sos

`scipy.signal.zpk2sos(z, p, k, pairing='nearest')`

Return second-order sections from zeros, poles, and gain of a system.

**Parameters**

- `z` : array_like
  Zeros of the transfer function.
- `p` : array_like
  Poles of the transfer function.
- `k` : float
  System gain.
- `pairing` : {'nearest', 'keep_odd'}, optional
  The method to use to combine pairs of poles and zeros into sections. See Notes below.

**Returns**

- `sos` : ndarray
  Array of second-order filter coefficients, with shape `(n_sections, 6)`. See `sosfilt` for the SOS filter format specification.

**See also:**

`sosfilt`

**Notes**

The algorithm used to convert ZPK to SOS format is designed to minimize errors due to numerical precision issues. The pairing algorithm attempts to minimize the peak gain of each biquadratic section. This is done by pairing poles with the nearest zeros, starting with the poles closest to the unit circle.

**Algorithms**

The current algorithms are designed specifically for use with digital filters. (The output coefficients are not correct for analog filters.)

The steps in the pairing='nearest' and pairing='keep_odd' algorithms are mostly shared. The nearest algorithm attempts to minimize the peak gain, while 'keep_odd' minimizes peak gain under the constraint that odd-order systems should retain one section as first order. The algorithm steps and are as follows:

As a pre-processing step, add poles or zeros to the origin as necessary to obtain the same number of poles and zeros for pairing. If `pairing == 'nearest'` and there are an odd number of poles, add an additional pole and a zero at the origin.

The following steps are then iterated over until no more poles or zeros remain:

1. Take the (next remaining) pole (complex or real) closest to the unit circle to begin a new filter section.
2. If the pole is real and there are no other remaining real poles\(^1\), add the closest real zero to the section and leave it as a first order section. Note that after this step we are guaranteed to be left with an even number of real poles, complex poles, real zeros, and complex zeros for subsequent pairing iterations.
3. Else:
   1. If the pole is complex and the zero is the only remaining real zero\(^*\), then pair the pole with the next closest zero (guaranteed to be complex). This is necessary to ensure that there will be a real zero remaining to eventually create a first-order section (thus keeping the odd order).
   2. Else pair the pole with the closest remaining zero (complex or real).
   3. Proceed to complete the second-order section by adding another pole and zero to the current pole and zero in the section:

\(^1\)This conditional can only be met for specific odd-order inputs with the `pairing == 'keep_odd'` method.
1. If the current pole and zero are both complex, add their conjugates.
2. Else if the pole is complex and the zero is real, add the conjugate pole and the next closest real zero.
3. Else if the pole is real and the zero is complex, add the conjugate zero and the real pole closest to those zeros.
4. Else (we must have a real pole and real zero) add the next real pole closest to the unit circle, and then add the real zero closest to that pole.

New in version 0.16.0.

**Examples**

Design a 6th order low-pass elliptic digital filter for a system with a sampling rate of 8000 Hz that has a pass-band corner frequency of 1000 Hz. The ripple in the pass-band should not exceed 0.087 dB, and the attenuation in the stop-band should be at least 90 dB.

In the following call to `signal.ellip`, we could use `output='sos'`, but for this example, we'll use `output='zpk'`, and then convert to SOS format with `zpk2sos`:

```python
>>> from scipy import signal
>>> z, p, k = signal.ellip(6, 0.087, 90, 1000/(0.5*8000), output='zpk')
```

Now convert to SOS format.

```python
>>> sos = signal.zpk2sos(z, p, k)
```

The coefficients of the numerators of the sections:

```python
>>> sos[:, :3]
array([[ 0.0014154 , 0.00248707, 0.0014154 ],
      [ 1. , 0.72965193, 1. ],
      [ 1. , 0.17594966, 1. ]])
```

The symmetry in the coefficients occurs because all the zeros are on the unit circle.

The coefficients of the denominators of the sections:

```python
>>> sos[:, 3:]
array([[ 1. , 1. , 0.5 , 1. , -0.75, 0. ],
      [ 1. , 1. , 0. , 1. , -1.6 , 0.65]])
```

The next example shows the effect of the `pairing` option. We have a system with three poles and three zeros, so the SOS array will have shape (2, 6). The means there is, in effect, an extra pole and an extra zero at the origin in the SOS representation.

```python
>>> z1 = np.array([-1, -0.5-0.5j, -0.5+0.5j])
>>> p1 = np.array([0.75, 0.8+0.1j, 0.8-0.1j])
```

With `pairing='nearest'` (the default), we obtain

```python
>>> signal.zpk2sos(z1, p1, 1)
array([[ 1. , 1. , 0.5 , 1. , -0.75, 0. ],
      [ 1. , 1. , 0. , 1. , -1.6 , 0.65]])
```
The first section has the zeros \{-0.5-0.05j, -0.5+0.5j\} and the poles \{0, 0.75\}, and the second section has the zeros \{-1, 0\} and poles \{0.8+0.1j, 0.8-0.1j\}. Note that the extra pole and zero at the origin have been assigned to different sections.

With `pairing='keep_odd'`, we obtain:

```python
>>> signal.zpk2sos(z1, p1, 1, pairing='keep_odd')
array([[ 1. , 1. , 0. , 1. , -0.75, 0. ],
       [ 1. , 1. , 0.5 , 1. , -1.6 , 0.65]])
```

The extra pole and zero at the origin are in the same section. The first section is, in effect, a first-order section.

```python
calpy.signal.zpk2ss(calpy.signal.zpk2ss(z, p, k)
Zero-pole-gain representation to state-space representation

Parameters

- `z` [sequence] Zeros and poles.
- `p` [float] System gain.

Returns

- `A, B, C, D` [ndarray] State space representation of the system, in controller canonical form.
```

```python
calpy.signal.ss2tf(calpy.signal.ss2tf(A, B, C, D, input=0)
State-space to transfer function.

A, B, C, D defines a linear state-space system with p inputs, q outputs, and n state variables.

Parameters

- `A` [array_like] State (or system) matrix of shape \(n, n\)
- `B` [array_like] Input matrix of shape \(n, p\)
- `C` [array_like] Output matrix of shape \(q, n\)
- `D` [array_like] Feedthrough (or feedforward) matrix of shape \(q, p\)
- `input` [int, optional] For multiple-input systems, the index of the input to use.

Returns

- `num` [2-D ndarray] Numerator(s) of the resulting transfer function(s). `num` has one row for each of the system’s outputs. Each row is a sequence representation of the numerator polynomial.
- `den` [1-D ndarray] Denominator of the resulting transfer function(s). `den` is a sequence representation of the denominator polynomial.
```
Examples

Convert the state-space representation:

\[ \dot{x}(t) = \begin{bmatrix} -2 & -1 \\ 1 & 0 \end{bmatrix} x(t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix} u(t) \]

\[ y(t) = \begin{bmatrix} 1 & 2 \end{bmatrix} x(t) + \begin{bmatrix} 1 \end{bmatrix} u(t) \]

```python
to the transfer function:

\[ H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1} \]
```

```python
>>> from scipy.signal import ss2tf
>>> ss2tf(A, B, C, D)
(array([[1., 3., 3.]]), array([[1., 2., 1.]]))
```

`scipy.signal.ss2zpk`

`scipy.signal.ss2zpk(A, B, C, D, input=0)`

State-space representation to zero-pole-gain representation.

A, B, C, D defines a linear state-space system with p inputs, q outputs, and n state variables.

**Parameters**

- `A` : array_like  
  State (or system) matrix of shape (n, n)
- `B` : array_like  
  Input matrix of shape (n, p)
- `C` : array_like  
  Output matrix of shape (q, n)
- `D` : array_like  
  Feedthrough (or feedforward) matrix of shape (q, p)
- `input` : int, optional  
  For multiple-input systems, the index of the input to use.

**Returns**

- `z, p` : sequence  
  Zeros and poles.
- `k` : float  
  System gain.

`scipy.signal.sos2zpk`

`scipy.signal.sos2zpk(sos)`

Return zeros, poles, and gain of a series of second-order sections

**Parameters**

- `sos` : array_like  
  Array of second-order filter coefficients, must have shape (n_sections, 6). See `sosfilt` for the SOS filter format specification.

**Returns**

- `z` : ndarray  
  Zeros of the transfer function.
p [ndarray] Poles of the transfer function.
k [float] System gain.

Notes

The number of zeros and poles returned will be n_sections \times 2 even if some of these are (effectively) zero.
New in version 0.16.0.

scipy.signal.sos2tf

scipy.signal.sos2tf(sos)
Return a single transfer function from a series of second-order sections

Parameters

sos [array_like] Array of second-order filter coefficients, must have shape (n_sections, 6). See sosfilt for the SOS filter format specification.

Returns

b [ndarray] Numerator polynomial coefficients.
a [ndarray] Denominator polynomial coefficients.

Notes

New in version 0.16.0.

scipy.signal.cont2discrete

scipy.signal.cont2discrete(system, dt, method='zoh', alpha=None)
Transform a continuous to a discrete state-space system.

Parameters

system [a tuple describing the system or an instance of lti] The following gives the number of elements in the tuple and the interpretation:
• 1: (instance of lti)
• 2: (num, den)
• 3: (zeros, poles, gain)
• 4: (A, B, C, D)
dt [float] The discretization time step.
method [str, optional] Which method to use:
• gbt: generalized bilinear transformation
• bilinear: Tustin’s approximation (“gbt” with alpha=0.5)
• euler: Euler (or forward differencing) method (“gbt” with alpha=0)
• backward_diff: Backwards differencing (“gbt” with alpha=1.0)
• zoh: zero-order hold (default)
• foh: first-order hold (versionadded: 1.3.0)
• impulse: equivalent impulse response (versionadded: 1.3.0)
alpha [float within [0, 1], optional] The generalized bilinear transformation weighting parameter, which should only be specified with method=”gbt”, and is ignored otherwise

Returns
Based on the input type, the output will be of the form
- (num, den, dt) for transfer function input
- (zeros, poles, gain, dt) for zeros-poles-gain input
- (A, B, C, D, dt) for state-space system input

**Notes**

By default, the routine uses a Zero-Order Hold (zoh) method to perform the transformation. Alternatively, a generalized bilinear transformation may be used, which includes the common Tustin's bilinear approximation, an Euler's method technique, or a backwards differencing technique. The Zero-Order Hold (zoh) method is based on [1], the generalized bilinear approximation is based on [2] and [3], the First-Order Hold (foh) method is based on [4].

**scipy.signal.place_poles**

scipy.signal.place_poles(A, B, poles, method='YT', rtol=0.001, maxiter=30)

Compute K such that eigenvalues (A - dot(B, K))=poles.

K is the gain matrix such as the plant described by the linear system AX+BU will have its closed-loop poles, i.e. the eigenvalues A - B*K, as close as possible to those asked for in poles.

SISO, MISO and MIMO systems are supported.

**Parameters**

- A, B [ndarray] State-space representation of linear system AX + BU.
- poles [array_like] Desired real poles and/or complex conjugates poles. Complex poles are only supported with method="YT" (default).
- method: {'YT', 'KNV0'}, optional
  Which method to choose to find the gain matrix K. One of:
  - ‘YT’: Yang Tits
  - ‘KNV0’: Kautsky, Nichols, Van Dooren update method 0
  See References and Notes for details on the algorithms.
- rtol: float, optional
  After each iteration the determinant of the eigenvectors of A - B*K is compared to its previous value, when the relative error between these two values becomes lower than rtol the algorithm stops. Default is 1e-3.
- maxiter: int, optional
  Maximum number of iterations to compute the gain matrix. Default is 30.

**Returns**

- full_state_feedback [Bunch object]
  full_state_feedback is composed of:
  - gain_matrix [1-D ndarray] The closed loop matrix K such as the eigenvalues of A-BK are as close as possible to the requested poles.
computed_poles
[1-D ndarray] The poles corresponding to $A - BK$ sorted as first the real poles in increasing order, then the complex conjugates in lexicographic order.

requested_poles
[1-D ndarray] The poles the algorithm was asked to place sorted as above, they may differ from what was achieved.

$X$
[2-D ndarray] The transfer matrix such as $X \times \text{diag}(\text{poles}) = (A - B*K) \times X$ (see Notes)

rtol
[float] The relative tolerance achieved on $\text{det}(X)$ (see Notes). rtol will be NaN if it is possible to solve the system $\text{diag}(\text{poles}) = (A - B*K)$, or 0 when the optimization algorithms can't do anything i.e when $B$.shape[1] == 1.

nb_iter
[int] The number of iterations performed before converging. nb_iter will be NaN if it is possible to solve the system $\text{diag}(\text{poles}) = (A - B*K)$, or 0 when the optimization algorithms can't do anything i.e when $B$.shape[1] == 1.

Notes
The Tits and Yang (YT) [2] paper is an update of the original Kautsky et al. (KNV) paper [1]. KNV relies on rank-1 updates to find the transfer matrix $X$ such that $X \times \text{diag}(\text{poles}) = (A - B*K) \times X$, whereas YT uses rank-2 updates. This yields on average more robust solutions (see [2] pp 21-22), furthermore the YT algorithm supports complex poles whereas KNV does not in its original version. Only update method 0 proposed by KNV has been implemented here, hence the name 'KNV0'.

KNV extended to complex poles is used in Matlab's place function, YT is distributed under a non-free licence by Slicot under the name robpole. It is unclear and undocumented how KNV0 has been extended to complex poles (Tits and Yang claim on page 14 of their paper that their method can not be used to extend KNV to complex poles), therefore only YT supports them in this implementation.

As the solution to the problem of pole placement is not unique for MIMO systems, both methods start with a tentative transfer matrix which is altered in various way to increase its determinant. Both methods have been proven to converge to a stable solution, however depending on the way the initial transfer matrix is chosen they will converge to different solutions and therefore there is absolutely no guarantee that using 'KNV0' will yield results similar to Matlab's or any other implementation of these algorithms.

Using the default method 'YT' should be fine in most cases; 'KNV0' is only provided because it is needed by 'YT' in some specific cases. Furthermore 'YT' gives on average more robust results than 'KNV0' when $\text{abs} (\text{det}(X))$ is used as a robustness indicator.

[2] is available as a technical report on the following URL: https://hdl.handle.net/1903/5598

References

[1], [2]
Examples

A simple example demonstrating real pole placement using both KNV and YT algorithms. This is example number 1 from section 4 of the reference KNV publication ([1]):

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> A = np.array([[1.380, -0.2077, 6.715, -5.676 ],
... [-0.5814, -4.290, 0, 0.6750 ],
... [1.067, 4.273, -6.654, 5.893 ],
... [0.0480, 4.273, 1.343, -2.104 ]])

>>> B = np.array([[0, 5.679 ],
... [1.136, 1.136 ],
... [0, 0 ],
... [-3.146, 0 ]])

>>> P = np.array([-0.2, -0.5, -5.0566, -8.6659])

Now compute K with KNV method 0, with the default YT method and with the YT method while forcing 100 iterations of the algorithm and print some results after each call.

```python
>>> fsf1 = signal.place_poles(A, B, P, method='KNV0')
>>> fsf1.gain_matrix
array([[ 0.20071427, -0.96665799, 0.24066128, -0.10279785],
       [ 0.50587268, 0.57779091, 0.51795763, -0.41991442]])

>>> fsf2 = signal.place_poles(A, B, P)  # uses YT method
>>> fsf2.computed_poles
array([-8.6659, -5.0566, -0.5 , -0.2 ])

>>> fsf3 = signal.place_poles(A, B, P, rtol=-1, maxiter=100)
>>> fsf3.X
array([[ 0.52072442+0.j, -0.08409372+0.j, -0.56847937+0.j, 0.74823657+0.j],
       [-0.04977751+0.j, -0.80872954+0.j, 0.13566234+0.j, -0.29322906+0.j],
       [-0.82266932+0.j, -0.19168026+0.j, -0.56348322+0.j, -0.43815060+0.j],
       [ 0.22267347+0.j, 0.54967577+0.j, -0.58387806+0.j, -0.40271926+0.j]])
```

The absolute value of the determinant of X is a good indicator to check the robustness of the results, both 'KNV0' and 'YT' aim at maximizing it. Below a comparison of the robustness of the results above:

```python
>>> abs(np.linalg.det(fsf1.X)) < abs(np.linalg.det(fsf2.X))
True
>>> abs(np.linalg.det(fsf2.X)) < abs(np.linalg.det(fsf3.X))
True
```

Now a simple example for complex poles:

```python
>>> A = np.array([[0, 7/3., 0, 0 ],
... [0, 0, 0, 7/9. ],
... (continues on next page)
```
We can plot the desired and computed poles in the complex plane:

```python
>>> t = np.linspace(0, 2*np.pi, 401)
>>> plt.plot(np.cos(t), np.sin(t), 'k--')  # unit circle
>>> plt.plot(fsf.requested_poles.real, fsf.requested_poles.imag, 'wo', label='Desired')
>>> plt.plot(fsf.computed_poles.real, fsf.computed_poles.imag, 'bx', label='Placed')
>>> plt.grid()
>>> plt.axis('image')
>>> plt.axis([-1.1, 1.1, -1.1, 1.1])
>>> plt.legend(bbox_to_anchor=(1.05, 1), loc=2, numpoints=1)
```

**scipy.signal.chirp**

scipy.signal.chirp(t, f0, t1, f1, method='linear', phi=0, vertex_zero=True)

Frequency-swept cosine generator.

In the following, 'Hz' should be interpreted as 'cycles per unit'; there is no requirement here that the unit is one second. The important distinction is that the units of rotation are cycles, not radians. Likewise, t could be a measurement of space instead of time.

**Parameters**

- **t** [array_like] Times at which to evaluate the waveform.
- **f0** [float] Frequency (e.g. Hz) at time t=0.
- **t1** [float] Time at which f1 is specified.
- **f1** [float] Frequency (e.g. Hz) of the waveform at time t1.
- **method** [{'linear', 'quadratic', 'logarithmic', 'hyperbolic'}, optional] Kind of frequency sweep. If not given, linear is assumed. See Notes below for more details.
- **phi** [float, optional] Phase offset, in degrees. Default is 0.
- **vertex_zero** [bool, optional] This parameter is only used when method is 'quadratic'. It determines whether the vertex of the parabola that is the graph of the frequency is at t=0 or t=t1.

**Returns**

- **y** [ndarray] A numpy array containing the signal evaluated at t with the requested time-varying frequency. More precisely, the function returns \(\cos(\text{phase} + (\pi/180)\times\text{phi})\) where \(\text{phase}\) is the integral (from 0 to t) of \(2\pi f(t)\). \(f(t)\) is defined below.

**See also:**

- `sweep_poly`

**Notes**

There are four options for the method. The following formulas give the instantaneous frequency (in Hz) of the signal generated by chirp(). For convenience, the shorter names shown below may also be used.

**linear, lin, li:**

\[ f(t) = f_0 + (f_1 - f_0) \times \frac{t}{t_1} \]

**quadratic, quad, q:**

The graph of the frequency \(f(t)\) is a parabola through (0, f0) and (t1, f1). By default, the vertex of the parabola is at (0, f0). If vertex_zero is False, then the vertex is at (t1, f1). The formula is:

- if vertex_zero is True:
  
  \[ f(t) = f_0 + (f_1 - f_0) \times \frac{t^2}{t_1^2} \]

- else:
  
  \[ f(t) = f_1 - (f_1 - f_0) \times \frac{(t_1 - t)^2}{t_1^2} \]

To use a more general quadratic function, or an arbitrary polynomial, use the function scipy.signal.sweep_poly.
logarithmic, log, \( \log \):

\[
f(t) = f_0 \times (f_1/f_0)^{\frac{t}{t_1}}
\]

\( f_0 \) and \( f_1 \) must be nonzero and have the same sign.

This signal is also known as a geometric or exponential chirp.

hyperbolic, hyp:

\[
f(t) = \frac{f_0 \times f_1 \times t_1}{(f_0 - f_1) \times t + f_1 \times t_1}
\]

\( f_0 \) and \( f_1 \) must be nonzero.

**Examples**

The following will be used in the examples:

```python
>>> from scipy.signal import chirp, spectrogram
>>> import matplotlib.pyplot as plt
```

For the first example, we'll plot the waveform for a linear chirp from 6 Hz to 1 Hz over 10 seconds:

```python
>>> t = np.linspace(0, 10, 1500)
>>> w = chirp(t, f0=6, f1=1, t1=10, method='linear')
>>> plt.plot(t, w)
>>> plt.title("Linear Chirp, f(0)=6, f(10)=1")
>>> plt.xlabel('t (sec)')
>>> plt.show()
```

![Linear Chirp, f(0)=6, f(10)=1](image)

For the remaining examples, we'll use higher frequency ranges, and demonstrate the result using `scipy.signal.spectrogram`. We'll use a 4 second interval sampled at 7200 Hz.

```python
>>> fs = 7200
>>> T = 4
>>> t = np.arange(0, int(T*fs)) / fs
```

We'll use this function to plot the spectrogram in each example.
```python
>>> def plot_spectrogram(title, w, fs):
...     ff, tt, Sxx = spectrogram(w, fs=fs, nperseg=256, nfft=576)
...     plt.pcolormesh(tt, ff[:145], Sxx[:145], cmap='gray_r', shading='gouraud')
...     plt.title(title)
...     plt.xlabel('t (sec)')
...     plt.ylabel('Frequency (Hz)')
...     plt.grid()
...

Quadratic chirp from 1500 Hz to 250 Hz (vertex of the parabolic curve of the frequency is at t=0):
```n
```python
>>> w = chirp(t, f0=1500, f1=250, t1=T, method='quadratic')
>>> plot_spectrogram(f'Quadratic Chirp, f(0)=1500, f(\{T\})=250', w, fs)
>>> plt.show()
```

```
Quadratic Chirp, f(0)=1500, f(4)=250
```

```python
>>> w = chirp(t, f0=1500, f1=250, t1=T, method='quadratic', vertex_zero=False)
>>> plot_spectrogram(f'Quadratic Chirp, f(0)=1500, f(\{T\})=250\n' + ' (vertex_zero=False)', w, fs)
>>> plt.show()
```

Logarithmic chirp from 1500 Hz to 250 Hz:
```python
>>> w = chirp(t, f0=1500, f1=250, t1=T, method='logarithmic')
>>> plot_spectrogram(f'Logarithmic Chirp, f(0)=1500, f(\{T\})=250', w, fs)
>>> plt.show()
```

Hyperbolic chirp from 1500 Hz to 250 Hz:
```python
>>> w = chirp(t, f0=1500, f1=250, t1=T, method='hyperbolic')
>>> plot_spectrogram(f'Hyperbolic Chirp, f(0)=1500, f(\{T\})=250', w, fs)
>>> plt.show()
```
Quadratic Chirp, \( f(0)=1500, f(4)=250 \)
\( \text{vertex}_\text{zero}=\text{False} \)

Logarithmic Chirp, \( f(0)=1500, f(4)=250 \)
scipy.signal.gausspulse

scipy.signal.gausspulse(t, fc=1000, bw=0.5, bwr=-6, tpr=-60, retquad=False, retenv=False)

Return a Gaussian modulated sinusoid:

\[ \exp(-a t^2) \exp(1j*2*pi*fc*t). \]

If retquad is True, then return the real and imaginary parts (in-phase and quadrature). If retenv is True, then return the envelope (unmodulated signal). Otherwise, return the real part of the modulated sinusoid.

**Parameters**

- t [ndarray or the string ‘cutoff’] Input array.
- fc [float, optional] Center frequency (e.g. Hz). Default is 1000.
- bw [float, optional] Fractional bandwidth in frequency domain of pulse (e.g. Hz). Default is 0.5.
- bwr [float, optional] Reference level at which fractional bandwidth is calculated (dB). Default is -6.
- tpr [float, optional] If t is ‘cutoff’, then the function returns the cutoff time for when the pulse amplitude falls below tpr (in dB). Default is -60.
- retquad [bool, optional] If True, return the quadrature (imaginary) as well as the real part of the signal. Default is False.
- retenv [bool, optional] If True, return the envelope of the signal. Default is False.

**Returns**

- yQ [ndarray] Imaginary part of signal. Only returned if retquad is True.
- yenv [ndarray] Envelope of signal. Only returned if retenv is True.

See also:

scipy.signal.morlet
Examples

Plot real component, imaginary component, and envelope for a 5 Hz pulse, sampled at 100 Hz for 2 seconds:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(-1, 1, 2 * 100, endpoint=False)
>>> i, q, e = signal.gausspulse(t, fc=5, retquad=True, retenv=True)
>>> plt.plot(t, i, t, q, t, e, '--')
```

**scipy.signal.max_len_seq**

`scipy.signal.max_len_seq(nbits, state=None, length=None, taps=None)`

Maximum length sequence (MLS) generator.

**Parameters**

- `nbits` [int] Number of bits to use. Length of the resulting sequence will be \((2^{\text{nbits}}) - 1\). Note that generating long sequences (e.g., greater than `nbits` == 16) can take a long time.

- `state` [array_like, optional] If array, must be of length `nbits`, and will be cast to binary (bool) representation. If None, a seed of ones will be used, producing a repeatable representation. If `state` is all zeros, an error is raised as this is invalid. Default: None.

- `length` [int, optional] Number of samples to compute. If None, the entire length \((2^{\text{nbits}}) - 1\) is computed.

- `taps` [array_like, optional] Polynomial taps to use (e.g., \([7, 6, 1]\) for an 8-bit sequence). If None, taps will be automatically selected (for up to `nbits` == 32).

**Returns**

- `seq` [array] Resulting MLS sequence of 0’s and 1’s.

- `state` [array] The final state of the shift register.
Notes

The algorithm for MLS generation is generically described in:

https://en.wikipedia.org/wiki/Maximum_length_sequence

The default values for taps are specifically taken from the first option listed for each value of \texttt{nbits} in:

http://www.newwaveinstruments.com/resources/articles/m_sequence_linear_feedback_shift_register_lfsr.htm

New in version 0.15.0.

Examples

MLS uses binary convention:

```
>>> from scipy.signal import max_len_seq
>>> max_len_seq(4)[0]
array([1, 1, 1, 1, 0, 1, 0, 1, 1, 0, 0, 1, 0, 0, 0], dtype=int8)
```

MLS has a white spectrum (except for DC):

```
>>> import matplotlib.pyplot as plt
>>> from numpy.fft import fft, ifft, fftshift, fftfreq
>>> seq = max_len_seq(6)[0]*2-1  # +1 and -1
>>> spec = fft(seq)
>>> N = len(seq)
>>> plt.plot(fftshift(fftfreq(N)), fftshift(np.abs(spec)), '.-')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```

Circular autocorrelation of MLS is an impulse:
Linear autocorrelation of MLS is approximately an impulse:

```python
>>> acorr = np.correlate(seq, seq, 'full')
>>> plt.figure()
>>> plt.plot(np.arange(-N+1, N), acorr, '.-')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```

**scipy.signal.sawtooth**

`scipy.signal.sawtooth(t, width=1)`  
Return a periodic sawtooth or triangle waveform.

The sawtooth waveform has a period `2*pi`, rises from -1 to 1 on the interval 0 to `width*2*pi`, then drops from 1 to -1 on the interval `width*2*pi` to `2*pi`. `width` must be in the interval [0, 1].

Note that this is not band-limited. It produces an infinite number of harmonics, which are aliased back and forth across the frequency spectrum.

**Parameters**

- `t`  
  [array_like] Time.

- `width`  
  [array_like, optional] Width of the rising ramp as a proportion of the total cycle. Default is 1, producing a rising ramp, while 0 produces a falling ramp. `width = 0.5` produces a triangle wave. If an array, causes wave shape to change over time, and must be the same length as `t`.

**Returns**
y [ndarray] Output array containing the sawtooth waveform.

Examples

A 5 Hz waveform sampled at 500 Hz for 1 second:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(0, 1, 500)
>>> plt.plot(t, signal.sawtooth(2 * np.pi * 5 * t))
```
scipy.signal.square

scipy.signal.square(t, duty=0.5)

Return a periodic square-wave waveform.

The square wave has a period 2*pi, has value +1 from 0 to 2*pi*duty and -1 from 2*pi*duty to 2*pi.

duty must be in the interval [0,1].

Note that this is not band-limited. It produces an infinite number of harmonics, which are aliased back and forth
across the frequency spectrum.

Parameters

  t [array_like] The input time array.

  duty [array_like, optional] Duty cycle. Default is 0.5 (50% duty cycle). If an array, causes wave
  shape to change over time, and must be the same length as t.

Returns

  y [ndarray] Output array containing the square waveform.

Examples

A 5 Hz waveform sampled at 500 Hz for 1 second:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(0, 1, 500, endpoint=False)
>>> plt.plot(t, signal.square(2 * np.pi * 5 * t))
>>> plt.ylim(-2, 2)
```

A pulse-width modulated sine wave:

```python
>>> plt.figure()
>>> sig = np.sin(2 * np.pi * t)
>>> pwm = signal.square(2 * np.pi * 30 * t, duty=(sig + 1)/2)
>>> plt.subplot(2, 1, 1)
>>> plt.plot(t, sig)
>>> plt.subplot(2, 1, 2)
>>> plt.plot(t, pwm)
>>> plt.ylim(-1.5, 1.5)
```

scipy.signal.sweep_poly

scipy.signal.sweep_poly(t, poly, phi=0)

Frequency-swept cosine generator, with a time-dependent frequency.

This function generates a sinusoidal function whose instantaneous frequency varies with time. The frequency at
time t is given by the polynomial poly.

Parameters

  t [ndarray] Times at which to evaluate the waveform.

  poly [1-D array_like or instance of numpy.poly1d] The desired frequency expressed as a poly-
  nominal. If poly is a list or ndarray of length n, then the elements of poly are the coefficients
  of the polynomial, and the instantaneous frequency is

  \[ f(t) = \sum_{i=0}^{n-1} poly[i] \cdot t^i \]
6.22. Signal processing (scipy.signal)
If `poly` is an instance of `numpy.poly1d`, then the instantaneous frequency is

\[ f(t) = \text{poly}(t) \]

\[ \phi \] [float, optional] Phase offset, in degrees, Default: 0.

**Returns**

`sweep_poly`

[ndarray] A numpy array containing the signal evaluated at `t` with the requested time-varying frequency. More precisely, the function returns \( \cos(\text{phase} + (\pi/180)*\phi) \), where `phase` is the integral (from 0 to `t`) of \( 2 * \pi * f(t) \); `f(t)` is defined above.

**See also:**

`chirp`  

**Notes**

New in version 0.8.0.

If `poly` is a list or ndarray of length `n`, then the elements of `poly` are the coefficients of the polynomial, and the instantaneous frequency is:

\[ f(t) = \text{poly}[0]*t**(n-1) + \text{poly}[1]*t**(n-2) + \ldots + \text{poly}[n-1] \]

If `poly` is an instance of `numpy.poly1d`, then the instantaneous frequency is:

\[ f(t) = \text{poly}(t) \]

Finally, the output \( s \) is:

\[ \cos(\text{phase} + (\pi/180)*\phi) \]

where `phase` is the integral from 0 to `t` of \( 2 * \pi * f(t) \); `f(t)` as defined above.

**Examples**

Compute the waveform with instantaneous frequency:

\[ f(t) = 0.025*t^3 - 0.36*t^2 + 1.25*t + 2 \]

over the interval \( 0 <= t <= 10 \).

```python
>>> from scipy.signal import sweep_poly
>>> p = np.poly1d([0.025, -0.36, 1.25, 2.0])
>>> t = np.linspace(0, 10, 5001)
>>> w = sweep_poly(t, p)
```

Plot it:

```python
>>> import matplotlib.pyplot as plt
>>> plt.subplot(2, 1, 1)
>>> plt.plot(t, w)
>>> plt.title("Sweep Poly with frequency "+...
... "$f(t) = 0.025t^3 - 0.36t^2 + 1.25t + 2$")
>>> plt.subplot(2, 1, 2)
>>> plt.plot(t, p(t), 'r', label='f(t)')
>>> plt.legend()
```
Sweep Poly
with frequency $f(t) = 0.025t^3 - 0.36t^2 + 1.25t + 2$

scipy.signal.unit_impulse

scipy.signal.unit_impulse(shape, idx=None, dtype=<class 'float'>)

Unit impulse signal (discrete delta function) or unit basis vector.

**Parameters**

- **shape**  [int or tuple of int] Number of samples in the output (1-D), or a tuple that represents the shape of the output (N-D).
- **idx**  [None or int or tuple of int or 'mid', optional] Index at which the value is 1. If None, defaults to the 0th element. If idx='mid', the impulse will be centered at $\text{shape} \div 2$ in all dimensions. If an int, the impulse will be at idx in all dimensions.
- **dtype**  [data-type, optional] The desired data-type for the array, e.g., numpy.int8. Default is numpy.float64.

**Returns**

- **y**  [ndarray] Output array containing an impulse signal.

**Notes**

The 1D case is also known as the Kronecker delta.

New in version 0.19.0.
Examples

An impulse at the 0th element ($\delta[n]$):

```python
>>> from scipy import signal
>>> signal.unit_impulse(8)
array([ 1., 0., 0., 0., 0., 0., 0., 0.])
```

Impulse offset by 2 samples ($\delta[n - 2]$):

```python
>>> signal.unit_impulse(7, 2)
array([ 0., 0., 1., 0., 0., 0., 0.])
```

2-dimensional impulse, centered:

```python
>>> signal.unit_impulse((3, 3), 'mid')
array([[[ 0., 0., 0.],
        [ 0., 1., 0.],
        [ 0., 0., 0.]]])
```

Impulse at (2, 2), using broadcasting:

```python
>>> signal.unit_impulse((4, 4), 2)
array([[[ 0., 0., 0., 0.],
        [ 0., 0., 0., 0.],
        [ 0., 0., 1., 0.],
        [ 0., 0., 0., 0.]]])
```

Plot the impulse response of a 4th-order Butterworth lowpass filter:

```python
>>> imp = signal.unit_impulse(100, 'mid')
>>> b, a = signal.butter(4, 0.2)
>>> response = signal.lfilter(b, a, imp)
>>> import matplotlib.pyplot as plt
>>> plt.plot(np.arange(-50, 50), imp)
>>> plt.plot(np.arange(-50, 50), response)
>>> plt.margins(0.1, 0.1)
>>> plt.xlabel('Time [samples]')
>>> plt.ylabel('Amplitude')
>>> plt.grid(True)
>>> plt.show()
```

6.22.10 Window functions

For window functions, see the `scipy.signal.windows` namespace.

In the `scipy.signal` namespace, there is a convenience function to obtain these windows by name:

```python
get_window(window, Nx[, fftbins])
```

Return a window of a given length and type.
scipy.signal.get_window

scipy.signal.get_window(window, Nx, fftbins=True)

Return a window of a given length and type.

Parameters

- **window** [string, float, or tuple] The type of window to create. See below for more details.
- **Nx** [int] The number of samples in the window.
- **fftbins** [bool, optional] If True (default), create a “periodic” window, ready to use with `ifftshift` and be multiplied by the result of an FFT (see also `fftfreq`). If False, create a “symmetric” window, for use in filter design.

Returns

get_window

[ndarray] Returns a window of length Nx and type window

Notes

Window types:
- boxcar
- triang
- blackman
- hamming
- hann
- bartlett
- flattop
- parzen
- bohman
• blackmanharris
• nuttall
• barthann
• kaiser (needs beta)
• gaussian (needs standard deviation)
• general_gaussian (needs power, width)
• dpss (needs normalized half-bandwidth)
• chebwin (needs attenuation)
• exponential (needs center, decay scale)
• tukey (needs taper fraction)
• taylor (needs number of constant sidelobes, sidelobe level)

If the window requires no parameters, then window can be a string.

If the window requires parameters, then window must be a tuple with the first argument the string name of the window, and the next arguments the needed parameters.

If window is a floating point number, it is interpreted as the beta parameter of the kaiser window.

Each of the window types listed above is also the name of a function that can be called directly to create a window of that type.

**Examples**

```python
>>> from scipy import signal
>>> signal.get_window('triang', 7)
array([ 0.125, 0.375, 0.625, 0.875, 0.875, 0.625, 0.375])
>>> signal.get_window(('kaiser', 4.0), 9)
array([ 0.08848053, 0.29425961, 0.56437221, 0.82160913, 0.97885093,
        0.97885093, 0.82160913, 0.56437221, 0.29425961])
>>> signal.get_window(('exponential', None, 1.), 9)
array([ 0.011109 , 0.03019738, 0.082085 , 0.22313016, 0.60653066,
        0.60653066, 0.22313016, 0.082085 , 0.03019738])
>>> signal.get_window(4.0, 9)
array([ 0.08848053, 0.29425961, 0.56437221, 0.82160913, 0.97885093,
        0.97885093, 0.82160913, 0.56437221, 0.29425961])
```

### scipy.signal.cascade

`scipy.signal.cascade(hk, J=7)`

Return \( (x, \phi, \psi) \) at dyadic points \( K/2**J \) from filter coefficients.

**Parameters**

- **hk** [array_like] Coefficients of low-pass filter.
- **J** [int, optional] Values will be computed at grid points \( K/2**J \). Default is 7.

**Returns**

- **x** [ndarray] The dyadic points \( K/2**J \) for \( K=0...N * (2**J)-1 \) where \( \text{len}(hk) = \text{len}(gk) = N+1 \).
- **\phi** [ndarray] The scaling function \( \phi(x) \) at \( x: \phi(x) = \sum(hk \times \phi(2x-k)) \), where \( k \) is from 0 to \( N \).
- **\psi** [ndarray, optional] The wavelet function \( \psi(x) \) at \( x: \psi(x) = \sum(gk \times \phi(2x-k)) \), where \( k \) is from 0 to \( N \). \( \psi \) is only returned if \( gk \) is not None.

**Notes**

The algorithm uses the vector cascade algorithm described by Strang and Nguyen in “Wavelets and Filter Banks”. It builds a dictionary of values and slices for quick reuse. Then inserts vectors into final vector at the end.

### scipy.signal.daub

`scipy.signal.daub(p)`

The coefficients for the FIR low-pass filter producing Daubechies wavelets.

\( p \geq 1 \) gives the order of the zero at \( f=1/2 \). There are \( 2p \) filter coefficients.

**Parameters**

- **p** [int] Order of the zero at \( f=1/2 \), can have values from 1 to 34.

**Returns**

- **daub** [ndarray] Return

### scipy.signal.morlet

`scipy.signal.morlet(M, w=5.0, s=1.0, complete=True)`

Complex Morlet wavelet.

**Parameters**

- **M** [int] Length of the wavelet.
- **w** [float, optional] Omega0. Default is 5
- **s** [float, optional] Scaling factor, windowed from \(-s*2*pi \) to \(+s*2*pi \). Default is 1.
- **complete** [bool, optional] Whether to use the complete or the standard version.

**Returns**

6.22. Signal processing (`scipy.signal`)

morlet  
((M,) ndarray)

See also:
morlet2

Implementation of Morlet wavelet, compatible with cwt.

scipy.signal.gausspulse

Notes

The standard version:

\[ \pi^{**-0.25} \exp(1j*w*x) \exp(-0.5*(x**2)) \]

This commonly used wavelet is often referred to simply as the Morlet wavelet. Note that this simplified version can cause admissibility problems at low values of \( w \).

The complete version:

\[ \pi^{**-0.25} \exp(1j*w*x) - \exp(-0.5*(w**2)) \exp(-0.5*(x**2)) \]

This version has a correction term to improve admissibility. For \( w \) greater than 5, the correction term is negligible. Note that the energy of the return wavelet is not normalised according to \( s \).

The fundamental frequency of this wavelet in Hz is given by

\[ f = 2*s*w*r / M \]

where \( r \) is the sampling rate.

Note: This function was created before cwt and is not compatible with it.

scipy.signal.qmf

scipy.signal.qmf(hk)

Return high-pass qmf filter from low-pass

Parameters

hk  [array_like] Coefficients of high-pass filter.

scipy.signal.ricker

scipy.signal.ricker(points, a)

Return a Ricker wavelet, also known as the “Mexican hat wavelet”.

It models the function:

\[ A \times (1 - (x/a)**2) \exp(-0.5*(x/a)**2), \]

where \( A = 2/(\sqrt{3*a}*(\pi^{**0.25})) \).

Parameters

points  [int] Number of points in vector. Will be centered around 0.
a  [scalar] Width parameter of the wavelet.

Returns

vector  [(N,) ndarray] Array of length points in shape of ricker curve.
Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> points = 100
>>> a = 4.0
>>> vec2 = signal.ricker(points, a)
>>> print(len(vec2))
100
>>> plt.plot(vec2)
>>> plt.show()
```

![Graph](image)

**scipy.signal.morlet2**

```python
scipy.signal.morlet2(M, s, w=5)
```

Complex Morlet wavelet, designed to work with `cwt`. Returns the complete version of morlet wavelet, normalised according to $s$:

$$
\exp(1j*w*x/s) * \exp(-0.5*(x/s)**2) * \pi**(-0.25) * \sqrt{1/s}
$$

**Parameters**

- **M** [int] Length of the wavelet.
- **s** [float] Width parameter of the wavelet.
- **w** [float, optional] Omega0. Default is 5

**Returns**

- **morlet** [(M,) ndarray]

See also:
**morlet**

Implementation of Morlet wavelet, incompatible with *cwt*

**Notes**

New in version 1.4.0.

This function was designed to work with *cwt*. Because *morlet2* returns an array of complex numbers, the *dtype* argument of *cwt* should be set to *complex128* for best results.

Note the difference in implementation with *morlet*. The fundamental frequency of this wavelet in Hz is given by:

\[
f = \frac{w \times f_s}{2 \times s \times \pi}
\]

where \( f_s \) is the sampling rate and \( s \) is the wavelet width parameter. Similarly we can get the wavelet width parameter at \( f \):

\[
s = \frac{w \times f_s}{2 \times f \times \pi}
\]

**Examples**

```python
code snippet...
```

This example shows basic use of *morlet2* with *cwt* in time-frequency analysis:
```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t, dt = np.linspace(0, 1, 200, retstep=True)
>>> fs = 1/dt
>>> w = 6.
>>> sig = np.cos(2*np.pi*(50 + 10*t)*t) + np.sin(40*np.pi*t)
>>> freq = np.linspace(1, fs/2, 100)
>>> widths = w*fs / (2*freq*np.pi)
>>> cwtm = signal.cwt(sig, signal.morlet2, widths, w=w)
>>> plt.pcolormesh(t, freq, np.abs(cwtm), cmap='viridis', shading='gouraud')
>>> plt.show()
```

**scipy.signal.cwt**

scipy.signal.cwt(data, wavelet, widths, dtype=None, **kwargs)

Continuous wavelet transform.

Perform a continuous wavelet transform on data, using the wavelet function. A CWT performs a convolution with data using the wavelet function, which is characterized by a width parameter and length parameter. The wavelet function is allowed to be complex.

**Parameters**

- **data** *(N,)* ndarray data on which to perform the transform.
- **wavelet** [function] Wavelet function, which should take 2 arguments. The first argument is the number of points that the returned vector will have (len(wavelet(length,width)) == length). The second is a width parameter, defining the size of the wavelet (e.g. standard deviation of a gaussian). See ricker, which satisfies these requirements.
- **widths** *(M,)* sequence Widths to use for transform.
- **dtype** [data-type, optional] The desired data type of output. Defaults to float64 if the output of wavelet is real and complex128 if it is complex. New in version 1.4.0.
Keywords passed to wavelet function.

New in version 1.4.0.

Returns

cwt: (M, N) ndarray
Will have shape of (len(widths), len(data)).

Notes

New in version 1.4.0.

For non-symmetric, complex-valued wavelets, the input signal is convolved with the time-reversed complex-conjugate of the wavelet data [1].

\[
\text{length} = \min(10 \times \text{width}[\text{ii}], \text{len(data)})
\]

\[
cwt[\text{ii},:] = \text{signal.convolve(data, np.conj(wavelet(length, width[\text{ii}], \text{*kwargs}))[:,\text{::-1}], mode='same')}
\]

References

[1]

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(-1, 1, 200, endpoint=False)
>>> sig = np.cos(2 * np.pi * 7 * t) + signal.gausspulse(t - 0.4, fc=2)
>>> widths = np.arange(1, 31)
>>> cwtmatr = signal.cwt(sig, signal.ricker, widths)
>>> plt.imshow(cwtmatr, extent=[-1, 1, 1, 31], cmap='PRGn', aspect='auto',
...    vmax=abs(cwtmatr).max(), vmin=-abs(cwtmatr).max())
>>> plt.show()
```

6.22.12 Peak finding

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>argrelmin(data[, axis, order, mode])</td>
<td>Calculate the relative minima of data.</td>
</tr>
<tr>
<td>argrelmax(data[, axis, order, mode])</td>
<td>Calculate the relative maxima of data.</td>

</tr>
</tbody>
</table>
scipy.signal.argrelmin

`scipy.signal.argrelmin(data, axis=0, order=1, mode='clip')`

Calculate the relative minima of `data`.

**Parameters**

- `data` : [ndarray] Array in which to find the relative minima.
- `axis` : [int, optional] Axis over which to select from `data`. Default is 0.
- `order` : [int, optional] How many points on each side to use for the comparison to consider `comparator(n, n+x)` to be True.
- `mode` : [str, optional] How the edges of the vector are treated. Available options are 'wrap' (wrap around) or 'clip' (treat overflow as the same as the last (or first) element). Default 'clip'. See `numpy.take`.

**Returns**

- `extrema` : [tuple of ndarrays] Indices of the minima in arrays of integers. `extrema[k]` is the array of indices of axis `k` of `data`. Note that the return value is a tuple even when `data` is 1-D.

**See also:**

`argrelextrema, argrelmax, find_peaks`

**Notes**

This function uses `argrelextrema` with `np.less` as comparator. Therefore, it requires a strict inequality on both sides of a value to consider it a minimum. This means flat minima (more than one sample wide) are not detected. In case of 1-D `data` `find_peaks` can be used to detect all local minima, including flat ones, by calling it with negated `data`.

New in version 0.11.0.
Examples

```python
>>> from scipy.signal import argrelmin
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelmin(x)
(array([1, 5]),)
```  
```python
>>> y = np.array([[1, 2, 1, 2],
...                [2, 2, 0, 0],
...                [5, 3, 4, 4]])
...>>> argrelmin(y, axis=1)
(array([0, 2]), array([2, 1]))
```  

scipy.signal.argrelmax

scipy.signal.argrelmax(data, axis=0, order=1, mode='clip')

Calculate the relative maxima of data.

**Parameters**

data [ndarray] Array in which to find the relative maxima.
axis [int, optional] Axis over which to select from data. Default is 0.
order [int, optional] How many points on each side to use for the comparison to consider comparator(n, n+x) to be True.
mode [str, optional] How the edges of the vector are treated. Available options are 'wrap' (wrap around) or 'clip' (treat overflow as the same as the last (or first) element). Default 'clip'. See numpy.take.

**Returns**

extrema [tuple of ndarrays] Indices of the maxima in arrays of integers. extrema[k] is the array of indices of axis k of data. Note that the return value is a tuple even when data is 1-D.

See also:

argrelextrema, argrelmin, find_peaks

**Notes**

This function uses argrelextrema with np.greater as comparator. Therefore, it requires a strict inequality on both sides of a value to consider it a maximum. This means flat maxima (more than one sample wide) are not detected. In case of 1-D data find_peaks can be used to detect all local maxima, including flat ones.

New in version 0.11.0.
Examples

```python
>>> from scipy.signal import argrelextrema
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelextrema(x)
(array([3, 6]),)
>>> y = np.array([[1, 2, 1, 2],
                [2, 2, 0, 0],
                [5, 3, 4, 4]])
>>> argrelextrema(y, axis=1)
(array([0]), array([1]))
```

scipy.signal.argrelextrema

`scipy.signal.argrelextrema(data, comparator, axis=0, order=1, mode='clip')`

Calculate the relative extrema of `data`.

**Parameters**

- `data` [ndarray] Array in which to find the relative extrema.
- `comparator` [callable] Function to use to compare two data points. Should take two arrays as arguments.
- `axis` [int, optional] Axis over which to select from `data`. Default is 0.
- `order` [int, optional] How many points on each side to use for the comparison to consider `comparator(n, n+x)` to be True.
- `mode` [str, optional] How the edges of the vector are treated. ‘wrap’ (wrap around) or ‘clip’ (treat overflow as the same as the last (or first) element). Default is ‘clip’. See `numpy.take`.

**Returns**

- `extrema` [tuple of ndarrays] Indices of the maxima in arrays of integers. `extrema[k]` is the array of indices of axis `k` of `data`. Note that the return value is a tuple even when `data` is 1-D.

**See also:**

`argrelmin`, `argrelemax`

**Notes**

New in version 0.11.0.

**Examples**

```python
>>> from scipy.signal import argrelextrema
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelextrema(x, np.greater)
(array([3, 6]),)
>>> y = np.array([[1, 2, 1, 2],
                [2, 2, 0, 0],
                [5, 3, 4, 4]])
>>> argrelextrema(y, axis=1)
(array([0]), array([1]))
```
argrelextrema(y, np.less, axis=1)
(array([0, 2]), array([2, 1]))

scipy.signal.find_peaks

This function takes a 1-D array and finds all local maxima by simple comparison of neighboring values. Optionally, a subset of these peaks can be selected by specifying conditions for a peak’s properties.

Parameters

- **x** [sequence] A signal with peaks.
- **height** [number or ndarray or sequence, optional] Required height of peaks. Either a number, None, an array matching \( x \) or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required height.
- **threshold** [number or ndarray or sequence, optional] Required threshold of peaks, the vertical distance to its neighboring samples. Either a number, None, an array matching \( x \) or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required threshold.
- **distance** [number, optional] Required minimal horizontal distance (\( \geq 1 \)) in samples between neighbouring peaks. Smaller peaks are removed first until the condition is fulfilled for all remaining peaks.
- **prominence** [number or ndarray or sequence, optional] Required prominence of peaks. Either a number, None, an array matching \( x \) or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required prominence.
- **width** [number or ndarray or sequence, optional] Required width of peaks in samples. Either a number, None, an array matching \( x \) or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required width.
- **wlen** [int, optional] Used for calculation of the peaks prominences, thus it is only used if one of the arguments prominence or width is given. See argument wlen in peak_prominences for a full description of its effects.
- **rel_height** [float, optional] Used for calculation of the peaks width, thus it is only used if width is given. See argument rel_height in peak_widths for a full description of its effects.
- **plateau_size** [number or ndarray or sequence, optional] Required size of the flat top of peaks in samples. Either a number, None, an array matching \( x \) or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required plateau size.

New in version 1.2.0.

Returns

- **peaks** [ndarray] Indices of peaks in \( x \) that satisfy all given conditions.
- **properties** [dict] A dictionary containing properties of the returned peaks which were calculated as intermediate results during evaluation of the specified conditions:
  - **’peak_heights’**
    If height is given, the height of each peak in \( x \).
• ‘left_thresholds’, ‘right_thresholds’
  If threshold is given, these keys contain a peaks vertical distance to its neighbour samples.

• ‘prominences’, ‘right_bases’, ‘left_bases’
  If prominence is given, these keys are accessible. See peak_prominences for a description of their content.

• ‘width_heights’, ‘left_ips’, ‘right_ips’
  If width is given, these keys are accessible. See peak_widths for a description of their content.

• ‘plateau_sizes’, ‘left_edges’, ‘right_edges’
  If plateau_size is given, these keys are accessible and contain the indices of a peak’s edges (edges are still part of the plateau) and the calculated plateau sizes.
  New in version 1.2.0.

To calculate and return properties without excluding peaks, provide the open interval (None, None) as a value to the appropriate argument (excluding distance).

**Warns**

PeakPropertyWarning

Raised if a peak’s properties have unexpected values (see peak_prominences and peak_widths).

**Warning:** This function may return unexpected results for data containing NaNs. To avoid this, NaNs should either be removed or replaced.

See also:

**find_peaks_cwt**

Find peaks using the wavelet transformation.

**peak_prominences**

Directly calculate the prominence of peaks.

**peak_widths**

Directly calculate the width of peaks.

Notes

In the context of this function, a peak or local maximum is defined as any sample whose two direct neighbours have a smaller amplitude. For flat peaks (more than one sample of equal amplitude wide) the index of the middle sample is returned (rounded down in case the number of samples is even). For noisy signals the peak locations can be off because the noise might change the position of local maxima. In those cases consider smoothing the signal before searching for peaks or use other peak finding and fitting methods (like find_peaks_cwt).

Some additional comments on specifying conditions:

• Almost all conditions (excluding distance) can be given as half-open or closed intervals, e.g., 1 or (1, None) defines the half-open interval [1, ∞) while (None, 1) defines the interval (−∞, 1]. The open interval (None, None) can be specified as well, which returns the matching properties without exclusion of peaks.

• The border is always included in the interval used to select valid peaks.
For several conditions the interval borders can be specified with arrays matching \( x \) in shape which enables dynamic constrains based on the sample position.

The conditions are evaluated in the following order: \( \text{plateau size}, \text{height}, \text{threshold}, \text{distance}, \text{prominence}, \text{width} \). In most cases this order is the fastest one because faster operations are applied first to reduce the number of peaks that need to be evaluated later.

While indices in \( \text{peaks} \) are guaranteed to be at least \( \text{distance} \) samples apart, edges of flat peaks may be closer than the allowed \( \text{distance} \).

Use \( \text{wlen} \) to reduce the time it takes to evaluate the conditions for \( \text{prominence} \) or \( \text{width} \) if \( x \) is large or has many local maxima (see \( \text{peak_prominences} \)).

New in version 1.1.0.

**Examples**

To demonstrate this function's usage we use a signal \( x \) supplied with SciPy (see \( \text{scipy.misc.electrocardiogram} \)). Let's find all peaks (local maxima) in \( x \) whose amplitude lies above 0.

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.misc import electrocardiogram
>>> from scipy.signal import find_peaks
>>> x = electrocardiogram()[2000:4000]
>>> peaks, _ = find_peaks(x, height=0)
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.plot(np.zeros_like(x), "--", color="gray")
>>> plt.show()
```

We can select peaks below 0 with \( \text{height=(None, 0)} \) or use arrays matching \( x \) in size to reflect a changing condition for different parts of the signal.

```python
>>> border = np.sin(np.linspace(0, 3 * np.pi, x.size))
>>> peaks, _ = find_peaks(x, height=(-border, border))
```
Another useful condition for periodic signals can be given with the `distance` argument. In this case, we can easily select the positions of QRS complexes within the electrocardiogram (ECG) by demanding a distance of at least 150 samples.

```python
>>> peaks, _ = find_peaks(x, distance=150)
>>> np.diff(peaks)
array([186, 180, 177, 171, 177, 167, 164, 158, 162, 172])
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.show()
```

Especially for noisy signals peaks can be easily grouped by their prominence (see `peak_prominences`). E.g., we can select all peaks except for the mentioned QRS complexes by limiting the allowed prominence to 0.6.

```python
>>> peaks, properties = find_peaks(x, prominence=(None, 0.6))
>>> properties["prominences"].max()
0.5049999999999999
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.show()
```

And, finally, let's examine a different section of the ECG which contains beat forms of different shape. To select only the atypical heart beats, we combine two conditions: a minimal prominence of 1 and width of at least 20 samples.

```python
>>> x = electrocardiogram()[17000:18000]
>>> peaks, properties = find_peaks(x, prominence=1, width=20)
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.show()
```
```python
>>> properties['prominences'], properties['widths']
(array([1.495, 2.3 ]), array([36.93773946, 39.32723577]))
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.vlines(x=peaks, ymin=x[peaks] - properties['prominences'],
...            ymax=x[peaks], color="C1")
>>> plt.hlines(y=properties['width_heights'], xmin=properties['left_ips'],
...            xmax=properties['right_ips'], color="C1")
>>> plt.show()
```

### scipy.signal.find_peaks_cwt

`scipy.signal.find_peaks_cwt` (vector, widths, wavelet=None, max_distances=None, gap_thresh=None, min_length=None, min_snr=1, noise_perc=10, window_size=None)

Find peaks in a 1-D array with wavelet transformation.

The general approach is to smooth `vector` by convolving it with `wavelet(width)` for each width in `widths`. Relative maxima which appear at enough length scales, and with sufficiently high SNR, are accepted.

**Parameters**

- **vector** [ndarray] 1-D array in which to find the peaks.
- **widths** [sequence] 1-D array of widths to use for calculating the CWT matrix. In general, this range should cover the expected width of peaks of interest.
- **wavelet** [callable, optional] Should take two parameters and return a 1-D array to convolve with `vector`. The first parameter determines the number of points of the returned wavelet array, the second parameter is the scale (width) of the wavelet. Should be normalized and symmetric. Default is the ricker wavelet.
- **max_distances** [ndarray, optional] At each row, a ridge line is only connected if the relative max at row[n] is within `max_distances[n]` from the relative max at row[n+1]. Default value is `widths/4`.
- **gap_thresh**
[float, optional] If a relative maximum is not found within max_distances, there will be a gap. A ridge line is discontinued if there are more than gap_thresh points without connecting a new relative maximum. Default is the first value of the widths array i.e. widths[0].

**min_length**

[int, optional] Minimum length a ridge line needs to be acceptable. Default is \(\text{cwt}.\text{shape}[0] / 4\), i.e. 1/4-th the number of widths.

**min_snr**

[float, optional] Minimum SNR ratio. Default 1. The signal is the value of the cwt matrix at the shortest length scale (cwt[0, loc]), the noise is the noise_perc’th percentile of datapoints contained within a window of `window_size` around cwt[0, loc].

**noise_perc**

[float, optional] When calculating the noise floor, percentile of data points examined below which to consider noise. Calculated using \text{stats.scoreatpercentile}. Default is 10.

**window_size**

[int, optional] Size of window to use to calculate noise floor. Default is \(\text{cwt}.\text{shape}[1] / 20\).

Returns

**peaks_indices**

[ndarray] Indices of the locations in the vector where peaks were found. The list is sorted.

See also:

cwt

Continuous wavelet transform.

find_peaks

Find peaks inside a signal based on peak properties.

Notes

This approach was designed for finding sharp peaks among noisy data, however with proper parameter selection it should function well for different peak shapes.

The algorithm is as follows:

1. Perform a continuous wavelet transform on vector, for the supplied widths. This is a convolution of vector with wavelet(width) for each width in widths. See cwt.
2. Identify “ridge lines” in the cwt matrix. These are relative maxima at each row, connected across adjacent rows. See identify_ridge_lines
3. Filter the ridge_lines using filter_ridge_lines.

New in version 0.11.0.
References

[1]

Examples

```python
>>> from scipy import signal
>>> xs = np.arange(0, np.pi, 0.05)
>>> data = np.sin(xs)
>>> peakind = signal.find_peaks_cwt(data, np.arange(1,10))
>>> peakind, xs[peakind], data[peakind]
(array([32]), array([1.6]), array([0.9995736]))
```

`scipy.signal.peak_prominences`

`scipy.signal.peak_prominences(x, peaks, wlen=None)`

Calculate the prominence of each peak in a signal.

The prominence of a peak measures how much a peak stands out from the surrounding baseline of the signal and is defined as the vertical distance between the peak and its lowest contour line.

**Parameters**

- `x` [sequence] A signal with peaks.
- `peaks` [sequence] Indices of peaks in `x`.
- `wlen` [int, optional] A window length in samples that optionally limits the evaluated area for each peak to a subset of `x`. The peak is always placed in the middle of the window therefore the given length is rounded up to the next odd integer. This parameter can speed up the calculation (see Notes).

**Returns**

- `prominences` [ndarray] The calculated prominences for each peak in `peaks`.
- `left_bases, right_bases` [ndarray] The peaks’ bases as indices in `x` to the left and right of each peak. The higher base of each pair is a peak’s lowest contour line.

**Raises**

- `ValueError` If a value in `peaks` is an invalid index for `x`.

** Warns**

- `PeakPropertyWarning` For indices in `peaks` that don’t point to valid local maxima in `x`, the returned prominence will be 0 and this warning is raised. This also happens if `wlen` is smaller than the plateau size of a peak.

**Warning** This function may return unexpected results for data containing NaNs. To avoid this, NaNs should either be removed or replaced.

**See also:**

6.22. Signal processing (`scipy.signal`)
**find_peaks**

Find peaks inside a signal based on peak properties.

**peak_widths**

Calculate the width of peaks.

**Notes**

Strategy to compute a peak’s prominence:

1. Extend a horizontal line from the current peak to the left and right until the line either reaches the window border (see \( wlen \)) or intersects the signal again at the slope of a higher peak. An intersection with a peak of the same height is ignored.

2. On each side find the minimal signal value within the interval defined above. These points are the peak’s bases.

3. The higher one of the two bases marks the peak’s lowest contour line. The prominence can then be calculated as the vertical difference between the peaks height itself and its lowest contour line.

Searching for the peak’s bases can be slow for large \( x \) with periodic behavior because large chunks or even the full signal need to be evaluated for the first algorithmic step. This evaluation area can be limited with the parameter \( wlen \) which restricts the algorithm to a window around the current peak and can shorten the calculation time if the window length is short in relation to \( x \). However, this may stop the algorithm from finding the true global contour line if the peak’s true bases are outside this window. Instead, a higher contour line is found within the restricted window leading to a smaller calculated prominence. In practice, this is only relevant for the highest set of peaks in \( x \). This behavior may even be used intentionally to calculate “local” prominences.

New in version 1.1.0.

**References**

[1]

**Examples**

```python
>>> from scipy.signal import find_peaks, peak_prominences
>>> import matplotlib.pyplot as plt
```

Create a test signal with two overlayed harmonics

```python
>>> x = np.linspace(0, 6 * np.pi, 1000)
>>> x = np.sin(x) + 0.6 * np.sin(2.6 * x)
```

Find all peaks and calculate prominences

```python
>>> peaks, _ = find_peaks(x)
>>> prominences = peak_prominences(x, peaks)[0]
>>> prominences
array([1.24159486, 0.47840168, 0.28470524, 3.10716793, 0.2846030 ,
      0.47822491, 2.48340261, 0.47822491])
```

Calculate the height of each peak’s contour line and plot the results
Let's evaluate a second example that demonstrates several edge cases for one peak at index 5.

```python
>>> x = np.array([0, 1, 0, 3, 1, 3, 0, 4, 0])
>>> peaks = np.array([5])
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.show()
```
>>> peak_prominences(x, peaks)  # -> (prominences, left_bases, right_bases)
(array([3.]), array([2]), array([6]))

Note how the peak at index 3 of the same height is not considered as a border while searching for the left base. Instead, two minima at 0 and 2 are found in which case the one closer to the evaluated peak is always chosen. On the right side, however, the base must be placed at 6 because the higher peak represents the right border to the evaluated area.

>>> peak_prominences(x, peaks, wlen=3.1)
(array([2.]), array([4]), array([6]))

Here, we restricted the algorithm to a window from 3 to 7 (the length is 5 samples because wlen was rounded up to the next odd integer). Thus, the only two candidates in the evaluated area are the two neighboring samples and a smaller prominence is calculated.

**scipy.signal.peak_widths**

scipy.signal.peak_widths(x, peaks, rel_height=0.5, prominence_data=None, wlen=None)

Calculate the width of each peak in a signal.

This function calculates the width of a peak in samples at a relative distance to the peak’s height and prominence.

**Parameters**

- **x** [sequence] A signal with peaks.
- **peaks** [sequence] Indices of peaks in x.
- **rel_height** [float, optional] Chooses the relative height at which the peak width is measured as a percentage of its prominence. 1.0 calculates the width of the peak at its lowest contour line while 0.5 evaluates at half the prominence height. Must be at least 0. See notes for further explanation.
- **prominence_data** [tuple, optional] A tuple of three arrays matching the output of peak_prominences when called with the same arguments x and peaks. This data are calculated internally if not provided.
- **wlen** [int, optional] A window length in samples passed to peak_prominences as an optional argument for internal calculation of prominence_data. This argument is ignored if prominence_data is given.

**Returns**

- **widths** [ndarray] The widths for each peak in samples.
- **width_heights** [ndarray] The height of the contour lines at which the widths were evaluated.
- **left_ips, right_ips** [ndarray] Interpolated positions of left and right intersection points of a horizontal line at the respective evaluation height.

**Raises**

- **ValueError** If prominence_data is supplied but doesn’t satisfy the condition 0 <= left_base <= peak <= right_base < x.shape[0] for each peak, has the wrong dtype, is not C-contiguous or does not have the same shape.

**Warns**
PeakPropertyWarning

Raised if any calculated width is 0. This may stem from the supplied prominence_data or if rel_height is set to 0.

**Warning:** This function may return unexpected results for data containing NaNs. To avoid this, NaNs should either be removed or replaced.

See also:

- **find_peaks**
  
  Find peaks inside a signal based on peak properties.

- **peak_prominences**
  
  Calculate the prominence of peaks.

Notes

The basic algorithm to calculate a peak’s width is as follows:

- Calculate the evaluation height \( h_{eval} \) with the formula \( h_{eval} = h_{Peak} - P \cdot R \), where \( h_{Peak} \) is the height of the peak itself, \( P \) is the peak’s prominence and \( R \) a positive ratio specified with the argument rel_height.

- Draw a horizontal line at the evaluation height to both sides, starting at the peak’s current vertical position until the lines either intersect a slope, the signal border or cross the vertical position of the peak’s base (see peak_prominences for an definition). For the first case, intersection with the signal, the true intersection point is estimated with linear interpolation.

- Calculate the width as the horizontal distance between the chosen endpoints on both sides. As a consequence of this the maximal possible width for each peak is the horizontal distance between its bases.

As shown above to calculate a peak’s width its prominence and bases must be known. You can supply these yourself with the argument prominence_data. Otherwise, they are internally calculated (see peak_prominences).

New in version 1.1.0.

Examples

```python
>>> from scipy.signal import chirp, find_peaks, peak_widths
>>> import matplotlib.pyplot as plt

Create a test signal with two overlayed harmonics

```python
>>> x = np.linspace(0, 6 * np.pi, 1000)
>>> x = np.sin(x) + 0.6 * np.sin(2.6 * x)

Find all peaks and calculate their widths at the relative height of 0.5 (contour line at half the prominence height) and 1 (at the lowest contour line at full prominence height).

```python
>>> peaks, _ = find_peaks(x)
>>> results_half = peak_widths(x, peaks, rel_height=0.5)
>>> results_half[0]  # widths
array([ 64.25172825,  41.29465463,  35.46943289, 104.71586081, ...
```

(continues on next page)
Plot signal, peaks and contour lines at which the widths where calculated

```python
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.hlines(*results_half[1:], color="C2")
>>> plt.hlines(*results_full[1:], color="C3")
>>> plt.show()
```

6.22.13 Spectral analysis

- `periodogram(x[, fs, window, nfft, detrend, ...])` Estimate power spectral density using a periodogram.
- `welch(x[, fs, window, nperseg, noverlap, ...])` Estimate power spectral density using Welch’s method.
- `csd(x, y[, fs, window, nperseg, noverlap, ...])` Estimate the cross power spectral density, $P_{XY}$, using Welch’s method.
- `coherence(x, y[, fs, window, nperseg, ...])` Estimate the magnitude squared coherence estimate, $C_{XY}$, of discrete-time signals $X$ and $Y$ using Welch’s method.
- `spectrogram(x[, fs, window, nperseg, ...])` Compute a spectrogram with consecutive Fourier transforms.
- `lombscargle(x, y, freqs)` Computes the Lomb-Scargle periodogram.
- `vectorstrength(events, period)` Determine the vector strength of the events corresponding to the given period.
- `stft(x[, fs, window, nperseg, noverlap, ...])` Compute the Short Time Fourier Transform (STFT).
- `istft(Zxx[, fs, window, nperseg, noverlap, ...])` Perform the inverse Short Time Fourier transform (iSTFT).

**scipy.signal.periodogram**

`scipy.signal.periodogram(x, fs=1.0, window='boxcar', nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1)`

Estimate power spectral density using a periodogram.

**Parameters**

- `x` [array_like] Time series of measurement values
- `fs` [float, optional] Sampling frequency of the `x` time series. Defaults to 1.0.
- `window` [str or tuple or array_like, optional] Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array_like it will be used directly as the window and its length must be nperseg. Defaults to 'boxcar'.
- `nfft` [int, optional] Length of the FFT used. If `None` the length of `x` will be used.
- `detrend` [str or function or `False`, optional] Specifies how to detrend each segment. If `detrend` is a string, it is passed as the `type` argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If `detrend` is `False`, no detrending is done. Defaults to 'constant'.
- `return_onesided` [bool, optional] If `True`, return a one-sided spectrum for real data. If `False` return a two-sided spectrum. Defaults to `True`, but for complex data, a two-sided spectrum is always returned.
- `scaling` [{‘density’, ‘spectrum’}, optional] Selects between computing the power spectral density (‘density’) where $P_{xx}$ has units of V**2/Hz and computing the power spectrum (‘spectrum’) where $P_{xx}$ has units of V**2, if $x$ is measured in V and $fs$ is measured in Hz. Defaults to ‘density’.
- `axis` [int, optional] Axis along which the periodogram is computed; the default is over the last axis (i.e. `axis=-1`).

**Returns**

- `Pxx` [ndarray] Power spectral density or power spectrum of `x`.

**See also:**

- `welch`
  Estimate power spectral density using Welch’s method
- `lombscargle`
  Lomb-Scargle periodogram for unevenly sampled data

6.22. Signal processing (`scipy.signal`) 1987
Notes

New in version 0.12.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234)

Generate a test signal, a 2 Vrms sine wave at 1234 Hz, corrupted by 0.001 V**2/Hz of white noise sampled at 10 kHz.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2*np.sqrt(2)
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> x = amp*np.sin(2*np.pi*freq*time)
>>> x += np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
```  
Compute and plot the power spectral density.

```python
>>> f, Pxx_den = signal.periodogram(x, fs)
>>> plt.semilogy(f, Pxx_den)
>>> plt.ylim([1e-7, 1e2])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.show()
```

If we average the last half of the spectral density, to exclude the peak, we can recover the noise power on the signal.
Now compute and plot the power spectrum.

```python
>>> f, Pxx_spec = signal.periodogram(x, fs, 'flattop', scaling='spectrum')
>>> plt.figure()
>>> plt.semilogy(f, np.sqrt(Pxx_spec))
>>> plt.ylim([1e-4, 1e1])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('Linear spectrum [V RMS]')
>>> plt.show()
```

![Power spectrum plot](image)

The peak height in the power spectrum is an estimate of the RMS amplitude.

```python
>>> np.sqrt(Pxx_spec.max())
2.0077340678640727
```

**scipy.signal.welch**

The `scipy.signal.welch` function estimates power spectral density using Welch’s method.

- **Parameters**
  - `x` (array_like): Time series of measurement values
  - `fs` (float, optional): Sampling frequency of the `x` time series. Defaults to 1.0.
  - `window` (str or tuple or array_like, optional): Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array_like

```python
scipy.signal.welch(x, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1, average='mean')
```

Estimate power spectral density using Welch’s method.

Welch’s method [1] computes an estimate of the power spectral density by dividing the data into overlapping segments, computing a modified periodogram for each segment and averaging the periodograms.

**Parameters**

- `x` (array_like): Time series of measurement values
- `fs` (float, optional): Sampling frequency of the `x` time series. Defaults to 1.0.
- `window` (str or tuple or array_like, optional): Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array_like

```python
scipy.signal.welch(x, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1, average='mean')
```
it will be used directly as the window and its length must be nperseg. Defaults to a Hann window.

**nperseg**

[int, optional] Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array_like, is set to the length of the window.

**noverlap**

[int, optional] Number of points to overlap between segments. If None, noverlap = nperseg // 2. Defaults to None.

**nfft**

[int, optional] Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is nperseg. Defaults to None.

**detrend**

[str or function or False, optional] Specifies how to detrend each segment. If detrend is a string, it is passed as the type argument to the detrend function. If it is a function, it takes a segment and returns a detrended segment. If detrend is False, no detrending is done. Defaults to 'constant'.

**return_onesided**

[bool, optional] If True, return a one-sided spectrum for real data. If False return a two-sided spectrum. Defaults to True, but for complex data, a two-sided spectrum is always returned.

**scaling**

[{ 'density', 'spectrum' }, optional] Selects between computing the power spectral density ('density') where \( \hat{P}_{xx} \) has units of \( V^2/Hz \) and computing the power spectrum ('spectrum') where \( \hat{P}_{xx} \) has units of \( V^2 \), if \( x \) is measured in \( V \) and \( fs \) is measured in \( Hz \). Defaults to 'density'.

**axis**

[int, optional] Axis along which the periodogram is computed; the default is over the last axis (i.e. axis=-1).

**average**

[{ 'mean', 'median' }, optional] Method to use when averaging periodograms. Defaults to 'mean'. New in version 1.2.0.

**Returns**

**f**

[ndarray] Array of sample frequencies.

**Pxx**

[ndarray] Power spectral density or power spectrum of x.

**Notes**

An appropriate amount of overlap will depend on the choice of window and on your requirements. For the default Hann window an overlap of 50% is a reasonable trade off between accurately estimating the signal power, while not over counting any of the data. Narrower windows may require a larger overlap.

If noverlap is 0, this method is equivalent to Bartlett’s method [2].

New in version 0.12.0.
Generate a test signal, a 2 Vrms sine wave at 1234 Hz, corrupted by 0.001 V**2/Hz of white noise sampled at 10 kHz.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234)

>>> fs = 10e3
>>> N = 1e5
>>> amp = 2*np.sqrt(2)
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> x = amp*np.sin(2*np.pi*freq*time)
>>> x += np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
```

Compute and plot the power spectral density.

```python
>>> f, Pxx_den = signal.welch(x, fs, nperseg=1024)
>>> plt.semilogy(f, Pxx_den)
>>> plt.ylim([0.5e-3, 1])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.show()
```

If we average the last half of the spectral density, to exclude the peak, we can recover the noise power on the signal.
Now compute and plot the power spectrum.

```python
>>> f, Pxx_spec = signal.welch(x, fs, 'flattop', 1024, scaling='spectrum')
>>> plt.figure()
>>> plt.semilogy(f, np.sqrt(Pxx_spec))
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('Linear spectrum [V RMS]')
>>> plt.show()
```

The peak height in the power spectrum is an estimate of the RMS amplitude.

```python
>>> np.sqrt(Pxx_spec.max())
2.007340678640727
```

If we now introduce a discontinuity in the signal, by increasing the amplitude of a small portion of the signal by 50, we can see the corruption of the mean average power spectral density, but using a median average better estimates the normal behaviour.

```python
>>> f, Pxx_den = signal.welch(x, fs, nperseg=1024)
>>> f_med, Pxx_den_med = signal.welch(x, fs, nperseg=1024, average='median')
>>> plt.semilogy(f, Pxx_den, label='mean')
>>> plt.semilogy(f_med, Pxx_den_med, label='median')
>>> plt.ylim([0.5e-3, 1])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.legend()
>>> plt.show()
```
Estimate the cross power spectral density, $P_{xy}$, using Welch’s method.

Parameters

- $x$ [array_like] Time series of measurement values
- $y$ [array_like] Time series of measurement values
- $fs$ [float, optional] Sampling frequency of the $x$ and $y$ time series. Defaults to 1.0.
- window [str or tuple or array_like, optional] Desired window to use. If window is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If window is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Hann window.
- nperseg [int, optional] Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array_like, is set to the length of the window.
- noverlap: int, optional
  Number of points to overlap between segments. If None, noverlap = nperseg // 2. Defaults to None.
- nfft [int, optional] Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is nperseg. Defaults to None.
- detrend [str or function or False, optional] Specifies how to detrend each segment. If detrend is a string, it is passed as the type argument to the detrend function. If it is a function, it takes a segment and returns a detrended segment. If detrend is False, no detrending is done. Defaults to ‘constant’.
- return_onesided [bool, optional] If True, return a one-sided spectrum for real data. If False return a two-sided spectrum. Defaults to True, but for complex data, a two-sided spectrum is always returned.
- scaling [{‘density’, ‘spectrum’}, optional] Selects between computing the cross spectral density (‘density’) where $P_{xy}$ has units of $V^2/Hz$ and computing the cross spectrum (‘spectrum’) where $P_{xy}$ has units of $V^2$, if $x$ and $y$ are measured in $V$ and $fs$ is measured in Hz. Defaults to ‘density’.

axis  [int, optional] Axis along which the CSD is computed for both inputs; the default is over the last axis (i.e. axis=-1).

average  [{ 'mean', 'median' }, optional] Method to use when averaging periodograms. Defaults to 'mean'.
New in version 1.2.0.

Returns

f  [ndarray] Array of sample frequencies.
Pxy  [ndarray] Cross spectral density or cross power spectrum of x,y.

See also:

periodogram
Simple, optionally modified periodogram
lombscargle
Lomb-Scargle periodogram for unevenly sampled data
welch
Power spectral density by Welch’s method. [Equivalent to csd(x,x)]
coherece
Magnitude squared coherence by Welch’s method.

Notes

By convention, Pxy is computed with the conjugate FFT of X multiplied by the FFT of Y.
If the input series differ in length, the shorter series will be zero-padded to match.
An appropriate amount of overlap will depend on the choice of window and on your requirements. For the default Hann window an overlap of 50% is a reasonable trade off between accurately estimating the signal power, while not over counting any of the data. Narrower windows may require a larger overlap.
New in version 0.16.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Generate two test signals with some common features.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 20
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
```
>>> time = np.arange(N) / fs
>>> b, a = signal.butter(2, 0.25, 'low')
>>> x = np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
>>> y = signal.lfilter(b, a, x)
>>> x += amp*np.sin(2*np.pi*freq*time)
>>> y += np.random.normal(scale=0.1*np.sqrt(noise_power), size=time.shape)

Compute and plot the magnitude of the cross spectral density.

>>> f, Pxy = signal.csd(x, y, fs=1.0, nperseg=1024)
>>> plt.semilogy(f, np.abs(Pxy))
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('CSD [V**2/Hz]')
>>> plt.show()

**scipy.signal.coherence**

Estimate the magnitude squared coherence estimate, $C_{xy}$, of discrete-time signals $X$ and $Y$ using Welch's method.

$C_{xy} = \frac{|P_{xy}|^2}{P_{xx}P_{yy}}$, where $P_{xx}$ and $P_{yy}$ are power spectral density estimates of $X$ and $Y$, and $P_{xy}$ is the cross spectral density estimate of $X$ and $Y$.

**Parameters**

- **x** [array_like] Time series of measurement values
- **y** [array_like] Time series of measurement values
- **fs** [float, optional] Sampling frequency of the $x$ and $y$ time series. Defaults to 1.0.
- **window** [str or tuple or array_like, optional] Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array_like it will be used directly as the window and its length must be `nperseg`. Defaults to a Hann window.
**nperseg**  [int, optional] Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array_like, is set to the length of the window.

**noverlap**: int, optional
   Number of points to overlap between segments. If None, noverlap = nperseg // 2. Defaults to None.

**nfft**  [int, optional] Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is nperseg. Defaults to None.

**detrend**  [str or function or False, optional] Specifies how to detrend each segment. If detrend is a string, it is passed as the type argument to the detrend function. If it is a function, it takes a segment and returns a detrended segment. If detrend is False, no detrending is done. Defaults to ‘constant’.

**axis**  [int, optional] Axis along which the coherence is computed for both inputs; the default is over the last axis (i.e. axis=-1).

**Returns**

**f**  [ndarray] Array of sample frequencies.

**Cxy**  [ndarray] Magnitude squared coherence of x and y.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Generate two test signals with some common features.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 20
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> b, a = signal.butter(2, 0.25, 'low')
>>> x = np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
>>> y = signal.lfilter(b, a, x)
>>> x += amp*np.sin(2*np.pi*freq*time)
>>> y += np.random.normal(scale=0.1*np.sqrt(noise_power), size=time.shape)
```

Compute and plot the coherence.

```python
>>> f, Cxy = signal.coherence(x, y, fs, nperseg=1024)
>>> plt.semilogy(f, Cxy)
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('Coherence')
>>> plt.show()
```
scipy.signal.spectrogram

scipy.signal.spectrogram(x, fs=1.0, window='tukey', 0.25, nperseg=None, noverlap=None, nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1, mode='psd')

Compute a spectrogram with consecutive Fourier transforms.

Spectrograms can be used as a way of visualizing the change of a nonstationary signal's frequency content over time.

**Parameters**

- **x** [array_like] Time series of measurement values
- **fs** [float, optional] Sampling frequency of the x time series. Defaults to 1.0.
- **window** [str or tuple or array_like, optional] Desired window to use. If window is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If window is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Tukey window with shape parameter of 0.25.
- **nperseg** [int, optional] Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array_like, is set to the length of the window.
- **noverlap** [int, optional] Number of points to overlap between segments. If None, noverlap = nperseg // 8. Defaults to None.
- **nfft** [int, optional] Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is nperseg. Defaults to None.
- **detrend** [str or function or False, optional] Specifies how to detrend each segment. If detrend is a string, it is passed as the type argument to the detrend function. If it is a function, it takes a segment and returns a detrended segment. If detrend is False, no detrending is done. Defaults to 'constant'.
- **return_onesided** [bool, optional] If True, return a one-sided spectrum for real data. If False return a two-sided spectrum. Defaults to True, but for complex data, a two-sided spectrum is always returned.
- **scaling** [‘density’, ‘spectrum’, optional] Selects between computing the power spectral density (‘density’) where Sxx has units of V**2/Hz and computing the power spectrum (‘spectrum’) where Sxx has units of V**2, if x is measured in V and fs is measured in Hz. Defaults to ‘density’.
- **axis** [int, optional] Axis along which the spectrogram is computed; the default is over the last axis (i.e. axis=-1).
- **mode** [str, optional] Defines what kind of return values are expected. Options are [‘psd’, ‘complex’, ‘magnitude’, ‘angle’, ‘phase’]. ‘complex’ is equivalent to the output of stft with no padding or boundary extension. ‘magnitude’ returns the absolute magnitude of the STFT. ‘angle’ and ‘phase’ return the complex angle of the STFT, with and without unwrapping, respectively.

**Returns**

- **f** [ndarray] Array of sample frequencies.
- **t** [ndarray] Array of segment times.
- **Sxx** [ndarray] Spectrogram of x. By default, the last axis of Sxx corresponds to the segment times.

See also:

- **periodogram**
  Simple, optionally modified periodogram
- **lombscargle**
Lomb-Scargle periodogram for unevenly sampled data

**welch**

Power spectral density by Welch’s method.

**csd**

Cross spectral density by Welch’s method.

**Notes**

An appropriate amount of overlap will depend on the choice of window and on your requirements. In contrast to welch’s method, where the entire data stream is averaged over, one may wish to use a smaller overlap (or perhaps none at all) when computing a spectrogram, to maintain some statistical independence between individual segments. It is for this reason that the default window is a Tukey window with 1/8th of a window’s length overlap at each end.

New in version 0.16.0.

**References**

[1]

**Examples**

```python
>>> from scipy import signal
>>> from scipy.fft import fftshift
>>> import matplotlib.pyplot as plt

Generate a test signal, a 2 Vrms sine wave whose frequency is slowly modulated around 3kHz, corrupted by white noise of exponentially decreasing magnitude sampled at 10 kHz.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.01 * fs / 2
>>> time = np.arange(N) / float(fs)
>>> mod = 500*np.cos(2*np.pi*0.25*time)
>>> carrier = amp * np.sin(2*np.pi*3e3*time + mod)
>>> noise = np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
>>> noise *= np.exp(-time/5)
>>> x = carrier + noise

Compute and plot the spectrogram.

```python
>>> f, t, Sxx = signal.spectrogram(x, fs)
>>> plt.pcolormesh(t, f, Sxx, shading='gouraud')
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.show()
```

Note, if using output that is not one sided, then use the following:
```python
>>> f, t, Sxx = signal.spectrogram(x, fs, return_onesided=False)
>>> plt.pcolormesh(t, fftshift(f), fftshift(Sxx, axes=0), shading='gouraud')
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.show()
```
scipy.signal.lombscargle

scipy.signal.lombscargle(x, y, freqs)
Computes the Lomb-Scargle periodogram.

The Lomb-Scargle periodogram was developed by Lomb [1] and further extended by Scargle [2] to find, and test
the significance of weak periodic signals with uneven temporal sampling.

When normalize is False (default) the computed periodogram is unnormalized, it takes the value \((A^2) \times N/4\)
for a harmonic signal with amplitude A for sufficiently large N.

When normalize is True the computed periodogram is normalized by the residuals of the data around a constant
reference model (at zero).

Input arrays should be 1-D and will be cast to float64.

Parameters

- x [array_like] Sample times.
- freqs [array_like] Angular frequencies for output periodogram.
- precenter [bool, optional] Pre-center measurement values by subtracting the mean.
- normalize [bool, optional] Compute normalized periodogram.

Returns

- pgram [array_like] Lomb-Scargle periodogram.

Raises

ValueError
If the input arrays x and y do not have the same shape.

See also:

- istft
  Inverse Short Time Fourier Transform
- check_COLA
  Check whether the Constant OverLap Add (COLA) constraint is met
- welch
  Power spectral density by Welch’s method
- spectrogram
  Spectrogram by Welch’s method
- csd
  Cross spectral density by Welch’s method
Notes

This subroutine calculates the periodogram using a slightly modified algorithm due to Townsend [3] which allows
the periodogram to be calculated using only a single pass through the input arrays for each frequency.
The algorithm running time scales roughly as $O(x \cdot \text{freqs})$ or $O(N^2)$ for a large number of samples and frequencies.

References

[1], [2], [3]

Examples

```python
>>> import matplotlib.pyplot as plt
```

First define some input parameters for the signal:

```python
>>> A = 2.
>>> w = 1.
>>> phi = 0.5 * np.pi
>>> nin = 1000
>>> nout = 100000
>>> frac_points = 0.9 # Fraction of points to select
```

Randomly select a fraction of an array with timesteps:

```python
>>> r = np.random.rand(nin)
>>> x = np.linspace(0.01, 10*np.pi, nin)
>>> x = x[r >= frac_points]
```

Plot a sine wave for the selected times:

```python
>>> y = A * np.sin(w*x+phi)
```

Define the array of frequencies for which to compute the periodogram:

```python
>>> f = np.linspace(0.01, 10, nout)
```

Calculate Lomb-Scargle periodogram:

```python
>>> import scipy.signal as signal
>>> pgram = signal.lombscargle(x, y, f, normalize=True)
```

Now make a plot of the input data:

```python
>>> plt.subplot(2, 1, 1)
>>> plt.plot(x, y, 'b+')
```

Then plot the normalized periodogram:

```python
>>> plt.subplot(2, 1, 2)
>>> plt.plot(f, pgram)
>>> plt.show()
```
scipy.signal.vectorstrength

scipy.signal.vectorstrength(events, period)

Determine the vector strength of the events corresponding to the given period.

The vector strength is a measure of phase synchrony, how well the timing of the events is synchronized to a single period of a periodic signal.

If multiple periods are used, calculate the vector strength of each. This is called the “resonating vector strength”.

Parameters

- **events**: [1D array_like] An array of time points containing the timing of the events.
- **period**: [float or array_like] The period of the signal that the events should synchronize to. The period is in the same units as events. It can also be an array of periods, in which case the outputs are arrays of the same length.

Returns

- **strength**: [float or 1D array] The strength of the synchronization. 1.0 is perfect synchronization and 0.0 is no synchronization. If period is an array, this is also an array with each element containing the vector strength at the corresponding period.
- **phase**: [float or array] The phase that the events are most strongly synchronized to in radians. If period is an array, this is also an array with each element containing the phase for the corresponding period.

References

van Hemmen, JL and Vollmayr, AN. Resonating vector strength: what happens

scipy.signal.stft

```
scipy.signal.stft(x, fs=1.0, window='hann', nperseg=256, noverlap=None, nfft=None, detrend=False, return_onesided=True, boundary='zeros', padded=True, axis=-1)
```

Compute the Short Time Fourier Transform (STFT).

STFTs can be used as a way of quantifying the change of a nonstationary signal’s frequency and phase content over time.

**Parameters**

- `x` [array_like] Time series of measurement values
- `fs` [float, optional] Sampling frequency of the `x` time series. Defaults to 1.0.
- `window` [str or tuple or array_like, optional] Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array_like it will be used directly as the window and its length must be `nperseg`. Defaults to a Hann window.
- `nperseg` [int, optional] Length of each segment. Defaults to 256.
- `noverlap` [int, optional] Number of points to overlap between segments. If `None`, `noverlap = nperseg // 2`. Defaults to `None`. When specified, the COLA constraint must be met (see Notes below).
- `nfft` [int, optional] Length of the FFT used, if a zero padded FFT is desired. If `None`, the FFT length is `nperseg`. Defaults to `None`.
- `detrend` [str or function or `False`, optional] Specifies how to detrend each segment. If `detrend` is a string, it is passed as the `type` argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If `detrend` is `False`, no detrending is done. Defaults to `False`.
- `return_onesided` [bool, optional] If `True`, return a one-sided spectrum for real data. If `False` return a two-sided spectrum. Defaults to `True`, but for complex data, a two-sided spectrum is always returned.
- `boundary` [str or `None`, optional] Specifies whether the input signal is extended at both ends, and how to generate the new values, in order to center the first windowed segment on the first input point. This has the benefit of enabling reconstruction of the first input point when the employed window function starts at zero. Valid options are `['even', 'odd', 'constant', 'zeros', 'None']`. Defaults to `zeros`, for zero padding extension. i.e. [1, 2, 3, 4] is extended to [0, 1, 2, 3, 4, 0] for `nperseg=3`.
- `padded` [bool, optional] Specifies whether the input signal is zero-padded at the end to make the signal fit exactly into an integer number of window segments, so that all of the signal is included in the output. Defaults to `True`. Padding occurs after boundary extension, if `boundary` is not `None`, and `padded` is `True`, as is the default.
- `axis` [int, optional] Axis along which the STFT is computed; the default is over the last axis (i.e. `axis=-1`).

**Returns**

- `t` [ndarray] Array of segment times.
- `Zxx` [ndarray] STFT of `x`. By default, the last axis of `Zxx` corresponds to the segment times.

Lomb-Scargle periodogram for unevenly sampled data

Notes

In order to enable inversion of an STFT via the inverse STFT in `istft`, the signal windowing must obey the constraint of “Nonzero OverLap Add” (NOLA), and the input signal must have complete windowing coverage (i.e. \( (x.shape[\text{axis}] - \text{nperseg}) \% (\text{nperseg}-\text{noverlap}) == 0 \)). The padded argument may be used to accomplish this.

Given a time-domain signal \( x[n] \), a window \( w[n] \), and a hop size \( H = \text{nperseg} - \text{noverlap} \), the windowed frame at time index \( t \) is given by

\[
x_t[n] = x[n]w[n - tH]
\]

The overlap-add (OLA) reconstruction equation is given by

\[
x[n] = \sum_t x_t[n]w[n - tH] \sum_t w^2[n - tH]
\]

The NOLA constraint ensures that every normalization term that appears in the denominator of the OLA reconstruction equation is nonzero. Whether a choice of window, \( \text{nperseg} \), and \( \text{noverlap} \) satisfy this constraint can be tested with `check_NOLA`.

New in version 0.19.0.

[1], [2]
Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Generate a test signal, a 2 Vrms sine wave whose frequency is slowly modulated around 3kHz, corrupted by white noise of exponentially decreasing magnitude sampled at 10 kHz.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.01 * fs / 2
>>> time = np.arange(N) / float(fs)
>>> mod = 500 * np.cos(2 * np.pi * 0.25 * time)
>>> carrier = amp * np.sin(2 * np.pi * 3e3 * time + mod)
>>> noise = np.random.normal(scale=np.sqrt(noise_power),
... size=time.shape)
>>> noise *= np.exp(-time/5)
>>> x = carrier + noise
```

Compute and plot the STFT's magnitude.

```python
>>> f, t, Zxx = signal.stft(x, fs, nperseg=1000)
>>> plt.pcolormesh(t, f, np.abs(Zxx), vmin=0, vmax=amp, shading='gouraud')
>>> plt.title('STFT Magnitude')
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.show()
```

![STFT Magnitude](image)

STFT Magnitude

![Time Frequency](image)

Time [sec]

Frequency [Hz]

0 1000 2000 3000 4000 5000

0 2 4 6 8 10
scipy.signal.istft

```python
scipy.signal.istft(Zxx, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, input_onesided=True, boundary=True, time_axis=-1, freq_axis=-2)
```

Perform the inverse Short Time Fourier transform (iSTFT).

**Parameters**

- **Zxx** [array_like] STFT of the signal to be reconstructed. If a purely real array is passed, it will be cast to a complex data type.
- **fs** [float, optional] Sampling frequency of the time series. Defaults to 1.0.
- **window** [str or tuple or array_like, optional] Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Hann window. Must match the window used to generate the STFT for faithful inversion.
- **nperseg** [int, optional] Number of data points corresponding to each STFT segment. This parameter must be specified if the number of data points per segment is odd, or if the STFT was padded via `nfft > nperseg`. If `None`, the value depends on the shape of `Zxx` and `input_onesided`. If `input_onesided` is `True`, `nperseg=2*(Zxx.shape[freq_axis] - 1)`. Otherwise, `nperseg=Zxx.shape[freq_axis]`. Defaults to `None`.
- **noverlap** [int, optional] Number of points to overlap between segments. If `None`, half of the segment length. Defaults to `None`. When specified, the COLA constraint must be met (see Notes below), and should match the parameter used to generate the STFT. Defaults to `None`.
- **nfft** [int, optional] Number of FFT points corresponding to each STFT segment. This parameter must be specified if the STFT was padded via `nfft > nperseg`. If `None`, the default values are the same as for `nperseg`, detailed above, with one exception: if `input_onesided` is `True` and `nperseg==2*Zxx.shape[freq_axis] - 1`, `nfft` also takes on that value. This case allows the proper inversion of an odd-length unpadded STFT using `nfft=None`. Defaults to `None`.
- **input_onesided** [bool, optional] If `True`, interpret the input array as one-sided FFTs, such as is returned by `stft` with `return_onesided=True` and `numpy.fft.rfft`. If `False`, interpret the input as a a two-sided FFT. Defaults to `True`.
- **boundary** [bool, optional] Specifies whether the input signal was extended at its boundaries by supplying a non-`None` boundary argument to `stft`. Defaults to `True`.
- **time_axis** [int, optional] Where the time segments of the STFT is located; the default is the last axis (i.e. `axis=-1`).
- **freq_axis** [int, optional] Where the frequency axis of the STFT is located; the default is the penultimate axis (i.e. `axis=-2`).

**Returns**

- **t** [ndarray] Array of output data times.
- **x** [ndarray] iSTFT of `Zxx`.

- **stft**
  Short Time Fourier Transform
- **check_COLA**
  Check whether the Constant OverLap Add (COLA) constraint is met
- **check_NOLA**
  Check whether the Nonzero OverLap Add (NOLA) constraint is met
Notes

In order to enable inversion of an STFT via the inverse STFT with \texttt{istft}, the signal windowing must obey the constraint of “nonzero overlap add” (NOLA):

\[
\sum_t w^2[n - tH] \neq 0
\]

This ensures that the normalization factors that appear in the denominator of the overlap-add reconstruction equation

\[
x[n] = \frac{\sum_t x_t[n]w[n - tH]}{\sum_t w^2[n - tH]}
\]

are not zero. The NOLA constraint can be checked with the \texttt{check\_NOLA} function.

An STFT which has been modified (via masking or otherwise) is not guaranteed to correspond to a exactly realizable signal. This function implements the iSTFT via the least-squares estimation algorithm detailed in [2], which produces a signal that minimizes the mean squared error between the STFT of the returned signal and the modified STFT.

New in version 0.19.0.

References

[1], [2]

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Generate a test signal, a 2 Vrms sine wave at 50Hz corrupted by 0.001 V**2/Hz of white noise sampled at 1024 Hz.

```python
>>> fs = 1024
>>> N = 10*fs
>>> nperseg = 512
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / float(fs)
>>> carrier = amp * np.sin(2*np.pi*50*time)
>>> noise = np.random.normal(scale=np.sqrt(noise_power),
... size=time.shape)
>>> x = carrier + noise
``` Compute the STFT, and plot its magnitude

```python
>>> f, t, Zxx = signal.stft(x, fs=fs, nperseg=nperseg)
>>> plt.figure()
>>> plt.pcolormesh(t, f, np.abs(Zxx), vmin=0, vmax=amp, shading='gouraud')
>>> plt.ylim([f[1], f[-1]])
>>> plt.title('STFT Magnitude')
>>> plt.ylabel('Frequency [Hz]')
```

(continues on next page)
Zero the components that are 10% or less of the carrier magnitude, then convert back to a time series via inverse STFT:

```python
>>> Zxx = np.where(np.abs(Zxx) >= amp/10, Zxx, 0)
>>> _, xrec = signal.istft(Zxx, fs)
```

Compare the cleaned signal with the original and true carrier signals:

```python
>>> plt.figure()
>>> plt.plot(time, x, time, xrec, time, carrier)
>>> plt.xlim([2, 2.1])
>>> plt.xlabel('Time [sec]')
>>> plt.ylabel('Signal')
>>> plt.legend(['Carrier + Noise', 'Filtered via STFT', 'True Carrier'])
>>> plt.show()
```

Note that the cleaned signal does not start as abruptly as the original, since some of the coefficients of the transient were also removed:

```python
>>> plt.figure()
>>> plt.plot(time, x, time, xrec, time, carrier)
>>> plt.xlim([0, 0.1])
>>> plt.xlabel('Time [sec]')
>>> plt.ylabel('Signal')
>>> plt.legend(['Carrier + Noise', 'Filtered via STFT', 'True Carrier'])
>>> plt.show()
```
The upper graph shows a signal composed of a carrier and noise, filtered via STFT, with the true carrier overlayed. The time axis ranges from 2.00 to 2.10 seconds, and the signal axis ranges from -4 to 4.

The lower graph is a close-up of the upper graph, focusing on the interval from 0.00 to 0.10 seconds, with the same color coding for the signals.
scipy.signal.check_COLA

scipy.signal.check_COLA(window, nperseg, noverlap, tol=1e-10)
   Check whether the Constant OverLap Add (COLA) constraint is met

   Parameters
       window [str or tuple or array_like] Desired window to use. If window is a string or tuple, it is
               passed to get_window to generate the window values, which are DFT-even by default. See
               get_window for a list of windows and required parameters. If window is array_like
               it will be used directly as the window and its length must be nperseg.
       nperseg [int] Length of each segment.
       noverlap [int] Number of points to overlap between segments.
       tol [float, optional] The allowed variance of a bin’s weighted sum from the median bin sum.

   Returns
       verdict [bool] True if chosen combination satisfies COLA within tol, False otherwise

See also:
check_NOLA
   Check whether the Nonzero Overlap Add (NOLA) constraint is met

stft
   Short Time Fourier Transform

istft
   Inverse Short Time Fourier Transform

Notes

In order to enable inversion of an STFT via the inverse STFT in istft, it is sufficient that the signal windowing
obeys the constraint of “Constant OverLap Add” (COLA). This ensures that every point in the input data is equally
weighted, thereby avoiding aliasing and allowing full reconstruction.

Some examples of windows that satisfy COLA:

   • Rectangular window at overlap of 0, 1/2, 2/3, 3/4, …
   • Bartlett window at overlap of 1/2, 3/4, 5/6, …
   • Hann window at 1/2, 2/3, 3/4, …
   • Any Blackman family window at 2/3 overlap
   • Any window with noverlap = nperseg-1

A very comprehensive list of other windows may be found in [2], wherein the COLA condition is satisfied when
the “Amplitude Flatness” is unity.

New in version 0.19.0.
References

[1], [2]

Examples

```python
>>> from scipy import signal

Confirm COLA condition for rectangular window of 75% (3/4) overlap:

```python
>>> signal.check_COLA(signal.windows.boxcar(100), 100, 75)
True
```  
COLA is not true for 25% (1/4) overlap, though:

```python
>>> signal.check_COLA(signal.windows.boxcar(100), 100, 25)
False
```  
“Symmetrical” Hann window (for filter design) is not COLA:

```python
>>> signal.check_COLA(signal.windows.hann(120, sym=True), 120, 60)
False
```  
“Periodic” or “DFT-even” Hann window (for FFT analysis) is COLA for overlap of 1/2, 2/3, 3/4, etc.:

```python
>>> signal.check_COLA(signal.windows.hann(120, sym=False), 120, 60)
True
```  
```python
>>> signal.check_COLA(signal.windows.hann(120, sym=False), 120, 80)
True
```  
```python
>>> signal.check_COLA(signal.windows.hann(120, sym=False), 120, 90)
True
```  

c scipy.signal.check_NOLA

c scipy.signal.check_NOLA (window, nperseg, noverlap, tol=1e-10)

Check whether the Nonzero Overlap Add (NOLA) constraint is met

Parameters

- window [str or tuple or array_like] Desired window to use. If window is a string or tuple, it is passed to get_window to generate the window values, which are DFT-even by default. See get_window for a list of windows and required parameters. If window is array_like it will be used directly as the window and its length must be nperseg.

- nperseg [int] Length of each segment.

- noverlap [int] Number of points to overlap between segments.

- tol [float, optional] The allowed variance of a bin’s weighted sum from the median bin sum.

Returns

- verdict [bool] True if chosen combination satisfies the NOLA constraint within tol, False otherwise

See also:
check_COLA
Check whether the Constant OverLap Add (COLA) constraint is met

stft
Short Time Fourier Transform

istft
Inverse Short Time Fourier Transform

Notes
In order to enable inversion of an STFT via the inverse STFT in `istft`, the signal windowing must obey the constraint of “nonzero overlap add” (NOLA):

\[ \sum_t w^2[n - tH] \neq 0 \]

for all \( n \), where \( w \) is the window function, \( t \) is the frame index, and \( H \) is the hop size (\( H = \text{nperseg} - \text{noverlap} \)). This ensures that the normalization factors in the denominator of the overlap-add inversion equation are not zero. Only very pathological windows will fail the NOLA constraint.

New in version 1.2.0.

References
[1],[2]

Examples

```python
>>> from scipy import signal

Confirm NOLA condition for rectangular window of 75% (3/4) overlap:

>>> signal.check_NOLA(signal.windows.boxcar(100), 100, 75)
True

NOLA is also true for 25% (1/4) overlap:

>>> signal.check_NOLA(signal.windows.boxcar(100), 100, 25)
True

“Symmetrical” Hann window (for filter design) is also NOLA:

>>> signal.check_NOLA(signal.windows.hann(120, sym=True), 120, 60)
True

As long as there is overlap, it takes quite a pathological window to fail NOLA:

```python
>>> w = np.ones(64, dtype="float")
>>> w[::2] = 0
>>> signal.check_NOLA(w, 64, 32)
False
```
If there is not enough overlap, a window with zeros at the ends will not work:

```python
>>> signal.check_NOLA(signal.windows.hann(64), 64, 0)
False
>>> signal.check_NOLA(signal.windows.hann(64), 64, 1)
False
>>> signal.check_NOLA(signal.windows.hann(64), 64, 2)
True
```

**scipy.sparse.bsr_matrix**

```python
class scipy.sparse.bsr_matrix(arg1, shape=None, dtype=None, copy=False, blocksize=None)
```

Block Sparse Row matrix

*This can be instantiated in several ways:*

```python
bsr_matrix(D, [blocksize=(R,C)])
```

where D is a dense matrix or 2-D ndarray.

```python
bsr_matrix(S, [blocksize=(R,C)])
```

with another sparse matrix S (equivalent to S.tobsr())

```python
bsr_matrix((M, N), [blocksize=(R,C), dtype])
```

to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

```python
bsr_matrix((data, ij), [blocksize=(R,C), shape=(M, N))
```

where data and ij satisfy `a[ij[0, k], ij[1, k]] = data[k]`

```python
bsr_matrix((data, indices, indptr), [shape=(M, N)])
```

is the standard BSR representation where the block column indices for row i are stored in `indices[indptr[i]:indptr[i+1]]` and their corresponding block values are stored in `data[indptr[i]: indptr[i+1]]`. If the shape parameter is not supplied, the matrix dimensions are inferred from the index arrays.
Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Summary of BSR format

The Block Compressed Row (BSR) format is very similar to the Compressed Sparse Row (CSR) format. BSR is appropriate for sparse matrices with dense sub matrices like the last example below. Block matrices often arise in vector-valued finite element discretizations. In such cases, BSR is considerably more efficient than CSR and CSC for many sparse arithmetic operations.

Blocksize

The blocksize (R,C) must evenly divide the shape of the matrix (M,N). That is, R and C must satisfy the relationship M % R = 0 and N % C = 0.

If no blocksize is specified, a simple heuristic is applied to determine an appropriate blocksize.

Examples

```python
>>> from scipy.sparse import bsr_matrix
>>> bsr_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```python
>>> row = np.array([0, 0, 1, 2, 2])
>>> col = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> bsr_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])
```

```python
>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6]).repeat(4).reshape(6, 2, 2)
>>> bsr_matrix((data, indices, indptr), shape=(6, 6)).toarray()
array([[1, 1, 0, 0, 2, 2],
       [1, 1, 0, 0, 2, 2],
       [0, 0, 0, 0, 3, 3],
       [0, 0, 0, 0, 3, 3],
       [4, 4, 5, 5, 6, 6],
       [4, 4, 5, 5, 6, 6]])
```

Attributes

dtype [dtype] Data type of the matrix
ndim [int] Number of dimensions (this is always 2)
nnz Number of stored values, including explicit zeros.
data Data array of the matrix
indices BSR format index array
indptr BSR format index pointer array
**blocksize**  Block size of the matrix

**has_sorted_indices**  
Determine whether the matrix has sorted indices

</table>
scipy.sparse.bsr_matrix.__len__

bsr_matrix.__len__(self)

scipy.sparse.bsr_matrix.__mul__

bsr_matrix.__mul__(self, other)
    interpret other and call one of the following
    self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()

scipy.sparse.bsr_matrix.arcsin

bsr_matrix.arcsin(self)
    Element-wise arcsin.
    See numpy.arcsin for more information.

scipy.sparse.bsr_matrix.arcsinh

bsr_matrix.arcsinh(self)
    Element-wise arcsinh.
    See numpy.arcsinh for more information.

scipy.sparse.bsr_matrix.arctan

bsr_matrix.arctan(self)
    Element-wise arctan.
    See numpy.arctan for more information.

scipy.sparse.bsr_matrix.arctanh

bsr_matrix.arctanh(self)
    Element-wise arctanh.
    See numpy.arctanh for more information.

scipy.sparse.bsr_matrix.argmax

bsr_matrix.argmax(self, axis=None, out=None)
    Return indices of maximum elements along an axis.
    Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

    Parameters
    axis [[-2, -1, 0, 1, None], optional] Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.
### Parameters

- **axis** ([{-2, -1, 0, 1, None}, optional]) Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.
- **out** ([None, optional]) This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

### Returns

- **ind** ([numpy.matrix or int]) Indices of minimum elements. If matrix, its size along axis is 1.

### scipy.sparse.bsr_matrix.asformat

**bsr_matrix.asformat** *(self, format, copy=False)*

Return this matrix in the passed format.

#### Parameters

- **format** ([str, None]) The desired matrix format (“csr”, “csc”, “lil”, “dok”, “array”, …) or None for no conversion.
- **copy** ([bool, optional]) If True, the result is guaranteed to not share data with self.

#### Returns

- **A** ([This matrix in the passed format.])

### scipy.sparse.bsr_matrix.asfptype

**bsr_matrix.asfptype** *(self)*

Upcast matrix to a floating point format (if necessary)
scipy.sparse.bsr_matrix.astype

bsr_matrix.astype(self, dtype, casting='unsafe', copy=True)

Cast the matrix elements to a specified type.

**Parameters**

- **dtype** [string or numpy dtype] Typecode or data-type to which to cast the data.
- **casting** [{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
- **copy** [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.

scipy.sparse.bsr_matrix.ceil

bsr_matrix.ceil(self)

Element-wise ceil.

See numpy.ceil for more information.

scipy.sparse.bsr_matrix.check_format

bsr_matrix.check_format(self, full_check=True)

check whether the matrix format is valid

**Parameters**:

- **full_check**:
  
  True - rigorous check, O(N) operations : default False - basic check, O(1) operations

scipy.sparse.bsr_matrix.conj

bsr_matrix.conj(self, copy=True)

Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

**Parameters**

- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- A [The element-wise complex conjugate.]
**scipy.sparse.bsr_matrix.conjugate**

`bsr_matrix.conjugate(self, copy=True)`

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- `copy` [bool, optional] If True, the result is guaranteed to not share data with `self`.

**Returns**

- `A` [The element-wise complex conjugate.]

**scipy.sparse.bsr_matrix.copy**

`bsr_matrix.copy(self)`

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

**scipy.sparse.bsr_matrix.count_nonzero**

`bsr_matrix.count_nonzero(self)`

Number of non-zero entries, equivalent to `np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

**scipy.sparse.bsr_matrix.deg2rad**

`bsr_matrix.deg2rad(self)`

Element-wise `deg2rad`.

See `numpy.deg2rad` for more information.

**scipy.sparse.bsr_matrix.diagonal**

`bsr_matrix.diagonal(self, k=0)`

Returns the kth diagonal of the matrix.

**Parameters**

- `k` [int, optional] Which diagonal to get, corresponding to elements `a[i, i+k]`. Default: 0 (the main diagonal).

New in version 1.0.

**See also:**

- `numpy.diagonal`

Equivalent numpy function.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
```

```python
>>> A.diagonal(k=1)
array([2, 3])
```

**scipy.sparse.bsr_matrix.dot**

`bsr_matrix.dot(self, other)`

Ordinary dot product

**Examples**

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([1, -3, -1], dtype=int64)
```

**scipy.sparse.bsr_matrix.eliminate_zeros**

`bsr_matrix.eliminate_zeros(self)`

Remove zero elements in-place.

**scipy.sparse.bsr_matrix.expm1**

`bsr_matrix.expm1(self)`

Element-wise expm1.

See `numpy.expm1` for more information.

**scipy.sparse.bsr_matrix.floor**

`bsr_matrix.floor(self)`

Element-wise floor.

See `numpy.floor` for more information.
**scipy.sparse.bsr_matrix.getH**

```python
bsr_matrix.getH(self)
```

Return the Hermitian transpose of this matrix.

**See also:**

```python
numpy.matrix.getH
```

NumPy’s implementation of `getH` for matrices

**scipy.sparse.bsr_matrix.get_shape**

```python
bsr_matrix.get_shape(self)
```

Get shape of a matrix.

**scipy.sparse.bsr_matrix.getcol**

```python
bsr_matrix.getcol(self, j)
```

Returns a copy of column `j` of the matrix, as an (m x 1) sparse matrix (column vector).

**scipy.sparse.bsr_matrix.getformat**

```python
bsr_matrix.getformat(self)
```

Format of a matrix representation as a string.

**scipy.sparse.bsr_matrix.getmaxprint**

```python
bsr_matrix.getmaxprint(self)
```

Maximum number of elements to display when printed.

**scipy.sparse.bsr_matrix.getnnz**

```python
bsr_matrix.getnnz(self, axis=None)
```

Number of stored values, including explicit zeros.

**Parameters**

- `axis` : [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

```python
count_nonzero
```

Number of non-zero entries
scipy.sparse.bsr_matrix.getrow

bsr_matrix.getrow(self, i)
    Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

scipy.sparse.bsr_matrix.log1p

bsr_matrix.log1p(self)
    Element-wise log1p.
    See numpy.log1p for more information.

scipy.sparse.bsr_matrix.matmat

bsr_matrix.matmat(*args, **kwds)
    matmat is deprecated! BSR matmat is deprecated in SciPy 0.19.0. Use * operator instead.
    Multiply this sparse matrix by other matrix.

scipy.sparse.bsr_matrix.matvec

bsr_matrix.matvec(*args, **kwds)
    matvec is deprecated! BSR matvec is deprecated in SciPy 0.19.0. Use * operator instead.
    Multiply matrix by vector.

scipy.sparse.bsr_matrix.max

bsr_matrix.max(self, axis=None, out=None)
    Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

    Parameters
    axis [[-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e., axis = None).
    out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

    Returns
    amax [coo_matrix or scalar] Maximum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

    See also:
    min
    The minimum value of a sparse matrix along a given axis.
    numpy.matrix.max
    NumPy's implementation of 'max' for matrices
scipy.sparse.bsr_matrix.maximum

bsr_matrix.maximum(self, other)

Element-wise maximum between this and another matrix.

scipy.sparse.bsr_matrix.mean

bsr_matrix.mean(self, axis=None, dtype=None, out=None)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters

axis : [-2, -1, 0, 1, None] optional
    Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., axis = None).

dtype : data-type, optional
    Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype. New in version 0.18.0.

out : [np.matrix, optional]
    Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

Returns

m : [np.matrix]

See also:

numpy.matrix.mean

NumPy's implementation of 'mean' for matrices

scipy.sparse.bsr_matrix.min

bsr_matrix.min(self, axis=None, out=None)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters

axis : [-2, -1, 0, 1, None] optional
    Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e., axis = None).

out : [None, optional]
    This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amin : [coo_matrix or scalar]
    Minimum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:
max

The maximum value of a sparse matrix along a given axis.

numpy.matrix.min

NumPy's implementation of 'min' for matrices

scipy.sparse.bsr_matrix.minimum

bsr_matrix.minimum(self, other)

Element-wise minimum between this and another matrix.

scipy.sparse.bsr_matrix.multiply

bsr_matrix.multiply(self, other)

Point-wise multiplication by another matrix, vector, or scalar.

scipy.sparse.bsr_matrix.nonzero

bsr_matrix.nonzero(self)

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.bsr_matrix.power

bsr_matrix.power(self, n, dtype=None)

This function performs element-wise power.

Parameters

- **n** [n is a scalar]
- **dtype** [If dtype is not specified, the current dtype will be preserved.]
scipy.sparse.bsr_matrix.prune

bsr_matrix.prune(self)
Remove empty space after all non-zero elements.

scipy.sparse.bsr_matrix.rad2deg

bsr_matrix.rad2deg(self)
Element-wise rad2deg.
See numpy.rad2deg for more information.

scipy.sparse.bsr_matrix.reshape

bsr_matrix.reshape(self, shape, order='C', copy=False)
Gives a new shape to a sparse matrix without changing its data.

Parameters

shape  [length-2 tuple of ints] The new shape should be compatible with the original shape.
order  [{‘C’, ‘F’}, optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
copy  [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

reshaped_matrix  [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

numpy.matrix.reshape
NumPy’s implementation of ‘reshape’ for matrices

scipy.sparse.bsr_matrix.resize

bsr_matrix.resize(self, *shape)
Resize the matrix in-place to dimensions given by shape
Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

shape  [(int, int)] number of rows and columns in the new matrix
Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

**scipy.sparse.bsr_matrix.rint**

```python
csr_matrix.rint(self)
```

Element-wise rint.

See `numpy.rint` for more information.

**scipy.sparse.bsr_matrix.set_shape**

```python
csr_matrix.set_shape(self, shape)
```

See `reshape`.

**scipy.sparse.bsr_matrix.setdiag**

```python
csr_matrix.setdiag(self, values, k=0)
```

Set diagonal or off-diagonal elements of the array.

*Parameters*

- **values** [array_like] New values of the diagonal elements.
- **k** [int, optional] Which off-diagonal to set, corresponding to elements `a[i,i+k]`. Default: 0 (the main diagonal).

**scipy.sparse.bsr_matrix.sign**

```python
csr_matrix.sign(self)
```

Element-wise sign.

See `numpy.sign` for more information.
scipy.sparse.bsr_matrix.sin

bsr_matrix.sin(self)
    Element-wise sin.
    See numpy.sin for more information.

scipy.sparse.bsr_matrix.sinh

bsr_matrix.sinh(self)
    Element-wise sinh.
    See numpy.sinh for more information.

scipy.sparse.bsr_matrix.sort_indices

bsr_matrix.sort_indices(self)
    Sort the indices of this matrix in place

scipy.sparse.bsr_matrix.sorted_indices

bsr_matrix.sorted_indices(self)
    Return a copy of this matrix with sorted indices

scipy.sparse.bsr_matrix.sqrt

bsr_matrix.sqrt(self)
    Element-wise sqrt.
    See numpy.sqrt for more information.

scipy.sparse.bsr_matrix.sum

bsr_matrix.sum(self, axis=None, dtype=None, out=None)
    Sum the matrix elements over a given axis.

    Parameters
    axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to
    compute the sum of all the matrix elements, returning a scalar (i.e., axis = None).
    dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the
    elements are summed. The dtype of a is used by default unless a has an integer dtype
    of less precision than the default platform integer. In that case, if a is signed then the
    platform integer is used while if a is unsigned then an unsigned integer of the same
    precision as the platform integer is used.
    out [np.matrix, optional] Alternative output matrix in which to place the result. It must have
    the same shape as the expected output, but the type of the output values will be cast if
    necessary.
    New in version 0.18.0.
Returns

sum_along_axis

[np.matrix] A matrix with the same shape as self, with the specified axis removed.

See also:

numpy.matrix.sum

NumPy's implementation of 'sum' for matrices

scipy.sparse.bsr_matrix.sum_duplicates

bsr_matrix.sum_duplicates(self)

Eliminate duplicate matrix entries by adding them together

The is an in place operation

scipy.sparse.bsr_matrix.tan

bsr_matrix.tan(self)

Element-wise tan.

See numpy.tan for more information.

scipy.sparse.bsr_matrix.tanh

bsr_matrix.tanh(self)

Element-wise tanh.

See numpy.tanh for more information.

scipy.sparse.bsr_matrix.toarray

bsr_matrix.toarray(self, order=None, out=None)

Return a dense ndarray representation of this matrix.

Parameters

order [{‘C’, ‘F’}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.

out [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, out is required to be memory contiguous (either C or Fortran ordered).

Returns

arr [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed, the same object is returned after being modified in-place to contain the appropriate values.
**scipy.sparse.bsr_matrix.tobsr**

```python
csr_matrix.tobsr(self, blocksize=None, copy=False)
```
Convert this matrix into Block Sparse Row Format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

If blocksize=(R, C) is provided, it will be used for determining block size of the bsr_matrix.

**scipy.sparse.bsr_matrix.tocoo**

```python
csr_matrix.tocoo(self, copy=True)
```
Convert this matrix to COOrdinate format.

When copy=False the data array will be shared between this matrix and the resultant coo_matrix.

**scipy.sparse.bsr_matrix.tocsc**

```python
csr_matrix.tocsc(self, copy=False)
```
Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

**scipy.sparse.bsr_matrix.tocsr**

```python
csr_matrix.tocsr(self, copy=False)
```
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

**scipy.sparse.bsr_matrix.todense**

```python
csr_matrix.todense(self, order=None, out=None)
```
Return a dense matrix representation of this matrix.

**Parameters**

- `order` : ['C', 'F'], optional
  Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is `None`, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

- `out` : [ndarray, 2-D, optional]
  If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**

- `arr` : [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.
scipy.sparse.bsr_matrix.todia

bsr_matrix.todia(self, copy=False)
Convert this matrix to sparse DIAGONAL format.
With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.bsr_matrix.todok

bsr_matrix.todok(self, copy=False)
Convert this matrix to Dictionary Of Keys format.
With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.bsr_matrix.tolil

bsr_matrix.tolil(self, copy=False)
Convert this matrix to List of Lists format.
With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.bsr_matrix.transpose

bsr_matrix.transpose(self, axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters
axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns
p [self with the dimensions reversed.]

See also:
numpy.matrix.transpose
NumPy's implementation of 'transpose' for matrices

scipy.sparse.bsr_matrix.trunc

bsr_matrix.trunc(self)
Element-wise trunc.
See numpy.trunc for more information.
**scipy.sparse.coo_matrix**

```python
class scipy.sparse.coo_matrix(arg1, shape=None, dtype=None, copy=False)
```

A sparse matrix in COOrdinate format.

Also known as the ‘ijv’ or ‘triplet’ format.

*This can be instantiated in several ways:*

- `coo_matrix(D)`
  - with a dense matrix D
- `coo_matrix(S)`
  - with another sparse matrix S (equivalent to S.tocoo())
- `coo_matrix((M, N), [dtype])`
  - to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.
- `coo_matrix((data, (i, j)), [shape=(M, N)])`
  - to construct from three arrays:
    1. data[:] the entries of the matrix, in any order
    2. i[: ] the row indices of the matrix entries
    3. j[:] the column indices of the matrix entries

Where A[i[k], j[k]] = data[k]. When shape is not specified, it is inferred from the index arrays.

**Notes**

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

*Advantages of the COO format*

- facilitates fast conversion among sparse formats
- permits duplicate entries (see example)
- very fast conversion to and from CSR/CSC formats

*Disadvantages of the COO format*

- does not directly support:
  - arithmetic operations
  - slicing

*Intended Usage*

- COO is a fast format for constructing sparse matrices
- Once a matrix has been constructed, convert to CSR or CSC format for fast arithmetic and matrix vector operations
• By default when converting to CSR or CSC format, duplicate (i,j) entries will be summed together. This facilitates efficient construction of finite element matrices and the like. (see example)

Examples

```python
>>> # Constructing an empty matrix
>>> from scipy.sparse import coo_matrix
>>> coo_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```python
>>> # Constructing a matrix using ijv format
>>> row = np.array([0, 3, 1, 0])
>>> col = np.array([0, 3, 1, 2])
>>> data = np.array([4, 5, 7, 9])
>>> coo_matrix((data, (row, col)), shape=(4, 4)).toarray()
array([[4, 0, 9, 0],
       [0, 7, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 5]])
```

```python
>>> # Constructing a matrix with duplicate indices
>>> row = np.array([0, 0, 1, 3, 1, 0, 0])
>>> col = np.array([0, 2, 1, 3, 1, 0, 0])
>>> data = np.array([1, 1, 1, 1, 1, 1, 1])
>>> coo = coo_matrix((data, (row, col)), shape=(4, 4))
>>> # Duplicate indices are maintained until implicitly or explicitly summed
>>> np.max(coo.data)
1
>>> coo.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

Attributes

- **dtype** [dtype] Data type of the matrix
- **ndim** [int] Number of dimensions (this is always 2)
- **nnz** Number of stored values, including explicit zeros.
- **data** COO format data array of the matrix
- **row** COO format row index array of the matrix
- **col** COO format column index array of the matrix
### Methods

**__len__**(self)
interpret other and call one of the following

**__mul__**(self, other)
interpret other and call one of the following

**arcsin**(self)
Element-wise arcsin.

**arcsinh**(self)
Element-wise arcsinh.

**arctan**(self)
Element-wise arctan.

**arctanh**(self)
Element-wise arctanh.

**argmax**(self[, axis, out])
Return indices of maximum elements along an axis.

**argmin**(self[, axis, out])
Return indices of minimum elements along an axis.

**asformat**(self, format[, copy])
Return this matrix in the passed format.

**asfptype**(self)
Upcast matrix to a floating point format (if necessary)

**astype**(self, dtype[, casting, copy])
Cast the matrix elements to a specified type.

**ceil**(self)
Element-wise ceil.

**conj**(self[, copy])
Element-wise complex conjugation.

**conjugate**(self[, copy])
Element-wise complex conjugation.

**copy**(self)
Returns a copy of this matrix.

**count_nonzero**(self[, copy])
Number of non-zero entries, equivalent to

**deg2rad**(self)
Element-wise deg2rad.

**diagonal**(self[, k])
Returns the kth diagonal of the matrix.

**dot**(self, other)
Ordinary dot product

**eliminate_zeros**(self)
Remove zero entries from the matrix

**expm1**(self)
Element-wise expm1.

**floor**(self)
Element-wise floor.

**getH**(self)
Return the Hermitian transpose of this matrix.

**get_shape**(self)
Get shape of a matrix.

**getcol**(self, j)
Returns a copy of column \(j\) of the matrix, as an \((m \times 1)\) sparse matrix (column vector).

**getformat**(self)
Format of a matrix representation as a string.

**getmaxprint**(self)
Maximum number of elements to display when printed.

**getnnz**(self[, axis])
Number of stored values, including explicit zeros.

**getrow**(self, i)
Returns a copy of row \(i\) of the matrix, as a \((1 \times n)\) sparse matrix (row vector).

**log1p**(self)
Element-wise log1p.

**max**(self[, axis, out])
Return the maximum of the matrix or maximum along an axis.

**maximum**(self, other)
Element-wise maximum between this and another matrix.

**mean**(self[, axis, dtype, out])
Compute the arithmetic mean along the specified axis.

**mini**(self[, axis, out])
Return the minimum of the matrix or maximum along an axis.

**minimum**(self, other)
Element-wise minimum between this and another matrix.

**multiply**(self, other)
Point-wise multiplication by another matrix

**nonzero**(self)
nonzero indices

**power**(self, n[, dtype])
This function performs element-wise power.

**rad2deg**(self)
Element-wise rad2deg.

**reshape**(self, shape[, order, copy])
Gives a new shape to a sparse matrix without changing its data.

</tbody>
</table>

**scipy.sparse.coo_matrix.__len__**

coo_matrix.__len__(self)

**scipy.sparse.coo_matrix.__mul__**

coo_matrix.__mul__(self, other)

    interpret other and call one of the following

    self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()

**scipy.sparse.coo_matrix.arcsin**

coo_matrix.arcsin(self)

    Element-wise arcsin.

    See `numpy.arcsin` for more information.
scipy.sparse.coo_matrix.arcsinh

coo_matrix.arcsinh(self)
   Element-wise arcsinh.
   
   See numpy.arcsinh for more information.

scipy.sparse.coo_matrix.arctan

coo_matrix.arctan(self)
   Element-wise arctan.
   
   See numpy.arctan for more information.

scipy.sparse.coo_matrix.arctanh

coo_matrix.arctanh(self)
   Element-wise arctanh.
   
   See numpy.arctanh for more information.

scipy.sparse.coo_matrix.argmax

coo_matrix.argmax(self, axis=None, out=None)
   Return indices of maximum elements along an axis.
   Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

   Parameters
   axis        [[-2, -1, 0, 1, None], optional] Axis along which the argmax is computed. If None (default), index of the maximum element in the flattened data is returned.
   out         [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

   Returns
   ind         [numpy.matrix or int] Indices of maximum elements. If matrix, its size along axis is 1.

scipy.sparse.coo_matrix.argmin

coo_matrix.argmin(self, axis=None, out=None)
   Return indices of minimum elements along an axis.
   Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

   Parameters
   axis        [[-2, -1, 0, 1, None], optional] Axis along which the argmin is computed. If None (default), index of the minimum element in the flattened data is returned.
   out         [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.
**Returns**

ind  
[numpy.matrix or int] Indices of minimum elements. If matrix, its size along axis is 1.

### scipy.sparse.coo_matrix.asformat

**coo_matrix.asformat**(self, format, copy=False)

Return this matrix in the passed format.

**Parameters**

format  
[[str, None]] The desired matrix format (“csr”, “csc”, “lil”, “dok”, “array”, …) or None for no conversion.

copy  
[bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

A  
[This matrix in the passed format.]

### scipy.sparse.coo_matrix.asfptype

**coo_matrix.asfptype**(self)

Upcast matrix to a floating point format (if necessary)

### scipy.sparse.coo_matrix.astype

**coo_matrix.astype**(self, dtype, casting='unsafe', copy=True)

Cast the matrix elements to a specified type.

**Parameters**

dtype  
[string or numpy dtype] Typecode or data-type to which to cast the data.

casting  
[['no', 'equiv', 'safe', 'same_kind', 'unsafe'], optional] Controls what kind of data casting may occur. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.

copy  
[bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.

### scipy.sparse.coo_matrix.ceil

**coo_matrix.ceil**(self)

Element-wise ceil.

See numpy.ceil for more information.
scipy.sparse.coo_matrix.conj

\texttt{coo\_matrix.conj}(self, copy=\texttt{True})

Element-wise complex conjugation.

If the matrix is of non-complex data type and \texttt{copy} is False, this method does nothing and the data is not copied.

\textit{Parameters}

\texttt{copy} [bool, optional] If True, the result is guaranteed to not share data with self.

\textit{Returns}

\texttt{A} [The element-wise complex conjugate.]

scipy.sparse.coo_matrix.conjugate

\texttt{coo\_matrix.conjugate}(self, copy=\texttt{True})

Element-wise complex conjugation.

If the matrix is of non-complex data type and \texttt{copy} is False, this method does nothing and the data is not copied.

\textit{Parameters}

\texttt{copy} [bool, optional] If True, the result is guaranteed to not share data with self.

\textit{Returns}

\texttt{A} [The element-wise complex conjugate.]

scipy.sparse.coo_matrix.copy

\texttt{coo\_matrix.copy}(self)

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

scipy.sparse.coo_matrix.count_nonzero

\texttt{coo\_matrix.count\_nonzero}(self)

Number of non-zero entries, equivalent to

\texttt{np.count\_nonzero(a.toarray())}

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.
**scipy.sparse.coo_matrix.deg2rad**

```python
coo_matrix.deg2rad(self)
```

Element-wise deg2rad.

See `numpy.deg2rad` for more information.

**scipy.sparse.coo_matrix.diagonal**

```python
coo_matrix.diagonal(self, k=0)
```

Returns the kth diagonal of the matrix.

**Parameters**

- `k` : [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).

New in version 1.0.

See also:

- `numpy.diagonal`

Equivalent numpy function.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

**scipy.sparse.coo_matrix.dot**

```python
coo_matrix.dot(self, other)
```

Ordinary dot product.

**Examples**

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```
scipy.sparse.coo_matrix.eliminate_zeros

coo_matrix.eliminate_zeros(self)
   Remove zero entries from the matrix
   This is an in place operation

scipy.sparse.coo_matrix.expm1

coo_matrix.expm1(self)
   Element-wise expm1.
   See numpy.expm1 for more information.

scipy.sparse.coo_matrix.floor

coo_matrix.floor(self)
   Element-wise floor.
   See numpy.floor for more information.

scipy.sparse.coo_matrix.getH

coo_matrix.getH(self)
   Return the Hermitian transpose of this matrix.
   See also:

   numpy.matrix.getH
      NumPy's implementation of getH for matrices

scipy.sparse.coo_matrix.get_shape

coo_matrix.get_shape(self)
   Get shape of a matrix.

scipy.sparse.coo_matrix.getcol

coo_matrix.getcol(self, j)
   Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
scipy.sparse.coo_matrix.getformat

```python
coo_matrix.getformat(self)
```
Format of a matrix representation as a string.

scipy.sparse.coo_matrix.getmaxprint

```python
coo_matrix.getmaxprint(self)
```
Maximum number of elements to display when printed.

scipy.sparse.coo_matrix.getnnz

```python
coo_matrix.getnnz(self, axis=None)
```
Number of stored values, including explicit zeros.

**Parameters**
axis
[None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**
count_nonzero
Number of non-zero entries

scipy.sparse.coo_matrix.getrow

```python
coo_matrix.getrow(self, i)
```
Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

scipy.sparse.coo_matrix.log1p

```python
coo_matrix.log1p(self)
```
Element-wise log1p.

See numpy.log1p for more information.

scipy.sparse.coo_matrix.max

```python
coo_matrix.max(self, axis=None, out=None)
```
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters**
axis
[{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e., axis = None).

out
[None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.
Returns

amax  [coo_matrix or scalar] Maximum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

min
The minimum value of a sparse matrix along a given axis.

numpy.matrix.max
NumPy's implementation of 'max' for matrices

scipy.sparse.coo_matrix.maximum

coo_matrix.maximum(self, other)
Element-wise maximum between this and another matrix.

scipy.sparse.coo_matrix.mean

coo_matrix.mean(self, axis=None, dtype=None, out=None)
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters

axis  [-2, -1, 0, 1, None] optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., axis = None).

dtype  [data-type, optional] Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype.
New in version 0.18.0.

out  [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

m  [np.matrix]

See also:

numpy.matrix.mean
NumPy's implementation of 'mean' for matrices
scipy.sparse.coo_matrix.min

coo_matrix.min(self, axis=None, out=None)
Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just
the non-zero ones.

Parameters
axis \([-2, -1, 0, 1, \text{None}]\) optional] Axis along which the sum is computed. The default is
to compute the minimum over all the matrix elements, returning a scalar (i.e., \(axis = \text{None}\)).
out [None, optional] This argument is in the signature solely for NumPy compatibility rea-
sons. Do not pass in anything except for the default value, as this argument is not used.

Returns
amin [coo_matrix or scalar] Minimum of \(a\). If \(axis\) is None, the result is a scalar value. If
\(axis\) is given, the result is a sparse.coo_matrix of dimension \(a.\text{ndim} - 1\).

See also:
max
The maximum value of a sparse matrix along a given axis.
numpy.matrix.min
NumPy's implementation of 'min' for matrices

scipy.sparse.coo_matrix.minimum

coo_matrix.minimum(self, other)
Element-wise minimum between this and another matrix.

scipy.sparse.coo_matrix.multiply

coo_matrix.multiply(self, other)
Point-wise multiplication by another matrix

scipy.sparse.coo_matrix.nonzero

coo_matrix.nonzero(self)
nonzero indices
Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

**scipy.sparse.coo_matrix.power**

```python
coo_matrix.power(self, n, dtype=None)
```
This function performs element-wise power.

**Parameters**

- **n** [n is a scalar]
- **dtype** [If dtype is not specified, the current dtype will be preserved.]

**scipy.sparse.coo_matrix.rad2deg**

```python
coo_matrix.rad2deg(self)
```
Element-wise rad2deg.

See `numpy.rad2deg` for more information.

**scipy.sparse.coo_matrix.reshape**

```python
coo_matrix.reshape(self, shape, order='C', copy=False)
```
Gives a new shape to a sparse matrix without changing its data.

**Parameters**

- **shape** [length-2 tuple of ints] The new shape should be compatible with the original shape.
- **order** [‘C’, ‘F’], optional Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- **copy** [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- **reshaped_matrix** [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

- `numpy.matrix.reshape`
  NumPy’s implementation of ‘reshape’ for matrices
scipy.sparse.coo_matrix.resize

coo_matrix.resize(self, *shape)
    Resize the matrix in-place to dimensions given by shape
    Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying
    outside the new shape are removed.

    Parameters
        shape [(int, int)] number of rows and columns in the new matrix

    Notes
    The semantics are not identical to numpy.ndarray.resize or numpy.resize. Here, the same data
    will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy,
    resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a
    flattened representation.
    We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or
    replaced with new objects.

scipy.sparse.coo_matrix.rint

coo_matrix.rint(self)
    Element-wise rint.
    See numpy.rint for more information.

scipy.sparse.coo_matrix.set_shape

coo_matrix.set_shape(self, shape)
    See reshape.

scipy.sparse.coo_matrix.setdiag

coo_matrix.setdiag(self, values, k=0)
    Set diagonal or off-diagonal elements of the array.

    Parameters
        values [array_like] New values of the diagonal elements.
        Values may have any length. If the diagonal is longer than values, then the remaining
diagonal entries will not be set. If values are longer than the diagonal, then the remaining
values are ignored.
        If a scalar value is given, all of the diagonal is set to it.
        k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0
        (the main diagonal).
scipy.sparse.coo_matrix.sign

coo_matrix.sign(self)
Element-wise sign.
See numpy.sign for more information.

scipy.sparse.coo_matrix.sin

coo_matrix.sin(self)
Element-wise sin.
See numpy.sin for more information.

scipy.sparse.coo_matrix.sinh

coo_matrix.sinh(self)
Element-wise sinh.
See numpy.sinh for more information.

scipy.sparse.coo_matrix.sqrt

coo_matrix.sqrt(self)
Element-wise sqrt.
See numpy.sqrt for more information.

scipy.sparse.coo_matrix.sum

coo_matrix.sum(self, axis=None, dtype=None, out=None)
Sum the matrix elements over a given axis.

Parameters

axis : [-2, -1, 0, 1, None] optional
Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., axis = None).

dtype : [dtype, optional]
The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used.
New in version 0.18.0.

out : [np.matrix, optional]
Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

sum_along_axis
[np.matrix] A matrix with the same shape as self, with the specified axis removed.

See also:
**numpy.matrix.sum**

NumPy's implementation of 'sum' for matrices

**scipy.sparse.coo_matrix.sum_duplicates**

coo_matrix.sum_duplicates(self)

Eliminate duplicate matrix entries by adding them together

This is an in place operation

**scipy.sparse.coo_matrix.tan**

coo_matrix.tan(self)

Element-wise tan.

See `numpy.tan` for more information.

**scipy.sparse.coo_matrix.tanh**

coo_matrix.tanh(self)

Element-wise tanh.

See `numpy.tanh` for more information.

**scipy.sparse.coo_matrix.toarray**

coo_matrix.toarray(self, order=None, out=None)

See the docstring for `spmatrix.toarray`.

**scipy.sparse.coo_matrix.tobsr**

coo_matrix.tobsr(self, blocksize=None, copy=False)

Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

**scipy.sparse.coo_matrix.tocoo**

coo_matrix.tocoo(self, copy=False)

Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.
**scipy.sparse.coo_matrix.tocsc**

**coo_matrix.tocsc**(self, copy=False)

Convert this matrix to Compressed Sparse Column format

Duplicate entries will be summed together.

**Examples**

```python
>>> from numpy import array
>>> from scipy.sparse import coo_matrix
>>> row = array([0, 0, 1, 3, 1, 0, 0])
>>> col = array([0, 2, 1, 3, 1, 0, 0])
>>> data = array([1, 1, 1, 1, 1, 1, 1])
>>> A = coo_matrix((data, (row, col)), shape=(4, 4)).tocsc()
>>> A.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

**scipy.sparse.coo_matrix.tocsr**

**coo_matrix.tocsr**(self, copy=False)

Convert this matrix to Compressed Sparse Row format

Duplicate entries will be summed together.

**Examples**

```python
>>> from numpy import array
>>> from scipy.sparse import coo_matrix
>>> row = array([0, 0, 1, 3, 1, 0, 0])
>>> col = array([0, 2, 1, 3, 1, 0, 0])
>>> data = array([1, 1, 1, 1, 1, 1, 1])
>>> A = coo_matrix((data, (row, col)), shape=(4, 4)).tocsr()
>>> A.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```
scipy.sparse.coo_matrix.todense

coo_matrix.todense(self, order=None, out=None)
Return a dense matrix representation of this matrix.

Parameters

order

[{'C', 'F'}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

out

[ndarray, 2-D, optional] If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

arr

[numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

scipy.sparse.coo_matrix.todia

coo_matrix.todia(self, copy=False)
Convert this matrix to sparse DIAppogonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.coo_matrix.todok

coo_matrix.todok(self, copy=False)
Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.coo_matrix.tolil

coo_matrix.tolil(self, copy=False)
Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.coo_matrix.transpose

coo_matrix.transpose(self, axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters

axes

[None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [self with the dimensions reversed.]

See also:

numpy.matrix.transpose

NumPy's implementation of 'transpose' for matrices

scipy.sparse.coo_matrix.trunc

coo_matrix.trunc(self)

Element-wise trunc.

See numpy.trunc for more information.

scipy.sparse.csc_matrix

class scipy.sparse.csc_matrix(arg1, shape=None, dtype=None, copy=False)

Compressed Sparse Column matrix

This can be instantiated in several ways:

csc_matrix(D)
  with a dense matrix or rank-2 ndarray D

csc_matrix(S)
  with another sparse matrix S (equivalent to S.tocsc())

csc_matrix((M, N), [dtype])
  to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

csc_matrix((data, (row_ind, col_ind)), [shape=(M, N)])
  where data, row_ind and col_ind satisfy the relationship a[row_ind[k], col_ind[k]] = data[k].

csc_matrix((data, indices, indptr), [shape=(M, N)])
  is the standard CSC representation where the row indices for column i are stored in indices[indptr[i]:indptr[i+1]] and their corresponding values are stored in data[indptr[i]:indptr[i+1]]. If the shape parameter is not supplied, the matrix dimensions are inferred from the index arrays.

Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Advantages of the CSC format

• efficient arithmetic operations CSC + CSC, CSC * CSC, etc.
• efficient column slicing
• fast matrix vector products (CSR, BSR may be faster)

Disadvantages of the CSC format
- slow row slicing operations (consider CSR)
- changes to the sparsity structure are expensive (consider LIL or DOK)

**Examples**

```python
>>> import numpy as np
>>> from scipy.sparse import csc_matrix
>>> csc_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)

>>> row = np.array([0, 2, 2, 0, 1, 2])
>>> col = np.array([0, 0, 1, 2, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csc_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 4],
       [0, 0, 5],
       [2, 3, 6]])

>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csc_matrix((data, indices, indptr), shape=(3, 3)).toarray()
array([[1, 0, 4],
       [0, 0, 5],
       [2, 3, 6]])
```

**Attributes**
- **dtype** [dtype] Data type of the matrix
- **ndim** [int] Number of dimensions (this is always 2)
- **nnz** Number of stored values, including explicit zeros.
- **data** Data array of the matrix
- **indices** CSC format index array
- **indptr** CSC format index pointer array
- **has_sorted_indices** Determine whether the matrix has sorted indices

**Methods**
- `__len__(self)`
- `__mul__(self, other)` interpret other and call one of the following
- `arcsin(self)` Element-wise arcsin.
- `arcsinh(self)` Element-wise arcsinh.
- `arctan(self)` Element-wise arctan.
- `arctanh(self)` Element-wise arctanh.
- `argmax(self[, axis, out])` Return indices of maximum elements along an axis.
### Table 175 – continued from previous page

<table>

<tr>
<td><code>expm1(self)</code></td>
<td>Element-wise expm1.</td>
</tr>
<tr>
<td><code>floor(self)</code></td>
<td>Element-wise floor.</td>
</tr>
<tr>
<td><code>getH(self)</code></td>
<td>Return the Hermitian transpose of this matrix.</td>
</tr>
<tr>
<td><code>get_shape(self)</code></td>
<td>Get shape of a matrix.</td>
</tr>
<tr>
<td><code>getcol(i)</code></td>
<td>Returns a copy of column i of the matrix, as a (m x 1) CSC matrix (column vector).</td>
</tr>
<tr>
<td><code>getformat(self)</code></td>
<td>Format of a matrix representation as a string.</td>
</tr>
<tr>
<td><code>getmaxprint(self)</code></td>
<td>Maximum number of elements to display when printed.</td>
</tr>
<tr>
<td><code>getnnz(self[, axis])</code></td>
<td>Number of stored values, including explicit zeros.</td>
</tr>
<tr>
<td><code>getrow(i)</code></td>
<td>Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).</td>
</tr>
<tr>
<td><code>log1p(self)</code></td>
<td>Element-wise log1p.</td>
</tr>
<tr>
<td><code>max(self[, axis, out])</code></td>
<td>Return the maximum of the matrix or maximum along an axis.</td>
</tr>
<tr>
<td><code>maximum(self, other)</code></td>
<td>Element-wise maximum between this and another matrix.</td>
</tr>
<tr>
<td><code>mean(self[, axis, dtype, out])</code></td>
<td>Compute the arithmetic mean along the specified axis.</td>
</tr>
<tr>
<td><code>min(self[, axis, out])</code></td>
<td>Return the minimum of the matrix or maximum along an axis.</td>
</tr>
<tr>
<td><code>minimum(self, other)</code></td>
<td>Element-wise minimum between this and another matrix.</td>
</tr>
<tr>
<td><code>multiply(other)</code></td>
<td>Point-wise multiplication by another matrix, vector, or scalar.</td>
</tr>
<tr>
<td><code>nonzero(self)</code></td>
<td>Nonzero indices.</td>
</tr>
<tr>
<td><code>power(self[, n[, dtype]])</code></td>
<td>This function performs element-wise power.</td>
</tr>
<tr>
<td><code>prune(self)</code></td>
<td>Remove empty space after all non-zero elements.</td>
</tr>
<tr>
<td><code>rad2deg(self)</code></td>
<td>Element-wise rad2deg.</td>
</tr>
<tr>
<td><code>reshape(shape[, order, copy])</code></td>
<td>Gives a new shape to a sparse matrix without changing its data.</td>
</tr>
<tr>
<td><code>resize(shape)</code></td>
<td>Resize the matrix in-place to dimensions given by shape.</td>
</tr>
<tr>
<td><code>rint(self)</code></td>
<td>Element-wise rint.</td>
</tr>
<tr>
<td><code>set_shape(shape)</code></td>
<td>See reshape.</td>
</tr>
<tr>
<td><code>setdiag(values[, k])</code></td>
<td>Set diagonal or off-diagonal elements of the array.</td>
</tr>
<tr>
<td><code>sign(self)</code></td>
<td>Element-wise sign.</td>
</tr>
<tr>
<td><code>sin(self)</code></td>
<td>Element-wise sin.</td>

```python
scipy.sparse.csc_matrix.__len__

csc_matrix.__len__(self)
```

```python
scipy.sparse.csc_matrix.__mul__

csc_matrix.__mul__(self, other)
```

- Interpret other and call one of the following:
  - `self._mul_scalar`  
  - `self._mul_vector`  
  - `self._mul_multivector`  
  - `self._mul_sparse_matrix`

```python
scipy.sparse.csc_matrix.arcsin

csc_matrix.arcsin(self)
```

- Element-wise arcsin.
  - See `numpy.arcsin` for more information.
scipy.sparse.csc_matrix.arcsinh

csc_matrix.arcsinh(self)
    Element-wise arcsinh.
    See numpy.arcsinh for more information.

scipy.sparse.csc_matrix.arctan

csc_matrix.arctan(self)
    Element-wise arctan.
    See numpy.arctan for more information.

scipy.sparse.csc_matrix.arctanh

csc_matrix.arctanh(self)
    Element-wise arctanh.
    See numpy.arctanh for more information.

scipy.sparse.csc_matrix.argmax

csc_matrix.argmax(self, axis=None, out=None)
    Return indices of maximum elements along an axis.
    Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

    Parameters
    axis [-2, -1, 0, 1, None], optional) Axis along which the argmax is computed. If None (default), index of the maximum element in the flattened data is returned.
    out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

    Returns
    ind [numpy.matrix or int] Indices of maximum elements. If matrix, its size along axis is 1.

scipy.sparse.csc_matrix.argmin

csc_matrix.argmin(self, axis=None, out=None)
    Return indices of minimum elements along an axis.
    Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

    Parameters
    axis [-2, -1, 0, 1, None], optional) Axis along which the argmin is computed. If None (default), index of the minimum element in the flattened data is returned.
    out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.
**Returns**

ind  
[ind] Indices of minimum elements. If matrix, its size along axis is 1.

```python
csc_matrix.asformat(self, format, copy=False)
```

Return this matrix in the passed format.

**Parameters**

- **format**  
  [[str, None]] The desired matrix format ("csr", "csc", "lil", "dok", "array", …) or None for no conversion.

- **copy**  
  [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

A  
[This matrix in the passed format.]

```python
csc_matrix.asfptype(self)
```

Upcast matrix to a floating point format (if necessary)

```python
csc_matrix.astype(self, dtype, casting='unsafe', copy=True)
```

Cast the matrix elements to a specified type.

**Parameters**

- **dtype**  
  [string or numpy dtype] Typecode or data-type to which to cast the data.

- **casting**  
  [{‘no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’}, optional] Controls what kind of data casting may occur. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.

- **copy**  
  [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.

```python
csc_matrix.ceil(self)
```

Element-wise ceil.

See `numpy.ceil` for more information.
scipy.sparse.csc_matrix.check_format

csc_matrix.check_format(self, full_check=True)
check whether the matrix format is valid

Parameters

full_check [bool, optional] If True, rigorous check, O(N) operations. Otherwise basic check, O(1) operations (default True).

scipy.sparse.csc_matrix.conj

csc_matrix.conj(self, copy=True)
Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.csc_matrix.conjugate

csc_matrix.conjugate(self, copy=True)
Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.csc_matrix.copy

csc_matrix.copy(self)
Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.
scipy.sparse.csc_matrix.count_nonzero

csc_matrix.count_nonzero(self)
    Number of non-zero entries, equivalent to
    np.count_nonzero(a.toarray())
    Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data
    attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.csc_matrix.deg2rad

csc_matrix.deg2rad(self)
    Element-wise deg2rad.
    See numpy.deg2rad for more information.

scipy.sparse.csc_matrix.diagonal

csc_matrix.diagonal(self, k=0)
    Returns the kth diagonal of the matrix.

    Parameters
    k
        [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0
        (the main diagonal).
        New in version 1.0.

    See also:

    numpy.diagonal
    Equivalent numpy function.

Examples

    >>> from scipy.sparse import csr_matrix
    >>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
    >>> A.diagonal()
    array([1, 0, 5])
    >>> A.diagonal(k=1)
    array([2, 3])

scipy.sparse.csc_matrix.dot

csc_matrix.dot(self, other)
    Ordinary dot product
Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

**scipy.sparse.csc_matrix.eliminate_zeros**

```python
csc_matrix.eliminate_zeros(self)
```
Remove zero entries from the matrix
This is an *in place* operation.

**scipy.sparse.csc_matrix.expm1**

```python
csc_matrix.expm1(self)
```
Element-wise expm1.
See `numpy.expm1` for more information.

**scipy.sparse.csc_matrix.floor**

```python
csc_matrix.floor(self)
```
Element-wise floor.
See `numpy.floor` for more information.

**scipy.sparse.csc_matrix.getH**

```python
csc_matrix.getH(self)
```
Return the Hermitian transpose of this matrix.
See also:

`numpy.matrix.getH`
NumPy's implementation of `getH` for matrices
scipy.sparse.csc_matrix.get_shape

csc_matrix.get_shape(self)
Get shape of a matrix.

scipy.sparse.csc_matrix.getcol

csc_matrix.getcol(self, i)
Returns a copy of column i of the matrix, as a (m x 1) CSC matrix (column vector).

scipy.sparse.csc_matrix.getformat

csc_matrix.getformat(self)
Format of a matrix representation as a string.

scipy.sparse.csc_matrix.getmaxprint

csc_matrix.getmaxprint(self)
Maximum number of elements to display when printed.

scipy.sparse.csc_matrix.getnnz

csc_matrix.getnnz(self, axis=None)
Number of stored values, including explicit zeros.

    Parameters
    axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

    See also:

count_nonzero
Number of non-zero entries

scipy.sparse.csc_matrix.getrow

csc_matrix.getrow(self, i)
Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).
**scipy.sparse.csc_matrix.log1p**

```python
csc_matrix.log1p(self)
```
Element-wise log1p.

See `numpy.log1p` for more information.

**scipy.sparse.csc_matrix.max**

```python
csc_matrix.max(self, axis=None, out=None)
```
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters**

- **axis**
  
  [-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e., `axis = None`).

- **out**
  
  [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- **amax**
  
  [coo_matrix or scalar] Maximum of `a`. If `axis` is None, the result is a scalar value. If `axis` is given, the result is a sparse.coo_matrix of dimension `a.ndim - 1`.

See also:

- **min**
  
  The minimum value of a sparse matrix along a given axis.

  ```
  numpy.matrix.max
  ```

  NumPy's implementation of `max` for matrices

**scipy.sparse.csc_matrix.maximum**

```python
csc_matrix.maximum(self, other)
```
Element-wise maximum between this and another matrix.

**scipy.sparse.csc_matrix.mean**

```python
csc_matrix.mean(self, axis=None, dtype=None, out=None)
```
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. `float64` intermediate and return values are used for integer inputs.

**Parameters**

- **axis**
  
  [-2, -1, 0, 1, None] optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., `axis = None`).

- **dtype**
  
  [data-type, optional] Type to use in computing the mean. For integer inputs, the default is `float64`; for floating point inputs, it is the same as the input dtype.

  New in version 0.18.0.
out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

Returns

m [np.matrix]

See also:

numpy.matrix.mean

NumPy’s implementation of ‘mean’ for matrices

scipy.sparse.csc_matrix.min

csc_matrix.min(self, axis=None, out=None)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e., axis = None).

out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amin [coo_matrix or scalar] Minimum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

max

The maximum value of a sparse matrix along a given axis.

numpy.matrix.min

NumPy’s implementation of ‘min’ for matrices

scipy.sparse.csc_matrix.minimum

csc_matrix.minimum(self, other)

Element-wise minimum between this and another matrix.
scipy.sparse.csc_matrix.multiply

csc_matrix.multiply(self, other)
Point-wise multiplication by another matrix, vector, or scalar.

scipy.sparse.csc_matrix.nonzero

csc_matrix.nonzero(self)
nonzero indices
Returns a tuple of arrays (row, col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.csc_matrix.power

csc_matrix.power(self, n, dtype=None)
This function performs element-wise power.

Parameters

- n [n is a scalar]
- dtype [If dtype is not specified, the current dtype will be preserved.]

scipy.sparse.csc_matrix.prune

csc_matrix.prune(self)
Remove empty space after all non-zero elements.

scipy.sparse.csc_matrix.rad2deg

csc_matrix.rad2deg(self)
Element-wise rad2deg.
See numpy.rad2deg for more information.
scipy.sparse.csc_matrix.reshape

csc_matrix.reshape(self, shape, order='C', copy=False)
Gives a new shape to a sparse matrix without changing its data.

Parameters

- shape [length-2 tuple of ints] The new shape should be compatible with the original shape.
- order [{'C', 'F'}, optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

- reshaped_matrix [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

numpy.matrix.reshape
NumPy’s implementation of ‘reshape’ for matrices

scipy.sparse.csc_matrix.resize

csc_matrix.resize(self, *shape)
Resize the matrix in-place to dimensions given by shape

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

- shape [(int, int)] number of rows and columns in the new matrix

Notes

The semantics are not identical to numpy.ndarray.resize or numpy.resize. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.
**scipy.sparse.csc_matrix.rint**

csc_matrix.rint(self)

Element-wise rint.

See `numpy.rint` for more information.

**scipy.sparse.csc_matrix.set_shape**

csc_matrix.set_shape(self, shape)

See reshape.

**scipy.sparse.csc_matrix.setdiag**

csc_matrix.setdiag(self, values, k=0)

Set diagonal or off-diagonal elements of the array.

- **Parameters**
  - `values` [array_like] New values of the diagonal elements. Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored. If a scalar value is given, all of the diagonal is set to it.
  - `k` [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

**scipy.sparse.csc_matrix.sign**

csc_matrix.sign(self)

Element-wise sign.

See `numpy.sign` for more information.

**scipy.sparse.csc_matrix.sin**

csc_matrix.sin(self)

Element-wise sin.

See `numpy.sin` for more information.

**scipy.sparse.csc_matrix.sinh**

csc_matrix.sinh(self)

Element-wise sinh.

See `numpy.sinh` for more information.
scipy.sparse.csc_matrix.sort_indices

csc_matrix.sort_indices(self)
Sort the indices of this matrix in place

scipy.sparse.csc_matrix.sorted_indices

csc_matrix.sorted_indices(self)
Return a copy of this matrix with sorted indices

scipy.sparse.csc_matrix.sqrt

csc_matrix.sqrt(self)
Element-wise sqrt.
See numpy.sqrt for more information.

scipy.sparse.csc_matrix.sum

csc_matrix.sum(self, axis=None, dtype=None, out=None)
Sum the matrix elements over a given axis.

Parameters
axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., axis = None).
dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used. New in version 0.18.0.
out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

Returns
sum_along_axis [np.matrix] A matrix with the same shape as self, with the specified axis removed.

See also:
numpy.matrix.sum
NumPy's implementation of 'sum' for matrices
scipy.sparse.csc_matrix.sum_duplicates

csc_matrix.sum_duplicates(self)
    Eliminate duplicate matrix entries by adding them together
    This is an in place operation.

scipy.sparse.csc_matrix.tan

csc_matrix.tan(self)
    Element-wise tan.
    See numpy.tan for more information.

scipy.sparse.csc_matrix.tanh

csc_matrix.tanh(self)
    Element-wise tanh.
    See numpy.tanh for more information.

scipy.sparse.csc_matrix.toarray

csc_matrix.toarray(self, order=None, out=None)
    Return a dense ndarray representation of this matrix.

Parameters

order [{‘C’, ‘F’}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.

out [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, out is required to be memory contiguous (either C or Fortran ordered).

Returns

arr [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed, the same object is returned after being modified in-place to contain the appropriate values.

scipy.sparse.csc_matrix.tobsr

csc_matrix.tobsr(self, blocksize=None, copy=False)
    Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.
scipy.sparse.csc_matrix.tocoo

csc_matrix.tocoo(self, copy=True)
    Convert this matrix to COOrdinate format.
    With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

scipy.sparse.csc_matrix.tocsc

csc_matrix.tocsc(self, copy=False)
    Convert this matrix to Compressed Sparse Column format.
    With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.csc_matrix.tocsr

csc_matrix.tocsr(self, copy=False)
    Convert this matrix to Compressed Sparse Row format.
    With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.csc_matrix.todense

csc_matrix.todense(self, order=None, out=None)
    Return a dense matrix representation of this matrix.
    Parameters
    order [{‘C’, ‘F’}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.
    out [ndarray, 2-D, optional] If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.
    Returns
    arr [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

scipy.sparse.csc_matrix.todia

csc_matrix.todia(self, copy=False)
    Convert this matrix to sparse DIAgonal format.
    With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.
scipy.sparse.csc_matrix.todok

csc_matrix.todok (self, copy=False)
Convert this matrix to Dictionary Of Keys format.
With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.csc_matrix.tolil

csc_matrix.tolil (self, copy=False)
Convert this matrix to List of Lists format.
With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.csc_matrix.transpose

csc_matrix.transpose (self, axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters
    axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
    copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns
    p [self with the dimensions reversed.]

See also:

    numpy.matrix.transpose
    NumPy’s implementation of ‘transpose’ for matrices

scipy.sparse.csc_matrix.trunc

csc_matrix.trunc (self)
Element-wise trunc.
See numpy.trunc for more information.
**scipy.sparse.csr_matrix**

```python
class scipy.sparse.csr_matrix(arg1, shape=None, dtype=None, copy=False)
```

Compressed Sparse Row matrix

This can be instantiated in several ways:

- `csr_matrix(D)`
  with a dense matrix or rank-2 ndarray `D`

- `csr_matrix(S)`
  with another sparse matrix `S` (equivalent to `S.tocsr()`)

- `csr_matrix((M, N), [dtype])`
  to construct an empty matrix with shape `(M, N)` `dtype` is optional, defaulting to `dtype='d'`.

- `csr_matrix((data, (row_ind, col_ind)), [shape=(M, N)])`
  where `data`, `row_ind` and `col_ind` satisfy the relationship \( a[row\_ind[k], col\_ind[k]] = data[k] \).

- `csr_matrix((data, indices, indptr), [shape=(M, N)])`
  is the standard CSR representation where the column indices for row `i` are stored in `indices[indptr[i]:indptr[i+1]]` and their corresponding values are stored in `data[indptr[i]:indptr[i+1]]`. If the shape parameter is not supplied, the matrix dimensions are inferred from the index arrays.

**Notes**

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

**Advantages of the CSR format**

- efficient arithmetic operations `CSR + CSR`, `CSR * CSR`, etc.
- efficient row slicing
- fast matrix vector products

**Disadvantages of the CSR format**

- slow column slicing operations (consider CSC)
- changes to the sparsity structure are expensive (consider LIL or DOK)
Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> csr_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```python
>>> row = np.array([0, 0, 1, 2, 2])
>>> col = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csr_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])
```

Duplicate entries are summed together:

```python
>>> row = np.array([0, 1, 2, 0])
>>> col = np.array([0, 1, 1, 0])
>>> data = np.array([1, 2, 4, 8])
>>> csr_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[9, 0, 0],
       [0, 2, 0],
       [0, 4, 0]])
```

As an example of how to construct a CSR matrix incrementally, the following snippet builds a term-document matrix from texts:

```python
>>> docs = [['hello', 'world', 'hello'], ['goodbye', 'cruel', 'world']]
>>> indptr = [0]
>>> indices = []
>>> data = []
>>> vocabulary = {}
>>> for d in docs:
...     for term in d:
...             index = vocabulary.setdefault(term, len(vocabulary))
...             indices.append(index)
...             data.append(1)
...             indptr.append(len(indices))
...     csr_matrix((data, indices, indptr), dtype=int).toarray()
array([[2, 1, 0, 0],
       [0, 1, 1, 1]])
```
**Attributes**

- **dtype** [dtype] Data type of the matrix
- **ndim** [int] Number of dimensions (this is always 2)
- **nnz** Number of stored values, including explicit zeros.
- **data** CSR format data array of the matrix
- **indices** CSR format index array of the matrix
- **indptr** CSR format index pointer array of the matrix
- **has_sorted_indices**
  Determine whether the matrix has sorted indices

**Methods**

```python
__len__(self)
__mul__(self, other) interpret other and call one of the following
arcsin(self) Element-wise arcsin.
arcsinh(self) Element-wise arcsinh.
arctan(self) Element-wise arctan.
arctanh(self) Element-wise arctanh.
argmax(self[, axis, out]) Return indices of maximum elements along an axis.
argmin(self[, axis, out]) Return indices of minimum elements along an axis.
asformat(self, format[, copy]) Return this matrix in the passed format.
asfptype(self) Upcast matrix to a floating point format (if necessary)
astype(self, dtype[, casting, copy]) Cast the matrix elements to a specified type.
ceil(self) Element-wise ceil.
check_format(self[, full_check]) check whether the matrix format is valid
conj(self[, copy]) Element-wise complex conjugation.
conjugate(self[, copy]) Element-wise complex conjugation.
copy(self) Returns a copy of this matrix.
count_nonzero(self) Number of non-zero entries, equivalent to
deg2rad(self) Element-wise deg2rad.
diagonal(self[, k]) Returns the kth diagonal of the matrix.
dot(self, other) Ordinary dot product
eliminate_zeros(self) Remove zero entries from the matrix
expm1(self) Element-wise expm1.
floor(self) Element-wise floor.
getH(self) Return the Hermitian transpose of this matrix.
get_shape(self) Get shape of a matrix.
getcol(self, i) Returns a copy of column i of the matrix, as a (m x 1) CSR matrix (column vector).
getformat(self) Format of a matrix representation as a string.
getmaxprint(self) Maximum number of elements to display when printed.
getnnz(self[, axis]) Number of stored values, including explicit zeros.
getrow(self, i) Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).
log1p(self) Element-wise log1p.
max(self[, axis, out]) Return the maximum of the matrix or maximum along an axis.
```

</table>
scipy.sparse.csr_matrix.__len__

csr_matrix.__len__(self)

scipy.sparse.csr_matrix.__mul__

csr_matrix.__mul__(self, other)
    interpret other and call one of the following
    self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()

scipy.sparse.csr_matrix.arcsin

csr_matrix.arcsin(self)
    Element-wise arcsin.
    See numpy.arcsin for more information.

scipy.sparse.csr_matrix.arcsinh

csr_matrix.arcsinh(self)
    Element-wise arcsinh.
    See numpy.arcsinh for more information.

scipy.sparse.csr_matrix.arctan

csr_matrix.arctan(self)
    Element-wise arctan.
    See numpy.arctan for more information.

scipy.sparse.csr_matrix.arctanh

csr_matrix.arctanh(self)
    Element-wise arctanh.
    See numpy.arctanh for more information.

scipy.sparse.csr_matrix.argmax

csr_matrix.argmax(self, axis=None, out=None)
    Return indices of maximum elements along an axis.
    Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

    Parameters
    axis       [-2, -1, 0, 1, None], optional] Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.
### scipy.sparse.csr_matrix.argmin

**csr_matrix.argmin**(self, axis=None, out=None)

Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters**

- **axis** [-2, -1, 0, 1, None, optional] Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.
- **out** [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- **ind** [numpy.matrix or int] Indices of minimum elements. If matrix, its size along `axis` is 1.

### scipy.sparse.csr_matrix.asformat

**csr_matrix.asformat**(self, format, copy=False)

Return this matrix in the passed format.

**Parameters**

- **format** [str, None] The desired matrix format ("csr", "csc", "lil", "dok", "array", ...) or None for no conversion.
- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- **A** [This matrix in the passed format.]

### scipy.sparse.csr_matrix.asfptype

**csr_matrix.asfptype**(self)

Upcast matrix to a floating point format (if necessary)
**scipy.sparse.csr_matrix.astype**

csr_matrix.astype (self, dtype, casting='unsafe', copy=True)

Cast the matrix elements to a specified type.

**Parameters**

- **dtype** [string or numpy dtype] Typecode or data-type to which to cast the data.
- **casting** [{‘no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’}, optional] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
- **copy** [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.

**scipy.sparse.csr_matrix.ceil**

csr_matrix.ceil (self)

Element-wise ceil.

See numpy.ceil for more information.

**scipy.sparse.csr_matrix.check_format**

csr_matrix.check_format (self, full_check=True)

check whether the matrix format is valid

**Parameters**

- **full_check** [bool, optional] If True, rigorous check, O(N) operations. Otherwise basic check, O(1) operations (default True).

**scipy.sparse.csr_matrix.conj**

csr_matrix.conj (self, copy=True)

Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

**Parameters**

- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- **A** [The element-wise complex conjugate.]
**scipy.sparse.csr_matrix.conjugate**

`csr_matrix.conjugate(self, copy=True)`

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- `copy` [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- `A` [The element-wise complex conjugate.]

**scipy.sparse.csr_matrix.copy**

`csr_matrix.copy(self)`

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

**scipy.sparse.csr_matrix.count_nonzero**

`csr_matrix.count_nonzero(self)`

Number of non-zero entries, equivalent to `np.count_nonzero(a.toarray())`

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

**scipy.sparse.csr_matrix.deg2rad**

`csr_matrix.deg2rad(self)`

Element-wise deg2rad.

See `numpy.deg2rad` for more information.

**scipy.sparse.csr_matrix.diagonal**

`csr_matrix.diagonal(self, k=0)`

Returns the kth diagonal of the matrix.

**Parameters**

- `k` [int, optional] Which diagonal to get, corresponding to elements `a[i, i+k]`. Default: 0 (the main diagonal).

**See also:**

- `numpy.diagonal`

  Equivalent numpy function.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

`scipy.sparse.csr_matrix.dot`

csr_matrix.dot(self, other)
Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

`scipy.sparse.csr_matrix.eliminate_zeros`

csr_matrix.eliminate_zeros(self)
Remove zero entries from the matrix
This is an in place operation.

`scipy.sparse.csr_matrix.expm1`

csr_matrix.expm1(self)
Element-wise expm1.
See numpy.expm1 for more information.

`scipy.sparse.csr_matrix.floor`

csr_matrix.floor(self)
Element-wise floor.
See numpy.floor for more information.
scipy.sparse.csr_matrix.getH

csr_matrix.getH(self)
    Return the Hermitian transpose of this matrix.

    See also:

    numpy.matrix.getH
        NumPy's implementation of getH for matrices

scipy.sparse.csr_matrix.get_shape

csr_matrix.get_shape(self)
    Get shape of a matrix.

scipy.sparse.csr_matrix.getcol

csr_matrix.getcol(self, i)
    Returns a copy of column i of the matrix, as a (m x 1) CSR matrix (column vector).

scipy.sparse.csr_matrix.getformat

csr_matrix.getformat(self)
    Format of a matrix representation as a string.

scipy.sparse.csr_matrix.getmaxprint

csr_matrix.getmaxprint(self)
    Maximum number of elements to display when printed.

scipy.sparse.csr_matrix.getnnz

csr_matrix.getnnz(self, axis=\texttt{None})
    Number of stored values, including explicit zeros.

    Parameters
    \begin{itemize}
    \item \texttt{axis} \hspace{1cm} [\texttt{None}, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.
    \end{itemize}

    See also:

    count_nonzero
        Number of non-zero entries
scipy.sparse.csr_matrix.getrow

csr_matrix.getrow(self, i)

Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).

scipy.sparse.csr_matrix.log1p

csr_matrix.log1p(self)

Element-wise log1p.

See numpy.log1p for more information.

scipy.sparse.csr_matrix.max

csr_matrix.max(self, axis=None, out=None)

Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e., axis = None).

out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amax [coo_matrix or scalar] Maximum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

min

The minimum value of a sparse matrix along a given axis.

numpy.matrix.max

NumPy’s implementation of ‘max’ for matrices

scipy.sparse.csr_matrix.maximum

csr_matrix.maximum(self, other)

Element-wise maximum between this and another matrix.
scipy.sparse.csr_matrix.mean

```python
csr_matrix.mean(self, axis=None, dtype=None, out=None)
```

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. `float64` intermediate and return values are used for integer inputs.

**Parameters**

- **axis**
  
  [[-2, -1, 0, 1, None] optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., `axis = None`).

- **dtype**
  
  [data-type, optional] Type to use in computing the mean. For integer inputs, the default is `float64`; for floating point inputs, it is the same as the input dtype.

  New in version 0.18.0.

- **out**
  
  [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

  New in version 0.18.0.

**Returns**

- **m**
  
  [np.matrix]

See also:

- `numpy.matrix.mean`
  
  NumPy's implementation of 'mean' for matrices

scipy.sparse.csr_matrix.min

```python
csr_matrix.min(self, axis=None, out=None)
```

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters**

- **axis**
  
  [[-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e., `axis = None`).

- **out**
  
  [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- **amin**
  
  [coo_matrix or scalar] Minimum of `a`. If `axis` is None, the result is a scalar value. If `axis` is given, the result is a sparse.coo_matrix of dimension `a.ndim - 1`.

See also:

- `max`
  
  The maximum value of a sparse matrix along a given axis.

- `numpy.matrix.min`
  
  NumPy's implementation of 'min' for matrices
**scipy.sparse.csr_matrix.minimum**

```
csr_matrix.minimum(self, other)
```
Element-wise minimum between this and another matrix.

**scipy.sparse.csr_matrix.multiply**

```
csr_matrix.multiply(self, other)
```
Point-wise multiplication by another matrix, vector, or scalar.

**scipy.sparse.csr_matrix.nonzero**

```
csr_matrix.nonzero(self)
```
nonzero indices
Returns a tuple of arrays (row, col) containing the indices of the non-zero elements of the matrix.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

**scipy.sparse.csr_matrix.power**

```
csr_matrix.power(self, n, dtype=None)
```
This function performs element-wise power.

**Parameters**

- `n` [n is a scalar]
- `dtype` [If dtype is not specified, the current dtype will be preserved.]

**scipy.sparse.csr_matrix.prune**

```
csr_matrix.prune(self)
```
Remove empty space after all non-zero elements.

**scipy.sparse.csr_matrix.rad2deg**

```
csr_matrix.rad2deg(self)
```
Element-wise rad2deg.

See `numpy.rad2deg` for more information.
scipy.sparse.csr_matrix.reshape

csr_matrix.reshape(self, shape, order='C', copy=False)
Gives a new shape to a sparse matrix without changing its data.

Parameters

- **shape** [length-2 tuple of ints] The new shape should be compatible with the original shape.
- **order** [{'C', 'F'}, optional] Read the elements using this index order. 'C' means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- **copy** [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

- **reshaped_matrix** [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

- **numpy.matrix.reshape**
  NumPy's implementation of 'reshape' for matrices

scipy.sparse.csr_matrix.resize

csr_matrix.resize(self, *shape)
Resize the matrix in-place to dimensions given by shape
Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

- **shape** [(int, int)] number of rows and columns in the new matrix

Notes

The semantics are not identical to numpy.ndarray.resize or numpy.resize. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.
scipy.sparse.csr_matrix.rint

csr_matrix.rint(self)
   Element-wise rint.
   See numpy.rint for more information.

scipy.sparse.csr_matrix.set_shape

csr_matrix.set_shape(self, shape)
   See reshape.

scipy.sparse.csr_matrix.setdiag

csr_matrix.setdiag(self, values, k=0)
   Set diagonal or off-diagonal elements of the array.

   Parameters

   values [array_like] New values of the diagonal elements.
   Values may have any length. If the diagonal is longer than values, then the remaining
diagonal entries will not be set. If values are longer than the diagonal, then the remaining
values are ignored.
   If a scalar value is given, all of the diagonal is set to it.

   k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0
   (the main diagonal).

scipy.sparse.csr_matrix.sign

csr_matrix.sign(self)
   Element-wise sign.
   See numpy.sign for more information.

scipy.sparse.csr_matrix.sin

csr_matrix.sin(self)
   Element-wise sin.
   See numpy.sin for more information.

scipy.sparse.csr_matrix.sinh

csr_matrix.sinh(self)
   Element-wise sinh.
   See numpy.sinh for more information.
scipy.sparse.csr_matrix.sort_indices

csr_matrix.sort_indices(self)
Sort the indices of this matrix in place

scipy.sparse.csr_matrix.sorted_indices

csr_matrix.sorted_indices(self)
Return a copy of this matrix with sorted indices

scipy.sparse.csr_matrix.sqrt

csr_matrix.sqrt(self)
Element-wise sqrt.
See numpy.sqrt for more information.

scipy.sparse.csr_matrix.sum

csr_matrix.sum(self, axis=None, dtype=None, out=None)
Sum the matrix elements over a given axis.

Parameters
axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., axis = None).
dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used. New in version 0.18.0.
out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

Returns
sum_along_axis [np.matrix] A matrix with the same shape as self, with the specified axis removed.

See also:

numpy.matrix.sum
NumPy's implementation of 'sum' for matrices
scipy.sparse.csr_matrix.sum_duplicates

csr_matrix.sum_duplicates(self)
   Eliminate duplicate matrix entries by adding them together
   This is an in place operation.

scipy.sparse.csr_matrix.tan

csr_matrix.tan(self)
   Element-wise tan.
   See numpy.tan for more information.

scipy.sparse.csr_matrix.tanh

csr_matrix.tanh(self)
   Element-wise tanh.
   See numpy.tanh for more information.

scipy.sparse.csr_matrix.toarray

csr_matrix.toarray(self, order=None, out=None)
   Return a dense ndarray representation of this matrix.
   Parameters
   order [{'C', 'F'}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.
   out [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, out is required to be memory contiguous (either C or Fortran ordered).
   Returns
   arr [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed, the same object is returned after being modified in-place to contain the appropriate values.

scipy.sparse.csr_matrix.tobsr

csr_matrix.tobsr(self, blocksize=None, copy=True)
   Convert this matrix to Block Sparse Row format.
   With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.
   When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.
**scipy.sparse.csr_matrix.tocoo**

```python
csr_matrix.tocoo(self, copy=True)
```
Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

**scipy.sparse.csr_matrix.tocsc**

```python
csr_matrix.tocsc(self, copy=False)
```
Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

**scipy.sparse.csr_matrix.tocsr**

```python
csr_matrix.tocsr(self, copy=False)
```
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

**scipy.sparse.csr_matrix.todense**

```python
csr_matrix.todense(self, order=None, out=None)
```
Return a dense matrix representation of this matrix.

**Parameters**
- `order`: [{‘C’, ‘F’}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.
- `out`: [ndarray, 2-D, optional] If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**
- `arr`: [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

**scipy.sparse.csr_matrix.todia**

```python
csr_matrix.todia(self, copy=False)
```
Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.
```python
scipy.sparse.csr_matrix.todok

csr_matrix.todok(self, copy=False)
Convert this matrix to Dictionary Of Keys format.
With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.csr_matrix.tolil

csr_matrix.tolil(self, copy=False)
Convert this matrix to List of Lists format.
With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.csr_matrix.transpose

csr_matrix.transpose(self, axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters
axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns
p [self with the dimensions reversed.]

See also:
numpy.matrix.transpose
NumPy’s implementation of ‘transpose’ for matrices

scipy.sparse.csr_matrix.trunc

csr_matrix.trunc(self)
Element-wise trunc.
See numpy.trunc for more information.
```

__getitem__
scipy.sparse.dia_matrix

class scipy.sparse.dia_matrix(arg1, shape=None, dtype=None, copy=False)
Sparse matrix with DIAgonal storage

This can be instantiated in several ways:

dia_matrix(D)
with a dense matrix
dia_matrix(S)
with another sparse matrix S (equivalent to S.todia())
dia_matrix((M, N), [dtype])
to construct an empty matrix with shape (M, N), dtype is optional, defaulting to dtype='d'.
dia_matrix((data, offsets), shape=(M, N))
where the data[k,:] stores the diagonal entries for diagonal offsets[k] (See example below)

Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import dia_matrix
>>> dia_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)

>>> data = np.array([[1, 2, 3, 4]]).repeat(3, axis=0)
>>> offsets = np.array([0, -1, 2])
>>> dia_matrix((data, offsets), shape=(4, 4)).toarray()
array([[1, 0, 3, 0],
       [1, 2, 1, 4],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])

>>> from scipy.sparse import dia_matrix
>>> n = 10
>>> ex = np.ones(n)
>>> data = np.array([ex, 2 * ex, ex])
>>> offsets = np.array([-1, 0, 1])
>>> dia_matrix((data, offsets), shape=(n, n)).toarray()
array([[2., 1., 0., ..., 0., 0., 0.],
       [1., 2., 1., ..., 0., 0., 0.],
       [0., 1., 2., ..., 0., 0., 0.]])
```

(continues on next page)
...,
[0., 0., 0., ..., 2., 1., 0.],
[0., 0., 0., ..., 1., 2., 1.],
[0., 0., 0., ..., 0., 1., 2.])

Attributes

dtype [dtype] Data type of the matrix
ndim [int] Number of dimensions (this is always 2)
nnz Number of stored values, including explicit zeros.
data DIA format data array of the matrix
offsets DIA format offset array of the matrix

Methods

__len__ (self) interpret other and call one of the following
__mul__ (self, other) interpret other and call one of the following
arcsin(self) Element-wise arcsin.
arcsinh(self) Element-wise arcsinh.
arctan(self) Element-wise arctan.
arctanh(self) Element-wise arctanh.
asformat(self, format[, copy]) Return this matrix in the passed format.
asfptype(self) Upcast matrix to a floating point format (if necessary)
astype(self, dtype[, casting, copy]) Cast the matrix elements to a specified type.
ceil(self) Element-wise ceil.
conj(self[, copy]) Element-wise complex conjugation.
conjugate(self[, copy]) Element-wise complex conjugation.
copy(self) Returns a copy of this matrix.
count_nonzero(self) Number of non-zero entries, equivalent to
deg2rad(self) Element-wise deg2rad.
diagonal(self[, k]) Returns the kth diagonal of the matrix.
dot(self, other) Ordinary dot product
expm1(self) Element-wise expm1.
floor(self) Element-wise floor.
getH(self) Return the Hermitian transpose of this matrix.
get_shape(self) Get shape of a matrix.
getcol(self, j) Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
getformat(self) Format of a matrix representation as a string.
getmaxprint(self) Maximum number of elements to display when printed.
getnnz(self[, axis]) Number of stored values, including explicit zeros.
getrow(self, i) Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
log1p(self) Element-wise log1p.
maximum(self, other) Element-wise maximum between this and another matrix.
mean(self[, axis, dtype, out]) Compute the arithmetic mean along the specified axis.

### scipy.sparse.dia_matrix.__len__

```python
dia_matrix.__len__(self)
```

### scipy.sparse.dia_matrix.__mul__

```python
dia_matrix.__mul__(self, other)
```

Interpret other and call one of the following:

- `self._mul_scalar()`
- `self._mul_vector()`
- `self._mul_multivector()`
- `self._mul_sparse_matrix()`
scipy.sparse.dia_matrix.arcsin

dia_matrix.arcsin(self)

Element-wise arcsin.

See numpy.arcsin for more information.

scipy.sparse.dia_matrix.arcsinh

dia_matrix.arcsinh(self)

Element-wise arcsinh.

See numpy.arcsinh for more information.

scipy.sparse.dia_matrix.arctan

dia_matrix.arctan(self)

Element-wise arctan.

See numpy.arctan for more information.

scipy.sparse.dia_matrix.arctanh

dia_matrix.arctanh(self)

Element-wise arctanh.

See numpy.arctanh for more information.

scipy.sparse.dia_matrix.asformat

dia_matrix.asformat(self, format=None, copy=False)

Return this matrix in the passed format.

Parameters

- **format** [{str, None}] The desired matrix format (“csr”, “csc”, “lil”, “dok”, “array”, …) or None for no conversion.
- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

- A [This matrix in the passed format.]
**scipy.sparse.dia_matrix.asfptype**

`dia_matrix.asfptype(self)`

Upcast matrix to a floating point format (if necessary)

**scipy.sparse.dia_matrix.astype**

`dia_matrix.astype(self, dtype, casting='unsafe', copy=True)`

Cast the matrix elements to a specified type.

**Parameters**

- **dtype** [string or numpy dtype] Typecode or data-type to which to cast the data.
- **casting** [{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
- **copy** [bool, optional] If `copy` is False, the result might share some memory with this matrix. If `copy` is True, it is guaranteed that the result and this matrix do not share any memory.

**scipy.sparse.dia_matrix.ceil**

`dia_matrix.ceil(self)`

Element-wise ceiling.

See `numpy.ceil` for more information.

**scipy.sparse.dia_matrix.conj**

`dia_matrix.conj(self, copy=True)`

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- **A** [The element-wise complex conjugate.]
scipy.sparse.dia_matrix.conjugate

dia_matrix.conjugate(self, copy=True)

Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters

- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

- **A** [The element-wise complex conjugate.]

scipy.sparse.dia_matrix.copy

dia_matrix.copy(self)

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

scipy.sparse.dia_matrix.count_nonzero

dia_matrix.count_nonzero(self)

Number of non-zero entries, equivalent to np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.dia_matrix.deg2rad

dia_matrix.deg2rad(self)

Element-wise deg2rad.

See numpy.deg2rad for more information.

scipy.sparse.dia_matrix.diagonal

dia_matrix.diagonal(self, k=0)

Returns the kth diagonal of the matrix.

Parameters

- **k** [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).

New in version 1.0.

See also:

- **numpy.diagonal**

Equivalent numpy function.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

**scipy.sparse.dia_matrix.dot**

dia_matrix.dot(self, other)
Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

**scipy.sparse.dia_matrix.expm1**

dia_matrix.expm1(self)
Element-wise expm1.

See numpy.expm1 for more information.

**scipy.sparse.dia_matrix.floor**

dia_matrix.floor(self)
Element-wise floor.

See numpy.floor for more information.

**scipy.sparse.dia_matrix.getH**

dia_matrix.getH(self)
Return the Hermitian transpose of this matrix.

See also:

numpy.matrix.getH

NumPy's implementation of getH for matrices
scipy.sparse.dia_matrix.get_shape

dia_matrix.get_shape(self)
    Get shape of a matrix.

scipy.sparse.dia_matrix.getcol

dia_matrix.getcol(self, j)
    Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.dia_matrix.getformat

dia_matrix.getformat(self)
    Format of a matrix representation as a string.

scipy.sparse.dia_matrix.getmaxprint

dia_matrix.getmaxprint(self)
    Maximum number of elements to display when printed.

scipy.sparse.dia_matrix.getnnz

dia_matrix.getnnz(self, axis=None)
    Number of stored values, including explicit zeros.

    Parameters

    axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

    See also:

count_nonzero

    Number of non-zero entries

scipy.sparse.dia_matrix.getrow

dia_matrix.getrow(self, i)
    Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
**scipy.sparse.dia_matrix.log1p**

dia_matrix.log1p(self)

Element-wise log1p.

See `numpy.log1p` for more information.

**scipy.sparse.dia_matrix.maximum**

dia_matrix.maximum(self, other)

Element-wise maximum between this and another matrix.

**scipy.sparse.dia_matrix.mean**

dia_matrix.mean(self, axis=None, dtype=None, out=None)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. `float64` intermediate and return values are used for integer inputs.

**Parameters**

- **axis** : {-2, -1, 0, 1, None} optional
  Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., `axis = None`).

- **dtype** : [data-type, optional]
  Type to use in computing the mean. For integer inputs, the default is `float64`; for floating point inputs, it is the same as the input dtype. New in version 0.18.0.

- **out** : [np.matrix, optional]
  Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

**Returns**

- **m** : [np.matrix]

See also:

- `numpy.matrix.mean`

NumPy's implementation of ‘mean’ for matrices

**scipy.sparse.dia_matrix.minimum**

dia_matrix.minimum(self, other)

Element-wise minimum between this and another matrix.
scipy.sparse.dia_matrix.multiply

dia_matrix.multiply(self, other)
    Point-wise multiplication by another matrix

scipy.sparse.dia_matrix.nonzero

dia_matrix.nonzero(self)
    nonzero indices
    Returns a tuple of arrays (row, col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.dia_matrix.power

dia_matrix.power(self, n, dtype=None)
    This function performs element-wise power.

Parameters

- **n** [n is a scalar]
- **dtype** [If dtype is not specified, the current dtype will be preserved.]

scipy.sparse.dia_matrix.rad2deg

dia_matrix.rad2deg(self)
    Element-wise rad2deg.
    See numpy.rad2deg for more information.

scipy.sparse.dia_matrix.reshape

dia_matrix.reshape(self, shape, order='C', copy=False)
    Gives a new shape to a sparse matrix without changing its data.

Parameters

- **shape** [length-2 tuple of ints] The new shape should be compatible with the original shape. [['C', 'F'], optional] Read the elements using this index order. 'C' means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. 'F' means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- **copy** [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.
### Returns

`reshaped_matrix`

[sparse matrix] A sparse matrix with the given `shape`, not necessarily of the same format as the current object.

### See also:

`numpy.matrix.reshape`

NumPy’s implementation of ‘reshape’ for matrices

### scipy.sparse.dia_matrix.resize

`dia_matrix.resize(self, *shape)`

Resize the matrix in-place to dimensions given by `shape`

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

### Parameters

- `shape` : [(int, int)] number of rows and columns in the new matrix

### Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

### scipy.sparse.dia_matrix.rint

`dia_matrix.rint(self)`

Element-wise rint.

See `numpy.rint` for more information.

### scipy.sparse.dia_matrix.set_shape

`dia_matrix.set_shape(self, shape)`

See `reshape`. 
scipy.sparse.dia_matrix.setdiag

dia_matrix.setdiag(self, values, k=0)
    Set diagonal or off-diagonal elements of the array.

Parameters
values     [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining
diagonal entries will not be set. If values are longer than the diagonal, then the remaining
values are ignored.
If a scalar value is given, all of the diagonal is set to it.
k         [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0
            (the main diagonal).

scipy.sparse.dia_matrix.sign

dia_matrix.sign(self)
    Element-wise sign.
    See numpy.sign for more information.

scipy.sparse.dia_matrix.sin

dia_matrix.sin(self)
    Element-wise sin.
    See numpy.sin for more information.

scipy.sparse.dia_matrix.sinh

dia_matrix.sinh(self)
    Element-wise sinh.
    See numpy.sinh for more information.

scipy.sparse.dia_matrix.sqrt

dia_matrix.sqrt(self)
    Element-wise sqrt.
    See numpy.sqrt for more information.
scipy.sparse.dia_matrix.sum

dia_matrix.sum(self, axis=None, dtype=None, out=None)

Sum the matrix elements over a given axis.

Parameters

- **axis**
  - `[{-2, -1, 0, 1, None} optional]` Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., `axis = None`).

- **dtype**
  - `[dtype, optional]` The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of `a` is used by default unless `a` has an integer dtype of less precision than the default platform integer. In that case, if `a` is signed then the platform integer is used while if `a` is unsigned then an unsigned integer of the same precision as the platform integer is used.

  New in version 0.18.0.

- **out**
  - `[np.matrix, optional]` Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

  New in version 0.18.0.

Returns

- **sum_along_axis**
  - `[np.matrix]` A matrix with the same shape as `self`, with the specified axis removed.

See also:

- `numpy.matrix.sum`
  - NumPy’s implementation of ‘sum’ for matrices

scipy.sparse.dia_matrix.tan

dia_matrix.tan(self)

Element-wise tan.

See `numpy.tan` for more information.

scipy.sparse.dia_matrix.tanh

dia_matrix.tanh(self)

Element-wise tanh.

See `numpy.tanh` for more information.
**scipy.sparse.dia_matrix.toarray**

```python
dia_matrix.toarray(self, order=None, out=None)
```

Return a dense ndarray representation of this matrix.

**Parameters**

- `order` [{‘C’, ‘F’}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

- `out` [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, `out` is required to be memory contiguous (either C or Fortran ordered).

**Returns**

- `arr` [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed, the same object is returned after being modified in-place to contain the appropriate values.

**scipy.sparse.dia_matrix.tobsr**

```python
dia_matrix.tobsr(self, blocksize=None, copy=False)
```

Convert this matrix to Block Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When `blocksize=(R, C)` is provided, it will be used for construction of the bsr_matrix.

**scipy.sparse.dia_matrix.tocoo**

```python
dia_matrix.tocoo(self, copy=False)
```

Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant coo_matrix.

**scipy.sparse.dia_matrix.tocsc**

```python
dia_matrix.tocsc(self, copy=False)
```

Convert this matrix to Compressed Sparse Column format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant csc_matrix.
scipy.sparse.dia_matrix.tocsr

dia_matrix.tocsr(self, copy=False)
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.dia_matrix.todense

dia_matrix.todense(self, order=None, out=None)
Return a dense matrix representation of this matrix.

Parameters
order : ['C', 'F'], optional
Whether to store multi-dimensional data in C (row-major) or For- tran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.

out : ndarray, 2-D, optional
If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns
arr : numpy.matrix, 2-D
A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

scipy.sparse.dia_matrix.todia

dia_matrix.todia(self, copy=False)
Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.dia_matrix.todok

dia_matrix.todok(self, copy=False)
Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.dia_matrix.tolil

dia_matrix.tolil(self, copy=False)
Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.
scipy.sparse.dia_matrix.transpose

dia_matrix.transpose (self, axes=None, copy=False)

Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [self with the dimensions reversed.]

See also:

numpy.matrix.transpose

NumPy's implementation of 'transpose' for matrices

scipy.sparse.dia_matrix.trunc

dia_matrix.trunc (self)

Element-wise trunc.

See numpy.trunc for more information.

scipy.sparse.dok_matrix

class scipy.sparse.dok_matrix (arg1, shape=None, dtype=None, copy=False)

Dictionary Of Keys based sparse matrix.

This is an efficient structure for constructing sparse matrices incrementally.

This can be instantiated in several ways:

dok_matrix(D)

with a dense matrix, D
dok_matrix(S)

with a sparse matrix, S
dok_matrix((M,N), [dtype])

create the matrix with initial shape (M,N) dtype is optional, defaulting to dtype='d'
Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Allows for efficient O(1) access of individual elements. Duplicates are not allowed. Can be efficiently converted to a coo_matrix once constructed.

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import dok_matrix
>>> S = dok_matrix((5, 5), dtype=np.float32)
>>> for i in range(5):
...     for j in range(5):
...         S[i, j] = i + j  # Update element
```

Attributes

- **dtype** [dtype] Data type of the matrix
- **ndim** [int] Number of dimensions (this is always 2)
- **nnz** Number of stored values, including explicit zeros.

Methods

- **__len__(self)** Return len(self).
- **__mul__(self, other)** interpret other and call one of the following
- **asformat(self, format[, copy])** Return this matrix in the passed format.
- **asfptype(self)** Upcast matrix to a floating point format (if necessary)
- **astype(self, dtype[, casting, copy])** Cast the matrix elements to a specified type.
- **clear()**
- **conj(self[, copy])** Element-wise complex conjugation.
- **conjugate(self[, copy])** Element-wise complex conjugation.
- **copy(self)** Returns a copy of this matrix.
- **count_nonzero(self)** Number of non-zero entries, equivalent to
- **diagonal(self[, k])** Returns the kth diagonal of the matrix.
- **dot(self, other)** Ordinary dot product
- **fromkeys(iterable[, value])** Create a new dictionary with keys from iterable and values set to value.
- **get(self, key[, default])** This overrides the dict.get method, providing type checking but otherwise equivalent functionality.
- **getH(self)** Return the Hermitian transpose of this matrix.
- **get_shape(self)** Get shape of a matrix.
- **getcol(self, j)** Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
- **getformat(self)** Format of a matrix representation as a string.
- **getmaxprint(self)** Maximum number of elements to display when printed.

</tr>
<tr>
<td><code>values()</code></td>
<td></td>
</tr>
</tbody>
</table>
```python
dok_matrix.__len__(self)
    Return len(self).

dok_matrix.__mul__(self, other)
    interpret other and call one of the following
    self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()

scipy.sparse.dok_matrix.asformat

dok_matrix.asformat(self, format, copy=False)
    Return this matrix in the passed format.

    Parameters
    format [{str, None}] The desired matrix format ("csr", "csc", "lil", "dok", "array", ...) or None
    for no conversion.
    copy [bool, optional] If True, the result is guaranteed to not share data with self.

    Returns
    A [This matrix in the passed format.]

scipy.sparse.dok_matrix.asfptype

dok_matrix.asfptype(self)
    Upcast matrix to a floating point format (if necessary)

scipy.sparse.dok_matrix.astype

dok_matrix.astype(self, dtype, casting='unsafe', copy=True)
    Cast the matrix elements to a specified type.

    Parameters
    dtype [string or numpy dtype] Typecode or data-type to which to cast the data.
    casting [{‘no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’}, optional] Controls what kind of data casting
    may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types
    should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’
    means only casts which can preserve values are allowed. ‘same_kind’ means only safe
    casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data
    conversions may be done.
    copy [bool, optional] If copy is False, the result might share some memory with this matrix.
    If copy is True, it is guaranteed that the result and this matrix do not share any memory.
```
scipy.sparse.dok_matrix.clear

dok_matrix.clear()

scipy.sparse.dok_matrix.conj

dok_matrix.conj(self, copy=True)
Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters

- copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

- A [The element-wise complex conjugate.]

scipy.sparse.dok_matrix.conjtransp

dok_matrix.conjtransp(self)
Return the conjugate transpose.

scipy.sparse.dok_matrix.conjugate

dok_matrix.conjugate(self, copy=True)
Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters

- copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

- A [The element-wise complex conjugate.]

scipy.sparse.dok_matrix.copy

dok_matrix.copy(self)
Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.
scipy.sparse.dok_matrix.count_nonzero

dok_matrix.count_nonzero(self)
   Number of non-zero entries, equivalent to
   np.count_nonzero(a.toarray())
   Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data
   attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.dok_matrix.diagonal

dok_matrix.diagonal(self, k=0)
   Returns the kth diagonal of the matrix.

   Parameters
   k [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0
   (the main diagonal).
   New in version 1.0.

   See also:

   numpy.diagonal

   Equivalent numpy function.

Examples

>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])

scipy.sparse.dok_matrix.dot

dok_matrix.dot(self, other)
   Ordinary dot product

Examples

>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
scipy.sparse.dok_matrix.fromkeys

dok_matrix.fromkeys(iterable, value=None)
Create a new dictionary with keys from iterable and values set to value.

scipy.sparse.dok_matrix.get

dok_matrix.get(self, key, default=0.0)
This overrides the dict.get method, providing type checking but otherwise equivalent functionality.

scipy.sparse.dok_matrix.getH

dok_matrix.getH(self)
Return the Hermitian transpose of this matrix.
See also:

numpy.matrix.getH
NumPy's implementation of getH for matrices

scipy.sparse.dok_matrix.get_shape

dok_matrix.get_shape(self)
Get shape of a matrix.

scipy.sparse.dok_matrix.getcol

dok_matrix.getcol(self, j)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.dok_matrix.getformat

dok_matrix.getformat(self)
Format of a matrix representation as a string.

scipy.sparse.dok_matrix.getmaxprint

dok_matrix.getmaxprint(self)
Maximum number of elements to display when printed.
scipy.sparse.dok_matrix.getnnz

dok_matrix.getnnz (self, axis=None)

Number of stored values, including explicit zeros.

Parameters

axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:

count_nonzero

Number of non-zero entries

scipy.sparse.dok_matrix.getrow

dok_matrix.getrow (self, i)

Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

scipy.sparse.dok_matrix.items

dok_matrix.items ()

scipy.sparse.dok_matrix.keys

dok_matrix.keys ()

scipy.sparse.dok_matrix.maximum

dok_matrix.maximum (self, other)

Element-wise maximum between this and another matrix.

scipy.sparse.dok_matrix.mean

dok_matrix.mean (self, axis=None, dtype=None, out=None)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters

axis [-2, -1, 0, 1, None] optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., axis = None).

dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype. New in version 0.18.0.
out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

m [np.matrix]

See also:

numpy.matrix.mean

NumPy’s implementation of ‘mean’ for matrices

scipy.sparse.dok_matrix.minimum

dok_matrix.minimum(self, other)
Element-wise minimum between this and another matrix.

scipy.sparse.dok_matrix.multiply

dok_matrix.multiply(self, other)
Point-wise multiplication by another matrix

scipy.sparse.dok_matrix.nonzero

dok_matrix.nonzero(self)
nonzero indices
Returns a tuple of arrays (row, col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.dok_matrix.pop

dok_matrix.pop()
If key is not found, d is returned if given, otherwise KeyError is raised
scipy.sparse.dok_matrix.popitem

dok_matrix.popitem()
    2-tuple; but raise KeyError if D is empty.

scipy.sparse.dok_matrix.power

dok_matrix.power(self, n, dtype=None)
    Element-wise power.

scipy.sparse.dok_matrix.reshape

dok_matrix.reshape(self, shape, order='C', copy=False)
    Gives a new shape to a sparse matrix without changing its data.

    Parameters
    ----------
    shape : [length-2 tuple of ints] The new shape should be compatible with the original shape.
    order : [{'C', 'F'}, optional] Read the elements using this index order. ‘C’ means to read and
            write the elements using C-like index order; e.g., read entire first row, then second row,
            etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read
            entire first column, then second column, etc.
    copy : [bool, optional] Indicates whether or not attributes of self should be copied whenever
           possible. The degree to which attributes are copied varies depending on the type of
           sparse matrix being used.

    Returns
    -------
    reshaped_matrix : [sparse matrix] A sparse matrix with the given shape, not necessarily of the same
                      format as the current object.

    See also:
    --------
    numpy.matrix.reshape
        NumPy's implementation of 'reshape' for matrices

scipy.sparse.dok_matrix.resize

dok_matrix.resize(self, *shape)
    Resize the matrix in-place to dimensions given by shape

    Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying
    outside the new shape are removed.

    Parameters
    ----------
    shape : [(int, int)] number of rows and columns in the new matrix
Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

```python
dok_matrix.set_shape(self, shape)
See reshape.
```

```python
dok_matrix.setdefault(self, key, default=None, /)

Insert key with a value of default if key is not in the dictionary.

Return the value for key if key is in the dictionary, else default.
```

```python
dok_matrix.setdiag(self, values, k=0)
Set diagonal or off-diagonal elements of the array.

Parameters

values [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.
If a scalar value is given, all of the diagonal is set to it.

k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).
```

```python
dok_matrix.sum(self, axis=None, dtype=None, out=None)
Sum the matrix elements over a given axis.

Parameters

axis [/-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., axis = None).

dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used.
New in version 0.18.0.
```
out   [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

New in version 0.18.0.

Returns

sum_along_axis   [np.matrix] A matrix with the same shape as self, with the specified axis removed.

See also:

numpy.matrix.sum

NumPy's implementation of 'sum' for matrices

scipy.sparse.dok_matrix.toarray

dok_matrix.toarray (self, order=None, out=None)

Return a dense ndarray representation of this matrix.

Parameters

order   [{'C', 'F'}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.

out   [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, out is required to be memory contiguous (either C or Fortran ordered).

Returns

arr   [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed, the same object is returned after being modified in-place to contain the appropriate values.

scipy.sparse.dok_matrix.tobsr

dok_matrix.tobsr (self, blocksize=None, copy=False)

Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

scipy.sparse.dok_matrix.tocoo

dok_matrix.tocoo (self, copy=False)

Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.
**scipy.sparse.dok_matrix.tocsc**

*dok_matrix.tocsc*(self, copy=False)

Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

**scipy.sparse.dok_matrix.tocsr**

*dok_matrix.tocsr*(self, copy=False)

Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

**scipy.sparse.dok_matrix.todense**

*dok_matrix.todense*(self, order=None, out=None)

Return a dense matrix representation of this matrix.

**Parameters**

order \[\{’C’, ’F’\}, optional\] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

out \[ndarray, 2-D, optional\] If specified, uses this array (or *numpy.matrix*) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**

arr \[numpy.matrix, 2-D\] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a *numpy.matrix*), it will be filled with the appropriate values and returned wrapped in a *numpy.matrix* object that shares the same memory.

**scipy.sparse.dok_matrix.todia**

*dok_matrix.todia*(self, copy=False)

Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

**scipy.sparse.dok_matrix.todok**

*dok_matrix.todok*(self, copy=False)

Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.
scipy.sparse.dok_matrix.tolil

dok_matrix.tolil(self, copy=False)

Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.dok_matrix.transpose

dok_matrix.transpose(self, axes=None, copy=False)

Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [self with the dimensions reversed.]

See also:

numpy.matrix.transpose

NumPy’s implementation of ‘transpose’ for matrices

scipy.sparse.dok_matrix.update

dok_matrix.update(self, val)

If E is present and has a .keys() method, then does: for k in E: D[k] = E[k] If E is present and lacks a .keys() method, then does: for k, v in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]

scipy.sparse.dok_matrix.values

dok_matrix.values()

__getitem__

scipy.sparse.lil_matrix

class scipy.sparse.lil_matrix(arg1, shape=None, dtype=None, copy=False)

Row-based list of list sparse matrix

This is a structure for constructing sparse matrices incrementally. Note that inserting a single item can take linear time in the worst case; to construct a matrix efficiently, make sure the items are pre-sorted by index, per row.

This can be instantiated in several ways:

lil_matrix(D)

with a dense matrix or rank-2 ndarray D

6.23. Sparse matrices (scipy.sparse)
lil_matrix(S)

    with another sparse matrix S (equivalent to S.tolil())

lil_matrix((M, N), [dtype])

    to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Advantages of the LIL format

• supports flexible slicing
• changes to the matrix sparsity structure are efficient

Disadvantages of the LIL format

• arithmetic operations LIL + LIL are slow (consider CSR or CSC)
• slow column slicing (consider CSC)
• slow matrix vector products (consider CSR or CSC)

Intended Usage

• LIL is a convenient format for constructing sparse matrices
• once a matrix has been constructed, convert to CSR or CSC format for fast arithmetic and matrix vector operations
• consider using the COO format when constructing large matrices

Data Structure

• An array (self.rows) of rows, each of which is a sorted list of column indices of non-zero elements.
• The corresponding nonzero values are stored in similar fashion in self.data.

Attributes

dtype [dtype] Data type of the matrix
ndim [int] Number of dimensions (this is always 2)
nnz Number of stored values, including explicit zeros.
data LIL format data array of the matrix
rows LIL format row index array of the matrix

</tbody>
</table>
scipy.sparse.lil_matrix.__len__

```
lil_matrix.__len__(self)
```

scipy.sparse.lil_matrix.__mul__

```
lil_matrix.__mul__(self, other)

interpret other and call one of the following

self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()
```

scipy.sparse.lil_matrix.asformat

```
lil_matrix.asformat(self, format, copy=False)

Return this matrix in the passed format.

Parameters

format [[str, None]] The desired matrix format ("csr", "csc", "lil", "dok", "array", ...) or None for no conversion.

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [This matrix in the passed format.]
```

scipy.sparse.lil_matrix.asfptype

```
lil_matrix.asfptype(self)

Upcast matrix to a floating point format (if necessary)
```

scipy.sparse.lil_matrix.astype

```
lil_matrix.astype(self, dtype, casting='unsafe', copy=True)

Cast the matrix elements to a specified type.

Parameters

dtype [string or numpy dtype] Typecode or data-type to which to cast the data.

casting [['no', 'equiv', 'safe', 'same_kind', 'unsafe'], optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.

copy [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.
**scipy.sparse.lil_matrix.conj**

_lil_matrix.conj(self, copy=True)_

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- **A** [The element-wise complex conjugate.]

**scipy.sparse.lil_matrix.conjugate**

_lil_matrix.conjugate(self, copy=True)_

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- **A** [The element-wise complex conjugate.]

**scipy.sparse.lil_matrix.copy**

_lil_matrix.copy(self)_

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

**scipy.sparse.lil_matrix.count_nonzero**

_lil_matrix.count_nonzero(self)_

Number of non-zero entries, equivalent to

np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.
scipy.sparse.lil_matrix.diagonal

lil_matrix.diagonal(self, k=0)
Returns the kth diagonal of the matrix.

Parameters

k [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
New in version 1.0.

See also:

numpy.diagonal
Equivalent numpy function.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

scipy.sparse.lil_matrix.dot

lil_matrix.dot(self, other)
Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.lil_matrix.getH

lil_matrix.getH(self)
Return the Hermitian transpose of this matrix.

See also:

numpy.matrix.getH
NumPy’s implementation of getH for matrices
scipy.sparse.lil_matrix.get_shape

```python
lil_matrix.get_shape(self)
```
Get shape of a matrix.

scipy.sparse.lil_matrix.getcol

```python
lil_matrix.getcol(self, j)
```
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.lil_matrix.getformat

```python
lil_matrix.getformat(self)
```
Format of a matrix representation as a string.

scipy.sparse.lil_matrix.getmaxprint

```python
lil_matrix.getmaxprint(self)
```
Maximum number of elements to display when printed.

scipy.sparse.lil_matrix.getnnz

```python
lil_matrix.getnnz(self, axis=None)
```
Number of stored values, including explicit zeros.

**Parameters**

- **axis** [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

- count_nonzero
  Number of non-zero entries

scipy.sparse.lil_matrix.getrow

```python
lil_matrix.getrow(self, i)
```
Returns a copy of the ‘i’th row.
scipy.sparse.lil_matrix.getrowview

lil_matrix.getrowview(self, i)
Returns a view of the ‘i’th row (without copying).

scipy.sparse.lil_matrix.maximum

lil_matrix.maximum(self, other)
Element-wise maximum between this and another matrix.

scipy.sparse.lil_matrix.mean

lil_matrix.mean(self, axis=None, dtype=None, out=None)
Compute the arithmetic mean along the specified axis.
Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters
axis 
[-2, -1, 0, 1, None] optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., axis = None).
dtype 
[data-type, optional] Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype.
New in version 0.18.0.
out 
[np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns
m 
[np.matrix]
See also:

numpy.matrix.mean
NumPy’s implementation of ‘mean’ for matrices

scipy.sparse.lil_matrix.minimum

lil_matrix.minimum(self, other)
Element-wise minimum between this and another matrix.
scipy.sparse.lil_matrix.multiply

lil_matrix.multiply(self, other)
Point-wise multiplication by another matrix

scipy.sparse.lil_matrix.nonzero

lil_matrix.nonzero(self)
nonzero indices
Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.lil_matrix.power

lil_matrix.power(self, n, dtype=None)
Element-wise power.

scipy.sparse.lil_matrix.reshape

lil_matrix.reshape(self, shape, order='C', copy=False)
Gives a new shape to a sparse matrix without changing its data.

Parameters

- shape [length-2 tuple of ints] The new shape should be compatible with the original shape.
- order [‘C’, ‘F’], optional) Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

- reshaped_matrix [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

- numpy.matrix.reshape
  NumPy’s implementation of ‘reshape’ for matrices.
scipy.sparse.lil_matrix.resize

lil_matrix.resize(self, *shape)

Resize the matrix in-place to dimensions given by shape

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

shape [(int, int)] number of rows and columns in the new matrix

Notes

The semantics are not identical to numpy.ndarray.resize or numpy.resize. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

scipy.sparse.lil_matrix.set_shape

lil_matrix.set_shape(self, shape)

See reshape.

scipy.sparse.lil_matrix.setdiag

lil_matrix.setdiag(self, values, k=0)

Set diagonal or off-diagonal elements of the array.

Parameters

values [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.
If a scalar value is given, all of the diagonal is set to it.

k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

scipy.sparse.lil_matrix.sum

lil_matrix.sum(self, axis=None, dtype=None, out=None)

Sum the matrix elements over a given axis.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., axis = None).
**dtype**  [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of `a` is used by default unless `a` has an integer dtype of less precision than the default platform integer. In that case, if `a` is signed then the platform integer is used while if `a` is unsigned then an unsigned integer of the same precision as the platform integer is used.

New in version 0.18.0.

**out**  [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

New in version 0.18.0.

**Returns**

**sum_along_axis**  [np.matrix] A matrix with the same shape as `self`, with the specified axis removed.

See also:

- **numpy.matrix.sum**
  NumPy's implementation of 'sum' for matrices

### scipy.sparse.lil_matrix.toarray

**lil_matrix.toarray** *(self, order=None, out=None)*

Return a dense ndarray representation of this matrix.

**Parameters**

- **order**  [{’C’, ’F’}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ’None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

- **out**  [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, `out` is required to be memory contiguous (either C or Fortran ordered).

**Returns**

- **arr**  [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed, the same object is returned after being modified in-place to contain the appropriate values.

### scipy.sparse.lil_matrix.tobsr

**lil_matrix.tobsr** *(self, blocksize=None, copy=False)*

Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.
`scipy.sparse.lil_matrix.tocoo`

```
lil_matrix.tocoo(self, copy=False)
```

Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

`scipy.sparse.lil_matrix.tocsc`

```
lil_matrix.tocsc(self, copy=False)
```

Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

`scipy.sparse.lil_matrix.tocsr`

```
lil_matrix.tocsr(self, copy=False)
```

Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

`scipy.sparse.lil_matrix.todense`

```
lil_matrix.todense(self, order=None, out=None)
```

Return a dense matrix representation of this matrix.

**Parameters**

*order*  
[{'C', 'F'}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

*out*  
[ndarray, 2-D, optional] If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**

*arr*  
`numpy.matrix`, 2-D A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

`scipy.sparse.lil_matrix.todia`

```
lil_matrix.todia(self, copy=False)
```

Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.
scipy.sparse.lil_matrix.todok

```
lil_matrix.todok(self, copy=False)
```
Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.lil_matrix.tolil

```
lil_matrix.tolil(self, copy=False)
```
Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.lil_matrix.transpose

```
lil_matrix.transpose(self, axes=None, copy=False)
```
Reverses the dimensions of the sparse matrix.

Parameters

- **axes**
  [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.

- **copy**
  [bool, optional] Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

- **p**
  [self with the dimensions reversed.]

See also:

- **numpy.matrix.transpose**
  NumPy’s implementation of ‘transpose’ for matrices

scipy.sparse.spmatrix

```
class scipy.sparse.spmatrix(maxprint=50)
```
This class provides a base class for all sparse matrices. It cannot be instantiated. Most of the work is provided by subclasses.

Attributes

- **nnz**
  Number of stored values, including explicit zeros.

- **shape**
  Get shape of a matrix.

</tbody>
</table>
scipy.sparse.spmatrix.__len__

spmatrix.__len__(self)

scipy.sparse.spmatrix.__mul__

spmatrix.__mul__(self, other)
   interpret other and call one of the following
   self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()

scipy.sparse.spmatrix.asformat

spmatrix.asformat(self, format, copy=False)
   Return this matrix in the passed format.

   Parameters
   format [[str, None]] The desired matrix format (“csr”, “csc”, “lil”, “dok”, “array”, …) or None
   for no conversion.
   copy [bool, optional] If True, the result is guaranteed to not share data with self.

   Returns
   A [This matrix in the passed format.]

scipy.sparse.spmatrix.asfptype

spmatrix.asfptype(self)
   Upcast matrix to a floating point format (if necessary)

scipy.sparse.spmatrix.astype

spmatrix.astype(self, dtype, casting='unsafe', copy=True)
   Cast the matrix elements to a specified type.

   Parameters
   dtype [string or numpy dtype] Typecode or data-type to which to cast the data.
   casting [{'no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’}, optional] Controls what kind of data casting may occur. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
   copy [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.
**scipy.sparse.spmatrix.conj**

```python
spmatrix.conj(self, copy=True)
```

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- `copy` [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- `A` [The element-wise complex conjugate.]

**scipy.sparse.spmatrix.conjugate**

```python
spmatrix.conjugate(self, copy=True)
```

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- `copy` [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- `A` [The element-wise complex conjugate.]

**scipy.sparse.spmatrix.copy**

```python
spmatrix.copy(self)
```

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

**scipy.sparse.spmatrix.count_nonzero**

```python
spmatrix.count_nonzero(self)
```

Number of non-zero entries, equivalent to

```python
np.count_nonzero(a.toarray())
```

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.
scipy.sparse.spmatrix.diagonal

```python
diagonal(self, k=0)
```

Returns the kth diagonal of the matrix.

**Parameters**

- **k** ([int, optional]) Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
  New in version 1.0.

**See also:**

- `numpy.diagonal`

Equivalent numpy function.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

scipy.sparse.spmatrix.dot

```python
dot(self, other)
```

Ordinary dot product.

**Examples**

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.spmatrix.getH

```python
getH(self)
```

Return the Hermitian transpose of this matrix.

**See also:**

- `numpy.matrix.getH`

NumPy’s implementation of `getH` for matrices.
scipy.sparse.spmatrix.get_shape

spmatrix.get_shape(self)
Get shape of a matrix.

scipy.sparse.spmatrix.getcol

spmatrix.getcol(self, j)
Returns a copy of column j of the matrix, as a (m x 1) sparse matrix (column vector).

scipy.sparse.spmatrix.getformat

spmatrix.getformat(self)
Format of a matrix representation as a string.

scipy.sparse.spmatrix.getmaxprint

spmatrix.getmaxprint(self)
Maximum number of elements to display when printed.

scipy.sparse.spmatrix.getnnz

spmatrix.getnnz(self, axis=None)
Number of stored values, including explicit zeros.
Parameters
axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:
count_nonzero
Number of non-zero entries

scipy.sparse.spmatrix.getrow

spmatrix.getrow(self, i)
Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
scipy.sparse.spmatrix.maximum

```python
spmatrix.maximum(self, other)
```

Element-wise maximum between this and another matrix.

scipy.sparse.spmatrix.mean

```python
spmatrix.mean(self, axis=None, dtype=None, out=None)
```

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. `float64` intermediate and return values are used for integer inputs.

**Parameters**

- `axis` : [-2, -1, 0, 1, None] optional
  - Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., `axis = None`).

- `dtype` : [data-type, optional]
  - Type to use in computing the mean. For integer inputs, the default is `float64`; for floating point inputs, it is the same as the input `dtype`. New in version 0.18.0.

- `out` : [np.matrix, optional]
  - Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

**Returns**

m : np.matrix

See also:

- `numpy.matrix.mean`
  - NumPy's implementation of ‘mean’ for matrices

scipy.sparse.spmatrix.minimum

```python
spmatrix.minimum(self, other)
```

Element-wise minimum between this and another matrix.

scipy.sparse.spmatrix.multiply

```python
spmatrix.multiply(self, other)
```

Point-wise multiplication by another matrix.
scipy.sparse.spmatrix.nonzero

```python
spmatrix.nonzero(self)
```

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```python
>>> import scipy.sparse
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.spmatrix.power

```python
spmatrix.power(self, n, dtype=None)
```

Element-wise power.

scipy.sparse.spmatrix.reshape

```python
spmatrix.reshape(self, shape, order='C', copy=False)
```

Gives a new shape to a sparse matrix without changing its data.

**Parameters**

- **shape** ([length-2 tuple of ints] The new shape should be compatible with the original shape.
- **order** ([{'C', 'F'}, optional] Read the elements using this index order. 'C' means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. 'F' means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- **copy** [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- **reshaped_matrix** [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

**See also:**

- **numpy.matrix.reshape**
    NumPy's implementation of 'reshape' for matrices
**scipy.sparse.spmatrix.resize**

```python
spmatrix.resize(self, shape)
```

Resize the matrix in-place to dimensions given by `shape`.

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

**Parameters**

- `shape` : [(int, int)] number of rows and columns in the new matrix

**Notes**

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

**scipy.sparse.spmatrix.set_shape**

```python
spmatrix.set_shape(self, shape)
```

See `reshape`.

**scipy.sparse.spmatrix.setdiag**

```python
spmatrix.setdiag(self, values, k=0)
```

Set diagonal or off-diagonal elements of the array.

**Parameters**

- `values` : [array_like] New values of the diagonal elements. Values may have any length. If the diagonal is longer than `values`, then the remaining diagonal entries will not be set. If `values` are longer than the diagonal, then the remaining values are ignored.

- `k` : [int, optional] Which off-diagonal to set, corresponding to elements `a[i,i+k]`. Default: 0 (the main diagonal).

**scipy.sparse.spmatrix.sum**

```python
spmatrix.sum(self, axis=None, dtype=None, out=None)
```

Sum the matrix elements over a given axis.

**Parameters**

- `axis` : [-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., `axis = None`).

---

6.23. Sparse matrices (`scipy.sparse`)
dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the
elements are summed. The dtype of a is used by default unless a has an integer dtype
of less precision than the default platform integer. In that case, if a is signed then the
platform integer is used while if a is unsigned then an unsigned integer of the same
precision as the platform integer is used.
New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have
the same shape as the expected output, but the type of the output values will be cast if
necessary.
New in version 0.18.0.

Returns

sum_along_axis [np.matrix] A matrix with the same shape as self, with the specified axis removed.

See also:

numpy.matrix.sum

NumPy's implementation of `sum` for matrices

scipy.sparse.spmatrix.toarray

spmatrix.toarray(self, order=None, out=None)

Return a dense ndarray representation of this matrix.

Parameters

order [{‘C’, ‘F’}, optional] Whether to store multidimensional data in C (row-major) or Fortran
(column-major) order in memory. The default is ‘None’, indicating the NumPy default
of C-ordered. Cannot be specified in conjunction with the out argument.

out [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of alloc-
ating a new array to return. The provided array must have the same shape and dtype
as the sparse matrix on which you are calling the method. For most sparse types, out is
required to be memory contiguous (either C or Fortran ordered).

Returns

arr [ndarray, 2-D] An array with the same shape and containing the same data represented
by the sparse matrix, with the requested memory order. If out was passed, the same
object is returned after being modified in-place to contain the appropriate values.

scipy.sparse.spmatrix.tobsr

spmatrix.tobsr(self, blocksize=None, copy=False)

Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.
scipy.sparse.spmatrix.tocoo

spmatrix.tocoo(self, copy=False)
Convert this matrix to COOrdinate format.
With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

scipy.sparse.spmatrix.tocsc

spmatrix.tocsc(self, copy=False)
Convert this matrix to Compressed Sparse Column format.
With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.spmatrix.tocsr

spmatrix.tocsr(self, copy=False)
Convert this matrix to Compressed Sparse Row format.
With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.spmatrix.todense

spmatrix.todense(self, order=None, out=None)
Return a dense matrix representation of this matrix.

Parameters

order [{‘C’, ‘F’}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.

out [ndarray, 2-D, optional] If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

arr [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

scipy.sparse.spmatrix.todia

spmatrix.todia(self, copy=False)
Convert this matrix to sparse DIAgonal format.
With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.
**scipy.sparse.spmatrix.todok**

```python
spmatrix.todok(self, copy=False)
```

Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

**scipy.sparse.spmatrix.tolil**

```python
spmatrix.tolil(self, copy=False)
```

Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

**scipy.sparse.spmatrix.transpose**

```python
spmatrix.transpose(self, axes=None, copy=False)
```

Reverses the dimensions of the sparse matrix.

**Parameters**

- `axes` [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
- `copy` [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- `p` [self with the dimensions reversed.]

**See also:**

- `numpy.matrix.transpose`
  NumPy’s implementation of ‘transpose’ for matrices

### Functions

Building sparse matrices:

- `eye(m[, n, k, dtype, format])` Sparse matrix with ones on diagonal
- `identity(n[, dtype, format])` Identity matrix in sparse format
- `kron(A, B[, format])` Kronecker product of sparse matrices A and B
- `kronsum(A, B[, format])` Kronecker sum of sparse matrices A and B
- `diags(diagonals[, offsets, shape, format, dtype])` Construct a sparse matrix from diagonals.
- `spdiags(data, diags, m, n[, format])` Return a sparse matrix from diagonals.
- `block_diag(mats[, format, dtype])` Build a block diagonal sparse matrix from provided matrices.
- `tril(A[, k, format])` Return the lower triangular portion of a matrix in sparse format
- `triu(A[, k, format])` Return the upper triangular portion of a matrix in sparse format

### scipy.sparse.eye

**scipy.sparse.eye** *(m, n=None, k=0, dtype=class 'float', format=None)*

Sparse matrix with ones on diagonal

Returns a sparse (m x n) matrix where the kth diagonal is all ones and everything else is zeros.

**Parameters**

- **m** [int] Number of rows in the matrix.
- **n** [int, optional] Number of columns. Default: m.
- **k** [int, optional] Diagonal to place ones on. Default: 0 (main diagonal).
- **dtype** [dtype, optional] Data type of the matrix.
- **format** [str, optional] Sparse format of the result, e.g., format="csr", etc.

**Examples**

```python
>>> from scipy import sparse
>>> sparse.eye(3).toarray()
array([[ 1., 0., 0.],
       [ 0., 1., 0.],
       [ 0., 0., 1.]])
>>> sparse.eye(3, dtype=np.int8)
<3x3 sparse matrix of type '<class 'numpy.int8'>'
with 3 stored elements (1 diagonals) in DIAgonal format>
```

### scipy.sparse.identity

**scipy.sparse.identity** *(n, dtype='d', format=None)*

Identity matrix in sparse format

Returns an identity matrix with shape (n,n) using a given sparse format and dtype.

**Parameters**

- **n** [int] Shape of the identity matrix.
- **dtype** [dtype, optional] Data type of the matrix
- **format** [str, optional] Sparse format of the result, e.g., format="csr", etc.
Examples

```python
>>> from scipy.sparse import identity
>>> identity(3).toarray()
array([[ 1.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.]])
>>> identity(3, dtype='int8', format='dia')
<3x3 sparse matrix of type '<class 'numpy.int8'>'
     with 3 stored elements (1 diagonals) in DIAgonal format>
```

**scipy.sparse.kron**

**scipy.sparse.kron** (*A, B, format=None*)

Kronecker product of sparse matrices *A* and *B*

**Parameters**

- **A**  
  [sparse or dense matrix] first matrix of the product

- **B**  
  [sparse or dense matrix] second matrix of the product

- **format**  
  [str, optional] format of the result (e.g. “csr”)

**Returns**

Kronecker product in a sparse matrix format

**Examples**

```python
>>> from scipy import sparse
>>> A = sparse.csr_matrix(np.array([[0, 2], [5, 0]]))
>>> B = sparse.csr_matrix(np.array([[1, 2], [3, 4]]))
>>> sparse.kron(A, B).toarray()
array([[ 0,  0,  2,  4],
       [ 0,  0,  6,  8],
       [ 5, 10,  0,  0],
       [15, 20,  0,  0]])
```

```python
>>> sparse.kron(A, [[1, 2], [3, 4]]).toarray()
array([[ 0,  0,  2,  4],
       [ 0,  0,  6,  8],
       [ 5, 10,  0,  0],
       [15, 20,  0,  0]])
```

**scipy.sparse.kronsum**

**scipy.sparse.kronsum** (*A, B, format=None*)

Kronecker sum of sparse matrices *A* and *B*

Kronecker sum of two sparse matrices is a sum of two Kronecker products kron(I_n,A) + kron(B,I_m) where *A* has shape (m,m) and *B* has shape (n,n) and I_m and I_n are identity matrices of shape (m,m) and (n,n), respectively.

**Parameters**

- **A**  
  square matrix

- **B**  
  square matrix

- **format**  
  [str] format of the result (e.g. “csr”)

2142 Chapter 6. API Reference
Returns

Kronecker sum in a sparse matrix format

```python
scipy.sparse.diags(diagonals, offsets=0, shape=None, format=None, dtype=None)
```

Construct a sparse matrix from diagonals.

Parameters

- `diagonals` [sequence of array_like] Sequence of arrays containing the matrix diagonals, corresponding to `offsets`.
- `offsets` [sequence of int or an int, optional]
  - Diagonals to set:
    - k = 0 the main diagonal (default)
    - k > 0 the kth upper diagonal
    - k < 0 the kth lower diagonal
- `shape` [tuple of int, optional] Shape of the result. If omitted, a square matrix large enough to contain the diagonals is returned.
- `format` ["{"dia", "csr", "csc", "lil", ...}, optional] Matrix format of the result. By default (format=None) an appropriate sparse matrix format is returned. This choice is subject to change.
- `dtype` [dtype, optional] Data type of the matrix.

See also:

- `spdiags`
  - construct matrix from diagonals

Notes

This function differs from `spdiags` in the way it handles off-diagonals.

The result from `diags` is the sparse equivalent of:

```python
np.diag(diagonals[0], offsets[0])
+ ...
+ np.diag(diagonals[k], offsets[k])
```

Repeated diagonal offsets are disallowed.

New in version 0.11.

Examples

```python
>>> from scipy.sparse import diags
>>> diagonals = [[1, 2, 3, 4], [1, 2, 3], [1, 2]]
>>> diags(diagonals, [0, -1, 2]).toarray()
array([[1, 0, 1, 0],
       [1, 2, 0, 2],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
```

Broadcasting of scalars is supported (but shape needs to be specified):
```python
>>> diags([1, -2, 1], [-1, 0, 1], shape=(4, 4)).toarray()
array([[-2.,  1.,  0.,  0.],
       [ 1., -2.,  1.,  0.],
       [ 0.,  1., -2.,  1.],
       [ 0.,  0.,  1., -2.]]
```

If only one diagonal is wanted (as in `numpy.diag`), the following works as well:

```python
>>> diags([1, 2, 3], 1).toarray()
array([[ 0.,  1.,  0.,  0.],
       [ 0.,  0.,  2.,  0.],
       [ 0.,  0.,  0.,  3.],
       [ 0.,  0.,  0.,  0.]]
```

**scipy.sparse.spdiags**

`scipy.sparse.spdiags(data, diags, m, n, format=None)`

Return a sparse matrix from diagonals.

**Parameters**

- **data** [array_like] matrix diagonals stored row-wise
- **diags** [diagonals to set]
  - `k=0` the main diagonal
  - `k>0` the k-th upper diagonal
  - `k<0` the k-th lower diagonal
- **m, n** [int] shape of the result
- **format** [str, optional] Format of the result. By default (format=None) an appropriate sparse matrix format is returned. This choice is subject to change.

**See also:**

- `diags` more convenient form of this function
- `dia_matrix` the sparse DIAgonal format.

**Examples**

```python
>>> from scipy.sparse import spdiags
>>> data = np.array([[1, 2, 3, 4], [1, 2, 3, 4], [1, 2, 3, 4]])
>>> diags = np.array([0, -1, 2])
>>> spdiags(data, diags, 4, 4).toarray()
array([[1, 0, 3, 0],
       [1, 2, 0, 4],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
```
scipy.sparse.block_diag

scipy.sparse.block_diag(mats, format=None, dtype=None)

Build a block diagonal sparse matrix from provided matrices.

Parameters

mats [sequence of matrices] Input matrices.
format [str, optional] The sparse format of the result (e.g., “csr”). If not given, the matrix is returned in “coo” format.
dtype [dtype specifier, optional] The data-type of the output matrix. If not given, the dtype is determined from that of blocks.

Returns

res [sparse matrix]

See also:
bmat, diags

Notes

New in version 0.11.0.

Examples

```python
>>> from scipy.sparse import coo_matrix, block_diag
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> C = coo_matrix([[7]])
>>> block_diag((A, B, C)).toarray()
array([[1, 2, 0, 0],
       [3, 4, 0, 0],
       [0, 0, 5, 0],
       [0, 0, 6, 0],
       [0, 0, 0, 7]])
```

scipy.sparse.tril

scipy.sparse.tril(A, k=0, format=None)

Return the lower triangular portion of a matrix in sparse format

Returns the elements on or below the k-th diagonal of the matrix A.

- k = 0 corresponds to the main diagonal
- k > 0 is above the main diagonal
- k < 0 is below the main diagonal

Parameters

A [dense or sparse matrix] Matrix whose lower triangular portion is desired.
k [integer] The top-most diagonal of the lower triangle.
format [string] Sparse format of the result, e.g. format=”csr”, etc.

Returns
L [sparse matrix] Lower triangular portion of A in sparse format.

See also:

\texttt{triu}

upper triangle in sparse format

\textbf{Examples}

\begin{verbatim}
>>> from scipy.sparse import csr_matrix, tril
>>> A = csr_matrix([[1, 2, 0, 0, 3], [4, 5, 0, 6, 7], [0, 0, 8, 9, 0]],
                  dtype='int32')
>>> A.toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> tril(A).toarray()
array([[1, 0, 0, 0, 0],
       [4, 5, 0, 0, 0],
       [0, 0, 8, 0, 0]])
>>> tril(A).nnz
4
>>> tril(A, k=1).toarray()
array([[1, 2, 0, 0, 0],
       [4, 5, 0, 0, 0],
       [0, 0, 8, 9, 0]])
>>> tril(A, k=-1).toarray()
array([[0, 0, 0, 0, 0],
       [4, 0, 0, 0, 0],
       [0, 0, 0, 0, 0]])
>>> tril(A, format='csc')
<3x5 sparse matrix of type '<class 'numpy.int32'>'
  with 4 stored elements in Compressed Sparse Column format>
\end{verbatim}

\texttt{scipy.sparse.triu}

\texttt{scipy.sparse.triu}(A, k=0, format=None)

Return the upper triangular portion of a matrix in sparse format

\textit{Returns the elements on or above the k-th diagonal of the matrix A.}

\begin{itemize}
  \item k = 0 corresponds to the main diagonal
  \item k > 0 is above the main diagonal
  \item k < 0 is below the main diagonal
\end{itemize}

\textbf{Parameters}

\begin{itemize}
  \item A [dense or sparse matrix] Matrix whose upper triangular portion is desired.
  \item k [integer] The bottom-most diagonal of the upper triangle.
  \item format [string] Sparse format of the result, e.g. format=”csr”, etc.
\end{itemize}

\textbf{Returns}
L  [sparse matrix] Upper triangular portion of A in sparse format.

See also:

tril

lower triangle in sparse format

Examples

```python
>>> from scipy.sparse import csr_matrix, triu
>>> A = csr_matrix([[1, 2, 0, 0, 3], [4, 5, 0, 6, 7], [0, 0, 8, 9, 0]],
                 dtype='int32')
>>> A.toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A).toarray()
array([[1, 2, 0, 0, 3],
       [0, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A).nnz
8
>>> triu(A, k=1).toarray()
array([[0, 2, 0, 0, 3],
       [0, 0, 0, 6, 7],
       [0, 0, 0, 9, 0]])
>>> triu(A, k=-1).toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A, format='csc')
<3x5 sparse matrix of type '<class 'numpy.int32'>'
  with 8 stored elements in Compressed Sparse Column format>
```

scipy.sparse.bmat

scipy.sparse.bmat (blocks, format=None, dtype=None)
Build a sparse matrix from sparse sub-blocks

Parameters

blocks [array_like] Grid of sparse matrices with compatible shapes. An entry of None implies an all-zero matrix.
format [{‘bsr’, ‘coo’, ‘csc’, ‘csr’, ‘dia’, ‘dok’, ‘lil’}, optional] The sparse format of the result (e.g. “csr”). By default an appropriate sparse matrix format is returned. This choice is subject to change.
dtype [dtype, optional] The data-type of the output matrix. If not given, the dtype is determined from that of blocks.

Returns

bmat [sparse matrix]

See also:

block_diag, diags
Examples

```python
>>> from scipy.sparse import coo_matrix, bmat
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> C = coo_matrix([[7]])
>>> bmat([[A, B], [None, C]]).toarray()
array([[1, 2, 5],
       [3, 4, 6],
       [0, 0, 7]])
>>> bmat([[A, None], [None, C]]).toarray()
array([[1, 2, 0],
       [3, 4, 0],
       [0, 0, 7]])
```

**scipy.sparse.hstack**

**scipy.sparse.hstack** *(blocks, format=None, dtype=None)*

Stack sparse matrices horizontally (column wise)

**Parameters**

- **blocks**: sequence of sparse matrices with compatible shapes
- **format**: [str] sparse format of the result (e.g., “csr”) by default an appropriate sparse matrix format is returned. This choice is subject to change.
- **dtype**: [dtype, optional] The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

**See also:**

**vstack**

stack sparse matrices vertically (row wise)

Examples

```python
>>> from scipy.sparse import coo_matrix, hstack
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> hstack([A, B]).toarray()
array([[1, 2, 5],
       [3, 4, 6]])
```

**scipy.sparse.vstack**

**scipy.sparse.vstack** *(blocks, format=None, dtype=None)*

Stack sparse matrices vertically (row wise)

**Parameters**

- **blocks**: sequence of sparse matrices with compatible shapes
- **format**: [str, optional] sparse format of the result (e.g., “csr”) by default an appropriate sparse matrix format is returned. This choice is subject to change.

**Examples**

```python
>>> from scipy.sparse import coo_matrix, vstack
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> vstack([A, B]).toarray()
array([[1, 2, 5],
       [3, 4, 6]])
```
**dtype**  [dtype, optional] The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

See also:

**hstack**

stack sparse matrices horizontally (column wise)

**Examples**

```python
>>> from scipy.sparse import coo_matrix, vstack
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5, 6]])
>>> vstack([A, B]).toarray()
array([[1, 2],
       [3, 4],
       [5, 6]])
```

**scipy.sparse.rand**

**scipy.sparse.rand** (*m*, *n*, *density=0.01*, *format='coo'*, *dtype=None*, *random_state=None*)

Generate a sparse matrix of the given shape and density with uniformly distributed values.

**Parameters**

- **m, n**  [int] shape of the matrix
- **density**  [real, optional] density of the generated matrix: density equal to one means a full matrix, density of 0 means a matrix with no non-zero items.
- **format**  [str, optional] sparse matrix format.
- **dtype**  [dtype, optional] type of the returned matrix values.
- **random_state**  [{numpy.random.RandomState, int, np.random.Generator}, optional] Random number generator or random seed. If not given, the singleton numpy.random will be used.

**Returns**

- **res**  [sparse matrix]

See also:

**scipy.sparse.random**

Similar function that allows a user-specified random data source.

**Notes**

Only float types are supported for now.
Examples

```python
>>> from scipy.sparse import rand
>>> matrix = rand(3, 4, density=0.25, format="csr", random_state=42)
>>> matrix
<3x4 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in Compressed Sparse Row format>
>>> matrix.todense()
matrix([[0.05641158, 0. , 0. , 0.65088847],
        [0. , 0. , 0. , 0.14286682],
        [0. , 0. , 0. , 0. ]])
```

scipy.sparse.random

`scipy.sparse.random(m, n, density=0.01, format='coo', dtype=None, random_state=None, data_rvs=None)`

Generate a sparse matrix of the given shape and density with randomly distributed values.

**Parameters**

- `m, n` [int] shape of the matrix
- `density` [real, optional] density of the generated matrix: density equal to one means a full matrix, density of 0 means a matrix with no non-zero items.
- `format` [str, optional] sparse matrix format.
- `dtype` [dtype, optional] type of the returned matrix values.
- `random_state` [[numpy.random.RandomState, int], optional] Random number generator or random seed. If not given, the singleton `numpy.random` will be used. This random state will be used for sampling the sparsity structure, but not necessarily for sampling the values of the structurally nonzero entries of the matrix.
- `data_rvs` [callable, optional] Samples a requested number of random values. This function should take a single argument specifying the length of the ndarray that it will return. The structurally nonzero entries of the sparse random matrix will be taken from the array sampled by this function. By default, uniform (0, 1) random values will be sampled using the same random state as is used for sampling the sparsity structure.

**Returns**

- `res` [sparse matrix]

**Notes**

Only float types are supported for now.

Examples

```python
>>> from scipy.sparse import random
>>> from scipy import stats

>>> class CustomRandomState(np.random.RandomState):
...     def randint(self, k):
...         i = np.random.randint(k)
...         return i - i % 2
```
>>> np.random.seed(12345)
>>> rs = CustomRandomState()
>>> rvs = stats.poisson(25, loc=10).rvs
>>> S = random(3, 4, density=0.25, random_state=rs, data_rvs=rvs)
>>> S.A
array([[36.,  0., 33.,  0.],
       [ 0.,  0.,  0.,  0.],
       [ 0.,  0.36,  0.,  0.]], 
     # random

>>> from scipy.sparse import random
>>> from scipy.stats import rv_continuous
>>> class CustomDistribution(rv_continuous):
...     def _rvs(self, size=None, random_state=None):
...         return random_state.randn(*size)
>>> X = CustomDistribution(seed=2906)
>>> Y = X()  # get a frozen version of the distribution
>>> S = random(3, 4, density=0.25, random_state=2906, data_rvs=Y.rvs)
>>> S.A
array([[ 0.  ,  0.  ,  0.  ,  0.  ],
       [ 0.13569738,  1.9467163 , -0.81205367,  0.  ],
       [ 0.  ,  0.  ,  0.  ,  0.  ]])

Save and load sparse matrices:

**save_npz**

```
scipy.sparse.save_npz(file, matrix[, compressed])
```

Save a sparse matrix to a file using .npz format.

**load_npz**

```
scipy.sparse.load_npz(file)
```

Load a sparse matrix from a file using .npz format.

**scipy.sparse.save_npz**

```
scipy.sparse.save_npz (file, matrix, compressed=True)
```

Save a sparse matrix to a file using .npz format.

**Parameters**

- **file**
  
  [str or file-like object] Either the file name (string) or an open file (file-like object) where the data will be saved. If file is a string, the .npz extension will be appended to the file name if it is not already there.

- **matrix**
  
  **spmatrix (format: \`\`csc\`\`, \`\`csr\`\`, \`\`bsr\`\`, \`\`dia\`\` or \`\`coo\`\`)**

  The sparse matrix to save.

- **compressed**

  [bool, optional] Allow compressing the file. Default: True

**See also:**

**scipy.sparse.load_npz**

Load a sparse matrix from a file using .npz format.

**numpy.savez**

Save several arrays into a .npz archive.

**numpy.savez_compressed**

Save several arrays into a compressed .npz archive.
Examples

Store sparse matrix to disk, and load it again:

```python
>>> import scipy.sparse
>>> sparse_matrix = scipy.sparse.csc_matrix(np.array([[0, 0, 3],
                                                    [4, 0, 0]]))
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
  with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)
>>> scipy.sparse.save_npz('/tmp/sparse_matrix.npz', sparse_matrix)
>>> sparse_matrix = scipy.sparse.load_npz('/tmp/sparse_matrix.npz')
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
  with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)
```

**scipy.sparse.load_npz**

`scipy.sparse.load_npz(file)`

Load a sparse matrix from a file using .npz format.

**Parameters**

- file: [str or file-like object] Either the file name (string) or an open file (file-like object) where the data will be loaded.

**Returns**

- result: [csc_matrix, csr_matrix, bsr_matrix, dia_matrix or coo_matrix] A sparse matrix containing the loaded data.

**Raises**

- IOError: If the input file does not exist or cannot be read.

See also:

**scipy.sparse.save_npz**

Save a sparse matrix to a file using .npz format.

**numpy.load**

Load several arrays from a .npz archive.
Examples

Store sparse matrix to disk, and load it again:

```python
>>> import scipy.sparse
>>> sparse_matrix = scipy.sparse.csc_matrix(np.array([[0, 0, 3], [4, 0, -0]]))
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
  with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)
>>> scipy.sparse.save_npz('/tmp/sparse_matrix.npz', sparse_matrix)
>>> sparse_matrix = scipy.sparse.load_npz('/tmp/sparse_matrix.npz')
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
  with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)
```

Sparse matrix tools:

```plaintext
find(A) Return the indices and values of the nonzero elements of a matrix
```

**scipy.sparse.find**

**scipy.sparse.find(A)**

Return the indices and values of the nonzero elements of a matrix

**Parameters**

- **A** [dense or sparse matrix] Matrix whose nonzero elements are desired.

**Returns**

- **(I,J,V)** [tuple of arrays] I, J, and V contain the row indices, column indices, and values of the nonzero matrix entries.

**Examples**

```python
>>> from scipy.sparse import csr_matrix, find
>>> A = csr_matrix([[7.0, 8.0, 0], [0, 0, 9.0]])
>>> find(A)
(array([0, 0, 1], dtype=int32), array([0, 1, 2], dtype=int32), array([7., 8., 9.]))
```

Identifying sparse matrices:
**issparse(x)**
Is x of a sparse matrix type?

**isspmatrix(x)**
Is x of a sparse matrix type?

**isspmatrix_csc(x)**
Is x of csc_matrix type?

**isspmatrix_csr(x)**
Is x of csr_matrix type?

**isspmatrix_bsr(x)**
Is x of bsr_matrix type?

**isspmatrix_lil(x)**
Is x of lil_matrix type?

**isspmatrix_dok(x)**
Is x of dok_matrix type?

**isspmatrix_coo(x)**
Is x of coo_matrix type?

**isspmatrixDia(x)**
Is x of dia_matrix type?

### scipy.sparse.issparse

scipy.sparse.issparse(x)
Is x of a sparse matrix type?

**Parameters**
- x: object to check for being a sparse matrix

**Returns**
- bool: True if x is a sparse matrix, False otherwise

**Notes**

issparse and isspmatrix are aliases for the same function.

**Examples**

```python
>>> from scipy.sparse import csr_matrix, isspmatrix
>>> isspmatrix(csr_matrix([[5]]))
True
```

```python
>>> from scipy.sparse import isspmatrix
>>> isspmatrix(5)
False
```

### scipy.sparse.isspmatrix

scipy.sparse.isspmatrix(x)
Is x of a sparse matrix type?

**Parameters**
- x: object to check for being a sparse matrix

**Returns**
- bool: True if x is a sparse matrix, False otherwise

---

2154 Chapter 6. API Reference
Notes

issparse and isspmatrix are aliases for the same function.

Examples

```python
>>> from scipy.sparse import csr_matrix, isspmatrix
>>> isspmatrix(csr_matrix([[5]]))
True

>>> from scipy.sparse import isspmatrix
>>> isspmatrix(5)
False
```

scipy.sparse.isspmatrix_csc

```python
def isspmatrix_csc(x):
    
    Parameters
    ----------
    x : object
        object to check for being a csc matrix

    Returns
    -------
    bool : True if x is a csc matrix, False otherwise
```

Examples

```python
>>> from scipy.sparse import csc_matrix, isspmatrix_csc
>>> isspmatrix_csc(csc_matrix([[5]]))
True

>>> from scipy.sparse import csc_matrix, csr_matrix, isspmatrix_csc
>>> isspmatrix_csc(csr_matrix([[5]]))
False
```

scipy.sparse.isspmatrix_csr

```python
def isspmatrix_csr(x):
    
    Parameters
    ----------
    x : object
        object to check for being a csr matrix

    Returns
    -------
    bool : True if x is a csr matrix, False otherwise
```
Examples

```python
>>> from scipy.sparse import csr_matrix, isspmatrix_csr
>>> isspmatrix_csr(csr_matrix([[5]]))
True

>>> from scipy.sparse import csc_matrix, csr_matrix, isspmatrix_csc
>>> isspmatrix_csr(csc_matrix([5]))
False
```

`scipy.sparse.isspmatrix_bsr`

`scipy.sparse.isspmatrix_bsr(x)`
Is x of a bsr_matrix type?

Parameters

- `x` : object to check for being a bsr matrix

Returns

- `bool` : True if x is a bsr matrix, False otherwise

Examples

```python
>>> from scipy.sparse import bsr_matrix, isspmatrix_bsr
>>> isspmatrix_bsr(bsr_matrix([5]))
True

>>> from scipy.sparse import bsr_matrix, csr_matrix, isspmatrix_bsr
>>> isspmatrix_bsr(csr_matrix([5]))
False
```

`scipy.sparse.isspmatrix_lil`

`scipy.sparse.isspmatrix_lil(x)`
Is x of lil_matrix type?

Parameters

- `x` : object to check for being a lil matrix

Returns

- `bool` : True if x is a lil matrix, False otherwise
Examples

```python
>>> from scipy.sparse import lil_matrix, isspmatrix_lil
>>> isspmatrix_lil(lil_matrix([[5]]))
True

>>> from scipy.sparse import lil_matrix, csr_matrix, isspmatrix_lil
>>> isspmatrix_lil(csr_matrix([[5]]))
False
```

**scipy.sparse.isspmatrix_dok**

`scipy.sparse.isspmatrix_dok(x)`

Is x of dok_matrix type?

*Parameters*

- `x` : object to check for being a dok matrix

*Returns*

- `bool` : True if x is a dok matrix, False otherwise

Examples

```python
>>> from scipy.sparse import dok_matrix, isspmatrix_dok
>>> isspmatrix_dok(dok_matrix([[5]]))
True

>>> from scipy.sparse import dok_matrix, csr_matrix, isspmatrix_dok
>>> isspmatrix_dok(csr_matrix([[5]]))
False
```

**scipy.sparse.isspmatrix_coo**

`scipy.sparse.isspmatrix_coo(x)`

Is x of coo_matrix type?

*Parameters*

- `x` : object to check for being a coo matrix

*Returns*

- `bool` : True if x is a coo matrix, False otherwise
Examples

```python
>>> from scipy.sparse import coo_matrix, isspmatrix_coo
>>> isspmatrix_coo(coo_matrix([[5]]))
True

>>> from scipy.sparse import coo_matrix, csr_matrix, isspmatrix_coo
>>> isspmatrix_coo(csr_matrix([[5]]))
False
```

`scipy.sparse.isspmatrix_coo`

`scipy.sparse.isspmatrix_coo(x)`
Is x of coo_matrix type?

**Parameters**
- `x`: object to check for being a coo matrix

**Returns**
- `bool`: True if x is a coo matrix, False otherwise

Examples

```python
>>> from scipy.sparse import dia_matrix, isspmatrix_coo
>>> isspmatrix_coo(dia_matrix([[5]]))
True

>>> from scipy.sparse import dia_matrix, csr_matrix, isspmatrix_coo
>>> isspmatrix_coo(csr_matrix([[5]]))
False
```

### 6.23.2 Usage information

There are seven available sparse matrix types:

1. `csc_matrix`: Compressed Sparse Column format
2. `csr_matrix`: Compressed Sparse Row format
3. `bsr_matrix`: Block Sparse Row format
4. `lil_matrix`: List of Lists format
5. `dok_matrix`: Dictionary of Keys format
6. `coo_matrix`: COOrdinate format (aka IJV, triplet format)
7. `dia_matrix`: DIAgonal format

To construct a matrix efficiently, use either `dok_matrix` or `lil_matrix`. The `lil_matrix` class supports basic slicing and fancy indexing with a similar syntax to NumPy arrays. As illustrated below, the COO format may also be used to efficiently construct matrices. Despite their similarity to NumPy arrays, it is strongly discouraged to use NumPy functions directly on these matrices because NumPy may not properly convert them for computations, leading to unexpected (and incorrect) results. If you do want to apply a NumPy function to these matrices, first check if SciPy has its own implementation for the given sparse matrix class, or convert the sparse matrix to a NumPy array (e.g., using the `toarray()` method of the class) first before applying the method.

To perform manipulations such as multiplication or inversion, first convert the matrix to either CSC or CSR format. The `lil_matrix` format is row-based, so conversion to CSR is efficient, whereas conversion to CSC is less so.

All conversions among the CSR, CSC, and COO formats are efficient, linear-time operations.

### Matrix vector product

To do a vector product between a sparse matrix and a vector simply use the matrix `dot` method, as described in its docstring:

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```
**Warning:** As of NumPy 1.7, \textit{np.dot} is not aware of sparse matrices, therefore using it will result in unexpected results or errors. The corresponding dense array should be obtained first instead:

```python
>>> np.dot(A.toarray(), v)
array([ 1, -3, -1], dtype=int64)
```

but then all the performance advantages would be lost.

The CSR format is specially suitable for fast matrix vector products.

**Example 1**

Construct a 1000x1000 \texttt{lil\_matrix} and add some values to it:

```python
>>> from scipy.sparse import lil_matrix
>>> from scipy.sparse.linalg import spsolve
>>> from numpy.linalg import solve, norm
>>> from numpy.random import rand

>>> A = lil_matrix((1000, 1000))
>>> A[0, :100] = rand(100)
>>> A[1, 100:200] = A[0, :100]
>>> A.setdiag(rand(1000))
```

Now convert it to CSR format and solve \(Ax = b\) for \(x\):

```python
>>> A = A.tocsr()
>>> b = rand(1000)
>>> x = spsolve(A, b)
```

Convert it to a dense matrix and solve, and check that the result is the same:

```python
>>> x_ = solve(A.toarray(), b)
```

Now we can compute norm of the error with:

```python
>>> err = norm(x-x_)
>>> err < 1e-10
True
```

It should be small :)  

**Example 2**

Construct a matrix in COO format:

```python
>>> from scipy import sparse
>>> from numpy import array

>>> I = array([0,3,1,0])
>>> J = array([0,3,1,2])
>>> V = array([4,5,7,9])
>>> A = sparse.coo_matrix((V, (I,J)), shape=(4,4))
```
Notice that the indices do not need to be sorted.
Duplicate (i,j) entries are summed when converting to CSR or CSC.

```python
>>> I = array([0,0,1,3,1,0,0])
>>> J = array([0,2,1,3,1,0,0])
>>> V = array([[1,1,1,1,1,1]])
>>> B = sparse.coo_matrix((V,(I,J)),shape=(4,4)).tocsr()
```

This is useful for constructing finite-element stiffness and mass matrices.

**Further details**

CSR column indices are not necessarily sorted. Likewise for CSC row indices. Use the .sorted_indices() and .sort_indices() methods when sorted indices are required (e.g., when passing data to other libraries).

### 6.24 Sparse linear algebra (scipy.sparse.linalg)

#### 6.24.1 Abstract linear operators

```python
class scipy.sparse.linalg.LinearOperator(*args, **kwargs)
```

Common interface for performing matrix vector products

```python
aslinearoperator(A)
```

Return A as a LinearOperator.

The `scipy.sparse.linalg.LinearOperator` class provides a common interface for performing matrix vector products. Many iterative methods (e.g., cg, gmres) do not need to know the individual entries of a matrix to solve a linear system $A \cdot x = b$. Such solvers only require the computation of matrix vector products, $A \cdot v$ where $v$ is a dense vector. This class serves as an abstract interface between iterative solvers and matrix-like objects.

To construct a concrete `LinearOperator`, either pass appropriate callables to the constructor of this class, or subclass it. A subclass must implement either one of the methods `matvec` and `matmat`, and the attributes/properties `shape` (pair of integers) and `dtype` (may be None). It may call the `__init__` on this class to have these attributes validated. Implementing `matvec` automatically implements `matmat` (using a naive algorithm) and vice-versa.

Optionally, a subclass may implement `_rmatvec` or `_adjoint` to implement the Hermitian adjoint (conjugate transpose). As with `matvec` and `matmat`, implementing either `_rmatvec` or `_adjoint` implements the other automatically. Implementing `_adjoint` is preferable; `_rmatvec` is mostly there for backwards compatibility.

**Parameters**

- `matvec` [callable f(v)] Returns returns $A \cdot v$.
- `rmatvec` [callable f(v)] Returns $A^H \cdot v$, where $A^H$ is the conjugate transpose of $A$.
- `matmat` [callable f(V)] Returns $A \cdot V$, where $V$ is a dense matrix with dimensions (N, K).
- `dtype` [dtype] Data type of the matrix.
- `rmatmat` [callable f(V)] Returns $A^H \cdot V$, where $V$ is a dense matrix with dimensions (M, K).
See also:

```
aslinearoperator
```

Construct LinearOperators

Notes

The user-defined matvec() function must properly handle the case where v has shape (N,) as well as the (N,1) case. The shape of the return type is handled internally by LinearOperator.

LinearOperator instances can also be multiplied, added with each other and exponentiated, all lazily: the result of these operations is always a new, composite LinearOperator, that defers linear operations to the original operators and combines the results.

More details regarding how to subclass a LinearOperator and several examples of concrete LinearOperator instances can be found in the external project PyLops.

Examples

```python
>>> import numpy as np
>>> from scipy.sparse.linalg import LinearOperator
>>> def mv(v):
...    return np.array([2*v[0], 3*v[1]])
...>>> A = LinearOperator((2,2), matvec=mv)
>>> A
<2x2 _CustomLinearOperator with dtype=float64>
>>> A.matvec(np.ones(2))
array([ 2.,  3.])
>>> A * np.ones(2)
array([ 2.,  3.])
```

Attributes

- **args** [tuple] For linear operators describing products etc. of other linear operators, the operands of the binary operation.
- **ndim** [int] Number of dimensions (this is always 2)

Methods

- **__call__**(self, x) Call self as a function.
- **adjoint**(self) Hermitian adjoint.
- **dot**(self, x) Matrix-matrix or matrix-vector multiplication.
- **matmat**(self, X) Matrix-matrix multiplication.
- **matvec**(self, x) Matrix-vector multiplication.
- **rmatmat**(self, X) Adjoint matrix-matrix multiplication.
- **rmatvec**(self, x) Adjoint matrix-vector multiplication.
- **transpose**(self) Transpose this linear operator.
**scipy.sparse.linalg.LinearOperator.__call__**

LinearOperator.__call__(self, x)

Call self as a function.

**scipy.sparse.linalg.LinearOperator.adjoint**

LinearOperator.adjoint(self)

Hermitian adjoint.

Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.

Can be abbreviated self.H instead of self.adjoint().

**Returns**

**scipy.sparse.linalg.LinearOperator.dot**

LinearOperator.dot(self, x)

Matrix-matrix or matrix-vector multiplication.

**Parameters**

x [array_like] 1-d or 2-d array, representing a vector or matrix.

**Returns**

Ax [array] 1-d or 2-d array (depending on the shape of x) that represents the result of applying this linear operator on x.

**scipy.sparse.linalg.LinearOperator.matmat**

LinearOperator.matmat(self, X)

Matrix-matrix multiplication.

Performs the operation y=A*X where A is an MxN linear operator and X dense N*K matrix or ndarray.

**Parameters**

X [[matrix, ndarray]] An array with shape (N,K).

**Returns**

Y [[matrix, ndarray]] A matrix or ndarray with shape (M,K) depending on the type of the X argument.

**Notes**

This matmat wraps any user-specified matmat routine or overridden _matmat method to ensure that y has the correct type.
**scipy.sparse.linalg.LinearOperator.matvec**

`LinearOperator.matvec(self, x)`

Matrix-vector multiplication.

Performs the operation `y = A*x` where `A` is an MxN linear operator and `x` is a column vector or 1-d array.

**Parameters**

- `x` : `[matrix, ndarray]` An array with shape `(N,)` or `(N,1).

**Returns**

- `y` : `[matrix, ndarray]` A matrix or ndarray with shape `(M,)` or `(M,1)` depending on the type and shape of the `x` argument.

**Notes**

This matvec wraps the user-specified matvec routine or overridden `matvec` method to ensure that `y` has the correct shape and type.

**scipy.sparse.linalg.LinearOperator.rmatmat**

`LinearOperator.rmatmat(self, X)`

Adjoint matrix-matrix multiplication.

Performs the operation `y = A^H * x` where `A` is an MxN linear operator and `x` is a column vector or 1-d array, or 2-d array. The default implementation defers to the adjoint.

**Parameters**

- `X` : `[matrix, ndarray]` A matrix or 2D array.

**Returns**

- `Y` : `[matrix, ndarray]` A matrix or 2D array depending on the type of the input.

**Notes**

This rmatmat wraps the user-specified rmatmat routine.

**scipy.sparse.linalg.LinearOperator.rmatvec**

`LinearOperator.rmatvec(self, x)`

Adjoint matrix-vector multiplication.

Performs the operation `y = A^H * x` where `A` is an MxN linear operator and `x` is a column vector or 1-d array.

**Parameters**

- `x` : `[matrix, ndarray]` An array with shape `(M,)` or `(M,1).

**Returns**

- `y` : `[matrix, ndarray]` A matrix or ndarray with shape `(N,)` or `(N,1)` depending on the type and shape of the `x` argument.
Notes

This rmatvec wraps the user-specified rmatvec routine or overridden _rmatvec method to ensure that y has
the correct shape and type.

**scipy.sparse.linalg.LinearOperator.transpose**

LinearOperator.transpose(self)

Transpose this linear operator.

Returns a LinearOperator that represents the transpose of this one. Can be abbreviated self.T instead of
self.transpose().

__mul__

**scipy.sparse.linalg.aslinearoperator**

scipy.sparse.linalg.aslinearoperator(A)

Return A as a LinearOperator.

'A' may be any of the following types:

- ndarray
- matrix
- sparse matrix (e.g. csr_matrix, lil_matrix, etc.)
- LinearOperator
- An object with .shape and .matvec attributes

See the LinearOperator documentation for additional information.

Notes

If 'A' has no .dtype attribute, the data type is determined by calling LinearOperator.matvec - set the .dtype
attribute to prevent this call upon the linear operator creation.

Examples

```python
def from scipy.sparse.linalg import aslinearoperator
>>> M = np.array([[1,2,3],[4,5,6]], dtype=np.int32)
>>> aslinearoperator(M)
<2x3 MatrixLinearOperator with dtype=int32>
```
6.24.2 Matrix Operations

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{inv(A)}</td>
<td>Compute the inverse of a sparse matrix</td>
</tr>
<tr>
<td>\texttt{expm(A)}</td>
<td>Compute the matrix exponential using Pade approximation.</td>
</tr>
<tr>
<td>\texttt{expm_multiply(A, B[, start, stop, num, endpoint])}</td>
<td>Compute the action of the matrix exponential of ( A ) on ( B ).</td>
</tr>
</tbody>
</table>

**scipy.sparse.linalg.inv**

\texttt{scipy.sparse.linalg.inv}(A) 
Compute the inverse of a sparse matrix

**Parameters**

- \( A \) 
  
  [(M, M) ndarray or sparse matrix] square matrix to be inverted

**Returns**

- \( A^{-1} \) 
  
  [(M, M) ndarray or sparse matrix] inverse of \( A \)

**Notes**

This computes the sparse inverse of \( A \). If the inverse of \( A \) is expected to be non-sparse, it will likely be faster to convert \( A \) to dense and use scipy.linalg.inv.

**Examples**

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import inv
>>> A = csc_matrix([[1., 0.], [1., 2.]])
>>> Ainv = inv(A)
>>> Ainv
<2x2 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv)
<2x2 sparse matrix of type '<class 'numpy.float64'>'
  with 2 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv).todense()
matrix([[ 1., 0.],
    [ 0., 1.]])
```

New in version 0.12.0.
scipy.sparse.linalg.expm

scipy.sparse.linalg.expm(A)

Compute the matrix exponential using Pade approximation.

**Parameters**

A [(M,M) array_like or sparse matrix] 2D Array or Matrix (sparse or dense) to be exponentiated

**Returns**

expA [(M,M) ndarray] Matrix exponential of A

**Notes**

This is algorithm (6.1) which is a simplification of algorithm (5.1).

New in version 0.12.0.

**References**

[1]

**Examples**

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import expm
>>> A = csc_matrix([[1, 0, 0], [0, 2, 0], [0, 0, 3]])
>>> A.todense()
matrix([[1, 0, 0],
        [0, 2, 0],
        [0, 0, 3]], dtype=int64)
>>> Aexp = expm(A)
>>> Aexp
<3x3 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in Compressed Sparse Column format>
>>> Aexp.todense()
matrix([[ 2.71828183, 0. , 0. ],
        [ 0. , 7.3890561 , 0. ],
        [ 0. , 0. , 20.08553692]])
```

scipy.sparse.linalg.expm_multiply

scipy.sparse.linalg.expm_multiply(A, B, start=None, stop=None, num=None, endpoint=None)

Compute the action of the matrix exponential of A on B.

**Parameters**

A [transposable linear operator] The operator whose exponential is of interest.
B [ndarray] The matrix or vector to be multiplied by the matrix exponential of A.
start [scalar, optional] The starting time point of the sequence.
stop [scalar, optional] The end time point of the sequence, unless endpoint is set to False. In that case, the sequence consists of all but the last of num + 1 evenly spaced time points, so that stop is excluded. Note that the step size changes when endpoint is False.

num [int, optional] Number of time points to use.

endpoint [bool, optional] If True, stop is the last time point. Otherwise, it is not included.

Returns
expm_A_B [ndarray] The result of the action $e^{t_k A} B$.

Notes
The optional arguments defining the sequence of evenly spaced time points are compatible with the arguments of numpy.linspace.

The output ndarray shape is somewhat complicated so I explain it here. The ndim of the output could be either 1, 2, or 3. It would be 1 if you are computing the expm action on a single vector at a single time point. It would be 2 if you are computing the expm action on a vector at multiple time points, or if you are computing the expm action on a matrix at a single time point. It would be 3 if you want the action on a matrix with multiple columns at multiple time points. If multiple time points are requested, expm_A_B[0] will always be the action of the expm at the first time point, regardless of whether the action is on a vector or a matrix.

References
[1], [2]

Examples
```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import expm, expm_multiply
>>> A = csc_matrix([[1, 0], [0, 1]])
>>> A.todense()
matrix([[1, 0],
        [0, 1]], dtype=int64)
>>> B = np.array([np.exp(-1.), np.exp(-2.)])
>>> B
array([0.36787944, 0.13533528])
>>> expm_multiply(A, B, start=1, stop=2, num=3, endpoint=True)
array([[ 1. , 0.36787944],
       [ 1.64872127, 0.60653066],
       [ 2.71828183, 1. ]])
>>> expm(A).dot(B)                     # Verify 1st timestep
array([1. , 0.36787944])
>>> expm(1.5*A).dot(B)                # Verify 2nd timestep
array([1.64872127, 0.60653066])
>>> expm(2*A).dot(B)                  # Verify 3rd timestep
array([2.71828183, 1. ])
```
6.24.3 Matrix norms

<table>
<thead>
<tr>
<th>norm(x[, ord, axis])</th>
<th>Norm of a sparse matrix</th>
</tr>
</thead>
<tbody>
<tr>
<td>onenormest(A[, t, itmax, compute_y, compute_w])</td>
<td>Compute a lower bound of the 1-norm of a sparse matrix.</td>
</tr>
</tbody>
</table>

**scipy.sparse.linalg.norm**

```python
scipy.sparse.linalg.norm(x, ord=None, axis=None)
```

Norm of a sparse matrix

This function is able to return one of seven different matrix norms, depending on the value of the `ord` parameter.

**Parameters**

- `x` ([a sparse matrix]) Input sparse matrix.
- `ord` ([{non-zero int, inf, -inf, ‘fro’}, optional]) Order of the norm (see table under Notes). inf means numpy’s inf object.
- `axis` ([{int, 2-tuple of ints, None}, optional]) If `axis` is an integer, it specifies the axis of `x` along which to compute the vector norms. If `axis` is a 2-tuple, it specifies the axes that hold 2-D matrices, and the matrix norms of these matrices are computed. If `axis` is None then either a vector norm (when `x` is 1-D) or a matrix norm (when `x` is 2-D) is returned.

**Returns**

- `n` [float or ndarray]

**Notes**

Some of the ord are not implemented because some associated functions like, _multi_svd_norm, are not yet available for sparse matrix.

This docstring is modified based on numpy.linalg.norm. https://github.com/numpy/numpy/blob/master/numpy/linalg/linalg.py

The following norms can be calculated:

<table>
<thead>
<tr>
<th>ord</th>
<th>norm for sparse matrices</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Frobenius norm</td>
</tr>
<tr>
<td>'fro'</td>
<td>Frobenius norm</td>
</tr>
<tr>
<td>inf</td>
<td>max(sum(abs(x), axis=1))</td>
</tr>
<tr>
<td>-inf</td>
<td>min(sum(abs(x), axis=1))</td>
</tr>
<tr>
<td>0</td>
<td>abs(x).sum(axis=axis)</td>
</tr>
<tr>
<td>1</td>
<td>max(sum(abs(x), axis=0))</td>
</tr>
<tr>
<td>-1</td>
<td>min(sum(abs(x), axis=0))</td>
</tr>
<tr>
<td>2</td>
<td>Not implemented</td>
</tr>
<tr>
<td>-2</td>
<td>Not implemented</td>
</tr>
<tr>
<td>other</td>
<td>Not implemented</td>
</tr>
</tbody>
</table>

The Frobenius norm is given by [1]:

$$\|A\|_F = \left[ \sum_{i,j} \text{abs}(a_{i,j})^2 \right]^{1/2}$$
References

[1]

Examples

```python
>>> from scipy.sparse import *
>>> import numpy as np
>>> from scipy.sparse.linalg import norm
>>> a = np.arange(9) - 4
>>> a
array([-4, -3, -2, -1, 0, 1, 2, 3, 4])
>>> b = a.reshape((3, 3))
>>> b
array([[-4, -3, -2],
       [-1,  0,  1],
       [ 2,  3,  4]])

>>> b = csr_matrix(b)
>>> norm(b)
7.745966692414834
>>> norm(b, 'fro')
7.745966692414834
>>> norm(b, np.inf)
9
>>> norm(b, -np.inf)
2
>>> norm(b, 1)
7
>>> norm(b, -1)
6
```

**scipy.sparse.linalg.onenormest**

`scipy.sparse.linalg.onenormest (A, t=2, itmax=5, compute_v=False, compute_w=False)`

Compute a lower bound of the 1-norm of a sparse matrix.

**Parameters**

- **A** : [ndarray or other linear operator] A linear operator that can be transposed and that can produce matrix products.
- **t** : [int, optional] A positive parameter controlling the tradeoff between accuracy versus time and memory usage. Larger values take longer and use more memory but give more accurate output.
- **itmax** : [int, optional] Use at most this many iterations.
- **compute_v** : [bool, optional] Request a norm-maximizing linear operator input vector if True.
- **compute_w** : [bool, optional] Request a norm-maximizing linear operator output vector if True.

**Returns**

- **est** : [float] An underestimate of the 1-norm of the sparse matrix.

v [ndarray, optional] The vector such that \|Av\|_1 = est*\|v\|_1. It can be thought of as an input to the linear operator that gives an output with particularly large norm.

w [ndarray, optional] The vector Av which has relatively large 1-norm. It can be thought of as an output of the linear operator that is relatively large in norm compared to the input.

Notes

This is algorithm 2.4 of [1].

In [2] it is described as follows. “This algorithm typically requires the evaluation of about 4t matrix-vector products and almost invariably produces a norm estimate (which is, in fact, a lower bound on the norm) correct to within a factor 3.”

New in version 0.13.0.

[1], [2]

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import onenormest
>>> A = csc_matrix([[1., 0., 0.],
                  [5., 8., 2.],
                  [0., -1., 0.]],
                  dtype=float)
>>> A.todense()
matrix([[ 1., 0., 0.],
        [ 5., 8., 2.],
        [ 0., -1., 0.]])
>>> onenormest(A)
9.0
>>> np.linalg.norm(A.todense(), ord=1)
9.0
```

6.24.4 Solving linear problems

Direct methods for linear equation systems:

</tbody>
</table>

6.24. Sparse linear algebra (scipy.sparse.linalg)

scipy.sparse.linalg.spsolve

scipy.sparse.linalg.spsolve(A, b, permc_spec=None, use_umfpack=True)

Solve the sparse linear system $Ax = b$, where $b$ may be a vector or a matrix.

Parameters

- **A** [ndarray or sparse matrix] The square matrix $A$ will be converted into CSC or CSR form.
- **b** [ndarray or sparse matrix] The matrix or vector representing the right hand side of the equation. If a vector, b.shape must be (n,) or (n, 1).
- **permc_spec** [str, optional] How to permute the columns of the matrix for sparsity preservation. (default: ‘COLAMD’)
  - NATURAL: natural ordering.
  - MMD_ATA: minimum degree ordering on the structure of $A^T A$.
  - MMD_AT_PLUS_A: minimum degree ordering on the structure of $A^T + A$.
  - COLAMD: approximate minimum degree column ordering
- **use_umfpack** [bool, optional] if True (default) then use umfpack for the solution. This is only referenced if b is a vector and scikit-umfpack is installed.

Returns

- **x** [ndarray or sparse matrix] the solution of the sparse linear equation. If b is a vector, then x is a vector of size A.shape[1] If b is a matrix, then x is a matrix of size (A.shape[1], b.shape[1])

Notes

For solving the matrix expression $AX = B$, this solver assumes the resulting matrix $X$ is sparse, as is often the case for very sparse inputs. If the resulting $X$ is dense, the construction of this sparse result will be relatively expensive. In that case, consider converting $A$ to a dense matrix and using scipy.linalg.solve or its variants.

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spsolve
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> B = csc_matrix([[2, 0], [-1, 0], [2, 0]], dtype=float)
>>> x = spsolve(A, B)
>>> np.allclose(A.dot(x).todense(), B.todense())
True
```

scipy.sparse.linalg.spsolve_triangular

scipy.sparse.linalg.spsolve_triangular(A, b, lower=True, overwrite_A=False, overwrite_b=False, unit_diagonal=False)

Solve the equation $A \times = b$ for $x$, assuming $A$ is a triangular matrix.

Parameters

- **A** [(M, M) sparse matrix] A sparse square triangular matrix. Should be in CSR format.
- **b** [(M,) or (M, N) array_like] Right-hand side matrix in $A \times = b$
- **lower** [bool, optional] Whether $A$ is a lower or upper triangular matrix. Default is lower triangular matrix.
overwrite_A
[bool, optional] Allow changing A. The indices of A are going to be sorted and zero entries are going to be removed. Enabling gives a performance gain. Default is False.

overwrite_b
[bool, optional] Allow overwriting data in b. Enabling gives a performance gain. Default is False. If overwrite_b is True, it should be ensured that b has an appropriate dtype to be able to store the result.

unit_diagonal
[bool, optional] If True, diagonal elements of a are assumed to be 1 and will not be referenced.
New in version 1.4.0.

Returns

x
[(M,) or (M, N) ndarray] Solution to the system A x = b. Shape of return matches shape of b.

Raises

LinAlgError
If A is singular or not triangular.

ValueError
If shape of A or shape of b do not match the requirements.

Notes

New in version 0.19.0.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.linalg import spsolve_triangular
>>> A = csr_matrix([[3, 0, 0], [1, -1, 0], [2, 0, 1]], dtype=float)
>>> B = np.array([[2, 0], [-1, 0], [2, 0]], dtype=float)
>>> x = spsolve_triangular(A, B)
>>> np.allclose(A.dot(x), B)
True
```

scipy.sparse.linalg.factorized

scipy.sparse.linalg.factorized(A)
Return a function for solving a sparse linear system, with A pre-factorized.

Parameters

A
[(N, N) array_like] Input.

Returns

solve
[callable] To solve the linear system of equations given in A, the solve callable should be passed an ndarray of shape (N,).
Examples

```python
>>> from scipy.sparse.linalg import factorized
>>> A = np.array([[ 3., 2., -1. ],
... [ 2., -2., 4. ],
... [-1., 0.5, -1. ]])
>>> solve = factorized(A)  # Makes LU decomposition.
>>> rhs1 = np.array([1, -2, 0])
>>> solve(rhs1)  # Uses the LU factors.
array([ 1., -2., -2.])
```

```
scipy.sparse.linalg.MatrixRankWarning

exception scipy.sparse.linalg.MatrixRankWarning

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

scipy.sparse.linalg.use_solver

scipy.sparse.linalg.use_solver(**kwargs)
Select default sparse direct solver to be used.

Parameters

useUmfpack
[bool, optional] Use UMFPACK over SuperLU. Has effect only if scikits.umfpack is installed. Default: True

assumeSortedIndices
[bool, optional] Allow UMFPACK to skip the step of sorting indices for a CSR/CSC matrix. Has effect only if useUmfpack is True and scikits.umfpack is installed. Default: False

Notes

The default sparse solver is umfpack when available (scikits.umfpack is installed). This can be changed by passing useUmfpack = False, which then causes the always present SuperLU based solver to be used.

Umfpack requires a CSR/CSC matrix to have sorted column/row indices. If sure that the matrix fulfills this, pass assumeSortedIndices=True to gain some speed.

Iterative methods for linear equation systems:

- `bicg(A, b[, x0, tol, maxiter, M, callback, atol])` Use BiConjugate Gradient iteration to solve \( Ax = b \).
- `bicgstab(A, b[, x0, tol, maxiter, M, …])` Use BiConjugate Gradient STABilized iteration to solve \( Ax = b \).
- `cg(A, b[, x0, tol, maxiter, M, callback, atol])` Use Conjugate Gradient iteration to solve \( Ax = b \).
- `cgs(A, b[, x0, tol, maxiter, M, callback, atol])` Use Conjugate Gradient Squared iteration to solve \( Ax = b \).
- `gmres(A, b[, x0, tol, restart, maxiter, M, …])` Use Generalized Minimal RESidual iteration to solve \( Ax = b \).
- `lgmres(A, b[, x0, tol, maxiter, M, …])` Solve a matrix equation using the LGMRES algorithm.

**scipy.sparse.linalg.bicg**

`scipy.sparse.linalg.bicg(A, b, x0=None, tol=1e-05, maxiter=None, M=None, callback=None, atol=None)`

Use BiConjugate Gradient iteration to solve $A\mathbf{x} = \mathbf{b}$.

**Parameters**

- **A**
  - [{sparse matrix, dense matrix, LinearOperator}]
  - The real or complex $N$-by-$N$ matrix of the linear system. Alternatively, $A$ can be a linear operator which can produce $A\mathbf{x}$ and $A^T \mathbf{x}$ using, e.g., `scipy.sparse.linalg.LinearOperator`.

- **b**
  - [{array, matrix}]
  - Right hand side of the linear system. Has shape $(N,)$ or $(N,1)$.

**Returns**

- **x**
  - [{array, matrix}]
  - The converged solution.
- **info**
  - [integer]
  - Provides convergence information:
    - 0: successful exit
    - >0: convergence to tolerance not achieved, number of iterations
    - <0: illegal input or breakdown

**Other Parameters**

- **x0**
  - [{array, matrix}]
  - Starting guess for the solution.
- **tol, atol**
  - [float, optional]
  - Tolerances for convergence, $\text{norm(residual)} \leq \max(tol*\text{norm(b)}, \text{atol})$. The default for `atol` is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for `atol` will be changed in a future release. For future compatibility, specify `atol` explicitly.

- **maxiter**
  - [integer]
  - Maximum number of iterations. Iteration will stop after `maxiter` steps even if the specified tolerance has not been achieved.
- **M**
  - [{sparse matrix, dense matrix, LinearOperator}]
  - Preconditioner for $A$. The preconditioner should approximate the inverse of $A$. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- **callback**
  - [function]
  - User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.
Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import bicg
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = bicg(A, b)
>>> print(exitCode)  # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

**scipy.sparse.linalg.bicgstab**

Use BIConjugate Gradient STABilized iteration to solve $Ax = b$.

### Parameters
- **A** ([sparse matrix, dense matrix, LinearOperator]) The real or complex N-by-N matrix of the linear system. Alternatively, $A$ can be a linear operator which can produce $Ax$ using, e.g., `scipy.sparse.linalg.LinearOperator`.
- **b** ([array, matrix]) Right hand side of the linear system. Has shape (N,) or (N,1).

### Returns
- **x** ([array, matrix]) The converged solution.
- **info** [integer] Provides convergence information:
  - 0: successful exit
  - >0: convergence to tolerance not achieved, number of iterations
  - <0: illegal input or breakdown

### Other Parameters
- **x0** ([array, matrix]) Starting guess for the solution.
- **tol, atol** ([float, optional]) Tolerances for convergence, $\text{norm} \text{(residual)} \leq \text{max} (\text{tol} \text{* norm(b)}, \text{atol})$. The default for atol is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for atol will be changed in a future release. For future compatibility, specify atol explicitly.

- **maxiter** [integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **M** ([sparse matrix, dense matrix, LinearOperator]) Preconditioner for $A$. The preconditioner should approximate the inverse of $A$. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- **callback** [function] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.
scipy.sparse.linalg.cg

Use Conjugate Gradient iteration to solve \( Ax = b \).

**Parameters**

- \( A \) ([sparse matrix, dense matrix, LinearOperator]) The real or complex N-by-N matrix of the linear system. \( A \) must represent a hermitian, positive definite matrix. Alternatively, \( A \) can be a linear operator which can produce \( Ax \) using, e.g., scipy.sparse.linalg.LinearOperator.

- \( b \) ([array, matrix]) Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- \( x \) ([array, matrix]) The converged solution.
- \( info \) ([integer]) Provides convergence information:
  - 0 : successful exit
  - >0 : convergence to tolerance not achieved, number of iterations
  - <0 : illegal input or breakdown

**Other Parameters**

- \( x0 \) ([array, matrix]) Starting guess for the solution.
- \( tol, atol \) ([float, optional]) Tolerances for convergence, \( \text{norm(residual)} \leq \max(tol*\text{norm(b)}, \ atol) \). The default for \( atol \) is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for \( atol \) will be changed in a future release. For future compatibility, specify \( atol \) explicitly.

- \( maxiter \) ([integer]) Maximum number of iterations. Iteration will stop after \( maxiter \) steps even if the specified tolerance has not been achieved.

- \( M \) ([sparse matrix, dense matrix, LinearOperator]) Preconditioner for \( A \). The preconditioner should approximate the inverse of \( A \). Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

- \( callback \) ([function]) User-supplied function to call after each iteration. It is called as \( \text{callback(xk)} \), where \( xk \) is the current solution vector.

scipy.sparse.linalg.cgs

Use Conjugate Gradient Squared iteration to solve \( Ax = b \).

**Parameters**

- \( A \) ([sparse matrix, dense matrix, LinearOperator]) The real-valued N-by-N matrix of the linear system. Alternatively, \( A \) can be a linear operator which can produce \( Ax \) using, e.g., scipy.sparse.linalg.LinearOperator.

- \( b \) ([array, matrix]) Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- \( x \) ([array, matrix]) The converged solution.
- \( info \) ([integer])
Provides convergence information:

\begin{itemize}
\item 0: successful exit
\item >0: convergence to tolerance not achieved, number of iterations
\item <0: illegal input or breakdown
\end{itemize}

Other Parameters

- **x0**\{array, matrix\} Starting guess for the solution.
- **tol, atol**\{float, optional\} Tolerances for convergence, \( \text{norm(residual)} \leq \max(\text{tol*norm(b)}, \ \text{atol}) \). The default for atol is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for atol will be changed in a future release. For future compatibility, specify atol explicitly.

- **maxiter** integer Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **M**\{sparse matrix, dense matrix, LinearOperator\} Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- **callback** function User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

\texttt{scipy.sparse.linalg.gmres}

\texttt{scipy.sparse.linalg.gmres}(A, b, x0=\text{None}, tol=1e-05, restart=\text{None}, maxiter=\text{None}, M=\text{None}, callback=\text{None}, restart=\text{None}, atol=\text{None}, callback_type=\text{None})

Use Generalized Minimal RESidual iteration to solve \( Ax = b \).

**Parameters**

- **A**\{sparse matrix, dense matrix, LinearOperator\} The real or complex N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce Ax using, e.g., \texttt{scipy.sparse.linalg.LinearOperator}.
- **b**\{array, matrix\} Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- **x**\{array, matrix\} The converged solution.
- **info**\[int\] Provides convergence information:

\begin{itemize}
\item 0: successful exit
\item >0: convergence to tolerance not achieved, number of iterations
\item <0: illegal input or breakdown
\end{itemize}

Other Parameters

- **x0**\{array, matrix\} Starting guess for the solution (a vector of zeros by default).
- **tol, atol**\{float, optional\} Tolerances for convergence, \( \text{norm(residual)} \leq \max(\text{tol*norm(b)}, \ \text{atol}) \). The default for atol is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for atol will be changed in a future release. For future compatibility, specify atol explicitly.
restart [int, optional] Number of iterations between restarts. Larger values increase iteration cost, but may be necessary for convergence. Default is 20.

maxiter [int, optional] Maximum number of iterations (restart cycles). Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

M [{sparse matrix, dense matrix, LinearOperator}] Inverse of the preconditioner of A. M should approximate the inverse of A and be easy to solve for (see Notes). Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance. By default, no preconditioner is used.

callback [function] User-supplied function to call after each iteration. It is called as callback(args), where args are selected by callback_type.

callback_type [{‘x’, ‘pr_norm’, ‘legacy’}, optional]
Callback function argument requested:

- x: current iterate (ndarray), called on every restart
- pr_norm: relative (preconditioned) residual norm (float), called on every inner iteration
- legacy (default): same as pr_norm, but also changes the meaning of ‘maxiter’ to count inner iterations instead of restart cycles.

restrt [int, optional] DEPRECATED - use restart instead.

See also:

LinearOperator

Notes

A preconditioner, P, is chosen such that P is close to A but easy to solve for. The preconditioner parameter required by this routine is M = P^-1. The inverse should preferably not be calculated explicitly. Rather, use the following template to produce M:

```python
# Construct a linear operator that computes P^-1 * x.
import scipy.sparse.linalg as spla
M_x = lambda x: spla.spsolve(P, x)
M = spla.LinearOperator((n, n), M_x)
```

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import gmres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = gmres(A, b)
>>> print(exitCode)          # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```
scipy.sparse.linalg.lgmres

scipy.sparse.linalg.lgmres(A, b, x0=None, tol=1e-05, maxiter=1000, M=None, callback=None, inner_m=30, outer_k=3, outer_v=None, store_outer_Av=True, prepend_outer_v=False, atol=None)

Solve a matrix equation using the LGMRES algorithm.

The LGMRES algorithm [1] [2] is designed to avoid some problems in the convergence in restarted GMRES, and often converges in fewer iterations.

Parameters

- **A** ([sparse matrix, dense matrix, LinearOperator]) The real or complex N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce Ax using, e.g., scipy.sparse.linalg.LinearOperator.
- **b** ([array, matrix]) Right hand side of the linear system. Has shape (N,) or (N,1).
- **x0** ([array, matrix]) Starting guess for the solution.
- **tol, atol** [float, optional] Tolerances for convergence, \( \text{norm(residual)} \leq \max(\text{tol} \times \text{norm(b)}, \text{atol}) \). The default for atol is tol.

Warning: The default value for atol will be changed in a future release. For future compatibility, specify atol explicitly.

- **maxiter** [int, optional] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **M** ([sparse matrix, dense matrix, LinearOperator], optional) Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- **callback** [function, optional] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.
- **inner_m** [int, optional] Number of inner GMRES iterations per each outer iteration.
- **outer_k** [int, optional] Number of vectors to carry between inner GMRES iterations. According to [1], good values are in the range of 1…3. However, note that if you want to use the additional vectors to accelerate solving multiple similar problems, larger values may be beneficial.
- **outer_v** [list of tuples, optional] List containing tuples \((v, Av)\) of vectors and corresponding matrix-vector products, used to augment the Krylov subspace, and carried between inner GMRES iterations. The element \(Av\) can be None if the matrix-vector product should be re-evaluated. This parameter is modified in-place by lgmres, and can be used to pass “guess” vectors in and out of the algorithm when solving similar problems.
- **store_outer_Av** [bool, optional] Whether LGMRES should store also \(A*v\) in addition to vectors \(v\) in the outer_v list. Default is True.
- **prepend_outer_v** [bool, optional] Whether to put outer_v augmentation vectors before Krylov iterates. In standard LGMRES, prepend_outer_v=False.

Returns

- **x** [array or matrix] The converged solution.
- **info** [int] Provides convergence information:
  - 0 : successful exit
  - >0 : convergence to tolerance not achieved, number of iterations
  - <0 : illegal input or breakdown
Notes

The LGMRES algorithm [1] [2] is designed to avoid the slowing of convergence in restarted GMRES, due to alternating residual vectors. Typically, it often outperforms GMRES(m) of comparable memory requirements by some measure, or at least is not much worse.

Another advantage in this algorithm is that you can supply it with ‘guess’ vectors in the outer_v argument that augment the Krylov subspace. If the solution lies close to the span of these vectors, the algorithm converges faster. This can be useful if several very similar matrices need to be inverted one after another, such as in Newton-Krylov iteration where the Jacobian matrix often changes little in the nonlinear steps.

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lgmres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = lgmres(A, b)
>>> print(exitCode)  # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

scipy.sparse.linalg.minres

scipy.sparse.linalg.minres(A, b, x0=None, shift=0.0, tol=1e-05, maxiter=None, M=None, callback=None, show=False, check=False)

Use MINimum RESidual iteration to solve Ax=b

MINRES minimizes norm(A*x - b) for a real symmetric matrix A. Unlike the Conjugate Gradient method, A can be indefinite or singular.

If shift != 0 then the method solves (A - shift*I)x = b

Parameters

- **A** : [sparse matrix, dense matrix, LinearOperator] The real symmetric N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce Ax using, e.g., scipy.sparse.linalg.LinearOperator.
- **b** : [array, matrix] Right hand side of the linear system. Has shape (N,) or (N,1).

Returns

- **x** : [array, matrix] The converged solution.
- **info** : [integer] Provides convergence information:
  - 0 : successful exit
  - >0 : convergence to tolerance not achieved, number of iterations
  - <0 : illegal input or breakdown

Other Parameters
x0  [{array, matrix}] Starting guess for the solution.
tol  [float] Tolerance to achieve. The algorithm terminates when the relative residual is below tol.
maxiter  [integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
M  [{sparse matrix, dense matrix, LinearOperator}] Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
callback  [function] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

True
```

scipy.sparse.linalg.qmr

scipy.sparse.linalg.qmr(A, b, x0=None, tol=1e-05, maxiter=None, M1=None, M2=None, callback=None, atol=None)

Use Quasi-Minimal Residual iteration to solve $Ax = b$.

Parameters

- **A**  [{sparse matrix, dense matrix, LinearOperator}] The real-valued N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce $Ax$ and $A^T x$ using, e.g., scipy.sparse.linalg.LinearOperator.
- **b**  [{array, matrix}] Right hand side of the linear system. Has shape (N,) or (N,1).

Returns

- **x**  [{array, matrix}] The converged solution.
- **info**  [integer]
Provides convergence information:

- 0: successful exit
- >0: convergence to tolerance not achieved, number of iterations
- <0: illegal input or breakdown

Other Parameters

- **x0**
  - [array, matrix] Starting guess for the solution.
- **tol, atol**
  - [float, optional] Tolerances for convergence, \( \text{norm(residual)} \leq \max(\text{tol} \times \text{norm(b)}, \text{atol}) \). The default for atol is 'legacy', which emulates a different legacy behavior.
  - **Warning:** The default value for atol will be changed in a future release. For future compatibility, specify atol explicitly.

- **maxiter**
  - [integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **M1**
  - [[sparse matrix, dense matrix, LinearOperator]] Left preconditioner for A.
- **M2**
  - [[sparse matrix, dense matrix, LinearOperator]] Right preconditioner for A. Used together with the left preconditioner M1. The matrix M1*A*M2 should have better conditioned than A alone.
- **callback**
  - [function] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

>>> print(exitCode)  # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

**scipy.sparse.linalg.gcrotmk**

Solve a matrix equation using flexible GCROT(m,k) algorithm.

Parameters

- **A**
  - [[sparse matrix, dense matrix, LinearOperator]] The real or complex N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce Ax using, e.g., scipy.sparse.linalg.LinearOperator.
- **b**
  - [[array, matrix]] Right hand side of the linear system. Has shape (N,) or (N,1).
- **x0**
  - [[array, matrix]] Starting guess for the solution.

\[ \text{tol, atol} \quad [\text{float, optional}] \quad \text{Tolerances for convergence, } \frac{\text{norm(residual)}}{\text{max}(\text{tol} \cdot \text{norm(b)}, \text{atol})}. \quad \text{The default for atol is } \text{tol}. \]

**Warning:** The default value for \( \text{atol} \) will be changed in a future release. For future compatibility, specify \( \text{atol} \) explicitly.

\[ \text{maxiter} \quad [\text{int, optional}] \quad \text{Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.} \]

\[ \text{M} \quad [\{	ext{sparse matrix, dense matrix, LinearOperator} \}, \text{optional}] \quad \text{Preconditioner for A. The preconditioner should approximate the inverse of A. gcrotmk is a 'flexible' algorithm and the preconditioner can vary from iteration to iteration. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.} \]

\[ \text{callback} \quad [\text{function, optional}] \quad \text{User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.} \]

\[ \text{m} \quad [\text{int, optional}] \quad \text{Number of inner FGMRES iterations per each outer iteration. Default: 20} \]

\[ \text{k} \quad [\text{int, optional}] \quad \text{Number of vectors to carry between inner FGMRES iterations. According to [2], good values are around m. Default: m} \]

\[ \text{CU} \quad [\text{list of tuples, optional}] \quad \text{List of tuples } (c, u) \text{ which contain the columns of the matrices C and U in the GCROT(m,k) algorithm. For details, see [2]. The list given and vectors contained in it are modified in-place. If not given, start from empty matrices. The c elements in the tuples can be None, in which case the vectors are recomputed via } c = A \cdot u \text{ on start and orthogonalized as described in [3].} \]

\[ \text{discard_C} \quad [\text{bool, optional}] \quad \text{Discard the C-vectors at the end. Useful if recycling Krylov subspaces for different linear systems.} \]

\[ \text{truncate} \quad [\{'\text{oldest}', '\text{smallest}'\}, \text{optional}] \quad \text{Truncation scheme to use. Drop: oldest vectors, or vectors with smallest singular values using the scheme discussed in [1,2]. See [2] for detailed comparison. Default: ‘oldest’} \]

**Returns**

\[ \text{x} \quad [\text{array or matrix}] \quad \text{The solution found.} \]

\[ \text{info} \quad [\text{int}] \quad \text{Provides convergence information:} \]

2184 Chapter 6. API Reference
scipy.sparse.linalg.lsqr

scipy.sparse.linalg.lsqr(A, b, damp=0.0, atol=1e-08, btol=1e-08, conlim=100000000.0, iter_lim=None, show=False, calc_var=False, x0=None)

Find the least-squares solution to a large, sparse, linear system of equations.

The function solves \( Ax = b \) or \( \min ||Ax - b||^2 \) or \( \min ||Ax - b||^2 + d^2 ||x||^2 \).

The matrix A may be square or rectangular (over-determined or under-determined), and may have any rank.

1. Unsymmetric equations -- solve \( A^*x = b \)
2. Linear least squares -- solve \( A^*x = b \) in the least-squares sense
3. Damped least squares -- solve \( (A + \text{damp}^2I)x = (b, 0) \) in the least-squares sense

Parameters

- **A**
  [{sparse matrix, ndarray, LinearOperator}] Representation of an m-by-n matrix. Alternatively, A can be a linear operator which can produce \( Ax \) and \( A^T x \) using, e.g., scipy.sparse.linalg.LinearOperator.
- **b**
  [array_like, shape(m,)] Right-hand side vector b.
- **damp**
  [float] Damping coefficient.
- **atol, btol**
  [float, optional] Stopping tolerances. If both are 1.0e-9 (say), the final residual norm should be accurate to about 9 digits. (The final x will usually have fewer correct digits, depending on cond(A) and the size of damp.)
- **conlim**
  [float, optional] Another stopping tolerance. lsqr terminates if an estimate of \text{cond}(A)\) exceeds conlim. For compatible systems \( Ax = b \), conlim could be as large as 1.0e+12 (say). For least-squares problems, conlim should be less than 1.0e+8. Maximum precision can be obtained by setting atol = btol = conlim = zero, but the number of iterations may then be excessive.
- **iter_lim**
  [int, optional] Explicit limitation on number of iterations (for safety).
- **show**
  [bool, optional] Display an iteration log.
- **calc_var**
  [bool, optional] Whether to estimate diagonals of \( (A'A + \text{damp}^2I)^{-1} \) (if damp == 0) or more generally \( (A'A + \text{damp}^2I)^{-1} \). This is well defined if A has full

Returns

- **x**
  [ndarray of float] The final solution.
- **istop**
  [int] Gives the reason for termination. 1 means x is an approximate solution to \( Ax = b \). 2 means x approximately solves the least-squares problem.
- **itn**
  [int] Iteration number upon termination.
- **r1norm**
  [float] \( \| r \|_1 \), where \( r = b - Ax \).
- **r2norm**
  [float] \( \sqrt{ \| r \|^2 + \text{damp}^2 \| x \|^2 } \). Equal to \( r1norm \) if damp == 0.
- **anorm**
  [float] Estimate of Frobenius norm of Abar = [[A]; [damp*I]].
- **acond**
  [float] Estimate of cond(Abar).
- **arnorm**
  [float] Estimate of norm(A'*r - damp^2*x).
- **xnorm**
  [float] norm(x)
- **var**
  [ndarray of float] If calc_var is True, estimates all diagonals of \( (A'A)^{-1} \) (if damp == 0) or more generally \( (A'A + \text{damp}^2I)^{-1} \). This is well defined if A has full

6.24. Sparse linear algebra (scipy.sparse.linalg) 2185
column rank or \( \text{damp} > 0 \). (Not sure what \text{var} means if \( \text{rank}(A) < n \) and \( \text{damp} = 0 \).)

**Notes**

LSQR uses an iterative method to approximate the solution. The number of iterations required to reach a certain accuracy depends strongly on the scaling of the problem. Poor scaling of the rows or columns of \( A \) should therefore be avoided where possible.

For example, in problem 1 the solution is unaltered by row-scaling. If a row of \( A \) is very small or large compared to the other rows of \( A \), the corresponding row of (\( A \ b \)) should be scaled up or down.

In problems 1 and 2, the solution \( x \) is easily recovered following column-scaling. Unless better information is known, the nonzero columns of \( A \) should be scaled so that they all have the same Euclidean norm (e.g., 1.0).

In problem 3, there is no freedom to re-scale if \( \text{damp} \) is nonzero. However, the value of \( \text{damp} \) should be assigned only after attention has been paid to the scaling of \( A \).

The parameter \text{damp} is intended to help regularize ill-conditioned systems, by preventing the true solution from being very large. Another aid to regularization is provided by the parameter \text{cond}, which may be used to terminate iterations before the computed solution becomes very large.

If some initial estimate \( x_0 \) is known and if \( \text{damp} = 0 \), one could proceed as follows:

1. Compute a residual vector \( r_0 = b - A*x_0 \).
2. Use LSQR to solve the system \( A*d_x = r_0 \).
3. Add the correction \( d_x \) to obtain a final solution \( x = x_0 + d_x \).

This requires that \( x_0 \) be available before and after the call to LSQR. To judge the benefits, suppose LSQR takes \( k1 \) iterations to solve \( A*x = b \) and \( k2 \) iterations to solve \( A*d_x = r_0 \). If \( x_0 \) is “good”, \( \text{norm}(r_0) \) will be smaller than \( \text{norm}(b) \). If the same stopping tolerances \( \text{atol} \) and \( \text{btol} \) are used for each system, \( k1 \) and \( k2 \) will be similar, but the final solution \( x_0 + d_x \) should be more accurate. The only way to reduce the total work is to use a larger stopping tolerance for the second system. If some value \( \text{btol} \) is suitable for \( A*x = b \), the larger value \( \text{btol} \cdot \text{norm}(b)/\text{norm}(r_0) \) should be suitable for \( A*d_x = r_0 \).

Preconditioning is another way to reduce the number of iterations. If it is possible to solve a related system \( M*x = b \) efficiently, where \( M \) approximates \( A \) in some helpful way (e.g. \( M - A \) has low rank or its elements are small relative to those of \( A \) ), LSQR may converge more rapidly on the system \( A*(\text{inverse})*z = b \), after which \( x \) can be recovered by solving \( M*x = z \).

If \( A \) is symmetric, LSQR should not be used!

Alternatives are the symmetric conjugate-gradient method (\text{cg}) and/or \text{SYMMLQ}. \text{SYMMLQ} is an implementation of symmetric \text{cg} that applies to any symmetric \( A \) and will converge more rapidly than LSQR. If \( A \) is positive definite, there are other implementations of symmetric \text{cg} that require slightly less work per iteration than \text{SYMMLQ} (but will take the same number of iterations).
References

[1], [2], [3]

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsqr
>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)

The first example has the trivial solution \([0, 0]\)

```python
>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
The exact solution is \(x = 0\)
>>> istop
0
>>> x
array([ 0., 0.])
``` 

The stopping code \(istop=0\) returned indicates that a vector of zeros was found as a solution. The returned solution \(x\) indeed contains \([0, 0, 0]\). The next example has a non-trivial solution:

```python
>>> b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, r1norm = lsqr(A, b)[:4]
>>> istop
1
>>> x
array([ 1., -1.])
>>> itn
1
>>> r1norm
4.40892098500627e-16
```

As indicated by \(istop=1\), \(lsqr\) found a solution obeying the tolerance limits. The given solution \([1., -1.]\) obviously solves the equation. The remaining return values include information about the number of iterations \((itn=1)\) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```python
>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, r1norm = lsqr(A, b)[:4]
>>> istop
2
>>> x
array([1.00333333, -0.99666667])
>>> A.dot(x)-b
array([0.00333333, -0.00333333, 0.00333333])
>>> r1norm
0.005773502691896255
```

\(istop\) indicates that the system is inconsistent and thus \(x\) is rather an approximate solution to the corresponding least-squares problem. \(r1norm\) contains the norm of the minimal residual that was found.
scipy.sparse.linalg.lsmr

scipy.sparse.linalg.lsmr(A, b, damp=0.0, atol=1e-06, btol=1e-06, conlim=100000000.0, maxiter=None, show=False, x0=None)

Iterative solver for least-squares problems.

lsmr solves the system of linear equations $Ax = b$. If the system is inconsistent, it solves the least-squares problem $\min ||b - Ax||_2$. $A$ is a rectangular matrix of dimension $m$-by-$n$, where all cases are allowed: $m = n$, $m > n$, or $m < n$. $b$ is a vector of length $m$. The matrix $A$ may be dense or sparse (usually sparse).

**Parameters**

- **A** : [matrix, sparse matrix, ndarray, LinearOperator] Matrix $A$ in the linear system. Alternatively, $A$ can be a linear operator which can produce $Ax$ and $A^H x$ using, e.g., scipy.sparse.linalg.LinearOperator.
- **b** : [array_like, shape (m,)] Vector $b$ in the linear system.
- **damp** : [float] Damping factor for regularized least-squares. $lsmr$ solves the regularized least-squares problem:

$$
\min ||(b) - (A)x||_2 \\
\text{subject to } (damp*I)x
$$

where damp is a scalar. If damp is None or 0, the system is solved without regularization.

- **atol**, **btol** : [float, optional] Stopping tolerances. $lsmr$ continues iterations until a certain backward error estimate is smaller than some quantity depending on atol and btol. Let $r = b - Ax$ be the residual vector for the current approximate solution $x$. If $Ax = b$ seems to be consistent, $lsmr$ terminates when $\text{norm}(r) \leq \text{atol} \times \text{norm}(A) \times \text{norm}(x) + \text{btol} \times \text{norm}(b)$. Otherwise, $lsmr$ terminates when $\text{norm}(A^H r) \leq \text{atol} \times \text{norm}(A) \times \text{norm}(r)$. If both tolerances are 1.0e-6 (say), the final $\text{norm}(r)$ should be accurate to about 6 digits. (The final $x$ will usually have fewer correct digits, depending on $\text{cond}(A)$ and the size of LAMBDA.) If $\text{atol}$ or $\text{btol}$ is None, a default value of 1.0e-6 will be used. Ideally, they should be estimates of the relative error in the entries of $A$ and $b$ respectively. For example, if the entries of $A$ have 7 correct digits, set $\text{atol} = 1e-7$. This prevents the algorithm from doing unnecessary work beyond the uncertainty of the input data.

- **conlim** : [float, optional] $lsmr$ terminates if an estimate of $\text{cond}(A)$ exceeds $\text{conlim}$. For compatible systems $Ax = b$, $\text{conlim}$ could be as large as 1.0e+12 (say). For least-squares problems, $\text{conlim}$ should be less than 1.0e+8. If $\text{conlim}$ is None, the default value is $1e+8$. Maximum precision can be obtained by setting $\text{atol} = \text{btol} = \text{conlim} = 0$, but the number of iterations may then be excessive.

- **maxiter** : [int, optional] $lsmr$ terminates if the number of iterations reaches $\text{maxiter}$. The default is $\text{maxiter} = \min(m, n)$. For ill-conditioned systems, a larger value of $\text{maxiter}$ may be needed.

- **show** : [bool, optional] Print iterations logs if $\text{show}=\text{True}$.

- **x0** : [array_like, shape (n,), optional] Initial guess of $x$, if None zeros are used. New in version 1.0.0.

**Returns**

- **x** : [ndarray of float] Least-square solution returned.
- **istop** : [int] istop gives the reason for stopping:

  $\begin{align*}
  \text{istop} &= 0 \text{ means } x=0 \text{ is a solution. If } x0 \text{ was given, } x0 \text{ is a solution.} \\
  \text{istop} &= 1 \text{ means } x \text{ is an approximate solution to } A^\ast x = B, \text{ according to } \text{atol} \text{ and } \text{btol}. 
  \end{align*}$

(continues on next page)

(continued from previous page)

= 2 means x approximately solves the least-squares problem according to atol.
= 3 means COND(A) seems to be greater than CONLIM.
= 4 is the same as 1 with atol = btol = eps.
= (machine precision)
= 5 is the same as 2 with atol = eps.
= 6 is the same as 3 with CONLIM = 1/eps.
= 7 means ITN reached maxiter before the other stopping conditions were satisfied.

[1], [2]

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsqr
>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)
```

The first example has the trivial solution [0, 0]

```python
>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
>>> istop
0
>>> x
array([ 0., 0.])
```

The stopping code istop=0 returned indicates that a vector of zeros was found as a solution. The returned solution x indeed contains [0, 0]. The next example has a non-trivial solution:

```python
>>> b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
>>> istop
1
```

(continues on next page)
As indicated by istop=1, lsmr found a solution obeying the tolerance limits. The given solution \([1., -1.]\) obviously solves the equation. The remaining return values include information about the number of iterations (itn=1) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```python
>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, normr = lsmr(A, b)[:-4]
```

```python
>>> istop
2
```

```python
>>> x
array([ 1.00333333, -0.99666667])
```

```python
>>> A.dot(x) - b
array([ 0.00333333, -0.00333333, 0.00333333])
```

```
>>> normr
0.005773502691896255
```

istop indicates that the system is inconsistent and thus x is rather an approximate solution to the corresponding least-squares problem. normr contains the minimal distance that was found.

### 6.24.5 Matrix factorizations

**Eigenvalue problems:**

- **eigs(A, k, M, sigma, which, v0, ncv, …)**
  - Find k eigenvalues and eigenvectors of the square matrix A.
- **eigsh(A, k, M, sigma, which, v0, ncv, …)**
  - Find k eigenvalues and eigenvectors of the real symmetric square matrix or complex Hermitian matrix A.
- **lobpcg(A, X[, B, M, Y, tol, maxiter, …])**
  - Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

**scipy.sparse.linalg.eigs**

- **scipy.sparse.linalg.eigs(A, k=6, M=None, sigma=None, which='LM', v0=None, ncv=None, maxiter=None, tol=0, return_eigenvectors=True, Minv=None, OPinv=None, OPpart=None)**
  - Find k eigenvalues and eigenvectors of the square matrix A.
  - Solves \( A * x[i] = w[i] * x[i] \), the standard eigenvalue problem for \( w[i] \) eigenvalues with corresponding eigenvectors \( x[i] \).
  - If \( M \) is specified, solves \( A * x[i] = w[i] * M * x[i] \), the generalized eigenvalue problem for \( w[i] \) eigenvalues with corresponding eigenvectors \( x[i] \)

**Parameters**
A  [ndarray, sparse matrix or LinearOperator] An array, sparse matrix, or LinearOperator representing the operation $A \times x$, where $A$ is a real or complex square matrix.

k  [int, optional] The number of eigenvalues and eigenvectors desired. $k$ must be smaller than $N-1$. It is not possible to compute all eigenvectors of a matrix.

M  [ndarray, sparse matrix or LinearOperator, optional] An array, sparse matrix, or LinearOperator representing the operation $M \times x$ for the generalized eigenvalue problem $A \times x = w \times M \times x$.

M must represent a real symmetric matrix if $A$ is real, and must represent a complex Hermitian matrix if $A$ is complex. For best results, the data type of $M$ should be the same as that of $A$. Additionally:

If $\sigma$ is None, $M$ is positive definite
If $\sigma$ is specified, $M$ is positive semi-definite

If $\sigma$ is None, eigs requires an operator to compute the solution of the linear equation $M \times x = b$. This is done internally via a (sparse) LU decomposition for an explicit matrix $M$, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator $Minv$, which gives $x = Minv \times b = M^{-1} \times b$.

$\sigma$  [real or complex, optional] Find eigenvalues near $\sigma$ using shift-invert mode. This requires an operator to compute the solution of the linear system $[A - \sigma \times M] \times x = b$, where $M$ is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices $A$ & $M$, or via an iterative solver if either $A$ or $M$ is a general linear operator. Alternatively, the user can supply the matrix or operator $OPinv$, which gives $x = OPinv \times b = [A - \sigma \times M]^{-1} \times b$. For a real matrix $A$, shift-invert can either be done in imaginary mode or real mode, specified by the parameter $OPpart$ ($'r'$ or $'i'$). Note that when $\sigma$ is specified, the keyword 'which' (below) refers to the shifted eigenvalues $w'[i]$ where:

If $A$ is real and $OPpart == 'r'$ (default),

$w'[i] = 1/2 \times [1/(w[i]-\sigma) + 1/(w[i]-\text{conj}(\sigma))].$

If $A$ is real and $OPpart == 'i'$,

$w'[i] = 1/2i \times [1/(w[i]-\sigma) - 1/(w[i]-\text{conj}(\sigma))].$

If $A$ is complex, $w'[i] = 1/(w[i]-\sigma)$.

$v0$  [ndarray, optional] Starting vector for iteration. Default: random

ncv  [int, optional] The number of Lanczos vectors generated $ncv$ must be greater than $k$; it is recommended that $ncv > 2\times k$. Default: $\min(n, \max(2\times k + 1, 20))$

which  [str, ['LM' | 'SM' | 'LR' | 'SR' | 'LI' | 'SI'], optional] Which $k$ eigenvectors and eigenvalues to find:

'LM': largest magnitude
'SM': smallest magnitude
'LR': largest real part
'SR': smallest real part
'LI': largest imaginary part
'SI': smallest imaginary part

When $\sigma$ != None, 'which' refers to the shifted eigenvalues $w'[i]$ (see discussion in 'sigma', above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

maxiter  [int, optional] Maximum number of Arnoldi update iterations allowed. Default: $n\times 10$

tol  [float, optional] Relative accuracy for eigenvalues (stopping criterion) The default value of 0 implies machine precision.

return_eigenvectors  [bool, optional] Return eigenvectors (True) in addition to eigenvalues

Minv  [ndarray, sparse matrix or LinearOperator, optional] See notes in M, above.

OPinv  [ndarray, sparse matrix or LinearOperator, optional] See notes in sigma, above.

OPpart  ['r' or 'i', optional] See notes in sigma, above
**Returns**

- `w` [ndarray] Array of k eigenvalues.
- `v` [ndarray] An array of k eigenvectors. `v[:, i]` is the eigenvector corresponding to the eigenvalue `w[i]`.

**Raises**

- `ArpackNoConvergence`

When the requested convergence is not obtained. The currently converged eigenvalues and eigenvectors can be found as `eigenvalues` and `eigenvectors` attributes of the exception object.

**See also:**

- `eigsh`
eigenvalues and eigenvectors for symmetric matrix A
- `svds`singular value decomposition for a matrix A

**Notes**

This function is a wrapper to the ARPACK [1] SNEUPD, DNEUPD, CNEUPD, ZNEUPD, functions which use the Implicitly Restarted Arnoldi Method to find the eigenvalues and eigenvectors [2].

**References**

[1],[2]

**Examples**

Find 6 eigenvectors of the identity matrix:

```python
>>> from scipy.sparse.linalg import eigs
>>> id = np.eye(13)
>>> vals, vecs = eigs(id, k=6)
>>> vals
array([ 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j])
>>> vecs.shape
(13, 6)
```

**scipy.sparse.linalg.eigsh**

`scipy.sparse.linalg.eigsh(A, k=6, M=None, sigma=None, which='LM', tol=0, return_eigenvectors=True, Minv=None, OPinv=None, mode='normal')`

Find k eigenvalues and eigenvectors of the real symmetric square matrix or complex Hermitian matrix A.

Solves $A \cdot x[i] = w[i] \cdot x[i]$, the standard eigenvalue problem for $w[i]$ eigenvalues with corresponding eigenvectors $x[i]$. 
If M is specified, solves $A \times x[i] = w[i] \times M \times x[i]$, the generalized eigenvalue problem for $w[i]$ eigenvalues with corresponding eigenvectors $x[i]$.

Note that there is no specialized routine for the case when A is a complex Hermitian matrix. In this case, `eigsh()` will call `eigs()` and return the real parts of the eigenvalues thus obtained.

**Parameters**

- **A** [ndarray, sparse matrix or LinearOperator]: A square operator representing the operation $A \times x$, where $A$ is real symmetric or complex Hermitian. For buckling mode (see below) $A$ must additionally be positive-definite.

- **k** [int, optional]: The number of eigenvalues and eigenvectors desired. $k$ must be smaller than $N$. It is not possible to compute all eigenvectors of a matrix.

**Returns**

- **w** [array]: Array of $k$ eigenvalues.

- **v** [array]: An array representing the $k$ eigenvectors. The column $v[:, i]$ is the eigenvector corresponding to the eigenvalue $w[i]$.

**Other Parameters**

- **M** [An $N \times N$ matrix, array, sparse matrix, or linear operator representing]: the operation $M \times x$ for the generalized eigenvalue problem $A \times x = w \times M \times x$.

  - $M$ must represent a real symmetric matrix if $A$ is real, and must represent a complex Hermitian matrix if $A$ is complex. For best results, the data type of $M$ should be the same as that of $A$. Additionally:
    - If sigma is None, $M$ is symmetric positive definite.
    - If sigma is specified, $M$ is symmetric positive semi-definite.
    - In buckling mode, $M$ is symmetric indefinite.

  - If sigma is None, eigsh requires an operator to compute the solution of the linear equation $M \times x = b$. This is done internally via a (sparse) LU decomposition for an explicit matrix $M$, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator $M_{inv}$, which gives $x = M_{inv} \times b = M^{-1} \times b$.

- **sigma** [real]: Find eigenvalues near sigma using shift-invert mode. This requires an operator to compute the solution of the linear system $[A - sigma \times M] \times x = b$, where $M$ is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices $A$ & $M$, or via an iterative solver if either $A$ or $M$ is a general linear operator. Alternatively, the user can supply the matrix or operator $OP_{inv}$, which gives $x = OP_{inv} \times b = [A - sigma \times M]^{-1} \times b$. Note that when sigma is specified, the keyword 'which' refers to the shifted eigenvalues $w'[i]$ where:
  - if mode == 'normal', $w'[i] = 1 / (w[i] - sigma)$.
  - if mode == 'cayley', $w'[i] = (w[i] + sigma) / (w[i] - sigma)$.
  - if mode == 'buckling', $w'[i] = w[i] / (w[i] - sigma)$.

  (see further discussion in 'mode' below)

- **v0** [ndarray, optional]: Starting vector for iteration. Default: random

- **ncv** [int, optional]: The number of Lanczos vectors generated $ncv$ must be greater than $k$ and smaller than $n$; it is recommended that $ncv > 2 \times k$. Default: $\min(n, \max(2 \times k + 1, 20))$

- **which** [str ['LM' | 'SM' | 'LA' | 'SA' | 'BE']]: If $A$ is a complex Hermitian matrix, ‘BE’ is invalid. Which $k$ eigenvectors and eigenvalues to find:
  - ‘LM’: Largest (in magnitude) eigenvalues.
  - ‘SM’: Smallest (in magnitude) eigenvalues.
  - ‘LA’: Largest (algebraic) eigenvalues.
  - ‘SA’: Smallest (algebraic) eigenvalues.
  - ‘BE’: Half (k/2) from each end of the spectrum.
When k is odd, return one more (k/2+1) from the high end. When sigma != None, ‘which’ refers to the shifted eigenvalues w’[i] (see discussion in ‘sigma’, above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

maxiter [int, optional] Maximum number of Arnoldi update iterations allowed. Default: n*10

tol [float] Relative accuracy for eigenvalues (stopping criterion). The default value of 0 implies machine precision.

Minv [N x N matrix, array, sparse matrix, or LinearOperator] See notes in M, above.

OPinv [N x N matrix, array, sparse matrix, or LinearOperator] See notes in sigma, above.

return_eigenvectors [bool] Return eigenvectors (True) in addition to eigenvalues. This value determines the order in which eigenvalues are sorted. The sort order is also dependent on the which variable.

For which = ‘LM’ or ‘SA’:
  If return_eigenvectors is True, eigenvalues are sorted by algebraic value.
  If return_eigenvectors is False, eigenvalues are sorted by absolute value.

For which = ‘BE’ or ‘LA’:
  eigenvalues are always sorted by algebraic value.

For which = ‘SM’:
  If return_eigenvectors is True, eigenvalues are sorted by algebraic value.
  If return_eigenvectors is False, eigenvalues are sorted by decreasing absolute value.

mode [string ['normal' | 'buckling' | 'cayley']] Specify strategy to use for shift-invert mode. This argument applies only for real-valued A and sigma != None. For shift-invert mode, ARPACK internally solves the eigenvalue problem \( \Omega P \times[i] = w'[i] \times B \times[i] \) and transforms the resulting Ritz vectors \( x'[i] \) and Ritz values \( w'[i] \) into the desired eigenvectors and eigenvalues of the problem \( A \times[i] = w[i] \times M \times[i] \). The modes are as follows:

  ‘normal’ : \( \Omega = [A - sigma \times M]^{-1} \times M \times[i] = 1 / (w[i] - sigma) \)
  ‘buckling’ : \( \Omega = [A - sigma \times M]^{-1} \times A \times[i] = w[i] / (w[i] - sigma) \)
  ‘cayley’ : \( \Omega = [A - sigma \times M]^{-1} \times [A + sigma \times M] \times[i] = (w[i] + sigma) / (w[i] - sigma) \)

The choice of mode will affect which eigenvalues are selected by the keyword ‘which’, and can also impact the stability of convergence (see [2] for a discussion).

Raises

ArpackNoConvergence

When the requested convergence is not obtained.

The currently converged eigenvalues and eigenvectors can be found as eigenvalues and eigenvectors attributes of the exception object.

See also:

eigs

  eigenvalues and eigenvectors for a general (nonsymmetric) matrix A

svds

  singular value decomposition for a matrix A
Notes

This function is a wrapper to the ARPACK [1] SSEUPD and DSEUPD functions which use the Implicitly Restarted Lanczos Method to find the eigenvalues and eigenvectors [2].

References

[1], [2]

Examples

```python
>>> from scipy.sparse.linalg import eigsh
>>> identity = np.eye(13)
>>> eigenvalues, eigenvectors = eigsh(identity, k=6)
>>> eigenvalues
array([1., 1., 1., 1., 1., 1.])
>>> eigenvectors.shape
(13, 6)
```

**scipy.sparse.linalg.lobpcg**

`scipy.sparse.linalg.lobpcg(A, X=None, B=None, M=None, Y=None, tol=None, maxiter=None, largest=True, verbosityLevel=0, retLambdaHistory=False, retResidualsHistory=False)`

Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

LOBPCG is a preconditioned eigensolver for large symmetric positive definite (SPD) generalized eigenproblems.

**Parameters**

- **A**
  - [sparse matrix, dense matrix, LinearOperator] The symmetric linear operator of the problem, usually a sparse matrix. Often called the “stiffness matrix”.
- **X**
  - [ndarray, float32 or float64] Initial approximation to the k eigenvectors (non-sparse). If A has shape=(n,n) then X should have shape=(n,k).
- **B**
  - [dense matrix, sparse matrix, LinearOperator], optional] The right hand side operator in a generalized eigenproblem. By default,B = Identity. Often called the “mass matrix”.
- **M**
  - [dense matrix, sparse matrix, LinearOperator], optional] Preconditioner to A; by default M = Identity. M should approximate the inverse of A.
- **Y**
  - [ndarray, float32 or float64, optional] n-by-sizeY matrix of constraints (non-sparse), sizeY < n The iterations will be performed in the B-orthogonal complement of the column-space of Y. Y must be full rank.
- **tol**
  - [scalar, optional] Solver tolerance (stopping criterion). The default is tol=n*sqrt(eps).
- **maxiter**
  - [int, optional] Maximum number of iterations. The default is maxiter = 20.
- **largest**
  - [bool, optional] When True, solve for the largest eigenvalues, otherwise the smallest.
- **verbosityLevel**
  - [int, optional] Controls solver output. The default is verbosityLevel=0.
- **retLambdaHistory**
  - [bool, optional] Whether to return eigenvalue history. Default is False.
- **retResidualsHistory**
  - [bool, optional] Whether to return history of residual norms. Default is False.

**Returns**

w [ndarray] Array of k eigenvalues
v [ndarray] An array of k eigenvectors. v has the same shape as X.
lambdas [list of ndarray, optional] The eigenvalue history, if retLambdaHistory is True.
rnorms [list of ndarray, optional] The history of residual norms, if retResidualNormsHistory is True.

Notes

If both retLambdaHistory and retResidualNormsHistory are True, the return tuple has the following format (lambda, V, lambda history, residual norms history).

In the following n denotes the matrix size and m the number of required eigenvalues (smallest or largest).

The LOBPCG code internally solves eigenproblems of the size 3m on every iteration by calling the “standard” dense eigensolver, so if m is not small enough compared to n, it does not make sense to call the LOBPCG code, but rather one should use the “standard” eigensolver, e.g. numpy or scipy function in this case. If one calls the LOBPCG algorithm for 5m > n, it will most likely break internally, so the code tries to call the standard function instead.

It is not that n should be large for the LOBPCG to work, but rather the ratio n / m should be large. If you call LOBPCG with m=1 and n=10, it works though n is small. The method is intended for extremely large n / m [4].

The convergence speed depends basically on two factors:

1. How well relatively separated the seeking eigenvalues are from the rest of the eigenvalues. One can try to vary m to make this better.

2. How well conditioned the problem is. This can be changed by using proper preconditioning. For example, a rod vibration test problem (under tests directory) is ill-conditioned for large n, so convergence will be slow, unless efficient preconditioning is used. For this specific problem, a good simple preconditioner function would be a linear solve for A, which is easy to code since A is tridiagonal.

References

[1], [2], [3], [4]

Examples

Solve $A x = \lambda x$ with constraints and preconditioning.

```python
>>> import numpy as np
>>> from scipy.sparse import spdiags, issparse
>>> from scipy.sparse.linalg import lobpcg, LinearOperator
>>> n = 100
>>> vals = np.arange(1, n + 1)
>>> A = spdiags(vals, 0, n, n)
>>> A.toarray()
array([[ 1., 0., 0., ..., 0., 0., 0.],
       [ 0., 2., 0., ..., 0., 0., 0.],
       [ 0., 0., 3., ..., 0., 0., 0.],
       ...,
       [ 0., 0., 0., ..., 98., 0., 0.],
       [ 0., 0., 0., ..., 0., 99., 0.],
       [ 0., 0., 0., ..., 0., 0., 100.])
```

Constraints:
>>> Y = np.eye(n, 3)

Initial guess for eigenvectors, should have linearly independent columns. Column dimension = number of requested eigenvalues.

>>> X = np.random.rand(n, 3)

Preconditioner in the inverse of A in this example:

```python
>>> invA = spdiags([1./vals], 0, n, n)
```

The preconditioner must be defined by a function:

```python
def precond( x ):
    ...
    return invA @ x
```

The argument x of the preconditioner function is a matrix inside `lobpcg`, thus the use of matrix-matrix product @.

The preconditioner function is passed to `lobpcg` as a `LinearOperator`:

```python
>>> M = LinearOperator(matvec=precond, matmat=precond,
    ...
    shape=(n, n), dtype=float)
```

Let us now solve the eigenvalue problem for the matrix A:

```python
>>> eigenvalues, _ = lobpcg(A, X, Y=Y, M=M, largest=False)
>>> eigenvalues
array([4., 5., 6.])
```

Note that the vectors passed in Y are the eigenvectors of the 3 smallest eigenvalues. The results returned are orthogonal to those.

Singular values problems:

```python
svds(A[, k, ncv, tol, which, v0, maxiter, ...])
```

Compute the largest or smallest k singular values/vectors for a sparse matrix.

**scipy.sparse.linalg.svds**

```python
scipy.sparse.linalg.svds(A, k=6, ncv=None, tol=0, which='LM', v0=None, maxiter=None, return_singular_vectors=True, solver='arpack')
```

Compute the largest or smallest k singular values/vectors for a sparse matrix. The order of the singular values is not guaranteed.

**Parameters**

- **A** ([sparse matrix, LinearOperator]) Array to compute the SVD on, of shape (M, N)
- **k** [int, optional] Number of singular values and vectors to compute. Must be $1 \leq k < \min(A.shape)$.
- **ncv** [int, optional] The number of Lanczos vectors generated ncv must be greater than k+1 and smaller than n; it is recommended that ncv > 2*k Default: $\min(n, \max(2k + 1, 20))$
- **which** [str, ['LM' | 'SM'], optional] Which k singular values to find:
• ‘LM’: largest singular values  
• ‘SM’: smallest singular values  
New in version 0.12.0.

v0  
[ndarray, optional] Starting vector for iteration, of length min(A.shape). Should be an (approximate) left singular vector if N > M and a right singular vector otherwise. Default: random  
New in version 0.12.0.

maxiter  
[int, optional] Maximum number of iterations.  
New in version 0.12.0.

return_singular_vectors  
[bool or str, optional]  
• True: return singular vectors (True) in addition to singular values.  
New in version 0.12.0.  
• “u”: only return the u matrix, without computing vh (if N > M).  
• “vh”: only return the vh matrix, without computing u (if N <= M).  
New in version 0.16.0.

solver  

Returns

- u  
  [ndarray, shape=(M, k)] Unitary matrix having left singular vectors as columns. If return Singular vectors is “vh”, this variable is not computed, and None is returned instead.
- s  
  [ndarray, shape=(k,)] The singular values.
- vt  
  [ndarray, shape=(k, N)] Unitary matrix having right singular vectors as rows. If return Singular vectors is “u”, this variable is not computed, and None is returned instead.

Notes

This is a naive implementation using ARPACK or LOBPCG as an eigensolver on A.H * A or A * A.H, depending on which one is more efficient.

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import svds, eigs
>>> A = csc_matrix([[1, 0, 0], [5, 0, 2], [0, -1, 0], [0, 0, 3]], dtype=float)
>>> u, s, vt = svds(A, k=2)
>>> s
array([5.6059665, 2.7519338])
>>> np.sqrt(eigs(A.dot(A.T), k=2)[0]).real
array([5.6059665, 2.7519338])
```

Chapter 6. API Reference
**scipy.sparse.linalg.splu**

`scipy.sparse.linalg.splu(A, perm_spec=None, diag_pivot_thresh=None, relax=None, panel_size=None, options={})`

Compute the LU decomposition of a sparse, square matrix.

**Parameters**

- **A**
  - [sparse matrix] Sparse matrix to factorize. Should be in CSR or CSC format.

- **perm_spec**
  - [str, optional] How to permute the columns of the matrix for sparsity preservation. (default: 'COLAMD')
    - **NATURAL**: natural ordering.
    - **MMD_ATA**: minimum degree ordering on the structure of $A^T A$.
    - **MMD_AT_PLUS_A**: minimum degree ordering on the structure of $A^T + A$.
    - **COLAMD**: approximate minimum degree column ordering

- **diag_pivot_thresh**
  - [float, optional] Threshold used for a diagonal entry to be an acceptable pivot. See SuperLU user’s guide for details [1]

- **relax**
  - [int, optional] Expert option for customizing the degree of relaxing supernodes. See SuperLU user's guide for details [1]

- **panel_size**
  - [int, optional] Expert option for customizing the panel size. See SuperLU user’s guide for details [1]

- **options**
  - [dict, optional] Dictionary containing additional expert options to SuperLU. See SuperLU user guide [1] (section 2.4 on the ‘Options’ argument) for more details. For example, you can specify `options=dict(Equil=False, IterRefine='SINGLE'))` to turn equilibration off and perform a single iterative refinement.

**Returns**

- **invA**
  - [scipy.sparse.linalg.SuperLU] Object, which has a `solve` method.

**See also:**

- **spilu**
  - incomplete LU decomposition

**Notes**

This function uses the SuperLU library.

**References**

[1]
Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import splu
>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]],
                  dtype=float)
>>> B = splu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([ 1. , -3. , -1.5])
>>> A.dot(B.solve(x))
array([ 1., 2., 3.])
>>> B.solve(A.dot(x))
array([ 1., 2., 3.])

scipy.sparse.linalg.spilu

scipy.sparse.linalg.spilu(A, drop_tol=None, fill_factor=None, drop_rule=None, diag_pivot_thresh=None, relax=None, panel_size=None, options=None)

Compute an incomplete LU decomposition for a sparse, square matrix.

The resulting object is an approximation to the inverse of A.

Parameters

- `A` ((N, N) array_like) Sparse matrix to factorize
- `drop_tol` [float, optional] Drop tolerance (0 <= tol <= 1) for an incomplete LU decomposition. (default: 1e-4)
- `fill_factor` [float, optional] Specifies the fill ratio upper bound (>= 1.0) for ILU. (default: 10)
- `diag_pivot_thresh` [None] (default: None)
- `relax` [None] (default: None)
- `panel_size` [None] (default: None)
- `options` [None] (default: None)

Returns

- `invA_approx` [scipy.sparse.linalg.SuperLU] Object, which has a `solve` method.

See also:

- `splu`
  complete LU decomposition
Notes

To improve the better approximation to the inverse, you may need to increase fill_factor AND decrease drop_tol. This function uses the SuperLU library.

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spilu
>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]])
>>> B = spilu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([ 1. , -3. , -1.5])
>>> A.dot(B.solve(x))
array([ 1., 2., 3.])
>>> B.solve(A.dot(x))
array([ 1., 2., 3.])
```

scipy.sparse.linalg.SuperLU

class scipy.sparse.linalg.SuperLU

LU factorization of a sparse matrix.

Factorization is represented as:

$$Pr \cdot A \cdot Pc = L \cdot U$$

To construct these SuperLU objects, call the splu and spilu functions.

Notes

New in version 0.14.0.

Examples

The LU decomposition can be used to solve matrix equations. Consider:

```python
>>> import numpy as np
>>> from scipy.sparse import csc_matrix, linalg as sla
>>> A = csc_matrix([[1,2,0,4],[1,0,0,1],[1,0,2,1],[2,2,1,0.]])
```

This can be solved for a given right-hand side:

```python
>>> lu = sla.splu(A)
>>> b = np.array([1, 2, 3, 4])
>>> x = lu.solve(b)
>>> A.dot(x)
array([ 1., 2., 3., 4.])
```
The `lu` object also contains an explicit representation of the decomposition. The permutations are represented as mappings of indices:

```python
>>> lu.perm_r
array([0, 2, 1, 3], dtype=int32)
>>> lu.perm_c
array([2, 0, 1, 3], dtype=int32)
```

The `L` and `U` factors are sparse matrices in CSC format:

```python
>>> lu.L.A
array([[ 1.,  0.,  0.,  0.],
       [ 0.,  1.,  0.,  0.],
       [ 0.,  0.,  1.,  0.],
       [ 1.,  0.5,  0.5,  1.]])
>>> lu.U.A
array([[ 2.,  0.,  1.,  4.],
       [ 0.,  2.,  1.,  1.],
       [ 0.,  0.,  1.,  1.],
       [ 0.,  0.,  0.,  5.]])
```

The permutation matrices can be constructed:

```python
>>> Pr = csc_matrix((np.ones(4), (lu.perm_r, np.arange(4))))
>>> Pc = csc_matrix((np.ones(4), (np.arange(4), lu.perm_c)))
```

We can reassemble the original matrix:

```python
>>> (Pr.T * (lu.L * lu.U) * Pc.T).A
array([[ 1.,  2.,  0.,  4.],
       [ 1.,  0.,  0.,  1.],
       [ 1.,  0.,  2.,  1.],
       [ 2.,  2.,  1.,  0.]])
```

**Attributes**

- `shape`: Shape of the original matrix as a tuple of ints.
- `nnz`: Number of nonzero elements in the matrix.
- `perm_c`: Permutation `Pc` represented as an array of indices.
- `perm_r`: Permutation `Pr` represented as an array of indices.
- `L`: Lower triangular factor with unit diagonal as a `scipy.sparse.csc_matrix`.
- `U`: Upper triangular factor as a `scipy.sparse.csc_matrix`.

**Methods**

- `solve(rhs[, trans])`: Solves linear system of equations with one or several right-hand sides.
**scipy.sparse.linalg.SuperLU.solve**

```python
SuperLU.solve(rhs[, trans])
```

Solves linear system of equations with one or several right-hand sides.

**Parameters**

- `rhs` [ndarray, shape (n,) or (n, k)] Right hand side(s) of equation
- `trans` [{'N', 'T', 'H'}, optional] Type of system to solve:

<table>
<thead>
<tr>
<th>trans</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'N'</td>
<td>$A \times x = rhs$ (default)</td>
</tr>
<tr>
<td>'T'</td>
<td>$A^T \times x = rhs$</td>
</tr>
<tr>
<td>'H'</td>
<td>$A^H \times x = rhs$</td>
</tr>
</tbody>
</table>

i.e., normal, transposed, and hermitian conjugate.

**Returns**

- `x` [ndarray, shape `rhs.shape`] Solution vector(s)

### 6.24.6 Exceptions

scipy.sparse.csgraph.connected_components

scipy.sparse.csgraph.connected_components(csgraph[, directed=True, connection='weak', return_labels=True])

Analyze the connected components of a sparse graph

New in version 0.11.0.

Parameters

csgraph [array_like or sparse matrix] The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
directed [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

connection [str, optional] ['weak'|'strong']. For directed graphs, the type of connection to use. Nodes i and j are strongly connected if a path exists both from i to j and from j to i. A directed graph is weakly connected if replacing all of its directed edges with undirected edges produces a connected (undirected) graph. If directed == False, this keyword is not referenced.

return_labels [bool, optional] If True (default), then return the labels for each of the connected components.

Returns

n_components: int
    The number of connected components.

labels: ndarray
    The length-N array of labels of the connected components.

References

[1]

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import connected_components

>>> graph = [
    ... [0, 1, 1, 0, 0],
    ... [0, 0, 1, 0, 0],
    ... [0, 0, 0, 0, 0],
    ... [0, 0, 0, 0, 1],
    ... [0, 0, 0, 0, 0]
    ...
]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 1
(1, 2) 1
(3, 4) 1

>>> n_components, labels = connected_components(csgraph=graph,
    ... directed=False, return_labels=True)
>>> n_components
2
>>> labels
array([0, 0, 0, 1, 1], dtype=int32)
```
scipy.sparse.csgraph.laplacian

`scipy.sparse.csgraph.laplacian(csgraph, normed=False, return_diag=False, use_out_degree=False)`

Return the Laplacian matrix of a directed graph.

**Parameters**

- `csgraph` [array_like or sparse matrix, 2 dimensions] compressed-sparse graph, with shape (N, N).
- `normed` [bool, optional] If True, then compute symmetric normalized Laplacian.
- `return_diag` [bool, optional] If True, then also return an array related to vertex degrees.
- `use_out_degree` [bool, optional] If True, then use out-degree instead of in-degree. This distinction matters only if the graph is asymmetric. Default: False.

**Returns**

- `lap` [ndarray or sparse matrix] The N x N laplacian matrix of csgraph. It will be a NumPy array (dense) if the input was dense, or a sparse matrix otherwise.
- `diag` [ndarray, optional] The length-N diagonal of the Laplacian matrix. For the normalized Laplacian, this is the array of square roots of vertex degrees or 1 if the degree is zero.

**Notes**

The Laplacian matrix of a graph is sometimes referred to as the “Kirchoff matrix” or the “admittance matrix”, and is useful in many parts of spectral graph theory. In particular, the eigen-decomposition of the laplacian matrix can give insight into many properties of the graph.

**Examples**

```python
>>> from scipy.sparse import csgraph
>>> G = np.arange(5) * np.arange(5)[:, np.newaxis]
>>> G
array([[ 0,  0,  0,  0,  0],
       [ 0,  1,  2,  3,  4],
       [ 0,  2,  4,  6,  8],
       [ 0,  3,  6,  9, 12],
       [ 0,  4,  8, 12, 16]])
>>> csgraph.laplacian(G, normed=False)
array([[ 0,  0,  0,  0,  0],
       [ 0,  9, -2, -3, -4],
       [ 0, -2, 16, -6, -8],
       [ 0, -3, -6, 21, -12],
       [ 0, -4, -8, -12, 24]])
```
scipy.sparse.csgraph.shortest_path

**scipy.sparse.csgraph.shortest_path** *(csgraph, method='auto', directed=True, return_predecessors=False, unweighted=False, overwrite=False, indices=None)*

Perform a shortest-path graph search on a positive directed or undirected graph.

New in version 0.11.0.

**Parameters**

- **csgraph** *[array, matrix, or sparse matrix, 2 dimensions]* The N x N array of distances representing the input graph.

- **method** *[string ['auto'|'FW'|'D'], optional]* Algorithm to use for shortest paths. Options are:

  - ‘FW’ – Floyd-Warshall algorithm. Computational cost is \(O[N^3]\). The input csgraph will be converted to a dense representation.
  - ‘D’ – Dijkstra’s algorithm with Fibonacci heaps. Computational cost is approximately \(O[N(N*k + N*log(N))]\), where \(k\) is the average number of connected edges per node. The input csgraph will be converted to a csr representation.
  - ‘BF’ – Bellman-Ford algorithm. This algorithm can be used when weights are negative. If a negative cycle is encountered, an error will be raised. Computational cost is approximately \(O[N(N^2 k)]\), where \(k\) is the average number of connected edges per node. The input csgraph will be converted to a csr representation.
  - ‘J’ – Johnson’s algorithm. Like the Bellman-Ford algorithm, Johnson’s algorithm is designed for use when the weights are negative. It combines the Bellman-Ford algorithm with Dijkstra’s algorithm for faster computation.

- **directed** *[bool, optional]* If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]

- **return_predecessors** *[bool, optional]* If True, return the size (N, N) predecessor matrix

- **unweighted** *[bool, optional]* If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

- **overwrite** *[bool, optional]* If True, overwrite csgraph with the result. This applies only if method == ‘FW’ and csgraph is a dense, c-ordered array with dtype=float64.

- **indices** *[array_like or int, optional]* If specified, only compute the paths from the points at the given indices. Incompatible with method == ‘FW’.

**Returns**

- **dist_matrix** *[ndarray]* The N x N matrix of distances between graph nodes. dist_matrix[i, j] gives the shortest distance from point i to point j along the graph.

- **predecessors** *[ndarray]* Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index...
of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

Raises

NegativeCycleError:
if there are negative cycles in the graph

Notes

As currently implemented, Dijkstra’s algorithm and Johnson’s algorithm do not work for graphs with direction-dependent distances when directed == False. i.e., if csgraph[i,j] and csgraph[j,i] are non-equal edges, method='D' may yield an incorrect result.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import shortest_path

>>> graph = [
  ... [0, 1, 2, 0],
  ... [0, 0, 0, 1],
  ... [2, 0, 0, 3],
  ... [0, 0, 0, 0]
  ...
]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> dist_matrix, predecessors = shortest_path(csgraph=graph,
...   directed=False, indices=0, return_predecessors=True)
>>> dist_matrix
array([ 0., 1., 2., 2.])
>>> predecessors
array([-9999, 0, 0, 1], dtype=int32)
```

scipy.sparse.csgraph.dijkstra

scipy.sparse.csgraph.dijkstra(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False, limit=np.inf, min_only=False)

Dijkstra algorithm using Fibonacci Heaps

New in version 0.11.0.

Parameters

- **csgraph** [array, matrix, or sparse matrix, 2 dimensions] The N x N array of non-negative distances representing the input graph.
directed [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j] and from point j to i along paths csgraph[j, i]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j or j to i along either csgraph[i, j] or csgraph[j, i].

indices [array_like or int, optional] if specified, only compute the paths from the points at the given indices.

return_predecessors [bool, optional] If True, return the size (N, N) predecessor matrix

unweighted [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

limit [float, optional] The maximum distance to calculate, must be >= 0. Using a smaller limit will decrease computation time by aborting calculations between pairs that are separated by a distance > limit. For such pairs, the distance will be equal to np.inf (i.e., not connected). New in version 0.14.0.

min_only [bool, optional] If False (default), for every node in the graph, find the shortest path from every node in indices. If True, for every node in the graph, find the shortest path from any of the nodes in indices (which can be substantially faster). New in version 1.3.0.

Returns
dist_matrix [ndarray, shape ([n_indices, ]n_nodes,)] The matrix of distances between graph nodes. If min_only=False, dist_matrix has shape (n_indices, n_nodes) and dist_matrix[i, j] gives the shortest distance from point i to point j along the graph. If min_only=True, dist_matrix has shape (n_nodes, ) and contains for a given node the shortest path to that node from any of the nodes in indices.

predecessors [ndarray, shape ([n_indices, ]n_nodes,)] If min_only=False, this has shape (n_indices, n_nodes), otherwise it has shape (n_nodes,). Returned only if return_predecessors == True. The matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

sources [ndarray, shape (n_nodes,)] Returned only if min_only=True and return_predecessors=True. Contains the index of the source which had the shortest path to each target. If no path exists within the limit, this will contain -9999. The value at the indices passed will be equal to that index (i.e. the fastest way to reach node i, is to start on node i).

Notes

As currently implemented, Dijkstra’s algorithm does not work for graphs with direction-dependent distances when directed == False. i.e., if csgraph[i,j] and csgraph[j,i] are not equal and both are nonzero, setting directed=False will not yield the correct result.

Also, this routine does not work for graphs with negative distances. Negative distances can lead to infinite cycles that must be handled by specialized algorithms such as Bellman-Ford’s algorithm or Johnson’s algorithm.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import dijkstra

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 3) 3

>>> dist_matrix, predecessors = dijkstra(csgraph=graph, directed=False, indices=0, return_predecessors=True)
>>> dist_matrix
array([ 0., 1., 2., 2.])
>>> predecessors
array([-9999, 0, 0, 1], dtype=int32)
```

`scipy.sparse.csgraph.floyd_warshall`

`scipy.sparse.csgraph.floyd_warshall(csgraph, directed=True, return_predecessors=False, unweighted=False, overwrite=False)`

Compute the shortest path lengths using the Floyd-Warshall algorithm
New in version 0.11.0.

Parameters

- `csgraph` [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.
- `directed` [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
- `return_predecessors` [bool, optional] If True, return the size (N, N) predecessor matrix
- `unweighted` [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- `overwrite` [bool, optional] If True, overwrite csgraph with the result. This applies only if csgraph is a dense, c-ordered array with dtype=float64.

Returns

- `dist_matrix` [ndarray] The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.
predecessors

[ndarray] Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

Raises

NegativeCycleError:

if there are negative cycles in the graph

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import floyd_warshall

>>> graph = [
    ... [0, 1, 2, 0],
    ... [0, 0, 0, 1],
    ... [2, 0, 0, 3],
    ... [0, 0, 0, 0]
    ... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> dist_matrix, predecessors = floyd_warshall(csgraph=graph,
    ... directed=False, return_predecessors=True)
>>> dist_matrix
array([[ 0., 1., 2., 2.],
        [ 1., 0., 3., 1.],
        [ 2., 3., 0., 3.],
        [ 2., 1., 3., 0.]]),
>>> predecessors
array([[-9999,  0,  0,  1],
        [ 1, -9999,  0,  1],
        [ 2,   0,  9999,  2],
        [ 1,  3,  3, -9999]], dtype=int32)
```
ComputetheshortestpathlengthsusingtheBellman-Fordalgorithm.

The Bellman-Ford algorithm can robustly deal with graphs with negative weights. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, Dijkstra’s algorithm may be faster.

New in version 0.11.0.

Parameters

- **csgraph** [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.
- **directed** [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].
- **indices** [array_like or int, optional] if specified, only compute the paths from the points at the given indices.
- **return_predecessors** [bool, optional] If True, return the size (N, N) predecessor matrix
- **unweighted** [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

Returns

- **dist_matrix** [ndarray] The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.
- **predecessors** [ndarray] Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

Raises

- **NegativeCycleError:** if there are negative cycles in the graph

Notes

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra’s algorithm is a better choice.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import bellman_ford

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
 (0, 1) 1
 (0, 2) 2
 (1, 3) 1
 (2, 0) 2
 (2, 3) 3

>>> dist_matrix, predecessors = bellman_ford(csgraph=graph, directed=False, indices=0, return_predecessors=True)
>>> dist_matrix
array([[ 0., 1., 2., 2.]])
>>> predecessors
array([-9999,  0,  0,  1], dtype=int32)
```

`scipy.sparse.csgraph.johnson`

`scipy.sparse.csgraph.johnson`(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False)

Compute the shortest path lengths using Johnson's algorithm.

Johnson’s algorithm combines the Bellman-Ford algorithm and Dijkstra's algorithm to quickly find shortest paths in a way that is robust to the presence of negative cycles. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, dijkstra may be faster.

New in version 0.11.0.

Parameters

- `csgraph` [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.
- `directed` [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
- `indices` [array_like or int, optional] if specified, only compute the paths from the points at the given indices.
- `return_predecessors` [bool, optional] If True, return the size (N, N) predecessor matrix
- `unweighted` [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
Returns

**dist_matrix**

[ndarray] The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.

**predecessors**

[ndarray] Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

Raises

**NegativeCycleError**: if there are negative cycles in the graph

Notes

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra's algorithm is a better choice.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import johnson

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> dist_matrix, predecessors = johnson(csgraph=graph, directed=False,
                                           indices=0, return_predecessors=True)
>>> dist_matrix
array([0., 1., 2., 2.])
>>> predecessors
array([[-9999, 0, 0, 1], dtype=int32)
```
scipy.sparse.csgraph.breadth_first_order

scipy.sparse.csgraph.breadth_first_order(csgraph, i_start, directed=True, return_predecessors=True)

Return a breadth-first ordering starting with specified node.

Note that a breadth-first order is not unique, but the tree which it generates is unique.

New in version 0.11.0.

Parameters

- csgraph : [array_like or sparse matrix] The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i_start : [int] The index of starting node.
- directed : [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].
- return_predecessors : [bool, optional] If True (default), then return the predecessor array (see below).

Returns

- node_array : [ndarray, one dimension] The breadth-first list of nodes, starting with specified node. The length of node_array is the number of nodes reachable from the specified node.
- predecessors : [ndarray, one dimension] Returned only if return_predecessors is True. The length-N list of predecessors of each node in a breadth-first tree. If node i is in the tree, then its parent is given by predecessors[i]. If node i is not in the tree (and for the parent node) then predecessors[i] = -9999.

Examples

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_order

>>> graph = [
    ... [0, 1, 2, 0],
    ... [0, 0, 0, 1],
    ... [2, 0, 0, 3],
    ... [0, 0, 0],
    ... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> breadth_first_order(graph, 0)
(array([0, 1, 2, 3], dtype=int32), array([-9999, 0, 0, 1],
       dtype=int32))
scipy.sparse.csgraph.depth_first_order

scipy.sparse.csgraph.depth_first_order(csgraph, i_start, directed=True, return_predecessors=True)

Return a depth-first ordering starting with specified node.

Note that a depth-first order is not unique. Furthermore, for graphs with cycles, the tree generated by a depth-first search is not unique either.

New in version 0.11.0.

Parameters

- csgraph [array_like or sparse matrix] The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i_start [int] The index of starting node.
- directed [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].
- return_predecessors [bool, optional] If True (default), then return the predecessor array (see below).

Returns

- node_array [ndarray, one dimension] The depth-first list of nodes, starting with specified node. The length of node_array is the number of nodes reachable from the specified node.
- predecessors [ndarray, one dimension] Returned only if return_predecessors is True. The length-N list of predecessors of each node in a depth-first tree. If node i is in the tree, then its parent is given by predecessors[i]. If node i is not in the tree (and for the parent node) then predecessors[i] = -9999.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_order

>>> graph = [
... [0, 1 , 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> depth_first_order(graph, 0)
(array([0, 1, 3, 2], dtype=int32), array([-9999, 0, 0, 1],
... dtype=int32))
```
scipy.sparse.csgraph.breadth_first_tree

scipy.sparse.csgraph.breadth_first_tree(csgraph, i_start, directed=True)

Return the tree generated by a breadth-first search

Note that a breadth-first tree from a specified node is unique.

New in version 0.11.0.

Parameters

- csgraph [array_like or sparse matrix] The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i_start [int] The index of starting node.
- directed [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

Returns

- cstree [csr matrix] The N x N directed compressed-sparse representation of the breadth-first tree drawn from csgraph, starting at the specified node.

Examples

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

```
    input graph           breadth first tree from (0)

    (0)                (0)
      / \                / \ 
    3 8                3 8
      / \                / \ 
    (3)---5---(1)      (3)  (1)
          /              /
         /               /
        6 2             2
          /              /
        (2)             (2)
```

In compressed sparse representation, the solution looks like this:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
                  ... [0, 0, 2, 5],
                  ... [0, 0, 6, 0],
                  ... [0, 0, 0, 0]])
>>> Tcsr = breadth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 3],
       [0, 0, 2, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])
```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. A breadth-first tree from a given node is unique.
scipy.sparse.csgraph.depth_first_tree

scipy.sparse.csgraph.depth_first_tree(csgraph, i_start, directed=True)

Return a tree generated by a depth-first search.

Note that a tree generated by a depth-first search is not unique: it depends on the order that the children of each node are searched.

New in version 0.11.0.

Parameters

- csgraph [array_like or sparse matrix] The `N x N` matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i_start [int] The index of starting node.
- directed [bool, optional] If True (default), then operate on a directed graph: only move from point `i` to point `j` along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point `i` to `j` along `csgraph[i,j]` or `csgraph[j,i]`.

Returns

- cstree [csr matrix] The `N x N` directed compressed-sparse representation of the depth-first tree drawn from csgraph, starting at the specified node.

Examples

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

<table>
<thead>
<tr>
<th>input graph</th>
<th>depth first tree from (0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(0)</td>
<td>(0)</td>
</tr>
<tr>
<td>/ \</td>
<td>\ /</td>
</tr>
<tr>
<td>3 8</td>
<td>8</td>
</tr>
<tr>
<td>/ \</td>
<td>\ /</td>
</tr>
<tr>
<td>(3)---5---(1)</td>
<td>(3) (1)</td>
</tr>
<tr>
<td>\ /</td>
<td>\ /</td>
</tr>
<tr>
<td>6 2</td>
<td>6 2</td>
</tr>
<tr>
<td>\ /</td>
<td>\ /</td>
</tr>
<tr>
<td>(2)</td>
<td>(2)</td>
</tr>
</tbody>
</table>

In compressed sparse representation, the solution looks like this:

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                 [0, 0, 2, 5],
...                 [0, 0, 0, 6],
...                 [0, 0, 0, 0]])
>>> Tcsr = depth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 0],
       [0, 0, 2, 0],
       [0, 0, 0, 6],
       [0, 0, 0, 0]])
```
Note that the resulting graph is a Directed Acyclic Graph which spans the graph. Unlike a breadth-first tree, a depth-first tree of a given graph is not unique if the graph contains cycles. If the above solution had begun with the edge connecting nodes 0 and 3, the result would have been different.

**scipy.sparse.csgraph.minimum_spanning_tree**

```python
scipy.sparse.csgraph.minimum_spanning_tree(csgraph, overwrite=False)
```

Return a minimum spanning tree of an undirected graph

A minimum spanning tree is a graph consisting of the subset of edges which together connect all connected nodes, while minimizing the total sum of weights on the edges. This is computed using the Kruskal algorithm.

New in version 0.11.0.

**Parameters**

- `csgraph` [array_like or sparse matrix, 2 dimensions] The N x N matrix representing an undirected graph over N nodes (see notes below).
- `overwrite` [bool, optional] if true, then parts of the input graph will be overwritten for efficiency.

**Returns**

- `span_tree` [csr matrix] The N x N compressed-sparse representation of the undirected minimum spanning tree over the input (see notes below).

**Notes**

This routine uses undirected graphs as input and output. That is, if graph[i, j] and graph[j, i] are both zero, then nodes i and j do not have an edge connecting them. If either is nonzero, then the two are connected by the minimum nonzero value of the two.

This routine loses precision when users input a dense matrix. Small elements < 1E-8 of the dense matrix are rounded to zero. All users should input sparse matrices if possible to avoid it.

**Examples**

The following example shows the computation of a minimum spanning tree over a simple four-component graph:

```
input graph               minimum spanning tree
(0) / \ (0)               (0)
/  \ /  \
3 8 3
/ \ /  \\
(3)---5---(1)            (3)---5---(1)
\ /  /
6 2 2
\ /  \\
(2)                 (2)
```

It is easy to see from inspection that the minimum spanning tree involves removing the edges with weights 8 and 6. In compressed sparse representation, the solution looks like this:
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import minimum_spanning_tree
>>> X = csr_matrix([[0, 8, 0, 3],
                  ... [0, 0, 2, 5],
                  ... [0, 0, 0, 6],
                  ... [0, 0, 0, 0]])
>>> Tcsr = minimum_spanning_tree(X)
>>> Tcsr.toarray().astype(int)
array([[0, 0, 0, 3],
       [0, 0, 2, 5],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int32)

scipy.sparse.csgraph.reverse_cuthill_mckee

scipy.sparse.csgraph.reverse_cuthill_mckee(graph, symmetric_mode=False)

Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.

It is assumed by default, symmetric_mode=False, that the input matrix is not symmetric and works on the matrix \(A + A^T\). If you are guaranteed that the matrix is symmetric in structure (values of matrix elements do not matter) then set symmetric_mode=True.

Parameters

graph [sparse matrix] Input sparse in CSC or CSR sparse matrix format.
symmetric_mode [bool, optional] Is input matrix guaranteed to be symmetric.

Returns

perm [ndarray] Array of permuted row and column indices.

Notes

New in version 0.15.0.

References

Examples

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import reverse_cuthill_mckee

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 1],
... [2, 0, 3],
... [0, 0, 0] ]

(continues on next page)
```python
... 
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> reverse_cuthill_mckee(graph)
array([3, 2, 1, 0], dtype=int32)
```

### `scipy.sparse.csgraph.maximum_flow`

**`scipy.sparse.csgraph.maximum_flow(csgraph, source, sink)`**

Maximize the flow between two vertices in a graph.

New in version 1.4.0.

**Parameters**

- `csgraph` [csr_matrix] The square matrix representing a directed graph whose (i, j)'th entry is an integer representing the capacity of the edge between vertices i and j.
- `source` [int] The source vertex from which the flow flows.
- `sink` [int] The sink vertex to which the flow flows.

**Returns**

- `res` [MaximumFlowResult] A maximum flow represented by a `MaximumFlowResult` which includes the value of the flow in `flow_value`, and the residual graph in `residual`.

**Raises**

- `TypeError`: if the input graph is not in CSR format.
- `ValueError`: if the capacity values are not integers, or the source or sink are out of bounds.

**Notes**

This solves the maximum flow problem on a given directed weighted graph: A flow associates to every edge a value, also called a flow, less than the capacity of the edge, so that for every vertex (apart from the source and the sink vertices), the total incoming flow is equal to the total outgoing flow. The value of a flow is the sum of the flow of all edges leaving the source vertex, and the maximum flow problem consists of finding a flow whose value is maximal.

By the max-flow min-cut theorem, the maximal value of the flow is also the total weight of the edges in a minimum cut.

To solve the problem, we use the Edmonds–Karp algorithm. [1] This particular implementation strives to exploit sparsity. Its time complexity is $O(VE^2)$ and its space complexity is $O(E)$.

The maximum flow problem is usually defined with real valued capacities, but we require that all capacities are integral to ensure convergence. When dealing with rational capacities, or capacities belonging to $\mathbb{Q}$ for some fixed $x \in \mathbb{R}$, it is possible to reduce the problem to the integral case by scaling all capacities accordingly.

Solving a maximum-flow problem can be used for example for graph cuts optimization in computer vision [3].
References

[1], [2], [3]

Examples

Perhaps the simplest flow problem is that of a graph of only two vertices with an edge from source (0) to sink (1):

(0) --5--> (1)

Here, the maximum flow is simply the capacity of the edge:

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import maximum_flow
>>> graph = csr_matrix([[0, 5], [0, 0]])
>>> maximum_flow(graph, 0, 1).flow_value
5
```

If, on the other hand, there is a bottleneck between source and sink, that can reduce the maximum flow:

(0) --5--> (1) --3--> (2)

```python
>>> graph = csr_matrix([[0, 5, 0], [0, 0, 3], [0, 0, 0]])
>>> maximum_flow(graph, 0, 2).flow_value
3
```

A less trivial example is given in [2], Chapter 26.1:

```python
>>> graph = csr_matrix([[0, 16, 13, 0, 0, 0],
... [0, 10, 0, 12, 0, 0],
... [0, 4, 0, 0, 14, 0],
... [0, 0, 9, 0, 0, 20],
... [0, 0, 7, 0, 4],
... [0, 0, 0, 0, 0, 0]])
>>> maximum_flow(graph, 0, 5).flow_value
23
```

It is possible to reduce the problem of finding a maximum matching in a bipartite graph to a maximum flow problem: Let $G = ((U, V), E)$ be a bipartite graph. Then, add to the graph a source vertex with edges to every vertex in $U$ and a sink vertex with edges from every vertex in $V$. Finally, give every edge in the resulting graph a capacity of 1. Then, a maximum flow in the new graph gives a maximum matching in the original graph consisting of the edges in $E$ whose flow is positive.

Assume that the edges are represented by a $|U| \times |V|$ matrix in CSR format whose $(i, j)$’th entry is 1 if there is an edge from $i \in U$ to $j \in V$ and 0 otherwise; that is, the input is of the form required by maximum_bipartite_matching. Then the CSR representation of the graph constructed above contains this matrix as a block. Here’s an example:

```python
>>> graph = csr_matrix([[0, 1, 0, 1], [1, 0, 1, 0], [0, 1, 1, 0]])
>>> print(graph.toarray())
[[0 1 0 1]
 [1 0 1 0]
 [0 1 1 0]]
```
>>> i, j = graph.shape
>>> n = graph.nnz
>>> indptr = np.concatenate([[0],
...                         graph.indptr + i,
...                         np.arange(n + i + 1, n + i + j + 1),
...                         [n + i + j]])
>>> indices = np.concatenate([np.arange(i, i + 1),
...                            graph.indices + i + 1,
...                            np.repeat(i + j + 1, j)])
>>> data = np.ones(n + i + j, dtype=int)
>>> graph_flow = csr_matrix((data, indices, indptr))
>>> print(graph_flow.toarray())
[0 1 1 1 0 0 0 0 0]
[0 0 0 0 1 0 1 0 0]
[0 0 0 0 1 0 1 0 0]
[0 0 0 0 0 0 0 0 1]
[0 0 0 0 0 0 0 0 1]
[0 0 0 0 0 0 0 0 1]
[0 0 0 0 0 0 0 0 1]
[0 0 0 0 0 0 0 0 1]
[0 0 0 0 0 0 0 0 0]

At this point, we can find the maximum flow between the added sink and the added source and the desired matching can be obtained by restricting the residual graph to the block corresponding to the original graph:

>>> flow = maximum_flow(graph_flow, 0, i+j+1)
>>> matching = flow.residual[1:i+1, i+1:i+j+1]
>>> print(matching.toarray())
[[0 1 0 0]
 [1 0 0 0]
 [0 0 1 0]]

This tells us that the first, second, and third vertex in $U$ are matched with the second, first, and third vertex in $V$ respectively.

While this solves the maximum bipartite matching problem in general, note that algorithms specialized to that problem, such as maximum_bipartite_matching, will generally perform better.

This approach can also be used to solve various common generalizations of the maximum bipartite matching problem. If, for instance, some vertices can be matched with more than one other vertex, this may be handled by modifying the capacities of the new graph appropriately.

**scipy.sparse.csgraph.maximum_bipartite_matching**

scipy.sparse.csgraph.maximum_bipartite_matching(graph, perm_type='row')

Returns a matching of a bipartite graph whose cardinality is as least that of any given matching of the graph.

**Parameters**

- **graph** [sparse matrix] Input sparse in CSR format whose rows represent one partition of the graph and whose columns represent the other partition. An edge between two vertices is indicated by the corresponding entry in the matrix existing in its sparse representation.
perm_type
[str, {'row', 'column'}] Which partition to return the matching in terms of: If 'row', the function produces an array whose length is the number of columns in the input, and whose j'th element is the row matched to the j'th column. Conversely, if perm_type is 'column', this returns the columns matched to each row.

Returns
perm [ndarray] A matching of the vertices in one of the two partitions. Unmatched vertices are represented by a -1 in the result.

Notes
This function implements the Hopcroft–Karp algorithm [1]. Its time complexity is \(O(|E|\sqrt{|V|})\), and its space complexity is linear in the number of rows. In practice, this asymmetry between rows and columns means that it can be more efficient to transpose the input if it contains more columns than rows.

By Konig's theorem, the cardinality of the matching is also the number of vertices appearing in a minimum vertex cover of the graph.

Note that if the sparse representation contains explicit zeros, these are still counted as edges.

The implementation was changed in SciPy 1.4.0 to allow matching of general bipartite graphs, where previous versions would assume that a perfect matching existed. As such, code written against 1.4.0 will not necessarily work on older versions.

References
[1]

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import maximum_bipartite_matching

As a simple example, consider a bipartite graph in which the partitions contain 2 and 3 elements respectively. Suppose that one partition contains vertices labelled 0 and 1, and that the other partition contains vertices labelled A, B, and C. Suppose that there are edges connecting 0 and C, 1 and A, and 1 and B. This graph would then be represented by the following sparse matrix:

```python
>>> graph = csr_matrix([[0, 0, 1], [1, 1, 0]])
```

Here, the 1s could be anything, as long as they end up being stored as elements in the sparse matrix. We can now calculate maximum matchings as follows:

```python
>>> print(maximum_bipartite_matching(graph, perm_type='column'))
[2 0]
>>> print(maximum_bipartite_matching(graph, perm_type='row'))
[1 -1 0]
```

The first output tells us that 1 and 2 are matched with C and A respectively, and the second output tells us that A, B, and C are matched with 1, nothing, and 0 respectively.

Note that explicit zeros are still converted to edges. This means that a different way to represent the above graph is by using the CSR structure directly as follows:
```python
>>> data = [0, 0, 0]
>>> indices = [2, 0, 1]
>>> indptr = [0, 1, 3]
>>> graph = csr_matrix((data, indices, indptr))
>>> print(maximum_bipartite_matching(graph, perm_type='column'))
[2 0]
>>> print(maximum_bipartite_matching(graph, perm_type='row'))
[1 -1 0]
```

When one or both of the partitions are empty, the matching is empty as well:

```python
>>> graph = csr_matrix((2, 0))
>>> print(maximum_bipartite_matching(graph, perm_type='column'))
[-1 -1]
>>> print(maximum_bipartite_matching(graph, perm_type='row'))
[]
```

When the input matrix is square, and the graph is known to admit a perfect matching, i.e. a matching with the property that every vertex in the graph belongs to some edge in the matching, then one can view the output as the permutation of rows (or columns) turning the input matrix into one with the property that all diagonal elements are non-empty:

```python
>>> a = [[0, 1, 2, 0], [1, 0, 0, 1], [2, 0, 0, 3], [0, 1, 3, 0]]
>>> graph = csr_matrix(a)
>>> perm = maximum_bipartite_matching(graph, perm_type='row')
>>> print(graph[perm].toarray())
[[1 0 0 1]
 [0 1 2 0]
 [0 1 3 0]
 [2 0 0 3]]
```

**scipy.sparse.csgraph.min_weight_full_bipartite_matching**

Returns the minimum weight full matching of a bipartite graph.

New in version 1.6.0.

**Parameters**

- `biadjacency_matrix` [sparse matrix] Biadjacency matrix of the bipartite graph: A sparse matrix in CSR, CSC, or COO format whose rows represent one partition of the graph and whose columns represent the other partition. An edge between two vertices is indicated by the corresponding entry in the matrix, and the weight of the edge is given by the value of that entry. This should not be confused with the full adjacency matrix of the graph, as we only need the submatrix defining the bipartite structure.

- `maximize` [bool (default: False)] Calculates a maximum weight matching if true.

**Returns**

- `row_ind, col_ind` [array] An array of row indices and one of corresponding column indices giving the optimal matching. The total weight of the matching can be computed as `graph[row_ind, col_ind]`. 

6.25. Compressed sparse graph routines *(scipy.sparse.csgraph)*
col_ind].sum(). The row indices will be sorted; in the case of a square matrix they will be equal to numpy.arange(graph.shape[0]).

Notes

Let $G = ((U, V), E)$ be a weighted bipartite graph with non-zero weights $w : E \rightarrow \mathbb{R} \setminus \{0\}$. This function then produces a matching $M \subseteq E$ with cardinality

$$|M| = \min(|U|, |V|),$$

which minimizes the sum of the weights of the edges included in the matching, $\sum_{e \in M} w(e)$, or raises an error if no such matching exists.

When $|U| = |V|$, this is commonly referred to as a perfect matching; here, since we allow $|U|$ and $|V|$ to differ, we follow Karp [1] and refer to the matching as full.

This function implements the LAPJVsp algorithm [2], short for “Linear assignment problem, Jonker–Volgenant, sparse”.

The problem it solves is equivalent to the rectangular linear assignment problem. [3] As such, this function can be used to solve the same problems as scipy.optimize.linear_sum_assignment. That function may perform better when the input is dense, or for certain particular types of inputs, such as those for which the $(i, j)$’th entry is the distance between two points in Euclidean space.

If no full matching exists, this function raises a ValueError. For determining the size of the largest matching in the graph, see maximum_bipartite_matching.

We require that weights are non-zero only to avoid issues with the handling of explicit zeros when converting between different sparse representations. Zero weights can be handled by adding a constant to all weights, so that the resulting matrix contains no zeros.

References

[1], [2], [3]

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import min_weight_full_bipartite_matching

Let us first consider an example in which all weights are equal:

```python
>>> biadjacency_matrix = csr_matrix([[1, 1, 1], [1, 0, 0], [0, 1, 0]])
```

Here, all we get is a perfect matching of the graph:

```python
>>> print(min_weight_full_bipartite_matching(biadjacency_matrix)[1])
[2 0 1]
```

That is, the first, second, and third rows are matched with the third, first, and second column respectively. Note that in this example, the 0 in the input matrix does not correspond to an edge with weight 0, but rather a pair of vertices not paired by an edge.

Note also that in this case, the output matches the result of applying maximum_bipartite_matching:
>>> from scipy.sparse.csgraph import maximum_bipartite_matching
>>> biadjacency = csr_matrix([[1, 1, 1], [1, 0, 0], [0, 1, 0]])
>>> print(maximum_bipartite_matching(biadjacency, perm_type='column'))
[2 0 1]

When multiple edges are available, the ones with lowest weights are preferred:

>>> biadjacency = csr_matrix([[3, 3, 6], [4, 3, 5], [10, 1, 8]])
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(col_ind)
[0 2 1]

The total weight in this case is $3 + 5 + 1 = 9$:

>>> print(biadjacency[row_ind, col_ind].sum())
9

When the matrix is not square, i.e. when the two partitions have different cardinalities, the matching is as large as the smaller of the two partitions:

>>> biadjacency = csr_matrix([[0, 1, 1], [0, 2, 3]])
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(col_ind)
[0 1 2]

When one or both of the partitions are empty, the matching is empty as well:

>>> biadjacency = csr_matrix((2, 0))
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(col_ind)
[]

In general, we will always reach the same sum of weights as if we had used `scipy.optimize.linear_sum_assignment` but note that for that one, missing edges are represented by a matrix entry of `float('inf')`. Let us generate a random sparse matrix with integer entries between 1 and 10:

```python
>>> import numpy as np
>>> from scipy.sparse import random
>>> from scipy.optimize import linear_sum_assignment
>>> sparse = random(10, 10, random_state=42, density=.5, format='coo') * -10
>>> sparse.data = np.ceil(sparse.data)
>>> dense = sparse.toarray()
>>> dense = np.full(sparse.shape, np.inf)
>>> dense[sparse.row, sparse.col] = sparse.data
>>> sparse = sparse.tocsr()
>>> row_ind, col_ind = linear_sum_assignment(dense)
>>> print(dense[row_ind, col_ind].sum())
28.0
>>> row_ind, col_ind = min_weight_full_bipartite_matching(sparse)
```

(continues on next page)
```python
>>> print(sparse[row_ind, col_ind].sum())
28.0
```

### scipy.sparse.csgraph.structural_rank

`scipy.sparse.csgraph.structural_rank(graph)`

Compute the structural rank of a graph (matrix) with a given sparsity pattern.

The structural rank of a matrix is the number of entries in the maximum transversal of the corresponding bipartite graph, and is an upper bound on the numerical rank of the matrix. A graph has full structural rank if it is possible to permute the elements to make the diagonal zero-free.

New in version 0.19.0.

**Parameters**

- **graph**
  - [sparse matrix] Input sparse matrix.

**Returns**

- **rank**
  - [int] The structural rank of the sparse graph.

**References**

[1], [2]

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import structural_rank

>>> graph = [
... [0, 1, 2, 0],
... [1, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 1, 3, 0],
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 0) 1
(1, 3) 1
(2, 0) 2
(2, 3) 3
(3, 1) 1
(3, 2) 3

>>> structural_rank(graph)
4
```
scipy.sparse.csgraph.NegativeCycleError

exception scipy.sparse.csgraph.NegativeCycleError(message="")

    with_traceback()
    Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

construct_dist_matrix(graph, predecessors[, directed=True, null_value=np.inf]) Construct distance matrix from a predecessor matrix

New in version 0.11.0.

Parameters

- graph [array_like or sparse] The N x N matrix representation of a directed or undirected graph. If dense, then non-edges are indicated by zeros or infinities.
- predecessors [array_like] The N x N matrix of predecessors of each node (see Notes below).
- directed [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then operate on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].
- null_value [bool, optional] value to use for distances between unconnected nodes. Default is np.inf

Returns

dist_matrix [ndarray] The N x N matrix of distances between nodes along the path specified by the predecessor matrix. If no path exists, the distance is zero.
Notes

The predecessor matrix is of the form returned by \texttt{shortest_path}. Row \textit{i} of the predecessor matrix contains information on the shortest paths from point \textit{i}: each entry \texttt{predecessors[i, j]} gives the index of the previous node in the path from point \textit{i} to point \textit{j}. If no path exists between point \textit{i} and \textit{j}, then \texttt{predecessors[i, j]} = -9999

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import construct_dist_matrix

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 1, 0],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 3) 3

>>> pred = np.array([[-9999, 0, 0, 2],
... [1, -9999, 0, 1],
... [2, 0, -9999, 2],
... [1, 3, 3, -9999]], dtype=np.int32)

>>> construct_dist_matrix(graph=graph, predecessors=pred, directed=False)
array([[ 0., 1., 2., 5.],
[ 1., 0., 3., 1.],
[ 2., 3., 0., 3.],
[ 2., 1., 3., 0.]]),

\texttt{scipy.sparse.csgraph.csgraph_from_dense}

\texttt{scipy.sparse.csgraph.csgraph_from_dense}(\texttt{graph, null_value=0, nan_null=True, infinity_null=True})

Construct a CSR-format sparse graph from a dense matrix.

New in version 0.11.0.

Parameters

- \texttt{graph} \[array_like\] Input graph. Shape should be (n_nodes, n_nodes).
- \texttt{null_value} \[float or None (optional)\] Value that denotes non-edges in the graph. Default is zero.
- \texttt{infinity_null} \[bool\] If True (default), then infinite entries (both positive and negative) are treated as null edges.
- \texttt{nan_null} \[bool\] If True (default), then NaN entries are treated as non-edges.

Returns
csgraph  [csr_matrix] Compressed sparse representation of graph,

Examples

```python
>>> from scipy.sparse.csgraph import csgraph_from_dense

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]

>>> csgraph_from_dense(graph)
<4x4 sparse matrix of type '<class 'numpy.float64'>'
with 4 stored elements in Compressed Sparse Row format>
```

scipy.sparse.csgraph.csgraph_from_masked

scipy.sparse.csgraph.csgraph_from_masked(graph)

Construct a CSR-format graph from a masked array.

New in version 0.11.0.

Parameters

- graph  [MaskedArray] Input graph. Shape should be (n_nodes, n_nodes).

Returns

- csgraph  [csr_matrix] Compressed sparse representation of graph,

Examples

```python
>>> import numpy as np

>>> from scipy.sparse.csgraph import csgraph_from_masked

>>> graph_masked = np.ma.masked_array(data=[
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ],
... mask=[[ True, False, False , True],
... [ True , True , True , False],
... [ True , True , True , False],
... [ True , True , True , True]],
... fill_value = 0)

>>> csgraph_from_masked(graph_masked)
<4x4 sparse matrix of type '<class 'numpy.float64'>'
with 4 stored elements in Compressed Sparse Row format>
```
scipy.sparse.csgraph.csgraph_masked_from_dense

scipy.sparse.csgraph.csgraph_masked_from_dense(graph, null_value=0, nan_null=True, infinity_null=True, copy=True)

Construct a masked array graph representation from a dense matrix.

New in version 0.11.0.

Parameters

- **graph** [array_like] Input graph. Shape should be (n_nodes, n_nodes).
- **null_value** [float or None (optional)] Value that denotes non-edges in the graph. Default is zero.
- **infinity_null** [bool] If True (default), then infinite entries (both positive and negative) are treated as null edges.
- **nan_null** [bool] If True (default), then NaN entries are treated as non-edges

Returns

- **csgraph** [MaskedArray] masked array representation of graph

Examples

```python
>>> from scipy.sparse.csgraph import csgraph_masked_from_dense

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]

>>> csgraph_masked_from_dense(graph)
mixed_array(data=[[--, 1, 2, --],
[--, --, --, 1],
[--, --, --, 3],
[--, --, --, --]],
mask=[[ True, False, False, True],
[ True, True, True, False],
[ True, True, True, False],
[ True, True, True, True]],
fill_value=0)
```

scipy.sparse.csgraph.csgraph_to_dense

scipy.sparse.csgraph.csgraph_to_dense(csgraph, null_value=0)

Convert a sparse graph representation to a dense representation

New in version 0.11.0.

Parameters

- **csgraph** [csr_matrix, csc_matrix, or lil_matrix] Sparse representation of a graph.
null_value  [float, optional] The value used to indicate null edges in the dense representation. Default is 0.

Returns

graph  [ndarray] The dense representation of the sparse graph.

Notes

For normal sparse graph representations, calling csgraph_to_dense with null_value=0 produces an equivalent result to using dense format conversions in the main sparse package. When the sparse representations have repeated values, however, the results will differ. The tools in scipy.sparse will add repeating values to obtain a final value. This function will select the minimum among repeating values to obtain a final value. For example, here we'll create a two-node directed sparse graph with multiple edges from node 0 to node 1, of weights 2 and 3. This illustrates the difference in behavior:

```python
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([2, 3])
>>> indices = np.array([1, 1])
>>> indptr = np.array([0, 2, 2])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 2],
       [0, 0]])
>>> csgraph.csgraph_to_dense(M)
array([[0., 2.],
       [0., 0.]])
```

The reason for this difference is to allow a compressed sparse graph to represent multiple edges between any two nodes. As most sparse graph algorithms are concerned with the single lowest-cost edge between any two nodes, the default scipy.sparse behavior of summing multiple weights does not make sense in this context.

The other reason for using this routine is to allow for graphs with zero-weight edges. Let's look at the example of a two-node directed graph, connected by an edge of weight zero:

```python
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([0.0])
>>> indices = np.array([1])
>>> indptr = np.array([0, 1, 1])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 0],
       [0, 0]])
>>> csgraph.csgraph_to_dense(M, np.inf)
array([[inf,  0.],
       [inf, inf]])
```

In the first case, the zero-weight edge gets lost in the dense representation. In the second case, we can choose a different null value and see the true form of the graph.
Examples

```python
>>> from scipy.sparse import csr_matrix
csr_matrix
>>> from scipy.sparse.csgraph import csgraph_to_dense

csr_matrix

>>> graph = csr_matrix( [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ])

>>> graph
<4x4 sparse matrix of type '<class 'numpy.int64'>'
with 4 stored elements in Compressed Sparse Row format>

>>> csgraph_to_dense(graph)

array([[ 0., 1., 2., 0.],
        [ 0., 0., 0., 1.],
        [ 0., 0., 0., 3.],
        [ 0., 0., 0., 0.]])
```

### scipy.sparse.csgraph.csgraph_to_masked

`scipy.sparse.csgraph.csgraph_to_masked(csgraph)`

Convert a sparse graph representation to a masked array representation

New in version 0.11.0.

**Parameters**

- `csgraph` [csr_matrix, csc_matrix, or lil_matrix] Sparse representation of a graph.

**Returns**

- `graph` [MaskedArray] The masked dense representation of the sparse graph.

Examples

```python
>>> from scipy.sparse import csr_matrix
csr_matrix
>>> from scipy.sparse.csgraph import csgraph_to_masked

csr_matrix

>>> graph = csr_matrix( [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ])

>>> graph
<4x4 sparse matrix of type '<class 'numpy.int64'>'
with 4 stored elements in Compressed Sparse Row format>
```
```python
>>> csgraph_to_masked(graph)
masked_array(
    data=[[--, 1.0, 2.0, --],
          [--, --, --, 1.0],
          [--, --, --, 3.0],
          [--, --, --, --]],
    mask=[[ True, False, False, True],
          [ True, True, True, False],
          [ True, True, True, False],
          [ True, True, True, True]],
    fill_value=1e+20)
```

**scipy.sparse.csgraph.reconstruct_path**

`scipy.sparse.csgraph.reconstruct_path(csgraph, predecessors, directed=True)`

Construct a tree from a graph and a predecessor list.

New in version 0.11.0.

**Parameters**

- `csgraph` [array_like or sparse matrix] The N x N matrix representing the directed or undirected graph from which the predecessors are drawn.
- `predecessors` [array_like, one dimension] The length-N array of indices of predecessors for the tree. The index of the parent of node i is given by predecessors[i].
- `directed` [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then operate on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

**Returns**

- `cstree` [csr matrix] The N x N directed compressed-sparse representation of the tree drawn from csgraph which is encoded by the predecessor list.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import reconstruct_path

>>> graph = [
            ...
            [0, 1, 2, 0],
            [0, 0, 0, 1],
            [0, 0, 0, 3],
            [0, 0, 0, 0]
            ...
            ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 3) 3
```
```python
>>> pred = np.array([-9999, 0, 0, 1], dtype=np.int32)
```

```python
>>> cstree = reconstruct_path(csgraph=graph, predecessors=pred, 
→ directed=False)
```

```python
>>> cstree.todense()
```

```
matrix([[ 0., 1., 2., 0.],
         [ 0., 0., 0., 1.],
         [ 0., 0., 0., 0.],
         [ 0., 0., 0., 0.]]
```

### 6.25.2 Graph Representations

This module uses graphs which are stored in a matrix format. A graph with N nodes can be represented by an (N x N) adjacency matrix G. If there is a connection from node i to node j, then G[i, j] = w, where w is the weight of the connection. For nodes i and j which are not connected, the value depends on the representation:

- for dense array representations, non-edges are represented by G[i, j] = 0, infinity, or NaN.
- for dense masked representations (of type np.ma.MaskedArray), non-edges are represented by masked values. This can be useful when graphs with zero-weight edges are desired.
- for sparse array representations, non-edges are represented by non-entries in the matrix. This sort of sparse representation also allows for edges with zero weights.

As a concrete example, imagine that you would like to represent the following undirected graph:

```
G

(0)
/ | \
1 2
/ | \
(2) (1)
```

This graph has three nodes, where node 0 and 1 are connected by an edge of weight 2, and nodes 0 and 2 are connected by an edge of weight 1. We can construct the dense, masked, and sparse representations as follows, keeping in mind that an undirected graph is represented by a symmetric matrix:

```python
>>> G_dense = np.array([[0, 2, 1], 
                     ... [2, 0, 0], 
                     ... [1, 0, 0]])
```

```python
>>> G_masked = np.ma.masked_values(G_dense, 0)
```

```python
>>> from scipy.sparse import csr_matrix
```

```python
>>> G_sparse = csr_matrix(G_dense)
```

This becomes more difficult when zero edges are significant. For example, consider the situation when we slightly modify the above graph:

```
G2

(0)
/ | \
0 2
```

(continues on next page)
This is identical to the previous graph, except nodes 0 and 2 are connected by an edge of zero weight. In this case, the dense representation above leads to ambiguities: how can non-edges be represented if zero is a meaningful value? In this case, either a masked or sparse representation must be used to eliminate the ambiguity:

```python
>>> G2_data = np.array([[np.inf, 2, 0], ...
                       [2, np.inf, np.inf],
                       [0, np.inf, np.inf]])
>>> G2_masked = np.ma.masked_invalid(G2_data)
>>> from scipy.sparse.csgraph import csgraph_from_dense
>>> # G2_sparse = csr_matrix(G2_data) would give the wrong result
>>> G2_sparse = csgraph_from_dense(G2_data, null_value=np.inf)
>>> G2_sparse.data
array([ 2., 0., 2., 0.])
```

Here we have used a utility routine from the csgraph submodule in order to convert the dense representation to a sparse representation which can be understood by the algorithms in submodule. By viewing the data array, we can see that the zero values are explicitly encoded in the graph.

**Directed vs. undirected**

Matrices may represent either directed or undirected graphs. This is specified throughout the csgraph module by a boolean keyword. Graphs are assumed to be directed by default. In a directed graph, traversal from node i to node j can be accomplished over the edge $G_{i,j}$, but not the edge $G_{j,i}$. Consider the following dense graph:

```python
>>> G_dense = np.array([[0, 1, 0],
                       [2, 0, 3],
                       [0, 4, 0]])
```

When `directed=True` we get the graph:

```
---1---   ---3---
(0) ---1----(1) ---3----(2)
```

In a non-directed graph, traversal from node i to node j can be accomplished over either $G_{i,j}$ or $G_{j,i}$. If both edges are not null, and the two have unequal weights, then the smaller of the two is used.

So for the same graph, when `directed=False` we get the graph:

```
(0) ---1--(1) --2--(2)
```

Note that a symmetric matrix will represent an undirected graph, regardless of whether the ‘directed’ keyword is set to True or False. In this case, using `directed=True` generally leads to more efficient computation.

The routines in this module accept as input either scipy.sparse representations (csr, csc, or lil format), masked representations, or dense representations with non-edges indicated by zeros, infinities, and NaN entries.
6.26 Spatial algorithms and data structures (scipy.spatial)

6.26.1 Spatial transformations

These are contained in the `scipy.spatial.transform` submodule.

6.26.2 Nearest-neighbor queries

<table>

**scipy.spatial.KDTree**

```python
class scipy.spatial.KDTree(data, leafsize=10, compact_nodes=True, copy_data=False, balanced_tree=True, boxsize=None)
```

This class provides an index into a set of k-dimensional points which can be used to rapidly look up the nearest neighbors of any point.

**Parameters**

- `data` [array_like, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles, and so modifying this data will result in bogus results. The data are also copied if the kd-tree is built with `copy_data=True`.
- `leafsize` [positive int, optional] The number of points at which the algorithm switches over to brute-force. Default: 10.
- `compact_nodes` [bool, optional] If True, the kd-tree is built to shrink the hyperrectangles to the actual data range. This usually gives a more compact tree that is robust against degenerated input data and gives faster queries at the expense of longer build time. Default: True.
- `copy_data` [bool, optional] If True the data is always copied to protect the kd-tree against data corruption. Default: False.
- `balanced_tree` [bool, optional] If True, the median is used to split the hyperrectangles instead of the midpoint. This usually gives a more compact tree and faster queries at the expense of longer build time. Default: True.
- `boxsize` [array_like or scalar, optional] Apply a m-d toroidal topology to the KDTree. The topology is generated by \( x_i + n_i L_i \) where \( n_i \) are integers and \( L_i \) is the boxsize along i-th dimension. The input data shall be wrapped into \([0, L_i)\). A ValueError is raised if any of the data is outside of this bound.
Notes

The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary tree, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value.

During construction, the axis and splitting point are chosen by the “sliding midpoint” rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the r closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the r approximate closest neighbors.

For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

Attributes

- **data** [ndarray, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles. The data are also copied if the kd-tree is built with `copy_data=True`.
- **leafsize** [positive int] The number of points at which the algorithm switches over to brute-force.
- **m** [int] The dimension of a single data-point.
- **n** [int] The number of data points.
- **maxes** [ndarray, shape (m,)] The maximum value in each dimension of the n data points.
- **mins** [ndarray, shape (m,)] The minimum value in each dimension of the n data points.
- **size** [int] The number of nodes in the tree.

Methods

- `count_neighbors(self, other, r[, p, ...])` Count how many nearby pairs can be formed.
- `query(self, x[, k, eps, p, ...])` Query the kd-tree for nearest neighbors
- `query_ball_point(self, x, r[, p, eps, ...])` Find all points within distance r of point(s) x.
- `query_ball_tree(self, other, r[, p, eps])` Find all pairs of points between self and other whose distance is at most r.
- `query_pairs(self, r[, p, eps, output_type])` Find all pairs of points in self whose distance is at most r.
- `sparse_distance_matrix(self, other, max_distance)` Compute a sparse distance matrix

scipy.spatial.KDTree.count_neighbors

KDTree.count_neighbors (self, other, r=2.0, p=2.0, weights=None, cumulative=True)

Count how many nearby pairs can be formed.

Count the number of pairs \((x_1, x_2)\) can be formed, with \(x_1\) drawn from self and \(x_2\) drawn from other, and where \(\text{distance}(x_1, x_2, p) \leq r\).

Data points on self and other are optionally weighted by the weights argument. (See below)

This is adapted from the “two-point correlation” algorithm described by Gray and Moore [1]. See notes for further discussion.

Parameters

- **other** [KDTree] The other tree to draw points from, can be the same tree as self.
The radius to produce a count for. Multiple radii are searched with a single tree traversal. If the count is non-cumulative (cumulative=False), \( r \) defines the edges of the bins, and must be non-decreasing.

\[ \text{result}[i] = \begin{cases} \text{count} & \text{if } \left( \frac{-\infty}{0} \leq r[i] \right) \leq r[i] \leq \left( \frac{0}{n} \right) \leq r[i] \end{cases} \]

Notes

Pair-counting is the basic operation used to calculate the two point correlation functions from a data set composed of position of objects.

Two point correlation function measures the clustering of objects and is widely used in cosmology to quantify the large scale structure in our Universe, but it may be useful for data analysis in other fields where self-similar assembly of objects also occur.

The Landy-Szalay estimator for the two point correlation function of \( D \) measures the clustering signal in \( D \).

For example, given the position of two sets of objects,

- objects \( D \) (data) contains the clustering signal, and
- objects \( R \) (random) that contains no signal,

\[
\xi(r) = \frac{\langle D, D \rangle - f \langle D, R \rangle + f^2 \langle R, R \rangle}{f^2 \langle R, R \rangle},
\]

where the brackets represents counting pairs between two data sets in a finite bin around \( r \) (distance), corresponding to setting \( \text{cumulative} = \text{False} \), and \( f = \frac{\text{float(len(D))}}{\text{float(len(R))}} \) is the ratio between number of objects from data and random.

The algorithm implemented here is loosely based on the dual-tree algorithm described in [1]. We switch between two different pair-cumulation scheme depending on the setting of \( \text{cumulative} \). The computing time of the method we use when for \( \text{cumulative} == \text{False} \) does not scale with the total number of bins. The algorithm for \( \text{cumulative} == \text{True} \) scales linearly with the number of bins, though it is slightly faster when only 1 or 2 bins are used. [5].
As an extension to the naive pair-counting, weighted pair-counting counts the product of weights instead of number of pairs. Weighted pair-counting is used to estimate marked correlation functions ([3], section 2.2), or to properly calculate the average of data per distance bin (e.g. [4], section 2.1 on redshift).

**Examples**

You can count neighbors number between two kd-trees within a distance:

```python
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> np.random.seed(21701)
>>> points1 = np.random.random((5, 2))
>>> points2 = np.random.random((5, 2))
>>> kd_tree1 = KDTree(points1)
>>> kd_tree2 = KDTree(points2)
>>> kd_tree1.count_neighbors(kd_tree2, 0.2)
9
```

This number is same as the total pair number calculated by `query_ball_tree`:

```python
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> sum([len(i) for i in indexes])
9
```

### scipy.spatial.KDTree.query

`KDTree.query(self, x, k=1, eps=0, p=2, distance_upper_bound=inf, workers=1)`

Query the kd-tree for nearest neighbors

**Parameters**

- `x` [array_like, last dimension self.m] An array of points to query.
- `k` [int or Sequence[int], optional] Either the number of nearest neighbors to return, or a list of the k-th nearest neighbors to return, starting from 1.
- `eps` [nonnegative float, optional] Return approximate nearest neighbors; the kth returned value is guaranteed to be no further than (1+eps) times the distance to the real kth nearest neighbor.
- `p` [float, 1<=p<=infinity, optional] Which Minkowski p-norm to use. 1 is the sum-of-absolute-values “Manhattan” distance 2 is the usual Euclidean distance infinity is the maximum-coordinate-difference distance A large, finite p may cause a ValueError if overflow can occur.
- `distance_upper_bound` [nonnegative float, optional] Return only neighbors within this distance. This is used to prune tree searches, so if you are doing a series of nearest-neighbor queries, it may help to supply the distance to the nearest neighbor of the most recent point.
- `workers` [int, optional] Number of workers to use for parallel processing. If -1 is given all CPU threads are used. Default: 1.

**Returns**

- `d` [float or array of floats] The distances to the nearest neighbors. If `x` has shape `tuple+(self.m,)`, then `d` has shape `tuple+(k,)`. When `k == 1`, the last dimension of the output is squeezed. Missing neighbors are indicated with infinite distances. Hits are sorted by distance (nearest first).
Deprecated since version 1.6.0: If \( k = \text{None} \), then \( d \) is an object array of shape tuple, containing lists of distances. This behavior is deprecated and will be removed in SciPy 1.8.0, use \texttt{query\_ball\_point} instead.

\[ i \]
integer or array of integers] The index of each neighbor in \texttt{self.data.i} is the same shape as \( d \). Missing neighbors are indicated with \texttt{self.n}.

Examples

```python
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> x, y = np.mgrid[0:5, 2:8]
>>> tree = KDTree(np.c_[x.ravel(), y.ravel()])

To query the nearest neighbours and return squeezed result, use
```
```python
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=1)
>>> print(dd, ii)
[2. 0.14142136] [0 13]
```

To query the nearest neighbours and return unsqueezed result, use
```python
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1])
>>> print(dd, ii)
[[2. 0.14142136]] [[0]
[13]]
```
scipy.spatial.KDTree.query_ball_point

KDTree.query_ball_point(self, x, r, p=2.0, eps=0, workers=1, return_sorted=None, return_length=False)

Find all points within distance r of point(s) x.

Parameters

- **x** : [array_like, shape tuple + (self.m,)] The point or points to search for neighbors of.
- **r** : [array_like, float] The radius of points to return, must broadcast to the length of x.
- **p** : [float, optional] Which Minkowski p-norm to use. Should be in the range [1, inf]. A finite large p may cause a ValueError if overflow can occur.
- **eps** : [nonnegative float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than \( r / (1 + \text{eps}) \), and branches are added in bulk if their furthest points are nearer than \( r \times (1 + \text{eps}) \).
- **workers** : [int, optional] Number of jobs to schedule for parallel processing. If -1 is given all processors are used. Default: 1. New in version 1.6.0.
- **return_sorted** : [bool, optional] Sorts returned indicies if True and does not sort them if False. If None, does not sort single point queries, but does sort multi-point queries which was the behavior before this option was added. New in version 1.6.0.
- **return_length** : [bool, optional] Return the number of points inside the radius instead of a list of the indices. New in version 1.6.0.

Returns

- **results** : [list or array of lists] If x is a single point, returns a list of the indices of the neighbors of x. If x is an array of points, returns an object array of shape tuple containing lists of neighbors.

Notes

If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a KDTree and using query_ball_tree.

Examples

```python
>>> from scipy import spatial
>>> x, y = np.mgrid[0:5, 0:5]
>>> points = np.c_[x.ravel(), y.ravel()]
>>> tree = spatial.KDTree(points)
>>> sorted(tree.query_ball_point([[2, 0], [1]]))
[5, 10, 11, 15]
```

Query multiple points and plot the results:

```python
>>> import matplotlib.pyplot as plt
>>> points = np.asarray(points)
>>> plt.plot(points[:,0], points[:,1], '.')
>>> for results in tree.query_ball_point(([2, 0], [3, 3]), 1):
...     nearby_points = points[results]...
```

(continues on next page)
... plt.plot(nearby_points[:, 0], nearby_points[:, 1], 'o')
>>> plt.margins(0.1, 0.1)
>>> plt.show()

 scipy.spatial.KDTree.query_ball_tree

KDTree.query_ball_tree (self, other, r=2.0, eps=0)
Find all pairs of points between self and other whose distance is at most r

Parameters
  other    [KDTree instance] The tree containing points to search against.
  r        [float] The maximum distance, has to be positive.
  p        [float, optional] Which Minkowski norm to use. p has to meet the condition 1 <= p <= infinity.
  eps      [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than r/(1+eps), and branches are added in bulk if their furthest points are nearer than r * (1+eps). eps has to be non-negative.

Returns
  results  [list of lists] For each element self.data[i] of this tree, results[i] is a list of the indices of its neighbors in other.data.

Examples
You can search all pairs of points between two kd-trees within a distance:

```python
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> np.random.seed(21701)
>>> points1 = np.random.random((15, 2))
>>> points2 = np.random.random((15, 2))
```
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points1[:, 0], points1[:, 1], "xk", markersize=14)
>>> plt.plot(points2[:, 0], points2[:, 1], "og", markersize=14)
>>> kd_tree1 = KDTree(points1)
>>> kd_tree2 = KDTree(points2)
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> for i in range(len(indexes)):
...    for j in indexes[i]:
...        plt.plot([points1[i, 0], points2[j, 0]],
...                 [points1[i, 1], points2[j, 1]], "-r")
>>> plt.show()
**scipy.spatial.KDTree.query_pairs**

`KDTree.query_pairs(self, r, p=2.0, eps=0, output_type='set')`

Find all pairs of points in `self` whose distance is at most `r`.

**Parameters**

- `r` [positive float] The maximum distance.
- `p` [float, optional] Which Minkowski norm to use. `p` has to meet the condition `1 <= p <= infinity`.
- `eps` [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than `r/(1+eps)`, and branches are added in bulk if their furthest points are nearer than `r * (1+eps)`. `eps` has to be non-negative.
- `output_type` [string, optional] Choose the output container, ‘set’ or ‘ndarray’. Default: ‘set’

**Returns**

- `results` [set or ndarray] Set of pairs `(i, j)`, with `i < j`, for which the corresponding positions are close. If `output_type` is ‘ndarray’, an ndarray is returned instead of a set.

**Examples**

You can search all pairs of points in a kd-tree within a distance:

```python
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> np.random.seed(21701)
>>> points = np.random.random((20, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points[:, 0], points[:, 1], "xk", markersize=14)
>>> kd_tree = KDTree(points)
>>> pairs = kd_tree.query_pairs(r=0.2)
>>> for (i, j) in pairs:
...     plt.plot([points[i, 0], points[j, 0]],
...              [points[i, 1], points[j, 1]], "-r")
>>> plt.show()
```

**scipy.spatial.KDTree.sparse_distance_matrix**

`KDTree.sparse_distance_matrix(self, other, max_distance, p=2.0, output_type='dok_matrix')`

Compute a sparse distance matrix

Computes a distance matrix between two KD Trees, leaving as zero any distance greater than max_distance.

**Parameters**

- `other` [KDTree]
- `max_distance` [positive float] Which Minkowski `p`-norm to use. A finite large `p` may cause a `ValueError` if overflow can occur.
- `p` [float, `1<=p<=infinity`] Which Minkowski `p`-norm to use. A finite large `p` may cause a `ValueError` if overflow can occur.

New in version 1.6.0.
6.26. Spatial algorithms and data structures (scipy.spatial)
Returns

result [dok_matrix, coo_matrix, dict or ndarray] Sparse matrix representing the results in “dictionary of keys” format. If a dict is returned the keys are (i,j) tuples of indices. If output_type is ‘ndarray’ a record array with fields ‘i’, ‘j’, and ‘v’ is returned.

Examples

You can compute a sparse distance matrix between two kd-trees:

```python
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> np.random.seed(21701)
>>> points1 = np.random.random((5, 2))
>>> points2 = np.random.random((5, 2))
>>> kd_tree1 = KDTree(points1)
>>> kd_tree2 = KDTree(points2)
>>> sdm = kd_tree1.sparse_distance_matrix(kd_tree2, 0.3)
>>> sdm.toarray()
array([[0.20220215, 0.14538496, 0., 0.10257199, 0.],
       [0.13491385, 0.27251306, 0., 0.18793787, 0.],
       [0.19262396, 0., 0., 0.25795122, 0.],
       [0.14859639, 0.07076002, 0., 0.04065851, 0.],
       [0.17308768, 0., 0., 0.24823138, 0.]])
```

You can check distances above the max_distance are zeros:

```python
>>> from scipy.spatial import distance_matrix
>>> distance_matrix(points1, points2)
array([[0.20220215, 0.14538496, 0.43588092, 0.10257199, 0.4555495],
       [0.13491385, 0.27251306, 0.65944131, 0.18793787, 0.68184154],
       [0.19262396, 0.34121593, 0.72176889, 0.25795122, 0.74538858],
       [0.14859639, 0.48505773, 0.72760803, 0.04065851, 0.50043591],
       [0.17308768, 0.32837991, 0.75017239]])
```

scipy.spatial.cKDTree

class scipy.spatial.cKDTree(data, leafsize=16, compact_nodes=True, copy_data=False, balanced_tree=True, boxsize=None)

dkd-tree for quick nearest-neighbor lookup

This class provides an index into a set of k-dimensional points which can be used to rapidly look up the nearest neighbors of any point.

Parameters

data [array_like, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles, and so modifying this data will result in bogus results. The data are also copied if the kd-tree is built with copy_data=True.
leafsize  [positive int, optional] The number of points at which the algorithm switches over to brute-force. Default: 16.

compact_nodes
[bool, optional] If True, the kd-tree is built to shrink the hyperrectangles to the actual data range. This usually gives a more compact tree that is robust against degenerated input data and gives faster queries at the expense of longer build time. Default: True.

copy_data  [bool, optional] If True the data is always copied to protect the kd-tree against data corruption. Default: False.

balanced_tree  [bool, optional] If True, the median is used to split the hyperrectangles instead of the midpoint. This usually gives a more compact tree and faster queries at the expense of longer build time. Default: True.

boxsize  [array_like or scalar, optional] Apply a m-d toroidal topology to the KDTre.. The topology is generated by $x_i + n_i L_i$ where $n_i$ are integers and $L_i$ is the boxsize along i-th dimension. The input data shall be wrapped into $[0, L_i)$. A ValueError is raised if any of the data is outside of this bound.

Notes
The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary tree, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value.

During construction, the axis and splitting point are chosen by the “sliding midpoint” rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the $r$ closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the $r$ approximate closest neighbors.

For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

Attributes

data  [ndarray, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles. The data are also copied if the kd-tree is built with copy_data=True.

leafsize  [positive int] The number of points at which the algorithm switches over to brute-force.

m  [int] The dimension of a single data-point.

n  [int] The number of data points.

maxes  [ndarray, shape (m,)] The maximum value in each dimension of the n data points.

mins  [ndarray, shape (m,)] The minimum value in each dimension of the n data points.

tree  [object, class cKDTreeNode] This attribute exposes a Python view of the root node in the cKDTree object. A full Python view of the kd-tree is created dynamically on the first access. This attribute allows you to create your own query functions in Python.

size  [int] The number of nodes in the tree.
Methods

```python
count_neighbors(self, other, r[, p,...])  # Count how many nearby pairs can be formed.
query(self, x[, k, eps, p,...])  # Query the kd-tree for nearest neighbors
query_ball_point(self, x, r[, p, eps,...])  # Find all points within distance r of point(s) x.
query_ball_tree(self, other, r[, p, eps])  # Find all pairs of points between self and other whose distance is at most r.
query_pairs(self, r[, p, eps])  # Find all pairs of points in self whose distance is at most r.
sparse_distance_matrix(self, other, max_distance)  # Compute a sparse distance matrix
```

**scipy.spatial.cKDTree.count_neighbors**

```python
cKDTree.count_neighbors(self, other, r, p=2.0, weights=None, cumulative=True)
```

Count how many nearby pairs can be formed.

Count the number of pairs \((x_1, x_2)\) can be formed, with \(x_1\) drawn from self and \(x_2\) drawn from other, and where \(\text{distance}(x_1, x_2, p) \leq r\).

Data points on self and other are optionally weighted by the weights argument. (See below)

This is adapted from the “two-point correlation” algorithm described by Gray and Moore [1]. See notes for further discussion.

**Parameters**

- **other**  
  [cKDTree instance] The other tree to draw points from, can be the same tree as self.
- **r**  
  [float or one-dimensional array of floats] The radius to produce a count for. Multiple radii are searched with a single tree traversal. If the count is non-cumulative (cumulative=False), r defines the edges of the bins, and must be non-decreasing.
- **p**  
  [float, optional] \(1 \leq p \leq \infty\). Which Minkowski p-norm to use. Default 2.0. A finite large p may cause a ValueError if overflow can occur.
- **weights**  
  [tuple, array_like, or None, optional] If None, the pair-counting is unweighted. If given as a tuple, weights[0] is the weights of points in self, and weights[1] is the weights of points in other; either can be None to indicate the points are unweighted. If given as an array_like, weights is the weights of points in self and other. For this to make sense, self and other must be the same tree. If self and other are two different trees, a ValueError is raised. Default: None
- **cumulative**  
  [bool, optional] Whether the returned counts are cumulative. When cumulative is set to False the algorithm is optimized to work with a large number of bins (>10) specified by r. When cumulative is set to True, the algorithm is optimized to work with a small number of r. Default: True

**Returns**

- **result**  
  [scalar or 1-D array] The number of pairs. For unweighted counts, the result is integer. For weighted counts, the result is float. If cumulative is False, result[i] contains the counts with (-inf if i == 0 else r[i-1]) < R <= r[i]
Notes

Pair-counting is the basic operation used to calculate the two point correlation functions from a data set composed of position of objects.

Two point correlation function measures the clustering of objects and is widely used in cosmology to quantify the large scale structure in our Universe, but it may be useful for data analysis in other fields where self-similar assembly of objects also occur.

The Landy-Szalay estimator for the two point correlation function of \( D \) measures the clustering signal in \( D \).

\[ \xi(r) = \frac{<D,D>-2f<R,D>+f^2<R,R>}{f^2<R,R>}, \]

where the brackets represents counting pairs between two data sets in a finite bin around \( r \) (distance), corresponding to setting \( cumulative=False \), and \( f = \frac{\text{float(len(D))}}{\text{float(len(R))}} \) is the ratio between number of objects from data and random.

The algorithm implemented here is loosely based on the dual-tree algorithm described in [1]. We switch between two different pair-cumulation scheme depending on the setting of \( cumulative \). The computing time of the method we use when for \( cumulative == False \) does not scale with the total number of bins. The algorithm for \( cumulative == True \) scales linearly with the number of bins, though it is slightly faster when only 1 or 2 bins are used. [5].

As an extension to the naive pair-counting, weighted pair-counting counts the product of weights instead of number of pairs. Weighted pair-counting is used to estimate marked correlation functions ([3], section 2.2), or to properly calculate the average of data per distance bin (e.g. [4], section 2.1 on redshift).

Examples

You can count neighbors number between two kd-trees within a distance:

```
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> np.random.seed(21701)
>>> points1 = np.random.random((5, 2))
>>> points2 = np.random.random((5, 2))
>>> kd_tree1 = cKDTree(points1)
>>> kd_tree2 = cKDTree(points2)
>>> kd_tree1.count_neighbors(kd_tree2, 0.2)
9
```

This number is same as the total pair number calculated by `query_ball_tree`:

```
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> sum([len(i) for i in indexes])
9
```
scipy.spatial.cKDTree.query

**ckDTree.query** *(self, x, k=1, eps=0, p=2, distance_upper_bound=np.inf, workers=1)*

Query the kd-tree for nearest neighbors

**Parameters**

- **x** [array_like, last dimension self.m] An array of points to query.
- **k** [list of integer or integer] The list of k-th nearest neighbors to return. If k is an integer it is treated as a list of [1, … k] (range(1, k+1)). Note that the counting starts from 1.
- **eps** [non-negative float] Return approximate nearest neighbors; the k-th returned value is guaranteed to be no further than (1+eps) times the distance to the real k-th nearest neighbor.
- **p** [float, 1<=p<=infinity] Which Minkowski p-norm to use. 1 is the sum-of-absolute-values “Manhattan” distance 2 is the usual Euclidean distance infinity is the maximum-coordinate-difference distance A finite large p may cause a ValueError if overflow can occur.
- **distance_upper_bound** [nonnegative float] Return only neighbors within this distance. This is used to prune tree searches, so if you are doing a series of nearest-neighbor queries, it may help to supply the distance to the nearest neighbor of the most recent point.
- **workers** [int, optional] Number of workers to use for parallel processing. If -1 is given all CPU threads are used. Default: 1.

Changed in version 1.6.0: The “n_jobs” argument was renamed “workers”. The old name “n_jobs” is deprecated and will stop working in SciPy 1.8.0.

**Returns**

- **d** [array of floats] The distances to the nearest neighbors. If x has shape tuple+(self.m,), then d has shape tuple+(k,). When k == 1, the last dimension of the output is squeezed. Missing neighbors are indicated with infinite distances.
- **i** [ndarray of ints] The index of each neighbor in self.data. If x has shape tuple+(self.m,), then i has shape tuple+(k,). When k == 1, the last dimension of the output is squeezed. Missing neighbors are indicated with self.n.

**Notes**

If the KD-Tree is periodic, the position x is wrapped into the box.

When the input k is a list, a query for arange(max(k)) is performed, but only columns that store the requested values of k are preserved. This is implemented in a manner that reduces memory usage.

**Examples**

```python
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> x, y = np.mgrid[0:5, 2:8]
>>> tree = cKDTree(np.c_[x.ravel(), y.ravel()])

To query the nearest neighbours and return squeezed result, use

```python
dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=1)
```
To query the nearest neighbours and return unsqueezed result, use

```python
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1])
>>> print(dd, ii)
[[2.  ]
 [0.14142136]] [[ 0]
 [13]]
```

To query the second nearest neighbours and return unsqueezed result, use

```python
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[2])
>>> print(dd, ii)
[[2.23606798]
 [0.90553851]] [[ 6]
 [12]]
```

To query the first and second nearest neighbours, use

```python
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[2])
>>> print(dd, ii)
[[2. 2.23606798]
 [0.14142136 0.90553851]] [[ 0 6]
 [13 12]]
```

or, be more specific

```python
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1, 2])
>>> print(dd, ii)
[[2. 2.23606798]
 [0.14142136 0.90553851]] [[ 0 6]
 [13 12]]
```

`scipy.spatial.cKDTree.query_ball_point`

`cKDTree.query_ball_point(self, x, r, p=2.0, eps=0, workers=1, return_sorted=None, return_length=False)`

Find all points within distance `r` of point(s) `x`.

**Parameters**

- `x` : array_like, shape tuple + (self.m,) The point or points to search for neighbors of.
- `r` : array_like, float The radius of points to return, shall broadcast to the length of `x`.
- `p` : float, optional Which Minkowski p-norm to use. Should be in the range [1, inf]. A finite large `p` may cause a ValueError if overflow can occur.
- `eps` : nonnegative float, optional Approximate search. Branches of the tree are not explored if their nearest points are further than `r / (1 + eps)`, and branches are added in bulk if their furthest points are nearer than `r * (1 + eps)`.
- `workers` : int, optional Number of jobs to schedule for parallel processing. If -1 is given all processors are used. Default: 1.
  Changed in version 1.6.0: The “n_jobs” argument was renamed “workers”. The old name “n_jobs” is deprecated and will stop working in SciPy 1.8.0.
- `return_sorted` : bool, optional Sorts returned indicies if True and does not sort them if False. If None, does not sort single point queries, but does sort multi-point queries which was the behavior before this option was added.
  New in version 1.2.0.
return_length: bool, optional

Return the number of points inside the radius instead of a list of the indices. .. version-added:: 1.3.0

Returns

results [list or array of lists] If \( x \) is a single point, returns a list of the indices of the neighbors of \( x \). If \( x \) is an array of points, returns an object array of shape tuple containing lists of neighbors.

Notes

If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a cKDTree and using query_ball_tree.

Examples

```python
>>> from scipy import spatial
>>> x, y = np.mgrid[0:4, 0:4]
>>> points = np.c_[x.ravel(), y.ravel()]
>>> tree = spatial.cKDTree(points)
>>> tree.query_ball_point([[2, 0], 1])
[4, 8, 9, 12]
```

Query multiple points and plot the results:

```python
>>> import matplotlib.pyplot as plt
>>> points = np.asarray(points)
>>> plt.plot(points[:,0], points[:,1], '.

>>> for results in tree.query_ball_point([[2, 0], [3, 3]], 1):
...    nearby_points = points[results]
...    plt.plot(nearby_points[:,0], nearby_points[:,1], 'o')
>>> plt.margins(0.1, 0.1)
>>> plt.show()
```
**scipy.spatial.cKDTree.query_ball_tree**

```python
cKDTree.query_ball_tree(self, other, r, p=2.0, eps=0)
```

Find all pairs of points between `self` and `other` whose distance is at most `r`

**Parameters**

- **other**  
  [cKDTree instance] The tree containing points to search against.
- **r**  
  [float] The maximum distance, has to be positive.
- **p**  
  [float, optional] Which Minkowski norm to use. `p` has to meet the condition `1 <= p <= infinity`. A finite large `p` may cause a `ValueError` if overflow can occur.
- **eps**  
  [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than `r / (1 + eps)`, and branches are added in bulk if their furthest points are nearer than `r * (1 + eps)`. `eps` has to be non-negative.

**Returns**

- **results**  
  [list of lists] For each element `self.data[i]` of this tree, `results[i]` is a list of the indices of its neighbors in `other.data`.

**Examples**

You can search all pairs of points between two kd-trees within a distance:

```python
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> np.random.seed(21701)
>>> points1 = np.random.random((15, 2))
>>> points2 = np.random.random((15, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points1[:, 0], points1[:, 1], "xk", markersize=14)
>>> plt.plot(points2[:, 0], points2[:, 1], "og", markersize=14)
>>> kd_tree1 = cKDTree(points1)
>>> kd_tree2 = cKDTree(points2)
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> for i in range(len(indexes)):
...     for j in indexes[i]:
...         plt.plot([points1[i, 0], points2[j, 0]],
...                  [points1[i, 1], points2[j, 1]], "-r")
>>> plt.show()
```

**scipy.spatial.cKDTree.query_pairs**

```python
cKDTree.query_pairs(self, r, p=2.0, eps=0)
```

Find all pairs of points in `self` whose distance is at most `r`.

**Parameters**

- **r**  
  [positive float] The maximum distance.
- **p**  
  [float, optional] Which Minkowski norm to use. `p` has to meet the condition `1 <= p <= infinity`. A finite large `p` may cause a `ValueError` if overflow can occur.
- **eps**  
  [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than `r / (1 + eps)`, and branches are added in bulk if their furthest points are nearer than `r * (1 + eps)`. `eps` has to be non-negative.
- **output_type**  
  [string, optional] Choose the output container, ‘set’ or ‘ndarray’. Default: ‘set’
Returns
results [set or ndarray] Set of pairs \((i, j)\), with \(i < j\), for which the corresponding positions are close. If \(\text{output} \_ \text{type} \) is \'ndarray\', an ndarray is returned instead of a set.

Examples

You can search all pairs of points in a kd-tree within a distance:

```python
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> np.random.seed(21701)
>>> points = np.random.random((20, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points[:, 0], points[:, 1], "xk", markersize=14)
>>> kd_tree = cKDTree(points)
>>> pairs = kd_tree.query_pairs(r=0.2)
>>> for (i, j) in pairs:
...     plt.plot([points[i, 0], points[j, 0]],
...              [points[i, 1], points[j, 1]], ",-r")
>>> plt.show()
```

\texttt{scipy.spatial.cKDTree.sparse_distance_matrix}

\texttt{cKDTree.sparse\_distance\_matrix}(self, other, max\_distance, p=2.0)

Computes a sparse distance matrix between two cKDTrees, leaving as zero any distance greater than \(\text{max} \_ \text{distance}\).

Parameters

other [cKDTree]  
max_distance [positive float]  
p [float, 1<=p<=\infty] Which Minkowski p-norm to use. A finite large \(p\) may cause a ValueError if overflow can occur.

Returns

result [dok\_matrix, coo\_matrix, dict or ndarray] Sparse matrix representing the results in “dictionary of keys” format. If a dict is returned the keys are \((i,j)\) tuples of indices. If output\_type is ‘ndarray’ a record array with fields ‘i’, ‘j’, and ‘v’ is returned,
Examples

You can compute a sparse distance matrix between two kd-trees:

```python
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> np.random.seed(21701)
>>> points1 = np.random.random((5, 2))
>>> points2 = np.random.random((5, 2))
>>> kd_tree1 = cKDTree(points1)
>>> kd_tree2 = cKDTree(points2)
>>> sdm = kd_tree1.sparse_distance_matrix(kd_tree2, 0.3)
>>> sdm.toarray()
array([[0.20220215, 0.14538496, 0., 0.10257199, 0.],
       [0.13491385, 0.27251306, 0., 0.18793787, 0.],
       [0.19262396, 0., 0., 0.25795122, 0.],
       [0.14859639, 0.07076002, 0., 0.04065851, 0.],
       [0.17308768, 0., 0., 0.24823138, 0.]]
```

You can check distances above the `max_distance` are zeros:

```python
>>> from scipy.spatial import distance_matrix
>>> distance_matrix(points1, points2)
array([[0.20220215, 0.14538496, 0.43588092, 0.10257199, 0.4555495],
       [0.13491385, 0.27251306, 0.65944131, 0.18793787, 0.68184154],
       [0.19262396, 0.34121593, 0.72176889, 0.25795122, 0.74538858],
       [0.14859639, 0.07076002, 0.48505773, 0.04065851, 0.50043591],
       [0.17308768, 0.32837991, 0.72760803, 0.24823138, 0.75017239]])
```

**scipy.spatial.Rectangle**

```python
class scipy.spatial.Rectangle(maxes, mins)
```

Hyperrectangle class.

Represents a Cartesian product of intervals.

**Methods**

- `max_distance_point(self, x[, p])`: Return the maximum distance between input and points in the hyperrectangle.
- `max_distance_rectangle(self, other[, p])`: Compute the maximum distance between points in the two hyperrectangles.
- `min_distance_point(self, x[, p])`: Return the minimum distance between input and points in the hyperrectangle.
- `min_distance_rectangle(self, other[, p])`: Compute the minimum distance between points in the two hyperrectangles.
- `split(self, d, split)`: Produce two hyperrectangles by splitting.
- `volume(self)`: Total volume.
scipy.spatial.Rectangle.max_distance_point

Rectangle.max_distance_point(self, x, p=2.0)
Return the maximum distance between input and points in the hyperrectangle.

Parameters
- x : array_like
  Input array.
- p : float, optional
  Input.

scipy.spatial.Rectangle.max_distance_rectangle

Rectangle.max_distance_rectangle(self, other, p=2.0)
Compute the maximum distance between points in the two hyperrectangles.

Parameters
- other : hyperrectangle
  Input.
- p : float, optional
  Input.

scipy.spatial.Rectangle.min_distance_point

Rectangle.min_distance_point(self, x, p=2.0)
Return the minimum distance between input and points in the hyperrectangle.

Parameters
- x : array_like
  Input.
- p : float, optional
  Input.

scipy.spatial.Rectangle.min_distance_rectangle

Rectangle.min_distance_rectangle(self, other, p=2.0)
Compute the minimum distance between points in the two hyperrectangles.

Parameters
- other : hyperrectangle
  Input.
- p : float
  Input.

scipy.spatial.Rectangle.split

Rectangle.split(self, d, split)
Produce two hyperrectangles by splitting.

In general, if you need to compute maximum and minimum distances to the children, it can be done more efficiently by updating the maximum and minimum distances to the parent.

Parameters
- d : int
  Axis to split hyperrectangle along.
- split : float
  Position along axis d to split at.
**scipy.spatial.Rectangle.volume**

Rectangle.volume(self)

Total volume.

Distance metrics are contained in the `scipy.spatial.distance` submodule.

### 6.26.3 Delaunay triangulation, convex hulls, and Voronoi diagrams

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delaunay(points[, furthest_site, …])</td>
<td>Delaunay tessellation in N dimensions.</td>
</tr>
<tr>

</tr>
</tbody>
</table>

**scipy.spatial.Delaunay**

```python
class scipy.spatial.Delaunay(points, furthest_site=False, incremental=False, qhull_options=None)
```

Delaunay tessellation in N dimensions.

New in version 0.9.

**Parameters**

- `points` [ndarray of floats, shape (npoints, ndim)] Coordinates of points to triangulate
- `furthest_site` [bool, optional] Whether to compute a furthest-site Delaunay triangulation. Default: False
- `incremental` [bool, optional] Allow adding new points incrementally. This takes up some additional resources.
- `qhull_options` [str, optional] Additional options to pass to Qhull. See Qhull manual for details. Option “Qt” is always enabled. Default: “Qbb Qc Qz Q12” for ndim > 4 and “Qbb Qc Qz Q12” otherwise. Incremental mode omits “Qz”.

**Raises**

- `QhullError` Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.
- `ValueError` Raised if an incompatible array is given as input.
Notes

The tessellation is computed using the Qhull library.

**Note:** Unless you pass in the Qhull option “QJ”, Qhull does not guarantee that each input point appears as a vertex in the Delaunay triangulation. Omitted points are listed in the `coplanar` attribute.

Examples

Triangulation of a set of points:

```python
>>> points = np.array([[0.0, 0.0], [1.1, 0.0], [0.0, 1.0], [1.0, 1.0]])
>>> from scipy.spatial import Delaunay
>>> tri = Delaunay(points)
```

We can plot it:

```python
>>> import matplotlib.pyplot as plt
>>> plt.triplot(points[:,0], points[:,1], tri.simplices)
>>> plt.plot(points[:,0], points[:,1], 'o')
>>> plt.show()
```

Point indices and coordinates for the two triangles forming the triangulation:

```python
>>> tri.simplices
array([[2, 3, 0],  # may vary
        [3, 1, 0]], dtype=int32)
```

Note that depending on how rounding errors go, the simplices may be in a different order than above.

```python
>>> points[tri.simplices]
array([[[ 1. , 0. ],  # may vary
```
Triangle 0 is the only neighbor of triangle 1, and it’s opposite to vertex 1 of triangle 1:

```python
>>> tri.neighbors[1]
array([-1,  0, -1], dtype=int32)
>>> points[tri.simplices[1,1]]
array([ 0. ,  1.1])
```

We can find out which triangle points are in:

```python
>>> p = np.array([(0.1, 0.2), (1.5, 0.5), (0.5, 1.05)])
>>> tri.find_simplex(p)
array([ 1, -1,  1], dtype=int32)
```

The returned integers in the array are the indices of the simplex the corresponding point is in. If -1 is returned, the point is in no simplex. Be aware that the shortcut in the following example only works correctly for valid points as invalid points result in -1 which is itself a valid index for the last simplex in the list.

```python
>>> p_valids = np.array([(0.1, 0.2), (0.5, 1.05)])
>>> tri.simplices[tri.find_simplex(p_valids)]
array([[3, 1, 0], # may vary
       [3, 1, 0]], dtype=int32)
```

We can also compute barycentric coordinates in triangle 1 for these points:

```python
>>> b = tri.transform[1,:2].dot(np.transpose(p - tri.transform[1,2]))
>>> np.c_[np.transpose(b), 1 - b.sum(axis=0)]
array([[ 0.1 ,  0.09090909,  0.80909091],
       [ 1.5 , -0.90909091,  0.40909091],
       [ 0.5 ,  0.5 ,  0. ]])
```

The coordinates for the first point are all positive, meaning it is indeed inside the triangle. The third point is on a vertex, hence its null third coordinate.

**Attributes**

- **points** [ndarray of double, shape (npoints, ndim)] Coordinates of input points.
- **simplices** [ndarray of ints, shape (nsimplex, ndim+1)] Indices of the points forming the simplices in the triangulation. For 2-D, the points are oriented counterclockwise.
- **neighbors** [ndarray of ints, shape (nsimplex, ndim+1)] Indices of neighbor simplices for each simplex. The kth neighbor is opposite to the kth vertex. For simplices at the boundary, -1 denotes no neighbor.
- **equations** [ndarray of double, shape (nsimplex, ndim+2)] [normal, offset] forming the hyperplane equation of the facet on the paraboloid (see Qhull documentation for more).
- **paraboloid_scale, paraboloid_shift** [float] Scale and shift for the extra paraboloid dimension (see Qhull documentation for more).
- **transform** [ndarray of double, shape (nsimplex, ndim+1, ndim)] Affine transform from x to the barycentric coordinates c.
**vertex_to_simplex**

[ndarray of int, shape (npoints,)] Lookup array, from a vertex, to some simplex which it is a part of.

**convex_hull**

[ndarray of int, shape (nfaces, ndim)] Vertices of facets forming the convex hull of the point set.

**coplanar**

[ndarray of int, shape (ncoplanar, 3)] Indices of coplanar points and the corresponding indices of the nearest facet and the nearest vertex. Coplanar points are input points which were not included in the triangulation due to numerical precision issues.

If option "Qc" is not specified, this list is not computed.

New in version 0.12.0.

**vertices**

Same as simplices, but deprecated.

**vertex_neighbor_vertices**

[tuple of two ndarrays of int; (indptr, indices)] Neighboring vertices of vertices.

**furthest_site**

True if this was a furthest site triangulation and False if not.

New in version 1.4.0.

**scipy.spatial.Delaunay.add_points**

Delaunay .add_points (points, restart=False)  
Process a set of additional new points.

**Parameters**

- **points**  
  [ndarray] New points to add. The dimensionality should match that of the initial points.

- **restart**  
  [bool, optional] Whether to restart processing from scratch, rather than adding points incrementally.

**Raises**

- **QhullError**  
  Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**See also:**

- close
Notes

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after `close` has been called.

scipy.spatial.Delaunay.close

Delaunay.close()

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

scipy.spatial.Delaunay.find_simplex

Delaunay.find_simplex(self, xi, bruteforce=False, tol=None)

Find the simplices containing the given points.

Parameters

- **tri** ([DelaunayInfo] Delaunay triangulation)
- **xi** ([ndarray of double, shape (…, ndim)] Points to locate)
- **bruteforce** [bool, optional] Whether to only perform a brute-force search
- **tol** [float, optional] Tolerance allowed in the inside-triangle check. Default is $100*\text{eps}$.

Returns

- **i** ([ndarray of int, same shape as $xi$]) Indices of simplices containing each point. Points outside the triangulation get the value -1.

Notes

This uses an algorithm adapted from Qhull's `qh_findbestfacet`, which makes use of the connection between a convex hull and a Delaunay triangulation. After finding the simplex closest to the point in $N+1$ dimensions, the algorithm falls back to directed search in $N$ dimensions.

scipy.spatial.Delaunay.lift_points

Delaunay.lift_points(self, x)

Lift points to the Qhull paraboloid.

scipy.spatial.Delaunay.plane_distance

Delaunay.plane_distance(self, xi)

Compute hyperplane distances to the point $xi$ from all simplices.

scipy.spatial.ConvexHull

class scipy.spatial.ConvexHull(points, incremental=False, qhull_options=None)

Convex hulls in $N$ dimensions.

New in version 0.12.0.

Parameters

- **points** ([ndarray of floats, shape (npoints, ndim)]) Coordinates of points to construct a convex hull from
incremental

[bool, optional] Allow adding new points incrementally. This takes up some additional resources.

qhull_options

[str, optional] Additional options to pass to Qhull. See Qhull manual for details. (Default: “Qx” for ndim > 4 and “” otherwise) Option “Qt” is always enabled.

Raises

QhullError

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

ValueError

Raised if an incompatible array is given as input.

Notes

The convex hull is computed using the Qhull library.

References

[Qhull]

Examples

Convex hull of a random set of points:

```python
>>> from scipy.spatial import ConvexHull, convex_hull_plot_2d
>>> points = np.random.rand(30, 2)  # 30 random points in 2-D
>>> hull = ConvexHull(points)
```

Plot it:

```python
>>> import matplotlib.pyplot as plt
>>> plt.plot(points[:,0], points[:,1], 'o')
>>> for simplex in hull.simplices:
...    plt.plot(points[simplex, 0], points[simplex, 1], 'k-')
```

We could also have directly used the vertices of the hull, which for 2-D are guaranteed to be in counterclockwise order:

```python
>>> plt.plot(points[hull.vertices,0], points[hull.vertices,1], 'r--', lw=2)
>>> plt.plot(points[hull.vertices[0],0], points[hull.vertices[0],1], 'ro')
>>> plt.show()
```

Facets visible from a point:

Create a square and add a point above the square.

```python
>>> generators = np.array([[0.2, 0.2],
...                        [0.2, 0.4],
...                        [0.4, 0.4],
```

(continues on next page)
Call ConvexHull with the QG option. QG4 means compute the portions of the hull not including point 4, indicating the facets that are visible from point 4.

```python
>>> hull = ConvexHull(points=generators,
...                    qhull_options='QG4')
```

The "good" array indicates which facets are visible from point 4.

```python
>>> print(hull.simplices)
[[0 1],
 [0 2],
 [2 3],
 [3 0]]

>>> print(hull.good)
[False True False False]
```

Now plot it, highlighting the visible facets.

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1,1,1)
>>> for visible_facet in hull.simplices[hull.good]:
...     ax.plot(hull.points[visible_facet, 0],
...             hull.points[visible_facet, 1],
...             color='violet',
...             lw=6)
```

Attributes
points [ndarray of double, shape (npoints, ndim)] Coordinates of input points.
vertices [ndarray of ints, shape (nvertices,)] Indices of points forming the vertices of the convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order.
simplices [ndarray of ints, shape (nfacet, ndim)] Indices of points forming the simplical facets of the convex hull.
neighbors [ndarray of ints, shape (nfacet, ndim)] Indices of neighbor facets for each facet. The kth neighbor is opposite to the kth vertex. -1 denotes no neighbor.
equations [ndarray of double, shape (nfacet, ndim+1)] [normal, offset] forming the hyperplane equation of the facet (see Qhull documentation for more).
coplanar [ndarray of int, shape (ncoplanar, 3)] Indices of coplanar points and the corresponding indices of the nearest facets and nearest vertex indices. Coplanar points are input points which were not included in the triangulation due to numerical precision issues. If option “Qc” is not specified, this list is not computed.
good [ndarray of bool or None] A one-dimensional Boolean array indicating which facets are good. Used with options that compute good facets, e.g. QGn and QG-n. Good facets are defined as those that are visible (n) or invisible (-n) from point n, where n is the nth point in ‘points’. The ‘good’ attribute may be used as an index into ‘simplices’ to return the good (visible) facets: simplices[good]. A facet is visible from the outside of the hull only, and neither coplanarity nor degeneracy count as cases of visibility. If a “QGn” or “QG-n” option is not specified, None is returned. New in version 1.3.0.
area [float] Surface area of the convex hull when input dimension > 2. When input points are 2-dimensional, this is the perimeter of the convex hull. New in version 0.17.0.
volume [float] Volume of the convex hull when input dimension > 2. When input points are 2-dimensional, this is the area of the convex hull. New in version 0.17.0.

**scipy.spatial.ConvexHull.add_points**

ConvexHull.add_points(points, restart=False)
Process a set of additional new points.

- **Parameters**
  - points  
    *ndarray*  
    [New points to add. The dimensionality should match that of the initial points.]
  - restart  
    *bool, optional*  
    [Whether to restart processing from scratch, rather than adding points incrementally.]

- **Raises**
  - QhullError
    [Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.]

**See also:**

- close

**Notes**

You need to specify incremental=True when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after close has been called.

**scipy.spatial.ConvexHull.close**

ConvexHull.close()
Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

**scipy.spatial.Voronoi**

class scipy.spatial.Voronoi(points, furthest_site=False, incremental=False, qhull_options=None)
Voronoi diagrams in N dimensions.
New in version 0.12.0.

- **Parameters**
  - points  
    *ndarray of floats, shape (npoints, ndim)*  
    [Coordinates of points to construct a convex hull from.]
  - furthest_site  
    *bool, optional*  
    [Whether to compute a furthest-site Voronoi diagram. Default: False]
  - incremental  
    *bool, optional*  
    [Allow adding new points incrementally. This takes up some additional resources.]
qhull_options

[\text{str, optional}] Additional options to pass to Qhull. See Qhull manual for details. (Default: “Qbb Qc Qz Qx” for ndim > 4 and “Qbb Qc Qz” otherwise. Incremental mode omits “Qz”.)

\textit{Raises}

\textbf{QhullError}

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

\textbf{ValueError}

Raised if an incompatible array is given as input.

\textbf{Notes}

The Voronoi diagram is computed using the \texttt{Qhull} library.

\textbf{Examples}

Voronoi diagram for a set of point:

```python
>>> points = np.array([[0, 0], [0, 1], [0, 2], [1, 0], [1, 1], [1, 2], ...
                      [2, 0], [2, 1], [2, 2]])
>>> from scipy.spatial import Voronoi, voronoi_plot_2d
>>> vor = Voronoi(points)
```

Plot it:

```python
>>> import matplotlib.pyplot as plt
>>> fig = voronoi_plot_2d(vor)
>>> plt.show()
```

The Voronoi vertices:
There is a single finite Voronoi region, and four finite Voronoi ridges:

```python
>>> vor.vertices
array([[0.5, 0.5],
       [0.5, 1.5],
       [1.5, 0.5],
       [1.5, 1.5]])
```

```python
>>> vor.regions
[[], [-1, 0], [-1, 1], [1, -1, 0], [3, -1, 2], [-1, 3], [-1, 2], [0, 1, 3, 2], [2, -1, 0], [3, -1, 1]]
```

```python
>>> vor.ridge_vertices
[[-1, 0], [-1, 0], [-1, 1], [-1, 1], [0, 1], [-1, 3], [-1, 2], [2, 3], [-1, 3], [-1, 2], [1, 3], [0, 2]]
```

The ridges are perpendicular between lines drawn between the following input points:

```python
>>> vor.ridge_points
array([[0, 3],
       [0, 1],
       [2, 5],
       [2, 1],
       [1, 4],
       [7, 8],
       [7, 6],
       [7, 4],
       [8, 5],
       [6, 3],
       [4, 5],
       [4, 3]], dtype=int32)
```

**Attributes**

- **points** [ndarray of double, shape (npoints, ndim)] Coordinates of input points.
- **vertices** [ndarray of double, shape (nvertices, ndim)] Coordinates of the Voronoi vertices.
- **ridge_points** [ndarray of ints, shape (nridges, 2)] Indices of the points between which each Voronoi ridge lies.
- **ridge_vertices** [list of list of ints, shape (nridges, *]) Indices of the Voronoi vertices forming each Voronoi ridge.
- **regions** [list of list of ints, shape (nregions, *]) Indices of the Voronoi vertices forming each Voronoi region. -1 indicates vertex outside the Voronoi diagram.
- **point_region** [list of ints, shape (npoints)] Index of the Voronoi region for each input point. If qhull option “Qc” was not specified, the list will contain -1 for points that are not associated with a Voronoi region.
- **furthest_site** True if this was a furthest site triangulation and False if not. New in version 1.4.0.

**scipy.spatial.Voronoi.add_points**

Voronoi.add_points(points, restart=False)
Process a set of additional new points.

**Parameters**

- points
  - [ndarray] New points to add. The dimensionality should match that of the initial points.
- restart
  - [bool, optional] Whether to restart processing from scratch, rather than adding points incrementally.

**Raises**

- QhullError
  - Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**See also:**

- close

**Notes**

You need to specify incremental=True when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after close has been called.

**scipy.spatial.Voronoi.close**

Voronoi.close()
Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

**scipy.spatial.SphericalVoronoi**

class scipy.spatial.SphericalVoronoi(points, radius=1, center=None, threshold=1e-06)
Voronoi diagrams on the surface of a sphere.

New in version 0.18.0.

**Parameters**

- points
  - [ndarray of floats, shape (npoints, ndim)] Coordinates of points from which to construct a spherical Voronoi diagram.
- radius
  - [float, optional] Radius of the sphere (Default: 1)
- center
  - [ndarray of floats, shape (ndim,)] Center of sphere (Default: origin)
- threshold
  - [float] Threshold for detecting duplicate points and mismatches between points and sphere parameters. (Default: 1e-06)

**Raises**
ValueError

If there are duplicates in points. If the provided radius is not consistent with points.

See also:

Voronoi

Conventional Voronoi diagrams in N dimensions.

Notes

The spherical Voronoi diagram algorithm proceeds as follows. The Convex Hull of the input points (generators) is calculated, and is equivalent to their Delaunay triangulation on the surface of the sphere [Carolı]. The Convex Hull neighbour information is then used to order the Voronoi region vertices around each generator. The latter approach is substantially less sensitive to floating point issues than angle-based methods of Voronoi region vertex sorting.

Empirical assessment of spherical Voronoi algorithm performance suggests quadratic time complexity (loglinear is optimal, but algorithms are more challenging to implement).

References

[Carolı], [VanOosterom]

Examples

Do some imports and take some points on a cube:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import SphericalVoronoi, geometric_slerp
>>> from mpl_toolkits.mplot3d import proj3d
>>> # set input data
>>> points = np.array([[0, 0, 1], [0, 0, -1], [1, 0, 0],
...                     [0, 1, 0], [0, -1, 0], [-1, 0, 0], ])
```

Calculate the spherical Voronoi diagram:

```python
>>> radius = 1
>>> center = np.array([0, 0, 0])
>>> sv = SphericalVoronoi(points, radius, center)
```

Generate plot:

```python
>>> # sort vertices (optional, helpful for plotting)
>>> sv.sort_vertices_of_regions()
>>> t_vals = np.linspace(0, 1, 2000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111, projection='3d')
>>> # plot the unit sphere for reference (optional)
>>> u = np.linspace(0, 2 * np.pi, 100)
>>> v = np.linspace(0, np.pi, 100)
>>> x = np.outer(np.cos(u), np.sin(v))
>>> y = np.outer(np.sin(u), np.sin(v))
>>> z = np.outer(np.ones(np.size(u)), np.cos(v))
```

(continues on next page)
>>> ax.plot_surface(x, y, z, color='y', alpha=0.1)
>>> # plot generator points
>>> ax.scatter(points[:, 0], points[:, 1], points[:, 2], c='b')
>>> # plot Voronoi vertices
>>> ax.scatter(sv.vertices[:, 0], sv.vertices[:, 1], sv.vertices[:, 2],
... c='g')
>>> # indicate Voronoi regions (as Euclidean polygons)
>>> for region in sv.regions:
...     n = len(region)
...     for i in range(n):
...         start = sv.vertices[region][i]
...         end = sv.vertices[region][(i + 1) % n]
...         result = geometric_slerp(start, end, t_vals)
...         ax.plot(result[:, 0],
...                 result[:, 1],
...                 result[:, 2],
...                 c='k')
>>> ax.azim = 10
>>> ax.elev = 40
>>> _ = ax.set_xticks([])
>>> _ = ax.set_yticks([])
>>> _ = ax.set_zticks([])
>>> fig.set_size_inches(4, 4)
>>> plt.show()
**points**  [double array of shape (npoints, ndim)] the points in ndim dimensions to generate the Voronoi diagram from

**radius**  [double] radius of the sphere

**center**  [double array of shape (ndim,)] center of the sphere

**vertices**  [double array of shape (nvertices, ndim)] Voronoi vertices corresponding to points

**regions**  [list of list of integers of shape (npoints, _)] the n-th entry is a list consisting of the indices of the vertices belonging to the n-th point in points

### Methods

**`calculate_areas(self)`** Calculates the areas of the Voronoi regions.

**scipy.spatial.SphericalVoronoi.calculate_areas**

*SphericalVoronoi.calculate_areas (self)*

Calculates the areas of the Voronoi regions.

For 2D point sets, the regions are circular arcs. The sum of the areas is \(2 \times \pi \times \text{radius}\).

For 3D point sets, the regions are spherical polygons. The sum of the areas is \(4 \times \pi \times \text{radius}^2\).

New in version 1.5.0.

**Returns**

**areas**  [double array of shape (npoints,)] The areas of the Voronoi regions.

**scipy.spatial.HalfspaceIntersection**

class *scipy.spatial.HalfspaceIntersection*(halfspaces, interior_point, incremental=False, qhull_options=None)

Halfspace intersections in N dimensions.

New in version 0.19.0.

**Parameters**

**halfspaces**  [ndarray of floats, shape (nineq, ndim+1)] Stacked Inequalities of the form \(Ax + b \leq 0\) in format \([A; b]\)

**interior_point**  [ndarray of floats, shape (ndim,)] Point clearly inside the region defined by halfspaces. Also called a feasible point, it can be obtained by linear programming.

**incremental**  [bool, optional] Allow adding new halfspaces incrementally. This takes up some additional resources.

**qhull_options**  [str, optional] Additional options to pass to Qhull. See Qhull manual for details. (Default: “Qx” for ndim > 4 and “” otherwise) Option “H” is always enabled.

**Raises**

**QhullError**

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**ValueError**

Raised if an incompatible array is given as input.
Notes

The intersections are computed using the Qhull library. This reproduces the “qhalf” functionality of Qhull.

References

[Qhull], [1]

Examples

Halfspace intersection of planes forming some polygon

```python
>>> from scipy.spatial import HalfspaceIntersection
>>> halfspaces = np.array([[-1, 0., 0.], ...
...                           [0., -1., 0.], ...
...                           [2., 1., -4.], ...
...                           [-0.5, 1., -2.]])
>>> feasible_point = np.array([0.5, 0.5])
>>> hs = HalfspaceIntersection(halfspaces, feasible_point)
```

Plot halfspaces as filled regions and intersection points:

```python
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1, 1, 1, aspect='equal')
>>> ax.set_xlim(xlim)
>>> ax.set_ylim(ylim)
>>> x = np.linspace(-1, 3, 100)
>>> symbols = ['-', '+', 'x', '*']
>>> signs = [0, 0, -1, -1]
>>> fmt = "{color}:
... "edgecolor": "b", "alpha": 0.5"
>>> for h, sym, sign in zip(halfspaces, symbols, signs):
...     hlist = h.tolist()
...     fmt["hatch"] = sym
...     if h[1] == 0:
...         ax.axvline(-h[2]/h[0], label='({})x+{}y+{}=0'.format(*hlist))
...     xi = np.linspace(xlim[sign], -h[2]/h[0], 100)
...     ax.fill_between(xi, ylim[sign], **fmt)
...     else:
...         ax.plot(x, (-h[2]-h[0]*x)/h[1], label='({})x+{}y+{}=0'.format(*hlist))
...     xi = np.linspace(xlim[sign], -h[2]/h[0], 100)
...     ax.fill_between(xi, (-h[2]-h[0]*x)/h[1], ylim[sign], **fmt)
>>> x, y = zip(*hs.intersections)
>>> ax.plot(x, y, 'o', markersize=8)
```

By default, qhull does not provide with a way to compute an interior point. This can easily be computed using linear programming. Considering halfspaces of the form $A x + b \leq 0$, solving the linear program:

\[
\begin{align*}
\max & \quad y \\
\text{s.t.} & \quad Ax + y ||A_i|| \leq -b
\end{align*}
\]

With $A_i$ being the rows of $A$, i.e. the normals to each plane.
Will yield a point $x$ that is furthest inside the convex polyhedron. To be precise, it is the center of the largest hypersphere of radius $y$ inscribed in the polyhedron. This point is called the Chebyshev center of the polyhedron (see [1] 4.3.1, pp148-149). The equations outputted by Qhull are always normalized.

```python
>>> from scipy.optimize import linprog
>>> from matplotlib.patches import Circle
>>> norm_vector = np.reshape(np.linalg.norm(halfspaces[:, :-1], axis=1), ...
                              (halfspaces.shape[0], 1))
>>> c = np.zeros((halfspaces.shape[1],))
>>> c[-1] = -1
>>> A = np.hstack((halfspaces[:, :-1], norm_vector))
>>> b = - halfspaces[:, -1:]
>>> res = linprog(c, A_ub=A, b_ub=b, bounds=(None, None))
>>> x = res.x[:-1]
>>> y = res.x[-1]
>>> circle = Circle(x, radius=y, alpha=0.3)
>>> ax.add_patch(circle)
>>> plt.legend(bbox_to_anchor=(1.6, 1.0))
>>> plt.show()
```

`Attributes`

- `halfspaces` [ndarray of double, shape (nineq, ndim+1)] Input halfspaces.
- `interior_point`:ndarray of floats, shape (ndim,)  
  Input interior point.
- `intersections` [ndarray of double, shape (ninter, ndim)] Intersections of all halfspaces.
- `dual_points` [ndarray of double, shape (nineq, ndim)] Dual points of the input halfspaces.
- `dual_facets` [list of lists of ints] Indices of points forming the (non necessarily simplicial) facets of the dual convex hull.
- `dual_vertices`
Indices of halfspaces forming the vertices of the dual convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order.

dual_equations
[ndarray of double, shape (nfacet, ndim+1)] [normal, offset] forming the hyperplane equation of the dual facet (see Qhull documentation for more).

dual_area
[ndarray of ints, shape (nvertices,)] Indices of halfspaces forming the vertices of the dual convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order.

dual_volume

Area of the dual convex hull

dual_volume
[ndarray of double, shape (nfacet, ndim+1)] [normal, offset] forming the hyperplane equation of the dual facet (see Qhull documentation for more).

dual_volume
[ndarray of double, shape (nfacet, ndim+1)] [normal, offset] forming the hyperplane equation of the dual facet (see Qhull documentation for more).

dual_volume

Area of the dual convex hull

dual_volume

Volume of the dual convex hull

dual_volume

Methods

**add_halfspaces(halfspaces[, restart])** Process a set of additional new halfspaces.

**close()** Finish incremental processing.

scipy.spatial.HalfspaceIntersection.add_halfspaces

HalfspaceIntersection.add_halfspaces(halfspaces, restart=False)

Process a set of additional new halfspaces.

Parameters

halfspaces
[ndarray] New halfspaces to add. The dimensionality should match that of the initial halfspaces.

restart
[bool, optional] Whether to restart processing from scratch, rather than adding halfspaces incrementally.

Raises

QhullError Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

See also:

close

Notes

You need to specify incremental=True when constructing the object to be able to add halfspaces incrementally. Incremental addition of halfspaces is also not possible after close has been called.

scipy.spatial.HalfspaceIntersection.close

HalfspaceIntersection.close()

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.
6.26.4 Plotting helpers

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>delaunay_plot_2d(tri[, ax])</code></td>
<td>Plot the given Delaunay triangulation in 2-D</td>

</tbody>
</table>

**scipy.spatial.delaunay_plot_2d**

`scipy.spatial.delaunay_plot_2d(tri, ax=None)`  
Plot the given Delaunay triangulation in 2-D

**Parameters**

- `tri`  
  [scipy.spatial.Delaunay instance] Triangulation to plot
- `ax`  
  [matplotlib.axes.Axes instance, optional] Axes to plot on

**Returns**

- `fig`  
  [matplotlib.figure.Figure instance] Figure for the plot

**See also:**

Delaunay  
`matplotlib.pyplot.triplot`

**Notes**

Requires Matplotlib.

**Examples**

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import Delaunay, delaunay_plot_2d

The Delaunay triangulation of a set of random points:

```python
>>> points = np.random.rand(30, 2)
>>> tri = Delaunay(points)
```

Plot it:

```python
>>> _ = delaunay_plot_2d(tri)
>>> plt.show()
```
scipy.spatial.convex_hull_plot_2d

scipy.spatial.convex_hull_plot_2d(hull, ax=None)
Plot the given convex hull diagram in 2-D

Parameters

- hull [scipy.spatial.ConvexHull instance] Convex hull to plot
- ax [matplotlib.axes.Axes instance, optional] Axes to plot on

Returns

- fig [matplotlib.figure.Figure instance] Figure for the plot

See also:

ConvexHull

Notes

Requires Matplotlib.

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import ConvexHull, convex_hull_plot_2d

The convex hull of a random set of points:

```
```python
>>> _ = convex_hull_plot_2d(hull)
>>> plt.show()
```

```plaintext
scipy.spatial.voronoi_plot_2d

scipy.spatial.voronoi_plot_2d(vor, ax=None, **kw)
Plot the given Voronoi diagram in 2-D

**Parameters**
- **vor** [scipy.spatial.Voronoi instance] Diagram to plot
- **ax** [matplotlib.axes.Axes instance, optional] Axes to plot on
- **show_points**: bool, optional
  Add the Voronoi points to the plot.
- **show_vertices**: bool, optional
  Add the Voronoi vertices to the plot.
- **line_colors**: string, optional
  Specifies the line color for polygon boundaries
- **line_width**: float, optional
  Specifies the line width for polygon boundaries
- **line_alpha**: float, optional
  Specifies the line alpha for polygon boundaries
- **point_size**: float, optional
  Specifies the size of points

**Returns**
- **fig** [matplotlib.figure.Figure instance] Figure for the plot

**See also:**

Voronoi

6.26. Spatial algorithms and data structures (scipy.spatial) 2283
Notes

Requires Matplotlib.

Examples

Set of point:

```
>>> import matplotlib.pyplot as plt
>>> points = np.random.rand(10,2)  #random
```

Voronoi diagram of the points:

```
>>> from scipy.spatial import Voronoi, voronoi_plot_2d
>>> vor = Voronoi(points)
```

using `voronoi_plot_2d` for visualisation:

```
>>> fig = voronoi_plot_2d(vor)
```

using `voronoi_plot_2d` for visualisation with enhancements:

```
>>> fig = voronoi_plot_2d(vor, show_vertices=False, line_colors='orange',
...                        line_width=2, line_alpha=0.6, point_size=2)
>>> plt.show()
```

Tutorial
6.26.5 Simplex representation

The simplices (triangles, tetrahedra, etc.) appearing in the Delaunay tessellation (N-D simplices), convex hull facets, and Voronoi ridges (N-1-D simplices) are represented in the following scheme:

```
tess = Delaunay(points)
hull = ConvexHull(points)
voro = Voronoi(points)
```

```
# coordinates of the jth vertex of the ith simplex
tess.points[tess.simplices[i, j], :]  # tessellation element
hull.points[hull.simplices[i, j], :]  # convex hull facet
voro.vertices[voro.ridge_vertices[i, j], :]  # ridge between Voronoi cells
```

For Delaunay triangulations and convex hulls, the neighborhood structure of the simplices satisfies the condition: `tess.neighbors[i, j]` is the neighboring simplex of the `i`th simplex, opposite to the `j`-vertex. It is -1 in case of no neighbor.

Convex hull facets also define a hyperplane equation:

```
(hull.equations[i, :-1] * coord).sum() + hull.equations[i, -1] == 0
```

Similar hyperplane equations for the Delaunay triangulation correspond to the convex hull facets on the corresponding N+1-D paraboloid.

The Delaunay triangulation objects offer a method for locating the simplex containing a given point, and barycentric coordinate computations.
### Functions

#### scipy.spatial.tsearch

**scipy.spatial.tsearch(tri, xi)**

Find simplices containing the given points. This function does the same thing as `Delaunay.find_simplex`.

New in version 0.9.

**See also:**

`Delaunay.find_simplex`

**Examples**

```python
>>> import numpy as np
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import Delaunay, delaunay_plot_2d, tsearch
```

The Delaunay triangulation of a set of random points:

```python
>>> pts = np.random.rand(20, 2)
>>> tri = Delaunay(pts)
>>> _ = delaunay_plot_2d(tri)
```

Find the simplices containing a given set of points:

```python
>>> loc = np.random.uniform(0.2, 0.8, (5, 2))
>>> s = tsearch(tri, loc)
>>> plt.triplot(pts[:, 0], pts[:, 1], tri.simplices[s], 'b-', mask=s==-1)
>>> plt.scatter(loc[:, 0], loc[:, 1], c='r', marker='x')
>>> plt.show()
```

#### scipy.spatial.distance_matrix

**scipy.spatial.distance_matrix(x, y, p=2, threshold=1000000)**

Compute the distance matrix.

Returns the matrix of all pair-wise distances.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x</code></td>
<td>$(M, K)$ array_like Matrix of $M$ vectors in $K$ dimensions.</td>
</tr>
<tr>
<td><code>y</code></td>
<td>$(N, K)$ array_like Matrix of $N$ vectors in $K$ dimensions.</td>
</tr>
<tr>
<td><code>p</code></td>
<td>[float, $1 \leq p \leq \infty$] Which Minkowski $p$-norm to use.</td>
</tr>
<tr>
<td><code>threshold</code></td>
<td>[positive int] If $M \times N \times K &gt; \text{threshold}$, algorithm uses a Python loop instead of large temporary arrays.</td>
</tr>
</tbody>
</table>

6.26. Spatial algorithms and data structures (scipy.spatial) 2287

**Returns**

**result**

[(M, N) ndarray] Matrix containing the distance from every vector in x to every vector in y.

**Examples**

```python
>>> from scipy.spatial import distance_matrix
>>> distance_matrix([[0, 0], [0, 1]], [[1, 0], [1, 1]])
