SciPy (pronounced “Sigh Pie”) is an open-source software for mathematics, science, and engineering.

Getting started

New to SciPy? Check out the getting started guides. They contain an introduction to SciPy’s main concepts and links to additional tutorials.

To the getting started guides
User guide

The user guide provides in-depth information on the key concepts of SciPy with useful background information and explanation.

To the user guide
API reference

The reference guide contains a detailed description of the SciPy API. The reference describes how the methods work and which parameters can be used. It assumes that you have an understanding of the key concepts.

Saw a typo in the documentation? Want to improve existing functionalities? The contributing guidelines will guide you through the process of improving SciPy.

To the development guide
1.1 Installation

Working with conda?
SciPy is part of the Anaconda distribution and can be installed with Anaconda or Miniconda:

```
conda install scipy
```

Prefer pip?
SciPy can be installed via pip from PyPI.

```
pip install scipy
```

In-depth instructions?
Installing a specific version? Installing from source? Check the advanced installation page.

Learn more

1.1.1 Installing and upgrading

Information on how to install SciPy and/or the SciPy Stack (a larger set of packages for scientific computing with Python) can be found at https://scipy.org/install/.

It is recommended that users use a scientific Python distribution or binaries for their platform. If building from source is required, documentation about that can be found at building/index.

If you already have SciPy installed and want to upgrade to a newer version, use the same install mechanism as you have used to install SciPy before. Before upgrading to a newer version, it is recommended to check that your own code does not use any deprecated SciPy functionality. To do so, run your code with `python -Wd`. 
1.2 Tutorials

For a quick overview of SciPy functionality, see the user guide.

You can also refer to the reference guide for an exhaustive list of all what is possible with SciPy.
2.1 Introduction

SciPy is a collection of mathematical algorithms and convenience functions built on the NumPy extension of Python. It adds significant power to the interactive Python session by providing the user with high-level commands and classes for manipulating and visualizing data. With SciPy, an interactive Python session becomes a data-processing and system-prototyping environment rivaling systems, such as MATLAB, IDL, Octave, R-Lab, and SciLab.

The additional benefit of basing SciPy on Python is that this also makes a powerful programming language available for use in developing sophisticated programs and specialized applications. Scientific applications using SciPy benefit from the development of additional modules in numerous niches of the software landscape by developers across the world. Everything from parallel programming to web and data-base subroutines and classes have been made available to the Python programmer. All of this power is available in addition to the mathematical libraries in SciPy.

This tutorial will acquaint the first-time user of SciPy with some of its most important features. It assumes that the user has already installed the SciPy package. Some general Python facility is also assumed, such as could be acquired by working through the Python distribution’s Tutorial. For further introductory help the user is directed to the NumPy documentation.

For brevity and convenience, we will often assume that the main packages (numpy, scipy, and matplotlib) have been imported as:

```python
>>> import numpy as np
>>> import matplotlib as mpl
>>> import matplotlib.pyplot as plt
```

These are the import conventions that our community has adopted after discussion on public mailing lists. You will see these conventions used throughout NumPy and SciPy source code and documentation. While we obviously don’t require you to follow these conventions in your own code, it is highly recommended.
2.1.1 SciPy Organization

SciPy is organized into subpackages covering different scientific computing domains. These are summarized in the following table:

<table>
<thead>
<tr>
<th>Subpackage</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster</td>
<td>Clustering algorithms</td>
</tr>
<tr>
<td>constants</td>
<td>Physical and mathematical constants</td>

</tr>
<tr>
<td>spatial</td>
<td>Spatial data structures and algorithms</td>
</tr>
<tr>
<td>special</td>
<td>Special functions</td>
</tr>
<tr>
<td>stats</td>
<td>Statistical distributions and functions</td>
</tr>
</tbody>
</table>

SciPy sub-packages need to be imported separately, for example:

```python
>>> from scipy import linalg, optimize
```

Because of their ubiquitousness, some of the functions in these subpackages are also made available in the `scipy` namespace to ease their use in interactive sessions and programs. In addition, many basic array functions from `numpy` are also available at the top-level of the `scipy` package. Before looking at the sub-packages individually, we will first look at some of these common functions.

2.1.2 Finding Documentation

SciPy and NumPy have documentation versions in both HTML and PDF format available at https://docs.scipy.org/, that cover nearly all available functionality. However, this documentation is still work-in-progress and some parts may be incomplete or sparse. As we are a volunteer organization and depend on the community for growth, your participation - everything from providing feedback to improving the documentation and code - is welcome and actively encouraged.

Python’s documentation strings are used in SciPy for on-line documentation. There are two methods for reading them and getting help. One is Python’s command `help` in the `pydoc` module. Entering this command with no arguments (i.e. `>>> help`) launches an interactive help session that allows searching through the keywords and modules available to all of Python. Secondly, running the command `help(obj)` with an object as the argument displays that object’s calling signature, and documentation string.

The `pydoc` method of `help` is sophisticated but uses a pager to display the text. Sometimes this can interfere with the terminal within which you are running the interactive session. A `numpy/scipy`-specific help system is also available under the command `numpy.info`. The signature and documentation string for the object passed to the `help` command are printed to standard output (or to a writeable object passed as the third argument). The second keyword argument of `numpy.info` defines the maximum width of the line for printing. If a module is passed as the argument to `help` then a list of the functions and classes defined in that module is printed. For example:

```python
>>> np.info(optimize.fmin)
```

(continues on next page)
Minimize a function using the downhill simplex algorithm.

Parameters
-----------
func : callable func(x,*args)
    The objective function to be minimized.
x0 : ndarray
    Initial guess.
args : tuple
    Extra arguments passed to func, i.e. `func(x,*args)`.
callback : callable
    Called after each iteration, as callback(xk), where xk is the current parameter vector.

Returns
-------
xopt : ndarray
    Parameter that minimizes function.
fopt : float
    Value of function at minimum: `fopt = func(xopt)`.
iter : int
    Number of iterations performed.
funcalls : int
    Number of function calls made.
warnflag : int
    1 : Maximum number of function evaluations made.
    2 : Maximum number of iterations reached.
allvecs : list
    Solution at each iteration.

Other parameters
----------------
xtol : float
    Relative error in xopt acceptable for convergence.
ftol : number
    Relative error in func(xopt) acceptable for convergence.
maxiter : int
    Maximum number of iterations to perform.
maxfun : number
    Maximum number of function evaluations to make.
full_output : bool
    Set to True if fopt and warnflag outputs are desired.
disp : bool
    Set to True to print convergence messages.
retall : bool
    Set to True to return list of solutions at each iteration.

Notes
-----
Uses a Nelder-Mead simplex algorithm to find the minimum of function of
Another useful command is `dir`, which can be used to look at the namespace of a module or package.

### 2.2 Special functions (`scipy.special`)

The main feature of the `scipy.special` package is the definition of numerous special functions of mathematical physics. Available functions include airy, elliptic, bessel, gamma, beta, hypergeometric, parabolic cylinder, mathieu, spheroidal wave, struve, and kelvin. There are also some low-level stats functions that are not intended for general use as an easier interface to these functions is provided by the `stats` module. Most of these functions can take array arguments and return array results following the same broadcasting rules as other math functions in Numerical Python. Many of these functions also accept complex numbers as input. For a complete list of the available functions with a one-line description type `>>> help(special)`. Each function also has its own documentation accessible using `help`. If you don’t see a function you need, consider writing it and contributing it to the library. You can write the function in either C, Fortran, or Python. Look in the source code of the library for examples of each of these kinds of functions.

#### 2.2.1 Bessel functions of real order (`jv, jn_zeros`)

Bessel functions are a family of solutions to Bessel’s differential equation with real or complex order \( \alpha \):

\[
x^2 \frac{d^2 y}{dx^2} + x \frac{dy}{dx} + (x^2 - \alpha^2)y = 0
\]

Among other uses, these functions arise in wave propagation problems, such as the vibrational modes of a thin drum head. Here is an example of a circular drum head anchored at the edge:

```python
>>> from scipy import special
>>> def drumhead_height(n, k, distance, angle, t):
...     kth_zero = special.jn_zeros(n, k)[-1]
...     return np.cos(t) * np.cos(n*angle) * special.jn(n, distance*kth_zero)
>>> theta = np.linspace(0, 2*np.pi, 50)
>>> radius = np.linspace(0, 0.5, 50)
>>> x = np.array([r * np.cos(theta) for r in radius])
>>> y = np.array([r * np.sin(theta) for r in radius])
>>> z = np.array([drumhead_height(1, 1, r, theta, 0.5) for r in radius])
```

```python
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_axes(rect=(0, 0.05, 0.95, 0.95), projection='3d')
>>> ax.plot_surface(x, y, z, rstride=1, cstride=1, cmap='RdBu_r', vmin=-0.5, ...
...     vmax=0.5)
>>> ax.set_xlabel('X')
>>> ax.set_ylabel('Y')
>>> ax.set_xticks(np.arange(-1, 1.1, 0.5))
>>> ax.set_yticks(np.arange(-1, 1.1, 0.5))
>>> ax.set_zlabel('Z')
>>> plt.show()
```
2.2.2 Cython Bindings for Special Functions (scipy.special.cython_special)

SciPy also offers Cython bindings for scalar, typed versions of many of the functions in special. The following Cython code gives a simple example of how to use these functions:

```
cimport scipy.special.cython_special as csc
cdef:
    double x = 1
    double complex z = 1 + 1j
    double si, ci, rgam
    double complex cgam

    rgam = csc.gamma(x)
    print(rgam)
    cgam = csc.gamma(z)
    print(cgam)
    csc.sici(x, &si, &ci)
    print(si, ci)
```

(See the Cython documentation for help with compiling Cython.) In the example the function `csc.gamma` works essentially like its ufunc counterpart `gamma`, though it takes C types as arguments instead of NumPy arrays. Note, in particular, that the function is overloaded to support real and complex arguments; the correct variant is selected at compile time. The function `csc.sici` works slightly differently from `sici`; for the ufunc we could write `ai, bi = sici(x)`, whereas in the Cython version multiple return values are passed as pointers. It might help to think of this as analogous to calling a ufunc with an output array: `sici(x, out=(si, ci))`.

There are two potential advantages to using the Cython bindings:

- they avoid Python function overhead
- they do not require the Python Global Interpreter Lock (GIL)

The following sections discuss how to use these advantages to potentially speed up your code, though, of course, one should always profile the code first to make sure putting in the extra effort will be worth it.
Avoiding Python Function Overhead

For the ufuncs in special, Python function overhead is avoided by vectorizing, that is, by passing an array to the function. Typically, this approach works quite well, but sometimes it is more convenient to call a special function on scalar inputs inside a loop, for example, when implementing your own ufunc. In this case, the Python function overhead can become significant. Consider the following example:

```python
import scipy.special as sc
cimport scipy.special.cython_special as csc

def python_tight_loop():
    cdef:
        int n
        double x = 1

    for n in range(100):
        sc.jv(n, x)

def cython_tight_loop():
    cdef:
        int n
        double x = 1

    for n in range(100):
        csc.jv(n, x)
```

On one computer python_tight_loop took about 131 microseconds to run and cython_tight_loop took about 18.2 microseconds to run. Obviously this example is contrived: one could just call special.jv(np.arange(100), 1) and get results just as fast as in cython_tight_loop. The point is that if Python function overhead becomes significant in your code, then the Cython bindings might be useful.

Releasing the GIL

One often needs to evaluate a special function at many points, and typically the evaluations are trivially parallelizable. Since the Cython bindings do not require the GIL, it is easy to run them in parallel using Cython’s prange function. For example, suppose that we wanted to compute the fundamental solution to the Helmholtz equation:

\[ \Delta_x G(x, y) + k^2 G(x, y) = \delta(x - y), \]

where \( k \) is the wavenumber and \( \delta \) is the Dirac delta function. It is known that in two dimensions the unique (radiating) solution is

\[ G(x, y) = \frac{i}{4} H_0^{(1)}(k|x - y|), \]

where \( H_0^{(1)} \) is the Hankel function of the first kind, i.e., the function hankel1. The following example shows how we could compute this function in parallel:

```python
from libc.math cimport fabs
cimport cython
from cython.parallel cimport prange

import numpy as np
import scipy.special as sc
```

(continues on next page)
cimport scipy.special.cython_special as csc

def serial_G(k, x, y):
    return 0.25*j*csc.hankel1(0, k*np.abs(x - y))

@cython.boundscheck(False)
@cython.wraparound(False)
cdef void _parallel_G(double k, double[:, :] x, double[:, :] y, double complex[:, :] out) nogil:
    cdef int i, j
    for i in prange(x.shape[0]):
        for j in range(y.shape[0]):
            out[i, j] = 0.25j*csc.hankel1(0, k*fabs(x[i, j] - y[i, j]))

def parallel_G(k, x, y):
    out = np.empty_like(x, dtype='complex128')
    _parallel_G(k, x, y, out)
    return out

(For help with compiling parallel code in Cython see here.) If the above Cython code is in a file test.pyx, then we can write an informal benchmark which compares the parallel and serial versions of the function:

```python
import timeit
import numpy as np
from test import serial_G, parallel_G

def main():
    k = 1
    x, y = np.linspace(-100, 100, 1000), np.linspace(-100, 100, 1000)
    x, y = np.meshgrid(x, y)

    def serial():
        serial_G(k, x, y)

    def parallel():
        parallel_G(k, x, y)

    time_serial = timeit.timeit(serial, number=3)
    time_parallel = timeit.timeit(parallel, number=3)
    print("Serial method took {:.3} seconds".format(time_serial))
    print("Parallel method took {:.3} seconds".format(time_parallel))

if __name__ == "__main__":
    main()
```

On one quad-core computer the serial method took 1.29 seconds and the parallel method took 0.29 seconds.
Some functions are not included in special because they are straightforward to implement with existing functions in NumPy and SciPy. To prevent reinventing the wheel, this section provides implementations of several such functions, which hopefully illustrate how to handle similar functions. In all examples NumPy is imported as np and special is imported as sc.

The binary entropy function:

```python
def binary_entropy(x):
    return -(sc.xlogy(x, x) + sc.xlog1py(1 - x, -x))/np.log(2)
```

A rectangular step function on [0, 1]:

```python
def step(x):
    return 0.5*(np.sign(x) + np.sign(1 - x))
```

Translating and scaling can be used to get an arbitrary step function.

The ramp function:

```python
def ramp(x):
    return np.maximum(0, x)
```

## 2.3 Integration (scipy.integrate)

The `scipy.integrate` sub-package provides several integration techniques including an ordinary differential equation integrator. An overview of the module is provided by the help command:

```python
>>> help(integrate)
Methods for Integrating Functions given function object.
    quad       -- General purpose integration.
    dblquad    -- General purpose double integration.
    tplquad    -- General purpose triple integration.
    fixed_quad -- Integrate func(x) using Gaussian quadrature of order n.
    quadrature -- Integrate with given tolerance using Gaussian quadrature.
    romberg    -- Integrate func using Romberg integration.

Methods for Integrating Functions given fixed samples.

    trapezoid   -- Use trapezoidal rule to compute integral.
    cumulative_trapezoid -- Use trapezoidal rule to cumulatively compute integral.
    simpson     -- Use Simpson's rule to compute integral from samples.
    romb        -- Use Romberg Integration to compute integral from (2**k + 1) evenly-spaced samples.

See the special module's orthogonal polynomials (special) for Gaussian quadrature roots and weights for other weighting factors and regions.

Interface to numerical integrators of ODE systems.
```
odeint -- General integration of ordinary differential equations.
ode -- Integrate ODE using VODE and ZVODE routines.

2.3.1 General integration (quad)

The function \texttt{quad} is provided to integrate a function of one variable between two points. The points can be ±∞ (± inf) to indicate infinite limits. For example, suppose you wish to integrate a bessel function \( j_v(2.5, x) \) along the interval \([0, 4.5]\).

\[ I = \int_{0}^{4.5} J_{2.5}(x) \, dx. \]

This could be computed using \texttt{quad}:

```python
>>> import scipy.integrate as integrate
>>> import scipy.special as special
>>> result = integrate.quad(lambda x: special.jv(2.5, x), 0, 4.5)
>>> result
(1.117817938078325, 7.8663172481899801e-09)
```

```python
>>> from numpy import sqrt, sin, cos, pi
>>> I = sqrt(2/pi)*(18.0/27*sqrt(2)*cos(4.5) - 4.0/27*sqrt(2)*sin(4.5) + ...
                        sqrt(2*pi)*special.fresnel(3/sqrt(pi))[0])
>>> I
1.117817938088701
```

```python
>>> print(abs(result[0]-I))
1.03761443881e-11
```

The first argument to \texttt{quad} is a “callable” Python object (i.e., a function, method, or class instance). Notice the use of a lambda- function in this case as the argument. The next two arguments are the limits of integration. The return value is a tuple, with the first element holding the estimated value of the integral and the second element holding an upper bound on the error. Notice, that in this case, the true value of this integral is

\[ I = \sqrt{\frac{2}{\pi}} \left( \frac{18}{27} \sqrt{2} \cos(4.5) - \frac{4}{27} \sqrt{2} \sin(4.5) + \sqrt{2\pi} \text{Si}\left( \frac{3}{\sqrt{\pi}} \right) \right), \]

where

\[ \text{Si}(x) = \int_{0}^{x} \sin\left( \frac{\pi}{2} t^2 \right) \, dt. \]

is the Fresnel sine integral. Note that the numerically-computed integral is within \(1.04 \times 10^{-11}\) of the exact result — well below the reported error bound.

If the function to integrate takes additional parameters, they can be provided in the \texttt{args} argument. Suppose that the following integral shall be calculated:

\[ I(a, b) = \int_{0}^{1} ax^2 + b \, dx. \]

This integral can be evaluated by using the following code:

2.3. Integration (scipy.integrate)
Infinite inputs are also allowed in `quad` by using \pm \infty as one of the arguments. For example, suppose that a numerical value for the exponential integral:

\[ E_n(x) = \int_0^\infty e^{-xt} t^n \, dt. \]

is desired (and the fact that this integral can be computed as `special.expn(n, x)` is forgotten). The functionality of the function `special.expn` can be replicated by defining a new function `vec_expint` based on the routine `quad`:

```python
>>> from scipy.integrate import quad
>>> def integrand(t, n, x):
...     return np.exp(-x*t) / t**n
...>>> def expint(n, x):
...     return quad(integrand, 1, np.inf, args=(n, x))[0]
...>>> vec_expint = np.vectorize(expint)
>>> vec_expint(3, np.arange(1.0, 4.0, 0.5))
array([ 0.1097, 0.0567, 0.0301, 0.0163, 0.0089, 0.0049])
```

The function which is integrated can even use the quad argument (though the error bound may underestimate the error due to possible numerical error in the integrand from the use of `quad`). The integral in this case is

\[ I_n = \int_0^\infty \int_1^\infty \frac{e^{-xt}}{t^n} \, dt \, dx = \frac{1}{n}. \]

```python
>>> result = quad(lambda x: expint(3, x), 0, np.inf)
>>> print(result)
(0.33333333334560266, 2.8548934485373678e-09)
```

```python
>>> I3 = 1.0/3.0
>>> print(I3)
0.333333333333
```

```python
>>> print(I3 - result[0])
8.77306560731e-11
```

This last example shows that multiple integration can be handled using repeated calls to `quad`. 
2.3.2 General multiple integration (dblquad, tplquad, nquad)

The mechanics for double and triple integration have been wrapped up into the functions `dblquad` and `tplquad`. These functions take the function to integrate and four, or six arguments, respectively. The limits of all inner integrals need to be defined as functions.

An example of using double integration to compute several values of \( I_n \) is shown below:

```python
>>> from scipy.integrate import quad, dblquad
>>> def I(n):
...     return dblquad(lambda t, x: np.exp(-x*t)/t**n, 0, np.inf, lambda x: 1, lambda x: np.inf)
...
>>> print(I(4))
(0.2500000000043577, 1.29830334693681e-08)
>>> print(I(3))
(0.33333333325010883, 1.3888461883425516e-08)
>>> print(I(2))
(0.4999999999985751, 1.3894083651858995e-08)
```

As example for non-constant limits consider the integral

\[
I = \int_{y=0}^{1/2} \int_{x=0}^{1-2y} xy \, dx \, dy = \frac{1}{96}.
\]

This integral can be evaluated using the expression below (Note the use of the non-constant lambda functions for the upper limit of the inner integral):

```python
>>> from scipy.integrate import dblquad
>>> area = dblquad(lambda x, y: x*y, 0, 0.5, lambda x: 0, lambda x: 1-2*x)
>>> area
(0.010416666666666668, 1.1564823173178715e-16)
```

For n-fold integration, scipy provides the function `nquad`. The integration bounds are an iterable object: either a list of constant bounds, or a list of functions for the non-constant integration bounds. The order of integration (and therefore the bounds) is from the innermost integral to the outermost one.

The integral from above

\[
I_n = \int_0^{\infty} \int_1^{\infty} \frac{e^{-xt}}{t^n} \, dt \, dx = \frac{1}{n}
\]

can be calculated as

```python
>>> from scipy import integrate
>>> N = 5
>>> def f(t, x):
...     return np.exp(-x*t) / t**N
... >>> integrate.nquad(f, [[1, np.inf], [0, np.inf]])
(0.20000000000002294, 1.2239614263187945e-08)
```

Note that the order of arguments for \( f \) must match the order of the integration bounds; i.e., the inner integral with respect to \( t \) is on the interval \([1, \infty]\) and the outer integral with respect to \( x \) is on the interval \([0, \infty]\).
Non-constant integration bounds can be treated in a similar manner; the example from above

\[ I = \int_{y=0}^{1/2} \int_{x=0}^{1-2y} xy \, dx \, dy = \frac{1}{96}. \]

can be evaluated by means of

```python
>>> from scipy import integrate
>>> def f(x, y):
...     return x*y
...>
>>> def bounds_y():
...     return [0, 0.5]
...>
>>> def bounds_x(y):
...     return [0, 1-2*y]
...>
>>> integrate.nquad(f, [bounds_x, bounds_y])
(0.010416666666666668, 4.101620128472366e-16)
```

which is the same result as before.

### 2.3.3 Gaussian quadrature

A few functions are also provided in order to perform simple Gaussian quadrature over a fixed interval. The first is `fixed_quad`, which performs fixed-order Gaussian quadrature. The second function is `quadrature`, which performs Gaussian quadrature of multiple orders until the difference in the integral estimate is beneath some tolerance supplied by the user. These functions both use the module `scipy.special.orthogonal`, which can calculate the roots and quadrature weights of a large variety of orthogonal polynomials (the polynomials themselves are available as special functions returning instances of the polynomial class — e.g., `special.legendre`).

### 2.3.4 Romberg Integration

Romberg’s method [WPR] is another method for numerically evaluating an integral. See the help function for `romberg` for further details.

### 2.3.5 Integrating using Samples

If the samples are equally-spaced and the number of samples available is \(2^k + 1\) for some integer \(k\), then Romberg `romb` integration can be used to obtain high-precision estimates of the integral using the available samples. Romberg integration uses the trapezoid rule at step-sizes related by a power of two and then performs Richardson extrapolation on these estimates to approximate the integral with a higher degree of accuracy.

In case of arbitrary spaced samples, the two functions `trapezoid` and `simpson` are available. They are using Newton-Coates formulas of order 1 and 2 respectively to perform integration. The trapezoidal rule approximates the function as a straight line between adjacent points, while Simpson’s rule approximates the function between three adjacent points as a parabola.

For an odd number of samples that are equally spaced Simpson’s rule is exact if the function is a polynomial of order 3 or less. If the samples are not equally spaced, then the result is exact only if the function is a polynomial of order 2 or less.
```python
>>> import numpy as np
>>> def f1(x):
...     return x**2
... >>> def f2(x):
...     return x**3
... >>> x = np.array([1, 3, 4])
>>> y1 = f1(x)
>>> from scipy import integrate
>>> I1 = integrate.simpson(y1, x)
>>> print(I1)
21.0
```

This corresponds exactly to

\[
\int_1^4 x^2 \, dx = 21,
\]

whereas integrating the second function

```python
>>> y2 = f2(x)
>>> I2 = integrate.simpson(y2, x)
>>> print(I2)
61.5
```

does not correspond to

\[
\int_1^4 x^3 \, dx = 63.75
\]

because the order of the polynomial in \( f_2 \) is larger than two.

### 2.3.6 Faster integration using low-level callback functions

A user desiring reduced integration times may pass a C function pointer through `scipy.LowLevelCallable` to `quad`, `dblquad`, `tplquad` or `nquad` and it will be integrated and return a result in Python. The performance increase here arises from two factors. The primary improvement is faster function evaluation, which is provided by compilation of the function itself. Additionally we have a speedup provided by the removal of function calls between C and Python in `quad`. This method may provide a speed improvements of ~2x for trivial functions such as sine but can produce a much more noticeable improvements (10x+) for more complex functions. This feature then, is geared towards a user with numerically intensive integrations willing to write a little C to reduce computation time significantly.

The approach can be used, for example, via `ctypes` in a few simple steps:

1.) Write an integrand function in C with the function signature `double f(int n, double *x, void *user_data)`, where \( x \) is an array containing the point the function \( f \) is evaluated at, and \( user_data \) to arbitrary additional data you want to provide.

```c
/* testlib.c */
double f(int n, double *x, void *user_data) {
    double c = *(double *)user_data;
    return c + x[0] - x[1] * x[2]; /* corresponds to \( c + x - y \cdot z \) */
}
```
2.) Now compile this file to a shared/dynamic library (a quick search will help with this as it is OS-dependent). The user must link any math libraries, etc., used. On Linux this looks like:

```
$ gcc -shared -fPIC -o testlib.so testlib.c
```

The output library will be referred to as testlib.so, but it may have a different file extension. A library has now been created that can be loaded into Python with `ctypes`.

3.) Load shared library into Python using `ctypes` and set `restypes` and `argtypes` - this allows SciPy to interpret the function correctly:

```python
import os, ctypes
from scipy import integrate, LowLevelCallable

lib = ctypes.CDLL(os.path.abspath('testlib.so'))
lib.f.retype = ctypes.c_double
lib.f.argtypes = (ctypes.c_int, ctypes.POINTER(ctypes.c_double), ctypes.c_void_p)

c = ctypes.c_double(1.0)
user_data = ctypes.cast(ctypes.pointer(c), ctypes.c_void_p)
func = LowLevelCallable(lib.f, user_data)
```

The last void *user_data in the function is optional and can be omitted (both in the C function and ctypes argtypes) if not needed. Note that the coordinates are passed in as an array of doubles rather than a separate argument.

4.) Now integrate the library function as normally, here using `nquad`:

```python
>>> integrate.nquad(func, [[0, 10], [-10, 0], [-1, 1]])
(1200.0, 1.1102230246251565e-11)
```

The Python tuple is returned as expected in a reduced amount of time. All optional parameters can be used with this method including specifying singularities, infinite bounds, etc.

### 2.3.7 Ordinary differential equations (solve_ivp)

Integrating a set of ordinary differential equations (ODEs) given initial conditions is another useful example. The function `solve_ivp` is available in SciPy for integrating a first-order vector differential equation:

$$\frac{dy}{dt} = f(y, t),$$

given initial conditions $y(0) = y_0$, where $y$ is a length $N$ vector and $f$ is a mapping from $\mathbb{R}^N$ to $\mathbb{R}^N$. A higher-order ordinary differential equation can always be reduced to a differential equation of this type by introducing intermediate derivatives into the $y$ vector.

For example, suppose it is desired to find the solution to the following second-order differential equation:

$$\frac{d^2w}{dz^2} - zw(z) = 0$$

with initial conditions $w(0) = \frac{1}{\sqrt{3\pi f(\frac{1}{3})}}$ and $\frac{dw}{dz} |_{z=0} = -\frac{1}{\sqrt{3\pi f(\frac{1}{3})}}$. It is known that the solution to this differential equation with these boundary conditions is the Airy function

$$w = Ai(z),$$
which gives a means to check the integrator using `special.airy`.

First, convert this ODE into standard form by setting \( y = \frac{dw}{dz}, w \) and \( t = z \). Thus, the differential equation becomes

\[
\frac{dy}{dt} = \begin{bmatrix} ty_1 \\ y_0 \end{bmatrix} = \begin{bmatrix} 0 & t \\ 1 & 0 \end{bmatrix} \begin{bmatrix} y_0 \\ y_1 \end{bmatrix} = \begin{bmatrix} 0 & t \\ 1 & 0 \end{bmatrix} y.
\]

In other words,

\[
f (y, t) = A (t) y.
\]

As an interesting reminder, if \( A (t) \) commutes with \( \int_0^t A (\tau) \, d\tau \) under matrix multiplication, then this linear differential equation has an exact solution using the matrix exponential:

\[
y(t) = \exp \left( \int_0^t A (\tau) \, d\tau \right) y (0),
\]

However, in this case, \( A (t) \) and its integral do not commute.

This differential equation can be solved using the function `solve_ivp`. It requires the derivative, \( fprime \), the time span \([t_{start}, t_{end}]\) and the initial conditions vector, \( y0 \), as input arguments and returns an object whose \( y \) field is an array with consecutive solution values as columns. The initial conditions are therefore given in the first output column.

```python
>>> from scipy.integrate import solve_ivp
>>> from scipy.special import gamma, airy
>>> y1_0 = +1 / 3**(2/3) / gamma(2/3)
>>> y0_0 = -1 / 3**(1/3) / gamma(1/3)
>>> y0 = [y0_0, y1_0]
>>> def func(t, y):
...     return [t*y[1], y[0]]
...
>>> t_span = [0, 4]
>>> sol1 = solve_ivp(func, t_span, y0)
>>> print("sol1.t: {}").format(sol1.t))
sol1.t: [0. 0.10097672 1.04643602 1.91060117 2.49872472 3.08684827
3.62692846 4.]
```

As it can be seen `solve_ivp` determines its time steps automatically if not specified otherwise. To compare the solution of `solve_ivp` with the `airy` function the time vector created by `solve_ivp` is passed to the `airy` function.

```python
>>> print("sol1.y[1][::6]: {}").format(sol1.y[1][::6]))
sol1.y[1][::6]: [0.35502805 0.19145234 0.06368989 0.0205917 0.00554734 0.
...00106409
```

The solution of `solve_ivp` with its standard parameters shows a big deviation to the `airy` function. To minimize this deviation, relative and absolute tolerances can be used.

```python
>>> rtol, atol = (1e-8, 1e-8)
>>> sol2 = solve_ivp(func, t_span, y0, rtol=rtol, atol=atol)
>>> print("sol2.y[1][::6]: {}").format(sol2.y[1][::6]))
sol2.y[1][::6]: [0.35502805 0.19145234 0.06368989 0.0205917 0.00554734 0.
...00106409]
```

(continues on next page)
To specify user defined time points for the solution of `solve_ivp`, `solve_ivp` offers two possibilities that can also be used complementarily. By passing the `t_eval` option to the function call `solve_ivp` returns the solutions of these time points of `t_eval` in its output.

```python
>>> import numpy as np
>>> t = np.linspace(0, 4, 100)
>>> sol3 = solve_ivp(func, t_span, y0, t_eval=t)
```

If the jacobian matrix of function is known, it can be passed to the `solve_ivp` to achieve better results. Please be aware however that the default integration method `RK45` does not support jacobian matrices and thereby another integration method has to be chosen. One of the integration methods that support a jacobian matrix is the for example the `Radau` method of following example.

```python
>>> def gradient(t, y):
...     return 
>>>     [0, t],
>>>     [1, 0]
>>> sol4 = solve_ivp(func, t_span, y0, method='Radau', jac=gradient)
```

Solving a system with a banded Jacobian matrix

`odeint` can be told that the Jacobian is banded. For a large system of differential equations that are known to be stiff, this can improve performance significantly.

As an example, we'll solve the 1-D Gray-Scott partial differential equations using the method of lines [MOL]. The Gray-Scott equations for the functions \(u(x, t)\) and \(v(x, t)\) on the interval \(x \in [0, L]\) are

\[
\begin{align*}
\frac{\partial u}{\partial t} &= D_u \frac{\partial^2 u}{\partial x^2} - uv^2 + f(1-u) \\
\frac{\partial v}{\partial t} &= D_v \frac{\partial^2 v}{\partial x^2} + uv^2 - (f+k)v
\end{align*}
\]

where \(D_u\) and \(D_v\) are the diffusion coefficients of the components \(u\) and \(v\), respectively, and \(f\) and \(k\) are constants. (For more information about the system, see [http://groups.csail.mit.edu/mac/projects/amorphous/GrayScott/](http://groups.csail.mit.edu/mac/projects/amorphous/GrayScott/))

We'll assume Neumann (i.e., “no flux”) boundary conditions:

\[
\begin{align*}
\frac{\partial u}{\partial x}(0, t) &= 0, & \frac{\partial v}{\partial x}(0, t) &= 0, & \frac{\partial u}{\partial x}(L, t) &= 0, & \frac{\partial v}{\partial x}(L, t) &= 0
\end{align*}
\]

To apply the method of lines, we discretize the \(x\) variable by defining the uniformly spaced grid of \(N\) points \(\{x_0, x_1, ..., x_{N-1}\}\), with \(x_0 = 0\) and \(x_{N-1} = L\). We define \(u_j(t) \equiv u(x_j, t)\) and \(v_j(t) \equiv v(x_j, t)\), and replace the \(x\) derivatives with finite differences. That is,

\[
\frac{\partial^2 u}{\partial x^2}(x_j, t) \to \frac{u_{j-1}(t) - 2u_j(t) + u_{j+1}(t)}{(\Delta x)^2}
\]

We then have a system of \(2N\) ordinary differential equations:

\[
\begin{align*}
\frac{du_j}{dt} &= \frac{D_u}{(\Delta x)^2} (u_{j-1} - 2u_j + u_{j+1}) - u_jv_j^2 + f(1-u_j) \\
\frac{dv_j}{dt} &= \frac{D_v}{(\Delta x)^2} (v_{j-1} - 2v_j + v_{j+1}) + u_jv_j^2 - (f+k)v_j
\end{align*}
\]

(2.1)
For convenience, the \((t)\) arguments have been dropped.

To enforce the boundary conditions, we introduce “ghost” points \(x_{-1}\) and \(x_N\), and define \(u_{-1}(t) \equiv u_1(t), u_N(t) \equiv u_{N-2}(t)\); \(v_{-1}(t)\) and \(v_N(t)\) are defined analogously.

Then
\[
\frac{du_0}{dt} = \frac{D_u}{(\Delta x)^2} (2u_1 - 2u_0) - u_0 v_0^2 + f(1 - u_0) \tag{2.2}
\]
\[
\frac{dv_0}{dt} = \frac{D_v}{(\Delta x)^2} (2v_1 - 2v_0) + u_0 v_0^2 - (f + k)v_0
\]
and
\[
\frac{du_{N-1}}{dt} = \frac{D_u}{(\Delta x)^2} (2u_{N-2} - 2u_{N-1}) - u_{N-1} v_{N-1}^2 + f(1 - u_{N-1}) \tag{2.3}
\]
\[
\frac{dv_{N-1}}{dt} = \frac{D_v}{(\Delta x)^2} (2v_{N-2} - 2v_{N-1}) + u_{N-1} v_{N-1}^2 - (f + k)v_{N-1}
\]

Our complete system of \(2N\) ordinary differential equations is (2.1) for \(k = 1, 2, \ldots, N - 2\), along with (2.2) and (2.3).

We can now starting implementing this system in code. We must combine \(\{u_k\}\) and \(\{v_k\}\) into a single vector of length \(2N\). The two obvious choices are \(\{u_0, u_1, \ldots, u_{N-1}, v_0, v_1, \ldots, v_{N-1}\}\) and \(\{u_0, v_0, u_1, v_1, \ldots, u_{N-1}, v_{N-1}\}\). Mathematically, it does not matter, but the choice affects how efficiently \texttt{odeint} can solve the system. The reason is in how the order affects the pattern of the nonzero elements of the Jacobian matrix.

When the variables are ordered as \(\{u_0, u_1, \ldots, u_{N-1}, v_0, v_1, \ldots, v_{N-1}\}\), the pattern of nonzero elements of the Jacobian matrix is

\[
\begin{array}{cccccccccccc}
* & * & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
* & * & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & * & * & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & * & * & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & * & * & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & * & * & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & * & * & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & * & * & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & * & * & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * & * & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * & * & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * & * \\
\end{array}
\]

The Jacobian pattern with variables interleaved as \(\{u_0, v_0, u_1, v_1, \ldots, u_{N-1}, v_{N-1}\}\) is

\[
\begin{array}{cccccccccccc}
* & * & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
* & * & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
* & 0 & * & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & * & * & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & * & * & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & * & * & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & * & * & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & * & * & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & * & * & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & * & * & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * & * & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * & * & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * & * \\
\end{array}
\]

In both cases, there are just five nontrivial diagonals, but when the variables are interleaved, the bandwidth is much smaller. That is, the main diagonal and the two diagonals immediately above and the two immediately below the main diagonal are the nonzero diagonals. This is important, because the inputs \texttt{mu} and \texttt{ml} of \texttt{odeint} are the upper and lower bandwidths of the Jacobian matrix. When the variables are interleaved, \texttt{mu} and \texttt{ml} are 2. When the variables are stacked with \(\{u_k\}\) following \(\{v_k\}\), the upper and lower bandwidths are \(N\).

With that decision made, we can write the function that implements the system of differential equations.

First, we define the functions for the source and reaction terms of the system:

2.3. Integration (\texttt{scipy.integrate})
def G(u, v, f, k):
    return f * (1 - u) - u*v**2

def H(u, v, f, k):
    return -(f + k) * v + u*v**2

Next, we define the function that computes the right-hand side of the system of differential equations:

def grayscott1d(y, t, f, k, Du, Dv, dx):
    
    """Differential equations for the 1-D Gray-Scott equations.
    The ODEs are derived using the method of lines.
    """
    # The vectors u and v are interleaved in y. We define
    # views of u and v by slicing y.
    u = y[::2]
    v = y[1::2]

    # dydt is the return value of this function.
    dydt = np.empty_like(y)

    # Just like u and v are views of the interleaved vectors
    # in y, dudt and dvdt are views of the interleaved output
    # vectors in dydt.
    dudt = dydt[:2]
    dvdt = dydt[1::2]

    # Compute du/dt and dv/dt. The end points and the interior points
    # are handled separately.
    dudt[0] = G(u[0], v[0], f, k) + Du * (-2.0*u[0] + 2.0*u[1]) / dx**2
    dudt[1:-1] = G(u[1:-1], v[1:-1], f, k) + Du * np.diff(u, 2) / dx**2
    dudt[-1] = G(u[-1], v[-1], f, k) + Du * (-2.0*u[-1] + 2.0*u[-2]) / dx**2

    dvdt[0] = H(u[0], v[0], f, k) + Dv * (-2.0*v[0] + 2.0*v[1]) / dx**2
    dvdt[1:-1] = H(u[1:-1], v[1:-1], f, k) + Dv * np.diff(v, 2) / dx**2
    dvdt[-1] = H(u[-1], v[-1], f, k) + Dv * (-2.0*v[-1] + 2.0*v[-2]) / dx**2

    return dydt

We won't implement a function to compute the Jacobian, but we will tell odeint that the Jacobian matrix is banded. This allows the underlying solver (LSODA) to avoid computing values that it knows are zero. For a large system, this improves the performance significantly, as demonstrated in the following ipython session.

First, we define the required inputs:

In [30]: rng = np.random.default_rng()
In [31]: y0 = rng.standard_normal(5000)
In [32]: t = np.linspace(0, 50, 11)
In [33]: f = 0.024
In [34]: k = 0.055
In [35]: Du = 0.01
In [36]: Dv = 0.005
In [37]: dx = 0.025

Time the computation without taking advantage of the banded structure of the Jacobian matrix:

In [38]: %timeit sola = odeint(grayscott1d, y0, t, args=(f, k, Du, Dv, dx))
1 loop, best of 3: 25.2 s per loop

Now set ml=2 and mu=2, so odeint knows that the Jacobian matrix is banded:

In [39]: %timeit solb = odeint(grayscott1d, y0, t, args=(f, k, Du, Dv, dx), ml=2, mu=2)
10 loops, best of 3: 191 ms per loop

That is quite a bit faster!

Let’s ensure that they have computed the same result:

In [41]: np.allclose(sola, solb)
Out[41]: True

The `scipy.optimize` package provides several commonly used optimization algorithms. A detailed listing is available: `scipy.optimize` (can also be found by `help(scipy.optimize)`).
2.4.1 Unconstrained minimization of multivariate scalar functions (**minimize**)

The **minimize** function provides a common interface to unconstrained and constrained minimization algorithms for multivariate scalar functions in **scipy.optimize**. To demonstrate the minimization function, consider the problem of minimizing the Rosenbrock function of \( N \) variables:

\[
f(x) = \sum_{i=1}^{N-1} 100 \left( x_{i+1} - x_i^2 \right)^2 + \left( 1 - x_i \right)^2.
\]

The minimum value of this function is 0 which is achieved when \( x_i = 1 \).

Note that the Rosenbrock function and its derivatives are included in **scipy.optimize**. The implementations shown in the following sections provide examples of how to define an objective function as well as its jacobian and hessian functions.

**Nelder-Mead Simplex algorithm (**method='Nelder-Mead'**)**

In the example below, the **minimize** routine is used with the Nelder-Mead simplex algorithm (selected through the **method** parameter):

```python
>>> import numpy as np
>>> from scipy.optimize import minimize

>>> def rosen(x):
...     return sum(100.0*(x[1:]-x[:-1]**2)**2.0 + (1-x[:-1])**2.0)

>>> x0 = np.array([1.3, 0.7, 0.8, 1.9, 1.2])
>>> res = minimize(rosen, x0, method='nelder-mead',
...     options={'xatol': 1e-8, 'disp': True})
Optimization terminated successfully.
Current function value: 0.000000
Iterations: 339
Function evaluations: 571

>>> print(res.x)
[1. 1. 1. 1. 1.]
```

The simplex algorithm is probably the simplest way to minimize a fairly well-behaved function. It requires only function evaluations and is a good choice for simple minimization problems. However, because it does not use any gradient evaluations, it may take longer to find the minimum.

Another optimization algorithm that needs only function calls to find the minimum is Powell's method available by setting **method='powell'** in **minimize**.
Broyden-Fletcher-Goldfarb-Shanno algorithm (method='BFGS')

In order to converge more quickly to the solution, this routine uses the gradient of the objective function. If the gradient is not given by the user, then it is estimated using first-differences. The Broyden-Fletcher-Goldfarb-Shanno (BFGS) method typically requires fewer function calls than the simplex algorithm even when the gradient must be estimated.

To demonstrate this algorithm, the Rosenbrock function is again used. The gradient of the Rosenbrock function is the vector:

\[
\frac{\partial f}{\partial x_j} = 200 (x_j - x_{j-1}^2) - 400 x_j (x_{j+1} - x_j^2) - 2 (1 - x_j).
\]

This expression is valid for the interior derivatives. Special cases are

\[
\frac{\partial f}{\partial x_0} = - 400 x_0 (x_1 - x_0^2) - 2 (1 - x_0),
\]

\[
\frac{\partial f}{\partial x_{N-1}} = 200 (x_{N-1} - x_{N-2}^2).
\]

A Python function which computes this gradient is constructed by the code-segment:

```python
>>> def rosen_der(x):
...     xm = x[1:-1]
...     xm_m1 = x[:-2]
...     xm_p1 = x[2:]
...     der = np.zeros_like(x)
...     der[1:-1] = 200*(xm-xm_m1**2) - 400*(xm_p1 - xm)*xm - 2*(1-xm)
...     der[0] = -400*x[0]*(x[1]-x[0])**2 - 2*(1-x[0])
...     der[-1] = 200*(x[-1]-x[-2])**2
...     return der
```

This gradient information is specified in the `minimize` function through the `jac` parameter as illustrated below.

```python
>>> res = minimize(rosen, x0, method='BFGS', jac=rosen_der,
...                 options={'disp': True})
Optimization terminated successfully.
         Current function value: 0.000000
         Iterations: 51 # may vary
         Function evaluations: 63
         Gradient evaluations: 63
>>> res.x
array([1., 1., 1., 1., 1.])
```

Newton-Conjugate-Gradient algorithm (method='Newton-CG')

Newton-Conjugate Gradient algorithm is a modified Newton’s method and uses a conjugate gradient algorithm to (approximately) invert the local Hessian [NW]. Newton’s method is based on fitting the function locally to a quadratic form:

\[
f(x) \approx f(x_0) + \nabla f(x_0) \cdot (x - x_0) + \frac{1}{2} (x - x_0)^T H(x_0) (x - x_0) .
\]

where \( H(x_0) \) is a matrix of second-derivatives (the Hessian). If the Hessian is positive definite then the local minimum of this function can be found by setting the gradient of the quadratic form to zero, resulting in

\[ x_{opt} = x_0 - H^{-1} \nabla f. \]
The inverse of the Hessian is evaluated using the conjugate-gradient method. An example of employing this method to minimizing the Rosenbrock function is given below. To take full advantage of the Newton-CG method, a function which computes the Hessian must be provided. The Hessian matrix itself does not need to be constructed, only a vector which is the product of the Hessian with an arbitrary vector needs to be available to the minimization routine. As a result, the user can provide either a function to compute the Hessian matrix, or a function to compute the product of the Hessian with an arbitrary vector.

**Full Hessian example:**

The Hessian of the Rosenbrock function is

\[
H_{ij} = \frac{\partial^2 f}{\partial x_i \partial x_j} = 200 (\delta_{i,j} - 2x_{i-1}\delta_{i-1,j}) - 400x_i (\delta_{i+1,j} - 2x_{i+1}\delta_{i,j}) - 400\delta_{i,j} (x_{i+1} - x_i^2) + 2\delta_{i,j},
\]

\[
= (202 + 1200x_i^2 - 400x_{i+1}) \delta_{i,j} - 400x_i \delta_{i+1,j} - 400x_{i-1}\delta_{i-1,j},
\]

if \( i, j \in [1, N - 2] \) with \( i, j \in [0, N - 1] \) defining the \( N \times N \) matrix. Other non-zero entries of the matrix are

\[
\frac{\partial^2 f}{\partial x_0 \partial x_1} = 1200x_0^2 - 400x_1 + 2,
\]

\[
\frac{\partial^2 f}{\partial x_0 \partial x_0} = -400x_0,
\]

\[
\frac{\partial^2 f}{\partial x_{N-1} \partial x_{N-2}} = -400x_{N-2},
\]

\[
\frac{\partial^2 f}{\partial x_{N-1}^2} = 200.
\]

For example, the Hessian when \( N = 5 \) is

\[
H = \begin{bmatrix}
1200x_0^2 - 400x_1 + 2 & -400x_0 & 0 & 0 & 0 \\
-400x_0 & 202 + 1200x_1^2 - 400x_2 & -400x_1 & 0 & 0 \\
0 & -400x_1 & 202 + 1200x_2^2 - 400x_3 & -400x_2 & 0 \\
0 & 0 & -400x_2 & 202 + 1200x_3^2 - 400x_4 & -400x_3 \\
0 & 0 & 0 & 0 & 200
\end{bmatrix}.
\]

The code which computes this Hessian along with the code to minimize the function using Newton-CG method is shown in the following example:

```python
>>> def rosen_hess(x):
...     x = np.asarray(x)
...     H = np.diag(-400*x[1:-1],1) - np.diag(400*x[1:-1],-1)
...     diagonal = np.zeros_like(x)
...     diagonal[0] = 1200*x[0]**2 - 400*x[1]+2
...     diagonal[-1] = 200
...     diagonal[1:-1] = 202 + 1200*x[1:-1]**2 - 400*x[2]
...     H = H + np.diag(diagonal)
...     return H
```

```python
>>> res = minimize(rosen, x0, method='Newton-CG',
...                 jac=rosen_der, hess=rosen_hess,
...                 options={'xtol': 1e-8, 'disp': True})
```

Optimization terminated successfully.
Current function value: 0.000000
Iterations: 19 # may vary
Function evaluations: 22

(continues on next page)
Gradient evaluations: 19
Hessian evaluations: 19

>>> res.x
array([1., 1., 1., 1., 1.])

Hessian product example:

For larger minimization problems, storing the entire Hessian matrix can consume considerable time and memory. The Newton-CG algorithm only needs the product of the Hessian times an arbitrary vector. As a result, the user can supply code to compute this product rather than the full Hessian by giving a `hess` function which take the minimization vector as the first argument and the arbitrary vector as the second argument (along with extra arguments passed to the function to be minimized). If possible, using Newton-CG with the Hessian product option is probably the fastest way to minimize the function.

In this case, the product of the Rosenbrock Hessian with an arbitrary vector is not difficult to compute. If \( p \) is the arbitrary vector, then \( H(x)p \) has elements:

\[
H(x)p = \begin{bmatrix}
(1200x_0^2 - 400x_1 + 2)p_0 - 400x_0p_1 \\
\vdots \\
-400x_{i-1}p_{i-1} + (202 + 1200x_i^2 - 400x_{i+1})p_i - 400x_ip_{i+1} \\
\vdots \\
-400x_{N-2}p_{N-2} + 200p_{N-1}
\end{bmatrix}.
\]

Code which makes use of this Hessian product to minimize the Rosenbrock function using `minimize` follows:

```python
>>> def rosen_hess_p(x, p):
...     x = np.asarray(x)
...     Hp = np.zeros_like(x)
...     Hp[0] = (1200*x[0]**2 - 400*x[1] + 2)*p[0] - 400*x[0]*p[1]
...     Hp[1:-1] = -400*x[:-2]*p[:-2] + (202 + 1200*x[1:-1]**2 - 400*x[2:])*p[1:-1] -
...     Hp[-2] = -400*x[-2]*p[-2] + 200*p[-1]
...     return Hp

>>> res = minimize(rosen, x0, method='Newton-CG',
...     jac=rosen_der, hess=rosen_hess_p,
...     options={'xtol': 1e-8, 'disp': True})
Optimization terminated successfully.
  Current function value: 0.000000
  Iterations: 20     # may vary
  Function evaluations: 23
  Gradient evaluations: 20
  Hessian evaluations: 44

>>> res.x
array([1., 1., 1., 1., 1.])
```

According to [NW] p. 170 the Newton-CG algorithm can be inefficient when the Hessian is ill-conditioned because of the poor quality search directions provided by the method in those situations. The method `trust-ncg`, according to the authors, deals more effectively with this problematic situation and will be described next.
Trust-Region Newton-Conjugate-Gradient Algorithm (method='trust-ncg')

The Newton-CG method is a line search method: it finds a direction of search minimizing a quadratic approximation of the function and then uses a line search algorithm to find the (nearly) optimal step size in that direction. An alternative approach is to, first, fix the step size limit $\Delta$ and then find the optimal step $p$ inside the given trust-radius by solving the following quadratic subproblem:

$$
\min_p f(x_k) + \nabla f(x_k) \cdot p + \frac{1}{2} p^T H(x_k) p;
$$
subject to: $\|p\| \leq \Delta$.

The solution is then updated $x_{k+1} = x_k + p$ and the trust-radius $\Delta$ is adjusted according to the degree of agreement of the quadratic model with the real function. This family of methods is known as trust-region methods. The trust-ncg algorithm is a trust-region method that uses a conjugate gradient algorithm to solve the trust-region subproblem [NW].

Full Hessian example:

```python
>>> res = minimize(rosen, x0, method='trust-ncg',
...                   jac=rosen_der, hess=rosen_hess,
...                   options={'gtol': 1e-8, 'disp': True})
Optimization terminated successfully.
Current function value: 0.000000
Iterations: 20  # may vary
Function evaluations: 21
Gradient evaluations: 20
Hessian evaluations: 19
```  

Hessian product example:

```python
>>> res = minimize(rosen, x0, method='trust-ncg',
...                   jac=rosen_der, hess=rosen_hess_p,
...                   options={'gtol': 1e-8, 'disp': True})
Optimization terminated successfully.
Current function value: 0.000000
Iterations: 20  # may vary
Function evaluations: 21
Gradient evaluations: 20
Hessian evaluations: 0
```  

Trust-Region Truncated Generalized Lanczos / Conjugate Gradient Algorithm (method='trust-krylov')

Similar to the trust-ncg method, the trust-krylov method is a method suitable for large-scale problems as it uses the hessian only as linear operator by means of matrix-vector products. It solves the quadratic subproblem more accurately than the trust-ncg method.

$$
\min_p f(x_k) + \nabla f(x_k) \cdot p + \frac{1}{2} p^T H(x_k) p;
$$
subject to: $\|p\| \leq \Delta$. 

2.4. Optimization (scipy.optimize)
This method wraps the [TRLIB] implementation of the [GLTR] method solving exactly a trust-region subproblem restricted to a truncated Krylov subspace. For indefinite problems it is usually better to use this method as it reduces the number of nonlinear iterations at the expense of few more matrix-vector products per subproblem solve in comparison to the trust-ncg method.

**Full Hessian example:**

```python
>>> res = minimize(rosen, x0, method='trust-krylov',
...   jac=rosen_der, hess=rosen_hess,
...   options={'gtol': 1e-8, 'disp': True})
Optimization terminated successfully.
Current function value: 0.000000
Iterations: 19 # may vary
Function evaluations: 20
Gradient evaluations: 20
Hessian evaluations: 18

>>> res.x
array([1., 1., 1., 1., 1.])
```

**Hessian product example:**

```python
>>> res = minimize(rosen, x0, method='trust-krylov',
...   jac=rosen_der, hess=rosen_hess_p,
...   options={'gtol': 1e-8, 'disp': True})
Optimization terminated successfully.
Current function value: 0.000000
Iterations: 19 # may vary
Function evaluations: 20
Gradient evaluations: 20
Hessian evaluations: 0

>>> res.x
array([1., 1., 1., 1., 1.])
```

**Trust-Region Nearly Exact Algorithm (method='trust-exact')**

All methods Newton-CG, trust-ncg and trust-krylov are suitable for dealing with large-scale problems (problems with thousands of variables). That is because the conjugate gradient algorithm approximately solve the trust-region subproblem (or invert the Hessian) by iterations without the explicit Hessian factorization. Since only the product of the Hessian with an arbitrary vector is needed, the algorithm is specially suited for dealing with sparse Hessians, allowing low storage requirements and significant time savings for those sparse problems.

For medium-size problems, for which the storage and factorization cost of the Hessian are not critical, it is possible to obtain a solution within fewer iteration by solving the trust-region subproblems almost exactly. To achieve that, a certain nonlinear equations is solved iteratively for each quadratic subproblem [CGT]. This solution requires usually 3 or 4 Cholesky factorizations of the Hessian matrix. As the result, the method converges in fewer number of iterations and takes fewer evaluations of the objective function than the other implemented trust-region methods. The Hessian product option is not supported by this algorithm. An example using the Rosenbrock function follows:

```python
>>> res = minimize(rosen, x0, method='trust-exact',
...   jac=rosen_der, hess=rosen_hess,
...   options={'gtol': 1e-8, 'disp': True})
Optimization terminated successfully.
Current function value: 0.000000
```

(continues on next page)
Iterations: 13  # may vary
Function evaluations: 14
Gradient evaluations: 13
Hessian evaluations: 14

```
res.x
array([1., 1., 1., 1., 1.])
```

### 2.4.2 Constrained minimization of multivariate scalar functions (minimize)

The `minimize` function provides algorithms for constrained minimization, namely `trust-constr`, 'SLSQP' and 'COBYLA'. They require the constraints to be defined using slightly different structures. The method 'trust-constr' requires the constraints to be defined as a sequence of objects `LinearConstraint` and `NonlinearConstraint`. Methods 'SLSQP' and 'COBYLA', on the other hand, require constraints to be defined as a sequence of dictionaries, with keys `type`, `fun` and `jac`.

As an example let us consider the constrained minimization of the Rosenbrock function:

\[
\begin{align*}
\min_{x_0, x_1} & \quad 100 (x_1 - x_0^2)^2 + (1 - x_0)^2 \\
\text{subject to:} & \quad x_0 + 2x_1 \leq 1 \\
& \quad x_0^2 + x_1 \leq 1 \\
& \quad x_0^2 - x_1 \leq 1 \\
& \quad 2x_0 + x_1 = 1 \\
& \quad 0 \leq x_0 \leq 1 \\
& \quad -0.5 \leq x_1 \leq 2.0.
\end{align*}
\]

This optimization problem has the unique solution \([x_0, x_1] = [0.4149, 0.1701]\), for which only the first and fourth constraints are active.

#### Trust-Region Constrained Algorithm (method='trust-constr')

The trust-region constrained method deals with constrained minimization problems of the form:

\[
\begin{align*}
\min_x & \quad f(x) \\
\text{subject to:} & \quad c^l \leq c(x) \leq c^u, \\
& \quad x^l \leq x \leq x^u.
\end{align*}
\]

When \(c^l_j = c^u_j\) the method reads the \(j\)-th constraint as an equality constraint and deals with it accordingly. Besides that, one-sided constraint can be specified by setting the upper or lower bound to `np.inf` with the appropriate sign.

The implementation is based on [EQSQP] for equality-constraint problems and on [TRIP] for problems with inequality constraints. Both are trust-region type algorithms suitable for large-scale problems.
Defining Bounds Constraints:
The bound constraints $0 \leq x_0 \leq 1$ and $-0.5 \leq x_1 \leq 2.0$ are defined using a `Bounds` object.

```python
>>> from scipy.optimize import Bounds
>>> bounds = Bounds([0, -0.5], [1.0, 2.0])
```

Defining Linear Constraints:
The constraints $x_0 + 2x_1 \leq 1$ and $2x_0 + x_1 = 1$ can be written in the linear constraint standard format:

$$
\begin{bmatrix}
-\infty \\
1
\end{bmatrix} \leq 
\begin{bmatrix}
1 & 2 \\
2 & 1
\end{bmatrix}
\begin{bmatrix}
x_0 \\
x_1
\end{bmatrix} \leq 
\begin{bmatrix}
1 \\
1
\end{bmatrix},
$$

and defined using a `LinearConstraint` object.

```python
>>> from scipy.optimize import LinearConstraint
>>> linear_constraint = LinearConstraint([[1, 2], [2, 1]], [-np.inf, 1], [1, -1])
```

Defining Nonlinear Constraints:
The nonlinear constraint:

$$
c(x) = \begin{bmatrix} x_0^2 + x_1 \\ x_0^2 - x_1 \end{bmatrix} \leq \begin{bmatrix} 1 \\
1
\end{bmatrix},
$$

with Jacobian matrix:

$$
J(x) = \begin{bmatrix} 2x_0 & 1 \\
2x_0 & -1
\end{bmatrix},
$$

and linear combination of the Hessians:

$$
H(x,v) = \sum_{i=0}^{1} v_i \nabla^2 c_i(x) = v_0 \begin{bmatrix} 2 & 0 \\
0 & 0
\end{bmatrix} + v_1 \begin{bmatrix} 2 & 0 \\
0 & 0
\end{bmatrix},
$$
is defined using a `NonlinearConstraint` object.

```python
>>> def cons_f(x):
...     return [x[0]**2 + x[1], x[0]**2 - x[1]]
>>> def cons_J(x):
...     return [[2*x[0], 1], [2*x[0], -1]]
>>> def cons_H(x, v):
...     return v[0]*np.array([[2, 0], [0, 0]]) + v[1]*np.array([[2, 0], [-1, 0]])
>>> from scipy.optimize import NonlinearConstraint
>>> nonlinear_constraint = NonlinearConstraint(cons_f, -np.inf, 1, jac=cons_J, hess=cons_H)
```

Alternatively, it is also possible to define the Hessian $H(x,v)$ as a sparse matrix,

```python
>>> from scipy.sparse import csc_matrix
>>> def cons_H_sparse(x, v):
...     return v[0]*csc_matrix([[2, 0], [0, 0]]) + v[1]*csc_matrix([[2, 0], [-1, 0]])
>>> nonlinear_constraint = NonlinearConstraint(cons_f, -np.inf, 1, jac=cons_J, hess=cons_H_sparse)
```

or as a `LinearOperator` object.
When the evaluation of the Hessian $H(x,v)$ is difficult to implement or computationally infeasible, one may use HessianUpdateStrategy. Currently available strategies are BFGS and SR1.

Alternatively, the Hessian may be approximated using finite differences.

The Jacobian of the constraints can be approximated by finite differences as well. In this case, however, the Hessian cannot be computed with finite differences and needs to be provided by the user or defined using HessianUpdateStrategy.

Solving the Optimization Problem:

The optimization problem is solved using:

When needed, the objective function Hessian can be defined using a LinearOperator object,
or a Hessian-vector product through the parameter \texttt{hessp}.

Alternatively, the first and second derivatives of the objective function can be approximated. For instance, the Hessian can be approximated with \texttt{SR1} quasi-Newton approximation and the gradient with finite differences.

**Sequential Least SQares Programming (SLSQP) Algorithm (method=’SLSQP’)**

The SLSQP method deals with constrained minimization problems of the form:

\[
\begin{align*}
\min_{x} & \quad f(x) \\
\text{subject to} & \quad c_j(x) = 0, \quad j \in \mathcal{E} \\
& \quad c_j(x) \geq 0, \quad j \in \mathcal{I} \\
& \quad lb_i \leq x_i \leq ub_i, \quad i = 1, \ldots, N.
\end{align*}
\]

Where \(\mathcal{E}\) or \(\mathcal{I}\) are sets of indices containing equality and inequality constraints.

Both linear and nonlinear constraints are defined as dictionaries with keys \texttt{type}, \texttt{fun} and \texttt{jac}.
And the optimization problem is solved with:

```python
>>> x0 = np.array([0.5, 0])
>>> res = minimize(rosen, x0, method='SLSQP', jac=rosen_der,
...                constraints=[eq_cons, ineq_cons], options={'ftol': 1e-9,
...                'disp': True},
...                bounds=bounds)
# may vary
Optimization terminated successfully.  (Exit mode 0)
Current function value: 0.342717574857755
Iterations: 5
Function evaluations: 6
Gradient evaluations: 5
>>> print(res.x)
[0.41494475 0.1701105 ]
```

Most of the options available for the method 'trust-constr' are not available for 'SLSQP'.

### 2.4.3 Global optimization

Global optimization aims to find the global minimum of a function within given bounds, in the presence of potentially many local minima. Typically, global minimizers efficiently search the parameter space, while using a local minimizer (e.g., minimize) under the hood. SciPy contains a number of good global optimizers. Here, we’ll use those on the same objective function, namely the (aptly named) eggholder function:

```python
>>> def eggholder(x):
...     return -((x[1] + 47) * np.sin(np.sqrt(abs(x[0] / 2 + (x[1] + 47))))
...            + x[0] * np.sin(np.sqrt(abs(x[0] - (x[1] + 47)))))
```

This function looks like an egg carton:

```python
>>> bounds = [(-512, 512), (-512, 512)]
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.mplot3d import Axes3D
>>> x = np.arange(-512, 513)
>>> y = np.arange(-512, 513)
>>> xgrid, ygrid = np.meshgrid(x, y)
>>> xy = np.stack([xgrid, ygrid])
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.mplot3d import Axes3D
>>> x = np.arange(-512, 513)
>>> y = np.arange(-512, 513)
>>> xgrid, ygrid = np.meshgrid(x, y)
>>> xy = np.stack([xgrid, ygrid])
```
```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111, projection='3d')
>>> ax.view_init(45, -45)
>>> ax.plot_surface(xgrid, ygrid, eggholder(xy), cmap='terrain')
>>> ax.set_xlabel('x')
>>> ax.set_ylabel('y')
>>> ax.set_zlabel('eggholder(x, y)')
>>> plt.show()
```

We now use the global optimizers to obtain the minimum and the function value at the minimum. We’ll store the results in a dictionary so we can compare different optimization results later.

```python
>>> from scipy import optimize
>>> results = dict()
>>> results['shgo'] = optimize.shgo(eggholder, bounds)
>>> results['shgo']
    fun: -935.3379515604197 # may vary
    funl: array([-935.33795156])
    message: 'Optimization terminated successfully.'
    nfev: 42
    nit: 2
    nlfev: 37
    nlhev: 0
    nljev: 9
    success: True
    x: array([439.48096952, 453.97740589])
    xl: array([[439.48096952, 453.97740589]])
```
All optimizers return an `OptimizeResult`, which in addition to the solution contains information on the number of function evaluations, whether the optimization was successful, and more. For brevity, we won’t show the full output of the other optimizers:

```python
>>> results['DE'] = optimize.differential_evolution(eggholder, bounds)
>>> results['BH'] = optimize.basinhopping(eggholder, bounds)
```

`shgo` has a second method, which returns all local minima rather than only what it thinks is the global minimum:

```python
>>> results['shgo_sobol'] = optimize.shgo(eggholder, bounds, n=200, iters=5,
...                                          sampling_method='sobol')
```

We’ll now plot all found minima on a heatmap of the function:

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> im = ax.imshow(eggholder(xy), interpolation='bilinear', origin='lower',
...                 cmap='gray')
>>> ax.set_xlabel('x')
>>> ax.set_ylabel('y')

>>> def plot_point(res, marker='o', color=None):
...     ax.plot(512 + res.x[0], 512 + res.x[1], marker=marker, color=color, ms=10)

>>> plot_point(results['BH'], color='y')  # basinhopping - yellow
>>> plot_point(results['DE'], color='c')   # differential_evolution - cyan
>>> plot_point(results['DA'], color='w')   # dual_annealing. - white

>>> # SHGO produces multiple minima, plot them all (with a smaller marker_size)
>>> plot_point(results['shgo'], color='r', marker='+')
>>> plot_point(results['shgo_sobol'], color='r', marker='x')

>>> for i in range(results['shgo_sobol'].xl.shape[0]):
...     ax.plot(512 + results['shgo_sobol'].xl[i, 0], 512 + results['shgo_sobol'].xl[i, 1],
...             'ro', ms=2)

>>> ax.set_xlim([-4, 514*2])
>>> ax.set_ylim([-4, 514*2])
>>> plt.show()
```
2.4.4 Least-squares minimization (least_squares)

SciPy is capable of solving robustified bound-constrained nonlinear least-squares problems:

$$\begin{align*}
\min_x \frac{1}{2} \sum_{i=1}^{m} \rho (f_i(x)^2) \\
\text{subject to } lb \leq x \leq ub
\end{align*}$$

Here $f_i(x)$ are smooth functions from $\mathbb{R}^n$ to $\mathbb{R}$, we refer to them as residuals. The purpose of a scalar-valued function $\rho(\cdot)$ is to reduce the influence of outlier residuals and contribute to robustness of the solution, we refer to it as a loss function. A linear loss function gives a standard least-squares problem. Additionally, constraints in a form of lower and upper bounds on some of $x_j$ are allowed.

All methods specific to least-squares minimization utilize a $m \times n$ matrix of partial derivatives called Jacobian and defined as $J_{ij} = \partial f_i / \partial x_j$. It is highly recommended to compute this matrix analytically and pass it to `least_squares`, otherwise, it will be estimated by finite differences, which takes a lot of additional time and can be very inaccurate in hard cases.

Function `least_squares` can be used for fitting a function $\varphi(t; x)$ to empirical data $\{(t_i, y_i), i = 0, \ldots, m-1\}$. To do this, one should simply precompute residuals as $f_i(x) = w_i(\varphi(t_i; x) - y_i)$, where $w_i$ are weights assigned to each observation.
Example of solving a fitting problem

Here we consider an enzymatic reaction\(^1\). There are 11 residuals defined as

\[
f_i(x) = \frac{x_0(u_i^2 + u_i x_1)}{u_i^2 + u_i x_2 + x_3} - y_i, \quad i = 0, \ldots, 10,
\]

where \(y_i\) are measurement values and \(u_i\) are values of the independent variable. The unknown vector of parameters is \(x = (x_0, x_1, x_2, x_3)^T\). As was said previously, it is recommended to compute Jacobian matrix in a closed form:

\[
J_{i0} = \frac{\partial f_i}{\partial x_0} = \frac{u_i^2 + u_i x_1}{u_i^2 + u_i x_2 + x_3}
\]

(2.6)

\[
J_{i1} = \frac{\partial f_i}{\partial x_1} = \frac{u_i x_0}{u_i^2 + u_i x_2 + x_3}
\]

(2.7)

\[
J_{i2} = \frac{\partial f_i}{\partial x_2} = -\frac{x_0(u_i^2 + u_i x_1) u_i}{(u_i^2 + u_i x_2 + x_3)^2}
\]

(2.8)

\[
J_{i3} = \frac{\partial f_i}{\partial x_3} = -\frac{x_0(u_i^2 + u_i x_1)}{(u_i^2 + u_i x_2 + x_3)^2}
\]

(2.9)

We are going to use the “hard” starting point defined in\(^2\). To find a physically meaningful solution, avoid potential division by zero and assure convergence to the global minimum we impose constraints \(0 \leq x_j \leq 100, j = 0, 1, 2, 3\).

The code below implements least-squares estimation of \(x\) and finally plots the original data and the fitted model function:

```python
>>> from scipy.optimize import least_squares

>>> def model(x, u):
...     return x[0] * (u ** 2 + x[1] * u) / (u ** 2 + x[2] * u + x[3])

>>> def fun(x, u, y):
...     return model(x, u) - y

>>> def jac(x, u, y):
...     J = np.empty((u.size, x.size))
...     den = u ** 2 + x[2] * u + x[3]
...     num = u ** 2 + x[1] * u
...     J[:, 0] = num / den
...     J[:, 1] = x[0] * u / den
...     J[:, 2] = -x[0] * num / den ** 2
...     J[:, 3] = -x[0] * num / den ** 2
...     return J

>>> x0 = np.array([2.5, 3.9, 4.15, 3.9])
>>> args = (u, y)
>>> res = least_squares(fun, x0, jac=jac, bounds=(0, 100), args=args, verbose=1)
```

(continues on next page)

\(^2\) M. Averick et al., “The MINPACK-2 Test Problem Collection”.

2.4. Optimization (scipy.optimize)
# may vary
`ftol` termination condition is satisfied.
Function evaluations 130, initial cost 4.4383e+00, final cost 1.5375e-04,
→ first-order optimality 4.92e-08.
>>> res.x
array([ 0.19280596, 0.19130423, 0.12306063, 0.13607247])

```python
>>> import matplotlib.pyplot as plt
>>> u_test = np.linspace(0, 5)
>>> y_test = model(res.x, u_test)
>>> plt.plot(u, y, 'o', markersize=4, label='data')
>>> plt.plot(u_test, y_test, label='fitted model')
>>> plt.xlabel("u")
>>> plt.ylabel("y")
>>> plt.legend(loc='lower right')
>>> plt.show()
```

## Further examples

Three interactive examples below illustrate usage of `least_squares` in greater detail.

1. **Large-scale bundle adjustment in scipy** demonstrates large-scale capabilities of `least_squares` and how to efficiently compute finite difference approximation of sparse Jacobian.

2. **Robust nonlinear regression in scipy** shows how to handle outliers with a robust loss function in a nonlinear regression.

3. **Solving a discrete boundary-value problem in scipy** examines how to solve a large system of equations and use bounds to achieve desired properties of the solution.

For the details about mathematical algorithms behind the implementation refer to documentation of `least_squares`. 
2.4.5 Univariate function minimizers (minimize_scalar)

Often only the minimum of an univariate function (i.e., a function that takes a scalar as input) is needed. In these circumstances, other optimization techniques have been developed that can work faster. These are accessible from the `minimize_scalar` function, which proposes several algorithms.

**Unconstrained minimization (method='brent')**

There are, actually, two methods that can be used to minimize an univariate function: `brent` and `golden`, but `golden` is included only for academic purposes and should rarely be used. These can be respectively selected through the `method` parameter in `minimize_scalar`. The `brent` method uses Brent’s algorithm for locating a minimum. Optimally, a bracket (the `bracket` parameter) should be given which contains the minimum desired. A bracket is a triple \((a, b, c)\) such that \(f(a) > f(b) < f(c)\) and \(a < b < c\). If this is not given, then alternatively two starting points can be chosen and a bracket will be found from these points using a simple marching algorithm. If these two starting points are not provided, 0 and 1 will be used (this may not be the right choice for your function and result in an unexpected minimum being returned).

Here is an example:

```python
>>> from scipy.optimize import minimize_scalar
>>> f = lambda x: (x - 2) * (x + 1)**2
>>> res = minimize_scalar(f, method='brent')
>>> print(res.x)
1.0
```

**Bounded minimization (method='bounded')**

Very often, there are constraints that can be placed on the solution space before minimization occurs. The `bounded` method in `minimize_scalar` is an example of a constrained minimization procedure that provides a rudimentary interval constraint for scalar functions. The interval constraint allows the minimization to occur only between two fixed endpoints, specified using the mandatory `bounds` parameter.

For example, to find the minimum of \(J_1(x)\) near \(x = 5\), `minimize_scalar` can be called using the interval \([4, 7]\) as a constraint. The result is \(x_{\text{min}} = 5.3314\):

```python
>>> from scipy.special import j1
>>> res = minimize_scalar(j1, bounds=(4, 7), method='bounded')
>>> res.x
5.33144184241
```

2.4.6 Custom minimizers

Sometimes, it may be useful to use a custom method as a (multivariate or univariate) minimizer, for example, when using some library wrappers of `minimize` (e.g., `basinhopping`).

We can achieve that by, instead of passing a method name, passing a callable (either a function or an object implementing a `__call__` method) as the `method` parameter.

Let us consider an (admittedly rather virtual) need to use a trivial custom multivariate minimization method that will just search the neighborhood in each dimension independently with a fixed step size:
```python
from scipy.optimize import OptimizeResult

def custmin(fun, x0, args=(), maxfev=None, stepsize=0.1,
             maxiter=100, callback=None, **options):
    bestx = x0
    besty = fun(x0)
    funcalls = 1
    niter = 0
    improved = True
    stop = False
    
    while improved and not stop and niter < maxiter:
        improved = False
        niter += 1
        for dim in range(np.size(x0)):
            for s in [bestx[dim] - stepsize, bestx[dim] + stepsize]:
                testx = np.copy(bestx)
                testx[dim] = s
                testy = fun(testx, *args)
                funcalls += 1
                if testy < besty:
                    besty = testy
                    bestx = testx
                    improved = True
        if callback is not None:
            callback(bestx)
        if maxfev is not None and funcalls >= maxfev:
            stop = True
            break
    return OptimizeResult(fun=besty, x=bestx, nit=niter,
                           nfev=funcalls, success=(niter > 1))
```

This will work just as well in case of univariate optimization:

```python
def custmin(fun, bracket, args=(), maxfev=None, stepsize=0.1,
            maxiter=100, callback=None, **options):
    bestx = (bracket[1] + bracket[0]) / 2.0
    besty = fun(bestx)
    funcalls = 1
    niter = 0
    improved = True
    stop = False

    while improved and not stop and niter < maxiter:
        improved = False
        niter += 1
        for testx in [bestx - stepsize, bestx + stepsize]:
            testy = fun(testx, *args)
            funcalls += 1
```

(continues on next page)
if testy < besty:
  besty = testy
  bestx = testx
  improved = True

if callback is not None:
  callback(bestx)

if maxfev is not None and funcalls >= maxfev:
  stop = True
  break

return OptimizeResult(fun=besty, x=bestx, nit=niter, nfev=funcalls, success=(niter > 1))

>>> f(x):
  return (x - 2)**2 + (x + 2)**2

>>> res = minimize_scalar(f, bracket=(-3.5, 0), method=custmin,
                         options=dict(stepsize = 0.05))

>>> res
-2.0

2.4.7 Root finding

Scalar functions

If one has a single-variable equation, there are multiple different root finding algorithms that can be tried. Most of these algorithms require the endpoints of an interval in which a root is expected (because the function changes signs). In general, brentq is the best choice, but the other methods may be useful in certain circumstances or for academic purposes. When a bracket is not available, but one or more derivatives are available, then newton (or halley, secant) may be applicable. This is especially the case if the function is defined on a subset of the complex plane, and the bracketing methods cannot be used.

Fixed-point solving

A problem closely related to finding the zeros of a function is the problem of finding a fixed point of a function. A fixed point of a function is the point at which evaluation of the function returns the point: \( g(x) = x \). Clearly, the fixed point of \( g \) is the root of \( f(x) = g(x) - x \). Equivalently, the root of \( f \) is the fixed point of \( g(x) = f(x) + x \). The routine fixed_point provides a simple iterative method using Aitkens sequence acceleration to estimate the fixed point of \( g \) given a starting point.

Sets of equations

Finding a root of a set of non-linear equations can be achieved using the root function. Several methods are available, amongst which hybr (the default) and lm, which, respectively, use the hybrid method of Powell and the Levenberg-Marquardt method from MINPACK.

The following example considers the single-variable transcendental equation

\[ x + 2 \cos(x) = 0, \]

a root of which can be found as follows:
Consider now a set of non-linear equations

\[
\begin{align*}
    x_0 \cos(x_1) &= 4, \\
    x_0 x_1 - x_1 &= 5.
\end{align*}
\]

We define the objective function so that it also returns the Jacobian and indicate this by setting the `jac` parameter to `True`. Also, the Levenberg-Marquardt solver is used here.

```python
>>> def func2(x):
    ...     f = [x[0] * np.cos(x[1]) - 4,    
    ...         x[1]*x[0] - x[1] - 5]
    ...     df = np.array([[-np.sin(x[1]), -x[0] * np.sin(x[1])],  
                    [x[1], x[0] - 1]])
    ...     return f, df

>>> sol = root(func2, [1, 1], jac=True, method='lm')
>>> sol.x
array([ 6.50409711, 0.90841421])
```

### Root finding for large problems

Methods `hybr` and `lm` in `root` cannot deal with a very large number of variables \((N)\), as they need to calculate and invert a dense \(N \times N\) Jacobian matrix on every Newton step. This becomes rather inefficient when \(N\) grows.

Consider, for instance, the following problem: we need to solve the following integrodifferential equation on the square \([0,1] \times [0,1]\):

\[
(\partial_x^2 + \partial_y^2)P + 5 \left( \int_0^1 \int_0^1 \cosh(P) \, dx \, dy \right)^2 = 0
\]

with the boundary condition \(P(x,1) = 1\) on the upper edge and \(P = 0\) elsewhere on the boundary of the square. This can be done by approximating the continuous function \(P\) by its values on a grid, \(P_{n,m} \approx P(nh, mh)\), with a small grid spacing \(h\). The derivatives and integrals can then be approximated; for instance \(\partial_x^2 P(x, y) \approx (P(x + h, y) - 2P(x, y) + P(x - h, y))/h^2\). The problem is then equivalent to finding the root of some function `residual(P)`, where \(P\) is a vector of length \(N_x N_y\).

Now, because \(N_x N_y\) can be large, methods `hybr` or `lm` in `root` will take a long time to solve this problem. The solution can, however, be found using one of the large-scale solvers, for example `krylov`, `broyden2`, or `anderson`. These use what is known as the inexact Newton method, which instead of computing the Jacobian matrix exactly, forms an approximation for it.

The problem we have can now be solved as follows:
import numpy as np
from scipy.optimize import root
from numpy import cosh, zeros_like, mgrid, zeros

# parameters
nx, ny = 75, 75
hx, hy = 1. / (nx-1), 1. / (ny-1)

P_left, P_right = 0, 0
P_top, P_bottom = 1, 0

def residual(P):
    d2x = zeros_like(P)
    d2y = zeros_like(P)

    d2x[1:-1] = (P[2:] - 2*P[1:-1] + P[:0])/hx/hx
    d2x[0] = (P[1] - 2*P[0] + P_left)/hx/hx
    d2x[-1] = (P_right - 2*P[-1] + P[-2])/hx/hx

    d2y[:,1:-1] = (P[:,2:] - 2*P[:,1:-1] + P[:,-2])/hy/hy
    d2y[:,0] = (P[:,1] - 2*P[:,0] + P_bottom)/hy/hy
    d2y[:,-1] = (P_top - 2*P[:,-1] + P[:,-2])/hy/hy

    return d2x + d2y + 5*cosh(P).mean()**2

# solve
guess = zeros((nx, ny), float)
sol = root(residual, guess, method='krylov', options={'disp': True})
#sol = root(residual, guess, method='broyden2', options={'disp': True, 'max_rank': 50})
#sol = root(residual, guess, method='anderson', options={'disp': True, 'M': 10})
print('Residual: %g' % abs(residual(sol.x)).max())

# visualize
import matplotlib.pyplot as plt
x, y = mgrid[0:1:(nx+1j), 0:1:(ny+1j)]
plt.pcolormesh(x, y, sol.x, shading='gouraud')
plt.colorbar()
plt.show()

Still too slow? Preconditioning.

When looking for the zero of the functions $f_i(x) = 0$, $i = 1, 2, ..., N$, the krylov solver spends most of the time inverting the Jacobian matrix,

$$J_{ij} = \frac{\partial f_j}{\partial x_i}.$$

If you have an approximation for the inverse matrix $M \approx J^{-1}$, you can use it for preconditioning the linear-inversion problem. The idea is that instead of solving $Js = y$ one solves $MJJs = My$: since matrix $MJ$ is “closer” to the identity matrix than $J$ is, the equation should be easier for the Krylov method to deal with.
The matrix $M$ can be passed to `root` with method `krylov` as an option `options[\texttt{\textquoteleft\textquoteleft jac_options\textquoteRight\textquoteLeft\textquoteRight}][\texttt{\textquoteleft\textquoteLeft inner_M\textquoteRight\textquoteRight}]`. It can be a (sparse) matrix or a \texttt{scipy.sparse.linalg.LinearOperator} instance.

For the problem in the previous section, we note that the function to solve consists of two parts: the first one is the application of the Laplace operator, $[\partial_x^2 + \partial_y^2]P$, and the second is the integral. We can actually easily compute the Jacobian corresponding to the Laplace operator part: we know that in 1-D

$$\partial_x^2 \approx \frac{1}{h_x^2} \begin{pmatrix} -2 & 1 & 0 & 0 & \cdots \\ 1 & -2 & 1 & 0 & \cdots \\ 0 & 1 & -2 & 1 & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots \end{pmatrix} = h_x^{-2}L$$

so that the whole 2-D operator is represented by

$$J_1 = \partial_x^2 + \partial_y^2 \approx h_x^{-2}L \otimes I + h_y^{-2}I \otimes L$$

The matrix $J_2$ of the Jacobian corresponding to the integral is more difficult to calculate, and since all of it entries are nonzero, it will be difficult to invert. $J_1$ on the other hand is a relatively simple matrix, and can be inverted by \texttt{scipy.sparse.linalg.spilu} (or the inverse can be approximated by \texttt{scipy.sparse.linalg.spilu}). So we are content to take $M \approx J_1^{-1}$ and hope for the best.

In the example below, we use the preconditioner $M = J_1^{-1}$.

```python
import numpy as np
from scipy.optimize import root
from scipy.sparse import spdiags, kron
from scipy.sparse.linalg import spilu, LinearOperator
from numpy import cosh, zeros_like, mgrid, zeros, eye

# parameters
nx, ny = 75, 75
hx, hy = 1./(nx-1), 1./(ny-1)

P_left, P_right = 0, 0
P_top, P_bottom = 1, 0
```
```python
def get_preconditioner():
    """Compute the preconditioner M""
    diags_x = zeros((3, nx))
    diags_x[0, :] = 1/hx/hx
    diags_x[1, :] = -2/hx/hx
    diags_x[2, :] = 1/hx/hx
    Lx = spdiags(diags_x, [-1, 0, 1], nx, nx)
    diags_y = zeros((3, ny))
    diags_y[0, :] = 1/gy/gy
    diags_y[1, :] = -2/gy/gy
    diags_y[2, :] = 1/gy/gy
    Ly = spdiags(diags_y, [-1, 0, 1], ny, ny)
    J1 = kron(Lx, eye(ny)) + kron(eye(nx), Ly)

    # Now we have the matrix 'J_1'. We need to find its inverse 'M' --
    # however, since an approximate inverse is enough, we can use
    # the *incomplete LU* decomposition
    J1_ilu = spilu(J1)

    # This returns an object with a method .solve() that evaluates
    # the corresponding matrix-vector product. We need to wrap it into
    # a LinearOperator before it can be passed to the Krylov methods:
    M = LinearOperator(shape=(nx*ny, nx*ny), matvec=J1_ilu.solve)
    return M

def solve(preconditioning=True):
    """Compute the solution""
    count = [0]

    def residual(P):
        count[0] += 1
        d2x = zeros_like(P)
        d2y = zeros_like(P)

        d2x[1:-1] = (P[2:] - 2*P[1:-1] + P[:2])/hx/hx
        d2x[0] = (P[1] - 2*P[0] + P_left)/hx/hx
        d2x[-1] = (P_right - 2*P[-1] + P[-2])/hx/hx

        d2y[:, 1:-1] = (P[:, 2:] - 2*P[:, 1:-1] + P[:, :2])/hy/hy
        d2y[:, 0] = (P[:, 1] - 2*P[:, 0] + P_bottom)/hy/hy
        d2y[:, -1] = (P_top - 2*P[:, -1] + P[:, -2])/hy/hy

        return d2x + d2y + 5*cosh(P).mean()**2

    if preconditioning:
        preconditioning (continued on next page)
```

(continued from previous page)
M = get_preconditioner()
else:
    M = None

# solve
guess = zeros((nx, ny), float)
sol = root(residual, guess, method='krylov',
options={'disp': True,
          'jac_options': {'inner_M': M}})
print('Residual', abs(residual(sol.x)).max())
print('Evaluations', count[0])
return sol.x

def main():
    sol = solve(preconditioning=True)

    # visualize
    import matplotlib.pyplot as plt
    x, y = mgrid[0:1:(nx*1j), 0:1:(ny*1j)]
    plt.clf()
    plt.pcolor(x, y, sol)
    plt.clim(0, 1)
    plt.colorbar()
    plt.show()

if __name__ == '__main__':
    main()

Resulting run, first without preconditioning:

| Iteration | |F(x)| | Tol | Step |
|-----------|-------|------|-----|
| 0         | |803.614| 0.000257947 |
| 1         | |345.912| 0.166755 |
| 2         | |139.159| 0.145657 |
| 3         | |27.3682| 0.0348109 |
| 4         | |1.03303| 0.00128227 |
| 5         | |0.0406634| 0.00139451 |
| 6         | |0.0034431| 0.00645373 |
| 7         | |0.00153671| 0.00179246 |
| 8         | |6.7424e-06| 0.00173256 |

Residual 3.57078908664e-07
Evaluations 317

and then with preconditioning:

| Iteration | |F(x)| | Tol | Step |
|-----------|-------|------|-----|
| 0         | |136.993| 7.49599e-06 |
| 1         | |4.80983| 0.00110945 |
| 2         | |0.195942| 0.00149362 |
| 3         | |0.000563597| 7.44604e-06 |
| 4         | |1.00698e-09| 2.87308e-12 |
Using a preconditioner reduced the number of evaluations of the residual function by a factor of 4. For problems where the residual is expensive to compute, good preconditioning can be crucial — it can even decide whether the problem is solvable in practice or not.

Preconditioning is an art, science, and industry. Here, we were lucky in making a simple choice that worked reasonably well, but there is a lot more depth to this topic than is shown here.

2.4.8 Linear programming (linprog)

The function linprog can minimize a linear objective function subject to linear equality and inequality constraints. This kind of problem is well known as linear programming. Linear programming solves problems of the following form:

$$\min_x c^T x$$

such that $A_{ub} x \leq b_{ub}$,

$A_{eq} x = b_{eq}$,

$l \leq x \leq u$,

where $x$ is a vector of decision variables; $c$, $b_{ub}$, $b_{eq}$, $l$, and $u$ are vectors; and $A_{ub}$ and $A_{eq}$ are matrices.

In this tutorial, we will try to solve a typical linear programming problem using linprog.

Linear programming example

Consider the following simple linear programming problem:

$$\max_{x_1, x_2, x_3, x_4} 29x_1 + 45x_2$$

such that $x_1 - x_2 - 3x_3 \leq 5$

$2x_1 - 3x_2 - 7x_3 + 3x_4 \geq 10$

$2x_1 + 8x_2 + x_3 = 60$

$4x_1 + 4x_2 + x_4 = 60$

$0 \leq x_0$

$0 \leq x_1 \leq 5$

$x_2 \leq 0.5$

$-3 \leq x_3$

We need some mathematical manipulations to convert the target problem to the form accepted by linprog.

First of all, let’s consider the objective function. We want to maximize the objective function, but linprog can only accept a minimization problem. This is easily remedied by converting the maximize $29x_1 + 45x_2$ to minimizing $-29x_1 - 45x_2$. Also, $x_3, x_4$ are not shown in the objective function. That means the weights corresponding with $x_3, x_4$ are zero. So, the objective function can be converted to:

$$\min_{x_1, x_2, x_3, x_4} -29x_1 - 45x_2 + 0x_3 + 0x_4$$

If we define the vector of decision variables $x = [x_1, x_2, x_3, x_4]^T$, the objective weights vector $c$ of linprog in this problem should be

$$c = [-29, -45, 0, 0]^T$$
Next, let’s consider the two inequality constraints. The first one is a “less than” inequality, so it is already in the form accepted by `linprog`. The second one is a “greater than” inequality, so we need to multiply both sides by $-1$ to convert it to a “less than” inequality. Explicitly showing zero coefficients, we have:

\[
\begin{align*}
x_1 - x_2 - 3x_3 + 0x_4 & \leq 5 \\
-2x_1 + 3x_2 + 7x_3 - 3x_4 & \leq -10
\end{align*}
\]

These equations can be converted to matrix form:

\[
A_{ub} x \leq b_{ub}
\]

where

\[
A_{ub} = \begin{bmatrix} 1 & -1 & -3 & 0 \\ -2 & 3 & 7 & -3 \end{bmatrix},
\]

\[
b_{ub} = \begin{bmatrix} 5 \\ -10 \end{bmatrix}
\]

Next, let’s consider the two equality constraints. Showing zero weights explicitly, these are:

\[
\begin{align*}
2x_1 + 8x_2 + 1x_3 + 0x_4 &= 60 \\
4x_1 + 4x_2 + 0x_3 + 1x_4 &= 60
\end{align*}
\]

These equations can be converted to matrix form:

\[
A_{eq} x = b_{eq}
\]

where

\[
A_{eq} = \begin{bmatrix} 2 & 8 & 1 & 0 \\ 4 & 4 & 0 & 1 \end{bmatrix},
\]

\[
b_{eq} = \begin{bmatrix} 60 \\ 60 \end{bmatrix}
\]

Lastly, let’s consider the separate inequality constraints on individual decision variables, which are known as “box constraints” or “simple bounds”. These constraints can be applied using the bounds argument of `linprog`. As noted in the `linprog` documentation, the default value of bounds is `(0, None)`, meaning that the lower bound on each decision variable is 0, and the upper bound on each decision variable is infinity: all the decision variables are non-negative. Our bounds are different, so we will need to specify the lower and upper bound on each decision variable as a tuple and group these tuples into a list.

Finally, we can solve the transformed problem using `linprog`.

```python
>>> import numpy as np
>>> from scipy.optimize import linprog
>>> c = np.array([-29.0, -45.0, 0.0, 0.0])
>>> A_ub = np.array([[1.0, -1.0, -3.0, 0.0],
...                   [-2.0, 3.0, 7.0, -3.0]])
>>> b_ub = np.array([5.0, -10.0])
>>> A_eq = np.array([[2.0, 8.0, 1.0, 0.0],
...                   [4.0, 4.0, 0.0, 1.0]])
>>> b_eq = np.array([60.0, 60.0])
>>> x0_bounds = (0, None)
>>> x1_bounds = (0, 5.0)
>>> x2_bounds = (-np.inf, 0.5) # +/- np.inf can be used instead of None
>>> x3_bounds = (-3.0, None)
>>> bounds = [x0_bounds, x1_bounds, x2_bounds, x3_bounds]
```

(continues on next page)
The result states that our problem is infeasible, meaning that there is no solution vector that satisfies all the constraints. That doesn't necessarily mean we did anything wrong; some problems truly are infeasible. Suppose, however, that we decided to change our bound constraint on $x_1$ to $0 \leq x_1 \leq 6$. After adjusting our code $x1\_bounds = (0, 6)$ to reflect the change and executing it again:

```python
>>> x1_bounds = (0, 6)
>>> bounds = [x0_bounds, x1_bounds, x2_bounds, x3_bounds]
>>> result = linprog(c, A_ub=A_ub, b_ub=b_ub, A_eq=A_eq, b_eq=b_eq, ...
    ...bounds=bounds)
>>> print(result)
    con: array([9.78840831e-09, 1.04662945e-08]) # may vary
    fun: -505.97435889013434 # may vary
    message: 'Optimization terminated successfully.'
    nit: 4 # may vary
    slack: array([ 6.52747190e-10, -2.26730279e-09]) # may vary
    status: 0
    success: True
    x: array([ 9.41025641, 5.17948718, -0.25641026, 1.64102564]) # may vary
```

The result shows the optimization was successful. We can check the objective value (result.fun) is same as $c^T x$:

```python
>>> x = np.array(result.x)
>>> print(c @ x)
-505.97435889013434 # may vary
```

We can also check that all constraints are satisfied within reasonable tolerances:

```python
>>> print(b_ub - (A_ub @ x).flatten()) # this is equivalent to result.slack
    [ 6.52747190e-10, -2.26730279e-09] # may vary
>>> print(b_eq - (A_eq @ x).flatten()) # this is equivalent to result.con
    [ 9.78840831e-09, 1.04662945e-08] # may vary
>>> print([0 <= result.x[0], 0 <= result.x[1] <= 6.0, result.x[2] <= 0.5, -3.0 <= result.x[3]])
    [True, True, True, True]
```

If we need greater accuracy, typically at the expense of speed, we can solve using the revised simplex method:
```python
>>> result = linprog(c, A_ub=A_ub, b_ub=b_ub, A_eq=A_eq, b_eq=b_eq,...
... bounds=bounds, method='revised simplex')
>>> print(result)
con: array([0.00000000e+00, 7.10542736e-15]) # may vary
fun: -505.97435897435895 # may vary
message: 'Optimization terminated successfully.'
nit: 5 # may vary
slack: array([ 1.77635684e-15, -3.55271368e-15]) # may vary
status: 0
success: True
x: array([ 9.41025641, 5.17948718, -0.25641026, 1.64102564]) # may
... vary
```

2.4.9 Assignment problems

Linear sum assignment problem example

Consider the problem of selecting students for a swimming medley relay team. We have a table showing times for each swimming style of five students:

<table>
<thead>
<tr>
<th>Student</th>
<th>backstroke</th>
<th>breaststroke</th>
<th>butterfly</th>
<th>freestyle</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>43.5</td>
<td>47.1</td>
<td>48.4</td>
<td>38.2</td>
</tr>
<tr>
<td>B</td>
<td>45.5</td>
<td>42.1</td>
<td>49.6</td>
<td>36.8</td>
</tr>
<tr>
<td>C</td>
<td>43.4</td>
<td>39.1</td>
<td>42.1</td>
<td>43.2</td>
</tr>
<tr>
<td>D</td>
<td>46.5</td>
<td>44.1</td>
<td>44.5</td>
<td>41.2</td>
</tr>
<tr>
<td>E</td>
<td>46.3</td>
<td>47.8</td>
<td>50.4</td>
<td>37.2</td>
</tr>
</tbody>
</table>

We need to choose a student for each of the four swimming styles such that the total relay time is minimized. This is a typical linear sum assignment problem. We can use `linear_sum_assignment` to solve it.

The linear sum assignment problem is one of the most famous combinatorial optimization problems. Given a “cost matrix” *C*, the problem is to choose

- exactly one element from each row
- without choosing more than one element from any column
- such that the sum of the chosen elements is minimized

In other words, we need to assign each row to one column such that the sum of the corresponding entries is minimized.

Formally, let *X* be a boolean matrix where *X*[i, j] = 1 iff row *i* is assigned to column *j*. Then the optimal assignment has cost

\[
\min \sum_i \sum_j C_{i,j} X_{i,j}
\]

The first step is to define the cost matrix. In this example, we want to assign each swimming style to a student. `linear_sum_assignment` is able to assign each row of a cost matrix to a column. Therefore, to form the cost matrix, the table above needs to be transposed so that the rows correspond with swimming styles and the columns correspond with students:

```python
>>> import numpy as np
>>> cost = np.array([[43.5, 45.5, 43.4, 46.5, 46.3],
...                   [54.5, 49.6, 42.1, 44.5, 41.2],
...                   [48.4, 44.1, 42.1, 44.5, 41.2],
...                   [38.2, 39.1, 42.1, 43.2, 43.2],
...                   [36.8, 44.1, 44.5, 41.2, 37.2]],
...                   [43.5, 45.5, 43.4, 46.5, 46.3],
...                   [54.5, 49.6, 42.1, 44.5, 41.2],
...                   [48.4, 44.1, 42.1, 44.5, 41.2],
...                   [38.2, 39.1, 42.1, 43.2, 43.2],
...                   [36.8, 44.1, 44.5, 41.2, 37.2]],
```
We can solve the assignment problem with `linear_sum_assignment`:

```python
>>> from scipy.optimize import linear_sum_assignment
>>> row_ind, col_ind = linear_sum_assignment(cost)
```

The `row_ind` and `col_ind` are optimal assigned matrix indexes of the cost matrix:

```python
>>> row_ind
array([0, 1, 2, 3])
>>> col_ind
array([0, 2, 3, 1])
```

The optimal assignment is:

```python
>>> styles = np.array(['backstroke', 'breaststroke', 'butterfly', 'freestyle'])
>>> students = np.array(['A', 'B', 'C', 'D', 'E'])
>>> zip(styles, students)
[('backstroke', 'A'), ('breaststroke', 'C'), ('butterfly', 'D'), ('freestyle', 'B')]
```

The optimal total medley time is:

```python
>>> cost[row_ind, col_ind].sum()
163.89999999999998
```

Note that this result is not the same as the sum of the minimum times for each swimming style:

```python
>>> np.min(cost, axis=1).sum()
161.39999999999998
```

because student “C” is the best swimmer in both “breaststroke” and “butterfly” style. We cannot assign student “C” to both styles, so we assigned student C to the “breaststroke” style and D to the “butterfly” style to minimize the total time.

### 2.5 Interpolation (scipy.interpolate)

**Contents**

- `Interpolation (scipy.interpolate)`
  - `1-D interpolation (interp1d)`
  - `Multivariate data interpolation (griddata)`
There are several general interpolation facilities available in SciPy, for data in 1, 2, and higher dimensions:

- A class representing an interpolant (`interp1d`) in 1-D, offering several interpolation methods.
- Convenience function `griddata` offering a simple interface to interpolation in N dimensions (N = 1, 2, 3, 4, …). Object-oriented interface for the underlying routines is also available.
- Functions for 1- and 2-D (smoothed) cubic-spline interpolation, based on the FORTRAN library FITPACK. They are both procedural and object-oriented interfaces for the FITPACK library.
- Interpolation using radial basis functions.

### 2.5.1 1-D interpolation (`interp1d`)

The `interp1d` class in `scipy.interpolate` is a convenient method to create a function based on fixed data points, which can be evaluated anywhere within the domain defined by the given data using linear interpolation. An instance of this class is created by passing the 1-D vectors comprising the data. The instance of this class defines a `__call__` method and can therefore be treated like a function which interpolates between known data values to obtain unknown values (it also has a docstring for help). Behavior at the boundary can be specified at instantiation time. The following example demonstrates its use, for linear and cubic spline interpolation:

```python
>>> from scipy.interpolate import interp1d

>>> x = np.linspace(0, 10, num=11, endpoint=True)
>>> y = np.cos(-x**2/9.0)
>>> f = interp1d(x, y)
>>> f2 = interp1d(x, y, kind='cubic')

>>> xnew = np.linspace(0, 10, num=41, endpoint=True)
>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'o', xnew, f(xnew), '-', xnew, f2(xnew), '--')
>>> plt.legend(['data', 'linear', 'cubic'], loc='best')
>>> plt.show()
```

Another set of interpolations in `interp1d` is `nearest`, `previous`, and `next`, where they return the nearest, previous, or next point along the x-axis. Nearest and next can be thought of as a special case of a causal interpolating filter. The following example demonstrates their use, using the same data as in the previous example:

```python
>>> from scipy.interpolate import interp1d

>>> x = np.linspace(0, 10, num=11, endpoint=True)
>>> y = np.cos(-x**2/9.0)
>>> f = interp1d(x, y)
>>> xnew = np.linspace(0, 10, num=41, endpoint=True)
>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'o', xnew, f(xnew), '-', xnew, f(xnew), 'o', xnew, f(xnew), 'o')
>>> plt.legend(['data', 'linear', 'cubic'], loc='best')
>>> plt.show()
```
2.5. Interpolation (scipy.interpolate)

```python
>>> x = np.linspace(0, 10, num=11, endpoint=True)
>>> y = np.cos(-x**2/9.0)
>>> f1 = interp1d(x, y, kind='nearest')
>>> f2 = interp1d(x, y, kind='previous')
>>> f3 = interp1d(x, y, kind='next')

>>> xnew = np.linspace(0, 10, num=1001, endpoint=True)
>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'o')
>>> plt.plot(xnew, f1(xnew), '-', xnew, f2(xnew), '--', xnew, f3(xnew), ':')
>>> plt.legend(['data', 'nearest', 'previous', 'next'], loc='best')
>>> plt.show()
```
2.5.2 Multivariate data interpolation (griddata)

Suppose you have multidimensional data, for instance, for an underlying function \( f(x, y) \) you only know the values at points \((x[i], y[i])\) that do not form a regular grid.

Suppose we want to interpolate the 2-D function

```python
>>> def func(x, y):
...     return x*(1-x)*np.cos(4*np.pi*x) * np.sin(4*np.pi*y**2)**2
```

on a grid in \([0, 1] \times [0, 1]\)

```python
>>> grid_x, grid_y = np.mgrid[0:1:100j, 0:1:200j]
```

but we only know its values at 1000 data points:

```python
>>> rng = np.random.default_rng()
>>> points = rng.random((1000, 2))
>>> values = func(points[:, 0], points[:, 1])
```

This can be done with `griddata`—below, we try out all of the interpolation methods:

```python
>>> from scipy.interpolate import griddata
>>> grid_z0 = griddata(points, values, (grid_x, grid_y), method='nearest')
>>> grid_z1 = griddata(points, values, (grid_x, grid_y), method='linear')
>>> grid_z2 = griddata(points, values, (grid_x, grid_y), method='cubic')
```

One can see that the exact result is reproduced by all of the methods to some degree, but for this smooth function the piecewise cubic interpolant gives the best results:

```python
>>> import matplotlib.pyplot as plt
>>> plt.subplot(221)
>>> plt.imshow(func(grid_x, grid_y).T, extent=(0,1,0,1), origin='lower')
>>> plt.plot(points[:,0], points[:,1], 'k', ms=1)
>>> plt.title('Original')
>>> plt.subplot(222)
>>> plt.imshow(grid_z0.T, extent=(0,1,0,1), origin='lower')
>>> plt.title('Nearest')
>>> plt.subplot(223)
>>> plt.imshow(grid_z1.T, extent=(0,1,0,1), origin='lower')
>>> plt.title('Linear')
>>> plt.subplot(224)
>>> plt.imshow(grid_z2.T, extent=(0,1,0,1), origin='lower')
>>> plt.title('Cubic')
>>> plt.gcf().set_size_inches(6, 6)
>>> plt.show()
```
2.5. Interpolation (\texttt{scipy.interpolate})

Cubic
2.5.3 Spline interpolation

Spline interpolation requires two essential steps: (1) a spline representation of the curve is computed, and (2) the spline is evaluated at the desired points. In order to find the spline representation, there are two different ways to represent a curve and obtain (smoothing) spline coefficients: directly and parametrically. The direct method finds the spline representation of a curve in a 2-D plane using the function `splrep`. The first two arguments are the only ones required, and these provide the \( x \) and \( y \) components of the curve. The normal output is a 3-tuple, \((t,c,k)\), containing the knot-points, \( t \), the coefficients \( c \) and the order \( k \) of the spline. The default spline order is cubic, but this can be changed with the input keyword, \( k \).

For curves in N-D space the function `splprep` allows defining the curve parametrically. For this function only 1 input argument is required. This input is a list of \( N \)-arrays representing the curve in N-D space. The length of each array is the number of curve points, and each array provides one component of the N-D datapoint. The parameter variable is given with the keyword argument, \( u \), which defaults to an equally-spaced monotonic sequence between 0 and 1. The default output consists of two objects: a 3-tuple, \((t,c,k)\), containing the spline representation and the parameter variable \( u \).

The keyword argument, \( s \), is used to specify the amount of smoothing to perform during the spline fit. The default value of \( s \) is \( s = m - \sqrt{2}m \) where \( m \) is the number of data-points being fit. Therefore, if no smoothing is desired a value of \( s = 0 \) should be passed to the routines.

Once the spline representation of the data has been determined, functions are available for evaluating the spline (`splev`) and its derivatives (`splev`, `spalde`) at any point and the integral of the spline between any two points (`splint`). In addition, for cubic splines \((k = 3)\) with 8 or more knots, the roots of the spline can be estimated (`sproot`). These functions are demonstrated in the example that follows.

```python
>>> import numpy as np
>>> import matplotlib.pyplot as plt
>>> from scipy import interpolate

Cubic-spline

```> x = np.arange(0, 2*np.pi+np.pi/4, 2*np.pi/8)
>>> y = np.sin(x)
>>> tck = interpolate.splrep(x, y, s=0)
>>> xnew = np.arange(0, 2*np.pi, np.pi/50)
>>> ynew = interpolate.splev(xnew, tck, der=0)

```> plt.figure()
>>> plt.plot(x, y, 'x', xnew, ynew, xnew, np.sin(xnew), x, y, 'b')
>>> plt.legend(['Linear', 'Cubic Spline', 'True'])
>>> plt.axis([-0.05, 6.33, -1.05, 1.05])
>>> plt.title('Cubic-spline interpolation')
>>> plt.show()

Derivative of spline

```> yder = interpolate.splev(xnew, tck, der=1)
>>> plt.figure()
>>> plt.plot(xnew, yder, xnew, np.cos(xnew), '--')
>>> plt.legend(['Cubic Spline', 'True'])
>>> plt.axis([-0.05, 6.33, -1.05, 1.05])
>>> plt.title('Derivative estimation from spline')
>>> plt.show()
```
2.5. Interpolation (scipy.interpolate)
All derivatives of spline

```python
>>> yders = interpolate.spalde(xnew, tck)
>>> plt.figure()
>>> for i in range(len(yders[0])):
...     plt.plot(xnew, [d[i] for d in yders], '--', label=f'{i} derivative')
>>> plt.legend()
>>> plt.axis([-0.05, 6.33, -1.05, 1.05])
>>> plt.title('All derivatives of a B-spline')
>>> plt.show()
```

Integral of spline

```python
>>> def integ(x, tck, constant=-1):
...     x = np.atleast_1d(x)
...     out = np.zeros(x.shape, dtype=x.dtype)
...     for n in range(len(out)):
...         out[n] = interpolate.splint(0, x[n], tck)
...     out += constant
...     return out
```

```python
>>> yint = integ(xnew, tck)
>>> plt.figure()
>>> plt.plot(xnew, yint, xnew, -np.cos(xnew), '--')
>>> plt.legend(['Cubic Spline', 'True'])
>>> plt.axis([-0.05, 6.33, -1.05, 1.05])
>>> plt.title('Integral estimation from spline')
>>> plt.show()
```

Roots of spline

```python
>>> interpolate.sproot(tck)
```
```
array([3.1416])
```

Notice that `sproot` failed to find an obvious solution at the edge of the approximation interval, \( x = 0 \). If we define the
Integral estimation from spline
Cubic Spline
True

Spline on a slightly larger interval, we recover both roots $x = 0$ and $x = 2\pi$:

```python
>>> x = np.linspace(-np.pi/4, 2.*np.pi + np.pi/4, 21)
>>> y = np.sin(x)
>>> tck = interpolate.splrep(x, y, s=0)
>>> interpolate.sproot(tck)
array([0., 3.1416])
```

Parametric spline

```python
>>> t = np.arange(0, 1.1, .1)
>>> x = np.sin(2*np.pi*t)
>>> y = np.cos(2*np.pi*t)
>>> tck, u = interpolate.splprep([x, y], s=0)
>>> unew = np.arange(0, 1.01, 0.01)
>>> out = interpolate.splev(unew, tck)
>>> plt.figure()
>>> plt.plot(x, y, 'x', out[0], out[1], np.sin(2*np.pi*unew), np.cos(2*np.pi*unew), x, y, 'b')
>>> plt.legend(['Linear', 'Cubic Spline', 'True'])
>>> plt.axis([-1.05, 1.05, -1.05, 1.05])
>>> plt.title('Spline of parametrically-defined curve')
>>> plt.show()
```
### Spline interpolation in 1-d: Object-oriented (UnivariateSpline)

The spline-fitting capabilities described above are also available via an object-oriented interface. The 1-D splines are objects of the `UnivariateSpline` class, and are created with the `x` and `y` components of the curve provided as arguments to the constructor. The class defines the `__call__` method, allowing the object to be called with the `x`-axis values, at which the spline should be evaluated, returning the interpolated `y`-values. This is shown in the example below for the subclass `InterpolatedUnivariateSpline`. The `integral`, `derivatives`, and `roots` methods are also available on `UnivariateSpline` objects, allowing definite integrals, derivatives, and roots to be computed for the spline.

The `UnivariateSpline` class can also be used to smooth data by providing a non-zero value of the smoothing parameter `s`, with the same meaning as the `s` keyword of the `splrep` function described above. This results in a spline that has fewer knots than the number of data points, and hence is no longer strictly an interpolating spline, but rather a smoothing spline. If this is not desired, the `InterpolatedUnivariateSpline` class is available. It is a subclass of `UnivariateSpline` that always passes through all points (equivalent to forcing the smoothing parameter to 0). This class is demonstrated in the example below.

The `LSQUnivariateSpline` class is the other subclass of `UnivariateSpline`. It allows the user to specify the number and location of internal knots explicitly with the parameter `t`. This allows for the creation of customized splines with non-linear spacing, to interpolate in some domains and smooth in others, or change the character of the spline.

```python
>>> import numpy as np
>>> import matplotlib.pyplot as plt
>>> from scipy import interpolate

InterpolatedUnivariateSpline

```n
```python
>>> x = np.arange(0, 2*np.pi+np.pi/4, 2*np.pi/8)
>>> y = np.sin(x)
>>> s = interpolate.InterpolatedUnivariateSpline(x, y)
>>> xnew = np.arange(0, 2*np.pi, np.pi/50)
>>> ynew = s(xnew)

>>> plt.figure()
>>> plt.plot(x, y, 'x', xnew, ynew, xnew, np.sin(xnew), x, y, 'b')
```
LSQUnivariateSpline with non-uniform knots

```python
>>> t = [np.pi/2-.1, np.pi/2+.1, 3*np.pi/2-.1, 3*np.pi/2+.1]
>>> s = interpolate.LSQUnivariateSpline(x, y, t, k=2)
>>> ynew = s(xnew)
```

2-D spline representation: Procedural (`bisplrep`)

For (smooth) spline-fitting to a 2-D surface, the function `bisplrep` is available. This function takes as required inputs the 1-D arrays `x`, `y`, and `z`, which represent points on the surface $z = f(x, y)$. The default output is a list `[tx, ty, c, kx, ky]` whose entries represent respectively, the components of the knot positions, the coefficients of the spline, and the order of the spline in each coordinate. It is convenient to hold this list in a single object, `tck`, so that it can be passed easily to the function `bisplev`. The keyword, $s$, can be used to change the amount of smoothing performed on the data while determining the appropriate spline. The default value is $s = m - \sqrt{2m}$, where $m$ is the number of data points in the $x$, $y$, and $z$ vectors. As a result, if no smoothing is desired, then $s = 0$ should be passed to `bisplrep`.

To evaluate the 2-D spline and its partial derivatives (up to the order of the spline), the function `bisplev` is required. This function takes as the first two arguments two 1-D arrays whose cross-product specifies the domain over which to evaluate the spline. The third argument is the `tck` list returned from `bisplrep`. If desired, the fourth and fifth arguments provide the orders of the partial derivative in the $x$ and $y$ direction, respectively.
It is important to note that 2-D interpolation should not be used to find the spline representation of images. The algorithm used is not amenable to large numbers of input points. The signal-processing toolbox contains more appropriate algorithms for finding the spline representation of an image. The 2-D interpolation commands are intended for use when interpolating a 2-D function as shown in the example that follows. This example uses the `mgrid` command in NumPy which is useful for defining a “mesh-grid” in many dimensions. (See also the `ogrid` command if the full-mesh is not needed). The number of output arguments and the number of dimensions of each argument is determined by the number of indexing objects passed in `mgrid`.

```python
>>> import numpy as np
>>> from scipy import interpolate
>>> import matplotlib.pyplot as plt

Define function over a sparse 20x20 grid

```python
>>> x, y = np.mgrid[-1:1:21j,-1:1:21j]
>>> z = (x+y) * np.exp(-6.0*(x**2+y**2))
```  
```python
>>> plt.figure()
>>> lims = dict(cmap='RdBu_r', vmin=-0.25, vmax=0.25)
>>> plt.pcolormesh(x, y, z, shading='flat', **lims)
>>> plt.colorbar()
>>> plt.title("Sparsely sampled function.")
>>> plt.show()
```

Interpolate function over a new 70x70 grid

```python
>>> xnew, ynew = np.mgrid[-1:1:71j,-1:1:71j]
>>> xnew = xnew_edges[:-1, :1] + np.diff(xnew_edges[:, 0])[0] / 2.
>>> ynew = ynew_edges[:-1, :1] + np.diff(ynew_edges[0, :2])[0] / 2.
>>> tck = interpolate.bisplrep(x, y, z, s=0)
>>> znew = interpolate.bisplev(xnew[:, 0], ynew[0, :], tck)
```
```python
>>> plt.figure()
>>> plt.pcolormesh(xnew_edges, ynew_edges, znew, shading='flat', **lims)
>>> plt.colorbar()
>>> plt.title("Interpolated function.")
>>> plt.show()
```
2-D spline representation: Object-oriented (BivariateSpline)

The BivariateSpline class is the 2-D analog of the UnivariateSpline class. It and its subclasses implement the FITPACK functions described above in an object-oriented fashion, allowing objects to be instantiated that can be called to compute the spline value by passing in the two coordinates as the two arguments.

2.5.4 Using radial basis functions for smoothing/interpolation

Radial basis functions can be used for smoothing/interpolating scattered data in N dimensions, but should be used with caution for extrapolation outside of the observed data range.

1-D Example

This example compares the usage of the Rbf and UnivariateSpline classes from the scipy.interpolate module.

```python
>>> import numpy as np
>>> from scipy.interpolate import Rbf, InterpolatedUnivariateSpline
>>> import matplotlib.pyplot as plt

>>> # setup data
>>> x = np.linspace(0, 10, 9)
>>> y = np.sin(x)
>>> xi = np.linspace(0, 10, 101)

>>> # use fitpack2 method
>>> ius = InterpolatedUnivariateSpline(x, y)
>>> yi = ius(xi)

>>> plt.subplot(2, 1, 1)
>>> plt.plot(x, y, 'bo')
>>> plt.plot(xi, yi, 'g')
>>> plt.plot(xi, np.sin(xi), 'r')
>>> plt.title('Interpolation using univariate spline')

>>> # use RBF method
>>> rbf = Rbf(x, y)
>>> fi = rbf(xi)

>>> plt.subplot(2, 1, 2)
>>> plt.plot(x, y, 'bo')
>>> plt.plot(xi, fi, 'g')
>>> plt.plot(xi, np.sin(xi), 'r')
>>> plt.title('Interpolation using RBF - multiquadrics')
>>> plt.show()
```
2-D Example

This example shows how to interpolate scattered 2-D data:

```python
>>> import numpy as np
>>> from scipy.interpolate import Rbf
>>> import matplotlib.pyplot as plt
>>> from matplotlib import cm

>>> # 2-d tests - setup scattered data
>>> rng = np.random.default_rng()
>>> x = rng.random(100)*4.0-2.0
>>> y = rng.random(100)*4.0-2.0
>>> z = x*np.exp(-x**2-y**2)
>>> edges = np.linspace(-2.0, 2.0, 101)
>>> centers = edges[:-1] + np.diff(edges[1:])[0] / 2.
>>> XI, YI = np.meshgrid(centers, centers)

>>> # use RBF
>>> rbf = Rbf(x, y, z, epsilon=2)
>>> ZI = rbf(XI, YI)

>>> # plot the result
>>> plt.subplot(1, 1, 1)
>>> X_edges, Y_edges = np.meshgrid(edges, edges)
>>> lims = dict(cmap='RdBu_r', vmin=-0.4, vmax=0.4)
>>> plt.pcolormesh(X_edges, Y_edges, ZI, shading='flat', **lims)
>>> plt.scatter(x, y, 100, z, edgecolor='w', lw=0.1, **lims)
>>> plt.title('RBF interpolation - multiquadrics')
>>> plt.xlim(-2, 2)
>>> plt.ylim(-2, 2)
>>> plt.colorbar()
```

Fourier analysis is a method for expressing a function as a sum of periodic components, and for recovering the signal from those components. When both the function and its Fourier transform are replaced with discretized counterparts, it is called the discrete Fourier transform (DFT). The DFT has become a mainstay of numerical computing in part because of a very fast algorithm for computing it, called the Fast Fourier Transform (FFT), which was known to Gauss (1805) and was brought to light in its current form by Cooley and Tukey \[CT65\]. Press et al. \[NR07\] provide an accessible introduction to Fourier analysis and its applications.

### 2.6.1 Fast Fourier transforms

1-D discrete Fourier transforms

The FFT $y[k]$ of length $N$ of the length-$N$ sequence $x[n]$ is defined as

$$y[k] = \sum_{n=0}^{N-1} e^{-2\pi j \frac{kn}{N}} x[n],$$

and the inverse transform is defined as follows

$$x[n] = \frac{1}{N} \sum_{k=0}^{N-1} e^{2\pi j \frac{kn}{N}} y[k].$$

These transforms can be calculated by means of $\text{fft}$ and $\text{ifft}$, respectively, as shown in the following example.

```python
>>> from scipy.fft import fft, ifft
>>> x = np.array([1.0, 2.0, 1.0, -1.0, 1.5])
>>> y = fft(x)
>>> y
array([4.5+0.j, 2.08155948-1.65109876j, -1.83155948+1.60822041j, -1.83155948-1.60822041j, 2.08155948+1.65109876j])
>>> yinv = ifft(y)
>>> yinv
array([1.0+0.j, 2.0+0.j, 1.0+0.j, -1.0+0.j, 1.5+0.j])
```

From the definition of the FFT it can be seen that

$$y[0] = \sum_{n=0}^{N-1} x[n].$$

In the example

```python
>>> np.sum(x)
4.5
```

which corresponds to $y[0]$. For $N$ even, the elements $y[1]...y[N/2-1]$ contain the positive-frequency terms, and the elements $y[N/2]...y[N-1]$ contain the negative-frequency terms, in order of decreasingly negative frequency. For $N$ odd, the elements $y[1]...y[(N-1)/2]$ contain the positive-frequency terms, and the elements $y[(N+1)/2]...y[N-1]$ contain the negative-frequency terms, in order of decreasingly negative frequency.

In case the sequence $x$ is real-valued, the values of $y[n]$ for positive frequencies is the conjugate of the values $y[n]$ for negative frequencies (because the spectrum is symmetric). Typically, only the FFT corresponding to positive frequencies is plotted.

The example plots the FFT of the sum of two sines.
The FFT input signal is inherently truncated. This truncation can be modeled as multiplication of an infinite signal with a rectangular window function. In the spectral domain this multiplication becomes convolution of the signal spectrum with the window function spectrum, being of form \( \sin(x)/x \). This convolution is the cause of an effect called spectral leakage (see [WPW]). Windowing the signal with a dedicated window function helps mitigate spectral leakage. The example below uses a Blackman window from scipy.signal and shows the effect of windowing (the zero component of the FFT has been truncated for illustrative purposes).

```python
>>> from scipy.fft import fft, fftfreq
>>> # Number of sample points
>>> N = 600
>>> # sample spacing
>>> T = 1.0 / 800.0
>>> x = np.linspace(0.0, N*T, N, endpoint=False)
>>> y = np.sin(50.0 * 2.0*np.pi*x) + 0.5*np.sin(80.0 * 2.0*np.pi*x)
>>> yf = fft(y)
>>> xf = fftfreq(N, T)[:N//2]
>>> import matplotlib.pyplot as plt
>>> plt.plot(xf, 2.0/N * np.abs(yf[0:N//2]))
>>> plt.grid()
>>> plt.show()
```
In case the sequence x is complex-valued, the spectrum is no longer symmetric. To simplify working with the FFT functions, scipy provides the following two helper functions.

The function `fftfreq` returns the FFT sample frequency points.

```python
>>> from scipy.fft import fftfreq
>>> freq = fftfreq(8, 0.125)
>>> freq
array([ 0., 1., 2., 3., -4., -3., -2., -1.])
```

In a similar spirit, the function `fftshift` allows swapping the lower and upper halves of a vector, so that it becomes suitable for display.

```python
>>> from scipy.fft import fftshift
>>> x = np.arange(8)
>>> fftshift(x)
array([4, 5, 6, 7, 0, 1, 2, 3])
```

The example below plots the FFT of two complex exponentials; note the asymmetric spectrum.

```python
>>> from scipy.fft import fft, fftfreq, fftshift
>>> # number of signal points
>>> N = 400
>>> # sample spacing
>>> T = 1.0 / 800.0
>>> x = np.linspace(0.0, N*T, N, endpoint=False)
>>> y = np.exp(50.0 * 1.j * 2.0*np.pi*x) + 0.5*np.exp(-80.0 * 1.j * 2.0*np.pi*x -pi*x)
```

2.6. Fourier Transforms (scipy.fft)
The function \texttt{rfft} calculates the FFT of a real sequence and outputs the complex FFT coefficients $y[n]$ for only half of the frequency range. The remaining negative frequency components are implied by the Hermitian symmetry of the FFT for a real input ($y[n] = \text{conj}(y[-n])$). In case of $N$ being even: $[\text{Re}(y[0]) + 0j, y[1], \ldots, \text{Re}(y[N/2]) + 0j]$; in case of $N$ being odd $[\text{Re}(y[0]) + 0j, y[1], \ldots, y[N/2]]$. The terms shown explicitly as $\text{Re}(y[k]) + 0j$ are restricted to be purely real since, by the hermitian property, they are their own complex conjugate.

The corresponding function \texttt{irfft} calculates the IFFT of the FFT coefficients with this special ordering.
Notice that the `rfft` of odd and even length signals are of the same shape. By default, `irfft` assumes the output signal should be of even length. And so, for odd signals, it will give the wrong result:

```python
>>> irfft(yr)
array([ 1.70788987,  2.40843925, -0.37366961,  0.75734049])
```

To recover the original odd-length signal, we must pass the output shape by the `n` parameter.

```python
>>> irfft(yr, n=len(x))
array([ 1. ,  2. ,  1. , -1. ,  1.5])
```

## 2.6. Fourier Transforms (scipy.fft)

The functions `fft` and `ifft` provide 2-D FFT and IFFT, respectively. Similarly, `fftn` and `ifftn` provide N-D FFT, and IFFT, respectively.

For real-input signals, similarly to `rfft`, we have the functions `rfft2` and `irfft2` for 2-D real transforms; `rfftn` and `irfftn` for N-D real transforms.

The example below demonstrates a 2-D IFFT and plots the resulting (2-D) time-domain signals.

```python
>>> from scipy.fft import ifftn
>>> import matplotlib.pyplot as plt
>>> import matplotlib.cm as cm
>>> N = 30
>>> f, ((ax1, ax2, ax3), (ax4, ax5, ax6)) = plt.subplots(2, 3, sharex='col', sharey='row')
>>> xf = np.zeros((N,N))
>>> xf[0, 5] = 1
>>> xf[0, N-5] = 1
>>> Z = ifftn(xf)
>>> ax1.imshow(xf, cmap=cm.Reds)
>>> ax4.imshow(np.real(Z), cmap=cm.gray)
>>> xf = np.zeros((N, N))
>>> xf[5, 0] = 1
>>> xf[N-5, 0] = 1
>>> Z = ifftn(xf)
>>> ax2.imshow(xf, cmap=cm.Reds)
>>> ax5.imshow(np.real(Z), cmap=cm.gray)
>>> xf = np.zeros((N, N))
>>> xf[5, 10] = 1
>>> xf[N-5, N-10] = 1
>>> Z = ifftn(xf)
>>> ax3.imshow(xf, cmap=cm.Reds)
>>> ax6.imshow(np.real(Z), cmap=cm.gray)
>>> plt.show()
```
2.6.2 Discrete Cosine Transforms

SciPy provides a DCT with the function \texttt{dct} and a corresponding IDCT with the function \texttt{idct}. There are 8 types of the DCT [WPC], [Mak]; however, only the first 4 types are implemented in scipy. “The” DCT generally refers to DCT type 2, and “the” Inverse DCT generally refers to DCT type 3. In addition, the DCT coefficients can be normalized differently (for most types, scipy provides \texttt{None} and \texttt{ortho}). Two parameters of the \texttt{dct/idct} function calls allow setting the DCT type and coefficient normalization.

For a single dimension array \( x \), \( \text{dct}(x, \text{norm}='\text{ortho}') \) is equal to MATLAB \( \text{dct}(x) \).

**Type I DCT**

SciPy uses the following definition of the unnormalized DCT-I (\texttt{norm=None}):

\[
y[k] = x_0 + (-1)^k x_{N-1} + 2 \sum_{n=1}^{N-2} x[n] \cos \left( \frac{\pi n k}{N-1} \right), \quad 0 \leq k < N.
\]

Note that the DCT-I is only supported for input size > 1.

**Type II DCT**

SciPy uses the following definition of the unnormalized DCT-II (\texttt{norm=None}):

\[
y[k] = 2 \sum_{n=0}^{N-1} x[n] \cos \left( \frac{\pi (2n + 1) k}{2N} \right), \quad 0 \leq k < N.
\]

In case of the normalized DCT (\texttt{norm='ortho'}), the DCT coefficients \( y[k] \) are multiplied by a scaling factor \( f \):

\[
f = \begin{cases} 
\sqrt{1/(4N)}, & \text{if } k = 0 \\
\sqrt{1/(2N)}, & \text{otherwise} 
\end{cases}
\]

In this case, the DCT “base functions” \( \phi_k[n] = 2f \cos \left( \frac{\pi (2n + 1) k}{2N} \right) \) become orthonormal:

\[
\sum_{n=0}^{N-1} \phi_k[n] \phi_l[n] = \delta_{lk}.
\]
Type III DCT

SciPy uses the following definition of the unnormalized DCT-III (norm=None):

\[ y[k] = x_0 + 2 \sum_{n=1}^{N-1} x[n] \cos \left( \frac{\pi n (2k + 1)}{2N} \right) \quad 0 \leq k < N, \]

or, for norm='ortho':

\[ y[k] = \frac{x_0}{\sqrt{N}} + \frac{2}{\sqrt{N}} \sum_{n=1}^{N-1} x[n] \cos \left( \frac{\pi n (2k + 1)}{2N} \right) \quad 0 \leq k < N. \]

Type IV DCT

SciPy uses the following definition of the unnormalized DCT-IV (norm=None):

\[ y[k] = 2 \sum_{n=0}^{N-1} x[n] \cos \left( \frac{\pi (2n+1)(2k + 1)}{4N} \right) \quad 0 \leq k < N, \]

or, for norm='ortho':

\[ y[k] = \sqrt{\frac{2}{N}} \sum_{n=0}^{N-1} x[n] \cos \left( \frac{\pi (2n+1)(2k + 1)}{4N} \right) \quad 0 \leq k < N \]

DCT and IDCT

The (unnormalized) DCT-III is the inverse of the (unnormalized) DCT-II, up to a factor of \(2N\). The orthonormalized DCT-III is exactly the inverse of the orthonormalized DCT-II. The function \texttt{idct} performs the mappings between the DCT and IDCT types, as well as the correct normalization.

The following example shows the relation between DCT and IDCT for different types and normalizations.

```python
>>> from scipy.fft import dct, idct
>>> x = np.array([1.0, 2.0, 1.0, -1.0, 1.5])
```

The DCT-II and DCT-III are each other’s inverses, so for an orthonormal transform we return back to the original signal.

```python
>>> dct(dct(x, type=2, norm='ortho'), type=3, norm='ortho')
array([ 1. , 2. , 1. , -1. , 1.5])
```

Doing the same under default normalization, however, we pick up an extra scaling factor of \(2N = 10\) since the forward transform is unnormalized.

```python
>>> dct(dct(x, type=2), type=3)
array([ 10., 20., 10., -10., 15.])
```

For this reason, we should use the function \texttt{idct} using the same type for both, giving a correctly normalized result.

```python
>>> # Normalized inverse: no scaling factor
>>> idct(dct(x, type=2), type=2)
array([ 1. , 2. , 1. , -1. , 1.5])
```

Analogous results can be seen for the DCT-I, which is its own inverse up to a factor of \(2(N - 1)\).

2.6. Fourier Transforms (\texttt{scipy.fft})
>>> dct(dct(x, type=1, norm='ortho'), type=1, norm='ortho')
array([ 1. ,  2. ,  1. , -1. ,  1.5])
>>> # Unnormalized round-trip via DCT-I: scaling factor 2*(N-1) = 8
>>> dct(dct(x, type=1), type=1)
array([ 8. , 16. ,  8. , -8. , 12. ])
>>> # Normalized inverse: no scaling factor
>>> idct(dct(x, type=1), type=1)
array([ 1. ,  2. ,  1. , -1. ,  1.5])

And for the DCT-IV, which is also its own inverse up to a factor of $2N$.

>>> dct(dct(x, type=4, norm='ortho'), type=4, norm='ortho')
array([ 1. ,  2. ,  1. , -1. ,  1.5])
>>> # Unnormalized round-trip via DCT-IV: scaling factor $2N = 10$
>>> dct(dct(x, type=4), type=4)
array([ 10. , 20. , 10. , -10. , 15. ])
>>> # Normalized inverse: no scaling factor
>>> idct(dct(x, type=4), type=4)
array([ 1. ,  2. ,  1. , -1. ,  1.5])

**Example**

The DCT exhibits the “energy compaction property”, meaning that for many signals only the first few DCT coefficients have significant magnitude. Zeroing out the other coefficients leads to a small reconstruction error, a fact which is exploited in lossy signal compression (e.g. JPEG compression).

The example below shows a signal $x$ and two reconstructions ($x_{20}$ and $x_{15}$) from the signal’s DCT coefficients. The signal $x_{20}$ is reconstructed from the first 20 DCT coefficients, $x_{15}$ is reconstructed from the first 15 DCT coefficients. It can be seen that the relative error of using 20 coefficients is still very small (~0.1%), but provides a five-fold compression rate.

```python
>>> from scipy.fft import dct, idct
>>> import matplotlib.pyplot as plt
>>> N = 100
>>> t = np.linspace(0, 20, N, endpoint=False)
>>> x = np.exp(-t/3) * np.cos(2 * t)
>>> y = dct(x, norm='ortho')
>>> window = np.zeros(N)
>>> window[:20] = 1
>>> yr = idct(y * window, norm='ortho')
>>> sum(abs(x-yr)**2) / sum(abs(x)**2)
0.0009872817275276098
>>> plt.plot(t, x, '-bx')
>>> plt.plot(t, yr, 'ro')
>>> window[:15] = 1
>>> yr = idct(y * window, norm='ortho')
>>> sum(abs(x-yr)**2) / sum(abs(x)**2)
0.06196643004256714
>>> plt.plot(t, yr, 'g+')
>>> plt.legend([['x', '$x_{20}$', '$x_{15}$'])
>>> plt.grid()
>>> plt.show()
```
2.6.3 Discrete Sine Transforms

SciPy provides a DST [Mak] with the function `dst` and a corresponding IDST with the function `idst`.

There are, theoretically, 8 types of the DST for different combinations of even/odd boundary conditions and boundary offsets [WPS], only the first 4 types are implemented in scipy.

**Type I DST**

DST-I assumes the input is odd around \( n = -1 \) and \( n = N \). SciPy uses the following definition of the unnormalized DST-I (\( \text{norm}=\text{None} \)):

\[
y[k] = 2 \sum_{n=0}^{N-1} x[n] \sin \left( \frac{\pi(n + 1)(k + 1)}{N + 1} \right), \quad 0 \leq k < N.
\]

Note also that the DST-I is only supported for input size > 1. The (unnormalized) DST-I is its own inverse, up to a factor of \( 2(N+1) \).

**Type II DST**

DST-II assumes the input is odd around \( n = -1/2 \) and even around \( n = N \). SciPy uses the following definition of the unnormalized DST-II (\( \text{norm}=\text{None} \)):

\[
y[k] = 2 \sum_{n=0}^{N-1} x[n] \sin \left( \frac{\pi(n + 1/2)(k + 1)}{N} \right), \quad 0 \leq k < N.
\]
Type III DST

DST-III assumes the input is odd around n=-1 and even around n=N-1. SciPy uses the following definition of the unnormalized DST-III (norm=None):

\[ y[k] = (-1)^k x[N - 1] + 2 \sum_{n=0}^{N-2} x[n] \sin \left( \frac{\pi(n + 1)(k + 1/2)}{N} \right), \quad 0 \leq k < N. \]

Type IV DST

SciPy uses the following definition of the unnormalized DST-IV (norm=None):

\[ y[k] = 2 \sum_{n=0}^{N-1} x[n] \sin \left( \frac{\pi(2n + 1)(2k + 1)}{4N} \right) \quad 0 \leq k < N, \]

or, for norm='ortho':

\[ y[k] = \sqrt{\frac{2}{N}} \sum_{n=0}^{N-1} x[n] \sin \left( \frac{\pi(2n + 1)(2k + 1)}{4N} \right) \quad 0 \leq k < N, \]

DST and IDST

The following example shows the relation between DST and IDST for different types and normalizations.

```python
>>> from scipy.fft import dst, idst
>>> x = np.array([1.0, 2.0, 1.0, -1.0, 1.5])
```

The DST-II and DST-III are each other’s inverses, so for an orthonormal transform we return back to the original signal.

```python
>>> dst(dst(x, type=2, norm='ortho'), type=3, norm='ortho')
array([ 1. ,  2. ,  1. , -1. ,  1.5])
```

Doing the same under default normalization, however, we pick up an extra scaling factor of \(2N = 10\) since the forward transform is unnormalized.

```python
>>> dst(dst(x, type=2), type=3)
array([ 10.,  20.,  10., -10.,  15.])
```

For this reason, we should use the function `idst` using the same type for both, giving a correctly normalized result.

```python
>>> idst(dst(x, type=2), type=2)
array([ 1. ,  2. ,  1. , -1. ,  1.5])
```

Analogous results can be seen for the DST-I, which is its own inverse up to a factor of \(2(N - 1)\).

```python
>>> dst(dst(x, type=1, norm='ortho'), type=1, norm='ortho')
array([ 1. ,  2. ,  1. , -1. ,  1.5])
>>> # scaling factor \(2*(N+1) = 12\)
>>> dst(dst(x, type=1), type=1)
array([ 12.,  24.,  12., -12.,  18.])
>>> # no scaling factor
>>> idst(dst(x, type=1), type=1)
array([ 1. ,  2. ,  1. , -1. ,  1.5])
```
And for the DST-IV, which is also its own inverse up to a factor of $2N$.

```python
>>> dst(dst(x, type=4, norm='ortho'), type=4, norm='ortho')
array([ 1. , 2. , 1. , -1. , 1.5])
>>> # scaling factor 2*N = 10
>>> dst(dst(x, type=4), type=4)
array([ 10., 20., 10., -10., 15.])
>>> # no scaling factor
>>> idst(dst(x, type=4), type=4)
array([ 1. , 2. , 1. , -1. , 1.5])
```

### 2.6.4 Fast Hankel Transform

SciPy provides the functions `fht` and `ifht` to perform the Fast Hankel Transform (FHT) and its inverse (IFHT) on logarithmically-spaced input arrays.

The FHT is the discretised version of the continuous Hankel transform defined by [Ham00]

$$ A(k) = \int_0^\infty a(r) J_\mu(kr) k \, dr , $$

with $J_\mu$ the Bessel function of order $\mu$. Under a change of variables $r \to \log r$, $k \to \log k$, this becomes

$$ A(e^{\log k}) = \int_0^\infty a(e^{\log r}) J_\mu(e^{\log k+\log r}) e^{\log k+\log r} d\log r $$

which is a convolution in logarithmic space. The FHT algorithm uses the FFT to perform this convolution on discrete input data.

Care must be taken to minimise numerical ringing due to the circular nature of FFT convolution. To ensure that the low-ringing condition [Ham00] holds, the output array can be slightly shifted by an offset computed using the `fhtoffset` function.

### 2.6.5 References

### 2.7 Signal Processing (scipy.signal)

The signal processing toolbox currently contains some filtering functions, a limited set of filter design tools, and a few B-spline interpolation algorithms for 1- and 2-D data. While the B-spline algorithms could technically be placed under the interpolation category, they are included here because they only work with equally-spaced data and make heavy use of filter-theory and transfer-function formalism to provide a fast B-spline transform. To understand this section, you will need to understand that a signal in SciPy is an array of real or complex numbers.

#### 2.7.1 B-splines

A B-spline is an approximation of a continuous function over a finite domain in terms of B-spline coefficients and knot points. If the knot points are equally spaced with spacing $\Delta x$, then the B-spline approximation to a 1-D function is the finite-basis expansion.

$$ y(x) \approx \sum_j c_j \beta^\nu \left( \frac{x}{\Delta x} - j \right). $$
In two dimensions with knot-spacing \( \Delta x \) and \( \Delta y \), the function representation is

\[
z(x, y) \approx \sum_j \sum_k c_{jk} \beta^o \left( \frac{x}{\Delta x} - j \right) \beta^o \left( \frac{y}{\Delta y} - k \right).
\]

In these expressions, \( \beta^o (\cdot) \) is the space-limited B-spline basis function of order \( o \). The requirement of equally-spaced knot-points and equally-spaced data points, allows the development of fast (inverse-filtering) algorithms for determining the coefficients, \( c_j \), from sample-values, \( y_m \). Unlike the general spline interpolation algorithms, these algorithms can quickly find the spline coefficients for large images.

The advantage of representing a set of samples via B-spline basis functions is that continuous-domain operators (derivatives, re-sampling, integral, etc.), which assume that the data samples are drawn from an underlying continuous function, can be computed with relative ease from the spline coefficients. For example, the second derivative of a spline is

\[
y''(x) = \frac{1}{\Delta x^2} \sum_j c_j \beta'^o \left( \frac{x}{\Delta x} - j \right).
\]

Using the property of B-splines that

\[
\frac{d^2 \beta^o(w)}{dw^2} = \beta^{o-2}(w + 1) - 2\beta^{o-2}(w) + \beta^{o-2}(w - 1),
\]

it can be seen that

\[
y''(x) = \frac{1}{\Delta x^2} \sum_j c_j \left[ \beta^{o-2} \left( \frac{x}{\Delta x} - j + 1 \right) - 2\beta^{o-2} \left( \frac{x}{\Delta x} - j \right) + \beta^{o-2} \left( \frac{x}{\Delta x} - j - 1 \right) \right].
\]

If \( o = 3 \), then at the sample points:

\[
\Delta x^2 y'(x)|_{x=n\Delta x} = \sum_j c_j \delta_{n-j+1} - 2c_j \delta_{n-j} + c_j \delta_{n-j-1},
\]

\[
= c_{n+1} - 2c_n + c_{n-1}.
\]

Thus, the second-derivative signal can be easily calculated from the spline fit. If desired, smoothing splines can be found to make the second derivative less sensitive to random errors.

The savvy reader will have already noticed that the data samples are related to the knot coefficients via a convolution operator, so that simple convolution with the sampled B-spline function recovers the original data from the spline coefficients. The output of convolutions can change depending on how the boundaries are handled (this becomes increasingly more important as the number of dimensions in the dataset increases). The algorithms relating to B-splines in the signal-processing subpackage assume mirror-symmetric boundary conditions. Thus, spline coefficients are computed based on that assumption, and data-samples can be recovered exactly from the spline coefficients by assuming them to be mirror-symmetric also.

Currently the package provides functions for determining second- and third- order cubic spline coefficients from equally-spaced samples in one and two dimensions (\texttt{gspline1d, gspline2d, cspline1d, cspline2d}). The package also supplies a function ( \texttt{bspline} ) for evaluating the B-spline basis function, \( \beta^o(x) \) for arbitrary order and \( x \). For large \( o \), the B-spline basis function can be approximated well by a zero-mean Gaussian function with standard-deviation equal to \( \sigma_o = (o + 1) / 12 \):

\[
\beta^o(x) \approx \frac{1}{\sqrt{2\pi\sigma_o^2}} \exp \left( -\frac{x^2}{2\sigma_o^2} \right).
\]

A function to compute this Gaussian for arbitrary \( x \) and \( o \) is also available ( \texttt{gauss_spline} ). The following code and figure use spline-filtering to compute an edge-image (the second derivative of a smoothed spline) of a raccoon’s face, which is an array returned by the command \texttt{scipy.misc.face}. The command \texttt{sepfir2d} was used to apply a separable 2-D FIR filter with mirror-symmetric boundary conditions to the spline coefficients. This function is ideally-suited for reconstructing samples from spline coefficients and is faster than \texttt{convolve2d}, which convolves arbitrary 2-D filters and allows for choosing mirror-symmetric boundary conditions.
>>> import numpy as np
>>> from scipy import signal, misc
>>> import matplotlib.pyplot as plt

```python
>>> image = misc.face(gray=True).astype(np.float32)
>>> derfilt = np.array([1.0, -2, 1.0], dtype=np.float32)
>>> ck = signal.cspline2d(image, 8.0)
>>> deriv = (signal.sepfir2d(ck, derfilt, [1]) +
...         signal.sepfir2d(ck, [1], derfilt))
```

Alternatively, we could have done:

```python
laplacian = np.array([[0, 1, 0], [1, -4, 1], [0, 1, 0]], dtype=np.float32)
deriv2 = signal.convolve2d(ck, laplacian, mode='same', boundary='symm')
```

```python
>>> plt.figure()
>>> plt.imshow(image)
>>> plt.gray()
>>> plt.title('Original image')
>>> plt.show()
```

![Original image](image)

```python
>>> plt.figure()
>>> plt.imshow(deriv)
>>> plt.gray()
>>> plt.title('Output of spline edge filter')
>>> plt.show()
```

```python
>>> plt.figure()
>>> plt.imshow(deriv2)
>>> plt.gray()
>>> plt.title('Output of separable filter')
>>> plt.show()
```
2.7.2 Filtering

Filtering is a generic name for any system that modifies an input signal in some way. In SciPy, a signal can be thought of as a NumPy array. There are different kinds of filters for different kinds of operations. There are two broad kinds of filtering operations: linear and non-linear. Linear filters can always be reduced to multiplication of the flattened NumPy array by an appropriate matrix resulting in another flattened NumPy array. Of course, this is not usually the best way to compute the filter, as the matrices and vectors involved may be huge. For example, filtering a $512 \times 512$ image with this method would require multiplication of a $512^2 \times 512^2$ matrix with a $512^2$ vector. Just trying to store the $512^2 \times 512^2$ matrix using a standard NumPy array would require 68,719,476,736 elements. At 4 bytes per element this would require 256GB of memory. In most applications, most of the elements of this matrix are zero and a different method for computing the output of the filter is employed.

Convolution/Correlation

Many linear filters also have the property of shift-invariance. This means that the filtering operation is the same at different locations in the signal and it implies that the filtering matrix can be constructed from knowledge of one row (or column) of the matrix alone. In this case, the matrix multiplication can be accomplished using Fourier transforms.

Let $x[n]$ define a 1-D signal indexed by the integer $n$. Full convolution of two 1-D signals can be expressed as

$$y[n] = \sum_{k=-\infty}^{\infty} x[k] h[n-k].$$

This equation can only be implemented directly if we limit the sequences to finite-support sequences that can be stored in a computer, choose $n = 0$ to be the starting point of both sequences, let $K + 1$ be that value for which $x[n] = 0$ for all $n \geq K + 1$ and $M + 1$ be that value for which $h[n] = 0$ for all $n \geq M + 1$, then the discrete convolution expression is

$$y[n] = \sum_{k=\max(n-M,0)}^{\min(n,K)} x[k] h[n-k].$$
For convenience, assume $K \geq M$. Then, more explicitly, the output of this operation is

\[
\begin{align*}
y[0] &= x[0] h[0] \\
&\quad \vdots \\
&\quad \vdots \\
&\quad \vdots \\
y[K + M] &= x[K] h[M].
\end{align*}
\]

Thus, the full discrete convolution of two finite sequences of lengths $K + 1$ and $M + 1$, respectively, results in a finite sequence of length $K + M + 1 = (K + 1) + (M + 1) - 1$.

1-D convolution is implemented in SciPy with the function `convolve`. This function takes as inputs the signals $x$, $h$, and two optional flags ‘mode’ and ‘method’, and returns the signal $y$.

The first optional flag, ‘mode’, allows for the specification of which part of the output signal to return. The default value of ‘full’ returns the entire signal. If the flag has a value of ‘same’, then only the middle $K$ values are returned, starting at $y \left\lceil \frac{M}{2} \right\rceil$, so that the output has the same length as the first input. If the flag has a value of ‘valid’, then only the middle $K - M + 1 = (K + 1) - (M + 1) + 1$ output values are returned, where $z$ depends on all of the values of the smallest input from $h[0]$ to $h[M]$. In other words, only the values $y[M]$ to $y[K]$ inclusive are returned.

The second optional flag, ‘method’, determines how the convolution is computed, either through the Fourier transform approach with `fftconvolve` or through the direct method. By default, it selects the expected faster method. The Fourier transform method has order $O(N \log N)$, while the direct method has order $O(N^2)$. Depending on the big O constant and the value of $N$, one of these two methods may be faster. The default value, ‘auto’, performs a rough calculation and chooses the expected faster method, while the values ‘direct’ and ‘fft’ force computation with the other two methods.

The code below shows a simple example for convolution of 2 sequences:

```python
>>> x = np.array([1.0, 2.0, 3.0])
>>> h = np.array([0.0, 1.0, 0.0, 0.0, 0.0])
>>> signal.convolve(x, h)
array([ 0. , 1. , 2. , 3. , 0. , 0. , 0. ])
>>> signal.convolve(x, h, 'same')
array([ 2. , 3. , 0. ])
```

This same function `convolve` can actually take N-D arrays as inputs and will return the N-D convolution of the two arrays, as is shown in the code example below. The same input flags are available for that case as well.

```python
>>> x = np.array([[1., 1., 0., 0., 0.], [1., 1., 0., 0., 0.], [0., 0., 0., 0., 0.], [0., -0., 0., 0., 0.]])
>>> h = np.array([[1., 0., 0., 0., 0.], [0., 0., 0., 0., 0.], [0., 0., 1., 0., 0.], [0., -0., 0., 0., 0.]])
>>> signal.convolve(x, h)
array([[ 1., 1., 0., 0., 0.], [ 0., 0., 0., 0., 0.],
       [ 0., 0., 0., 0., 0.]],
       (continues on next page))
```

2.7. Signal Processing (*scipy.signal*)
Correlation is very similar to convolution except that the minus sign becomes a plus sign. Thus,

\[ w[n] = \sum_{k=-\infty}^{\infty} y[k] x[n+k], \]

is the (cross) correlation of the signals \( y \) and \( x \). For finite-length signals with \( y[n] = 0 \) outside of the range \([0, K]\) and \( x[n] = 0 \) outside of the range \([0, M]\), the summation can simplify to

\[ w[n] = \sum_{k=\max(0,-n)}^{\min(K,M-n)} y[k] x[n+k]. \]

Assuming again that \( K \geq M \), this is

\[
\begin{align*}
    w[-K] &= y[K] x[0] \\
    & \vdots \\
    & \vdots \\
    & \vdots \\
    w[M] &= y[0] x[M].
\end{align*}
\]

The SciPy function \texttt{correlate} implements this operation. Equivalent flags are available for this operation to return the full \( K + M + 1 \) length sequence (‘full’) or a sequence with the same size as the largest sequence starting at \( w[-K+\lfloor M/2 \rfloor] \) (‘same’) or a sequence where the values depend on all the values of the smallest sequence (‘valid’). This final option returns the \( K - M + 1 \) values \( w[M-K] \) to \( w[0] \) inclusive.

The function \texttt{correlate} can also take arbitrary N-D arrays as input and return the N-D convolution of the two arrays on output.

When \( N = 2 \), \texttt{correlate} and/or \texttt{convolve} can be used to construct arbitrary image filters to perform actions such as blurring, enhancing, and edge-detection for an image.

```python
>>> import numpy as np
>>> from scipy import signal, misc
>>> import matplotlib.pyplot as plt
```
Calculating the convolution in the time domain as above is mainly used for filtering when one of the signals is much smaller than the other ($K \gg M$), otherwise linear filtering is more efficiently calculated in the frequency domain provided by the function `fftconvolve`. By default, `convolve` estimates the fastest method using `choose_conv_method`.

If the filter function $w[n,m]$ can be factored according to

$$h[n,m] = h_1[n]h_2[m],$$

convolution can be calculated by means of the function `sepfir2d`. As an example, we consider a Gaussian filter

$$h[n,m] \propto e^{-x^2-y^2} = e^{-x^2}e^{-y^2},$$

which is often used for blurring.
```python
>>> import numpy as np
>>> from scipy import signal, misc
>>> import matplotlib.pyplot as plt

>>> image = misc.ascent()
>>> w = signal.windows.gaussian(51, 10.0)
>>> image_new = signal.sepfir2d(image, w, w)

>>> plt.figure()
>>> plt.imshow(image)
>>> plt.gray()
>>> plt.title('Original image')
>>> plt.show()
```
Difference-equation filtering

A general class of linear 1-D filters (that includes convolution filters) are filters described by the difference equation

\[ \sum_{k=0}^{N} a_k y[n - k] = \sum_{k=0}^{M} b_k x[n - k], \]

where \( x[n] \) is the input sequence and \( y[n] \) is the output sequence. If we assume initial rest so that \( y[n] = 0 \) for \( n < 0 \), then this kind of filter can be implemented using convolution. However, the convolution filter sequence \( h[n] \) could be infinite if \( a_k \neq 0 \) for \( k \geq 1 \). In addition, this general class of linear filter allows initial conditions to be placed on \( y[n] \) for \( n < 0 \) resulting in a filter that cannot be expressed using convolution.

The difference equation filter can be thought of as finding \( y[n] \) recursively in terms of its previous values

\[ a_0 y[n] = -a_1 y[n - 1] - \cdots - a_N y[n - N] + \cdots + b_0 x[n] + \cdots + b_M x[n - M]. \]

Often, \( a_0 = 1 \) is chosen for normalization. The implementation in SciPy of this general difference equation filter is a little more complicated than would be implied by the previous equation. It is implemented so that only one signal needs to be delayed. The actual implementation equations are (assuming \( a_0 = 1 \)):

\[
\begin{align*}
y[n] & = b_0 x[n] + z_0[n - 1] \\
z_0[n] & = b_1 x[n] + z_1[n - 1] - a_1 y[n] \\
z_1[n] & = b_2 x[n] + z_2[n - 1] - a_2 y[n] \\
& \vdots \quad \vdots \\
z_{K-2}[n] & = b_{K-1} x[n] + z_{K-1}[n - 1] - a_{K-1} y[n] \\
z_{K-1}[n] & = b_K x[n] - a_K y[n],
\end{align*}
\]
where \( K = \max(N, M) \). Note that \( b_K = 0 \) if \( K > M \) and \( a_K = 0 \) if \( K > N \). In this way, the output at time \( n \) depends only on the input at time \( n \) and the value of \( z_0 \) at the previous time. This can always be calculated as long as the \( K \) values \( z_0[n-1] \ldots z_{K-1}[n-1] \) are computed and stored at each time step.

The difference-equation filter is called using the command `lfilter` in SciPy. This command takes as inputs the vector \( b \), the vector, \( a \), a signal \( x \) and returns the vector \( y \) (the same length as \( x \) ) computed using the equation given above. If \( x \) is \( N \)-D, then the filter is computed along the axis provided. If desired, initial conditions providing the values of \( z_0[−1] \) to \( z_{K-1}[−1] \) can be provided or else it will be assumed that they are all zero. If initial conditions are provided, then the final conditions on the intermediate variables are also returned. These could be used, for example, to restart the calculation in the same state.

Sometimes, it is more convenient to express the initial conditions in terms of the signals \( x[n] \) and \( y[n] \). In other words, perhaps you have the values of \( x[−M] \) to \( x[−1] \) and the values of \( y[−N] \) to \( y[−1] \) and would like to determine what values of \( z_m[−1] \) should be delivered as initial conditions to the difference-equation filter. It is not difficult to show that, for \( 0 \leq m < K \),

\[
z_m[n] = \sum_{p=0}^{K-m-1} (b_{m+p+1}x[n-p] - a_{m+p+1}y[n-p]) .
\]

Using this formula, we can find the initial-condition vector \( z_0[−1] \) to \( z_{K-1}[−1] \) given initial conditions on \( y \) (and \( x \)). The command `lfilter` performs this function.

As an example, consider the following system:

\[
y[n] = \frac{1}{2} x[n] + \frac{1}{4} x[n-1] + \frac{1}{3} y[n-1]
\]

The code calculates the signal \( y[n] \) for a given signal \( x[n] \); first for initial conditions \( y[−1] = 0 \) (default case), then for \( y[−1] = 2 \) by means of `lfilter`.

```python
>>> import numpy as np
call signal

>>> x = np.array([1., 0., 0., 0.])
>>> b = np.array([1.0/2, 1.0/4])
>>> a = np.array([1.0, -1.0/3])
>>> signal.lfilter(b, a, x)
anarray([0.5, 0.41666667, 0.13888889, 0.0462963])
>>> zi = signal.lfilter(b, a, y=2.)
>>> signal.lfilter(b, a, x, zi=zi)
anarray([ 1.16666667, 0.63888889, 0.21296296, 0.070987655])
```

Note that the output signal \( y[n] \) has the same length as the length as the input signal \( x[n] \).

### Analysis of Linear Systems

Linear system described a linear-difference equation can be fully described by the coefficient vectors \( a \) and \( b \) as was done above; an alternative representation is to provide a factor \( k \), \( N_z \) zeros \( z_k \) and \( N_p \) poles \( p_k \), respectively, to describe the system by means of its transfer function \( H(z) \), according to

\[
H(z) = k \frac{(z - z_1)(z - z_2)\ldots(z - z_{N_z})}{(z - p_1)(z - p_2)\ldots(z - p_{N_p})}.
\]

This alternative representation can be obtained with the scipy function `tf2zpk`; the inverse is provided by `zpk2tf`.

For the above example we have
i.e., the system has a zero at \( z = -1/2 \) and a pole at \( z = 1/3 \).

The scipy function \( \text{freqz} \) allows calculation of the frequency response of a system described by the coefficients \( a_k \) and \( b_k \). See the help of the \( \text{freqz} \) function for a comprehensive example.

### Filter Design

Time-discrete filters can be classified into finite response (FIR) filters and infinite response (IIR) filters. FIR filters can provide a linear phase response, whereas IIR filters cannot. SciPy provides functions for designing both types of filters.

#### FIR Filter

The function \( \text{firwin} \) designs filters according to the window method. Depending on the provided arguments, the function returns different filter types (e.g., low-pass, band-pass...).

The example below designs a low-pass and a band-stop filter, respectively.

```python
>>> import numpy as np
>>> import scipy.signal as signal
>>> import matplotlib.pyplot as plt

>>> b1 = signal.firwin(40, 0.5)
>>> b2 = signal.firwin(41, [0.3, 0.8])
>>> w1, h1 = signal.freqz(b1)
>>> w2, h2 = signal.freqz(b2)

>>> plt.title('Digital filter frequency response')
>>> plt.plot(w1, 20*np.log10(np.abs(h1)), 'b')
>>> plt.plot(w2, 20*np.log10(np.abs(h2)), 'r')
>>> plt.xlabel('Frequency (rad/sample)')
>>> plt.ylabel('Amplitude Response (dB)')
>>> plt.grid()
>>> plt.show()
```

Note that \( \text{firwin} \) uses, per default, a normalized frequency defined such that the value 1 corresponds to the Nyquist frequency, whereas the function \( \text{freqz} \) is defined such that the value \( \pi \) corresponds to the Nyquist frequency.

The function \( \text{firwin2} \) allows design of almost arbitrary frequency responses by specifying an array of corner frequencies and corresponding gains, respectively.

The example below designs a filter with such an arbitrary amplitude response.

```python
>>> import numpy as np
>>> import scipy.signal as signal
>>> import matplotlib.pyplot as plt

>>> b = signal.firwin2(150, [0.0, 0.3, 0.6, 1.0], [1.0, 2.0, 0.5, 0.0])
>>> w, h = signal.freqz(b)
```
Note the linear scaling of the y-axis and the different definition of the Nyquist frequency in `firwin2` and `freqz` (as explained above).
IIR Filter

SciPy provides two functions to directly design IIR \texttt{iirdesign} and \texttt{iirfilter}, where the filter type (e.g., elliptic) is passed as an argument and several more filter design functions for specific filter types, e.g., \texttt{ellip}.

The example below designs an elliptic low-pass filter with defined pass-band and stop-band ripple, respectively. Note the much lower filter order (order 4) compared with the FIR filters from the examples above in order to reach the same stop-band attenuation of $\approx 60$ dB.

```python
>>> import numpy as np
>>> import scipy.signal as signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.iirfilter(4, Wn=0.2, rp=5, rs=60, btype='lowpass', ftype='ellip')
>>> w, h = signal.freqz(b, a)

>>> plt.title('Digital filter frequency response')
>>> plt.plot(w, 20*np.log10(np.abs(h)))
>>> plt.title('Digital filter frequency response')
>>> plt.ylabel('Amplitude Response [dB]')
>>> plt.xlabel('Frequency (rad/sample)')
>>> plt.grid()
>>> plt.show()
```

Filter Coefficients

Filter coefficients can be stored in several different formats:

- `ba` or `tf` = transfer function coefficients
- `zpk` = zeros, poles, and overall gain
- `ss` = state-space system representation
- `sos` = transfer function coefficients of second-order sections

Functions, such as \texttt{tf2zpk} and \texttt{zpk2ss}, can convert between them.
Transfer function representation

The `ba` or `tf` format is a 2-tuple \((b, a)\) representing a transfer function, where \(b\) is a length \(M+1\) array of coefficients of the \(M\)-order numerator polynomial, and \(a\) is a length \(N+1\) array of coefficients of the \(N\)-order denominator, as positive, descending powers of the transfer function variable. So the tuple of \(b = [b_0, b_1, ..., b_M]\) and \(a = [a_0, a_1, ..., a_N]\) can represent an analog filter of the form:

\[
H(s) = \frac{b_0 s^M + b_1 s^{(M-1)} + \cdots + b_M}{a_0 s^N + a_1 s^{(N-1)} + \cdots + a_N} = \frac{\sum_{i=0}^{M} b_i s^{(M-i)}}{\sum_{i=0}^{N} a_i s^{(N-i)}}
\]

or a discrete-time filter of the form:

\[
H(z) = \frac{b_0 z^M + b_1 z^{(M-1)} + \cdots + b_M}{a_0 z^N + a_1 z^{(N-1)} + \cdots + a_N} = \frac{\sum_{i=0}^{M} b_i z^{(M-i)}}{\sum_{i=0}^{N} a_i z^{(N-i)}}.
\]

This “positive powers” form is found more commonly in controls engineering. If \(M\) and \(N\) are equal (which is true for all filters generated by the bilinear transform), then this happens to be equivalent to the “negative powers” discrete-time form preferred in DSP:

\[
H(z) = \frac{b_0 + b_1 z^{-1} + \cdots + b_M z^{-M}}{a_0 + a_1 z^{-1} + \cdots + a_N z^{-N}} = \frac{\sum_{i=0}^{M} b_i z^{-i}}{\sum_{i=0}^{N} a_i z^{-i}}.
\]

Although this is true for common filters, remember that this is not true in the general case. If \(M\) and \(N\) are not equal, the discrete-time transfer function coefficients must first be converted to the “positive powers” form before finding the poles and zeros.

This representation suffers from numerical error at higher orders, so other formats are preferred when possible.

Zeros and poles representation

The `zpk` format is a 3-tuple \((z, p, k)\), where \(z\) is an \(M\)-length array of the complex zeros of the transfer function \(z = [z_0, z_1, ..., z_{M-1}]\), \(p\) is an \(N\)-length array of the complex poles of the transfer function \(p = [p_0, p_1, ..., p_{N-1}]\), and \(k\) is a scalar gain. These represent the digital transfer function:

\[
H(z) = k \cdot \frac{(z - z_0)(z - z_1) \cdots (z - z_{M-1})}{(z - p_0)(z - p_1) \cdots (z - p_{N-1})} = k \frac{\prod_{i=0}^{M-1} (z - z_i)}{\prod_{i=0}^{N-1} (z - p_i)}
\]

or the analog transfer function:

\[
H(s) = k \cdot \frac{(s - z_0)(s - z_1) \cdots (s - z_{M-1})}{(s - p_0)(s - p_1) \cdots (s - p_{N-1})} = k \frac{\prod_{i=0}^{M-1} (s - z_i)}{\prod_{i=0}^{N-1} (s - p_i)}.
\]

Although the sets of roots are stored as ordered NumPy arrays, their ordering does not matter: \([-1, -2], [-3, -4], 1\) is the same filter as \([-2, -1], [-4, -3], 1\).

State-space system representation

The `ss` format is a 4-tuple of arrays \((A, B, C, D)\) representing the state-space of an \(N\)-order digital/discrete-time system of the form:

\[
x[k+1] = Ax[k] + Bu[k] \\
y[k] = Cx[k] + Du[k]
\]
or a continuous/analog system of the form:

\[
\dot{x}(t) = Ax(t) + Bu(t)
\]
\[
y(t) = Cx(t) + Du(t),
\]

with \( P \) inputs, \( Q \) outputs and \( N \) state variables, where:

- \( x \) is the state vector
- \( y \) is the output vector of length \( Q \)
- \( u \) is the input vector of length \( P \)
- \( A \) is the state matrix, with shape \((N, N)\)
- \( B \) is the input matrix with shape \((N, P)\)
- \( C \) is the output matrix with shape \((Q, N)\)
- \( D \) is the feedthrough or feedforward matrix with shape \((Q, P)\). (In cases where the system does not have a direct feedthrough, all values in \( D \) are zero.)

State-space is the most general representation and the only one that allows for multiple-input, multiple-output (MIMO) systems. There are multiple state-space representations for a given transfer function. Specifically, the “controllable canonical form” and “observable canonical form” have the same coefficients as the \( \text{tf} \) representation, and, therefore, suffer from the same numerical errors.

**Second-order sections representation**

The \( \text{sos} \) format is a single 2-D array of shape \((n\_sections, 6)\), representing a sequence of second-order transfer functions which, when cascaded in series, realize a higher-order filter with minimal numerical error. Each row corresponds to a second-order \( \text{tf} \) representation, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients:

\[
[b_0, b_1, b_2, a_0, a_1, a_2]
\]

The coefficients are typically normalized, such that \( a_0 \) is always 1. The section order is usually not important with floating-point computation; the filter output will be the same, regardless of the order.

**Filter transformations**

The IIR filter design functions first generate a prototype analog low-pass filter with a normalized cutoff frequency of 1 rad/sec. This is then transformed into other frequencies and band types using the following substitutions:

<table>
<thead>
<tr>
<th>Type</th>
<th>Transformation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1p21p</td>
<td>( s \to \frac{s}{\omega_0} )</td>
</tr>
<tr>
<td>1p2hp</td>
<td>( s \to \frac{s}{\omega_0^2} )</td>
</tr>
<tr>
<td>1p2bp</td>
<td>( s \to \frac{s + \omega_0^2}{s + \text{BW}^2} )</td>
</tr>
<tr>
<td>1p2bs</td>
<td>( s \to \frac{\text{BW}}{s + \text{BW}^2} )</td>
</tr>
</tbody>
</table>

Here, \( \omega_0 \) is the new cutoff or center frequency, and \( \text{BW} \) is the bandwidth. These preserve symmetry on a logarithmic frequency axis.

To convert the transformed analog filter into a digital filter, the \textit{bilinear} transform is used, which makes the following substitution:

\[
s \to \frac{2z - 1}{Tz + 1},
\]

where \( T \) is the sampling time (the inverse of the sampling frequency).
Other filters

The signal processing package provides many more filters as well.

Median Filter

A median filter is commonly applied when noise is markedly non-Gaussian or when it is desired to preserve edges. The median filter works by sorting all of the array pixel values in a rectangular region surrounding the point of interest. The sample median of this list of neighborhood pixel values is used as the value for the output array. The sample median is the middle-array value in a sorted list of neighborhood values. If there are an even number of elements in the neighborhood, then the average of the middle two values is used as the median. A general purpose median filter that works on N-D arrays is `medfilt`. A specialized version that works only for 2-D arrays is available as `medfilt2d`.

Order Filter

A median filter is a specific example of a more general class of filters called order filters. To compute the output at a particular pixel, all order filters use the array values in a region surrounding that pixel. These array values are sorted and then one of them is selected as the output value. For the median filter, the sample median of the list of array values is used as the output. A general-order filter allows the user to select which of the sorted values will be used as the output. So, for example, one could choose to pick the maximum in the list or the minimum. The order filter takes an additional argument besides the input array and the region mask that specifies which of the elements in the sorted list of neighbor array values should be used as the output. The command to perform an order filter is `order_filter`.

Wiener filter

The Wiener filter is a simple deblurring filter for denoising images. This is not the Wiener filter commonly described in image-reconstruction problems but, instead, it is a simple, local-mean filter. Let $x$ be the input signal, then the output is

$$
y = \begin{cases} 
\frac{\sigma_x^2}{\sigma_x^2} m_x + \left(1 - \frac{\sigma_x^2}{\sigma_x^2}\right) x & \sigma_x^2 \geq \sigma^2, \\
\frac{m_x}{\sigma_x^2} & \sigma_x^2 < \sigma^2,
\end{cases}
$$

where $m_x$ is the local estimate of the mean and $\sigma_x^2$ is the local estimate of the variance. The window for these estimates is an optional input parameter (default is $3 \times 3$). The parameter $\sigma^2$ is a threshold noise parameter. If $\sigma$ is not given, then it is estimated as the average of the local variances.

Hilbert filter

The Hilbert transform constructs the complex-valued analytic signal from a real signal. For example, if $x = \cos \omega n$, then $y = \text{hilbert}(x)$ would return (except near the edges) $y = \exp(j\omega n)$. In the frequency domain, the hilbert transform performs

$$
Y = X \cdot H,
$$

where $H$ is 2 for positive frequencies, 0 for negative frequencies, and 1 for zero-frequencies.

Analog Filter Design

The functions `iirdesign`, `iirfilter`, and the filter design functions for specific filter types (e.g., `ellip`) all have a flag `analog`, which allows the design of analog filters as well.

The example below designs an analog (IIR) filter, obtains via `tf2zpk` the poles and zeros and plots them in the complex $s$-plane. The zeros at $\omega \approx 150$ and $\omega \approx 300$ can be clearly seen in the amplitude response.

```python
>>> import numpy as np
>>> import scipy.signal as signal
>>> import matplotlib.pyplot as plt
```
2.7.3 Spectral Analysis

Periodogram Measurements

The scipy function `periodogram` provides a method to estimate the spectral density using the periodogram method. The example below calculates the periodogram of a sine signal in white Gaussian noise.
Spectral Analysis using Welch’s Method

An improved method, especially with respect to noise immunity, is Welch’s method, which is implemented by the scipy function `welch`.

The example below estimates the spectrum using Welch’s method and uses the same parameters as the example above. Note the much smoother noise floor of the spectrogram.

```python
>>> import numpy as np
>>> import scipy.signal as signal
>>> import matplotlib.pyplot as plt

>>> fs = 10e3
>>> N = 1e5
>>> amp = 2*np.sqrt(2)  
>>> freq = 1270.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> x = amp*np.sin(2*np.pi*freq*time)
>>> x += np.random.normal(scale=np.sqrt(noise_power), size=time.shape)

>>> f, P_per_spec = signal.periodogram(x, fs, 'flattop', scaling='spectrum')

>>> plt.semilogy(f, P_per_spec)
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD')
>>> plt.grid()
>>> plt.show()
```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2*np.sqrt(2)
>>> freq = 1270.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> x = amp*np.sin(2*np.pi*freq*time)
>>> x += np.random.normal(scale=np.sqrt(noise_power), size=time.shape)

>>> f, Pwelch_spec = signal.welch(x, fs, scaling='spectrum')

>>> plt.semilogy(f, Pwelch_spec)
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD')
>>> plt.grid()
>>> plt.show()

Lomb-Scargle Periodograms (lombscargle)

Least-squares spectral analysis (LSSA)\(^1\)\(^2\) is a method of estimating a frequency spectrum, based on a least-squares fit of sinusoids to data samples, similar to Fourier analysis. Fourier analysis, the most used spectral method in science, generally boosts long-periodic noise in long-gapped records; LSSA mitigates such problems.

The Lomb-Scargle method performs spectral analysis on unevenly-sampled data and is known to be a powerful way to find, and test the significance of, weak periodic signals.

For a time series comprising \(N\) measurements \(X_j \equiv X(t_j)\) sampled at times \(t_j\), where \((j = 1, \ldots, N)\), assumed to have been scaled and shifted, such that its mean is zero and its variance is unity, the normalized Lomb-Scargle periodogram at

---

---

2.7. Signal Processing (scipy.signal)
Here, $\omega \equiv 2\pi f$ is the angular frequency. The frequency-dependent time offset $\tau$ is given by

$$
\tan 2\omega \tau = \frac{\sum_{j}^{N} \sin 2\omega t_{j}}{\sum_{j}^{N} \cos 2\omega t_{j}}.
$$

The function calculates the periodogram using a slightly modified algorithm due to Townsend\(^3\), which allows the periodogram to be calculated using only a single pass through the input arrays for each frequency.

The equation is refactored as:

$$
P_{n}(f) = \frac{1}{2} \left[ \frac{\left( c_{\tau} X \cos \omega (t_{j} - \tau) + s_{\tau} X \sin \omega (t_{j} - \tau) \right)^{2}}{\sum_{j}^{N} \cos^{2} \omega (t_{j} - \tau)} + \frac{\left( c_{\tau} X \sin \omega (t_{j} - \tau) - s_{\tau} X \cos \omega (t_{j} - \tau) \right)^{2}}{\sum_{j}^{N} \sin^{2} \omega (t_{j} - \tau)} \right].
$$

and

$$
\tan 2\omega \tau = \frac{2CS}{CC - SS}.
$$

Here,

$$
c_{\tau} = \cos \omega \tau, \quad s_{\tau} = \sin \omega \tau,
$$

---

while the sums are

\[
XC = \sum_{j}^{N_t} X_j \cos \omega t_j \\
XS = \sum_{j}^{N_t} X_j \sin \omega t_j \\
CC = \sum_{j}^{N_t} \cos^2 \omega t_j \\
SS = \sum_{j}^{N_t} \sin^2 \omega t_j \\
CS = \sum_{j}^{N_t} \cos \omega t_j \sin \omega t_j.
\]

This requires \(N_f (2N_t + 3)\) trigonometric function evaluations giving a factor of \(\sim 2\) speed increase over the straightforward implementation.

### 2.7.4 Detrend

SciPy provides the function `detrend` to remove a constant or linear trend in a data series in order to see effect of higher order.

The example below removes the constant and linear trend of a second-order polynomial time series and plots the remaining signal components.

```python
>>> import numpy as np
>>> import scipy.signal as signal
>>> import matplotlib.pyplot as plt

>>> t = np.linspace(-10, 10, 20)
>>> y = 1 + t + 0.01*t**2
>>> yconst = signal.detrend(y, type='constant')
>>> ylin = signal.detrend(y, type='linear')

>>> plt.plot(t, y, '-rx')
>>> plt.plot(t, yconst, '-bo')
>>> plt.plot(t, ylin, '-k+')
>>> plt.grid()
>>> plt.legend(["signal", 'const. detrend', 'linear detrend'])
>>> plt.show()
```

2.8 Linear Algebra (scipy.linalg)

When SciPy is built using the optimized ATLAS LAPACK and BLAS libraries, it has very fast linear algebra capabilities. If you dig deep enough, all of the raw LAPACK and BLAS libraries are available for your use for even more speed. In this section, some easier-to-use interfaces to these routines are described.

All of these linear algebra routines expect an object that can be converted into a 2-D array. The output of these routines is also a 2-D array.

2.8.1 scipy.linalg vs numpy.linalg

scipy.linalg contains all the functions in numpy.linalg, plus some other more advanced ones not contained in numpy.linalg.

Another advantage of using scipy.linalg over numpy.linalg is that it is always compiled with BLAS/LAPACK support, while for numpy this is optional. Therefore, the scipy version might be faster depending on how numpy was installed.

Therefore, unless you don’t want to add scipy as a dependency to your numpy program, use scipy.linalg instead of numpy.linalg.
2.8.2 numpy.matrix vs 2-D numpy.ndarray

The classes that represent matrices, and basic operations, such as matrix multiplications and transpose are a part of numpy. For convenience, we summarize the differences between numpy.matrix and numpy.ndarray here.

numpy.matrix is matrix class that has a more convenient interface than numpy.ndarray for matrix operations. This class supports, for example, MATLAB-like creation syntax via the semicolon, has matrix multiplication as default for the * operator, and contains I and T members that serve as shortcuts for inverse and transpose:

```python
>>> import numpy as np
>>> A = np.mat('1 2;3 4')
>>> A
matrix([[1, 2],
        [3, 4]])
>>> A.I
matrix([[-2., 1.],
        [1.5, -0.5]])
>>> b = np.mat('[5 6]')
>>> b
matrix([[5, 6]])
>>> b.T
matrix([[5],
        [6]])
>>> A*b.T
matrix([[17],
        [39]])
```

Despite its convenience, the use of the numpy.matrix class is discouraged, since it adds nothing that cannot be accomplished with 2-D numpy.ndarray objects, and may lead to a confusion of which class is being used. For example, the above code can be rewritten as:

```python
>>> import numpy as np
>>> from scipy import linalg
>>> A = np.array([[1,2],[3,4]])
>>> A
array([[1, 2],
       [3, 4]])
>>> linalg.inv(A)
array([[-2., 1.],
       [1.5, -0.5]])
>>> b = np.array([[5,6]]) #2D array
>>> b
array([[5, 6]])
>>> b.T
array([[5],
       [6]])
>>> A*b #not matrix multiplication!
array([[ 5, 12],
       [15, 24]])
>>> A.dot(b.T) #matrix multiplication
array([[17],
       [39]])
>>> b = np.array([5,6]) #1D array
>>> b
(continues on next page)
```
array([5, 6])
>>> b.T  #not matrix transpose!
array([5, 6])
>>> A.dot(b)  #does not matter for multiplication
array([17, 39])

scipy.linalg operations can be applied equally to numpy.matrix or to 2D numpy.ndarray objects.

2.8.3 Basic routines

Finding the inverse

The inverse of a matrix $A$ is the matrix $B$, such that $AB = I$, where $I$ is the identity matrix consisting of ones down the main diagonal. Usually, $B$ is denoted $B = A^{-1}$. In SciPy, the matrix inverse of the NumPy array, $A$, is obtained using `linalg.inv(A)`, or using $A.I$ if $A$ is a Matrix. For example, let

$$
A = \begin{bmatrix}
1 & 3 & 5 \\
2 & 5 & 1 \\
2 & 3 & 8
\end{bmatrix},
$$

then

$$
A^{-1} = \frac{1}{25} \begin{bmatrix}
-37 & 9 & 22 \\
14 & 2 & -9 \\
4 & -3 & 1
\end{bmatrix} = \begin{bmatrix}
-1.48 & 0.36 & 0.88 \\
0.56 & 0.08 & -0.36 \\
0.16 & -0.12 & 0.04
\end{bmatrix}.
$$

The following example demonstrates this computation in SciPy

```python
>>> import numpy as np
>>> from scipy import linalg
>>> A = np.array([[1, 3, 5], [2, 5, 1], [2, 3, 8]])
>>> A
array([[1, 3, 5],
       [2, 5, 1],
       [2, 3, 8]])
>>> linalg.inv(A)
array([[-1.48,  0.36,  0.88],
       [ 0.56,  0.08, -0.36],
       [ 0.16, -0.12,  0.04]])
>>> A.dot(linalg.inv(A))  #double check
array([[ 1.00000000e+00, -1.11022302e-16, -5.55111512e-17],
       [ 3.05311332e-16,  1.00000000e+00, 1.87350135e-16],
       [ 2.22044605e-16, -1.11022302e-16,  1.00000000e+00]])
```
Solving a linear system

Solving linear systems of equations is straightforward using the scipy command `linalg.solve`. This command expects an input matrix and a right-hand side vector. The solution vector is then computed. An option for entering a symmetric matrix is offered, which can speed up the processing when applicable. As an example, suppose it is desired to solve the following simultaneous equations:

\[
\begin{align*}
x + 3y + 5z &= 10 \\
2x + 5y + z &= 8 \\
2x + 3y + 8z &= 3
\end{align*}
\]

We could find the solution vector using a matrix inverse:

\[
\begin{bmatrix}
x \\
y \\
z
\end{bmatrix} = \begin{bmatrix}
1 & 3 & 5 \\
2 & 5 & 1 \\
2 & 3 & 8
\end{bmatrix}^{-1} \begin{bmatrix}
10 \\
8 \\
3
\end{bmatrix} = \begin{bmatrix}
1 \\
8 \\
3
\end{bmatrix} = \begin{bmatrix}
-232 \\
129 \\
19
\end{bmatrix} = \begin{bmatrix}
-9.28 \\
5.16 \\
0.76
\end{bmatrix}.
\]

However, it is better to use the `linalg.solve` command, which can be faster and more numerically stable. In this case, it, however, gives the same answer as shown in the following example:

```python
>>> import numpy as np
>>> from scipy import linalg
>>> A = np.array([[1, 2], [3, 4]]
>>> A
array([[1, 2],
       [3, 4]])
>>> b = np.array([[5], [6]])
>>> b
array([[5],
       [6]])
>>> linalg.inv(A).dot(b)  # slow
array([[-4.],
       [ 4.5]])
>>> A.dot(linalg.inv(A).dot(b)) - b  # check
array([[ 8.88178420e-16],
       [ 2.66453526e-15]])
>>> np.linalg.solve(A, b)  # fast
array([[-4.],
       [ 4.5]])
>>> A.dot(np.linalg.solve(A, b)) - b  # check
array([[ 0.],
       [ 0.0]])
```

Finding the determinant

The determinant of a square matrix \(A\) is often denoted \(|A|\) and is a quantity often used in linear algebra. Suppose \(a_{ij}\) are the elements of the matrix \(A\) and let \(M_{ij} = |A_{ij}|\) be the determinant of the matrix left by removing the \(i^{th}\) row and \(j^{th}\) column from \(A\). Then, for any row \(i\),

\[
|A| = \sum_j (-1)^{i+j} a_{ij} M_{ij}.
\]

This is a recursive way to define the determinant, where the base case is defined by accepting that the determinant of a \(1 \times 1\) matrix is the only matrix element. In SciPy the determinant can be calculated with `linalg.det`. For example,
the determinant of

\[
A = \begin{bmatrix}
 1 & 3 & 5 \\
 2 & 5 & 1 \\
 2 & 3 & 8
\end{bmatrix}
\]

is

\[
|A| = 1 \begin{vmatrix}
 5 & 1 \\
 3 & 8
\end{vmatrix} - 3 \begin{vmatrix}
 2 & 1 \\
 2 & 8
\end{vmatrix} + 5 \begin{vmatrix}
 2 & 5 \\
 2 & 3
\end{vmatrix}
= 1(5 \cdot 8 - 3 \cdot 1) - 3(2 \cdot 8 - 2 \cdot 1) + 5(2 \cdot 3 - 2 \cdot 5) = -25.
\]

In SciPy, this is computed as shown in this example:

```python
>>> import numpy as np
>>> from scipy import linalg
>>> A = np.array([[1, 2], [3, 4]])
>>> A
array([[1, 2],
       [3, 4]])
>>> linalg.det(A)
-2.0
```

### Computing norms

Matrix and vector norms can also be computed with SciPy. A wide range of norm definitions are available using different parameters to the order argument of `linalg.norm`. This function takes a rank-1 (vectors) or a rank-2 (matrices) array and an optional order argument (default is 2). Based on these inputs, a vector or matrix norm of the requested order is computed.

For vector \( x \), the order parameter can be any real number including \( \infty \) or \( -\infty \). The computed norm is

\[
\|x\| = \begin{cases}
  \max |x_i| & \text{ord} = \infty \\
  \min |x_i| & \text{ord} = -\infty \\
  \left(\sum_i |x_i|^{\text{ord}}\right)^{1/\text{ord}} & |\text{ord}| < \infty.
\end{cases}
\]

For matrix \( A \), the only valid values for norm are \( \pm 2, \pm 1, \pm \infty \), and ‘fro’ (or ‘f’). Thus,

\[
\|A\| = \begin{cases}
  \max_i \sum_j |a_{ij}| & \text{ord} = \infty \\
  \min_i \sum_j |a_{ij}| & \text{ord} = -\infty \\
  \max_j \sum_i |a_{ij}| & \text{ord} = 1 \\
  \min_j \sum_i |a_{ij}| & \text{ord} = -1 \\
  \max \sigma_i & \text{ord} = 2 \\
  \min \sigma_i & \text{ord} = -2 \\
  \sqrt{\text{trace}(A^H A)} & \text{ord} = \text{‘fro’}
\end{cases}
\]

where \( \sigma_i \) are the singular values of \( A \).

Examples:

```python
>>> import numpy as np
>>> from scipy import linalg
>>> A = np.array([[1, 2], [3, 4]])
>>> A
```

(continues on next page)
array([[1, 2],
       [3, 4]])

```python
>>> linalg.norm(A)
5.4772255750516612
```

```python
>>> linalg.norm(A, 'fro')  # frobenius norm is the default
5.4772255750516612
```

```python
>>> linalg.norm(A, 1)  # L1 norm (max column sum)
6
```

```python
>>> linalg.norm(A, -1)
4
```

```python
>>> linalg.norm(A, np.inf)  # L inf norm (max row sum)
7
```

### Solving linear least-squares problems and pseudo-inverses

Linear least-squares problems occur in many branches of applied mathematics. In this problem, a set of linear scaling coefficients is sought that allows a model to fit the data. In particular, it is assumed that data \( y_i \) is related to data \( x_i \) through a set of coefficients \( c_j \) and model functions \( f_j(x_i) \) via the model

\[
y_i = \sum_j c_j f_j(x_i) + \epsilon_i,
\]

where \( \epsilon_i \) represents uncertainty in the data. The strategy of least squares is to pick the coefficients \( c_j \) to minimize

\[
J(c) = \sum_i \left| y_i - \sum_j c_j f_j(x_i) \right|^2.
\]

Theoretically, a global minimum will occur when

\[
\frac{\partial J}{\partial c_n^*} = 0 = \sum_i \left(y_i - \sum_j c_j f_j(x_i)\right) (-f_n^*(x_i))
\]

or

\[
\sum_j c_j \sum_i f_j(x_i) f_n^*(x_i) = \sum_i y_i f_n^*(x_i)
\]

\[
A^H A c = A^H y
\]

, where

\[
\{A\}_{ij} = f_j(x_i).
\]

When \( A^H A \) is invertible, then

\[
c = (A^H A)^{-1} A^H y = A^\dagger y,
\]

where \( A^\dagger \) is called the pseudo-inverse of \( A \). Notice that using this definition of \( A \) the model can be written

\[
y = A c + \epsilon.
\]

The command ```linalg.lstsq``` will solve the linear least-squares problem for \( c \) given \( A \) and \( y \). In addition, ```linalg.pinv``` or ```linalg.pinv2``` (uses a different method based on singular value decomposition) will find \( A^\dagger \) given \( A \).
The following example and figure demonstrate the use of `linalg.lstsq` and `linalg.pinv` for solving a data-fitting problem. The data shown below were generated using the model:

\[ y_i = c_1 e^{-x_i} + c_2 x_i, \]

where \( x_i = 0.1i \) for \( i = 1 \ldots 10 \), \( c_1 = 5 \), and \( c_2 = 4 \). Noise is added to \( y_i \) and the coefficients \( c_1 \) and \( c_2 \) are estimated using linear least squares.

```python
>>> import numpy as np
>>> from scipy import linalg
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()

>>> c1, c2 = 5.0, 2.0
>>> i = np.r_[1:11]
>>> xi = 0.1*i
>>> yi = c1*np.exp(-xi) + c2*xi
>>> zi = yi + 0.05 * np.max(yi) * rng.standard_normal(len(yi))

>>> A = np.c_[np.exp(-xi)[:, np.newaxis], xi[:, np.newaxis]]
>>> c, resid, rank, sigma = linalg.lstsq(A, zi)

>>> xi2 = np.r_[0.1:1.0:100j]
>>> yi2 = c[0]*np.exp(-xi2) + c[1]*xi2

>>> plt.plot(xi,zi,'x',xi2,yi2)
>>> plt.axis([0,1.1,3.0,5.5])
>>> plt.xlabel('\$x_i\$')
>>> plt.title('Data fitting with linalg.lstsq')
>>> plt.show()
```

![Data fitting with linalg.lstsq](image)
Generalized inverse

The generalized inverse is calculated using the command `linalg.pinv` or `linalg.pinv2`. These two commands differ in how they compute the generalized inverse. The first uses the linalg.lstsq algorithm, while the second uses singular value decomposition. Let $A$ be an $M \times N$ matrix, then if $M > N$, the generalized inverse is

$$A^\dagger = (A^HA)^{-1} A^H,$$

while if $M < N$ matrix, the generalized inverse is

$$A^\# = A^H (AA^H)^{-1}.$$

In the case that $M = N$, then

$$A^\dagger = A^\# = A^{-1},$$

as long as $A$ is invertible.

2.8.4 Decompositions

In many applications, it is useful to decompose a matrix using other representations. There are several decompositions supported by SciPy.

Eigenvalues and eigenvectors

The eigenvalue-eigenvector problem is one of the most commonly employed linear algebra operations. In one popular form, the eigenvalue-eigenvector problem is to find for some square matrix $A$ scalars $\lambda$ and corresponding vectors $v$, such that

$$Av = \lambda v.$$

For an $N \times N$ matrix, there are $N$ (not necessarily distinct) eigenvalues — roots of the (characteristic) polynomial

$$|A - \lambda I| = 0.$$

The eigenvectors, $v$, are also sometimes called right eigenvectors to distinguish them from another set of left eigenvectors that satisfy

$$v^H_L A = \lambda v^H_L$$

or

$$A^H v_L = \lambda^* v_L.$$

With its default optional arguments, the command `linalg.eig` returns $\lambda$ and $v$. However, it can also return $v_L$ and just $\lambda$ by itself (`linalg.eigvals` returns just $\lambda$ as well).

In addition, `linalg.eig` can also solve the more general eigenvalue problem

$$Av = \lambda Bv,$$

$$A^H v_L = \lambda^* B^H v_L$$

for square matrices $A$ and $B$. The standard eigenvalue problem is an example of the general eigenvalue problem for $B = I$. When a generalized eigenvalue problem can be solved, it provides a decomposition of $A$ as

$$A = B V \Lambda V^{-1},$$
where \( V \) is the collection of eigenvectors into columns and \( \Lambda \) is a diagonal matrix of eigenvalues.

By definition, eigenvectors are only defined up to a constant scale factor. In SciPy, the scaling factor for the eigenvectors is chosen so that \( \|v\|^2 = \sum_i v_i^2 = 1 \).

As an example, consider finding the eigenvalues and eigenvectors of the matrix

\[
A = \begin{bmatrix}
1 & 5 & 2 \\
2 & 4 & 1 \\
3 & 6 & 2
\end{bmatrix}.
\]

The characteristic polynomial is

\[
|A - \lambda I| = (1 - \lambda) [(4 - \lambda) (2 - \lambda) - 6] - 5 [2 (2 - \lambda) - 3] + 2 [12 - 3 (4 - \lambda)] = -\lambda^3 + 7\lambda^2 + 8\lambda - 3.
\]

The roots of this polynomial are the eigenvalues of \( A \):

\[
\lambda_1 = 7.9579 \\
\lambda_2 = -1.2577 \\
\lambda_3 = 0.2997.
\]

The eigenvectors corresponding to each eigenvalue can be found using the original equation. The eigenvectors associated with these eigenvalues can then be found.

```python
>>> import numpy as np
>>> from scipy import linalg
>>> A = np.array([[1, 2], [3, 4]])
>>> la, v = linalg.eig(A)
>>> 11, 12 = la
>>> print(la) # eigenvalues
(-0.3722813232690143+0j) (5.372281323269014+0j)
>>> print(v[:, 0]) # first eigenvector
[-0.82456484 0.56576746]
>>> print(v[:, 1]) # second eigenvector
[-0.41597356 -0.90937671]
>>> print(np.sum(abs(v**2), axis=0)) # eigenvectors are unitary
[1. 1.]
>>> v1 = np.array(v[:, 0]).T
>>> print(linalg.norm(A.dot(v1) - 11*v1)) # check the computation
3.23682852457e-16
```

Singular value decomposition

Singular value decomposition (SVD) can be thought of as an extension of the eigenvalue problem to matrices that are not square. Let \( A \) be an \( M \times N \) matrix with \( M \) and \( N \) arbitrary. The matrices \( A^H A \) and \( AA^H \) are square hermitian matrices\(^1\) of size \( N \times N \) and \( M \times M \), respectively. It is known that the eigenvalues of square hermitian matrices are real and non-negative. In addition, there are at most \( \min(M, N) \) identical non-zero eigenvalues of \( A^H A \) and \( AA^H \). Define these positive eigenvalues as \( \sigma_i^2 \). The square-root of these are called singular values of \( A \). The eigenvectors of \( A^H A \) are collected by columns into an \( N \times N \) unitary\(^2\) matrix \( V \), while the eigenvectors of \( AA^H \) are collected by columns in

\(^1\) A hermitian matrix \( D \) satisfies \( D^H = D \).

\(^2\) A unitary matrix \( D \) satisfies \( D^H D = I = DD^H \) so that \( D^{-1} = D^H \).
the unitary matrix $U$, the singular values are collected in an $M \times N$ zero matrix $\Sigma$ with main diagonal entries set to the singular values. Then

$$A = U \Sigma V^H$$

is the singular value decomposition of $A$. Every matrix has a singular value decomposition. Sometimes, the singular values are called the spectrum of $A$. The command `linalg.svd` will return $U$, $V^H$, and $\sigma_i$ as an array of the singular values. To obtain the matrix $\Sigma$, use `linalg.diagsvd`. The following example illustrates the use of `linalg.svd`:

```python
>>> import numpy as np
>>> from scipy import linalg
>>> A = np.array([[1, 2, 3], [4, 5, 6]])
>>> A
array([[1, 2, 3],
       [4, 5, 6]])
>>> M,N = A.shape
>>> U,s,Vh = linalg.svd(A)
>>> Sig = linalg.diagsvd(s,M,N)
>>> U, Vh = U, Vh
>>> U
array([[-0.3863177 , -0.92236578],
       [-0.92236578, 0.3863177 ]])
>>> Sig
array([[ 9.508032 , 0. , 0. ],
       [ 0. , 0.77286964, 0. ]])
>>> Vh
array([[-0.42866713, -0.56630692, -0.7039467 ],
       [ 0.80596391, 0.11238241, -0.58119908],
       [ 0.40824829, -0.81649658, 0.40824829]])
>>> U.dot(Sig.dot(Vh)) #check computation
array([[ 1., 2., 3.],
       [ 4., 5., 6.]])

LU decomposition

The LU decomposition finds a representation for the $M \times N$ matrix $A$ as

$$A = P L U,$$

where $P$ is an $M \times M$ permutation matrix (a permutation of the rows of the identity matrix), $L$ is in $M \times K$ lower triangular or trapezoidal matrix ($K = \min(M,N)$) with unit-diagonal, and $U$ is an upper triangular or trapezoidal matrix. The SciPy command for this decomposition is `linalg.lu`.

Such a decomposition is often useful for solving many simultaneous equations where the left-hand side does not change but the right-hand side does. For example, suppose we are going to solve

$$A x_i = b_i$$

for many different $b_i$. The LU decomposition allows this to be written as

$$P L U x_i = b_i.$$

Because $L$ is lower-triangular, the equation can be solved for $U x_i$ and, finally, $x_i$ very rapidly using forward- and back-substitution. An initial time spent factoring $A$ allows for very rapid solution of similar systems of equations in the future. If the intent for performing LU decomposition is for solving linear systems, then the command `linalg.lu_factor` should be used followed by repeated applications of the command `linalg.lu_solve` to solve the system for each new right-hand side.
Cholesky decomposition

Cholesky decomposition is a special case of LU decomposition applicable to Hermitian positive definite matrices. When
\[ A = A^H \] and \[ x^H Ax \geq 0 \] for all \( x \), then decompositions of \( A \) can be found so that
\[ A = U^H U \]
\[ A = LL^H \]

, where \( L \) is lower triangular and \( U \) is upper triangular. Notice that \( L = U^H \). The command \texttt{linalg.cholesky} computes the Cholesky factorization. For using the Cholesky factorization to solve systems of equations, there are also \texttt{linalg.cho_factor} and \texttt{linalg.cho_solve} routines that work similarly to their LU decomposition counterparts.

QR decomposition

The QR decomposition (sometimes called a polar decomposition) works for any \( M \times N \) array and finds an \( M \times M \) unitary matrix \( Q \) and an \( M \times N \) upper-trapezoidal matrix \( R \), such that
\[ A = QR. \]

Notice that if the SVD of \( A \) is known, then the QR decomposition can be found.
\[ A = U\Sigma V^H = QR \]

implies that \( Q = U \) and \( R = \Sigma V^H \). Note, however, that in SciPy independent algorithms are used to find QR and SVD decompositions. The command for QR decomposition is \texttt{linalg.qr}.

Schur decomposition

For a square \( N \times N \) matrix, \( A \), the Schur decomposition finds (not necessarily unique) matrices \( T \) and \( Z \), such that
\[ A = ZTZ^H, \]

where \( Z \) is a unitary matrix and \( T \) is either upper triangular or quasi upper triangular, depending on whether or not a real Schur form or complex Schur form is requested. For a real Schur form both \( T \) and \( Z \) are real-valued when \( A \) is real-valued. When \( A \) is a real-valued matrix, the real Schur form is only quasi upper triangular because 2 \( \times \) 2 blocks extrude from the main diagonal corresponding to any complex-valued eigenvalues. The command \texttt{linalg.schur} finds the Schur decomposition, while the command \texttt{linalg.rsf2csf} converts \( T \) and \( Z \) from a real Schur form to a complex Schur form. The Schur form is especially useful in calculating functions of matrices.

The following example illustrates the Schur decomposition:

```python
>>> from scipy import linalg
>>> A = np.mat('[1 3 2; 1 4 5; 2 3 6]')
>>> T, Z = linalg.schur(A)
>>> T1, Z1 = linalg.schur(A, 'complex')
>>> T2, Z2 = linalg.rsf2csf(T, Z)
>>> T
array([[ 9.90012467,  1.78947961, -0.65498528],
        [ 0.     ,  0.54993766, -1.57754789],
        [ 0.     ,  0.51260928,  0.54993766]])
>>> T2
array([[ 9.90012467+0.00000000e+00j, -0.32436598+1.55463542e+00j, -0.65498528+0.00000000e+00j],
        [ 0.     +0.00000000e+00j,  0.54993766+0.00000000e+00j, -1.57754789+0.00000000e+00j],
        [ 0.     +0.00000000e+00j,  0.51260928+0.00000000e+00j,  0.54993766+0.00000000e+00j]])
```
>>> abs(T1 - T2)  # different

        [ 8.88225111e-16, 8.88312432e-16, 4.44104848e-15]])
```

### Interpolative decomposition

`scipy.linalg.interpolative` contains routines for computing the interpolative decomposition (ID) of a matrix. For a matrix $A \in \mathbb{C}^{m \times n}$ of rank $k \leq \min\{m, n\}$ this is a factorization

$$ A \Pi = [A \Pi_1 \quad A \Pi_2] = A \Pi_1 [I \quad T], $$

where $\Pi = [\Pi_1, \Pi_2]$ is a permutation matrix with $\Pi_1 \in \{0, 1\}^{n \times k}$, i.e., $A \Pi_2 = A \Pi_1 T$. This can equivalently be written as $A = BP$, where $B = A \Pi_1$ and $P = [I; T] \Pi^T$ are the skeleton and interpolation matrices, respectively.

See also:

`scipy.linalg.interpolative` — for more information.

### 2.8.5 Matrix functions

Consider the function $f(x)$ with Taylor series expansion

$$ f(x) = \sum_{k=0}^{\infty} \frac{f^{(k)}(0)}{k!} x^k. $$

A matrix function can be defined using this Taylor series for the square matrix $A$ as

$$ f(A) = \sum_{k=0}^{\infty} \frac{f^{(k)}(0)}{k!} A^k. $$

While this serves as a useful representation of a matrix function, it is rarely the best way to calculate a matrix function.
Exponential and logarithm functions

The matrix exponential is one of the more common matrix functions. The preferred method for implementing the matrix exponential is to use scaling and a Padé approximation for \( e^x \). This algorithm is implemented as `linalg.expm`.

The inverse of the matrix exponential is the matrix logarithm defined as the inverse of the matrix exponential:

\[
A \equiv \exp(\log(A)).
\]

The matrix logarithm can be obtained with `linalg.logm`.

Trigonometric functions

The trigonometric functions, \( \sin \), \( \cos \), and \( \tan \), are implemented for matrices in `linalg.sinm`, `linalg.cosm`, and `linalg.tanm`, respectively. The matrix sine and cosine can be defined using Euler's identity as

\[
\sin(A) = \frac{e^{jA} - e^{-jA}}{2j},
\]

\[
\cos(A) = \frac{e^{jA} + e^{-jA}}{2}.
\]

The tangent is

\[
\tan(x) = \frac{\sin(x)}{\cos(x)} = [\cos(x)]^{-1} \sin(x)
\]

and so the matrix tangent is defined as

\[
[\cos(A)]^{-1} \sin(A).
\]

Hyperbolic trigonometric functions

The hyperbolic trigonometric functions, \( \sinh \), \( \cosh \), and \( \tanh \), can also be defined for matrices using the familiar definitions:

\[
\sinh(A) = \frac{e^A - e^{-A}}{2},
\]

\[
\cosh(A) = \frac{e^A + e^{-A}}{2},
\]

\[
\tanh(A) = [\cosh(A)]^{-1} \sinh(A).
\]

These matrix functions can be found using `linalg.sinhm`, `linalg.coshm`, and `linalg.tanhm`.

Arbitrary function

Finally, any arbitrary function that takes one complex number and returns a complex number can be called as a matrix function using the command `linalg.funm`. This command takes the matrix and an arbitrary Python function. It then implements an algorithm from Golub and Van Loan's book “Matrix Computations” to compute the function applied to the matrix using a Schur decomposition. Note that the function needs to accept complex numbers as input in order to work with this algorithm. For example, the following code computes the zeroth-order Bessel function applied to a matrix.
```python
>>> from scipy import special, linalg
>>> rng = np.random.default_rng()
>>> A = rng.random((3, 3))
>>> B = linalg.funm(A, lambda x: special.jv(0, x))
>>> A
array([[0.06369197, 0.90647174, 0.98024544],
       [0.68752227, 0.5604377 , 0.49142032],
       [0.86754578, 0.9746787 , 0.37932682]])
>>> B
array([[ 0.6929219 , -0.29728805, -0.15930896],
       [-0.16226043, 0.71967826, -0.22709386],
       [-0.19945564, -0.33379957, 0.70259022]])
>>> linalg.eigvals(A)
array([ 1.94835336+0.j, -0.72219681+0.j, -0.22270006+0.j])
>>> special.jv(0, linalg.eigvals(A))
array([0.25375345+0.j, 0.87379738+0.j, 0.98763955+0.j])
>>> linalg.eigvals(B)
array([0.25375345+0.j, 0.87379738+0.j, 0.98763955+0.j])
```

Note how, by virtue of how matrix analytic functions are defined, the Bessel function has acted on the matrix eigenvalues.

### 2.8.6 Special matrices

SciPy and NumPy provide several functions for creating special matrices that are frequently used in engineering and science.

2.9 Sparse eigenvalue problems with ARPACK

2.9.1 Introduction

ARPACK\(^1\) is a Fortran package which provides routines for quickly finding a few eigenvalues/eigenvectors of large sparse matrices. In order to find these solutions, it requires only left-multiplication by the matrix in question. This operation is performed through a reverse-communication interface. The result of this structure is that ARPACK is able to find eigenvalues and eigenvectors of any linear function mapping a vector to a vector.

All of the functionality provided in ARPACK is contained within the two high-level interfaces `scipy.sparse.linalg.eigs` and `scipy.sparse.linalg.eigsh`. `eigs` provides interfaces for finding the eigenvalues/vectors of real or complex nonsymmetric square matrices, while `eigsh` provides interfaces for real-symmetric or complex-hermitian matrices.

2.9.2 Basic functionality

ARPACK can solve either standard eigenvalue problems of the form

\[ Ax = \lambda x \]

or general eigenvalue problems of the form

\[ Ax = \lambda Mx. \]

The power of ARPACK is that it can compute only a specified subset of eigenvalue/eigenvector pairs. This is accomplished through the keyword `which`. The following values of `which` are available:

- `which = 'LM'`: Eigenvalues with largest magnitude (`eigs`, `eigsh`), that is, largest eigenvalues in the euclidean norm of complex numbers.
- `which = 'SM'`: Eigenvalues with smallest magnitude (`eigs`, `eigsh`), that is, smallest eigenvalues in the euclidean norm of complex numbers.
- `which = 'LR'`: Eigenvalues with largest real part (`eigs`).
- `which = 'SR'`: Eigenvalues with smallest real part (`eigs`).
- `which = 'LI'`: Eigenvalues with largest imaginary part (`eigs`).
- `which = 'SI'`: Eigenvalues with smallest imaginary part (`eigs`).
- `which = 'LA'`: Eigenvalues with largest algebraic value (`eigsh`), that is, largest eigenvalues inclusive of any negative sign.
- `which = 'SA'`: Eigenvalues with smallest algebraic value (`eigsh`), that is, smallest eigenvalues inclusive of any negative sign.
- `which = 'BE'`: Eigenvalues from both ends of the spectrum (`eigsh`).

Note that ARPACK is generally better at finding extremal eigenvalues, that is, eigenvalues with large magnitudes. In particular, using `which = 'SM'` may lead to slow execution time and/or anomalous results. A better approach is to use shift-invert mode.

\(^1\) [http://www.caam.rice.edu/software/ARPACK/](http://www.caam.rice.edu/software/ARPACK/)
2.9.3 Shift-invert mode

Shift-invert mode relies on the following observation. For the generalized eigenvalue problem

\[ Ax = \lambda M x, \]

it can be shown that

\[ (A - \sigma M)^{-1} M x = \nu x, \]

where

\[ \nu = \frac{1}{\lambda - \sigma}. \]

2.9.4 Examples

Imagine you’d like to find the smallest and largest eigenvalues and the corresponding eigenvectors for a large matrix. ARPACK can handle many forms of input: dense matrices, such as `numpy.ndarray` instances, sparse matrices, such as `scipy.sparse.csr_matrix`, or a general linear operator derived from `scipy.sparse.linalg.LinearOperator`. For this example, for simplicity, we’ll construct a symmetric, positive-definite matrix.

```python
>>> import numpy as np
>>> from scipy.linalg import eig, eigh
>>> from scipy.sparse.linalg import eigs, eigsh
>>> np.set_printoptions(suppress=True)
>>> rng = np.random.default_rng()
>>> X = rng.random((100, 100)) - 0.5
>>> X = np.dot(X, X.T)  # create a symmetric matrix
```

We now have a symmetric matrix `X`, with which to test the routines. First, compute a standard eigenvalue decomposition using `eigh`:

```python
>>> evals_all, evecs_all = eigh(X)
```

As the dimension of `X` grows, this routine becomes very slow. Especially, if only a few eigenvectors and eigenvalues are needed, ARPACK can be a better option. First let’s compute the largest eigenvalues (`which = 'LM'`) of `X` and compare them to the known results:

```python
>>> evals_large, evecs_large = eigsh(X, 3, which='LM')
>>> print(evals_all[-3:])
[29.22435321 30.05590784 30.58591252]
>>> print(evals_large)
[29.22435321 30.05590784 30.58591252]
>>> print(np.dot(evecs_large.T, evecs_all[:, -3:]))
array([[[-1.  0.  0.], # may vary (signs)
         [ 0.  1.  0.],
         [-0.  0. -1.]]])
```

The results are as expected. ARPACK recovers the desired eigenvalues and they match the previously known results. Furthermore, the eigenvectors are orthogonal, as we’d expect. Now, let’s attempt to solve for the eigenvalues with smallest magnitude:

```python
```
Oops. We see that, as mentioned above, ARPACK is not quite as adept at finding small eigenvalues. There are a few ways this problem can be addressed. We could increase the tolerance (tol) to lead to faster convergence:

```
>>> evals_small, evecs_small = eigsh(X, 3, which='SM', tol=1E-2)
>>> evals_all[:3]
array([0.00053181, 0.00298319, 0.01387821])
>>> evals_small
array([0.00053181, 0.00298319, 0.01387821])
>>> np.dot(evecs_small.T, evecs_all[:, :3])
array([[ 0.99999999 0.00000024 -0.00000049],
       [-0.00000023 0.99999999 0.00000056],
       [ 0.00000031 -0.00000037 0.99999852]])
```

This works, but we lose the precision in the results. Another option is to increase the maximum number of iterations (maxiter) from 1000 to 5000:

```
>>> evals_small, evecs_small = eigsh(X, 3, which='SM', maxiter=5000)
>>> evals_all[:3]
array([0.00053181, 0.00298319, 0.01387821])
>>> evals_small
array([0.00053181, 0.00298319, 0.01387821])
>>> np.dot(evecs_small.T, evecs_all[:, :3])
array([[ 1. 0. 0.],
       [ 0. 1. 0.],
       [ 0. 0. -1.]])
```

We get the results we’d hoped for, but the computation time is much longer. Fortunately, ARPACK contains a mode that allows a quick determination of non-external eigenvalues: shift-invert mode. As mentioned above, this mode involves transforming the eigenvalue problem to an equivalent problem with different eigenvalues. In this case, we hope to find eigenvalues near zero, so we’ll choose sigma = 0. The transformed eigenvalues will then satisfy $\nu = 1/(\lambda - \sigma) = 1/\lambda$, so our small eigenvalues $\lambda$ become large eigenvalues $\nu$.

```
>>> evals_small, evecs_small = eigsh(X, 3, sigma=0, which='LM')
>>> evals_all[:3]
array([0.00053181, 0.00298319, 0.01387821])
>>> evals_small
array([0.00053181, 0.00298319, 0.01387821])
>>> np.dot(evecs_small.T, evecs_all[:, :3])
array([[ 1. 0. 0.],
       [ 0. -1. -0.],
       [-0. -0. 1.]])
```

We get the results we were hoping for, with much less computational time. Note that the transformation from $\nu \rightarrow \lambda$ takes place entirely in the background. The user need not worry about the details.

The shift-invert mode provides more than just a fast way to obtain a few small eigenvalues. Say, you desire to find internal eigenvalues and eigenvectors, e.g., those nearest to $\lambda = 1$. Simply set sigma = 1 and ARPACK will take care of the rest.
The eigenvalues come out in a different order, but they're all there. Note that the shift-invert mode requires the internal solution of a matrix inverse. This is taken care of automatically by `eigsh` and `eigs`, but the operation can also be specified by the user. See the docstring of `scipy.sparse.linalg.eigsh` and `scipy.sparse.linalg.eigs` for details.

### 2.9.5 Use of LinearOperator

We consider now the case where you’d like to avoid creating a dense matrix and use `scipy.sparse.linalg.LinearOperator` instead. Our first linear operator applies element-wise multiplication between the input vector and a vector $d$ provided by the user to the operator itself. This operator mimics a diagonal matrix with the elements of $d$ along the main diagonal and it has the main benefit that the forward and adjoint operations are simple element-wise multiplications other than matrix-vector multiplications. For a diagonal matrix, we expect the eigenvalues to be equal to the elements along the main diagonal, in this case $d$. The eigenvalues and eigenvectors obtained with `eigsh` are compared to those obtained by using `eigh` when applied to the dense matrix:

```python
>>> from scipy.sparse.linalg import LinearOperator
>>> class Diagonal(LinearOperator):
...     def __init__(self, diag, dtype='float32'):
...         self.diag = diag
...         self.shape = (len(self.diag), len(self.diag))
...         self.dtype = np.dtype(dtype)
...     def _matvec(self, x):
...         return self.diag*x
...     def _rmatvec(self, x):
...         return self.diag*x
```

```python
>>> N = 100
>>> rng = np.random.default_rng()
>>> d = rng.normal(0, 1, N).astype(np.float64)
>>> D = np.diag(d)
>>> Dop = Diagonal(d, dtype=np.float64)
```

```python
>>> evals_all, evecs_all = eigh(D)
>>> evals_large, evecs_large = eigsh(Dop, 3, which='LA', maxiter=1e3)
>>> evals_all[-3:]
array([1.53092498, 1.77243671, 2.00582508])
>>> evals_large
array([1.53092498, 1.77243671, 2.00582508])
>>> print(np.dot(evecs_large.T, evecs_all[:, -3:]))
array([[-1.  0.  0.],  # may vary (signs)
       [-0. -0.  1.],
       [ 1.  0.  0.]])
```
In this case, we have created a quick and easy Diagonal operator. The external library PyLops provides similar capabilities in the Diagonal operator, as well as several other operators.

Finally, we consider a linear operator that mimics the application of a first-derivative stencil. In this case, the operator is equivalent to a real nonsymmetric matrix. Once again, we compare the estimated eigenvalues and eigenvectors with those from a dense matrix that applies the same first derivative to an input signal:

```python
>>> class FirstDerivative(LinearOperator):
...     def __init__(self, N, dtype='float32'):
...         self.N = N
...         self.shape = (self.N, self.N)
...         self.dtype = np.dtype(dtype)
...     def _matvec(self, x):
...         y = np.zeros(self.N, self.dtype)
...         y[1:-1] = (0.5*x[2:]-0.5*x[0:-2])
...         return y
...     def _rmatvec(self, x):
...         y = np.zeros(self.N, self.dtype)
...         y[0:-2] = y[0:-2] - (0.5*x[1:-1])
...         y[2:] = y[2:] + (0.5*x[1:-1])
...         return y

>>> N = 21
>>> D = np.diag(0.5*np.ones(N-1), k=1) - np.diag(0.5*np.ones(N-1), k=-1)
>>> D[0] = D[-1] = 0  # take away edge effects
>>> Dop = FirstDerivative(N, dtype=np.float64)

>>> evals_all, evecs_all = eig(D)
>>> evals_large, evecs_large = eigs(Dop, 4, which='LI')
>>> evals_all_imag = evals_all.imag
>>> isort_imag = np.argsort(np.abs(evals_all_imag))
>>> evals_all_imag = evals_all_imag[isort_imag]
>>> evals_large_imag = evals_large.imag
>>> isort_imag = np.argsort(np.abs(evals_large_imag))
>>> evals_large_imag = evals_large_imag[isort_imag]
>>> evals_all_imag[-4:]
array([-0.95105652, 0.95105652, -0.98768834, 0.98768834])
>>> evals_large_imag
array([0.95105652, -0.95105652, 0.98768834, -0.98768834])
```

Note that the eigenvalues of this operator are all imaginary. Moreover, the keyword which='LI' of scipy.sparse.linalg.eigs produces the eigenvalues with largest absolute imaginary part (both positive and negative). Again, a more advanced implementation of the first-derivative operator is available in the PyLops library under the name of FirstDerivative operator.
2.9.6 References

2.10 Compressed Sparse Graph Routines (scipy.sparse.csgraph)

2.10.1 Example: Word Ladders

A Word Ladder is a word game invented by Lewis Carroll, in which players find paths between words by switching one letter at a time. For example, one can link “ape” and “man” in the following way:

ape → apt → ait → bit → big → bag → mag → man

Note that each step involves changing just one letter of the word. This is just one possible path from “ape” to “man”, but is it the shortest possible path? If we desire to find the shortest word-ladder path between two given words, the sparse graph submodule can help.

First, we need a list of valid words. Many operating systems have such a list built in. For example, on linux, a word list can often be found at one of the following locations:

```
/usr/share/dict
/var/lib/dict
```

Another easy source for words are the Scrabble word lists available at various sites around the internet (search with your favorite search engine). We'll first create this list. The system word lists consist of a file with one word per line. The following should be modified to use the particular word list you have available:

```python
>>> word_list = open('/usr/share/dict/words').readlines()
>>> word_list = map(str.strip, word_list)
```

We want to look at words of length 3, so let's select just those words of the correct length. We'll also eliminate words which start with upper-case (proper nouns) or contain non-alphanumeric characters, like apostrophes and hyphens. Finally, we'll make sure everything is lower-case for comparison later:

```python
>>> word_list = [word for word in word_list if len(word) == 3]
>>> word_list = [word for word in word_list if word[0].islower()]
>>> word_list = [word for word in word_list if word.isalpha()]
>>> word_list = list(map(str.lower, word_list))
```

```python
len(word_list)
586  # may vary
```

Now we have a list of 586 valid three-letter words (the exact number may change depending on the particular list used). Each of these words will become a node in our graph, and we will create edges connecting the nodes associated with each pair of words which differs by only one letter.

There are efficient ways to do this, and inefficient ways to do this. To do this as efficiently as possible, we're going to use some sophisticated numpy array manipulation:

```python
>>> import numpy as np
>>> word_list = np.asarray(word_list)
>>> word_list.dtype # these are unicode characters in Python 3
dtype('<U3')
>>> word_list.sort() # sort for quick searching later
```

We have an array where each entry is three unicode characters long. We'd like to find all pairs where exactly one character is different. We'll start by converting each word to a 3-D vector:
```python
>>> word_bytes = np.ndarray((word_list.size, word_list.itemsize),
...                        dtype='uint8',
...                        buffer=word_list.data)
>>> # each unicode character is four bytes long. We only need first byte
>>> # we know there are three characters in each word
>>> word_bytes = word_bytes[:, ::word_list.itemsize//3]
>>> word_bytes.shape
(586, 3)  # may vary
```

Now, we’ll use the Hamming distance between each point to determine which pairs of words are connected. The Hamming distance measures the fraction of entries between two vectors which differ: any two words with a Hamming distance equal to $1/N$, where $N$ is the number of letters, are connected in the word ladder:

```python
>>> from scipy.spatial.distance import pdist, squareform
>>> from scipy.sparse import csr_matrix
>>> hamming_dist = pdist(word_bytes, metric='hamming')
>>> # there are three characters in each word
>>> graph = csr_matrix(squareform(hamming_dist < 1.5 / 3))
```

When comparing the distances, we don’t use an equality because this can be unstable for floating point values. The inequality produces the desired result, as long as no two entries of the word list are identical. Now, that our graph is set up, we’ll use a shortest path search to find the path between any two words in the graph:

```python
>>> i1 = word_list.searchsorted('ape')
>>> i2 = word_list.searchsorted('man')
>>> word_list[i1]  
'ape'
>>> word_list[i2]  
'man'
```

We need to check that these match, because if the words are not in the list, that will not be the case. Now, all we need is to find the shortest path between these two indices in the graph. We’ll use Dijkstra’s algorithm, because it allows us to find the path for just one node:

```python
>>> from scipy.sparse.csgraph import dijkstra
>>> distances, predecessors = dijkstra(graph, indices=i1,
...                                           return_predecessors=True)
>>> print(distances[i2])
5.0  # may vary
```

So we see that the shortest path between “ape” and “man” contains only five steps. We can use the predecessors returned by the algorithm to reconstruct this path:

```python
>>> path = []
>>> i = 12
>>> while i != i1:
...     path.append(word_list[i])
...     i = predecessors[i]
>>> path.append(word_list[i1])
>>> print(path[::-1])
['ape', 'apt', 'opt', 'oat', 'mat', 'man']  # may vary
```

This is three fewer links than our initial example: the path from “ape” to “man” is only five steps.
Using other tools in the module, we can answer other questions. For example, are there three-letter words which are not linked in a word ladder? This is a question of connected components in the graph:

```python
>>> from scipy.sparse.csgraph import connected_components
>>> N_components, component_list = connected_components(graph)
>>> print(N_components)
15  # may vary
```

In this particular sample of three-letter words, there are 15 connected components: that is, 15 distinct sets of words with no paths between the sets. How many words are there in each of these sets? We can learn this from the list of components:

```python
>>> [np.sum(component_list == i) for i in range(N_components)]
[571, 1, 1, 1, 2, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]  # may vary
```

There is one large connected set and 14 smaller ones. Let's look at the words in the smaller ones:

```python
>>> [list(word_list[np.nonzero(component_list == i)]) for i in range(1, N_components)]
[['aha'],  # may vary
 ['chi'],
 ['ebb'],
 ['ems', 'emu'],
 ['gnu'],
 ['ism'],
 ['khz'],
 ['nth'],
 ['ova'],
 ['qua'],
 ['ugh'],
 ['ups'],
 ['urn'],
 ['use']]
```

These are all the three-letter words which do not connect to others via a word ladder.

We might also be curious about which words are maximally separated. Which two words take the most links to connect? We can determine this by computing the matrix of all shortest paths. Note that, by convention, the distance between two non-connected points is reported to be infinity, so we'll need to remove these before finding the maximum:

```python
>>> distances, predecessors = dijkstra(graph, return_predecessors=True)
>>> max_distance = np.max(distances[~np.isinf(distances)])
>>> print(max_distance)
13.0  # may vary
```

So, there is at least one pair of words which takes 13 steps to get from one to the other! Let's determine which these are:

```python
>>> i1, i2 = np.nonzero(distances == max_distance)
>>> list(zip(word_list[i1], word_list[i2]))
[('imp', 'ohm'),  # may vary
 ('imp', 'ohs'),
 ('ohm', 'imp'),
 ('ohm', 'ump'),
 ('ohs', 'imp'),
 ('ohs', 'ump'),
 ...]
```

(continues on next page)
We see that there are two pairs of words which are maximally separated from each other: ‘imp’ and ‘ump’ on the one hand, and ‘ohm’ and ‘ohs’ on the other. We can find the connecting list in the same way as above:

```python
>>> path = []
>>> i = i2[0]
>>> while i != i1[0]:
...     path.append(word_list[i])
...     i = predecessors[i1[0], i]
>>> path.append(word_list[i1[0]])
>>> print(path[:-1])
['imp', 'amp', 'asp', 'ass', 'ads', 'add', 'aid', 'mid', 'mod', 'moo', 'too', →'tho', 'oho', 'ohm'] # may vary
```

This gives us the path we desired to see.

Word ladders are just one potential application of scipy’s fast graph algorithms for sparse matrices. Graph theory makes appearances in many areas of mathematics, data analysis, and machine learning. The sparse graph tools are flexible enough to handle many of these situations.

### 2.11 Spatial data structures and algorithms (*scipy.spatial*)

*scipy.spatial* can compute triangulations, Voronoi diagrams, and convex hulls of a set of points, by leveraging the Qhull library.

Moreover, it contains *KDTree* implementations for nearest-neighbor point queries, and utilities for distance computations in various metrics.

#### 2.11.1 Delaunay triangulations

The Delaunay triangulation is a subdivision of a set of points into a non-overlapping set of triangles, such that no point is inside the circumcircle of any triangle. In practice, such triangulations tend to avoid triangles with small angles.

Delaunay triangulation can be computed using *scipy.spatial* as follows:

```python
>>> from scipy.spatial import Delaunay
>>> points = np.array([[0, 0], [0, 1.1], [1, 0], [1, 1]])
>>> tri = Delaunay(points)
```

We can visualize it:

```python
>>> import matplotlib.pyplot as plt
>>> plt.triplot(points[:,0], points[:,1], tri.simplices)
>>> plt.plot(points[:,0], points[:,1], 'o')
```

And add some further decorations:

```python
>>> for j, p in enumerate(points):
...     plt.text(p[0]-0.03, p[1]+0.03, j, ha='right') # label the points
```
The structure of the triangulation is encoded in the following way: the `simplices` attribute contains the indices of the points in the `points` array that make up the triangle. For instance:

```python
>>> 1 = 1
>>> tri.simplices[i, :]
array([3, 1, 0], dtype=int32)
>>> points[tri.simplices[i, :]]
array([[ 1., 1.],
       [ 0., 1.1],
       [ 0., 0. ]])
```

Moreover, neighboring triangles can also be found:

```python
>>> tri.neighbors[i]
array([-1, 0, -1], dtype=int32)
```

What this tells us is that this triangle has triangle #0 as a neighbor, but no other neighbors. Moreover, it tells us that neighbor 0 is opposite the vertex 1 of the triangle:

```python
>>> points[tri.simplices[i, 1]]
array([ 0., 1.1])
```

Indeed, from the figure, we see that this is the case.

Qhull can also perform tessellations to simplices for higher-dimensional point sets (for instance, subdivision into tetrahedra in 3-D).
Coplanar points

It is important to note that not all points necessarily appear as vertices of the triangulation, due to numerical precision issues in forming the triangulation. Consider the above with a duplicated point:

```python
>>> points = np.array([[0, 0], [0, 1], [1, 0], [1, 1], [1, 1]])
>>> tri = Delaunay(points)
>>> np.unique(tri.simplices.ravel())
array([0, 1, 2, 3], dtype=int32)
```

Observe that point #4, which is a duplicate, does not occur as a vertex of the triangulation. That this happened is recorded:

```python
>>> tri.coplanar
array([[4, 0, 3]], dtype=int32)
```

This means that point 4 resides near triangle 0 and vertex 3, but is not included in the triangulation.

Note that such degeneracies can occur not only because of duplicated points, but also for more complicated geometrical reasons, even in point sets that at first sight seem well-behaved.

However, Qhull has the “QJ” option, which instructs it to perturb the input data randomly until degeneracies are resolved:

```python
>>> tri = Delaunay(points, qhull_options="QJ Pp")
```

Two new triangles appeared. However, we see that they are degenerate and have zero area.

### 2.11.2 Convex hulls

A convex hull is the smallest convex object containing all points in a given point set. These can be computed via the Qhull wrappers in `scipy.spatial` as follows:

```python
>>> from scipy.spatial import ConvexHull
>>> rng = np.random.default_rng()
>>> points = rng.random((30, 2))  # 30 random points in 2-D
>>> hull = ConvexHull(points)

The convex hull is represented as a set of N 1-D simplices, which in 2-D means line segments. The storage scheme is exactly the same as for the simplices in the Delaunay triangulation discussed above.

We can illustrate the above result:
>>> import matplotlib.pyplot as plt
>>> plt.plot(points[:,0], points[:,1], 'o')
>>> for simplex in hull.simplices:
...    plt.plot(points[simplex,0], points[simplex,1], 'k-')
>>> plt.show()

The same can be achieved with `scipy.spatial.convex_hull_plot_2d`.

### 2.11.3 Voronoi diagrams

A Voronoi diagram is a subdivision of the space into the nearest neighborhoods of a given set of points.

There are two ways to approach this object using `scipy.spatial`. First, one can use the `KDTree` to answer the question “which of the points is closest to this one”, and define the regions that way:

```python
>>> from scipy.spatial import KDTree
>>> points = np.array([[0, 0], [0, 1], [0, 2], [1, 0], [1, 1], [1, 2], ...
...                     [2, 0], [2, 1], [2, 2]])
>>> tree = KDTree(points)
>>> tree.query([0.1, 0.1])
(0.14142135623730953, 0)
```

So the point (0.1, 0.1) belongs to region 0. In color:

```python
>>> x = np.linspace(-0.5, 2.5, 31)
>>> y = np.linspace(-0.5, 2.5, 33)
>>> xx, yy = np.meshgrid(x, y)
>>> xy = np.c_[xx.ravel(), yy.ravel()]
>>> import matplotlib.pyplot as plt
>>> dx_half, dy_half = np.diff(x[:2])[0] / 2., np.diff(y[:2])[0] / 2.
>>> x_edges = np.concatenate((x - dx_half, [x[-1] + dx_half]))
>>> y_edges = np.concatenate((y - dy_half, [y[-1] + dy_half]))
>>> plt.pcolormesh(x_edges, y_edges, tree.query(xy)[1].reshape(33, 31),...
...                shading='flat')
```

(continues on next page)
This does not, however, give the Voronoi diagram as a geometrical object.

The representation in terms of lines and points can be again obtained via the Qhull wrappers in `scipy.spatial`:

```python
>>> from scipy.spatial import Voronoi
>>> vor = Voronoi(points)
>>> vor.vertices
array([[0.5, 0.5],
       [0.5, 1.5],
       [1.5, 0.5],
       [1.5, 1.5]])
```

The Voronoi vertices denote the set of points forming the polygonal edges of the Voronoi regions. In this case, there are 9 different regions:

```python
>>> vor.regions
[[], [-1, 0], [-1, 1], [1, -1, 0], [3, -1, 2], [-1, 3], [-1, 2], [0, 1, 3, 2],
 [-1, -1], [2, -1, 0], [3, -1, 1]]
```

Negative value -1 again indicates a point at infinity. Indeed, only one of the regions, [0, 1, 3, 2], is bounded. Note here that due to similar numerical precision issues as in Delaunay triangulation above, there may be fewer Voronoi regions than input points.

The ridges (lines in 2-D) separating the regions are described as a similar collection of simplices as the convex hull pieces:

```python
>>> vor.ridge_vertices
[[-1, 0], [-1, 0], [-1, 1], [-1, 1], [0, 1], [-1, 3], [-1, 2], [2, 3], [-1,
 -3], [-1, 2], [1, 3], [0, 2]]
```

These numbers present the indices of the Voronoi vertices making up the line segments. -1 is again a point at infinity — only 4 of the 12 lines are a bounded line segment, while others extend to infinity.
The Voronoi ridges are perpendicular to the lines drawn between the input points. To which two points each ridge corresponds is also recorded:

```python
>>> vor.ridge_points
array([[0, 3],
       [0, 1],
       [2, 5],
       [2, 1],
       [1, 4],
       [7, 8],
       [7, 6],
       [7, 4],
       [8, 5],
       [6, 3],
       [4, 5],
       [4, 3]], dtype=int32)
```

This information, taken together, is enough to construct the full diagram.

We can plot it as follows. First, the points and the Voronoi vertices:

```python
>>> plt.plot(points[:, 0], points[:, 1], 'o')
>>> plt.plot(vor.vertices[:, 0], vor.vertices[:, 1], '*')
>>> plt.xlim(-1, 3); plt.ylim(-1, 3)
```

Plotting the finite line segments goes as for the convex hull, but now we have to guard for the infinite edges:

```python
>>> for simplex in vor.ridge_vertices:
...     simplex = np.asarray(simplex)
...     if np.all(simplex >= 0):
...         plt.plot(vor.vertices[simplex, 0], vor.vertices[simplex, 1], 'k-')
```  
```python
>>> center = points.mean(axis=0)
>>> for pointidx, simplex in zip(vor.ridge_points, vor.ridge_vertices):
...     simplex = np.asarray(simplex)
...     i = simplex[simplex >= 0][0] # finite end Voronoi vertex
...     t = points[pointidx[1]] - points[pointidx[0]] # tangent
...     t = t / np.linalg.norm(t)
...     n = np.array([-t[1], t[0]]) # normal
...     midpoint = points[pointidx].mean(axis=0)
...     far_point = vor.vertices[i] + np.sign(np.dot(midpoint - center, -n)) * n * 100
...     plt.plot([vor.vertices[i, 0], far_point[0]],
...              [vor.vertices[i, 1], far_point[1]], 'k-')
>>> plt.show()
```

This plot can also be created using `scipy.spatial.voronoi_plot_2d`.

Voronoi diagrams can be used to create interesting generative art. Try playing with the settings of this `mandala` function to create your own!
```python
>>> import numpy as np
>>> from scipy import spatial
>>> import matplotlib.pyplot as plt

>>> def mandala(n_iter, n_points, radius):
    ...     """Creates a mandala figure using Voronoi tessellations.
    ...
    ...     Parameters
    ...     ----------
    ...     n_iter : int
    ...         Number of iterations, i.e. how many times the equidistant points will
    ...         be generated.
    ...     n_points : int
    ...         Number of points to draw per iteration.
    ...     radius : scalar
    ...         The radial expansion factor.

```
2.12 Statistics (scipy.stats)

2.12.1 Introduction

In this tutorial, we discuss many, but certainly not all, features of scipy.stats. The intention here is to provide a user with a working knowledge of this package. We refer to the reference manual for further details.

Note: This documentation is work in progress.
Discrete Statistical Distributions

Discrete random variables take on only a countable number of values. The commonly used distributions are included in SciPy and described in this document. Each discrete distribution can take one extra integer parameter: \( L \). The relationship between the general distribution \( p \) and the standard distribution \( p_0 \) is

\[
p(x) = p_0(x - L)
\]

which allows for shifting of the input. When a distribution generator is initialized, the discrete distribution can either specify the beginning and ending (integer) values \( a \) and \( b \) which must be such that

\[
p_0(x) = 0 \quad x < a \text{ or } x > b
\]

in which case, it is assumed that the pdf function is specified on the integers \( a + mk \leq b \) where \( k \) is a non-negative integer (0, 1, 2, . . .) and \( m \) is a positive integer multiplier. Alternatively, the two lists \( x_k \) and \( p(x_k) \) can be provided directly in which case a dictionary is set up internally to evaluate probabilities and generate random variates.

Probability Mass Function (PMF)

The probability mass function of a random variable \( X \) is defined as the probability that the random variable takes on a particular value.

\[
p(x_k) = P[X = x_k]
\]

This is also sometimes called the probability density function, although technically

\[
f(x) = \sum_k p(x_k) \delta(x - x_k)
\]

is the probability density function for a discrete distribution\(^1\).

Cumulative Distribution Function (CDF)

The cumulative distribution function is

\[
F(x) = P[X \leq x] = \sum_{x_k \leq x} p(x_k)
\]

and is also useful to be able to compute. Note that

\[
F(x_k) - F(x_{k-1}) = p(x_k)
\]

Survival Function

The survival function is just

\[
S(x) = 1 - F(x) = P[X > k]
\]

the probability that the random variable is strictly larger than \( k \).

Percent Point Function (Inverse CDF)

The percent point function is the inverse of the cumulative distribution function and is

\[
G(q) = F^{-1}(q)
\]

for discrete distributions, this must be modified for cases where there is no \( x_k \) such that \( F(x_k) = q \). In these cases we choose \( G(q) \) to be the smallest value \( x_k = G(q) \) for which \( F(x_k) \geq q \). If \( q = 0 \) then we define \( G(0) = a - 1 \). This definition allows random variates to be defined in the same way as with continuous rv’s using the inverse cdf on a uniform distribution to generate random variates.

\(^1\) XXX: Unknown layout Plain Layout: Note that we will be using \( p \) to represent the probability mass function and a parameter (a XXX: probability). The usage should be obvious from context.
Inverse survival function

The inverse survival function is the inverse of the survival function

\[ Z(\alpha) = S^{-1}(\alpha) = G(1 - \alpha) \]

and is thus the smallest non-negative integer \( k \) for which \( F(k) \geq 1 - \alpha \) or the smallest non-negative integer \( k \) for which \( S(k) \leq \alpha \).

Hazard functions

If desired, the hazard function and the cumulative hazard function could be defined as

\[ h(x) = \frac{p(x)}{1 - F(x)} \]

and

\[ H(x) = \sum_{x_k \leq x} h(x_k) = \sum_{x_k \leq x} \frac{F(x_k) - F(x_{k-1})}{1 - F(x_k)}. \]

Moments

Non-central moments are defined using the PDF

\[ \mu'_m = E[X^m] = \sum_k x_k^m p(x_k). \]

Central moments are computed similarly \( \mu = \mu'_1 \)

\[ \mu_m = E[(X - \mu)^m] = \sum_k (x_k - \mu)^m p(x_k) \]

\[ = \sum_{k=0}^{m} (-1)^{m-k} \binom{m}{k} \mu^{m-k} \mu'_k \]

The mean is the first moment

\[ \mu = \mu'_1 = E[X] = \sum_k x_k p(x_k) \]

the variance is the second central moment

\[ \mu_2 = E[(X - \mu)^2] = \sum_{x_k} x_k^2 p(x_k) - \mu^2. \]

Skewness is defined as

\[ \gamma_1 = \frac{\mu_3}{\mu_2^{3/2}} \]

while (Fisher) kurtosis is

\[ \gamma_2 = \frac{\mu_4}{\mu_2^2} - 3, \]

so that a normal distribution has a kurtosis of zero.
Moment generating function

The moment generating function is defined as

\[ M_X(t) = E[e^{Xt}] = \sum_{x_k} e^{x_k t} p(x_k) \]

Moments are found as the derivatives of the moment generating function evaluated at 0.

Fitting data

To fit data to a distribution, maximizing the likelihood function is common. Alternatively, some distributions have well-known minimum variance unbiased estimators. These will be chosen by default, but the likelihood function will always be available for minimizing.

If \( f_i(k; \theta) \) is the PDF of a random-variable where \( \theta \) is a vector of parameters (e.g. \( L \) and \( S \)), then for a collection of \( N \) independent samples from this distribution, the joint distribution the random vector \( k \) is

\[ f(k; \theta) = \prod_{i=1}^{N} f_i(k_i; \theta). \]

The maximum likelihood estimate of the parameters \( \theta \) are the parameters which maximize this function with \( x \) fixed and given by the data:

\[ \hat{\theta} = \arg \max_{\theta} f(k; \theta) \]
\[ = \arg \min_{\theta} l_k(\theta). \]

Where

\[ l_k(\theta) = -\sum_{i=1}^{N} \log f(k_i; \theta) \]
\[ = -N \log f(k_i; \theta) \]

Standard notation for mean

We will use

\[ \overline{y(x)} = \frac{1}{N} \sum_{i=1}^{N} y(x_i) \]

where \( N \) should be clear from context.

Combinations

Note that

\[ k! = k \cdot (k - 1) \cdot (k - 2) \cdot \ldots \cdot 1 = \Gamma(k + 1) \]

and has special cases of

\[ 0! \equiv 1 \]
\[ k! \equiv 0 \quad k < 0 \]

and

\[ \binom{n}{k} = \frac{n!}{(n-k)!k!} \]

If \( n < 0 \) or \( k < 0 \) or \( k > n \) we define \( \binom{n}{k} = 0 \)
Discrete Distributions in `scipy.stats`

Bernoulli Distribution

A Bernoulli random variable of parameter $p$ takes one of only two values $X = 0$ or $X = 1$. The probability of success ($X = 1$) is $p$, and the probability of failure ($X = 0$) is $1 - p$. It can be thought of as a binomial random variable with $n = 1$. The PMF is $p(k) = 0$ for $k \neq 0, 1$ and

$$
p(k; p) = \begin{cases} 
1 - p & k = 0 \\
p & k = 1 
\end{cases}
$$

$$
F(x; p) = \begin{cases} 
0 & x < 0 \\
1 - p & 0 \leq x < 1 \\
1 & 1 \leq x 
\end{cases}
$$

$$
G(q; p) = \begin{cases} 
0 & 0 \leq q < 1 - p \\
1 - p & 1 - p \leq q \leq 1 
\end{cases}
$$

$$
\mu = p
$$

$$
\mu_2 = p(1 - p)
$$

$$
\gamma_3 = \frac{1 - 2p}{\sqrt{p(1 - p)}}
$$

$$
\gamma_4 = \frac{1 - 6p(1 - p)}{p(1 - p)}
$$

$$
M(t) = 1 - p(1 - e^t)
$$

$$
\mu'_m = p
$$

$$
h[X] = p \log p + (1 - p) \log (1 - p)
$$

Implementation: `scipy.stats.bernoulli`

Beta-Binomial Distribution

The beta-binomial distribution is a binomial distribution with a probability of success $p$ that follows a beta distribution. The probability mass function for `betabinom`, defined for $0 \leq k \leq n$, is:

$$
f(k; n, a, b) = \binom{n}{k} \frac{B(k + a, n - k + b)}{B(a, b)}
$$

for $k$ in $\{0, 1, \ldots, n\}$, where $B(a, b)$ is the Beta function.

In the limiting case of $a = b = 1$, the beta-binomial distribution reduces to a discrete uniform distribution:

$$
f(k; n, 1, 1) = \frac{1}{n + 1}
$$

In the limiting case of $n = 1$, the beta-binomial distribution reduces to a Bernoulli distribution with the shape parameter $p = a/(a + b)$:

$$
f(k; 1, a, b) = \begin{cases} 
a/(a + b) & \text{if } k = 0 \\
b/(a + b) & \text{if } k = 1 
\end{cases}
$$

Implementation: `scipy.stats.betabinom`
Binomial Distribution

A binomial random variable with parameters \((n, p)\) can be described as the sum of \(n\) independent Bernoulli random variables of parameter \(p\);

\[
Y = \sum_{i=1}^{n} X_i.
\]

Therefore, this random variable counts the number of successes in \(n\) independent trials of a random experiment where the probability of success is \(p\).

\[
p(k; n, p) = \binom{n}{k} p^k (1 - p)^{n-k} \quad k \in \{0, 1, \ldots, n\},
\]

\[
F(x; n, p) = \sum_{k \leq x} \binom{n}{k} p^k (1 - p)^{n-k} = I_{1-p} (n - \lfloor x \rfloor, \lfloor x \rfloor + 1) \quad x \geq 0
\]

where the incomplete beta integral is

\[
I_x(a, b) = \frac{\Gamma(a + b)}{\Gamma(a) \Gamma(b)} \int_0^x t^{a-1} (1 - t)^{b-1} dt.
\]

Now

\[
\mu = np
\]

\[
\mu_2 = np(1 - p)
\]

\[
\gamma_1 = \frac{1 - 2p}{\sqrt{np(1 - p)}}
\]

\[
\gamma_2 = \frac{1 - 6p(1 - p)}{np(1 - p)}.
\]

\[
M(t) = \left[1 - p \left(1 - e^t\right)\right]^n
\]

Implementation: \texttt{scipy.stats.binom}

Boltzmann (truncated Planck) Distribution

\[
p(k; N, \lambda) = \frac{1 - e^{-\lambda}}{1 - e^{-\lambda N}} \exp(-\lambda k) \quad k \in \{0, 1, \ldots, N - 1\}
\]

\[
F(x; N, \lambda) = \begin{cases} 
0 & x < 0 \\
\frac{\exp(-\lambda \lfloor x \rfloor + 1)}{\exp(-\lambda N)} & 0 \leq x < N - 1 \\
1 - \exp(-\lambda N) & x \geq N - 1
\end{cases}
\]

\[
G(q, \lambda) = -\frac{1}{\lambda} \log \left[1 - q \left(1 - e^{-\lambda N}\right)\right] - 1
\]
Define $z = e^{-\lambda}$

\[
\begin{align*}
\mu & = \frac{z}{1-z} - \frac{Nz^N}{1-z^N} \\
\mu_2 & = \frac{z}{(1-z)^2} - \frac{N^2z^N}{(1-z^N)^2} \\
\gamma_1 & = \frac{z (1 + z) \left( \frac{1-z^N}{1-z} \right)^3 - N^3z^N (1 + z^N)}{\left[ z \left( \frac{1-z^N}{1-z} \right)^2 - N^2z^N \right]^{3/2}} \\
\gamma_2 & = \frac{z \left( 1 + 4z + z^2 \right) \left( \frac{1-z^N}{1-z} \right)^4 - N^4z^N (1 + 4z^N + z^2N)}{\left[ z \left( \frac{1-z^N}{1-z} \right)^2 - N^2z^N \right]^2} \\
M (t) & = \frac{1 - e^{N(t-\lambda)}}{1 - e^{t-\lambda}} \frac{1 - e^{-\lambda}}{1 - e^{-\lambda N}}
\end{align*}
\]

Implementation: `scipy.stats.boltzmann`

**Planck (discrete exponential) Distribution**

Named Planck because of its relationship to the black-body problem he solved.

\[
\begin{align*}
p (k; \lambda) & = (1 - e^{-\lambda}) e^{-\lambda k} \quad k \lambda \geq 0 \\
F (x; \lambda) & = 1 - e^{-\lambda (\lfloor x \rfloor + 1)} \quad x \lambda \geq 0 \\
G (q; \lambda) & = \left\lfloor -\frac{1}{\lambda} \log [1 - q] - 1 \right\rfloor.
\end{align*}
\]

\[
\begin{align*}
\mu & = \frac{1}{e^\lambda - 1} \\
\mu_2 & = \frac{e^{-\lambda}}{(1 - e^{-\lambda})^2} \\
\gamma_1 & = 2 \cosh \left( \frac{\lambda}{2} \right) \\
\gamma_2 & = 4 + 2 \cosh (\lambda) \\
M (t) & = \frac{1 - e^{-\lambda}}{1 - e^{t-\lambda}} \\
h [X] & = \frac{\lambda e^{-\lambda}}{1 - e^{-\lambda}} - \log (1 - e^{-\lambda})
\end{align*}
\]

Implementation: `scipy.stats.planck`
**Poisson Distribution**

The Poisson random variable counts the number of successes in \( n \) independent Bernoulli trials in the limit as \( n \to \infty \) and \( p \to 0 \) where the probability of success in each trial is \( p \) and \( np = \lambda \geq 0 \) is a constant. It can be used to approximate the Binomial random variable or in its own right to count the number of events that occur in the interval \([0, t]\) for a process satisfying certain “sparsity” constraints. The functions are:

\[
p(k; \lambda) = e^{-\lambda} \frac{\lambda^k}{k!} \quad k \geq 0,
\]

\[
F(x; \lambda) = \sum_{n=0}^{\lfloor x \rfloor} e^{-\lambda} \frac{\lambda^n}{n!} = \frac{1}{\Gamma(\lfloor x \rfloor + 1)} \int_0^\infty t^{\lfloor x \rfloor} e^{-t} dt,
\]

\[
\mu = \lambda
\]
\[
\mu_2 = \lambda
\]
\[
\gamma_1 = \frac{1}{\sqrt{\lambda}}
\]
\[
\gamma_2 = \frac{1}{\lambda}
\]

\[M(t) = \exp[\lambda(e^t - 1)].\]

Implementation: `scipy.stats.poisson`

**Geometric Distribution**

The geometric random variable with parameter \( p \in (0, 1) \) can be defined as the number of trials required to obtain a success where the probability of success on each trial is \( p \). Thus,

\[
p(k; p) = (1-p)^{k-1} p \quad k \geq 1
\]
\[
F(x; p) = 1 - (1-p)^{\lfloor x \rfloor} \quad x \geq 1
\]
\[
G(q; p) = \begin{bmatrix} \log(1-q) \\ \log(1-p) \end{bmatrix}
\]

\[
\mu = \frac{1}{p}
\]
\[
\mu_2 = \frac{1-p}{p^2}
\]
\[
\gamma_1 = \frac{2-p}{\sqrt{1-p}}
\]
\[
\gamma_2 = \frac{p^2 - 6p + 6}{1-p}
\]

\[M(t) = \frac{p}{e^t - (1-p)}\]

Implementation: `scipy.stats.geom`
Negative Binomial Distribution

The negative binomial random variable with parameters $n$ and $p \in (0, 1)$ can be defined as the number of extra independent trials (beyond $n$) required to accumulate a total of $n$ successes where the probability of a success on each trial is $p$. Equivalently, this random variable is the number of failures encountered while accumulating $n$ successes during independent trials of an experiment that succeeds with probability $p$. Thus,

$$
p(k; n, p) = \binom{k + n - 1}{n - 1} p^n (1 - p)^k \quad k \geq 0
$$

$$
F(x; n, p) = \sum_{i=0}^{\lfloor x \rfloor} \binom{i + n - 1}{i} p^n (1 - p)^i \quad x \geq 0
$$

$$
= I_p(n, \lfloor x \rfloor + 1) \quad x \geq 0
$$

$$
\mu = \frac{n (1 - p)}{p}
$$

$$
\mu_2 = \frac{n (1 - p)}{p^2}
$$

$$
\gamma_1 = \frac{2 - p}{\sqrt{n (1 - p)}}
$$

$$
\gamma_2 = \frac{p^2 + 6 (1 - p)}{n (1 - p)}.
$$

Recall that $I_p(a, b)$ is the incomplete beta integral.

Implementation: `scipy.stats.nbinom`

Hypergeometric Distribution

The hypergeometric random variable with parameters $(M, n, N)$ counts the number of “good” objects in a sample of size $N$ chosen without replacement from a population of $M$ objects where $n$ is the number of “good” objects in the total population.

$$
p(k; N, n, M) = \binom{n}{k} \binom{M - n}{N - k} \binom{M}{N} \quad N - (M - n) \leq k \leq \min(n, N)
$$

$$
F(x; N, n, M) = \sum_{k=0}^{\lfloor x \rfloor} \binom{m}{k} \binom{N - m}{n - k} \binom{N}{n},
$$

$$
\mu = \frac{nN}{M}
$$

$$
\mu_2 = \frac{nN (M - n) (M - N)}{M^2 (M - 1)}
$$

$$
\gamma_1 = \frac{(M - 2n) (M - 2N)}{M - 2} \sqrt{\frac{M - 1}{nN (M - m) (M - n)}}
$$

$$
\gamma_2 = \frac{g(N, n, M)}{nN (M - n) (M - 3) (M - 2) (N - M)}
$$
where (defining $m = M - n$)

$$g(N, n, M) = m^3 - m^5 + 3m^2n - 6m^3n + m^4n + 3mn^2$$

$$-12m^2n^2 + 8m^3n^2 + n^3 - 6mn^3 + 8m^2n^3$$

$$+mn^4 - n^5 - 6m^3N + 6m^4N + 18m^2nN$$

$$-6m^3nN + 18mn^2N - 24m^2n^2N - 6n^3N$$

$$-6mn^3N + 6n^4N + 6m^2N^2 - 6m^3N^2 - 24mnN^2$$

$$+12m^2N^2 + 6n^2N^2 + 12mn^2N^2 - 6n^3N^2.$$  

Implementation: `scipy.stats.hypergeom`

**Fisher’s Noncentral Hypergeometric Distribution**

A random variable has Fisher’s Noncentral Hypergeometric distribution with parameters

$M \in \mathbb{N}, n \in [0, M], N \in [0, M], \omega > 0$,

if its probability mass function is given by

$$p(x; M, n, N, \omega) = \binom{n}{x} \binom{M-n}{N-x} \omega^x,$$

for $x \in [x_l, x_u]$, where $x_l = \max(0, N - (M - n))$, $x_u = \min(N, n)$,

$$P_k = \sum_{y=x_l}^{x_u} \binom{n}{y} \binom{M-n}{N-y} \omega^y y^k,$$

and the binomial coefficients are

$$\binom{n}{k} = \frac{n!}{k!(n-k)!}.$$

Other functions of this distribution are

$$\mu = \frac{P_0}{P_1},$$

$$\mu_2 = \frac{P_2}{P_0} - \left(\frac{P_1}{P_0}\right)^2.$$

Wallenius’ Noncentral Hypergeometric Distribution

A random variable has Wallenius’ Noncentral Hypergeometric distribution with parameters $M \in \mathbb{N}, n \in [0, M], N \in [0, M], \omega > 0,$ if its probability mass function is given by

$$p(x; N, n, M) = \binom{n}{x} \binom{M-n}{N-x} \int_{0}^{1} \left(1 - \frac{t^\omega}{D} \right)^x \left(1 - \frac{t^1/D}{N-x} \right)^{N-x} dt$$

for $x \in [x_l, x_u]$, where $x_l = \max(0, N - (M - n)), x_u = \min(N, n)$,

$$D = \omega(n - x) + ((M - n) - (N - x)),$$

and the binomial coefficients are

$$\binom{n}{k} \equiv \frac{n!}{k!(n-k)!}.$$  

References

Implementation: scipy.stats.nchypergeom_wallenius

Negative Hypergeometric Distribution

Consider a box containing $M$ balls: $n$ red and $M - n$ blue. We randomly sample balls from the box, one at a time and without replacement, until we have picked $r$ blue balls. nhypergeom is the distribution of the number of red balls $k$ we have picked.

$$p(k; M, n, r) = \binom{k+r-1}{k} \binom{M-r-k}{n-k} \binom{M}{n} 0 \leq k \leq M - n,$$

$$F(x; M, n, r) = \sum_{k=0}^{\lfloor x \rfloor} p(k; M, n, r),$$

$$\mu = \frac{rn}{M-n+1},$$

$$\mu_2 = \frac{rn(M + 1)}{(M-n+1)(M-n+2)} \left(1 - \frac{r}{M-n+1} \right)$$

for $k \in 0, 1, \ldots, n$, where the binomial coefficients are defined as,

$$\binom{n}{k} \equiv \frac{n!}{k!(n-k)!}.$$  

The cumulative distribution, survivor function, hazard function, cumulative hazard function, inverse distribution function, moment generating function, and characteristic function on the support of $k$ are mathematically intractable.

Implementation: scipy.stats.nhypergeom
Zipf (Zeta) Distribution

A random variable has the zeta distribution (also called the zipf distribution) with parameter $\alpha > 1$ if its probability mass function is given by

$$p(k; \alpha) = \frac{1}{\zeta(\alpha) k^\alpha} \quad k \geq 1$$

where

$$\zeta(\alpha) = \sum_{n=1}^{\infty} \frac{1}{n^\alpha}$$

is the Riemann zeta function. Other functions of this distribution are

$$F(x; \alpha) = \frac{1}{\zeta(\alpha)} \sum_{k=1}^{\lfloor x \rfloor} \frac{1}{k^\alpha}$$

$$\mu = \frac{\zeta_1}{\zeta_0} \quad \alpha > 2$$

$$\mu_2 = \frac{\zeta_2 \zeta_0 - \zeta_1^2}{\zeta_0^2} \quad \alpha > 3$$

$$\gamma_1 = \frac{\zeta_3 \zeta_0^2 - 3 \zeta_0 \zeta_1 \zeta_2 + 2 \zeta_1^3}{(\zeta_2 \zeta_0 - \zeta_1^2)^{3/2}} \quad \alpha > 4$$

$$\gamma_2 = \frac{\zeta_4 \zeta_0^3 - 4 \zeta_3 \zeta_1 \zeta_0^2 + 12 \zeta_2 \zeta_1^2 \zeta_0 - 6 \zeta_1^4 - 3 \zeta_2^2 \zeta_0^2}{(\zeta_2 \zeta_0 - \zeta_1^2)^2}$$

$$M(t) = \frac{\text{Li}_n(e^t)}{\zeta(\alpha)}$$

where $\zeta_i = \zeta(\alpha - i)$ and $\text{Li}_n(z)$ is the $n$th polylogarithm function of $z$ defined as

$$\text{Li}_n(z) = \sum_{k=1}^{\infty} \frac{z^k}{k^n}$$

$$\mu'_n = M^{(n)}(t) \bigg|_{t=0} = \frac{\text{Li}_{n-n}(e^t)}{\zeta(\alpha)} \bigg|_{t=0} = \frac{\zeta(\alpha - n)}{\zeta(\alpha)}$$

Implementation: `scipy.stats.zipf`

Zipfian Distribution

A random variable has the Zipfian distribution with parameters $s \geq 0$ and $N \in \{1, 2, 3, \ldots\}$ if its probability mass function is given by

$$p(k; s, N) = \frac{1}{H_{N,s} k^s} \quad k \in \{1, 2, \ldots, n-1, n\}$$

where

$$H_{N,s} = \sum_{n=1}^{N} \frac{1}{n^s}$$
is the $N^{th}$ generalized harmonic number of order $s$. Other functions of this distribution are

$$ F(x; s, N) = \frac{H_{k,s}}{H_{N,s}} $$

$$ \mu = \frac{H_{N,s-1}}{H_{N,s}} $$

$$ \mu_2 = \frac{H_{N,s-2}}{H_{N,s}} - \frac{H_{N,s-1}^2}{H_{N,s}^2} $$

$$ \gamma_1 = \frac{H_{N,s-3}}{H_{N,s}} - \frac{3H_{N,s-1}H_{N,s-2}}{H_{N,s}^2} + \frac{2H_{N,s-1}^3}{H_{N,s}^3}, \quad \text{and} $$

$$ \gamma_2 = \frac{H_{N,s}^3 H_{N,s-4} - 4H_{N,s}^2 H_{N,s-1} H_{N,s-3} + 6H_{N,s} H_{N,s-1}^2 H_{N,s-2} - 3H_{N,s-1}^4}{(H_{N,s-2} H_{N,s} - H_{N,s-1}^2)^2}. $$

References

Implementation: scipy.stats.zipfian

Logarithmic (Log-Series, Series) Distribution

The logarithmic distribution with parameter $p$ has a probability mass function with terms proportional to the Taylor series expansion of $\log (1 - p)$

$$ p(k; p) = -\frac{p^k}{k \log (1 - p)} \quad k \geq 1 $$

$$ F(x; p) = -\frac{1}{\log (1 - p)} \sum_{k=1}^{[x]} \frac{p^k}{k} = 1 + \frac{p^{1+[x]} \Phi(p, 1, 1+[x])}{\log (1 - p)} $$

where

$$ \Phi(z, s, a) = \sum_{k=0}^{\infty} \frac{z^k}{(a+k)^s} $$

is the Lerch Transcendent. Also define $r = \log (1 - p)$

$$ \mu = -\frac{p}{(1 - p) r} $$

$$ \mu_2 = -\frac{p [p + r]}{(1 - p)^2 r^2} $$

$$ \gamma_1 = -\frac{2p^2 + 3pr + (1 + p) r^2}{r (p + r) \sqrt{-p (p + r)}} $$

$$ \gamma_2 = -\frac{6p^3 + 12p^2 r + p (4p + 7) r^2 + (p^2 + 4p + 1) r^3}{p (p + r)^2}. $$
\[ M(t) = -\frac{1}{\log (1-p)} \sum_{k=1}^{\infty} \frac{e^{tk} p^k}{k} = \frac{\log (1 - pe^t)}{\log (1 - p)} \]

Thus,
\[ \mu'_n = M^{(n)}(t) \bigg|_{t=0} = \frac{\text{Li}_{1-n}(pe^t)}{\log (1 - p)} \bigg|_{t=0} = -\frac{\text{Li}_{1-n}(p)}{\log (1 - p)}. \]

Implementation: `scipy.stats.logser`

**Discrete Uniform (randint) Distribution**

The discrete uniform distribution with parameters \((a, b)\) constructs a random variable that has an equal probability of being any one of the integers in the half-open range \([a, b)\). If \(a\) is not given it is assumed to be zero and the only parameter is \(b\). Therefore,

\[ p(k, a, b) = \frac{1}{b-a} \quad a \leq k < b \]

\[ F(x; a, b) = \frac{|x| - a}{b - a} \quad a \leq x < b \]

\[ G(q; a, b) = \frac{q(b - a) + a}{b + a - 1} \]

\[ \mu = \frac{(b - a - 1)(b - a + 1)}{2} \]

\[ \mu_2 = \frac{(b - a - 1)(b - a + 1)}{12} \]

\[ \gamma_1 = 0 \]

\[ \gamma_2 = -\frac{6}{5} \frac{(b - a)^2 + 1}{(b - a - 1)(b - a + 1)}. \]

\[ M(t) = \frac{1}{b-a} \sum_{k=a}^{b-1} e^{tk} = e^{bt} - e^{at} \]

\[ \frac{(b-a)}{(b-a)(e^a - 1)} \]

Implementation: `scipy.stats.randint`

**Discrete Laplacian Distribution**

Defined over all integers for \(a > 0\)

\[ p(k) = \tanh \left( \frac{a}{2} \right) e^{-a|k|}, \]

\[ F(x) = \begin{cases} e^{ax} / (e^{ax} + 1) & |x| < 0, \\ 1 - e^{-(x+1)/a} & |x| \geq 0. \end{cases} \]

\[ G(q) = \begin{cases} \frac{1}{a} \log \left[ q \left( e^a + 1 \right) - 1 \right] & q < \frac{1}{1+e^a}, \\ \frac{1}{a} \log \left[ (1 - q) (1 + e^a) \right] & q \geq \frac{1}{1+e^a}. \end{cases} \]
\[ M(t) = \tanh \left( \frac{a}{2} \right) \sum_{k=\infty}^{\infty} e^{tk} e^{-a|k|} \]
\[ = C \left( 1 + \sum_{k=1}^{\infty} e^{-(t+a)k} + \sum_{1}^{\infty} e^{(t-a)k} \right) \]
\[ = \tanh \left( \frac{a}{2} \right) \left( 1 + \frac{e^{-(t+a)}}{1-e^{-(t+a)}} + \frac{e^{t-a}}{1-e^{t-a}} \right) \]
\[ = \frac{\tanh \left( \frac{a}{2} \right) \sinh a}{\cosh a - \cosh t}. \]

Thus,
\[ \mu_n' = M^{(n)}(0) = [1 + (-1)^n] \text{Li}_{-n}(e^{-a}) \]

where \( \text{Li}_{-n}(z) \) is the polylogarithm function of order \(-n\) evaluated at \(z\).

\[ h[X] = -\log \left( \tanh \left( \frac{a}{2} \right) \right) + \frac{a}{\sinh a} \]

Implementation: `scipy.stats.dlaplace`

**Yule-Simon Distribution**

A Yule-Simon random variable with parameter \( \alpha > 0 \) can be represented as a mixture of exponential random variates. To see this write \( W \) as an exponential random variate with rate \( \rho \) and a Geometric random variate \( K \) with probability \( 1 - \exp(-W) \) then \( K \) marginally has a Yule-Simon distribution. The latent variable representation described above is used for random variate generation.

\[ p(k; \alpha) = \frac{\Gamma(k) \Gamma(\alpha + 1)}{\Gamma(k + \alpha + 1)} \]
\[ F(k; \alpha) = 1 - \frac{k \Gamma(k) \Gamma(\alpha + 1)}{\Gamma(k + \alpha + 1)} \]

for \( k = 1, 2, \ldots \).

Now
\[ \mu = \frac{\alpha}{\alpha - 1} \]
\[ \mu_2 = \frac{\alpha^2}{(\alpha - 1)^2(\alpha - 2)} \]
\[ \gamma_1 = \frac{\sqrt{(\alpha - 2)(\alpha + 1)^2}}{\alpha(\alpha - 3)} \]
\[ \gamma_2 = \frac{(\alpha + 3) + (\alpha^2 - 49\alpha - 22)}{\alpha(\alpha - 4)(\alpha - 3)} \]

for \( \alpha > 1 \) otherwise the mean is infinite and the variance does not exist. For the variance, \( \alpha > 2 \) otherwise the variance does not exist. Similarly, for the skewness and kurtosis to be finite, \( \alpha > 3 \) and \( \alpha > 4 \) respectively.

Implementation: `scipy.stats.yulesimon`
Continuous Statistical Distributions

Overview

All distributions will have location (L) and Scale (S) parameters along with any shape parameters needed, the names for the shape parameters will vary. Standard form for the distributions will be given where \( L = 0.0 \) and \( S = 1.0 \). The nonstandard forms can be obtained for the various functions using (note \( U \) is a standard uniform random variate).

</tbody>
</table>

Moments

Non-central moments are defined using the PDF

\[
\mu_n' = \int_{-\infty}^{\infty} x^n f(x) \, dx.
\]

Note, that these can always be computed using the PPF. Substitute \( x = G(q) \) in the above equation and get

\[
\mu_n' = \int_{0}^{1} G^n(q) \, dq
\]

which may be easier to compute numerically. Note that \( q = F(x) \) so that \( dq = f(x) \, dx \). Central moments are computed similarly \( \mu = \mu_1' \)

\[
\mu_n = \int_{-\infty}^{\infty} (x - \mu)^n f(x) \, dx
= \int_{0}^{1} (G(q) - \mu)^n \, dq
= \sum_{k=0}^{n} \binom{n}{k} (-\mu)^k \mu'_n \]
In particular

\[
\begin{align*}
\mu_3 &= \mu_3' - 3\mu_2' + 2\mu^3 \\
&= \mu_3' - 3\mu_2 - \mu^3 \\
\mu_4 &= \mu_4' - 4\mu_3' + 6\mu_2^2 - 3\mu^4 \\
&= \mu_4' - 4\mu_3 - 6\mu_2\mu_2 - \mu^4
\end{align*}
\]

Skewness is defined as

\[
\gamma_1 = \sqrt{\beta_1} = \frac{\mu_3}{\mu_2^{3/2}}
\]

while (Fisher) kurtosis is

\[
\gamma_2 = \frac{\mu_4}{\mu_2^2} - 3,
\]

so that a normal distribution has a kurtosis of zero.

**Median and mode**

The median, \( m_n \) is defined as the point at which half of the density is on one side and half on the other. In other words, \( F(m_n) = \frac{1}{2} \) so that

\[
m_n = G \left( \frac{1}{2} \right).
\]

In addition, the mode, \( m_d \), is defined as the value for which the probability density function reaches it’s peak

\[
m_d = \arg \max_x f(x).
\]

**Fitting data**

To fit data to a distribution, maximizing the likelihood function is common. Alternatively, some distributions have well-known minimum variance unbiased estimators. These will be chosen by default, but the likelihood function will always be available for minimizing.

If \( f(x; \theta) \) is the PDF of a random-variable where \( \theta \) is a vector of parameters (e.g. \( L \) and \( S \)), then for a collection of \( N \) independent samples from this distribution, the joint distribution the random vector \( x \) is

\[
f(x; \theta) = \prod_{i=1}^{N} f(x_i; \theta).
\]

The maximum likelihood estimate of the parameters \( \theta \) are the parameters which maximize this function with \( x \) fixed and given by the data:

\[
\theta_{es} = \arg \max_{\theta} f(x; \theta) = \arg \min_{\theta} l_x(\theta).
\]

Where

\[
l_x(\theta) = -\sum_{i=1}^{N} \log f(x_i; \theta) = -N \log f(x_i; \theta)
\]
Note that if $\theta$ includes only shape parameters, the location and scale parameters can be fit by replacing $x_i$ with $(x_i - L) / S$ in the log-likelihood function adding $N \log S$ and minimizing, thus

$$
\ln_x (L, S; \theta) = N \log S - \sum_{i=1}^{N} \log f \left( \frac{x_i - L}{S}; \theta \right)
$$

$$
= N \log S + \ln_{x-s} (\theta)
$$

If desired, sample estimates for $L$ and $S$ (not necessarily maximum likelihood estimates) can be obtained from samples estimates of the mean and variance using

$$
\hat{S} = \sqrt{\frac{\mu_2}{\mu_2}}
$$

$$
\hat{L} = \mu - \hat{S} \mu
$$

where $\mu$ and $\mu_2$ are assumed known as the mean and variance of the untransformed distribution (when $L = 0$ and $S = 1$) and

$$
\hat{\mu} = \frac{1}{N} \sum_{i=1}^{N} x_i = \bar{x}
$$

$$
\hat{\mu_2} = \frac{1}{N-1} \sum_{i=1}^{N} (x_i - \hat{\mu})^2 = \frac{N}{N-1} (\bar{x} - \mu)^2
$$

**Standard notation for mean**

We will use

$$
y(x) = \frac{1}{N} \sum_{i=1}^{N} y(x_i)
$$

where $N$ should be clear from context as the number of samples $x_i$

### Continuous Distributions in `scipy.stats`

#### Alpha Distribution

One shape parameter $\alpha > 0$ (parameter $\beta$ in DATAPLOT is a scale-parameter). The support for the standard form is $x > 0$.

$$f(x;\alpha) = \frac{1}{x^2\Phi(\alpha)\sqrt{2\pi}} \exp \left(-\frac{1}{2} \left( \alpha - \frac{1}{x} \right)^2 \right)$$

$$F(x;\alpha) = \frac{\Phi(\alpha - \frac{1}{x})}{\Phi(\alpha)}$$

$$G(q;\alpha) = \left[ \alpha - \Phi^{-1}(q\Phi(\alpha)) \right]^{-1}$$

$$M(t) = \frac{1}{\Phi(\alpha)\sqrt{2\pi}} \int_0^\infty \frac{e^{xt}}{x^2} \exp \left(-\frac{1}{2} \left( \alpha - \frac{1}{x} \right)^2 \right) \, dx$$

No moments?

$$l_x(\alpha) = N \log \left[ \Phi(\alpha) \sqrt{2\pi} \right] + 2N \log x + \frac{N}{2} \alpha^2 - \alpha x^{-1} + \frac{1}{2} x^{-2}$$

Implementation: `scipy.stats.alpha`

#### Anglit Distribution

Defined over $x \in \left[ -\frac{\pi}{4}, \frac{\pi}{4} \right]$.

$$f(x) = \sin \left( 2x + \frac{\pi}{2} \right) = \cos (2x)$$

$$F(x) = \sin^2 \left( x + \frac{\pi}{4} \right)$$

$$G(q) = \arcsin \left( \sqrt{q} \right) - \frac{\pi}{4}$$
\[ \mu = 0 \]
\[ \mu_2 = \frac{\pi^2}{16} - \frac{1}{2} \]
\[ \gamma_1 = 0 \]
\[ \gamma_2 = -2 \frac{\pi^4 - 96}{(\pi^2 - 8)^2} \]

\[ h[X] = 1 - \log 2 \approx 0.30685281944005469058 \]

\[ M(t) = \int_{-\frac{\pi}{4}}^{\frac{\pi}{4}} \cos(2x)e^{xt}dx \]
\[ = \frac{4 \cosh(\frac{\pi t}{4})}{t^2 + 4} \]

\[ l_x(\cdot) = -N \log[\cos(2x)] \]

Implementation: \texttt{scipy.stats.anglit}

**Arcsine Distribution**

Defined over \( x \in [0, 1] \). To get the definition presented in Johnson, Kotz, and Balakrishnan, substitute \( x = \frac{u+1}{2} \), i.e. \( L = -1 \) and \( S = 2 \).

\[ f(x) = \frac{1}{\pi \sqrt{x(1-x)}} \]
\[ F(x) = \frac{2}{\pi} \arcsin(\sqrt{x}) \]
\[ G(q) = \sin^2\left(\frac{\pi}{2} q\right) \]

\[ M(t) = 1 + \sum_{k=1}^{\infty} \left( \frac{k-1}{\prod_{r=0}^{k-1} \frac{2r+1}{2r+2}} \right) \frac{t^k}{k!} \]

\[ \mu'_n = \frac{1}{\pi} \int_0^1 x^{n-1/2} (1-x)^{-1/2} \, dx \]
\[ = \frac{1}{\pi} B\left(\frac{1}{2}, n + \frac{1}{2}\right) = \frac{(2n-1)!!}{2^n n!} \]

\[ \mu = \frac{1}{2} \]
\[ \mu_2 = \frac{1}{8} \]
\[ \gamma_1 = 0 \]
\[ \gamma_2 = -\frac{3}{2} \]

\[ h[X] = \log\left(\frac{\pi}{4}\right) \approx -0.2415644752704904468 \]

\[ l_x(\cdot) = N \log \pi + \frac{N}{2} \log x + \frac{N}{2} \log (1-x) \]
References

Implementation: scipy.stats.arcsine

**Beta Distribution**

There are two shape parameters \( a, b > 0 \) and the support is \( x \in [0, 1] \).

\[
\begin{align*}
    f(x; a, b) &= \frac{\Gamma(a + b)}{\Gamma(a) \Gamma(b)} x^{a-1} (1 - x)^{b-1} \\
    F(x; a, b) &= \int_0^x f(y; a, b) \, dy = I(x; a, b) \\
    G(q; a, b) &= I^{-1}(q; a, b) \\
    M(t) &= \frac{\Gamma(a)}{\Gamma(a + b)} \, _1F_1(a; a + b; t) \\
    \mu &= \frac{a}{a + b} \\
    \mu_2 &= \frac{ab(a + b + 1)}{(a + b)^2} \\
    \gamma_1 &= 2 \frac{b - a}{a + b + 2} \sqrt{\frac{a + b + 1}{ab}} \\
    \gamma_2 &= \frac{6 (a^2 + a^2 (1 - 2b) + b^2 (b + 1) - 2ab (b + 2))}{ab(a + b + 2)(a + b + 3)} \\
    m_d &= \frac{(a - 1)}{(a + b - 2)} a + b \neq 2
\end{align*}
\]

where \( I(x; a, b) \) is the regularized incomplete Beta function. \( f(x; a, 1) \) is also called the Power-function distribution.

\[
l_x(a, b) = -N \log \Gamma(a + b) + N \log \Gamma(a) + N \log \Gamma(b) - N(a - 1) \log x - N(b - 1) \log (1 - x)
\]

Implementation: scipy.stats.beta

**Beta Prime Distribution**

There are two shape parameters \( a, b > 0 \) and the support is \( x \in [0, \infty) \). Note the CDF evaluation uses Eq. 3.194.1 on pg. 313 of Gradshteyn & Ryzhik (sixth edition).

\[
\begin{align*}
    f(x; \alpha, \beta) &= \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha) \Gamma(\beta)} x^{\alpha-1} (1 + x)^{-\alpha - \beta} \\
    F(x; \alpha, \beta) &= \frac{\Gamma(\alpha + \beta)}{\alpha \Gamma(\alpha) \Gamma(\beta)} x^{\alpha-2} F_1(\alpha + \beta, \alpha; 1 + \alpha; -x) \\
    G(q; \alpha, \beta) &= F^{-1}(x; \alpha, \beta) \\
    \mu'_n &= \left\{ \begin{array}{ll}
        \frac{\Gamma(n+\alpha)\Gamma(\beta-n)}{\Gamma(\alpha)\Gamma(\beta)} & \beta > n \\
        \frac{(\alpha)_n}{(\beta-n)_n} & \text{otherwise}
        \end{array} \right.
\end{align*}
\]
Therefore,

\[ \mu = \frac{\alpha}{\beta - 1} \quad \text{for } \beta > 1 \]

\[ \mu_2 = \frac{\alpha (\alpha + 1)}{(\beta - 2) (\beta - 1)} - \frac{\alpha^2}{(\beta - 1)^2} \quad \text{for } \beta > 2 \]

\[ \gamma_1 = \frac{\alpha (\alpha + 1) (\alpha + 2) - 3\mu_2 - \mu^3}{\mu_2^{3/2}} \quad \text{for } \beta > 3 \]

\[ \gamma_2 = \frac{\mu_4}{\mu_2^2} - 3 \mu_4 \quad \text{for } \beta > 4 \]

\[ \mu_4 = \frac{\alpha (\alpha + 1) (\alpha + 2) (\alpha + 3)}{(\beta - 4) (\beta - 3) (\beta - 2) (\beta - 1)} - 4\mu_3 - 6\mu_2 \mu_2 - \mu^4 \quad \text{for } \beta > 4 \]

Implementation: `scipy.stats.betaprime`

**Bradford Distribution**

There is one shape parameter, \( c > 0 \), and the support is \( x \in [0, 1] \).

Let \( k = \log (1 + c) \)

Then

\[ f(x; c) = \frac{c}{k (1 + cx)} \]

\[ F(x; c) = \frac{\log (1 + cx)}{k} \]

\[ G(q; c) = \frac{(1 + c)^q - 1}{c} \]

\[ M(t) = \frac{1}{k} e^{-t/c} \left[ \text{Ei} \left( t + \frac{t}{c} \right) - \text{Ei} \left( \frac{t}{c} \right) \right] \]

\[ \mu = \frac{c - k}{ek} \]

\[ \mu_2 = \frac{(c + 2)k - 2c}{2ck^2} \]

\[ \gamma_1 = \frac{\sqrt{2} \left( 12c^2 - 9kc(c + 2) + 2k^2 (c(c + 3) + 3) \right)}{\sqrt{c(c(k - 2) + 2k) (3c(k - 2) + 6k)}} \]

\[ \gamma_2 = \frac{c^3 (k - 3) (k (3k - 16) + 24) + 12kc^2 (k - 4) (k - 3) + 6ck^2 (3k - 14) + 12k^3}{3c (c(k - 2) + 2k)^2} \]

\[ m_d = 0 \]

\[ m_n = \sqrt{1 + c - 1} \]

\[ h[X] = \frac{1}{2} \log (1 + c) - \log \left( \frac{c}{\log (1 + c)} \right) \]

where \( \text{Ei} (z) \) is the exponential integral function.

Implementation: `scipy.stats.bradford`
Burr Distribution

There are two shape parameters \( c, d > 0 \) and the support is \( x \in [0, \infty) \).

Let

\[
\mu = \frac{\Gamma (1 - \frac{1}{c}) \Gamma \left( \frac{1}{c} + d \right)}{\Gamma (d)}
\]

\[
\mu_2 = \frac{k}{\Gamma^2 (d)}
\]

\[
\gamma_1 = \frac{1}{\sqrt{k^3}} \left[ 2 \Gamma^3 \left( 1 - \frac{1}{c} \right) \Gamma^3 \left( \frac{1}{c} + d \right) + \Gamma^2 (d) \Gamma \left( 1 - \frac{3}{c} \right) \Gamma \left( \frac{3}{c} + d \right) 
- 3 \Gamma (d) \Gamma \left( 1 - \frac{2}{c} \right) \Gamma \left( 1 - \frac{1}{c} \right) \Gamma \left( \frac{1}{c} + d \right) \Gamma \left( \frac{2}{c} + d \right) \right]
\]

\[
\gamma_2 = -3 + \frac{1}{k^2} \left[ 6 \Gamma (d) \Gamma \left( 1 - \frac{2}{c} \right) \Gamma^2 \left( 1 - \frac{1}{c} \right) \Gamma^2 \left( \frac{1}{c} + d \right) \Gamma \left( \frac{2}{c} + d \right) 
- 3 \Gamma^4 \left( 1 - \frac{1}{c} \right) \Gamma^4 \left( \frac{1}{c} + d \right) + \Gamma^3 (d) \Gamma \left( 1 - \frac{4}{c} \right) \Gamma \left( \frac{4}{c} + d \right) 
- 4 \Gamma^2 (d) \Gamma \left( 1 - \frac{3}{c} \right) \Gamma \left( 1 - \frac{1}{c} \right) \Gamma \left( \frac{1}{c} + d \right) \Gamma \left( \frac{3}{c} + d \right) \right]
\]

\[
m_d = \left( \frac{cd - 1}{c + 1} \right)^{1/c} \quad \text{if } cd > 1, \text{ otherwise } 0
\]

\[
m_n = \left( q^{1/d} - 1 \right)^{-1/c}
\]

Implementation: \texttt{scipy.stats.burr}
Burr12 Distribution

There are two shape parameters $c, d > 0$ and the support is $x \in [0, \infty)$. The Burr12 distribution is also known as the Singh-Maddala distribution.

$$f(x; c, d) = cd \frac{x^{c-1}}{(1 + x^c)^{d+1}}$$
$$F(x; c, d) = 1 - (1 + x^c)^{-d}$$
$$G(q; c, d) = \left( (1 - q)^{-1/d} - 1 \right)^{-1/c}$$
$$S(x; c, d) = (1 + x^c)^{-d}$$

$$\mu = dB \left( d - \frac{1}{c}, 1 + \frac{1}{c} \right)$$
$$\mu_n = dB \left( d - \frac{n}{c}, 1 + \frac{n}{c} \right)$$
$$m_d = \left( \frac{c-1}{cd+1} \right)^{1/c} \text{ if } c > 1, \text{ otherwise } 0$$
$$m_n = \left( 2^{1/d} - 1 \right)^{-1/c}$$

where $B(a, b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}$ is the Beta function.

Implementation: `scipy.stats.burr12`

Cauchy Distribution

The support is $x \in \mathbb{R}$.

$$f(x) = \frac{1}{\pi (1 + x^2)}$$
$$F(x) = \frac{1}{2} + \frac{1}{\pi} \tan^{-1} x$$
$$G(q) = \tan \left( \pi q - \frac{\pi}{2} \right)$$

$$m_d = 0$$
$$m_n = 0$$

No finite moments. This is the $t$ distribution with one degree of freedom.

$$h[X] = \log (4\pi)$$
$$\approx 2.5310242469692907930.$$}

Implementation: `scipy.stats.cauchy`
Skewed Cauchy Distribution

This distribution is a generalization of the Cauchy distribution. It has a single shape parameter $-1 < a < 1$ that skews the distribution. The special case $a = 0$ yields the Cauchy distribution.

Functions

\[
 f(x, a) = \begin{cases} 
 \frac{1}{\pi \left( (ax+1)^2 + 1 \right)}, & x \geq 0; \\
 \frac{1}{\pi \left( (-ax+1)^2 + 1 \right)}, & x < 0. 
\end{cases}
\]

\[
 F(x, a) = \begin{cases} 
 \frac{1}{2} + \frac{1+a}{\pi} \arctan \left( \frac{x}{1+a} \right), & x \geq 0; \\
 \frac{1}{2} + \frac{1-a}{\pi} \arctan \left( \frac{x}{1-a} \right), & x < 0. 
\end{cases}
\]

The mean, variance, skewness, and kurtosis are all undefined.

References

Implementation: scipy.stats.skewcauchy
Chi Distribution

Generated by taking the (positive) square-root of chi-squared variates. The one shape parameter is \( \nu \), a positive integer, the degrees of freedom. The support is \( x \geq 0 \).

\[
 f(x; \nu) = \frac{x^{\nu-1}e^{-x^2/2}}{2^{\nu/2-1}\Gamma(\frac{\nu}{2})}
\]

\[
 F(x; \nu) = \frac{\gamma\left(\frac{\nu}{2}, \frac{x^2}{2}\right)}{\Gamma(\frac{\nu}{2})}
\]

\[
 G(q; \nu) = \sqrt{2\gamma^{-1}\left(\frac{\nu}{2}, q\Gamma(\frac{\nu}{2})\right)}
\]

\[
 M(t) = \Gamma\left(\frac{\nu}{2}\right)_1F_1\left(\frac{\nu}{2}, \frac{1}{2}; \frac{t^2}{2}\right) + \frac{t}{\sqrt{2}}\Gamma\left(\frac{1+\nu}{2}\right)_1F_1\left(\frac{1+\nu}{2}, \frac{3}{2}; \frac{t^2}{2}\right)
\]

\[
 \mu = \frac{\sqrt{2\Gamma(\frac{\nu+1}{2})}}{\Gamma(\frac{\nu}{2})}
\]

\[
 \mu_2 = \nu - \mu^2
\]

\[
 \gamma_1 = \frac{2\mu^3 + \mu (1-2\nu)}{\mu_2^{3/2}}
\]

\[
 \gamma_2 = \frac{2\nu (1-\nu) - 6\mu^4 + 4\mu^2 (2\nu - 1)}{\mu_2^2}
\]

\[
 m_d = \sqrt{\nu - 1} \quad \nu \geq 1
\]

\[
 m_n = \sqrt{2\gamma^{-1}\left(\frac{\nu}{2}, \frac{1}{2}; \Gamma\left(\frac{\nu}{2}\right)\right)}
\]

Implementation: \texttt{scipy.stats.chi}

Chi-squared Distribution

This is the gamma distribution with \( L = 0.0 \) and \( S = 2.0 \) and \( \alpha = \nu/2 \) where \( \nu \) is called the degrees of freedom. If \( Z_1 \dots Z_\nu \) are all standard normal distributions, then \( W = \sum_k Z_k^2 \) has (standard) chi-square distribution with \( \nu \) degrees of freedom.

The standard form (most often used in standard form only) has support \( x \geq 0 \).

\[
 f(x; \alpha) = \frac{1}{2\Gamma(\frac{\alpha}{2})}\left(\frac{x}{2}\right)^{\alpha/2-1}e^{-x/2}
\]

\[
 F(x; \alpha) = \frac{\gamma\left(\frac{\alpha}{2}, \frac{x}{2}\right)}{\Gamma(\frac{\alpha}{2})}
\]

\[
 G(q; \alpha) = 2\gamma^{-1}\left(\frac{\alpha}{2}, q\Gamma(\frac{\alpha}{2})\right)
\]

where \( \gamma \) is the lower incomplete gamma function, \( \gamma(s, x) = \int_0^x t^{s-1}e^{-t}dt \).

\[
 M(t) = \frac{\Gamma\left(\frac{\alpha}{2}\right)}{\left(\frac{1}{2} - t\right)^{\alpha/2}}
\]
\[
\mu = \nu
\]
\[
\mu_2 = 2\nu
\]
\[
\gamma_1 = \frac{2\sqrt{2}}{\sqrt{\nu}}
\]
\[
\gamma_2 = \frac{12}{\nu}
\]
\[
m_d = \frac{\nu}{2} - 1
\]

Implementation: \texttt{scipy.stats.chi2}

**Cosine Distribution**

Approximation to the normal distribution. The support is \([-\pi, \pi]\).

\[
f(x) = \frac{1}{2\pi} (1 + \cos x)
\]
\[
F(x) = \frac{1}{2\pi} (\pi + x + \sin x)
\]
\[
G(q) = F^{-1}(q)
\]
\[
M(t) = \frac{\sinh (\pi t)}{\pi t (1 + t^2)}
\]
\[
\mu = m_d = m_n = 0
\]
\[
\mu_2 = \frac{\pi^2}{3} - 2
\]
\[
\gamma_1 = 0
\]
\[
\gamma_2 = -6 \left( \pi^4 - 90 \right)
\]
\[
\frac{5 \left( \pi^2 - 6 \right)^2}
\]

\[
h[X] = \log (4\pi) - 1
\]
\[
\approx 1.5310242469692907930.
\]

Implementation: \texttt{scipy.stats.cosine}

**Double Gamma Distribution**

The double gamma is the signed version of the Gamma distribution. For \(\alpha > 0\):

\[
f(x; \alpha) = \frac{1}{2\Gamma(\alpha)} |x|^{\alpha-1} e^{-|x|}
\]
\[
F(x; \alpha) = \begin{cases} 
  \frac{1}{2} - \frac{\gamma(\alpha, x)}{2\Gamma(\alpha)} & x \leq 0 \\
  \frac{1}{2} + \frac{\gamma(\alpha, x)}{2\Gamma(\alpha)} & x > 0 
\end{cases}
\]
\[
G(q; \alpha) = \begin{cases} 
  -\gamma^{-1}(\alpha, |2q - 1| \Gamma(\alpha)) & q \leq \frac{1}{2} \\
  \gamma^{-1}(\alpha, |2q - 1| \Gamma(\alpha)) & q > \frac{1}{2} 
\end{cases}
\]
\[
M(t) = \frac{1}{2(1 - t)^\alpha} + \frac{1}{2(1 + t)^\alpha}
\]
\[
\begin{align*}
\mu &= m_n &= 0 \\
\mu_2 &= \alpha (\alpha + 1) \\
\gamma_1 &= 0 \\
\gamma_2 &= \frac{(\alpha + 2)(\alpha + 3)}{\alpha(\alpha + 1)} - 3 \\
m_d &= NA
\end{align*}
\]

Implementation: \texttt{scipy.stats.dgamma}

**Double Weibull Distribution**

This is a signed form of the Weibull distribution. There is one shape parameter \( c > 0 \). Support is \( x \in \mathbb{R} \).

\[
\begin{align*}
f(x;c) &= \frac{c}{2} |x|^c \exp(-|x|^c) \\
F(x;c) &= \begin{cases} \\
\frac{1}{2} \exp(-|x|^c) & x \leq 0 \\
1 - \frac{1}{2} \exp(-|x|^c) & x > 0 
\end{cases} \\
G(q;c) &= \begin{cases} \\
-\log^{1/c} \left( \frac{1}{2q} \right) & q \leq \frac{1}{2} \\
\log^{1/c} \left( \frac{1}{2-1} \right) & q > \frac{1}{2} 
\end{cases}
\end{align*}
\]

\[
\begin{align*}
\mu' &= \mu_n &= \begin{cases} \\
\Gamma \left( 1 + \frac{n}{c} \right) & n \text{ even} \\
0 & n \text{ odd}
\end{cases} \\
m_n &= m &= 0 \\
\mu_2 &= \Gamma \left( \frac{c + 2}{c} \right) \\
\gamma_1 &= 0 \\
\gamma_2 &= \frac{\Gamma \left( 1 + \frac{2}{c} \right)}{\Gamma^2 \left( 1 + \frac{2}{c} \right)} \\
m_d &= NA \text{ bimodal}
\end{align*}
\]

Implementation: \texttt{scipy.stats.dweibull}

**Erlang Distribution**

This is just the Gamma distribution with shape parameter \( \alpha = n \) an integer.

Implementation: \texttt{scipy.stats.erlang}

**Exponential Distribution**

This is a special case of the Gamma (and Erlang) distributions with shape parameter \( \alpha = 1 \) and the same location and scale parameters. The standard form is therefore \( x \geq 0 \).

\[
\begin{align*}
f(x) &= e^{-x} \\
F(x) &= \gamma(1,x) = 1 - e^{-x} \\
G(q) &= -\log(1-q) \\
\mu' &= n!
\end{align*}
\]
\[ M(t) = \frac{1}{1-t} \]

\[ \mu = 1 \]
\[ \mu_2 = 1 \]
\[ \gamma_1 = 2 \]
\[ \gamma_2 = 6 \]
\[ m_d = 0 \]
\[ h[X] = 1. \]

Implementation: `scipy.stats.expon`

**Exponentiated Weibull Distribution**

Two positive shape parameters \( a, c > 0 \), and the support is \( x \in [0, \infty) \).

\[ f(x; a, c) = ac[1 - \exp(-x^c)]^{a-1}\exp(-x^c)x^{c-1} \]
\[ F(x; a, c) = [1 - \exp(-x^c)]^a \]
\[ G(q; a, c) = \left[ -\log\left(1 - q^{1/a}\right) \right]^{1/c} \]

Implementation: `scipy.stats.exponweib`

**Exponential Power Distribution**

One positive shape parameter \( b \). The support is \( x \geq 0 \).

\[ f(x; b) = ebx^{b-1}\exp\left(x^b - e^b\right) \]
\[ F(x; b) = 1 - \exp\left(1 - e^b\right) \]
\[ G(q; b) = \log(1 - \log(1 - q))^{1/b} \]

Implementation: `scipy.stats.exponpow`

**Fatigue Life (Birnbaum-Saunders) Distribution**

This distribution’s pdf is the average of the inverse-Gaussian \((\mu = 1)\) and reciprocal inverse-Gaussian pdf \((\mu = 1)\). We follow the notation of JKB here with \( \beta = S \). There is one shape parameter \( c > 0 \), and the support is \( x \geq 0 \).

\[ f(x; c) = \frac{x + 1}{2c\sqrt{2\pi}x^3}\exp\left(-\frac{(x - 1)^2}{2xc^2}\right) \]
\[ F(x; c) = \Phi\left(\frac{1}{c}\left(\sqrt{x} - \frac{1}{\sqrt{x}}\right)\right) \]
\[ G(q; c) = \frac{1}{4}\left[c\Phi^{-1}(q) + \sqrt{c^2\left(\Phi^{-1}(q)\right)^2 + 4}\right]^2 \]
\[ M(t) = cv\sqrt{2\pi}\exp\left(\frac{1}{c^2}\left(1 - \sqrt{1 - 2c^2t}\right)\right) \left(1 + \frac{1}{\sqrt{1 - 2c^2t}}\right) \]
\[
\mu = \frac{c^2}{2} + 1 \\
\mu_2 = c^2 \left( \frac{5}{4}c^2 + 1 \right) \\
\gamma_1 = \frac{4c\sqrt{11c^2 + 6}}{(5c^2 + 4)^{3/2}} \\
\gamma_2 = \frac{6c^2 (93c^2 + 41)}{(5c^2 + 4)^2}
\]

Implementation: `scipy.stats.fatiguelife`

**Fisk (Log Logistic) Distribution**

Special case of the Burr distribution with \( d = 1 \). There is are one shape parameter \( c > 0 \) and the support is \( x \in [0, \infty) \).

Let \( k = \Gamma \left( 1 - \frac{2}{c} \right) \Gamma \left( \frac{2}{c} + 1 \right) - \Gamma^2 \left( 1 - \frac{1}{c} \right) \Gamma \left( \frac{1}{c} + 1 \right) \)

\[
f(x; c, d) = \frac{cx^{c-1}}{(1 + x^c)^d}
\]

\[
F(x; c, d) = (1 + x^{-c})^{-1}
\]

\[
G(q; c, d) = (q^{-1} - 1)^{-1/c}
\]

\[
\mu = \Gamma \left( 1 - \frac{1}{c} \right) \Gamma \left( \frac{1}{c} + 1 \right)
\]

\[
\mu_2 = k
\]

\[
\gamma_1 = \frac{1}{\sqrt{k^3}} \left[ 2 \Gamma^3 \left( 1 - \frac{1}{c} \right) \Gamma \left( \frac{1}{c} + 1 \right) + \Gamma \left( 1 - \frac{3}{c} \right) \Gamma \left( \frac{3}{c} + 1 \right) \\
-3 \Gamma \left( 1 - \frac{2}{c} \right) \Gamma \left( 1 - \frac{1}{c} \right) \Gamma \left( \frac{1}{c} + 1 \right) \Gamma \left( \frac{2}{c} + 1 \right) \right]
\]

\[
\gamma_2 = -3 + \frac{1}{k^2} \left[ 6 \Gamma \left( 1 - \frac{2}{c} \right) \Gamma \left( 1 - \frac{1}{c} \right) \Gamma \left( \frac{1}{c} + 1 \right) \Gamma \left( \frac{2}{c} + 1 \right) \\
-3 \Gamma^4 \left( 1 - \frac{1}{c} \right) \Gamma \left( \frac{1}{c} + 1 \right) + \Gamma \left( 1 - \frac{4}{c} \right) \Gamma \left( \frac{4}{c} + 1 \right) \\
-4 \Gamma \left( 1 - \frac{3}{c} \right) \Gamma \left( 1 - \frac{1}{c} \right) \Gamma \left( \frac{1}{c} + 1 \right) \Gamma \left( \frac{3}{c} + 1 \right) \right]
\]

\[
m_d = \left( \frac{c - 1}{c + 1} \right)^{1/c} \text{ if } c > 1, \text{ otherwise } 0
\]

\[
m_n = 1
\]

\[
h[X] = 2 - \log c
\]

Implementation: `scipy.stats.fisk`
Folded Cauchy Distribution

This formula can be expressed in terms of the standard formulas for the Cauchy distribution (call the cdf $C(x)$ and the pdf $d(x)$). If $Y$ is cauchy then $|Y|$ is folded cauchy. There is one shape parameter $c$ and the support is $x \geq 0$.

\[
\begin{align*}
    f(x; c) &= \frac{1}{\pi (1 + (x - c)^2)} + \frac{1}{\pi (1 + (x + c)^2)} \\
    F(x; c) &= \frac{1}{\pi} \tan^{-1}(x - c) + \frac{1}{\pi} \tan^{-1}(x + c) \\
    G(q; c) &= F^{-1}(q; c)
\end{align*}
\]

No moments

Implementation: `scipy.stats.foldcauchy`

Folded Normal Distribution

If $Z$ is Normal with mean $L$ and $\sigma = S$, then $|Z|$ is a folded normal with shape parameter $c = |L|/S$, location parameter 0 and scale parameter $S$. This is a special case of the non-central chi distribution with one-degree of freedom and non-centrality parameter $c^2$. Note that $c \geq 0$. The standard form of the folded normal is

\[
\begin{align*}
    f(x; c) &= \sqrt{\frac{2}{\pi}} \cosh(cx) \exp \left(-\frac{x^2 + c^2}{2}\right) \\
    F(x; c) &= \Phi(x - c) - \Phi(-x - c) = \Phi(x - c) + \Phi(x + c) - 1 \\
    G(q; c) &= F^{-1}(q; c) \\
    M(t) &= \exp \left(\frac{t}{2} (t - 2c)\right) (1 + e^{2ct}) \\
    k &= \text{erf} \left(\frac{c}{\sqrt{2}}\right) \\
    p &= \exp \left(-\frac{c^2}{2}\right) \\
    \mu &= \sqrt{\frac{2}{\pi}} p + ck \\
    \mu_2 &= c^2 + 1 - \mu^2 \\
    \gamma_1 &= \frac{\pi p^3 \left(4 - \frac{\pi}{p^2} (2c^2 + 1)\right) + 2ck \left(6p^2 + 3cpk \sqrt{2\pi} + \pi c (k^2 - 1)\right)}{\pi \mu_2^{3/2}} \\
    \gamma_2 &= \frac{e^4 + 6c^2 + 3 + 6 (c^2 + 1) \mu^2 - 3\mu^4 - 4p\mu \left(\sqrt{\frac{2}{\pi}} (c^2 + 2) + \frac{ck}{\pi} (c^2 + 3)\right)}{\mu_2^2}
\end{align*}
\]

Implementation: `scipy.stats.foldnorm`
Fratio (or F) Distribution

The distribution of \((X_1/X_2)\) if \(X_1\) is chi-squared with \(v_1\) degrees of freedom and \(X_2\) is chi-squared with \(v_2\) degrees of freedom. The support is \(x \geq 0\).

\[
\begin{align*}
 f \left( x; v_1, v_2 \right) &= \frac{\nu_2^{\nu_2/2} \nu_1^{\nu_1/2} x^{\nu_1/2 - 1}}{(\nu_2 + \nu_1 x)^{(\nu_1 + \nu_2)/2}} B \left( \frac{\nu_1}{2}, \frac{\nu_2}{2} \right) \\
 F \left( x; v_1, v_2 \right) &= I \left( \frac{\nu_1 x}{\nu_2 + \nu_1 x}, \frac{\nu_1}{2}, \frac{\nu_2}{2} \right) \\
 G \left( q; v_1, v_2 \right) &= \left( \frac{\nu_2}{I^{-1} \left( q; \nu_1/2, \nu_2/2 \right)} - \frac{\nu_1}{\nu_2} \right)^{-1} \\
 \mu &= \frac{\nu_2}{\nu_2 - 2} \quad \text{for } \nu_2 > 2 \\
 \mu_2 &= \frac{2\nu_2^2 (\nu_1 + \nu_2 - 2)}{\nu_1 (\nu_2 - 2)^2 (\nu_2 - 4)} \quad \text{for } \nu_2 > 4 \\
 \gamma_1 &= 2 \left( \frac{2\nu_1 + \nu_2 - 2}{\nu_2 - 6} \right) \sqrt{\frac{2 (\nu_2 - 4)}{\nu_1 (\nu_1 + \nu_2 - 2)}} \quad \text{for } \nu_2 > 6 \\
 \gamma_2 &= 3 \left( \frac{8 + (\nu_2 - 6) \gamma_1^2}{2
u - 16} \right) \quad \text{for } \nu_2 > 8
\end{align*}
\]

where \(I (x; a, b) = I_x (a, b)\) is the regularized incomplete Beta function.

Implementation: \texttt{scipy.stats.f}

Gamma Distribution

The standard form for the gamma distribution is \((\alpha > 0)\) valid for \(x \geq 0\).

\[
\begin{align*}
 f \left( x; \alpha \right) &= \frac{1}{\Gamma(\alpha)} x^{\alpha - 1} e^{-x} \\
 F \left( x; \alpha \right) &= \frac{\gamma (\alpha, x)}{\Gamma(\alpha)} \\
 G \left( q; \alpha \right) &= \gamma^{-1} (\alpha, q\Gamma(\alpha))
\end{align*}
\]

where \(\gamma\) is the lower incomplete gamma function, \(\gamma (s, x) = \int_0^x \frac{ts^{-1} e^{-t}}{\Gamma(s)} dt\).

\[
\begin{align*}
 M \left( t \right) &= \frac{1}{\left( 1 - t \right)^\alpha} \\
 \mu &= \alpha \\
 \mu_2 &= \alpha \sqrt{\alpha} \\
 \gamma_1 &= \frac{2}{\sqrt{\alpha}} \\
 \gamma_2 &= \frac{6}{\alpha} \\
 m_d &= \alpha - 1 \\
 h \left[ X \right] &= \Psi (\alpha) [1 - a] + a + \log \Gamma (\alpha)
\end{align*}
\]

where \(\Psi (\alpha) = \frac{\Gamma' (\alpha)}{\Gamma (\alpha)}\).

Implementation: \texttt{scipy.stats.gamma}
Generalized Logistic Distribution

Has been used in the analysis of extreme values. There is one shape parameter \( c > 0 \). The support is \( x \in \mathcal{R} \).

\[
\begin{align*}
  f (x; c) &= \frac{c \exp (-x)}{[1 + \exp (-x)]^c + 1} \\
  F (x; c) &= \frac{1}{[1 + \exp (-x)]^c} \\
  G (q; c) &= -\log \left( q^{1/c} - 1 \right) \\
  M (t) &= \frac{c}{1 - t} \, _2F_1 (1 + c, 1 - t; 2 - t; -1) \\
  \mu &= \gamma + \psi_0 (c) \\
  \mu_2 &= \frac{\pi^2}{6} + \psi_1 (c) \\
  \gamma_1 &= \frac{\psi_2 (c) + 2\zeta (3)}{\mu_2^{3/2}} \\
  \gamma_2 &= \frac{\left( \frac{\pi^4}{72} + \psi_3 (c) \right)}{\mu_2^2} \\
  m_d &= \log c \\
  m_n &= -\log \left( 2^{1/c} - 1 \right)
\end{align*}
\]

Note that the polygamma function is

\[
\psi_n (z) = \frac{d^{n+1}}{dz^{n+1}} \log \Gamma (z) = (-1)^{n+1} n! \sum_{k=0}^{\infty} \frac{1}{(z + k)^{n+1}} = (-1)^{n+1} n! \zeta (n + 1, z)
\]

where \( \zeta (k, x) \) is a generalization of the Riemann zeta function called the Hurwitz zeta function. Note that \( \zeta (n) \equiv \zeta (n, 1) \).

Implementation: \texttt{scipy.stats.genlogistic}

Generalized Pareto Distribution

There is one shape parameter \( c \neq 0 \). The support is \( x \geq 0 \) if \( c > 0 \), and \( 0 \leq x < \frac{1}{|c|} \) if \( c \) is negative.

\[
\begin{align*}
  f (x; c) &= (1 + cx)^{-1 - \frac{c}{|c|}} \\
  F (x; c) &= 1 - \frac{1}{(1 + cx)^{1/c}} \\
  G (q; c) &= \frac{1}{c} \left[ \left( \frac{1}{1 - q} \right)^c - 1 \right] \\
  M (t) &= \left\{ \begin{array}{ll}
  (-\frac{1}{c})^{\frac{c}{|c|}} e^{-\frac{c}{|c|} \left[ \Gamma \left( 1 - \frac{1}{c} \right) + \gamma \left( -\frac{1}{c}, -\frac{1}{c} \right) / \Gamma \left( \frac{1}{c} \right) \right]} - \pi \csc \left( \frac{\pi}{c} \right) / \Gamma \left( \frac{1}{c} \right) & c > 0 \\
  \left( \frac{|c|}{T} \right)^{1/|c|} \Gamma \left( \frac{1}{|c|} \right) \left[ \frac{T}{\Gamma \left( \frac{1}{c} \right)} \right] & c < 0
  \end{array} \right.
\end{align*}
\]
\[
\mu_n' = \frac{(-1)^n}{c^n} \sum_{k=0}^{n} \binom{n}{k} \frac{(-1)^k}{1 - ck} \quad \text{if } cn < 1
\]

\[
\mu'_1 = \frac{1}{1 - c} \quad c < 1
\]

\[
\mu'_2 = \frac{2}{(1 - 2c)(1 - c)} \quad c < \frac{1}{2}
\]

\[
\mu'_3 = \frac{6}{(1 - c)(1 - 2c)(1 - 3c)} \quad c < \frac{1}{3}
\]

\[
\mu'_4 = \frac{24}{(1 - c)(1 - 2c)(1 - 3c)(1 - 4c)} \quad c < \frac{1}{4}
\]

Thus,

\[
\mu = \mu'_1
\]

\[
\mu_2 = \mu'_2 - \mu^2
\]

\[
\gamma_1 = \frac{\mu'_3 - 3\mu_2}{\mu_2^{3/2}}
\]

\[
\gamma_2 = \frac{\mu'_4 - 4\mu_3 - 6\mu^2\mu_2 - \mu^4}{\mu_2^2} - 3
\]

\[
h[X] = 1 + c \quad c > 0
\]

Implementation: \texttt{scipy.stats.genpareto}

**Generalized Exponential Distribution**

Three positive shape parameters \(a, b, c > 0\) with support \(x \geq 0\).

\[
f(x; a, b, c) = (a + b (1 - e^{-cx})) \exp \left( ax - bx + \frac{b}{c} (1 - e^{-cx}) \right)
\]

\[
F(x; a, b, c) = 1 - \exp \left( ax - bx + \frac{b}{c} (1 - e^{-cx}) \right)
\]

\[
G(q; a, b, c) = F^{-1}
\]

Implementation: \texttt{scipy.stats.genexpon}

**Generalized Extreme Value Distribution**

Extreme value distributions with one shape parameter \(c\).

If \(c > 0\), the support is \(-\infty < x \leq 1/c\). If \(c < 0\), the support is \(\frac{1}{c} \leq x < \infty\).

\[
f(x; c) = \exp \left( - (1 - cx)^{1/c} \right) (1 - cx)^{1/c - 1}
\]

\[
F(x; c) = \exp \left( - (1 - cx)^{1/c} \right)
\]

\[
G(q; c) = \frac{1}{c} (1 - (-\log q)^c)
\]

\[
\mu'_n = \frac{1}{c^n} \sum_{k=0}^{n} \binom{n}{k} (-1)^k \Gamma (ck + 1) \quad \text{if } cn > -1
\]
So,

\[
\begin{align*}
\mu_1' &= \frac{1}{c} (1 - \Gamma (1 + c)) \quad c > -1 \\
\mu_2' &= \frac{1}{c^2} (1 - 2\Gamma (1 + c) + \Gamma (1 + 2c)) \quad c > -\frac{1}{2} \\
\mu_3' &= \frac{1}{c^3} (1 - 3\Gamma (1 + c) + 3\Gamma (1 + 2c) - \Gamma (1 + 3c)) \quad c > -\frac{1}{3} \\
\mu_4' &= \frac{1}{c^4} (1 - 4\Gamma (1 + c) + 6\Gamma (1 + 2c) - 4\Gamma (1 + 3c) + \Gamma (1 + 4c)) \quad c > -\frac{1}{4}
\end{align*}
\]

For \( c = 0 \) the distribution is the same as the (left-skewed) Gumbel distribution, and the support is \( \mathbb{R} \).

\[
\begin{align*}
\mu &= \gamma = -\psi_0 (1) \\
\mu_2 &= \frac{\pi^2}{6} \\
\gamma_1 &= \frac{12\sqrt{6}}{\pi^3} \zeta (3) \\
\gamma_2 &= \frac{12}{5}
\end{align*}
\]

Implementation: \texttt{scipy.stats.genextreme}

### Generalized Gamma Distribution

A general probability form that reduces to many common distributions. There are two shape parameters \( a > 0 \) and \( c \neq 0 \). The support is \( x \geq 0 \).

\[
\begin{align*}
f (x; a, c) &= \frac{|c| x^{ca-1}}{\Gamma (a)} \exp (-x^c) \\
F (x; a, c) &= \begin{cases} 
\frac{\gamma(a,x^c)}{\Gamma(a)} & c > 0 \\
1 - \frac{\gamma(a,x^c)}{\Gamma(a)} & c < 0
\end{cases} \\
G (q; a, c) &= \begin{cases} 
\gamma^{-1} (a, \Gamma (a) q)^{1/c} & c > 0 \\
\gamma^{-1} (a, \Gamma (a) (1 - q))^{1/c} & c < 0
\end{cases}
\end{align*}
\]
where $\gamma$ is the lower incomplete gamma function, $\gamma(s, x) = \int_0^x t^{s-1} e^{-t} dt$.

$$
\begin{align*}
\mu'_n &= \frac{\Gamma(a + \frac{n}{c})}{\Gamma(a)} \\
\mu &= \frac{\Gamma(a + \frac{1}{c})}{\Gamma(a)} \\
\mu_2 &= \frac{\Gamma(a + \frac{2}{c})}{\Gamma(a)} - \mu^2 \\
\gamma_1 &= \frac{\Gamma(a + \frac{3}{c})}{\Gamma(a)} \mu_2 \left( \frac{\mu_3^{3/2}}{\mu_2^2} \right) - 3 \\
\gamma_2 &= \frac{\Gamma(a + \frac{4}{c})}{\Gamma(a)} \mu_2 \left( \frac{\mu_3^{3/2}}{\mu_2^2} \right) - 3 \\
\mu_d &= \left( \frac{ac - 1}{c} \right)^{1/c} \\
\end{align*}
$$

Special cases are Weibull ($a = 1$), half-normal ($a = 1/2, c = 2$) and ordinary gamma distributions $c = 1$. If $c = -1$ then it is the inverted gamma distribution.

$$
h[X] = a - a\Psi(a) + \frac{1}{c}\Psi(a) + \log \Gamma(a) - \log |c|.
$$

Implementation: \texttt{scipy.stats.gengamma}

**Generalized Half-Logistic Distribution**

One shape parameter $c > 0$ and support $x \in [0, 1/c]$.

$$
\begin{align*}
\frac{f(x; c)}{dx} &= \frac{2(1 - cx)^{\frac{1}{c} - 1}}{(1 + (1 - cx)^{1/c})^2} \\
F(x; c) &= \frac{1 - (1 - cx)^{1/c}}{1 + (1 - cx)^{1/c}} \\
G(q; c) &= \frac{1}{c} \left[ 1 - \left( \frac{1 - q}{1 + q} \right)^c \right] \\
h[X] &= 2 - (2c + 1) \log 2.
\end{align*}
$$

Implementation: \texttt{scipy.stats.genhalflogistic}

**Generalized Hyperbolic Distribution**

The Generalized Hyperbolic Distribution is defined as the normal variance-mean mixture with Generalized Inverse Gaussian distribution as the mixing distribution. The “hyperbolic” characterization refers to the fact that the shape of the log-probability distribution can be described as a hyperbola. Hyperbolic distributions are sometime referred to as semifat tailed because their probability density decrease slower than “sub-hyperbolic” distributions (e.g. normal distribution, whose log-probability decreases quadratically), but faster than other “extreme value” distributions (e.g. pareto distribution, whose log-probability decreases logarithmically).
Functions

Different parameterizations exist in the literature; SciPy implements the “4th parametrization” in Prause (1999).

\[ f(x, p, a, b) = \frac{(a^2 - b^2)^{p/2}}{\sqrt{2\pi a}p^{-0.5}K_p\left(\sqrt{a^2 - b^2}\right)} e^{bx} \times K_{p-1/2}(a\sqrt{1 + x^2}) \left(\frac{1}{\sqrt{1 + x^2}}\right)^{1/2-p} \]

for:

- \( x, p \in (-\infty; \infty) \)
- \(|b| < a \) if \( p \geq 0 \)
- \(|b| \leq a \) if \( p < 0 \)
- \( K_p(.) \) denotes the modified Bessel function of the second kind and order \( p \) (scipy.special.kn)

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, \( f(x, p, a, b, \text{loc}, \text{scale}) \) is identically equivalent to \( \frac{1}{\text{scale}} f(y, p, a, b) \) with \( y = \frac{1}{\text{scale}}(x - \text{loc}) \).

This parameterization derives from the original \((\lambda, \alpha, \beta, \delta, \mu)\) parameterization in Barndorff (1978) by setting:

- \( \lambda = p \)
- \( \alpha = \frac{a}{\delta} = \frac{\hat{\alpha}}{\delta} \)
- \( \beta = \frac{b}{\delta} = \frac{\hat{\beta}}{\delta} \)
- \( \delta = \text{scale} \)
- \( \mu = \text{location} \)

Random variates for the scipy.stats.genhyperbolic can be efficiently sampled from the above-mentioned normal variance-mean mixture where scipy.stats.geninvgauss is parametrized as \( \text{GIG}(p = p, b = \sqrt{\hat{\alpha}^2 - \hat{\beta}^2}, \text{loc} = \text{location}, \text{scale} = \frac{1}{\sqrt{\hat{\alpha}^2 - \hat{\beta}^2}}) \) so that: \( GH(p, \hat{\alpha}, \hat{\beta}) = \hat{\beta} \cdot \text{GIG} + \sqrt{\text{GIG}} \cdot N(0, 1) \)

The “generalized” characterization suggests the fact that this distribution is a superclass of several other probability distributions, for instance:

- \( f(p = -\nu/2, a = 0, b = 0, \text{loc} = 0, \text{scale} = \sqrt{\nu}) \) has a Student’s t-distribution (scipy.stats.t) with \( \nu \) degrees of freedom.
- \( f(p = 1, a = \hat{\alpha}, b = \hat{\beta}, \text{loc} = \mu, \text{scale} = \delta) \) has a Hyperbolic Distribution.
- \( f(p = -1/2, a = \hat{\alpha}, b = \hat{\beta}, \text{loc} = \mu, \text{scale} = \delta) \) has a Normal Inverse Gaussian Distribution (scipy.stats.norminvgauss).
- \( f(p = 1, a = \delta, b = 0, \text{loc} = \mu, \text{scale} = \delta) \) has a Laplace Distribution (scipy.stats.laplace) for \( \delta \to 0 \)

Examples

It is useful to understand how the parameters affect the shape of the distribution. While it is fairly straightforward to interpret the meaning of \( b \) as the skewness, understanding the difference between \( a \) and \( p \) is not as obvious, as both affect the kurtosis of the distribution. \( a \) can be interpreted as the speed of the decay of the probability density (where \( a > 1 \) the asymptotic decay is faster than \( \log \) and vice versa) or - equivalently - as the slope of the log-probability hyperbola asymptote (where \( a > 1 \) decay is faster than \( |1| \) and vice versa). \( p \) can be seen as the width of the shoulders of the probability density distribution (where \( p < 1 \) results in narrow shoulders and vice versa) or - equivalently - as the shape of the log-probability hyperbola, which is convex for \( p < 1 \) and concave otherwise.
import numpy as np
from matplotlib import pyplot as plt
from scipy import stats

p, a, b, loc, scale = 1, 1, 0, 0, 1

References

Implementation: \texttt{scipy.stats.genhyperbolic}

Generalized Inverse Gaussian Distribution

The probability density function is given by:

\[ f(x; p, b) = x^{p-1} \exp(-b(x + 1/x)/2)/(2K_p(b)), \]

where \( x > 0 \) is a real number and the parameters \( p, b \) satisfy \( b > 0 \). \( K_v \) is the modified Bessel function of second kind of order \( v \) (\texttt{scipy.special.kv}).

If \( X \) is \texttt{geninvgauss}(p, b), then the distribution of \( 1/X \) is \texttt{geninvgauss}(-p, b). The inverse Gaussian distribution (\texttt{scipy.stats.invgauss}) is a special case with \( p=-1/2 \).

Implementation: \texttt{scipy.stats.geninvgauss}

Generalized Normal Distribution

This distribution is also known as the exponential power distribution. It has a single shape parameter \( \beta > 0 \). It reduces to a number of common distributions.

Functions

\[ f(x; \beta) = \frac{\beta}{2\Gamma(1/\beta)} e^{-|x|^\beta} \]

\[ F(x; \beta) = \frac{1}{2} + \text{sgn}(x) \frac{\gamma(1/\beta, x^\beta)}{2\Gamma(1/\beta)} \]
\( \gamma \) is the lower incomplete gamma function. \( \gamma (s, x) = \int_0^x t^{s-1}e^{-t}dt. \)

\[
h [X; \beta] = \frac{1}{\beta} - \log \left( \frac{\beta}{2 \Gamma (1/\beta)} \right)
\]

**Moments**

\[
\mu = 0 \\
m_n = 0 \\
m_d = 0 \\
\mu_2 = \frac{\Gamma (3/\beta)}{\gamma (1/\beta)} \\
\gamma_1 = 0 \\
\gamma_2 = \frac{\Gamma (5/\beta) \Gamma (1/\beta)}{\Gamma (3/\beta)^2} - 3
\]

**Special Cases**

- Laplace distribution (\( \beta = 1 \))
- Normal distribution with \( \mu_2 = 1/2 \) (\( \beta = 2 \))
- Uniform distribution over the interval \([-1, 1]\) (\( \beta \to \infty \))

**Sources**

- https://en.wikipedia.org/wiki/Generalized_normal_distribution#Version_1
- https://en.wikipedia.org/wiki/Incomplete_gamma_function#Lower_incomplete_Gamma_function

**Implementation:** scipy.stats.gennorm

**Gilbrat Distribution**

Special case of the log-normal with \( \sigma = 1 \) and \( S = 1.0 \), typically also \( L = 0.0 \).)

\[
f (x; \sigma) = \frac{1}{x \sqrt{2\pi}} \exp \left( -\frac{1}{2} (\log x)^2 \right) \\
F (x; \sigma) = \Phi (\log x) = \frac{1}{2} \left( 1 + \text{erf} \left( \frac{\log x}{\sqrt{2}} \right) \right) \\
G (q; \sigma) = \exp (\Phi^{-1} (q))
\]

\[
\mu = \sqrt{e} \\
\mu_2 = e [e - 1] \\
\gamma_1 = \sqrt{e - 1} (2 + e) \\
\gamma_2 = e^4 + 2e^3 + 3e^2 - 6
\]
\[ h[X] = \log \left( \sqrt{2\pi e} \right) \approx 1.4189385332046727418 \]

Implementation: `scipy.stats.gilbrat`

**Gompertz (Truncated Gumbel) Distribution**

For \( x \geq 0 \) and \( c > 0 \). In JKB the two shape parameters \( b, a \) are reduced to the single shape-parameter \( c = b/a \). As \( a \) is just a scale parameter when \( a \neq 0 \). If \( a = 0 \), the distribution reduces to the exponential distribution scaled by \( 1/b \). Thus, the standard form is given as

\[
\begin{align*}
    f(x; c) &= e^x \exp \left( -c(e^x - 1) \right) \\
    F(x; c) &= 1 - \exp \left( -c(e^x - 1) \right) \\
    G(q; c) &= \log \left( 1 - \frac{1}{c} \log (1 - q) \right)
\end{align*}
\]

\[ h[X] = 1 - \log (c) - e^c \text{Ei} (1, c), \]

where

\[
\text{Ei} (n, x) = \int_1^{\infty} t^{-n} \exp (-xt) \, dt
\]

Implementation: `scipy.stats.gompertz`

**Gumbel (LogWeibull, Fisher-Tippett, Type I Extreme Value) Distribution**

One of a class of extreme value distributions (right-skewed).

\[
\begin{align*}
    f(x) &= \exp \left( - (x + e^{-x}) \right) \\
    F(x) &= \exp (-e^{-x}) \\
    G(q) &= -\log (-\log (q))
\end{align*}
\]

\[ M(t) = \Gamma (1 - t) \]

\[
\begin{align*}
    \mu &= \gamma = -\psi_0 (1) \\
    \mu_2 &= \frac{\pi^2}{6} \\
    \gamma_1 &= \frac{12\sqrt{6}}{\pi^3} \zeta (3) \\
    \gamma_2 &= \frac{12}{5} \\
    m_d &= 0 \\
    m_n &= -\log (\log 2)
\end{align*}
\]

\[ h[X] \approx 1.0608407169541684911 \]

Implementation: `scipy.stats.gumbel_r`
Gumbel Left-skewed (for minimum order statistic) Distribution

\[ f(x) = \exp(x - e^x) \]
\[ F(x) = 1 - \exp(-e^x) \]
\[ G(q) = \log(-\log(1-q)) \]
\[ M(t) = \Gamma(1+t) \]

Note, that \( \mu \) is negative the mean for the right-skewed distribution. Similar for median and mode. All other moments are the same.

\[ h[X] \approx 1.0608407169541684911. \]

Implementation: `scipy.stats.gumbel_l`

HalfCauchy Distribution

If \( Z \) is Hyperbolic Secant distributed then \( e^Z \) is Half-Cauchy distributed. Also, if \( W \) is (standard) Cauchy distributed, then \(|W|\) is Half-Cauchy distributed. Special case of the Folded Cauchy distribution with \( c = 0 \). The support is \( x \geq 0 \). The standard form is

\[ f(x) = \frac{2}{\pi (1 + x^2)} \]
\[ F(x) = \frac{2}{\pi} \arctan(x) \]
\[ G(q) = \tan\left(\frac{\pi}{2} q\right) \]
\[ M(t) = \cos t + \frac{2}{\pi} \left[ \text{Si}(t) \cos t - \text{Ci}(-t) \sin t \right] \]

where \( \text{Si}(t) = \int_0^t \frac{\sin x}{x} dx \), \( \text{Ci}(t) = -\int_t^\infty \frac{\cos x}{x} dx \).

\[ m_d = 0 \]
\[ m_m = \tan\left(\frac{\pi}{4}\right) \]

No moments, as the integrals diverge.

\[ h[X] = \log(2\pi) \]
\[ \approx 1.8378770664093454836. \]

Implementation: `scipy.stats.halfcauchy`

HalfNormal Distribution

This is a special case of the chi distribution with \( L = a \) and \( S = b \) and \( \nu = 1 \). This is also a special case of the folded normal with shape parameter \( c = 0 \) and \( S = S \). If \( Z \) is (standard) normally distributed then, \(|Z|\) is half-normal. The standard form is

\[ f(x) = \sqrt{\frac{2}{\pi}} e^{-x^2/2} \]
\[ F(x) = 2\Phi(x) - 1 \]
\[ G(q) = \Phi^{-1}\left(\frac{1+q}{2}\right) \]
\[ M(t) = \sqrt{2\pi e^{2/2}} \Phi(t) \]

\[ \mu = \sqrt{\frac{2}{\pi}} \]

\[ \mu_2 = 1 - \frac{2}{\pi} \]

\[ \gamma_1 = \sqrt{\frac{2(4 - \pi)}{(\pi - 2)^{3/2}}} \]

\[ \gamma_2 = \frac{8(\pi - 3)}{(\pi - 2)^2} \]

\[ m_d = 0 \]

\[ m_n = \Phi^{-1}\left(\frac{3}{4}\right) \]

\[ h[X] = \log\left(\sqrt{\frac{\pi e}{2}}\right) \approx 0.72579135264472743239. \]

Implementation: \texttt{scipy.stats.halfnorm}

**Half-Logistic Distribution**

In the limit as \( c \to \infty \) for the generalized half-logistic we have the half-logistic defined over \( x \geq 0 \). Also, the distribution of \(|X|\) where \( X \) has logistic distribution.

\[ f(x) = \frac{2e^{-x}}{(1 + e^{-x})^2} = \frac{1}{2}\text{sech}^2\left(\frac{x}{2}\right) \]

\[ F(x) = \frac{1 - e^{-x}}{1 + e^{-x}} = \tanh\left(\frac{x}{2}\right) \]

\[ G(q) = \log\left(\frac{1 + q}{1 - q}\right) = 2\text{arctanh}(q) \]

\[ M(t) = 1 - t\psi_0\left(\frac{1}{2} - \frac{t}{2}\right) + t\psi_0\left(1 - \frac{t}{2}\right) \]

where \( \psi_m \) is the polygamma function \( \psi_m(z) = \frac{d^{m+1}}{dz^{m+1}} \log(\Gamma(z)) \).

\[ \mu'_n = 2\left(1 - 2^{1-n}\right)n!\zeta(n) \quad n \neq 1 \]

\[ \mu'_1 = 2\log(2) \]

\[ \mu'_2 = 2\zeta(2) = \frac{\pi^2}{3} \]

\[ \mu'_3 = 9\zeta(3) \]

\[ \mu'_4 = 42\zeta(4) = \frac{7\pi^4}{15} \]

\[ h[X] = 2 - \log(2) \approx 1.3068528194400546906. \]

Implementation: \texttt{scipy.stats.halflogistic}
Hyperbolic Secant Distribution

Related to the logistic distribution and used in lifetime analysis. Standard form is (defined over all \( x \))

\[
\begin{align*}
  f(x) &= \frac{1}{\pi} \text{sech}(x) \\
  F(x) &= \frac{2}{\pi} \arctan(e^x) \\
  G(q) &= \log\left(\tan\left(\frac{\pi}{2} q\right)\right) \\
  M(t) &= \sec\left(\frac{\pi}{2} t\right)
\end{align*}
\]

\[
\mu'_n = \frac{1 + (-1)^n}{2\pi^2} n! \left[ \zeta\left(n + 1, \frac{1}{4}\right) - \zeta\left(n + 1, \frac{3}{4}\right) \right]
\]

where \( C_m \) is an integer given by

\[
C_m = \frac{(2m)! \left[ \zeta\left(2m + 1, \frac{1}{4}\right) - \zeta\left(2m + 1, \frac{3}{4}\right) \right]}{\pi^{2m+1} 2^{2m}}
\]

\[
= 4 (-1)^{m-1} \frac{16^m}{2m+1} B_{2m+1}\left(\frac{1}{4}\right)
\]

where \( B_{2m+1}\left(\frac{1}{4}\right) \) is the Bernoulli polynomial of order \( 2m + 1 \) evaluated at \( 1/4 \). Thus

\[
\mu'_n = \begin{cases} 
  0 & n \text{ odd} \\
  C_{n/2} \pi^n & n \text{ even}
\end{cases}
\]

Gauss Hypergeometric Distribution

The four shape parameters are \( \alpha > 0, \beta > 0, -\infty < \gamma < \infty, \) and \( z > -1 \). The support is \( x \in [0, 1] \).

Let \( C = \frac{1}{B(\alpha, \beta)} \frac{\Gamma(\gamma \alpha + \beta)}{\Gamma(\alpha + \beta)} \frac{\Gamma(\gamma)}{\Gamma(\gamma + n)} \frac{\Gamma(\gamma + n + \alpha + \beta)}{\Gamma(\gamma + n + \alpha + \beta + n)} \frac{B_n(\gamma, \alpha + n; \alpha + \beta; -z)}{\Gamma(\gamma + n + \alpha + \beta; -z)} \)

\[
\begin{align*}
  f(x; \alpha, \beta, \gamma, z) &= C x^{\alpha-1} (1-x)^{\beta-1} \\
  \mu'_n &= \frac{B(n + \alpha, \beta)}{B(\alpha, \beta)} \frac{\Gamma(\gamma + n + \alpha + \beta)}{\Gamma(\gamma + n + \alpha + \beta + n)} \frac{\Gamma(\gamma + n + \alpha + \beta + n)}{\Gamma(\gamma + n + \alpha + \beta + n + \alpha + \beta)} \frac{B_n(\gamma, \alpha + n; \alpha + \beta; -z)}{\Gamma(\gamma + n + \alpha + \beta; -z)}
\end{align*}
\]

Implementation: \texttt{scipy.stats.hypsecant}

Implementation: \texttt{scipy.stats.gausshyper}
Inverted Gamma Distribution

Special case of the generalized Gamma distribution with \( c = -1 \) and \( a > 0 \) and support \( x \geq 0 \).

\[
\begin{align*}
    f (x; a) &= \frac{x^{-a-1}}{\Gamma(a)} \exp \left( -\frac{1}{x} \right) \\
    F (x; a) &= \frac{\Gamma \left( a, \frac{1}{x} \right)}{\Gamma(a)} \\
    G (q; a) &= \left\{ \Gamma^{-1} \left( a, \Gamma(a) q \right) \right\}^{-1} \\
    \mu'_n &= \frac{\Gamma(a-n)}{\Gamma(a)} \quad a > n
\end{align*}
\]

\[
\begin{align*}
    \mu &= \frac{1}{a-1} \quad a > 1 \\
    \mu_2 &= \frac{1}{(a-2)(a-1)} - \mu^2 \quad a > 2 \\
    \gamma_1 &= \frac{1}{(a-3)(a-2)(a-1)} - 3\mu_2 - \mu^3 \\
    \gamma_2 &= \frac{1}{(a-4)(a-3)(a-2)(a-1)} - 4\mu_3 - 6\mu^2\mu_2 - \mu^4 - 3 \\
    m_d &= \frac{1}{a+1} \\
    h [X] &= a - (a+1) \psi(a) + \log \Gamma(a).
\end{align*}
\]

where \( \Psi \) is the digamma function \( \psi(z) = \frac{d}{dz} \log(\Gamma(z)) \).

Implementation: \texttt{scipy.stats.invgamma}

Inverse Normal (Inverse Gaussian) Distribution

The standard form involves the shape parameter \( \mu \) (in most definitions, \( L = 0.0 \) is used). (In terms of the regress documentation \( \mu = A/B \) and \( B = S \) and \( L \) is not a parameter in that distribution. A standard form is \( x > 0 \)

\[
\begin{align*}
    f (x; \mu) &= \frac{1}{\sqrt{2\pi} x^3} \exp \left( -\frac{(x - \mu)^2}{2x\mu^2} \right). \\
    F (x; \mu) &= \Phi \left( \frac{1}{\sqrt{x}} \frac{x - \mu}{\mu} \right) + \exp \left( \frac{2}{\mu} \right) \Phi \left( -\frac{1}{\sqrt{x}} \frac{x + \mu}{\mu} \right) \\
    G (q; \mu) &= F^{-1} (q; \mu)
\end{align*}
\]

\[
\begin{align*}
    \mu &= \mu \\
    \mu_2 &= \mu^3 \\
    \gamma_1 &= 3\sqrt{\mu} \\
    \gamma_2 &= 15\mu \\
    m_d &= \frac{\mu}{2} \left( \sqrt{9\mu^2 + 4} - 3\mu \right)
\end{align*}
\]

This is related to the canonical form or JKB “two-parameter” inverse Gaussian when written in it's full form with scale parameter \( S \) and location parameter \( L \) by taking \( L = 0 \) and \( S \equiv \lambda \), then \( \mu S \) is equal to \( \mu_2 \) where \( \mu_2 \) is the parameter
used by JKB. We prefer this form because of its consistent use of the scale parameter. Notice that in JKB the skew \((\sqrt{\beta_1})\) and the kurtosis \((\beta_2 - 3)\) are both functions only of \(\mu_2/\lambda = \mu S/S = \mu\) as shown here, while the variance and mean of the standard form here are transformed appropriately.

Implementation: `scipy.stats.invgauss`

Inverted Weibull Distribution

There is one shape parameter \(c > 0\) and the support is \(x \geq 0\). Then

\[
\begin{align*}
 f(x; c) &= cx^{-c-1} \exp(-x^{-c}) \\
 F(x; c) &= \exp(-x^{-c}) \\
 G(q; c) &= (-\log q)^{-1/c} \\
 h[X] &= 1 + \gamma + \frac{\gamma}{c} - \log(c)
\end{align*}
\]

where \(\gamma\) is Euler’s constant.

Implementation: `scipy.stats.invweibull`

Johnson SB Distribution

There are two shape parameters \(a \in \mathbb{R}\) and \(b > 0\), and the support is \(x \in [0, 1]\).

\[
\begin{align*}
 f(x; a, b) &= \frac{b}{x(1-x)} \phi\left(a + b \log \frac{x}{1-x}\right) \\
 F(x; a, b) &= \Phi\left(a + b \log \frac{x}{1-x}\right) \\
 G(q; a, b) &= \frac{1}{1 + \exp\left(-\frac{1}{b} (\Phi^{-1}(q) - a)\right)}
\end{align*}
\]

Implementation: `scipy.stats.johnsonsb`

Johnson SU Distribution

There are two shape parameters \(a \in \mathbb{R}\) and \(b > 0\), and the support is \(x \in \mathbb{R}\).

\[
\begin{align*}
 f(x; a, b) &= \frac{b}{\sqrt{x^2 + 1}} \phi\left(a + b \log\left(x + \sqrt{x^2 + 1}\right)\right) \\
 F(x; a, b) &= \Phi\left(a + b \log\left(x + \sqrt{x^2 + 1}\right)\right) \\
 G(q; a, b) &= \sinh\left(\frac{\Phi^{-1}(q) - a}{b}\right)
\end{align*}
\]

Implementation: `scipy.stats.johnsonsu`
KSone Distribution

This is the distribution of maximum positive differences between an empirical distribution function, computed from \(n\) samples or observations, and a comparison (or target) cumulative distribution function.

Writing \(D_{n}^{+} = \sup_{t} (F_{\text{empirical},n}(t) - F_{\text{target}}(t))\), \texttt{ksone} is the distribution of the \(D_{n}^{+}\) values. (The distribution of \(D_{n}^{-} = \sup_{t} (F_{\text{target}}(t) - F_{\text{empirical},n}(t))\) differences follows the same distribution, so \texttt{ksone} can be used for one-sided tests on either side.)

There is one shape parameter \(n\), a positive integer, and the support is \(x \in [0,1]\).

\[
F(n,x) = 1 - \sum_{j=0}^{\lfloor n(1-x) \rfloor} \binom{n}{j} x^j \left(1 - \frac{j}{n}\right)^{n-j} = 1 - \text{scipy.special.smirnov}(n,x)
\]

\[
\lim_{n \to \infty} F\left(n, \frac{x}{\sqrt{n}}\right) = e^{-2x^2}
\]

References

Implementation: \texttt{scipy.stats.ksone}

KStwo Distribution

This is the distribution of the maximum absolute differences between an empirical distribution function, computed from \(n\) samples or observations, and a comparison (or target) cumulative distribution function, which is assumed to be continuous. (The “two” in the name is because this is the two-sided difference. \texttt{ksone} is the distribution of the positive differences, \(D_{n}^{+}\), hence it concerns one-sided differences. \texttt{kstwo} is the limiting distribution of the \textit{normalized} maximum absolute differences \(\sqrt{n}D_{n}\).)

Writing \(D_{n} = \sup_{t} |F_{\text{empirical},n}(t) - F_{\text{target}}(t)|\), \texttt{kstwo} is the distribution of the \(D_{n}\) values.

\texttt{kstwo} can also be used with the differences between two empirical distribution functions, for sets of observations with \(m\) and \(n\) samples respectively. Writing \(D_{m,n} = \sup_{t} |F_{1,m}(t) - F_{2,n}(t)|\), where \(F_{1,m}\) and \(F_{2,n}\) are the two empirical distribution functions, then \(\Pr(D_{m,n} \leq x) \approx \Pr(D_{N} \leq x)\) under appropriate conditions, where \(N = \sqrt{\frac{mN}{m+n}}\).

There is one shape parameter \(n\), a positive integer, and the support is \(x \in [0,1]\).

The implementation follows Simard & L’Ecuyer, which combines exact algorithms of Durbin and Pomeranz with asymptotic estimates of Li-Chien, Pelz and Good to compute the CDF with 5-15 accurate digits.
Examples

```python
>>> from scipy.stats import kstwo

Show the probability of a gap at least as big as 0, 0.5 and 1.0 for a sample of size 5

```python
>>> kstwo.sf([0, 0.5, 1.0], 5)
array([1. , 0.112, 0. ])
```

Compare a sample of size 5 drawn from a source N(0.5, 1) distribution against a target N(0, 1) CDF.

```python
>>> from scipy.stats import norm

```python
>>> n = 5

```python
>>> gendist = norm(0.5, 1)  # Normal distribution, mean 0.5, stddev 1
```

```python
>>> x = np.sort(gendist.rvs(size=n, random_state=np.random.default_rng()))
```

```python
>>> x
array([-1.59113056, -0.66335147, 0.54791569, 0.78009321, 1.27641365])
```

```python
>>> target = norm(0)
```

```python
>>> cdfs = target.cdf(x)
```

```python
>>> cdfs
array([0.0557901 , 0.25355274, 0.7081251 , 0.78233199, 0.89909533])
```

```python
# Construct the Empirical CDF and the K-S statistics (Dn+, Dn-, Dn)
>>> ecdfs = np.arange(n+1, dtype=float)/n
>>> cols = np.column_stack([x, ecdfs[1:], cdfs, cdfs - ecdfs[:n], ecdfs[1:] - cdfs])
```

```python
>>> np.set_printoptions(precision=3)
>>> cols
array([[[-1.591, 0.2 , 0.056, 0.056, 0.144],
        [-0.663, 0.4 , 0.254, 0.054, 0.146],
        [ 0.548, 0.6 , 0.708, 0.308, -0.108],
        [ 0.78 , 0.8 , 0.782, 0.182, 0.018],
        [ 1.276, 1. , 0.899, 0.099, 0.101]]])
```

```python
>>> gaps = cols[:, -2:]
```

```python
>>> Dnmp = np.max(gaps, axis=0)
```

```python
>>> Dn = np.max(Dnmp)
```

```python
>>> iminus, iplus = np.argmax(gaps, axis=0)
```

```python
>>> print('Dn- = %f (at x=%.2f)' % (Dnmp[0], x[iminus]))
Dn- = 0.308125 (at x=0.55)
```

```python
>>> print('Dn+ = %f (at x=%.2f)' % (Dnmp[1], x[iplus]))
Dn+ = 0.146447 (at x=-0.66)
```

```python
>>> print('Dn = %f' % (Dn))
Dn = 0.308125
```

```python
>>> probs = kstwo.sf(Dn, n)
```

```python
>>> print(chr(10).join(['For a sample of size %d drawn from a N(0, 1) distribution:' % n,
...                      'Kolmogorov-Smirnov 2-sided n=%d: Prob(Dn >= %f) = %.4f' % (n, Dn,
...                      probs)])
```

For a sample of size 5 drawn from a N(0, 1) distribution:
Kolmogorov-Smirnov 2-sided n=5: Prob(Dn >= 0.308125) = 0.6319

Plot the Empirical CDF against the target N(0, 1) CDF
Writing is the distribution of the unnormalized positive differences, $D_n$. Implementation:

```python
>>> import matplotlib.pyplot as plt
>>> plt.step(np.concatenate([[-3], x]), ecdfs, where='post', label='Empirical CDF')
>>> x3 = np.linspace(-3, 3, 100)
>>> plt.plot(x3, target.cdf(x3), label='CDF for N(0, 1)')
>>> plt.ylim([0, 1]); plt.grid(True); plt.legend();
>>> plt.vlines([x[iminus]], ecdfs[iminus], cdfs[iminus], color='r', linestyle='--', lw=4)
>>> plt.vlines([x[iplus]], cdfs[iplus], ecdfs[iplus+1], color='m', linestyle='--', lw=4)
>>> plt.annotate('Dn-', xy=(x[iminus], (ecdfs[iminus] + cdfs[iminus])/2), xytext=(x[iminus] + 1, (ecdfs[iminus] + cdfs[iminus])/2 - 0.02), arrowprops=dict(facecolor='white', edgecolor='r', shrink=0.05), size=15, color='r');
>>> plt.annotate('Dn+', xy=(x[iplus], (ecdfs[iplus] + cdfs[iplus])/2), xytext=(x[iplus] - 2, (ecdfs[iplus] + cdfs[iplus])/2 - 0.02), arrowprops=dict(facecolor='white', edgecolor='m', shrink=0.05), size=15, color='m');
>>> plt.show()
```

References

Implementation: `scipy.stats.kstwo`

**KStwobign Distribution**

This is the limiting distribution of the normalized maximum absolute differences between an empirical distribution function, computed from $n$ samples or observations, and a comparison (or target) cumulative distribution function. (ksone is the distribution of the unnormalized positive differences, $D_n^+$.)

Writing $D_n = \sup_t |F_{\text{empirical}, n}(t) - F_{\text{target}}(t)|$, the normalization factor is $\sqrt{n}$, and kstwobign is the limiting distribution of the $\sqrt{n}D_n$ values as $n \to \infty$.

Note that $D_n = \max(D_n^+, D_n^-)$, but $D_n^+$ and $D_n^-$ are not independent.

kstwobign can also be used with the differences between two empirical distribution functions, for sets of observations with $m$ and $n$ samples respectively, where $m$ and $n$ are “big”. Writing $D_{m,n} = \sup_t |F_{1,m}(t) - F_{2,n}(t)|$, where...
$F_{1,m}$ and $F_{2,n}$ are the two empirical distribution functions, then $\text{kstwobign}$ is also the limiting distribution of the

$$\sqrt{\frac{mn}{m+n}} D_{m,n} \text{ values, as } m, n \to \infty \text{ and } m/n \to a \neq 0, \infty.$$ 

There are no shape parameters, and the support is $x \in [0, \infty)$.

$$F(x) = 1 - 2 \sum_{k=1}^{\infty} (-1)^k e^{-2k^2 x^2}$$

$$= \sqrt{2\pi} x \sum_{k=1}^{\infty} e^{-(2k-1)^2 \pi^2/(8x^2)}$$

$$= 1 - \text{scipy.special.kolmogorov}(n, x)$$

$$f(x) = 8x \sum_{k=1}^{\infty} (-1)^{k-1} k^2 e^{-2k^2 x^2}$$

References

Implementation: scipy.stats.kstwobign

Laplace (Double Exponential, Bilateral Exponential) Distribution

$$f(x) = \frac{1}{2} e^{-|x|}$$

$$F(x) = \begin{cases} \frac{1}{2} e^x & x \leq 0 \\ 1 - \frac{1}{2} e^{-x} & x > 0 \end{cases}$$

$$G(q) = \begin{cases} \log (2q) & q \leq \frac{1}{2} \\ -\log (2 - 2q) & q > \frac{1}{2} \end{cases}$$

$$m_d = m_n = \mu = 0$$

$$\mu_2 = 2$$

$$\gamma_1 = 0$$

$$\gamma_2 = 3$$

The ML estimator of the location parameter is

$$\hat{L} = \text{median} (X_i)$$

where $X_i$ is a sequence of $N$ mutually independent Laplace RV’s and the median is some number between the $\frac{1}{2} N$th and the $(N/2 + 1)$th order statistic ( e.g. take the average of these two) when $N$ is even. Also,

$$\hat{S} = \frac{1}{N} \sum_{j=1}^{N} |X_j - \hat{L}|.$$
Replace \( \hat{L} \) with \( L \) if it is known. If \( L \) is known then this estimator is distributed as \( (2N)^{-1} S \cdot \chi_{2N}^2 \).

\[
h[X] = \log(2e) \\
\approx 1.6931471805599453094.
\]

Implementation: `scipy.stats.laplace`

Asymmetric Laplace Distribution

This distribution is a generalization of the Laplace distribution. It has a single shape parameter \( \kappa > 0 \) that species the distribution’s asymmetry. The special case \( \kappa = 1 \) yields the Laplace distribution.

Functions

\[
F(x, \kappa) = \begin{cases} 
1 - \frac{\kappa^{-1}}{\kappa + \kappa^{-1}} \exp(-x\kappa), & x \geq 0; \\
\frac{\kappa}{\kappa + \kappa^{-1}} \exp(x/\kappa), & x < 0.
\end{cases}
\]

\[
f(x, \kappa) = \begin{cases} 
\frac{1}{\kappa + \kappa^{-1}} \exp(-x\kappa), & x \geq 0; \\
\frac{1}{\kappa + \kappa^{-1}} \exp(x/\kappa), & x < 0.
\end{cases}
\]

\[
\mu = \kappa^{-1} - \kappa \\
\mu_2 = \kappa^{-2} + \kappa^2 \\
\gamma_1 = \frac{2(1 - \kappa^6)}{(1 + \kappa^4)^{3/2}} \\
\gamma_2 = \frac{6(1 + \kappa^8)}{(1 + \kappa^4)^2}
\]

References

Implementation: `scipy.stats.laplace_asymmetric`

Left-skewed Lévy Distribution

Special case of Lévy-stable distribution with \( \alpha = \frac{1}{2} \) and \( \beta = -1 \). The support is \( x \leq 0 \). In standard form

\[
f(x) = \frac{1}{|x|\sqrt{2\pi|x|}} \exp\left(-\frac{1}{2|x|}\right) \\
F(x) = 2\Phi\left(\frac{1}{\sqrt{|x|}}\right) - 1 \\
G(q) = \left[\Phi^{-1}\left(q + \frac{1}{2}\right)\right]^{-2}.
\]
No moments.

Implementation: `scipy.stats.levy_1`

**Lévy Distribution**

A special case of Lévy-stable distributions with $\alpha = \frac{1}{2}$ and $\beta = 1$ and support $x \geq 0$. In standard form it is defined for $x > 0$ as

$$
\begin{align*}
f(x) &= \frac{1}{x \sqrt{2\pi x}} \exp \left( -\frac{1}{2x} \right) \\
F(x) &= 2 \left[ 1 - \Phi \left( \frac{1}{\sqrt{x}} \right) \right] \\
G(q) &= \left[ \Phi^{-1} \left( 1 - \frac{q}{2} \right) \right]^{-2}.
\end{align*}
$$

It has no finite moments.

Implementation: `scipy.stats.levy`

**Logistic (Sech-squared) Distribution**

A special case of the Generalized Logistic distribution with $c = 1$. The support is $x \in \mathbb{R}$.

This distribution function has a direct connection with the Fermi-Dirac distribution via its survival function. I.e. `scipy.stats.logistic.sf` is equivalent to the Fermi-Dirac distribution.

$$
\begin{align*}
f(x) &= \frac{\exp(-x)}{(1 + \exp(-x))^2} \\
F(x) &= \frac{1}{1 + \exp(-x)} \\
G(q) &= -\log(1/q - 1) \\
S(x) &= n_F(x) = \frac{1}{1 + \exp(x)}
\end{align*}
$$

$$
\begin{align*}
\mu &= \gamma + \psi_0(1) = 0 \\
\mu_2 &= \frac{\pi^2}{6} + \psi_1(1) = \frac{\pi^2}{3} \\
\gamma_1 &= \frac{\psi_2(1) + 2\zeta(3)}{\mu_2^{3/2}} = 0 \\
\gamma_2 &= \frac{\left( \frac{\pi^4}{15} + \psi_3(1) \right)}{\mu_2^2} = 6 \\
m_d &= \log 1 = 0 \\
m_n &= -\log(2 - 1) = 0
\end{align*}
$$

where $\psi_m$ is the polygamma function $\psi_m(z) = \frac{d^{m+1}}{dz^{m+1}} \log(\Gamma(z))$.

$$h[X] = 1.$$
Log Double Exponential (Log-Laplace) Distribution

One shape parameter \( c > 0 \). The support is \( x \geq 0 \).

\[
\begin{align*}
f(x; c) &= \begin{cases} 
\frac{c^2 x^{c-1}}{\Gamma(c)} & 0 < x < 1 \\
\frac{x^c}{\Gamma(c)} & x \geq 1
\end{cases} \\
F(x; c) &= \begin{cases} 
\frac{1}{2} x^c & 0 < x < 1 \\
1 - \frac{x^c}{\Gamma(c)} & x \geq 1
\end{cases} \\
G(q; c) &= \begin{cases} 
\left(\frac{2q}{\Gamma(c)}\right)^{1/c} & 0 \leq q < \frac{1}{2} \\
\left(\frac{2 - 2q}{\Gamma(c)}\right)^{-1/c} & \frac{1}{2} \leq q \leq 1
\end{cases}
\end{align*}
\]

\[h(X) = \log \left(\frac{2e}{c}\right)\]

Implementation: \texttt{scipy.stats.loglaplace}

Log Gamma Distribution

A single shape parameter \( c > 0 \). The support is \( x \in \mathbb{R} \).

\[
\begin{align*}
f(x; c) &= \frac{\exp(cx - e^x)}{\Gamma(c)} \\
F(x; c) &= \frac{\gamma(c, e^x)}{\Gamma(c)} \\
G(q; c) &= \log \left(\frac{\gamma^{-1}(c, q\Gamma(c))}{\gamma(c, e^x)}\right)
\end{align*}
\]

where \( \gamma \) is the lower incomplete gamma function, \( \gamma(s, x) = \int_0^x t^{s-1}e^{-t}dt \).

\[
\begin{align*}
\mu'_n &= \int_0^\infty [\log y]^n y^{c-1} \exp(-y) \, dy. \\
\mu &= \mu'_1 \\
\mu_2 &= \mu'_2 - \mu^2 \\
\gamma_1 &= \frac{\mu'_3 - 3\mu\mu_2 - \mu^3}{\mu_2^{3/2}} \\
\gamma_2 &= \frac{\mu'_4 - 4\mu\mu_3 - 6\mu^2\mu_2 - \mu^4}{\mu_2^2} - 3
\end{align*}
\]

Implementation: \texttt{scipy.stats.loggamma}

Log Normal (Cobb-Douglass) Distribution

Has one shape parameter \( \sigma > 0 \). (Notice that the “Regress” \( A = \log S \) where \( S \) is the scale parameter and \( A \) is the mean of the underlying normal distribution). The support is \( x \geq 0 \).

\[
\begin{align*}
f(x; \sigma) &= \frac{1}{\sigma x \sqrt{2\pi}} \exp \left( -\frac{1}{2} \left( \frac{\log x}{\sigma} \right)^2 \right) \\
F(x; \sigma) &= \Phi \left( \frac{\log x}{\sigma} \right) \\
G(q; \sigma) &= \exp \left( \sigma \Phi^{-1}(q) \right)
\end{align*}
\]
\[ \mu = \exp(\sigma^2/2) \]
\[ \mu_2 = \exp(\sigma^2) \left[ \exp(\sigma^2) - 1 \right] \]
\[ \gamma_1 = \sqrt{p - 1} (2 + p) \]
\[ \gamma_2 = p^4 + 2p^3 + 3p^2 - 6 \quad p = e^{\sigma^2} \]

Notice that using JKB notation we have \( \theta = L, \zeta = \log S \) and we have given the so-called antilognormal form of the distribution. This is more consistent with the location, scale parameter description of general probability distributions.

\[ h[X] = \frac{1}{2} \left[ 1 + \log(2\pi) + 2\log \sigma \right]. \]

Also, note that if \( X \) is a log-normally distributed random-variable with \( L = 0 \) and \( S \) and shape parameter \( \sigma \). Then, \( \log X \) is normally distributed with variance \( \sigma^2 \) and mean \( \log S \).

Implementation: `scipy.stats.lognorm`

**Log-Uniform Distribution**

This random variable is log-uniform. That is, if \( \text{loguniform}(10**-1, 10**1) \) is specified, \( 0.1, 1, 10 \) are all equally likely.

There are two shape parameters \( a, b > 0 \) and the support is \( x \in [a, b] \).

\[ f(x; a, b) = \frac{1}{x \log(b/a)} \]
\[ F(x; a, b) = \frac{\log(x/a)}{\log(b/a)} \]
\[ G(q; a, b) = a \exp(q \log(b/a)) = a \left( \frac{b}{a} \right)^q \]

\[ d = \log(a/b) \]
\[ \mu = \frac{a - b}{d} \]
\[ \mu_2 = \frac{a + b}{2} - \mu^2 = \left( a - b \right) \left[ a(d - 2) + b(d + 2) \right] \]
\[ \gamma_1 = \sqrt{\frac{12d(a - b)^2 + d^2 \left( a^2 (2d - 9) + 2abd + b^2 (2d + 9) \right)}{3d\sqrt{a - b} \left[ a(d - 2) + b(d + 2) \right]^{3/2}}} \]
\[ \gamma_2 = -36(a - b)^3 + 36d(a - b)^2(a + b) - 16d^2(a^2 - b^3) + 3d^3(a^2 + b^2)(a + b) - 3 \]
\[ m_d = \frac{a}{3(a - b) \left[ a(d - 2) + b(d + 2) \right]^2} \]
\[ m_n = \frac{\sqrt{ab}}{3(a - b) \left[ a(d - 2) + b(d + 2) \right]^2} \]

\[ h[X] = \frac{1}{2} \log(ab) + \log \left[ \log \left( \frac{b}{a} \right) \right]. \]

Implementation: `scipy.stats.loguniform`
Maxwell Distribution

This is a special case of the Chi distribution with $L = 0$ and $S = \frac{1}{\sqrt{a}}$ and $\nu = 3$. The support is $x \geq 0$.

\[
f(x) = \sqrt{\frac{2}{\pi}} x e^{-x^2/2} \]

\[
F(x) = \frac{\gamma(\frac{3}{2}, \frac{x^2}{2})}{\Gamma(\frac{3}{2})} \]

\[
G(q) = \sqrt{2\gamma^{-1}\left(\frac{3}{2}, q\Gamma(\frac{3}{2})\right)} \]

\[
\mu = 2\sqrt{\frac{2}{\pi}} \]

\[
\mu_2 = 3 - \frac{8}{\pi} \]

\[
\gamma_1 = \sqrt{2} \frac{32 - 10\pi}{(3\pi - 8)^{3/2}} \]

\[
\gamma_2 = -12\pi^2 + 160\pi - 384 \]

\[
m_d = \sqrt{2} \]

\[
m_n = \sqrt{2}\gamma^{-1}\left(\frac{3}{2}, \frac{1}{2}\Gamma(\frac{3}{2})\right) \]

\[h[X] = \log\left(\sqrt{\frac{2\pi}{e}}\right) + \gamma.\]

Implementation: \texttt{scipy.stats.maxwell}

Mielke's Beta-Kappa Distribution

A generalized F distribution. Two shape parameters $\kappa$ and $\theta$, with support $x \geq 0$. The $\beta$ in the DATAPLOT reference is a scale parameter.

\[
f(x; \kappa, \theta) = \frac{\kappa x^{\kappa-1}}{(1 + x^\theta)^{1+\frac{\kappa}{\theta}}} \]

\[
F(x; \kappa, \theta) = \frac{x^\kappa}{(1 + x^\theta)^{\kappa/\theta}} \]

\[
G(q; \kappa, \theta) = \left(\frac{q^{\theta/\kappa}}{1 - q^{\theta/\kappa}}\right)^{1/\theta} \]

Implementation: \texttt{scipy.stats.mielke}
Nakagami Distribution

Generalization of the chi distribution. Shape parameter is $\nu > 0$. The support is $x \geq 0$.

$$f(x; \nu) = \frac{2\nu^\nu}{\Gamma(\nu)} x^{2\nu-1} \exp \left(-\nu x^2\right)$$

$$F(x; \nu) = \frac{\gamma(\nu, \nu x^2)}{\Gamma(\nu)}$$

$$G(q; \nu) = \sqrt{\frac{1}{\nu} \Gamma^{-1}(\nu, q \Gamma(\nu))}$$

where $\gamma$ is the lower incomplete gamma function, $\gamma(\nu, x) = \int_0^x t^{\nu-1} e^{-t} dt$.

$$\mu = \frac{\Gamma(\nu + \frac{1}{2})}{\sqrt{\nu} \Gamma(\nu)}$$

$$\mu_2 = [1 - \mu^2]$$

$$\gamma_1 = \frac{\mu(1 - 4\nu \mu_2)}{2\nu \mu_2^2}$$

$$\gamma_2 = -6\mu^4 + (8\nu - 2) \mu^2 - 2\nu + 1$$

Implementation: scipy.stats.nakagami

MLE of the Nakagami Distribution in SciPy (nakagami.fit)

The probability density function of the nakagami distribution in SciPy is

$$f(x; \nu, \mu, \sigma) = \frac{2\nu^\nu}{\sigma^\nu \Gamma(\nu)} \left(\frac{x - \mu}{\sigma}\right)^{2\nu-1} \exp \left(-\nu \left(\frac{x - \mu}{\sigma}\right)^2\right)$$

for $x$ such that $\frac{x - \mu}{\sigma} \geq 0$, where $\nu \geq \frac{1}{2}$ is the shape parameter, $\mu$ is the location, and $\sigma$ is the scale.

The log-likelihood function is therefore

$$l(\nu, \mu, \sigma) = \sum_{i=1}^{N} \log \left(2\nu^\nu \frac{x_i - \mu}{\sigma^\nu \Gamma(\nu)} \left(\frac{x_i - \mu}{\sigma}\right)^{2\nu-1} \exp \left(-\nu \left(\frac{x_i - \mu}{\sigma}\right)^2\right)\right),$$

which can be expanded as

$$l(\nu, \mu, \sigma) = N \log(2) + N \nu \log(\nu) - N \log(\Gamma(\nu)) - 2N \nu \log(\sigma) + (2\nu - 1) \sum_{i=1}^{N} \log(x_i - \mu) - \nu \sigma^{-2} \sum_{i=1}^{N} (x_i - \mu)^2,$$

Leaving supports constraints out, the first-order condition for optimality on the likelihood derivatives gives estimates of parameters:

$$\frac{\partial l}{\partial \nu}(\nu, \mu, \sigma) = N \left(1 + \log(\nu) - \psi^{(0)}(\nu)\right) + 2 \sum_{i=1}^{N} \log \left(\frac{x_i - \mu}{\sigma}\right) - \sum_{i=1}^{N} \left(\frac{x_i - \mu}{\sigma}\right)^2 = 0$$

$$\frac{\partial l}{\partial \mu}(\nu, \mu, \sigma) = (1 - 2\nu) \sum_{i=1}^{N} \frac{1}{x_i - \mu} + 2\nu \sigma^{-2} \sum_{i=1}^{N} x_i - \mu = 0$$

$$\frac{\partial l}{\partial \sigma}(\nu, \mu, \sigma) = -2N\nu \frac{1}{\sigma} + 2\nu \sigma^{-3} \sum_{i=1}^{N} (x_i - \mu)^2 = 0$$

2.12. Statistics (scipy.stats) 187
where \( \psi^{(0)} \) is the polygamma function of order 0; i.e., \( \psi^{(0)}(\nu) = \frac{d}{d\nu} \log \Gamma(\nu) \).

However, the support of the distribution is the values of \( x \) for which \( \frac{x-\mu}{\sigma} \geq 0 \), and this provides an additional constraint that
\[
\mu \leq \min_i x_i. \tag{7}
\]
For \( \nu = \frac{1}{2} \), the partial derivative of the log-likelihood with respect to \( \mu \) reduces to:
\[
\frac{\partial l}{\partial \mu}(\nu, \mu, \sigma) = \sigma^2 \sum_{i=1}^{N} (x_i - \mu), \tag{2.10}
\]
which is positive when the support constraint is satisfied. Because the partial derivative with respect to \( \mu \) is positive, increasing \( \mu \) increases the log-likelihood, and therefore the constraint is active at the maximum likelihood estimate for \( \mu = \min_i x_i \). \( \tag{8} \)

For \( \nu \) sufficiently greater than \( \frac{1}{2} \), the likelihood equation \( \frac{\partial l}{\partial \mu}(\nu, \mu, \sigma) = 0 \) has a solution, and this solution provides the maximum likelihood estimate for \( \mu \). In either case, however, the condition \( \mu = \min_i x_i \) provides a reasonable initial guess for numerical optimization.

Furthermore, the likelihood equation for \( \sigma \) can be solved explicitly, and it provides the maximum likelihood estimate
\[
\sigma = \sqrt{\frac{\sum_{i=1}^{N} (x_i - \mu)^2}{N}}. \tag{9}
\]
Hence, the \_fitstart method for \texttt{nakagami} uses
\[
\mu_0 = \min_i x_i \quad \text{and} \quad \sigma_0 = \sqrt{\frac{\sum_{i=1}^{N} (x_i - \mu_0)^2}{N}} \tag{2.11}
\]
as initial guesses for numerical optimization accordingly.

### Noncentral chi-squared Distribution

The distribution of \( \sum_{i=1}^{\nu} (Z_i + \delta_i)^2 \) where \( Z_i \) are independent standard normal variables and \( \delta_i \) are constants. \( \lambda = \sum_{i=1}^{\nu} \delta_i^2 > 0 \). (In communications it is called the Marcum-Q function). It can be thought of as a Generalized Rayleigh-Rice distribution.

The two shape parameters are \( \nu \), a positive integer, and \( \lambda \), a positive real number. The support is \( x \geq 0 \).
\[
f(x; \nu, \lambda) = e^{-(\lambda+x)/2} \frac{1}{2} \left( \frac{x}{\lambda} \right)^{(\nu-2)/4} I_{(\nu-2)/2} \left( \sqrt{\lambda x} \right)
\]
\[
F(x; \nu, \lambda) = \sum_{j=0}^{\infty} \left\{ \frac{(\lambda/2)^j}{j!} e^{-\lambda/2} \right\} \Pr [\lambda_{\nu+2j}^2 \leq x]
\]
\[
G(q; \nu, \lambda) = F^{-1}(q; \nu, \lambda)
\]
\[
\mu = \nu + \lambda
\]
\[
\mu_2 = 2(\nu + 2\lambda)
\]
\[
\gamma_1 = \sqrt{8(\nu + 3\lambda)} \quad \frac{1}{(\nu + 2\lambda)^{3/2}}
\]
\[
\gamma_2 = 12(\nu + 4\lambda) \quad \frac{1}{(\nu + 2\lambda)^2}
\]
where \( I_\nu(y) \) is a modified Bessel function of the first kind.
Noncentral F Distribution

The distribution of \((X_1/X_2) (\nu_2/\nu_1)\) if \(X_1\) is non-central chi-squared with \(\nu_1\) degrees of freedom and parameter \(\lambda\), and \(X_2\) is chi-squared with \(\nu_2\) degrees of freedom.

There are 3 shape parameters: the degrees of freedom \(\nu_1 > 0\) and \(\nu_2 > 0\); and \(\lambda \geq 0\).

\[
f(x; \lambda, \nu_1, \nu_2) = \exp \left[ \frac{\lambda}{2} + \frac{(\lambda \nu_1 x)}{2(\nu_1 x + \nu_2)} \right] \nu_1^{\nu_1/2} \nu_2^{\nu_2/2} x^{\nu_1/2-1} \times (\nu_2 + \nu_1 x)^{-(\nu_1+\nu_2)/2} \frac{\Gamma \left( \frac{\nu_2}{2} \right) \Gamma \left( 1 + \frac{\nu_2}{2} \right) L_{\nu_2/2}^{\nu_1/2-1} \left( -\frac{\lambda \nu_1 x}{2(\nu_1 x + \nu_2)} \right)}{B \left( \frac{\nu_1}{2}, \frac{\nu_2}{2} \right) \Gamma \left( \frac{\nu_1+\nu_2}{2} \right)}
\]

where \(L_{\nu_2/2}^{\nu_1/2-1}(x)\) is an associated Laguerre polynomial.

If \(\lambda = 0\), the distribution becomes equivalent to the Fisher distribution with \(\nu_1\) and \(\nu_2\) degrees of freedom.

Implementation: \texttt{scipy.stats.ncf}

Noncentral t Distribution

The distribution of the ratio

\[
\frac{U + \lambda}{\chi_{\nu}/\sqrt{\nu}}
\]
where $U$ and $\chi_\nu$ are independent and distributed as a standard normal and chi with $\nu$ degrees of freedom. Note $\lambda > 0$ and $\nu > 0$.

\[
\begin{align*}
    f(x; \lambda, \nu) &= \frac{\nu^{\nu/2} \Gamma(\nu + 1)}{2^{\nu/2} \lambda^{\nu/2} (\nu + x^2)^{\nu/2} \Gamma(\nu/2)} \\
    &\quad \times \left\{ \frac{\sqrt{2} \lambda x \text{F}_1 \left( \frac{\nu}{2} + 1; \frac{1}{2}; \frac{\lambda^2 x^2}{2(\nu + x^2)} \right)}{(\nu + x^2) \Gamma \left( \frac{\nu + 1}{2} \right)} \\
    &\quad - \frac{\text{F}_1 \left( \frac{\nu + 1}{2}; \frac{1}{2}; \frac{\lambda^2 x^2}{2(\nu + x^2)} \right)}{\sqrt{\nu + x^2} \Gamma \left( \frac{\nu}{2} + 1 \right)} \right\} \\
    &= \frac{\Gamma(\nu + 1)}{2^{(\nu-1)/2} \sqrt{\pi} \Gamma(\nu/2)} \exp \left[ -\frac{\nu \lambda^2}{\nu + x^2} \right] \\
    &\quad \times \left( \frac{\nu}{\nu + x^2} \right)^{(\nu-1)/2} H_{\nu} \left( -\frac{\lambda x}{\sqrt{\nu + x^2}} \right)
\end{align*}
\]

\[
F(x; \lambda, \nu) = \begin{cases} 
    \tilde{F}_{\nu, \mu}(x) & x \geq 0 \\
    1 - \tilde{F}_{\nu, -\mu}(x) & x < 0
\end{cases}
\]

where

\[
\begin{align*}
    \tilde{F}_{\nu, \mu}(x) &= \Phi(-\mu) + \frac{1}{2} \sum_{j=0}^{\infty} [p_j I_y \left( j + 1; \frac{\nu}{2} \right) + q_j I_y \left( j + 1; \frac{\nu}{2} \right)] \\
    y &= \frac{x^2}{\nu^2 + \nu} \\
    p_j &= \frac{e^{-\mu^2/2}}{j!} \left( \frac{\mu^2}{2} \right)^j \\
    q_j &= \frac{\mu e^{-\mu^2/2}}{\sqrt{2} \Gamma(j + 3/2)} \left( \frac{\mu^2}{2} \right)^j
\end{align*}
\]

where $I_y(a, b)$ is the regularized incomplete beta function and Airy’s $Hh$ function is $H_{\nu}(x) = \frac{1}{\Gamma(\nu+1)} \int_0^\infty t^{\nu} e^{-\frac{(t+x)^2}{2}} dt$.

Implementation: `scipy.stats.nct`

**Normal Distribution**

\[
\begin{align*}
    f(x) &= \frac{e^{-x^2/2}}{\sqrt{2\pi}} \\
    F(x) &= \Phi(x) = \frac{1}{2} + \frac{1}{2} \text{erf} \left( \frac{x}{\sqrt{2}} \right) \\
    G(q) &= \Phi^{-1}(q)
\end{align*}
\]

\[
\begin{align*}
    m_d &= m_n = \mu = 0 \\
    \mu_2 &= 1 \\
    \gamma_1 &= 0 \\
    \gamma_2 &= 0
\end{align*}
\]
\[ h[X] = \log \left( \sqrt{2\pi e} \right) \approx 1.4189385332046727418 \]

Implementation: \texttt{scipy.stats.norm}

**Normal Inverse Gaussian Distribution**

The probability density function is given by:

\[
f(x; a, b) = \frac{a \exp \left( \sqrt{a^2 - b^2 + bx} \right)}{\pi \sqrt{1 + x^2}} K_1 \left( a \sqrt{1 + x^2} \right),
\]

where \(x\) is a real number, the parameter \(a\) is the tail heaviness and \(b\) is the asymmetry parameter satisfying \(a > 0\) and \(|b| \leq a\). \(K_1\) is the modified Bessel function of second kind (\texttt{scipy.special.k1}).

A normal inverse Gaussian random variable with parameters \(a\) and \(b\) can be expressed as \(X = bV + \sqrt(V)X\) where \(X\) is \texttt{norm(0,1)} and \(V\) is \texttt{invgauss(mu=1/sqrt(a**2 - b**2))}. Hence, the normal inverse Gaussian distribution is a special case of normal variance-mean mixtures.

Another common parametrization of the distribution is given by the following expression of the pdf:

\[
g(x, \alpha, \beta, \delta, \mu) = \frac{\alpha \delta K_1 \left( \alpha \sqrt{\delta^2 + (x - \mu)^2} \right)}{\pi \sqrt{\delta^2 + (x - \mu)^2}} e^{\delta \sqrt{\alpha^2 - \beta^2 + \beta(x-\mu)}}
\]

In SciPy, this corresponds to \(a = \alpha \delta, b = \beta \delta, \text{loc} = \mu, \text{scale} = \delta\).

Implementation: \texttt{scipy.stats.norminvgauss}

**Pareto Distribution**

One shape parameter \(b > 0\) and support \(x \geq 1\). The standard form is

\[
f(x; b) = \frac{b}{x^{b+1}}
\]

\[
F(x; b) = 1 - \frac{1}{x^b}
\]

\[
G(q; b) = (1 - q)^{-1/b}
\]

\[
\mu = \frac{b}{b - 1} \quad b > 1
\]

\[
\mu_2 = \frac{b}{(b - 2)(b - 1)^2} \quad b > 2
\]

\[
\gamma_1 = \frac{2(b + 1)\sqrt{b - 2}}{(b - 3)\sqrt{b}} \quad b > 3
\]

\[
\gamma_2 = \frac{6(b^3 + b^2 - 6b - 2)}{b(b^2 - 7b + 12)} \quad b > 4
\]

\[
h(X) = \frac{1}{c} + 1 - \log(c)
\]

Implementation: \texttt{scipy.stats.pareto}
Pareto Second Kind (Lomax) Distribution

This is Pareto of the first kind with \( L = -1.0 \). There is one shape parameter \( c > 0 \) and support \( x \geq 0 \).

\[
\begin{align*}
  f(x;c) &= \frac{c}{(1+x)^{c+1}} \\
  F(x;c) &= 1 - \frac{1}{(1+x)^c} \\
  G(q;c) &= (1-q)^{-1/c} - 1 \\
  h[X] &= \frac{1}{c} + 1 - \log(c).
\end{align*}
\]

Implementation: \texttt{scipy.stats.lomax}

Power Log Normal Distribution

A generalization of the log-normal distribution with shape parameters \( \sigma > 0, c > 0 \) and support \( x \geq 0 \).

\[
\begin{align*}
  f(x;\sigma,c) &= \frac{c}{x\sigma} \phi \left( \frac{\log x}{\sigma} \right) \left( \Phi \left( -\frac{\log x}{\sigma} \right) \right)^{c-1} \\
  F(x;\sigma,c) &= 1 - \left( \Phi \left( -\frac{\log x}{\sigma} \right) \right)^c \\
  G(q;\sigma,c) &= \exp \left( -\sigma \Phi^{-1} \left( (1-q)^{1/c} \right) \right) \\
  \mu'_n &= \int_0^1 \exp \left( -n\sigma \Phi^{-1} \left( y^{1/c} \right) \right) dy \\
  \mu &= \mu'_1 \\
  \mu_2 &= \mu'_2 - \mu^2 \\
  \gamma_1 &= \frac{\mu'_3 - 3\mu\mu_2 - \mu^3}{\mu_2^2} \\
  \gamma_2 &= \frac{\mu'_4 - 4\mu\mu'_3 - 6\mu^2\mu_2 - \mu^4}{\mu_2^2} - 3
\end{align*}
\]

This distribution reduces to the log-normal distribution when \( c = 1 \).

Implementation: \texttt{scipy.stats.powerlognorm}

Power Normal Distribution

A generalization of the normal distribution, with one shape parameter \( c > 0 \) and support \( x \geq 0 \).

\[
\begin{align*}
  f(x;c) &= c\phi(x) \left( \Phi \left( -x \right) \right)^{c-1} \\
  F(x;c) &= 1 - \left( \Phi \left( -x \right) \right)^c \\
  G(q;c) &= -\Phi^{-1} \left( (1-q)^{1/c} \right) \\
  \mu'_n &= (-1)^n \int_0^1 \left[ \Phi^{-1} \left( y^{1/c} \right) \right]^n dy
\end{align*}
\]
\[
\begin{align*}
\mu &= \mu_1' \\
\mu_2 &= \mu_1' - \mu_2 \\
\gamma_1 &= \frac{\mu_3' - 3\mu_2' - \mu_3}{\mu_2^{3/2}} \\
\gamma_2 &= \frac{\mu_4' - 4\mu_3' - 6\mu_2' - \mu_4}{\mu_2^2} - 3
\end{align*}
\]

For \( c = 1 \) this reduces to the normal distribution.

Implementation: \texttt{scipy.stats.powernorm}

**Power-function Distribution**

A special case of the beta distribution with \( b = 1 \). There is one shape parameter \( a > 0 \) and support \( x \in [0, 1] \).

\[
\begin{align*}
\mu &= \frac{a}{a+1} \\
\mu_2 &= \frac{a(a+2)}{(a+1)^2} \\
\gamma_1 &= 2(1-a)\sqrt{\frac{a+2}{a(a+3)}} \\
\gamma_2 &= \frac{6(a^3-a^2-6a+2)}{a(a+3)(a+4)} \\
m_d &= 1 \\
&= 1 - \frac{1}{a} - \log(a)
\end{align*}
\]

Implementation: \texttt{scipy.stats.powerlaw}

**R-distribution Distribution**

A general-purpose distribution with a variety of shapes controlled by one shape parameter \( c > 0 \). The support of the standard distribution is \( x \in [-1, 1] \).

\[
\begin{align*}
\mu &= \frac{(1-x^2)^{c/2-1}}{B\left(\frac{1}{2}, \frac{c}{2}\right)} \\
F(x;c) &= \frac{1}{2} + \frac{x}{B\left(\frac{1}{2}, \frac{c}{2}\right)} {}_2F_1\left(\frac{1}{2}, 1 - \frac{c}{2}; \frac{3}{2}; x^2\right) \\
\mu'_n &= \frac{(1+(-1)^n)}{2} \frac{B\left(\frac{n+1}{2}, \frac{c}{2}\right)}{B\left(\frac{n}{2}, \frac{c}{2}\right)}
\end{align*}
\]

The R-distribution with parameter \( n \) is the distribution of the correlation coefficient of a random sample of size \( n \) drawn from a bivariate normal distribution with \( \rho = 0 \). The mean of the standard distribution is always zero and as the sample size grows, the distribution’s mass concentrates more closely about this mean.

Implementation: \texttt{scipy.stats.rdist}
Rayleigh Distribution

This is a special case of the Chi distribution with $L = 0.0$ and $\nu = 2$ (no location parameter is generally used), the mode of the distribution is $S$.

$$f(r) = re^{-r^2/2}$$
$$F(r) = 1 - e^{-r^2/2}$$
$$G(q) = \sqrt{-2\log(1-q)}$$

$$\mu = \sqrt{\frac{\pi}{2}}$$
$$\mu_2 = \frac{4 - \pi}{2}$$
$$\gamma_1 = \frac{2(\pi - 3)\sqrt{\pi}}{(4 - \pi)^{3/2}}$$
$$\gamma_2 = \frac{24\pi - 6\pi^2 - 16}{(4 - \pi)^2}$$
$$m_d = 1$$
$$m_n = \sqrt{2\log(2)}$$
$$h[X] = \frac{\gamma}{2} + \log\left(\frac{e}{\sqrt{2}}\right)$$
$$\mu_n' = \sqrt{2\pi}\Gamma\left(\frac{n}{2} + 1\right)$$

Implementation: `scipy.stats.rayleigh`

Rice Distribution

There is one shape parameter $b \geq 0$ (the “distance from the origin”) and the support is $x \geq 0$.

$$f(x; b) = x\exp\left(-\frac{x^2 + b^2}{2}\right)I_0(xb)$$
$$F(x; b) = \int_0^x \alpha\exp\left(-\frac{\alpha^2 + b^2}{2}\right)I_0(ab)\,d\alpha$$

were $I_0(y)$ is the modified Bessel function of the first kind of order 0.

$$\mu_n' = \sqrt{2\pi}\Gamma\left(1 + \frac{n}{2}\right)\Phi\left(-\frac{n}{2}; 1; -\frac{b^2}{2}\right)$$

Implementation: `scipy.stats.rice`

Reciprocal Inverse Gaussian Distribution

The pdf is found from the inverse gaussian (IG), $f_{RIG}(x; \mu) = \frac{1}{x}f_{IG}\left(\frac{1}{x}; \mu\right)$ defined for $x \geq 0$ as

$$f_{IG}(x; \mu) = \frac{1}{\sqrt{2\pi x^3}}\exp\left(-\frac{(x - \mu)^2}{2x\mu^2}\right),$$
$$F_{IG}(x; \mu) = \Phi\left(\frac{\mu - x}{\sqrt{x}/\mu}\right) + \exp\left(\frac{2}{\mu}\right)\Phi\left(-\frac{1}{\sqrt{x}}\frac{x + \mu}{\mu}\right)$$
\[ f_{RIG}(x; \mu) = \frac{1}{\sqrt{2\pi x}} \exp\left(-\frac{(1-\mu x)^2}{2x\mu^2}\right) \]

\[ F_{RIG}(x; \mu) = 1 - F_{IG}\left(\frac{1}{x}, \mu\right) \]

\[ = 1 - \Phi\left(\frac{1}{\sqrt{x}} \frac{1-\mu x}{\mu}\right) - \exp\left(\frac{2}{\mu}\right) \Phi\left(-\frac{1}{\sqrt{x}} \frac{1 + \mu x}{\mu}\right) \]

Implementation: \texttt{scipy.stats.recipinvgauss}

**Semicircular Distribution**

Defined on \( x \in [-1, 1] \)

\[ f(x) = \frac{2}{\pi} \sqrt{1-x^2} \]

\[ F(x) = \frac{1}{2} + \frac{1}{\pi} \left[ x\sqrt{1-x^2} + \arcsin x \right] \]

\[ G(q) = F^{-1}(q) \]

\[ m_d = m_n = \mu = 0 \]

\[ \mu_2 = \frac{1}{4} \]

\[ \gamma_1 = 0 \]

\[ \gamma_2 = -1 \]

\[ h[X] = 0.64472988584940017414. \]

Implementation: \texttt{scipy.stats.semicircular}

**Studentized Range Distribution**

This distribution has two shape parameters, \( k > 1 \) and \( \nu > 0 \), and the support is \( x \geq 0 \).

\[ f(x; k, \nu) = \frac{k(k-1)\nu^{\nu/2}}{\Gamma(\nu/2)2^{\nu/2-1}} \int_0^\infty \int_{-\infty}^\infty s^{\nu-1}e^{-\nu s^2/2}\phi(z)\phi(sx + z)[\Phi(sx + z) - \Phi(z)]^{k-2}dz\,ds \]

\[ F(q; k, \nu) = \frac{k\nu^{\nu/2}}{\Gamma(\nu/2)2^{\nu/2-1}} \int_0^\infty \int_{-\infty}^\infty s^{\nu-1}e^{-\nu s^2/2}\phi(z)[\Phi(sq + z) - \Phi(z)]^{k-1}dz\,ds \]

Note: \( \phi(z) \) and \( \Phi(z) \) represent the normal PDF and normal CDF, respectively.

When \( \nu \) exceeds 100,000, the asymptotic approximation of \( F(x; k, \nu = \infty) \) is used:

\[ F(x; k, \nu = \infty) = k \int_{-\infty}^\infty \phi(z)[\Phi(x + z) - \Phi(z)]^{k-1}dz \]

Implementation: \texttt{scipy.stats.studentized_range}
Student t Distribution

There is one shape parameter $\nu > 0$ and the support is $x \in \mathbb{R}$.

$$\begin{align*}
  f(x;\nu) &= \frac{\Gamma(\frac{\nu+1}{2})}{\sqrt{\nu\pi}\Gamma(\frac{\nu}{2}) \left[1 + \frac{x^2}{\nu}\right]^\frac{\nu+1}{2}} \\
  F(x;\nu) &= \begin{cases} 
  \frac{1}{2} I \left(\frac{\nu}{\nu+x^2}; \frac{\nu}{2}, \frac{1}{2}\right) & x \leq 0 \\
  1 - \frac{1}{2} I \left(\frac{\nu}{\nu+x^2}; \frac{\nu}{2}, \frac{1}{2}\right) & x \geq 0 
\end{cases} \\
  G(q;\nu) &= \begin{cases} 
  \frac{1}{\nu} \left[ I^{-1}(2q, \frac{\nu}{2}) - I^{-1}(2q, \frac{\nu}{2}, \frac{1}{2}) \right] & q \leq \frac{1}{2} \\
  \frac{1}{\nu} \left[ I^{-1}(2q, \frac{\nu}{2}, \frac{1}{2}) - I^{-1}(2q, \frac{\nu}{2}) \right] & q \geq \frac{1}{2}
\end{cases}
\end{align*}$$

where $I(a; x) = \frac{\Gamma(a+1)}{\Gamma(a)} \int_0^x t^{a-1} (1-t)^{a-1} dt$ is the incomplete beta integral and $I^{-1}(a, b; x) = y$ is the inverse incomplete beta function. As $\nu \to \infty$, this distribution approaches the standard normal distribution.

$$h[X] = \frac{\nu+1}{2} \left[ \psi\left(\frac{1+\nu}{2}\right) - \psi\left(\frac{\nu}{2}\right) \right] + \ln \left[ \sqrt{n} B\left(\frac{\nu}{2}, \frac{1}{2}\right) \right]$$

where $\psi(x)$ is the digamma function and $B(x, y)$ is the beta function.

References

Implementation: scipy.stats.t

Trapezoidal Distribution

Two shape parameters $c \in [0, 1], d \in [0, 1]$ giving the distances to the first and second modes as a percentage of the total extent of the non-zero portion. The location parameter is the start of the non-zero portion, and the scale-parameter is the width of the non-zero portion. In standard form we have $x \in [0, 1]$.

$$\begin{align*}
  u(c,d) &= \frac{2}{d-c+1} \\
  f(x;c,d) &= \begin{cases} 
  \frac{u}{x} & x < c \\
  u & c \leq x \leq d \\
  u \frac{1-x}{d-x} & x > d
\end{cases} \\
  F(x;c,d) &= \begin{cases} 
  \frac{uc}{x} + u(x-c) & x < c \\
  1 - u(1-x)^2 & c \leq x \leq d \\
  \frac{\sqrt{qc(d-c+1)}}{x} & x > d
\end{cases} \\
  G(q;c,d) &= \begin{cases} 
  \frac{q}{n} + \frac{c}{d} & q \leq c \\
  1 - \frac{2(1-q)(1-d)}{u} & q > d
\end{cases}
\end{align*}$$

Implementation: scipy.stats.trapezoid
Triangular Distribution

One shape parameter $c \in [0, 1]$ giving the distance to the peak as a percentage of the total extent of the non-zero portion. The location parameter is the start of the non-zero portion, and the scale-parameter is the width of the non-zero portion. In standard form we have $x \in [0, 1]$.

$$
 f(x; c) = \begin{cases} 
 \frac{2x}{c} & x < c \\
 \frac{1-x}{1-c} & x \geq c 
\end{cases} \\
 F(x; c) = \begin{cases} 
 \frac{x^2}{c^2} & x < c \\
 \frac{x^2 - 2x + x}{c^2} & x \geq c 
\end{cases} \\
 G(q; c) = \begin{cases} 
 \frac{\sqrt{cq}}{1 - \sqrt{(1-c)(1-q)}} & q < c \\
 1 - \sqrt{(1-c)(1-q)} & q \geq c 
\end{cases}
$$

$$
\mu = \frac{c}{3} + \frac{1}{3} \\
\mu_2 = \frac{1 - c + c^2}{18} \\
\gamma_1 = \frac{\sqrt{2}(2c-1)(c+1)(c-2)}{5(1-c+c^2)^{3/2}} \\
\gamma_2 = -\frac{3}{5} \\

h(X) = \log \left( \frac{1}{2} \sqrt{e} \right) \\
\approx -0.19314718055994530942.
$$

Implementation: `scipy.stats.triang`

Truncated Exponential Distribution

This is an exponential distribution defined only over a certain region $0 \leq x \leq B$. In standard form this is

$$
 f(x; B) = \frac{e^{-x}}{1 - e^{-B}} \\
 F(x; B) = \frac{1 - e^{-x}}{1 - e^{-B}} \\
 G(q; B) = -\log\left(1 - q + qe^{-B}\right) \\

\mu'_n = \Gamma(1+n) - \Gamma(1+n,B) \\

h[X] = \log\left(e^B - 1\right) + \frac{1 + e^B (B - 1)}{1 - e^B}.
$$

Implementation: `scipy.stats.truncexpon`
Truncated Normal Distribution

A normal distribution restricted to lie within a certain range given by two parameters \( A \) and \( B \). Notice that this \( A \) and \( B \) correspond to the bounds on \( x \) in standard form. For \( x \in [A, B] \) we get

\[
\begin{align*}
  f(x; A, B) &= \frac{\phi(x)}{\Phi(B) - \Phi(A)} \\
  F(x; A, B) &= \frac{\Phi(x) - \Phi(A)}{\Phi(B) - \Phi(A)} \\
  G(q; A, B) &= \Phi^{-1}(q\Phi(B) + \Phi(A)(1-q))
\end{align*}
\]

where

\[
\begin{align*}
  \phi(x) &= \frac{1}{\sqrt{2\pi}} e^{-x^2/2} \\
  \Phi(x) &= \int_{-\infty}^{x} \phi(u) du.
\end{align*}
\]

\[
\begin{align*}
  \mu &= \frac{\phi(A) - \phi(B)}{\Phi(B) - \Phi(A)} \\
  \mu_2 &= 1 + \frac{A\phi(A) - B\phi(B)}{\Phi(B) - \Phi(A)} - \left(\frac{\phi(A) - \phi(B)}{\Phi(B) - \Phi(A)}\right)^2
\end{align*}
\]

Implementation: scipy.stats.truncnorm

Tukey-Lambda Distribution

There is one shape parameter \( \lambda \). The support is \( x \in \mathbb{R} \).

\[
\begin{align*}
  f(x; \lambda) &= F'(x; \lambda) = \frac{1}{G'(F(x; \lambda); \lambda)} = \frac{1}{F^{-1}(x; \lambda) + [1 - F(x; \lambda)]^{\lambda-1}} \\
  F(x; \lambda) &= G^{-1}(x; \lambda) \\
  G(p; \lambda) &= \frac{p^\lambda - (1-p)^\lambda}{\lambda}
\end{align*}
\]

\[
\begin{align*}
  \mu &= 0 \\
  \mu_2 &= \int_0^1 G^2(p; \lambda) \, dp \\
  &= \frac{2\Gamma(\lambda + \frac{3}{2}) - \lambda^2 - 4\lambda \sqrt{\pi} \Gamma(\lambda)(1 - 2\lambda)}{\lambda^2 (1 + 2\lambda) \Gamma(\lambda + \frac{3}{2})} \\
  \gamma_1 &= 0 \\
  \gamma_2 &= \frac{\mu_4}{\mu_2^2} - 3 \\
  \mu_4 &= \frac{3\Gamma(\lambda) \Gamma(\lambda + \frac{1}{2}) 2^{-2\lambda}}{\lambda^3 \Gamma(2\lambda + \frac{3}{2})} + \frac{2}{\lambda^4 (1 + 4\lambda)} - \frac{2\sqrt{3}\Gamma(\lambda) 2^{-6\lambda} 3^\lambda \Gamma(\lambda + \frac{1}{2}) \Gamma(\lambda + \frac{2}{3})}{\lambda^3 \Gamma(2\lambda + \frac{3}{2}) \Gamma(\lambda + \frac{1}{2})}.\]
\]
Notice that the \( \lim_{\lambda \to 0} G(p; \lambda) = \log \frac{p}{1-p} \)

\[
\log \left( \frac{p}{1-p} \right) = \log \left( \frac{\mu}{\mu^2} \right)
\]

\[
h[X] = \int_0^1 \log |G'(p)| dp
\]

\[
= \int_0^1 \log \left[ p^{\lambda-1} + (1-p)^{\lambda-1} \right] dp.
\]

Implementation: `scipy.stats.tukeylambda`

### Uniform Distribution

Standard form \( x \in [0, 1] \). In general form, the lower limit is \( L \), the upper limit is \( S + L \).

\[
f(x) = 1
\]

\[
F(x) = x
\]

\[
G(q) = q
\]

\[
\mu = \frac{1}{2}
\]

\[
\mu_2 = \frac{1}{12}
\]

\[
\gamma_1 = 0
\]

\[
\gamma_2 = -\frac{6}{5}
\]

\[
h[X] = 0
\]

Implementation: `scipy.stats.uniform`

### Von Mises Distribution

There is one shape parameter \( \kappa > 0 \), with support \( x \in [-\pi, \pi] \). For values of \( \kappa < 100 \) the PDF and CDF formulas below are used. Otherwise, a normal approximation with variance \( 1/\kappa \) is used. [Note that the PDF and CDF functions below are periodic with period \( 2\pi \). If an input outside \( x \in [-\pi, \pi] \) is given, it is converted to the equivalent angle in this range.]

\[
f(x; \kappa) = \frac{e^{\kappa \cos x}}{2\pi I_0(\kappa)}
\]

\[
F(x; \kappa) = \frac{1}{2} + \frac{x}{2\pi} + \sum_{k=1}^{\infty} \frac{I_k(\kappa) \sin(kx)}{I_0(\kappa)} \pi k
\]

\[
G(q; \kappa) = F^{-1}(x; \kappa)
\]

where \( I_k(\kappa) \) is a modified Bessel function of the first kind.

\[
\mu = 0
\]

\[
\mu_2 = \int_{-\pi}^{\pi} x^2 f(x; \kappa) dx
\]

\[
\gamma_1 = 0
\]

\[
\gamma_2 = \frac{\int_{-\pi}^{\pi} x^4 f(x; \kappa) dx}{\mu_2^2} - 3
\]

This can be used for defining circular variance.

Implementation: `scipy.stats.vonmises`
Wald Distribution

Special case of the Inverse Normal with shape parameter set to 1.0. It has support $x \geq 0$.

$$
\begin{align*}
f(x) &= \frac{1}{\sqrt{2\pi x^3}} \exp \left( -\frac{(x-1)^2}{2x} \right).
F(x) &= \Phi \left( \frac{x-1}{\sqrt{x}} \right) + \exp(2) \Phi \left( -\frac{x+1}{\sqrt{x}} \right)
G(q; \mu) &= F^{-1}(q; \mu)
\end{align*}
$$

$\mu = 1$
$\mu_2 = 1$
$\gamma_1 = 3$
$\gamma_2 = 15$
$m_d = \frac{1}{2} (\sqrt{13} - 3)$

Implementation: scipy.stats.wald

Weibull Maximum Extreme Value Distribution

Defined for $x < 0$ and $c > 0$.

$$
\begin{align*}
f(x; c) &= c (-x)^{c-1} \exp (-(-x)^c)
F(x; c) &= \exp (-(-x)^c)
G(q; c) &= -(-\log q)^{1/c}
\end{align*}
$$

The mean is the negative of the right-skewed Frechet distribution given above, and the other statistical parameters can be computed from

$$
\begin{align*}
\mu_n &= (-1)^n \Gamma \left( 1 + \frac{n}{c} \right).
\mu &= -\Gamma \left( 1 + \frac{1}{c} \right)
\mu_2 &= \Gamma \left( 1 + \frac{2}{c} \right) - \Gamma^2 \left( 1 + \frac{1}{c} \right)
\gamma_1 &= -\Gamma \left( 1 + \frac{1}{c} \right) - 3 \Gamma \left( 1 + \frac{2}{c} \right) \Gamma \left( 1 + \frac{1}{c} \right) + 2 \Gamma^3 \left( 1 + \frac{1}{c} \right)
\gamma_2 &= \frac{\Gamma \left( 1 + \frac{2}{c} \right) - 4 \Gamma \left( 1 + \frac{1}{c} \right) \Gamma \left( 1 + \frac{3}{c} \right) + 6 \Gamma^2 \left( 1 + \frac{1}{c} \right) \Gamma \left( 1 + \frac{2}{c} \right) - 3 \Gamma^4 \left( 1 + \frac{1}{c} \right)}{\mu_2^2} - 3
m_d &= \begin{cases} 
- \left( \frac{c-1}{c} \right)^{\frac{1}{2}} & \text{if } c > 1 \\
0 & \text{if } c \leq 1 
\end{cases}
m_n &= -\ln (2)^{\frac{1}{2}}
\end{align*}
$$

$h[X] = -\frac{\gamma}{c} - \log(c) + \gamma + 1$

where $\gamma$ is Euler’s constant and equal to

$\gamma \approx 0.57721566490153286061$.

Implementation: scipy.stats.weibull_max
Weibull Minimum Extreme Value Distribution

A type of extreme-value distribution with a lower bound. Defined for \( x > 0 \) and \( c > 0 \)

\[
\begin{align*}
f(x; c) &= cx^{c-1} \exp(-x^c) \\
F(x; c) &= 1 - \exp(-x^c) \\
G(q; c) &= [-\log(1 - q)]^{1/c}
\end{align*}
\]

\[
\mu'_n = \Gamma \left( 1 + \frac{n}{c} \right)
\]

\[
\begin{align*}
\mu &= \Gamma \left( 1 + \frac{1}{c} \right) \\
\mu_2 &= \Gamma \left( 1 + \frac{2}{c} \right) - \Gamma^2 \left( 1 + \frac{1}{c} \right) \\
\gamma_1 &= \frac{\mu_3/2}{\mu_2^3/2} \\
\gamma_2 &= \frac{\mu_4}{\mu_2^2} - 3 \left( 1 + \frac{1}{c} \right) \\
m_d &= \begin{cases} 
\left( \frac{c-1}{c} \right)^{1/2} & \text{if } c > 1 \\
0 & \text{if } c \leq 1
\end{cases} \\
m_n &= \ln \left( 2^{1/2} \right)
\end{align*}
\]

\[
h[X] = -\frac{\gamma}{c} - \log(c) + \gamma + 1
\]

where \( \gamma \) is Euler’s constant and equal to \( \gamma \approx 0.57721566490153286061 \).

Implementation: `scipy.stats.weibull_min`

Wrapped Cauchy Distribution

There is one shape parameter \( c \in (0, 1) \) with support \( x \in [0, 2\pi] \).

\[
\begin{align*}
f(x; c) &= \frac{1 - c^2}{2\pi (1 + c^2 - 2c \cos x)} \\
g_c(x) &= \frac{1}{\pi} \arctan \left( \frac{1 + c \tan \left( \frac{x}{2} \right)}{1 - c} \right) \\
r_c(q) &= 2 \arctan \left( \frac{1 - c}{1 + c} \tan(\pi q) \right) \\
F(x; c) &= \begin{cases} 
g_c(x) & 0 \leq x < \pi \\
1 - g_c(2\pi - x) & \pi \leq x \leq 2\pi
\end{cases} \\
G(q; c) &= \begin{cases} 
r_c(q) & 0 \leq q < \frac{1}{2} \\
2\pi - r_c(1 - q) & \frac{1}{2} \leq q \leq 1
\end{cases}
\end{align*}
\]

\[
h[X] = \log \left( 2\pi \left( 1 - c^2 \right) \right).
\]

Implementation: `scipy.stats.wrapcauchy`
Universal Non-Uniform Random Number Sampling in SciPy

SciPy provides an interface to many universal non-uniform random number generators to sample random variates from a wide variety of univariate continuous and discrete distributions. Implementations of a fast C library called UNU.RAN are used for speed and performance. Please look at UNU.RAN's documentation for an in-depth explanation of these methods. It is heavily referred to for writing this tutorial and the documentation of all the generators.

Introduction

Random variate generation is the small field of research that deals with algorithms to generate random variates from various distributions. It is common to assume that a uniform random number generator is available. This is a program that produces a sequence of independent and identically distributed continuous U(0,1) random variates (i.e. uniform random variates on the interval (0,1)). Of course, real-world computers can never generate ideal random numbers and they cannot produce numbers of arbitrary precision but state-of-the-art uniform random number generators come close to this aim. Thus random variate generation deals with the problem of transforming such a sequence of U(0,1) random numbers into non-uniform random variates. These methods are universal and work in a black-box fashion.

Some methods to do that are:

- The Inversion method: When the inverse $F^{-1}$ of the cumulative distribution function is known, then random variate generation is easy. We just generate a uniformly U(0,1) distributed random number $U$ and return $X = F^{-1}(U)$. As closed form solutions for the inverse are rarely available, one usually needs to rely on approximations of the inverse (e.g. ndtri, stdtrit). In general, the implementation of special functions is quite slow compared to the inversion methods in UNU.RAN.

- The Rejection Method: The rejection method, often called acceptance-rejection method, has been suggested by John von Neumann in 1951\(^1\). It involves computing an upper bound to the PDF (also called the hat function) and using the inversion method to generate a random variate, say $Y$, from this bound. Then a uniform random number can be drawn between 0 to the value of the upper bound at $Y$. If this number is less than the PDF at $Y$, return the sample otherwise reject it. See TransformedDensityRejection.

- The Ratio-of-Uniforms Method: This is a type of acceptance-rejection method which uses minimal bounding rectangles to construct the hat function. See scipy.stats.rvs_ratio_uniforms.

- Inversion for Discrete Distributions: The difference compared to the continuous case is that $F$ is now a step-function. To realize this in a computer, a search algorithm is used, the simplest of which is sequential search. A uniform random number is generated from U(0, 1) and probabilities are summed until the cumulative probability exceeds the uniform random number. The index at which this happens is the required random variate and is returned.

More details on these algorithms can be found in the appendix of the UNU.RAN user manual.

When generating random variates of a distribution, two factors are important to determine the speed of a generator: the setup step and the actual sampling. Depending on the situation, different generators can be optimal. For example, if one repeatedly needs to draw large samples from a given distribution with a fixed shape parameter, a slow setup is acceptable if the sampling is fast. This is called the fixed parameter case. If one aims to generate samples of a distribution for different shape parameters (the varying parameter case), an expensive setup that needs to be repeated for each parameter would lead to very poor performance. In such a situation, a fast setup is crucial to achieve good performance. An overview of the setup and sampling speed of the different methods is shown in the table below.

For more details on the generators implemented in UNU.RAN, please refer to\(^2\) and\(^3\).

### Basic concepts of the Interface

Every generator needs to be set up before one can start sampling from it. This can be done by instantiating an object of that class. Most of the generators take a distribution object as input which contains the implementation of required methods like PDF, CDF, etc. In addition to the distribution object, one can also pass parameters used to set up the generator. It is also possible to truncate the distributions using a `domain` parameter. All generators need a stream of uniform random numbers that are transformed into random variates of the given distribution. This is done by passing a `random_state` parameter with a NumPy BitGenerator as the uniform random number generator. `random_state` can either be an integer, `np.random.Generator`, or `np.random.RandomState`.

**Warning:** Use of NumPy < 1.19.0 is discouraged as it doesn’t have a fast Cython API for generating uniform random numbers and might be too slow for practical use.

All the generators have a common `rvs` method that can be used to draw samples from the given distribution.

An example of this interface is shown below:

```python
>>> from scipy.stats.sampling import TransformedDensityRejection
>>> from math import exp

>>> class StandardNormal:
...     def pdf(self, x: float) -> float:
```

As shown in the example, we first initialize a distribution object that contains an implementation of the methods required by the generator. In our case, we use the `TransformedDensityRejection` (TDR) method which requires a PDF and its derivative w.r.t. \( x \) (i.e. the variate).

**Note:** Note that the methods of the distribution (i.e. pdf, dpdf, etc) need not be vectorized. They should accept and return floats.

**Note:** One can also pass the SciPy distributions as arguments. However, note that the object doesn’t always have all the information required by some generators like the derivative of PDF for the TDR method. Relying on SciPy distributions might also reduce performance due to the vectorization of the methods like pdf and cdf. In both cases, one can implement a custom distribution object that contains all the required methods and that is not vectorized as shown in the example above.

In the above example, we have set up an object of the `TransformedDensityRejection` method to sample from a standard normal distribution. Now, we can start sampling from our distribution by calling the rvs method:

```
>>> rng.rvs()
-1.526829048388144
>>> rng.rvs((5, 3))
array([[ 2.06206883,  0.15205036,  1.11587367],
       [-0.30775562,  0.29879802, -0.61858268],
       [-1.01049115,  0.78853694, -0.23060766],
       [-0.60954752,  0.29071797, -0.57167182],
       [ 0.9331694 , -0.95605208,  1.72195199]])
```

We can also check that the samples are drawn from the correct distribution by visualizing the histogram of the samples:

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import norm
>>> from scipy.stats.sampling import TransformedDensityRejection
>>> from math import exp

>>> class StandardNormal:
...     def pdf(self, x: float) -> float:
...         # note that the normalization constant isn't required
...         return exp(-0.5 * x*x)
...     def dpdf(self, x: float) -> float:
...         return -x * exp(-0.5 * x*x)

>>> dist = StandardNormal()
>>> urng = np.random.default_rng()
>>> rng = TransformedDensityRejection(dist, random_state=urng)
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import norm
>>> from scipy.stats.sampling import TransformedDensityRejection
>>> from math import exp

>>> class StandardNormal:
...     def pdf(self, x: float) -> float:
...         # note that the normalization constant isn't required
...         return exp(-0.5 * x*x)
...     def dpdf(self, x: float) -> float:
...         return -x * exp(-0.5 * x*x)

>>> dist = StandardNormal()
>>> urng = np.random.default_rng()
>>> rng = TransformedDensityRejection(dist, random_state=urng)
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import norm
>>> from scipy.stats.sampling import TransformedDensityRejection
>>> from math import exp

>>> class StandardNormal:
...     def pdf(self, x: float) -> float:
...         # note that the normalization constant isn't required
...         return exp(-0.5 * x*x)
...     def dpdf(self, x: float) -> float:
...         return -x * exp(-0.5 * x*x)
```

(continues on next page)
```python
>>> dist = StandardNormal()
>>> urng = np.random.default_rng()
>>> rng = TransformedDensityRejection(dist, random_state=urng)
>>> rvs = rng.rvs(size=1000)
>>> x = np.linspace(rvs.min()-0.1, rvs.max()+0.1, num=1000)
>>> fx = norm.pdf(x)
>>> plt.plot(x, fx, 'r-', lw=2, label='true distribution')
>>> plt.hist(rvs, bins=20, density=True, alpha=0.8, label='random variates')
>>> plt.xlabel('x')
>>> plt.ylabel('PDF(x)')
>>> plt.title('Transformed Density Rejection Samples')
>>> plt.legend()
>>> plt.show()
```

Note: Please note the difference between the rvs method of the distributions present in `scipy.stats` and the one provided by these generators. UNU.RAN generators must be considered independent in a sense that they will generally produce a different stream of random numbers than the one produced by the equivalent distribution in `scipy.stats` for any seed. The implementation of rvs in `scipy.stats.rv_continuous` usually relies on the NumPy module `np.random` for well-known distributions (e.g., for the normal distribution, the beta distribution) and transformations of other distributions (e.g., normal inverse Gaussian `scipy.stats.norminvgauss` and the lognormal `scipy.stats.lognorm` distribution). If no specific method is implemented, `scipy.stats.rv_continuous` defaults to a numerical inversion method of the CDF that is very slow. As UNU.RAN transforms uniform random numbers differently than SciPy or NumPy, the resulting stream of RVs is different even for the same stream of uniform random numbers. For example, the random number stream of SciPy's `scipy.stats.norm` and UNU.RAN's `TransformedDensityRejection` would not be the same even for the same `random_state`:

```python
>>> from scipy.stats.sampling import norm, TransformedDensityRejection
>>> from copy import copy
>>> dist = StandardNormal()
>>> urng1 = np.random.default_rng()
>>> urng1_copy = copy(urng1)
>>> rng = TransformedDensityRejection(dist, random_state=urng1)
>>> urng2 = np.random.default_rng()
>>> urng2_copy = copy(urng2)
>>> rng = TransformedDensityRejection(dist, random_state=urng2)
```

(continues on next page)
We can pass a domain parameter to truncate the distribution:

```python
>>> rng = TransformedDensityRejection(dist, domain=(-1, 1), random_state=urng)
>>> rng.rvs((5, 3))
array([[-0.99865691, 0.38104014, 0.31633526],
    [ 0.88433909, -0.45181849, 0.78574461],
    [ 0.3337244 , 0.12924307, 0.40499404],
    [-0.51865761, 0.43252222, -0.6514866 ],
    [-0.82666174, 0.71525582, 0.49006743]])
```

Invalid and bad arguments are handled either by SciPy or by UNU.RAN. The latter throws a **UNURANError** that follows a common format:

**UNURANError:** [**objet id:** <object id>] <error code>: <reason> => <type of error>

where:

- **<object id>** is the ID of the object given by UNU.RAN
- **<error code>** is an error code representing a type of error.
- **<reason>** is the reason why the error occurred.
- **<type of error>** is a short description of the type of error.

The <reason> shows what caused the error. This, by itself, should contain enough information to help debug the error. In addition, <error id> and <type of error> can be used to investigate different classes of error in UNU.RAN. A complete list of all the error codes and their descriptions can be found in the Section 8.4 of the UNU.RAN user manual.

An example of an error generated by UNU.RAN is shown below:

**UNURANError:** [**objet id:** TDR.003] 50 : PDF(x) < 0.! => (generator) (possible) invalid data

This shows that UNU.RAN failed to initialize an object with ID **TDR.003** because the PDF was < 0. i.e. negative. This falls under the type “possible invalid data for the generator” and has error code 50.

Warnings thrown by UNU.RAN also follow the same format.

**Generators in scipy.stats.sampling**

**Transformed Density Rejection (TDR)**

- Required: T-concave PDF, dPDF
- Optional: mode, center
- Speed:
  - Set-up: slow
  - Sampling: fast
TDR is an acceptance/rejection method that uses the concavity of a transformed density to construct hat function and squeezes automatically. Such PDFs are called T-concave. Currently the following transformations are implemented:

\[
c = 0 : T(x) = \log(x)
\]

\[
c = -0.5 : T(x) = \frac{1}{\sqrt{x}} \text{ (Default)}
\]

In addition to the PDF, it also requires the derivative of the PDF w.r.t \( x \) (i.e. the variate). These functions must be present as methods of a python object which can then be passed to the generators to instantiate their object. The variant that is implemented uses squeezes proportional to hat function \(^1\).

An example of using this method is shown below:

```python
>>> from scipy.stats.sampling import TransformedDensityRejection
>>> from scipy.stats import norm

>>> class StandardNormal:
...     def pdf(self, x):
...         # note that the normalization constant is not required
...         return np.exp(-0.5 * x*x)
...     def dpdf(self, x):
...         return -x * np.exp(-0.5 * x*x)
...

>>> dist = StandardNormal()
>>> urng = np.random.default_rng()
>>> rng = TransformedDensityRejection(dist, random_state=urng)
>>> rng.rvs()
-1.526829048388144
```

In the above example, we have used the TDR method to sample from the standard normal distribution. Note that we can drop the normalization constant while computing the PDF. This usually helps speed up the sampling stage. Also, note that the PDF doesn’t need to be vectorized. It should accept and return a scalar.

It is also possible to evaluate the inverse of the CDF of the hat distribution directly using the `ppf_hat` method.

```python
>>> rng.ppf_hat(0.5)
-0.00018050266342362759
>>> norm.ppf(0.5)
0.0

>>> u = np.linspace(0, 1, num=10)
>>> rng.ppf_hat(u)
array([-inf, -1.22227372, -0.7656556 , -0.43135731, -0.14002921,
       0.13966423, 0.43096141, 0.76517113, 1.22185606, inf])
```

Apart from the PPF method, other attributes can be accessed to see how well the generator fits the given distribution. These are:

- ‘squeeze_hat_ratio’: (area below squeeze) / (area below hat) for the generator. It is a number between 0 and 1. Closer to 1 means that the hat and the squeeze functions tightly envelop the distribution and fewer PDF evaluations are required to generate samples. The expected number of evaluations of the density is bounded by \( 1/ \)

\(^1\) UNU-RAN reference manual, Section 5.3.16, “TDR - Transformed Density Rejection”, http://statmath.wu.ac.at/software/unuran/doc/unuran.html#TDR
squeeze_hat_ratio) - 1 per sample. By default, it is kept above 0.99 but that can be changed by passing a max_squeeze_hat_ratio parameter.

- ’hat_area’: area below the hat for the generator.
- ’squeeze_area’: area below the squeeze for the generator.

```python
>>> rng.squeeze_hat_ratio
0.9947024204884917
>>> rng.hat_area
2.510253139791547
>>> rng.squeeze_area
2.4969548741894876
>>> rng.squeeze_hat_ratio == rng.squeeze_area / rng.hat_area
True
```

The distribution can be truncated by passing a domain parameter:

```python
>>> urng = np.random.default_rng()
>>> rng = TransformedDensityRejection(dist, domain=[0, 1], random_state=urng)
>>> rng.rvs(10)
array([0.05452512, 0.97251362, 0.49955877, 0.82789729, 0.33048885,
       0.55558548, 0.23168323, 0.13423275, 0.73176575, 0.35739799])
```

If the domain is not specified, the support method of the dist object is used to determine the domain:

```python
>>> class StandardNormal:
...     def pdf(self, x):
...         return np.exp(-0.5 * x*x)
...     def dpdf(self, x):
...         return -x * np.exp(-0.5 * x*x)
...     def support(self):
...         return -np.inf, np.inf
... >>> dist = StandardNormal()
>>> urng = np.random.default_rng()
>>> rng = TransformedDensityRejection(dist, random_state=urng)
>>> rng.rvs(10)
array([-1.52682905,  2.06206883,  0.15205036,  1.11587367, -0.30775562,
       0.29879802, -0.61858268, -1.01049115,  0.78853694, -0.23060766])
```

If the dist object does not provide a support method, the domain is assumed to be (-np.inf, np.inf).

To increase squeeze_hat_ratio, pass max_squeeze_hat_ratio:

```python
>>> dist = StandardNormal()
>>> rng = TransformedDensityRejection(dist, max_squeeze_hat_ratio=0.999,
...                                     random_state=urng)
>>> rng.squeeze_hat_ratio
0.999364900465214
```

Let's see how this affects the callbacks to the PDF method of the distribution:

```python
>>> from copy import copy
>>> class StandardNormal:
... ```
...    def __init__(self):
...        self.callbacks = 0
...    def pdf(self, x):
...        self.callbacks += 1
...        return np.exp(-0.5 * x * x)
...    def dpdf(self, x):
...        return -x * np.exp(-0.5 * x * x)

>>> dist1 = StandardNormal()
>>> urng1 = np.random.default_rng()
>>> urng2 = copy(urng1)
>>> rng1 = TransformedDensityRejection(dist1, random_state=urng1)
>>> dist1.callbacks  # evaluations during setup
139
>>> dist1.callbacks = 0  # don't consider evaluations during setup
>>> rvs = rng1.rvs(100000)
>>> dist1.callbacks  # evaluations during sampling
527
>>> dist2 = StandardNormal()
>>> # use the same stream of uniform random numbers
>>> rng2 = TransformedDensityRejection(dist2, max_squeeze_hat_ratio=0.999,
...    random_state=urng2)
>>> dist2.callbacks  # evaluations during setup
467
>>> dist2.callbacks = 0  # don't consider evaluations during setup
>>> rvs = rng2.rvs(100000)
>>> dist2.callbacks  # evaluations during sampling
84

As we can see, far fewer PDF evaluations are required during sampling when we increase the `squeeze_hat_ratio`. The PPF-hat function is also more accurate:

```python
>>> abs(norm.ppf(0.975) - rng1.ppf_hat(0.975))
0.0027054565421578136
>>> abs(norm.ppf(0.975) - rng2.ppf_hat(0.975))
0.0004782408447630044
```

Though, notice that this comes at the cost of increased PDF evaluations during setup.

For densities with modes not close to 0, it is suggested to set either the mode or the center of the distribution by passing `mode` or `center` parameters. The latter is the approximate location of the mode or the mean of the distribution. This location provides some information about the main part of the PDF and is used to avoid numerical problems.

```python
>>> # mode = 0 for our distribution
>>> # if exact mode is not available, pass 'center' parameter instead
>>> rng = TransformedDensityRejection(dist, mode=0.)
```

By default, the method uses 30 construction points to construct the hat. This can be changed by passing a `construction_points` parameter which can either be an array of construction points or an integer representing the number of construction points to use.

```python
>>> rng = TransformedDensityRejection(dist,
...    construction_points=[-5, 0, 5])
```
This method accepts many other set-up parameters. See the documentation for an exclusive list. More information of the parameters and the method can be found in Section 5.3.16 of the UNU.RAN user manual.

Please see Page 207, 1 and 2 for more details on this method.

References

Discrete Alias Urn (DAU)

- Required: probability vector (PV) or the PMF along with a finite domain
- Speed:
  - Set-up: slow (linear with the vector-length)
  - Sampling: very fast

DAU samples from distributions with arbitrary but finite probability vectors (PV) of length N. The algorithm is based on an ingenious method by A.J. Walker and requires a table of size (at least) N. It needs one random number and only one comparison for each generated random variate. The setup time for constructing the tables is O(N).

```python
>>> import numpy as np
>>> from scipy.stats.sampling import DiscreteAliasUrn
>>> pv = [0.18, 0.02, 0.8]
>>> urng = np.random.default_rng()
>>> rng = DiscreteAliasUrn(pv, random_state=urng)
>>> rng.rvs()
0
```

By default, the probability vector is indexed starting at 0. However, this can be changed by passing a domain parameter. When domain is given in combination with the PV, it has the effect of relocating the distribution from \((0, \text{len}(pv))\) to \((\text{domain}[0], \text{domain}[0] + \text{len}(pv))\). domain[1] is ignored in this case.

```python
>>> rng = DiscreteAliasUrn(pv, domain=(10, 13), random_state=urng)
>>> rng.rvs()
12
```

The method also works when no probability vector but a PMF is given. In that case, a bounded (finite) domain must also be given either by passing the domain parameter explicitly or by providing a support method in the distribution object:

```python
>>> class Distribution:
...     def __init__(self, c):
...         self.c = c
...     def pmf(self, x):
...         return x**self.c
...     def support(self):
...         return (0, 10)
... >>> dist = Distribution(2)
... >>> rng = DiscreteAliasUrn(dist, random_state=urng)
```

```python
>>> rng.rvs()
10

>>> import matplotlib.pyplot as plt
>>> from scipy.stats.sampling import DiscreteAliasUrn
>>> class Distribution:
...     def __init__(self, c):
...         self.c = c
...     def pmf(self, x):
...         return x**self.c
...     def support(self):
...         return (0, 10)
...
>>> dist = Distribution(2)
>>> urng = np.random.default_rng()
>>> rng = DiscreteAliasUrn(dist, random_state=urng)
>>> rvs = rng.rvs(1000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> x = np.arange(1, 11)
>>> fx = dist.pmf(x)
>>> fx = fx / fx.sum()
>>> ax.plot(x, fx, 'bo', label='true distribution')
>>> ax.vlines(x, 0, fx, lw=2)
>>> ax.hist(rvs, bins=np.r_[x, 11]-0.5, density=True, alpha=0.5, color='r', label='samples')
>>> ax.set_xlabel('x')
>>> ax.set_ylabel('PMF(x)')
>>> ax.set_title('Discrete Alias Urn Samples')
>>> plt.legend()
>>> plt.show()
```
Note: As `DiscreteAliasUrn` expects PMF with signature `def pmf(self, x: float) -> float`, it first vectorizes the PMF using `np.vectorize` and then evaluates it over all the points in the domain. But if the PMF is already vectorized, it is much faster to just evaluate it at each point in the domain and pass the obtained PV instead along with the domain. For example, `pmf` methods of SciPy’s discrete distributions are vectorized and a PV can be obtained by doing:

```python
>>> from scipy.stats import binom
>>> from scipy.stats.sampling import DiscreteAliasUrn
>>> dist = binom(10, 0.2)  # distribution object
>>> domain = dist.support()  # the domain of your distribution
>>> x = np.arange(domain[0], domain[1] + 1)
>>> pv = dist.pmf(x)
>>> rng = DiscreteAliasUrn(pv, domain=domain)
```

Domain is required here to relocate the distribution.

The performance can be slightly influenced by setting the size of the used table which can be changed by passing a `urn_factor` parameter.

```python
>>> # use a table twice the length of PV.
>>> urn_factor = 2
>>> rng = DiscreteAliasUrn(pv, urn_factor=urn_factor, random_state=urng)
>>> rng.rvs()
2
```

Note: It is recommended to keep this parameter under 2.

Please see\(^1\) and\(^2\) for more details on this method.

**Polynomial interpolation based INVersion of CDF (PINV)**

- Required: PDF
- Optional: CDF, mode, center
- Speed:
  - Set-up: (very) slow
  - Sampling: (very) fast

Polynomial interpolation based INVersion of CDF (PINV) is an inversion method that only requires the density function to sample from a distribution. It is based on Polynomial interpolation of the PPF and Gauss-Lobatto integration of the PDF. It provides control over the interpolation error and integration error. Its primary purpose is to provide very fast sampling which is nearly the same for any given distribution at the cost of moderate to slow setup time. It is the fastest known inversion method for the fixed-parameter case.

The inversion method is the simplest and most flexible to sample nonuniform random variates. For a target distribution with CDF $F$ and a uniform random variate $U$ sampled from Uniform$(0, 1)$, a random variate $X$ is generated by transforming the uniform random variate $U$ using the PPF (inverse CDF) of the distribution:

$$X = F^{-1}(U)$$

This method is suitable for stochastic simulations because of its advantages. Some of the most attractive are:

- It preserves the structural properties of the uniform random number sampler.
- Transforms a uniform random variate $U$ one-to-one into non-uniform random variates $X$.
- Easy and efficient sampling from truncated distributions.

Unfortunately, the PPF is rarely available in closed form or too slow when available. For many distributions, the CDF is also not easy to obtain. This method addresses both the shortcomings. The user only has to provide the PDF and optionally a point near the mode (called “center”) together with the size of the maximal acceptable error. It uses a combination of an adaptive and a simple Gauss-Lobatto quadrature to obtain the CDF and Newton’s interpolation to obtain the PPF. The method is not exact, as it only produces random variates of the approximated distribution. Nevertheless, the maximal tolerated approximation error can be set close to the machine precision. The concept of u-error is used to measure and control the error. It is defined as:

$$\epsilon_u(u) = |u - F(F_a^{-1}(u))|$$

where $u \in (0, 1)$ is a quantile where we want to measure the error and $F_a^{-1}$ is the approximated PPF of the given distribution.

The maximal u-error is the criterion for approximation errors when calculating the CDF and PPF numerically. The maximal tolerated u-error of an algorithm is called the u-resolution of the algorithm and denoted by $\epsilon_u$:

$$\sup_{u \in (0, 1)} |u - F(F_a^{-1}(u))| \leq \epsilon_u$$

The main advantage of the u-error is that it can be easily computed if the CDF is available. We refer to\(^1\) for a more detailed discussion.

Also, the method only works for bounded distributions. In case of infinite tails, the ends of the tails are cut off such that the area under them is less than or equal to $0.05 \epsilon_u$.

There are some restrictions for the given distribution:

- The support of the distribution (i.e., the region where the PDF is strictly positive) must be connected. In practice this means, that the region where PDF is “not too small” must be connected. Unimodal densities satisfy this condition. If this condition is violated then the domain of the distribution might be truncated.
- When the PDF is integrated numerically, then the given PDF must be continuous and should be smooth.
- The PDF must be bounded.
- The algorithm has problems when the distribution has heavy tails (as then the inverse CDF becomes very steep at 0 or 1) and the requested u-resolution is very small. E.g., the Cauchy distribution is likely to show this problem when the requested u-resolution is less then 1.e-12.

| Warning: | This method does not work for densities with constant parts (e.g. uniform distribution) and segmentation faults if such a density is passed to the constructor. It is recommended to use the composition method to sample from such distributions. |

Following four steps are carried out by the algorithm during setup:

• Computing the end points of the distribution: If a finite support is given, this step is skipped. Otherwise, the ends of the tails are cut off such that the area under them is less than or equal to $0.05\epsilon_u$.

• The domain is divided into subintervals to compute the CDF and PPF.

• The CDF is computed using Gauss-Lobatto quadrature such that the integration error is at most $0.05 I_0\epsilon_u$ where $I_0$ is approximately the total area under the PDF.

• The PPF is computed using Newton’s interpolating formula with maximum interpolation error $0.9\epsilon_u$.

To initialize the generator to sample from a standard normal distribution, do:

```python
>>> from scipy.stats.sampling import NumericalInversePolynomial
>>> class StandardNormal:
...     def pdf(self, x):
...         return np.exp(-0.5 * x*x)
...
>>> dist = StandardNormal()
>>> urng = np.random.default_rng()
>>> rng = NumericalInversePolynomial(dist, random_state=urng)
```

The generator has been set up and we can start sampling from our distribution:

```python
>>> rng.rvs((5, 3))
aray([[-1.52449963,  1.31933688,  2.05884468],
      [ 0.48883931,  0.15207903, -0.02150773],
      [ 1.11486463,  1.95449597, -0.30724928],
      [ 0.98546430,  0.29867424,  0.75603041],
      [-0.61776203,  0.16033378, -1.00933003]])
```

We can look at the histogram of the random variates to check how well they fit our distribution:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import norm
>>> from scipy.stats.sampling import NumericalInversePolynomial
>>> class StandardNormal:
...     def pdf(self, x):
...         return np.exp(-0.5 * x*x)
...
>>> dist = StandardNormal()
>>> urng = np.random.default_rng()
>>> rng = NumericalInversePolynomial(dist, random_state=urng)
>>> rvs = rng.rvs(10000)
>>> x = np.linspace(rvs.min()-0.1, rvs.max()+0.1, num=10000)
>>> fx = norm.pdf(x)
>>> plt.plot(x, fx, "r-", label="pdf")
>>> plt.hist(rvs, bins=50, density=True, alpha=0.8, label="rvs")
>>> plt.xlabel("x")
>>> plt.ylabel("PDF(x)")
>>> plt.title("Samples drawn using PINV method.")
>>> plt.legend()
>>> plt.show()
```

The maximum tolerated error (i.e. u-resolution) can be changed by passing the `u_resolution` keyword during initialization:
Samples drawn using PINV method.

```python
>>> rng = NumericalInversePolynomial(dist, u_resolution=1e-12,
...                                          random_state=urng)
```

This leads to a more accurate approximation of the PPF and the generated RVs follow the exact distribution more closely. Although, note that it comes at the cost of an expensive setup.

The setup time mainly depends on the number of times the PDF is evaluated. It is more costly for PDFs that are difficult to evaluate. Note that we can ignore the normalization constant to speed up the evaluations of the PDF. PDF evaluations increase during setup for small values of `u_resolution`.

```python
>>> from scipy.stats.sampling import NumericalInversePolynomial
>>> class StandardNormal:
...     def __init__(self):
...         selfcallbacks = 0
...     def pdf(self, x):
...         self.callbacks += 1
...         return np.exp(-0.5 * x*x)
...
>>> dist = StandardNormal()
>>> urng = np.random.default_rng()
>>> # u_resolution = 10^-8
>>> # => less PDF evaluations required
>>> # => faster setup
>>> rng = NumericalInversePolynomial(dist, u_resolution=1e-8,
...                                          random_state=urng)
>>> dist.callbacks
4095
>>> dist.callbacks = 0  # reset the number of callbacks
>>> # u_resolution = 10^-10 (default)
>>> # => more PDF evaluations required
>>> # => slow setup
>>> rng = NumericalInversePolynomial(dist, u_resolution=1e-10,
...                                          random_state=urng)
>>> dist.callbacks
(continues on next page)
As we can see, the number of PDF evaluations required is very high and a fast PDF is critical to the algorithm. Though, this helps reduce the number of subintervals required to achieve the error goal which saves memory and makes sampling fast. *NumericalInverseHermite* is a similar inversion method that inverts the CDF based on Hermite interpolation and provides control over the maximum tolerated error via u-resolution. But it makes use of a lot more intervals compared to *NumericalInversePolynomial*:

```python
from scipy.stats.sampling import NumericalInverseHermite
>>> rng_hermite = NumericalInverseHermite(norm(), tol=1e-12)
>>> rng_hermite.intervals
3000
>>> rng_poly = NumericalInversePolynomial(norm(), u_resolution=1e-12)
>>> rng_poly.intervals
252
```

When exact CDF of a distribution is available, one can estimate the u-error achieved by the algorithm by calling the `u_error` method:

```python
from scipy.special import ndtr
class StandardNormal:
    def pdf(self, x):
        return np.exp(-0.5 * x*x)
    def cdf(self, x):
        return ndtr(x)

>>> dist = StandardNormal()
>>> rng = NumericalInversePolynomial(dist, random_state=urng)
>>> rng.u_error(sample_size=100_000)
UError(max_error=8.785949745515609e-11, mean_absolute_error=2.9307548109436816e-11)
```

*u_error* runs a monte carlo simulation with a given number of samples to estimate the u-error. In the above example, 100,000 samples are used by the simulation to approximate the u-error. It returns the maximum u-error (*max_error*) and the mean absolute u-error (*mean_absolute_error*) in a *UError* namedtuple. As we can see, *max_error* is below the default u_resolution (1e-10).

It is also possible to evaluate the PPF of the given distribution once the generator is initialized:

```python
>>> rng.ppf(0.975)
1.959963985701268
>>> norm.ppf(0.975)
1.959963984540054
```
We can use this, for example, to check the maximum and mean absolute u-error:

```python
>>> u = np.linspace(0.001, 0.999, num=1_000_000)
>>> u_errors = np.abs(u - dist.cdf(rng.ppf(u)))
>>> u_errors.max()
8.78600525666684e-11
>>> u_errors.mean()
2.932144940323206e-11
```

The approximate PPF method provided by the generator is much faster to evaluate than the exact PPF of the distribution. During setup, a table of CDF points is stored that can be used to approximate the CDF once the generator has been created:

```python
>>> rng.cdf(1.959963984540054)
0.9750000000004245
>>> norm.cdf(1.959963984540054)
0.975
```

We can use this to check if the integration error while computing the CDF exceeds $0.05I_0\epsilon_u$. Here $I_0$ is $\sqrt{2\pi}$ (the normalization constant for the standard normal distribution):

```python
>>> x = np.linspace(-10, 10, num=100_000)
>>> x_error = np.abs(dist.cdf(x) - rng.cdf(x))
>>> x_error.max()
4.506062190046123e-12
>>> I0 = np.sqrt(2*np.pi)
>>> max_integration_error = 0.05 * I0 * 1e-10
>>> x_error.max() <= max_integration_error
True
```

The CDF table computed during setup is used to evaluate the CDF and only some further fine-tuning is required. This reduces the calls to the PDF but as the fine-tuning step uses the simple Gauss-Lobatto quadrature, the PDF is called several times, slowing down the computation.

References

Discrete Guide Table (DGT)

- Required: probability vector (PV) or the PMF along with a finite domain
- Speed:
  - Set-up: slow (linear with the vector-length)
  - Sampling: very fast

DGT samples from arbitrary but finite probability vectors. Random numbers are generated by the inversion method, i.e.

1. Generate a random number $U \sim U(0,1)$.
2. Find smallest integer $I$ such that $F(I) = P(X<=I) >= U$.

Step (2) is the crucial step. Using sequential search requires $O(E(X))$ comparisons, where $E(X)$ is the expectation of the distribution. Indexed search, however, uses a guide table to jump to some $I' \leq I$ near $I$ to find $X$ in constant time. Indeed the expected number of comparisons is reduced to 2, when the guide table has the same size as the probability vector.
(this is the default). For larger guide tables this number becomes smaller (but is always larger than 1), for smaller tables it becomes larger.

On the other hand the setup time for guide table is O(N), where N denotes the length of the probability vector (for size 1 no preprocessing is required). Moreover, for very large guide tables memory effects might even reduce the speed of the algorithm. So we do not recommend to use guide tables that are more than three times larger than the given probability vector. If only a few random numbers have to be generated, (much) smaller table sizes are better. The size of the guide table relative to the length of the given probability vector can be set by the `guide_factor` parameter:

```python
>>> import numpy as np
>>> from scipy.stats.sampling import DiscreteGuideTable
>>> pv = [0.18, 0.02, 0.8]
>>> urng = np.random.default_rng()
>>> rng = DiscreteGuideTable(pv, random_state=urng)
>>> rng.rvs()
2
```

By default, the probability vector is indexed starting at 0. However, this can be changed by passing a `domain` parameter. When `domain` is given in combination with the PV, it has the effect of relocating the distribution from \((0, \text{len}(pv))\) to \((\text{domain}[0], \text{domain}[0] + \text{len}(pv))\). `domain[1]` is ignored in this case.

```python
>>> rng = DiscreteGuideTable(pv, random_state=urng, domain=(10, 13))
>>> rng.rvs()
10
```

The method also works when no probability vector but a PMF is given. In that case, a bounded (finite) domain must also be given either by passing the `domain` parameter explicitly or by providing a `support` method in the distribution object:

```python
>>> class Distribution:
...     def __init__(self, c):
...         self.c = c
...     def pmf(self, x):
...         return x ** self.c
...     def support(self):
...         return 0, 10
... >>> dist = Distribution(2)
>>> rng = DiscreteGuideTable(dist, random_state=urng)
>>> rng.rvs()
9
```

**Note:** As `DiscreteGuideTable` expects PMF with signature `def pmf(self, x: float) -> float`, it first vectorizes the PMF using `np.vectorize` and then evaluates it over all the points in the domain. But if the PMF is already vectorized, it is much faster to just evaluate it at each point in the domain and pass the obtained PV instead along with the domain. For example, `pmf` methods of SciPy's discrete distributions are vectorized and a PV can be obtained by doing:

```python
>>> from scipy.stats import binom
>>> dist = binom(10, 0.2)  # distribution object
>>> domain = dist.support()  # the domain of your distribution
>>> x = np.arange(domain[0], domain[1] + 1)
```

(continues on next page)
Domain is required here to relocate the distribution

The size of the guide table relative to the probability vector may be set using the `guide_factor` parameter. Larger guide tables result in faster generation time but require a more expensive setup.

```
>>> guide_factor = 2
>>> rng = DiscreteGuideTable(pv, random_state=urng, guide_factor=guide_factor)
>>> rng.rvs()
2
```

Unfortunately, the PPF is rarely available in closed form or too slow when available. The user only has to provide the probability vector and the PPF (inverse CDF) can be evaluated using `ppf` method. This method calculates the (exact) PPF of the given distribution.

For example to calculate the PPF of a binomial distribution with \( n = 4 \) and \( p = 0.1 \): we can set up a guide table as follows:

```
>>> n, p = 4, 0.1
>>> dist = stats.binom(n, p)
>>> rng = DiscreteGuideTable(dist, random_state=42)
>>> rng.ppf(0.5)
0.0
```

Please see\(^1\) and\(^2\) for more details on this method.

**Hermite interpolation based INVersion of CDF (HINV)**

- **Required**: CDF
- **Optional**: PDF, dPDF
- **Speed**:
  - **Set-up**: (very) slow
  - **Sampling**: (very) fast

HINV is a variant of numerical inversion, where the inverse CDF is approximated using Hermite interpolation, i.e., the interval \([0,1]\) is split into several intervals and in each interval the inverse CDF is approximated by polynomials constructed by means of values of the CDF and PDF at interval boundaries. This makes it possible to improve the accuracy by splitting a particular interval without recomputations in unaffected intervals. Three types of splines are implemented: linear, cubic, and quintic interpolation. For linear interpolation only the CDF is required. Cubic interpolation also requires PDF and quintic interpolation PDF and its derivative.

These splines have to be computed in a setup step. However, it only works for distributions with bounded domain; for distributions with unbounded domain the tails are chopped off such that the probability for the tail regions is small compared to the given \(u\)-resolution.

---

\(^{1}\) UNU.RAN reference manual, Section 5.8.4, “DGT - (Discrete) Guide Table method (indexed search)” https://statmath.wu.ac.at/unuran/doc/unuran.html#DGT

The method is not exact, as it only produces random variates of the approximated distribution. Nevertheless, the maximal numerical error in “u-direction” (i.e. $|U - CDF(X)|$ where $X$ is the approximate percentile corresponding to the quantile $U$, i.e. $X = approx_{ppf}(U)$) can be set to the required resolution (within machine precision). Notice that very small values of the u-resolution are possible but may increase the cost for the setup step.

**NumericalInverseHermite** approximates the inverse of a continuous statistical distribution’s CDF with a Hermite spline. Order of the hermite spline can be specified by passing the `order` parameter.

As described in\(^1\), it begins by evaluating the distribution’s PDF and CDF at a mesh of quantiles $x$ within the distribution’s support. It uses the results to fit a Hermite spline $H$ such that $H(p) == x$, where $p$ is the array of percentiles corresponding with the quantiles $x$. Therefore, the spline approximates the inverse of the distribution’s CDF to machine precision at the percentiles $p$, but typically, the spline will not be as accurate at the midpoints between the percentile points:

$$p_{\text{mid}} = (p[-1] + p[1:]) / 2$$

so the mesh of quantiles is refined as needed to reduce the maximum “u-error”:

$$u_{\text{error}} = \text{np.max(np.abs(dist.cdf(H(p_mid)) - p_mid))}$$

below the specified tolerance $u_{\text{resolution}}$. Refinement stops when the required tolerance is achieved or when the number of mesh intervals after the next refinement could exceed the maximum allowed number of intervals (100000).

```python
from scipy.stats.sampling import NumericalInverseHermite
from scipy.stats import norm, genexpon
from scipy.special import ndtr
```

To create a generator to sample from the standard normal distribution, do:

```python
>>> class StandardNormal:
...    def pdf(self, x):
...        return 1/np.sqrt(2*np.pi) * np.exp(-x**2 / 2)
...    def cdf(self, x):
...        return ndtr(x)
...>>> dist = StandardNormal()
>>> urng = np.random.default_rng()
>>> rng = NumericalInverseHermite(dist, random_state=urng)
```

The **NumericalInverseHermite** has a method that approximates the PPF of the distribution.

```python
>>> rng = NumericalInverseHermite(dist)
>>> p = np.linspace(0.01, 0.99, 99) # percentiles from 1% to 99%
>>> np.allclose(rng.ppf(p), norm.ppf(p))
True
```

Depending on the implementation of the distribution’s random sampling method, the random variates generated may be nearly identical, given the same random state.

```python
>>> dist = genexpon(9, 16, 3)
>>> rng = NumericalInverseHermite(dist)
>>> # `seed` ensures identical random streams are used by each `rvs` method
>>> seed = 500072020
>>> rvs1 = dist.rvs(size=100, random_state=np.random.default_rng(seed))
```

To check that the random variates closely follow the given distribution, we can look at its histogram:

```python
>>> dist = StandardNormal()
>>> urng = np.random.default_rng()
>>> rng = NumericalInverseHermite(dist, random_state=urng)
>>> rvs = rvs(10000)
>>> x = np.linspace(rvs.min()-0.1, rvs.max()+0.1, 1000)
>>> fx = norm.pdf(x)
>>> plt.plot(x, fx, 'r-', lw=2, label='true distribution')
>>> plt.hist(rvs, bins=20, density=True, alpha=0.8, label='random variates')
>>> plt.xlabel('x')
>>> plt.ylabel('PDF(x)')
>>> plt.title('Numerical Inverse Hermite Samples')
>>> plt.legend()
>>> plt.show()
```

Given the derivative of the PDF w.r.t the variate (i.e. \(x\)), we can use quintic Hermite interpolation to approximate the PPF by passing the `order` parameter:

```python
>>> class StandardNormal:
...     def pdf(self, x):
...         return 1/np.sqrt(2*np.pi) * np.exp(-x**2 / 2)
...     def dpdf(self, x):
...         return -1/np.sqrt(2*np.pi) * x * np.exp(-x**2 / 2)
...     def cdf(self, x):
...         return ndtr(x)
... >>> dist = StandardNormal()
>>> urng = np.random.default_rng()
```
```python
>>> rng = NumericalInverseHermite(dist, order=5, random_state=urng)
```

Higher orders result in a fewer number of intervals:

```python
>>> rng3 = NumericalInverseHermite(dist, order=3)
>>> rng5 = NumericalInverseHermite(dist, order=5)
>>> rng3.intervals, rng5.intervals
(3000, 522)
```

The u-error can be estimated by calling the `u_error` method. It runs a small Monte-Carlo simulation to estimate the u-error. By default, 100,000 samples are used. This can be changed by passing the `sample_size` argument:

```python
>>> rng1 = NumericalInverseHermite(dist, u_resolution=1e-10)
>>> rng1.u_error(sample_size=1000000)  # uses one million samples
UError(max_error=9.53167544892608e-11, mean_absolute_error=2.4501362916864e-11)
```

This returns a named tuple which contains the maximum u-error and the mean absolute u-error.

The u-error can be reduced by decreasing the u-resolution (maximum allowed u-error):

```python
>>> rng2 = NumericalInverseHermite(dist, u_resolution=1e-13)
>>> rng2.u_error(sample_size=1000000)
UError(max_error=9.32027892364129e-14, mean_absolute_error=1.5194172675685075e-14)
```

Note that this comes at the cost of computation time as a result of the increased setup time and number of intervals.

```python
>>> rng1.intervals
1022
>>> rng2.intervals
5687
```

```python
from timeit import timeit
>>> f = lambda: NumericalInverseHermite(dist, u_resolution=1e-10)
>>> timeit(f, number=1)
0.017409582000254886  # may vary
>>> f = lambda: NumericalInverseHermite(dist, u_resolution=1e-13)
>>> timeit(f, number=1)
0.08671202100003939  # may vary
```

See Page 220 and 2 for more details on this method.

Simple Ratio-of-Uniforms (SROU)

- Required: PDF, area under PDF if different than 1
- Optional: mode, CDF at mode
- Speed:
  - Set-up: fast
  - Sampling: slow

SROU is based on the ratio-of-uniforms method that uses universal inequalities for constructing a (universal) bounding rectangle. It works for T-concave distributions with $T(x) = -1/\sqrt{x}$.

```python
>>> from scipy.stats.sampling import SimpleRatioUniforms
```

Suppose we have the normal distribution:

```python
>>> class StdNorm:
...     def pdf(self, x):
...         return np.exp(-0.5 * x**2)
```

Notice that the PDF doesn’t integrate to 1. We can either pass the exact area under the PDF during initialization of the generator or an upper bound to the exact area under the PDF. Also, it is recommended to pass the mode of the distribution to speed up the setup:

```python
>>> urng = np.random.default_rng()
>>> dist = StdNorm()
>>> rng = SimpleRatioUniforms(dist, mode=0,
...     pdf_area=np.sqrt(2*np.pi),
...     random_state=urng)
```

Now, we can use the `rvs` method to generate samples from the distribution:

```python
>>> rvs = rng.rvs(10)
```

If the CDF at mode is available, it can be set to improve the performance of `rvs`:

```python
>>> from scipy.stats import norm
>>> rng = SimpleRatioUniforms(dist, mode=0,
...     pdf_area=np.sqrt(2*np.pi),
...     cdf_at_mode=norm.cdf(0),
...     random_state=urng)
>>> rvs = rng.rvs(1000)
```

We can check that the samples are from the given distribution by visualizing its histogram:

```python
>>> from scipy.stats.sampling import SimpleRatioUniforms
>>> from scipy.stats import norm
>>> import matplotlib.pyplot as plt
>>> class StdNorm:
...     def pdf(self, x):
...         return np.exp(-0.5 * x**2)
```

(continues on next page)
The main advantage of the method is a fast setup. This can be beneficial if one repeatedly needs to generate small to moderate samples of a distribution with different shape parameters. In such a situation, the setup step of `sampling.NumericalInverseHermite` or `sampling.NumericalInversePolynomial` will lead to poor performance. As an example, assume we are interested to generate 100 samples for the Gamma distribution with 1000 different shape parameters given by `np.arange(1.5, 5, 1000).

```python
>>> import math
>>> class GammaDist:
...     def __init__(self, p):
...         self.p = p
...     def pdf(self, x):
...         return x**(self.p-1) * np.exp(-x)

>>> urng = np.random.default_rng()
```
```python
>>> p = np.arange(1.5, 5, 1000)
>>> res = np.empty((1000, 100))
>>> for i in range(1000):
...     dist = GammaDist(p[i])
...     rng = SimpleRatioUniforms(dist, mode=p[i]-1,
...     pdf_area=math.gamma(p[i]),
...     random_state=urng)
...     with np.suppress_warnings() as sup:
...         sup.filter(RuntimeWarning, "invalid value encountered in double_
...         scalars")
...         sup.filter(RuntimeWarning, "overflow encountered in exp")
...         res[i] = rng.rvs(100)
```

See¹,², and³ for more details.

2.12.2 Random variables

There are two general distribution classes that have been implemented for encapsulating *continuous random variables* and *discrete random variables*. Over 80 continuous random variables (RVs) and 10 discrete random variables have been implemented using these classes. Besides this, new routines and distributions can be easily added by the end user. (If you create one, please contribute it.)

All of the statistics functions are located in the sub-package `scipy.stats` and a fairly complete listing of these functions can be obtained using `info(stats)`. The list of the random variables available can also be obtained from the docstring for the stats sub-package.

In the discussion below, we mostly focus on continuous RVs. Nearly everything also applies to discrete variables, but we point out some differences here: *Specific points for discrete distributions*.

In the code samples below, we assume that the `scipy.stats` package is imported as

```python
>>> from scipy import stats
```

and in some cases we assume that individual objects are imported as

```python
>>> from scipy.stats import norm
```

---

Getting help

First of all, all distributions are accompanied with help functions. To obtain just some basic information, we print the relevant docstring:

```python
print(stats.norm.__doc__)
```

To find the support, i.e., upper and lower bounds of the distribution, call:

```python
>>> print('bounds of distribution lower: %s, upper: %s' % norm.support())
bounds of distribution lower: -inf, upper: inf
```

We can list all methods and properties of the distribution with `dir(norm)`. As it turns out, some of the methods are private, although they are not named as such (their names do not start with a leading underscore), for example `vecdf`, are only available for internal calculation (those methods will give warnings when one tries to use them, and will be removed at some point).

To obtain the real main methods, we list the methods of the frozen distribution. (We explain the meaning of a frozen distribution below).

```python
>>> rv = norm()
>>> dir(rv) # reformatted
['__class__', '__delattr__', '__dict__', '__dir__', '__doc__', '__eq__',
 '_format__', '__ge__', '__getattribute__', '__gt__', '__hash__',
 '_init__', '__le__', '__lt__', '__module__', '__ne__', '__new__',

 'logpdf', 'logpmf', 'logsf', 'mean', 'median', 'moment', 'pdf', 'pmf',
 'ppf', 'random_state', 'rvs', 'sf', 'stats', 'std', 'var']
```

Finally, we can obtain the list of available distribution through introspection:

```python
>>> dist_continu = [d for d in dir(stats) if...
... isinstance(getattr(stats, d), stats.rv_continuous)]
>>> dist_discrete = [d for d in dir(stats) if...
... isinstance(getattr(stats, d), stats.rv_discrete)]
>>> print('number of continuous distributions: %d' % len(dist_continu))
number of continuous distributions: 104
>>> print('number of discrete distributions: %d' % len(dist_discrete))
number of discrete distributions: 19
```

Common methods

The main public methods for continuous RVs are:

- `rvs`: Random Variates
- `pdf`: Probability Density Function
- `cdf`: Cumulative Distribution Function
- `sf`: Survival Function (1-CDF)
- `ppf`: Percent Point Function (Inverse of CDF)
- `isf`: Inverse Survival Function (Inverse of SF)
- `stats`: Return mean, variance, (Fisher’s) skew, or (Fisher’s) kurtosis
• moment: non-central moments of the distribution

Let’s take a normal RV as an example.

```python
>>> norm.cdf(0)
0.5
```

To compute the cdf at a number of points, we can pass a list or a numpy array.

```python
>>> norm.cdf([-1., 0, 1])
array([ 0.15865525, 0.5, 0.84134475])
>>> import numpy as np
>>> norm.cdf(np.array([-1., 0, 1]))
array([ 0.15865525, 0.5, 0.84134475])
```

Thus, the basic methods, such as pdf, cdf, and so on, are vectorized.

Other generally useful methods are supported too:

```python
>>> norm.mean(), norm.std(), norm.var()
(0.0, 1.0, 1.0)
>>> norm.stats(moments="mv")
(array(0.0), array(1.0))
```

To find the median of a distribution, we can use the percent point function `ppf`, which is the inverse of the cdf:

```python
>>> norm.ppf(0.5)
0.0
```

To generate a sequence of random variates, use the `size` keyword argument:

```python
>>> norm.rvs(size=3)
array([-0.35687759, 1.34347647, -0.11710531]) # random
```

Don’t think that `norm.rvs(5)` generates 5 variates:

```python
>>> norm.rvs(5)
5.471435163732493 # random
```

Here, 5 with no keyword is being interpreted as the first possible keyword argument, `loc`, which is the first of a pair of keyword arguments taken by all continuous distributions. This brings us to the topic of the next subsection.

### Random number generation

Drawing random numbers relies on generators from `numpy.random` package. In the examples above, the specific stream of random numbers is not reproducible across runs. To achieve reproducibility, you can explicitly `seed` a random number generator. In NumPy, a generator is an instance of `numpy.random.Generator`. Here is the canonical way to create a generator:

```python
>>> from numpy.random import default_rng
>>> rng = default_rng()
```

And fixing the seed can be done like this:

```python
>>> # do NOT copy this value
>>> rng = default_rng(30143931238479871608357552876690613766)
```
Warning: Do not use this number or common values such as 0. Using just a small set of seeds to instantiate larger state spaces means that there are some initial states that are impossible to reach. This creates some biases if everyone uses such values. A good way to get a seed is to use a `numpy.random.SeedSequence`:

```python
>>> from numpy.random import SeedSequence
>>> print(SeedSequence().entropy)
301439351238479871608357552876690613766  # random
```

The `random_state` parameter in distributions accepts an instance of `numpy.random.Generator` class, or an integer, which is then used to seed an internal `Generator` object:

```python
>>> norm.rvs(size=5, random_state=rng)
array([-1.19097569,  1.43270697, -0.3126519 , -0.72058873,  0.47143516])  # random
```

For further info, see NumPy’s documentation.

To learn more about the random number samplers implemented in SciPy, see non-uniform random number sampling tutorial and quasi monte carlo tutorial

### Shifting and scaling

All continuous distributions take `loc` and `scale` as keyword parameters to adjust the location and scale of the distribution, e.g., for the standard normal distribution, the location is the mean and the scale is the standard deviation.

```python
>>> norm.stats(loc=3, scale=4, moments="mv")
(array(3.0), array(16.0))
```

In many cases, the standardized distribution for a random variable $X$ is obtained through the transformation $(X - \text{loc}) / \text{scale}$. The default values are $\text{loc} = 0$ and $\text{scale} = 1$.

Smart use of `loc` and `scale` can help modify the standard distributions in many ways. To illustrate the scaling further, the $cdf$ of an exponentially distributed RV with mean $1/\lambda$ is given by

$$F(x) = 1 - \exp(-\lambda x)$$

By applying the scaling rule above, it can be seen that by taking $\text{scale} = 1./\lambda$ we get the proper scale.

```python
>>> from scipy.stats import expon
>>> expon.mean(scale=3.)
3.0
```

**Note:** Distributions that take shape parameters may require more than simple application of `loc` and/or `scale` to achieve the desired form. For example, the distribution of 2-D vector lengths given a constant vector of length $R$ perturbed by independent $N(0, \sigma^2)$ deviations in each component is $\text{rice}(R/\sigma, \text{scale} = \sigma)$. The first argument is a shape parameter that needs to be scaled along with $x$.

The uniform distribution is also interesting:

```python
>>> from scipy.stats import uniform
>>> uniform.cdf([0, 1, 2, 3, 4, 5], loc=1, scale=4)
array([ 0. , 0. , 0.25, 0.5 , 0.75, 1. ])
```
Finally, recall from the previous paragraph that we are left with the problem of the meaning of `norm.rvs(5)`. As it turns out, calling a distribution like this, the first argument, i.e., the 5, gets passed to set the `loc` parameter. Let’s see:

```python
>>> np.mean(norm.rvs(5, size=500))
5.0098355106969992  # random
```

Thus, to explain the output of the example of the last section: `norm.rvs(5)` generates a single normally distributed random variate with mean ```loc=5, because of the default size=1.

We recommend that you set `loc` and `scale` parameters explicitly, by passing the values as keywords rather than as arguments. Repetition can be minimized when calling more than one method of a given RV by using the technique of **Freezing a Distribution**, as explained below.

**Shape parameters**

While a general continuous random variable can be shifted and scaled with the `loc` and `scale` parameters, some distributions require additional shape parameters. For instance, the gamma distribution with density

$$
\gamma(x,a) = \frac{\lambda^a x^{a-1} e^{-\lambda x}}{\Gamma(a)}
$$

requires the shape parameter `a`. Observe that setting `\lambda` can be obtained by setting the `scale` keyword to `1/\lambda`.

Let’s check the number and name of the shape parameters of the gamma distribution. (We know from the above that this should be 1.)

```python
>>> from scipy.stats import gamma
>>> gamma.numargs
1
>>> gamma.shapes
'a'
```

Now, we set the value of the shape variable to 1 to obtain the exponential distribution, so that we compare easily whether we get the results we expect.

```python
>>> gamma(a=1, scale=2.).stats(moments="mv")
(array(2.0), array(4.0))
```

Notice that we can also specify shape parameters as keywords:

```python
>>> gamma(a=1, scale=2.).stats(moments="mv")
(array(2.0), array(4.0))
```

**Freezing a distribution**

Passing the `loc` and `scale` keywords time and again can become quite bothersome. The concept of **freezing** a RV is used to solve such problems.

```python
>>> rv = gamma(1, scale=2.)
```

By using `rv` we no longer have to include the scale or the shape parameters anymore. Thus, distributions can be used in one of two ways, either by passing all distribution parameters to each method call (such as we did earlier) or by freezing the parameters for the instance of the distribution. Let us check this:
>>> rv.mean(), rv.std()
(2.0, 2.0)

This is, indeed, what we should get.

**Broadcasting**

The basic methods `pdf`, and so on, satisfy the usual NumPy broadcasting rules. For example, we can calculate the critical values for the upper tail of the $t$ distribution for different probabilities and degrees of freedom.

```python
>>> stats.t.isf([0.1, 0.05, 0.01], [[10], [11]])
array([[ 1.37218364, 1.81246112, 2.76376946],
       [ 1.36343032, 1.79588482, 2.71807918]])
```

Here, the first row contains the critical values for 10 degrees of freedom and the second row for 11 degrees of freedom (d.o.f.). Thus, the broadcasting rules give the same result of calling `isf` twice:

```python
>>> stats.t.isf([0.1, 0.05, 0.01], 10)
array([ 1.37218364, 1.81246112, 2.76376946])
>>> stats.t.isf([0.1, 0.05, 0.01], 11)
array([ 1.36343032, 1.79588482, 2.71807918])
```

If the array with probabilities, i.e., [0.1, 0.05, 0.01] and the array of degrees of freedom i.e., [10, 11, 12], have the same array shape, then element-wise matching is used. As an example, we can obtain the 10% tail for 10 d.o.f., the 5% tail for 11 d.o.f. and the 1% tail for 12 d.o.f. by calling

```python
>>> stats.t.isf([0.1, 0.05, 0.01], [10, 11, 12])
array([ 1.37218364, 1.79588482, 2.68099799])
```

**Specific points for discrete distributions**

Discrete distributions have mostly the same basic methods as the continuous distributions. However `pdf` is replaced by the probability mass function `pmf`, no estimation methods, such as `fit`, are available, and `scale` is not a valid keyword parameter. The location parameter, keyword `loc`, can still be used to shift the distribution.

The computation of the cdf requires some extra attention. In the case of continuous distribution, the cumulative distribution function is, in most standard cases, strictly monotonic increasing in the bounds $(a,b)$ and has, therefore, a unique inverse. The cdf of a discrete distribution, however, is a step function, hence the inverse cdf, i.e., the percent point function, requires a different definition:

$$\text{ppf}(q) = \min(x : \text{cdf}(x) \geq q, x \text{ integer})$$

For further info, see the docs [here](#).

We can look at the hypergeometric distribution as an example

```python
>>> from scipy.stats import hypergeom
>>> [M, n, N] = [20, 7, 12]
```

If we use the cdf at some integer points and then evaluate the ppf at those cdf values, we get the initial integers back, for example...
```python
>>> x = np.arange(4) * 2
array([0, 2, 4, 6])
>>> prb = hypergeom.cdf(x, M, n, N)
array([ 1.03199174e-04, 5.21155831e-02, 6.08359133e-01, 9.89783282e-01])
>>> hypergeom.ppf(prb, M, n, N)
array([ 0., 2., 4., 6.])

If we use values that are not at the kinks of the cdf step function, we get the next higher integer back:

```python
>>> hypergeom.ppf(prb + 1e-8, M, n, N)
array([ 1., 3., 5., 7.])
>>> hypergeom.ppf(prb - 1e-8, M, n, N)
array([ 0., 2., 4., 6.])
```

### Fitting distributions

The main additional methods of the not frozen distribution are related to the estimation of distribution parameters:

- `fit`: maximum likelihood estimation of distribution parameters, including location and scale
- `fit_loc_scale`: estimation of location and scale when shape parameters are given
- `nllf`: negative log likelihood function
- `expect`: calculate the expectation of a function against the pdf or pmf

### Performance issues and cautionary remarks

The performance of the individual methods, in terms of speed, varies widely by distribution and method. The results of a method are obtained in one of two ways: either by explicit calculation, or by a generic algorithm that is independent of the specific distribution.

Explicit calculation, on the one hand, requires that the method is directly specified for the given distribution, either through analytic formulas or through special functions in `scipy.special` or `numpy.random` for `rvs`. These are usually relatively fast calculations.

The generic methods, on the other hand, are used if the distribution does not specify any explicit calculation. To define a distribution, only one of pdf or cdf is necessary; all other methods can be derived using numeric integration and root finding. However, these indirect methods can be very slow. As an example, `rgh = stats.gausshyper.rvs(0.5, 2, 2, 2, size=100)` creates random variables in a very indirect way and takes about 19 seconds for 100 random variables on my computer, while one million random variables from the standard normal or from the t distribution take just above one second.
Remaining issues

The distributions in scipy.stats have recently been corrected and improved and gained a considerable test suite; however, a few issues remain:

- The distributions have been tested over some range of parameters; however, in some corner ranges, a few incorrect results may remain.
- The maximum likelihood estimation in `fit` does not work with default starting parameters for all distributions and the user needs to supply good starting parameters. Also, for some distribution using a maximum likelihood estimator might inherently not be the best choice.

2.12.3 Building specific distributions

The next examples show how to build your own distributions. Further examples show the usage of the distributions and some statistical tests.

Making a continuous distribution, i.e., subclassing `rv_continuous`

Making continuous distributions is fairly simple.

```python
>>> from scipy import stats
>>> class deterministic_gen(stats.rv_continuous):
...     def _cdf(self, x):
...         return np.where(x < 0, 0., 1.)
...     def _stats(self):
...         return 0., 0., 0., 0.

>>> deterministic = deterministic_gen(name="deterministic")
>>> deterministic.cdf(np.arange(-3, 3, 0.5))
array([ 0., 0., 0., 0., 0., 0., 1., 1., 1., 1., 1., 1.])
```

Interestingly, the `pdf` is now computed automatically:

```python
>>> deterministic.pdf(np.arange(-3, 3, 0.5))
array([ 0.00000000e+00, 0.00000000e+00, 0.00000000e+00,
        0.00000000e+00, 0.00000000e+00, 0.00000000e+00,
        5.83333333e+04, 4.16333634e-12, 4.16333634e-12,
        4.16333634e-12, 4.16333634e-12])
```

Be aware of the performance issues mentioned in Performance issues and cautionary remarks. The computation of unspecified common methods can become very slow, since only general methods are called, which, by their very nature, cannot use any specific information about the distribution. Thus, as a cautionary example:

```python
>>> from scipy.integrate import quad
>>> quad(deterministic.pdf, -1e-1, 1e-1)
(4.163336342344337e-13, 0.0)
```

But this is not correct: the integral over this pdf should be 1. Let’s make the integration interval smaller:

```python
>>> quad(deterministic.pdf, -1e-3, 1e-3)  # warning removed
(1.00007687229173, 0.0010625571718182458)
```
This looks better. However, the problem originated from the fact that the pdf is not specified in the class definition of the deterministic distribution.

**Subclassing `rv_discrete`**

In the following, we use `stats.rv_discrete` to generate a discrete distribution that has the probabilities of the truncated normal for the intervals centered around the integers.

**General info**

From the docstring of `rv_discrete`, `help(stats.rv_discrete),`

> “You can construct an arbitrary discrete rv where \( P\{X=x_k\} = p_k \) by passing to the `rv_discrete` initialization method (through the `values=` keyword) a tuple of sequences \((x_k, p_k)\) which describes only those values of \( X \) (\( x_k \)) that occur with nonzero probability (\( p_k \))."

Next to this, there are some further requirements for this approach to work:

- The keyword `name` is required.
- The support points of the distribution \( x_k \) have to be integers.
- The number of significant digits (decimals) needs to be specified.

In fact, if the last two requirements are not satisfied, an exception may be raised or the resulting numbers may be incorrect.

**An example**

Let's do the work. First:

```python
>>> npoints = 20  # number of integer support points of the distribution...
     # minus 1
>>> npointsh = npoints // 2
>>> npointshf = float(npoints)
>>> nbound = 4  # bounds for the truncated normal
>>> normbound = (1+1/npointshf) * nbound  # actual bounds of truncated normal
>>> grid = np.arange(-npointsh, npointsh+2, 1)  # integer grid
>>> gridlimitsnorm = (grid-0.5) / npointsh * nbound  # bin limits for the_
     # truncnorm
>>> gridlimits = grid - 0.5  # used later in the analysis
>>> grid = grid[:-1]
>>> probs = np.diff(stats.truncnorm.cdf(gridlimitsnorm, -normbound, _
     #normbound))
>>> gridint = grid
```

And, finally, we can subclass `rv_discrete`:

```python
>>> normdiscrete = stats.rv_discrete(values=(gridint, ...
     ... np.round(probs, decimals=7)), name='normdiscrete')
```

Now that we have defined the distribution, we have access to all common methods of discrete distributions.

```python
>>> print('mean = $6.4f$, variance = $6.4f$, skew = $6.4f$, kurtosis = $6.4f$ %
     ... normdiscrete.stats(moments='mvsk'))
mean = -0.0000, variance = 6.3302, skew = 0.0000, kurtosis = -0.0076
```

```python
>>> nd_std = np.sqrt(normdiscrete.stats(moments='v'))
```
Testing the implementation

Let's generate a random sample and compare observed frequencies with the probabilities.

```python
>>> n_sample = 500
>>> rvs = normdiscrete.rvs(size=n_sample)
>>> f, l = np.histogram(rvs, bins=gridlimits)
>>> sfreq = np.vstack([gridint, f, probs*n_sample]).T
>>> print(sfreq)
[[[-1.00000000e+01  0.00000000e+00  2.95019349e-02] # random
  [-9.00000000e+00  0.00000000e+00  1.32294142e-01]
  [-8.00000000e+00  0.00000000e+00  5.06497902e-01]
  [-7.00000000e+00  2.00000000e+00  1.65568919e+00]
  [-6.00000000e+00  1.00000000e+00  4.62125309e+00]
  [-5.00000000e+00  9.00000000e+00  1.10137298e+01]
  [-4.00000000e+00  2.60000000e+01  2.24137683e+01]
  [-3.00000000e+00  3.70000000e+01  3.89503370e+01]
  [-2.00000000e+00  5.10000000e+01  5.78004747e+01]
  [-1.00000000e+00  7.10000000e+01  7.32455414e+01]
  [  0.00000000e+00  7.40000000e+01  7.92618251e+01]
  [  1.00000000e+00  8.90000000e+01  7.32455414e+01]
  [  2.00000000e+00  5.50000000e+01  5.78004747e+01]
  [  3.00000000e+00  5.00000000e+01  3.89503370e+01]
  [  4.00000000e+00  1.70000000e+01  2.24137683e+01]
  [  5.00000000e+00  1.10000000e+01  1.10137298e+01]
  [  6.00000000e+00  4.00000000e+00  4.62125309e+00]
  [  7.00000000e+00  3.00000000e+00  1.65568919e+00]
  [  8.00000000e+00  0.00000000e+00  5.06497902e-01]
  [  9.00000000e+00  0.00000000e+00  1.32294142e-01]
  [ 1.00000000e+01  0.00000000e+00  2.95019349e-02]]
```

Next, we can test whether our sample was generated by our norm-discrete distribution. This also verifies whether the random numbers were generated correctly.

The chisquare test requires that there are a minimum number of observations in each bin. We combine the tail bins into larger bins so that they contain enough observations.
The p-value in this case is high, so we can be quite confident that our random sample was actually generated by the distribution.

### 2.12.4 Analysing one sample

First, we create some random variables. We set a seed so that in each run we get identical results to look at. As an example we take a sample from the Student t distribution:

```python
>>> x = stats.t.rvs(10, size=1000)
```

Here, we set the required shape parameter of the t distribution, which in statistics corresponds to the degrees of freedom, to 10. Using size=1000 means that our sample consists of 1000 independently drawn (pseudo) random numbers. Since we did not specify the keyword arguments `loc` and `scale`, those are set to their default values zero and one.

#### Descriptive statistics

`x` is a numpy array, and we have direct access to all array methods, e.g.,

```python
>>> print(x.min())  # equivalent to np.min(x)
-3.78975572422  # random
>>> print(x.max())  # equivalent to np.max(x)
5.26327732981   # random
>>> print(x.mean()) # equivalent to np.mean(x)
```

(continues on next page)
How do the sample properties compare to their theoretical counterparts?

```python
>>> m, v, s, k = stats.t.stats(10, moments='mvsk')
>>> n, (smin, smax), sm, sv, ss, sk = stats.describe(x)
```
However, the standard normal distribution has a variance of 1, while our sample has a variance of 1.29. If we standardize our sample and test it against the normal distribution, then the p-value is again large enough that we cannot reject the hypothesis that the sample came from the normal distribution.

```python
>>> d, pval = stats.kstest((x - x.mean()) / x.std(), 'norm')
>>> print('KS-statistic D = %.3f pvalue = %.4f' % (d, pval))
KS-statistic D = 0.032 pvalue = 0.2397 # random
```

Note: The Kolmogorov-Smirnov test assumes that we test against a distribution with given parameters, since, in the last case, we estimated mean and variance, this assumption is violated and the distribution of the test statistic, on which the p-value is based, is not correct.

### Tails of the distribution

Finally, we can check the upper tail of the distribution. We can use the percent point function `ppf`, which is the inverse of the cdf function, to obtain the critical values, or, more directly, we can use the inverse of the survival function

```python
>>> crit01, crit05, crit10 = stats.t.ppf([1-0.01, 1-0.05, 1-0.10], 10)
>>> print('critical values from ppf at 1%, 5% and 10% %.4f %.4f %.4f' % (crit01, crit05, crit10))
critical values from ppf at 1%, 5% and 10% 2.7638 1.8125 1.3722
```

In all three cases, our sample has more weight in the top tail than the underlying distribution. We can briefly check a larger sample to see if we get a closer match. In this case, the empirical frequency is quite close to the theoretical probability, but if we repeat this several times, the fluctuations are still pretty large.

```python
>>> freq05l = np.sum(stats.t.rvs(10, size=10000) > crit05) / 10000.0 * 100
>>> print('larger sample % frequency at 5% tail %.4f' % freq05l)
larger sample % frequency at 5% tail 4.8000 # random
```

We can also compare it with the tail of the normal distribution, which has less weight in the tails:

```python
>>> print('tail prob. of normal at 1%, 5% and 10% %.4f %.4f %.4f %.4f' %
...     tuple(stats.norm.sf([crit01, crit05, crit10]*100)))
tail prob. of normal at 1%, 5% and 10% 0.2857 3.4957 8.5003
```

The chisquare test can be used to test whether for a finite number of bins, the observed frequencies differ significantly from the probabilities of the hypothesized distribution.
We see that the standard normal distribution is clearly rejected, while the standard t-distribution cannot be rejected. Since
the variance of our sample differs from both standard distributions, we can again redo the test taking the estimate for scale
and location into account.

The fit method of the distributions can be used to estimate the parameters of the distribution, and the test is repeated
using probabilities of the estimated distribution.

Taking account of the estimated parameters, we can still reject the hypothesis that our sample came from a normal
distribution (at the 5% level), but again, with a p-value of 0.95, we cannot reject the t-distribution.

**Special tests for normal distributions**

Since the normal distribution is the most common distribution in statistics, there are several additional functions available
to test whether a sample could have been drawn from a normal distribution.

First, we can test if skew and kurtosis of our sample differ significantly from those of a normal distribution:

These two tests are combined in the normality test
In all three tests, the p-values are very low and we can reject the hypothesis that the our sample has skew and kurtosis of the normal distribution.

Since skew and kurtosis of our sample are based on central moments, we get exactly the same results if we test the standardized sample:

```python
>>> print('normaltest teststat = %6.3f pvalue = %6.4f' %
      ... stats.normaltest((x-x.mean())/x.std()))
normaltest teststat = 30.379 pvalue = 0.0000 # random
```

Because normality is rejected so strongly, we can check whether the normaltest gives reasonable results for other cases:

```python
>>> print('normaltest teststat = %6.3f pvalue = %6.4f' %
      ... stats.normaltest(stats.t.rvs(10, size=100)))
normaltest teststat = 4.698 pvalue = 0.0955 # random
>>> print('normaltest teststat = %6.3f pvalue = %6.4f' %
      ... stats.normaltest(stats.norm.rvs(size=1000)))
normaltest teststat = 0.613 pvalue = 0.7361 # random
```

When testing for normality of a small sample of t-distributed observations and a large sample of normal-distributed observations, then in neither case can we reject the null hypothesis that the sample comes from a normal distribution. In the first case, this is because the test is not powerful enough to distinguish a t and a normally distributed random variable in a small sample.

### 2.12.5 Comparing two samples

In the following, we are given two samples, which can come either from the same or from different distribution, and we want to test whether these samples have the same statistical properties.

#### Comparing means

Test with sample with identical means:

```python
>>> rvs1 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> rvs2 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> stats.ttest_ind(rvs1, rvs2)
Ttest_indResult(statistic=-0.5489, pvalue=0.5832) # random
```

Test with sample with different means:

```python
>>> rvs3 = stats.norm.rvs(loc=8, scale=10, size=500)
>>> stats.ttest_ind(rvs1, rvs3)
Ttest_indResult(statistic=-4.5334, pvalue=6.5071e-06) # random
```
Kolmogorov-Smirnov test for two samples \texttt{ks\_2samp}

For the example, where both samples are drawn from the same distribution, we cannot reject the null hypothesis, since the pvalue is high

\begin{verbatim}
>>> stats.ks_2samp(rvs1, rvs2)
KstestResult(statistic=0.026, pvalue=0.9959527565364388) # random
\end{verbatim}

In the second example, with different location, i.e., means, we can reject the null hypothesis, since the pvalue is below 1%

\begin{verbatim}
>>> stats.ks_2samp(rvs1, rvs3)
KstestResult(statistic=0.114, pvalue=0.00299005061044668) # random
\end{verbatim}

### 2.12.6 Kernel density estimation

A common task in statistics is to estimate the probability density function (PDF) of a random variable from a set of data samples. This task is called density estimation. The most well-known tool to do this is the histogram. A histogram is a useful tool for visualization (mainly because everyone understands it), but doesn’t use the available data very efficiently. Kernel density estimation (KDE) is a more efficient tool for the same task. The \texttt{gaussian\_kde} estimator can be used to estimate the PDF of univariate as well as multivariate data. It works best if the data is unimodal.

#### Univariate estimation

We start with a minimal amount of data in order to see how \texttt{gaussian\_kde} works and what the different options for bandwidth selection do. The data sampled from the PDF are shown as blue dashes at the bottom of the figure (this is called a rug plot):

\begin{verbatim}
>>> from scipy import stats
>>> import matplotlib.pyplot as plt

>>> x1 = np.array([-7, -5, 1, 4, 5], dtype=np.float64)
>>> kde1 = stats.gaussian_kde(x1)
>>> kde2 = stats.gaussian_kde(x1, bw_method='silverman')

>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)

>>> ax.plot(x1, np.zeros(x1.shape), 'b+', ms=20) # rug plot
>>> x_eval = np.linspace(-10, 10, num=200)
>>> ax.plot(x_eval, kde1(x_eval), 'k-', label="Scott's Rule")
>>> ax.plot(x_eval, kde2(x_eval), 'r-', label="Silverman's Rule")

>>> plt.show()
\end{verbatim}

We see that there is very little difference between Scott’s Rule and Silverman’s Rule, and that the bandwidth selection with a limited amount of data is probably a bit too wide. We can define our own bandwidth function to get a less smoothed-out result.

\begin{verbatim}
>>> def my_kde_bandwidth(obj, fac=1./5):
...     """We use Scott's Rule, multiplied by a constant factor.""
...     return np.power(obj.n, -1./(obj.d+4)) * fac
\end{verbatim}
We see that if we set bandwidth to be very narrow, the obtained estimate for the probability density function (PDF) is simply the sum of Gaussians around each data point.

We now take a more realistic example and look at the difference between the two available bandwidth selection rules. Those rules are known to work well for (close to) normal distributions, but even for unimodal distributions that are quite
strongly non-normal they work reasonably well. As a non-normal distribution we take a Student’s T distribution with 5
degrees of freedom.

```python
import numpy as np
import matplotlib.pyplot as plt
from scipy import stats

rng = np.random.default_rng()
x1 = rng.normal(size=200) # random data, normal distribution
xs = np.linspace(x1.min()-1, x1.max()+1, 200)

kde1 = stats.gaussian_kde(x1)
kde2 = stats.gaussian_kde(x1, bw_method='silverman')

fig = plt.figure(figsize=(8, 6))
ax1 = fig.add_subplot(211)
ax1.plot(x1, np.zeros(x1.shape), 'b+', ms=12) # rug plot
ax1.plot(xs, kde1(xs), 'k-', label="Scott's Rule")
ax1.plot(xs, kde2(xs), 'b-', label="Silverman's Rule")
ax1.plot(xs, stats.norm.pdf(xs), 'r--', label="True PDF")

ax1.set_xlabel('x')
ax1.set_ylabel('Density')
ax1.set_title("Normal (top) and Student's T$_{(df=5)}$ (bottom) distributions")
ax1.legend(loc=1)

x2 = stats.t.rvs(5, size=200, random_state=rng) # random data, T distribution
xs = np.linspace(x2.min()-1, x2.max()+1, 200)

kde3 = stats.gaussian_kde(x2)
kde4 = stats.gaussian_kde(x2, bw_method='silverman')

ax2 = fig.add_subplot(212)
ax2.plot(x2, np.zeros(x2.shape), 'b+', ms=12) # rug plot
ax2.plot(xs, kde3(xs), 'k-', label="Scott's Rule")
ax2.plot(xs, kde4(xs), 'b-', label="Silverman's Rule")
ax2.plot(xs, stats.t.pdf(xs, 5), 'r--', label="True PDF")

ax2.set_xlabel('x')
ax2.set_ylabel('Density')
plt.show()
```

We now take a look at a bimodal distribution with one wider and one narrower Gaussian feature. We expect that this will be a more difficult density to approximate, due to the different bandwidths required to accurately resolve each feature.

```python
>>> from functools import partial

>>> loc1, scale1, size1 = (-2, 1, 175)
>>> loc2, scale2, size2 = (2, 0.2, 50)
>>> x2 = np.concatenate([np.random.normal(loc=loc1, scale=scale1, size=size1),
  (continues on next page)
Normal (top) and Student's $T_{\nu=5}$ (bottom) distributions

- Scott's Rule
- Silverman's Rule
- True PDF
>>> x_eval = np.linspace(x2.min() - 1, x2.max() + 1, 500)

>>> kde = stats.gaussian_kde(x2)
>>> kde2 = stats.gaussian_kde(x2, bw_method='silverman')
>>> kde3 = stats.gaussian_kde(x2, bw_method=partial(my_kde_bandwidth, fac=0.2))
>>> kde4 = stats.gaussian_kde(x2, bw_method=partial(my_kde_bandwidth, fac=0.5))

>>> pdf = stats.norm.pdf
>>> bimodal_pdf = pdf(x_eval, loc=loc1, scale=scale1) * float(size1) / x2.size + \\
... pdf(x_eval, loc=loc2, scale=scale2) * float(size2) / x2.size

As expected, the KDE is not as close to the true PDF as we would like due to the different characteristic size of the two features of the bimodal distribution. By halving the default bandwidth (Scott * 0.5), we can do somewhat better, while using a factor 5 smaller bandwidth than the default doesn’t smooth enough. What we really need, though, in this case, is a non-uniform (adaptive) bandwidth.

Multivariate estimation

With {gaussian_kde} we can perform multivariate, as well as univariate estimation. We demonstrate the bivariate case. First, we generate some random data with a model in which the two variates are correlated.

```python
>>> def measure(n):
...    """Measurement model, return two coupled measurements.""
...    m1 = np.random.normal(size=n)
...    m2 = np.random.normal(scale=0.5, size=n)
...    return m1+m2, m1-m2
```
2.12. Statistics (scipy.stats)
Then we apply the KDE to the data:

```python
>>> X, Y = np.mgrid[xmin:xmax:100j, ymin:ymax:100j]
>>> positions = np.vstack([X.ravel(), Y.ravel()])
>>> values = np.vstack([m1, m2])
>>> kernel = stats.gaussian_kde(values)
>>> Z = np.reshape(kernel.evaluate(positions).T, X.shape)
```

Finally, we plot the estimated bivariate distribution as a colormap and plot the individual data points on top.

```python
>>> fig = plt.figure(figsize=(8, 6))
>>> ax = fig.add_subplot(111)
>>> ax.imshow(np.rot90(Z), cmap=plt.cm.gist_earth_r,
... extent=[xmin, xmax, ymin, ymax])
>>> ax.plot(m1, m2, 'k.', markersize=2)
>>> ax.set_xlim([xmin, xmax])
>>> ax.set_ylim([ymin, ymax])
>>> plt.show()
```

**Multiscale Graph Correlation (MGC)**

With `multiscale_graphcorr`, we can test for independence on high dimensional and nonlinear data. Before we start, let’s import some useful packages:

```python
>>> import numpy as np
>>> import matplotlib.pyplot as plt; plt.style.use('classic')
>>> from scipy.stats import multiscale_graphcorr
```

Let’s use a custom plotting function to plot the data relationship:

```python
>>> import matplotlib.pyplot as plt
>>> def mgc_plot(x, y, sim_name, mgc_dict=None, only_viz=False, only_mgc=False):
...     # simulation
...     if not only_mgc:
...         sim = np.random.random(len(x))
...     if only_viz:
...         # Plot sim and MGC-plot"
...         plt.figure(figsize=(8, 8))
...         ax = plt.gca()
...         ax.set_title(sim_name + " Simulation", fontsize=20)
...         ax.scatter(x, y)
...         ax.set_xlabel('X', fontsize=15)
...         ax.set_ylabel('Y', fontsize=15)
...         ax.axis('equal')
```

(continues on next page)
2.12. Statistics (scipy.stats)
Let's look at some linear data first:

```python
>>> rng = np.random.default_rng()
>>> x = np.linspace(-1, 1, num=100)
>>> y = x + 0.3 * rng.random(x.size)
```

The simulation relationship can be plotted below:

```python
>>> mgc_plot(x, y, "Linear", only_viz=True)
```

Now, we can see the test statistic, p-value, and MGC map visualized below. The optimal scale is shown on the map as a red "x":

```python
>>> stat, pvalue, mgc_dict = multiscale_graphcorr(x, y)
>>> print("MGC test statistic: ", round(stat, 1))
MGC test statistic: 1.0
>>> print("P-value: ", round(pvalue, 1))
P-value: 0.0
>>> mgc_plot(x, y, "Linear", mgc_dict, only_mgc=True)
```

It is clear from here, that MGC is able to determine a relationship between the input data matrices because the p-value is
Linear Simulation

![Linear Simulation Plot](image-url)
very low and the MGC test statistic is relatively high. The MGC-map indicates a **strongly linear relationship**. Intuitively, this is because having more neighbors will help in identifying a linear relationship between $x$ and $y$. The optimal scale in this case is **equivalent to the global scale**, marked by a red spot on the map.

The same can be done for nonlinear data sets. The following $x$ and $y$ arrays are derived from a nonlinear simulation:

```python
>>> unif = np.array(rng.uniform(0, 5, size=100))
>>> x = unif * np.cos(np.pi * unif)
>>> y = unif * np.sin(np.pi * unif) + 0.4 * rng.random(x.size)
```

The simulation relationship can be plotted below:

```python
>>> mgc_plot(x, y, "Spiral", only_viz=True)
```

Now, we can see the test statistic, p-value, and MGC map visualized below. The optimal scale is shown on the map as a
red “x”:

```python
>>> stat, pvalue, mgc_dict = multiscale_graphcorr(x, y)
>>> print("MGC test statistic: ", round(stat, 1))
MGC test statistic: 0.2 # random
>>> print("P-value: ", round(pvalue, 1))
P-value: 0.0
>>> mgc_plot(x, y, "Spiral", mgc_dict, only_mgc=True)
```

It is clear from here, that MGC is able to determine a relationship again because the p-value is very low and the MGC test statistic is relatively high. The MGC-map indicates a strongly nonlinear relationship. The optimal scale in this case is equivalent to the local scale, marked by a red spot on the map.
2.12.7 Quasi-Monte Carlo

Before talking about Quasi-Monte Carlo (QMC), a quick introduction about Monte Carlo (MC). MC methods, or MC experiments, are a broad class of computational algorithms that rely on repeated random sampling to obtain numerical results. The underlying concept is to use randomness to solve problems that might be deterministic in principle. They are often used in physical and mathematical problems and are most useful when it is difficult or impossible to use other approaches. MC methods are mainly used in three problem classes: optimization, numerical integration, and generating draws from a probability distribution.

Generating random numbers with specific properties is a more complex problem than it sounds. Simple MC methods are designed to sample points to be independent and identically distributed (IID). But generating multiple sets of random points can produce radically different results.

In both cases in the plot above, points are generated randomly without any knowledge about previously drawn points. It is clear that some regions of the space are left unexplored - which can cause problems in simulations as a particular set of points might trigger a totally different behaviour.

A great benefit of MC is that it has known convergence properties. Let’s look at the mean of the squared sum in 5 dimensions:

\[ f(x) = \left( \sum_{j=1}^{5} x_j \right)^2, \]

with \( x_j \sim U(0, 1) \). It has a known mean value, \( \mu = 5/3 + 5(5 - 1)/4 \). Using MC sampling, we can compute that mean numerically, and the approximation error follows a theoretical rate of \( O(n^{-1/2}) \).

Although the convergence is ensured, practitioners tend to want to have an exploration process which is more deterministic. With normal MC, a seed can be used to have a repeatable process. But fixing the seed would break the convergence property: a given seed could work for a given class of problem and break for another one.

What is commonly done to walk through the space in a deterministic manner, is to use a regular grid spanning all parameter dimensions, also called a saturated design. Let’s consider the unit-hypercube, with all bounds ranging from 0 to 1. Now, having a distance of 0.1 between points, the number of points required to fill the unit interval would be 10. In a 2-dimensional hypercube the same spacing would require 100, and in 3 dimensions 1,000 points. As the number of dimensions grows, the number of experiments which is required to fill the space rises exponentially as the dimensionality of the space increases. This exponential growth is called “the curse of dimensionality”.
To mitigate this issue, QMC methods have been designed. They are deterministic, have a good coverage of the space and some of them can be continued and retain good properties. The main difference with MC methods is that the points are not IID but they know about previous points. Hence, some methods are also referred to as sequences.

This figure presents 2 sets of 256 points. The design of the left is a plain MC whereas the design of the right is a QMC design using the Sobol’ method. We clearly see that the QMC version is more uniform. The points sample better near the boundaries and there are less clusters or gaps.

One way to assess the uniformity is to use a measure called the discrepancy. Here the discrepancy of Sobol’ points is better than crude MC.

Coming back to the computation of the mean, QMC methods also have better rates of convergence for the error. They can achieve $O(n^{-1})$ for this function, and even better rates on very smooth functions. This figure shows that the Sobol’ method has a rate of $O(n^{-1})$:
MC—$C^2 = 0.0035$

Sobol'—$C^2 = 1.1e-05$

2.12. Statistics (scipy.stats)
We refer to the documentation of `scipy.stats.qmc` for more mathematical details.

**Calculate the discrepancy**

Let’s consider two sets of points. From the figure below, it is clear that the design on the left covers more of the space than the design on the right. This can be quantified using a discrepancy measure. The lower the discrepancy, the more uniform a sample is.

```python
>>> import numpy as np
>>> from scipy.stats import qmc
>>> space_1 = np.array([[1, 3], [2, 6], [3, 2], [4, 5], [5, 1], [6, 4]])
>>> space_2 = np.array([[1, 5], [2, 4], [3, 3], [4, 2], [5, 1], [6, 6]])
>>> l_bounds = [0.5, 0.5]
>>> u_bounds = [6.5, 6.5]
>>> space_1 = qmc.scale(space_1, l_bounds, u_bounds, reverse=True)
>>> space_2 = qmc.scale(space_2, l_bounds, u_bounds, reverse=True)
>>> qmc.discrepancy(space_1)
0.008142039609053464
>>> qmc.discrepancy(space_2)
0.010456854423869011
```

![Discrepancy plots](image)

**Using a QMC engine**

Several QMC samplers/engines are implemented. Here we look at two of the most used QMC methods: *Sobol* and *Halton* sequences.

```python
# """Sobol' and Halton sequences."""
from scipy.stats import qmc
import numpy as np
import matplotlib.pyplot as plt
```

(continues on next page)
rng = np.random.default_rng()
n_sample = 256
dim = 2
sample = {}

# Sobol'
engine = qmc.Sobol(d=dim, seed=rng)
sample['Sobol'] = engine.random(n_sample)

# Halton
engine = qmc.Halton(d=dim, seed=rng)
sample['Halton'] = engine.random(n_sample)

fig, axs = plt.subplots(1, 2, figsize=(8, 4))

for i, kind in enumerate(sample):
    axs[i].scatter(sample[kind][:, 0], sample[kind][:, 1])
    axs[i].set_aspect('equal')
    axs[i].set_xlabel(r'$x_1$')
    axs[i].set_ylabel(r'$x_2$')
    axs[i].set_title(f'{kind}—$C^2 = {qmc.discrepancy(sample[kind]):.2f}$')

plt.tight_layout()
plt.show()}
Warning: QMC methods require particular care and the user must read the documentation to avoid common pitfalls. *Sobol'* for instance requires a number of points following a power of 2. Also, thinning, burning or other point selection can break the properties of the sequence and result in a set of points which would not be better than MC.

QMC engines are state-aware. Meaning that you can continue the sequence, skip some points, or reset it. Let's take 5 points from *Halton*. And then ask for a second set of 5 points:

```python
>>> from scipy.stats import qmc
>>> engine = qmc.Halton(d=2)
>>> engine.random(5)
array([[0.22166437, 0.07980522], # random
       [0.72166437, 0.93165708],
       [0.47166437, 0.41313856],
       [0.97166437, 0.19091633],
       [0.01853937, 0.74647189]])
>>> engine.random(5)
array([[0.51853937, 0.52424967], # random
       [0.26853937, 0.30202745],
       [0.76853937, 0.857583 ],
       [0.14353937, 0.63536078],
       [0.64353937, 0.01807683]])
```

Now we reset the sequence. Asking for 5 points leads to the same first 5 points:

```python
>>> engine.reset()
>>> engine.random(5)
array([[0.22166437, 0.07980522], # random
       [0.72166437, 0.93165708],
       [0.47166437, 0.41313856],
       [0.97166437, 0.19091633],
       [0.01853937, 0.74647189]])
```

And here we advance the sequence to get the same second set of 5 points:

```python
>>> engine.reset()
>>> engine.fast_forward(5)
>>> engine.random(5)
array([[0.51853937, 0.52424967], # random
       [0.26853937, 0.30202745],
       [0.76853937, 0.857583 ],
       [0.14353937, 0.63536078],
       [0.64353937, 0.01807683]])
```

Note: By default, both *Sobol* and *Halton* are scrambled. The convergence properties are better, and it prevents the appearance of fringes or noticeable patterns of points in high dimensions. There should be no practical reason not to use the scrambled version.
Making a QMC engine, i.e., subclassing QMCEngine

To make your own QMCEngine, a few methods have to be defined. Following is an example wrapping numpy.random.Generator.

```python
>>> import numpy as np
>>> from scipy.stats import qmc
>>> class RandomEngine(qmc.QMCEngine):
...     def __init__(self, d, seed=None):
...         super().__init__(d=d, seed=seed)
...         self.rng = np.random.default_rng(self.rng_seed)

...     def random(self, n=1):
...         self.num_generated += n
...         return self.rng.random((n, self.d))

...     def reset(self):
...         self.rng = np.random.default_rng(self.rng_seed)
...         self.num_generated = 0
...         return self

...     def fast_forward(self, n):
...         self.random(n)
...         return self
```

Then we use it as any other QMC engine:

```python
>>> engine = RandomEngine(2)
>>> engine.random(5)
array([[0.22733602, 0.31675834],  # random
       [0.79736546, 0.67625467],
       [0.39110955, 0.33281393],
       [0.59830875, 0.18673419],
       [0.67275604, 0.94180287]])
>>> engine.reset()
>>> engine.random(5)
array([[0.22733602, 0.31675834],  # random
       [0.79736546, 0.67625467],
       [0.39110955, 0.33281393],
       [0.59830875, 0.18673419],
       [0.67275604, 0.94180287]])
```
Guidelines on using QMC

- QMC has rules! Be sure to read the documentation or you might have no benefit over MC.
- Use Sobol if you need exactly $2^m$ points.
- Halton allows to sample, or skip, an arbitrary number of points. This is at the cost of a slower rate of convergence than Sobol.
- Never remove the first points of the sequence. It will destroy the properties.
- Scrambling is always better.
- If you use LHS based methods, you cannot add points without losing the LHS properties. (There are some methods to do so, but this is not implemented.)

2.13 Multidimensional image processing (scipy.ndimage)

2.13.1 Introduction

Image processing and analysis are generally seen as operations on 2-D arrays of values. There are, however, a number of fields where images of higher dimensionality must be analyzed. Good examples of these are medical imaging and biological imaging. numpy is suited very well for this type of applications due to its inherent multidimensional nature. The scipy.ndimage packages provides a number of general image processing and analysis functions that are designed to operate with arrays of arbitrary dimensionality. The packages currently includes: functions for linear and non-linear filtering, binary morphology, B-spline interpolation, and object measurements.

2.13.2 Properties shared by all functions

All functions share some common properties. Notably, all functions allow the specification of an output array with the output argument. With this argument, you can specify an array that will be changed in-place with the result with the operation. In this case, the result is not returned. Usually, using the output argument is more efficient, since an existing array is used to store the result.

The type of arrays returned is dependent on the type of operation, but it is, in most cases, equal to the type of the input. If, however, the output argument is used, the type of the result is equal to the type of the specified output argument. If no output argument is given, it is still possible to specify what the result of the output should be. This is done by simply assigning the desired numpy type object to the output argument. For example:

```python
>>> from scipy.ndimage import correlate
>>> correlate(np.arange(10), [1, 2.5])
array([ 0,  2,  6,  9, 13, 16, 20, 23, 27, 30])
>>> correlate(np.arange(10), [1, 2.5], output=np.float64)
array([ 0.,  2.5,  6.,  9.5, 13., 16.5, 20., 23.5, 27., 30.5])
```
2.13.3 Filter functions

The functions described in this section all perform some type of spatial filtering of the input array: the elements in the output are some function of the values in the neighborhood of the corresponding input element. We refer to this neighborhood of elements as the filter kernel, which is often rectangular in shape but may also have an arbitrary footprint. Many of the functions described below allow you to define the footprint of the kernel by passing a mask through the footprint parameter. For example, a cross-shaped kernel can be defined as follows:

```python
>>> footprint = np.array([[0, 1, 0], [1, 1, 1], [0, 1, 0]])
```

```
>>>
```

Usually, the origin of the kernel is at the center calculated by dividing the dimensions of the kernel shape by two. For instance, the origin of a 1-D kernel of length three is at the second element. Take, for example, the correlation of a 1-D array with a filter of length 3 consisting of ones:

```python
>>> from scipy.ndimage import correlate1d
>>> a = [0, 0, 0, 1, 0, 0, 0]
>>> correlate1d(a, [1, 1, 1])
array([0, 0, 1, 1, 1, 0, 0])
```

Sometimes, it is convenient to choose a different origin for the kernel. For this reason, most functions support the origin parameter, which gives the origin of the filter relative to its center. For example:

```python
>>> a = [0, 0, 0, 1, 0, 0, 0]
>>> correlate1d(a, [1, 1, 1], origin = -1)
array([0, 1, 1, 1, 0, 0, 0])
```

The effect is a shift of the result towards the left. This feature will not be needed very often, but it may be useful, especially for filters that have an even size. A good example is the calculation of backward and forward differences:

```python
>>> a = [0, 0, 0, 1, 1, 0, 0]
>>> correlate1d(a, [-1, 1]) # backward difference
array([ 0, 0, 1, 0, 0, -1, 0])
>>> correlate1d(a, [-1, 1], origin = -1) # forward difference
array([ 0, 1, 0, 0, -1, 0, 0])
```

We could also have calculated the forward difference as follows:

```python
>>> correlate1d(a, [0, -1, 1])
array([ 0, 1, 0, 0, -1, 0, 0])
```

However, using the origin parameter instead of a larger kernel is more efficient. For multidimensional kernels, origin can be a number, in which case the origin is assumed to be equal along all axes, or a sequence giving the origin along each axis.

Since the output elements are a function of elements in the neighborhood of the input elements, the borders of the array need to be dealt with appropriately by providing the values outside the borders. This is done by assuming that the arrays are extended beyond their boundaries according to certain boundary conditions. In the functions described below, the boundary conditions can be selected using the mode parameter, which must be a string with the name of the boundary condition. The following boundary conditions are currently supported:
<table>
<thead>
<tr>
<th>mode</th>
<th>description</th>
<th>example</th>
</tr>
</thead>
<tbody>
<tr>
<td>“nearest”</td>
<td>use the value at the boundary</td>
<td>[1 2 3] -&gt; [1 2 3 3]</td>
</tr>
<tr>
<td>“wrap”</td>
<td>periodically replicate the array</td>
<td>[1 2 3] -&gt; [3 1 2 3 1]</td>
</tr>
<tr>
<td>“reflect”</td>
<td>reflect the array at the boundary</td>
<td>[1 2 3] -&gt; [1 2 3 3]</td>
</tr>
<tr>
<td>“mirror”</td>
<td>mirror the array at the boundary</td>
<td>[1 2 3] -&gt; [2 1 2 3 2]</td>
</tr>
<tr>
<td>“constant”</td>
<td>use a constant value, default is 0.0</td>
<td>[1 2 3] -&gt; [0 1 2 3 0]</td>
</tr>
</tbody>
</table>

The following synonyms are also supported for consistency with the interpolation routines:

<table>
<thead>
<tr>
<th>mode</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>“grid-constant”</td>
<td>equivalent to “constant”*</td>
</tr>
<tr>
<td>“grid-mirror”</td>
<td>equivalent to “reflect”</td>
</tr>
<tr>
<td>“grid-wrap”</td>
<td>equivalent to “wrap”</td>
</tr>
</tbody>
</table>

* “grid-constant” and “constant” are equivalent for filtering operations, but have different behavior in interpolation functions. For API consistency, the filtering functions accept either name.

The “constant” mode is special since it needs an additional parameter to specify the constant value that should be used.

Note that modes mirror and reflect differ only in whether the sample at the boundary is repeated upon reflection. For mode mirror, the point of symmetry is exactly at the final sample, so that value is not repeated. This mode is also known as whole-sample symmetric since the point of symmetry falls on the final sample. Similarly, reflect is often refered to as half-sample symmetric as the point of symmetry is half a sample beyond the array boundary.

Note: The easiest way to implement such boundary conditions would be to copy the data to a larger array and extend the data at the borders according to the boundary conditions. For large arrays and large filter kernels, this would be very memory consuming, and the functions described below, therefore, use a different approach that does not require allocating large temporary buffers.

**Correlation and convolution**

- The `correlate1d` function calculates a 1-D correlation along the given axis. The lines of the array along the given axis are correlated with the given `weights`. The `weights` parameter must be a 1-D sequence of numbers.
- The function `correlate` implements multidimensional correlation of the input array with a given kernel.
- The `convolve1d` function calculates a 1-D convolution along the given axis. The lines of the array along the given axis are convoluted with the given `weights`. The `weights` parameter must be a 1-D sequence of numbers.
- The function `convolve` implements multidimensional convolution of the input array with a given kernel.

Note: A convolution is essentially a correlation after mirroring the kernel. As a result, the `origin` parameter behaves differently than in the case of a correlation: the results is shifted in the opposite direction.
Smoothing filters

- The `gaussian_filter1d` function implements a 1-D Gaussian filter. The standard deviation of the Gaussian filter is passed through the parameter `sigma`. Setting `order = 0` corresponds to convolution with a Gaussian kernel. An order of 1, 2, or 3 corresponds to convolution with the first, second, or third derivatives of a Gaussian. Higher-order derivatives are not implemented.

- The `gaussian_filter` function implements a multidimensional Gaussian filter. The standard deviations of the Gaussian filter along each axis are passed through the parameter `sigma` as a sequence or numbers. If `sigma` is not a sequence but a single number, the standard deviation of the filter is equal along all directions. The order of the filter can be specified separately for each axis. An order of 0 corresponds to convolution with a Gaussian kernel. An order of 1, 2, or 3 corresponds to convolution with the first, second, or third derivatives of a Gaussian. Higher-order derivatives are not implemented. The `order` parameter must be a number, to specify the same order for all axes, or a sequence of numbers to specify a different order for each axis. The example below shows the filter applied on test data with different values of `sigma`. The `order` parameter is kept at 0.

Note: The multidimensional filter is implemented as a sequence of 1-D Gaussian filters. The intermediate arrays are stored in the same data type as the output. Therefore, for output types with a lower precision, the results may be imprecise because intermediate results may be stored with insufficient precision. This can be prevented by specifying a more precise output type.

- The `uniform_filter1d` function calculates a 1-D uniform filter of the given `size` along the given axis.

- The `uniform_filter` implements a multidimensional uniform filter. The sizes of the uniform filter are given for each axis as a sequence of integers by the `size` parameter. If `size` is not a sequence, but a single number, the sizes along all axes are assumed to be equal.

Note: The multidimensional filter is implemented as a sequence of 1-D uniform filters. The intermediate arrays are stored in the same data type as the output. Therefore, for output types with a lower precision, the results may
be imprecise because intermediate results may be stored with insufficient precision. This can be prevented by specifying a more precise output type.

Filters based on order statistics

• The \texttt{minimum_filter1d} function calculates a 1-D minimum filter of the given size along the given axis.

• The \texttt{maximum_filter1d} function calculates a 1-D maximum filter of the given size along the given axis.

• The \texttt{minimum_filter} function calculates a multidimensional minimum filter. Either the sizes of a rectangular kernel or the footprint of the kernel must be provided. The \texttt{size} parameter, if provided, must be a sequence of sizes or a single number, in which case the size of the filter is assumed to be equal along each axis. The \texttt{footprint}, if provided, must be an array that defines the shape of the kernel by its non-zero elements.

• The \texttt{maximum_filter} function calculates a multidimensional maximum filter. Either the sizes of a rectangular kernel or the footprint of the kernel must be provided. The \texttt{size} parameter, if provided, must be a sequence of sizes or a single number, in which case the size of the filter is assumed to be equal along each axis. The \texttt{footprint}, if provided, must be an array that defines the shape of the kernel by its non-zero elements.

• The \texttt{rank_filter} function calculates a multidimensional rank filter. The \texttt{rank} may be less than zero, i.e., \texttt{rank} = -1 indicates the largest element. Either the sizes of a rectangular kernel or the footprint of the kernel must be provided. The \texttt{size} parameter, if provided, must be a sequence of sizes or a single number, in which case the size of the filter is assumed to be equal along each axis. The \texttt{footprint}, if provided, must be an array that defines the shape of the kernel by its non-zero elements.

• The \texttt{percentile_filter} function calculates a multidimensional percentile filter. The \texttt{percentile} may be less than zero, i.e., \texttt{percentile} = -20 equals \texttt{percentile} = 80. Either the sizes of a rectangular kernel or the footprint of the kernel must be provided. The \texttt{size} parameter, if provided, must be a sequence of sizes or a single number, in which case the size of the filter is assumed to be equal along each axis. The \texttt{footprint}, if provided, must be an array that defines the shape of the kernel by its non-zero elements.

• The \texttt{median_filter} function calculates a multidimensional median filter. Either the sizes of a rectangular kernel or the footprint of the kernel must be provided. The \texttt{size} parameter, if provided, must be a sequence of sizes or a single number, in which case the size of the filter is assumed to be equal along each axis. The \texttt{footprint} if provided, must be an array that defines the shape of the kernel by its non-zero elements.

Derivatives

Derivative filters can be constructed in several ways. The function \texttt{gaussian_filter1d}, described in \textit{Smoothing filters}, can be used to calculate derivatives along a given axis using the \texttt{order} parameter. Other derivative filters are the Prewitt and Sobel filters:

• The \texttt{prewitt} function calculates a derivative along the given axis.

• The \texttt{sobel} function calculates a derivative along the given axis.

The Laplace filter is calculated by the sum of the second derivatives along all axes. Thus, different Laplace filters can be constructed using different second-derivative functions. Therefore, we provide a general function that takes a function argument to calculate the second derivative along a given direction.

• The function \texttt{generic_laplace} calculates a Laplace filter using the function passed through \texttt{derivative2} to calculate second derivatives. The function \texttt{derivative2} should have the following signature

\begin{verbatim}
derivative2(input, axis, output, mode, cval, *extra_arguments, **extra_keywords)
\end{verbatim}
It should calculate the second derivative along the dimension `axis`. If `output` is not `None`, it should use that for the output and return `None`, otherwise it should return the result. `mode`, `cval` have the usual meaning.

The `extra_arguments` and `extra_keywords` arguments can be used to pass a tuple of extra arguments and a dictionary of named arguments that are passed to `derivative2` at each call.

For example

```python
def d2(input, axis, output, mode, cval):
    ...    return correlate1d(input, [1, -2, 1], axis, output, mode, cval, 0)
...    a = np.zeros((5, 5))
    a[2, 2] = 1
    from scipy.ndimage import generic_laplace
    generic_laplace(a, d2)
array([[ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  1., -4.,  1.,  0.],
       [ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.]]
```

To demonstrate the use of the `extra_arguments` argument, we could do

```python
def d2(input, axis, output, mode, cval, weights):
    ...    return correlate1d(input, weights, axis, output, mode, cval, 0,)
...    a = np.zeros((5, 5))
    a[2, 2] = 1
    generic_laplace(a, d2, extra_arguments = ([1, -2, 1],))
array([[ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  1., -4.,  1.,  0.],
       [ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.]]
```

or

```python
generic_laplace(a, d2, extra_keywords = {'weights': [1, -2, 1]})
array([[ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  1., -4.,  1.,  0.],
       [ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.]]
```

The following two functions are implemented using `generic_laplace` by providing appropriate functions for the second-derivative function:

- The function `laplace` calculates the Laplace using discrete differentiation for the second derivative (i.e., convolution with `[1, -2, 1]`).
- The function `gaussian_laplace` calculates the Laplace filter using `gaussian_filter` to calculate the second derivatives. The standard deviations of the Gaussian filter along each axis are passed through the parameter `sigma` as a sequence or numbers. If `sigma` is not a sequence but a single number, the standard deviation of the filter is equal along all directions.

The gradient magnitude is defined as the square root of the sum of the squares of the gradients in all directions. Similar to the generic Laplace function, there is a `generic_gradient_magnitude` function that calculates the gradient.
magnitude of an array.

- The function `generic_gradient_magnitude` calculates a gradient magnitude using the function passed through `derivative` to calculate first derivatives. The function `derivative` should have the following signature

```python
derivative(input, axis, output, mode, cval, *extra_arguments, **extra_keywords)
```

It should calculate the derivative along the dimension `axis`. If `output` is not `None`, it should use that for the output and return `None`, otherwise it should return the result. `mode`, `cval` have the usual meaning.

The `extra_arguments` and `extra_keywords` arguments can be used to pass a tuple of extra arguments and a dictionary of named arguments that are passed to `derivative` at each call.

For example, the `sobel` function fits the required signature

```python
>>> a = np.zeros((5, 5))
>>> a[2, 2] = 1
>>> from scipy.ndimage import sobel, generic_gradient_magnitude
>>> generic_gradient_magnitude(a, sobel)
array([[ 0., 0., 0., 0., 0.],
       [0., 1.41421356, 2., 1.41421356, 0.],
       [0., 2., 0., 2., 0.],
       [0., 1.41421356, 2., 1.41421356, 0.],
       [0., 0., 0., 0., 0.]])
```

See the documentation of `generic_laplace` for examples of using the `extra_arguments` and `extra_keywords` arguments.

The `sobel` and `prewitt` functions fit the required signature and can, therefore, be used directly with `generic_gradient_magnitude`.

- The function `gaussian_gradient_magnitude` calculates the gradient magnitude using `gaussian_filter` to calculate the first derivatives. The standard deviations of the Gaussian filter along each axis are passed through the parameter `sigma` as a sequence or numbers. If `sigma` is not a sequence but a single number, the standard deviation of the filter is equal along all directions.

**Generic filter functions**

To implement filter functions, generic functions can be used that accept a callable object that implements the filtering operation. The iteration over the input and output arrays is handled by these generic functions, along with such details as the implementation of the boundary conditions. Only a callable object implementing a callback function that does the actual filtering work must be provided. The callback function can also be written in C and passed using a `PyCapsule` (see Extending scipy.ndimage in C for more information).

- The `generic_filter1d` function implements a generic 1-D filter function, where the actual filtering operation must be supplied as a python function (or other callable object). The `generic_filter1d` function iterates over the lines of an array and calls `function` at each line. The arguments that are passed to `function` are 1-D arrays of the `numpy.float64` type. The first contains the values of the current line. It is extended at the beginning and the end, according to the `filter_size` and `origin` arguments. The second array should be modified in-place to provide the output values of the line. For example, consider a correlation along one dimension:

```python
>>> a = np.arange(12).reshape(3,4)
>>> correlate1d(a, [1, 2, 3])
array([[ 3,  8, 14, 17],
       [13, 18, 24, 27],
       [23, 28, 34, 37]])
```
The same operation can be implemented using `generic_filter1d`, as follows:

```python
>>> def fnc(iline, oline):
...     oline[:] = iline[:-2] + 2 * iline[1:-1] + 3 * iline[2:]
... >>> from scipy.ndimage import generic_filter1d
>>> generic_filter1d(a, fnc, 3)
array([[ 3,  8, 14, 17],
       [27, 32, 38, 41],
       [51, 56, 62, 65]])
```

Here, the origin of the kernel was (by default) assumed to be in the middle of the filter of length 3. Therefore, each input line had been extended by one value at the beginning and at the end, before the function was called.

Optionally, extra arguments can be defined and passed to the filter function. The `extra_arguments` and `extra_keywords` arguments can be used to pass a tuple of extra arguments and/or a dictionary of named arguments that are passed to derivative at each call. For example, we can pass the parameters of our filter as an argument

```python
>>> def fnc(iline, oline, a, b):
...     oline[:] = iline[:-2] + a * iline[1:-1] + b * iline[2:]
... >>> generic_filter1d(a, fnc, 3, extra_arguments=(2, 3))
array([[ 3,  8, 14, 17],
       [27, 32, 38, 41],
       [51, 56, 62, 65]])
```

or

```python
>>> generic_filter1d(a, fnc, 3, extra_keywords={'a':2, 'b':3})
array([[ 3,  8, 14, 17],
       [27, 32, 38, 41],
       [51, 56, 62, 65]])
```

- The `generic_filter` function implements a generic filter function, where the actual filtering operation must be supplied as a python function (or other callable object). The `generic_filter` function iterates over the array and calls `function` at each element. The argument of `function` is a 1-D array of the `numpy.float64` type that contains the values around the current element that are within the footprint of the filter. The function should return a single value that can be converted to a double precision number. For example, consider a correlation:

```python
>>> a = np.arange(12).reshape(3,4)
>>> correlate(a, [[1, 0], [0, 3]])
array([[ 0,  3,  7, 11],
       [12, 15, 19, 23],
       [28, 31, 35, 39]])
```

The same operation can be implemented using `generic_filter`, as follows:

```python
>>> def fnc(buffer):
...     return (buffer * np.array([1, 3])).sum()
... ```
from scipy.ndimage import generic_filter

generic_filter(a, fnc, footprint=[[1, 0], [0, 1]])
array([[ 0,  3,  7, 11],
       [12, 15, 19, 23],
       [28, 31, 35, 39]])

Here, a kernel footprint was specified that contains only two elements. Therefore, the filter function receives a buffer of length equal to two, which was multiplied with the proper weights and the result summed.

When calling `generic_filter`, either the sizes of a rectangular kernel or the footprint of the kernel must be provided. The `size` parameter, if provided, must be a sequence of sizes or a single number, in which case the size of the filter is assumed to be equal along each axis. The `footprint`, if provided, must be an array that defines the shape of the kernel by its non-zero elements.

Optionally, extra arguments can be defined and passed to the filter function. The `extra_arguments` and `extra_keywords` arguments can be used to pass a tuple of extra arguments and/or a dictionary of named arguments that are passed to derivative at each call. For example, we can pass the parameters of our filter as an argument

```
>>> def fnc(buffer, weights):
...     weights = np.asarray(weights)
...     return (buffer * weights).sum()
... >>> generic_filter(a, fnc, footprint=[[1, 0], [0, 1]],
...     extra_arguments=(1, 3))
array([[ 0,  3,  7, 11],
       [12, 15, 19, 23],
       [28, 31, 35, 39]])
```

or

```
>>> generic_filter(a, fnc, footprint=[[1, 0], [0, 1]],
                     extra_keywords={'weights': [1, 3]})
array([[ 0,  3,  7, 11],
       [12, 15, 19, 23],
       [28, 31, 35, 39]])
```

These functions iterate over the lines or elements starting at the last axis, i.e., the last index changes the fastest. This order of iteration is guaranteed for the case that it is important to adapt the filter depending on spatial location. Here is an example of using a class that implements the filter and keeps track of the current coordinates while iterating. It performs the same filter operation as described above for `generic_filter`, but additionally prints the current coordinates:

```
>>> a = np.arange(12).reshape(3,4)
>>> class fnc_class:
...     def __init__(self, shape):
...         # store the shape:
...         self.shape = shape
...         # initialize the coordinates:
...         self.coordinates = [0] * len(shape)
...     def filter(self, buffer):
...         result = (buffer * np.array([1, 3])).sum()
...         print(self.coordinates)
...         # calculate the next coordinates:
...         # (continues on next page)
```
... axes = list(range(len(self.shape)))
... axes.reverse()
... for jj in axes:
...     if self.coordinates[jj] < self.shape[jj] - 1:
...         self.coordinates[jj] += 1
...     break
... else:
...     self.coordinates[jj] = 0
... return result
...
>>> fnc = fnc_class(shape = (3, 4))
>>> generic_filter(a, fnc.filter, footprint = [[1, 0], [0, 1]])

... array([[ 0, 3, 7, 11],
         [12, 15, 19, 23],
         [28, 31, 35, 39]])

For the `generic_filter1d` function, the same approach works, except that this function does not iterate over the axis that is being filtered. The example for `generic_filter1d` then becomes this:

```python
>>> a = np.arange(12).reshape(3, 4)
>>> class fnc1d_class:
...
...
...
>>> fnc1d_class(shape = (3, 4))
>>> generic_filter1d(a, fnc1d.filter, axis = -1)

... array([[ 0, 3, 7, 11],
         [12, 15, 19, 23],
         [28, 31, 35, 39]])
```
...     self.coordinates[jj] += 1
...     break
...     else:
...         self.coordinates[jj] = 0
...
>>> fnc = fncld_class(shape = (3,4))
>>> generic_filter1d(a, fnc.filter, 3)
array([[ 3,  8, 14, 17],
       [27, 32, 38, 41],
       [51, 56, 62, 65]])

Fourier domain filters

The functions described in this section perform filtering operations in the Fourier domain. Thus, the input array of such a function should be compatible with an inverse Fourier transform function, such as the functions from the numpy.fft module. We, therefore, have to deal with arrays that may be the result of a real or a complex Fourier transform. In the case of a real Fourier transform, only half of the of the symmetric complex transform is stored. Additionally, it needs to be known what the length of the axis was that was transformed by the real fft. The functions described here provide a parameter $n$ that, in the case of a real transform, must be equal to the length of the real transform axis before transformation. If this parameter is less than zero, it is assumed that the input array was the result of a complex Fourier transform. The parameter $axis$ can be used to indicate along which axis the real transform was executed.

- The fourier_shift function multiplies the input array with the multidimensional Fourier transform of a shift operation for the given shift. The shift parameter is a sequence of shifts for each dimension or a single value for all dimensions.

- The fourier_gaussian function multiplies the input array with the multidimensional Fourier transform of a Gaussian filter with given standard deviations sigma. The sigma parameter is a sequence of values for each dimension or a single value for all dimensions.

- The fourier_uniform function multiplies the input array with the multidimensional Fourier transform of a uniform filter with given sizes size. The size parameter is a sequence of values for each dimension or a single value for all dimensions.

- The fourier_ellipsoid function multiplies the input array with the multidimensional Fourier transform of an elliptically-shaped filter with given sizes size. The size parameter is a sequence of values for each dimension or a single value for all dimensions. This function is only implemented for dimensions 1, 2, and 3.

2.13.4 Interpolation functions

This section describes various interpolation functions that are based on B-spline theory. A good introduction to B-splines can be found in\(^1\) with detailed algorithms for image interpolation given in\(^5\).

Spline pre-filters

Interpolation using splines of an order larger than 1 requires a pre-filtering step. The interpolation functions described in section Interpolation functions apply pre-filtering by calling \texttt{spline_filter}, but they can be instructed not to do this by setting the \texttt{prefilter} keyword equal to False. This is useful if more than one interpolation operation is done on the same array. In this case, it is more efficient to do the pre-filtering only once and use a pre-filtered array as the input of the interpolation functions. The following two functions implement the pre-filtering:

- The \texttt{spline_filter1d} function calculates a 1-D spline filter along the given axis. An output array can optionally be provided. The order of the spline must be larger than 1 and less than 6.
- The \texttt{spline_filter} function calculates a multidimensional spline filter.

\textbf{Note:} The multidimensional filter is implemented as a sequence of 1-D spline filters. The intermediate arrays are stored in the same data type as the output. Therefore, if an output with a limited precision is requested, the results may be imprecise because intermediate results may be stored with insufficient precision. This can be prevented by specifying a output type of high precision.

Interpolation boundary handling

The interpolation functions all employ spline interpolation to effect some type of geometric transformation of the input array. This requires a mapping of the output coordinates to the input coordinates, and therefore, the possibility arises that input values outside the boundaries may be needed. This problem is solved in the same way as described in Filter functions for the multidimensional filter functions. Therefore, these functions all support a \texttt{mode} parameter that determines how the boundaries are handled, and a \texttt{cval} parameter that gives a constant value in case that the ‘constant’ mode is used. The behavior of all modes, including at non-integer locations is illustrated below. Note the boundaries are not handled the same for all modes: \texttt{reflect} (aka grid-mirror) and \texttt{grid-wrap} involve symmetry or repetition about a point that is half way between image samples (dashed vertical lines) while modes \texttt{mirror} and \texttt{wrap} treat the image as if it's extent ends exactly at the first and last sample point rather than 0.5 samples past it.

The coordinates of image samples fall on integer sampling locations in the range from 0 to $\text{shape}[i] - 1$ along each axis, $i$. The figure below illustrates the interpolation of a point at location $(3.7, 3.3)$ within an image of shape $(7, 7)$. For an interpolation of order $n$, $n + 1$ samples are involved along each axis. The filled circles illustrate the sampling locations involved in the interpolation of the value at the location of the red x.

Interpolation functions

- The \texttt{geometric_transform} function applies an arbitrary geometric transform to the input. The given \texttt{mapping} function is called at each point in the output to find the corresponding coordinates in the input. \texttt{mapping} must be a callable object that accepts a tuple of length equal to the output array rank and returns the corresponding input coordinates as a tuple of length equal to the input array rank. The output shape and output type can optionally be provided. If not given, they are equal to the input shape and type.

For example:

```python
>>> a = np.arange(12).reshape(4, 3).astype(np.float64)
>>> def shift_func(output_coordinates):
...     return (output_coordinates[0] - 0.5, output_coordinates[1] - 0.5)
...
>>> from scipy.ndimage import geometric_transform
>>> geometric_transform(a, shift_func)
array([[ 0. ,  0. ,  0. ],
       [ 0. ,  0. ,  0. ]],
```

Optionally, extra arguments can be defined and passed to the filter function. The `extra_arguments` and `extra_keywords` arguments can be used to pass a tuple of extra arguments and/or a dictionary of named arguments that are passed to derivative at each call. For example, we can pass the shifts in our example as arguments:

```python
>>> def shift_func(output_coordinates, s0, s1):
...     return (output_coordinates[0] - s0, output_coordinates[1] - s1)
...
```

```python
>>> geometric_transform(a, shift_func, extra_arguments = (0.5, 0.5))
array([[ 0. , 1.3625, 2.7375],
       [ 0. , 4.8125, 6.1875],
       [ 0. , 8.2625, 9.6375]])
```

or

```python
>>> geometric_transform(a, shift_func, extra_keywords = {'s0': 0.5, 's1': 0.5})
array([[ 0. , 1.3625, 2.7375],
       [ 0. , 4.8125, 6.1875],
       [ 0. , 8.2625, 9.6375]])
```

**Note:** The mapping function can also be written in C and passed using a `scipy.LowLevelCallable`. See [Extending scipy.ndimage in C](https://docs.scipy.org/doc/scipy/reference/extend.html) for more information.

- The function `map_coordinates` applies an arbitrary coordinate transformation using the given array of coordinates. The shape of the output is derived from that of the coordinate array by dropping the first axis. The parameter `coordinates` is used to find for each point in the output the corresponding coordinates in the input. The values of `coordinates` along the first axis are the coordinates in the input array at which the output value is found. (See also the numarray `coordinates` function.) Since the coordinates may be non-integer coordinates, the value of the input at these coordinates is determined by spline interpolation of the requested order.

Here is an example that interpolates a 2D array at (0.5, 0.5) and (1, 2):

```python
>>> a = np.arange(12).reshape(4, 3).astype(np.float64)
>>> a
array([[ 0.,  1.,  2.],
       [ 3.,  4.,  5.],
       [ 6.,  7.,  8.],
       [ 9., 10., 11.]])
```

```python
>>> from scipy.ndimage import map_coordinates
>>> map_coordinates(a, [[0.5, 2], [0.5, 1]])
array([ 1.3625,  7.])
```

- The `affine_transform` function applies an affine transformation to the input array. The given transformation `matrix` and `offset` are used to find for each point in the output the corresponding coordinates in the input. The value of the input at the calculated coordinates is determined by spline interpolation of the requested order. The transformation `matrix` must be 2-D or can also be given as a 1-D sequence or array. In the latter case, it is assumed
that the matrix is diagonal. A more efficient interpolation algorithm is then applied that exploits the separability of
the problem. The output shape and output type can optionally be provided. If not given, they are equal to the input
shape and type.

- The `shift` function returns a shifted version of the input, using spline interpolation of the requested `order`.
- The `zoom` function returns a rescaled version of the input, using spline interpolation of the requested `order`.
- The `rotate` function returns the input array rotated in the plane defined by the two axes given by the parameter `axes`, using spline interpolation of the requested `order`. The angle must be given in degrees. If `reshape` is true, then
  the size of the output array is adapted to contain the rotated input.

### 2.13.5 Morphology

#### Binary morphology

- The `generate_binary_structure` function generates a binary structuring element for use in binary mor-
  phology operations. The `rank` of the structure must be provided. The size of the structure that is returned is equal
to three in each direction. The value of each element is equal to one if the square of the Euclidean distance from the
element to the center is less than or equal to connectivity. For instance, 2-D 4-connected and 8-connected structures
  are generated as follows:

```python
>>> from scipy.ndimage import generate_binary_structure
>>> generate_binary_structure(2, 1)
array([[False,  True, False],
       [ True,  True,  True],
       [False,  True, False]], dtype=bool)
>>> generate_binary_structure(2, 2)
array([[ True,  True,  True],
       [ True,  True,  True],
       [ True,  True,  True]], dtype=bool)
```

Most binary morphology functions can be expressed in terms of the basic operations erosion and dilation.

- The `binary_erosion` function implements binary erosion of arrays of arbitrary rank with the given struct-
 uring element. The origin parameter controls the placement of the structuring element, as described in Filter
  functions. If no structuring element is provided, an element with connectivity equal to one is generated using
  `generate_binary_structure`. The `border_value` parameter gives the value of the array outside bound-
  aries. The erosion is repeated `iterations` times. If `iterations` is less than one, the erosion is repeated until the result
does not change anymore. If a `mask` array is given, only those elements with a true value at the corresponding mask
  element are modified at each iteration.

- The `binary_dilation` function implements binary dilation of arrays of arbitrary rank with the given struct-
 uring element. The origin parameter controls the placement of the structuring element, as described in Filter
  functions. If no structuring element is provided, an element with connectivity equal to one is generated using
  `generate_binary_structure`. The `border_value` parameter gives the value of the array outside bound-
  aries. The dilation is repeated `iterations` times. If `iterations` is less than one, the dilation is repeated until the result
does not change anymore. If a `mask` array is given, only those elements with a true value at the corresponding mask
  element are modified at each iteration.

Here is an example of using `binary_dilation` to find all elements that touch the border, by repeatedly dilating an
empty array from the border using the data array as the mask:

```python
>>> struct = np.array([[0, 1, 0], [1, 1, 1], [0, 1, 0]])
>>> a = np.array([[1,0,0,0,0], [1,1,0,1,0], [0,0,1,1,0], [0,0,0,0,0]])
```
The `binary_erosion` and `binary_dilation` functions both have an `iterations` parameter, which allows the erosion or dilation to be repeated a number of times. Repeating an erosion or a dilation with a given structure \( n \) times is equivalent to an erosion or a dilation with a structure that is \( n-1 \) times dilated with itself. A function is provided that allows the calculation of a structure that is dilated a number of times with itself:

- The `iterate_structure` function returns a structure by dilation of the input structure \( \text{iteration} - 1 \) times with itself.

For instance:

```python
>>> struct = generate_binary_structure(2, 1)
>>> struct
array([[False,  True, False],
       [ True,  True,  True],
       [False,  True, False]], dtype=bool)
>>> from scipy.ndimage import iterate_structure
>>> iterate_structure(struct, 2)
array([[False, False,  True, False, False],
       [False,  True,  True,  True, False],
       [ True,  True,  True,  True,  True],
       [False,  True,  True, False, False],
       [False, False,  True, False, False]], dtype=bool)
```

If the origin of the original structure is equal to 0, then it is also equal to 0 for the iterated structure. If not, the origin must also be adapted if the equivalent of the `*iterations` erosions or dilations must be achieved with the iterated structure. The adapted origin is simply obtained by multiplying with the number of iterations. For convenience, the :func:`iterate_structure` also returns the adapted origin if the `*origin` parameter is not `None`:

```python
>>> iterate_structure(struct, 2, -1)
(array([[False, False,  True, False, False],
        [False,  True,  True,  True, False],
        [ True,  True,  True,  True,  True],
        [False,  True,  True, False, False],
        [False, False,  True, False, False]], dtype=bool), [-2, -2])
```

Other morphology operations can be defined in terms of erosion and dilation. The following functions provide a few of
these operations for convenience:

- The `binary_opening` function implements binary opening of arrays of arbitrary rank with the given structuring element. Binary opening is equivalent to a binary erosion followed by a binary dilation with the same structuring element. The origin parameter controls the placement of the structuring element, as described in Filter functions. If no structuring element is provided, an element with connectivity equal to one is generated using `generate_binary_structure`. The iterations parameter gives the number of erosions that is performed followed by the same number of dilations.

- The `binary_closing` function implements binary closing of arrays of arbitrary rank with the given structuring element. Binary closing is equivalent to a binary dilation followed by a binary erosion with the same structuring element. The origin parameter controls the placement of the structuring element, as described in Filter functions. If no structuring element is provided, an element with connectivity equal to one is generated using `generate_binary_structure`. The iterations parameter gives the number of dilations that is performed followed by the same number of erosions.

- The `binary_fill_holes` function is used to close holes in objects in a binary image, where the structure defines the connectivity of the holes. The origin parameter controls the placement of the structuring element, as described in Filter functions. If no structuring element is provided, an element with connectivity equal to one is generated using `generate_binary_structure`.

- The `binary_hit_or_miss` function implements a binary hit-or-miss transform of arrays of arbitrary rank with the given structuring elements. The hit-or-miss transform is calculated by erosion of the input with the first structure, erosion of the logical not of the input with the second structure, followed by the logical and of these two erosions. The origin parameters control the placement of the structuring elements, as described in Filter functions. If `origin2` equals `None`, it is set equal to the `origin1` parameter. If the first structuring element is not provided, a structuring element with connectivity equal to one is generated using `generate_binary_structure`. If `structure2` is not provided, it is set equal to the logical not of `structure1`.

### Grey-scale morphology

Grey-scale morphology operations are the equivalents of binary morphology operations that operate on arrays with arbitrary values. Below, we describe the grey-scale equivalents of erosion, dilation, opening and closing. These operations are implemented in a similar fashion as the filters described in Filter functions, and we refer to this section for the description of filter kernels and footprints, and the handling of array borders. The grey-scale morphology operations optionally take a `structure` parameter that gives the values of the structuring element. If this parameter is not given, the structuring element is assumed to be flat with a value equal to zero. The shape of the structure can optionally be defined by the `footprint` parameter. If this parameter is not given, the structure is assumed to be rectangular, with sizes equal to the dimensions of the `structure` array, or by the `size` parameter if `structure` is not given. The `size` parameter is only used if both `structure` and `footprint` are not given, in which case the structuring element is assumed to be rectangular and flat with the dimensions given by `size`. The `size` parameter, if provided, must be a sequence of sizes or a single number in which case the size of the filter is assumed to be equal along each axis. The `footprint` parameter, if provided, must be an array that defines the shape of the kernel by its non-zero elements.

Similarly to binary erosion and dilation, there are operations for grey-scale erosion and dilation:

- The `grey_erosion` function calculates a multidimensional grey-scale erosion.
- The `grey_dilation` function calculates a multidimensional grey-scale dilation.

Grey-scale opening and closing operations can be defined similarly to their binary counterparts:

- The `grey_opening` function implements grey-scale opening of arrays of arbitrary rank. Grey-scale opening is equivalent to a grey-scale erosion followed by a grey-scale dilation.
- The `grey_closing` function implements grey-scale closing of arrays of arbitrary rank. Grey-scale opening is equivalent to a grey-scale dilation followed by a grey-scale erosion.
• The **morphological_gradient** function implements a grey-scale morphological gradient of arrays of arbitrary rank. The grey-scale morphological gradient is equal to the difference of a grey-scale dilation and a grey-scale erosion.

• The **morphological_laplace** function implements a grey-scale morphological laplace of arrays of arbitrary rank. The grey-scale morphological laplace is equal to the sum of a grey-scale dilation and a grey-scale erosion minus twice the input.

• The **white_tophat** function implements a white top-hat filter of arrays of arbitrary rank. The white top-hat is equal to the difference of the input and a grey-scale opening.

• The **black_tophat** function implements a black top-hat filter of arrays of arbitrary rank. The black top-hat is equal to the difference of a grey-scale closing and the input.

### 2.13.6 Distance transforms

Distance transforms are used to calculate the minimum distance from each element of an object to the background. The following functions implement distance transforms for three different distance metrics: Euclidean, city block, and chessboard distances.

• The function **distance_transform_cdt** uses a chamfer type algorithm to calculate the distance transform of the input, by replacing each object element (defined by values larger than zero) with the shortest distance to the background (all non-object elements). The structure determines the type of chamfering that is done. If the structure is equal to 'cityblock', a structure is generated using `generate_binary_structure` with a squared distance equal to 1. If the structure is equal to 'chessboard', a structure is generated using `generate_binary_structure` with a squared distance equal to the rank of the array. These choices correspond to the common interpretations of the city block and the chessboard distance metrics in two dimensions.

In addition to the distance transform, the feature transform can be calculated. In this case, the index of the closest background element is returned along the first axis of the result. The **return_distances**, and **return_indices** flags can be used to indicate if the distance transform, the feature transform, or both must be returned.

The **distances** and **indices** arguments can be used to give optional output arrays that must be of the correct size and type (both `numpy.int32`). The basics of the algorithm used to implement this function are described in².

• The function **distance_transform_edt** calculates the exact Euclidean distance transform of the input, by replacing each object element (defined by values larger than zero) with the shortest Euclidean distance to the background (all non-object elements).

In addition to the distance transform, the feature transform can be calculated. In this case, the index of the closest background element is returned along the first axis of the result. The **return_distances** and **return_indices** flags can be used to indicate if the distance transform, the feature transform, or both must be returned.

Optionally, the sampling along each axis can be given by the **sampling** parameter, which should be a sequence of length equal to the input rank, or a single number in which the sampling is assumed to be equal along all axes.

The **distances** and **indices** arguments can be used to give optional output arrays that must be of the correct size and type (`numpy.float64` and `numpy.int32`). The algorithm used to implement this function is described in³.

• The function **distance_transform_bf** uses a brute-force algorithm to calculate the distance transform of the input, by replacing each object element (defined by values larger than zero) with the shortest distance to the background (all non-object elements). The metric must be one of “euclidean”, “cityblock”, or “chessboard”.

In addition to the distance transform, the feature transform can be calculated. In this case, the index of the closest background element is returned along the first axis of the result. The **return_distances** and **return_indices** flags can be used to indicate if the distance transform, the feature transform, or both must be returned.

---

Optional, the sampling along each axis can be given by the `sampling` parameter, which should be a sequence of length equal to the input rank, or a single number in which the sampling is assumed to be equal along all axes. This parameter is only used in the case of the Euclidean distance transform.

The `distances` and `indices` arguments can be used to give optional output arrays that must be of the correct size and type (`numpy.float64` and `numpy.int32`).

---

**Note:** This function uses a slow brute-force algorithm, the function `distance_transform_cdt` can be used to more efficiently calculate city block and chessboard distance transforms. The function `distance_transform_edt` can be used to more efficiently calculate the exact Euclidean distance transform.

---

### 2.13.7 Segmentation and labeling

Segmentation is the process of separating objects of interest from the background. The most simple approach is, probably, intensity thresholding, which is easily done with `numpy` functions:

```python
>>> a = np.array([[1, 2, 2, 1, 1, 0],
                 ...               [0, 2, 3, 1, 2, 0],
                 ...               [1, 1, 1, 3, 3, 2],
                 ...               [1, 1, 1, 1, 2, 1]])
>>> np.where(a > 1, 1, 0)
array([[0, 1, 1, 0, 0, 0],
       [0, 1, 1, 0, 1, 0],
       [0, 0, 0, 1, 1, 1],
       [0, 0, 0, 0, 1, 0]])
```

The result is a binary image, in which the individual objects still need to be identified and labeled. The function `label` generates an array where each object is assigned a unique number:

- The `label` function generates an array where the objects in the input are labeled with an integer index. It returns a tuple consisting of the array of object labels and the number of objects found, unless the `output` parameter is given, in which case only the number of objects is returned. The connectivity of the objects is defined by a structuring element. For instance, in 2D using a 4-connected structuring element gives:

```python
>>> a = np.array([[0, 1, 1, 0, 0, 0], [0, 1, 1, 1, 1, 0], [0, 0, 0, 1, 1, 1], [0, 0, 0, 0, 1, -0]])
>>> s = [[0, 1, 0], [1, 1, 1], [0, 1, 0]]
>>> from scipy.ndimage import label
>>> label(a, s)
(array([[0, 1, 1, 0, 0, 0],
       [0, 1, 1, 0, 2, 0],
       [0, 0, 0, 2, 2, 2],
       [0, 0, 0, 0, 2, 0]]), 2)
```

These two objects are not connected because there is no way in which we can place the structuring element, such that it overlaps with both objects. However, an 8-connected structuring element results in only a single object:

```python
>>> a = np.array([[0, 1, 1, 0, 0, 0], [0, 1, 1, 0, 1, 0], [0, 0, 0, 1, 1, 1], [0, 0, 0, 0, 1, -0]])
>>> s = [[1, 1, 1], [1, 1, 1], [1, 1, 1]]
>>> label(a, s)[0]
array([[0, 1, 1, 0, 0, 0],
       [0, 1, 1, 0, 1, 0],
       [0, 0, 0, 1, 1, 1],
       [0, 0, 0, 0, 1, 0]],
       dtype=int32)
```

(continues on next page)
If no structuring element is provided, one is generated by calling `generate_binary_structure` (see Binary morphology) using a connectivity of one (which in 2D is the 4-connected structure of the first example). The input can be of any type, any value not equal to zero is taken to be part of an object. This is useful if you need to 're-label' an array of object indices, for instance, after removing unwanted objects. Just apply the label function again to the index array. For instance:

```python
>>> l, n = label([[1, 0, 1, 0]],
               [0, 1, 1, 0],
               [0, 0, 0, 1, 1],
               [0, 0, 0, 0, 1])
```

Note: The structuring element used by `label` is assumed to be symmetric.

There is a large number of other approaches for segmentation, for instance, from an estimation of the borders of the objects that can be obtained by derivative filters. One such approach is watershed segmentation. The function `watershed_ift` generates an array where each object is assigned a unique label, from an array that localizes the object borders, generated, for instance, by a gradient magnitude filter. It uses an array containing initial markers for the objects:

- The `watershed_ift` function applies a watershed from markers algorithm, using Image Foresting Transform, as described in

- The inputs of this function are the array to which the transform is applied, and an array of markers that designate the objects by a unique label, where any non-zero value is a marker. For instance:

```python
>>> input = np.array([[0, 0, 0, 0, 0, 0],
                    [0, 1, 1, 1, 1, 0],
                    [0, 1, 0, 0, 0, 1],
                    [0, 1, 0, 0, 0, 1],
                    [0, 1, 1, 1, 1, 0],
                    [0, 0, 0, 0, 0, 0]], np.uint8)
>>> markers = np.array([[1, 0, 0, 0, 0, 0],
                      [0, 0, 0, 0, 0, 0],
                      [0, 0, 0, 2, 0, 0],
                      [0, 0, 0, 0, 0, 0],
                      [0, 0, 0, 0, 0, 0],
                      [0, 0, 0, 0, 0, 0]], np.int8)
>>> from scipy.ndimage import watershed_ift
>>> watershed_ift(input, markers)
```

---

Here, two markers were used to designate an object (marker = 2) and the background (marker = 1). The order in which these are processed is arbitrary: moving the marker for the background to the lower-right corner of the array yields a different result:

```python
>>> markers = np.array([[0, 0, 0, 0, 0, 0],
                       [0, 0, 0, 0, 0, 0],
                       [0, 0, 0, 2, 0, 0],
                       [0, 0, 0, 0, 0, 0],
                       [0, 0, 0, 0, 0, 0],
                       [0, 0, 0, 0, 0, 0]], np.int8)
>>> watershed_ift(input, markers)
array([[1, 1, 1, 1, 1, 1, 1],
       [1, 1, 1, 1, 1, 1, 1],
       [1, 2, 2, 2, 2, 1, 1],
       [1, 1, 2, 2, 2, 1, 1],
       [1, 1, 1, 1, 1, 1, 1],
       [1, 1, 1, 1, 1, 1, 1]], dtype=int8)
```

The result is that the object (marker = 2) is smaller because the second marker was processed earlier. This may not be the desired effect if the first marker was supposed to designate a background object. Therefore, `watershed_ift` treats markers with a negative value explicitly as background markers and processes them after the normal markers. For instance, replacing the first marker by a negative marker gives a result similar to the first example:

```python
>>> markers = np.array([[0, 0, 0, 0, 0, 0],
                       [0, 0, 0, 0, 0, 0],
                       [0, 0, 0, 0, 0, 0],
                       [0, 0, 0, 0, 0, 0],
                       [0, 0, 0, 0, 0, 0],
                       [0, 0, 0, 0, 0, 0]], np.int8)
>>> watershed_ift(input, markers)
array([[1, 1, 1, 1, 1, 1, 1],
       [1, 1, 1, 1, 1, 1, 1],
       [1, 2, 2, 2, 2, 1, 1],
       [1, 1, 2, 2, 2, 1, 1],
       [1, 1, 1, 1, 1, 1, 1],
       [1, 1, 1, 1, 1, 1, 1]], dtype=int8)
```

The connectivity of the objects is defined by a structuring element. If no structuring element is provided, one is generated by calling `generate_binary_structure` (see Binary morphology) using a connectivity of one (which in 2D is a 4-connected structure.) For example, using an 8-connected structure with the last example yields a different object:

```python
>>> markers = np.array([[0, 0, 0, 0, 0, 0],
                       [0, 0, 0, 0, 0, 0],
                       [0, 0, 0, 0, 0, 0],
                       [0, 0, 0, 0, 0, 0],
                       [0, 0, 0, 0, 0, 0],
                       [0, 0, 0, 0, 0, 0]], np.int8)
>>> watershed_ift(input, markers)
array([[-1, -1, -1, -1, -1, -1],
       [-1, 2, 2, 2, -1, -1],
       [-1, 2, 2, 2, 2, -1],
       [-1, 2, 2, 2, 2, -1],
       [-1, 2, 2, 2, 2, -1],
       [-1, -1, 2, 2, -1, -1]], dtype=int8)
```
```python
>>> watershed_ift(input, markers,
...                     structure = [[1,1,1], [1,1,1], [1,1,1]])
array([[-1, -1, -1, -1, -1, -1, -1],
       [-1, 2, 2, 2, 2, 2, -1],
       [-1, 2, 2, 2, 2, 2, -1],
       [-1, 2, 2, 2, 2, 2, -1],
       [-1, 2, 2, 2, 2, 2, -1],
       [-1, -1, -1, -1, -1, -1, -1]], dtype=int8)
```

**Note:** The implementation of `watershed_ift` limits the data types of the input to `numpy.uint8` and `numpy.uint16`.

### 2.13.8 Object measurements

Given an array of labeled objects, the properties of the individual objects can be measured. The `find_objects` function can be used to generate a list of slices that for each object, give the smallest sub-array that fully contains the object:

- The `find_objects` function finds all objects in a labeled array and returns a list of slices that correspond to the smallest regions in the array that contains the object.

For instance:

```python
>>> a = np.array([[0, 1, 0, 0, 0, 0], [0, 1, 0, 1, 0, 0], [0, 0, 0, 1, 1, 1], [0, 0, 0, 0, 0, 1], [0]])
>>> l, n = label(a)
>>> from scipy.ndimage import find_objects
>>> f = find_objects(l)
>>> a[f[0]]
array([[1, 1],
       [1, 1]])
>>> a[f[1]]
array([[0, 1, 0],
       [1, 1, 1],
       [0, 1, 0]])
```

The function `find_objects` returns slices for all objects, unless the `max_label` parameter is larger then zero, in which case only the first `max_label` objects are returned. If an index is missing in the `label` array, `None` is return instead of a slice. For example:

```python
>>> from scipy.ndimage import find_objects
>>> find_objects([[1, 0, 3, 4], max_label = 3)
[(slice(0, 1, None),), None, (slice(2, 3, None),)]
```

The list of slices generated by `find_objects` is useful to find the position and dimensions of the objects in the array, but can also be used to perform measurements on the individual objects. Say, we want to find the sum of the intensities of an object in image:

```python
>>> image = np.arange(4 * 6).reshape(4, 6)
>>> mask = np.array([[0,1,1,0,0,0],[0,1,1,0,0,0],[0,0,0,1,1,1],[0,0,0,0,1,0]])
```
Then we can calculate the sum of the elements in the second object:

```python
>>> np.where(labels[slices[1]] == 2, image[slices[1]], 0).sum()
80
```

That is, however, not particularly efficient and may also be more complicated for other types of measurements. Therefore, a few measurements functions are defined that accept the array of object labels and the index of the object to be measured. For instance, calculating the sum of the intensities can be done by:

```python
>>> from scipy.ndimage import sum as ndi_sum
>>> ndi_sum(image, labels, 2)
80
```

For large arrays and small objects, it is more efficient to call the measurement functions after slicing the array:

```python
>>> ndi_sum(image[slices[1]], labels[slices[1]], 2)
80
```

Alternatively, we can do the measurements for a number of labels with a single function call, returning a list of results. For instance, to measure the sum of the values of the background and the second object in our example, we give a list of labels:

```python
>>> ndi_sum(image, labels, [0, 2])
array([178.0, 80.0])
```

The measurement functions described below all support the `index` parameter to indicate which object(s) should be measured. The default value of `index` is `None`. This indicates that all elements where the label is larger than zero should be treated as a single object and measured. Thus, in this case the `labels` array is treated as a mask defined by the elements that are larger than zero. If `index` is a number or a sequence of numbers it gives the labels of the objects that are measured. If `index` is a sequence, a list of the results is returned. Functions that return more than one result return their result as a tuple if `index` is a single number, or as a tuple of lists if `index` is a sequence.

- The `sum` function calculates the sum of the elements of the object with label(s) given by `index`, using the `labels` array for the object labels. If `index` is `None`, all elements with a non-zero label value are treated as a single object. If `label` is `None`, all elements of `input` are used in the calculation.

- The `mean` function calculates the mean of the elements of the object with label(s) given by `index`, using the `labels` array for the object labels. If `index` is `None`, all elements with a non-zero label value are treated as a single object. If `label` is `None`, all elements of `input` are used in the calculation.

- The `variance` function calculates the variance of the elements of the object with label(s) given by `index`, using the `labels` array for the object labels. If `index` is `None`, all elements with a non-zero label value are treated as a single object. If `label` is `None`, all elements of `input` are used in the calculation.

- The `standard_deviation` function calculates the standard deviation of the elements of the object with label(s) given by `index`, using the `labels` array for the object labels. If `index` is `None`, all elements with a non-zero label value are treated as a single object. If `label` is `None`, all elements of `input` are used in the calculation.

- The `minimum` function calculates the minimum of the elements of the object with label(s) given by `index`, using the `labels` array for the object labels. If `index` is `None`, all elements with a non-zero label value are treated as a single object. If `label` is `None`, all elements of `input` are used in the calculation.
• The maximum function calculates the maximum of the elements of the object with label(s) given by index, using the labels array for the object labels. If index is None, all elements with a non-zero label value are treated as a single object. If label is None, all elements of input are used in the calculation.

• The minimum_position function calculates the position of the minimum of the elements of the object with label(s) given by index, using the labels array for the object labels. If index is None, all elements with a non-zero label value are treated as a single object. If label is None, all elements of input are used in the calculation.

• The maximum_position function calculates the position of the maximum of the elements of the object with label(s) given by index, using the labels array for the object labels. If index is None, all elements with a non-zero label value are treated as a single object. If label is None, all elements of input are used in the calculation.

• The extrema function calculates the minimum, the maximum, and their positions, of the elements of the object with label(s) given by index, using the labels array for the object labels. If index is None, all elements of input are used in the calculation. The result is a tuple formed by the results of the functions minimum, maximum, minimum_position, and maximum_position that are described above.

• The center_of_mass function calculates the center of mass of the object with label(s) given by index, using the labels array for the object labels. If index is None, all elements with a non-zero label value are treated as a single object. If label is None, all elements of input are used in the calculation.

• The histogram function calculates a histogram of the object with label(s) given by index, using the labels array for the object labels. If index is None, all elements with a non-zero label value are treated as a single object. If label is None, all elements of input are used in the calculation. Histograms are defined by their minimum (min), maximum (max), and the number of bins (bins). They are returned as 1-D arrays of type numpy.int32.

2.13.9 Extending scipy.ndimage in C

A few functions in scipy.ndimage take a callback argument. This can be either a python function or a scipy.LowLevelCallable containing a pointer to a C function. Using a C function will generally be more efficient, since it avoids the overhead of calling a python function on many elements of an array. To use a C function, you must write a C extension that contains the callback function and a Python function that returns a scipy.LowLevelCallable containing a pointer to the callback.

An example of a function that supports callbacks is geometric_transform, which accepts a callback function that defines a mapping from all output coordinates to corresponding coordinates in the input array. Consider the following python example, which uses geometric_transform to implement a shift function.

```python
from scipy import ndimage

def transform(output_coordinates, shift):
    input_coordinates = output_coordinates[0] - shift, output_coordinates[1] - shift
    return input_coordinates

im = np.arange(12).reshape(4, 3).astype(np.float64)
shift = 0.5
print(ndimage.geometric_transform(im, transform, extra_arguments=(shift,)))
```

We can also implement the callback function with the following C code:

```c
#include <Python.h>

/* example.c */
```

(continues on next page)
```c
#include <numpy/npy_common.h>

static int _transform(npy_intp *output_coordinates, double *input_coordinates,
   int output_rank, int input_rank, void *user_data)
{
    npy_intp i;
    double shift = *(double *)user_data;

    for (i = 0; i < input_rank; i++) {
        input_coordinates[i] = output_coordinates[i] - shift;
    }
    return 1;
}

static char *transform_signature = "int (npy_intp *, double *, int, int, void *)";

static PyObject *py_get_transform(PyObject *obj, PyObject *args)
{
    if (!PyArg_ParseTuple(args, "")) return NULL;
    return PyCapsule_New(_transform, transform_signature, NULL);
}

static PyMethodDef ExampleMethods[] = {
    {"get_transform", (PyCFunction)py_get_transform, METH_VARARGS, ""},
    {NULL, NULL, 0, NULL}
};

/* Initialize the module */
static struct PyModuleDef example = {
    PyModuleDef_HEAD_INIT,
    "example",
    NULL,
    -1,
    ExampleMethods,
    NULL,
    NULL,
    NULL,
    NULL
};

PyMODINIT_FUNC
PyInit_example(void)
{
    return PyModule_Create(&example);
}
```

More information on writing Python extension modules can be found [here](#). If the C code is in the file `example.c`, then it can be compiled with the following `setup.py`,

from distutils.core import setup, Extension
import numpy

shift = Extension('example',
                   ['example.c'],
                   include_dirs=[numpy.get_include()]
                 )

setup(name='example',
       ext_modules=[shift]
)

and now running the script

import ctypes
import numpy as np
from scipy import ndimage, LowLevelCallable

from example import get_transform

shift = 0.5

user_data = ctypes.c_double(shift)
ptr = ctypes.cast(ctypes.pointer(user_data), ctypes.c_void_p)
callback = LowLevelCallable(get_transform(), ptr)
im = np.arange(12).reshape(4, 3).astype(np.float64)
print(ndimage.geometric_transform(im, callback))

produces the same result as the original python script.

In the C version, _transform is the callback function and the parameters output_coordinates and input_coordinates play the same role as they do in the python version, while output_rank and input_rank provide the equivalents of len(output_coordinates) and len(input_coordinates). The variable shift is passed through user_data instead of extra_arguments. Finally, the C callback function returns an integer status, which is one upon success and zero otherwise.

The function py_transform wraps the callback function in a PyCapsule. The main steps are:

- Initialize a PyCapsule. The first argument is a pointer to the callback function.
- The second argument is the function signature, which must match exactly the one expected by ndimage.
- Above, we used scipy.LowLevelCallable to specify user_data that we generated with ctypes.

A different approach would be to supply the data in the capsule context, that can be set by PyCapsule_SetContext and omit specifying user_data in scipy.LowLevelCallable. However, in this approach we would need to deal with allocation/freeing of the data — freeing the data after the capsule has been destroyed can be done by specifying a non-NULL callback function in the third argument of PyCapsule_New.

C callback functions for ndimage all follow this scheme. The next section lists the ndimage functions that accept a C callback function and gives the prototype of the function.

See also:

The functions that support low-level callback arguments are:

generic_filter, generic_filter1d, geometric_transform

2.13. Multidimensional image processing (scipy.ndimage)  285
Below, we show alternative ways to write the code, using Numba, Cython, ctypes, or cffi instead of writing wrapper code in C.

### Numba

Numba provides a way to write low-level functions easily in Python. We can write the above using Numba as:

```python
# example.py
import numpy as np
import ctypes
from scipy import ndimage, LowLevelCallable
from numba import cfunc, types, carray

@cfunc(types.intc(types.CPointer(types.intp),
           types.CPointer(types.double),
           types.intc,
           types.intc,
           types.voidptr))
def transform(output_coordinates_ptr, input_coordinates_ptr, output_rank, input_rank, user_data):
    input_coordinates = carray(input_coordinates_ptr, (input_rank,))
    output_coordinates = carray(output_coordinates_ptr, (output_rank,))
    shift = carray(user_data, (1,), types.double)[0]

    for i in range(input_rank):
        input_coordinates[i] = output_coordinates[i] - shift

    return 1

shift = 0.5

# Then call the function
user_data = ctypes.c_double(shift)
ptr = ctypes.cast(ctypes.pointer(user_data), ctypes.c_void_p)
callback = LowLevelCallable(transform.ctypes, ptr)

im = np.arange(12).reshape(4, 3).astype(np.float64)
print(ndimage.geometric_transform(im, callback))
```

### Cython

Functionally the same code as above can be written in Cython with somewhat less boilerplate as follows:

```cython
# example.pyx

from numpy cimport npy_intp as intp
cdef api int transform(intp *output_coordinates, double *input_coordinates, int output_rank, int input_rank, void *user_data):
    cdef intp i
    cdef double shift = (<double *>user_data)[0]
```

(continues on next page)
```python
for i in range(input_rank):
    input_coordinates[i] = output_coordinates[i] - shift
return 1
```

### cffi

With cffi, you can interface with a C function residing in a shared library (DLL). First, we need to write the shared library, which we do in C — this example is for Linux/OSX:

```c
/*
   example.c
   Needs to be compiled with "gcc -std=c99 -shared -fPIC -o example.so example.c"
   or similar
*/
#include <stdint.h>

int _transform(intptr_t *output_coordinates, double *input_coordinates,
               int output_rank, int input_rank, void *user_data)
{
    int i;
    double shift = *(double *)user_data;

    for (i = 0; i < input_rank; i++) {
        input_coordinates[i] = output_coordinates[i] - shift;
    }
    return 1;
}
```

The Python code calling the library is:

```python
import os
import numpy as np
```

(continues on next page)
from scipy import ndimage, LowLevelCallable
import cffi

# Construct the FFI object, and copypaste the function declaration
ffi = cffi.FFI()
ffi.cdef(""
int _transform(intptr_t *output_coordinates, double *input_coordinates,
    int output_rank, int input_rank, void *user_data);
"")

# Open library
lib = ffi.dlopen(os.path.abspath("example.so"))

# Do the function call
user_data = ffi.new("double *", 0.5)
callback = LowLevelCallable(lib._transform, user_data)
im = np.arange(12).reshape(4, 3).astype(np.float64)
print(ndimage.geometric_transform(im, callback))

You can find more information in the cffi documentation.

c types

With c types, the C code and the compilation of the so/DLL is as for cffi above. The Python code is different:

# script.py
import os
import cffi
import numpy as np
from scipy import ndimage, LowLevelCallable

lib = cffi.CDLL(os.path.abspath('example.so'))

shift = 0.5

user_data = cffi.c_double(shift)
ptr = cffi.cast(cffi.pointer(user_data), cffi.c_void_p)

# Ctypes has no built-in intptr type, so override the signature
# instead of trying to get it via ctypes
callback = LowLevelCallable(lib._transform, ptr,
    "int _transform(intptr_t *, double *, int, int, void *)")

# Perform the call
im = np.arange(12).reshape(4, 3).astype(np.float64)
print(ndimage.geometric_transform(im, callback))

You can find more information in the ctypes documentation.

NumPy IO routines

2.14.1 MATLAB files

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>loadmat</code></td>
<td>Load MATLAB file.</td>
</tr>
<tr>
<td><code>savemat</code></td>
<td>Save a dictionary of names and arrays into a MATLAB-style .mat file.</td>
</tr>
<tr>
<td><code>whosmat</code></td>
<td>List variables inside a MATLAB file.</td>
</tr>
</tbody>
</table>

The basic functions

We'll start by importing `scipy.io` and calling it `sio` for convenience:

```python
>>> import scipy.io as sio
```

If you are using IPython, try tab-completing on `sio`. Among the many options, you will find:

```python
sio.loadmat
sio.savemat
sio.whosmat
```

These are the high-level functions you will most likely use when working with MATLAB files. You'll also find:

```python
sio.matlab
```

This is the package from which `loadmat`, `savemat`, and `whosmat` are imported. Within `sio.matlab`, you will find the `mio` module. This module contains the machinery that `loadmat` and `savemat` use. From time to time you may find yourself re-using this machinery.

How do I start?

You may have a .mat file that you want to read into SciPy. Or, you want to pass some variables from SciPy / NumPy into MATLAB.

To save us using a MATLAB license, let's start in Octave. Octave has MATLAB-compatible save and load functions. Start Octave ( octave at the command line for me):

```octave
octave:1> a = 1:12
a =
   1   2   3   4   5   6   7   8   9  10  11  12
octave:2> a = reshape(a, [1 3 4])
a =
```

(continues on next page)
ans(:,:1) =
   1  2  3
ans(:,:2) =
   4  5  6
ans(:,:3) =
   7  8  9
ans(:,:4) =
  10 11 12

octave:3> save -6 octave_a.mat a $ MATLAB 6 compatible
octave:4> ls octave_a.mat
octave_a.mat

Now, to Python:

```python
>>> mat_contents = sio.loadmat('octave_a.mat')
```

```plaintext
mat_contents
{'a': array([[[ 1.,  4.,  7., 10.],
              [ 2.,  5.,  8., 11.],
              [ 3.,  6.,  9., 12.]]]),
   '__version__': '1.0',
   '__header__': 'MATLAB 5.0 MAT-file, written by
Octave 3.6.3, 2013-02-17 21:02:11 UTC',
   '__globals__': []}
```

```python
>>> oct_a = mat_contents['a']
```

```python
>>> oct_a
array([[[ 1.,  4.,  7., 10.],
         [ 2.,  5.,  8., 11.],
         [ 3.,  6.,  9., 12.]]])
```

```python
>>> oct_a.shape
(1, 3, 4)
```

Now let’s try the other way round:

```python
>>> import numpy as np
```

```python
>>> vect = np.arange(10)
```

```python
>>> vect.shape
(10,)
```

```python
>>> sio.savemat('np_vector.mat', {'vect':vect})
```

Then back to Octave:

```octave
octave:8> load np_vector.mat
octave:9> vect
vect =
```

(continues on next page)
If you want to inspect the contents of a MATLAB file without reading the data into memory, use the `whosmat` command:

```matlab
>> sio.whosmat('octave_a.mat')
[('a', (1, 3, 4), 'double')]
```

`whosmat` returns a list of tuples, one for each array (or other object) in the file. Each tuple contains the name, shape and data type of the array.

**MATLAB structs**

MATLAB structs are a little bit like Python dicts, except the field names must be strings. Any MATLAB object can be a value of a field. As for all objects in MATLAB, structs are, in fact, arrays of structs, where a single struct is an array of shape (1, 1).

```matlab
>> my_struct = struct('field1', 1, 'field2', 2)
my_struct =
    { [1x1 struct] }
>> save -6 octave_struct.mat my_struct
```

We can load this in Python:

```python
>>> mat_contents = sio.loadmat('octave_struct.mat')
```

```python
>>> mat_contents
{'my_struct': array([[([1.0], [2.0])]
    dtype=[('field1', 'O'), ('field2', 'O')]), '__version__': '1.0', '__header__': 'MATLAB 5.0 MAT-file, written by Octave 3.6.3, 2013-02-17 21:23:14 UTC', '__globals__': []}
```

```python
>>> oct_struct = mat_contents['my_struct']
>>> oct_struct.shape
(1, 1)
>>> val = oct_struct[0,0]
```

```python
>>> val
array([([1.0], [2.0])])
```

```python
>>> val['field1']
array([[ 1.]])
```

```python
>>> val['field2']
array([[ 2.]])
```

```python
>>> val.dtype
dtype([('field1', 'O'), ('field2', 'O')))
```
In the SciPy versions from 0.12.0, MATLAB structs come back as NumPy structured arrays, with fields named for the struct fields. You can see the field names in the dtype output above. Note also:

```python
>>> val = oct_struct[0,0]
```

and:

```octave
octave:13> size(my_struct)
ans =
    1   1
```

So, in MATLAB, the struct array must be at least 2-D, and we replicate that when we read into SciPy. If you want all length 1 dimensions squeezed out, try this:

```python
>>> mat_contents = sio.loadmat('octave_struct.mat', squeeze_me=True)
>>> oct_struct = mat_contents['my_struct']
>>> oct_struct.shape
()
```

Sometimes, it’s more convenient to load the MATLAB structs as Python objects rather than NumPy structured arrays - it can make the access syntax in Python a bit more similar to that in MATLAB. In order to do this, use the struct_as_record=False parameter setting to loadmat.

```python
>>> mat_contents = sio.loadmat('octave_struct.mat', struct_as_record=False)
>>> oct_struct = mat_contents['my_struct']
>>> oct_struct[0,0].field1
array([[ 1.]])
```

```python
struct_as_record=False works nicely with squeeze_me:
```

```python
>>> mat_contents = sio.loadmat('octave_struct.mat', struct_as_record=False,...
          squeeze_me=True)
>>> oct_struct = mat_contents['my_struct']
>>> oct_struct.shape # but no - it's a scalar
Traceback (most recent call last):
  File "<stdin>"", line 1, in <module>
AttributeError: 'mat_struct' object has no attribute 'shape'
>>> type(oct_struct)
<class 'scipy.io.matlab.mio5_params.mat_struct'>
>>> oct_struct.field1
1.0
```

Saving struct arrays can be done in various ways. One simple method is to use dict:

```python
>>> a_dict = {'field1': 0.5, 'field2': 'a string'}
>>> sio.savemat('saved_struct.mat', {'a_dict': a_dict})
```

loaded as:

```octave
octave:21> load saved_struct
octave:22> a_dict
a_dict =
    scalar structure containing the fields:
```

(continues on next page)
field2 = a string
field1 = 0.50000

You can also save structs back again to MATLAB (or Octave in our case) like this:

```python
>> dt = [('f1', 'f8'), ('f2', 'S10')]
>> arr = np.zeros((2,), dtype=dt)
>> arr
array([(0.0, ''), (0.0, '')],
      dtype=[('f1', '<f8'), ('f2', 'S10')])
>> arr[0]['f1'] = 0.5
>> arr[0]['f2'] = 'python'
>> arr[1]['f1'] = 99
>> arr[1]['f2'] = 'not perl'
>> sio.savemat('np_struct_arr.mat', {'arr': arr})
```

MATLAB cell arrays

Cell arrays in MATLAB are rather like Python lists, in the sense that the elements in the arrays can contain any type of MATLAB object. In fact, they are most similar to NumPy object arrays, and that is how we load them into NumPy.

```octave
octave:14> my_cells = {1, [2, 3]}
my_cells =
  [1,1] = 1
  [1,2] =
    2 3

octave:15> save -6 octave_cells.mat my_cells
```

Back to Python:

```python
>>> mat_contents = sio.loadmat('octave_cells.mat')
>>> oct_cells = mat_contents['my_cells']
>>> print(oct_cells.dtype)
object
>>> val = oct_cells[0,0]
>>> val
array([[ 1.0]])
>>> print(val.dtype)
float64
```

Saving to a MATLAB cell array just involves making a NumPy object array:

```python
>>> obj_arr = np.zeros((2,), dtype=np.object)
>>> obj_arr[0] = 1
>>> obj_arr[1] = 'a string'
```
>>> obj_arr
array([[1, 'a string'], dtype=object])
>>> sio.savemat('np_cells.mat', {'obj_arr':obj_arr})

octave:16> load np_cells.mat
octave:17> obj_arr
obj_arr =
{
  [1,1] = 1
  [2,1] = a string
}

2.14.2 IDL files

\texttt{readsav(file\_name[, idict, python\_dict, ...])} \quad \text{Read an IDL .sav file.}

2.14.3 Matrix Market files

\texttt{mminfo(source)} \quad \text{Return size and storage parameters from Matrix Market file-like 'source'\text{.}}
\texttt{mmread(source)} \quad \text{Reads the contents of a Matrix Market file-like 'source' into a matrix.}
\texttt{mmwrite(target, a[, comment, field, ...])} \quad \text{Writes the sparse or dense array \textit{a} to Matrix Market file-like \textit{target}.}

2.14.4 Wav sound files (scipy.io.wavfile)

\texttt{read(filename[, mmap])} \quad \text{Open a WAV file.}
\texttt{write(filename, rate, data)} \quad \text{Write a NumPy array as a WAV file.}

2.14.5 Arff files (scipy.io.arff)

\texttt{loadarff(f)} \quad \text{Read an arff file.}
2.14.6 Netcdf

\texttt{netcdf\_file(filename, mode, mmap, version, ...)} \hspace{1em} A file object for NetCDF data.

Allows reading of NetCDF files (version of \texttt{pupynere} package)
CHAPTER THREE

SCIPY API

3.1 Importing from SciPy

In Python the distinction between what is the public API of a library and what are private implementation details is not always clear. Unlike in other languages like Java, it is possible in Python to access “private” function or objects. Occasionally this may be convenient, but be aware that if you do so your code may break without warning in future releases. Some widely understood rules for what is and isn’t public in Python are:

• Methods / functions / classes and module attributes whose names begin with a leading underscore are private.
• If a class name begins with a leading underscore, none of its members are public, whether or not they begin with a leading underscore.
• If a module name in a package begins with a leading underscore none of its members are public, whether or not they begin with a leading underscore.
• If a module or package defines __all__, that authoritatively defines the public interface.
• If a module or package doesn’t define __all__, then all names that don’t start with a leading underscore are public.

Note: Reading the above guidelines one could draw the conclusion that every private module or object starts with an underscore. This is not the case; the presence of underscores do mark something as private, but the absence of underscores do not mark something as public.

In SciPy there are modules whose names don’t start with an underscore, but that should be considered private. To clarify which modules these are, we define below what the public API is for SciPy, and give some recommendations for how to import modules/functions/objects from SciPy.

3.2 Guidelines for importing functions from SciPy

The scipy namespace itself only contains functions imported from numpy. These functions still exist for backwards compatibility, but should be imported from numpy directly.

Everything in the namespaces of scipy submodules is public. In general, it is recommended to import functions from submodule namespaces. For example, the function curve_fit (defined in scipy/optimiz/_minpack_py.py) should be imported like this:

```python
from scipy import optimize
result = optimize.curve_fit(...)```

This form of importing submodules is preferred for all submodules except `scipy.io` (because `io` is also the name of a module in the Python stdlib):

```python
from scipy import interpolate
from scipy import integrate
import scipy.io as spio
```

In some cases, the public API is one level deeper. For example, the `scipy.sparse.linalg` module is public, and the functions it contains are not available in the `scipy.sparse` namespace. Sometimes it may result in more easily understandable code if functions are imported from one level deeper. For example, in the following it is immediately clear that `lomax` is a distribution if the second form is chosen:

```python
# first form
from scipy import stats
stats.lomax(...)

# second form
from scipy.stats import distributions
distributions.lomax(...)
```

In that case, the second form can be chosen if it is documented in the next section that the submodule in question is public.

### 3.3 API definition

Every submodule listed below is public. That means that these submodules are unlikely to be renamed or changed in an incompatible way, and if that is necessary, a deprecation warning will be raised for one SciPy release before the change is made.

- `scipy.cluster`
  - `scipy.cluster.vq`
  - `scipy.cluster.hierarchy`
- `scipy.constants`
- `scipy.fft`
- `scipy.fftpack`
- `scipy.integrate`
- `scipy.interpolate`
- `scipy.io`
  - `scipy.io.arff`
  - `scipy.io.matlab`
  - `scipy.io.wavfile`
- `scipy.linalg`
  - `scipy.linalg.blas`
  - `scipy.linalg.cython_blas`
  - `scipy.linalg.lapack`
  - `scipy.linalg.cython_lapack`
### 3.3.1 Clustering package (**scipy.cluster**)

**scipy.cluster.vq**

Clustering algorithms are useful in information theory, target detection, communications, compression, and other areas. The *vq* module only supports vector quantization and the k-means algorithms.

**scipy.cluster.hierarchy**

The *hierarchy* module provides functions for hierarchical and agglomerative clustering. Its features include generating hierarchical clusters from distance matrices, calculating statistics on clusters, cutting linkages to generate flat clusters, and visualizing clusters with dendrograms.

### 3.3.2 K-means clustering and vector quantization (**scipy.cluster.vq**)

Provides routines for k-means clustering, generating code books from k-means models and quantizing vectors by comparing them with centroids in a code book.

**scipy.cluster.vq.whiten**

`scipy.cluster.vq.whiten(obs, check_finite=True)`

Normalize a group of observations on a per feature basis.

Before running k-means, it is beneficial to rescale each feature dimension of the observation set by its standard deviation (i.e., “whiten” it - as in “white noise” where each frequency has equal power). Each feature is divided by its standard deviation across all observations to give it unit variance.

**Parameters**

- **obs** [ndarray] Each row of the array is an observation. The columns are the features seen during each observation.

  ```
  >>> #   f0  f1  f2
  >>> obs = [[ 1., 1., 1.],  # o0
  ...          [ 2., 2., 2.],  # o1
  ...          [ 3., 3., 3.],  # o2
  ...          [ 4., 4., 4.]] # o3
  ```

- **check_finite** [bool, optional] Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs. Default: True

**Returns**

- **result** [ndarray] Contains the values in `obs` scaled by the standard deviation of each column.

**Examples**

```python
>>> from scipy.cluster.vq import whiten
>>> features = np.array([[1.9, 2.3, 1.7],
...                       [1.5, 2.5, 2.2],
...                       [0.8, 0.6, 1.7]])
>>> whiten(features)
array([[ 4.17944278,  2.69811351,  7.21248917],
       [ 3.29956009,  2.93273208,  9.33380951],
       [ 1.75976538,  0.7038557 ,  7.21248917]])
```

**scipy.cluster.vq.vq**

`scipy.cluster.vq.vq(obs, code_book, check_finite=True)`

Assign codes from a code book to observations.

Assigns a code from a code book to each observation. Each observation vector in the ‘M’ by ‘N’ `obs` array is compared with the centroids in the code book and assigned the code of the closest centroid.

The features in `obs` should have unit variance, which can be achieved by passing them through the whiten function. The code book can be created with the k-means algorithm or a different encoding algorithm.
Parameters

**obs**

[ndarray] Each row of the ‘M’ x ‘N’ array is an observation. The columns are the “features” seen during each observation. The features must be whitened first using the `whiten` function or something equivalent.

**code_book**

[ndarray] The code book is usually generated using the k-means algorithm. Each row of the array holds a different code, and the columns are the features of the code.

```python
>>> # f0  f1  f2  f3
>>> code_book = [
... [ 1.,  2.,  3.,  4.],   #c0
... [ 1.,  2.,  3.,  4.],   #c1
... [ 1.,  2.,  3.,  4.]]   #c2
```

**check_finite**

[bool, optional] Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs. Default: True

Returns

**code**

[ndarray] A length M array holding the code book index for each observation.

**dist**

[ndarray] The distortion (distance) between the observation and its nearest code.

Examples

```python
>>> from numpy import array
>>> from scipy.cluster.vq import vq
>>> code_book = array([[1.,1.,1.],
...                     [2.,2.,2.]])
>>> features = array([[ 1.9,2.3,1.7],
...                    [ 1.5,2.5,2.2],
...                    [ 0.8,0.6,1.7]])
>>> vq(features,code_book)
(array([1, 1, 0], 'i'), array([ 0.43588989,  0.73484692,  0.83066239]))
```

**scipy.cluster.vq.kmeans**

`scipy.cluster.vq.kmeans( obs, k_or_guess, iter=20, thresh=1e-05, check_finite=True, *, seed=None)`

Performs k-means on a set of observation vectors forming k clusters.

The k-means algorithm adjusts the classification of the observations into clusters and updates the cluster centroids until the position of the centroids is stable over successive iterations. In this implementation of the algorithm, the stability of the centroids is determined by comparing the absolute value of the change in the average Euclidean distance between the observations and their corresponding centroids against a threshold. This yields a code book mapping centroids to codes and vice versa.

Parameters

**obs**

[ndarray] Each row of the M by N array is an observation vector. The columns are the features seen during each observation. The features must be whitened first with the `whiten` function.
k_or_guess

[int or ndarray] The number of centroids to generate. A code is assigned to each centroid, which is also the row index of the centroid in the code_book matrix generated. The initial k centroids are chosen by randomly selecting observations from the observation matrix. Alternatively, passing a k by N array specifies the initial k centroids.

iter

[int, optional] The number of times to run k-means, returning the codebook with the lowest distortion. This argument is ignored if initial centroids are specified with an array for the k_or_guess parameter. This parameter does not represent the number of iterations of the k-means algorithm.

thresh

[float, optional] Terminates the k-means algorithm if the change in distortion since the last k-means iteration is less than or equal to threshold.

check_finite

[bool, optional] Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs. Default: True

seed

[None, int, numpy.random.Generator, numpy.random.RandomState], optional

Seed for initializing the pseudo-random number generator. If seed is None (or numpy.random), the numpy.random.RandomState singleton is used. If seed is an int, a new RandomState instance is used, seeded with seed. If seed is already a Generator or RandomState instance then that instance is used. The default is None.

Returns

codebook

[ndarray] A k by N array of k centroids. The ith centroid codebook[i] is represented with the code i. The centroids and codes generated represent the lowest distortion seen, not necessarily the globally minimal distortion. Note that the number of centroids is not necessarily the same as the k_or_guess parameter, because centroids assigned to no observations are removed during iterations.

distortion

[float] The mean (non-squared) Euclidean distance between the observations passed and the centroids generated. Note the difference to the standard definition of distortion in the context of the k-means algorithm, which is the sum of the squared distances.

See also:

kmeans2

a different implementation of k-means clustering with more methods for generating initial centroids but without using a distortion change threshold as a stopping criterion.

whiten

must be called prior to passing an observation matrix to kmeans.

Notes

For more functionalities or optimal performance, you can use sklearn.cluster.KMeans. This is a benchmark result of several implementations.
Examples

```python
>>> from numpy import array
>>> from scipy.cluster.vq import vq, kmeans, whiten
>>> import matplotlib.pyplot as plt

>>> features = array([[ 1.9, 2.3],
                     [ 1.5, 2.5],
                     [ 0.8, 0.6],
                     [ 0.4, 1.8],
                     [ 0.1, 0.1],
                     [ 0.2, 1.8],
                     [ 2.0, 0.5],
                     [ 0.3, 1.5],
                     [ 1.0, 1.0]])

>>> whitened = whiten(features)
>>> book = np.array((whitened[0], whitened[2]))
>>> kmeans(whitened, book)
(array([[ 2.3110306 , 2.86287398],
          [ 0.93218041, 1.24398691]], 0.85684700941625547)

>>> codes = 3
>>> kmeans(whitened, codes)
(array([[ 2.3110306 , 2.86287398],
          [ 1.32544402, 0.65607529],
          [ 0.40782893, 2.02786907]], 0.5196582527686241)

>>> # Create 50 datapoints in two clusters a and b
>>> pts = 50
>>> rng = np.random.default_rng()
>>> a = rng.multivariate_normal([0, 0], [[4, 1], [1, 4]], size=pts)
>>> b = rng.multivariate_normal([30, 10],
                               [[10, 2], [2, 1]],
                               size=pts)
>>> features = np.concatenate((a, b))
>>> whitened = whiten(features)
>>> # Find 2 clusters in the data
>>> codebook, distortion = kmeans(whitened, 2)
>>> # Plot whitened data and cluster centers in red
>>> plt.scatter(whitened[:, 0], whitened[:, 1])
>>> plt.scatter(codebook[:, 0], codebook[:, 1], c='r')
>>> plt.show()
```
scipy.cluster.vq.kmeans2

Classify a set of observations into k clusters using the k-means algorithm.

The algorithm attempts to minimize the Euclidean distance between observations and centroids. Several initialization methods are included.

**Parameters**

- `data` ([ndarray]) A ‘M’ by ‘N’ array of ‘M’ observations in ‘N’ dimensions or a length ‘M’ array of ‘M’ 1-D observations.
- `k` ([int or ndarray]) The number of clusters to form as well as the number of centroids to generate. If `minit` initialization string is ‘matrix’, or if a ndarray is given instead, it is interpreted as initial cluster to use instead.
- `iter` ([int, optional]) Number of iterations of the k-means algorithm to run. Note that this differs in meaning from the *iters* parameter to the kmeans function.
- `thresh` ([float, optional]) (not used yet)
- `minit` ([str, optional]) Method for initialization. Available methods are ‘random’, ‘points’, ‘++’ and ‘matrix’:
  - ‘random’: generate k centroids from a Gaussian with mean and variance estimated from the data.
  - ‘points’: choose k observations (rows) at random from data for the initial centroids.
  - ‘++’: choose k observations accordingly to the kmeans++ method (careful seeding)
  - ‘matrix’: interpret the k parameter as a k by M (or length k array for 1-D data) array of initial centroids.
- `missing` ([str, optional]) Method to deal with empty clusters. Available methods are ‘warn’ and ‘raise’:
  - ‘warn’: give a warning and continue.
  - ‘raise’: raise an ClusterError and terminate the algorithm.
- `check_finite` ([bool, optional]) Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs. Default: True
- `seed` ([None, int, numpy.random.Generator, numpy.random.RandomState], optional)
Seed for initializing the pseudo-random number generator. If `seed` is None (or `numpy.random`), the `numpy.random.RandomState` singleton is used. If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already a `Generator` or `RandomState` instance then that instance is used. The default is None.

**Returns**

- `centroid` [ndarray] A ‘k’ by ‘N’ array of centroids found at the last iteration of k-means.
- `label` [ndarray] label[i] is the code or index of the centroid the ith observation is closest to.

See also:

- `kmeans`

References

[1]

**Examples**

```python
>>> from scipy.cluster.vq import kmeans2
>>> import matplotlib.pyplot as plt
```

Create `z`, an array with shape (100, 2) containing a mixture of samples from three multivariate normal distributions.

```python
>>> rng = np.random.default_rng()
>>> a = rng.multivariate_normal([0, 6], [[2, 1], [1, 1.5]], size=45)
>>> b = rng.multivariate_normal([2, 0], [[1, -1], [-1, 3]], size=30)
>>> c = rng.multivariate_normal([6, 4], [[5, 0], [0, 1.2]], size=25)
>>> z = np.concatenate((a, b, c))
>>> rng.shuffle(z)
```

Compute three clusters.

```python
>>> centroid, label = kmeans2(z, 3, minit='points')
>>> centroid
array([[ 2.22274463, -0.61666946],
        [ 0.54069047,  5.86541444],
        [ 6.73846769,  4.01991898]])
```

How many points are in each cluster?

```python
>>> counts = np.bincount(label)
>>> counts
array([29, 51, 20]) # may vary
```

Plot the clusters.

```python
>>> w0 = z[label == 0]
>>> w1 = z[label == 1]
>>> w2 = z[label == 2]
>>> plt.plot(w0[:, 0], w0[:, 1], 'o', alpha=0.5, label='cluster 0')
>>> plt.plot(w1[:, 0], w1[:, 1], 'd', alpha=0.5, label='cluster 1')
>>> plt.plot(w2[:, 0], w2[:, 1], 's', alpha=0.5, label='cluster 2')
```

(continues on next page)
Background information

The k-means algorithm takes as input the number of clusters to generate, k, and a set of observation vectors to cluster. It returns a set of centroids, one for each of the k clusters. An observation vector is classified with the cluster number or centroid index of the centroid closest to it.

A vector v belongs to cluster i if it is closer to centroid i than any other centroid. If v belongs to i, we say centroid i is the dominating centroid of v. The k-means algorithm tries to minimize distortion, which is defined as the sum of the squared distances between each observation vector and its dominating centroid. The minimization is achieved by iteratively reclassifying the observations into clusters and recalculating the centroids until a configuration is reached in which the centroids are stable. One can also define a maximum number of iterations.

Since vector quantization is a natural application for k-means, information theory terminology is often used. The centroid index or cluster index is also referred to as a “code” and the table mapping codes to centroids and, vice versa, is often referred to as a “code book”. The result of k-means, a set of centroids, can be used to quantize vectors. Quantization aims to find an encoding of vectors that reduces the expected distortion.

All routines expect obs to be an M by N array, where the rows are the observation vectors. The codebook is a k by N array, where the ith row is the centroid of code word i. The observation vectors and centroids have the same feature dimension.

As an example, suppose we wish to compress a 24-bit color image (each pixel is represented by one byte for red, one for blue, and one for green) before sending it over the web. By using a smaller 8-bit encoding, we can reduce the amount of data by two thirds. Ideally, the colors for each of the 256 possible 8-bit encoding values should be chosen to minimize distortion of the color. Running k-means with k=256 generates a code book of 256 codes, which fills up all possible 8-bit sequences. Instead of sending a 3-byte value for each pixel, the 8-bit centroid index (or code word) of the dominating centroid is transmitted. The code book is also sent over the wire so each 8-bit code can be translated back to a 24-bit pixel value representation. If the image of interest was of an ocean, we would expect many 24-bit blues to be represented by 8-bit codes. If it was an image of a human face, more flesh-tone colors would be represented in the code book.
3.3.3 Hierarchical clustering (scipy.cluster.hierarchy)

These functions cut hierarchical clusterings into flat clusterings or find the roots of the forest formed by a cut by providing the flat cluster ids of each observation.

<table>

</table>

**scipy.cluster.hierarchy.fcluster**

Form flat clusters from the hierarchical clustering defined by the given linkage matrix.

**Parameters**

- **Z** [ndarray] The hierarchical clustering encoded with the matrix returned by the `linkage` function.
- **t** [scalar]
  - For criteria ‘inconsistent’, ‘distance’ or ‘monocrit’, this is the threshold to apply when forming flat clusters.
  - For ‘maxclust’ or ‘maxclust_monocrit’ criteria, this would be max number of clusters requested.
- **criterion** [str, optional] The criterion to use in forming flat clusters. This can be any of the following values:
  - **inconsistent**: If a cluster node and all its descendants have an inconsistent value less than or equal to t, then all its leaf descendants belong to the same flat cluster. When no non-singleton cluster meets this criterion, every node is assigned to its own cluster. (Default)
  - **distance**: Forms flat clusters so that the original observations in each flat cluster have no greater a cophenetic distance than t.
  - **maxclust**: Finds a minimum threshold r so that the cophenetic distance between any two original observations in the same flat cluster is no more than r and no more than t flat clusters are formed.
  - **monocrit**: Forms a flat cluster from a cluster node c with index i when monocrit[j] <= t.
  
  For example, to threshold on the maximum mean distance as computed in the inconsistency matrix R with a threshold of 0.8 do:

  ```python
  MR = maxRstat(Z, R, 3)
  fcluster(Z, t=0.8, criterion='monocrit', ...monocrit=MR)
  ```

- **maxclust_monocrit**: Forms a flat cluster from a non-singleton cluster node c when monocrit[i] <= r for all cluster indices i below and including c. r is minimized such that no more than t flat clusters are formed. monocrit must be monotonic. For example, to minimize the threshold t on maximum inconsistency values so that no more than 3 flat clusters are formed, do:

```python
MR = maxRstat(Z, R, 3)
...monocrit=MR)
```
MI = maxinconsts(Z, R)
fcluster(Z, t=3, criterion='maxclust_monocrit', mono
crit=MI)

depth [int, optional] The maximum depth to perform the inconsistency calculation. It has no mean-
ing for the other criteria. Default is 2.

R [ndarray, optional] The inconsistency matrix to use for the ‘inconsistent’ criterion. This ma-
trix is computed if not provided.

monocrit [ndarray, optional] An array of length n-1. monocrit[i] is the statistics upon which non-
singleton i is thresholded. The monocrit vector must be monotonic, i.e., given a node c
with index i, for all node indices j corresponding to nodes below c, monocrit[i] >=
monocrit[j].

Returns

fcluster [ndarray] An array of length n. T[i] is the flat cluster number to which original observation
i belongs.

See also:

linkage

for information about hierarchical clustering methods work.

Examples

```python
>>> from scipy.cluster.hierarchy import ward, fcluster
>>> from scipy.spatial.distance import pdist

All cluster linkage methods - e.g., scipy.cluster.hierarchy.ward generate a linkage matrix Z as their
output:

>>> X = [[0., 0.], [0., 1.], [1., 0.],
            ... [0., 4.], [0., 3.], [1., 4.],
            ... [4., 0.], [3., 0.], [4., 1.],
            ... [4., 4.], [3., 4.], [4., 3.]]

>>> Z = ward(pdist(X))

>>> Z
array([[ 0. ,  1. ,  1. ,  2. ],
       [ 3. ,  4. ,  1. ,  2. ],
       [ 6. ,  7. ,  1. ,  2. ],
       [ 9. , 10. ,  1. ,  2. ],
       [ 2. , 12. , 1.29099445,  3. ],
       [ 5. , 13. , 1.29099445,  3. ],
       [ 8. , 14. , 1.29099445,  3. ],
       [11. , 15. , 1.29099445,  3. ],
       [16. , 17. , 5.77350269,  6. ],
       [18. , 19. , 5.77350269,  6. ],
       [20. , 21. , 8.16496581, 12. ]])
```

This matrix represents a dendrogram, where the first and second elements are the two clusters merged at each step,
the third element is the distance between these clusters, and the fourth element is the size of the new cluster - the
number of original data points included.

`scipy.cluster.hierarchy.fcluster` can be used to flatten the dendrogram, obtaining as a result an assignment of the original data points to single clusters.

This assignment mostly depends on a distance threshold $t$ - the maximum inter-cluster distance allowed:

```python
>>> fcluster(Z, t=0.9, criterion='distance')
array([ 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12], dtype=int32)
```

```python
>>> fcluster(Z, t=1.1, criterion='distance')
array([1, 1, 2, 3, 4, 5, 6, 7, 7, 8], dtype=int32)
```

```python
>>> fcluster(Z, t=3, criterion='distance')
array([1, 1, 1, 2, 2, 3, 3, 4, 4], dtype=int32)
```

```python
>>> fcluster(Z, t=9, criterion='distance')
array([1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1], dtype=int32)
```

In the first case, the threshold $t$ is too small to allow any two samples in the data to form a cluster, so 12 different clusters are returned.

In the second case, the threshold is large enough to allow the first 4 points to be merged with their nearest neighbors. So, here, only 8 clusters are returned.

The third case, with a much higher threshold, allows for up to 8 data points to be connected - so 4 clusters are returned here.

Lastly, the threshold of the fourth case is large enough to allow for all data points to be merged together - so a single cluster is returned.

**scipy.cluster.hierarchy.fclusterdata**

`scipy.cluster.hierarchy.fclusterdata(X, t, criterion='inconsistent', metric='euclidean', depth=2, method='single', R=None)`

Cluster observation data using a given metric.

Clusters the original observations in the n-by-m data matrix $X$ (n observations in m dimensions), using the euclidean distance metric to calculate distances between original observations, performs hierarchical clustering using the single linkage algorithm, and forms flat clusters using the inconsistency method with $t$ as the cut-off threshold.

A 1-D array $T$ of length $n$ is returned. $T[i]$ is the index of the flat cluster to which the original observation $i$ belongs.

### Parameters

- **X**
  - [(N, M) ndarray] N by M data matrix with N observations in M dimensions.
  - [scalar]

- **t**
  - [scalar]

  For criteria ‘inconsistent’, ‘distance’ or ‘monocrit’,
  this is the threshold to apply when forming flat clusters.

- **criterion**
  - [str, optional] Specifies the criterion for forming flat clusters. Valid values are ‘inconsistent’ (default), ‘distance’, or ‘maxclust’ cluster formation algorithms. See `fcluster` for descriptions.

- **metric**
  - [str or function, optional] The distance metric for calculating pairwise distances. See `distance.pdist` for descriptions and linkage to verify compatibility with the linkage method.

3.3. API definition 309
**depth** [int, optional] The maximum depth for the inconsistency calculation. See `inconsistent` for more information.

**method** [str, optional] The linkage method to use (single, complete, average, weighted, median centroid, ward). See `linkage` for more information. Default is “single”.

**R** [ndarray, optional] The inconsistency matrix. It will be computed if necessary if it is not passed.

**Returns**

**fclusterdata**

[numpy.ndarray] A vector of length n. T[i] is the flat cluster number to which original observation i belongs.

**See also:**

`scipy.spatial.distance.pdist` pairwise distance metrics

**Notes**

This function is similar to the MATLAB function `clusterdata`.

**Examples**

```python
>>> from scipy.cluster.hierarchy import fclusterdata
```

This is a convenience method that abstracts all the steps to perform in a typical SciPy’s hierarchical clustering workflow.

- Transform the input data into a condensed matrix with `scipy.spatial.distance.pdist`.
- Apply a clustering method.
- Obtain flat clusters at a user defined distance threshold t using `scipy.cluster.hierarchy.fcluster`.

```python
>>> X = [
    [0, 0], [0, 1], [1, 0],
    [0, 4], [0, 3], [1, 4],
    [4, 0], [3, 0], [4, 1],
    [4, 4], [3, 4], [4, 3]
]
```

```python
>>> fclusterdata(X, t=1)
array([[3, 3, 3, 4, 4, 4, 2, 2, 2, 1, 1, 1], dtype=int32)
```

The output here (for the dataset X, distance threshold t, and the default settings) is four clusters with three data points each.
scipy.cluster.hierarchy.leaders

scipy.cluster.hierarchy.leaders(Z, T)

Return the root nodes in a hierarchical clustering.

Returns the root nodes in a hierarchical clustering corresponding to a cut defined by a flat cluster assignment vector T. See the fcluster function for more information on the format of T.

For each flat cluster j of the k flat clusters represented in the n-sized flat cluster assignment vector T, this function finds the lowest cluster node i in the linkage tree Z, such that:

- leaf descendants belong only to flat cluster j (i.e., T[p] == j for all p in S(i), where S(i) is the set of leaf ids of descendant leaf nodes with cluster node i)
- there does not exist a leaf that is not a descendant with i that also belongs to cluster j (i.e., T[q] != j for all q not in S(i)). If this condition is violated, T is not a valid cluster assignment vector, and an exception will be thrown.

Parameters

Z [ndarray] The hierarchical clustering encoded as a matrix. See linkage for more information.
T [ndarray] The flat cluster assignment vector.

Returns

L [ndarray] The leader linkage node id's stored as a k-element 1-D array, where k is the number of flat clusters found in T.
M [ndarray] The leader linkage node id's stored as a k-element 1-D array, where k is the number of flat clusters found in T. This allows the set of flat cluster ids to be any arbitrary set of k integers.

L[j] = i is the linkage cluster node id that is the leader of flat cluster with id M[j]. If i < n, i corresponds to an original observation, otherwise it corresponds to a non-singleton cluster.

For example: if L[3]=2 and M[3]=8, the flat cluster with id 8's leader is linkage node 2.

See also:

fcluster

for the creation of flat cluster assignments.

Examples

>>> from scipy.cluster.hierarchy import ward, fcluster, leaders
>>> from scipy.spatial.distance import pdist

Given a linkage matrix Z - obtained after apply a clustering method to a dataset X - and a flat cluster assignment array T:

>>> X = [[0, 0], [0, 1], [1, 0],
...     [0, 4], [0, 3], [1, 4],
...     [4, 0], [3, 0], [4, 1],
...     [4, 4], [3, 4], [4, 3]]
```python
>>> Z = ward(pdist(X))
array([[ 0. , 1. , 1. , 2. ],
       [ 3. , 4. , 1. , 2. ],
       [ 6. , 7. , 1. , 2. ],
       [ 9. , 10. , 1. , 2. ],
       [ 2. , 12. , 1.29099445, 3. ],
       [ 5. , 13. , 1.29099445, 3. ],
       [ 8. , 14. , 1.29099445, 3. ],
       [11. , 15. , 1.29099445, 3. ],
       [16. , 17. , 5.77350269, 6. ],
       [18. , 19. , 5.77350269, 6. ],
       [20. , 21. , 8.16496581, 12. ]])
>>> T = fcluster(Z, 3, criterion='distance')
array([1, 1, 1, 2, 2, 2, 3, 3, 3, 4, 4, 4], dtype=int32)
```

`scipy.cluster.hierarchy.leaders` returns the indices of the nodes in the dendrogram that are the leaders of each flat cluster:

```python
>>> L, M = leaders(Z, T)
>>> L
array([16, 17, 18, 19], dtype=int32)
```

(remember that indices 0-11 point to the 12 data points in X, whereas indices 12-22 point to the 11 rows of Z)

`scipy.cluster.hierarchy.leaders` also returns the indices of the flat clusters in T:

```python
>>> M
array([1, 2, 3, 4], dtype=int32)
```

These are routines for agglomerative clustering.

- `linkage(y[, method, metric, optimal_ordering])` Perform hierarchical/agglomerative clustering.
- `single(y)` Perform single/min/nearest linkage on the condensed distance matrix y.
- `complete(y)` Perform complete/max/farthest point linkage on a condensed distance matrix.
- `average(y)` Perform average/UPGMA linkage on a condensed distance matrix.
- `weighted(y)` Perform weighted/WPGMA linkage on the condensed distance matrix.
- `centroid(y)` Perform centroid/UPGMC linkage.
- `median(y)` Perform median/WPGMC linkage.
- `ward(y)` Perform Ward's linkage on a condensed distance matrix.
Perform hierarchical/aggregate clustering.

The input y may be either a 1-D condensed distance matrix or a 2-D array of observation vectors.

If y is a 1-D condensed distance matrix, then y must be a \( \binom{n}{2} \) sized vector, where n is the number of original observations paired in the distance matrix. The behavior of this function is very similar to the MATLAB linkage function.

A \((n-1)\) by 4 matrix \( Z \) is returned. At the \( i \)-th iteration, clusters with indices \( Z[i, 0] \) and \( Z[i, 1] \) are combined to form cluster \( n+i \). A cluster with an index less than \( n \) corresponds to one of the \( n \) original observations. The distance between clusters \( Z[i, 0] \) and \( Z[i, 1] \) is given by \( Z[i, 2] \). The fourth value \( Z[i, 3] \) represents the number of original observations in the newly formed cluster.

The following linkage methods are used to compute the distance \( d(s, t) \) between two clusters \( s \) and \( t \). The algorithm begins with a forest of clusters that have yet to be used in the hierarchy being formed. When two clusters \( s \) and \( t \) from this forest are combined into a single cluster \( u \), \( s \) and \( t \) are removed from the forest, and \( u \) is added to the forest. When only one cluster remains in the forest, the algorithm stops, and this cluster becomes the root.

A distance matrix is maintained at each iteration. The \( d[i, j] \) entry corresponds to the distance between cluster \( i \) and \( j \) in the original forest.

At each iteration, the algorithm must update the distance matrix to reflect the distance of the newly formed cluster \( u \) with the remaining clusters in the forest.

Suppose there are \(|u| \) original observations \( u[0], \ldots, u[|u|-1] \) in cluster \( u \) and \(|v| \) original objects \( v[0], \ldots, v[|v|-1] \) in cluster \( v \). Recall, \( s \) and \( t \) are combined to form cluster \( u \). Let \( v \) be any remaining cluster in the forest that is not \( u \).

The following are methods for calculating the distance between the newly formed cluster \( u \) and each \( v \).

- **method='single'** assigns
  
  \[
  d(u, v) = \min(dist(u[i], v[j]))
  \]
  
  for all points \( i \) in cluster \( u \) and \( j \) in cluster \( v \). This is also known as the Nearest Point Algorithm.

- **method='complete'** assigns
  
  \[
  d(u, v) = \max(dist(u[i], v[j]))
  \]
  
  for all points \( i \) in cluster \( u \) and \( j \) in cluster \( v \). This is also known by the Farthest Point Algorithm or Voor Hees Algorithm.

- **method='average'** assigns
  
  \[
  d(u, v) = \frac{\sum_{ij} d(u[i], v[j])}{(|u| \cdot |v|)}
  \]
  
  for all points \( i \) and \( j \) where \(|u| \) and \(|v| \) are the cardinalities of clusters \( u \) and \( v \), respectively. This is also called the UPGMA algorithm.

- **method='weighted'** assigns
  
  \[
  d(u, v) = \frac{(dist(s, v) + dist(t, v))}{2}
  \]
  
  where cluster \( u \) was formed with cluster \( s \) and \( t \) and \( v \) is a remaining cluster in the forest (also called WPGMA).
• method=’centroid’ assigns

$$dist(s, t) = ||c_s - c_t||_2$$

where $c_s$ and $c_t$ are the centroids of clusters $s$ and $t$, respectively. When two clusters $s$ and $t$ are combined into a new cluster $u$, the new centroid is computed over all the original objects in clusters $s$ and $t$. The distance then becomes the Euclidean distance between the centroid of $u$ and the centroid of a remaining cluster $v$ in the forest. This is also known as the UPGMC algorithm.

• method=’median’ assigns $d(s, t)$ like the centroid method. When two clusters $s$ and $t$ are combined into a new cluster $u$, the average of centroids $s$ and $t$ give the new centroid $u$. This is also known as the WPGMC algorithm.

• method=’ward’ uses the Ward variance minimization algorithm. The new entry $d(u, v)$ is computed as follows,

$$d(u, v) = \sqrt{\frac{|v| + |s|}{T} d(v, s)^2 + \frac{|v| + |t|}{T} d(v, t)^2 - \frac{|v|}{T} d(s, t)^2}$$

where $u$ is the newly joined cluster consisting of clusters $s$ and $t$, $v$ is an unused cluster in the forest, $T = |v| + |s| + |t|$, and $|\ast|$ is the cardinality of its argument. This is also known as the incremental algorithm.

Warning: When the minimum distance pair in the forest is chosen, there may be two or more pairs with the same minimum distance. This implementation may choose a different minimum than the MATLAB version.

**Parameters**

**y** [ndarray] A condensed distance matrix. A condensed distance matrix is a flat array containing the upper triangular of the distance matrix. This is the form that pdist returns. Alternatively, a collection of $m$ observation vectors in $n$ dimensions may be passed as an $m$ by $n$ array. All elements of the condensed distance matrix must be finite, i.e., no NaNs or infs.

**method** [str, optional] The linkage algorithm to use. See the Linkage Methods section below for full descriptions.

**metric** [str or function, optional] The distance metric to use in the case that y is a collection of observation vectors; ignored otherwise. See the pdist function for a list of valid distance metrics. A custom distance function can also be used.

**optimal_ordering** [bool, optional] If True, the linkage matrix will be reordered so that the distance between successive leaves is minimal. This results in a more intuitive tree structure when the data are visualized. defaults to False, because this algorithm can be slow, particularly on large datasets [2]. See also the optimal_leaf_ordering function. New in version 1.0.0.

**Returns**

**Z** [ndarray] The hierarchical clustering encoded as a linkage matrix.

**See also:**

scipy.spatial.distance.pdist

pairwise distance metrics
Notes

1. For method `single`, an optimized algorithm based on minimum spanning tree is implemented. It has time complexity $O(n^2)$. For methods `complete`, `average`, `weighted` and `ward`, an algorithm called nearest-neighbors chain is implemented. It also has time complexity $O(n^2)$. For other methods, a naive algorithm is implemented with $O(n^3)$ time complexity. All algorithms use $O(n^2)$ memory. Refer to [1] for details about the algorithms.

2. Methods `centroid`, `median`, and `ward` are correctly defined only if Euclidean pairwise metric is used. If $y$ is passed as precomputed pairwise distances, then it is the user’s responsibility to assure that these distances are in fact Euclidean, otherwise the produced result will be incorrect.

References

[1], [2]

Examples

```python
>>> from scipy.cluster.hierarchy import dendrogram, linkage
>>> from matplotlib import pyplot as plt
>>> X = [[i] for i in [2, 8, 0, 4, 1, 9, 9, 0]]

>>> Z = linkage(X, 'ward')
>>> fig = plt.figure(figsize=(25, 10))
>>> dn = dendrogram(Z)

>>> Z = linkage(X, 'single')
>>> fig = plt.figure(figsize=(25, 10))
>>> dn = dendrogram(Z)
>>> plt.show()
```
scipy.cluster.hierarchy.single

scipy.cluster.hierarchy.single(y)
Perform single/min/nearest linkage on the condensed distance matrix y.

Parameters

- y : [ndarray] The upper triangular of the distance matrix. The result of pdist is returned in this form.

Returns

See also:

- linkage
  for advanced creation of hierarchical clusterings.

- scipy.spatial.distance.pdist
  pairwise distance metrics

Examples

```python
>>> from scipy.cluster.hierarchy import single, fcluster
>>> from scipy.spatial.distance import pdist
```

First, we need a toy dataset to play with:

```
x x x x
x x
x x
```

```python
```
Then, we get a condensed distance matrix from this dataset:

```python
>>> y = pdist(X)
```

Finally, we can perform the clustering:

```python
>>> Z = single(y)
```

The linkage matrix Z represents a dendrogram - see `scipy.cluster.hierarchy.linkage` for a detailed explanation of its contents.

We can use `scipy.cluster.hierarchy.fcluster` to see to which cluster each initial point would belong given a distance threshold:

```python
>>> fcluster(Z, 0.9, criterion='distance')
array([ 7,  8,  9, 10, 11, 12,  4,  5,  6,  1,  2,  3], dtype=int32)
```

```python
>>> fcluster(Z, 1, criterion='distance')
array([ 3,  3,  4,  4,  4,  2,  2,  1,  1,  1], dtype=int32)
```

```python
>>> fcluster(Z, 2, criterion='distance')
array([ 1,  1,  1,  1,  1,  1,  1,  1,  1,  1], dtype=int32)
```

Also, `scipy.cluster.hierarchy.dendrogram` can be used to generate a plot of the dendrogram.

### scipy.cluster.hierarchy.complete

`scipy.cluster.hierarchy.complete(y)`

Perform complete/max/farthest point linkage on a condensed distance matrix.

**Parameters**

- **y** : [ndarray] The upper triangular of the distance matrix. The result of `pdist` is returned in this form.

**Returns**

- **Z** : [ndarray] A linkage matrix containing the hierarchical clustering. See the `linkage` function documentation for more information on its structure.

**See also:**

3.3. API definition
linkage
for advanced creation of hierarchical clusterings.

scipy.spatial.distance.pdist
pairwise distance metrics

Examples

```python
>>> from scipy.cluster.hierarchy import complete, fcluster
>>> from scipy.spatial.distance import pdist

First, we need a toy dataset to play with:

```
 x x   x x
 x     x
 x     x
 x x   x x
```

```python
>>> X = [[0, 0], [0, 1], [1, 0],
...       [0, 4], [0, 3], [1, 4],
...       [4, 0], [3, 0], [4, 1],
...       [4, 4], [3, 4], [4, 3]]
```

Then, we get a condensed distance matrix from this dataset:

```python
>>> y = pdist(X)
```

Finally, we can perform the clustering:

```python
>>> Z = complete(y)
```

```python
array([[ 0. , 1. , 1. , 2. ],
       [ 3. , 4. , 1. , 2. ],
       [ 6. , 7. , 1. , 2. ],
       [ 9. , 10. , 1. , 2. ],
       [ 2. , 12. , 1.41421356, 3. ],
       [ 5. , 13. , 1.41421356, 3. ],
       [ 8. , 14. , 1.41421356, 3. ],
       [11. , 15. , 1.41421356, 3. ],
       [16. , 17. , 4.12310563, 6. ],
       [18. , 19. , 4.12310563, 6. ],
       [20. , 21. , 5.65685425, 12. ]])
```

The linkage matrix \( Z \) represents a dendrogram - see `scipy.cluster.hierarchy.linkage` for a detailed explanation of its contents.

We can use `scipy.cluster.hierarchy.fcluster` to see to which cluster each initial point would belong given a distance threshold:

```python
>>> fcluster(Z, 0.9, criterion='distance')
array([1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12], dtype=int32)
```

```python
>>> fcluster(Z, 1.5, criterion='distance')
```

(continues on next page)
array([1, 1, 1, 2, 2, 2, 3, 3, 3, 4, 4, 4], dtype=int32)

>>> fcluster(Z, 4.5, criterion='distance')
array([1, 1, 1, 1, 1, 1, 2, 2, 2, 2, 2, 2], dtype=int32)

>>> fcluster(Z, 6, criterion='distance')
array([1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1], dtype=int32)

Also, `scipy.cluster.hierarchy.dendrogram` can be used to generate a plot of the dendrogram.

### scipy.cluster.hierarchy.average

**scipy.cluster.hierarchy.average(y)**

Perform average/UPGMA linkage on a condensed distance matrix.

**Parameters**

- **y** [ndarray] The upper triangular of the distance matrix. The result of `pdist` is returned in this form.

**Returns**

- **Z** [ndarray] A linkage matrix containing the hierarchical clustering. See `linkage` for more information on its structure.

See also:

**linkage**

for advanced creation of hierarchical clusterings.

**scipy.spatial.distance.pdist**

pairwise distance metrics

### Examples

```python
>>> from scipy.cluster.hierarchy import average, fcluster

>>> from scipy.spatial.distance import pdist
```

First, we need a toy dataset to play with:

```python
x x x x
x x
x x
x x x x
```

```python
>>> X = [[0, 0], [0, 1], [1, 0],
...      [0, 4], [0, 3], [1, 4],
...      [4, 0], [3, 0], [4, 1],
...      [4, 4], [3, 4], [4, 3]]
```

Then, we get a condensed distance matrix from this dataset:

```python
>>> y = pdist(X)
```
Finally, we can perform the clustering:

```python
>>> Z = average(y)
>>> Z
array([[ 0. ,  1. ,  1. ,  2. ],
[ 3. ,  4. ,  1. ,  2. ],
[ 6. ,  7. ,  1. ,  2. ],
[ 9. , 10. ,  1. ,  2. ],
[ 2. , 12. , 1.20710678, 3. ],
[ 5. , 13. , 1.20710678, 3. ],
[ 8. , 14. , 1.20710678, 3. ],
[11. , 15. , 1.20710678, 3. ],
[16. , 17. , 3.39675184, 6. ],
[18. , 19. , 3.39675184, 6. ],
[20. , 21. , 4.09206523, 12. ]])
```

The linkage matrix $Z$ represents a dendrogram - see `scipy.cluster.hierarchy.linkage` for a detailed explanation of its contents.

We can use `scipy.cluster.hierarchy.fcluster` to see to which cluster each initial point would belong given a distance threshold:

```python
>>> fcluster(Z, 0.9, criterion='distance')
array([ 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12], dtype=int32)
>>> fcluster(Z, 1.5, criterion='distance')
array([1, 1, 2, 2, 2, 3, 3, 3, 4, 4, 4], dtype=int32)
>>> fcluster(Z, 4.0, criterion='distance')
array([1, 1, 1, 1, 2, 2, 2, 2, 2, 2, 2], dtype=int32)
>>> fcluster(Z, 6.0, criterion='distance')
array([1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1], dtype=int32)
```

Also, `scipy.cluster.hierarchy.dendrogram` can be used to generate a plot of the dendrogram.

**scipy.cluster.hierarchy.weighted**

`scipy.cluster.hierarchy.weighted(y)`

Perform weighted/WPGMA linkage on the condensed distance matrix.

See `linkage` for more information on the return structure and algorithm.

**Parameters**

- `y` [ndarray] The upper triangular of the distance matrix. The result of `pdist` is returned in this form.

**Returns**

- `Z` [ndarray] A linkage matrix containing the hierarchical clustering. See `linkage` for more information on its structure.

See also:

- `linkage`
  
  for advanced creation of hierarchical clusterings.

- `scipy.spatial.distance.pdist`
  
  pairwise distance metrics
Examples

```python
>>> from scipy.cluster.hierarchy import weighted, fcluster
>>> from scipy.spatial.distance import pdist
```

First, we need a toy dataset to play with:

```
  x  x  x  x
  x  x
  x  x
  x  x  x  x
```

```python
>>> X = [[0, 0], [0, 1], [1, 0],
      ... [0, 4], [0, 3], [1, 4],
      ... [4, 0], [3, 0], [4, 1],
      ... [4, 4], [3, 4], [4, 3]]
```

Then, we get a condensed distance matrix from this dataset:

```python
>>> y = pdist(X)
```

Finally, we can perform the clustering:

```
>>> Z = weighted(y)
>>> Z
array([[ 0. , 1. , 1. , 2. ],
       [ 6. , 7. , 1. , 2. ],
       [ 3. , 4. , 1. , 2. ],
       [ 9. , 11. , 1. , 2. ],
       [ 2. , 12. , 1.20710678, 3. ],
       [ 8. , 13. , 1.20710678, 3. ],
       [ 5. , 14. , 1.20710678, 3. ],
       [10. , 15. , 1.20710678, 3. ],
       [18. , 19. , 3.05595762, 6. ],
       [16. , 17. , 3.32379407, 6. ],
       [20. , 21. , 4.06357713, 12. ]])
```

The linkage matrix $Z$ represents a dendogram - see `scipy.cluster.hierarchy.linkage` for a detailed explanation of its contents.

We can use `scipy.cluster.hierarchy.fcluster` to see to which cluster each initial point would belong given a distance threshold:

```
>>> fcluster(Z, 0.9, criterion='distance')
array([ 7,  8,  9,  1,  2,  3, 10, 11, 12,  4,  6,  5], dtype=int32)
```

```
>>> fcluster(Z, 1.5, criterion='distance')
array([ 3,  3,  1,  1,  1,  4,  4,  4,  2,  2,  2,  2], dtype=int32)
```

```
>>> fcluster(Z, 4, criterion='distance')
array([ 2,  2,  2,  1,  1,  2,  2,  2,  1,  1,  1], dtype=int32)
```

```
>>> fcluster(Z, 6, criterion='distance')
array([1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1], dtype=int32)
```

Also, `scipy.cluster.hierarchy.dendrogram` can be used to generate a plot of the dendrogram.
scipy.cluster.hierarchy.centroid

scipy.cluster.hierarchy.centroid(y)
Perform centroid/UPGMC linkage.

See linkage for more information on the input matrix, return structure, and algorithm.

The following are common calling conventions:

1. \( Z = \text{centroid}(y) \)
   
   Performs centroid/UPGMC linkage on the condensed distance matrix \( y \).

2. \( Z = \text{centroid}(X) \)
   
   Performs centroid/UPGMC linkage on the observation matrix \( X \) using Euclidean distance as the distance metric.

Parameters

- **y** [ndarray] A condensed distance matrix. A condensed distance matrix is a flat array containing the upper triangular of the distance matrix. This is the form that pdist returns. Alternatively, a collection of \( m \) observation vectors in \( n \) dimensions may be passed as an \( m \) by \( n \) array.

Returns

- **Z** [ndarray] A linkage matrix containing the hierarchical clustering. See the linkage function documentation for more information on its structure.

See also:

- linkage
  
  for advanced creation of hierarchical clusterings.
- scipy.spatial.distance.pdist
  
  pairwise distance metrics

Examples

```python
>>> from scipy.cluster.hierarchy import centroid, fcluster
>>> from scipy.spatial.distance import pdist

First, we need a toy dataset to play with:

```
  x x x x
  x  x
  x  x
  x x x x
```

```python
>>> X = [[0, 0], [0, 1], [1, 0],
      ... [0, 4], [0, 3], [1, 4],
      ... [4, 0], [3, 0], [4, 1],
      ... [4, 4], [3, 4], [4, 3]]
```

Then, we get a condensed distance matrix from this dataset:
Finally, we can perform the clustering:

```python
>>> Z = centroid(y)
```

```
array([[ 0.  ,  1.  ,  1.  ,  2.  ],
       [ 3.  ,  4.  ,  1.  ,  2.  ],
       [ 9.  , 10.  ,  1.  ,  2.  ],
       [ 6.  ,  7.  ,  1.  ,  2.  ],
       [ 2.  , 12.  , 1.11803399, 3.  ],
       [ 5.  , 13.  , 1.11803399, 3.  ],
       [ 8.  , 15.  , 1.11803399, 3.  ],
       [11.  , 14.  , 1.11803399, 3.  ],
       [18.  , 19.  , 3.33333333, 6.  ],
       [16.  , 17.  , 3.33333333, 6.  ],
       [20.  , 21.  , 3.33333333, 12.  ]])
```

The linkage matrix Z represents a dendrogram - see `scipy.cluster.hierarchy.linkage` for a detailed explanation of its contents.

We can use `scipy.cluster.hierarchy.fcluster` to see to which cluster each initial point would belong given a distance threshold:

```python
>>> fcluster(Z, 0.9, criterion='distance')
array([ 7,  8,  9, 10, 11, 12,  1,  2,  3,  4,  5,  6], dtype=int32)
>>> fcluster(Z, 1.1, criterion='distance')
array([ 5,  6,  7,  8,  1,  1,  2,  3,  3,  4], dtype=int32)
>>> fcluster(Z, 2, criterion='distance')
array([ 3,  3,  4,  4,  1,  1,  2,  2,  2], dtype=int32)
>>> fcluster(Z, 4, criterion='distance')
array([ 1,  1,  1,  1,  1,  1,  1,  1,  1,  1,  1], dtype=int32)
```

Also, `scipy.cluster.hierarchy.dendrogram` can be used to generate a plot of the dendrogram.

**scipy.cluster.hierarchy.median**

**scipy.cluster.hierarchy.median(y)**

Perform median/WPGMC linkage.

See `linkage` for more information on the return structure and algorithm.

The following are common calling conventions:

1. Z = median(y)
   Performs median/WPGMC linkage on the condensed distance matrix y. See `linkage` for more information on the return structure and algorithm.

2. Z = median(X)
   Performs median/WPGMC linkage on the observation matrix X using Euclidean distance as the distance metric. See `linkage` for more information on the return structure and algorithm.

**Parameters**

- **y** [ndarray] A condensed distance matrix. A condensed distance matrix is a flat array containing the upper triangular of the distance matrix. This is the form that `pdist` returns.
Alternatively, a collection of m observation vectors in n dimensions may be passed as an m by n array.

**Returns**

Z. [ndarray] The hierarchical clustering encoded as a linkage matrix.

See also:

- `linkage` for advanced creation of hierarchical clusterings.
- `scipy.spatial.distance.pdist` pairwise distance metrics

**Examples**

```python
>>> from scipy.cluster.hierarchy import median, fcluster
>>> from scipy.spatial.distance import pdist
```

First, we need a toy dataset to play with:

```
x x x x
x  x
x  x
x x x x
```

```python
>>> X = [[0, 0], [0, 1], [1, 0],
... [0, 4], [0, 3], [1, 4],
... [4, 0], [3, 0], [4, 1],
... [4, 4], [3, 4], [4, 3]]
```

Then, we get a condensed distance matrix from this dataset:

```python
>>> y = pdist(X)
```

Finally, we can perform the clustering:

```python
>>> Z = median(y)
>>> Z
array([[ 0. , 1. , 1. , 2. ],
       [ 3. , 4. , 1. , 2. ],
       [ 9. , 10. , 1. , 2. ],
       [ 6. , 7. , 1. , 2. ],
       [ 2. , 12. , 1.11803399, 3. ],
       [ 5. , 13. , 1.11803399, 3. ],
       [ 8. , 15. , 1.11803399, 3. ],
       [11. , 14. , 1.11803399, 3. ],
       [18. , 19. , 3. , 6. ],
       [16. , 17. , 3.5 , 6. ],
       [20. , 21. , 3.25 , 12. ]])
```
The linkage matrix $Z$ represents a dendrogram - see `scipy.cluster.hierarchy.linkage` for a detailed explanation of its contents.

We can use `scipy.cluster.hierarchy.fcluster` to see to which cluster each initial point would belong given a distance threshold:

```python
>>> fcluster(Z, 0.9, criterion='distance')
array([7, 8, 9, 10, 11, 12, 1, 2, 3, 4, 5, 6], dtype=int32)
>>> fcluster(Z, 1.1, criterion='distance')
array([5, 5, 6, 7, 7, 8, 1, 1, 2, 3, 3, 4], dtype=int32)
>>> fcluster(Z, 2, criterion='distance')
array([3, 3, 4, 4, 4, 1, 1, 2, 2, 2], dtype=int32)
>>> fcluster(Z, 4, criterion='distance')
array([1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1], dtype=int32)
```

Also, `scipy.cluster.hierarchy.dendrogram` can be used to generate a plot of the dendrogram.

**scipy.cluster.hierarchy.ward**

`scipy.cluster.hierarchy.ward(y)`

Perform Ward’s linkage on a condensed distance matrix.

See `linkage` for more information on the return structure and algorithm.

The following are common calling conventions:

1. $Z = \text{ward}(y)$ Performs Ward’s linkage on the condensed distance matrix $y$.
2. $Z = \text{ward}(X)$ Performs Ward’s linkage on the observation matrix $X$ using Euclidean distance as the distance metric.

**Parameters**

- **y** [ndarray] A condensed distance matrix. A condensed distance matrix is a flat array containing the upper triangular of the distance matrix. This is the form that `pdist` returns. Alternatively, a collection of $m$ observation vectors in $n$ dimensions may be passed as an $m$ by $n$ array.

**Returns**

- **Z** [ndarray] The hierarchical clustering encoded as a linkage matrix. See `linkage` for more information on the return structure and algorithm.

See also:

- `linkage` for advanced creation of hierarchical clusterings.
- `scipy.spatial.distance.pdist` pairwise distance metrics
Examples

```python
>>> from scipy.cluster.hierarchy import ward, fcluster
>>> from scipy.spatial.distance import pdist
```

First, we need a toy dataset to play with:

```
x x x x
x   x
x   x
x x x x
```

```python
>>> X = [[0, 0], [0, 1], [1, 0],
      ... [0, 4], [0, 3], [1, 4],
      ... [4, 0], [3, 0], [4, 1],
      ... [4, 4], [3, 4], [4, 3]]
```

Then, we get a condensed distance matrix from this dataset:

```python
>>> y = pdist(X)
```

Finally, we can perform the clustering:

```python
>>> Z = ward(y)
```

```
array([[ 0. ,  1. ,  1. ,  2. ],
       [ 3. ,  4. ,  1. ,  2. ],
       [ 6. ,  7. ,  1. ,  2. ],
       [ 9. , 10. ,  1. ,  2. ],
       [ 2. , 12. , 1.29099445, 3. ],
       [ 5. , 13. , 1.29099445, 3. ],
       [ 8. , 14. , 1.29099445, 3. ],
       [11. , 15. , 1.29099445, 3. ],
       [16. , 17. , 5.77350269, 6. ],
       [18. , 19. , 5.77350269, 6. ],
       [20. , 21. , 8.16496581, 12. ]])
```

The linkage matrix `Z` represents a dendrogram - see `scipy.cluster.hierarchy.linkage` for a detailed explanation of its contents.

We can use `scipy.cluster.hierarchy.fcluster` to see to which cluster each initial point would belong given a distance threshold:

```python
>>> fcluster(Z, 0.9, criterion='distance')
array([ 1,  2,  3,  4,  5,  6,  7,  8,  9, 10, 11, 12], dtype=int32)
```

```python
>>> fcluster(Z, 1.1, criterion='distance')
array([1, 1, 2, 3, 4, 5, 6, 7, 8], dtype=int32)
```

```python
>>> fcluster(Z, 3, criterion='distance')
array([1, 1, 2, 2, 3, 3, 3, 4, 4, 4], dtype=int32)
```

```python
>>> fcluster(Z, 9, criterion='distance')
array([1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1], dtype=int32)
```

Also, `scipy.cluster.hierarchy.dendrogram` can be used to generate a plot of the dendrogram.
These routines compute statistics on hierarchies.

**cophenet**

`cophenet(Z[, Y])`  
Calculate the cophenetic distances between each observation in the hierarchical clustering defined by the linkage `Z`.

**from_mlab_linkage**

`from_mlab_linkage(Z)`  
Convert a linkage matrix generated by MATLAB(TM) to a new linkage matrix compatible with this module.

**inconsistent**

`inconsistent(Z[, d])`  
Calculate inconsistency statistics on a linkage matrix.

**maxinconsts**

`maxinconsts(Z, R)`  
Return the maximum inconsistency coefficient for each non-singleton cluster and its children.

**maxdists**

`maxdists(Z)`  
Return the maximum distance between any non-singleton cluster.

**maxRstat**

`maxRstat(Z, R, i)`  
Return the maximum statistic for each non-singleton cluster and its children.

**to_mlab_linkage**

`to_mlab_linkage(Z)`  
Convert a linkage matrix to a MATLAB(TM) compatible one.

---

**scipy.cluster.hierarchy.cophenet**

**scipy.cluster.hierarchy.cophenet** *(Z, Y=None)*  
Calculate the cophenetic distances between each observation in the hierarchical clustering defined by the linkage `Z`.

Suppose `p` and `q` are original observations in disjoint clusters `s` and `t`, respectively and `s` and `t` are joined by a direct parent cluster `u`. The cophenetic distance between observations `i` and `j` is simply the distance between clusters `s` and `t`.

**Parameters**

- `Z`  
  [ndarray] The hierarchical clustering encoded as an array (see `linkage` function).
- `Y`  
  [ndarray (optional)] Calculates the cophenetic correlation coefficient `c` of a hierarchical clustering defined by the linkage matrix `Z` of a set of `n` observations in `m` dimensions. `Y` is the condensed distance matrix from which `Z` was generated.

**Returns**

- `c`  
  [ndarray] The cophenetic correlation distance (if `Y` is passed).
- `d`  
  [ndarray] The cophenetic distance matrix in condensed form. The `ij` th entry is the cophenetic distance between original observations `i` and `j`.

**See also:**

- `linkage`  
  for a description of what a linkage matrix is.
- `scipy.spatial.distance.squareform`  
  transforming condensed matrices into square ones.
Examples

```python
>>> from scipy.cluster.hierarchy import single, cophenet
>>> from scipy.spatial.distance import pdist, squareform
```

Given a dataset $X$ and a linkage matrix $Z$, the cophenetic distance between two points of $X$ is the distance between the largest two distinct clusters that each of the points:

```python
>>> X = [[0, 0], [0, 1], [1, 0],
       ... [0, 4], [0, 3], [1, 4],
       ... [4, 0], [3, 0], [4, 1],
       ... [4, 4], [3, 4], [4, 3]]

X corresponds to this dataset

```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
In this example, the cophenetic distance between points on X that are very close (i.e., in the same corner) is 1. For other pairs of points is 2, because the points will be located in clusters at different corners - thus, the distance between these clusters will be larger.

**scipy.cluster.hierarchy.from_mlab_linkage**

`scipy.cluster.hierarchy.from_mlab_linkage(Z)`

Convert a linkage matrix generated by MATLAB(TM) to a new linkage matrix compatible with this module.

The conversion does two things:

- the indices are converted from 1..N to 0..(N-1) form, and
- a fourth column $Z[:,3]$ is added where $Z[i,3]$ represents the number of original observations (leaves) in the non-singleton cluster $i$.

This function is useful when loading in linkages from legacy data files generated by MATLAB.

**Parameters**

**Returns**

$ZS$ [ndarray] A linkage matrix compatible with `scipy.cluster.hierarchy`.

**See also:**

`linkage` for a description of what a linkage matrix is.

`to_mlab_linkage` transform from SciPy to MATLAB format.

**Examples**

```python
>>> import numpy as np
>>> from scipy.cluster.hierarchy import ward, from_mlab_linkage
```

Given a linkage matrix in MATLAB format `mZ`, we can use `scipy.cluster.hierarchy.from_mlab_linkage` to import it into SciPy format:

```python
>>> mZ = np.array([[1, 2, 1], [4, 5, 1], [7, 8, 1],
                 ... [10, 11, 1], [3, 13, 1.29099445],
                 ... [6, 14, 1.29099445],
                 ... [9, 15, 1.29099445],
                 ... [12, 16, 1.29099445],
                 ... [17, 18, 5.77350269],
                 ... [19, 20, 5.77350269],
                 ... [21, 22, 8.16496581]])
```
As expected, the linkage matrix $Z$ returned includes an additional column counting the number of original samples in each cluster. Also, all cluster indices are reduced by 1 (MATLAB format uses 1-indexing, whereas SciPy uses 0-indexing).

**scipy.cluster.hierarchy.inconsistent**

`scipy.cluster.hierarchy.inconsistent(Z, d=2)`

Calculate inconsistency statistics on a linkage matrix.

**Parameters**

- **$Z$** [ndarray] The $(n-1)$ by 4 matrix encoding the linkage (hierarchical clustering). See `linkage` documentation for more information on its form.
- **d** [int, optional] The number of links up to $d$ levels below each non-singleton cluster.

**Returns**

- **$R$** [ndarray] A $(n-1)$ by 4 matrix where the $i$'th row contains the link statistics for the non-singleton cluster $i$. The link statistics are computed over the link heights for links $d$ levels below the cluster $i$. $R[i,0]$ and $R[i,1]$ are the mean and standard deviation of the link heights, respectively; $R[i,2]$ is the number of links included in the calculation; and $R[i,3]$ is the inconsistency coefficient,

$$\frac{Z[i,2] - R[i,0]}{R[i,1]}$$

**Notes**

This function behaves similarly to the MATLAB(TM) inconsistent function.
Examples

```python
>>> from scipy.cluster.hierarchy import inconsistent, linkage
>>> from matplotlib import pyplot as plt
>>> X = [[1] for i in [2, 8, 0, 4, 1, 9, 9, 0]]
>>> Z = linkage(X, 'ward')
>>> print(Z)
[[ 5. 6. 0. 2. ]
 [ 2. 7. 0. 2. ]
 [ 0. 4. 1. 2. ]
 [ 1. 8. 1.15470054 3. ]
 [ 9. 10. 2.12132034 4. ]
 [ 3. 12. 4.11096096 5. ]
>>> inconsistent(Z)
array([[ 0. , 0. , 1. , 0. ],
 [ 0. , 0. , 1. , 0. ],
 [ 1. , 0. , 1. , 0. ],
 [ 0.57735027, 0.81649658, 2. , 0.70710678],
 [ 1.04044011, 1.06123822, 3. , 1.01850858],
 [ 3.11614065, 1.40688837, 2. , 0.70710678],
 [ 6.44583366, 6.76770586, 3. , 1.12682288]])
```

**scipy.cluster.hierarchy.maxinconsts**

`scipy.cluster.hierarchy.maxinconsts(Z, R)`

Return the maximum inconsistency coefficient for each non-singleton cluster and its children.

**Parameters**

- **Z** ([ndarray]) The hierarchical clustering encoded as a matrix. See `linkage` for more information.
- **R** ([ndarray]) The inconsistency matrix.

**Returns**

- **MI** ([ndarray]) A monotonic \((n-1)\)-sized numpy array of doubles.

**See also:**

- `linkage`
  for a description of what a linkage matrix is.
- `inconsistent`
  for the creation of an inconsistency matrix.
Examples

```python
>>> from scipy.cluster.hierarchy import median, inconsistent, maxinconsts
>>> from scipy.spatial.distance import pdist

Given a data set \( X \), we can apply a clustering method to obtain a linkage matrix \( Z \). `scipy.cluster.hierarchy.inconsistent` can be used to obtain the inconsistency matrix \( R \) associated to this clustering process:

```python
>>> X = [[0, 0], [0, 1], [1, 0],
      ... [0, 4], [0, 3], [1, 4],
      ... [4, 0], [3, 0], [4, 1],
      ... [4, 4], [3, 4], [4, 3]]

>>> Z = median(pdist(X))
>>> R = inconsistent(Z)

Z
array([[ 0. ,  1. ,  1. ,  2. ],
       [ 3. ,  4. ,  1. ,  2. ],
       [ 9. , 10. ,  1. ,  2. ],
       [ 6. ,  7. ,  1. ,  2. ],
       [ 2. , 12. , 1.11803399, 3. ],
       [ 5. , 13. , 1.11803399, 3. ],
       [ 8. , 15. , 1.11803399, 3. ],
       [11. , 14. , 1.11803399, 3. ],
       [18. , 19. ,  3. ,  6. ],
       [16. , 17. ,  3.5 ,  6. ],
       [20. , 21. ,  3.25 , 12. ]])

R
array([[1. , 0. , 1. , 0. ],
       [1. , 0. , 1. , 0. ],
       [1. , 0. , 1. , 0. ],
       [1. , 0. , 1. , 0. ],
       [1.05901699, 0.08346263, 2. , 0.70710678],
       [1.05901699, 0.08346263, 2. , 0.70710678],
       [1.05901699, 0.08346263, 2. , 0.70710678],
       [1.05901699, 0.08346263, 2. , 0.70710678],
       [1.74535599, 1.08655358, 3. , 1.15470054],
       [1.91202266, 1.37522872, 3. , 1.15470054],
       [3.25 , 0.25 , 3. , 0. ]])
```

Here, `scipy.cluster.hierarchy.maxinconsts` can be used to compute the maximum value of the inconsistency statistic (the last column of \( R \)) for each non-singleton cluster and its children:

```python
>>> maxinconsts(Z, R)
array([0. , 0. , 0. , 0. , 0.70710678, 0.70710678, 0.70710678, 0.70710678, 1.15470054, 1.15470054, 1.15470054])
```
scipy.cluster.hierarchy.maxdists

scipy.cluster.hierarchy.maxdists(Z)

Return the maximum distance between any non-singleton cluster.

Parameters

Z [ndarray] The hierarchical clustering encoded as a matrix. See linkage for more information.

Returns

maxdists [ndarray] A \((n-1)\) sized numpy array of doubles; \(MD[i]\) represents the maximum distance between any cluster (including singletons) below and including the node with index \(i\). More specifically, \(MD[i] = Z[Q(i) - n, 2].max()\) where \(Q(i)\) is the set of all node indices below and including node \(i\).

See also:

linkage

for a description of what a linkage matrix is.

is_monotonic

for testing for monotonicity of a linkage matrix.

Examples

```python
>>> from scipy.cluster.hierarchy import median, maxdists
>>> from scipy.spatial.distance import pdist

Given a linkage matrix \(Z\), scipy.cluster.hierarchy.maxdists computes for each new cluster generated (i.e., for each row of the linkage matrix) what is the maximum distance between any two child clusters.

Due to the nature of hierarchical clustering, in many cases this is going to be just the distance between the two child clusters that were merged to form the current one - that is, \(Z[:,2]\).

However, for non-monotonic cluster assignments such as scipy.cluster.hierarchy.median clustering this is not always the case: There may be cluster formations were the distance between the two clusters merged is smaller than the distance between their children.

We can see this in an example:

```python
>>> X = [[0, 0], [0, 1], [1, 0],
      ... [0, 4], [0, 3], [1, 4],
      ... [4, 0], [3, 0], [4, 1],
      ... [4, 4], [3, 4], [4, 3]]
>>> Z = median(pdist(X))
>>> Z
array([[ 0. ,  1. ,  1. ,  2. ],
       [ 3. ,  4. ,  1. ,  2. ],
       [ 9. , 10. ,  1. ,  2. ],
       [ 6. ,  7. ,  1. ,  2. ],
       [ 2. , 12. , 1.11803399, 3. ],
       [ 5. , 13. , 1.11803399, 3. ]],
      (continues on next page)
Note that while the distance between the two clusters merged when creating the last cluster is 3.25, there are two children (clusters 16 and 17) whose distance is larger (3.5). Thus, \texttt{scipy.cluster.hierarchy.maxdists} returns 3.5 in this case.

\texttt{scipy.cluster.hierarchy.maxRstat}

\texttt{scipy.cluster.hierarchy.maxRstat}(Z, R, i)

Return the maximum statistic for each non-singleton cluster and its children.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{Z} [array_like] The hierarchical clustering encoded as a matrix. See \texttt{linkage} for more information.
  \item \texttt{R} [array_like] The inconsistency matrix.
  \item \texttt{i} [int] The column of \texttt{R} to use as the statistic.
\end{itemize}

\textbf{Returns}

\texttt{MR} [ndarray] Calculates the maximum statistic for the \texttt{i}th column of the inconsistency matrix \texttt{R} for each non-singleton cluster node. \texttt{MR[j]} is the maximum over \texttt{R[Q(j)-n, i]}, where \texttt{Q(j)} the set of all node ids corresponding to nodes below and including \texttt{j}.

\textbf{See also:}

\texttt{linkage}

for a description of what a linkage matrix is.

\texttt{inconsistent}

for the creation of an inconsistency matrix.

\textbf{Examples}

\begin{verbatim}
>>> from scipy.cluster.hierarchy import median, inconsistent, maxRstat
>>> from scipy.spatial.distance import pdist

Given a data set \texttt{X}, we can apply a clustering method to obtain a linkage matrix \texttt{Z}. \texttt{scipy.cluster.hierarchy.inconsistent} can be also used to obtain the inconsistency matrix \texttt{R} associated to this clustering process:

>>> X = [[0, 0], [0, 1], [1, 0],
      ... [0, 4], [0, 3], [1, 4],
      ... [4, 0], [3, 0], [4, 1],
      ... [4, 4], [3, 4], [4, 3]]
\end{verbatim}
>>> Z = median(pdist(X))
>>> R = inconsistent(Z)

```
array([[1. , 0. , 1. , 0. ],
       [1. , 0. , 1. , 0. ],
       [1. , 0. , 1. , 0. ],
       [1. , 0. , 1. , 0. ],
       [1.05901699, 0.08346263, 2. , 0. 70710678],
       [1.05901699, 0.08346263, 2. , 0. 70710678],
       [1.05901699, 0.08346263, 2. , 0. 70710678],
       [1.05901699, 0.08346263, 2. , 0. 70710678],
       [1.74535599, 1.08655358, 3. , 1.15470054],
       [1.91202266, 1.37522872, 3. , 1.15470054],
       [3.25 , 0.25 , 3. , 0. ]])
```

`scipy.cluster.hierarchy.maxRstat` can be used to compute the maximum value of each column of `R`, for each non-singleton cluster and its children:

```
>>> maxRstat(Z, R, 0)
a rray([1. , 1. , 1. , 1. , 1.05901699,
       1.05901699, 1.05901699, 1.05901699, 1.74535599, 1.91202266,
       3.25 ])
>>> maxRstat(Z, R, 1)
a rray([0. , 0. , 0. , 0. , 0.08346263,
       0.08346263, 0.08346263, 0.08346263, 1.08655358, 1.37522872125 ,
       1.37522872])
>>> maxRstat(Z, R, 3)
a rray([0. , 0. , 0. , 0. , 0.70710678,
       0.70710678, 0.70710678, 0.70710678, 1.15470054, 1.15470054,
       1.15470054])
```

`scipy.cluster.hierarchy.to_mlab_linkage`

`scipy.cluster.hierarchy.to_mlab_linkage(Z)`

Convert a linkage matrix to a MATLAB(TM) compatible one.

Converts a linkage matrix `Z` generated by the linkage function of this module to a MATLAB(TM) compatible one. The return linkage matrix has the last column removed and the cluster indices are converted to `1..N` indexing.

**Parameters**

`Z`  

**Returns**

`to_mlab_linkage`  
[ndarray] A linkage matrix compatible with MATLAB(TM)'s hierarchical clustering functions.

The return linkage matrix has the last column removed and the cluster indices are converted to `1..N` indexing.

**See also:**

`linkage`

for a description of what a linkage matrix is.
from_mlab_linkage

transform from Matlab to SciPy format.

Examples

```python
>>> from scipy.cluster.hierarchy import ward, to_mlab_linkage
>>> from scipy.spatial.distance import pdist

>>> X = [[0, 0], [0, 1], [1, 0],
     ... [0, 4], [0, 3], [1, 4],
     ... [4, 0], [3, 0], [4, 1],
     ... [4, 4], [3, 4], [4, 3]]

>>> Z = ward(pdist(X))
>>> Z
array([[ 0. ,  1. ,  1. ,  2. ],
       [ 3. ,  4. ,  1. ,  2. ],
       [ 6. ,  7. ,  1. ,  2. ],
       [ 9. , 10. ,  1. ,  2. ],
       [ 2. , 12. , 1.29099445, 3. ],
       [ 5. , 13. , 1.29099445, 3. ],
       [ 8. , 14. , 1.29099445, 3. ],
       [11. , 15. , 1.29099445, 3. ],
       [16. , 17. , 5.77350269, 6. ],
       [18. , 19. , 5.77350269, 6. ],
       [20. , 21. , 8.16496581, 12. ]])

After a linkage matrix \( Z \) has been created, we can use `scipy.cluster.hierarchy.to_mlab_linkage` to convert it into MATLAB format:

```python
>>> mZ = to_mlab_linkage(Z)
>>> mZ
array([[ 1. ,  2. ,  1. ],
       [ 4. ,  5. ,  1. ],
       [ 7. ,  8. ,  1. ],
       [10. , 11. ,  1. ],
       [ 3. , 13. , 1.29099445],
       [ 6. , 14. , 1.29099445],
       [ 9. , 15. , 1.29099445],
       [12. , 16. , 1.29099445],
       [17. , 18. , 5.77350269],
       [19. , 20. , 5.77350269],
       [21. , 22. , 8.16496581]])
```

The new linkage matrix \( mZ \) uses 1-indexing for all the clusters (instead of 0-indexing). Also, the last column of the original linkage matrix has been dropped.

Routines for visualizing flat clusters.

```
    dendrogram(Z[, p, truncate_mode, ...])
```
Plot the hierarchical clustering as a dendrogram.

scipy.cluster.hierarchy.dendrogram

```
scipy.cluster.hierarchy.dendrogram (Z, p=30, truncate_mode=None, color_threshold=None, get_leaves=True, orientation='top', labels=None, count_sort=False, distance_sort=False, show_leaf_counts=True, no_plot=False, no_labels=False, leaf_font_size=None, leaf_rotation=None, leaf_label_func=None, show_contracted=False, link_color_func=None, ax=None, above_threshold_color='C0')
```

Plot the hierarchical clustering as a dendrogram.

The dendrogram illustrates how each cluster is composed by drawing a U-shaped link between a non-singleton cluster and its children. The top of the U-link indicates a cluster merge. The two legs of the U-link indicate which clusters were merged. The length of the two legs of the U-link represents the distance between the child clusters. It is also the cophenetic distance between original observations in the two children clusters.

**Parameters**

- **Z** [ndarray] The linkage matrix encoding the hierarchical clustering to render as a dendrogram. See the `linkage` function for more information on the format of Z.
- **p** [int, optional] The p parameter for `truncate_mode`. truncate_mode [str, optional] The dendrogram can be hard to read when the original observation matrix from which the linkage is derived is large. Truncation is used to condense the dendrogram. There are several modes:
  - **None** No truncation is performed (default). Note: 'none' is an alias for None that's kept for backward compatibility.
  - **'lastp'** The last p non-singleton clusters formed in the linkage are the only non-leaf nodes in the linkage; they correspond to rows Z[n-p-2:end] in Z. All other non-singleton clusters are contracted into leaf nodes.
  - **'level'** No more than p levels of the dendrogram tree are displayed. A “level” includes all nodes with p merges from the final merge. Note: 'mtica' is an alias for 'level' that’s kept for backward compatibility.
- **color_threshold** [double, optional] For brevity, let t be the color_threshold. Colors all the descendent links below a cluster node k the same color if k is the first node below the cut threshold t. All links connecting nodes with distances greater than or equal to the threshold are colored with the default matplotlib color 'C0'. If t is less than or equal to zero, all nodes are colored 'C0'. If color_threshold is None or 'default', corresponding with MATLAB(TM) behavior, the threshold is set to 0.7*max(Z[:,2]).
- **get_leaves** [bool, optional] Includes a list R['leaves']=H in the result dictionary. For each i, H[i] == j, cluster node j appears in position i in the left-to-right traversal of the leaves, where j < 2n − 1 and i < n.
- **orientation** [str, optional] The direction to plot the dendrogram, which can be any of the following strings:
  - **'top'** Plots the root at the top, and plot descendent links going downwards. (default).
  - **'bottom'** Plots the root at the bottom, and plot descendent links going upwards.
  - **'left'** Plots the root at the left, and plot descendent links going right.
  - **'right'** Plots the root at the right, and plot descendent links going left.
- **labels** [ndarray, optional] By default, labels is None so the index of the original observation is used to label the leaf nodes. Otherwise, this is an n-sized sequence, with n == Z.shape[0] + 1. The labels[i] value is the text to put under the i th leaf node only if it corresponds to an original observation and not a non-singleton cluster.
count_sort
[str or bool, optional] For each node n, the order (visually, from left-to-right) n’s two descendant links are plotted is determined by this parameter, which can be any of the following values:

**False** Nothing is done.

'ascending' or True

The child with the minimum number of original objects in its cluster is plotted first.

'descending'

The child with the maximum number of original objects in its cluster is plotted first.

Note, distance_sort and count_sort cannot both be True.

distance_sort
[str or bool, optional] For each node n, the order (visually, from left-to-right) n’s two descendant links are plotted is determined by this parameter, which can be any of the following values:

**False** Nothing is done.

'ascending' or True

The child with the minimum distance between its direct descendents is plotted first.

'descending'

The child with the maximum distance between its direct descendents is plotted first.

Note distance_sort and count_sort cannot both be True.

show_leaf_counts
[bool, optional] When True, leaf nodes representing $k > 1$ original observation are labeled with the number of observations they contain in parentheses.

no_plot
[bool, optional] When True, the final rendering is not performed. This is useful if only the data structures computed for the rendering are needed or if matplotlib is not available.

no_labels
[bool, optional] When True, no labels appear next to the leaf nodes in the rendering of the dendrogram.

leaf_rotation
[double, optional] Specifies the angle (in degrees) to rotate the leaf labels. When unspecified, the rotation is based on the number of nodes in the dendrogram (default is 0).

leaf_font_size
[int, optional] Specifies the font size (in points) of the leaf labels. When unspecified, the size based on the number of nodes in the dendrogram.

leaf_label_func
[lambda or function, optional] When leaf_label_func is a callable function, for each leaf with cluster index $k < 2n - 1$. The function is expected to return a string with the label for the leaf.

Indices $k < n$ correspond to original observations while indices $k \geq n$ correspond to non-singleton clusters.

For example, to label singletons with their node id and non-singletons with their id, count, and inconsistency coefficient, simply do:

```python
# First define the leaf label function.
def llf(id):
    if id < n:
        return str(id)
    else:
        return '[%d %d %.2f]' % (id, count, R[n-id, 3])
```

(continues on next page)
# The text for the leaf nodes is going to be big so force
# a rotation of 90 degrees.
dendrogram(Z, leaf_label_func=llf, leaf_rotation=90)

# leaf_label_func can also be used together with...
# ... `truncate_mode` parameter,
# ... in which case you will get your leaves labeled after...
# ... truncation:
dendrogram(Z, leaf_label_func=llf, leaf_rotation=90,
          truncate_mode='level', p=2)

**show_contracted**

[bool, optional] When True the heights of non-singleton nodes contracted into a leaf node
are plotted as crosses along the link connecting that leaf node. This really is only useful when
truncation is used (see `truncate_mode` parameter).

**link_color_func**

[callable, optional] If given, `link_color_function` is called with each non-singleton id corre-
sponding to each U-shaped link it will paint. The function is expected to return the color to
paint the link, encoded as a matplotlib color string code. For example:

```python
dendrogram(Z, link_color_func=lambda k: colors[k])
```

colors the direct links below each untruncated non-singleton node `k` using `colors[k]`.

**ax**

[matplotlib Axes instance, optional] If None and `no_plot` is not True, the dendrogram will be
plotted on the current axes. Otherwise if `no_plot` is not True the dendrogram will be plotted
on the given Axes instance. This can be useful if the dendrogram is part of a more complex
figure.

**above_threshold_color**

[str, optional] This matplotlib color string sets the color of the links above the
color_threshold. The default is 'C0'.

**Returns**

R [dict] A dictionary of data structures computed to render the dendrogram. Its has the fol-
lowing keys:

- **'color_list'**
  A list of color names. The k'th element represents the color of the k'th link.

- **'icoord' and 'dcoord'**
  Each of them is a list of lists. Let `icoord = [I1, I2, ..., Ip]` where
  `Ik = [xk1, xk2, xk3, xk4]` and `dcoord = [D1, D2, ..., Dp]`
  where `Dk = [yk1, yk2, yk3, yk4]`, then the k'th link painted is
  `(xk1, yk1) - (xk2, yk2) - (xk3, yk3) - (xk4, yk4)`.

- **'ivl'**
  A list of labels corresponding to the leaf nodes.

- **'leaves'**
  For each i, H[i] == j, cluster node j appears in position i in the left-to-right
  traversal of the leaves, where j < 2n−1 and i < n. If j is less than n, the i-th
  leaf node corresponds to an original observation. Otherwise, it corresponds to
  a non-singleton cluster.

- **'leaves_color_list'**
  A list of color names. The k'th element represents the color of the k'th leaf.

See also:

- `linkage`
- `set_link_color_palette`
Notes

It is expected that the distances in $Z[:, 2]$ be monotonic, otherwise crossings appear in the dendrogram.

Examples

```python
>>> from scipy.cluster import hierarchy
>>> import matplotlib.pyplot as plt
```

A very basic example:

```python
>>> ytdist = np.array([662., 877., 255., 996., 295., 468., 268.,
                      400., 754., 564., 138., 219., 869., 669.])
>>> Z = hierarchy.linkage(ytdist, 'single')
>>> plt.figure()
>>> dn = hierarchy.dendrogram(Z)
```

Now, plot in given axes, improve the color scheme and use both vertical and horizontal orientations:

```python
>>> hierarchy.set_link_color_palette(['m', 'c', 'y', 'k'])
>>> fig, axes = plt.subplots(1, 2, figsize=(8, 3))
>>> dn1 = hierarchy.dendrogram(Z, ax=axes[0], above_threshold_color='y',
                              ... orientation='top')
>>> dn2 = hierarchy.dendrogram(Z, ax=axes[1],
                              ... above_threshold_color='#bcbddc',
                              ... orientation='right')
>>> hierarchy.set_link_color_palette(None)  # reset to default after use
>>> plt.show()
```

These are data structures and routines for representing hierarchies as tree objects.

**scipy.cluster.hierarchy.ClusterNode**

```python
class scipy.cluster.hierarchy.ClusterNode (id, left=None, right=None, dist=0, count=1)
```

A tree node class for representing a cluster.

Leaf nodes correspond to original observations, while non-leaf nodes correspond to non-singleton clusters.

The `to_tree` function converts a matrix returned by the linkage function into an easy-to-use tree representation.

All parameter names are also attributes.

**Parameters**

- `id` [int] The node id.
- `left` [ClusterNode instance, optional] The left child tree node.
- `right` [ClusterNode instance, optional] The right child tree node.
- `dist` [float, optional] Distance for this cluster in the linkage matrix.
- `count` [int, optional] The number of samples in this cluster.

**See also:**

`to_tree` for converting a linkage matrix Z into a tree object.

**Methods**

- `get_count()` The number of leaf nodes (original observations) belonging to the cluster node nd.
- `get_id()` The identifier of the target node.
- `get_left()` Return a reference to the left child tree object.
- `get_right()` Return a reference to the right child tree object.
- `is_leaf()` Return True if the target node is a leaf.
- `pre_order([func])` Perform pre-order traversal without recursive function calls.

**scipy.cluster.hierarchy.ClusterNode.get_count**

The number of leaf nodes (original observations) belonging to the cluster node nd. If the target node is a leaf, 1 is returned.

**Returns**

- `get_count` [int] The number of leaf nodes below the target node.
scipy.cluster.hierarchy.ClusterNode.get_id

ClusterNode.get_id()  
The identifier of the target node.  

For 0 <= i < n, i corresponds to original observation i. For n <= i < 2n-1, i corresponds to non-singleton cluster formed at iteration i-n.  

Returns  
id  [int] The identifier of the target node.

scipy.cluster.hierarchy.ClusterNode.get_left

ClusterNode.get_left()  
Return a reference to the left child tree object.  

Returns  
left  [ClusterNode] The left child of the target node. If the node is a leaf, None is returned.

scipy.cluster.hierarchy.ClusterNode.get_right

ClusterNode.get_right()  
Return a reference to the right child tree object.  

Returns  
right  [ClusterNode] The left child of the target node. If the node is a leaf, None is returned.

scipy.cluster.hierarchy.ClusterNode.is_leaf

ClusterNode.is_leaf()  
Return True if the target node is a leaf.  

Returns  
leafness  [bool] True if the target node is a leaf node.
scipy.cluster.hierarchy.ClusterNode.pre_order

ClusterNode.pre_order(func=<function ClusterNode.<lambda>>)
Perform pre-order traversal without recursive function calls.

When a leaf node is first encountered, func is called with the leaf node as its argument, and its result is appended to the list.

For example, the statement:

```python
ids = root.pre_order(lambda x: x.id)
```

returns a list of the node ids corresponding to the leaf nodes of the tree as they appear from left to right.

Parameters

func [function] Applied to each leaf ClusterNode object in the pre-order traversal. Given the i-th leaf node in the pre-order traversal n[i], the result of func(n[i]) is stored in L[i]. If not provided, the index of the original observation to which the node corresponds is used.

Returns

L [list] The pre-order traversal.

scipy.cluster.hierarchy.leaves_list

scipy.cluster.hierarchy.leaves_list(Z)
Return a list of leaf node ids.

The return corresponds to the observation vector index as it appears in the tree from left to right. Z is a linkage matrix.

Parameters

Z [ndarray] The hierarchical clustering encoded as a matrix. Z is a linkage matrix. See linkage for more information.

Returns

leaves_list [ndarray] The list of leaf node ids.

See also:
dendrogram
for information about dendrogram structure.

Examples

```python
>>> from scipy.cluster.hierarchy import ward, dendrogram, leaves_list
>>> from scipy.spatial.distance import pdist
>>> from matplotlib import pyplot as plt

>>> X = [[0, 0], [0, 1], [1, 0],
...     [0, 4], [0, 3], [1, 4],
...     [4, 0], [3, 0], [4, 1],
...     [4, 4], [3, 4], [4, 3]]
```
```
>>> Z = ward(pdist(X))
```

The linkage matrix $Z$ represents a dendrogram, that is, a tree that encodes the structure of the clustering performed. `scipy.cluster.hierarchy.leaves_list` shows the mapping between indices in the $X$ dataset and leaves in the dendrogram:

```
>>> leaves_list(Z)
array([ 2,  0,  1,  5,  3,  4,  8,  6,  7, 11,  9, 10], dtype=int32)
```

```
>>> fig = plt.figure(figsize=(25, 10))
>>> dn = dendrogram(Z)
>>> plt.show()
```

`scipy.cluster.hierarchy.to_tree`

`scipy.cluster.hierarchy.to_tree(Z, rd=False)`

Convert a linkage matrix into an easy-to-use tree object.

The reference to the root `ClusterNode` object is returned (by default).

Each `ClusterNode` object has a `left`, `right`, `dist`, `id`, and `count` attribute. The left and right attributes point to `ClusterNode` objects that were combined to generate the cluster. If both are `None` then the `ClusterNode` object is a leaf node, its count must be 1, and its distance is meaningless but set to 0.

Note: This function is provided for the convenience of the library user. `ClusterNodes` are not used as input to any of the functions in this library.

**Parameters**

- **Z** ([ndarray]) The linkage matrix in proper form (see the `linkage` function documentation).
- **rd** ([bool, optional]) When False (default), a reference to the root `ClusterNode` object is returned. Otherwise, a tuple $(r, d)$ is returned. $r$ is a reference to the root node while $d$ is a list of `ClusterNode` objects - one per original entry in the linkage matrix plus entries for all clustering steps. If a cluster id is less than the number of samples $n$ in the data that the linkage matrix describes, then it corresponds to a singleton cluster (leaf node). See `linkage` for more information on the assignment of cluster ids to clusters.

**Returns**
tree  [ClusterNode or tuple (ClusterNode, list of ClusterNode)] If \( rd \) is False, a ClusterNode. If \( rd \) is True, a list of length \( 2^n - 1 \), with \( n \) the number of samples. See the description of \( rd \) above for more details.

See also:

linkage, is_valid_linkage, ClusterNode

Examples

```python
>>> from scipy.cluster import hierarchy
>>> rng = np.random.default_rng()
>>> x = rng.random((5, 2))
>>> Z = hierarchy.linkage(x)
>>> hierarchy.to_tree(Z)
<scipy.cluster.hierarchy.ClusterNode object at ...>
>>> rootnode, nodelist = hierarchy.to_tree(Z, rd=True)
>>> rootnode
<scipy.cluster.hierarchy.ClusterNode object at ...>
>>> len(nodelist)
9
```

### scipy.cluster.hierarchy.cut_tree

**scipy.cluster.hierarchy.cut_tree** \((Z, n\_clusters=None, height=None)\)

Given a linkage matrix \( Z \), return the cut tree.

**Parameters**

- **Z**  
  [scipy.cluster.linkage array] The linkage matrix.
- **n_clusters**  
  [array_like, optional] Number of clusters in the tree at the cut point.
- **height**  
  [array_like, optional] The height at which to cut the tree. Only possible for ultrametric trees.

**Returns**

- **cutree**  
  [array] An array indicating group membership at each agglomeration step. I.e., for a full cut tree, in the first column each data point is in its own cluster. At the next step, two nodes are merged. Finally, all singleton and non-singleton clusters are in one group. If \( n\_clusters \) or \( height \) are given, the columns correspond to the columns of \( n\_clusters \) or \( height \).

**Examples**

```python
>>> from scipy import cluster
>>> import numpy as np
>>> from numpy.random import default_rng
>>> rng = default_rng()
>>> X = rng.random((50, 4))
>>> Z = cluster.hierarchy.ward(X)
>>> cutree = cluster.hierarchy.cut_tree(Z, n_clusters=[5, 10])
>>> cutree[:10]
array([[0, 0],
       [1, 1],
       ...
```

(continues on next page)
scipy.cluster.hierarchy.optimal_leaf_ordering

`scipy.cluster.hierarchy.optimal_leaf_ordering(Z, y, metric='euclidean')`

Given a linkage matrix Z and distance, reorder the cut tree.

**Parameters**

- **Z** [ndarray] The hierarchical clustering encoded as a linkage matrix. See `linkage` for more information on the return structure and algorithm.
- **y** [ndarray] The condensed distance matrix from which Z was generated. Alternatively, a collection of m observation vectors in n dimensions may be passed as an m by n array.
- **metric** [str or function, optional] The distance metric to use in the case that y is a collection of observation vectors; ignored otherwise. See the `pdist` function for a list of valid distance metrics. A custom distance function can also be used.

**Returns**

- **Z_ordered** [ndarray] A copy of the linkage matrix Z, reordered to minimize the distance between adjacent leaves.

**Examples**

```python
>>> from scipy.cluster import hierarchy
>>> rng = np.random.default_rng()
>>> X = rng.standard_normal((10, 10))
>>> Z = hierarchy.ward(X)
>>> hierarchy.leaves_list(Z)
array([0, 3, 1, 9, 2, 5, 7, 4, 6, 8], dtype=int32)
>>> hierarchy.leaves_list(hierarchy.optimal_leaf_ordering(Z, X))
array([3, 0, 2, 5, 7, 4, 8, 6, 9, 1], dtype=int32)
```

These are predicates for checking the validity of linkage and inconsistency matrices as well as for checking isomorphism of two flat cluster assignments.

<table>

scipy.cluster.hierarchy.is_valid_im

scipy.cluster.hierarchy.is_valid_im(R, warning=False, throw=False, name=None)

Return True if the inconsistency matrix passed is valid.

It must be a $n \times 4$ array of doubles. The standard deviations $R[:,1]$ must be nonnegative. The link counts $R[:,2]$ must be positive and no greater than $n - 1$.

Parameters

- $R$ [ndarray] The inconsistency matrix to check for validity.
- warning [bool, optional] When True, issues a Python warning if the linkage matrix passed is invalid.
- throw [bool, optional] When True, throws a Python exception if the linkage matrix passed is invalid.
- name [str, optional] This string refers to the variable name of the invalid linkage matrix.

Returns

- $b$ [bool] True if the inconsistency matrix is valid.

See also:

- linkage
  for a description of what a linkage matrix is.
- inconsistent
  for the creation of a inconsistency matrix.

Examples

```python
>>> from scipy.cluster.hierarchy import ward, inconsistent, is_valid_im
>>> from scipy.spatial.distance import pdist
```

Given a data set $X$, we can apply a clustering method to obtain a linkage matrix $Z$. scipy.cluster.hierarchy.inconsistent can be also used to obtain the inconsistency matrix $R$ associated to this clustering process:

```python
>>> X = [[0, 0], [0, 1], [1, 0],
      [0, 4], [0, 3], [1, 4],
      [4, 0], [3, 0], [4, 1],
      [4, 4], [3, 4], [4, 3]]
```

```python
>>> Z = ward(pdist(X))
```

```python
>>> R = inconsistent(Z)
```

```python
>>> Z
array([[ 0. , 1. , 1. , 2. ],
       [ 3. , 4. , 1. , 2. ],
       [ 6. , 7. , 1. , 2. ],
       [ 9. , 10. , 1. , 2. ],
       [ 2. , 12. , 1.29099445, 3. ]], dtype=object)
```

(continues on next page)
Now we can use `scipy.cluster.hierarchy.is_valid_im` to verify that `R` is correct:

```python
>>> is_valid_im(R)
True
```

However, if `R` is wrongly constructed (e.g., one of the standard deviations is set to a negative value), then the check will fail:

```python
>>> R[-1,1] = R[-1,1] * -1
>>> is_valid_im(R)
False
```

### `scipy.cluster.hierarchy.is_valid linkage`

`scipy.cluster.hierarchy.is_valid linkage(Z, warning=False, throw=False, name=None)`

Check the validity of a linkage matrix.

A linkage matrix is valid if it is a 2-D array (type double) with `n` rows and 4 columns. The first two columns must contain indices between 0 and `2n - 1`. For a given row `i`, the following two expressions have to hold:

\[ 0 \leq Z[i, 0] \leq i + n - 1 \leq Z[i, 1] \leq i + n - 1 \]

I.e., a cluster cannot join another cluster unless the cluster being joined has been generated.

**Parameters**

- `Z` : [array_like] Linkage matrix.
- `warning` : [bool, optional] When True, issues a Python warning if the linkage matrix passed is invalid.
- `throw` : [bool, optional] When True, throws a Python exception if the linkage matrix passed is invalid.
- `name` : [str, optional] This string refers to the variable name of the invalid linkage matrix.

**Returns**

- `b` : [bool] True if the inconsistency matrix is valid.

**See also:**
**linkage**

for a description of what a linkage matrix is.

**Examples**

```python
>>> from scipy.cluster.hierarchy import ward, is_valid_linkage
>>> from scipy.spatial.distance import pdist

All linkage matrices generated by the clustering methods in this module will be valid (i.e., they will have the appropriate dimensions and the two required expressions will hold for all the rows).

We can check this using `scipy.cluster.hierarchy.is_valid_linkage`:

```python
>>> X = [[0, 0], [0, 1], [1, 0],
       ... [0, 4], [0, 3], [1, 4],
       ... [4, 0], [3, 0], [4, 1],
       ... [4, 4], [3, 4], [4, 3]]

>>> Z = ward(pdist(X))
>>> Z
array([[ 0.,  1.,  1.,  2.],
       [ 3.,  4.,  1.,  2.],
       [ 6.,  7.,  1.,  2.],
       [ 9., 10.,  1.,  2.],
       [ 2., 12., 1.29099445, 3.],
       [ 5., 13., 1.29099445, 3.],
       [ 8., 14., 1.29099445, 3.],
       [11., 15., 1.29099445, 3.],
       [16., 17., 5.77350269, 6.],
       [18., 19., 5.77350269, 6.],
       [20., 21., 8.16496581, 12.]])
```

```python
>>> is_valid_linkage(Z)
True
```

However, if we create a linkage matrix in a wrong way — or if we modify a valid one in a way that any of the required expressions don’t hold anymore, then the check will fail:

```python
>>> Z[3][1] = 20     # the cluster number 20 is not defined at this point
>>> is_valid_linkage(Z)
False
```

**scipy.cluster.hierarchy.is_isomorphic**

**scipy.cluster.hierarchy.is_isomorphic(T1, T2)**

Determine if two different cluster assignments are equivalent.

**Parameters**

- **T1** 
  - [array_like] An assignment of singleton cluster ids to flat cluster ids.

- **T2** 
  - [array_like] An assignment of singleton cluster ids to flat cluster ids.

**Returns**

- **b** 
  - [bool] Whether the flat cluster assignments T1 and T2 are equivalent.
See also:

**linkage**

for a description of what a linkage matrix is.

**fcluster**

for the creation of flat cluster assignments.

### Examples

```python
>>> from scipy.cluster.hierarchy import fcluster, is_isomorphic
>>> from scipy.cluster.hierarchy import single, complete
>>> from scipy.spatial.distance import pdist

Two flat cluster assignments can be isomorphic if they represent the same cluster assignment, with different labels. For example, we can use the `scipy.cluster.hierarchy.single`: method and flatten the output to four clusters:

```python
>>> X = [[0, 0], [0, 1], [1, 0],
...      [0, 4], [0, 3], [1, 4],
...      [4, 0], [3, 0], [4, 1],
...      [4, 4], [3, 4], [4, 3]]

>>> Z = single(pdist(X))
>>> T = fcluster(Z, 1, criterion='distance')
>>> T
array([3, 3, 3, 4, 4, 4, 2, 2, 2, 1, 1, 1], dtype=int32)
```

We can then do the same using the `scipy.cluster.hierarchy.complete`: method:

```python
>>> Z = complete(pdist(X))
>>> T_ = fcluster(Z, 1.5, criterion='distance')
>>> T_
array([1, 1, 1, 2, 2, 2, 3, 3, 3, 4, 4, 4], dtype=int32)
```

As we can see, in both cases we obtain four clusters and all the data points are distributed in the same way - the only thing that changes are the flat cluster labels (3 => 1, 4 =>2, 2 =>3 and 4 =>1), so both cluster assignments are isomorphic:

```python
>>> is_isomorphic(T, T_)
```

True
**scipy.cluster.hierarchy.is_monotonic**

`scipy.cluster.hierarchy.is_monotonic(Z)`

Return True if the linkage passed is monotonic.

The linkage is monotonic if for every cluster $s$ and $t$ joined, the distance between them is no less than the distance between any previously joined clusters.

**Parameters**

- **Z**: [ndarray] The linkage matrix to check for monotonicity.

**Returns**

- **b**: [bool] A boolean indicating whether the linkage is monotonic.

**See also:**

`linkage` for a description of what a linkage matrix is.

**Examples**

```python
>>> from scipy.cluster.hierarchy import median, ward, is_monotonic
>>> from scipy.spatial.distance import pdist

By definition, some hierarchical clustering algorithms - such as `scipy.cluster.hierarchy.ward` - produce monotonic assignments of samples to clusters; however, this is not always true for other hierarchical methods - e.g. `scipy.cluster.hierarchy.median`.

Given a linkage matrix $Z$ (as the result of a hierarchical clustering method) we can test programmatically whether it has the monotonicity property or not, using `scipy.cluster.hierarchy.is_monotonic`:

```python
>>> X = [[0, 0], [0, 1], [1, 0],
      ... [0, 4], [0, 3], [1, 4],
      ... [4, 0], [3, 0], [4, 1],
      ... [4, 4], [3, 4], [4, 3]]

>>> Z = ward(pdist(X))

>>> is_monotonic(Z)
True
```
>>> Z = median(pdist(X))
>>> Z
array([[ 0. ,  1. ,  1. ,  2. ],
       [ 3. ,  4. ,  1. ,  2. ],
       [ 9. , 10. ,  1. ,  2. ],
       [ 6. ,  7. ,  1. ,  2. ],
       [ 2. , 12. ,  1.11803399, 3. ],
       [ 5. , 13. ,  1.11803399, 3. ],
       [ 8. , 15. ,  1.11803399, 3. ],
       [11. , 14. ,  1.11803399, 3. ],
       [18. , 19. ,  3. ,  6. ],
       [16. , 17. ,  3.5 ,  6. ],
       [20. , 21. ,  3.25 , 12. ]])
>>> is_monotonic(Z)
False

Note that this method is equivalent to just verifying that the distances in the third column of the linkage matrix appear in a monotonically increasing order.

**scipy.cluster.hierarchy.correspond**

*scipy.cluster.hierarchy.correspond*(Z, Y)

Check for correspondence between linkage and condensed distance matrices. They must have the same number of original observations for the check to succeed. This function is useful as a sanity check in algorithms that make extensive use of linkage and distance matrices that must correspond to the same set of original observations.

**Parameters**

- **Z** [array_like] The linkage matrix to check for correspondence.
- **Y** [array_like] The condensed distance matrix to check for correspondence.

**Returns**

- **b** [bool] A boolean indicating whether the linkage matrix and distance matrix could possibly correspond to one another.

**See also:**

*linkage* for a description of what a linkage matrix is.

**Examples**

```python
>>> from scipy.cluster.hierarchy import ward, correspond
>>> from scipy.spatial.distance import pdist
```

This method can be used to check if a given linkage matrix Z has been obtained from the application of a cluster method over a dataset X:
```python
>>> X = [[0, 0], [0, 1], [1, 0],
...      [0, 4], [0, 3], [1, 4],
...      [4, 0], [3, 0], [4, 1],
...      [4, 4], [3, 4], [4, 3]]
>>> X_condensed = pdist(X)
>>> Z = ward(X_condensed)

Here, we can compare Z and X (in condensed form):

```python
>>> correspond(Z, X_condensed)
True
```
**scipy.cluster.hierarchy.set_link_color_palette**

`scipy.cluster.hierarchy.set_link_color_palette(palette)`

Set list of matplotlib color codes for use by dendrogram.

Note that this palette is global (i.e., setting it once changes the colors for all subsequent calls to `dendrogram`) and that it affects only the the colors below `color_threshold`.

Note that `dendrogram` also accepts a custom coloring function through its `link_color_func` keyword, which is more flexible and non-global.

**Parameters**

- **palette** [list of str or None] A list of matplotlib color codes. The order of the color codes is the order in which the colors are cycled through when color thresholding in the dendrogram.

  If None, resets the palette to its default (which are matplotlib default colors C1 to C9).

**Returns**

None

See also:

dendrogram

**Notes**

Ability to reset the palette with None added in SciPy 0.17.0.

**Examples**

```python
>>> from scipy.cluster import hierarchy
>>> ytdist = np.array([662., 877., 255., 412., 996., 295., 468., 268.,
                     ...  402., 754., 564., 138., 219., 869., 669.])
>>> Z = hierarchy.linkage(ytdist, 'single')
>>> dn = hierarchy.dendrogram(Z, no_plot=True)
>>> dn['color_list']
['C1', 'C0', 'C0', 'C0', 'C0']
>>> hierarchy.set_link_color_palette(['c', 'm', 'y', 'k'])
>>> dn = hierarchy.dendrogram(Z, no_plot=True, above_threshold_color='b')
>>> dn['color_list']
['c', 'b', 'b', 'b', 'b']
>>> dn = hierarchy.dendrogram(Z, no_plot=True, color_threshold=267,
                           above_threshold_color='k')
>>> dn['color_list']
['c', 'm', 'k', 'k']
```

Now, reset the color palette to its default:

```python
>>> hierarchy.set_link_color_palette(None)
```

Utility classes:
DisjointSet([elements])

Disjoint set data structure for incremental connectivity queries.

**scipy.cluster.hierarchy.DisjointSet**

```python
class scipy.cluster.hierarchy.DisjointSet (elements=None)

Disjoint set data structure for incremental connectivity queries.
New in version 1.6.0.
```

**Notes**

This class implements the disjoint set \([1]\), also known as the union-find or merge-find data structure. The `find` operation (implemented in `__getitem__`) implements the path halving variant. The `merge` method implements the merge by size variant.

**References**

[1]

**Examples**

```python
>>> from scipy.cluster.hierarchy import DisjointSet

Initialize a disjoint set:

```python
>>> disjoint_set = DisjointSet([1, 2, 3, 'a', 'b'])
```

Merge some subsets:

```python
>>> disjoint_set.merge(1, 2)
True
>>> disjoint_set.merge(3, 'a')
True
>>> disjoint_set.merge('a', 'b')
True
>>> disjoint_set.merge('b', 'b')
False
```

Find root elements:

```python
>>> disjoint_set[2]
1
>>> disjoint_set['b']
3
```

Test connectivity:
List elements in disjoint set:

```python
>>> list(disjoint_set)
[1, 2, 3, 'a', 'b']
```

Get the subset containing ‘a’:

```python
>>> disjoint_set.subset('a')
{'a', 3, 'b'}
```

Get all subsets in the disjoint set:

```python
>>> disjoint_set.subsets()
[{{1, 2}, {'a', 3, 'b'}}]
```

**Attributes**

- **n_subsets** [int] The number of subsets.

**Methods**

<table>

**scipy.cluster.hierarchy.DisjointSet.add**

DisjointSet.add(x)
Add element x to disjoint set

**scipy.cluster.hierarchy.DisjointSet.merge**

DisjointSet.merge(x, y)
Merge the subsets of x and y.

The smaller subset (the child) is merged into the larger subset (the parent). If the subsets are of equal size, the root element which was first inserted into the disjoint set is selected as the parent.

**Parameters**

- **x, y** [hashable object] Elements to merge.

**Returns**

- **merged** [bool] True if x and y were in disjoint sets, False otherwise.
scipy.cluster.hierarchy.DisjointSet.connected

DisjointSet.connected(x, y)
Test whether x and y are in the same subset.

Parameters
x, y [hashable object] Elements to test.

Returns
result [bool] True if x and y are in the same set, False otherwise.

scipy.cluster.hierarchy.DisjointSet.subset

DisjointSet.subset(x)
Get the subset containing x.

Parameters
x [hashable object] Input element.

Returns
result [set] Subset containing x.

scipy.cluster.hierarchy.DisjointSet.subsets

DisjointSet.subsets()
Get all the subsets in the disjoint set.

Returns
result [list] Subsets in the disjoint set.

scipy.cluster.hierarchy.DisjointSet.__getitem__

DisjointSet.__getitem__(x)
Find the root element of x.

Parameters
x [hashable object] Input element.

Returns
root [hashable object] Root element of x.

3.3.4 Constants (scipy.constants)

Physical and mathematical constants and units.

### Constants database

In addition to the above variables, `scipy.constants` also contains the 2018 CODATA recommended values [CODATA2018] database containing more physical constants.

<table>
<thead>
<tr>
<th>value(key)</th>
<th>Value in physical_constants indexed by key</th>
</tr>
</thead>
<tbody>
<tr>
<td>unit(key)</td>
<td>Unit in physical_constants indexed by key</td>
</tr>
<tr>
<td>precision(key)</td>
<td>Relative precision in physical_constants indexed by key</td>
</tr>
<tr>
<td>find([sub, displ])</td>
<td>Return list of physical_constant keys containing a given string.</td>
</tr>
</tbody>
</table>
Table 12 – continued from previous page

**ConstantWarning**

Accessing a constant no longer in current CODATA data set

---

**scipy.constants.value**

*scipy.constants.value*(key)

Value in `physical_constants` indexed by key

- **Parameters**
  - `key` ([Python string or unicode]) Key in dictionary `physical_constants`

- **Returns**
  - `value` ([float]) Value in `physical_constants` corresponding to `key`

**Examples**

```python
>>> from scipy import constants
>>> constants.value(u'elementary charge')
1.602176634e-19
```

**scipy.constants.unit**

*scipy.constants.unit*(key)

Unit in `physical_constants` indexed by key

- **Parameters**
  - `key` ([Python string or unicode]) Key in dictionary `physical_constants`

- **Returns**
  - `unit` ([Python string]) Unit in `physical_constants` corresponding to `key`

**Examples**

```python
>>> from scipy import constants
>>> constants.unit(u'proton mass')
'kg'
```

**scipy.constants.precision**

*scipy.constants.precision*(key)

Relative precision in `physical_constants` indexed by key

- **Parameters**
  - `key` ([Python string or unicode]) Key in dictionary `physical_constants`

- **Returns**
  - `prec` ([float]) Relative precision in `physical_constants` corresponding to `key`
Examples

```python
>>> from scipy import constants
>>> constants.precision(u'proton mass')
5.1e-37
```

**scipy.constants.find**

```
scipy.constants.find(sub=None, disp=False)
```

Return list of physical constant keys containing a given string.

**Parameters**

- `sub` [str, unicode] Sub-string to search keys for. By default, return all keys.
- `disp` [bool] If True, print the keys that are found and return None. Otherwise, return the list of keys without printing anything.

**Returns**

- `keys` [list or None] If `disp` is False, the list of keys is returned. Otherwise, None is returned.

Examples

```python
>>> from scipy.constants import find, physical_constants

Which keys in the `physical_constants` dictionary contain 'boltzmann'?

```python
>>> find('boltzmann')
['Boltzmann constant',
 'Boltzmann constant in Hz/K',
 'Boltzmann constant in eV/K',
 'Boltzmann constant in inverse meter per kelvin',
 'Stefan-Boltzmann constant']
```

Get the constant called 'Boltzmann constant in Hz/K':

```python
>>> physical_constants['Boltzmann constant in Hz/K']
(20836619120.0, 'Hz K^-1', 0.0)
```

Find constants with 'radius' in the key:

```python
>>> find('radius')
['Bohr radius',
 'classical electron radius',
 'deuteron rms charge radius',
 'proton rms charge radius']
```

```python
>>> physical_constants['classical electron radius']
(2.8179403262e-15, 'm', 1.3e-24)
```
scipy.constants.ConstantWarning

**exception** scipy.constants.ConstantWarning
Accessing a constant no longer in current CODATA data set

**with_traceback()**

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

scipy.constants.physical_constants
Dictionary of physical constants, of the format:

```
physical_constants[name] = (value, unit, uncertainty).
```

Available constants:

convert_temperature(val, old_scale, new_scale)

Convert from a temperature scale to another one among Celsius, Kelvin, Fahrenheit, and Rankine scales.

Parameters

- **val**: [array_like] Value(s) of the temperature(s) to be converted expressed in the original scale.
- **old_scale**: str
  Specifies as a string the original scale from which the temperature value(s) will be converted. Supported scales are Celsius (‘Celsius’, ‘celsius’, ‘C’ or ‘c’), Kelvin (‘Kelvin’, ‘kelvin’, ‘K’, ‘k’), Fahrenheit (‘Fahrenheit’, ‘fahrenheit’, ‘F’ or ‘°F’), and Rankine (‘Rankine’, ‘rankine’, ‘R’, ‘°R’).
- **new_scale**: str
  Specifies as a string the new scale to which the temperature value(s) will be converted. Supported scales are Celsius (‘Celsius’, ‘celsius’, ‘C’ or ‘c’), Kelvin (‘Kelvin’, ‘kelvin’, ‘K’, ‘k’), Fahrenheit (‘Fahrenheit’, ‘fahrenheit’, ‘F’ or ‘°F’), and Rankine (‘Rankine’, ‘rankine’, ‘R’, ‘°R’).
Returns

res [float or array of floats] Value(s) of the converted temperature(s) expressed in the new scale.

Notes

New in version 0.18.0.

Examples

```python
>>> from scipy.constants import convert_temperature
>>> convert_temperature(np.array([-40, 40]), 'Celsius', 'Kelvin')
array([ 233.15, 313.15])
```

<td>Convert wavelength to optical frequency</td>
</tr>
<tr>
<td>( \text{nu2lambda} ) (( \nu ))</td>
<td>Convert optical frequency to wavelength.</td>
</tr>
</tbody>
</table>

**scipy.constants.lambda2nu**

\[
\text{scipy.constants.lambda2nu} (\lambda) \\
\text{Convert wavelength to optical frequency}
\]

**Parameters**

- \( \lambda \) [array_like] Wavelength(s) to be converted.

**Returns**

- \( \nu \) [float or array of floats] Equivalent optical frequency.

**Notes**

Computes \( \nu = \frac{c}{\lambda} \) where \( c = 299792458.0 \), i.e., the (vacuum) speed of light in meters/second.

**Examples**

```python
>>> from scipy.constants import lambda2nu, speed_of_light
>>> lambda2nu(np.array((1, speed_of_light)))
array([ 2.99792458e+08, 1.00000000e+00])
```

**scipy.constants.nu2lambda**

\[
\text{scipy.constants.nu2lambda} (\nu) \\
\text{Convert optical frequency to wavelength.}
\]

**Parameters**

- \( \nu \) [array_like] Optical frequency to be converted.

**Returns**

- \( \lambda \) [float or array of floats] Equivalent wavelength(s).

**Notes**

Computes \( \lambda = \frac{c}{\nu} \) where \( c = 299792458.0 \), i.e., the (vacuum) speed of light in meters/second.
Examples

```python
>>> from scipy.constants import nu2lambda, speed_of_light
>>> nu2lambda(np.array((1, speed_of_light)))
array([ 2.99792458e+08, 1.00000000e+00])
```

scipy.fft.fft

The function computes the 1-D $n$-point discrete Fourier Transform (DFT) with the efficient Fast Fourier Transform (FFT) algorithm [1].

**Parameters**

- **x** [array_like] Input array, can be complex.
- **n** [int, optional] Length of the transformed axis of the output. If $n$ is smaller than the length of the input, the input is cropped. If it is larger, the input is padded with zeros. If $n$ is not given, the length of the input along the axis specified by `axis` is used.
- **axis** [int, optional] Axis over which to compute the FFT. If not given, the last axis is used.
norm [[“backward”, “ortho”, “forward”], optional] Normalization mode. Default is “backward”, meaning no normalization on the forward transforms and scaling by $1/n$ on the ifft. “forward” instead applies the $1/n$ factor on the forward transform. For norm="ortho", both directions are scaled by $1/\sqrt{n}$.

New in version 1.6.0: norm={"forward", "backward"} options were added

overwrite_x [bool, optional] If True, the contents of x can be destroyed; the default is False. See the notes below for more details.

workers [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from os.cpu_count(). See below for more details.

plan [object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy.

New in version 1.5.0.

Returns

out [complex ndarray] The truncated or zero-padded input, transformed along the axis indicated by axis, or the last one if axis is not specified.

Raises

IndexError

if axes is larger than the last axis of x.

See also:

ifft

The inverse of fft.

fft2

The 2-D FFT.

fftn

The N-D FFT.

rfftn

The N-D FFT of real input.

fftfreq

Frequency bins for given FFT parameters.

next_fast_len

Size to pad input to for most efficient transforms

Notes

FFT (Fast Fourier Transform) refers to a way the discrete Fourier Transform (DFT) can be calculated efficiently, by using symmetries in the calculated terms. The symmetry is highest when $n$ is a power of 2, and the transform is therefore most efficient for these sizes. For poorly factorizable sizes, scipy.fft uses Bluestein's algorithm [2] and so is never worse than $O(n \log n)$. Further performance improvements may be seen by zero-padding the input using next_fast_len.

If $x$ is a 1d array, then the fft is equivalent to

$$y[k] = \text{np.sum}(x * \text{np.exp}(-2j * \text{np.pi} * k * \text{np.arange}(n)/n))$$
The frequency term $f = k/n$ is found at $y[k]$. At $y[n/2]$ we reach the Nyquist frequency and wrap around to the negative-frequency terms. So, for an 8-point transform, the frequencies of the result are $[0, 1, 2, 3, -4, -3, -2, -1]$. To rearrange the fft output so that the zero-frequency component is centered, like $[-4, -3, -2, -1, 0, 1, 2, 3]$, use `fftshift`.

Transforms can be done in single, double, or extended precision (long double) floating point. Half precision inputs will be converted to single precision and non-floating-point inputs will be converted to double precision.

If the data type of $x$ is real, a “real FFT” algorithm is automatically used, which roughly halves the computation time. To increase efficiency a little further, use `rfft`, which does the same calculation, but only outputs half of the symmetrical spectrum. If the data are both real and symmetrical, the `dct` can again double the efficiency, by generating half of the spectrum from half of the signal.

When `overwrite_x=True` is specified, the memory referenced by $x$ may be used by the implementation in any way. This may include reusing the memory for the result, but this is in no way guaranteed. You should not rely on the contents of $x$ after the transform as this may change in future without warning.

The `workers` argument specifies the maximum number of parallel jobs to split the FFT computation into. This will execute independent 1-D FFTs within $x$. So, $x$ must be at least 2-D and the non-transformed axes must be large enough to split into chunks. If $x$ is too small, fewer jobs may be used than requested.

**References**

[1], [2]

**Examples**

```python
>>> import scipy.fftp
>>> scipy.fftp.fft(np.exp(2j * np.pi * np.arange(8) / 8))
array([-2.33486982e-16+1.14423775e-17j, 8.00000000e+00-1.25557246e-15j,
       2.33486982e-16+2.33486982e-16j, 0.00000000e+00+1.22464680e-16j,
       -1.14423775e-17+2.33486982e-16j, 0.00000000e+00+5.20784380e-16j,
       1.14423775e-17+1.14423775e-17j, 0.00000000e+00+1.22464680e-16j])
```

In this example, real input has an FFT which is Hermitian, i.e., symmetric in the real part and anti-symmetric in the imaginary part:

```python
>>> from scipy.fft import fft, fftfreq, fftshift
>>> import matplotlib.pyplot as plt
>>> t = np.arange(256)
>>> sp = fftshift(fft(np.sin(t)))
>>> freq = fftfreq(t.shape[-1])
>>> plt.plot(freq, sp.real, freq, sp.imag)
[<matplotlib.lines.Line2D object at 0x...>, <matplotlib.lines.Line2D...
>>> plt.show()
```
scipy.fft.ifft

scipy.fft.ifft(x, n=None, axis=-1, norm=None, overwrite_x=False, workers=None, *, plan=None)

Compute the 1-D inverse discrete Fourier Transform.

This function computes the inverse of the 1-D n-point discrete Fourier transform computed by \textit{fft}. In other words, \textit{ifft}(\textit{fft}(x)) == x to within numerical accuracy.

The input should be ordered in the same way as is returned by \textit{fft}, i.e.,

- \( x[0] \) should contain the zero frequency term,
- \( x[1:n//2] \) should contain the positive-frequency terms,
- \( x[n//2 + 1:] \) should contain the negative-frequency terms, in increasing order starting from the most negative frequency.

For an even number of input points, \( x[n//2] \) represents the sum of the values at the positive and negative Nyquist frequencies, as the two are aliased together. See \textit{fft} for details.

Parameters

\( x \) [array_like] Input array, can be complex.
\( n \) [int, optional] Length of the transformed axis of the output. If \( n \) is smaller than the length of the input, the input is cropped. If it is larger, the input is padded with zeros. If \( n \) is not given, the length of the input along the axis specified by \( axis \) is used. See notes about padding issues.
\( axis \) [int, optional] Axis over which to compute the inverse DFT. If not given, the last axis is used.
\( norm \) [{“backward”, “ortho”, “forward”}, optional] Normalization mode (see \textit{fft}). Default is “backward”.
\( overwrite_x \) [bool, optional] If True, the contents of \( x \) can be destroyed; the default is False. See \textit{fft} for more details.
\( workers \) [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from \textit{os.cpu_count()}. See \textit{fft} for more details.
\( plan \) [object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy.

New in version 1.5.0.
**Returns**

- `out` [complex ndarray] The truncated or zero-padded input, transformed along the axis indicated by `axis`, or the last one if `axis` is not specified.

**Raises**

- `IndexError` If `axes` is larger than the last axis of `x`.

**See also:**

- `fft`
  - The 1-D (forward) FFT, of which `ifft` is the inverse.

- `ifft2`
  - The 2-D inverse FFT.

- `ifftn`
  - The N-D inverse FFT.

**Notes**

If the input parameter `n` is larger than the size of the input, the input is padded by appending zeros at the end. Even though this is the common approach, it might lead to surprising results. If a different padding is desired, it must be performed before calling `ifft`.

If `x` is a 1-D array, then the `ifft` is equivalent to

\[
y[k] = \frac{\text{np.sum}(x \times \text{np.exp}(2j \times \text{np.pi} \times k \times \text{np.arange}(n)/n))}{\text{len}(x)}
\]

As with `fft`, `ifft` has support for all floating point types and is optimized for real input.

**Examples**

```python
>>> import scipy.fft
>>> scipy.fft.ifft([0, 4, 0, 0])
array([ 1.+0.j, 0.+1.j, -1.+0.j, 0.-1.j]) # may vary
```

Create and plot a band-limited signal with random phases:

```python
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
>>> t = np.arange(400)
>>> n = np.zeros((400,), dtype=complex)
>>> n[40:60] = np.exp(1j*rng.uniform(0, 2*np.pi, (20,)))
>>> s = scipy.fft.ifft(n)
>>> plt.plot(t, s.real, 'b-', t, s.imag, 'r--')
[<matplotlib.lines.Line2D object at ...>, <matplotlib.lines.Line2D object at ...>]
>>> plt.legend(('real', 'imaginary'))
<matplotlib.legend.Legend object at ...>
>>> plt.show()
```

scipy.fft.fft2

scipy.fft.fft2(x, s=None, axes=(-2, -1), norm=None, overwrite_x=False, workers=None, *, plan=None)

Compute the 2-D discrete Fourier Transform

This function computes the N-D discrete Fourier Transform over any axes in an M-D array by means of the Fast Fourier Transform (FFT). By default, the transform is computed over the last two axes of the input array, i.e., a 2-dimensional FFT.

Parameters

- **x** [array_like] Input array, can be complex
- **s** [sequence of ints, optional] Shape (length of each transformed axis) of the output (s[0] refers to axis 0, s[1] to axis 1, etc.). This corresponds to n for fft(x, n). Along each axis, if the given shape is smaller than that of the input, the input is cropped. If it is larger, the input is padded with zeros. if s is not given, the shape of the input along the axes specified by axes is used.
- **axes** [sequence of ints, optional] Axes over which to compute the FFT. If not given, the last two axes are used.
- **norm** [{“backward”, “ortho”, “forward”}, optional] Normalization mode (see fft). Default is “backward”.
- **overwrite_x** [bool, optional] If True, the contents of x can be destroyed; the default is False. See fft for more details.
- **workers** [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from os.cpu_count(). See fft for more details.
- **plan** [object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy. New in version 1.5.0.

Returns

- **out** [complex ndarray] The truncated or zero-padded input, transformed along the axes indicated by axes, or the last two axes if axes is not given.

Raises

ValueError
If \( s \) and \( axes \) have different length, or \( axes \) not given and \( \text{len}(s) \neq 2 \).

**IndexError**
If an element of \( axes \) is larger than than the number of axes of \( x \).

See also:

**ifft2**
The inverse 2-D FFT.

**fft**
The 1-D FFT.

**fftn**
The N-D FFT.

**fftsift**
Shifts zero-frequency terms to the center of the array. For 2-D input, swaps first and third quadrants, and second and fourth quadrants.

**Notes**

**fft2** is just **fftn** with a different default for \( axes \).

The output, analogously to **fft**, contains the term for zero frequency in the low-order corner of the transformed axes, the positive frequency terms in the first half of these axes, the term for the Nyquist frequency in the middle of the axes and the negative frequency terms in the second half of the axes, in order of decreasingly negative frequency.

See **fftn** for details and a plotting example, and **fft** for definitions and conventions used.

**Examples**

```python
>>> import scipy.fft
>>> x = np.mgrid[:5, :5][0]
>>> scipy.fft.fft2(x)
array([[ 50. +0.j , 0. +0.j , 0. +0.j , # may vary
         0. +0.j , 0. +0.j ],
        [-12.5+17.20477401j, 0. +0.j , 0. +0.j ,
          0. +0.j , 0. +0.j ],
        [-12.5+4.0614962j , 0. +0.j , 0. +0.j ,
          0. +0.j , 0. +0.j ],
        [-12.5-4.0614962j , 0. +0.j , 0. +0.j ,
          0. +0.j , 0. +0.j ],
        [-12.5-17.20477401j, 0. +0.j , 0. +0.j ,
          0. +0.j , 0. +0.j ]])
```
scipy.fft.ifft2

scipy.fft.ifft2(x, s=None, axes=(-2, -1), norm=None, overwrite_x=False, workers=None, *, plan=None)

Compute the 2-D inverse discrete Fourier Transform.

This function computes the inverse of the 2-D discrete Fourier Transform over any number of axes in an M-D array by means of the Fast Fourier Transform (FFT). In other words, ifft2(fft2(x)) == x to within numerical accuracy. By default, the inverse transform is computed over the last two axes of the input array.

The input, analogously to ifft, should be ordered in the same way as is returned by fft2, i.e., it should have the term for zero frequency in the low-order corner of the two axes, the positive frequency terms in the first half of these axes, the term for the Nyquist frequency in the middle of the axes and the negative frequency terms in the second half of both axes, in order of decreasingly negative frequency.

Parameters

- **x** [array_like] Input array, can be complex.
- **s** [sequence of ints, optional] Shape (length of each axis) of the output (s[0] refers to axis 0, s[1] to axis 1, etc.). This corresponds to n for ifft(x, n). Along each axis, if the given shape is smaller than that of the input, the input is cropped. If it is larger, the input is padded with zeros. If s is not given, the shape of the input along the axes specified by axes is used. See notes for issue on ifft zero padding.
- **axes** [sequence of ints, optional] Axes over which to compute the FFT. If not given, the last two axes are used.
- **norm** [{“backward”, “ortho”, “forward”}, optional] Normalization mode (see fft). Default is “backward”.
- **overwrite_x** [bool, optional] If True, the contents of x can be destroyed; the default is False. See fft for more details.
- **workers** [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from os.cpu_count(). See fft for more details.
- **plan** [object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy. New in version 1.5.0.

Returns

- **out** [complex ndarray] The truncated or zero-padded input, transformed along the axes indicated by axes, or the last two axes if axes is not given.

Raises

- **ValueError** If s and axes have different length, or axes not given and len(s) != 2.
- **IndexError** If an element of axes is larger than than the number of axes of x.

See also:

- **fft2**
  The forward 2-D FFT, of which ifft2 is the inverse.
- **ifftn**
  The inverse of the N-D FFT.
- **fft**
  The 1-D FFT.
**ifft**

The 1-D inverse FFT.

**Notes**

`ifft2` is just `fftn` with a different default for `axes`.

See `fftn` for details and a plotting example, and `fft` for definition and conventions used.

Zero-padding, analogously with `ifft`, is performed by appending zeros to the input along the specified dimension. Although this is the common approach, it might lead to surprising results. If another form of zero padding is desired, it must be performed before `ifft2` is called.

**Examples**

```python
>>> import scipy.fft
>>> x = 4 * np.eye(4)
>>> scipy.fft.ifft2(x)
array([[1.+0.j, 0.+0.j, 0.+0.j, 0.+0.j],
       [0.+0.j, 0.+0.j, 0.+0.j, 1.+0.j],
       [0.+0.j, 0.+0.j, 1.+0.j, 0.+0.j],
       [0.+0.j, 1.+0.j, 0.+0.j, 0.+0.j]])
```

**scipy.fftn**

`scipy.fft.fftn` computes the N-D discrete Fourier Transform over any number of axes in an M-D array by means of the Fast Fourier Transform (FFT).

This function computes the N-D discrete Fourier Transform over any number of axes in an M-D array by means of the Fast Fourier Transform (FFT).

**Parameters**

- **x** [array_like] Input array, can be complex.
- **s** [sequence of ints, optional] Shape (length of each transformed axis) of the output (s[0] refers to axis 0, s[1] to axis 1, etc.). This corresponds to n for `fftn(x, n)`. Along any axis, if the given shape is smaller than that of the input, the input is cropped. If it is larger, the input is padded with zeros. If s is not given, the shape of the input along the axes specified by axes is used.
- **axes** [sequence of ints, optional] Axes over which to compute the FFT. If not given, the last len(s) axes are used, or all axes if s is also not specified.
- **norm** [{“backward”, “ortho”, “forward”}, optional] Normalization mode (see `fft`). Default is “backward”.
- **overwrite_x** [bool, optional] If True, the contents of x can be destroyed; the default is False. See `fft` for more details.
- **workers** [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from `os.cpu_count()`. See `fft` for more details.
- **plan** [object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy.

**Returns**
out  [complex ndarray] The truncated or zero-padded input, transformed along the axes indicated by axes, or by a combination of s and x, as explained in the parameters section above.

Raises

ValueError
If s and axes have different length.

IndexError
If an element of axes is larger than than the number of axes of x.

See also:

ifftn
The inverse of fftn, the inverse N-D FFT.

fft
The 1-D FFT, with definitions and conventions used.

rfftn
The N-D FFT of real input.

fft2
The 2-D FFT.

fftshift
Shifts zero-frequency terms to centre of array.

Notes

The output, analogously to fft, contains the term for zero frequency in the low-order corner of all axes, the positive frequency terms in the first half of all axes, the term for the Nyquist frequency in the middle of all axes and the negative frequency terms in the second half of all axes, in order of decreasingly negative frequency.

Examples

```python
>>> import scipy.fft
>>> x = np.mgrid[:3, :3, :3][0]
>>> scipy.fft.fftn(x, axes=(1, 2))
array([[ 0.+0.j,  0.+0.j,  0.+0.j],
       [ 0.+0.j,  0.+0.j,  0.+0.j],
       [ 0.+0.j,  0.+0.j,  0.+0.j],
       [ 9.+0.j,  0.+0.j,  0.+0.j],
       [ 0.+0.j,  0.+0.j,  0.+0.j],
       [ 0.+0.j,  0.+0.j,  0.+0.j],
       [18.+0.j,  0.+0.j,  0.+0.j],
       [ 0.+0.j,  0.+0.j,  0.+0.j],
       [ 0.+0.j,  0.+0.j,  0.+0.j]]))
>>> scipy.fft.fftn(x, (2, 2), axes=(0, 1))
array([[ 2.+0.j,  2.+0.j,  2.+0.j],
       [ 0.+0.j,  0.+0.j,  0.+0.j],
       [-2.+0.j, -2.+0.j, -2.+0.j],
       [ 0.+0.j,  0.+0.j,  0.+0.j]]))
```
```python
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
>>> [X, Y] = np.meshgrid(2 * np.pi * np.arange(200) / 12,
...                      2 * np.pi * np.arange(200) / 34)
>>> S = np.sin(X) + np.cos(Y) + rng.uniform(0, 1, X.shape)
>>> FS = scipy.fft.fftn(S)
>>> plt.imshow(np.log(np.abs(scipy.fft.fftshift(FS))**2))
<matplotlib.image.AxesImage object at 0x...>
>>> plt.show()
```

**scipy.fft.ifftn**

`scipy.fft.ifftn(x, s=None, axes=None, norm=None, overwrite_x=False, workers=None, *, plan=None)`

Compute the N-D inverse discrete Fourier Transform.

This function computes the inverse of the N-D discrete Fourier Transform over any number of axes in an M-D array by means of the Fast Fourier Transform (FFT). In other words, `ifftn(fftn(x)) == x` to within numerical accuracy.

The input, analogously to `ifft`, should be ordered in the same way as is returned by `fftn`, i.e., it should have the term for zero frequency in all axes in the low-order corner, the positive frequency terms in the first half of all axes, the term for the Nyquist frequency in the middle of all axes and the negative frequency terms in the second half of all axes, in order of decreasingly negative frequency.

**Parameters**

- `x` [array_like] Input array, can be complex.
- `s` [sequence of ints, optional] Shape (length of each transformed axis) of the output. `s[0]` refers to axis 0, `s[1]` to axis 1, etc.). This corresponds to `n` for `ifft(x, n)`. Along any axis, if the given shape is smaller than that of the input, the input is cropped. If it is larger, the input is padded with zeros. If `s` is not given, the shape of the input along the axes specified by `axes` is used. See notes for issue on `ifft` zero padding.
- `axes` [sequence of ints, optional] Axes over which to compute the IFFT. If not given, the last `len(s)` axes are used, or all axes if `s` is also not specified.
- `norm` [“backward”, “ortho”, “forward”), optional] Normalization mode (see `fft`). Default is “backward”.

---

384  Chapter 3. SciPy API
overwrite_x

[bool, optional] If True, the contents of x can be destroyed; the default is False. See `fft` for more details.

workers

[int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from `os.cpu_count()`. See `fft` for more details.

plan

[object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy. New in version 1.5.0.

Returns

out

[complex ndarray] The truncated or zero-padded input, transformed along the axes indicated by `axes`, or by a combination of `s` or `x`, as explained in the parameters section above.

Raises

ValueError

If `s` and `axes` have different length.

IndexError

If an element of `axes` is larger than than the number of axes of `x`.

See also:

`fftn`

The forward N-D FFT, of which `ifftn` is the inverse.

`ifft`

The 1-D inverse FFT.

`ifft2`

The 2-D inverse FFT.

`ifftshift`

Undoes `fftshift`, shifts zero-frequency terms to beginning of array.

Notes

Zero-padding, analogously with `ifft`, is performed by appending zeros to the input along the specified dimension. Although this is the common approach, it might lead to surprising results. If another form of zero padding is desired, it must be performed before `ifftn` is called.

Examples

```python
>>> import scipy.fft
>>> x = np.eye(4)
>>> scipy.fft.ifftn(scipy.fft.fftn(x, axes=(0,)), axes=(1,))
tomake vary
array([[1.+0.j, 0.+0.j, 0.+0.j, 0.+0.j],
       [0.+0.j, 1.+0.j, 0.+0.j, 0.+0.j],
       [0.+0.j, 0.+0.j, 1.+0.j, 0.+0.j],
       [0.+0.j, 0.+0.j, 0.+0.j, 1.+0.j]])
```

Create and plot an image with band-limited frequency content:
```python
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
>>> n = np.zeros((200, 200), dtype=complex)
>>> n[60:80, 20:40] = np.exp(1j*rng.uniform(0, 2*np.pi, (20, 20)))
>>> im = scipy.fft.ifftn(n).real
>>> plt.imshow(im)
<matplotlib.image.AxesImage object at 0x...>
>>> plt.show()
```

### scipy.fft.rfft

`scipy.fft.rfft(x, n=None, axis=-1, norm=None, overwrite_x=False, workers=None, *, plan=None)`

Compute the 1-D discrete Fourier Transform for real input.

This function computes the 1-D $n$-point discrete Fourier Transform (DFT) of a real-valued array by means of an efficient algorithm called the Fast Fourier Transform (FFT).

**Parameters**

- **x** [array_like] Input array
- **n** [int, optional] Number of points along transformation axis in the input to use. If $n$ is smaller than the length of the input, the input is cropped. If it is larger, the input is padded with zeros. If $n$ is not given, the length of the input along the axis specified by `axis` is used.
- **axis** [int, optional] Axis over which to compute the FFT. If not given, the last axis is used.
- **norm** [{'backward', 'ortho', 'forward'}, optional] Normalization mode (see `fft`). Default is "backward".
- **overwrite_x** [bool, optional] If True, the contents of $x$ can be destroyed; the default is False. See `fft` for more details.
- **workers** [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from `os.cpu_count()`. See `fft` for more details.
- **plan** [object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy. New in version 1.5.0.

**Returns**
out [complex ndarray] The truncated or zero-padded input, transformed along the axis indicated by axis, or the last one if axis is not specified. If $n$ is even, the length of the transformed axis is $(n/2)+1$. If $n$ is odd, the length is $(n+1)/2$.

Raises

IndexError

If axis is larger than the last axis of $a$.

See also:

irfft

The inverse of rfft.

fft

The 1-D FFT of general (complex) input.

fftn

The N-D FFT.

rfft2

The 2-D FFT of real input.

rfftn

The N-D FFT of real input.

Notes

When the DFT is computed for purely real input, the output is Hermitian-symmetric, i.e., the negative frequency terms are just the complex conjugates of the corresponding positive-frequency terms, and the negative-frequency terms are therefore redundant. This function does not compute the negative frequency terms, and the length of the transformed axis of the output is therefore $n//2 + 1$.

When $X = \text{rfft}(x)$ and $fs$ is the sampling frequency, $X[0]$ contains the zero-frequency term $0*fs$, which is real due to Hermitian symmetry.

If $n$ is even, $A[-1]$ contains the term representing both positive and negative Nyquist frequency ($+fs/2$ and $-fs/2$), and must also be purely real. If $n$ is odd, there is no term at $fs/2$; $A[-1]$ contains the largest positive frequency ($fs/2*(n-1)/n$), and is complex in the general case.

If the input $a$ contains an imaginary part, it is silently discarded.

Examples

```python
>>> import scipy.fft
>>> scipy.fft.fft([0, 1, 0, 0])
array([ 1.+0.j,  0.-1.j, -1.+0.j,  0.+1.j]) # may vary
>>> scipy.fft.rfft([0, 1, 0, 0])
array([ 1.+0.j,  0.-1.j, -1.+0.j]) # may vary
```

Notice how the final element of the fft output is the complex conjugate of the second element, for real input. For rfft, this symmetry is exploited to compute only the non-negative frequency terms.
**scipy.fft.irfft**

`scipy.fft.irfft(x, n=None, axis=-1, norm=None, overwrite_x=False, workers=None, *, plan=None)`

Computes the inverse of `rfft`.

This function computes the inverse of the 1-D $n$-point discrete Fourier Transform of real input computed by `rfft`. In other words, $\text{irfft}(\text{rfft}(x), \text{len}(x)) = x$ to within numerical accuracy. (See Notes below for why `len(a)` is necessary here.)

The input is expected to be in the form returned by `rfft`, i.e., the real zero-frequency term followed by the complex positive frequency terms in order of increasing frequency. Since the discrete Fourier Transform of real input is Hermitian-symmetric, the negative frequency terms are taken to be the complex conjugates of the corresponding positive frequency terms.

**Parameters**

- `x` [array_like] The input array.
- `n` [int, optional] Length of the transformed axis of the output. For $n$ output points, $n/2+1$ input points are necessary. If the input is longer than this, it is cropped. If it is shorter than this, it is padded with zeros. If $n$ is not given, it is taken to be $2 \times (m-1)$, where $m$ is the length of the input along the axis specified by `axis`.
- `axis` [int, optional] Axis over which to compute the inverse FFT. If not given, the last axis is used.
- `norm` [{“backward”, “ortho”, “forward”}, optional] Normalization mode (see `fft`). Default is “backward”.
- `overwrite_x` [bool, optional] If True, the contents of $x$ can be destroyed; the default is False. See `fft` for more details.
- `workers` [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from `os.cpu_count()`. See `fft` for more details.
- `plan` [object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy. New in version 1.5.0.

**Returns**

- `out` [ndarray] The truncated or zero-padded input, transformed along the axis indicated by `axis`, or the last one if `axis` is not specified. The length of the transformed axis is $n$, or, if $n$ is not given, $2 \times (m-1)$ where $m$ is the length of the transformed axis of the input. To get an odd number of output points, $n$ must be specified.

**Raises**

- `IndexError` If `axis` is larger than the last axis of $x$.

See also:

- `rfft` The 1-D FFT of real input, of which `irfft` is inverse.
- `fft` The 1-D FFT.
- `irfft2` The inverse of the 2-D FFT of real input.
- `irfftn` The inverse of the N-D FFT of real input.
Notes

Returns the real valued $n$-point inverse discrete Fourier transform of $x$, where $x$ contains the non-negative frequency terms of a Hermitian-symmetric sequence. $n$ is the length of the result, not the input.

If you specify an $n$ such that $a$ must be zero-padded or truncated, the extra/removed values will be added/removed at high frequencies. One can thus resample a series to $m$ points via Fourier interpolation by: $a_{\text{resamp}} = \text{irfft}(\text{rfft}(a), m)$.

The default value of $n$ assumes an even output length. By the Hermitian symmetry, the last imaginary component must be 0 and so is ignored. To avoid losing information, the correct length of the real input must be given.

Examples

```python
>>> import scipy.fft
>>> scipy.fft.ifft([1, -1j, -1, 1j])
array([0.+0.j, 1.+0.j, 0.+0.j, 0.+0.j]) # may vary
>>> scipy.fft.irfft([1, -1j, -1])
array([0., 1., 0., 0.])
```

Notice how the last term in the input to the ordinary `ifft` is the complex conjugate of the second term, and the output has zero imaginary part everywhere. When calling `irfft`, the negative frequencies are not specified, and the output array is purely real.

`scipy.fft.rfft2`

`scipy.fft.rfft2` ($x$, $s$=None, $axes$=(-2, -1), $norm$=None, $overwrite_x$=False, $workers$=None, *, $plan$=None)

Compute the 2-D FFT of a real array.

Parameters

- $x$ [array] Input array, taken to be real.
- $s$ [sequence of ints, optional] Shape of the FFT.
- $axes$ [sequence of ints, optional] Axes over which to compute the FFT.
- $norm$ ["backward", "ortho", "forward"], optional] Normalization mode (see `fft`). Default is “backward”.
- $overwrite_x$ [bool, optional] If True, the contents of $x$ can be destroyed; the default is False. See `fft` for more details.
- $workers$ [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from `os.cpu_count()`. See `fft` for more details.
- $plan$ [object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy. New in version 1.5.0.

Returns

- $out$ [ndarray] The result of the real 2-D FFT.

See also:

- `irfft2`
  The inverse of the 2-D FFT of real input.
- `rfft`
  The 1-D FFT of real input.
rfftn

Compute the N-D discrete Fourier Transform for real input.

Notes

This is really just \texttt{rfftn} with different default behavior. For more details see \texttt{rfftn}.

\texttt{scipy.fft.irfft2}

\texttt{scipy.fft.irfft2}(x, s=None, axes=(- 2, - 1), norm=None, overwrite_x=False, workers=None, *, plan=None)

Computes the inverse of \texttt{rfft2}

Parameters

\begin{itemize}
\item \texttt{x} [array_like] The input array
\item \texttt{s} [sequence of ints, optional] Shape of the real output to the inverse FFT.
\item \texttt{axes} [sequence of ints, optional] The axes over which to compute the inverse fft. Default is the last two axes.
\item \texttt{norm} [\{“backward”, “ortho”, “forward”\}, optional] Normalization mode (see \texttt{fft}). Default is “backward”.
\item \texttt{overwrite_x} [bool, optional] If True, the contents of \texttt{x} can be destroyed; the default is False. See \texttt{fft} for more details.
\item \texttt{workers} [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from \texttt{os.cpu_count()}. See \texttt{fft} for more details.
\item \texttt{plan} [object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy. New in version 1.5.0.
\end{itemize}

Returns

\begin{itemize}
\item \texttt{out} [ndarray] The result of the inverse real 2-D FFT.
\end{itemize}

See also:

\begin{itemize}
\item \texttt{rfft2} The 2-D FFT of real input.
\item \texttt{irfft} The inverse of the 1-D FFT of real input.
\item \texttt{irfftn} The inverse of the N-D FFT of real input.
\end{itemize}

Notes

This is really \texttt{irfftn} with different defaults. For more details see \texttt{irfftn}.
scipy.fft.rfftn

scipy.fft.rfftn(x, s=None, axes=None, norm=None, overwrite_x=False, workers=None, *, plan=None)

Compute the N-D discrete Fourier Transform for real input.

This function computes the N-D discrete Fourier Transform over any number of axes in an M-D real array by means of the Fast Fourier Transform (FFT). By default, all axes are transformed, with the real transform performed over the last axis, while the remaining transforms are complex.

Parameters

- **x** [array_like] Input array, taken to be real.
- **s** [sequence of ints, optional] Shape (length along each transformed axis) to use from the input. (s[0] refers to axis 0, s[1] to axis 1, etc.). The final element of s corresponds to n for rfft(x, n), while for the remaining axes, it corresponds to n for fft(x, n). Along any axis, if the given shape is smaller than that of the input, the input is cropped. If it is larger, the input is padded with zeros. If s is not given, the shape of the input along the axes specified by axes is used.
- **axes** [sequence of ints, optional] Axes over which to compute the FFT. If not given, the last len(s) axes are used, or all axes if s is also not specified.
- **norm** [“backward”, “ortho”, “forward”, optional] Normalization mode (see fft). Default is “backward”.
- **overwrite_x** [bool, optional] If True, the contents of x can be destroyed; the default is False. See fft for more details.
- **workers** [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from os.cpu_count(). See fft for more details.
- **plan** [object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy. New in version 1.5.0.

Returns

- **out** [complex ndarray] The truncated or zero-padded input, transformed along the axes indicated by axes, or by a combination of s and x, as explained in the parameters section above. The length of the last axis transformed will be s[-1]//2+1, while the remaining transformed axes will have lengths according to s, or unchanged from the input.

Raises

- **ValueError** If s and axes have different length.
- **IndexError** If an element of axes is larger than than the number of axes of x.

See also:

- **irfftn**
  The inverse of rfftn, i.e., the inverse of the N-D FFT of real input.
- **fft**
  The 1-D FFT, with definitions and conventions used.
- **rfft**
  The 1-D FFT of real input.
- **fftn**
  The N-D FFT.
**rfft2**

The 2-D FFT of real input.

**Notes**

The transform for real input is performed over the last transformation axis, as by `rfft`, then the transform over the remaining axes is performed as by `fftn`. The order of the output is as for `rfft` for the final transformation axis, and as for `fftn` for the remaining transformation axes.

See `fft` for details, definitions and conventions used.

**Examples**

```python
>>> import scipy.fft
>>> x = np.ones((2, 2, 2))
>>> scipy.fft.rfftn(x)
array([[[[8.+0.j, 0.+0.j], # may vary
        [0.+0.j, 0.+0.j]],
        [[0.+0.j, 0.+0.j],
        [0.+0.j, 0.+0.j]]]])
```

```python
>>> scipy.fft.rfftn(x, axes=(2, 0))
array([[[[4.+0.j, 0.+0.j], # may vary
        [4.+0.j, 0.+0.j]],
        [[0.+0.j, 0.+0.j],
        [0.+0.j, 0.+0.j]]]])
```

**scipy.fft.irfftn**

*scipy.fft.irfftn*(x, s=None, axes=None, norm=None, overwrite_x=False, workers=None, *, plan=None)

Computes the inverse of `rfftn`

This function computes the inverse of the N-D discrete Fourier Transform for real input over any number of axes in an M-D array by means of the Fast Fourier Transform (FFT). In other words, `irfftn(rfftn(x), x.shape) == x` to within numerical accuracy. (The `a.shape` is necessary like `len(a)` is for `irfft`, and for the same reason.)

The input should be ordered in the same way as is returned by `rfftn`, i.e., as for `irfft` for the final transformation axis, and as for `ifftn` along all the other axes.

**Parameters**

- `x` [array_like] Input array.
- `s` [sequence of ints, optional] Shape (length of each transformed axis) of the output (s[0] refers to axis 0, s[1] to axis 1, etc.). s is also the number of input points used along this axis, except for the last axis, where s[-1]/2+1 points of the input are used. Along any axis, if the shape indicated by s is smaller than that of the input, the input is cropped. If it is larger, the input is padded with zeros. If s is not given, the shape of the input along the axes specified by axes is used. Except for the last axis which is taken to be 2*(m-1), where m is the length of the input along that axis.
- `axes` [sequence of ints, optional] Axes over which to compute the inverse FFT. If not given, the last `len(s)` axes are used, or all axes if s is also not specified.
- `norm` [“backward”, “ortho”, “forward”), optional] Normalization mode (see `fft`). Default is “backward”.

392 Chapter 3. SciPy API
overwrite_x
[bool, optional] If True, the contents of x can be destroyed; the default is False. See fft for more details.

workers
[int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from os.cpu_count(). See fft for more details.

plan
[object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy.
New in version 1.5.0.

Returns
out
[ndarray] The truncated or zero-padded input, transformed along the axes indicated by axes, or by a combination of s or x, as explained in the parameters section above. The length of each transformed axis is as given by the corresponding element of s, or the length of the input in every axis except for the last one if s is not given. In the final transformed axis the length of the output when s is not given is $2^*(m-1)$, where m is the length of the final transformed axis of the input. To get an odd number of output points in the final axis, s must be specified.

Raises
ValueError
  If s and axes have different length.

IndexError
  If an element of axes is larger than the number of axes of x.

See also:
rfftn
  The forward N-D FFT of real input, of which ifftn is the inverse.

fft
  The 1-D FFT, with definitions and conventions used.

irfft
  The inverse of the 1-D FFT of real input.

irfft2
  The inverse of the 2-D FFT of real input.

Notes
See fft for definitions and conventions used.
See rfft for definitions and conventions used for real input.

The default value of s assumes an even output length in the final transformation axis. When performing the final complex to real transformation, the Hermitian symmetry requires that the last imaginary component along that axis must be 0 and so it is ignored. To avoid losing information, the correct length of the real input must be given.
Examples

```python
>>> import scipy.fft
>>> x = np.zeros((3, 2, 2))
>>> x[0, 0, 0] = 3 * 2 * 2
>>> scipy.fft.irfftn(x)
array([[[[1., 1.],
        [1., 1.]],
       [[1., 1.],
        [1., 1.]],
       [[1., 1.],
        [1., 1.]]]])
```

scipy.fft.hfft

**scipy.fft.hfft** *(x, n=None, axis=-1, norm=None, overwrite_x=False, workers=None, *, plan=None)*

Compute the FFT of a signal that has Hermitian symmetry, i.e., a real spectrum.

**Parameters**

- `x`  
  [array_like] The input array.

- `n`  
  [int, optional] Length of the transformed axis of the output. For `n` output points, `n//2 + 1` input points are necessary. If the input is longer than this, it is cropped. If it is shorter than this, it is padded with zeros. If `n` is not given, it is taken to be `2*(m-1)`, where `m` is the length of the input along the axis specified by `axis`.

- `axis`  
  [int, optional] Axis over which to compute the FFT. If not given, the last axis is used.

- `norm`  
  [“backward”, “ortho”, “forward”, optional] Normalization mode (see `fft`). Default is “backward”.

- `overwrite_x`  
  [bool, optional] If True, the contents of `x` can be destroyed; the default is False. See `fft` for more details.

- `workers`  
  [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from `os.cpu_count()`. See `fft` for more details.

- `plan`  
  [object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy.

**Returns**

- `out`  
  [ndarray] The truncated or zero-padded input, transformed along the axis indicated by `axis`, or the last one if `axis` is not specified. The length of the transformed axis is `n`, or, if `n` is not given, `2*m - 2`, where `m` is the length of the transformed axis of the input. To get an odd number of output points, `n` must be specified, for instance, as `2*m - 1` in the typical case.

**Raises**

- `IndexError`  
  If `axis` is larger than the last axis of `a`.

**See also:**

- `rfft`
  Compute the 1-D FFT for real input.

- `ihfft`
  The inverse of `hfft`.
hfftn

Compute the N-D FFT of a Hermitian signal.

Notes

*hfft/*ihfft* are a pair analogous to *rfft/*irfft*, but for the opposite case: here the signal has Hermitian symmetry in the time domain and is real in the frequency domain. So, here, it’s *hfft*, for which you must supply the length of the result if it is to be odd. * even: ihfft(hfft(a, 2*len(a) - 2) == a, within roundoff error,* odd: ihfft(hfft(a, 2*len(a) - 1) == a, within roundoff error.

Examples

```python
>>> from scipy.fft import fft, hfft
>>> a = 2 * np.pi * np.arange(10) / 10
>>> signal = np.cos(a) + 3j * np.sin(3 * a)
>>> fft(signal).round(10)
array([-0.+0.j,  5.+0.j, -0.+0.j, 15.-0.j,  0.+0.j,  0.+0.j,
       -0.+0.j, -15.-0.j,  0.+0.j,  5.+0.j])
>>> hfft(signal[:6]).round(10)  # Input first half of signal
array([ 0.,  5.,  0., 15., -0.,  0., -15., -0.,  5.])
>>> hfft(signal, 10)  # Input entire signal and truncate
array([ 0.,  5.,  0., 15., -0.,  0., -15., -0.,  5.])
```

scipy.fft.ihfft

*scipy.fft.ihfft* (*x*, *n=None*, *axis=-1*, *norm=None*, *overwrite_x=False*, *workers=None*, *plan=None*)

Compute the inverse FFT of a signal that has Hermitian symmetry.

**Parameters**

- **x** : [array_like] Input array.
- **n** : [int, optional] Length of the inverse FFT, the number of points along transformation axis in the input to use. If *n* is smaller than the length of the input, the input is cropped. If it is larger, the input is padded with zeros. If *n* is not given, the length of the input along the axis specified by *axis* is used.
- **axis** : [int, optional] Axis over which to compute the inverse FFT. If not given, the last axis is used.
- **norm** : [{“backward”, “ortho”, “forward”}, optional] Normalization mode (see *fft*). Default is “backward”.
- **overwrite_x** : [bool, optional] If True, the contents of *x* can be destroyed; the default is False. See *fft* for more details.
- **workers** : [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from *os.cpu_count()* See *fft* for more details.
- **plan** : [object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy. New in version 1.5.0.

**Returns**

- **out** : [complex ndarray] The truncated or zero-padded input, transformed along the axis indicated by *axis*, or the last one if *axis* is not specified. The length of the transformed axis is *n*/2 + 1.

See also:
**hfft, irfft**

**Notes**

**hfft/ihfft** are a pair analogous to **rfft/irfft**, but for the opposite case: here, the signal has Hermitian symmetry in the time domain and is real in the frequency domain. So, here, it's **hfft**, for which you must supply the length of the result if it is to be odd: *even*: \( \text{ihfft}(\text{hfft}(a, 2*\text{len}(a) - 2)) = a \), within roundoff error, *odd*: \( \text{ihfft}(\text{hfft}(a, 2*\text{len}(a) - 1)) = a \), within roundoff error.

**Examples**

```python
>>> from scipy.fft import ifft, hfft
>>> spectrum = np.array([15, -4, 0, -1, 0, -4])
>>> ifft(spectrum)
array([ 1.+0.j, 2.+0.j, 3.+0.j, 4.+0.j, 3.+0.j, 2.+0.j]) # may vary
>>> ihfft(spectrum)
array([ 1.-0.j, 2.-0.j, 3.-0.j, 4.-0.j]) # may vary
```

**scipy.fft.hfft2**

Compute the 2-D FFT of a Hermitian complex array.

**Parameters**

- **x**: [array] Input array, taken to be Hermitian complex.
- **s**: [sequence of ints, optional] Shape of the real output.
- **axes**: [sequence of ints, optional] Axes over which to compute the FFT.
- **norm**: [{“backward”, “ortho”, “forward”}, optional] Normalization mode (see **fft**). Default is “backward”.
- **overwrite_x**: [bool, optional] If True, the contents of \( x \) can be destroyed; the default is False. See **fft** for more details.
- **workers**: [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from \( \text{os.cpu_count()} \). See **fft** for more details.
- **plan**: [object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy. New in version 1.5.0.

**Returns**

- **out**: [ndarray] The real result of the 2-D Hermitian complex real FFT.

**See also:**

**hfftn**

Compute the N-D discrete Fourier Transform for Hermitian complex input.
Notes

This is really just `hfftn` with different default behavior. For more details see `hfftn`.

`scipy.fft.ihfft2`

`scipy.fft.ihfft2(x, s=None, axes=(-2, -1), norm=None, overwrite_x=False, workers=None, *, plan=None)`

Compute the 2-D inverse FFT of a real spectrum.

**Parameters**

- `x` [array_like] The input array.
- `s` [sequence of ints, optional] Shape of the real input to the inverse FFT.
- `axes` [sequence of ints, optional] The axes over which to compute the inverse fft. Default is the last two axes.
- `norm` [{“backward”, “ortho”, “forward”}, optional] Normalization mode (see `fft`). Default is “backward”.
- `overwrite_x` [bool, optional] If True, the contents of `x` can be destroyed; the default is False. See `fft` for more details.
- `workers` [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from `os.cpu_count()`. See `fft` for more details.
- `plan` [object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy. New in version 1.5.0.

**Returns**

- `out` [ndarray] The result of the inverse real 2-D FFT.

See also:

`ihfftn`

Compute the inverse of the N-D FFT of Hermitian input.

Notes

This is really `ihfftn` with different defaults. For more details see `ihfftn`.

`scipy.fft.hfftn`

`scipy.fft.hfftn(x, s=None, axes=None, norm=None, overwrite_x=False, workers=None, *, plan=None)`

Compute the N-D FFT of Hermitian symmetric complex input, i.e., a signal with a real spectrum.

This function computes the N-D discrete Fourier Transform for a Hermitian symmetric complex input over any number of axes in an M-D array by means of the Fast Fourier Transform (FFT). In other words, `ihfftn(hfftn(x, s)) == x` to within numerical accuracy. (`s` here is `x.shape` with `s[-1] = x.shape[-1] * 2 - 1`, this is necessary for the same reason `x.shape` would be necessary for `irfft`.)

**Parameters**

- `x` [array_like] Input array.
- `s` [sequence of ints, optional] Shape (length of each transformed axis) of the output (`s[0]` refers to axis 0, `s[1]` to axis 1, etc.). `s` is also the number of input points used along this axis, except for the last axis, where `s[-1]//2+1` points of the input are used. Along any axis, if the shape indicated by `s` is smaller than that of the input, the input is cropped. If it is larger, the input is padded with zeros. If `s` is not given, the shape of the input along the axes
specified by axes is used. Except for the last axis which is taken to be \(2^{*} (m-1)\) where \(m\) is the length of the input along that axis.

- **axes**
  [sequence of ints, optional] Axes over which to compute the inverse FFT. If not given, the last \(\text{len}(s)\) axes are used, or all axes if \(s\) is also not specified.

- **norm**
  [\{“backward”, “ortho”, “forward”\}, optional] Normalization mode (see \(\text{fft}\)). Default is “backward”.

- **overwrite_x**
  [bool, optional] If True, the contents of \(x\) can be destroyed; the default is False. See \(\text{fft}\) for more details.

- **workers**
  [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from \(\text{os.cpu_count()}\). See \(\text{fft}\) for more details.

- **plan**
  [object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy.

New in version 1.5.0.

**Returns**

- **out**
  [ndarray] The truncated or zero-padded input, transformed along the axes indicated by \(axes\), or by a combination of \(s\) or \(x\), as explained in the parameters section above. The length of each transformed axis is as given by the corresponding element of \(s\), or the length of the input in every axis except for the last one if \(s\) is not given. In the final transformed axis the length of the output when \(s\) is not given is \(2^{*} (m-1)\) where \(m\) is the length of the final transformed axis of the input. To get an odd number of output points in the final axis, \(s\) must be specified.

**Raises**

- **ValueError**
  If \(s\) and \(axes\) have different length.

- **IndexError**
  If an element of \(axes\) is larger than the number of axes of \(x\).

**See also:**

- **ihfftn**
  The inverse N-D FFT with real spectrum. Inverse of \(hfftn\).

- **fft**
  The 1-D FFT, with definitions and conventions used.

- **rfft**
  Forward FFT of real input.

**Notes**

For a 1-D signal \(x\) to have a real spectrum, it must satisfy the Hermitian property:

\[
x[i] = np.conj(x[-i]) \quad \text{for all} \quad i
\]

This generalizes into higher dimensions by reflecting over each axis in turn:

\[
x[i, j, k, \ldots] = np.conj(x[-i, -j, -k, \ldots]) \quad \text{for all} \quad i, j, k, \ldots
\]

This should not be confused with a Hermitian matrix, for which the transpose is its own conjugate:

\[
x[i, j] = np.conj(x[j, i]) \quad \text{for all} \quad i, j
\]
The default value of \( s \) assumes an even output length in the final transformation axis. When performing the final complex to real transformation, the Hermitian symmetry requires that the last imaginary component along that axis must be 0 and so it is ignored. To avoid losing information, the correct length of the real input must be given.

**Examples**

```python
>>> import scipy.fft
>>> x = np.ones((3, 2, 2))
>>> scipy.fft.hfftn(x)
array([[ 12.,  0.],
       [  0.,  0.],
       [  0.,  0.],
       [  0.,  0.],
       [  0.,  0.],
       [  0.,  0.]])
```

**scipy.fft.ihfftn**

`scipy.fft.ihfftn(x, s=None, axes=None, norm=None, overwrite_x=False, workers=None, *, plan=None)`

Computes the N-D inverse discrete Fourier Transform for a real spectrum.

This function computes the N-D inverse discrete Fourier Transform over any number of axes in an M-D real array by means of the Fast Fourier Transform (FFT). By default, all axes are transformed, with the real transform performed over the last axis, while the remaining transforms are complex.

**Parameters**

- `x` [array_like] Input array, taken to be real.
- `s` [sequence of ints, optional] Shape (length along each transformed axis) to use from the input. (`s[0]` refers to axis 0, `s[1]` to axis 1, etc.). Along any axis, if the given shape is smaller than that of the input, the input is cropped. If it is larger, the input is padded with zeros. If `s` is not given, the shape of the input along the axes specified by `axes` is used.
- `axes` [sequence of ints, optional] Axes over which to compute the FFT. If not given, the last `len(s)` axes are used, or all axes if `s` is also not specified.
- `norm` [{“backward”, “ortho”, “forward”}, optional] Normalization mode (see `fft`). Default is “backward”.
- `overwrite_x` [bool, optional] If True, the contents of `x` can be destroyed; the default is False. See `fft` for more details.
- `workers` [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from `os.cpu_count()`. See `fft` for more details.
- `plan` [object, optional] This argument is reserved for passing in a precomputed plan provided by downstream FFT vendors. It is currently not used in SciPy. New in version 1.5.0.

**Returns**

- `out` [complex ndarray] The truncated or zero-padded input, transformed along the axes indicated by `axes`, or by a combination of `s` and `x`, as explained in the parameters section above. The length of the last axis transformed will be `s[-1]//2+1`, while the remaining transformed axes will have lengths according to `s`, or unchanged from the input.

**Raises**

- `ValueError` If `s` and `axes` have different length.

3.3. API definition 399
If an element of `axes` is larger than the number of axes of `x`.

See also:

**hfftn**

The forward N-D FFT of Hermitian input.

**hfft**

The 1-D FFT of Hermitian input.

**fft**

The 1-D FFT, with definitions and conventions used.

**fftn**

The N-D FFT.

**hfft2**

The 2-D FFT of Hermitian input.

Notes

The transform for real input is performed over the last transformation axis, as by `ihfft`, then the transform over the remaining axes is performed as by `ifftn`. The order of the output is the positive part of the Hermitian output signal, in the same format as `rfft`.

Examples

```python
>>> import scipy.fft
>>> x = np.ones((2, 2, 2))
>>> scipy.fft.ihfftn(x)
array([[ 1.+0.j,  0.+0.j],  # may vary
       [ 0.+0.j,  0.+0.j]],
       [[ 0.+0.j,  0.+0.j],
       [ 0.+0.j,  0.+0.j]])
>>> scipy.fft.ihfftn(x, axes=(2, 0))
array([[ 1.+0.j,  0.+0.j],  # may vary
       [ 1.+0.j,  0.+0.j]],
       [[ 0.+0.j,  0.+0.j],
       [ 0.+0.j,  0.+0.j]])
```

```python
scipy.fft.dct
```

Return the Discrete Cosine Transform of arbitrary type sequence x.

**Parameters**

- `x` [array_like] The input array.
- `type` [{1, 2, 3, 4}, optional] Type of the DCT (see Notes). Default type is 2.
- `n` [int, optional] Length of the transform. If `n < x.shape[axis]`, x is truncated. If `n > x.shape[axis]`, x is zero-padded. The default results in `n = x.shape[axis]`.
- `axis` [int, optional] Axis along which the dct is computed; the default is over the last axis (i.e., `axis=-1`).
- `norm` [{“backward”, “ortho”, “forward”}, optional] Normalization mode (see Notes). Default is “backward”.
- `overwrite_x` [bool, optional] If True, the contents of x can be destroyed; the default is False.
- `workers` [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from `os.cpu_count()`. See `fft` for more details.
- `orthogonalize` [bool, optional] Whether to use the orthogonalized DCT variant (see Notes). Defaults to True when `norm=="ortho"` and False otherwise. New in version 1.8.0.

**Returns**

- `y` [ndarray of real] The transformed input array.

**See also:**

- `idct` Inverse DCT
Notes

For a single dimension array \( x \), \( \text{dct}(x, \text{norm}='\text{ortho}') \) is equal to MATLAB \( \text{dct}(x) \).

**Warning:** For \( \text{type} \in \{1, 2, 3\}, \text{norm}='\text{ortho}' \) breaks the direct correspondence with the direct Fourier transform. To recover it you must specify \( \text{orthogonalize=False} \).

For \( \text{norm}='\text{ortho}' \) both the \text{dct} and \text{idct} are scaled by the same overall factor in both directions. By default, the transform is also orthogonalized which for types 1, 2 and 3 means the transform definition is modified to give orthogonality of the DCT matrix (see below).

For \( \text{norm}='\text{backward}' \), there is no scaling on \text{dct} and the \text{idct} is scaled by \( 1/N \) where \( N \) is the “logical” size of the DCT. For \( \text{norm}='\text{forward}' \) the \( 1/N \) normalization is applied to the forward \text{dct} instead and the \text{idct} is unnormalized.

There are, theoretically, 8 types of the DCT, only the first 4 types are implemented in SciPy. The DCT generally refers to DCT type 2, and ‘the’ Inverse DCT generally refers to DCT type 3.

**Type I**

There are several definitions of the DCT-I; we use the following (for \( \text{norm}='\text{backward}' \))

\[
y_k = x_0 + (-1)^k x_{N-1} + \sum_{n=1}^{N-2} x_n \cos \left( \frac{\pi kn}{N-1} \right)
\]

If \( \text{orthogonalize=True} \), \( x[0] \) and \( x[N-1] \) are multiplied by a scaling factor of \( \sqrt{2} \), and \( y[0] \) and \( y[N-1] \) are divided by \( \sqrt{2} \). When combined with \( \text{norm}='\text{ortho}' \), this makes the corresponding matrix of coefficients orthonormal (\( O \cdot O^\top = \text{np.eye}(N) \)).

**Note:** The DCT-I is only supported for input size \( > 1 \).

**Type II**

There are several definitions of the DCT-II; we use the following (for \( \text{norm}='\text{backward}' \))

\[
y_k = 2 \sum_{n=0}^{N-1} x_n \cos \left( \frac{\pi k(2n+1)}{2N} \right)
\]

If \( \text{orthogonalize=True} \), \( y[0] \) is divided by \( \sqrt{2} \) which, when combined with \( \text{norm}='\text{ortho}' \), makes the corresponding matrix of coefficients orthonormal (\( O \cdot O^\top = \text{np.eye}(N) \)).

**Type III**

There are several definitions, we use the following (for \( \text{norm}='\text{backward}' \))

\[
y_k = x_0 + 2 \sum_{n=1}^{N-1} x_n \cos \left( \frac{\pi (2k+1)n}{2N} \right)
\]

If \( \text{orthogonalize=True} \), \( x[0] \) terms are multiplied by \( \sqrt{2} \) which, when combined with \( \text{norm}='\text{ortho}' \), makes the corresponding matrix of coefficients orthonormal (\( O \cdot O^\top = \text{np.eye}(N) \)).

The (unnormalized) DCT-III is the inverse of the (unnormalized) DCT-II, up to a factor \( 2N \). The orthonormalized DCT-III is exactly the inverse of the orthonormalized DCT-II.

**Type IV**
There are several definitions of the DCT-IV; we use the following (for \( \text{norm} = \text{"backward"} \))

\[
y_k = 2 \sum_{n=0}^{N-1} x_n \cos \left( \frac{\pi(2k+1)(2n+1)}{4N} \right)
\]

orthogonalize has no effect here, as the DCT-IV matrix is already orthogonal up to a scale factor of \( 2N \).

References

[1], [2]

Examples

The Type 1 DCT is equivalent to the FFT (though faster) for real, even-symmetrical inputs. The output is also real and even-symmetrical. Half of the FFT input is used to generate half of the FFT output:

```python
>>> from scipy.fft import fft, dct
>>> fft(np.array([4., 3., 5., 10., 5., 3.])).real
array([ 30., -8., 6., -2., 6., -8.])
>>> dct(np.array([4., 3., 5., 10.]), 1)
array([ 30., -8., 6., -2.])
```

**scipy.fft.idct**

`scipy.fft.idct` \( (x, \text{type}=2, n=\text{None}, \text{axis}=\text{1}, \text{norm}=\text{None}, \text{overwrite}_x=\text{False}, \text{workers}=\text{None}, \text{orthogonalize}=\text{None}) \)

Return the Inverse Discrete Cosine Transform of an arbitrary type sequence.

**Parameters**

- \( x \) [array_like] The input array.
- \( \text{type} \) [[1, 2, 3, 4], optional] Type of the DCT (see Notes). Default type is 2.
- \( n \) [int, optional] Length of the transform. If \( n < x.\text{shape}[\text{axis}] \), \( x \) is truncated. If \( n > x.\text{shape}[\text{axis}] \), \( x \) is zero-padded. The default results in \( n = x.\text{shape}[\text{axis}] \).
- \( \text{axis} \) [int, optional] Axis along which the idct is computed; the default is over the last axis (i.e., \( \text{axis} = \text{1} \)).
- \( \text{norm} \) [['backward', 'ortho', 'forward'], optional] Normalization mode (see Notes). Default is “backward”.
- \( \text{overwrite}_x \) [bool, optional] If True, the contents of \( x \) can be destroyed; the default is False.
- \( \text{workers} \) [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from `os.cpu_count()`. See `fft` for more details.
- \( \text{orthogonalize} \) [bool, optional] Whether to use the orthogonalized IDCT variant (see Notes). Defaults to True when \( \text{norm} = \text{"ortho"} \) and False otherwise. New in version 1.8.0.

**Returns**

- \( \text{idct} \) [ndarray of real] The transformed input array.

See also:

- \( \text{dct} \)
  Forward DCT
Notes

For a single dimension array \( x \), \( \text{idct}(x, \text{norm='ortho'}) \) is equal to MATLAB \( \text{idct}(x) \).

**Warning:** For type in \{1, 2, 3\}, \text{norm='ortho'} breaks the direct correspondence with the inverse direct Fourier transform. To recover it you must specify \text{orthogonalize=False}.

For \text{norm='ortho'} both the \text{dct} and \text{idct} are scaled by the same overall factor in both directions. By default, the transform is also orthogonalized which for types 1, 2 and 3 means the transform definition is modified to give orthogonality of the IDCT matrix (see \text{dct} for the full definitions).

‘The’ IDCT is the IDCT-II, which is the same as the normalized DCT-III.

The IDCT is equivalent to a normal DCT except for the normalization and type. DCT type 1 and 4 are their own inverse and DCTs 2 and 3 are each other’s inverses.

Examples

The Type 1 DCT is equivalent to the DFT for real, even-symmetrical inputs. The output is also real and even-symmetrical. Half of the IFFT input is used to generate half of the IFFT output:

```python
>>> from scipy.fft import ifft, idct
>>> idct(np.array([ 30., -8., 6., -2., 6., -8.])).real
array([ 4., 3., 5., 10., 5., 3.])
```

`scipy.fft.dctn`

`scipy.fft.dctn (x, type=2, s=None, axes=None, norm=None, overwrite_x=False, workers=None, *, orthogonalize=None)`

Return multidimensional Discrete Cosine Transform along the specified axes.

**Parameters**

- \( x \) [array_like] The input array.
- \( \text{type} \) [[1, 2, 3, 4], optional] Type of the DCT (see Notes). Default type is 2.
- \( s \) [int or array_like of ints or None, optional] The shape of the result. If both \( s \) and \( \text{axes} \) (see below) are None, \( s \) is \( x \).shape; if \( s \) is None but \( \text{axes} \) is not None, then \( s \) is \numpy.take(x.shape, axes, axis=0). \) If \( s[i] > x.shape[i] \), the ith dimension is padded with zeros. If \( s[i] < x.shape[i] \), the ith dimension is truncated to length \( s[i] \). If any element of \( s \) is -1, the size of the corresponding dimension of \( x \) is used.
- \( \text{axes} \) [int or array_like of ints or None, optional] Axes over which the DCT is computed. If not given, the last \( \text{len} (s) \) axes are used, or all axes if \( s \) is also not specified.
- \( \text{norm} \) [[“backward”, “ortho”, “forward”], optional] Normalization mode (see Notes). Default is “backward”.
- \( \text{overwrite}_x \) [bool, optional] If True, the contents of \( x \) can be destroyed; the default is False.
- \( \text{workers} \) [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from \os.cpu_count(). \) See \text{fft} for more details.
- \( \text{orthogonalize} \) [bool, optional] Whether to use the orthogonalized DCT variant (see Notes). Defaults to \text{True} when \text{norm='ortho'} and \text{False} otherwise. New in version 1.8.0.
Returns

\(y\) [ndarray of real] The transformed input array.

See also:

idctn

Inverse multidimensional DCT

Notes

For full details of the DCT types and normalization modes, as well as references, see \(\text{dct}\).

Examples

```python
>>> from scipy.fft import dctn, idctn
>>> rng = np.random.default_rng()
>>> y = rng.standard_normal((16, 16))
>>> np.allclose(y, idctn(dctn(y)))
True
```

\texttt{scipy.fft.idctn}

\texttt{scipy.fft.idctn}(x, type=2, s=None, axes=None, norm=None, overwrite_x=False, workers=None, orthogonalize=None)

Return multidimensional Inverse Discrete Cosine Transform along the specified axes.

Parameters

- \(x\) [array_like] The input array.
- \(\text{type}\) [{1, 2, 3, 4}, optional] Type of the DCT (see Notes). Default type is 2.
- \(s\) [int or array_like of ints or None, optional] The shape of the result. If both \(s\) and \(axes\) (see below) are None, \(s\) is \(x.shape\); if \(s\) is None but \(axes\) is not None, then \(s\) is \(\text{numpy.take(x.shape, axes, axis=0)}\). If \(s[i] > x.shape[i]\), the \(i\)th dimension is padded with zeros. If \(s[i] < x.shape[i]\), the \(i\)th dimension is truncated to length \(s[i]\). If any element of \(s\) is -1, the size of the corresponding dimension of \(x\) is used.
- \(axes\) [int or array_like of ints or None, optional] Axes over which the IDCT is computed. If not given, the last \(\text{len(s)}\) axes are used, or all axes if \(s\) is also not specified.
- \(\text{norm}\) [{“backward”, “ortho”, “forward”}, optional] Normalization mode (see Notes). Default is “backward”.
- \(\text{overwrite}_x\) [bool, optional] If True, the contents of \(x\) can be destroyed; the default is False.
- \(\text{workers}\) [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from \(\text{os.cpu_count()}\). See \texttt{fft} for more details.
- \(\text{orthogonalize}\) [bool, optional] Whether to use the orthogonalized IDCT variant (see Notes). Defaults to \(\text{True}\) when \(\text{norm}==\text{"ortho"}\) and \(\text{False}\) otherwise.

New in version 1.8.0.

Returns

- \(y\) [ndarray of real] The transformed input array.

See also:
dctn

multidimensional DCT

Notes

For full details of the IDCT types and normalization modes, as well as references, see \texttt{idct}.

Examples

```python
>>> from scipy.fft import dctn, idctn
>>> rng = np.random.default_rng()
>>> y = rng.standard_normal((16, 16))
>>> np.allclose(y, idctn(dctn(y)))
True
```

\texttt{scipy.fft.dst}

\texttt{scipy.fft.dst}(x, type=2, n=None, axis=-1, norm=None, overwrite_x=False, workers=None, orthogonalize=None)

Return the Discrete Sine Transform of arbitrary type sequence \(x\).

\textbf{Parameters}

- \texttt{x} [array_like] The input array.
- \texttt{type} [[1, 2, 3, 4], optional] Type of the DST (see Notes). Default type is 2.
- \texttt{n} [int, optional] Length of the transform. If \(n < x.shape[axis]\), \(x\) is truncated. If \(n > x.shape[axis]\), \(x\) is zero-padded. The default results in \(n = x.shape[axis]\).
- \texttt{axis} [int, optional] Axis along which the dst is computed; the default is over the last axis (i.e., \texttt{axis=-1}).
- \texttt{norm} [{'backward', 'ortho', 'forward'}, optional] Normalization mode (see Notes). Default is “backward”.
- \texttt{overwrite_x} [bool, optional] If True, the contents of \(x\) can be destroyed; the default is False.
- \texttt{workers} [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from \texttt{os.cpu_count()}. See \texttt{fft} for more details.
- \texttt{orthogonalize} [bool, optional] Whether to use the orthogonalized DST variant (see Notes). Defaults to True when \texttt{norm="ortho"} and False otherwise. New in version 1.8.0.

\textbf{Returns}

- \texttt{dst} [ndarray of reals] The transformed input array.

\textbf{See also:}

\texttt{idst}

Inverse DST
For `norm="ortho"` both the `dst` and `idst` are scaled by the same overall factor in both directions. By default, the transform is also orthogonalized which for types 2 and 3 means the transform definition is modified to give orthogonality of the DST matrix (see below).

For `norm="backward"`, there is no scaling on the `dst` and the `idst` is scaled by $1/N$ where $N$ is the “logical” size of the DST.

There are, theoretically, 8 types of the DST for different combinations of even/odd boundary conditions and boundary offsets [1], only the first 4 types are implemented in SciPy.

**Type I**

There are several definitions of the DST-I; we use the following for `norm="backward"`. DST-I assumes the input is odd around $n = -1$ and $n = N$.

$$y_k = 2 \sum_{n=0}^{N-1} x_n \sin \left( \frac{\pi (k + 1)(n + 1)}{N + 1} \right)$$

Note that the DST-I is only supported for input size > 1. The (unnormalized) DST-I is its own inverse, up to a factor $2(N + 1)$. The orthonormalized DST-I is exactly its own inverse.

`orthogonalize` has no effect here, as the DST-I matrix is already orthogonal up to a scale factor of $2N$.

**Type II**

There are several definitions of the DST-II; we use the following for `norm="backward"`. DST-II assumes the input is odd around $n = -1/2$ and $n = N - 1/2$; the output is odd around $k = -1$ and even around $k = N - 1$

$$y_k = 2 \sum_{n=0}^{N-1} x_n \sin \left( \frac{\pi (k + 1)(2n + 1)}{2N} \right)$$

If `orthogonalize=True`, $y[0]$ is divided by $\sqrt{2}$ which, when combined with `norm="ortho"`, makes the corresponding matrix of coefficients orthonormal ($O \otimes O^T = np.eye(N)$).

**Type III**

There are several definitions of the DST-III, we use the following (for `norm="backward"`). DST-III assumes the input is odd around $n = -1$ and even around $n = N - 1$

$$y_k = (-1)^k x_{N-1} + 2 \sum_{n=0}^{N-2} x_n \sin \left( \frac{\pi (2k + 1)(n + 1)}{2N} \right)$$

If `orthogonalize=True`, $x[0]$ is multiplied by $\sqrt{2}$ which, when combined with `norm="ortho"`, makes the corresponding matrix of coefficients orthonormal ($O \otimes O^T = np.eye(N)$).

The (unnormalized) DST-III is the inverse of the (unnormalized) DST-II, up to a factor $2N$. The orthonormalized DST-III is exactly the inverse of the orthonormalized DST-II.

**Type IV**

There are several definitions of the DST-IV, we use the following (for `norm="backward"`). DST-IV assumes the input is odd around $n = -0.5$ and even around $n = N - 0.5$

$$y_k = 2 \sum_{n=0}^{N-1} x_n \sin \left( \frac{\pi (2k + 1)(2n + 1)}{4N} \right)$$

3.3. API definition
orthogonalize has no effect here, as the DST-IV matrix is already orthogonal up to a scale factor of $2N$.

The (unnormalized) DST-IV is its own inverse, up to a factor $2N$. The orthonormalized DST-IV is exactly its own inverse.

References

[1]

scipy.fft.idst

scipy.fft.idst($x$, type=2, $n$=None, axis=-1, norm=None, overwrite_x=False, workers=None, orthogonalize=None)

Return the Inverse Discrete Sine Transform of an arbitrary type sequence.

Parameters

- **x** [array_like] The input array.
- **type** [{1, 2, 3, 4}, optional] Type of the DST (see Notes). Default type is 2.
- **n** [int, optional] Length of the transform. If $n < x.shape[axis], x$ is truncated. If $n > x.shape[axis], x$ is zero-padded. The default results in $n = x.shape[axis]$.
- **axis** [int, optional] Axis along which the idst is computed; the default is over the last axis (i.e., axis=-1).
- **norm** [{“backward”, “ortho”, “forward”}, optional] Normalization mode (see Notes). Default is “backward”.
- **overwrite_x** [bool, optional] If True, the contents of $x$ can be destroyed; the default is False.
- **workers** [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from os.cpu_count(). See fft for more details.
- **orthogonalize** [bool, optional] Whether to use the orthogonalized IDST variant (see Notes). Defaults to True when norm=”ortho” and False otherwise.

New in version 1.8.0.

Returns

- **idst** [ndarray of real] The transformed input array.

See also:

dst

Forward DST

Notes

**Warning:** For type in {2, 3}, norm="ortho" breaks the direct correspondence with the inverse direct Fourier transform.

For norm="ortho" both the dst and idst are scaled by the same overall factor in both directions. By default, the transform is also orthogonalized which for types 2 and 3 means the transform definition is modified to give orthogonality of the DST matrix (see dst for the full definitions).

‘The’ IDST is the IDST-II, which is the same as the normalized DST-III.
The IDST is equivalent to a normal DST except for the normalization and type. DST type 1 and 4 are their own inverse and DSTs 2 and 3 are each other’s inverses.

**scipy.fft.dstn**

```python
scipy.fft.dstn(x, type=2, s=None, axes=None, norm=None, overwrite_x=False, workers=None, orthogonalize=None)
```

Return multidimensional Discrete SineTransform along the specified axes.

**Parameters**

- **x**
  - [array_like] The input array.
- **type**
  - [{1, 2, 3, 4}, optional] Type of the DST (see Notes). Default type is 2.
- **s**
  - [int or array_like of ints or None, optional] The shape of the result. If both s and axes (see below) are None, s is x.shape; if s is None but axes is not None, then s is numpy.take(x.shape, axes, axis=0). If s[i] > x.shape[i], the ith dimension is padded with zeros. If s[i] < x.shape[i], the ith dimension is truncated to length s[i]. If any element of shape is -1, the size of the corresponding dimension of x is used.
- **axes**
  - [int or array_like of ints or None, optional] Axes over which the DST is computed. If not given, the last len(s) axes are used, or all axes if s is also not specified.
- **norm**
  - [{“backward”, “ortho”, “forward”}, optional] Normalization mode (see Notes). Default is “backward”.
- **overwrite_x**
  - [bool, optional] If True, the contents of x can be destroyed; the default is False.
- **workers**
  - [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from os.cpu_count(). See fft for more details.
- **orthogonalize**
  - [bool, optional] Whether to use the orthogonalized DST variant (see Notes). Defaults to True when norm=”ortho” and False otherwise. New in version 1.8.0.

**Returns**

- **y**
  - [ndarray of real] The transformed input array.

See also:

**idstn**

Inverse multidimensional DST

**Notes**

For full details of the DST types and normalization modes, as well as references, see dst.

**Examples**

```python
>>> from scipy.fft import dstn, idstn
>>> rng = np.random.default_rng()
>>> y = rng.standard_normal((16, 16))
>>> np.allclose(y, idstn(dstn(y)))
True
```
scipy.fft.idstn

scipy.fft.idstn(x, type=2, s=None, axes=None, norm=None, overwrite_x=False, workers=None, orthogonalize=None)

Return multidimensional Inverse Discrete Sine Transform along the specified axes.

Parameters

- x [array_like] The input array.
- type [{1, 2, 3, 4}, optional] Type of the DST (see Notes). Default type is 2.
- s [int or array_like of ints or None, optional] The shape of the result. If both s and axes (see below) are None, s is x.shape; if s is None but axes is not None, then s is numpy.take(x.shape, axes, axis=0). If s[i] > x.shape[i], the ith dimension is padded with zeros. If s[i] < x.shape[i], the ith dimension is truncated to length s[i]. If any element of s is -1, the size of the corresponding dimension of x is used.
- axes [int or array_like of ints or None, optional] Axes over which the IDST is computed. If not given, the last len(s) axes are used, or all axes if s is also not specified.
- norm [{“backward”, “ortho”, “forward”}, optional] Normalization mode (see Notes). Default is “backward”.
- overwrite_x [bool, optional] If True, the contents of x can be destroyed; the default is False.
- workers [int, optional] Maximum number of workers to use for parallel computation. If negative, the value wraps around from os.cpu_count(). See fft for more details.
- orthogonalize [bool, optional] Whether to use the orthogonalized IDST variant (see Notes). Defaults to True when norm="ortho" and False otherwise. New in version 1.8.0.

Returns

- y [ndarray of real] The transformed input array.

See also:

dstn

multidimensional DST

Notes

For full details of the IDST types and normalization modes, as well as references, see idst.

Examples

```python
>>> from scipy.fft import dstn, idstn
>>> rng = np.random.default_rng()
>>> y = rng.standard_normal((16, 16))
>>> np.allclose(y, idstn(dstn(y)))
True
```
Fast Hankel Transforms

\[ fht(a, dln, mu[, offset, bias]) \]
Compute the fast Hankel transform.

\[ ifht(A, dln, mu[, offset, bias]) \]
Compute the inverse fast Hankel transform.

\[ \text{scipy.fft.fht} \]
\[ \text{scipy.fft.fht}(a, dln, mu[, offset, bias]) \]
Compute the fast Hankel transform.

Computes the discrete Hankel transform of a logarithmically spaced periodic sequence using the FFTLog algorithm [1], [2].

**Parameters**

- **a** [array_like (…, n)] Real periodic input array, uniformly logarithmically spaced. For multi-dimensional input, the transform is performed over the last axis.
- **dln** [float] Uniform logarithmic spacing of the input array.
- **mu** [float] Order of the Hankel transform, any positive or negative real number.
- **offset** [float, optional] Offset of the uniform logarithmic spacing of the output array.
- **bias** [float, optional] Exponent of power law bias, any positive or negative real number.

**Returns**

- **A** [array_like (…, n)] The transformed output array, which is real, periodic, uniformly logarithmically spaced, and of the same shape as the input array.

**See also:**

- **ifht**
  The inverse of \textit{fht}.

- **fhtoffset**
  Return an optimal offset for \textit{fht}.

**Notes**

This function computes a discrete version of the Hankel transform

\[ A(k) = \int_{0}^{\infty} a(r) J_\mu(kr) r \, dr , \]

where \( J_\mu \) is the Bessel function of order \( \mu \). The index \( \mu \) may be any real number, positive or negative.

The input array \( a \) is a periodic sequence of length \( n \), uniformly logarithmically spaced with spacing \( dln \),

\[ a_j = a(r_j) , \quad r_j = r_c \exp[(j - j_c) dln] \]

centred about the point \( r_c \). Note that the central index \( j_c = (n + 1)/2 \) is half-integral if \( n \) is even, so that \( r_c \) falls between two input elements. Similarly, the output array \( A \) is a periodic sequence of length \( n \), also uniformly logarithmically spaced with spacing \( dln \)

\[ A_j = A(k_j) , \quad k_j = k_c \exp[(j - j_c) dln] \]

centred about the point \( k_c \).
The centre points $r_c$ and $k_c$ of the periodic intervals may be chosen arbitrarily, but it would be usual to choose the product $k_c r_c = k_j r_{n-1-j} = k_{n-1-j} r_j$ to be unity. This can be changed using the `offset` parameter, which controls the logarithmic offset $\log(k_c) = \text{offset} - \log(r_c)$ of the output array. Choosing an optimal value for `offset` may reduce ringing of the discrete Hankel transform.

If the `bias` parameter is nonzero, this function computes a discrete version of the biased Hankel transform

$$A(k) = \int_{0}^{\infty} a_q(r) (kr)^q J_{\mu}(kr) \, k \, dr$$

where $q$ is the value of `bias`, and a power law bias $a_q(r) = a(r) (kr)^{-q}$ is applied to the input sequence. Biasing the transform can help approximate the continuous transform of $a(r)$ if there is a value $q$ such that $a_q(r)$ is close to a periodic sequence, in which case the resulting $A(k)$ will be close to the continuous transform.

References

[1], [2]

`scipy.fft.ifht`

`scipy.fft.ifht(A, dln, mu, offset=0.0, bias=0.0)`

Compute the inverse fast Hankel transform.

Computes the discrete inverse Hankel transform of a logarithmically spaced periodic sequence. This is the inverse operation to `fht`.

Parameters

- `A` [array_like (…, n)] Real periodic input array, uniformly logarithmically spaced. For multi-dimensional input, the transform is performed over the last axis.
- `dln` [float] Uniform logarithmic spacing of the input array.
- `mu` [float] Order of the Hankel transform, any positive or negative real number.
- `offset` [float, optional] Offset of the uniform logarithmic spacing of the output array.
- `bias` [float, optional] Exponent of power law bias, any positive or negative real number.

Returns

- `a` [array_like (…, n)] The transformed output array, which is real, periodic, uniformly logarithmically spaced, and of the same shape as the input array.

See also:

- `fht` Definition of the fast Hankel transform.
- `fhtoffset` Return an optimal offset for `ifht`. 

412 Chapter 3. SciPy API
Notes

This function computes a discrete version of the Hankel transform

$$a(r) = \int_0^\infty A(k) J_\mu(kr) r \, dk,$$

where $J_\mu$ is the Bessel function of order $\mu$. The index $\mu$ may be any real number, positive or negative.

See \texttt{fht} for further details.

\texttt{scipy.fft.fftshift}

\texttt{scipy.fft.fftshift}(x, axes=None)

Shift the zero-frequency component to the center of the spectrum.

This function swaps half-spaces for all axes listed (defaults to all). Note that $y[0]$ is the Nyquist component only if \texttt{len(x)} is even.

Parameters

- \textit{x} [array_like] Input array.
- \textit{axes} [int or shape tuple, optional] Axes over which to shift. Default is None, which shifts all axes.

Returns

- \textit{y} [ndarray] The shifted array.

See also:

- \texttt{ifftshift}

The inverse of \texttt{fftshift}.
Examples

```python
>>> freqs = np.fft.fftfreq(10, 0.1)
>>> freqs
array([ 0., 1., 2., ..., -3., -2., -1.])
>>> np.fft.fftshift(freqs)
array([-5., -4., -3., -2., -1.,  0.,  1.,  2.,  3.,  4.])
```

Shift the zero-frequency component only along the second axis:

```python
>>> freqs = np.fft.fftfreq(9, d=1./9).reshape(3, 3)
>>> freqs
array([[ 0.,  1.,  2.],
       [ 3.,  4., -4.],
       [-3., -2., -1.]])
>>> np.fft.fftshift(freqs, axes=(1,))
array([[ 2.,  0.,  1.],
       [-4.,  3.,  4.],
       [-1., -3., -2.]])
```

**scipy.fft.ifftshift**

The inverse of `fftshift`. Although identical for even-length `x`, the functions differ by one sample for odd-length `x`.

**Parameters**
- `x` [array_like] Input array.
- `axes` [int or shape tuple, optional] Axes over which to calculate. Defaults to None, which shifts all axes.

**Returns**

**See also:**

- `fftshift`
  Shift zero-frequency component to the center of the spectrum.

Examples

```python
>>> freqs = np.fft.fftfreq(9, d=1./9).reshape(3, 3)
>>> freqs
array([[ 0.,  1.,  2.],
       [ 3.,  4., -4.],
       [-3., -2., -1.]])
>>> np.fft.ifftshift(np.fft.fftshift(freqs))
array([[ 0.,  1.,  2.],
       [ 3.,  4., -4.],
       [-3., -2., -1.]])
```
**scipy.fft.fftfreq**

```python
scipy.fft.fftfreq(n, d=1.0)
```

Return the Discrete Fourier Transform sample frequencies.

The returned float array $f$ contains the frequency bin centers in cycles per unit of the sample spacing (with zero at the start). For instance, if the sample spacing is in seconds, then the frequency unit is cycles/second.

Given a window length $n$ and a sample spacing $d$:

$$
f = \begin{cases} 
0, 1, \ldots, \frac{n}{2} - 1, \frac{-n}{2}, \ldots, -1 & \text{if } n \text{ is even} \\
0, 1, \ldots, \frac{(n-1)}{2}, -\frac{(n-1)}{2}, \ldots, -1 & \text{if } n \text{ is odd}
\end{cases} / (d \times n)
$$

**Parameters**
- $n$ [int] Window length.
- $d$ [scalar, optional] Sample spacing (inverse of the sampling rate). Defaults to 1.

**Returns**
- $f$ [ndarray] Array of length $n$ containing the sample frequencies.

**Examples**

```python
>>> signal = np.array([-2, 8, 6, 4, 1, 0, 3, 5], dtype=float)
>>> fourier = np.fft.fft(signal)
>>> n = signal.size
>>> timestep = 0.1
>>> freq = np.fft.fftfreq(n, d=timestep)
>>> freq
array([ 0. , 1.25, 2.5 , ..., -3.75, -2.5 , -1.25])
```

**scipy.fft.rfftfreq**

```python
scipy.fft.rfftfreq(n, d=1.0)
```

Return the Discrete Fourier Transform sample frequencies (for usage with rfft, irfft).

The returned float array $f$ contains the frequency bin centers in cycles per unit of the sample spacing (with zero at the start). For instance, if the sample spacing is in seconds, then the frequency unit is cycles/second.

Given a window length $n$ and a sample spacing $d$:

$$
f = \begin{cases} 
0, 1, \ldots, \frac{n-1}{2}, \frac{-n}{2}, \ldots, -1 & \text{if } n \text{ is odd}
\end{cases} / (d \times n)
$$

Unlike `fftfreq` (but like `scipy.fftpack.rfftfreq`) the Nyquist frequency component is considered to be positive.

**Parameters**
- $n$ [int] Window length.
- $d$ [scalar, optional] Sample spacing (inverse of the sampling rate). Defaults to 1.

**Returns**
- $f$ [ndarray] Array of length $n//2 + 1$ containing the sample frequencies.
Examples

```python
>>> signal = np.array([-2, 8, 6, 4, 1, 0, 3, 5, -3, 4], dtype=float)
>>> fourier = np.fft.rfft(signal)
>>> n = signal.size
>>> sample_rate = 100
>>> freq = np.fft.fftfreq(n, d=1./sample_rate)
>>> freq
array([ 0., 10., 20., ..., -30., -20., -10.])
>>> freq = np.fft.rfftfreq(n, d=1./sample_rate)
>>> freq
array([ 0., 10., 20., 30., 40., 50.])
```

**scipy.fft.fhtoffset**

`scipy.fft.fhtoffset(dln, mu, initial=0.0, bias=0.0)`

Return optimal offset for a fast Hankel transform.

Returns an offset close to `initial` that fulfills the low-ringing condition of [1] for the fast Hankel transform \(fht\) with logarithmic spacing `dln`, order `mu` and bias `bias`.

**Parameters**

- `dln` [float] Uniform logarithmic spacing of the transform.
- `mu` [float] Order of the Hankel transform, any positive or negative real number.
- `initial` [float, optional] Initial value for the offset. Returns the closest value that fulfills the low-ringing condition.
- `bias` [float, optional] Exponent of power law bias, any positive or negative real number.

**Returns**

- `offset` [float] Optimal offset of the uniform logarithmic spacing of the transform that fulfills a low-ringing condition.

**See also:**

- `fht`

  Definition of the fast Hankel transform.

**References**

[1]

**scipy.fft.next_fast_len**

`scipy.fft.next_fast_len()`

Find the next fast size of input data to `fft`, for zero-padding, etc.

SciPy's FFT algorithms gain their speed by a recursive divide and conquer strategy. This relies on efficient functions for small prime factors of the input length. Thus, the transforms are fastest when using composites of the prime factors handled by the `fft` implementation. If there are efficient functions for all radices \(\leq n\), then the result will be a number \(x \geq \text{target}\) with only prime factors \(< n\). (Also known as \(n\)-smooth numbers)

**Parameters**

- `target` [int] Length to start searching from. Must be a positive integer.
- `real` [bool, optional] True if the FFT involves real input or output (e.g., `rfft` or `hfft` but not `fft`). Defaults to False.
**Returns**

| out    | [int] The smallest fast length greater than or equal to target. |

**Notes**

The result of this function may change in future as performance considerations change, for example, if new prime factors are added.

Calling `fft` or `ifft` with real input data performs an 'R2C' transform internally.

**Examples**

On a particular machine, an FFT of prime length takes 11.4 ms:

```python
>>> from scipy import fft
>>> rng = np.random.default_rng()
>>> min_len = 93059  # prime length is worst case for speed
>>> a = rng.standard_normal(min_len)
>>> b = fft.fft(a)
```

Zero-padding to the next regular length reduces computation time to 1.6 ms, a speedup of 7.3 times:

```python
>>> fft.next_fast_len(min_len, real=True)
93312
>>> b = fft.fft(a, 93312)
```

Rounding up to the next power of 2 is not optimal, taking 3.0 ms to compute; 1.9 times longer than the size given by `next_fast_len`:

```python
>>> b = fft.fft(a, 131072)
```

**scipy.fft.set_workers**

`scipy.fft.set_workers(workers)`

Context manager for the default number of workers used in `scipy.fft`

**Parameters**

| workers | [int] The default number of workers to use |

**Examples**

```python
>>> from scipy import fft, signal
>>> rng = np.random.default_rng()
>>> x = rng.standard_normal((128, 64))
>>> with fft.set_workers(4):
...     y = signal.fftconvolve(x, x)
```
**scipy.fft.get_workers**

`scipy.fft.get_workers()`

Returns the default number of workers within the current context

**Examples**

```python
>>> from scipy import fft
>>> fft.get_workers()
1
>>> with fft.set_workers(4):
...     fft.get_workers()
4
```

**Backend control**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>set_backend(backend[, coerce, only])</code></td>
<td>Context manager to set the backend within a fixed scope.</td>
</tr>
<tr>
<td><code>skip_backend(backend)</code></td>
<td>Context manager to skip a backend within a fixed scope.</td>
</tr>
<tr>
<td><code>set_global_backend(backend[, coerce, only,...])</code></td>
<td>Sets the global fft backend</td>
</tr>
<tr>
<td><code>register_backend(backend)</code></td>
<td>Register a backend for permanent use.</td>
</tr>
</tbody>
</table>

**scipy.fft.set_backend**

`scipy.fft.set_backend(backend, coerce=False, only=False)`

Context manager to set the backend within a fixed scope.

Upon entering the `with` statement, the given backend will be added to the list of available backends with the highest priority. Upon exit, the backend is reset to the state before entering the scope.

**Parameters**

- `backend` [{object, ‘scipy’}] The backend to use. Can either be a string containing the name of a known backend (‘scipy’) or an object that implements the uarray protocol.
- `coerce` [bool, optional] Whether to allow expensive conversions for the `x` parameter. e.g., copying a NumPy array to the GPU for a CuPy backend. Implies `only`.
- `only` [bool, optional] If `only` is `True` and this backend returns `NotImplemented`, then a BackendNotImplemented error will be raised immediately. Ignoring any lower priority backends.

**Examples**

```python
>>> import scipy.fft as fft
>>> with fft.set_backend('scipy', only=True):
...     fft.fft([1])  # Always calls the scipy implementation
array([1.+0.j])
```
**scipy.fft.skip_backend**

`scipy.fft.skip_backend(backend)`

Context manager to skip a backend within a fixed scope.

Within the context of a `with` statement, the given backend will not be called. This covers backends registered both locally and globally. Upon exit, the backend will again be considered.

**Parameters**

- `backend` [{object, 'scipy'}] The backend to skip. Can either be a `str` containing the name of a known backend `{scipy}` or an object that implements the uarray protocol.

**Examples**

```python
>>> import scipy.fft as fft
>>> fft.fft([[1]])  # Calls default SciPy backend
array([1.+0.j])
>>> with fft.skip_backend('scipy'):  # We explicitly skip the SciPy...
    ... fft.fft([[1]])  # leaving no implementation available
Traceback (most recent call last):
    ... BackendNotImplementedError: No selected backends had an implementation ...
```

**scipy.fft.set_global_backend**

`scipy.fft.set_global_backend(backend, coerce=False, only=False, try_last=False)`

Sets the global fft backend

This utility method replaces the default backend for permanent use. It will be tried in the list of backends automatically, unless the `only` flag is set on a backend. This will be the first tried backend outside the `set_backend` context manager.

**Parameters**

- `backend` [{object, 'scipy'}] The backend to use. Can either be a `str` containing the name of a known backend `{scipy}` or an object that implements the uarray protocol.
- `coerce` [bool] Whether to coerce input types when trying this backend.
- `only` [bool] If True, no more backends will be tried if this fails. Implied by `coerce=True`.
- `try_last` [bool] If True, the global backend is tried after registered backends.

**Raises**

- `ValueError`: If the backend does not implement `numpy.scipy.fft`.

**Notes**

This will overwrite the previously set global backend, which, by default, is the SciPy implementation.
Examples

We can set the global fft backend:

```python
>>> from scipy.fft import fft, set_global_backend
>>> set_global_backend("scipy")  # Sets global backend. "scipy" is the default backend.
>>> fft([1])  # Calls the global backend
array([1.+0.j])
```

`scipy.fft.register_backend`

`scipy.fft.register_backend(backend)`
Register a backend for permanent use.

Registered backends have the lowest priority and will be tried after the global backend.

**Parameters**

- `backend` ([object, 'scipy']) The backend to use. Can either be a str containing the name of a known backend ('scipy') or an object that implements the uarray protocol.

**Raises**

- `ValueError`: If the backend does not implement `numpy.scipy.fft`.

Examples

We can register a new fft backend:

```python
>>> from scipy.fft import fft, register_backend, set_global_backend
>>> class NoopBackend:  # Define an invalid Backend
...     __ua_domain__ = "numpy.scipy.fft"
...     def __ua_function__(self, func, args, kwargs):
...         return NotImplemented
>>> set_global_backend(NoopBackend())  # Set the invalid backend as global
>>> register_backend("scipy")  # Register a new backend
>>> fft([1])  # The registered backend is called because the global backend returns `NotImplemented`
array([1.+0.j])
>>> set_global_backend("scipy")  # Restore global backend to default
```

3.3.6 Legacy discrete Fourier transforms (`scipy.fftpack`)

**Warning:** This submodule is now considered legacy, new code should use `scipy.fft`.

Fast Fourier Transforms (FFTs)

```
fft(x, n, axis, overwrite_x)
```
Return discrete Fourier transform of real or complex sequence.

</tbody>
</table>

scipy.fftpack.fft

`scipy.fftpack.fft(x, n=None, axis=-1, overwrite_x=False)`

Return discrete Fourier transform of real or complex sequence.

The returned complex array contains \( y(0), y(1), \ldots, y(n-1) \), where

\[
y(j) = (x * \exp(-2\pi i \sqrt{-1} j \cdot \text{np.arange}(n)/n)).\text{sum}().
\]

Parameters

- \( x \) [array_like] Array to Fourier transform.
- \( n \) [int, optional] Length of the Fourier transform. If \( n < x.\text{shape}[axis] \), \( x \) is truncated. If \( n > x.\text{shape}[axis] \), \( x \) is zero-padded. The default results in \( n = x.\text{shape}[axis] \).
- \( axis \) [int, optional] Axis along which the fft's are computed; the default is over the last axis (i.e., \( axis=-1 \)).
- \( overwrite_x \) [bool, optional] If True, the contents of \( x \) can be destroyed; the default is False.

Returns

- \( z \) [complex ndarray] with the elements:

  \[
  \begin{align*}
  & [y(0), y(1), \ldots, y(n/2), y(1-n/2), \ldots, y(-1)] & \text{if } n \text{ is even} \\
  & [y(0), y(1), \ldots, y((n-1)/2), y(-(n-1)/2), \ldots, y(-1)] & \text{if } n \text{ is odd}
  \end{align*}
  \]
where:

\[
y(j) = \sum_{k=0}^{n-1} x[k] \cdot \exp(-\sqrt{-1} \cdot j \cdot k \cdot 2\pi/n), \quad j_\rightarrow = 0..n-1
\]

See also:

- **ifft**
  
  Inverse FFT

- **rfft**
  
  FFT of a real sequence

Notes

The packing of the result is “standard”: If \( A = \text{fft}(a, n) \), then \( A[0] \) contains the zero-frequency term, \( A[1:n/2] \) contains the positive-frequency terms, and \( A[n/2:] \) contains the negative-frequency terms, in order of decreasingly negative frequency. So, for an 8-point transform, the frequencies of the result are \([0, 1, 2, 3, -4, -3, -2, -1]\). To rearrange the fft output so that the zero-frequency component is centered, like \([-4, -3, -2, -1, 0, 1, 2, 3]\), use \texttt{fftshift}.

Both single and double precision routines are implemented. Half precision inputs will be converted to single precision. Non-floating-point inputs will be converted to double precision. Long-double precision inputs are not supported.

This function is most efficient when \( n \) is a power of two, and least efficient when \( n \) is prime.

Note that if \( x \) is real-valued, then \( A[j] = A[n-j].\text{conjugate}() \). If \( x \) is real-valued and \( n \) is even, then \( A[n/2] \) is real.

If the data type of \( x \) is real, a “real FFT” algorithm is automatically used, which roughly halves the computation time. To increase efficiency a little further, use \texttt{rfft}, which does the same calculation, but only outputs half of the symmetrical spectrum. If the data is both real and symmetrical, the \texttt{dct} can again double the efficiency by generating half of the spectrum from half of the signal.

Examples

```python
>>> from scipy.fftpack import fft, ifft
>>> x = np.arange(5)
>>> np.allclose(fft(ifft(x)), x, atol=1e-15)  # within numerical accuracy.
True
```

**scipy.fftpack.ifft**

\[
\text{scipy.fftpack.ifft}(x, n=None, axis=-1, overwrite_x=False)
\]

Return discrete inverse Fourier transform of real or complex sequence.

The returned complex array contains \( y(0), y(1), \ldots, y(n-1) \), where

\[
y(j) = (x * \exp(2\pi i \sqrt{-1} j \cdot \text{np.arange(n)}/n)).\text{mean}().
\]

**Parameters**

- \( x \)  
  
  [array_like] Transformed data to invert.
n  [int, optional] Length of the inverse Fourier transform. If \( n < x.\text{shape}[\text{axis}] \), \( x \) is truncated. If \( n > x.\text{shape}[\text{axis}] \), \( x \) is zero-padded. The default results in \( n = x.\text{shape}[\text{axis}] \).

axis  [int, optional] Axis along which the ifft's are computed; the default is over the last axis (i.e., \( \text{axis}=-1 \)).

overwrite_x  [bool, optional] If True, the contents of \( x \) can be destroyed; the default is False.

Returns

ifft  [ndarray of floats] The inverse discrete Fourier transform.

See also:

fft

Forward FFT

Notes

Both single and double precision routines are implemented. Half precision inputs will be converted to single precision. Non-floating-point inputs will be converted to double precision. Long-double precision inputs are not supported.

This function is most efficient when \( n \) is a power of two, and least efficient when \( n \) is prime.

If the data type of \( x \) is real, a “real IFFT” algorithm is automatically used, which roughly halves the computation time.

Examples

```python
>>> from scipy.fftpack import fft, ifft
>>> import numpy as np
>>> x = np.arange(5)
>>> np.allclose(ifft(fft(x)), x, atol=1e-15)  # within numerical accuracy.
True
```

scipy.fftpack.fft2

`scipy.fftpack.fft2(x, shape=None, axes=(- 2, - 1), overwrite_x=False)`

2-D discrete Fourier transform.

Return the 2-D discrete Fourier transform of the 2-D argument \( x \).

See also:

fftn

for detailed information.
Examples

```python
>>> from scipy.fftpack import fft2, ifft2
>>> y = np.mgrid[:5, :5][0]
>>> y
array([[0, 0, 0, 0, 0],
       [1, 1, 1, 1, 1],
       [2, 2, 2, 2, 2],
       [3, 3, 3, 3, 3],
       [4, 4, 4, 4, 4]])
>>> np.allclose(y, ifft2(fft2(y)))
True
```

**scipy.fftpack.ifft2**

scipy.fftpack.ifft2(x, shape=None, axes=(-2, -1), overwrite_x=False)

2-D discrete inverse Fourier transform of real or complex sequence.

Return inverse 2-D discrete Fourier transform of arbitrary type sequence x.

See ifft for more information.

See also:

fft2, ifft

Examples

```python
>>> from scipy.fftpack import fft2, ifft2
>>> y = np.mgrid[:5, :5][0]
>>> y
array([[0, 0, 0, 0, 0],
       [1, 1, 1, 1, 1],
       [2, 2, 2, 2, 2],
       [3, 3, 3, 3, 3],
       [4, 4, 4, 4, 4]])
>>> np.allclose(y, fft2(ifft2(y)))
True
```

**scipy.fftpack.fftn**

scipy.fftpack.fftn(x, shape=None, axes=None, overwrite_x=False)

Return multidimensional discrete Fourier transform.

The returned array contains:

\[
y[j_1, \ldots, j_d] = \sum_{k_1=0}^{n_1-1} \ldots \sum_{k_d=0}^{n_d-1} x[k_1, \ldots, k_d] \times \prod_{i=1}^{d} \exp\left(-\sqrt{-1} \times 2 \times \pi / n_i \times j_i \times k_i\right)
\]

where \(d = \text{len}(x.shape)\) and \(n = x.shape\).

Parameters

- **x** [array_like] The (N-D) array to transform.
shape [int or array_like of ints or None, optional] The shape of the result. If both `shape` and `axes` (see below) are None, `shape` is `x.shape`; if `shape` is None but `axes` is not None, then `shape` is `numpy.take(x.shape, axes, axis=0)`. If `shape[i] > x.shape[i]`, the `i`th dimension is padded with zeros. If `shape[i] < x.shape[i]`, the `i`th dimension is truncated to length `shape[i]`. If any element of `shape` is -1, the size of the corresponding dimension of `x` is used.

axes [int or array_like of ints or None, optional] The axes of `x` (y if `shape` is not None) along which the transform is applied. The default is over all axes.

overwrite_x [bool, optional] If True, the contents of `x` can be destroyed. Default is False.

Returns

y [complex-valued N-D NumPy array] The (N-D) DFT of the input array.

See also:

`ifftn`

Notes

If `x` is real-valued, then `y[..., j_i, ...] == y[..., n_i-j_i, ...].conjugate()`. Both single and double precision routines are implemented. Half precision inputs will be converted to single precision. Non-floating-point inputs will be converted to double precision. Long-double precision inputs are not supported.

Examples

```python
>>> from scipy.fftpack import fftn, ifftn
>>> y = (-np.arange(16), 8 - np.arange(16), np.arange(16))
>>> np.allclose(y, fftn(ifftn(y)))
True
```

scipy.fftpack.ifftn

`scipy.fftpack.ifftn(x, shape=None, axes=None, overwrite_x=False)`

Return inverse multidimensional discrete Fourier transform.

The sequence can be of an arbitrary type.

The returned array contains:

\[
y[j_1, \ldots, j_d] = \frac{1}{p} \sum_{k_1=0}^{n_1-1} \ldots \sum_{k_d=0}^{n_d-1} x[k_1, \ldots, k_d] \cdot \prod_{i=1}^{d} \exp(-1)^{2\pi i n_i^*} j_i \cdot k_i
\]

where \(d = \text{len}(x.shape)\), \(n = x.shape\), and \(p = \prod_{i=1}^{d} n_i\).

For description of parameters see `fftn`.

See also:

`fftn`

for detailed information.
Examples

```python
>>> from scipy.fftpack import fftn, ifftn
>>> import numpy as np
>>> y = (-np.arange(16), 8 - np.arange(16), np.arange(16))
>>> np.allclose(y, ifftn(fftn(y)))
True
```

**scipy.fftpack.rfft**

`scipy.fftpack.rfft(x, n=None, axis=-1, overwrite_x=False)`

Discrete Fourier transform of a real sequence.

**Parameters**

- **x**  
  [array_like, real-valued] The data to transform.

- **n**  
  [int, optional] Defines the length of the Fourier transform. If `n` is not specified (the default) then `n = x.shape[axis]`. If `n < x.shape[axis]`, `x` is truncated, if `n > x.shape[axis]`, `x` is zero-padded.

- **axis**  
  [int, optional] The axis along which the transform is applied. The default is the last axis.

- **overwrite_x**  
  [bool, optional] If set to true, the contents of `x` can be overwritten. Default is False.

**Returns**

- **z**  
  [real ndarray] The returned real array contains:

```
[y(0), Re(y(1)), Im(y(1)), ..., Re(y(n/2))] if n_\text{is even}
[y(0), Re(y(1)), Im(y(1)), ..., Re(y(n/2)), Im(y(n/2))] if n_\text{is odd}
```

where:

\[
y(j) = \sum[k=0..n-1] x[k] \times \exp(-\sqrt{-1} \times j \times k \times 2 \times \pi / n) \quad \text{if } j = 0..n-1
\]

**See also:**

`fft, irfft, scipy.fft.rfft`

**Notes**

Within numerical accuracy, \( y = rfft(\text{irfft}(y)) \).

Both single and double precision routines are implemented. Half precision inputs will be converted to single precision. Non-floating-point inputs will be converted to double precision. Long-double precision inputs are not supported.

To get an output with a complex datatype, consider using the newer function `scipy.fft.rfft`.
Examples

```python
>>> from scipy.fftpack import fft, rfft
>>> a = [9, -9, 1, 3]
>>> fft(a)
array([ 4. +0.j, 8.+12.j, 16. +0.j, 8.-12.j])
>>> rfft(a)
array([ 4.,  8., 12., 16.])
```

**scipy.fftpack.irfft**

`scipy.fftpack.irfft(x, n=None, axis=-1, overwrite_x=False)`

Return inverse discrete Fourier transform of real sequence `x`.

The contents of `x` are interpreted as the output of the `rfft` function.

**Parameters**

- `x` [array_like] Transformed data to invert.
- `n` [int, optional] Length of the inverse Fourier transform. If `n < x.shape[axis]`, `x` is truncated. If `n > x.shape[axis]`, `x` is zero-padded. The default results in `n = x.shape[axis].`
- `axis` [int, optional] Axis along which the ifft's are computed; the default is over the last axis (i.e., `axis=-1`).
- `overwrite_x` [bool, optional] If True, the contents of `x` can be destroyed; the default is False.

**Returns**

**See also:**

`rfft, ifft, scipy.fft.irfft`

**Notes**

The returned real array contains:

```
[y(0), y(1), ..., y(n-1)]
```

where for `n` is even:

```
y(j) = \frac{1}{n} (\sum_{k=1}^{n/2-1} (x[2*k-1]+\sqrt{-1}*x[2*k])
        * \exp(\sqrt{-1}*j*k* 2*pi/n)
    + \text{c.c.} + x[0] + (-1)^n (j) * x[n-1])
```

and for `n` is odd:

```
y(j) = \frac{1}{n} (\sum_{k=1}^{(n-1)/2} (x[2*k-1]+\sqrt{-1}*x[2*k])
        * \exp(\sqrt{-1}*j*k* 2*pi/n)
    + \text{c.c.} + x[0])
```

c.c. denotes complex conjugate of preceding expression.

For details on input parameters, see `rfft`.

To process (conjugate-symmetric) frequency-domain data with a complex datatype, consider using the newer function `scipy.fft.irfft`.
Examples

```python
>>> from scipy.fftpack import rfft, irfft
>>> a = [1.0, 2.0, 3.0, 4.0, 5.0]
>>> irfft(a)
array([ 2.6, -3.16405192, 1.24398433, -1.14955713, 1.46962473])
>>> irfft(rfft(a))
array([1., 2., 3., 4., 5.])
```

scipy.fftpack.dct

`scipy.fftpack.dct(x, type=2, n=None, axis=-1, norm=None, overwrite_x=False)`

Return the Discrete Cosine Transform of arbitrary type sequence `x`.

**Parameters**

- `x` [array_like] The input array.
- `type` [{1, 2, 3, 4}, optional] Type of the DCT (see Notes). Default type is 2.
- `n` [int, optional] Length of the transform. If `n < x.shape[axis]`, `x` is truncated. If `n > x.shape[axis]`, `x` is zero-padded. The default results in `n = x.shape[axis]`.
- `axis` [int, optional] Axis along which the dct is computed; the default is over the last axis (i.e., `axis=-1`).
- `norm` [{None,'ortho'},optional] Normalization mode (see Notes). Default is None.
- `overwrite_x` [bool,optional] If True, the contents of `x` can be destroyed; the default is False.

**Returns**

- `y` [ndarray of real] The transformed input array.

See also:

- `idct`

  Inverse DCT

**Notes**

For a single dimension array `x`, `dct(x, norm='ortho')` is equal to MATLAB `dct(x)`.

There are, theoretically, 8 types of the DCT, only the first 4 types are implemented in scipy. ‘The’ DCT generally refers to DCT type 2, and ‘the’ Inverse DCT generally refers to DCT type 3.

**Type I**

There are several definitions of the DCT-I; we use the following (for `norm=None`)

$$y_k = x_0 + (-1)^k x_{N-1} + 2 \sum_{n=1}^{N-2} x_n \cos \left(\frac{\pi kn}{N-1}\right)$$

If `norm='ortho'`, `x[0]` and `x[N-1]` are multiplied by a scaling factor of $\sqrt{2}$, and `y[k]` is multiplied by a scaling factor $f$

$$f = \begin{cases} 
\frac{1}{2} \sqrt{\frac{1}{N-1}}, & \text{if } k = 0 \text{ or } N - 1, \\
\frac{1}{2} \sqrt{\frac{2}{N-1}}, & \text{otherwise}
\end{cases}$$

New in version 1.2.0: Orthonormalization in DCT-I.
Note: The DCT-I is only supported for input size > 1.

Type II
There are several definitions of the DCT-II; we use the following (for norm=\text{None})

\[ y_k = 2 \sum_{n=0}^{N-1} x_n \cos \left( \frac{\pi k(2n+1)}{2N} \right) \]

If norm='ortho', \( y[k] \) is multiplied by a scaling factor \( f \)

\[ f = \begin{cases} \sqrt{\frac{1}{4N}} & \text{if } k = 0, \\ \sqrt{\frac{1}{2N}} & \text{otherwise} \end{cases} \]

which makes the corresponding matrix of coefficients orthonormal (\( O @ O.T = np.eye(N) \)).

Type III
There are several definitions, we use the following (for norm=\text{None})

\[ y_k = x_0 + 2 \sum_{n=1}^{N-1} x_n \cos \left( \frac{\pi (2k+1)n}{2N} \right) \]

or, for norm='ortho'

\[ y_k = \frac{x_0}{\sqrt{N}} + \sqrt{\frac{2}{N}} \sum_{n=1}^{N-1} x_n \cos \left( \frac{\pi (2k+1)n}{2N} \right) \]

The (unnormalized) DCT-III is the inverse of the (unnormalized) DCT-II, up to a factor 2N. The orthonormalized DCT-III is exactly the inverse of the orthonormalized DCT-II.

Type IV
There are several definitions of the DCT-IV; we use the following (for norm=\text{None})

\[ y_k = 2 \sum_{n=0}^{N-1} x_n \cos \left( \frac{\pi (2k+1)(2n+1)}{4N} \right) \]

If norm='ortho', \( y[k] \) is multiplied by a scaling factor \( f \)

\[ f = \frac{1}{\sqrt{2N}} \]

New in version 1.2.0: Support for DCT-IV.

References

[1], [2]
Examples

The Type 1 DCT is equivalent to the FFT (though faster) for real, even-symmetrical inputs. The output is also real and even-symmetrical. Half of the FFT input is used to generate half of the FFT output:

```python
>>> from scipy.fftpack import fft, dct
>>> fft(np.array([4., 3., 5., 10., 5., 3.])).real
array([ 30., -8.,  6., -2.,  6., -8.])
>>> dct(np.array([4., 3., 5., 10.]), 1)
array([ 30., -8.,  6., -2.])
```

`scipy.fftpack.idct`

Return the Inverse Discrete Cosine Transform of an arbitrary type sequence.

**Parameters**

- x: [array_like] The input array.
- type: [{1, 2, 3, 4}, optional] Type of the DCT (see Notes). Default type is 2.
- n: [int, optional] Length of the transform. If n < x.shape[axis], x is truncated. If n > x.shape[axis], x is zero-padded. The default results in n = x.shape[axis].
- axis: [int, optional] Axis along which the idct is computed; the default is over the last axis (i.e., axis=-1).
- norm: [{None, 'ortho'}, optional] Normalization mode (see Notes). Default is None.
- overwrite_x: [bool, optional] If True, the contents of x can be destroyed; the default is False.

**Returns**

- idct: [ndarray of real] The transformed input array.

See also:

- `dct`
  Forward DCT

**Notes**

For a single dimension array x, `idct(x, norm='ortho')` is equal to MATLAB `idct(x)`.

The’ IDCT is the IDCT of type 2, which is the same as DCT of type 3.

IDCT of type 1 is the DCT of type 1, IDCT of type 2 is the DCT of type 3, and IDCT of type 3 is the DCT of type 2. IDCT of type 4 is the DCT of type 4. For the definition of these types, see `dct`. 
Examples

The Type 1 DCT is equivalent to the DFT for real, even-symmetrical inputs. The output is also real and even-symmetrical. Half of the IFFT input is used to generate half of the IFFT output:

```python
>>> from scipy.fftpack import ifft, idct
>>> ifft(np.array([ 30., -8.,  6., -2.,  6., -8.])).real
array([ 4.,  3.,  5., 10.,  5.,  3.])
>>> idct(np.array([ 30., -8.,  6., -2.]), 1) / 6
array([ 4.,  3.,  5., 10.])
```

**scipy.fftpack.dctn**

Return multidimensional Discrete Cosine Transform along the specified axes.

**Parameters**

- **x** [array_like] The input array.
- **type** [{1, 2, 3, 4}, optional] Type of the DCT (see Notes). Default type is 2.
- **shape** [int or array_like of ints or None, optional] The shape of the result. If both `shape` and `axes` (see below) are None, `shape` is `x.shape`; if `shape` is None but `axes` is not None, then `shape` is `numpy.take(x.shape, axes, axis=0)` If `shape[i] > x.shape[i]`, the ith dimension is padded with zeros. If `shape[i] < x.shape[i]`, the ith dimension is truncated to length `shape[i]`. If any element of `shape` is -1, the size of the corresponding dimension of `x` is used.
- **axes** [int or array_like of ints or None, optional] Axes along which the DCT is computed. The default is over all axes.
- **norm** [{None, 'ortho'}, optional] Normalization mode (see Notes). Default is None.
- **overwrite_x** [bool, optional] If True, the contents of `x` can be destroyed; the default is False.

**Returns**

- **y** [ndarray of real] The transformed input array.

See also:

- **idctn**

  Inverse multidimensional DCT

**Notes**

For full details of the DCT types and normalization modes, as well as references, see `dct`.
Examples

```python
>>> from scipy.fftpack import dctn, idctn
>>> rng = np.random.default_rng()
>>> y = rng.standard_normal((16, 16))
>>> np.allclose(y, idctn(dctn(y, norm='ortho'), norm='ortho'))
True
```

**scipy.fftpack.idctn**

*scipy.fftpack.idctn*(x, type=2, shape=None, axes=None, norm=None, overwrite_x=False)

Return multidimensional Discrete Cosine Transform along the specified axes.

**Parameters**

- **x** [array_like] The input array.
- **type** [{1, 2, 3, 4}, optional] Type of the DCT (see Notes). Default type is 2.
- **shape** [int or array_like of ints or None, optional] The shape of the result. If both shape and axes (see below) are None, shape is x.shape; if shape is None but axes is not None, then shape is numpy.take(x.shape, axes, axis=0). If shape[i] > x.shape[i], the ith dimension is padded with zeros. If shape[i] < x.shape[i], the ith dimension is truncated to length shape[i]. If any element of shape is -1, the size of the corresponding dimension of x is used.
- **axes** [int or array_like of ints or None, optional] Axes along which the IDCT is computed. The default is over all axes.
- **norm** [{None, 'ortho'}, optional] Normalization mode (see Notes). Default is None.
- **overwrite_x** [bool, optional] If True, the contents of x can be destroyed; the default is False.

**Returns**

- **y** [ndarray of real] The transformed input array.

See also:

- **dctn**
  multidimensional DCT

**Notes**

For full details of the IDCT types and normalization modes, as well as references, see *idct*.  

**Examples**

```python
>>> from scipy.fftpack import dctn, idctn
>>> rng = np.random.default_rng()
>>> y = rng.standard_normal((16, 16))
>>> np.allclose(y, idctn(dctn(y, norm='ortho'), norm='ortho'))
True
```
scipy.fftpack.dst

scipy.fftpack.dst(x, type=2, n=None, axis=-1, norm=None, overwrite_x=False)

Return the Discrete Sine Transform of arbitrary type sequence x.

**Parameters**

- `x` : array_like
  The input array.
- `type` : {1, 2, 3, 4}, optional
  Type of the DST (see Notes). Default type is 2.
- `n` : int, optional
  Length of the transform. If `n < x.shape[axis]`, x is truncated. If `n > x.shape[axis]`, x is zero-padded. The default results in `n = x.shape[axis]`.
- `axis` : int, optional
  Axis along which the dst is computed; the default is over the last axis (i.e., `axis=-1`).
- `norm` : [{None, 'ortho'}, optional]
  Normalization mode (see Notes). Default is None.
- `overwrite_x` : bool, optional
  If True, the contents of x can be destroyed; the default is False.

**Returns**

- `dst` : ndarray of reals
  The transformed input array.

**See also:**

- idst
  Inverse DST

**Notes**

For a single dimension array x.

There are, theoretically, 8 types of the DST for different combinations of even/odd boundary conditions and boundary offsets [1], only the first 4 types are implemented in scipy.

**Type I**

There are several definitions of the DST-I; we use the following for `norm=None`. DST-I assumes the input is odd around `n=-1` and `n=N`.

\[
y_k = 2 \sum_{n=0}^{N-1} x_n \sin \left( \frac{\pi (k + 1)(n + 1)}{N + 1} \right)
\]

Note that the DST-I is only supported for input size > 1. The (unnormalized) DST-I is its own inverse, up to a factor \(2(N+1)\). The orthonormalized DST-I is exactly its own inverse.

**Type II**

There are several definitions of the DST-II; we use the following for `norm=None`. DST-II assumes the input is odd around `n=-1/2` and `n=N-1/2`; the output is odd around `k = -1` and even around `k=N-1`.

\[
y_k = 2 \sum_{n=0}^{N-1} x_n \sin \left( \frac{\pi (k + 1)(2n + 1)}{2N} \right)
\]

if `norm='ortho'`, \(y[k]\) is multiplied by a scaling factor \(f\)

\[
f = \begin{cases} \sqrt{\frac{1}{2N}} & \text{if } k = 0, \\ \sqrt{\frac{1}{1N}} & \text{otherwise} \end{cases}
\]

**Type III**

There are several definitions of the DST-III, we use the following (for norm=None). DST-III assumes the input is odd around $n=-1$ and even around $n=N-1$

$$y_k = (-1)^k x_{N-1} + 2 \sum_{n=0}^{N-2} x_n \sin \left( \frac{\pi(2k+1)(n+1)}{2N} \right)$$

The (unnormalized) DST-III is the inverse of the (unnormalized) DST-II, up to a factor $2N$. The orthonormalized DST-III is exactly the inverse of the orthonormalized DST-II.

New in version 0.11.0.

Type IV

There are several definitions of the DST-IV, we use the following (for norm=None). DST-IV assumes the input is odd around $n=0.5$ and even around $n=N-0.5$

$$y_k = 2 \sum_{n=0}^{N-1} x_n \sin \left( \frac{\pi(2k+1)(2n+1)}{4N} \right)$$

The (unnormalized) DST-IV is its own inverse, up to a factor $2N$. The orthonormalized DST-IV is exactly its own inverse.

New in version 1.2.0: Support for DST-IV.

References

[1]

scipy.fftpack.idst

scipy.fftpack.idst ($x$, $type=2$, $n=None$, $axis=-1$, $norm=None$, $overwrite_x=False$)

Return the Inverse Discrete Sine Transform of an arbitrary type sequence.

Parameters

- **x** [array_like] The input array.
- **type** [{1, 2, 3, 4}, optional] Type of the DST (see Notes). Default type is 2.
- **n** [int, optional] Length of the transform. If $n < x$.shape[axis], $x$ is truncated. If $n > x$.shape[axis], $x$ is zero-padded. The default results in $n = x$.shape[axis].
- **axis** [int, optional] Axis along which the idst is computed; the default is over the last axis (i.e., axis=-1).
- **norm** [{None, 'ortho'}, optional] Normalization mode (see Notes). Default is None.
- **overwrite_x** [bool, optional] If True, the contents of $x$ can be destroyed; the default is False.

Returns

- **idst** [ndarray of real] The transformed input array.

See also:

- **dst**

  Forward DST
Notes

'The' IDST is the IDST of type 2, which is the same as DST of type 3.
IDST of type 1 is the DST of type 1, IDST of type 2 is the DST of type 3, and IDST of type 3 is the DST of type 2. For the definition of these types, see dst.
New in version 0.11.0.

scipy.fftpack.dstn

scipy.fftpack.dstn(x, type=2, shape=None, axes=None, norm=None, overwrite_x=False)
Return multidimensional Discrete SineTransform along the specified axes.

Parameters

x [array_like] The input array.
type [{1, 2, 3, 4}, optional] Type of the DST (see Notes). Default type is 2.
shape [int or array_like of ints or None, optional] The shape of the result. If both shape and axes (see below) are None, shape is x.shape; if shape is None but axes is not None, then shape is numpy.take(x.shape, axes, axis=0). If shape[i] > x.shape[i], the ith dimension is padded with zeros. If shape[i] < x.shape[i], the ith dimension is truncated to length shape[i]. If any element of shape is -1, the size of the corresponding dimension of x is used.
axes [int or array_like of ints or None, optional] Axes along which the DCT is computed. The default is over all axes.
norm [{None, 'ortho'}, optional] Normalization mode (see Notes). Default is None.
overwrite_x [bool, optional] If True, the contents of x can be destroyed; the default is False.

Returns

y [ndarray of real] The transformed input array.

See also:

idstn

Inverse multidimensional DST

Notes

For full details of the DST types and normalization modes, as well as references, see dst.

Examples

>>> from scipy.fftpack import dstn, idstn
>>> rng = np.random.default_rng()
>>> y = rng.standard_normal((16, 16))
>>> np.allclose(y, idstn(dstn(y, norm='ortho'), norm='ortho'))
True
```python
scipy.fftpack.idstn(
x, type=2, shape=None, axes=None, norm=None, overwrite_x=False)
```

Return multidimensional Discrete SineTransform along the specified axes.

**Parameters**
- `x` [array_like] The input array.
- `type` [{1, 2, 3, 4}, optional] Type of the DST (see Notes). Default type is 2.
- `shape` [int or array_like of ints or None, optional] The shape of the result. If both `shape` and `axes` (see below) are None, `shape` is `x.shape`; if `shape` is None but `axes` is not None, then `shape` is `numpy.take(x.shape, axes, axis=0)`.
  If `shape[i] > x.shape[i]`, the `i`th dimension is padded with zeros. If `shape[i] < x.shape[i]`, the `i`th dimension is truncated to length `shape[i]`. If any element of `shape` is -1, the size of the corresponding dimension of `x` is used.
- `axes` [int or array_like of ints or None, optional] Axes along which the IDST is computed. The default is over all axes.
- `norm` [{None, 'ortho'}, optional] Normalization mode (see Notes). Default is None.
- `overwrite_x` [bool, optional] If True, the contents of `x` can be destroyed; the default is False.

**Returns**
- `y` [ndarray of real] The transformed input array.

**See also:**
- `dstn`
  multidimensional DST

**Notes**

For full details of the IDST types and normalization modes, as well as references, see `idst`.

**Examples**

```python
>>> from scipy.fftpack import dstn, idstn
>>> rng = np.random.default_rng()
>>> y = rng.standard_normal((16, 16))
>>> np.allclose(y, idstn(dstn(y, norm='ortho'), norm='ortho'))
True
```

**Differential and pseudo-differential operators**

- `diff(x[, order, period, _cache])` Return kth derivative (or integral) of a periodic sequence `x`.
- `tilbert(x, h[, period, _cache])` Return h-Tilbert transform of a periodic sequence `x`.
- `itilbert(x, h[, period, _cache])` Return inverse h-Tilbert transform of a periodic sequence `x`.
- `hilbert(x[, _cache])` Return Hilbert transform of a periodic sequence `x`.

</tbody>
</table>

**scipy.fftpack.diff**

scipy.fftpack.diff(x, order=1, period=None, _cache={})

Return kth derivative (or integral) of a periodic sequence x.

If x_j and y_j are Fourier coefficients of periodic functions x and y, respectively, then:

\[
y_j = \text{pow}(\sqrt{-1}^k \cdot 2 \cdot \pi / \text{period}, \text{order}) \cdot x_j
\]

\[
y_0 = 0 \text{ if order is not 0}.
\]

**Parameters**

- x [array_like] Input array.
- order [int, optional] The order of differentiation. Default order is 1. If order is negative, then integration is carried out under the assumption that x_0 == 0.
- period [float, optional] The assumed period of the sequence. Default period is 2*pi.

**Notes**

- If \( \text{sum}(x, \text{axis}=0) = 0 \) then \( \text{diff}(\text{diff}(x, k), -k) = x \) (within numerical accuracy).
- For odd order and even \( \text{len}(x) \), the Nyquist mode is taken zero.

**scipy.fftpack.tilbert**

scipy.fftpack.tilbert(x, h, period=None, _cache={})

Return h-Tilbert transform of a periodic sequence x.

If x_j and y_j are Fourier coefficients of periodic functions x and y, respectively, then:

\[
y_j = \sqrt{-1}^k \cdot \coth(j \cdot h \cdot 2 \cdot \pi / \text{period}) \cdot x_j
\]

\[
y_0 = 0
\]

**Parameters**

- x [array_like] The input array to transform.
- h [float] Defines the parameter of the Tilbert transform.
- period [float, optional] The assumed period of the sequence. Default period is 2*pi.

**Returns**

- tilbert [ndarray] The result of the transform.
Notes

If \( \sum(x, \text{axis}=0) == 0 \) and \( n = \text{len}(x) \) is odd, then \( \text{tilbert}(\text{tilbert}(x)) == x \).

If \( 2 * \pi * h / \text{period} \) is approximately 10 or larger, then numerically \( \text{tilbert} == \text{hilbert} \) (theoretically \( \text{oo-Tilbert} == \text{Hilbert} \)).

For even \( \text{len}(x) \), the Nyquist mode of \( x \) is taken zero.

**scipy.fftpack.itilbert**

```
scipy.fftpack.itilbert(x, h, period=None, _cache={})
```

Return inverse h-Tilbert transform of a periodic sequence \( x \).

If \( x_j \) and \( y_j \) are Fourier coefficients of periodic functions \( x \) and \( y \), respectively, then:

\[
\begin{align*}
y_j &= -\sqrt{-1} \tan(jh \cdot 2\pi/\text{period}) \cdot x_j \\
y_0 &= 0
\end{align*}
\]

For more details, see \( \text{tilbert} \).

**scipy.fftpack.hilbert**

```
scipy.fftpack.hilbert(x, _cache={})
```

Return Hilbert transform of a periodic sequence \( x \).

If \( x_j \) and \( y_j \) are Fourier coefficients of periodic functions \( x \) and \( y \), respectively, then:

\[
\begin{align*}
y_j &= \sqrt{-1} \cdot \text{sign}(j) \cdot x_j \\
y_0 &= 0
\end{align*}
\]

**Parameters**

- \( x \) [array_like] The input array, should be periodic.
- \( _\text{cache} \) [dict, optional] Dictionary that contains the kernel used to do a convolution with.

**Returns**

- \( y \) [ndarray] The transformed input.

**See also:**

**scipy.signal.hilbert**

Compute the analytic signal, using the Hilbert transform.

**Notes**

If \( \sum(x, \text{axis}=0) == 0 \) then \( \text{hilbert}(\text{ihilbert}(x)) == x \).

For even \( \text{len}(x) \), the Nyquist mode of \( x \) is taken zero.

The sign of the returned transform does not have a factor -1 that is more often than not found in the definition of the Hilbert transform. Note also that \( \text{scipy.signal.hilbert} \) does have an extra -1 factor compared to this function.
**scipy.fftpack.ihilbert**

`scipy.fftpack.ihilbert(x)`  
Return inverse Hilbert transform of a periodic sequence `x`.

If `x_j` and `y_j` are Fourier coefficients of periodic functions `x` and `y`, respectively, then:

\[
\begin{align*}
y_j &= -\sqrt{-1} \cdot \text{sign}(j) \cdot x_j \\
y_0 &= 0
\end{align*}
\]

**scipy.fftpack.cs_diff**

`scipy.fftpack.cs_diff(x, a, b, period=None, _cache={})`  
Return `(a, b)`-cosh/sinh pseudo-derivative of a periodic sequence.

If `x_j` and `y_j` are Fourier coefficients of periodic functions `x` and `y`, respectively, then:

\[
\begin{align*}
y_j &= -\sqrt{-1} \cdot \cosh(j \cdot a^2 \cdot \pi / \text{period}) / \sinh(j \cdot b^2 \cdot \pi / \text{period}) \cdot x_j \\
y_0 &= 0
\end{align*}
\]

**Parameters**  
- `x` : array_like  
  The array to take the pseudo-derivative from.  
- `a`, `b` : float  
  Defines the parameters of the cosh/sinh pseudo-differential operator.  
- `period` : float, optional  
  The period of the sequence. Default is `2*pi`.  

**Returns**  
- `cs_diff` : ndarray  
  Pseudo-derivative of periodic sequence `x`.  

**Notes**  
For even `len(x)`, the Nyquist mode of `x` is taken as zero.

**scipy.fftpack.sc_diff**

`scipy.fftpack.sc_diff(x, a, b, period=None, _cache={})`  
Return `(a, b)`-sinh/cosh pseudo-derivative of a periodic sequence `x`.

If `x_j` and `y_j` are Fourier coefficients of periodic functions `x` and `y`, respectively, then:

\[
\begin{align*}
y_j &= \sqrt{-1} \cdot \sinh(j \cdot a^2 \cdot \pi / \text{period}) / \cosh(j \cdot b^2 \cdot \pi / \text{period}) \cdot x_j \\
y_0 &= 0
\end{align*}
\]

**Parameters**  
- `x` : array_like  
  Input array.  
- `a`, `b` : float  
  Defines the parameters of the sinh/cosh pseudo-differential operator.  
- `period` : float, optional  
  The period of the sequence `x`. Default is `2*pi`.  

---

3.3. API definition  
439

Notes

\[ \text{sc} \text{d}_{\text{iff}}(\text{cs} \text{d}_{\text{iff}}(x, a, b), b, a) = x \] For even \( \text{len}(x) \), the Nyquist mode of \( x \) is taken as zero.

**scipy.fftpack.ss_diff**

`scipy.fftpack.ss_diff(x, a, b, period=None, _cache={})`

Return \((a, b)\)-sinh/sinh pseudo-derivative of a periodic sequence \( x \).

If \( x_j \) and \( y_j \) are Fourier coefficients of periodic functions \( x \) and \( y \), respectively, then:

\[
\begin{align*}
y_j &= \frac{\sinh(j \cdot a \cdot 2 \cdot \pi / \text{period})}{\sinh(j \cdot b \cdot 2 \cdot \pi / \text{period})} \times x_j \\
y_0 &= \frac{a}{b} \times x_0
\end{align*}
\]

**Parameters**

- \( x \) [array_like] The array to take the pseudo-derivative from.
- \( a, b \) Defines the parameters of the sinh/sinh pseudo-differential operator.
- \( \text{period} \) [float, optional] The period of the sequence \( x \). Default is \( 2 \cdot \pi \).

**Notes**

\[ \text{ss} \text{d}_{\text{iff}}(\text{ss} \text{d}_{\text{iff}}(x, a, b), b, a) = x \]

**scipy.fftpack.cc_diff**

`scipy.fftpack.cc_diff(x, a, b, period=None, _cache={})`

Return \((a, b)\)-cosh/cosh pseudo-derivative of a periodic sequence.

If \( x_j \) and \( y_j \) are Fourier coefficients of periodic functions \( x \) and \( y \), respectively, then:

\[
\begin{align*}
y_j &= \frac{\cosh(j \cdot a \cdot 2 \cdot \pi / \text{period})}{\cosh(j \cdot b \cdot 2 \cdot \pi / \text{period})} \times x_j \\
y_0 &= \frac{a}{b} \times x_0
\end{align*}
\]

**Parameters**

- \( x \) [array_like] The array to take the pseudo-derivative from.
- \( a, b \) [float] Defines the parameters of the sinh/sinh pseudo-differential operator.
- \( \text{period} \) [float, optional] The period of the sequence \( x \). Default is \( 2 \cdot \pi \).

**Returns**

- \( \text{cc} \text{d}_{\text{iff}} \) [ndarray] Pseudo-derivative of periodic sequence \( x \).

**Notes**

\[ \text{cc} \text{d}_{\text{iff}}(\text{cc} \text{d}_{\text{iff}}(x, a, b), b, a) = x \]
scipy.fftpack.shift

scipy.fftpack.shift(x, a, period=None, _cache=())
Shift periodic sequence x by a: y(u) = x(u+a).
If x_j and y_j are Fourier coefficients of periodic functions x and y, respectively, then:
\[ y_j = \exp(j \cdot a \cdot 2 \cdot \pi / \text{period} \cdot \sqrt{-1}) \cdot x_f \]

Parameters
- x: [array_like] The array to take the pseudo-derivative from.
- a: [float] Defines the parameters of the sinh/sinh pseudo-differential
- period: [float, optional] The period of the sequences x and y. Default period is 2*pi.

Helper functions

- fftshift(x[, axes]): Shift the zero-frequency component to the center of the spectrum.
- ifftshift(x[, axes]): The inverse of fftshift.
- fftfreq(n[, d]): Return the Discrete Fourier Transform sample frequencies.
- rfftfreq(n[, d]): DFT sample frequencies (for usage with rfft, irfft).
- next_fast_len(target): Find the next fast size of input data to fft, for zero-padding, etc.

scipy.fftpack.fftshift

scipy.fftpack.fftshift(x, axes=None)
Shift the zero-frequency component to the center of the spectrum.
This function swaps half-spaces for all axes listed (defaults to all). Note that y[0] is the Nyquist component only if len(x) is even.

Parameters
- x: [array_like] Input array.
- axes: [int or shape tuple, optional] Axes over which to shift. Default is None, which shifts all axes.

Returns
- y: [ndarray] The shifted array.

See also:
- ifftshift
  The inverse of fftshift.
Examples

```python
>>> freqs = np.fft.fftfreq(10, 0.1)
>>> freqs
array([ 0.,  1.,  2., ..., -3., -2., -1.])
>>> np.fft.fftshift(freqs)
array([-5., -4., -3., -2., -1.,  0.,  1.,  2.,  3.,  4.])
```

Shift the zero-frequency component only along the second axis:

```python
>>> freqs = np.fft.fftfreq(9, d=1./9).reshape(3, 3)
>>> freqs
array([[ 0.,  1.,  2.],
       [ 3.,  4., -4.],
       [-3., -2., -1.]])
>>> np.fft.fftshift(freqs, axes=(1,))
array([[ 2.,  0.,  1.],
       [-4.,  3.,  4.],
       [-1., -3., -2.]])
```

`scipy.fftpack.ifftshift`

`scipy.fftpack.ifftshift(x, axes=None)`

The inverse of `fftshift`. Although identical for even-length `x`, the functions differ by one sample for odd-length `x`.

**Parameters**

- `x` [array_like] Input array.
- `axes` [int or shape tuple, optional] Axes over which to calculate. Defaults to None, which shifts all axes.

**Returns**

**See also:**

`fftshift`

Shift zero-frequency component to the center of the spectrum.

Examples

```python
>>> freqs = np.fft.fftfreq(9, d=1./9).reshape(3, 3)
>>> freqs
array([[ 0.,  1.,  2.],
       [ 3.,  4., -4.],
       [-3., -2., -1.]])
>>> np.fft.ifftshift(np.fft.fftshift(freqs))
array([[ 0.,  1.,  2.],
       [ 3.,  4., -4.],
       [-3., -2., -1.]])
```
scipy.fftpack.fftfreq

**scipy.fftpack.fftfreq**\( (n, d=1.0) \)

Return the Discrete Fourier Transform sample frequencies.

The returned float array \( f \) contains the frequency bin centers in cycles per unit of the sample spacing (with zero at the start). For instance, if the sample spacing is in seconds, then the frequency unit is cycles/second.

Given a window length \( n \) and a sample spacing \( d \):

\[
\begin{align*}
f &= [0, 1, \ldots, n/2-1, -n/2, \ldots, -1] / (d \times n) \quad \text{if } n \text{ is even} \\
f &= [0, 1, \ldots, (n-1)/2, -(n-1)/2, \ldots, -1] / (d \times n) \quad \text{if } n \text{ is odd}
\end{align*}
\]

**Parameters**

\( n \)  
[int] Window length.

\( d \)  
[scalar, optional] Sample spacing (inverse of the sampling rate). Defaults to 1.

**Returns**

\( f \)  
[ndarray] Array of length \( n \) containing the sample frequencies.

**Examples**

```python
generate code here
```

scipy.fftpack.rfftfreq

**scipy.fftpack.rfftfreq**\( (n, d=1.0) \)

DFT sample frequencies (for usage with rfft, irfft).

The returned float array contains the frequency bins in cycles/unit (with zero at the start) given a window length \( n \) and a sample spacing \( d \):

\[
\begin{align*}
f &= [0,1,1,2,2,\ldots,n/2-1,n/2-1,n/2]/(d \times n) \quad \text{if } n \text{ is even} \\
f &= [0,1,1,2,2,\ldots,n/2-1,n/2-1,n/2,n/2]/(d \times n) \quad \text{if } n \text{ is odd}
\end{align*}
\]

**Parameters**

\( n \)  
[int] Window length.

\( d \)  
[scalar, optional] Sample spacing. Default is 1.

**Returns**

\( out \)  
[ndarray] The array of length \( n \), containing the sample frequencies.
Examples

```python
>> from scipy import fftpack
>> sig = np.array([-2, 8, 6, 4, 1, 0, 3, 5], dtype=float)
>> sig_fft = fftpack.rfft(sig)
>> n = sig_fft.size
>> timestep = 0.1
>> freq = fftpack.rfftfreq(n, d=timestep)
>> freq
array([ 0. , 1.25, 1.25, 2.5 , 2.5 , 3.75, 3.75, 5. ])
```

`scipy.fftpack.next_fast_len`

`scipy.fftpack.next_fast_len(target)`

Find the next fast size of input data to `fft`, for zero-padding, etc.

SciPy's FFTPACK has efficient functions for radix \(2, 3, 4, 5\), so this returns the next composite of the prime factors 2, 3, and 5 which is greater than or equal to `target`. (These are also known as 5-smooth numbers, regular numbers, or Hamming numbers.)

**Parameters**

- `target` [int] Length to start searching from. Must be a positive integer.

**Returns**

- `out` [int] The first 5-smooth number greater than or equal to `target`.

**Notes**

New in version 0.18.0.

**Examples**

On a particular machine, an FFT of prime length takes 133 ms:

```python
>>> from scipy import fftpack
>>> rng = np.random.default_rng()
>>> min_len = 10007  # prime length is worst case for speed
>>> a = rng.standard_normal(min_len)
>>> b = fftpack.fft(a)
```

Zero-padding to the next 5-smooth length reduces computation time to 211 us, a speedup of 630 times:

```python
>>> fftpack.next_fast_len(min_len)
10125
>>> b = fftpack.fft(a, 10125)
```

Rounding up to the next power of 2 is not optimal, taking 367 us to compute, 1.7 times as long as the 5-smooth size:

```python
>>> b = fftpack.fft(a, 16384)
```

Note that `fftshift`, `ifftshift` and `fftfreq` are numpy functions exposed by `fftpack`; importing them from numpy should be preferred.
Convolutions (scipy.fftpack.convolve)

```python
convolve(x, omega[, swap_real_imag, overwrite_x])
```
Wrapper for `convolve`.

```python
convolve_z(x, omega_real, omega_imag[, overwrite_x])
```
Wrapper for `convolve_z`.

```python
init_convolution_kernel(...)
```
Wrapper for `init_convolution_kernel`.

```python
destroy_convolve_cache
```

**scipy.fftpack.convolve.convolve**

`scipy.fftpack.convolve.convolve(x, omega[, swap_real_imag, overwrite_x])`
Wrapper for `convolve`.

**Parameters**

- `x` : [input rank-1 array('d') with bounds (n)]
- `omega` : [input rank-1 array('d') with bounds (n)]

**Returns**

- `y` : [rank-1 array('d') with bounds (n) and x storage]

**Other Parameters**

- `overwrite_x` : [input int, optional] Default: 0
- `swap_real_imag` : [input int, optional] Default: 0

**scipy.fftpack.convolve.convolve_z**

`scipy.fftpack.convolve.convolve_z(x, omega_real, omega_imag[, overwrite_x])`
Wrapper for `convolve_z`.

**Parameters**

- `x` : [input rank-1 array('d') with bounds (n)]
- `omega_real` : [input rank-1 array('d') with bounds (n)]
- `omega_imag` : [input rank-1 array('d') with bounds (n)]

**Returns**

- `y` : [rank-1 array('d') with bounds (n) and x storage]

**Other Parameters**

- `overwrite_x` : [input int, optional] Default: 0
**scipy.fftpack.convolve.init_convolution_kernel**

```python
scipy.fftpack.convolve.init_convolution_kernel(n, kernel_func[, d, zero_nyquist, kernel_func_extra_args])
```

Wrapper for `init_convolution_kernel`.

**Parameters**

- `n` [input int]
- `kernel_func` [call-back function]

**Returns**

- `omega` [rank-1 array('d') with bounds (n)]

**Other Parameters**

- `d` [input int, optional] Default: 0
- `kernel_func_extra_args` [input tuple, optional] Default: ()
- `zero_nyquist` [input int, optional] Default: d%2

**Notes**

Call-back functions:

```python
def kernel_func(k):
    return kernel_func

Required arguments:
    k : input int

Return objects:
    kernel_func : float
```

**scipy.fftpack.convolve.destroy_convolve_cache**

```python
scipy.fftpack.convolve.destroy_convolve_cache()
```

**scipy.integrate.quad**

Compute a definite integral.

Integrate func from a to b (possibly infinite interval) using a technique from the Fortran library QUADPACK.

**Parameters**

- **func**: [[function, scipy.LowLevelCallable]] A Python function or method to integrate. If func takes many arguments, it is integrated along the axis corresponding to the first argument. If the user desires improved integration performance, then f may be a scipy.LowLevelCallable with one of the signatures:
  
  - double func(double x)
  - double func(double x, void *user_data)
  - double func(int n, double *xx)
  - double func(int n, double *xx, void *user_data)

  The user_data is the data contained in the scipy.LowLevelCallable. In the call forms with xx, n is the length of the xx array which contains xx[0] == x and the rest of the items are numbers contained in the args argument of quad.

  In addition, certain ctypes call signatures are supported for backward compatibility, but those should not be used in new code.

- **a**: [float] Lower limit of integration (use numpy.inf for -infinity).
- **b**: [float] Upper limit of integration (use numpy.inf for +infinity).
- **args**: [tuple, optional] Extra arguments to pass to func.
- **full_output**: [int, optional] Non-zero to return a dictionary of integration information. If non-zero, warning messages are also suppressed and the message is appended to the output tuple.

**Returns**

- **y**: [float] The integral of func from a to b.
- **abserr**: [float] An estimate of the absolute error in the result.
- **infodict**: [dict] A dictionary containing additional information. Run scipy.integrate.quad_explain() for more information.
- **message**: A convergence message.
- **explain**: Appended only with ‘cos’ or ‘sin’ weighting and infinite integration limits, it contains an explanation of the codes in infodict[‘ierlst’]

**Other Parameters**

- **epsabs**: [float or int, optional] Absolute error tolerance. Default is 1.49e-8. quad tries to obtain an accuracy of abs(i-result) <= max(epsabs, epsrel*abs(i)) where i = integral of func from a to b, and result is the numerical approximation. See epsrel below.
- **epsrel**: [float or int, optional] Relative error tolerance. Default is 1.49e-8. If epsabs <= 0, epsrel must be greater than both 5e-29 and 50 * (machine epsilon). See epsabs above.
- **limit**: [float or int, optional] An upper bound on the number of subintervals used in the adaptive algorithm.
points  [(sequence of floats, ints), optional] A sequence of break points in the bounded integration interval where local difficulties of the integrand may occur (e.g., singularities, discontinu-
ities). The sequence does not have to be sorted. Note that this option cannot be used in conjunction with weight.

weight  [float or int, optional] String indicating weighting function. Full explanation for this and the remaining arguments can be found below.

wvar  [optional] Variables for use with weighting functions.

wopts  [optional] Optional input for reusing Chebyshev moments.

maxp1  [float or int, optional] An upper bound on the number of Chebyshev moments.

limlst  [int, optional] Upper bound on the number of cycles (>=3) for use with a sinusoidal weighting and an infinite end-point.

for coefficients and roots of orthogonal polynomials
Notes

Extra information for quad() inputs and outputs

If full_output is non-zero, then the third output argument (infodict) is a dictionary with entries as tabulated below. For infinite limits, the range is transformed to (0,1) and the optional outputs are given with respect to this transformed range. Let M be the input argument limit and let K be infodict['last']. The entries are:

'neval'

The number of function evaluations.

'last'

The number, K, of subintervals produced in the subdivision process.

'alist'

A rank-1 array of length M, the first K elements of which are the left end points of the subintervals in the partition of the integration range.

'blist'

A rank-1 array of length M, the first K elements of which are the right end points of the subintervals.

'rlist'

A rank-1 array of length M, the first K elements of which are the integral approximations on the subintervals.

'elist'

A rank-1 array of length M, the first K elements of which are the moduli of the absolute error estimates on the subintervals.

'iord'

A rank-1 integer array of length M, the first L elements of which are pointers to the error estimates over the subintervals with $L = K$ if $K \leq M/2 + 2$ or $L = M + 1 - K$ otherwise. Let $I$ be the sequence infodict['iord'] and let $E$ be the sequence infodict['elist']. Then $E[I[1]], \ldots, E[I[L]]$ forms a decreasing sequence.

If the input argument points is provided (i.e., it is not None), the following additional outputs are placed in the output dictionary. Assume the points sequence is of length $P$.

'pts'

A rank-1 array of length $P+2$ containing the integration limits and the break points of the intervals in ascending order. This is an array giving the subintervals over which integration will occur.

'level'

A rank-1 integer array of length $M (=limit)$, containing the subdivision levels of the subintervals, i.e., if $(aa, bb)$ is a subinterval of $(pts[1], pts[2])$ where $pts[0]$ and $pts[2]$ are adjacent elements of infodict['pts'], then $(aa, bb)$ has level $l$ if $|bb-aa| = |pts[2]-pts[1]| * 2^{*(-l)}$.

'ndin'

A rank-1 integer array of length $P+2$. After the first integration over the intervals $(pts[1], pts[2])$, the error estimates over some of the intervals may have been increased artificially in order to put their subdivision forward. This array has ones in slots corresponding to the subintervals for which this happens.

Weighting the integrand

The input variables, weight and wvar, are used to weight the integrand by a select list of functions. Different integration methods are used to compute the integral with these weighting functions, and these do not support specifying break points. The possible values of weight and the corresponding weighting functions are.
wvar holds the parameter w, (alpha, beta), or c depending on the weight selected. In these expressions, a and b are the integration limits.

For the ‘cos’ and ‘sin’ weighting, additional inputs and outputs are available.

For finite integration limits, the integration is performed using a Clenshaw-Curtis method which uses Chebyshev moments. For repeated calculations, these moments are saved in the output dictionary:

‘momcom’

The maximum level of Chebyshev moments that have been computed, i.e., if \( M_c \) is infodict[‘momcom’] then the moments have been computed for intervals of length \(|b-a| * 2**(-l)|\), \( l=0,1,\ldots,M_c \).

‘nnlog’

A rank-1 integer array of length \( M(=\text{limit}) \), containing the subdivision levels of the subintervals, i.e., an element of this array is equal to \( l \) if the corresponding subinterval is \(|b-a|* 2**(-l)|\).

‘chebmo’

A rank-2 array of shape (25, maxp1) containing the computed Chebyshev moments. These can be passed on to an integration over the same interval by passing this array as the second element of the sequence wopts and passing infodict[‘momcom’] as the first element.

If one of the integration limits is infinite, then a Fourier integral is computed (assuming w neq 0). If full_output is 1 and a numerical error is encountered, besides the error message attached to the output tuple, a dictionary is also appended to the output tuple which translates the error codes in the array info[‘ierlst’] to English messages. The output information dictionary contains the following entries instead of ‘last’, ‘alist’, ‘blist’, ‘rlist’, and ‘elist’:

‘lst’

The number of subintervals needed for the integration (call it \( K_f \)).

‘rslist’

A rank-1 array of length \( M_f=\text{limlst} \), whose first \( K_f \) elements contain the integral contribution over the interval \((a+(k-1)c, a+kc)\) where \( c = (2*\text{floor}(|w|) + 1) * \pi / |w| \) and \( k=1,2,\ldots,K_f \).

‘erlst’

A rank-1 array of length \( M_f \) containing the error estimate corresponding to the interval in the same position in infodict[‘rslist’].

‘ierlst’

A rank-1 integer array of length \( M_f \) containing an error flag corresponding to the interval in the same position in infodict[‘rslist’]. See the explanation dictionary (last entry in the output tuple) for the meaning of the codes.
Examples

Calculate $\int_0^4 x^2 \, dx$ and compare with an analytic result

```python
>>> from scipy import integrate
>>> x2 = lambda x: x**2
>>> integrate.quad(x2, 0, 4)
(21.333333333333332, 2.3684757858670003e-13)
>>> print(4**3 / 3.)  # analytical result
21.3333333333
```

Calculate $\int_0^\infty e^{-x} \, dx$

```python
>>> invexp = lambda x: np.exp(-x)
>>> integrate.quad(invexp, 0, np.inf)
(1.0, 5.842605999138044e-11)
```

Calculate $\int_0^{1} x^2 + y^2 \, dx$ with ctypes, holding y parameter as 1:

```python
testlib.c =>
    double func(int n, double args[n]){
        return args[0]*args[0] + args[1]*args[1];
    }
compile to library testlib.*
```

```python
from scipy import integrate
import ctypes
lib = ctypes.CDLL('/home/.../testlib.*') #use absolute path
lib.func.restype = ctypes.c_double
lib.func.argtypes = (ctypes.c_int, ctypes.c_double)
integrate.quad(lib.func, 0, 1, (1))
#(1.3333333333333333, 1.4802973661668752e-14)
print((1.0**3/3.0 + 1.0) - (0.0**3/3.0 + 0.0))  #Analytic result
# 1.3333333333333333
```

Be aware that pulse shapes and other sharp features as compared to the size of the integration interval may not be integrated correctly using this method. A simplified example of this limitation is integrating a y-axis reflected step function with many zero values within the integrals bounds.

```python
>>> y = lambda x: 1 if x<=0 else 0
>>> integrate.quad(y, -1, 1)
(1.0, 1.1102230246251565e-14)
>>> integrate.quad(y, -1, 100)
(1.0000000000000002199108, 1.0189464580163188e-08)
>>> integrate.quad(y, -1, 10000)
(0.0, 0.0)
```
Adaptive integration of a vector-valued function.

**Parameters**

- `f` [callable] Vector-valued function $f(x)$ to integrate.
- `a` [float] Initial point.
- `b` [float] Final point.
- `epsabs` [float, optional] Absolute tolerance.
- `epsrel` [float, optional] Relative tolerance.
- `norm` [{'max', '2'}, optional] Vector norm to use for error estimation.
- `cache_size` [int, optional] Number of bytes to use for memoization.
- `workers` [int or map-like callable, optional] If `workers` is an integer, part of the computation is done in parallel subdivided to this many tasks (using `multiprocessing.pool.Pool`). Supply -1 to use all cores available to the Process. Alternatively, supply a map-like callable, such as `multiprocessing.pool.Pool.map` for evaluating the population in parallel. This evaluation is carried out as `workers(func, iterable)`.
- `points` [list, optional] List of additional breakpoints.
- `full_output` [bool, optional] Return an additional info dictionary.
- `args` [tuple, optional] Extra arguments to pass to function, if any.

New in version 1.8.0.

**Returns**

- `res` [[float, array-like]] Estimate for the result
- `err` [float] Error estimate for the result in the given norm
- `info` [dict] Returned only when `full_output=True`. Info dictionary. Is an object with the attributes:
  - `status` [int] Indicator for convergence, success (0), failure (1), and failure due to rounding error (2).
  - `neval` [int] Number of function evaluations.
  - `intervals` [ndarray, shape (num_intervals, 2)] Start and end points of subdivision intervals.
  - `integrals` [ndarray, shape (num_intervals, …)] Integral for each interval. Note that at most `cache_size` values are recorded, and the array may contains `nan` for missing items.
  - `errors` [ndarray, shape (num_intervals,)] Estimated integration error for each interval.
Notes

The algorithm mainly follows the implementation of QUADPACK’s DQAG* algorithms, implementing global error control and adaptive subdivision.

The algorithm here has some differences to the QUADPACK approach:

Instead of subdividing one interval at a time, the algorithm subdivides N intervals with largest errors at once. This enables (partial) parallelization of the integration.

The logic of subdividing “next largest” intervals first is then not implemented, and we rely on the above extension to avoid concentrating on “small” intervals only.

The Wynn epsilon table extrapolation is not used (QUADPACK uses it for infinite intervals). This is because the algorithm here is supposed to work on vector-valued functions, in an user-specified norm, and the extension of the epsilon algorithm to this case does not appear to be widely agreed. For max-norm, using elementwise Wynn epsilon could be possible, but we do not do this here with the hope that the epsilon extrapolation is mainly useful in special cases.

References

Examples

We can compute integrations of a vector-valued function:

```python
>>> from scipy.integrate import quad_vec
>>> import matplotlib.pyplot as plt
>>> alpha = np.linspace(0.0, 2.0, num=30)
>>> f = lambda x: x**alpha
>>> x0, x1 = 0, 2
>>> y, err = quad_vec(f, x0, x1)
>>> plt.plot(alpha, y)
>>> plt.xlabel(r'$\alpha$')
>>> plt.ylabel(r'$\int_0^2 x^\alpha dx$')
>>> plt.show()
```

`scipy.integrate.dblquad`

`scipy.integrate.dblquad`(`func`, `a`, `b`, `gfun`, `hfun`, `args=()`, `epsabs=1.49e-08`, `epsrel=1.49e-08`)  
Compute a double integral.

Return the double (definite) integral of `func(y, x)` from `x = a..b` and `y = gfun(x) .. hfun(x).

Parameters

- **func**  
  [callable] A Python function or method of at least two variables: y must be the first argument and x the second argument.
- **a, b**  
  [float] The limits of integration in x: `a < b`
- **gfun**  
  [callable or float] The lower boundary curve in y which is a function taking a single floating point argument (x) and returning a floating point result or a float indicating a constant boundary curve.
- **hfun**  
  [callable or float] The upper boundary curve in y (same requirements as `gfun`).
- **args**  
  [sequence, optional] Extra arguments to pass to `func`. 

3.3. API definition 453

epsabs  [float, optional] Absolute tolerance passed directly to the inner 1-D quadrature integration. Default is 1.49e-8. *dblquad* tries to obtain an accuracy of \( \text{abs}(i - \text{result}) \leq \max(\text{epsabs}, \text{epsrel} \times \text{abs}(i)) \) where \( i \) is the inner integral of \( \text{func}(y, x) \) from \( gfun(x) \) to \( hfun(x) \), and \( \text{result} \) is the numerical approximation. See *epsrel* below.

epsrel  [float, optional] Relative tolerance of the inner 1-D integrals. Default is 1.49e-8. If \( \text{epsabs} \leq 0 \), \( \text{epsrel} \) must be greater than both 5e-29 and 50 \times \text{(machine epsilon)}. See *epsabs* above.

Returns

\text{y}  [float] The resultant integral.
\text{abserr}  [float] An estimate of the error.

**Examples**

Compute the double integral of $x \cdot y^2$ over the box $x$ ranging from 0 to 2 and $y$ ranging from 0 to 1.

```python
>>> from scipy import integrate
>>> f = lambda y, x: x * y**2
>>> integrate.dblquad(f, 0, 2, lambda x: 0, lambda x: 1)
(0.6666666666666667, 7.401486830834377e-15)
```

**scipy.integrate.tplquad**

Compute a triple (definite) integral.

Return the triple integral of $\func(z, y, x)$ from $x = a..b$, $y = gfun(x) .. hfun(x)$, and $z = qfun(x,y) .. rfun(x,y)$.

**Parameters**

- **func** [function] A Python function or method of at least three variables in the order $(z, y, x)$.
- **a, b** [float] The limits of integration in $x$: $a < b$
- **gfun** [function or float] The lower boundary curve in $y$ which is a function taking a single floating point argument ($x$) and returning a floating point result or a float indicating a constant boundary curve.
- **hfun** [function or float] The upper boundary curve in $y$ (same requirements as `gfun`).
- **qfun** [function or float] The lower boundary surface in $z$. It must be a function that takes two floats in the order ($x, y$) and returns a float or a float indicating a constant boundary surface.
- **rfun** [function or float] The upper boundary surface in $z$. (Same requirements as `qfun`).
- **args** [tuple, optional] Extra arguments to pass to `func`.
- **epsabs** [float, optional] Absolute tolerance passed directly to the innermost 1-D quadrature integration. Default is 1.49e-8.
- **epsrel** [float, optional] Relative tolerance of the innermost 1-D integrals. Default is 1.49e-8.

**Returns**

- **y** [float] The resultant integral.
- **abserr** [float] An estimate of the error.

Examples

Compute the triple integral of $x \cdot y \cdot z$, over $x$ ranging from 1 to 2, $y$ ranging from 2 to 3, $z$ ranging from 0 to 1.

```python
>>> from scipy import integrate
>>> f = lambda z, y, x: x * y * z
>>> integrate.tplquad(f, 1, 2, lambda x: 2, lambda x: 3, ...
    lambda x, y: 0, lambda x, y: 1)
(1.875, 3.324644794257407e-14)
```

scipy.integrate.nquad

scipy.integrate.nquad(func, ranges, args=None, opts=None, full_output=False)

Integration over multiple variables.

Wraps `quad` to enable integration over multiple variables. Various options allow improved integration of discontinuous functions, as well as the use of weighted integration, and generally finer control of the integration process.

**Parameters**

- **func**
  - `func` ([callable, scipy.LowLevelCallable]) The function to be integrated. Has arguments of $x_0$, $x_n$, $t_0$, ..., $t_m$, where integration is carried out over $x_0$, $x_n$, which must be floats. Where `$t_0$, ..., $t_m$' are extra arguments passed in `args`. Function signature should be `func(x0, x1, ..., xn, t0, t1, ..., tm)`. Integration is carried out in order. That is, integration over $x_0$ is the innermost integral, and $x_n$ is the outermost. If the user desires improved integration performance, then $f$ may be a `scipy.LowLevelCallable` with one of the signatures:
double func(int n, double *xx)
double func(int n, double *xx, void *user_data)

where \( n \) is the number of variables and args. The \( xx \) array contains the coordinates and extra arguments. \( \texttt{user
data} \) is the data contained in the \( \texttt{scipy.LowLevelCallable} \).

**ranges**

[iterable object] Each element of ranges may be either a sequence of 2 numbers, or else a callable that returns such a sequence. \( \texttt{ranges[0]} \) corresponds to integration over \( x_0 \) and so on. If an element of ranges is a callable, then it will be called with all of the integration arguments available, as well as any parametric arguments. e.g., if \( \text{func} = f(x_0, x_1, x_2, t_0, t_1) \), then \( \texttt{ranges[0]} \) may be defined as either \( (a, b) \) or else as \( (a, b) = \text{range0}(x_1, x_2, t_0, t_1) \).

**args**

[iterable object, optional] Additional arguments \( t_0, \ldots, t_n \), required by \( \text{func}, \text{ranges}, \) and \( \text{opts} \).

**opts**

[iterable object or dict, optional] Options to be passed to \( \texttt{quad} \). May be empty, a dict, or a sequence of dicts or functions that return a dict. If empty, the default options from \( \texttt{scipy.integrate.quad} \) are used. If a dict, the same options are used for all levels of integration. If a sequence, then each element of the sequence corresponds to a particular integration. e.g., \( \texttt{opts[0]} \) corresponds to integration over \( x_0 \), and so on. If a callable, the signature must be the same as for \( \text{ranges} \). The available options together with their default values are:

- \( \text{epsabs} = 1.49e-08 \)
- \( \text{epsrel} = 1.49e-08 \)
- \( \text{limit} = 50 \)
- \( \text{points} = \text{None} \)
- \( \text{weight} = \text{None} \)
- \( \text{wvar} = \text{None} \)
- \( \text{wopts} = \text{None} \)

For more information on these options, see \( \texttt{quad} \) and \( \texttt{quad_explain} \).

**full_output**

[bool, optional] Partial implementation of \( \texttt{full_output} \) from \( \texttt{scipy.integrate.quad} \). The number of integrand function evaluations \( \text{neval} \) can be obtained by setting \( \texttt{full_output=True} \) when calling \( \texttt{nquad} \).

**Returns**

- result [float] The result of the integration.
- abserr [float] The maximum of the estimates of the absolute error in the various integration results.
- out_dict [dict, optional] A dict containing additional information on the integration.

...           scale * (t0*x2 + t1*x3) + 1]
>>> def lim2(x3, t0, t1):
...   return [scale * (x3 + t0**2*t1**3) - 1,
...           scale * (x3 + t0**2*t1**3) + 1]
>>> def lim3(t0, t1):
...   return [scale * (t0+t1) - 1, scale * (t0+t1) + 1]
>>> def opts0(x1, x2, x3, t0, t1):
...   return {'points' : [t0 - t1*x1]}
>>> def opts1(x2, x3, t0, t1):
...   return {}
>>> def opts2(x3, t0, t1):
...   return {}
>>> def opts3(t0, t1):
...   return {}
>>> integrate.nquad(func2, [lim0, lim1, lim2, lim3], args=(0,0),
...   opts=[opts0, opts1, opts2, opts3])
(25.066666666666666, 2.782959048393725e-13)
```

**scipy.integrate.fixed_quad**

`scipy.integrate.fixed_quad(func, a, b, args=(), n=5)`

Compute a definite integral using fixed-order Gaussian quadrature.

Integrate `func` from `a` to `b` using Gaussian quadrature of order `n`.

**Parameters**

- `func` [callable] A Python function or method to integrate (must accept vector inputs). If integrating a vector-valued function, the returned array must have shape \((..., \text{len}(x))\).
- `a` [float] Lower limit of integration.
- `b` [float] Upper limit of integration.
- `args` [tuple, optional] Extra arguments to pass to function, if any.
- `n` [int, optional] Order of quadrature integration. Default is 5.

**Returns**

- `val` [float] Gaussian quadrature approximation to the integral.
None [None] Statically returned value of None

1.0
```
**scipy.integrate.quadrature**

*scipy.integrate.quadrature*(func, a, b, args=(), tol=1.49e-08, rtol=1.49e-08, maxiter=50, vec_func=True, miniter=1)

Compute a definite integral using fixed-tolerance Gaussian quadrature.

Integrate func from a to b using Gaussian quadrature with absolute tolerance tol.

**Parameters**

- **func** [function] A Python function or method to integrate.
- **a** [float] Lower limit of integration.
- **b** [float] Upper limit of integration.
- **args** [tuple, optional] Extra arguments to pass to function.
- **tol, rtol** [float, optional] Iteration stops when error between last two iterates is less than tol OR the relative change is less than rtol.
- **maxiter** [int, optional] Maximum order of Gaussian quadrature.
- **vec_func** [bool, optional] True or False if func handles arrays as arguments (is a “vector” function). Default is True.
- **miniter** [int, optional] Minimum order of Gaussian quadrature.

**Returns**

- **val** [float] Gaussian quadrature approximation (within tolerance) to integral.
- **err** [float] Difference between last two estimates of the integral.

1.0
```

scipy.integrate.romberg

scipy.integrate.romberg (function, a, b, args=(), tol=1.48e-08, rtol=1.48e-08, show=False, divmax=10, vec_func=False)

Romberg integration of a callable function or method.

Returns the integral of function (a function of one variable) over the interval (a, b).

If show is 1, the triangular array of the intermediate results will be printed. If vec_func is True (default is False), then function is assumed to support vector arguments.

Parameters

- function: [callable] Function to be integrated.
- a: [float] Lower limit of integration.
- b: [float] Upper limit of integration.

Returns

- results: [float] Result of the integration.

Other Parameters

- args: [tuple, optional] Extra arguments to pass to function. Each element of args will be passed as a single argument to func. Default is to pass no extra arguments.
- tol, rtol: [float, optional] The desired absolute and relative tolerances. Defaults are 1.48e-8.
- show: [bool, optional] Whether to print the results. Default is False.
- vec_func: [bool, optional] Whether func handles arrays as arguments (i.e., whether it is a “vector” function). Default is False.

See also:

- fixed_quad
  Fixed-order Gaussian quadrature.

</tr>
</tbody>
</table>

The final result is 0.421350396475 after 33 function evaluations.

```python
>>> print("%g %g" % (2*result, erf(1)))
0.842701 0.842701
```
**scipy.integrate.quad_explain**

`scipy.integrate.quad_explain(output=<_io.TextIOWrapper name='<stdout>' mode='w', encoding='utf-8'>)`

Print extra information about `integrate.quad` parameters and returns.

**Parameters**

- `output` [instance with “write” method, optional] Information about `quad` is passed to `output.write()`. Default is `sys.stdout`.

**Returns**

- `None`

**Examples**

We can show detailed information of the `integrate.quad` function in stdout:

```python
>>> from scipy.integrate import quad_explain
>>> quad_explain()
```

**scipy.integrate.newton_cotes**

`scipy.integrate.newton_cotes(rn, equal=0)`

Return weights and error coefficient for Newton-Cotes integration.

Suppose we have \((N+1)\) samples of \(f\) at the positions \(x_0, x_1, \ldots, x_N\). Then an \(N\)-point Newton-Cotes formula for the integral between \(x_0\) and \(x_N\) is:

\[
\int_{x_0}^{x_N} f(x) \, dx = \Delta x \sum_{i=0}^{N} a_i f(x_i) + B_N (\Delta x)^{N+2} f^{N+1}(\xi)
\]

where \(\xi \in [x_0, x_N]\) and \(\Delta x = \frac{x_N - x_0}{N}\) is the average samples spacing.

If the samples are equally-spaced and \(N\) is even, then the error term is \(B_N (\Delta x)^{N+3} f^{N+2}(\xi)\).

**Parameters**

- `rn` [int] The integer order for equally-spaced data or the relative positions of the samples with the first sample at 0 and the last at \(N\), where \(N+1\) is the length of \(rn\). \(N\) is the order of the Newton-Cotes integration.
- `equal` [int, optional] Set to 1 to enforce equally spaced data.

**Returns**

- `an` [ndarray] 1-D array of weights to apply to the function at the provided sample positions.
- `B` [float] Error coefficient.

**Notes**

Normally, the Newton-Cotes rules are used on smaller integration regions and a composite rule is used to return the total integral.

---

3.3. API definition 463
Examples

Compute the integral of sin(x) in [0, π]:

```python
>>> from scipy.integrate import newton_cotes
>>> def f(x):
...     return np.sin(x)
>>> a = 0
>>> b = np.pi
>>> exact = 2
>>> for N in [2, 4, 6, 8, 10]:
...     x = np.linspace(a, b, N + 1)
...     an, B = newton_cotes(N, 1)
...     dx = (b - a) / N
...     quad = dx * np.sum(an * f(x))
...     error = abs(quad - exact)
...     print('{:2d} {:10.9f} {:.5e}'.format(N, quad, error))

<tr>
<td><code>simpson</code></td>
<td>Integrate y(x) using samples along the given axis and the composite Simpson's rule.</td>
</tr>
<tr>
<td><code>romb</code></td>
<td>Romberg integration using samples of a function.</td>
</tr>
</tbody>
</table>
**scipy.integrate.trapezoid**

`scipy.integrate.trapezoid(y, x=None, dx=1.0, axis=-1)`  
Integrate along the given axis using the composite trapezoidal rule.

If `x` is provided, the integration happens in sequence along its elements - they are not sorted.

Integrate `y(x)` along each 1d slice on the given axis, compute $\int y(x) dx$. When `x` is specified, this integrates along the parametric curve, computing $\int_{t_0}^{t_f} y(t) \frac{dx}{dt} |_{x=x(t)} dt$.

**Parameters**

- **y** ([array_like]) Input array to integrate.
- **x** ([array_like, optional]) The sample points corresponding to the `y` values. If `x` is None, the sample points are assumed to be evenly spaced `dx` apart. The default is None.
- **dx** ([scalar, optional]) The spacing between sample points when `x` is None. The default is 1.
- **axis** ([int, optional]) The axis along which to integrate.

**Returns**

- **trapz** ([float or ndarray]) Definite integral of `y` = n-dimensional array as approximated along a single axis by the trapezoidal rule. If `y` is a 1-dimensional array, then the result is a float. If `n` is greater than 1, then the result is an ‘n-1’ dimensional array.

**See also:**

- `numpy.cumsum`

**Notes**

Image [2] illustrates trapezoidal rule – y-axis locations of points will be taken from `y` array, by default x-axis distances between points will be 1.0, alternatively they can be provided with `x` array or with `dx` scalar. Return value will be equal to combined area under the red lines.

**References**

[1], [2]

**Examples**

```python
>>> np.trapz([1, 2, 3])
4.0
>>> np.trapz([1, 2, 3], x=[4, 6, 8])
8.0
>>> np.trapz([1, 2, 3], dx=2)
8.0
```

Using a decreasing `x` corresponds to integrating in reverse:

```python
>>> np.trapz([1, 2, 3], x=[8, 6, 4])
-8.0
```

More generally `x` is used to integrate along a parametric curve. This finds the area of a circle, noting we repeat the sample which closes the curve:
```python
>>> theta = np.linspace(0, 2 * np.pi, num=1000, endpoint=True)
>>> np.trapz(np.cos(theta), x=np.sin(theta))
3.141571941375841

>>> a = np.arange(6).reshape(2, 3)
>>> a
array([[0, 1, 2],
       [3, 4, 5]])
>>> np.trapz(a, axis=0)
array([1.5, 2.5, 3.5])
>>> np.trapz(a, axis=1)
array([2., 8.])
```

**scipy.integrate.cumulative_trapezoid**

`scipy.integrate.cumulative_trapezoid(y, x=None, dx=1.0, axis=-1, initial=None)`

Cumulatively integrate y(x) using the composite trapezoidal rule.

**Parameters**

- **y**  
  [array_like] Values to integrate.
- **x**  
  [array_like, optional] The coordinate to integrate along. If None (default), use spacing `dx` between consecutive elements in `y`.
- **dx**  
  [float, optional] Spacing between elements of `y`. Only used if `x` is None.
- **axis**  
  [int, optional] Specifies the axis to cumulate. Default is -1 (last axis).
- **initial**  
  [scalar, optional] If given, insert this value at the beginning of the returned result. Typically this value should be 0. Default is None, which means no value at `x[0]` is returned and `res` has one element less than `y` along the axis of integration.

**Returns**

- **res**  
  [ndarray] The result of cumulative integration of `y` along `axis`. If `initial` is None, the shape is such that the axis of integration has one less value than `y`. If `initial` is given, the shape is equal to that of `y`.

  triple integrals
Examples

```python
>>> from scipy import integrate
>>> import matplotlib.pyplot as plt

>>> x = np.linspace(-2, 2, num=20)
>>> y = x
>>> y_int = integrate.cumulative_trapezoid(y, x, initial=0)
>>> plt.plot(x, y_int, 'ro', x, y[0] + 0.5 * x**2, 'b-')
>>> plt.show()
```

scipy.integrate.simps

`scipy.integrate.simps(y, x=None, dx=1.0, axis=-1, even='avg')`

Integrate y(x) using samples along the given axis and the composite Simpson’s rule. If x is None, spacing of dx is assumed.

If there are an even number of samples, N, then there are an odd number of intervals (N-1), but Simpson’s rule requires an even number of intervals. The parameter ‘even’ controls how this is handled.

**Parameters**

- `y` [array_like] Array to be integrated.
- `x` [array_like, optional] If given, the points at which y is sampled.
**dx**  
[float, optional] Spacing of integration points along axis of $x$. Only used when $x$ is None. Default is 1.

**axis**  
[int, optional] Axis along which to integrate. Default is the last axis.

**even**  
[str {'avg', 'first', 'last'}. optional]

- **‘avg’**  
  [Average two results: 1) use the first N-2 intervals with] a trapezoidal rule on the last interval and 2) use the last N-2 intervals with a trapezoidal rule on the first interval.

- **‘first’**  
  [Use Simpson's rule for the first N-2 intervals with] a trapezoidal rule on the last interval.

- **‘last’**  
  [Use Simpson's rule for the last N-2 intervals with a] trapezoidal rule on the first interval.

See also:

- **quad**  
  adaptive quadrature using QUADPACK

- **romberg**  
  adaptive Romberg quadrature

  integrators for sampled data

- **cumulative_trapezoid**  
  cumulative integration for sampled data

- **ode**  
  ODE integrators

- **odeint**  
  ODE integrators
Notes

For an odd number of samples that are equally spaced the result is exact if the function is a polynomial of order 3 or less. If the samples are not equally spaced, then the result is exact only if the function is a polynomial of order 2 or less.

Examples

```python
>>> from scipy import integrate
>>> x = np.arange(0, 10)
>>> y = np.arange(0, 10)

>>> integrate.simps(y, x)
40.5

>>> y = np.power(x, 3)
>>> integrate.simps(y, x)
1642.5
>>> integrate.quad(lambda x: x**3, 0, 9)[0]
1640.25

>>> integrate.simps(y, x, even='first')
1644.5
```

**scipy.integrate.romb**

`scipy.integrate.romb(y, dx=1.0, axis=-1, show=False)`

Romberg integration using samples of a function.

**Parameters**

- `y` [array_like] A vector of $2^k + 1$ equally-spaced samples of a function.
- `dx` [float, optional] The sample spacing. Default is 1.
- `axis` [int, optional] The axis along which to integrate. Default is -1 (last axis).
- `show` [bool, optional] When `y` is a single 1-D array, then if this argument is True print the table showing Richardson extrapolation from the samples. Default is False.

**Returns**

- `romb` [ndarray] The integrated result for `axis`.

**scipy.integrate.solve_ivp**

```python
scipy.integrate.solve_ivp(fun, t_span, y0[, method='RK45', t_eval=None, dense_output=False, events=None, vectorized=False, args=None, **options])
```

Solve an initial value problem for a system of ODEs.

This function numerically integrates a system of ordinary differential equations given an initial value:

\[
\frac{dy}{dt} = f(t, y) \\
y(t_0) = y_0
\]

Here \(t\) is a 1-D independent variable (time), \(y(t)\) is an \(N\)-D vector-valued function (state), and an \(N\)-D vector-valued function \(f(t, y)\) determines the differential equations. The goal is to find \(y(t)\) approximately satisfying the differential equations, given an initial value \(y(t_0) = y_0\).

Some of the solvers support integration in the complex domain, but note that for stiff ODE solvers, the right-hand side must be complex-differentiable (satisfy Cauchy-Riemann equations [11]). To solve a problem in the complex domain, pass \(y_0\) with a complex data type. Another option always available is to rewrite your problem for real and imaginary parts separately.

**Parameters**

- **fun** [callable] Right-hand side of the system. The calling signature is `fun(t, y)`. Here \(t\) is a scalar, and there are two options for the ndarray \(y\): It can either have shape (n,); then `fun` must return array-like with shape (n). Alternatively, it can have shape (n, k); then `fun` must return an array-like with shape (n, k), i.e., each column corresponds to a single column in \(y\). The choice between the two options is determined by `vectorized` argument (see below). The vectorized implementation allows a faster approximation of the Jacobian by finite differences (required for stiff solvers).

- **t_span** [2-tuple of floats] Interval of integration \((t_0, tf)\). The solver starts with \(t = t_0\) and integrates until it reaches \(t = tf\).

- **y0** [array_like, shape (n,)] Initial state. For problems in the complex domain, pass \(y_0\) with a complex data type (even if the initial value is purely real).

- **method** [string or `OdeSolver`, optional] Integration method to use:
  - ‘RK45’ (default): Explicit Runge-Kutta method of order 5(4) [1]. The error is controlled assuming accuracy of the fourth-order method, but steps are taken using the fifth-order
accurate formula (local extrapolation is done). A quartic interpolation polynomial is used for the dense output [2]. Can be applied in the complex domain.

- **'RK23':** Explicit Runge-Kutta method of order 3(2) [3]. The error is controlled assuming accuracy of the second-order method, but steps are taken using the third-order accurate formula (local extrapolation is done). A cubic Hermite polynomial is used for the dense output. Can be applied in the complex domain.

- **'DOP853':** Explicit Runge-Kutta method of order 8 [13]. Python implementation of the “DOP853” algorithm originally written in Fortran [14]. A 7-th order interpolation polynomial accurate to 7-th order is used for the dense output. Can be applied in the complex domain.

- **'Radau':** Implicit Runge-Kutta method of the Radau IIA family of order 5 [4]. The error is controlled with a third-order accurate embedded formula. A cubic polynomial which satisfies the collocation conditions is used for the dense output.

- **'BDF':** Implicit multi-step variable-order (1 to 5) method based on a backward differentiation formula for the derivative approximation [5]. The implementation follows the one described in [6]. A quasi-constant step scheme is used and accuracy is enhanced using the NDF modification. Can be applied in the complex domain.

- **'LSODA':** Adams/BDF method with automatic stiffness detection and switching [7], [8]. This is a wrapper of the Fortran solver from ODEPACK. Explicit Runge-Kutta methods ('RK23', 'RK45', 'DOP853') should be used for non-stiff problems and implicit methods ('Radau', 'BDF') for stiff problems [9]. Among Runge-Kutta methods, ‘DOP853’ is recommended for solving with high precision (low values of rtol and atol).

If not sure, first try to run ‘RK45’. If it makes unusually many iterations, diverges, or fails, your problem is likely to be stiff and you should use ‘Radau’ or ‘BDF’. ‘LSODA’ can also be a good universal choice, but it might be somewhat less convenient to work with as it wraps old Fortran code.

You can also pass an arbitrary class derived from `OdeSolver` which implements the solver.

**t_eval**
[array_like or None, optional] Times at which to store the computed solution, must be sorted and lie within t_span. If None (default), use points selected by the solver.

**dense_output**
[bool, optional] Whether to compute a continuous solution. Default is False.

**events**
[callable, or list of callables, optional] Events to track. If None (default), no events will be tracked. Each event occurs at the zeros of a continuous function of time and state. Each function must have the signature `event(t, y)` and return a float. The solver will find an accurate value of `t` at which `event(t, y(t)) = 0` using a root-finding algorithm. By default, all zeros will be found. The solver looks for a sign change over each step, so if multiple zero crossings occur within one step, events may be missed. Additionally each `event` function might have the following attributes:

- **terminal**: `bool`, `optional`
  Whether to terminate integration if this event occurs. Implicitly False if not assigned.

- **direction**: `float`, `optional`
  Direction of a zero crossing. If `direction` is positive, `event` will only trigger when going from negative to positive, and vice versa if `direction` is negative. If 0, then either direction will trigger event. Implicitly 0 if not assigned.

You can assign attributes like `event.terminal = True` to any function in Python.

**vectorized**
[bool, optional] Whether `fun` is implemented in a vectorized fashion. Default is False.

**args**
[tuple, optional] Additional arguments to pass to the user-defined functions. If given, the additional arguments are passed to all user-defined functions. So if, for example, `fun` has the signature `fun(t, y, a, b, c)`, then `jac` (if given) and any event functions must have the same signature, and `args` must be a tuple of length 3.

**options**
Options passed to a chosen solver. All options available for already implemented solvers are listed below.
**first_step**  [float or None, optional] Initial step size. Default is None which means that the algorithm should choose.

**max_step**  [float, optional] Maximum allowed step size. Default is np.inf, i.e., the step size is not bounded and determined solely by the solver.

**rtol, atol**  [float or array_like, optional] Relative and absolute tolerances. The solver keeps the local error estimates less than atol + rtol * abs(y). Here rtol controls a relative accuracy (number of correct digits), while atol controls absolute accuracy (number of correct decimal places). To achieve the desired rtol, set atol to be lower than the lowest value that can be expected from rtol * abs(y) so that rtol dominates the allowable error. If atol is larger than rtol * abs(y) the number of correct digits is not guaranteed. Conversely, to achieve the desired atol set rtol such that rtol * abs(y) is always lower than atol. If components of y have different scales, it might be beneficial to set different atol values for different components by passing array_like with shape (n,) for atol. Default values are 1e-3 for rtol and 1e-6 for atol.

**jac**  [array_like, sparse_matrix, callable or None, optional] Jacobian matrix of the right-hand side of the system with respect to y, required by the ‘Radau’, ‘BDF’ and ‘LSODA’ method. The Jacobian matrix has shape (n, n) and its element (i, j) is equal to \( \frac{\partial f_i}{\partial y_j} \). There are three ways to define the Jacobian:

- If array_like or sparse_matrix, the Jacobian is assumed to be constant. Not supported by ‘LSODA’.
- If callable, the Jacobian is assumed to depend on both t and y; it will be called as \( jac(t, y) \), as necessary. For ‘Radau’ and ‘BDF’ methods, the return value might be a sparse matrix.
- If None (default), the Jacobian will be approximated by finite differences. It is generally recommended to provide the Jacobian rather than relying on a finite-difference approximation.

**jac_sparsity**  [array_like, sparse_matrix or None, optional] Defines a sparsity structure of the Jacobian matrix for a finite-difference approximation. Its shape must be (n, n). This argument is ignored if jac is not None. If the Jacobian has only few non-zero elements in each row, providing the sparsity structure will greatly speed up the computations [10]. A zero entry means that a corresponding element in the Jacobian is always zero. If None (default), the Jacobian is assumed to be dense. Not supported by ‘LSODA’, see lband and uband instead.

**lband, uband**  [int or None, optional] Parameters defining the bandwidth of the Jacobian for the ‘LSODA’ method, i.e., \( jac[i, j] \neq 0 \) only for \( i - lband \leq j \leq i + uband \). Default is None. Setting these requires your jac routine to return the Jacobian in the packed format: the returned array must have n columns and uband + lband + 1 rows in which Jacobian diagonals are written. Specifically \( jac\_packed[uband + i - j, j] = jac[i, j] \). The same format is used in scipy.linalg.solve_banded (check for an illustration). These parameters can be also used with jac=None to reduce the number of Jacobian elements estimated by finite differences.

**min_step**  [float, optional] The minimum allowed step size for ‘LSODA’ method. By default min_step is zero.

**Returns**

- Bunch object with the following fields defined:
  - t  [ndarray, shape (n_points,)] Time points.
  - y  [ndarray, shape (n, n_points)] Values of the solution at t.
  - sol  [OdeSolution or None] Found solution as OdeSolution instance; None if dense_output was set to False.
  - t_events  [list of ndarray or None] Contains for each event type a list of arrays at which an event of that type event was detected. None if events was None.

**SciPy Reference Guide, Release 1.8.0**

| y_events  | [list of ndarray or None] For each value of t_events, the corresponding value of the solution. None if events was None. |
| nfev      | [int] Number of evaluations of the right-hand side. |
| njev      | [int] Number of evaluations of the Jacobian. |
| nlu        | [int] Number of LU decompositions. |
| status     | [int] Reason for algorithm termination: |
|            | • -1: Integration step failed. |
|            | • 0: The solver successfully reached the end of tspan. |
|            | • 1: A termination event occurred. |
| message    | [string] Human-readable description of the termination reason. |
| success    | [bool] True if the solver reached the interval end or a termination event occurred (status >= 0). |

**Examples**

Basic exponential decay showing automatically chosen time points.

```python
>>> from scipy.integrate import solve_ivp
>>> def exponential_decay(t, y):
...     return -0.5 * y
>>> sol = solve_ivp(exponential_decay, [0, 10], [2, 4, 8])
>>> print(sol.t)
[ 0. 0.11487653 1.26364188 3.06061781 4.81611105 6.57445806
 8.33328988 10.]
>>> print(sol.y)
[[2. 1.88836035 1.06327177 0.43319312 0.18017253 0.07483045
 0.03107158 0.01350781]
 [4. 3.7767207 2.12654355 0.86638624 0.36034507 0.14966091
 0.06214316 0.02701561]
 [8. 7.5534414 4.25308709 1.73277247 0.72069014 0.29932181
 0.12428631 0.05403123]]
```

Specifying points where the solution is desired.

```python
>>> sol = solve_ivp(exponential_decay, [0, 10], [2, 4, 8],
...                   t_eval=[0, 1, 2, 4, 10])
>>> print(sol.t)
[ 0 1 2 4 10]
>>> print(sol.y)
[[2. 1.21305369 0.73534021 0.27066736 0.01350938]
 [4. 2.42610739 1.47068043 0.54133472 0.02701876]
 [8. 4.85221478 2.94136085 1.08266944 0.05403753]]
```

Cannon fired upward with terminal event upon impact. The terminal and direction fields of an event are applied by monkey patching a function. Here y[0] is position and y[1] is velocity. The projectile starts at position 0 with velocity +10. Note that the integration never reaches t=100 because the event is terminal.

```python
>>> def upward_cannon(t, y):
...     return [y[1], -0.5]
>>> def hit_ground(t, y):
...     return y[0]
```

(continues on next page)
Use `dense_output` and `events` to find position, which is 100, at the apex of the cannonball’s trajectory. Apex is not defined as terminal, so both apex and hit_ground are found. There is no information at t=20, so the sol attribute is used to evaluate the solution. The sol attribute is returned by setting `dense_output=True`. Alternatively, the `y_events` attribute can be used to access the solution at the time of the event.

As an example of a system with additional parameters, we’ll implement the Lotka-Volterra equations [12].

We pass in the parameter values a=1.5, b=1, c=3 and d=1 with the `args` argument.

Compute a dense solution and plot it.

---

3.3. API definition 475
scipy.integrate.RK23

class scipy.integrate.RK23(fun, t0, y0, t_bound, max_step=inf, rtol=0.001, atol=1e-06, vectorized=False, first_step=None, **extraneous)

Explicit Runge-Kutta method of order 3(2).

This uses the Bogacki-Shampine pair of formulas [1]. The error is controlled assuming accuracy of the second-order method, but steps are taken using the third-order accurate formula (local extrapolation is done). A cubic Hermite polynomial is used for the dense output.

Can be applied in the complex domain.

Parameters

fun [callable] Right-hand side of the system. The calling signature is fun(t, y). Here t is a scalar and there are two options for ndarray y. It can either have shape (n,), then fun must return array_like with shape (n,). Or alternatively it can have shape (n, k), then fun must return array_like with shape (n, k), i.e. each column corresponds to a single column in y. The choice between the two options is determined by vectorized argument (see below).

t0 [float] Initial time.

y0 [array_like, shape (n,)] Initial state.

t_bound [float] Boundary time - the integration won’t continue beyond it. It also determines the direction of the integration.

first_step [float or None, optional] Initial step size. Default is None which means that the algorithm should choose.

max_step [float, optional] Maximum allowed step size. Default is np.inf, i.e., the step size is not bounded and determined solely by the solver.

rtol, atol [float and array_like, optional] Relative and absolute tolerances. The solver keeps the local error estimates less than atol + rtol * abs(y). Here rtol controls a relative accuracy (number of correct digits), while atol controls absolute accuracy (number of correct decimal places). To achieve the desired rtol, set atol to be lower than the lowest value that can be expected from rtol * abs(y) so that rtol dominates the allowable error. If atol is larger than rtol * abs(y) the number of correct digits is not guaranteed. Conversely, to achieve the desired atol set rtol such that rtol * abs(y) is always lower than atol. If components of y have different scales, it might be beneficial to set different atol values for different components by passing array_like with shape (n,) for atol. Default values are 1e-3 for rtol and 1e-6 for atol.
vectorized [bool, optional] Whether fun is implemented in a vectorized fashion. Default is False.

References

[1]

Attributes

n [int] Number of equations.
status [string] Current status of the solver: 'running', 'finished' or 'failed'.
t_bound [float] Boundary time.
direction [float] Integration direction: +1 or -1.
t [float] Current time.
y [ndarray] Current state.
t_old [float] Previous time. None if no steps were made yet.
step_size [float] Size of the last successful step. None if no steps were made yet.
nfev [int] Number of evaluations of the system's right-hand side.
njcv [int] Number of evaluations of the Jacobian. Is always 0 for this solver as it does not use the Jacobian.
nlu [int] Number of LU decompositions. Is always 0 for this solver.

Methods

dense_output() Compute a local interpolant over the last successful step.

step() Perform one integration step.

scipy.integrate.RK23.dense_output

RK23.dense_output() Compute a local interpolant over the last successful step.

Returns

sol [DenseOutput] Local interpolant over the last successful step.

scipy.integrate.RK23.step

RK23.step() Perform one integration step.

Returns

message [string or None] Report from the solver. Typically a reason for a failure if self.status is 'failed' after the step was taken or None otherwise.
Explicit Runge-Kutta method of order 5(4).

This uses the Dormand-Prince pair of formulas [1]. The error is controlled assuming accuracy of the fourth-order method accuracy, but steps are taken using the fifth-order accurate formula (local extrapolation is done). A quartic interpolation polynomial is used for the dense output [2].

Can be applied in the complex domain.

**Parameters**

- **fun** [callable] Right-hand side of the system. The calling signature is `fun(t, y)`. Here `t` is a scalar, and there are two options for the ndarray `y`: It can either have shape (n,); then `fun` must return array_like with shape (n,). Alternatively it can have shape (n, k); then `fun` must return an array_like with shape (n, k), i.e., each column corresponds to a single column in `y`. The choice between the two options is determined by `vectorized` argument (see below).
- **t0** [float] Initial time.
- **y0** [array_like, shape (n,)] Initial state.
- **t_bound** [float] Boundary time - the integration won’t continue beyond it. It also determines the direction of the integration.
- **first_step** [float or None, optional] Initial step size. Default is `None` which means that the algorithm should choose.
- **max_step** [float, optional] Maximum allowed step size. Default is `np.inf`, i.e., the step size is not bounded and determined solely by the solver.
- **rtol, atol** [float and array_like, optional] Relative and absolute tolerances. The solver keeps the local error estimates less than `atol + rtol * abs(y)`. Here `rtol` controls a relative accuracy (number of correct digits), while `atol` controls absolute accuracy (number of correct decimal places). To achieve the desired `rtol`, set `atol` to be lower than the lowest value that can be expected from `rtol * abs(y)` so that `rtol` dominates the allowable error. If `atol` is larger than `rtol * abs(y)` the number of correct digits is not guaranteed. Conversely, to achieve the desired `atol` set `rtol` such that `rtol * abs(y)` is always lower than `atol`. If components of `y` have different scales, it might be beneficial to set different `atol` values for different components by passing array_like with shape (n,) for `atol`. Default values are `1e-3` for `rtol` and `1e-6` for `atol`.
- **vectorized** [bool, optional] Whether `fun` is implemented in a vectorized fashion. Default is `False`.

`scipy.integrate.RK45.dense_output`

RK45.dense_output()

Compute a local interpolant over the last successful step.

Returns

- `sol` [DenseOutput] Local interpolant over the last successful step.

`scipy.integrate.RK45.step`

RK45.step()

Perform one integration step.

Returns

- `message` [string or None] Report from the solver. Typically a reason for a failure if `self.status` is ‘failed’ after the step was taken or None otherwise.

`scipy.integrate.DOP853`

class scipy.integrate.DOP853 (fun, t0, y0, t_bound, max_step=inf, rtol=0.001, atol=1e-06, vectorized=False, first_step=None, **extraneous)

Explicit Runge-Kutta method of order 8.

This is a Python implementation of “DOP853” algorithm originally written in Fortran [1], [2]. Note that this is not a literate translation, but the algorithmic core and coefficients are the same.

Can be applied in the complex domain.

Parameters

- `fun` [callable] Right-hand side of the system. The calling signature is `fun(t, y)`. Here, `t` is a scalar, and there are two options for the `ndarray` `y`: It can either have shape (n,); then `fun` must return `array_like` with shape (n,). Alternatively it can have shape (n, k); then `fun` must return an `array_like` with shape (n, k), i.e. each column corresponds to a single column in `y`. The choice between the two options is determined by `vectorized` argument (see below).
- `t0` [float] Initial time.
- `y0` [array_like, shape (n,)] Initial state.
- `t_bound` [float] Boundary time - the integration won’t continue beyond it. It also determines the direction of the integration.
- `first_step` [float or None, optional] Initial step size. Default is None which means that the algorithm should choose.
- `max_step` [float, optional] Maximum allowed step size. Default is np.inf, i.e. the step size is not bounded and determined solely by the solver.
- `rtol, atol` [float and array_like, optional] Relative and absolute tolerances. The solver keeps the local error estimates less than `atol + rtol * abs(y)`. Here `rtol` controls a relative accuracy (number of correct digits), while `atol` controls absolute accuracy (number of correct decimal places). To achieve the desired `rtol`, set `atol` to be lower than the lowest value that can be
expected from \( rtol \ast \text{abs}(y) \) so that \( rtol \) dominates the allowable error. If \( atol \) is larger than \( rtol \ast \text{abs}(y) \) the number of correct digits is not guaranteed. Conversely, to achieve the desired \( atol \) set \( rtol \) such that \( rtol \ast \text{abs}(y) \) is always lower than \( atol \). If components of \( y \) have different scales, it might be beneficial to set different \( atol \) values for different components by passing \( \text{array_like} \) with shape \((n,)\) for \( atol \). Default values are 1e-3 for \( rtol \) and 1e-6 for \( atol \).

\[ \text{sol} \quad \text{[DenseOutput]} \quad \text{Local interpolant over the last successful step}. \]
scipy.integrate.DOP853.step

DOP853.step()
Perform one integration step.

Returns

message [string or None] Report from the solver. Typically a reason for a failure if self.status is ‘failed’ after the step was taken or None otherwise.

scipy.integrate.Radau

class scipy.integrate.Radau (fun, t0, y0, t_bound, max_step=inf, rtol=0.001, atol=1e-06, jac=None, jac_sparsity=None, vectorized=False, first_step=None, **extraneous)

Implicit Runge-Kutta method of RadauIIA family of order 5.

The implementation follows [1]. The error is controlled with a third-order accurate embedded formula. A cubic polynomial which satisfies the collocation conditions is used for the dense output.

Parameters

fun [callable] Right-hand side of the system. The calling signature is fun(t, y). Here t is a scalar, and there are two options for the ndarray y: It can either have shape (n,); then fun must return array_like with shape (n,). Alternatively it can have shape (n, k); then fun must return an array_like with shape (n, k), i.e., each column corresponds to a single column in y. The choice between the two options is determined by vectorized argument (see below). The vectorized implementation allows a faster approximation of the Jacobian by finite differences (required for this solver).

t0 [float] Initial time.

y0 [array_like, shape(n,)] Initial state.

t_bound [float] Boundary time - the integration won’t continue beyond it. It also determines the direction of the integration.

first_step [float or None, optional] Initial step size. Default is None which means that the algorithm should choose.

max_step [float, optional] Maximum allowed step size. Default is np.inf, i.e., the step size is not bounded and determined solely by the solver.

rtol, atol [float and array_like, optional] Relative and absolute tolerances. The solver keeps the local error estimates less than atol + rtol * abs(y). Here rtol controls a relative accuracy (number of correct digits), while atol controls absolute accuracy (number of correct decimal places). To achieve the desired rtol, set atol to be lower than the lowest value that can be expected from rtol * abs(y) so that rtol dominates the allowable error. If atol is larger than rtol * abs(y) the number of correct digits is not guaranteed. Conversely, to achieve the desired atol set rtol such that rtol * abs(y) is always lower than atol. If components of y have different scales, it might be beneficial to set different atol values for different components by passing array_like with shape (n,) for atol. Default values are 1e-3 for rtol and 1e-6 for atol.

jac [{None, array_like, sparse_matrix, callable}, optional] Jacobian matrix of the right-hand side of the system with respect to y, required by this method. The Jacobian matrix has shape (n, n) and its element (i, j) is equal to d f_i / d y_j. There are three ways to define the Jacobian:
  • If array_like or sparse_matrix, the Jacobian is assumed to be constant.
  • If callable, the Jacobian is assumed to depend on both t and y; it will be called as jac(t, y) as necessary. For the ‘Radau’ and ‘BDF’ methods, the return value might be a sparse matrix.
  • If None (default), the Jacobian will be approximated by finite differences.

It is generally recommended to provide the Jacobian rather than relying on a finite-difference approximation.

5.3. API definition 481
jac_sparsity

[None, array_like, sparse matrix], optional] Defines a sparsity structure of the Jacobian matrix for a finite-difference approximation. Its shape must be (n, n). This argument is ignored if jac is not None. If the Jacobian has only few non-zero elements in each row, providing the sparsity structure will greatly speed up the computations [2]. A zero entry means that a corresponding element in the Jacobian is always zero. If None (default), the Jacobian is assumed to be dense.

vectorized

[bool, optional] Whether fun is implemented in a vectorized fashion. Default is False.

References

scipy.integrate.Radau.dense_output

Radau.dense_output()

Compute a local interpolant over the last successful step.

Returns

- sol [DenseOutput] Local interpolant over the last successful step.
**scipy.integrate.Radau.step**

Radau.step()

Perform one integration step.

**Returns**

message [string or None] Report from the solver. Typically a reason for a failure if self.status is ‘failed’ after the step was taken or None otherwise.

**scipy.integrate.BDF**

class scipy.integrate.BDF (fun, t0, y0, t_bound, max_step=inf, rtol=0.001, atol=1e-06, jac=None, jac_sparsity=None, vectorized=False, first_step=None, **extraneous)

Implicit method based on backward-differentiation formulas.

This is a variable order method with the order varying automatically from 1 to 5. The general framework of the BDF algorithm is described in [1]. This class implements a quasi-constant step size as explained in [2]. The error estimation strategy for the constant-step BDF is derived in [3]. An accuracy enhancement using modified formulas (NDF) [2] is also implemented.

Can be applied in the complex domain.

**Parameters**

fun [callable] Right-hand side of the system. The calling signature is fun(t, y). Here t is a scalar, and there are two options for the ndarray y: It can either have shape (n,); then fun must return array_like with shape (n,). Alternatively it can have shape (n, k); then fun must return an array_like with shape (n, k), i.e. each column corresponds to a single column in y. The choice between the two options is determined by vectorized argument (see below). The vectorized implementation allows a faster approximation of the Jacobian by finite differences (required for this solver).

t0 [float] Initial time.

y0 [array_like, shape (n,)] Initial state.

t_bound [float] Boundary time - the integration won’t continue beyond it. It also determines the direction of the integration.

first_step [float or None, optional] Initial step size. Default is None which means that the algorithm should choose.

max_step [float, optional] Maximum allowed step size. Default is np.inf, i.e., the step size is not bounded and determined solely by the solver.

rtol, atol [float and array_like, optional] Relative and absolute tolerances. The solver keeps the local error estimates less than atol + rtol * abs(y). Here rtol controls a relative accuracy (number of correct digits), while atol controls absolute accuracy (number of correct decimal places). To achieve the desired rtol, set atol to be lower than the lowest value that can be expected from rtol * abs(y) so that rtol dominates the allowable error. If atol is larger than rtol * abs(y) the number of correct digits is not guaranteed. Conversely, to achieve the desired atol set rtol such that rtol * abs(y) is always lower than atol. If components of y have different scales, it might be beneficial to set different atol values for different components by passing array_like with shape (n,) for atol. Default values are 1e-3 for rtol and 1e-6 for atol.

jac [{None, array_like, sparse_matrix, callable}, optional] Jacobian matrix of the right-hand side of the system with respect to y, required by this method. The Jacobian matrix has shape (n, n) and its element (i, j) is equal to d f_i / d y_j. There are three ways to define the Jacobian:
- If array_like or sparse_matrix, the Jacobian is assumed to be constant.
• If callable, the Jacobian is assumed to depend on both \( t \) and \( y \); it will be called as \( \text{jac}(t, y) \) as necessary. For the 'Radau' and 'BDF' methods, the return value might be a sparse matrix.

• If None (default), the Jacobian will be approximated by finite differences. It is generally recommended to provide the Jacobian rather than relying on a finite-difference approximation.

\( \text{jac} \) _sparsity_ 

[{None, array_like, sparse matrix}, optional] Defines a sparsity structure of the Jacobian matrix for a finite-difference approximation. Its shape must be (n, n). This argument is ignored if \( \text{jac} \) is not None. If the Jacobian has only few non-zero elements in each row, providing the sparsity structure will greatly speed up the computations [4]. A zero entry means that a corresponding element in the Jacobian is always zero. If None (default), the Jacobian is assumed to be dense.

\( \text{vectorized} \) [bool, optional] Whether \( \text{fun} \) is implemented in a vectorized fashion. Default is False.

References

[1], [2], [3], [4]

Attributes

- \( n \) [int] Number of equations.
- \( \text{t_bound} \) [float] Boundary time.
- \( \text{direction} \) [float] Integration direction: +1 or -1.
- \( t \) [float] Current time.
- \( y \) [ndarray] Current state.
- \( \text{t_old} \) [float] Previous time. None if no steps were made yet.

- \( \text{step}() \) Perform one integration step.

**scipy.integrate.BDF.dense_output**

\[ \text{BDF.dense_output()} \]

Compute a local interpolant over the last successful step.

**Returns**

- \( \text{sol} \) [DenseOutput] Local interpolant over the last successful step.
scipy.integrate.BDF.step

BDF.step()

Perform one integration step.

Returns

message [string or None] Report from the solver. Typically a reason for a failure if self.status is ‘failed’ after the step was taken or None otherwise.

scipy.integrate.LSODA

class scipy.integrate.LSODA (fun, t0, y0, t_bound, first_step=None, min_step=0.0, max_step=inf,
rtol=0.001, atol=1e-06, jac=None, lband=None, uband=None,
vectorized=False, **extraneous)

Adams/BDF method with automatic stiffness detection and switching.

This is a wrapper to the Fortran solver from ODEPACK [1]. It switches automatically between the nonstiff Adams method and the stiff BDF method. The method was originally detailed in [2].

Parameters

fun [callable] Right-hand side of the system. The calling signature is fun(t, y). Here t is a scalar, and there are two options for the ndarray y: It can either have shape (n,); then fun must return array_like with shape (n,). Alternatively it can have shape (n, k); then fun must return an array_like with shape (n, k), i.e. each column corresponds to a single column in y. The choice between the two options is determined by vectorized argument (see below). The vectorized implementation allows a faster approximation of the Jacobian by finite differences (required for this solver).

t0 [float] Initial time.

y0 [array_like, shape(n,)] Initial state.

t_bound [float] Boundary time - the integration won’t continue beyond it. It also determines the direction of the integration.

first_step [float or None, optional] Initial step size. Default is None which means that the algorithm should choose.

min_step [float, optional] Minimum allowed step size. Default is 0.0, i.e., the step size is not bounded and determined solely by the solver.

max_step [float, optional] Maximum allowed step size. Default is np.inf, i.e., the step size is not bounded and determined solely by the solver.

rtol, atol [float and array_like, optional] Relative and absolute tolerances. The solver keeps the local error estimates less than atol + rtol * abs(y). Here rtol controls a relative accuracy (number of correct digits), while atol controls absolute accuracy (number of correct decimal places). To achieve the desired rtol, set atol to be lower than the lowest value that can be expected from rtol * abs(y) so that rtol dominates the allowable error. If atol is larger than rtol * abs(y) the number of correct digits is not guaranteed. Conversely, to achieve the desired atol set rtol such that rtol * abs(y) is always lower than atol. If components of y have different scales, it might be beneficial to set different atol values for different components by passing array_like with shape (n,) for atol. Default values are 1e-3 for rtol and 1e-6 for atol.

jac [None or callable, optional] Jacobian matrix of the right-hand side of the system with respect to y. The Jacobian matrix has shape (n, n) and its element (i, j) is equal to \( \frac{\partial f_i}{\partial y_j} \). The function will be called as jac(t, y). If None (default), the Jacobian will be approximated by finite differences. It is generally recommended to provide the Jacobian rather than relying on a finite-difference approximation.

lband, uband [int or None] Parameters defining the bandwidth of the Jacobian, i.e., jac[i, j] != 0 only for i - lband <= j <= i + uband. Setting these requires your jac

3.3. API definition
routine to return the Jacobian in the packed format: the returned array must have \( n \) columns and \( \text{uband} + \text{lband} + 1 \) rows in which Jacobian diagonals are written. Specifically

\[
\text{jac}_\text{packed}[\text{uband} + i - j, j] = \text{jac}[i, j].
\]

The same format is used in \texttt{scipy.linalg.solve_banded} (check for an illustration). These parameters can be also used with \texttt{jac=None} to reduce the number of Jacobian elements estimated by finite differences.

\textbf{vectorized} [bool, optional] Whether \texttt{fun} is implemented in a vectorized fashion. A vectorized implementation offers no advantages for this solver. Default is \texttt{False}.

\section*{References}

\section*{Methods}

- \texttt{dense_output()} Compute a local interpolant over the last successful step.
- \texttt{step()} Perform one integration step.

\begin{verbatim}
scipy.integrate.LSODA.dense_output

LSODA.dense_output()
Compute a local interpolant over the last successful step.

Returns

sol [DenseOutput] Local interpolant over the last successful step.

scipy.integrate.LSODA.step

LSODA.step()
Perform one integration step.

Returns

message [string or None] Report from the solver. Typically a reason for a failure if self.status is ‘failed’ after the step was taken or None otherwise.
\end{verbatim}
**scipy.integrate.OdeSolver**

class scipy.integrate.OdeSolver (fun, t0, y0, t_bound, vectorized, support_complex=False)

Base class for ODE solvers.

In order to implement a new solver you need to follow the guidelines:

1. A constructor must accept parameters presented in the base class (listed below) along with any other parameters specific to a solver.

2. A constructor must accept arbitrary extraneous arguments **extraneous**, but warn that these arguments are irrelevant using common.warn_extraneous function. Do not pass these arguments to the base class.

3. A solver must implement a private method _step_impl(self) which propagates a solver one step further. It must return tuple (success, message), where success is a boolean indicating whether a step was successful, and message is a string containing description of a failure if a step failed or None otherwise.

4. A solver must implement a private method _dense_output_impl(self), which returns a DenseOutput object covering the last successful step.

5. A solver must have attributes listed below in Attributes section. Note that t_old and step_size are updated automatically.

6. Use fun(self, t, y) method for the system rhs evaluation, this way the number of function evaluations (nfev) will be tracked automatically.

7. For convenience, a base class provides fun_single(self, t, y) and fun_vectorized(self, t, y) for evaluating the rhs in non-vectorized and vectorized fashions respectively (regardless of how fun from the constructor is implemented). These calls don't increment nfev.

8. If a solver uses a Jacobian matrix and LU decompositions, it should track the number of Jacobian evaluations (njev) and the number of LU decompositions (nlu).

9. By convention, the function evaluations used to compute a finite difference approximation of the Jacobian should not be counted in nfev, thus use fun_single(self, t, y) or fun_vectorized(self, t, y) when computing a finite difference approximation of the Jacobian.

**Parameters**

- **fun** [callable] Right-hand side of the system. The calling signature is fun(t, y). Here t is a scalar and there are two options for ndarray y. It can either have shape (n,), then fun must return array_like with shape (n,). Or, alternatively, it can have shape (n, n_points), then fun must return array_like with shape (n, n_points) (each column corresponds to a single column in y). The choice between the two options is determined by vectorized argument (see below).

- t0 [float] Initial time.

- y0 [array_like, shape(n,)] Initial state.

- t_bound [float] Boundary time — the integration won’t continue beyond it. It also determines the direction of the integration.

- vectorized [bool] Whether fun is implemented in a vectorized fashion.

- support_complex [bool, optional] Whether integration in a complex domain should be supported. Generally determined by a derived solver class capabilities. Default is False.

**Attributes**

- n [int] Number of equations.

- t_bound [float] Boundary time.

- direction [float] Integration direction: +1 or -1.

- t [float] Current time.

- y [ndarray] Current state.

**scipy.integrate.OdeSolver.dense_output**

OdeSolver.dense_output()

Compute a local interpolant over the last successful step.

**Returns**

sol [DenseOutput] Local interpolant over the last successful step.

**scipy.integrate.OdeSolver.step**

OdeSolver.step()

Perform one integration step.

**Returns**

message [string or None] Report from the solver. Typically a reason for a failure if self.status is ‘failed’ after the step was taken or None otherwise.

**scipy.integrate.DenseOutput**

class scipy.integrate.DenseOutput(t_old, t)

Base class for local interpolant over step made by an ODE solver.

It interpolates between t_min and t_max (see Attributes below). Evaluation outside this interval is not forbidden, but the accuracy is not guaranteed.

**Attributes**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>t_min, t_max</td>
<td>[float] Time range of the interpolation.</td>
</tr>
</tbody>
</table>
Methods

```python
__call__(t) Evaluate the interpolant.
```

**scipy.integrate.DenseOutput.__call__**

```python
DenseOutput.__call__(t)
Evaluate the interpolant.

Parameters
- `t` [float or array_like with shape (n_points,)] Points to evaluate the solution at.

Returns
- `y` [ndarray, shape (n,) or (n, n_points)] Computed values. Shape depends on whether `t` was a scalar or a 1-D array.
```

**scipy.integrate.OdeSolution**

```python
class scipy.integrate.OdeSolution(ts, interpolants)
Continuous ODE solution.

It is organized as a collection of DenseOutput objects which represent local interpolants. It provides an algorithm to select a right interpolant for each given point.

The interpolants cover the range between $t_{min}$ and $t_{max}$ (see Attributes below). Evaluation outside this interval is not forbidden, but the accuracy is not guaranteed.

When evaluating at a breakpoint (one of the values in `ts`) a segment with the lower index is selected.

Parameters
- `ts` [array_like, shape (n_segments + 1,)] Time instants between which local interpolants are defined. Must be strictly increasing or decreasing (zero segment with two points is also allowed).
- `interpolants` [list of DenseOutput with n_segments elements] Local interpolants. An i-th interpolant is assumed to be defined between $t_{s}[i]$ and $t_{s}[i + 1]$.

Attributes
- `t_min, t_max` [float] Time range of the interpolation.

Methods

```python
__call__(t) Evaluate the solution.
```
scipy.integrate.OdeSolution.__call__

OdeSolution.__call__(t)
Evaluates the solution.

Parameters

- **t** ([float or array_like with shape (n_points,)]) Points to evaluate at.

Returns

- **y** ([ndarray, shape (n_states,) or (n_states, n_points)]) Computed values. Shape depends on whether \( t \) is a scalar or a 1-D array.

Old API

These are the routines developed earlier for SciPy. They wrap older solvers implemented in Fortran (mostly ODEPACK). While the interface to them is not particularly convenient and certain features are missing compared to the new API, the solvers themselves are of good quality and work fast as compiled Fortran code. In some cases, it might be worth using this old API.

```
odeint(func, y0, t[, args, Dfun, col_deriv, ...]) Integrate a system of ordinary differential equations.
ode(f[, jac]) A generic interface class to numeric integrators.
complex_ode(f[, jac]) A wrapper of ode for complex systems.
```

scipy.integrate.odeint

```
scipy.integrate.odeint (func, y0, t[, args=(), Dfun=None, col_deriv=0, full_output=0, ml=None, mu=None, rtol=None, atol=None, tcrit=None, h0=0.0, hmax=0.0, hmin=0.0, ixpr=0, mxstep=0, mxhnil=0, mxordn=12, mxords=5, printmessg=0, tfirst=False])
```

Integrate a system of ordinary differential equations.

**Note:** For new code, use **scipy.integrate.solve_ivp** to solve a differential equation.

Solve a system of ordinary differential equations using lsoda from the FORTRAN library odepack.

Solves the initial value problem for stiff or non-stiff systems of first order ode-s:

\[
\frac{dy}{dt} = \text{func}(y, t, ...) \quad \text{or} \quad \text{func}(t, y, ...)
\]

where \( y \) can be a vector.

**Note:** By default, the required order of the first two arguments of \text{func} are in the opposite order of the arguments in the system definition function used by the **scipy.integrate.ode** class and the function **scipy.integrate.solve_ivp**. To use a function with the signature \text{func}(t, y, ...), the argument \text{tfirst} must be set to True.

**Parameters**

- **func** ([callable(y, t, ...) or callable(t, y, ...)]) Computes the derivative of \( y \) at \( t \). If the signature is \text{callable}(t, y, ...), then the argument \text{tfirst} must be set True.
- **y0** ([array]) Initial condition on \( y \) (can be a vector).
`t` [array] A sequence of time points for which to solve for `y`. The initial value point should be the first element of this sequence. This sequence must be monotonically increasing or monotonically decreasing; repeated values are allowed.

`args` [tuple, optional] Extra arguments to pass to function.

`Dfun` [callable(y, t, ...) or callable(t, y, ...)] Gradient (Jacobian) of `func`. If the signature is `callable(t, y, ...)`, then the argument `tfirst` must be set `True`.

`col_deriv` [bool, optional] True if `Dfun` defines derivatives down columns (faster), otherwise `Dfun` should define derivatives across rows.

`full_output` [bool, optional] True if to return a dictionary of optional outputs as the second output

`printmessg` [bool, optional] Whether to print the convergence message

`tfirst` [bool, optional]
If `True`, the first two arguments of `func` (and `Dfun`, if given) must `t, y` instead of the default `y, t`.

New in version 1.1.0.

**Returns**

`y` [array, shape (len(t), len(y0))] Array containing the value of `y` for each desired time in `t`, with the initial value `y0` in the first row.

`infodict` [dict, only returned if `full_output == True`] Dictionary containing additional output information

<table>

</tbody>
</table>

`mused` a vector of method indicators for each successful time step: 1: adams (nonstiff), 2: bdf (stiff)

**Other Parameters**

`ml, mu` [int, optional] If either of these are not None or non-negative, then the Jacobian is assumed to be banded. These give the number of lower and upper non-zero diagonals in this banded matrix. For the banded case, `Dfun` should return a matrix whose rows contain the non-zero bands (starting with the lowest diagonal). Thus, the return matrix `jac` from `Dfun` should have shape `(ml + mu + 1, len(y0))` when `ml >=0` or `mu >=0`. The data in `jac` must be stored such that `jac[i - j + mu, j]` holds the derivative of the `i`th equation with respect to the `j`th state variable. If `col_deriv` is True, the transpose of this `jac` must be returned.

`rtol, atol` [float, optional] The input parameters `rtol` and `atol` determine the error control performed by the solver. The solver will control the vector, `e`, of estimated local errors in `y`, according to an inequality of the form $\max-norm \ of \ (e / \ ewt) \leq 1$, where `ewt` is a vector of.
positive error weights computed as $\text{ewt} = \text{rtol} \times \text{abs}(y) + \text{atol}$. rtol and atol can be either vectors the same length as y or scalars. Defaults to $1.49012e-8$.

tcrit
[ndarray, optional] Vector of critical points (e.g., singularities) where integration care should be taken.

h0
[float, (0: solver-determined), optional] The step size to be attempted on the first step.

hmax
[float, (0: solver-determined), optional] The maximum absolute step size allowed.

hmin
[float, (0: solver-determined), optional] The minimum absolute step size allowed.

ixpr
[bool, optional] Whether to generate extra printing at method switches.

mxstep
[int, (0: solver-determined), optional] Maximum number of (internally defined) steps allowed for each integration point in $t$.

mxhnil
[int, (0: solver-determined), optional] Maximum number of messages printed.

mxordn
[int, (0: solver-determined), optional] Maximum order to be allowed for the non-stiff (Adams) method.

mxords
[int, (0: solver-determined), optional] Maximum order to be allowed for the stiff (BDF) method.

a more object-oriented integrator based on VODE

quad
for finding the area under a curve

Examples

The second order differential equation for the angle $\theta$ of a pendulum acted on by gravity with friction can be written:

$$ \theta''(t) + b\theta'(t) + c\sin(\theta(t)) = 0 $$

where $b$ and $c$ are positive constants, and a prime (') denotes a derivative. To solve this equation with odeint, we must first convert it to a system of first order equations. By defining the angular velocity $\omega(t) = \theta'(t)$, we obtain the system:

$$ \theta'(t) = \omega(t) $$
$$ \omega'(t) = -b\omega(t) - c\sin(\theta(t)) $$

Let $y$ be the vector $[\theta, \omega]$. We implement this system in Python as:

```python
>>> def pend(y, t, b, c):
...     theta, omega = y
...     dydt = [omega, -b*omega - c*np.sin(theta)]
...     return dydt
...
```

We assume the constants are $b = 0.25$ and $c = 5.0$:

```python
>>> b = 0.25
>>> c = 5.0
```
For initial conditions, we assume the pendulum is nearly vertical with \( \theta(0) = \pi - 0.1 \), and is initially at rest, so \( \omega(0) = 0 \). Then the vector of initial conditions is

```python
>>> y0 = [np.pi - 0.1, 0.0]
```

We will generate a solution at 101 evenly spaced samples in the interval \( 0 \leq t \leq 10 \). So our array of times is:

```python
>>> t = np.linspace(0, 10, 101)
```

Call `odeint` to generate the solution. To pass the parameters \( b \) and \( c \) to `pend`, we give them to `odeint` using the `args` argument.

```python
>>> from scipy.integrate import odeint
>>> sol = odeint(pend, y0, t, args=(b, c))
```

The solution is an array with shape (101, 2). The first column is \( \theta(t) \), and the second is \( \omega(t) \). The following code plots both components.

```python
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, sol[:, 0], 'b', label='\theta(t)')
>>> plt.plot(t, sol[:, 1], 'g', label='\omega(t)')
>>> plt.legend(loc='best')
>>> plt.xlabel('t')
>>> plt.grid()
>>> plt.show()
```
scipy.integrate.ode

class scipy.integrate.ode(f, jac=None)

A generic interface class to numeric integrators.

Solve an equation system \( y'(t) = f(t, y) \) with (optional) \( \text{jac} = \frac{df}{dy} \).

Note: The first two arguments of \( f(t, y, \ldots) \) are in the opposite order of the arguments in the system
definition function used by scipy.integrate.odeint.

Parameters

f [callable f(t, y, *f_args)] Right-hand side of the differential equation. t is a scalar,
\( y\.shape == (n,) \). f_args is set by calling set_f_params(*args). f should
return a scalar, array or list (not a tuple).

jac [callable jac(t, y, *jac_args), optional] Jacobian of the right-hand side, \( jac[i, j] = \frac{df[i]}{dy[j]} \). jac_args is set by calling set_jac_params(*args).

See also:

odeint

an integrator with a simpler interface based on Isoda from ODEPACK

quad

for finding the area under a curve

Notes

Available integrators are listed below. They can be selected using the set_integrator method.

“vode”

Real-valued Variable-coefficient Ordinary Differential Equation solver, with fixed-leading-coefficient imple-
mentation. It provides implicit Adams method (for non-stiff problems) and a method based on backward
differentiation formulas (BDF) (for stiff problems).

Source: http://www.netlib.org/ode/vode.f

Warning: This integrator is not re-entrant. You cannot have two ode instances using the “vode” inte-
grator at the same time.

This integrator accepts the following parameters in set_integrator method of the ode class:
- atol : float or sequence absolute tolerance for solution
- rtol : float or sequence relative tolerance for solution
- lband : None or int
- uband : None or int Jacobian band width, \( jac[i,j] != 0 \) for \( i-lband <= j <= i+uband \). Setting these
requires your jac routine to return the jacobian in packed format, \( jac\_packed[i-j+uband, j] = jac[i,j] \).
The dimension of the matrix must be (lband+uband+1, len(y)).
- method: ‘adams’ or ‘bdf’ Which solver to use, Adams (non-stiff) or BDF (stiff)
- with_jacobian : bool This option is only considered when the user has not supplied a Jacobian function
and has not indicated (by setting either band) that the Jacobian is banded. In this case, with_jacobian
specifies whether the iteration method of the ODE solver’s correction step is chord iteration with an
internally generated full Jacobian or functional iteration with no Jacobian.
- nsteps : int Maximum number of (internally defined) steps allowed during one call to the solver.
- first_step : float
- min_step : float
• max_step : float Limits for the step sizes used by the integrator.
• order : int Maximum order used by the integrator, order <= 12 for Adams, <= 5 for BDF.

“zvode”

Complex-valued Variable-coefficient Ordinary Differential Equation solver, with fixed-leading-coefficient implementation. It provides implicit Adams method (for non-stiff problems) and a method based on backward differentiation formulas (BDF) (for stiff problems).

Source: http://www.netlib.org/ode/zvode.f

**Warning:** This integrator is not re-entrant. You cannot have two ode instances using the “zvode” integrator at the same time.

This integrator accepts the same parameters in set_integrator as the “vode” solver.

**Note:** When using ZVODE for a stiff system, it should only be used for the case in which the function f is analytic, that is, when each f(i) is an analytic function of each y(j). Analyticity means that the partial derivative df(i)/dy(j) is a unique complex number, and this fact is critical in the way ZVODE solves the dense or banded linear systems that arise in the stiff case. For a complex stiff ODE system in which f is not analytic, ZVODE is likely to have convergence failures, and for this problem one should instead use DVODE on the equivalent real system (in the real and imaginary parts of y).

“lsoda”

Real-valued Variable-coefficient Ordinary Differential Equation solver, with fixed-leading-coefficient implementation. It provides automatic method switching between implicit Adams method (for non-stiff problems) and a method based on backward differentiation formulas (BDF) (for stiff problems).

Source: http://www.netlib.org/odepack

**Warning:** This integrator is not re-entrant. You cannot have two ode instances using the “lsoda” integrator at the same time.

This integrator accepts the following parameters in set_integrator method of the ode class:

• atol : float or sequence absolute tolerance for solution
• rtol : float or sequence relative tolerance for solution
• lband : None or int
• uband : None or int Jacobian band width, jac[i,j] != 0 for i-lband <= j <= i+uband. Setting these requires your jac routine to return the jacobian in packed format, jac_packed[i-j+uband, j] = jac[i,j].
• with_jacobian : bool Not used.
• nsteps : int Maximum number of (internally defined) steps allowed during one call to the solver.
• first_step : float
• min_step : float
• max_step : float Limits for the step sizes used by the integrator.
• max_order_ns : int Maximum order used in the nonstiff case (default 12).
• max_order_s : int Maximum order used in the stiff case (default 5).
• max_hnil : int Maximum number of messages reporting too small step size (t + h = t) (default 0)
• ixpr : int Whether to generate extra printing at method switches (default False).

“dopri5”

This is an explicit runge-kutta method of order (4)5 due to Dormand & Prince (with stepsize control and dense output).

Authors:
E. Hairer and G. Wanner Universite de Geneve, Dept. de Mathematiques CH-1211 Geneve 24, Switzerland e-mail: ernst.hairer@math.unige.ch, gerhard.wanner@math.unige.ch

3.3. API definition
This code is described in [HNW93].

This integrator accepts the following parameters in set_integrator() method of the ode class:

- **atol**: float or sequence absolute tolerance for solution
- **rtol**: float or sequence relative tolerance for solution
- **nsteps**: int Maximum number of (internally defined) steps allowed during one call to the solver.
- **first_step**: float
- **max_step**: float
- **safety**: float Safety factor on new step selection (default 0.9)
- **ifactor**: float
- **dfactor**: float Maximum factor to increase/decrease step size by in one step
- **beta**: float Beta parameter for stabilised step size control.
- **verbosity**: int Switch for printing messages (< 0 for no messages).

“dop853”

This is an explicit runge-kutta method of order 8(5,3) due to Dormand & Prince (with stepsize control and dense output).

Options and references the same as “dopri5”.

**References**

[HNW93]

**Examples**

A problem to integrate and the corresponding jacobian:

```python
>>> from scipy.integrate import ode
>>> y0, t0 = [1.0j, 2.0], 0
>>> def f(t, y, arg1):
...     return [1j*arg1*y[0] + y[1], -arg1*y[1]**2]
>>> def jac(t, y, arg1):
...     return [[1j*arg1, 1], [0, -arg1*2*y[1]]]
```

The integration:

```python
>>> r = ode(f, jac).set_integrator('zvode', method='bdf')
>>> r.set_initial_value(y0, t0).set_f_params(2.0).set_jac_params(2.0)
>>> t1 = 10
>>> dt = 1
>>> while r.successful() and r.t < t1:
...     print(r.t+dt, r.integrate(r.t+dt))

Attributes

- **t** [float] Current time.
- **y** [ndarray] Current variable values.

Methods

- `get_return_code()` Extracts the return code for the integration to enable better control if the integration fails.
- `integrate(t[, step, relax])` Find $y = y(t)$, set $y$ as an initial condition, and return $y$.
- `set_f_params(*args)` Set extra parameters for user-supplied function $f$.
- `set_initial_value(y[, t])` Set initial conditions $y(t) = y$.
- `set_integrator(name, **integrator_params)` Set integrator by name.
- `set_jac_params(*args)` Set extra parameters for user-supplied function $jac$.
- `set_solout(solout)` Set callable to be called at every successful integration step.
- `successful()` Check if integration was successful.

`scipy.integrate.ode.get_return_code`

`ode.get_return_code()`

Extracts the return code for the integration to enable better control if the integration fails.

In general, a return code $> 0$ implies success, while a return code $< 0$ implies failure.

Notes

This section describes possible return codes and their meaning, for available integrators that can be selected by `set_integrator` method.

scipy.integrate.ode.integrate

ode.integrate(t, step=False, relax=False)
Find y=y(t), set y as an initial condition, and return y.

Parameters
- t [float] The endpoint of the integration step.
- step [bool] If True, and if the integrator supports the step method, then perform a single integration step and return. This parameter is provided in order to expose internals of the implementation, and should not be changed from its default value in most cases.
- relax [bool] If True and if the integrator supports the run_relax method, then integrate until t_1 >= t and return. relax is not referenced if step=True. This parameter is provided in order to expose internals of the implementation, and should not be changed from its default value in most cases.

Returns
- y [float] The integrated value at t

scipy.integrate.ode.set_f_params

ode.set_f_params(*args)
Set extra parameters for user-supplied function f.

scipy.integrate.ode.set_initial_value

ode.set_initial_value(y, t=0.0)
Set initial conditions y(t) = y.

scipy.integrate.ode.set_integrator

ode.set_integrator(name, **integrator_params)
Set integrator by name.

Parameters
- name [str] Name of the integrator.
- integrator_params Additional parameters for the integrator.

scipy.integrate.ode.set_jac_params

ode.set_jac_params(*args)
Set extra parameters for user-supplied function jac.
scipy.integrate.ode.set_solout

ode.set_solout(solout)
Set callable to be called at every successful integration step.

Parameters
solout  [callable] solout(t, y) is called at each internal integrator step, t is a scalar providing the current independent position y is the current solution y.shape == (n,)
solout should return -1 to stop integration otherwise it should return None or 0

scipy.integrate.ode.successful

ode.successful()
Check if integration was successful.

scipy.integrate.complex_ode

class scipy.integrate.complex_ode(f, jac=None)
A wrapper of ode for complex systems.

This functions similarly as ode, but re-maps a complex-valued equation system to a real-valued one before using the integrators.

Parameters
f    [callable f(t, y, *f_args)] Rhs of the equation. t is a scalar, y.shape == (n,).
f_args is set by calling set_f_params(*args).

jac  [callable jac(t, y, *jac_args)] Jacobian of the rhs, jac[i,j] = d f[i] / d y[j]. jac_args is set by calling set_f_params(*args).

Examples
For usage examples, see ode.

Attributes
    t    [float] Current time.
    y    [ndarray] Current variable values.

Methods

get_return_code()  Extracts the return code for the integration to enable better control if the integration fails.
integrate(t, step, relax)  Find y=y(t), set y as an initial condition, and return y.
set_f_params(*args)  Set extra parameters for user-supplied function f.
set_initial_value(y[, t])  Set initial conditions y(t) = y.
set_integrator(name, **integrator_params)  Set integrator by name.
set_jac_params(*args)  Set extra parameters for user-supplied function jac.
set_solout(solout)  Set callable to be called at every successful integration step.

continues on next page
successful()  
Check if integration was successful.

**scipy.integrate.complex_ode.get_return_code**

complex_ode.get_return_code()  
Extracts the return code for the integration to enable better control if the integration fails.

In general, a return code > 0 implies success, while a return code < 0 implies failure.

**Notes**

This section describes possible return codes and their meaning, for available integrators that can be selected by `set_integrator` method.

**scipy.integrate.complex_ode.integrate**

`complex_ode.integrate(t, step=False, relax=False)`

Find y=y(t), set y as an initial condition, and return y.

**Parameters**

- `t` [float] The endpoint of the integration step.
- `step` [bool] If True, and if the integrator supports the step method, then perform a single integration step and return. This parameter is provided in order to expose internals of the implementation, and should not be changed from its default value in most cases.
- `relax` [bool] If True and if the integrator supports the run_relax method, then integrate until t_1 >= t and return. relax is not referenced if step=True. This parameter is provided in order to expose internals of the implementation, and should not be changed from its default value in most cases.

**Returns**

- `y` [float] The integrated value at t
**scipy.integrate.complex_ode.set_f_params**

```python
complex_ode.set_f_params(*args)
```
Set extra parameters for user-supplied function $f$.

**scipy.integrate.complex_ode.set_initial_value**

```python
complex_ode.set_initial_value(y, t=0.0)
```
Set initial conditions $y(t) = y$.

**scipy.integrate.complex_ode.set_integrator**

```python
complex_ode.set_integrator(name, **integrator_params)
```
Set integrator by name.

**Parameters**
- `name` : [str] Name of the integrator
- `integrator_params` : Additional parameters for the integrator.

**scipy.integrate.complex_ode.set_jac_params**

```python
complex_ode.set_jac_params(*args)
```
Set extra parameters for user-supplied function $jac$.

**scipy.integrate.complex_ode.set_solout**

```python
complex_ode.set_solout(solout)
```
Set callable to be called at every successful integration step.

**Parameters**
- `solout` : [callable] $solout(t, y)$ is called at each internal integrator step, $t$ is a scalar providing the current independent position $y$ is the current solution $y.shape == (n,)$. $solout$ should return -1 to stop integration otherwise it should return None or 0.

**scipy.integrate.complex_ode.successful**

```python
complex_ode.successful()
```
Check if integration was successful.
Solving boundary value problems for ODE systems

```
solve_bvp(fun, bc, x, y[, p, S, fun_jac, ...])
```

Solve a boundary value problem for a system of ODEs.

### scipy.integrate.solve_bvp

This function numerically solves a first order system of ODEs subject to two-point boundary conditions:

\[
\frac{dy}{dx} = f(x, y, p) + S \cdot y / (x - a), \quad a \leq x \leq b
\]

\[
bc(y(a), y(b), p) = 0
\]

Here \(x\) is a 1-D independent variable, \(y(x)\) is an N-D vector-valued function and \(p\) is a k-D vector of unknown parameters which is to be found along with \(y(x)\). For the problem to be determined, there must be \(n + k\) boundary conditions, i.e., \(bc\) must be an \((n + k)\)-D function.

The last singular term on the right-hand side of the system is optional. It is defined by an \(n\)-by-\(n\) matrix \(S\), such that the solution must satisfy \(S \cdot y(a) = 0\). This condition will be forced during iterations, so it must not contradict boundary conditions. See [2] for the explanation how this term is handled when solving BVPs numerically.

Problems in a complex domain can be solved as well. In this case, \(y\) and \(p\) are considered to be complex, and \(f\) and \(bc\) are assumed to be complex-valued functions, but \(x\) stays real. Note that \(f\) and \(bc\) must be complex differentiable (satisfy Cauchy-Riemann equations [4]), otherwise you should rewrite your problem for real and imaginary parts separately. To solve a problem in a complex domain, pass an initial guess for \(y\) with a complex data type (see below).

### Parameters

- **fun**
  - [callable] Right-hand side of the system. The calling signature is \(f(x, y, p)\) if parameters are present. All arguments are ndarray: \(x\) with shape \((m,)\), \(y\) with shape \((n, m)\), meaning that \(y[:, i]\) corresponds to \(x[i]\), and \(p\) with shape \((k,)\). The return value must be an array with shape \((n, m)\) and with the same layout as \(y\).

- **bc**
  - [callable] Function evaluating residuals of the boundary conditions. The calling signature is \(bc(y(a), y(b), p)\) if parameters are present. All arguments are ndarray: \(ya\) and \(yb\) with shape \((n,)\), and \(p\) with shape \((k,)\). The return value must be an array with shape \((n + k,)\).

- **x**
  - [array_like, shape \((m,)\)] Initial mesh. Must be a strictly increasing sequence of real numbers with \(x[0] = a\) and \(x[-1] = b\).

- **y**
  - [array_like, shape \((n, m)\)] Initial guess for the function values at the mesh nodes, ith column corresponds to \(x[i]\). For problems in a complex domain pass \(y\) with a complex data type (even if the initial guess is purely real).

- **p**
  - [array_like with shape \((k,)\) or None, optional] Initial guess for the unknown parameters. If None (default), it is assumed that the problem doesn’t depend on any parameters.

- **S**
  - [array_like with shape \((n, n)\) or None] Matrix defining the singular term. If None (default), the problem is solved without the singular term.

- **fun_jac**
  - [callable or None, optional] Function computing derivatives of \(f\) with respect to \(y\) and \(p\). The calling signature is \(f_{jac}(x, y, p)\) if parameters are present. The return must contain 1 or 2 elements in the following order:
    * \(df_{dy} : array\_like\ with\ shape\ (n, n, m)\), where an element \((i, j, q)\) equals to \(df_i(x, q, y, p) / df_j(y, q, p)\).
    * \(df_{dp} : array\_like\ with\ shape\ (n, k, m)\), where an element \((i, j, q)\) equals to \(df_i(x, q, y, p) / dp_j\).
Here q numbers nodes at which x and y are defined, whereas i and j number vector components. If the problem is solved without unknown parameters, df_dp should not be returned.

If fun_jac is None (default), the derivatives will be estimated by the forward finite differences.

bc_jac
[callable or None, optional] Function computing derivatives of bc with respect to ya, yb, and p. The calling signature is bc_jac(ya, yb), or bc_jac(ya, yb, p) if parameters are present. The return must contain 2 or 3 elements in the following order:
• dbc_dya : array_like with shape (n, n), where an element (i, j) equals to d bc_i(ya, yb, p) / d ya_j.
• dbc_dyb : array_like with shape (n, n), where an element (i, j) equals to d bc_i(ya, yb, p) / d yb_j.
• dbc_dp: array_like with shape (n, k), where an element (i, j) equals to d bc_i(ya, yb, p) / d p_j.
If the problem is solved without unknown parameters, dbc_dp should not be returned.

If bc_jac is None (default), the derivatives will be estimated by the forward finite differences.

tol
[float, optional] Desired tolerance of the solution. If we define $r = y' - f(x, y)$, where y is the found solution, then the solver tries to achieve on each mesh interval $\text{norm}(r / (1 + abs(f)) < tol$, where norm is estimated in a root mean squared sense (using a numerical quadrature formula). Default is 1e-3.

max_nodes
[int, optional] Maximum allowed number of the mesh nodes. If exceeded, the algorithm terminates. Default is 1000.

verbose
[0, 1, 2], optional] Level of algorithm’s verbosity:
• 0 (default): work silently.
• 1: display a termination report.
• 2: display progress during iterations.

bc_tol
[float, optional] Desired absolute tolerance for the boundary condition residuals: bc value should satisfy $\text{abs(bc)} < bc_tol$ component-wise. Equals to tol by default. Up to 10 iterations are allowed to achieve this tolerance.

Returns
Bunch object with the following fields defined:
sol
[PPoly] Found solution for y as scipy.interpolate.PPoly instance, a C1 continuous cubic spline.

p
[ndarray or None, shape (k,)] Found parameters. None, if the parameters were not present in the problem.

x
[ndarray, shape (m,)] Nodes of the final mesh.

y
[ndarray, shape (n, m)] Solution values at the mesh nodes.

yp
[ndarray, shape (n, m)] Solution derivatives at the mesh nodes.

rms_residuals
[ndarray, shape (m - 1,)] RMS values of the relative residuals over each mesh interval (see the description of tol parameter).

niter
[int] Number of completed iterations.

status
[int] Reason for algorithm termination:
• 0: The algorithm converged to the desired accuracy.
• 1: The maximum number of mesh nodes is exceeded.
• 2: A singular Jacobian encountered when solving the collocation system.

message
[string] Verbal description of the termination reason.

success
[bool] True if the algorithm converged to the desired accuracy (status=0).
Notes

This function implements a 4th order collocation algorithm with the control of residuals similar to [1]. A collocation system is solved by a damped Newton method with an affine-invariant criterion function as described in [3].

Note that in [1] integral residuals are defined without normalization by interval lengths. So, their definition is different by a multiplier of h**0.5 (h is an interval length) from the definition used here.

New in version 0.18.0.

References

[1], [2], [3], [4]

Examples

In the first example, we solve Bratu's problem:

\[
\begin{align*}
    y'' + k \cdot \exp(y) &= 0 \\
    y(0) &= y(1) = 0 
\end{align*}
\]

for k = 1.

We rewrite the equation as a first-order system and implement its right-hand side evaluation:

\[
\begin{align*}
    y_1' &= y_2 \\
    y_2' &= -\exp(y_1) 
\end{align*}
\]

```python
>>> def fun(x, y):
...     return np.vstack((y[1], -np.exp(y[0])))
```

Implement evaluation of the boundary condition residuals:

```python
>>> def bc(ya, yb):
...     return np.array([ya[0], yb[0]])
```

Define the initial mesh with 5 nodes:

```python
>>> x = np.linspace(0, 1, 5)
```

This problem is known to have two solutions. To obtain both of them, we use two different initial guesses for y. We denote them by subscripts a and b.

```python
>>> y_a = np.zeros((2, x.size))
>>> y_b = np.zeros((2, x.size))
>>> y_b[0] = 3
```

Now we are ready to run the solver.

```python
>>> from scipy.integrate import solve_bvp
>>> res_a = solve_bvp(fun, bc, x, y_a)
>>> res_b = solve_bvp(fun, bc, x, y_b)
```

Let's plot the two found solutions. We take an advantage of having the solution in a spline form to produce a smooth plot.
We see that the two solutions have similar shape, but differ in scale significantly.

In the second example, we solve a simple Sturm-Liouville problem:

\[ y'' + k^2 y = 0 \]
\[ y(0) = y(1) = 0 \]

It is known that a non-trivial solution \( y = A \sin(k \cdot x) \) is possible for \( k = \pi \cdot n \), where \( n \) is an integer. To establish the normalization constant \( A = 1 \) we add a boundary condition:

\[ y'(0) = k \]

Again, we rewrite our equation as a first-order system and implement its right-hand side evaluation:

\[ y_1' = y_2 \]
\[ y_2' = -k^2 \cdot y_1 \]

```python
>>> def fun(x, y, p):
...     k = p[0]
...     return np.vstack((y[1], -k**2 * y[0]))
```

Note that parameters \( p \) are passed as a vector (with one element in our case).
Implement the boundary conditions:
```python
>>> def bc(ya, yb, p):
...     k = p[0]
...     return np.array([ya[0], yb[0], ya[1] - k])
```

Set up the initial mesh and guess for $y$. We aim to find the solution for $k = 2 \pi$, to achieve that we set values of $y$ to approximately follow $\sin(2 \pi x)$:

```python
>>> x = np.linspace(0, 1, 5)
>>> y = np.zeros((2, x.size))
>>> y[0, 1] = 1
>>> y[0, 3] = -1
```

Run the solver with 6 as an initial guess for $k$.

```python
>>> sol = solve_bvp(fun, bc, x, y, p=[6])
```

We see that the found $k$ is approximately correct:

```python
>>> sol.p[0]
6.28329460046
```

And, finally, plot the solution to see the anticipated sinusoid:

```python
>>> x_plot = np.linspace(0, 1, 100)
>>> y_plot = sol.sol(x_plot)[0]
>>> plt.plot(x_plot, y_plot)
>>> plt.xlabel("x")
>>> plt.ylabel("y")
>>> plt.show()
```
3.3.8 Interpolation (scipy.interpolate)

Sub-package for objects used in interpolation.

As listed below, this sub-package contains spline functions and classes, 1-D and multidimensional (univariate and multi-variate) interpolation classes, Lagrange and Taylor polynomial interpolators, and wrappers for FITPACK and DFITPACK functions.

Univariate interpolation

- **interp1d**
  - **BarycentricInterpolator**(xi[, yi, axis])
  - **KroghInterpolator**(xi, yi[, axis])
  - **barycentric_interpolate**(xi, yi, x[, axis])
  - **krogh_interpolate**(xi, yi, x[, der, axis])
  - **pchip_interpolate**(xi, yi, x[, der, axis])
  - **CubicHermiteSpline**(x, y, dydx[, axis,...])
  - **PchipInterpolator**(x, y[, axis, extrapolate])
  - **Akima1DInterpolator**(x, y[, axis])
  - **CubicSpline**(x, y[, axis,bc_type,extrapolate])
  - **PPoly**(c,x[, extrapolate, axis])
  - **BPoly**(c,x[, extrapolate, axis])

**scipy.interpolate.interp1d**

```
class scipy.interpolate.interp1d(x, y[, kind, axis, copy, ...])
```

Interpolate a 1-D function.

Parameters:
- **x**
- **y**
  - [(…,N,…) array_like] A N-D array of real values. The length of y along the interpolation axis must be equal to the length of x.
- **kind**
  - [str or int, optional] Specifies the kind of interpolation as a string or as an integer specifying the order of the spline interpolator to use. The string has to be one of 'linear', 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'previous', or 'next'. 'zero', 'slinear', 'quadratic' and 'cubic' refer to a spline interpolation of zeroth, first, second or third order; 'previous' and 'next' simply return the previous or next value of the point; 'nearest-up' and 'nearest' differ when interpolating half-integers (e.g. 0.5, 1.5) in that 'nearest-up' rounds up and 'nearest' rounds down. Default is 'linear'.
- **axis**
  - [int, optional] Specifies the axis of y along which to interpolate. Interpolation defaults to the last axis of y.
- **copy**
  - [bool, optional] If True, the class makes internal copies of x and y. If False, references to x and y are used. The default is to copy.
- **bounds_error**
  - [bool, optional] If True, a ValueError is raised any time extrapolation is attempted on a value outside of the range of x (where extrapolation is necessary). If False, out
of bounds values are assigned `fill_value`. By default, an error is raised unless `fill_value="extrapolate"`.

**fill_value**  
[array-like or (array-like, array_like) or “extrapolate”, optional]

- If a ndarray (or float), this value will be used to fill in for requested points outside of the data range. If not provided, then the default is NaN. The array-like must broadcast properly to the dimensions of the non-interpolation axes.
- If a two-element tuple, then the first element is used as a fill value for \(x_{\text{new}} < x[0]\) and the second element is used for \(x_{\text{new}} > x[-1]\). Anything that is not a 2-element tuple (e.g., list or ndarray, regardless of shape) is taken to be a single array-like argument meant to be used for both bounds as below, `above = fill_value, fill_value`. Using a two-element tuple or ndarray requires `bounds_error=False`. New in version 0.17.0.
- If “extrapolate”, then points outside the data range will be extrapolated.
  New in version 0.17.0.

**assume_sorted**  
[bool, optional] If False, values of \(x\) can be in any order and they are sorted first. If True, \(x\) has to be an array of monotonically increasing values.

See also:

- `splrep`, `splev`  
  Spline interpolation/smoothing based on FITPACK.

**UnivariateSpline**  
An object-oriented wrapper of the FITPACK routines.

**interp2d**  
2-D interpolation

Notes

Calling `interp1d` with NaNs present in input values results in undefined behaviour.

Input values \(x\) and \(y\) must be convertible to float values like `int` or `float`.

If the values in \(x\) are not unique, the resulting behavior is undefined and specific to the choice of `kind`, i.e., changing `kind` will change the behavior for duplicates.

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy import interpolate
>>> x = np.arange(0, 10)
>>> y = np.exp(-x/3.0)
>>> f = interpolate.interp1d(x, y)

>>> xnew = np.arange(0, 9, 0.1)
>>> ynew = f(xnew)  # use interpolation function returned by `interp1d`
>>> plt.plot(x, y, 'o', xnew, ynew, '-')
>>> plt.show()
```

Attributes
fill_value

The fill value.

Methods

__call__(x) Evaluate the interpolant

scipy.interpolate.interp1d.__call__

interp1d.__call__(x)
Evaluate the interpolant

Parameters

x [array_like] Points to evaluate the interpolant at.

Returns

y [array_like] Interpolated values. Shape is determined by replacing the interpolation axis in the original array with the shape of x.

Notes

Input values x must be convertible to float values like int or float.
class `scipy.interpolate.BarycentricInterpolator`(xi, yi=None, axis=0)

The interpolating polynomial for a set of points

Constructs a polynomial that passes through a given set of points. Allows evaluation of the polynomial, efficient changing of the y values to be interpolated, and updating by adding more x values. For reasons of numerical stability, this function does not compute the coefficients of the polynomial.

The values yi need to be provided before the function is evaluated, but none of the preprocessing depends on them, so rapid updates are possible.

**Parameters**

- **xi**: 1-D array of x coordinates of the points the polynomial should pass through
- **yi**: [array_like, optional] The y coordinates of the points the polynomial should pass through. If None, the y values will be supplied later via the `set_yi` method.
- **axis**: [int, optional] Axis in the yi array corresponding to the x-coordinate values.

**Notes**

This class uses a “barycentric interpolation” method that treats the problem as a special case of rational function interpolation. This algorithm is quite stable, numerically, but even in a world of exact computation, unless the x coordinates are chosen very carefully - Chebyshev zeros (e.g., \(\cos(i\pi/n)\)) are a good choice - polynomial interpolation itself is a very ill-conditioned process due to the Runge phenomenon.

Based on Berrut and Trefethen 2004, “Barycentric Lagrange Interpolation”.

**Attributes**

- **dtype**

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>call</strong>(x)</td>
<td>Evaluate the interpolating polynomial at the points x</td>
</tr>
<tr>
<td>add_xi(xi[, yi])</td>
<td>Add more x values to the set to be interpolated</td>
</tr>
<tr>
<td>set_yi(yi[, axis])</td>
<td>Update the y values to be interpolated</td>
</tr>
</tbody>
</table>

**scipy.interpolate.BarycentricInterpolator.__call__**

Evaluate the interpolating polynomial at the points x

**Parameters**

- **x**: [array_like] Points to evaluate the interpolant at.

**Returns**

- **y**: [array_like] Interpolated values. Shape is determined by replacing the interpolation axis in the original array with the shape of x.
Notes

Currently the code computes an outer product between x and the weights, that is, it constructs an intermediate array of size N by len(x), where N is the degree of the polynomial.

**scipy.interpolate.BarycentricInterpolator.add_xi**

BarycentricInterpolator.add_xi(xi, yi=None)

Add more x values to the set to be interpolated

The barycentric interpolation algorithm allows easy updating by adding more points for the polynomial to pass through.

**Parameters**

- **xi**
  - [array_like] The x coordinates of the points that the polynomial should pass through.
- **yi**
  - [array_like, optional] The y coordinates of the points the polynomial should pass through. Should have shape (xi.size, R); if R > 1 then the polynomial is vector-valued. If yi is not given, the y values will be supplied later. yi should be given if and only if the interpolator has y values specified.

**scipy.interpolate.BarycentricInterpolator.set_yi**

BarycentricInterpolator.set_yi(yi, axis=None)

Update the y values to be interpolated

The barycentric interpolation algorithm requires the calculation of weights, but these depend only on the xi. The yi can be changed at any time.

**Parameters**

- **yi**
  - [array_like] The y coordinates of the points the polynomial should pass through. If None, the y values will be supplied later.
- **axis**
  - [int, optional] Axis in the yi array corresponding to the x-coordinate values.

**scipy.interpolate.KroghInterpolator**

class scipy.interpolate.KroghInterpolator(xi, yi, axis=0)

Interpolating polynomial for a set of points.

The polynomial passes through all the pairs (xi,yi). One may additionally specify a number of derivatives at each point xi; this is done by repeating the value xi and specifying the derivatives as successive yi values.

Allows evaluation of the polynomial and all its derivatives. For reasons of numerical stability, this function does not compute the coefficients of the polynomial, although they can be obtained by evaluating all the derivatives.

**Parameters**

- **xi**
  - [array_like, length N] Known x-coordinates. Must be sorted in increasing order.
- **yi**
  - [array_like] Known y-coordinates. When an xi occurs two or more times in a row, the corresponding yi's represent derivative values.
- **axis**
  - [int, optional] Axis in the yi array corresponding to the x-coordinate values.
Notes

Be aware that the algorithms implemented here are not necessarily the most numerically stable known. Moreover, even in a world of exact computation, unless the x coordinates are chosen very carefully - Chebyshev zeros (e.g., \(\cos(i*\pi/n)\)) are a good choice - polynomial interpolation itself is a very ill-conditioned process due to the Runge phenomenon. In general, even with well-chosen x values, degrees higher than about thirty cause problems with numerical instability in this code.

Based on [1].

References

[1]

Examples

To produce a polynomial that is zero at 0 and 1 and has derivative 2 at 0, call

```python
>>> from scipy.interpolate import KroghInterpolator
>>> KroghInterpolator([0,0,1],[0,2,0])
```

This constructs the quadratic \(2*X^2-2*X\). The derivative condition is indicated by the repeated zero in the xi array; the corresponding yi values are 0, the function value, and 2, the derivative value.

For another example, given xi, yi, and a derivative ypi for each point, appropriate arrays can be constructed as:

```python
>>> rng = np.random.default_rng()
>>> xi = np.linspace(0, 1, 5)
>>> yi, ypi = rng.random((2, 5))
>>> xi_k, yi_k = np.repeat(xi, 2), np.ravel(np.dstack((yi,ypi)))
>>> KroghInterpolator(xi_k, yi_k)
```

To produce a vector-valued polynomial, supply a higher-dimensional array for yi:

```python
>>> KroghInterpolator([0,1],[[2,3],[4,5]])
```

This constructs a linear polynomial giving (2,3) at 0 and (4,5) at 1.

</tbody>
</table>
scipy.interpolate.KroghInterpolator.__call__

KroghInterpolator.__call__ (x)
Evaluate the interpolant

Parameters
x [array_like] Points to evaluate the interpolant at.

Returns
y [array_like] Interpolated values. Shape is determined by replacing the interpolation axis in the original array with the shape of x.

Notes
Input values x must be convertible to float values like int or float.

scipy.interpolate.KroghInterpolator.derivative

KroghInterpolator.derivative (x, der=1)
Evaluate one derivative of the polynomial at the point x

Parameters
x [array_like] Point or points at which to evaluate the derivatives

der [integer, optional] Which derivative to extract. This number includes the function value as 0th derivative.

Returns
d [ndarray] Derivative interpolated at the x-points. Shape of d is determined by replacing the interpolation axis in the original array with the shape of x.

Notes
This is computed by evaluating all derivatives up to the desired one (using self.derivatives()) and then discarding the rest.

scipy.interpolate.KroghInterpolator.derivatives

KroghInterpolator.derivatives (x, der=None)
Evaluate many derivatives of the polynomial at the point x

Parameters
x [array_like] Point or points at which to evaluate the derivatives

der [int or None, optional] How many derivatives to extract; None for all potentially nonzero derivatives (that is a number equal to the number of points). This number includes the function value as 0th derivative.

Returns

d  [ndarray] Array with derivatives; d[j] contains the jth derivative. Shape of d[j] is determined by replacing the interpolation axis in the original array with the shape of x.

Examples

```python
>>> from scipy.interpolate import KroghInterpolator
>>> KroghInterpolator([0,0,0],[1,2,3]).derivatives(0)
array([1.0,2.0,3.0])
>>> KroghInterpolator([0,0,0],[1,2,3]).derivatives([0,0])
array([[1.0,1.0],
       [2.0,2.0],
       [3.0,3.0]])
```

scipy.interpolate.barycentric_interpolate

```python
scipy.interpolate.barycentric_interpolate(xi, yi, x, axis=0)
```

Convenience function for polynomial interpolation.

Constructs a polynomial that passes through a given set of points, then evaluates the polynomial. For reasons of numerical stability, this function does not compute the coefficients of the polynomial.

This function uses a “barycentric interpolation” method that treats the problem as a special case of rational function interpolation. This algorithm is quite stable, numerically, but even in a world of exact computation, unless the x coordinates are chosen very carefully - Chebyshev zeros (e.g., cos(i*pi/n)) are a good choice - polynomial interpolation itself is a very ill-conditioned process due to the Runge phenomenon.

**Parameters**

- **xi**  
  [array_like] 1-D array of x coordinates of the points the polynomial should pass through.

- **yi**  
  [array_like] The y coordinates of the points the polynomial should pass through.

- **x**  
  [scalar or array_like] Points to evaluate the interpolator at.

- **axis**  
  [int, optional] Axis in the yi array corresponding to the x-coordinate values.

**Returns**

- **y**  
  [scalar or array_like] Interpolated values. Shape is determined by replacing the interpolation axis in the original array with the shape of x.

See also:

BarycentricInterpolator

Bary centric interpolator

**Notes**

Construction of the interpolation weights is a relatively slow process. If you want to call this many times with the same xi (but possibly varying yi or x) you should use the class BarycentricInterpolator. This is what this function uses internally.
Examples

We can interpolate 2D observed data using barycentric interpolation:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.interpolate import barycentric_interpolate
>>> x_observed = np.linspace(0.0, 10.0, 11)
>>> y_observed = np.sin(x_observed)
>>> x = np.linspace(min(x_observed), max(x_observed), num=100)
>>> y = barycentric_interpolate(x_observed, y_observed, x)
>>> plt.plot(x_observed, y_observed, 'o', label='observation')
>>> plt.plot(x, y, label='barycentric interpolation')
>>> plt.legend()
>>> plt.show()
```

```python
scipy.interpolate.krogh_interpolate
```

Convenience function for polynomial interpolation.

See *KroghInterpolator* for more details.

**Parameters**

- **xi**
  - [array_like] Known x-coordinates.

- **yi**
  - [array_like] Known y-coordinates, of shape (xi.size, R). Interpreted as vectors of length R, or scalars if R=1.

- **x**
  - [array_like] Point or points at which to evaluate the derivatives.

- **der**
  - [int or list, optional] How many derivatives to extract; None for all potentially nonzero derivatives (that is a number equal to the number of points), or a list of derivatives to extract. This number includes the function value as 0th derivative.

- **axis**
  - [int, optional] Axis in the yi array corresponding to the x-coordinate values.

**Returns**

- **d**
  - [ndarray] If the interpolator's values are R-D then the returned array will be the number of derivatives by N by R. If x is a scalar, the middle dimension will be dropped; if the yi are
scalars then the last dimension will be dropped.

See also:

**KroghInterpolator**

Krogh interpolator

Notes

Construction of the interpolating polynomial is a relatively expensive process. If you want to evaluate it repeatedly consider using the class KroghInterpolator (which is what this function uses).

Examples

We can interpolate 2D observed data using krogh interpolation:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.interpolate import krogh_interpolate
>>> x_observed = np.linspace(0.0, 10.0, 11)
>>> y_observed = np.sin(x_observed)
>>> x = np.linspace(min(x_observed), max(x_observed), num=100)
>>> y = krogh_interpolate(x_observed, y_observed, x)
>>> plt.plot(x_observed, y_observed, "o", label="observation")
>>> plt.plot(x, y, label="krogh interpolation")
>>> plt.legend()
>>> plt.show()
```

![Plot showing observed data and krogh interpolation](image_url)
scipy.interpolate.pchip_interpolate

`scipy.interpolate.pchip_interpolate(xi, yi, x, der=0, axis=0)`

Convenience function for pchip interpolation.

xi and yi are arrays of values used to approximate some function f, with \( yi = f(xi) \). The interpolant uses monotonic cubic splines to find the value of new points x and the derivatives there.

See `scipy.interpolate.PchipInterpolator` for details.

**Parameters**

- `xi` [array_like] A sorted list of x-coordinates, of length N.
- `yi` [array_like] A 1-D array of real values. yi’s length along the interpolation axis must be equal to the length of xi. If N-D array, use axis parameter to select correct axis.
- `x` [scalar or array_like] Of length M.
- `der` [int or list, optional] Derivatives to extract. The 0th derivative can be included to return the function value.
- `axis` [int, optional] Axis in the yi array corresponding to the x-coordinate values.

**Returns**

- `y` [scalar or array_like] The result, of length R or length M or M by R.

See also:

- `PchipInterpolator`
  
PCHIP 1-D monotonic cubic interpolator.

**Examples**

We can interpolate 2D observed data using pchip interpolation:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.interpolate import pchip_interpolate
>>> x_observed = np.linspace(0.0, 10.0, 11)
>>> y_observed = np.sin(x_observed)
>>> x = np.linspace(min(x_observed), max(x_observed), num=100)
>>> y = pchip_interpolate(x_observed, y_observed, x)
>>> plt.plot(x_observed, y_observed, "o", label="observation")
>>> plt.plot(x, y, label="pchip interpolation")
>>> plt.legend()
>>> plt.show()
```

scipy.interpolate.CubicHermiteSpline

class `scipy.interpolate.CubicHermiteSpline(x, y, dydx, axis=0, extrapolate=None)`

Piecewise-cubic interpolator matching values and first derivatives.

The result is represented as a `PPoly` instance.

**Parameters**

- `x` [array_like, shape (n,)] 1-D array containing values of the independent variable. Values must be real, finite and in strictly increasing order.
- `y` [array_like] Array containing values of the dependent variable. It can have arbitrary number of dimensions, but the length along `axis` (see below) must match the length of `x`. Values must be finite.
[array_like] Array containing derivatives of the dependent variable. It can have arbitrary number of dimensions, but the length along axis (see below) must match the length of x. Values must be finite.

axis
[int, optional] Axis along which y is assumed to be varying. Meaning that for x[i] the corresponding values are np.take(y, i, axis=axis). Default is 0.

extrapolate
[bool, 'periodic', None], optional] If bool, determines whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs. If 'periodic', periodic extrapolation is used. If None (default), it is set to True.

See also:

Akima1DInterpolator
Akima 1D interpolator.

PchipInterpolator
PCHIP 1-D monotonic cubic interpolator.

CubicSpline
Cubic spline data interpolator.

PPoly
Piecewise polynomial in terms of coefficients and breakpoints
Notes

If you want to create a higher-order spline matching higher-order derivatives, use `BPoly.from_derivatives`.

References

[1]

Attributes

- **x** [ndarray, shape (n,)] Breakpoints. The same `x` which was passed to the constructor.
- **c** [ndarray, shape (4, n-1, ...)] Coefficients of the polynomials on each segment. The trailing dimensions match the dimensions of `y`, excluding `axis`. For example, if `y` is 1-D, then `c[k, i]` is a coefficient for \((x-x[i])^{(3-k)}\) on the segment between `x[i]` and `x[i+1]`.
- **axis** [int] Interpolation axis. The same axis which was passed to the constructor.

Methods

- **__call__(x, nu=0, extrapolate=None)** Evaluate the piecewise polynomial or its derivative.
- **derivative(nu)** Construct a new piecewise polynomial representing the derivative.
- **antiderivative(nu)** Construct a new piecewise polynomial representing the antiderivative.
- **integrate(a, b, extrapolate=None)** Compute a definite integral over a piecewise polynomial.
- **roots([discontinuity, extrapolate])** Find real roots of the the piecewise polynomial.

```python
scipy.interpolate.CubicHermiteSpline.__call__(x, nu=0, extrapolate=None)
```

Evaluate the piecewise polynomial or its derivative.

**Parameters**

- **x** [array_like] Points to evaluate the interpolant at.
- **nu** [int, optional] Order of derivative to evaluate. Must be non-negative.
- **extrapolate** [{bool, ‘periodic’, None}, optional] If bool, determines whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs. If ‘periodic’, periodic extrapolation is used. If None (default), use `self.extrapolate`.

**Returns**

- **y** [array_like] Interpolated values. Shape is determined by replacing the interpolation axis in the original array with the shape of `x`.
Notes

Derivatives are evaluated piecewise for each polynomial segment, even if the polynomial is not differentiable at the breakpoints. The polynomial intervals are considered half-open, $[a, b)$, except for the last interval which is closed $[a, b]$.

scipy.interpolate.CubicHermiteSpline.derivative

CubicHermiteSpline.derivative(nu=1)

Construct a new piecewise polynomial representing the derivative.

Parameters

<table>
<thead>
<tr>
<th>nu</th>
<th>[int, optional] Order of derivative to evaluate. Default is 1, i.e., compute the first derivative. If negative, the antiderivative is returned.</th>
</tr>
</thead>
</table>

Returns

<table>
<thead>
<tr>
<th>pp</th>
<th>[PPoly] Piecewise polynomial of order $k2 = k - n$ representing the derivative of this polynomial.</th>
</tr>
</thead>
</table>

Notes

Derivatives are evaluated piecewise for each polynomial segment, even if the polynomial is not differentiable at the breakpoints. The polynomial intervals are considered half-open, $[a, b)$, except for the last interval which is closed $[a, b]$.

scipy.interpolate.CubicHermiteSpline.antiderivative

CubicHermiteSpline.antiderivative(nu=1)

Construct a new piecewise polynomial representing the antiderivative.

Antiderivative is also the indefinite integral of the function, and derivative is its inverse operation.

Parameters

<table>
<thead>
<tr>
<th>nu</th>
<th>[int, optional] Order of antiderivative to evaluate. Default is 1, i.e., compute the first integral. If negative, the derivative is returned.</th>
</tr>
</thead>
</table>

Returns

<table>
<thead>
<tr>
<th>pp</th>
<th>[PPoly] Piecewise polynomial of order $k2 = k + n$ representing the antiderivative of this polynomial.</th>
</tr>
</thead>
</table>

Notes

The antiderivative returned by this function is continuous and continuously differentiable to order $n-1$, up to floating point rounding error.

If antiderivative is computed and self.extrapolate='periodic', it will be set to False for the returned instance. This is done because the antiderivative is no longer periodic and its correct evaluation outside of the initially given x interval is difficult.
**scipy.interpolate.CubicHermiteSpline.integrate**

CubicHermiteSpline.integrate\(a, b, \text{extrapolate}=\text{None}\)

Compute a definite integral over a piecewise polynomial.

- **Parameters**
  - \(a\) [float] Lower integration bound
  - \(b\) [float] Upper integration bound
  - \(\text{extrapolate}\) [[bool, ‘periodic’, None], optional] If bool, determines whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs. If ‘periodic’, periodic extrapolation is used. If None (default), use self.extrapolate.

- **Returns**
  - \(\text{ig}\) [array_like] Definite integral of the piecewise polynomial over \([a, b]\)

**scipy.interpolate.CubicHermiteSpline.roots**

CubicHermiteSpline.roots\(\text{discontinuity}=\text{True}, \text{extrapolate}=\text{None}\)

Find real roots of the piecewise polynomial.

- **Parameters**
  - \(\text{discontinuity}\) [bool, optional] Whether to report sign changes across discontinuities at breakpoints as roots.
  - \(\text{extrapolate}\) [[bool, ‘periodic’, None], optional] If bool, determines whether to return roots from the polynomial extrapolated based on first and last intervals, ‘periodic’ works the same as False. If None (default), use self.extrapolate.

- **Returns**
  - \(\text{roots}\) [ndarray] Roots of the polynomial(s).
  - If the PPoly object describes multiple polynomials, the return value is an object array whose each element is an ndarray containing the roots.

**See also:**

PPoly.solve

**scipy.interpolate.PchipInterpolator**

class scipy.interpolate.PchipInterpolator\(x, y, \text{axis}=0, \text{extrapolate}=\text{None}\)

PCHIP 1-D monotonic cubic interpolation.

\(x\) and \(y\) are arrays of values used to approximate some function \(f\), with \(y=f(x)\). The interpolant uses monotonic cubic splines to find the value of new points. (PCHIP stands for Piecewise Cubic Hermite Interpolating Polynomial).

- **Parameters**
  - \(x\) [ndarray] A 1-D array of monotonically increasing real values. \(x\) cannot include duplicate values (otherwise \(f\) is overspecified)
  - \(y\) [ndarray] A 1-D array of real values. \(y\)'s length along the interpolation axis must be equal to the length of \(x\). If N-D array, use axis parameter to select correct axis.
  - \(\text{axis}\) [int, optional] Axis in the \(y\) array corresponding to the \(x\)-coordinate values.
extrapolate

[bool, optional] Whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs.

See also:

CubicHermiteSpline

Piecewise-cubic interpolator.

Akima1DInterpolator

Akima 1D interpolator.

CubicSpline

Cubic spline data interpolator.

PPoly

Piecewise polynomial in terms of coefficients and breakpoints.

Notes

The interpolator preserves monotonicity in the interpolation data and does not overshoot if the data is not smooth. The first derivatives are guaranteed to be continuous, but the second derivatives may jump at \( x_k \).

Determines the derivatives at the points \( x_k, f_k' \), by using PCHIP algorithm [1].

Let \( h_k = x_{k+1} - x_k \), and \( d_k = (y_{k+1} - y_k)/h_k \) are the slopes at internal points \( x_k \). If the signs of \( d_k \) and \( d_{k-1} \) are different or either of them equals zero, then \( f_k' = 0 \). Otherwise, it is given by the weighted harmonic mean

\[
\frac{w_1 + w_2}{f_k'} = \frac{w_1}{d_{k-1}} + \frac{w_2}{d_k}
\]

where \( w_1 = 2h_k + h_{k-1} \) and \( w_2 = h_k + 2h_{k-1} \).

The end slopes are set using a one-sided scheme [2].

**scipy.interpolate.PchipInterpolator.__call__**

PchipInterpolator.__call__(x, nu=0, extrapolate=None)

Evaluate the piecewise polynomial or its derivative.

**Parameters**

- **x** [array_like] Points to evaluate the interpolant at.
- **nu** [int, optional] Order of derivative to evaluate. Must be non-negative.
- **extrapolate** [{bool, ‘periodic’, None}, optional] If bool, determines whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs. If ‘periodic’, periodic extrapolation is used. If None (default), use self.extrapolate.

**Returns**

- **y** [array_like] Interpolated values. Shape is determined by replacing the interpolation axis in the original array with the shape of x.

**Notes**

Derivatives are evaluated piecewise for each polynomial segment, even if the polynomial is not differentiable at the breakpoints. The polynomial intervals are considered half-open, \([a, b)\), except for the last interval which is closed \([a, b]\).

**scipy.interpolate.PchipInterpolator.derivative**

PchipInterpolator.derivative(nu=1)

Construct a new piecewise polynomial representing the derivative.

**Parameters**

- **nu** [int, optional] Order of derivative to evaluate. Default is 1, i.e., compute the first derivative. If negative, the antiderivative is returned.

**Returns**

- **pp** [PPoly] Piecewise polynomial of order \(k2 = k - n\) representing the derivative of this polynomial.
Notes

Derivatives are evaluated piecewise for each polynomial segment, even if the polynomial is not differentiable at the breakpoints. The polynomial intervals are considered half-open, \([a, \, b)\), except for the last interval which is closed \([a, \, b]\).

**scipy.interpolate.PchipInterpolator.antiderivative**

PchipInterpolator\texttt{.antiderivative}(\texttt{nu}=1)

Construct a new piecewise polynomial representing the antiderivative.

Antiderivative is also the indefinite integral of the function, and derivative is its inverse operation.

**Parameters**

- \(\texttt{nu}\) [int, optional] Order of antiderivative to evaluate. Default is 1, i.e., compute the first integral. If negative, the derivative is returned.

**Returns**

- \(\texttt{pp}\) [PPoly] Piecewise polynomial of order \(k2 = k + n\) representing the antiderivative of this polynomial.

**Notes**

The antiderivative returned by this function is continuous and continuously differentiable to order \(n-1\), up to floating point rounding error.

If antiderivative is computed and \(\text{self.extrapolate} = \text{`periodic'}\), it will be set to False for the returned instance. This is done because the antiderivative is no longer periodic and its correct evaluation outside of the initially given \(x\) interval is difficult.

**scipy.interpolate.PchipInterpolator.roots**

PchipInterpolator\texttt{.roots}(\texttt{discontinuity=True, extrapolate=None})

Find real roots of the piecewise polynomial.

**Parameters**

- \(\texttt{discontinuity}\) [bool, optional] Whether to report sign changes across discontinuities at breakpoints as roots.

- \(\texttt{extrapolate}\) [{bool, ‘periodic’, None}, optional] If bool, determines whether to return roots from the polynomial extrapolated based on first and last intervals, ‘periodic’ works the same as False. If None (default), use \text{self.extrapolate}.

**Returns**

- \(\texttt{roots}\) [ndarray] Roots of the polynomial(s).

If the PPoly object describes multiple polynomials, the return value is an object array whose each element is an ndarray containing the roots.

See also:

PPoly.solve
scipy.interpolate.Akima1DInterpolator

class scipy.interpolate.Akima1DInterpolator(x, y, axis=0)

Akima interpolator

Fit piecewise cubic polynomials, given vectors \( x \) and \( y \). The interpolation method by Akima uses a continuously differentiable sub-spline built from piecewise cubic polynomials. The resultant curve passes through the given data points and will appear smooth and natural.

Parameters

- \( x \) [ndarray, shape (m,)] 1-D array of monotonically increasing real values.
- \( y \) [ndarray, shape (m, …)] N-D array of real values. The length of \( y \) along the first axis must be equal to the length of \( x \).
- \( axis \) [int, optional] Specifies the axis of \( y \) along which to interpolate. Interpolation defaults to the first axis of \( y \).

See also:

- PchipInterpolator
  - PCHIP 1-D monotonic cubic interpolator.
- CubicSpline
  - Cubic spline data interpolator.
- PPoly
  - Piecewise polynomial in terms of coefficients and breakpoints

Notes

New in version 0.14.

Use only for precise data, as the fitted curve passes through the given points exactly. This routine is useful for plotting a pleasingly smooth curve through a few given points for purposes of plotting.

scipy.interpolate.Akima1DInterpolator.__call__

Akima1DInterpolator.__call__(x, nu=0, extrapolate=None)

Evaluate the piecewise polynomial or its derivative.

Parameters

- x [array_like] Points to evaluate the interpolant at.
- nu [int, optional] Order of derivative to evaluate. Must be non-negative.
- extrapolate [[bool, ‘periodic’, None], optional] If bool, determines whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs. If ‘periodic’, periodic extrapolation is used. If None (default), use self.extrapolate.

Returns

- y [array_like] Interpolated values. Shape is determined by replacing the interpolation axis in the original array with the shape of x.

Notes

Derivatives are evaluated piecewise for each polynomial segment, even if the polynomial is not differentiable at the breakpoints. The polynomial intervals are considered half-open, [a, b), except for the last interval which is closed [a, b).

scipy.interpolate.Akima1DInterpolator.derivative

Akima1DInterpolator.derivative (nu=1)

Construct a new piecewise polynomial representing the derivative.

Parameters

- nu [int, optional] Order of derivative to evaluate. Default is 1, i.e., compute the first derivative. If negative, the antiderivative is returned.

Returns

- pp [PPoly] Piecewise polynomial of order k2 = k - n representing the derivative of this polynomial.
Notes

Derivatives are evaluated piecewise for each polynomial segment, even if the polynomial is not differentiable at the breakpoints. The polynomial intervals are considered half-open, \([a, b)\), except for the last interval which is closed \([a, b]\).

**scipy.interpolate.Akima1DInterpolator.antiderivative**

**Akima1DInterpolator.antiderivative**(nu=1)

Construct a new piecewise polynomial representing the antiderivative.

Antiderivative is also the indefinite integral of the function, and derivative is its inverse operation.

**Parameters**

- **nu** [int, optional] Order of antiderivative to evaluate. Default is 1, i.e., compute the first integral. If negative, the derivative is returned.

**Returns**

- **pp** [PPoly] Piecewise polynomial of order \(k2 = k + n\) representing the antiderivative of this polynomial.

**Notes**

The antiderivative returned by this function is continuous and continuously differentiable to order \(n-1\), up to floating point rounding error.

If antiderivative is computed and self.extrapolate='periodic', it will be set to False for the returned instance. This is done because the antiderivative is no longer periodic and its correct evaluation outside of the initially given \(x\) interval is difficult.

**scipy.interpolate.Akima1DInterpolator.roots**

**Akima1DInterpolator.roots**(discontinuity=True, extrapolate=None)

Find real roots of the piecewise polynomial.

**Parameters**

- **discontinuity** [bool, optional] Whether to report sign changes across discontinuities at breakpoints as roots.
- **extrapolate** [{bool, 'periodic', None}, optional] If bool, determines whether to return roots from the polynomial extrapolated based on first and last intervals, 'periodic' works the same as False. If None (default), use self.extrapolate.

**Returns**

- **roots** [ndarray] Roots of the polynomial(s).
  
  If the PPoly object describes multiple polynomials, the return value is an object array whose each element is an ndarray containing the roots.

**See also:**

PPoly.solve
Interpolate data with a piecewise cubic polynomial which is twice continuously differentiable [1]. The result is represented as a \( \text{PPoly} \) instance with breakpoints matching the given data.

**Parameters**

- **x**  
  [array_like, shape (n,)] 1-D array containing values of the independent variable. Values must be real, finite and in strictly increasing order.
- **y**  
  [array_like] Array containing values of the dependent variable. It can have arbitrary number of dimensions, but the length along `axis` (see below) must match the length of `x`. Values must be finite.
- **axis**  
  [int, optional] Axis along which `y` is assumed to be varying. Meaning that for `x[i]` the corresponding values are `np.take(y, i, axis=axis)`. Default is 0.
- **bc_type**  
  [string or 2-tuple, optional] Boundary condition type. Two additional equations, given by the boundary conditions, are required to determine all coefficients of polynomials on each segment [2].
  - 'not-a-knot' (default): The first and second segment at a curve end are the same polynomial. It is a good default when there is no information on boundary conditions.
  - 'periodic': The interpolated functions is assumed to be periodic of period \( x[-1] - x[0] \). The first and last value of `y` must be identical: \( y[0] == y[-1] \). This boundary condition will result in \( y'[0] == y'[-1] \) and \( y''[0] == y''[-1] \).
  - 'clamped': The first derivative at curves ends are zero. Assuming a 1D `y`, \( \text{bc_type} = ((1, 0.0), (1, 0.0)) \) is the same condition.
  - 'natural': The second derivative at curve ends are zero. Assuming a 1D `y`, \( \text{bc_type} = ((2, 0.0), (2, 0.0)) \) is the same condition.
  If `bc_type` is a 2-tuple, the first and the second value will be applied at the curve start and end respectively. The tuple values can be one of the previously mentioned strings (except 'periodic') or a tuple \( (\text{order}, \text{deriv_values}) \) allowing to specify arbitrary derivatives at curve ends:
    - `order`: the derivative order, 1 or 2.
    - `deriv_value`: array_like containing derivative values, shape must be the same as `y`, excluding `axis` dimension. For example, if `y` is 1-D, then `deriv_value` must be a scalar. If `y` is 3-D with the shape \( (n0, n1, n2) \) and `axis`=2, then `deriv_value` must be 2-D and have the shape \( (n0, n1) \).
- **extrapolate**  
  [[bool, 'periodic', None], optional] If bool, determines whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs. If 'periodic', periodic extrapolation is used. If None (default), `extrapolate` is set to 'periodic' for `bc_type='periodic'` and to True otherwise.

See also:

- **Akima1DInterpolator**
  Akima 1D interpolator.
- **PchipInterpolator**
  PCHIP 1-D monotonic cubic interpolator.
- **PPoly**
  Piecewise polynomial in terms of coefficients and breakpoints.
Notes

Parameters `bc_type` and `interpolate` work independently, i.e. the former controls only construction of a spline, and the latter only evaluation.

When a boundary condition is 'not-a-knot' and $n = 2$, it is replaced by a condition that the first derivative is equal to the linear interpolant slope. When both boundary conditions are 'not-a-knot' and $n = 3$, the solution is sought as a parabola passing through given points.

When 'not-a-knot' boundary conditions is applied to both ends, the resulting spline will be the same as returned by `splrep` (with $s=0$) and `InterpolatedUnivariateSpline`, but these two methods use a representation in B-spline basis.

New in version 0.18.0.

References

[1], [2]

Examples

In this example the cubic spline is used to interpolate a sampled sinusoid. You can see that the spline continuity property holds for the first and second derivatives and violates only for the third derivative.

```python
>>> from scipy.interpolate import CubicSpline
>>> import matplotlib.pyplot as plt
>>> x = np.arange(10)
>>> y = np.sin(x)
>>> cs = CubicSpline(x, y)
>>> xs = np.arange(-0.5, 9.6, 0.1)
>>> fig, ax = plt.subplots(figsize=(6.5, 4))
>>> ax.plot(x, y, 'o', label='data')
>>> ax.plot(xs, np.sin(xs), label='true')
>>> ax.plot(xs, cs(xs), label='S')
>>> ax.plot(xs, cs(xs, 1), label='S''')
>>> ax.plot(xs, cs(xs, 2), label='S''''')
>>> ax.set_xlim(-0.5, 9.5)
>>> ax.legend(loc='lower left', ncol=2)
>>> plt.show()
```

In the second example, the unit circle is interpolated with a spline. A periodic boundary condition is used. You can see that the first derivative values, $ds/dx=0$, $ds/dy=1$ at the periodic point $(1, 0)$ are correctly computed. Note that a circle cannot be exactly represented by a cubic spline. To increase precision, more breakpoints would be required.

```python
>>> theta = 2 * np.pi * np.linspace(0, 1, 5)
>>> y = np.c_[np.cos(theta), np.sin(theta)]
>>> cs = CubicSpline(theta, y, bc_type='periodic')
>>> print("ds/dx=\{:.1f\} ds/dy=\{:.1f\}".format(cs(0, 1)[0], cs(0, 1)[1]))
```

(continues on next page)
The third example is the interpolation of a polynomial \( y = x^3 \) on the interval \( 0 \leq x \leq 1 \). A cubic spline can represent this function exactly. To achieve that we need to specify values and first derivatives at endpoints of the interval. Note that \( y' = 3x^2 \) and thus \( y'(0) = 0 \) and \( y'(1) = 3 \).

```python
>>> cs = CubicSpline([0, 1], [0, 1], bc_type=((1, 0), (1, 3)))
>>> x = np.linspace(0, 1)
>>> np.allclose(x**3, cs(x))
True
```

**Attributes**

- **x** [ndarray, shape (n,)] Breakpoints. The same \( x \) which was passed to the constructor.
- **c** [ndarray, shape (4, n-1, …)] Coefficients of the polynomials on each segment. The trailing dimensions match the dimensions of \( y \), excluding \( axis \). For example, if \( y \) is 1-d, then \( c[k, i] \) is a coefficient for \( (x-x[i])^*(3-k) \) on the segment between \( x[i] \) and \( x[i+1] \).
- **axis** [int] Interpolation axis. The same \( axis \) which was passed to the constructor.
Methods

```python
__call__(x[,nu,extrapolate])
Evaluatethepiecewisepolynomialoritsderivative.

derivative([nu])
Construct anewpiecewisepolynomialrepresenting
the derivative.

antiderivative([nu])
Construct anewpiecewisepolynomialrepresenting
the antiderivative.

integrate(a,b[,extrapolate])
Compute a definite integral over a piecewise polyno-
mial.

roots([discontinuity,extrapolate])
Find real rootsof the the piecewise polynomial.
```

scipy.interpolate.CubicSpline.__call__

CubicSpline.__call__(x, nu=0, extrapolate=None)
Evaluate the piecewise polynomial or its derivative.

**Parameters**

- `x` [array_like] Points to evaluate the interpolant at.
- `nu` [int, optional] Order of derivative to evaluate. Must be non-negative.
- `extrapolate` [[bool, ‘periodic’, None], optional] If bool, determines whether to extrapolate to out-of-
bounds points based on first and last intervals, or to return NaNs. If ‘periodic’, periodic
extrapolation is used. If None (default), use self.extrapolate.

**Returns**
y  [array_like] Interpolated values. Shape is determined by replacing the interpolation axis in the original array with the shape of x.

Notes
Derivatives are evaluated piecewise for each polynomial segment, even if the polynomial is not differentiable at the breakpoints. The polynomial intervals are considered half-open, \([a, b)\), except for the last interval which is closed \([a, b]\).

scipy.interpolate.CubicSpline.derivative

CubicSpline.derivative\(\(nu=1\)\)
Construct a new piecewise polynomial representing the derivative.

Parameters
nu  [int, optional] Order of derivative to evaluate. Default is 1, i.e., compute the first derivative. If negative, the antiderivative is returned.

Returns
pp  [PPoly] Piecewise polynomial of order \(k2 = k - n\) representing the derivative of this polynomial.

Notes
Derivatives are evaluated piecewise for each polynomial segment, even if the polynomial is not differentiable at the breakpoints. The polynomial intervals are considered half-open, \([a, b)\), except for the last interval which is closed \([a, b]\).

scipy.interpolate.CubicSpline.antiderivative

CubicSpline.antiderivative\(\(nu=1\)\)
Construct a new piecewise polynomial representing the antiderivative.

Antiderivative is also the indefinite integral of the function, and derivative is its inverse operation.

Parameters
nu  [int, optional] Order of antiderivative to evaluate. Default is 1, i.e., compute the first integral. If negative, the derivative is returned.

Returns
pp  [PPoly] Piecewise polynomial of order \(k2 = k + n\) representing the antiderivative of this polynomial.
Notes

The antiderivative returned by this function is continuous and continuously differentiable to order n-1, up to floating point rounding error.

If antiderivative is computed and `self.extrapolate='periodic'`, it will be set to False for the returned instance. This is done because the antiderivative is no longer periodic and its correct evaluation outside of the initially given x interval is difficult.

**scipy.interpolate.CubicSpline.integrate**

```python
CubicSpline.integrate(a, b, extrapolate=None)
```

Compute a definite integral over a piecewise polynomial.

**Parameters**

- `a` [float]: Lower integration bound
- `b` [float]: Upper integration bound
- `extrapolate` [bool, ‘periodic’, None, optional]: If bool, determines whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs. If ‘periodic’, periodic extrapolation is used. If None (default), use `self.extrapolate`.

**Returns**

- `ig` [array_like]: Definite integral of the piecewise polynomial over [a, b]

**scipy.interpolate.CubicSpline.roots**

```python
CubicSpline.roots(discontinuity=True, extrapolate=None)
```

Find real roots of the the piecewise polynomial.

**Parameters**

- `discontinuity` [bool, optional]: Whether to report sign changes across discontinuities at breakpoints as roots.
- `extrapolate` [bool, ‘periodic’, None, optional]: If bool, determines whether to return roots from the polynomial extrapolated based on first and last intervals, ‘periodic’ works the same as False. If None (default), use `self.extrapolate`.

**Returns**

- `roots` [ndarray]: Roots of the polynomial(s).
  If the PPoly object describes multiple polynomials, the return value is an object array whose each element is an ndarray containing the roots.

**See also:**

- `PPoly.solve`
scipy.interpolate.PPoly

class scipy.interpolate.PPoly(c, x, extrapolate=None, axis=0)

Piecewise polynomial in terms of coefficients and breakpoints

The polynomial between $x[i]$ and $x[i+1]$ is written in the local power basis:

$$S = \sum (c[m, i] \times (xp - x[i])^{k-m} \text{ for } m \text{ in range}(k+1))$$

where $k$ is the degree of the polynomial.

Parameters

- **c** [ndarray, shape (k, m, ...)] Polynomial coefficients, order $k$ and $m$ intervals.
- **x** [ndarray, shape (m+1,)] Polynomial breakpoints. Must be sorted in either increasing or decreasing order.
- **extrapolate** [bool or 'periodic', optional] If bool, determines whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs. If 'periodic', periodic extrapolation is used. Default is True.
- **axis** [int, optional] Interpolation axis. Default is zero.

See also:

BPoly

piecewise polynomials in the Bernstein basis

Notes

High-order polynomials in the power basis can be numerically unstable. Precision problems can start to appear for orders larger than 20-30.

Attributes

- **x** [ndarray] Breakpoints.
- **c** [ndarray] Coefficients of the polynomials. They are reshaped to a 3-D array with the last dimension representing the trailing dimensions of the original coefficient array.
- **axis** [int] Interpolation axis.

Methods

- **__call__(x[, nu, extrapolate])** Evaluate the piecewise polynomial or its derivative.
- **derivative([nu])** Construct a new piecewise polynomial representing the derivative.
- **antiderivative([nu])** Construct a new piecewise polynomial representing the antiderivative.
- **integrate(a, b[, extrapolate])** Compute a definite integral over a piecewise polynomial.
- **solve(y[, discontinuity, extrapolate])** Find real solutions of the equation $pp(x) == y$.
- **roots([discontinuity, extrapolate])** Find real roots of the piecewise polynomial.
- **extend(c, x[, right])** Add additional breakpoints and coefficients to the polynomial.
- **from_spline(tck[, extrapolate])** Construct a piecewise polynomial from a spline
Table 49 – continued from previous page

| from_bernstein_basis(bp[, extrapolate]) | Construct a piecewise polynomial in the power basis from a polynomial in Bernstein basis. |
| construct_fast(c, x[, extrapolate, axis]) | Construct the piecewise polynomial without making checks. |

```python
from scipy.interpolate import PPoly

PPoly.__call__(x, nu=0, extrapolate=None)
```

Evaluate the piecewise polynomial or its derivative.

**Parameters**

- `x` : array_like
  Points to evaluate the interpolant at.
- `nu` : int, optional
  Order of derivative to evaluate. Must be non-negative.
- `extrapolate` : [bool, 'periodic', None], optional
  If bool, determines whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs. If 'periodic', periodic extrapolation is used. If None (default), use `self.extrapolate`.

**Returns**

- `y` : array_like
  Interpolated values. Shape is determined by replacing the interpolation axis in the original array with the shape of `x`.

**Notes**

Derivatives are evaluated piecewise for each polynomial segment, even if the polynomial is not differentiable at the breakpoints. The polynomial intervals are considered half-open, \([a, b)\), except for the last interval which is closed \([a, b]\).

```python
PPoly.derivative(nu=1)
```

Construct a new piecewise polynomial representing the derivative.

**Parameters**

- `nu` : int, optional
  Order of derivative to evaluate. Default is 1, i.e., compute the first derivative. If negative, the antiderivative is returned.

**Returns**

- `pp` : PPoly
  Piecewise polynomial of order \(k2 = k - n\) representing the derivative of this polynomial.
Notes

Derivatives are evaluated piecewise for each polynomial segment, even if the polynomial is not differentiable at the breakpoints. The polynomial intervals are considered half-open, \([a, b)\), except for the last interval which is closed \([a, b]\).

scipy.interpolate.PPoly.antiderivative

PPoly.antiderivative\((nu=1)\)
Construct a new piecewise polynomial representing the antiderivative.

Antiderivative is also the indefinite integral of the function, and derivative is its inverse operation.

Parameters

- **nu** [int, optional] Order of antiderivative to evaluate. Default is 1, i.e., compute the first integral. If negative, the derivative is returned.

Returns

- **pp** [PPoly] Piecewise polynomial of order \(k2 = k + n\) representing the antiderivative of this polynomial.

Notes

The antiderivative returned by this function is continuous and continuously differentiable to order \(n-1\), up to floating point rounding error.

If antiderivative is computed and \(self.extrapolate='periodic'\), it will be set to False for the returned instance. This is done because the antiderivative is no longer periodic and its correct evaluation outside of the initially given \(x\) interval is difficult.

scipy.interpolate.PPoly.integrate

PPoly.integrate\((a, b, extrapolate=None)\)
Compute a definite integral over a piecewise polynomial.

Parameters

- **a** [float] Lower integration bound
- **b** [float] Upper integration bound
- **extrapolate** [[bool, ‘periodic’, None], optional] If bool, determines whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs. If ‘periodic’, periodic extrapolation is used. If None (default), use \(self.extrapolate\).

Returns

- **ig** [array_like] Definite integral of the piecewise polynomial over \([a, b]\)
**scipy.interpolate.PPoly.solve**

PPoly.solve(y=0.0, discontinuity=True, extrapolate=None)

Find real solutions of the equation $pp(x) = y$.

**Parameters**

- **y** [float, optional] Right-hand side. Default is zero.
- **discontinuity** [bool, optional] Whether to report sign changes across discontinuities at breakpoints as roots.
- **extrapolate** [{bool, ‘periodic’, None}, optional] If bool, determines whether to return roots from the polynomial extrapolated based on first and last intervals, ‘periodic’ works the same as False. If None (default), use self.extrapolate.

**Returns**

- **roots** [ndarray] Roots of the polynomial(s).
  
  If the PPoly object describes multiple polynomials, the return value is an object array whose each element is an ndarray containing the roots.

**Notes**

This routine works only on real-valued polynomials.

If the piecewise polynomial contains sections that are identically zero, the root list will contain the start point of the corresponding interval, followed by a nan value.

If the polynomial is discontinuous across a breakpoint, and there is a sign change across the breakpoint, this is reported if the discontinuity parameter is True.

**Examples**

Finding roots of $[x^2 - 1, (x - 1)^2]$ defined on intervals $[-2, 1]$, $[1, 2]$: 

```python
>>> from scipy.interpolate import PPoly
>>> pp = PPoly(np.array([[1, -4, 3], [1, 0, 0]]).T, [-2, 1, 2])
>>> pp.solve()
array([-1., 1.])
```

**scipy.interpolate.PPoly.roots**

PPoly.roots(discontinuity=True, extrapolate=None)

Find real roots of the the piecewise polynomial.

**Parameters**

- **discontinuity** [bool, optional] Whether to report sign changes across discontinuities at breakpoints as roots.
- **extrapolate** [{bool, ‘periodic’, None}, optional] If bool, determines whether to return roots from the polynomial extrapolated based on first and last intervals, ‘periodic’ works the same as False. If None (default), use self.extrapolate.
Returns

roots [ndarray] Roots of the polynomial(s).

If the PPoly object describes multiple polynomials, the return value is an object array
whose each element is an ndarray containing the roots.

See also:

PPoly.solve

scipy.interpolate.PPoly.extend

PPoly.extend(c, x, right=None)

Add additional breakpoints and coefficients to the polynomial.

Parameters

c [ndarray, size (k, m, …)] Additional coefficients for polynomials in intervals. Note that
the first additional interval will be formed using one of the self.x end points.

x [ndarray, size (m,)] Additional breakpoints. Must be sorted in the same order as self.x
and either to the right or to the left of the current breakpoints.

right Deprecated argument. Has no effect.
Deprecated since version 0.19.

scipy.interpolate.PPoly.from_spline

classmethod PPoly.from_spline(tck, extrapolate=None)

Construct a piecewise polynomial from a spline

Parameters

tck A spline, as returned by splrep or a BSpline object.

extrapolate [bool or ‘periodic’, optional] If bool, determines whether to extrapolate to out-of-bounds
points based on first and last intervals, or to return NaNs. If ‘periodic’, periodic extrap-
olation is used. Default is True.

scipy.interpolate.PPoly.from_bernstein_basis

classmethod PPoly.from_bernstein_basis(bp, extrapolate=None)

Construct a piecewise polynomial in the power basis from a polynomial in Bernstein basis.

Parameters

bp [BPoly] A Bernstein basis polynomial, as created by BPoly

extrapolate [bool or ‘periodic’, optional] If bool, determines whether to extrapolate to out-of-bounds
points based on first and last intervals, or to return NaNs. If ‘periodic’, periodic extrap-
olation is used. Default is True.
scipy.interpolate.PPoly.construct_fast

classmethod PPoly.construct_fast(c, x, extrapolate=None, axis=0)
Construct the piecewise polynomial without making checks.

Takes the same parameters as the constructor. Input arguments c and x must be arrays of the correct shape and type. The c array can only be of dtypes float and complex, and x array must have dtype float.

scipy.interpolate.BPoly

class scipy.interpolate.BPoly(c, x, extrapolate=None, axis=0)
Piecewise polynomial in terms of coefficients and breakpoints.

The polynomial between x[i] and x[i + 1] is written in the Bernstein polynomial basis:

\[ S = \sum_{a} c[a, i] \cdot b(a, k; x) \text{ for } a \text{ in range}(k+1), \]

where k is the degree of the polynomial, and:

\[ b(a, k; x) = \binom{k}{a} \cdot t^a \cdot (1 - t)^{(k - a)}, \]

with \( t = (x - x[i]) / (x[i+1] - x[i]) \) and \( \binom{k}{a} \) is the binomial coefficient.

Parameters
- c [ndarray, shape (k, m, …)] Polynomial coefficients, order k and m intervals
- x [ndarray, shape (m+1,)] Polynomial breakpoints. Must be sorted in either increasing or decreasing order.
- extrapolate [bool, optional] If bool, determines whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs. If ‘periodic’, periodic extrapolation is used. Default is True.
- axis [int, optional] Interpolation axis. Default is zero.

See also:
PPoly

piecewise polynomials in the power basis

Notes

Properties of Bernstein polynomials are well documented in the literature, see for example [1] [2] [3].

References

[1], [2], [3]
Examples

```python
>>> from scipy.interpolate import BPoly
>>> x = [0, 1]
>>> c = [[1], [2], [3]]
>>> bp = BPoly(c, x)
```

This creates a 2nd order polynomial

\[
B(x) = 1 \times b_{0,2}(x) + 2 \times b_{1,2}(x) + 3 \times b_{2,2}(x) \\
= 1 \times (1 - x)^2 + 2 \times 2x(1 - x) + 3 \times x^2
\]

**Attributes**

- `x` [ndarray] Breakpoints.
- `c` [ndarray] Coefficients of the polynomials. They are reshaped to a 3-D array with the last dimension representing the trailing dimensions of the original coefficient array.
- `axis` [int] Interpolation axis.

**Methods**

- `__call__(x[, nu, extrapolate])` Evaluate the piecewise polynomial or its derivative.
- `extend(c, x[, right])` Add additional breakpoints and coefficients to the polynomial.
- `derivative(nu)` Construct a new piecewise polynomial representing the derivative.
- `antiderivative(nu)` Construct a new piecewise polynomial representing the antiderivative.
- `integrate(a, b[, extrapolate])` Compute a definite integral over a piecewise polynomial.
- `construct_fast(c, x[, extrapolate, axis])` Construct the piecewise polynomial without making checks.
- `from_power_basis(pp[, extrapolate])` Construct a piecewise polynomial in Bernstein basis from a power basis polynomial.
- `from_derivatives(xi, yi[, orders, extrapolate])` Construct a piecewise polynomial in the Bernstein basis, compatible with the specified values and derivatives at breakpoints.

**scipy.interpolate.BPoly.__call__**

BPoly.__call__(x, nu=0, extrapolate=None)

Evaluate the piecewise polynomial or its derivative.

**Parameters**

- `x` [array_like] Points to evaluate the interpolant at.
- `nu` [int, optional] Order of derivative to evaluate. Must be non-negative.
- `extrapolate` [[bool, ‘periodic’, None], optional] If bool, determines whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs. If ‘periodic’, periodic extrapolation is used. If None (default), use self.extrapolate.

**Returns**
y [array_like] Interpolated values. Shape is determined by replacing the interpolation axis in the original array with the shape of x.

Notes

Derivatives are evaluated piecewise for each polynomial segment, even if the polynomial is not differentiable at the breakpoints. The polynomial intervals are considered half-open, \([a, b)\), except for the last interval which is closed \([a, b]\).

scipy.interpolate.BPoly.extend

BPoly.extend(c, x, right=None)
Add additional breakpoints and coefficients to the polynomial.

Parameters

c [ndarray, size (k, m, ...)] Additional coefficients for polynomials in intervals. Note that the first additional interval will be formed using one of the self.x endpoints.
x [ndarray, size (m,)] Additional breakpoints. Must be sorted in the same order as self.x and either to the right or to the left of the current breakpoints.
right Deprecated argument. Has no effect. Deprecated since version 0.19.

scipy.interpolate.BPoly.derivative

BPoly.derivative(nu=1)
Construct a new piecewise polynomial representing the derivative.

Parameters

nu [int, optional] Order of derivative to evaluate. Default is 1, i.e., compute the first derivative. If negative, the antiderivative is returned.

Returns

bp [BPoly] Piecewise polynomial of order k - nu representing the derivative of this polynomial.

scipy.interpolate.BPoly.antiderivative

BPoly.antiderivative(nu=1)
Construct a new piecewise polynomial representing the antiderivative.

Parameters

nu [int, optional] Order of antiderivative to evaluate. Default is 1, i.e., compute the first integral. If negative, the derivative is returned.

Returns

bp [BPoly] Piecewise polynomial of order k + nu representing the antiderivative of this polynomial.
Notes

If antiderivative is computed and self.extrapolate='periodic', it will be set to False for the returned instance. This is done because the antiderivative is no longer periodic and its correct evaluation outside of the initially given x interval is difficult.

scipy.interpolate.BPoly.integrate

BPoly.integrate(a, b, extrapolate=None)

Compute a definite integral over a piecewise polynomial.

Parameters

- `a` [float] Lower integration bound
- `b` [float] Upper integration bound
- `extrapolate` [{bool, 'periodic', None}, optional] Whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs. If 'periodic', periodic extrapolation is used. If None (default), use self.extrapolate.

Returns

- `array_like` Definite integral of the piecewise polynomial over [a, b]

scipy.interpolate.BPoly.construct_fast

classmethod BPoly.construct_fast(c, x, extrapolate=None, axis=0)

Construct the piecewise polynomial without making checks.

Takes the same parameters as the constructor. Input arguments c and x must be arrays of the correct shape and type. The c array can only be of dtypes float and complex, and x array must have dtype float.

scipy.interpolate.BPoly.from_power_basis

classmethod BPoly.from_power_basis(pp, extrapolate=None)

Construct a piecewise polynomial in Bernstein basis from a power basis polynomial.

Parameters

- `pp` [PPoly] A piecewise polynomial in the power basis
- `extrapolate` [bool or ‘periodic’, optional] If bool, determines whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs. If ‘periodic’, periodic extrapolation is used. Default is True.
scipy.interpolate.BPoly.from_derivatives

classmethod BPoly.from_derivatives(xi, yi, orders=None, extrapolate=None)

Construct a piecewise polynomial in the Bernstein basis, compatible with the specified values and derivatives at breakpoints.

Parameters

xi : [array_like] sorted 1-D array of x-coordinates
yi : [array_like or list of array_likes] yi[i][j] is the j\textsuperscript{th} derivative known at \`\`xi[i]
orders : [None or int or array_like of ints. Default: None.] Specifies the degree of local polynomials. If not None, some derivatives are ignored.
extrapolate : [bool or `periodic`, optional] If bool, determines whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs. If `periodic`, periodic extrapolation is used. Default is True.

Notes

If \(k\) derivatives are specified at a breakpoint \(x\), the constructed polynomial is exactly \(k\) times continuously differentiable at \(x\), unless the order is provided explicitly. In the latter case, the smoothness of the polynomial at the breakpoint is controlled by the order.

Deduces the number of derivatives to match at each end from order and the number of derivatives available. If possible it uses the same number of derivatives from each end; if the number is odd it tries to take the extra one from \(y2\). In any case if not enough derivatives are available at one end or another it draws enough to make up the total from the other end.

If the order is too high and not enough derivatives are available, an exception is raised.

Examples

```python
>>> from scipy.interpolate import BPoly
>>> BPoly.from_derivatives([[0, 1], [1, 2], [3, 4]])

Creates a polynomial \(f(x)\) of degree 3, defined on \([0, 1]\) such that \(f(0) = 1\), \(df/dx(0) = 2\), \(f(1) = 3\), \(df/dx(1) = 4\).

```
LinearNDInterpolator
```

Piecewise linear interpolant in N dimensions.
NearestNDInterpolator

Nearest-neighbor interpolation in N dimensions.

CloughTocher2DInterpolator

Piecewise cubic, C1 smooth, curvature-minimizing interpolant in 2D.

Notes

New in version 0.9.

Examples

Suppose we want to interpolate the 2-D function

```python
>>> def func(x, y):
...   return x*(1-x)*np.cos(4*np.pi*x) * np.sin(4*np.pi*y**2)**2
```

on a grid in [0, 1]x[0, 1]

```python
>>> grid_x, grid_y = np.mgrid[0:1:100j, 0:1:200j]
```

but we only know its values at 1000 data points:

```python
>>> rng = np.random.default_rng()
>>> points = rng.random((1000, 2))
>>> values = func(points[:,0], points[:,1])
```

This can be done with `griddata`—below we try out all of the interpolation methods:

```python
>>> from scipy.interpolate import griddata
>>> grid_z0 = griddata(points, values, (grid_x, grid_y), method='nearest')
>>> grid_z1 = griddata(points, values, (grid_x, grid_y), method='linear')
>>> grid_z2 = griddata(points, values, (grid_x, grid_y), method='cubic')
```

One can see that the exact result is reproduced by all of the methods to some degree, but for this smooth function the piecewise cubic interpolant gives the best results:

```python
>>> import matplotlib.pyplot as plt
>>> plt.subplot(221)
>>> plt.imshow(func(grid_x, grid_y).T, extent=(0,1,0,1), origin='lower')
>>> plt.plot(points[:,0], points[:,1], 'k.', ms=1)
>>> plt.title('Original')
>>> plt.subplot(222)
>>> plt.imshow(grid_z0.T, extent=(0,1,0,1), origin='lower')
>>> plt.title('Nearest')
>>> plt.subplot(223)
>>> plt.imshow(grid_z1.T, extent=(0,1,0,1), origin='lower')
>>> plt.title('Linear')
>>> plt.subplot(224)
>>> plt.imshow(grid_z2.T, extent=(0,1,0,1), origin='lower')
>>> plt.title('Cubic')
>>> plt.gcf().set_size_inches(6, 6)
>>> plt.show()
```
scipy.interpolate.LinearNDInterpolator

class scipy.interpolate.LinearNDInterpolator(points, values, fill_value=np.nan, rescale=False)
Piecewise linear interpolant in $N > 1$ dimensions.
New in version 0.9.

Parameters

- **points** [ndarray of floats, shape (npoints, ndims); or Delaunay] Data point coordinates, or a pre-computed Delaunay triangulation.
- **values** [ndarray of float or complex, shape (npoints, ...)] Data values.
- **fill_value** [float, optional] Value used to fill in for requested points outside of the convex hull of the input points. If not provided, then the default is nan.
- **rescale** [bool, optional] Rescale points to unit cube before performing interpolation. This is useful if some of the input dimensions have incommensurable units and differ by many orders of magnitude.

See also:

`griddata`  
Interpolate unstructured D-D data.

`NearestNDInterpolator`  
Nearest-neighbor interpolation in $N$ dimensions.

`CloughTocher2DInterpolator`  
Piecewise cubic, C1 smooth, curvature-minimizing interpolant in 2D.

Notes

The interpolant is constructed by triangulating the input data with Qhull [1], and on each triangle performing linear barycentric interpolation.

References

[1]

Examples

We can interpolate values on a 2D plane:

```python
>>> from scipy.interpolate import LinearNDInterpolator
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
>>> x = rng.random(10) - 0.5
>>> y = rng.random(10) - 0.5
>>> z = np.hypot(x, y)
>>> X = np.linspace(min(x), max(x))
>>> Y = np.linspace(min(y), max(y))
>>> X, Y = np.meshgrid(X, Y)  # 2D grid for interpolation
>>> interp = LinearNDInterpolator(list(zip(x, y)), z)
>>> Z = interp(X, Y)
```
Methods

__call__(xi)  Evaluate interpolator at given points.

scipy.interpolate.LinearNDInterpolator.__call__

LinearNDInterpolator.__call__(xi)  Evaluate interpolator at given points.

Parameters

x1, x2, … xn: array-like of float
    Points where to interpolate data at. x1, x2, … xn can be array-like of float with broadcastable shape. or x1 can be array-like of float with shape (... , ndim)
scipy.interpolate.NearestNDInterpolator

class scipy.interpolate.NearestNDInterpolator(x, y, rescale=False, tree_options=None)

NearestNDInterpolator(x, y).

Nearest-neighbor interpolation in N > 1 dimensions.

New in version 0.9.

Parameters

- x : [(Npoints, Ndims) ndarray of floats] Data point coordinates.
- y : [(Npoints,) ndarray of float or complex] Data values.
- rescale : [boolean, optional] Rescale points to unit cube before performing interpolation. This is useful if some of the input dimensions have incommensurable units and differ by many orders of magnitude.
  New in version 0.14.0.
- tree_options : [dict, optional] Options passed to the underlying cKDTree.
  New in version 0.17.0.

CloughTocher2DInterpolator
Piecewise cubic, C1 smooth, curvature-minimizing interpolant in 2D.

Notes

Uses scipy.spatial.cKDTree

Examples

We can interpolate values on a 2D plane:

```python
>>> from scipy.interpolate import NearestNDInterpolator
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
>>> x = rng.random(10) - 0.5
>>> y = rng.random(10) - 0.5
>>> z = np.hypot(x, y)
>>> X = np.linspace(min(x), max(x))
>>> Y = np.linspace(min(y), max(y))
>>> X, Y = np.meshgrid(X, Y)  # 2D grid for interpolation
>>> interp = NearestNDInterpolator(list(zip(x, y)), z)
>>> Z = interp(X, Y)
>>> plt.pcolormesh(X, Y, Z, shading='auto')
>>> plt.plot(x, y, "ok", label="input point")
>>> plt.legend()
```
Methods

__call__(*args) Evaluate interpolator at given points.

scipy.interpolate.NearestNDInterpolator.__call__

NearestNDInterpolator.__call__(*args)
Evaluate interpolator at given points.

Parameters
x1, x2, ... xn: array-like of float
Points where to interpolate data at. x1, x2, ... xn can be array-like of float with broadcastable shape. or x1 can be array-like of float with shape (... , ndim)

scipy.interpolate.CloughTocher2DInterpolator

class scipy.interpolate.CloughTocher2DInterpolator(points, values, fill_value=nan, tol=1e-06, maxiter=400, rescale=False)
CloughTocher2DInterpolator(points, values, tol=1e-6).
Piecewise cubic, C1 smooth, curvature-minimizing interpolant in 2D.
New in version 0.9.

Parameters
points [ndarray of floats, shape (npoints, ndims); or Delaunay] Data point coordinates, or a pre-computed Delaunay triangulation.
values  [ndarray of float or complex, shape (npoints, …)] Data values.
fill_value  [float, optional] Value used to fill in for requested points outside of the convex hull of the input points. If not provided, then the default is nan.
maxiter  [int, optional] Maximum number of iterations in gradient estimation.
rescale  [bool, optional] Rescale points to unit cube before performing interpolation. This is useful if some of the input dimensions have incommensurable units and differ by many orders of magnitude.

griddata
Interpolate unstructured D-D data.
LinearNDInterpolator
Piecewise linear interpolant in N > 1 dimensions.
NearestNDInterpolator
Nearest-neighbor interpolation in N > 1 dimensions.

Notes

The interpolant is constructed by triangulating the input data with Qhull [1], and constructing a piecewise cubic interpolating Bezier polynomial on each triangle, using a Clough-Tocher scheme [CT]. The interpolant is guaranteed to be continuously differentiable.

The gradients of the interpolant are chosen so that the curvature of the interpolating surface is approximatively minimized. The gradients necessary for this are estimated using the global algorithm described in [Nielson83] and [Renka84].

Examples

We can interpolate values on a 2D plane:

```python
>>> from scipy.interpolate import CloughTocher2DInterpolator
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
>>> x = rng.random(10) - 0.5
>>> y = rng.random(10) - 0.5
>>> z = np.hypot(x, y)
>>> X = np.linspace(min(x), max(x))
>>> Y = np.linspace(min(y), max(y))
>>> X, Y = np.meshgrid(X, Y)  # 2D grid for interpolation
>>> interp = CloughTocher2DInterpolator(list(zip(x, y)), z)
>>> Z = interp(X, Y)
>>> plt.pcolormesh(X, Y, Z, shading='auto')
>>> plt.plot(x, y, "ok", label="input point")
```
>>> plt.legend()
>>> plt.colorbar()
>>> plt.axis("equal")
>>> plt.show()

Methods

```python
__call__(xi)
```
Evaluate interpolator at given points.

### scipy.interpolate.CloughTocher2DInterpolator.__call__

CloughTocher2DInterpolator.__call__(xi)
Evaluate interpolator at given points.

**Parameters**

- `x1, x2, ... xn`: array-like of float
  Points where to interpolate data at. `x1, x2, ... xn` can be array-like of float with broadcastable shape. `x1` can be array-like of float with shape `(..., ndim)`

### scipy.interpolate.RBFInterpolator

class scipy.interpolate.RBFInterpolator(y, d, neighbors=None, smoothing=0.0,
`kernel="thin_plate_spline", epsilon=None, degree=None`)

Radial basis function (RBF) interpolation in N dimensions.

**Parameters**

- `d`: [((P, ...) array_like] Data values at `y`.
- `neighbors`: [int, optional] If specified, the value of the interpolant at each evaluation point will be computed using only this many nearest data points. All the data points are used by default.
smoothing [float or (P,) array_like, optional] Smoothing parameter. The interpolant perfectly fits the data when this is set to 0. For large values, the interpolant approaches a least squares fit of a polynomial with the specified degree. Default is 0.

kernel [str, optional] Type of RBF. This should be one of
- ‘linear’: -r
- ‘thin_plate_spline’: r**2 * log(r)
- ‘cubic’: r**3
- ‘quintic’: -r**5
- ‘multiquadric’: -sqrt(1 + r**2)
- ‘inverse_multiquadric’: 1/sqrt(1 + r**2)
- ‘inverse_quadratic’: 1/(1 + r**2)
- ‘gaussian’: exp(-r**2)
Default is ‘thin_plate_spline’.

epsilon [float, optional] Shape parameter that scales the input to the RBF. If kernel is ‘linear’, ‘thin_plate_spline’, ‘cubic’, or ‘quintic’, this defaults to 1 and can be ignored because it has the same effect as scaling the smoothing parameter. Otherwise, this must be specified.

degree [int, optional] Degree of the added polynomial. For some RBFs the interpolant may not be well-posed if the polynomial degree is too small. Those RBFs and their corresponding minimum degrees are
- ‘multiquadric’: 0
- ‘linear’: 0
- ‘thin_plate_spline’: 1
- ‘cubic’: 1
- ‘quintic’: 2
The default value is the minimum degree for kernel or 0 if there is no minimum degree. Set this to -1 for no added polynomial.

NearestNDInterpolator
LinearNDInterpolator
CloughTocher2DInterpolator

Notes

An RBF is a scalar valued function in N-dimensional space whose value at \( x \) can be expressed in terms of \( r = ||x - c|| \), where \( c \) is the center of the RBF.

An RBF interpolant for the vector of data values \( d \), which are from locations \( y \), is a linear combination of RBFs centered at \( y \) plus a polynomial with a specified degree. The RBF interpolant is written as

\[
    f(x) = K(x, y)a + P(x)b,
\]

where \( K(x, y) \) is a matrix of RBFs with centers at \( y \) evaluated at the points \( x \), and \( P(x) \) is a matrix of monomials, which span polynomials with the specified degree, evaluated at \( x \). The coefficients \( a \) and \( b \) are the solution to the linear equations

\[
    (K(y, y) + \lambda I)a + P(y)b = d
\]

and

\[
    P(y)^T a = 0,
\]
where $\lambda$ is a non-negative smoothing parameter that controls how well we want to fit the data. The data are fit exactly when the smoothing parameter is 0.

The above system is uniquely solvable if the following requirements are met:

- $P(y)$ must have full column rank. $P(y)$ always has full column rank when $\textit{degree}$ is -1 or 0. When $\textit{degree}$ is 1, $P(y)$ has full column rank if the data point locations are not all collinear (N=2), coplanar (N=3), etc.
- If $\textit{kernel}$ is ‘multiquadric’, ‘linear’, ‘thin\_plate\_spline’, ‘cubic’, or ‘quintic’, then $\textit{degree}$ must not be lower than the minimum value listed above.
- If $\textit{smoothing}$ is 0, then each data point location must be distinct.

When using an RBF that is not scale invariant (‘multiquadric’, ‘inverse\_multiquadric’, ‘inverse\_quadratic’, or ‘gaussian’), an appropriate shape parameter must be chosen (e.g., through cross validation). Smaller values for the shape parameter correspond to wider RBFs. The problem can become ill-conditioned or singular when the shape parameter is too small.

The memory required to solve for the RBF interpolation coefficients increases quadratically with the number of data points, which can become impractical when interpolating more than about a thousand data points. To overcome memory limitations for large interpolation problems, the $\textit{neighbors}$ argument can be specified to compute an RBF interpolant for each evaluation point using only the nearest data points.

New in version 1.7.0.

Examples

Demonstrate interpolating scattered data to a grid in 2-D.

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.interpolate import RBFInterpolator
>>> from scipy.stats.qmc import Halton

>>> rng = np.random.default_rng()
>>> xobs = 2*Halton(2, seed=rng).random(100) - 1
>>> yobs = np.sum(xobs, axis=1)*np.exp(-6*np.sum(xobs**2, axis=1))

>>> xgrid = np.mgrid[-1:1:50j, -1:1:50j]
>>> xflat = xgrid.reshape(2, -1).T
>>> yflat = RBFInterpolator(xobs, yobs)(xflat)
>>> ygrid = yflat.reshape(50, 50)

>>> fig, ax = plt.subplots()
>>> ax.pcolormesh(*xgrid, ygrid, vmin=-0.25, vmax=0.25, shading='gouraud')
>>> p = ax.scatter(*xobs.T, c=yobs, s=50, ec='k', vmin=-0.25, vmax=0.25)
>>> fig.colorbar(p)
>>> plt.show()
```
Methods

__call__(x)  Evaluate the interpolant at x.

scipy.interpolate.RBFInterpolator.__call__

RBFInterpolator.__call__(x)
Evaluate the interpolant at x.

Parameters
x [(Q, N) array_like] Evaluation point coordinates.

Returns
(Q, ...) ndarray  Values of the interpolant at x.

c scipy.interpolate.Rbf

class scipy.interpolate.Rbf(*args, **kwargs)
A class for radial basis function interpolation of functions from N-D scattered data to an M-D domain.

Note: Rbf is legacy code, for new usage please use RBFInterpolator instead.

Parameters
*args [arrays] x, y, z, ..., d, where x, y, z, ... are the coordinates of the nodes and d is the array of values at the nodes
function [str or callable, optional] The radial basis function, based on the radius, r, given by the norm (default is Euclidean distance); the default is ‘multiquadric’:

```python
'multiquadric': sqrt((r/self.epsilon)**2 + 1)
'inverse': 1.0/sqrt((r/self.epsilon)**2 + 1)
'gaussian': exp(-(r/self.epsilon)**2)
'linear': r
'cubic': r**3
'quintic': r**5
'thin_plate': r**2 * log(r)
```

If callable, then it must take 2 arguments (self, r). The epsilon parameter will be available as self.epsilon. Other keyword arguments passed in will be available as well.

**epsilon** [float, optional] Adjustable constant for gaussian or multiquadrics functions - defaults to approximate average distance between nodes (which is a good start).

**smooth** [float, optional] Values greater than zero increase the smoothness of the approximation. 0 is for interpolation (default), the function will always go through the nodal points in this case.

**norm** [str, callable, optional] A function that returns the ‘distance’ between two points, with inputs as arrays of positions (x, y, z, ...), and an output as an array of distance. E.g., the default: ‘euclidean’, such that the result is a matrix of the distances from each point in x1 to each point in x2. For more options, see documentation of `scipy.spatial.distances.cdist`.

**mode** [str, optional] Mode of the interpolation, can be ‘1-D’ (default) or ‘N-D’. When it is ‘1-D’ the data d will be considered as 1-D and flattened internally. When it is ‘N-D’ the data d is assumed to be an array of shape (n_samples, m), where m is the dimension of the target domain.

See also:

**RBFInterpolator**

Examples

```python
>>> from scipy.interpolate import Rbf
>>> rng = np.random.default_rng()
>>> x, y, z, d = rng.random((4, 50))
>>> rbfi = Rbf(x, y, z, d)  # radial basis function interpolator instance
>>> xi = yi = zi = np.linspace(0, 1, 20)
>>> di = rbfi(xi, yi, zi)  # interpolated values
>>> di.shape
(20,)
```

Attributes

- **N** [int] The number of data points (as determined by the input arrays).
- **di** [ndarray] The 1-D array of data values at each of the data coordinates xi.
- **xi** [ndarray] The 2-D array of data coordinates.
- **function** [str or callable] The radial basis function. See description under Parameters.
- **epsilon** [float] Parameter used by gaussian or multiquadrics functions. See Parameters.
- **smooth** [float] Smoothing parameter. See description under Parameters.
- **norm** [str or callable] The distance function. See description under Parameters.
- **mode** [str] Mode of the interpolation. See description under Parameters.
- **nodes** [ndarray] A 1-D array of node values for the interpolation.
- **A** [internal property, do not use]
Methods

```
__call__(*args) Call self as a function.
```

**scipy.interpolate.Rbf.__call__**

```
Rbf.__call__(*args)
Call self as a function.
```

**scipy.interpolate.interp2d**

class scipy.interpolate.interp2d(x, y, z, kind='linear', copy=True, bounds_error=False, fill_value=None)

Interpolate over a 2-D grid.

x, y and z are arrays of values used to approximate some function f: z = f(x, y) which returns a scalar value z. This class returns a function whose call method uses spline interpolation to find the value of new points.

If x and y represent a regular grid, consider using `RectBivariateSpline`.

If z is a vector value, consider using `interpn`.

Note that calling `interp2d` with NaNs present in input values results in undefined behaviour.

**Parameters**

- **x, y** [array_like] Arrays defining the data point coordinates. If the points lie on a regular grid, x can specify the column coordinates and y the row coordinates, for example:

  ```
  >>> x = [0, 1, 2]; y = [0, 3]; z = [[1, 2, 3], [4, 5, 6]]
  ```

  Otherwise, x and y must specify the full coordinates for each point, for example:

  ```
  >>> x = [0, 1, 2, 0, 1, 2]; y = [0, 0, 0, 3, 3, 3]; z = [1, 2, 3, 4, 5, 6]
  ```

  If x and y are multidimensional, they are flattened before use.

- **z** [array_like] The values of the function to interpolate at the data points. If z is a multidimensional array, it is flattened before use. The length of a flattened z array is either len(x)*len(y) if x and y specify the column and row coordinates or len(z) == len(x) == len(y) if x and y specify coordinates for each point.

- **kind** [{'linear', 'cubic', 'quintic'}, optional] The kind of spline interpolation to use. Default is 'linear'.

- **copy** [bool, optional] If True, the class makes internal copies of x, y and z. If False, references may be used. The default is to copy.

- **bounds_error** [bool, optional] If True, when interpolated values are requested outside of the domain of the input data (x,y), a ValueError is raised. If False, then `fill_value` is used.

- **fill_value** [number, optional] If provided, the value to use for points outside of the interpolation domain. If omitted (None), values outside the domain are extrapolated via nearest-neighbor extrapolation.

**See also:**

- `RectBivariateSpline`

  Much faster 2-D interpolation if your input data is on a grid
**bisplrep, bisplev**

Spline interpolation based on FITPACK

**BivariateSpline**

a more recent wrapper of the FITPACK routines

**interp1d**

1-D version of this function

**Notes**

The minimum number of data points required along the interpolation axis is \((k+1)^2\), with \(k=1\) for linear, \(k=3\) for cubic and \(k=5\) for quintic interpolation.

The interpolator is constructed by **bisplrep**, with a smoothing factor of 0. If more control over smoothing is needed, **bisplrep** should be used directly.

**Examples**

Construct a 2-D grid and interpolate on it:

```python
>>> from scipy import interpolate
>>> x = np.arange(-5.01, 5.01, 0.25)
>>> y = np.arange(-5.01, 5.01, 0.25)
>>> xx, yy = np.meshgrid(x, y)
>>> z = np.sin(xx**2+yy**2)
>>> f = interpolate.interp2d(x, y, z, kind='cubic')
```

Now use the obtained interpolation function and plot the result:

```python
>>> import matplotlib.pyplot as plt
>>> xnew = np.arange(-5.01, 5.01, 1e-2)
>>> ynew = np.arange(-5.01, 5.01, 1e-2)
>>> znew = f(xnew, ynew)
>>> plt.plot(x, z[0, :], 'ro-', xnew, znew[0, :], 'b-')
>>> plt.show()
```

**Methods**

```python
__call__(x, y[, dx, dy, assume_sorted]) Interpolate the function.
```
scipy.interpolate.interp2d.__call__

`interp2d.__call__(x, y, dx=0, dy=0, assume_sorted=False)`

Interpolate the function.

**Parameters**

- **x**  
  [1-D array] x-coordinates of the mesh on which to interpolate.
- **y**  
  [1-D array] y-coordinates of the mesh on which to interpolate.
- **dx**  
  [int >= 0, < kx] Order of partial derivatives in x.
- **dy**  
  [int >= 0, < ky] Order of partial derivatives in y.
- **assume_sorted**  
  [bool, optional] If False, values of x and y can be in any order and they are sorted first. If True, x and y have to be arrays of monotonically increasing values.

**Returns**

- **z**  
  [2-D array with shape (len(y), len(x))] The interpolated values.

For data on a grid:

- **interpn**(points, values, xi[, method, ...]) Multidimensional interpolation on regular grids.
- **RegularGridInterpolator**(points, values[, ...]) Interpolation on a regular grid in arbitrary dimensions
- **RectBivariateSpline**(x, y, z[, bbox, kx, ky, s]) Bivariate spline approximation over a rectangular mesh.
scipy.interpolate.interpn

scipy.interpolate.interpn(points, values, xi, method='linear', bounds_error=True, fill_value=nan)

Multidimensional interpolation on regular grids.

**Parameters**

- **points** [tuple of ndarray of float, with shapes (m1,), ..., (mn,)] The points defining the regular grid in n dimensions.
- **values** [array_like, shape (m1, ..., mn, ...)] The data on the regular grid in n dimensions.
- **xi** [ndarray of shape (..., ndim)] The coordinates to sample the gridded data at
- **method** [str, optional] The method of interpolation to perform. Supported are “linear” and “nearest”, and “splinef2d”. “splinef2d” is only supported for 2-dimensional data.
- **bounds_error** [bool, optional] If True, when interpolated values are requested outside of the domain of the input data, a ValueError is raised. If False, then fill_value is used.
- **fill_value** [number, optional] If provided, the value to use for points outside of the interpolation domain. If None, values outside the domain are extrapolated. Extrapolation is not supported by method “splinef2d”.

**Returns**

- **values_x** [ndarray, shape xi.shape[:-1] + values.shape[ndim:]] Interpolated values at input coordinates.

**See also:**

- **NearestNDInterpolator**
  Nearest neighbor interpolation on unstructured data in N dimensions
- **LinearNDInterpolator**
  Piecewise linear interpolant on unstructured data in N dimensions
- **RegularGridInterpolator**
  Linear and nearest-neighbor Interpolation on a regular grid in arbitrary dimensions
RectBivariateSpline

Bivariate spline approximation over a rectangular mesh

Notes

New in version 0.14.

Examples

Evaluate a simple example function on the points of a regular 3-D grid:

```python
>>> from scipy.interpolate import interpn
def value_func_3d(x, y, z):
...     return 2 * x + 3 * y - z
>>> x = np.linspace(0, 4, 5)
>>> y = np.linspace(0, 5, 6)
>>> z = np.linspace(0, 6, 7)
>>> points = (x, y, z)
>>> values = value_func_3d(*np.meshgrid(*points, indexing='ij'))
```

Evaluate the interpolating function at a point

```python
>>> point = np.array([2.21, 3.12, 1.15])
>>> print(interpn(points, values, point))
[12.63]
```

scipy.interpolate.RegularGridInterpolator

```python
class scipy.interpolate.RegularGridInterpolator(points, values, method='linear', bounds_error=True, fill_value=nan)
```

Interpolation on a regular grid in arbitrary dimensions

The data must be defined on a regular grid; the grid spacing however may be uneven. Linear and nearest-neighbor interpolation are supported. After setting up the interpolator object, the interpolation method (linear or nearest) may be chosen at each evaluation.

**Parameters**

- `points` ([tuple of ndarray of float, with shapes (m1,), ..., (mn,)]): The points defining the regular grid in n dimensions.
- `values` ([array_like, shape (m1, ..., mn,...)]): The data on the regular grid in n dimensions.
- `method` ([str, optional]): The method of interpolation to perform. Supported are “linear” and “nearest”. This parameter will become the default for the object's `__call__` method. Default is “linear”.
- `bounds_error` ([bool, optional]): If True, when interpolated values are requested outside of the domain of the input data, a ValueError is raised. If False, then `fill_value` is used.
- `fill_value` ([number, optional]): If provided, the value to use for points outside of the interpolation domain. If None, values outside the domain are extrapolated.

See also:

NearestNDInterpolator

Nearest neighbor interpolation on unstructured data in N dimensions
**LinearNDInterpolator**

Piecewise linear interpolant on unstructured data in N dimensions

**Notes**

Contrary to LinearNDInterpolator and NearestNDInterpolator, this class avoids expensive triangulation of the input data by taking advantage of the regular grid structure.

If any of *points* have a dimension of size 1, linear interpolation will return an array of *nan* values. Nearest-neighbor interpolation will work as usual in this case.

New in version 0.14.

**References**

[1], [2], [3]

**Examples**

Evaluate a simple example function on the points of a 3-D grid:

```python
>>> from scipy.interpolate import RegularGridInterpolator
>>> def f(x, y, z):
...     return 2 * x**3 + 3 * y**2 - z
>>> x = np.linspace(1, 4, 11)
>>> y = np.linspace(4, 7, 22)
>>> z = np.linspace(7, 9, 33)
>>> xg, yg, zg = np.meshgrid(x, y, z, indexing='ij', sparse=True)
>>> data = f(xg, yg, zg)
```

data is now a 3-D array with \( \text{data}[i,j,k] = f(x[i], y[j], z[k]) \). Next, define an interpolating function from this data:

```python
>>> my_interpolating_function = RegularGridInterpolator((x, y, z), data)
```

Evaluate the interpolating function at the two points \( (x,y,z) = (2.1, 6.2, 8.3) \) and \( (3.3, 5.2, 7.1) \):

```python
>>> pts = np.array([[2.1, 6.2, 8.3], [3.3, 5.2, 7.1]])
>>> my_interpolating_function(pts)
array([ 125.80469388, 146.30069388])
```

which is indeed a close approximation to \( [f(2.1, 6.2, 8.3), f(3.3, 5.2, 7.1)] \).
Methods

```
__call__(xi[, method]) Interpolation at coordinates
```

`scipy.interpolate.RegularGridInterpolator.__call__`

RegularGridInterpolator.__call__(xi, method=None)
Interpolation at coordinates

**Parameters**

- **xi** : [ndarray of shape (..., ndim)] The coordinates to sample the gridded data at
- **method** : [str] The method of interpolation to perform. Supported are “linear” and “nearest”.

`scipy.interpolate.RectBivariateSpline`

```class scipy.interpolate.RectBivariateSpline(x, y, z, bbox=[None, None, None, None], kx=3, ky=3, s=0)```

Bivariate spline approximation over a rectangular mesh.
Can be used for both smoothing and interpolating data.

**Parameters**

- **x**, **y** : [array_like] 1-D arrays of coordinates in strictly ascending order.
- **z** : [array_like] 2-D array of data with shape (x.size, y.size).
- **bbox** : [array_like, optional] Sequence of length 4 specifying the boundary of the rectangular approximation domain. By default, bbox=[min(x), max(x), min(y), max(y)].
- **kx, ky** : [ints, optional] Degrees of the bivariate spline. Default is 3.
- **s** : [float, optional] Positive smoothing factor defined for estimation condition:
  \[ \sum (z[i] - f(x[i], y[i]))^2, \text{axis}=0 \] <= s where f is a spline function. Default is s=0, which is for interpolation.

```python
scipy.interpolate.RectBivariateSpline.__call__
```

RectBivariateSpline.__call__ (x, y, dx=0, dy=0, grid=True)

Evaluate the spline or its derivatives at given positions.

**Parameters**

- **x, y**
  - [array_like] Input coordinates.
  - If grid is False, evaluate the spline at points (x[i], y[i]), i=0, ..., len(x)-1. Standard NumPy broadcasting is obeyed.
  - If grid is True: evaluate spline at the grid points defined by the coordinate arrays x, y. The arrays must be sorted to increasing order.
  - Note that the axis ordering is inverted relative to the output of meshgrid.

- **dx**
  - [int] Order of x-derivative
  - New in version 0.14.0.

- **dy**
  - [int] Order of y-derivative
  - New in version 0.14.0.

- **grid**
  - [bool] Whether to evaluate the results on a grid spanned by the input arrays, or at points specified by the input arrays.
  - New in version 0.14.0.
scipy.interpolate.RectBivariateSpline.ev

RectBivariateSpline.ev(xi, yi, dx=0, dy=0)
Evaluated the spline at points

Returns the interpolated value at (xi[i], yi[i]), i=0,...,len(xi)-1.

Parameters

- **xi, yi** [array_like] Input coordinates. Standard Numpy broadcasting is obeyed.
- **dx** [int, optional] Order of x-derivative
  New in version 0.14.0.
- **dy** [int, optional] Order of y-derivative
  New in version 0.14.0.

scipy.interpolate.RectBivariateSpline.get_coeffs

RectBivariateSpline.get_coeffs()
Return spline coefficients.

scipy.interpolate.RectBivariateSpline.get_knots

RectBivariateSpline.get_knots()
Return a tuple (tx,ty) where tx,ty contain knots positions of the spline with respect to x-, y-variable, respectively. The position of interior and additional knots are given as t[k+1:-k-1] and t[:k+1]=b, t[-k-1:]=e, respectively.

scipy.interpolate.RectBivariateSpline.get_residual

RectBivariateSpline.get_residual()
Return weighted sum of squared residuals of the spline approximation: sum ((w[i]*(z[i]-s(x[i],y[i])))**2, axis=0)

scipy.interpolate.RectBivariateSpline.integral

RectBivariateSpline.integral(xa, xb, ya, yb)
Evaluate the integral of the spline over area [xa,xb] x [ya,yb].

Parameters

- **xa, xb** [float] The end-points of the x integration interval.
- **ya, yb** [float] The end-points of the y integration interval.

Returns

- **integ** [float] The value of the resulting integral.

- scipy.ndimage.map_coordinates

Tensor product polynomials:

3.3. API definition
NdPPoly(c, x[, extrapolate])

Piecewise tensor product polynomial

scipy.interpolate.NdPPoly

class scipy.interpolate.NdPPoly(c, x, extrapolate=None)

Piecewise tensor product polynomial

The value at point \( x' = (x', y', z', \ldots) \) is evaluated by first computing the interval indices \( i \) such that:

\[
\begin{align*}
    x[0][i[0]] & \leq x' < x[0][i[0]+1] \\
    x[1][i[1]] & \leq y' < x[1][i[1]+1] \\
    & \ldots
\end{align*}
\]

and then computing:

\[
S = \sum c[k0-m0-1,\ldots,kn-mn-1,i[0],\ldots,i[n]] \times (x[0][i[0]] - x[0][i[0]+1])^{m0} \\
    \times \ldots \\
    \times (x[n][i[n]] - x[n][i[n]+1])^{mn} \\
    \text{for } m0 \text{ in range}(k[0]+1) \\
    \ldots \\
    \text{for } mn \text{ in range}(k[n]+1)
\]

where \( k[j] \) is the degree of the polynomial in dimension \( j \). This representation is the piecewise multivariate power basis.

Parameters

- **c** : [ndarray, shape \((k0,\ldots,kn,m0,\ldots,mn,\ldots)\)] Polynomial coefficients, with polynomial order \( kj \) and \( mj+1 \) intervals for each dimension \( j \).
- **x** : [ndim-tuple of ndarrays, shapes \((mj+1,)\)] Polynomial breakpoints for each dimension. These must be sorted in increasing order.
- **extrapolate** : [bool, optional] Whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs. Default: True.

See also:

PPoly

piecewise polynomials in 1D

Notes

High-order polynomials in the power basis can be numerically unstable.

Attributes

- **x** : [tuple of ndarrays] Breakpoints.
- **c** : [ndarray] Coefficients of the polynomials.

### scipy.interpolate.NdPPoly.__call__

**NdPPoly.__call__(x, nu=None, extrapolate=None)**

Evaluate the piecewise polynomial or its derivative

**Parameters**

- **x**
  - [array-like] Points to evaluate the interpolant at.
- **nu**
  - [tuple, optional] Orders of derivatives to evaluate. Each must be non-negative.
- **extrapolate**
  - [bool, optional] Whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs.

**Returns**

- **y**
  - [array-like] Interpolated values. Shape is determined by replacing the interpolation axis in the original array with the shape of x.

**Notes**

Derivatives are evaluated piecewise for each polynomial segment, even if the polynomial is not differentiable at the breakpoints. The polynomial intervals are considered half-open, \([a, b)\), except for the last interval which is closed \([a, b]\).

### scipy.interpolate.NdPPoly.derivative

**NdPPoly.derivative(nu)**

Construct a new piecewise polynomial representing the derivative.

**Parameters**

- **nu**
  - [ndim-tuple of int] Order of derivatives to evaluate for each dimension. If negative, the antiderivative is returned.

**Returns**

- **pp**
  - [NdPPoly] Piecewise polynomial of orders \((k[0] - nu[0], \ldots, k[n] - nu[n])\) representing the derivative of this polynomial.
Notes

Derivatives are evaluated piecewise for each polynomial segment, even if the polynomial is not differentiable at the breakpoints. The polynomial intervals in each dimension are considered half-open, \([a, b)\), except for the last interval which is closed \([a, b]\).

scipy.interpolate.NdPPoly.antiderivative

\texttt{NdPPoly.antiderivative}(\texttt{nu})

Construct a new piecewise polynomial representing the antiderivative.

Antiderivative is also the indefinite integral of the function, and derivative is its inverse operation.

\textbf{Parameters}

- \texttt{nu} \texttt{[ndim-tuple of int]} Order of derivatives to evaluate for each dimension. If negative, the derivative is returned.

\textbf{Returns}

- \texttt{pp} \texttt{[PPoly]} Piecewise polynomial of order \(k2 = k + n\) representing the antiderivative of this polynomial.

\textbf{Notes}

The antiderivative returned by this function is continuous and continuously differentiable to order \(n-1\), up to floating point rounding error.

scipy.interpolate.NdPPoly.integrate

\texttt{NdPPoly.integrate}(\texttt{ranges}, \texttt{extrapolate=None})

Compute a definite integral over a piecewise polynomial.

\textbf{Parameters}

- \texttt{ranges} \texttt{[ndim-tuple of 2-tuples float]} Sequence of lower and upper bounds for each dimension, \([(a[0], b[0]), \ldots, (a[n-1], b[n-1])] \)
- \texttt{extrapolate} \texttt{[bool, optional]} Whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs.

\textbf{Returns}

- \texttt{ig} \texttt{[array_like]} Definite integral of the piecewise polynomial over \([a[0], b[0]] x \ldots x [a[n-1], b[n-1]]\)
scipy.interpolate.NdPPoly.integrate_1d

NdPPoly.integrate_1d(a, b, axis, extrapolate=None)
Compute NdPPoly representation for one dimensional definite integral
The result is a piecewise polynomial representing the integral:

\[ p(y, z, ...) = \int_a^b dx \, p(x, y, z, ...) \]

where the dimension integrated over is specified with the axis parameter.

Parameters

- **a, b** [float] Lower and upper bound for integration.
- **axis** [int] Dimension over which to compute the 1-D integrals
- **extrapolate** [bool, optional] Whether to extrapolate to out-of-bounds points based on first and last intervals, or to return NaNs.

Returns

- **ig** [NdPPoly or array-like] Definite integral of the piecewise polynomial over \([a, b]\). If the polynomial was 1D, an array is returned, otherwise, an NdPPoly object.

scipy.interpolate.NdPPoly.construct_fast

classmethod NdPPoly.construct_fast(c, x, extrapolate=None)
Construct the piecewise polynomial without making checks.
Takes the same parameters as the constructor. Input arguments \(c\) and \(x\) must be arrays of the correct shape and type. The \(c\) array can only be of dtypes float and complex, and \(x\) array must have dtype float.

1-D Splines

| B spline(t, c, k[, extrapolate, axis]) | Univariate spline in the B-spline basis. |
| make_interp_spline(x, y[, k, t, bc_type, ...]) | Compute the (coefficients of) interpolating B-spline. |
| make_lsq_spline(x, y, t[, k, w, axis, ...]) | Compute the (coefficients of) an LSQ B-spline. |

scipy.interpolate.BSpline

class scipy.interpolate.BSpline(t, c, k, extrapolate=True, axis=0)
Univariate spline in the B-spline basis.

\[
S(x) = \sum_{j=0}^{n-1} c_j B_{j,k}(x)
\]

where \(B_{j,k}\) are B-spline basis functions of degree \(k\) and knots \(t\).

Parameters

- **t** [ndarray, shape (n+\(k+1\),)] knots
- **c** [ndarray, shape (\(\geq n, \ldots\)) spline coefficients
- **k** [int] B-spline degree
extrapolate
[bool or ‘periodic’, optional] whether to extrapolate beyond the base interval, t[k] .. t[n], or to return nans. If True, extrapolates the first and last polynomial pieces of b-spline functions active on the base interval. If ‘periodic’, periodic extrapolation is used. Default is True.

axis [int, optional] Interpolation axis. Default is zero.

Notes
B-spline basis elements are defined via

\[ B_{i,k}(x) = \frac{x-t_i}{t_{i+k}-t_i}B_{i,k-1}(x) + \frac{t_{i+k+1}-x}{t_{i+k+1}-t_{i+1}}B_{i+1,k-1}(x) \]

Implementation details
• At least \( k+1 \) coefficients are required for a spline of degree \( k \), so that \( n \geq k+1 \). Additional coefficients, \( c[j] \) with \( j > n \), are ignored.
• B-spline basis elements of degree \( k \) form a partition of unity on the base interval, \( t[k] \leq x \leq t[n] \).

References
[1],[2]

Examples
Translating the recursive definition of B-splines into Python code, we have:

```python
>>> def B(x, k, i, t):
...     if k == 0:
...         return 1.0 if t[i] <= x < t[i+1] else 0.0
...     if t[i+k] == t[i]:
...         c1 = 0.0
...     else:
...         c1 = (x - t[i])/(t[i+k] - t[i]) * B(x, k-1, i, t)
...     if t[i+k+1] == t[i+1]:
...         c2 = 0.0
...     else:
...         c2 = (t[i+k+1] - x)/(t[i+k+1] - t[i+1]) * B(x, k-1, i+1, t)
...     return c1 + c2
```

```python
>>> def bspline(x, t, c, k):
...     n = len(t) - k - 1
...     assert (n >= k+1) and (len(c) >= n)
...     return sum(c[i] * B(x, k, i, t) for i in range(n))
```

Note that this is an inefficient (if straightforward) way to evaluate B-splines — this spline class does it in an equivalent, but much more efficient way.

Here we construct a quadratic spline function on the base interval \( 2 \leq x \leq 4 \) and compare with the naive way of evaluating the spline:
```python
>>> from scipy.interpolate import BSpline
>>> k = 2
>>> t = [0, 1, 2, 3, 4, 5, 6]
>>> c = [-1, 2, 0, -1]
>>> spl = BSpline(t, c, k)
>>> spl(2.5)
array(1.375)
>>> bspline(2.5, t, c, k)
1.375
```

Note that outside of the base interval results differ. This is because `BSpline` extrapolates the first and last polynomial pieces of B-spline functions active on the base interval.

```python
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> xx = np.linspace(1.5, 4.5, 50)
>>> ax.plot(xx, [bspline(x, t, c, k) for x in xx], 'r-', lw=3, label='naive')
>>> ax.plot(xx, spl(xx), 'b-', lw=4, alpha=0.7, label='BSpline')
>>> ax.grid(True)
>>> ax.legend(loc='best')
>>> plt.show()
```

**Attributes**

- `t` [ndarray] knot vector
- `c` [ndarray] spline coefficients
- `k` [int] spline degree
- `extrapolate` [bool] If True, extrapolates the first and last polynomial pieces of b-spline functions active on the base interval.
- `axis` [int] Interpolation axis.
- `tck` [tuple] Equivalent to `(self.t, self.c, self.k)` (read-only).

#### scipy.interpolate.BSpline.__call__

**BSpline.__call__(x, nu=0, extrapolate=None)**

Evaluate a spline function.

**Parameters**

- `x` [array_like] points to evaluate the spline at.
- `nu: int, optional` derivative to evaluate (default is 0).
- `extrapolate` [bool or ‘periodic’, optional] whether to extrapolate based on the first and last intervals or return nans. If ‘periodic’, periodic extrapolation is used. Default is `self.extrapolate`.

**Returns**

- `y` [array_like] Shape is determined by replacing the interpolation axis in the coefficient array with the shape of `x`.

#### scipy.interpolate.BSpline.basis_element

**classmethod BSpline.basis_element(t, extrapolate=True)**

Return a B-spline basis element $B(x | t[0], ..., t[k+1])$.

**Parameters**

- `t` [ndarray, shape (k+2,)] internal knots
- `extrapolate` [bool or ‘periodic’, optional] whether to extrapolate beyond the base interval, $t[0]$ .. $t[k+1]$, or to return nans. If ‘periodic’, periodic extrapolation is used. Default is True.

**Returns**

- `basis_element` [callable] A callable representing a B-spline basis element for the knot vector $t$. 
Notes

The degree of the B-spline, \( k \), is inferred from the length of \( t \) as \( \text{len}(t) - 2 \). The knot vector is constructed by appending and prepending \( k+1 \) elements to internal knots \( t \).

Examples

Construct a cubic B-spline:

```python
>>> from scipy.interpolate import BSpline
>>> b = BSpline.basis_element([0, 1, 2, 3, 4])
>>> k = b.k
>>> b.t[k:-k]
array([ 0., 1., 2., 3., 4.])
>>> k
3
```

Construct a quadratic B-spline on \([0, 1, 1, 2]\), and compare to its explicit form:

```python
>>> t = [-1, 0, 1, 1, 2]
>>> b = BSpline.basis_element(t[1:])
>>> def f(x):
...     return np.where(x < 1, x*x, (2. - x)**2)

>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> x = np.linspace(0, 2, 51)
>>> ax.plot(x, b(x), 'g', lw=3)
>>> ax.plot(x, f(x), 'r', lw=8, alpha=0.4)
>>> ax.grid(True)
>>> plt.show()
```

![Plot of cubic and quadratic B-spline](image.png)
scipy.interpolate.BSpline.derivative

BSpline.derivative(nu=1)
Return a B-spline representing the derivative.

Parameters

nu [int, optional] Derivative order. Default is 1.

Returns

b [BSpline object] A new instance representing the derivative.

See also:

splder, splantider

scipy.interpolate.BSpline.antiderivative

BSpline.antiderivative(nu=1)
Return a B-spline representing the antiderivative.

Parameters

nu [int, optional] Antiderivative order. Default is 1.

Returns

b [BSpline object] A new instance representing the antiderivative.

See also:

splder, splantider

Notes

If antiderivative is computed and self.extrapolate='periodic', it will be set to False for the returned instance. This is done because the antiderivative is no longer periodic and its correct evaluation outside of the initially given x interval is difficult.

scipy.interpolate.BSpline.integrate

BSpline.integrate(a, b, extrapolate=None)
Compute a definite integral of the spline.

Parameters

a [float] Lower limit of integration.
b [float] Upper limit of integration.
extrapolate [bool or 'periodic', optional] whether to extrapolate beyond the base interval, t[k] . t[-k-1], or take the spline to be zero outside of the base interval. If ‘periodic’, periodic extrapolation is used. If None (default), use self.extrapolate.

Returns

I [array_like] Definite integral of the spline over the interval [a, b].
Examples

Construct the linear spline \( x \) if \( x < 1 \) else \( 2 - x \) on the base interval \([0, 2]\), and integrate it

```python
>>> from scipy.interpolate import BSpline
>>> b = BSpline.basis_element([0, 1, 2])
>>> b.integrate(0, 1)
array(0.5)
```

If the integration limits are outside of the base interval, the result is controlled by the `extrapolate` parameter

```python
>>> b.integrate(-1, 1)
array(0.0)
>>> b.integrate(-1, 1, extrapolate=False)
array(0.5)
```

```python
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> ax.grid(True)
>>> ax.axvline(0, c='r', lw=5, alpha=0.5)  # base interval
>>> ax.axvline(2, c='r', lw=5, alpha=0.5)
>>> xx = [-1, 1, 2]
>>> ax.plot(xx, b(xx))
>>> plt.show()
```
scipy.interpolate.BSpline.construct_fast

classmethod BSpline.construct_fast(t, c, k, extrapolate=True, axis=0)
Construct a spline without making checks.
Accepts same parameters as the regular constructor. Input arrays t and c must of correct shape and dtype.

scipy.interpolate.BSpline.design_matrix

classmethod BSpline.design_matrix(x, t, k)
Returns a design matrix as a CSR format sparse array.

Parameters

- **x**
  [array_like, shape (n,)] Points to evaluate the spline at.
- **t**
  [array_like, shape (nt,)] Sorted 1D array of knots.
- **k**
  [int] B-spline degree.

Returns
design_matrix
[csr_array object] Sparse matrix in CSR format where in each row all the basis elements are evaluated at the certain point (first row - x[0], …, last row - x[-1]).

Notes

New in version 1.8.0.

In each row of the design matrix all the basis elements are evaluated at the certain point (first row - x[0], …, last row - x[-1]).

nt is a length of the vector of knots: as far as there are nt - k - 1 basis elements, nt should be not less than 2 * k + 2 to have at least k + 1 basis element.

Out of bounds x raises a ValueError.

Examples

Construct a design matrix for a B-spline

```python
>>> from scipy.interpolate import make_interp_spline, BSpline
>>> x = np.linspace(0, np.pi * 2, 4)
>>> y = np.sin(x)
>>> k = 3
>>> bspl = make_interp_spline(x, y, k=k)
>>> design_matrix = bspl.design_matrix(x, bspl.t, k)
>>> design_matrix.toarray()
[[1. , 0. , 0. , 0. ],
 [0.2962963 , 0.44444444, 0.22222222, 0.03703704],
 [0.03703704, 0.22222222, 0.44444444, 0.2962963 ],
 [0. , 0. , 0. , 1. ]]```

Construct a design matrix for some vector of knots
```python
>>> k = 2
>>> t = [-1, 0, 1, 2, 3, 4, 5, 6]
>>> x = [1, 2, 3, 4]
>>> design_matrix = BSpline.design_matrix(x, t, k).toarray()
>>> design_matrix
[[0.5, 0.5, 0., 0., 0.],
 [0., 0.5, 0.5, 0., 0.],
 [0., 0.5, 0.5, 0., 0.],
 [0., 0., 0.5, 0.5, 0.]]
```

This result is equivalent to the one created in the sparse format

```python
>>> c = np.eye(len(t) - k - 1)
>>> design_matrix_gh = BSpline(t, c, k)(x)
>>> np.allclose(design_matrix, design_matrix_gh, atol=1e-14)
True
```

### scipy.interpolate.BSpline.from_power_basis

**classmethod** `BSpline.from_power_basis`(pp, bc_type='not-a-knot')

Construct a polynomial in the B-spline basis from a piecewise polynomial in the power basis.

For now, accepts `CubicSpline` instances only.

**Parameters**
- **pp** `[CubicSpline]` A piecewise polynomial in the power basis, as created by `CubicSpline`
- **bc_type** `[string, optional]` Boundary condition type as in `CubicSpline`: one of the not-a-knot, natural, clamped, or periodic. Necessary for construction an instance of `BSpline` class. Default is not-a-knot.

**Returns**
- **b** `[BSpline object]` A new instance representing the initial polynomial in the B-spline basis.

**Notes**

New in version 1.8.0.

Accepts only `CubicSpline` instances for now.

The algorithm follows from differentiation the Marsden’s identity [1]: each of coefficients of spline interpolation function in the B-spline basis is computed as follows:

\[
c_j = \sum_{m=0}^{k} \frac{(k-m)!}{k!} c_{m,i} (-1)^{k-m} D^m p_{j,k}(x_i)
\]

- \(c_{m,i}\) - a coefficient of `CubicSpline`, \(D^m p_{j,k}(x_i)\) - an m-th derivative of a dual polynomial in \(x_i\).
- \(k\) always equals 3 for now.

First \(n - 2\) coefficients are computed in \(x_i = x_j\), e.g.

\[
c_1 = \sum_{m=0}^{k} \frac{(k-1)!}{k!} c_{m,1} D^m p_{j,3}(x_1)
\]
Last nod + 2 coefficients are computed in \(x[-2]\), nod - number of derivatives at the ends.

For example, consider \(x = [0, 1, 2, 3, 4]\), \(y = [1, 1, 1, 1]\) and bc_type = natural

The coefficients of CubicSpline in the power basis:

\[\begin{pmatrix}
0, 0, 0, 0, 0, 0 \\
0, 0, 0, 0, 0, 0 \\
0, 0, 0, 0, 0, 0 \\
1, 1, 1, 1, 1, 1
\end{pmatrix}\]

The knot vector: \(t = [0, 0, 0, 0, 1, 2, 3, 4, 4, 4]\)

In this case

\[c_j = \frac{0!}{k!} c_{3,j} k! = c_{3,j} = 1, j = 0, ..., 6\]

References

[1]

scipy.interpolate.make_interp_spline

\[\text{scipy.interpolate.make_interp_spline}(x, y, k=3, t=None, bc_type=None, axis=0, check_finite=True)\]

Compute the (coefficients of) interpolating B-spline.

Parameters

- **x**: [array_like, shape (n,)] Abscissas.
- **y**: [array_like, shape (n, ...)] Ordinates.
- **k**: [int, optional] B-spline degree. Default is cubic, k=3.
- **t**: [array_like, shape (nt + k + 1,), optional.] Knots. The number of knots needs to agree with the number of datapoints and the number of derivatives at the edges. Specifically, \(nt - n\) must equal \(len(deriv_l) + len(deriv_r)\).
- **bc_type**: [2-tuple or None] Boundary conditions. Default is None, which means choosing the boundary conditions automatically. Otherwise, it must be a length-two tuple where the first element sets the boundary conditions at \(x[0]\) and the second element sets the boundary conditions at \(x[-1]\). Each of these must be an iterable of pairs (order, value) which gives the values of derivatives of specified orders at the given edge of the interpolation interval. Alternatively, the following string aliases are recognized:
  - "clamped": The first derivatives at the ends are zero. This is equivalent to bc_type=((1, 0.0)), 
  - "natural": The second derivatives at ends are zero. This is equivalent to bc_type=((2, 0.0)), 
  - "not-a-knot" (default): The first and second segments are the same polynomial. This is equivalent to having bc_type=None.
  - "periodic": The values and the first \(k-1\) derivatives at the ends are equivalent.
- **axis**: [int, optional] Interpolation axis. Default is 0.
- **check_finite**: [bool, optional] Whether to check that the input arrays contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs. Default is True.

Returns

- **b**: [a BSpline object of the degree \(k\) and with knots \(t\).]

BSpline

base class representing the B-spline objects
CubicSpline

a cubic spline in the polynomial basis

make_lsq_spline

a similar factory function for spline fitting

UnivariateSpline

a wrapper over FITPACK spline fitting routines

splrep

a wrapper over FITPACK spline fitting routines

Examples

Use cubic interpolation on Chebyshev nodes:

```python
>>> def cheb_nodes(N):
...     jj = 2.*np.arange(N) + 1
...     x = np.cos(np.pi * jj / 2 / N)[::1]
...     return x

>>> x = cheb_nodes(20)
>>> y = np.sqrt(1 - x**2)

>>> from scipy.interpolate import BSpline, make_interp_spline
>>> b = make_interp_spline(x, y)
>>> np.allclose(b(x), y)
True
```

Note that the default is a cubic spline with a not-a-knot boundary condition

```python
>>> b.k
3
```

Here we use a ‘natural’ spline, with zero 2nd derivatives at edges:

```python
>>> l, r = [(2, 0.0)], [(2, 0.0)]
>>> b_n = make_interp_spline(x, y, bc_type=(l, r))  # or, bc_type="natural"
>>> np.allclose(b_n(x), y)
True
>>> x0, x1 = x[0], x[-1]
>>> np.allclose([b_n(x0, 2), b_n(x1, 2)], [0, 0])
True
```

Interpolation of parametric curves is also supported. As an example, we compute a discretization of a snail curve in polar coordinates

```python
>>> phi = np.linspace(0, 2.*np.pi, 40)
>>> r = 0.3 + np.cos(phi)
>>> x, y = r*np.cos(phi), r*np.sin(phi)  # convert to Cartesian coordinates
```
Build an interpolating curve, parameterizing it by the angle

```python
>>> from scipy.interpolate import make_interp_spline
>>> spl = make_interp_spline(phi, np.c_[x, y])
```

Evaluate the interpolant on a finer grid (note that we transpose the result to unpack it into a pair of x- and y-arrays)

```python
>>> phi_new = np.linspace(0, 2*np.pi, 100)
>>> x_new, y_new = spl(phi_new).T
```

Plot the result

```python
>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'o')
>>> plt.plot(x_new, y_new, '-')
>>> plt.show()
```

Build a B-spline curve with 2 dimensional y

```python
>>> x = np.linspace(0, 2*np.pi, 10)
>>> y = np.array([np.sin(x), np.cos(x)])
```

Periodic condition is satisfied because y coordinates of points on the ends are equivalent

```python
>>> ax = plt.axes(projection='3d')
>>> xx = np.linspace(0, 2*np.pi, 100)
>>> bspl = make_interp_spline(x, y, k=5, bc_type='periodic', axis=1)
>>> ax.plot3D(xx, *bspl(xx))
>>> ax.scatter3D(x, 'y', color='red')
>>> plt.show()
```
scipy.interpolate.make_lsq_spline

scipy.interpolate.make_lsq_spline(x, y, t, k=3, w=None, axis=0, check_finite=True)

Compute the (coefficients of) an LSQB-spline.

The result is a linear combination

\[ S(x) = \sum_j c_j B_j(x; t) \]

of the B-spline basis elements, \( B_j(x; t) \), which minimizes

\[ \sum_j \left( w_j \times (S(x_j) - y_j) \right)^2 \]

**Parameters**

- **x** [array_like, shape (m,)] Abscissas.
- **y** [array_like, shape (m, ...)] Ordinates.
- **t** [array_like, shape (n + k + 1,)] Knots. Knots and data points must satisfy Schoenberg-Whitney conditions.
- **k** [int, optional] B-spline degree. Default is cubic, \( k=3 \).
- **w** [array_like, shape (n,), optional] Weights for spline fitting. Must be positive. If None, then weights are all equal. Default is None.
- **axis** [int, optional] Interpolation axis. Default is zero.
- **check_finite** [bool, optional] Whether to check that the input arrays contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs. Default is True.

**Returns**

- **b** [a BSpline object of the degree \( k \) with knots \( t \).]

**See also:**

BSpline

base class representing the B-spline objects
make_interp_spline

a similar factory function for interpolating splines

LSQUnivariateSpline

a FITPACK-based spline fitting routine

splrep

a FITPACK-based fitting routine

Notes

The number of data points must be larger than the spline degree \( k \).

Knots \( t \) must satisfy the Schoenberg-Whitney conditions, i.e., there must be a subset of data points \( x[j] \) such that \( t[j] < x[j] < t[j+k+1], \) for \( j=0, 1, \ldots, n-k-2. \)

Examples

Generate some noisy data:

```python
>>> rng = np.random.default_rng()
>>> x = np.linspace(-3, 3, 50)
>>> y = np.exp(-x**2) + 0.1 * rng.standard_normal(50)
```

Now fit a smoothing cubic spline with a pre-defined internal knots. Here we make the knot vector \((k+1)\)-regular by adding boundary knots:

```python
>>> from scipy.interpolate import make_lsq_spline, BSpline
>>> t = [-1, 0, 1]
>>> k = 3
>>> t = np.r_[(x[0],)]**(k+1),
... t,
... (x[-1],)**(k+1)]
>>> spl = make_lsq_spline(x, y, t, k)
```

For comparison, we also construct an interpolating spline for the same set of data:

```python
>>> from scipy.interpolate import make_interp_spline
>>> spl_i = make_interp_spline(x, y)
```

Plot both:

```python
>>> import matplotlib.pyplot as plt
>>> xs = np.linspace(-3, 3, 100)
>>> plt.plot(x, y, 'ro', ms=5)
>>> plt.plot(xs, spl(xs), 'g-', lw=3, label='LSQ spline')
>>> plt.plot(xs, spl_i(xs), 'b-', lw=3, alpha=0.7, label='interp spline')
>>> plt.legend(loc='best')
>>> plt.show()
```

NaN handling: If the input arrays contain \texttt{nan} values, the result is not useful since the underlying spline fitting routines cannot deal with \texttt{nan}. A workaround is to use zero weights for not-a-number data points:
```python
>>> y[8] = np.nan
>>> w = np.isnan(y)
>>> y[w] = 0.
>>> tck = make_lsq_spline(x, y, t, w=~w)
```

Notice the need to replace a `nan` by a numerical value (precise value does not matter as long as the corresponding weight is zero.)

Functional interface to FITPACK routines:

- `splrep(x, y[, w, xb, xe, k, task, s, t, ...])` Find the B-spline representation of a 1-D curve.
- `splprep(x[, w, u, ub, ue, k, task, s, t, ...])` Find the B-spline representation of an N-D curve.
- `splev(x, tck[, der, ext])` Evaluate a B-spline or its derivatives.
- `splint(a, b, tck[, full_output])` Evaluate the definite integral of a B-spline between two given points.
- `sproot(tck[, mest])` Find the roots of a cubic B-spline.
- `spalde(x, tck)` Evaluate all derivatives of a B-spline.
- `splder(tck[, n])` Compute the spline representation of the derivative of a given spline.
- `splantider(tck[, n])` Compute the spline for the antiderivative (integral) of a given spline.
- `insert(x, tck[, m, per])` Insert knots into a B-spline.

**scipy.interpolate.splrep**

`scipy.interpolate.splrep(x, y, w=None, xb=None, xe=None, k=3, task=0, s=None, t=None, full_output=0, per=0, quiet=1)`

Find the B-spline representation of a 1-D curve.

Given the set of data points `(x[i], y[i])` determine a smooth spline approximation of degree `k` on the interval `xb <= x <= xe`.

**Parameters**

- `x, y` [array_like] The data points defining a curve `y = f(x)`.
w [array_like, optional] Strictly positive rank-1 array of weights the same length as x and y. The weights are used in computing the weighted least-squares spline fit. If the errors in the y values have standard-deviation given by the vector d, then w should be 1/d. Default is ones(len(x)).

xb, xe [float, optional] The interval to fit. If None, these default to x[0] and x[-1] respectively.

k [int, optional] The degree of the spline fit. It is recommended to use cubic splines. Even values of k should be avoided especially with small s values. 1 <= k <= 5

task [{1, 0, -1}, optional] If task==0 find t and c for a given smoothing factor, s. If task==1 find t and c for another value of the smoothing factor, s. There must have been a previous call with task=0 or task=1 for the same set of data (t will be stored an used internally) If task=-1 find the weighted least square spline for a given set of knots, t. These should be interior knots as knots on the ends will be added automatically.

s [float, optional] A smoothing condition. The amount of smoothness is determined by satisfying the conditions: sum((w * (y - g))**2, axis=0) <= s where g(x) is the smoothed interpolation of (x,y). The user can use s to control the tradeoff between closeness and smoothness of fit. Larger s means more smoothing while smaller values of s indicate less smoothing. Recommended values of s depend on the weights, w. If the weights represent the inverse of the standard-deviation of y, then a good s value should be found in the range (m-sqrt(2*m),m+sqrt(2*m)) where m is the number of datapoints in x, y, and w. default : s=m-sqrt(2*m)if weights are supplied. s=0.0 (interpolating) if no weights are supplied.

t [array_like, optional] The knots needed for task=-1. If given then task is automatically set to -1.

full_output [bool, optional] If non-zero, then return optional outputs.

per [bool, optional] If non-zero, data points are considered periodic with period x[m-1] - x[0] and a smooth periodic spline approximation is returned. Values of y[m-1] and w[m-1] are not used.

quiet [bool, optional] Non-zero to suppress messages. This parameter is deprecated; use standard Python warning filters instead.

Returns

tck [tuple] A tuple (t,c,k) containing the vector of knots, the B-spline coefficients, and the degree of the spline.

fp [array, optional] The weighted sum of squared residuals of the spline approximation.

ier [int, optional] An integer flag about splrep success. Success is indicated if ier<=0. If ier in [1,2,3] an error occurred but was not raised. Otherwise an error is raised.

msg [str, optional] A message corresponding to the integer flag, ier.

See also:

UnivariateSpline, BivariateSpline
splprep, splev, sproot, splalde, splint
bisplrep, bisplev
BSpline
make_interp_spline
Notes

See `splev` for evaluation of the spline and its derivatives. Uses the FORTRAN routine `curfit` from FITPACK.

The user is responsible for assuring that the values of \( x \) are unique. Otherwise, `splrep` will not return sensible results.

If provided, knots \( t \) must satisfy the Schoenberg-Whitney conditions, i.e., there must be a subset of data points \( x[j] \) such that \( t[j] < x[j] < t[j+k+1] \), for \( j = 0, 1, \ldots, n-k-2 \).

This routine zero-pads the coefficients array \( c \) to have the same length as the array of knots \( t \) (the trailing \( k+1 \) coefficients are ignored by the evaluation routines, `splev` and `BSpline`). This is in contrast with `splprep`, which does not zero-pad the coefficients.

Examples

You can interpolate 1-D points with a B-spline curve. Further examples are given in *in the tutorial*.

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.interpolate import splev, splrep
>>> x = np.linspace(0, 10, 10)
>>> y = np.sin(x)
>>> spl = splrep(x, y)
>>> x2 = np.linspace(0, 10, 200)
>>> y2 = splev(x2, spl)
>>> plt.plot(x, y, 'o', x2, y2)
>>> plt.show()
```

![B-spline interpolation example](image-url)
**scipy.interpolate.splprep**

`scipy.interpolate.splprep(x, w=None, u=None, ub=None, ue=None, k=3, task=0, s=None, t=None,
full_output=0, nest=None, per=0, quiet=1)`

Find the B-spline representation of an N-D curve.

Given a list of N rank-1 arrays, `x`, which represent a curve in N-D space parametrized by `u`, find a smooth approximating spline curve `g(u)`. Uses the FORTRAN routine parcuf from FITPACK.

**Parameters**

- **x**
  - [array_like] A list of sample vector arrays representing the curve.

- **w**
  - [array_like, optional] Strictly positive rank-1 array of weights the same length as `x[0]`. The weights are used in computing the weighted least-squares spline fit. If the errors in the `x` values have standard-deviation given by the vector `d`, then `w` should be `1/d`. Default is `ones(len(x[0]))`.

- **u**
  - [array_like, optional] An array of parameter values. If not given, these values are calculated automatically as `M = len(x[0])`, where
    - `v[0] = 0`
    - `v[i] = v[i-1] + distance(x[i], x[i-1])`
    - `u[i] = v[i] / v[M-1]`

- **ub, ue**
  - [int, optional] The end-points of the parameters interval. Defaults to `u[0]` and `u[-1]`.

- **k**
  - [int, optional] Degree of the spline. Cubic splines are recommended. Even values of `k` should be avoided especially with a small `s`-value. `1 <= k <= 5`, default is 3.

- **task**
  - [int, optional] If `task==0` (default), find `t` and `c` for a given smoothing factor, `s`. If `task==1`, find `t` and `c` for another value of the smoothing factor, `s`. There must have been a previous call with `task==0` or `task==1` for the same set of data. If `task=-1` find the weighted least square spline for a given set of knots, `t`.

- **s**
  - [float, optional] A smoothing condition. The amount of smoothness is determined by satisfying the conditions: `sum((w * (y - g))**2, axis=0) <= s`, where `g(x)` is the smoothed interpolation of `(x,y)`. The user can use `s` to control the trade-off between closeness and smoothness of fit. Larger `s` means more smoothing while smaller values of `s` indicate less smoothing. Recommended values of `s` depend on the weights, `w`. If the weights represent the inverse of the standard-deviation of `y`, then a good `s` value should be found in the range `(m-sqrt(2*m), m+sqrt(2*m))`, where `m` is the number of data points in `x`, `y`, and `w`.

- **t**
  - [int, optional] The knots needed for `task=-1`.

- **full_output**
  - [int, optional] If non-zero, then return optional outputs.

- **nest**
  - [int, optional] An over-estimate of the total number of knots of the spline to help in determining the storage space. By default `nest=m/2`. Always large enough is `nest=m+k+1`.

- **per**
  - [int, optional] If non-zero, data points are considered periodic with period `x[m-1] - x[0]` and a smooth periodic spline approximation is returned. Values of `y[m-1]` and `w[m-1]` are not used.

- **quiet**
  - [int, optional] Non-zero to suppress messages. This parameter is deprecated; use standard Python warning filters instead.

**Returns**

- **tck**
  - [tuple] `(t,c,k)` a tuple containing the vector of knots, the B-spline coefficients, and the degree of the spline.

- **u**
  - [array] An array of the values of the parameter.

- **fp**
  - [float] The weighted sum of squared residuals of the spline approximation.

- **ier**
  - [int] An integer flag about splrep success. Success is indicated if `ier<=0`. If `ier` in `[1,2,3]` an error occurred but was not raised. Otherwise an error is raised.

- **msg**
  - [str] A message corresponding to the integer flag, `ier`.

See also:
splrep, splev, sproot, splalde, splint
bisplrep, bisplev
UnivariateSpline, BivariateSpline
BSpline
make_interp_spline

Notes
See splev for evaluation of the spline and its derivatives. The number of dimensions N must be smaller than 11. The number of coefficients in the c array is k+1 less then the number of knots, len(t). This is in contrast with splrep, which zero-pads the array of coefficients to have the same length as the array of knots. These additional coefficients are ignored by evaluation routines, splev and BSpline.

References
[1], [2], [3]

Examples
Generate a discretization of a limacon curve in the polar coordinates:

```python
>>> phi = np.linspace(0, 2.*np.pi, 40)
>>> r = 0.5 + np.cos(phi)  # polar coords
>>> x, y = r * np.cos(phi), r * np.sin(phi)  # convert to cartesian
```

And interpolate:

```python
>>> from scipy.interpolate import splprep, splev
>>> tck, u = splprep([x, y], s=0)
>>> new_points = splev(u, tck)
```

Notice that (i) we force interpolation by using s=0, (ii) the parameterization, u, is generated automatically. Now plot the result:

```python
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> ax.plot(x, y, 'ro')
>>> ax.plot(new_points[0], new_points[1], 'r-')
>>> plt.show()
```
scipy.interpolate.splev

scipy.interpolate.splev(x, tck, der=0, ext=0)
Evaluate a B-spline or its derivatives.

Given the knots and coefficients of a B-spline representation, evaluate the value of the smoothing polynomial and its derivatives. This is a wrapper around the FORTRAN routines splev and splder of FITPACK.

**Parameters**

- **x** [array_like] An array of points at which to return the value of the smoothed spline or its derivatives. If tck was returned from splprep, then the parameter values, u should be given.
- **tck** [3-tuple or a BSpline object] If a tuple, then it should be a sequence of length 3 returned by splrep or splprep containing the knots, coefficients, and degree of the spline. (Also see Notes.)
- **der** [int, optional] The order of derivative of the spline to compute (must be less than or equal to k, the degree of the spline).
- **ext** [int, optional] Controls the value returned for elements of x not in the interval defined by the knot sequence.
  - if ext=0, return the extrapolated value.
  - if ext=1, return 0
  - if ext=2, raise a ValueError
  - if ext=3, return the boundary value.
  The default value is 0.

**Returns**

- **y** [ndarray or list of ndarrays] An array of values representing the spline function evaluated at the points in x. If tck was returned from splprep, then this is a list of arrays representing the curve in an N-D space.

See also:

- splprep, splrep, sproot, spalde, splint
- bisplrep, bisplev
- BSpline
Notes

Manipulating the tck-tuples directly is not recommended. In new code, prefer using `BSpline` objects.

References

[1], [2], [3]

Examples

Examples are given in the tutorial.

```python
scipy.interpolate.splint
```

Evaluate the definite integral of a B-spline between two given points.

**Parameters**

- `a, b` [float] The end-points of the integration interval.
- `tck` [tuple or a BSpline instance] If a tuple, then it should be a sequence of length 3, containing the vector of knots, the B-spline coefficients, and the degree of the spline (see `splev`).
- `full_output` [int, optional] Non-zero to return optional output.

**Returns**

- `integral` [float] The resulting integral.
- `wrk` [ndarray] An array containing the integrals of the normalized B-splines defined on the set of knots. (Only returned if `full_output` is non-zero)

See also:

- `splprep`, `splrep`, `sproot`, `spalde`, `splev`
- `bisplrep`, `bisplev`
- `BSpline`

Notes

`splint` silently assumes that the spline function is zero outside the data interval \((a, b)\).

Manipulating the tck-tuples directly is not recommended. In new code, prefer using the `BSpline` objects.

References

[1], [2]
Examples

Examples are given in the tutorial.

scipy.interpolate.sproot

scipy.interpolate.sproot(tck, mest=10)

Find the roots of a cubic B-spline.

Given the knots (>=8) and coefficients of a cubic B-spline return the roots of the spline.

Parameters

- **tck** [tuple or a BSpline object] If a tuple, then it should be a sequence of length 3, containing the vector of knots, the B-spline coefficients, and the degree of the spline. The number of knots must be >= 8, and the degree must be 3. The knots must be a monotonically increasing sequence.
- **mest** [int, optional] An estimate of the number of zeros (Default is 10).

Returns

- **zeros** [ndarray] An array giving the roots of the spline.

See also:

splprep, splrep, splint, spalde, splev

bsplrep, bisplev

Bsplines

Notes

Manipulating the tck-tuples directly is not recommended. In new code, prefer using the BSpline objects.

References

[1], [2], [3]

Examples

Examples are given in the tutorial.

scipy.interpolate.spalde

scipy.interpolate.spalde(x, tck)

Evaluate all derivatives of a B-spline.

Given the knots and coefficients of a cubic B-spline compute all derivatives up to order k at a point (or set of points).

Parameters

- **x** [array_like] A point or a set of points at which to evaluate the derivatives. Note that t (k) <= x <= t(n-k+1) must hold for each x.
- **tck** [tuple] A tuple (t, c, k), containing the vector of knots, the B-spline coefficients, and the degree of the spline (see splev).

Returns
results  [[ndarray, list of ndarrays]] An array (or a list of arrays) containing all derivatives up to order $k$ inclusive for each point $x$.

See also:

`splprep`, `splrep`, `splint`, `sproot`, `splev`, `bisplrep`, `bisplev`  

BSpline

References

[1], [2], [3]

Examples

Examples are given in the tutorial.

`scipy.interpolate.splder`

`scipy.interpolate.splder(tck, n=1)`  
Compute the spline representation of the derivative of a given spline

Parameters

- `tck`  
  [BSpline instance or a tuple of (t, c, k)] Spline whose derivative to compute
- `n`  
  [int, optional] Order of derivative to evaluate. Default: 1

Returns

- `BSpline` instance or tuple  
  Spline of order $k2 = k - n$ representing the derivative of the input spline. A tuple is returned iff the input argument `tck` is a tuple, otherwise a BSpline object is constructed and returned.

See also:

`splantider`, `splev`, `spalde`  

BSpline

Notes

New in version 0.13.0.

Examples

This can be used for finding maxima of a curve:

```python
>>> from scipy.interpolate import splrep, splder, sproot
>>> x = np.linspace(0, 10, 70)
>>> y = np.sin(x)
>>> spl = splrep(x, y, k=4)
```

Now, differentiate the spline and find the zeros of the derivative. (NB: `sproot` only works for order 3 splines, so we fit an order 4 spline):
scipy.interpolate.splantider

scipy.interpolate.splantider(tck, n=1)

Compute the spline for the antiderivative (integral) of a given spline.

Parameters

- tck [BSpline instance or a tuple of (t, c, k)] Spline whose antiderivative to compute
- n [int, optional] Order of antiderivative to evaluate. Default: 1

Returns

BSpline instance or a tuple of (t2, c2, k2)

Spline of order $k2 = k + n$ representing the antiderivative of the input spline. A tuple is returned if the input argument $tck$ is a tuple, otherwise a BSpline object is constructed and returned.

See also:

splder, splev, spalde

BSpline

Notes

The `splder` function is the inverse operation of this function. Namely, `splder(splantider(tck))` is identical to $tck$, modulo rounding error.

New in version 0.13.0.

Examples

```python
>>> from scipy.interpolate import splrep, splder, splantider, splev
>>> x = np.linspace(0, np.pi/2, 70)
>>> y = 1 / np.sqrt(1 - 0.8*np.sin(x)**2)
>>> spl = splrep(x, y)
```

The derivative is the inverse operation of the antiderivative, although some floating point error accumulates:

```python
>>> splev(1.7, spl), splev(1.7, splder(splantider(spl)))
(array(2.1565429877197317), array(2.1565429877201865))
```

Antiderivative can be used to evaluate definite integrals:

```python
>>> ispl = splantider(spl)
>>> splev(np.pi/2, ispl) - splev(0, ispl)
2.2572053588768486
```

This is indeed an approximation to the complete elliptic integral $K(m) = \int_0^{\pi/2} [1 - m \sin^2 x]^{-1/2} dx$: 
From scipy.special import ellipk

```python
e = 0.8
ellipk(e)
```

2.2572053268208538

**scipy.interpolate.insert**

scipy.interpolate.insert(x, tck, m=1, per=0)

Insert knots into a B-spline.

Given the knots and coefficients of a B-spline representation, create a new B-spline with a knot inserted \( m \) times at point \( x \). This is a wrapper around the FORTRAN routine insert of FITPACK.

**Parameters**

- **x** *(u)*: array_like A 1-D point at which to insert a new knot(s). If \( tck \) was returned from `splprep`, then the parameter values, \( u \) should be given.
- **tck**: [a BSpline instance or a tuple] If tuple, then it is expected to be a tuple \((t, c, k)\) containing the vector of knots, the B-spline coefficients, and the degree of the spline.
- **m**: [int, optional] The number of times to insert the given knot (its multiplicity). Default is 1.
- **per**: [int, optional] If non-zero, the input spline is considered periodic.

**Returns**

- **BSpline instance or a tuple**

  A new B-spline with knots \( t \), coefficients \( c \), and degree \( k \). \( t(k+1) \leq x \leq t(n-k) \), where \( k \) is the degree of the spline. In case of a periodic spline \( (\text{per} \neq 0) \) there must be either at least \( k \) interior knots \( t(j) \) satisfying \( t(k+1) < t(j) \leq x \) or at least \( k \) interior knots \( t(j) \) satisfying \( x \leq t(k+1) < t(n-k) \). A tuple is returned iff the input argument \( tck \) is a tuple, otherwise a BSpline object is constructed and returned.

**Notes**

Based on algorithms from [1] and [2].

Manipulating the tck-tuples directly is not recommended. In new code, prefer using the BSpline objects.

**References**

[1], [2]

**Examples**

You can insert knots into a B-spline.

```python
>>> from scipy.interpolate import splrep, insert
>>> x = np.linspace(0, 10, 5)
>>> y = np.sin(x)
>>> tck = splrep(x, y)
>>> tck[0]
array([ 0.,  0.,  0.,  0.,  5., 10., 10., 10., 10.])
```

A knot is inserted:
Some knots are inserted:

```python
>>> tck_inserted2 = insert(8, tck, m=3)
>>> tck_inserted2[0]
array([ 0., 0., 0., 0., 5., 8., 8., 8., 10., 10., 10., 10.])
```

Object-oriented FITPACK interface:

- **UnivariateSpline**
  - `UnivariateSpline(x, y[, w, bbox, k, s, ext, ...])` 1-D smoothing spline fit to a given set of data points.
  - Fits a spline $y = \text{spl}(x)$ of degree $k$ to the provided $x$, $y$ data. $s$ specifies the number of knots by specifying a smoothing condition.

  **Parameters**
  - $x$ [(N,) array_like] 1-D array of independent input data. Must be increasing; must be strictly increasing if $s$ is 0.
  - $y$ [(N,) array_like] 1-D array of dependent input data, of the same length as $x$.
  - $w$ [(N,) array_like, optional] Weights for spline fitting. Must be positive. If $w$ is None, weights are all equal. Default is None.
  - $bbox$ [(2,) array_like, optional] 2-sequence specifying the boundary of the approximation interval. If $bbox$ is None, $bbox=[x[0], x[-1]]$. Default is None.
  - $k$ [int, optional] Degree of the smoothing spline. Must be 1 $\leq k \leq 5$. $k = 3$ is a cubic spline. Default is 3.
  - $s$ [float or None, optional] Positive smoothing factor used to choose the number of knots. Number of knots will be increased until the smoothing condition is satisfied:
    \[
    \text{sum}(w[i] \ast (y[i]-\text{spl}(x[i])))^{*2}, \text{axis}=0) \leq s
    \]
    If $s$ is None, $s = \text{len}(w)$ which should be a good value if $1/w[i]$ is an estimate of the standard deviation of $y[i]$. If 0, spline will interpolate through all data points. Default is None.
  - $\text{ext}$ [int or str, optional] Controls the extrapolation mode for elements not in the interval defined by the knot sequence.
    - if $\text{ext}=0$ or 'extrapolate', return the extrapolated value.
    - if $\text{ext}=1$ or 'zeros', return 0
    - if $\text{ext}=2$ or 'raise', raise a ValueError
    - if $\text{ext}=3$ of 'const', return the boundary value.
    Default is 0.
  - $\text{check\_finite}$ [bool, optional] Whether to check that the input arrays contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination or nonsensical results) if the inputs do contain infinities or NaNs. Default is False.

- **InterpolatedUnivariateSpline**
  - Interpolating spline for a given set of data points.

- **LSQUnivariateSpline**
  - 1-D spline with explicit internal knots.

**scipy.interpolate.UnivariateSpline**

class scipy.interpolate.UnivariateSpline($x$, $y$=None, $bbox$=[None, None], $k=3$, $s$=None, $\text{ext}=0$, $\text{check\_finite}=\text{False}$)

1-D smoothing spline fit to a given set of data points.

Fits a spline $y = \text{spl}(x)$ of degree $k$ to the provided $x$, $y$ data. $s$ specifies the number of knots by specifying a smoothing condition.
See also:

**BivariateSpline**

a base class for bivariate splines.

**SmoothBivariateSpline**

a smoothing bivariate spline through the given points

**LSQBivariateSpline**

a bivariate spline using weighted least-squares fitting

**RectSphereBivariateSpline**

a bivariate spline over a rectangular mesh on a sphere

**SmoothSphereBivariateSpline**

a smoothing bivariate spline in spherical coordinates

**LSQSphereBivariateSpline**

a bivariate spline in spherical coordinates using weighted least-squares fitting

**RectBivariateSpline**

a bivariate spline over a rectangular mesh

**InterpolatedUnivariateSpline**

a interpolating univariate spline for a given set of data points.

**bisplrep**

a function to find a bivariate B-spline representation of a surface

**bisplev**

a function to evaluate a bivariate B-spline and its derivatives

**splrep**

a function to find the B-spline representation of a 1-D curve

**splev**

a function to evaluate a B-spline or its derivatives

**sproot**

a function to find the roots of a cubic B-spline

**splint**

a function to evaluate the definite integral of a B-spline between two given points

**spalde**

a function to evaluate all derivatives of a B-spline
Notes

The number of data points must be larger than the spline degree \( k \).

**NaN handling:** If the input arrays contain NaN values, the result is not useful, since the underlying spline fitting routines cannot deal with NaN. A workaround is to use zero weights for not-a-number data points:

```python
>>> from scipy.interpolate import UnivariateSpline
>>> x, y = np.array([1, 2, 3, 4]), np.array([1, np.nan, 3, 4])
>>> w = np.isnan(y)
>>> y[w] = 0.
>>> spl = UnivariateSpline(x, y, w=~w)
```

Notice the need to replace a NaN by a numerical value (precise value does not matter as long as the corresponding weight is zero.)

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.interpolate import UnivariateSpline
>>> rng = np.random.default_rng()
>>> x = np.linspace(-3, 3, 50)
>>> y = np.exp(-x**2) + 0.1 * rng.standard_normal(50)
>>> plt.plot(x, y, 'ro', ms=5)
```

Use the default value for the smoothing parameter:

```python
>>> spl = UnivariateSpline(x, y)
>>> xs = np.linspace(-3, 3, 1000)
>>> plt.plot(xs, spl(xs), 'g', lw=3)
```

Manually change the amount of smoothing:

```python
>>> spl.set_smoothing_factor(0.5)
>>> plt.plot(xs, spl(xs), 'b', lw=3)
>>> plt.show()
```

**scipy.interpolate.UnivariateSpline.__call__**

UnivariateSpline.__call__ (x, nu=0, ext=None)
Evaluate spline (or its nu-th derivative) at positions x.

**Parameters**

- `x` [array_like] A 1-D array of points at which to return the value of the smoothed spline or its derivatives. Note: x can be unordered but the evaluation is more efficient if x is (partially) ordered.
- `nu` [int] The order of derivative of the spline to compute.
- `ext` [int] Controls the value returned for elements of x not in the interval defined by the knot sequence.
  - if ext=0 or ‘extrapolate’, return the extrapolated value.
  - if ext=1 or ‘zeros’, return 0
  - if ext=2 or ‘raise’, raise a ValueError
  - if ext=3 or ‘const’, return the boundary value.
  The default value is 0, passed from the initialization of UnivariateSpline.

**scipy.interpolate.UnivariateSpline.antiderivative**

UnivariateSpline.antiderivative (n=1)
Construct a new spline representing the antiderivative of this spline.

**Parameters**

- `n` [int, optional] Order of antiderivative to evaluate. Default: 1

**Returns**

- `spline` [UnivariateSpline] Spline of order \( k2 = k + n \) representing the antiderivative of this spline.

**See also:**

splantider, derivative

**Notes**

New in version 0.13.0.
Examples

```python
>>> from scipy.interpolate import UnivariateSpline
>>> x = np.linspace(0, np.pi/2, 70)
>>> y = 1 / np.sqrt(1 - 0.8*np.sin(x)**2)
>>> spl = UnivariateSpline(x, y, s=0)
```

The derivative is the inverse operation of the antiderivative, although some floating point error accumulates:

```python
>>> spl(1.7), spl.antiderivative().derivative()(1.7)
(array(2.1565429877197317), array(2.1565429877201865))
```

Antiderivative can be used to evaluate definite integrals:

```python
>>> ispl = spl.antiderivative()
>>> ispl(np.pi/2) - ispl(0)
2.2572053588768486
```

This is indeed an approximation to the complete elliptic integral $K(m) = \int_0^{\pi/2} [1 - m \sin^2 x]^{-1/2} dx$:

```python
>>> from scipy.special import ellipk
>>> ellipk(0.8)
2.2572053268208538
```
**scipy.interpolate.UnivariateSpline.derivative**

UnivariateSpline.derivative\((n=1)\)
Construct a new spline representing the derivative of this spline.

**Parameters**

- \(n\) [int, optional] Order of derivative to evaluate. Default: 1

**Returns**

- spline [UnivariateSpline] Spline of order \(k2=k-n\) representing the derivative of this spline.

**See also:** splder, antiderivative

**Notes**

New in version 0.13.0.

**Examples**

This can be used for finding maxima of a curve:

```python
>>> from scipy.interpolate import UnivariateSpline
>>> x = np.linspace(0, 10, 70)
>>> y = np.sin(x)
>>> spl = UnivariateSpline(x, y, k=4, s=0)
```

Now, differentiate the spline and find the zeros of the derivative. (NB: sproot only works for order 3 splines, so we fit an order 4 spline):

```python
>>> spl.derivative().roots() / np.pi
array([ 0.50000001, 1.5 , 2.49999998])
```

This agrees well with roots \(\pi/2 + n\pi\) of \(\cos(x) = \sin'(x)\).

**scipy.interpolate.UnivariateSpline.derivatives**

UnivariateSpline.derivatives\((x)\)
Return all derivatives of the spline at the point \(x\).

**Parameters**

- \(x\) [float] The point to evaluate the derivatives at.

**Returns**

- der [ndarray, shape(k+1,)] Derivatives of the orders 0 to \(k\).
## Examples

```python
>>> from scipy.interpolate import UnivariateSpline
>>> x = np.linspace(0, 3, 11)
>>> y = x**2
>>> spl = UnivariateSpline(x, y)
>>> spl.derivatives(1.5)
array([2.25, 3.0, 2.0, 0])
```

### scipy.interpolate.UnivariateSpline.get_coeffs

`UnivariateSpline.get_coeffs()`

Return spline coefficients.

### scipy.interpolate.UnivariateSpline.get_knots

`UnivariateSpline.get_knots()`

Return positions of interior knots of the spline.

Internally, the knot vector contains 2\*k additional boundary knots.

### scipy.interpolate.UnivariateSpline.get_residual

`UnivariateSpline.get_residual()`

Return weighted sum of squared residuals of the spline approximation.

This is equivalent to:

```python
sum((w[i] * (y[i]-spl(x[i])))**2, axis=0)
```

### scipy.interpolate.UnivariateSpline.integral

`UnivariateSpline.integral(a, b)`

Return definite integral of the spline between two given points.

**Parameters**

- `a` [float] Lower limit of integration.
- `b` [float] Upper limit of integration.

**Returns**

- `integral` [float] The value of the definite integral of the spline between limits.
Examples

```python
>>> from scipy.interpolate import UnivariateSpline
>>> x = np.linspace(0, 3, 11)
>>> y = x**2
>>> spl = UnivariateSpline(x, y)
>>> spl.integral(0, 3)
9.0
```

which agrees with \( \int_0^3 x^2 \, dx = x^3/3 \) between the limits of 0 and 3.

A caveat is that this routine assumes the spline to be zero outside of the data limits:

```python
>>> spl.integral(-1, 4)
9.0
>>> spl.integral(-1, 0)
0.0
```

**scipy.interpolate.UnivariateSpline.roots**

UnivariateSpline.roots()

Return the zeros of the spline.

Restriction: only cubic splines are supported by fitpack.

**scipy.interpolate.UnivariateSpline.set_smoothing_factor**

UnivariateSpline.set_smoothing_factor(s)

Continue spline computation with the given smoothing factor \( s \) and with the knots found at the last call.

This routine modifies the spline in place.

**scipy.interpolate.InterpolatedUnivariateSpline**

class scipy.interpolate.InterpolatedUnivariateSpline(x, y, w=None, bbox=[None, None], k=3, ext=0, check_finite=False)

1-D interpolating spline for a given set of data points.

Fits a spline \( y = \text{spl}(x) \) of degree \( k \) to the provided \( x, y \) data. Spline function passes through all provided points. Equivalent to `UnivariateSpline` with \( s=0 \).

**Parameters**

- **x** : [(N,) array_like] Input dimension of data points – must be strictly increasing
- **y** : [(N,) array_like] Input dimension of data points
- **w** : [(N,) array_like, optional] Weights for spline fitting. Must be positive. If None (default), weights are all equal.
- **bbox** : [(2,) array_like, optional] 2-sequence specifying the boundary of the approximation interval. If None (default), bbox=[x[0], x[-1]].
- **k** : [int, optional] Degree of the smoothing spline. Must be 1 <= k <= 5.
- **ext** : [int or str, optional] Controls the extrapolation mode for elements not in the interval defined by the knot sequence.
• if ext=0 or 'extrapolate', return the extrapolated value.
• if ext=1 or 'zeros', return 0
• if ext=2 or 'raise', raise a ValueError
• if ext=3 of 'const', return the boundary value.
The default value is 0.

**check_finite**

[bool, optional] Whether to check that the input arrays contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination or nonsensical results) if the inputs do contain infinities or NaNs. Default is False.

See also:

**UnivariateSpline**

a smooth univariate spline to fit a given set of data points.

**LSQUnivariateSpline**

a spline for which knots are user-selected

**SmoothBivariateSpline**

a smoothing bivariate spline through the given points

**LSQBivariateSpline**

a bivariate spline using weighted least-squares fitting

**splrep**

a function to find the B-spline representation of a 1-D curve

**splev**

a function to evaluate a B-spline or its derivatives

**sproot**

a function to find the roots of a cubic B-spline

**splint**

a function to evaluate the definite integral of a B-spline between two given points

**spalde**

a function to evaluate all derivatives of a B-spline

**Notes**

The number of data points must be larger than the spline degree $k$. 
Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.interpolate import InterpolatedUnivariateSpline
>>> rng = np.random.default_rng()
>>> x = np.linspace(-3, 3, 50)
>>> y = np.exp(-x**2) + 0.1 * rng.standard_normal(50)
>>> spl = InterpolatedUnivariateSpline(x, y)
>>> plt.plot(x, y, 'ro', ms=5)
>>> xs = np.linspace(-3, 3, 1000)
>>> plt.plot(xs, spl(xs), 'g', lw=3, alpha=0.7)
>>> plt.show()
```

Notice that the `spl(x)` interpolates `y`:

```python
>>> spl.get_residual()
0.0
```

Methods

- `__call__(x[, nu, ext])`: Evaluate spline (or its nu-th derivative) at positions `x`.
- `antiderivative([n])`: Construct a new spline representing the antiderivative of this spline.
- `derivative([n])`: Construct a new spline representing the derivative of this spline.
- `derivatives(x)`: Return all derivatives of the spline at the point `x`.
- `get_coeffs()`: Return spline coefficients.
- `get_knots()`: Return positions of interior knots of the spline.
- `get_residual()`: Return weighted sum of squared residuals of the spline approximation.

scipy.interpolate.InterpolatedUnivariateSpline.__call__

`InterpolatedUnivariateSpline.__call__(x, nu=0, ext=None)`

Evaluate spline (or its nu-th derivative) at positions x.

**Parameters**

- `x` [array_like] A 1-D array of points at which to return the value of the smoothed spline or its derivatives. Note: x can be unordered but the evaluation is more efficient if x is (partially) ordered.
- `nu` [int] The order of derivative of the spline to compute.
- `ext` [int] Controls the value returned for elements of x not in the interval defined by the knot sequence.
  - if ext=0 or ‘extrapolate’, return the extrapolated value.
  - if ext=1 or ‘zeros’, return 0
  - if ext=2 or ‘raise’, raise a ValueError
  - if ext=3 or ‘const’, return the boundary value.
  The default value is 0, passed from the initialization of UnivariateSpline.

scipy.interpolate.InterpolatedUnivariateSpline.antiderivative

`InterpolatedUnivariateSpline.antiderivative(n=1)`

Construct a new spline representing the antiderivative of this spline.

**Parameters**

- `n` [int, optional] Order of antiderivative to evaluate. Default: 1

**Returns**

- `spline` [UnivariateSpline] Spline of order k2=k+n representing the antiderivative of this spline.

See also:

- `splantider`, `derivative`

**Notes**

New in version 0.13.0.
Examples

```python
>>> from scipy.interpolate import UnivariateSpline
>>> x = np.linspace(0, np.pi/2, 70)
>>> y = 1 / np.sqrt(1 - 0.8*np.sin(x)**2)
>>> spl = UnivariateSpline(x, y, s=0)

The derivative is the inverse operation of the antiderivative, although some floating point error accumulates:

```python
g>>> spl(1.7), spl.antiderivative().derivative()(1.7)
(2.1565429877197317, 2.1565429877201865)
```

Antiderivative can be used to evaluate definite integrals:

```python
g>>> ispl = spl.antiderivative()
>>> ispl(np.pi/2) - ispl(0)
2.2572053588768486
```

This is indeed an approximation to the complete elliptic integral $K(m) = \int_0^{\pi/2} \left[1 - m \sin^2 x\right]^{-1/2} dx$:

```python
g>>> from scipy.special import ellipk
>>> ellipk(0.8)
2.2572053268208538
```

SciPy.interpolate.InterpolatedUnivariateSpline.derivative

InterpolatedUnivariateSpline.derivative(n=1)

Construct a new spline representing the derivative of this spline.

**Parameters**

- **n** [int, optional] Order of derivative to evaluate. Default: 1

**Returns**

- **spline** [UnivariateSpline] Spline of order $k2=k-n$ representing the derivative of this spline.

**See also:**

- splder, antiderivative

**Notes**

New in version 0.13.0.
Examples

This can be used for finding maxima of a curve:

```python
>>> from scipy.interpolate import UnivariateSpline
>>> x = np.linspace(0, 10, 70)
>>> y = np.sin(x)
>>> spl = UnivariateSpline(x, y, k=4, s=0)
```

Now, differentiate the spline and find the zeros of the derivative. (NB: `sproot` only works for order 3 splines, so we fit an order 4 spline):

```python
>>> spl.derivative().roots() / np.pi
array([ 0.50000001, 1.5 , 2.49999998])
```

This agrees well with roots $\pi/2 + n\pi$ of $\cos(x) = \sin'(x)$.

**scipy.interpolate.InterpolatedUnivariateSpline.derivatives**

InterpolatedUnivariateSpline.derivatives(x)

Return all derivatives of the spline at the point x.

**Parameters**

- `x` [float] The point to evaluate the derivatives at.

**Returns**

- `der` [ndarray, shape(k+1,)] Derivatives of the orders 0 to k.

**Examples**

```python
>>> from scipy.interpolate import UnivariateSpline
>>> x = np.linspace(0, 3, 11)
>>> y = x**2
>>> spl = UnivariateSpline(x, y)
>>> spl.derivatives(1.5)
array([2.25, 3.0, 2.0, 0])
```

**scipy.interpolate.InterpolatedUnivariateSpline.get_coeffs**

InterpolatedUnivariateSpline.get_coeffs()

Return spline coefficients.
**scipy.interpolate.InterpolatedUnivariateSpline.get_knots**

InterpolatedUnivariateSpline.get_knots()
Return positions of interior knots of the spline.
Internally, the knot vector contains 2*\(k\) additional boundary knots.

**scipy.interpolate.InterpolatedUnivariateSpline.get_residual**

InterpolatedUnivariateSpline.get_residual()
Return weighted sum of squared residuals of the spline approximation.
This is equivalent to:

\[
\sum (w[i] \times (y[i] - spl(x[i])))^2, \text{ axis=0}
\]

**scipy.interpolate.InterpolatedUnivariateSpline.integral**

InterpolatedUnivariateSpline.integral\((a, b)\)
Return definite integral of the spline between two given points.

**Parameters**
- \(a\) \[float\] Lower limit of integration.
- \(b\) \[float\] Upper limit of integration.

**Returns**
- integral \[float\] The value of the definite integral of the spline between limits.

**Examples**

```python
>>> from scipy.interpolate import UnivariateSpline
>>> x = np.linspace(0, 3, 11)
>>> y = x**2
>>> spl = UnivariateSpline(x, y)
>>> spl.integral(0, 3)
9.0
```

which agrees with \(\int x^2 dx = x^3/3\) between the limits of 0 and 3.

A caveat is that this routine assumes the spline to be zero outside of the data limits:

```python
>>> spl.integral(-1, 4)
9.0
>>> spl.integral(-1, 0)
0.0
```
scipy.interpolate.InterpolatedUnivariateSpline.roots

InterpolatedUnivariateSpline.roots()
Return the zeros of the spline.
Restriction: only cubic splines are supported by fitpack.

scipy.interpolate.InterpolatedUnivariateSpline.set_smoothing_factor

InterpolatedUnivariateSpline.set_smoothing_factor(s)
Continue spline computation with the given smoothing factor s and with the knots found at the last call.
This routine modifies the spline in place.

validate_input

scipy.interpolate.LSQUnivariateSpline

class scipy.interpolate.LSQUnivariateSpline(x, y, t, w=None, bbox=[None, None], k=3, ext=0, check_finite=False)
1-D spline with explicit internal knots.
Fits a spline \( y = \text{spl}(x) \) of degree \( k \) to the provided \( x, y \) data. \( t \) specifies the internal knots of the spline

Parameters

\( x \) ([N,) array_like] Input dimension of data points – must be increasing
\( y \) ([N,) array_like] Input dimension of data points
\( t \) ([M,) array_like] interior knots of the spline. Must be in ascending order and:

\[
\text{bbox}[0] < t[0] < \ldots < t[-1] < \text{bbox}[-1]
\]

\( w \) ([N,) array_like, optional] weights for spline fitting. Must be positive. If None (default), weights are all equal.
\( bbox \) [(2,) array_like, optional] 2-sequence specifying the boundary of the approximation interval.
If None (default), \( bbox = [x[0], x[-1]] \).
\( k \) [int, optional] Degree of the smoothing spline. Must be 1 <= \( k \) <= 5. Default is \( k = 3 \), a cubic spline.
\( ext \) [int or str, optional] Controls the extrapolation mode for elements not in the interval defined by the knot sequence.
\bullet if ext=0 or 'extrapolate', return the extrapolated value.
\bullet if ext=1 or 'zeros', return 0
\bullet if ext=2 or 'raise', raise a \text{ValueError}
\bullet if ext=3 of 'const', return the boundary value.
The default value is 0.
\( \text{check_finite} \) [bool, optional] Whether to check that the input arrays contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination or nonsensical results) if the inputs do contain infinities or NaNs. Default is False.

Raises

\text{ValueError}
If the interior knots do not satisfy the Schoenberg-Whitney conditions

See also:
UnivariateSpline

- a smooth univariate spline to fit a given set of data points.

InterpolatedUnivariateSpline

- an interpolating univariate spline for a given set of data points.

spline

- a function to find the B-spline representation of a 1-D curve

splrep

- a function to evaluate a B-spline or its derivatives

sproot

- a function to find the roots of a cubic B-spline

splint

- a function to evaluate the definite integral of a B-spline between two given points

spalde

- a function to evaluate all derivatives of a B-spline

Notes

- The number of data points must be larger than the spline degree \( k \).
- Knots \( t \) must satisfy the Schoenberg-Whitney conditions, i.e., there must be a subset of data points \( x[j] \) such that \( t[j] < x[j] < t[j+k+1] \), for \( j=0, 1, \ldots, n-k-2 \).

Examples

```python
>>> from scipy.interpolate import LSQUnivariateSpline, UnivariateSpline
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
>>> x = np.linspace(-3, 3, 50)
>>> y = np.exp(-x**2) + 0.1 * rng.standard_normal(50)

Fit a smoothing spline with a pre-defined internal knots:

```python
>>> t = [-1, 0, 1]
>>> spl = LSQUnivariateSpline(x, y, t)
```  
```
>>> xs = np.linspace(-3, 3, 1000)
>>> plt.plot(x, y, 'ro', ms=5)
>>> plt.plot(xs, spl(xs), 'g-', lw=3)
>>> plt.show()
```  
Check the knot vector:

```python
>>> spl.get_knots()
array([-3., -1., 0., 1., 3.])
```

Constructing lsq spline using the knots from another spline:
```python
>>> x = np.arange(10)
>>> s = UnivariateSpline(x, x, s=0)
>>> s.get_knots()
array([ 0., 2., 3., 4., 5., 6., 7., 9.])
>>> knt = s.get_knots()
>>> s1 = LSQUnivariateSpline(x, x, knt[1:-1])  # Chop 1st and last knot
>>> s1.get_knots()
array([ 0., 2., 3., 4., 5., 6., 7., 9.])
```

</tbody>
</table>
scipy.interpolate.LSQUnivariateSpline.__call__

LSQUnivariateSpline.__call__(x, nu=0, ext=None)
Evaluate spline (or its nu-th derivative) at positions x.

Parameters
- **x** [array_like] A 1-D array of points at which to return the value of the smoothed spline or its derivatives. Note: x can be unordered but the evaluation is more efficient if x is (partially) ordered.
- **nu** [int] The order of derivative of the spline to compute.
- **ext** [int] Controls the value returned for elements of x not in the interval defined by the knot sequence.
  - if ext=0 or ‘extrapolate’, return the extrapolated value.
  - if ext=1 or ‘zeros’, return 0
  - if ext=2 or ‘raise’, raise a ValueError
  - if ext=3 or ‘const’, return the boundary value.
The default value is 0, passed from the initialization of UnivariateSpline.

scipy.interpolate.LSQUnivariateSpline.antiderivative

LSQUnivariateSpline.antiderivative(n=1)
Construct a new spline representing the antiderivative of this spline.

Parameters
- **n** [int, optional] Order of antiderivative to evaluate. Default: 1

Returns
- **spline** [UnivariateSpline] Spline of order k2=k+n representing the antiderivative of this spline.

See also:
splantider, derivative

Notes
New in version 0.13.0.

Examples

```python
>>> from scipy.interpolate import UnivariateSpline
>>> x = np.linspace(0, np.pi/2, 70)
>>> y = 1 / np.sqrt(1 - 0.8*np.sin(x)**2)
>>> spl = UnivariateSpline(x, y, s=0)
```

The derivative is the inverse operation of the antiderivative, although some floating point error accumulates:

```python
>>> spl(1.7), spl.antiderivative().derivative()(1.7)
(array(2.1565429877197317), array(2.1565429877201865))
```

Antiderivative can be used to evaluate definite integrals:
```python
>>> ispl = spl.antiderivative()
>>> ispl(np.pi/2) - ispl(0)
2.2572053588768486
```

This is indeed an approximation to the complete elliptic integral $K(m) = \int_0^{\pi/2} [1 - m \sin^2 x]^{-1/2} dx$:

```python
>>> from scipy.special import ellipk
>>> ellipk(0.8)
2.2572053268208538
```

### scipy.interpolate.LSQUnivariateSpline.derivative

**LSQUnivariateSpline.derivative**

Construct a new spline representing the derivative of this spline.

**Parameters**

- `n` [int, optional] Order of derivative to evaluate. Default: 1

**Returns**

- `spline` [UnivariateSpline] Spline of order $k-1$ representing the derivative of this spline.

**See also:**

- `splder`, `antiderivative`

**Notes**

New in version 0.13.0.

**Examples**

This can be used for finding maxima of a curve:

```python
>>> from scipy.interpolate import UnivariateSpline
>>> x = np.linspace(0, 10, 70)
>>> y = np.sin(x)
>>> spl = UnivariateSpline(x, y, k=4, s=0)
```

Now, differentiate the spline and find the roots of the derivative. (NB: `sroots` only works for order 3 splines, so we fit an order 4 spline):

```python
>>> spl.derivative().roots() / np.pi
array([ 0.50000001, 1.5, 2.49999998])
```

This agrees well with roots $\pi/2 + n\pi$ of $\cos(x) = \sin'(x)$.
scipy.interpolate.LSQUnivariateSpline.derivatives

LSQUnivariateSpline.derivatives(x)
Return all derivatives of the spline at the point x.

Parameters
x [float] The point to evaluate the derivatives at.

Returns
der [ndarray, shape(k+1,)] Derivatives of the orders 0 to k.

Examples

```python
>>> from scipy.interpolate import UnivariateSpline
>>> x = np.linspace(0, 3, 11)
>>> y = x**2
>>> spl = UnivariateSpline(x, y)
>>> spl.derivatives(1.5)
array([2.25, 3.0, 2.0, 0])
```

scipy.interpolate.LSQUnivariateSpline.get_coeffs

LSQUnivariateSpline.get_coeffs()
Return spline coefficients.

scipy.interpolate.LSQUnivariateSpline.get_knots

LSQUnivariateSpline.get_knots()
Return positions of interior knots of the spline.
Internally, the knot vector contains 2*k additional boundary knots.

scipy.interpolate.LSQUnivariateSpline.get_residual

LSQUnivariateSpline.get_residual()
Return weighted sum of squared residuals of the spline approximation.
This is equivalent to:

```python
sum((w[i] * (y[i] - spl(x[i])))**2, axis=0)
```
**scipy.interpolate.LSQUnivariateSpline.integral**

`LSQUnivariateSpline.integral(a, b)`  
Return definite integral of the spline between two given points.

**Parameters**

- a  
  [float] Lower limit of integration.
- b  
  [float] Upper limit of integration.

**Returns**

- integral  
  [float] The value of the definite integral of the spline between limits.

**Examples**

```python
>>> from scipy.interpolate import UnivariateSpline
>>> x = np.linspace(0, 3, 11)
>>> y = x**2
>>> spl = UnivariateSpline(x, y)
>>> spl.integral(0, 3)
9.0
```

which agrees with \( \int x^2 dx = \frac{x^3}{3} \) between the limits of 0 and 3.

A caveat is that this routine assumes the spline to be zero outside of the data limits:

```python
>>> spl.integral(-1, 4)
9.0
>>> spl.integral(-1, 0)
0.0
```

**scipy.interpolate.LSQUnivariateSpline.roots**

`LSQUnivariateSpline.roots()`  
Return the zeros of the spline.

Restriction: only cubic splines are supported by fitpack.

**scipy.interpolate.LSQUnivariateSpline.set_smoothing_factor**

`LSQUnivariateSpline.set_smoothing_factor(s)`  
Continue spline computation with the given smoothing factor s and with the knots found at the last call.

This routine modifies the spline in place.
2-D Splines

For data on a grid:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>RectBivariateSpline(x, y, z[, bbox, kx, ky, s])</code></td>
<td>Bivariate spline approximation over a rectangular mesh.</td>
</tr>
<tr>
<td><code>RectSphereBivariateSpline(u, v, r[, s,...])</code></td>
<td>Bivariate spline approximation over a rectangular mesh on a sphere.</td>
</tr>
</tbody>
</table>

**scipy.interpolate.RectSphereBivariateSpline**

**class** `scipy.interpolate.RectSphereBivariateSpline(u, v, r, s=0.0, pole_continuity=False, pole_values=None, pole_exact=False, pole_flat=False)`

Bivariate spline approximation over a rectangular mesh on a sphere.

Can be used for smoothing data.

New in version 0.11.0.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>u</code></td>
<td>[array_like] 1-D array of colatitude coordinates in strictly ascending order. Coordinates must be given in radians and lie within the open interval ((0, \pi)).</td>
</tr>
<tr>
<td><code>v</code></td>
<td>[array_like] 1-D array of longitude coordinates in strictly ascending order. Coordinates must be given in radians. First element ((v[0])) must lie within the interval ([-\pi, \pi]). Last element ((v[-1])) must satisfy (v[-1] &lt;= v[0] + 2*\pi).</td>
</tr>
<tr>
<td><code>r</code></td>
<td>[array_like] 2-D array of data with shape (u.size, v.size).</td>
</tr>
<tr>
<td><code>s</code></td>
<td>[float, optional] Positive smoothing factor defined for estimation condition ((s=0) is for interpolation).</td>
</tr>
<tr>
<td><code>pole_continuity</code></td>
<td>[bool or (bool, bool), optional] Order of continuity at the poles (u=0) ((\text{pole_continuity}[0])) and (u=\pi) ((\text{pole_continuity}[1])). The order of continuity at the pole will be 1 or 0 when this is True or False, respectively. Defaults to False.</td>
</tr>
<tr>
<td><code>pole_values</code></td>
<td>[float or (float, float), optional] Data values at the poles (u=0) and (u=\pi). Either the whole parameter or each individual element can be None. Defaults to None.</td>
</tr>
<tr>
<td><code>pole_exact</code></td>
<td>[bool or (bool, bool), optional] Data value exactness at the poles (u=0) and (u=\pi). If True, the value is considered to be the right function value, and it will be fitted exactly. If False, the value will be considered to be a data value just like the other data values. Defaults to False.</td>
</tr>
<tr>
<td><code>pole_flat</code></td>
<td>[bool or (bool, bool), optional] For the poles at (u=0) and (u=\pi), specify whether or not the approximation has vanishing derivatives. Defaults to False.</td>
</tr>
</tbody>
</table>

**See also:**

- `BivariateSpline`
  a base class for bivariate splines.
- `UnivariateSpline`
  a smooth univariate spline to fit a given set of data points.
- `SmoothBivariateSpline`
  a smoothing bivariate spline through the given points
LSQBivariateSpline
a bivariate spline using weighted least-squares fitting

SmoothSphereBivariateSpline
a smoothing bivariate spline in spherical coordinates

LSQSphereBivariateSpline
a bivariate spline in spherical coordinates using weighted least-squares fitting

RectBivariateSpline
a bivariate spline over a rectangular mesh.

bisplrep
a function to find a bivariate B-spline representation of a surface

bisplev
a function to evaluate a bivariate B-spline and its derivatives

Notes
Currently, only the smoothing spline approximation (iopt[0] = 0 and iopt[0] = 1 in the FITPACK routine) is supported. The exact least-squares spline approximation is not implemented yet.

When actually performing the interpolation, the requested v values must lie within the same length 2pi interval that the original v values were chosen from.

For more information, see the FITPACK site about this function.

Examples
Suppose we have global data on a coarse grid

```python
>>> lats = np.linspace(10, 170, 9) * np.pi / 180.
>>> lons = np.linspace(0, 350, 18) * np.pi / 180.
>>> data = np.dot(np.atleast_2d(90. - np.linspace(-80., 80., 18)).T,
    np.atleast_2d(180. - np.abs(np.linspace(0., 350., 9)))).

We want to interpolate it to a global one-degree grid

```python
>>> new_lats = np.linspace(1, 180, 180) * np.pi / 180
>>> new_lons = np.linspace(1, 360, 360) * np.pi / 180
>>> new_lats, new_lons = np.meshgrid(new_lats, new_lons)

Finally we interpolate the data. The RectSphereBivariateSpline object only takes 1-D arrays as input, therefore we need to do some reshaping.

```python
>>> from scipy.interpolate import RectSphereBivariateSpline
>>> lut = RectSphereBivariateSpline(lats, lons, data)
```
Looking at the original and the interpolated data, one can see that the interpolant reproduces the original data very well:

```python
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(211)
>>> ax1.imshow(data, interpolation='nearest')
>>> ax2 = fig.add_subplot(212)
>>> ax2.imshow(data_interp, interpolation='nearest')
>>> plt.show()
```

Choosing the optimal value of $s$ can be a delicate task. Recommended values for $s$ depend on the accuracy of the data values. If the user has an idea of the statistical errors on the data, she can also find a proper estimate for $s$. By assuming that, if she specifies the right $s$, the interpolator will use a spline $f(u,v)$ which exactly reproduces the function underlying the data, she can evaluate $\sum ((r(i,j)-s(u(i),v(j)))^2)$ to find a good estimate for this $s$. For example, if she knows that the statistical errors on her $r(i,j)$-values are not greater than 0.1, she may expect that a good $s$ should have a value not larger than $u.size * v.size * (0.1)^2$.

If nothing is known about the statistical error in $r(i,j)$, $s$ must be determined by trial and error. The best is then to start with a very large value of $s$ (to determine the least-squares polynomial and the corresponding upper bound $fp0$ for $s$) and then to progressively decrease the value of $s$ (say by a factor 10 in the beginning, i.e. $s = fp0 / 10, fp0 / 100, ...$ and more carefully as the approximation shows more detail) to obtain closer fits.

The interpolation results for different values of $s$ give some insight into this process:

```python
>>> fig2 = plt.figure()
>>> s = [3e9, 2e9, 1e9, 1e8]
>>> for idx, sval in enumerate(s, 1):
...     lut = RectSphereBivariateSpline(lats, lons, data, s=sval)
...     data_interp = lut.ev(new_lats.ravel(),
...     new_lons.ravel()).reshape((360, 180)).T

(continues on next page)
```
... ax = fig2.add_subplot(2, 2, idx)
... ax.imshow(data_interp, interpolation='nearest')
... ax.set_title(f"s = {sval:g}")

```python
global sval
>>> plt.show()
```

<tbody>
<tr>
<td>theta, phi</td>
<td>[array_like] Input coordinates. If <code>grid</code> is False, evaluate the spline at points (theta[i], phi[i]), i=0, ..., len(x)-1. Standard Numpy broadcasting is obeyed. If <code>grid</code> is True: evaluate spline at the grid points defined by the coordinate arrays theta, phi. The arrays must be sorted to increasing order.</td>
</tr>
</tbody>
</table>
sciPy.interpolate.RectSphereBivariateSpline.ev

RectSphereBivariateSpline.ev(theta, phi, dtheta=0, dphi=0)
Evaluate the spline at points
Returns the interpolated value at (theta[i], phi[i]), i=0,...,len(theta)-1.

Parameters
theta, phi [array_like] Input coordinates. Standard Numpy broadcasting is obeyed.
dtheta [int, optional] Order of theta-derivative
New in version 0.14.0.
dphi [int, optional] Order of phi-derivative
New in version 0.14.0.

sciPy.interpolate.RectSphereBivariateSpline.get_coeffs

RectSphereBivariateSpline.get_coeffs()
Return spline coefficients.

sciPy.interpolate.RectSphereBivariateSpline.get_knots

RectSphereBivariateSpline.get_knots()
Return a tuple (tx,ty) where tx,ty contain knots positions of the spline with respect to x-, y-variable, respectively. The position of interior and additional knots are given as t[k+1:-k-1] and t[:k+1]=b, t[-k-1:]=e, respectively.

sciPy.interpolate.RectSphereBivariateSpline.get_residual

RectSphereBivariateSpline.get_residual()
Return weighted sum of squared residuals of the spline approximation: sum ((w[i]*(z[i]-s(x[i],y[i])))**2,axis=0)
For unstructured data:

**scipy.interpolate.BivariateSpline**

**class scipy.interpolate.BivariateSpline**

Base class for bivariate splines.

This describes a spline \( s(x, y) \) of degrees \( kx \) and \( ky \) on the rectangle \([xb, xe] \times [yb, ye]\) calculated from a given set of data points \((x, y, z)\).

This class is meant to be subclassed, not instantiated directly. To construct these splines, call either `SmoothBivariateSpline` or `LSQBivariateSpline` or `RectBivariateSpline`.

See also:

- `UnivariateSpline`  
a smooth univariate spline to fit a given set of data points.

- `SmoothBivariateSpline`  
a smoothing bivariate spline through the given points

- `LSQBivariateSpline`  
a bivariate spline using weighted least-squares fitting

- `RectSphereBivariateSpline`  
a bivariate spline over a rectangular mesh on a sphere

- `SmoothSphereBivariateSpline`  
a smoothing bivariate spline in spherical coordinates

- `LSQSphereBivariateSpline`  
a bivariate spline in spherical coordinates using weighted least-squares fitting

- `RectBivariateSpline`  
a bivariate spline over a rectangular mesh.

- `bisplrep`  
a function to find a bivariate B-spline representation of a surface

- `bisplev`  
a function to evaluate a bivariate B-spline and its derivatives

**Methods**

- `__call__(x, y[, dx, dy, grid])`  
Evaluate the spline or its derivatives at given positions.

- `ev(xi, yi[, dx, dy])`  
Evaluate the spline at points

- `get_coeffs()`  
Return spline coefficients.

- `get_knots()`  
Return a tuple \((tx,ty)\) where \(tx,ty\) contain knots positions of the spline with respect to \(x\)-, \(y\)-variable, respectively.

- `get_residual()`  
Return weighted sum of squared residuals of the spline approximation: \( \sum ((w[i]*(z[i]-s(x[i],y[i])))**2, axis=0) \)

- `integral(xa, xb, ya, yb)`  
Evaluate the integral of the spline over area \([xa,xb] \times [ya,yb]\).
scipy.interpolate.BivariateSpline.__call__

BivariateSpline.__call__(x, y, dx=0, dy=0, grid=True)

Evaluate the spline or its derivatives at given positions.

**Parameters**

- **x, y**
  - [array_like] Input coordinates. If `grid` is False, evaluate the spline at points `(x[i], y[i]), i=0, ..., len(x)-1`. Standard Numpy broadcasting is obeyed. If `grid` is True: evaluate spline at the grid points defined by the coordinate arrays x, y. The arrays must be sorted to increasing order. Note that the axis ordering is inverted relative to the output of meshgrid.
- **dx**
  - [int] Order of x-derivative
  - New in version 0.14.0.
- **dy**
  - [int] Order of y-derivative
  - New in version 0.14.0.
- **grid**
  - [bool] Whether to evaluate the results on a grid spanned by the input arrays, or at points specified by the input arrays.
  - New in version 0.14.0.

scipy.interpolate.BivariateSpline.ev

BivariateSpline.ev(xi, yi, dx=0, dy=0)

Evaluate the spline at points

Returns the interpolated value at `(xi[i], yi[i]), i=0,...,len(xi)-1`.

**Parameters**

- **xi, yi**
  - [array_like] Input coordinates. Standard Numpy broadcasting is obeyed.
- **dx**
  - [int, optional] Order of x-derivative
  - New in version 0.14.0.
- **dy**
  - [int, optional] Order of y-derivative
  - New in version 0.14.0.

scipy.interpolate.BivariateSpline.get_coeffs

BivariateSpline.get_coeffs()

Return spline coefficients.

scipy.interpolate.BivariateSpline.get_knots

BivariateSpline.get_knots()

Return a tuple (tx,ty) where tx,ty contain knots positions of the spline with respect to x-, y-variable, respectively. The position of interior and additional knots are given as t[k+1::k-1] and t[:k+1]=b, t[-k-1::]=e, respectively.
scipy.interpolate.BivariateSpline.get_residual

BivariateSpline.get_residual()
Return weighted sum of squared residuals of the spline approximation: sum ((w[i]*(z[i]-s(x[i],y[i])))**2,axis=0)

scipy.interpolate.BivariateSpline.integral

BivariateSpline.integral(xa, xb, ya, yb)
Evaluate the integral of the spline over area [xa,xb] x [ya,yb].

Parameters
xa, xb [float] The end-points of the x integration interval.
ya, yb [float] The end-points of the y integration interval.

Returns
integ [float] The value of the resulting integral.

scipy.interpolate.SmoothBivariateSpline

class scipy.interpolate.SmoothBivariateSpline(x, y, z, w=None, bbox=[None, None, None, None], kx=3, ky=3, s=None, eps=1e-16)
Smooth bivariate spline approximation.

Parameters
x, y, z [array_like] 1-D sequences of data points (order is not important).
w [array_like, optional] Positive 1-D sequence of weights, of same length as x, y and z.
bbox [array_like, optional] Sequence of length 4 specifying the boundary of the rectangular approximation domain. By default, bbox=[min(x), max(x), min(y), max(y)].
kx, ky [ints, optional] Degrees of the bivariate spline. Default is 3.
s [float, optional] Positive smoothing factor defined for estimation condition: sum((w[i]*(z[i]-s(x[i], y[i])))**2, axis=0) <= s Default s=len(w) which should be a good value if 1/w[i] is an estimate of the standard deviation of z[i].
eps [float, optional] A threshold for determining the effective rank of an over-determined linear system of equations. eps should have a value within the open interval (0, 1), the default is 1e-16.

See also:
BivariateSpline
a base class for bivariate splines.
UnivariateSpline
a smooth univariate spline to fit a given set of data points.
LSQBivariateSpline
a bivariate spline using weighted least-squares fitting

**scipy.interpolate.SmoothBivariateSpline.__call__**

SmoothBivariateSpline.__call__(\(x, y, dx=0, dy=0, grid=True\))

Evaluate the spline or its derivatives at given positions.

**Parameters**

- **x**, **y**
  
  [array_like] Input coordinates.
  
  If \( grid \) is False, evaluate the spline at points \((x[i], y[i]), \ i = 0, \ldots, \ \text{len}(x) - 1\). Standard NumPy broadcasting is obeyed.
  
  If \( grid \) is True: evaluate spline at the grid points defined by the coordinate arrays \( x, y \). The arrays must be sorted to increasing order.
  
  Note that the axis ordering is inverted relative to the output of meshgrid.

  [int] Order of \( x \)-derivative
  
  New in version 0.14.0.

- **dy**
  
  [int] Order of \( y \)-derivative
  
  New in version 0.14.0.
grid    [bool] Whether to evaluate the results on a grid spanned by the input arrays, or at points specified by the input arrays.
        New in version 0.14.0.

scipy.interpolate.SmoothBivariateSpline.ev

SmoothBivariateSpline.ev (xi, yi, dx=0, dy=0)

Evaluate the spline at points

    Returns the interpolated value at (xi[i], yi[i]), i=0,...,len(xi)-1.

Parameters

    xi, yi    [array_like] Input coordinates. Standard Numpy broadcasting is obeyed.
    dx       [int, optional] Order of x-derivative
              New in version 0.14.0.
    dy       [int, optional] Order of y-derivative
              New in version 0.14.0.

scipy.interpolate.SmoothBivariateSpline.get_coeffs

SmoothBivariateSpline.get_coeffs()

Return spline coefficients.

scipy.interpolate.SmoothBivariateSpline.get_knots

SmoothBivariateSpline.get_knots()

Return a tuple (tx,ty) where tx,ty contain knots positions of the spline with respect to x-, y-variable, respectively. The position of interior and additional knots are given as t[k+1:-k-1] and t[:k+1]=b, t[-k-1:]=e, respectively.

scipy.interpolate.SmoothBivariateSpline.get_residual

SmoothBivariateSpline.get_residual()

Return weighted sum of squared residuals of the spline approximation: sum ((w[i]*(z[i]-
        s(x[i],y[i])))**2,axis=0)

scipy.interpolate.SmoothBivariateSpline.integral

SmoothBivariateSpline.integral (xa, xb, ya, yb)

Evaluate the integral of the spline over area [xa,xb] x [ya,yb].

Parameters

    xa, xb    [float] The end-points of the x integration interval.
    ya, yb    [float] The end-points of the y integration interval.

Returns

    integ     [float] The value of the resulting integral.
scipy.interpolate.SmoothSphereBivariateSpline

class scipy.interpolate.SmoothSphereBivariateSpline(theta, phi, r, w=None, s=0.0, eps=1e-16)

Smooth bivariate spline approximation in spherical coordinates.
New in version 0.11.0.

Parameters

theta, phi, r
[array_like] 1-D sequences of data points (order is not important). Coordinates must be
given in radians. Theta must lie within the interval \([0, \pi]\), and phi must lie within the
interval \([0, 2\pi]\).

w
[array_like, optional] Positive 1-D sequence of weights.

s
[float, optional] Positive smoothing factor defined for estimation condition:
\[
\sum ((w(i)*(r(i) - s(theta(i), phi(i))))**2, axis=0) \leq s
\]
Default \(s=len(w)\) which should be a good value if \(1/w[i]\) is an estimate of the
standard deviation of \(r[i]\).

eps
[float, optional] A threshold for determining the effective rank of an over-determined linear
system of equations. \(eps\) should have a value within the open interval \((0, 1)\), the default
is 1e-16.

See also:

BivariateSpline
a base class for bivariate splines.

UnivariateSpline
a smooth univariate spline to fit a given set of data points.

SmoothBivariateSpline
a smoothing bivariate spline through the given points

LSQBivariateSpline
a bivariate spline using weighted least-squares fitting

RectSphereBivariateSpline
a bivariate spline over a rectangular mesh on a sphere

LSQSphereBivariateSpline
a bivariate spline in spherical coordinates using weighted least-squares fitting

RectBivariateSpline
a bivariate spline over a rectangular mesh.

bisplrep
a function to find a bivariate B-spline representation of a surface

bisplev
a function to evaluate a bivariate B-spline and its derivatives
Notes

For more information, see the FITPACK site about this function.

Examples

Suppose we have global data on a coarse grid (the input data does not have to be on a grid):

```python
>>> theta = np.linspace(0., np.pi, 7)
>>> phi = np.linspace(0., 2*np.pi, 9)
>>> data = np.empty((theta.shape[0], phi.shape[0]))
>>> data[:1, :], data[0, :], data[-1, :] = 0., 0., 0.
>>> data[1:-1, 1], data[1:-1, -1] = 1., 1.
>>> data[1, 1:-1], data[-2, 1:-1] = 1., 1.
>>> data[2, 2:-2], data[-3, 2:-2] = 2., 2.
>>> data[3, 3:-2] = 3.
>>> data = np.roll(data, 4, 1)
```

We need to set up the interpolator object

```python
>>> lats, lons = np.meshgrid(theta, phi)
>>> from scipy.interpolate import SmoothSphereBivariateSpline
>>> lut = SmoothSphereBivariateSpline(lats.ravel(), lons.ravel(),
...                                           data.T.ravel(), s=3.5)
```

As a first test, we’ll see what the algorithm returns when run on the input coordinates

```python
>>> data_orig = lut(theta, phi)
```

Finally we interpolate the data to a finer grid

```python
>>> fine_lats = np.linspace(0., np.pi, 70)
>>> fine_lons = np.linspace(0., 2 * np.pi, 90)
```

```python
>>> data_smth = lut(fine_lats, fine_lons)
```

```python
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(131)
>>> ax1.imshow(data, interpolation='nearest')
>>> ax2 = fig.add_subplot(132)
>>> ax2.imshow(data_orig, interpolation='nearest')
>>> ax3 = fig.add_subplot(133)
>>> ax3.imshow(data_smth, interpolation='nearest')
>>> plt.show()
```
Methods

__call__(theta, phi[, dtheta, dphi, grid]) Evaluate the spline or its derivatives at given positions.
ev(theta, phi[, dtheta, dphi]) Evaluate the spline at points
get_coeffs() Return spline coefficients.
get_knots() Return a tuple (tx,ty) where tx,ty contain knots positions of the spline with respect to x-, y-variable, respectively.
get_residual() Return weighted sum of squared residuals of the spline approximation: sum ((w[i]*(z[i]-s(x[i],y[i])))**2,axis=0)

scipy.interpolate.SmoothSphereBivariateSpline.__call__

SmoothSphereBivariateSpline.__call__(theta, phi, dtheta=0, dphi=0, grid=True)
Evaluate the spline or its derivatives at given positions.

Parameters

theta, phi [array_like] Input coordinates.
If grid is False, evaluate the spline at points (theta[i], phi[i]), i=0, ..., len(x)-1. Standard Numpy broadcasting is obeyed.
If grid is True: evaluate spline at the grid points defined by the coordinate arrays theta, phi. The arrays must be sorted to increasing order.
dtheta [int, optional] Order of theta-derivative
New in version 0.14.0.
dphi [int] Order of phi-derivative
New in version 0.14.0.
grid [bool] Whether to evaluate the results on a grid spanned by the input arrays, or at points specified by the input arrays.
New in version 0.14.0.
```python
scipy.interpolate.SmoothSphereBivariateSpline.ev

SmoothSphereBivariateSpline.ev(theta, phi, dtheta=0, dphi=0)

Evaluate the spline at points

Returns the interpolated value at \( \{ \text{theta}[i], \text{phi}[i] \}, i=0,\ldots,\text{len(theta)-1} \).

**Parameters**

- **theta, phi** [array_like] Input coordinates. Standard NumPy broadcasting is obeyed.
- **dtheta** [int, optional] Order of theta-derivative
  New in version 0.14.0.
- **dphi** [int, optional] Order of phi-derivative
  New in version 0.14.0.
```

```python
scipy.interpolate.SmoothSphereBivariateSpline.get_coeffs

SmoothSphereBivariateSpline.get_coeffs()

Return spline coefficients.
```

```python
scipy.interpolate.SmoothSphereBivariateSpline.get_knots

SmoothSphereBivariateSpline.get_knots()

Return a tuple (tx,ty) where tx,ty contain knots positions of the spline with respect to x-, y-variable, respectively. The position of interior and additional knots are given as t[k+1:-k-1] and t[:k+1]=b, t[-k-1:]=e, respectively.
```

```python
scipy.interpolate.SmoothSphereBivariateSpline.get_residual

SmoothSphereBivariateSpline.get_residual()

Return weighted sum of squared residuals of the spline approximation:

\[
\sum \left( \frac{w[i] \cdot (z[i] - s(x[i],y[i]))}{2} \right)^2, \text{axis}=0
\]
```

```python
scipy.interpolate.LSQBivariateSpline

class scipy.interpolate.LSQBivariateSpline(x, y, z, tx, ty, w=None, bbox=[None, None, None, None], kx=3, ky=3, eps=None)

Weighted least-squares bivariate spline approximation.

**Parameters**

- **x, y, z** [array_like] 1-D sequences of data points (order is not important).
- **tx, ty** [array_like] Strictly ordered 1-D sequences of knots coordinates.
- **w** [array_like, optional] Positive 1-D array of weights, of the same length as x, y and z.
- **bbox** [(4,) array_like, optional] Sequence of length 4 specifying the boundary of the rectangular approximation domain. By default, bbox=[\( \min(x,tx) \), \( \max(x,tx) \), \( \min(y,ty) \), \( \max(y,ty) \)].
- **kx, ky** [ints, optional] Degrees of the bivariate spline. Default is 3.
- **eps** [float, optional] A threshold for determining the effective rank of an over-determined linear system of equations. eps should have a value within the open interval \((0, 1)\), the default is \(1e-16\).

See also:
```
**BivariateSpline**

a base class for bivariate splines.

**UnivariateSpline**

a smooth univariate spline to fit a given set of data points.

**SmoothUnivariateSpline**

a smoothing univariate spline through the given points

**RectSphereBivariateSpline**

a bivariate spline over a rectangular mesh on a sphere

**SmoothSphereBivariateSpline**

a smoothing bivariate spline in spherical coordinates

**LSQSphereBivariateSpline**

a bivariate spline in spherical coordinates using weighted least-squares fitting

**RectBivariateSpline**

a bivariate spline over a rectangular mesh.

**bisplrep**

a function to find a bivariate B-spline representation of a surface

**bisplev**

a function to evaluate a bivariate B-spline and its derivatives

**Notes**

The length of \(x\), \(y\) and \(z\) should be at least \((k_\text{x}+1) \times (k_\text{y}+1)\).

scipy.interpolate.LSQBivariateSpline.__call__

LSQBivariateSpline.__call__(x, y, dx=0, dy=0, grid=True)

Evaluate the spline or its derivatives at given positions.

**Parameters**

- **x, y**
  - array_like
  - Input coordinates.
  - If `grid` is False, evaluate the spline at points \((x[i], y[i]), i=0, \ldots, len(x)-1\). Standard Numpy broadcasting is obeyed.
  - If `grid` is True: evaluate spline at the grid points defined by the coordinate arrays \(x, y\). The arrays must be sorted to increasing order.
  - Note that the axis ordering is inverted relative to the output of meshgrid.

- **dx**
  - int
  - Order of x-derivative
  - New in version 0.14.0.

- **dy**
  - int
  - Order of y-derivative
  - New in version 0.14.0.

- **grid**
  - bool
  - Whether to evaluate the results on a grid spanned by the input arrays, or at points specified by the input arrays.
  - New in version 0.14.0.

scipy.interpolate.LSQBivariateSpline.ev

LSQBivariateSpline.ev(xi, yi, dx=0, dy=0)

Evaluate the spline at points

Returns the interpolated value at \((xi[i], yi[i]), i=0, \ldots, len(xi)-1\).

**Parameters**

- **xi, yi**
  - array_like
  - Input coordinates. Standard Numpy broadcasting is obeyed.

- **dx**
  - int, optional
  - Order of x-derivative
  - New in version 0.14.0.

- **dy**
  - int, optional
  - Order of y-derivative
  - New in version 0.14.0.

scipy.interpolate.LSQBivariateSpline.get_coeffs

LSQBivariateSpline.get_coeffs()

Return spline coefficients.

scipy.interpolate.LSQBivariateSpline.get_knots

LSQBivariateSpline.get_knots()

Return a tuple \((tx,ty)\) where \(tx,ty\) contain knots positions of the spline with respect to x-, y-variable, respectively. The position of interior and additional knots are given as \(t[k+1::k-1]\) and \(t[:k+1]=b, t[-k-1:]\) respectively.
scipy.interpolate.LSQBivariateSpline.get_residual

LSQBivariateSpline.get_residual()
Return weighted sum of squared residuals of the spline approximation: sum ((w[i]*(z[i]-s(x[i],y[i])))**2, axis=0)

scipy.interpolate.LSQBivariateSpline.integral

LSQBivariateSpline.integral(xa, xb, ya, yb)
Evaluate the integral of the spline over area [xa,xb] x [ya,yb].

Parameters
xa, xb [float] The end-points of the x integration interval.
ya, yb [float] The end-points of the y integration interval.

Returns
integ [float] The value of the resulting integral.

scipy.interpolate.LSQSphereBivariateSpline

class scipy.interpolate.LSQSphereBivariateSpline(theta, phi, r, tt, tp, w=None, eps=1e-16)
Weighted least-squares bivariate spline approximation in spherical coordinates.
Determines a smoothing bicubic spline according to a given set of knots in the theta and phi directions.
New in version 0.11.0.

Parameters
theta, phi, r
[array_like] 1-D sequences of data points (order is not important). Coordinates must be given in radians. Theta must lie within the interval [0, \pi], and phi must lie within the interval [0, 2\pi].
tt, tp
[array_like] Strictly ordered 1-D sequences of knots coordinates. Coordinates must satisfy 0 < tt[i] < \pi, 0 < tp[i] < 2*\pi.
w
[array_like, optional] Positive 1-D sequence of weights, of the same length as theta, phi and r.
eps
[float, optional] A threshold for determining the effective rank of an over-determined linear system of equations. eps should have a value within the open interval (0, 1), the default is 1e-16.

Notes
For more information, see the FITPACK site about this function.

Examples
Suppose we have global data on a coarse grid (the input data does not have to be on a grid):

```python
>>> from scipy.interpolate import LSQSphereBivariateSpline
>>> import matplotlib.pyplot as plt

>>> theta = np.linspace(0, np.pi, num=7)
>>> phi = np.linspace(0, 2*np.pi, num=9)
>>> data = np.empty((theta.shape[0], phi.shape[0]))
>>> data[1:-1,1], data[1:-1,-1] = 1., 1.
>>> data[1,1:-1], data[-2,1:-1] = 1., 1.
>>> data[2:-2,2], data[2:-2,-2] = 2., 2.
>>> data[2,2:-2], data[-3,2:-2] = 2., 2.
>>> data[3,3:-2] = 3.
>>> data = np.roll(data, 4, 1)
We need to set up the interpolator object. Here, we must also specify the coordinates of the knots to use.

```python
>>> lats, lons = np.meshgrid(theta, phi)
>>> knotst, knotsp = theta.copy(), phi.copy()
>>> knotst[0] += .0001
>>> knotst[-1] -= .0001
>>> knotsp[0] += .0001
>>> knotsp[-1] -= .0001
>>> lut = LSQSphereBivariateSpline(lats.ravel(), lons.ravel(),
... data.T.ravel(), knotst, knotsp)
```
As a first test, we’ll see what the algorithm returns when run on the input coordinates

```python
>>> data_orig = lut(theta, phi)
```
Finally we interpolate the data to a finer grid

```python
>>> fine_lats = np.linspace(0., np.pi, 70)
>>> fine_lons = np.linspace(0., 2*np.pi, 90)
>>> data_lsq = lut(fine_lats, fine_lons)

>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(131)
>>> ax1.imshow(data, interpolation='nearest')
>>> ax2 = fig.add_subplot(132)
>>> ax2.imshow(data_orig, interpolation='nearest')
>>> ax3 = fig.add_subplot(133)
>>> ax3.imshow(data_lsq, interpolation='nearest')
>>> plt.show()
```

### Methods

- **`__call__`**(theta, phi[, dtheta, dphi, grid])
  Evaluate the spline or its derivatives at given positions.

- **`ev`**(theta, phi[, dtheta, dphi])
  Evaluate the spline at points

- **`get_coeffs`**()
  Return spline coefficients.

- **`get_knots`**()
  Return a tuple (tx,ty) where tx,ty contain knots positions of the spline with respect to x-, y-variable, respectively.

- **`get_residual`**()
  Return weighted sum of squared residuals of the spline approximation: sum ((w[i]*(z[i]-s(x[i],y[i])))**2,axis=0)
The `LSQSphereBivariateSpline.__call__` method evaluates the spline or its derivatives at given positions.

**Parameters**

- `theta, phi` [array_like] Input coordinates. If `grid` is False, evaluate the spline at points `(theta[i], phi[i]), i=0, ..., len(x)-1`. Standard Numpy broadcasting is obeyed. If `grid` is True: evaluate spline at the grid points defined by the coordinate arrays `theta, phi`. The arrays must be sorted to increasing order.
- `grid` [bool] Whether to evaluate the results on a grid spanned by the input arrays, or at points specified by the input arrays. New in version 0.14.0.

The `LSQSphereBivariateSpline.ev` method evaluates the spline at points. It returns the interpolated value at `(theta[i], phi[i]), i=0,...,len(theta)-1`.

**Parameters**

The `LSQSphereBivariateSpline.get_coeffs` method returns spline coefficients.

The `LSQSphereBivariateSpline.get_knots` method returns a tuple `(tx,ty)` where `tx,ty` contain knots positions of the spline with respect to x-, y-variable, respectively. The position of interior and additional knots are given as `t[k+1:-k-1]` and `t[:k+1]=b, t[-k-1:] = e`, respectively.
scipy.interpolate.LSQSphereBivariateSpline.get_residual

LSQSphereBivariateSpline.get_residual()

Return weighted sum of squared residuals of the spline approximation: sum ((w[i]*(z[i]-
s(x[i],y[i])))**2,axis=0)

Low-level interface to FITPACK functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bisplrep(x, y, z[, w, xb, xe, yb, ye, kx, ...])</td>
<td>Find a bivariate B-spline representation of a surface.</td>
</tr>
<tr>
<td>bisplev(x, y, tck[, dx, dy])</td>
<td>Evaluate a bivariate B-spline and its derivatives.</td>
</tr>
</tbody>
</table>

scipy.interpolate.bisplrep

scipy.interpolate.bisplrep(x, y, z, w=None, xb=None, xe=None, yb=None, ye=None, kx=3, ky=3, task=0, s=None, eps=1e-16, tx=None, ty=None, full_output=0, nxest=None, nyest=None, quiet=1)

Find a bivariate B-spline representation of a surface.

Given a set of data points (x[i], y[i], z[i]) representing a surface z=f(x,y), compute a B-spline representation of the surface. Based on the routine SURFIT from FITPACK.

**Parameters**

- **x, y, z** [ndarray] Rank-1 arrays of data points.
- **w** [ndarray, optional] Rank-1 array of weights. By default w=np.ones(len(x)).
- **xb, xe** [float, optional] End points of approximation interval in x. By default xb = x.min(), xe=x.max().
- **yb, ye** [float, optional] End points of approximation interval in y. By default yb=y.min(), ye = y.max().
- **kx, ky** [int, optional] The degrees of the spline (1 <= kx, ky <= 5). Third order (kx=ky=3) is recommended.
- **task** [int, optional] If task=0, find knots in x and y and coefficients for a given smoothing factor, s. If task=1, find knots and coefficients for another value of the smoothing factor, s. bisplrep must have been previously called with task=0 or task=1. If task=-1, find coefficients for a given set of knots tx, ty.
- **s** [float, optional] A non-negative smoothing factor. If weights correspond to the inverse of the standard-deviation of the errors in z, then a good s-value should be found in the range (m-sqrt(2*m), m+sqrt(2*m)) where m=len(x).
- **eps** [float, optional] A threshold for determining the effective rank of an over-determined linear system of equations (0 < eps < 1). eps is not likely to need changing.
- **tx, ty** [ndarray, optional] Rank-1 arrays of the knots of the spline for task=-1
- **full_output** [int, optional] Non-zero to return optional outputs.
- **nxest, nyest** [int, optional] Over-estimates of the total number of knots. If None then nxest = max(kx+sqrt(m/2),2*kx+3), nyest = max(ky+sqrt(m/2),2*ky+3).
- **quiet** [int, optional] Non-zero to suppress printing of messages. This parameter is deprecated; use standard Python warning filters instead.

**Returns**

- **tck** [array_like] A list [tx, ty, c, kx, ky] containing the knots (tx, ty) and coefficients (c) of the bivariate B-spline representation of the surface along with the degree of the spline.
- **fp** [ndarray] The weighted sum of squared residuals of the spline approximation.
- **ier** [int] An integer flag about splrep success. Success is indicated if ier<=0. If ier in [1,2,3] an error occurred but was not raised. Otherwise an error is raised.
msg  [str] A message corresponding to the integer flag, ier.

Examples

Examples are given in the tutorial.

scipy.interpolate.bisplev

scipy.interpolate.bisplev(x, y, tck, dx=0, dy=0)

Evaluate a bivariate B-spline and its derivatives.

Return a rank-2 array of spline function values (or spline derivative values) at points given by the cross-product of the rank-1 arrays x and y. In special cases, return an array or just a float if either x or y or both are floats. Based on BISPEV from FITPACK.

Parameters

- x, y  [ndarray] Rank-1 arrays specifying the domain over which to evaluate the spline or its derivative.
- tck  [tuple] A sequence of length 5 returned by bisplrep containing the knot locations, the coefficients, and the degree of the spline: [tx, ty, c, kx, ky].
- dx, dy  [int, optional] The orders of the partial derivatives in x and y respectively.

Returns

vals  [ndarray] The B-spline or its derivative evaluated over the set formed by the cross-product of x and y.

**scipy.interpolate.lagrange**

`scipy.interpolate.lagrange(x, w)`

Return a Lagrange interpolating polynomial.

Given two 1-D arrays x and w, returns the Lagrange interpolating polynomial through the points (x, w).

Warning: This implementation is numerically unstable. Do not expect to be able to use more than about 20 points even if they are chosen optimally.

**Parameters**

- **x** [array_like] x represents the x-coordinates of a set of datapoints.
- **w** [array_like] w represents the y-coordinates of a set of datapoints, i.e., f(x).

**Returns**

- **lagrange** [numpy.poly1d instance] The Lagrange interpolating polynomial.

**Examples**

Interpolate \( f(x) = x^3 \) by 3 points.

```python
>>> from scipy.interpolate import lagrange
>>> x = np.array([0, 1, 2])
>>> y = x**3
>>> poly = lagrange(x, y)
```

Since there are only 3 points, Lagrange polynomial has degree 2. Explicitly, it is given by

\[
L(x) = 1 \times \frac{x(x - 2)}{-1} + 8 \times \frac{x(x - 1)}{2} = x(-2 + 3x)
\]
```python
>>> from numpy.polynomial.polynomial import Polynomial
>>> Polynomial(poly.coef[::-1]).coef
array([ 0., -2.,  3.])

>>> import matplotlib.pyplot as plt
>>> x_new = np.arange(0, 2.1, 0.1)
>>> plt.scatter(x, y, label='data')
>>> plt.plot(x_new, Polynomial(poly.coef[::-1])(x_new), label='Polynomial')
>>> plt.plot(x_new, 3*x_new**2 - 2*x_new + 0*x_new,
...          label=r'$3 x^2 - 2 x$', linestyle='--')
>>> plt.legend()
>>> plt.show()
```

### scipy.interpolate.approximate_taylor_polynomial

Estimate the Taylor polynomial of f at x by polynomial fitting.

**Parameters**

- `f` [callable] The function whose Taylor polynomial is sought. Should accept a vector of x values.
- `x` [scalar] The point at which the polynomial is to be evaluated.
- `degree` [int] The degree of the Taylor polynomial
- `scale` [scalar] The width of the interval to use to evaluate the Taylor polynomial. Function values spread over a range this wide are used to fit the polynomial. Must be chosen carefully.
- `order` [int or None, optional] The order of the polynomial to be used in the fitting; f will be evaluated order+1 times. If None, use `degree`.

**Returns**

- `p` [poly1d instance] The Taylor polynomial (translated to the origin, so that for example p(0)=f(x)).
Notes

The appropriate choice of “scale” is a trade-off; too large and the function differs from its Taylor polynomial too much to get a good answer, too small and round-off errors overwhelm the higher-order terms. The algorithm used becomes numerically unstable around order 30 even under ideal circumstances.

Choosing order somewhat larger than degree may improve the higher-order terms.

Examples

We can calculate Taylor approximation polynomials of sin function with various degrees:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.interpolate import approximate_taylor_polynomial
>>> x = np.linspace(-10.0, 10.0, num=100)
>>> plt.plot(x, np.sin(x), label="sin curve")
>>> for degree in np.arange(1, 15, step=2):
...     sin_taylor = approximate_taylor_polynomial(np.sin, 0, degree, 1,
...                                                 order=degree + 2)
...     plt.plot(x, sin_taylor(x), label=f"degree={degree}")
>>> plt.legend(bbox_to_anchor=(1.05, 1), loc='upper left',
...             borderaxespad=0.0, shadow=True)
>>> plt.tight_layout()
>>> plt.axis([-10, 10, -10, 10])
>>> plt.show()
```

![Image of Taylor approximation polynomials of sin function with various degrees]
scipy.interpolate.pade

scipy.interpolate.pade(an, m, n=None)

Return Pade approximation to a polynomial as the ratio of two polynomials.

Parameters

- **an** ([N,] array_like) Taylor series coefficients.
- **m** [int] The order of the returned approximating polynomial \( q \).
- **n** [int, optional] The order of the returned approximating polynomial \( p \). By default, the order is \( \text{len}(an) - 1 - m \).

Returns

- **p, q** [Polynomial class] The Pade approximation of the polynomial defined by \( an \) is \( \frac{p(x)}{q(x)} \).

Examples

```python
>>> from scipy.interpolate import pade
>>> e_exp = [1.0, 1.0, 1.0/2.0, 1.0/6.0, 1.0/24.0, 1.0/120.0]
>>> p, q = pade(e_exp, 2)

>>> e_exp.reverse()
>>> e_poly = np.poly1d(e_exp)

Compare \( e_{\text{poly}}(x) \) and the Pade approximation \( \frac{p(x)}{q(x)} \)

```)

```python
>>> e_poly(1)
2.7166666666666668

>>> p(1)/q(1)
2.7179487179487181
```

pchip is an alias of PchipInterpolator for backward compatibility (should not be used in new code).

### 3.3.9 Input and output (scipy.io)

SciPy has many modules, classes, and functions available to read data from and write data to a variety of file formats.

See also:

NumPy IO routines
### MATLAB® files

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>loadmat</code></td>
<td>Load MATLAB file.</td>
</tr>
<tr>
<td><code>savemat</code></td>
<td>Save a dictionary of names and arrays into a MATLAB-style .mat file.</td>
</tr>
<tr>
<td><code>whosmat</code></td>
<td>List variables inside a MATLAB file.</td>
</tr>
</tbody>
</table>

#### scipy.io.loadmat

`scipy.io.loadmat (file_name, mdict=None, appendmat=True, **kwargs)`

Load MATLAB file.

**Parameters**

- `file_name` [str] Name of the mat file (do not need .mat extension if appendmat=True). Can also pass open file-like object.
- `mdict` [dict, optional] Dictionary in which to insert matfile variables.
- `appendmat` [bool, optional] True to append the .mat extension to the end of the given filename, if not already present. Default is True.
- `byte_order` [str or None, optional] None by default, implying byte order guessed from mat file. Otherwise can be one of (‘native’, ‘=’, ‘little’, ‘<’, ‘BIG’, ‘>’).
- `mat_dtype` [bool, optional] If True, return arrays in same dtype as would be loaded into MATLAB (instead of the dtype with which they are saved).
- `squeeze_me` [bool, optional] Whether to squeeze unit matrix dimensions or not.
- `chars_as_strings` [bool, optional] Whether to convert char arrays to string arrays.
- `matlab_compatible` [bool, optional] Returns matrices as would be loaded by MATLAB (implies squeeze_me=False, chars_as_strings=False, mat_dtype=True, struct_as_record=True).
- `struct_as_record` [bool, optional] Whether to load MATLAB structs as NumPy record arrays, or as old-style NumPy arrays with dtype=object. Setting this flag to False replicates the behavior of scipy version 0.7.x (returning NumPy object arrays). The default setting is True, because it allows easier round-trip load and save of MATLAB files.
- `verify_compressed_data_integrity` [bool, optional] Whether the length of compressed sequences in the MATLAB file should be checked, to ensure that they are not longer than we expect. It is advisable to enable this (the default) because overlong compressed sequences in MATLAB files generally indicate that the files have experienced some sort of corruption.
- `variable_names` [None or sequence] If None (the default) - read all variables in file. Otherwise, variable_names should be a sequence of strings, giving names of the MATLAB variables to read from the file. The reader will skip any variable with a name not in this sequence, possibly saving some read processing.
- `simplify_cells` [False, optional] If True, return a simplified dict structure (which is useful if the mat file contains cell arrays). Note that this only affects the structure of the result and not its contents (which is identical for both output structures). If True, this automatically sets struct_as_record to False and squeeze_me to True, which is required to simplify cells.

**Returns**
mat_dict

[dict] dictionary with variable names as keys, and loaded matrices as values.

Notes

v4 (Level 1.0), v6 and v7 to 7.2 matfiles are supported.

You will need an HDF5 Python library to read MATLAB 7.3 format mat files. Because SciPy does not supply one, we do not implement the HDF5 / 7.3 interface here.

Examples

```python
>>> from os.path import dirname, join as pjoin
>>> import scipy.io as sio

Get the filename for an example .mat file from the tests/data directory.

```python
>>> data_dir = pjoin(dirname(sio.__file__), 'matlab', 'tests', 'data')
>>> mat_fname = pjoin(data_dir, 'testdouble_7.4_GLNX86.mat')
```

Load the .mat file contents.

```python
>>> mat_contents = sio.loadmat(mat_fname)

The result is a dictionary, one key/value pair for each variable:

```python
>>> sorted(mat_contents.keys())
['__globals__', '__header__', '__version__', 'testdouble']
```  
```python
>>> mat_contents['testdouble']
array([[0. , 0.78539816, 1.57079633, 2.35619449, 3.14159265,
       3.92699082, 4.71238898, 5.49778714, 6.28318531]])
```

By default SciPy reads MATLAB structs as structured NumPy arrays where the dtype fields are of type `object` and the names correspond to the MATLAB struct field names. This can be disabled by setting the optional argument `struct_as_record=False`.

Get the filename for an example .mat file that contains a MATLAB struct called `teststruct` and load the contents.

```python
>>> matstruct_fname = pjoin(data_dir, 'teststruct_7.4_GLNX86.mat')
>>> matstruct_contents = sio.loadmat(matstruct_fname)
>>> teststruct = matstruct_contents['teststruct']
```  
```python
teststruct.dtype

```
```  
```python
dtype([('stringfield', 'O'), ('doublefield', 'O'), ('complexfield', 'O'))]
```

The size of the structured array is the size of the MATLAB struct, not the number of elements in any particular field. The shape defaults to 2-D unless the optional argument `squeeze_me=True`, in which case all length 1 dimensions are removed.

```python
>>> teststruct.size
1
>>> teststruct.shape
(1, 1)
```

Get the ‘stringfield’ of the first element in the MATLAB struct.
Get the first element of the 'doublefield'.

>>> teststruct['doublefield'][0, 0]
array([[ 1.41421356,  2.71828183,  3.14159265]])

Load the MATLAB struct, squeezing out length 1 dimensions, and get the item from the 'complexfield'.

```python
>>> matstruct_squeezed = sio.loadmat(matstruct_fname, squeeze_me=True)
>>> matstruct_squeezed['teststruct'].shape
()  # Shape of the squeezed structure
>>> matstruct_squeezed['teststruct']['complexfield'].shape
()  # Shape of the 'complexfield'
>>> matstruct_squeezed['teststruct']['complexfield'].item()
array([[ 1.41421356+1.41421356j,  2.71828183+2.71828183j,
          3.14159265+3.14159265j]])
```

### scipy.io.savemat

`scipy.io.savemat(file_name, mdict, appendmat=True, format='5', do_compression=False, oned_as='row')`

Save a dictionary of names and arrays into a MATLAB-style .mat file.

This saves the array objects in the given dictionary to a MATLAB-style .mat file.

**Parameters**

- **file_name** [str or file-like object] Name of the .mat file (.mat extension not needed if `appendmat == True`). Can also pass open file_like object.
- **mdict** [dict] Dictionary from which to savemat file variables.
- **appendmat** [bool, optional] True (the default) to append the .mat extension to the end of the given file-name, if not already present.
- **format** [‘5’, ‘4’], string, optional ‘5’ (the default) for MATLAB 5 and up (to 7.2), ‘4’ for MATLAB 4 .mat files.
- **long_field_names** [bool, optional] False (the default) - maximum field name length in a structure is 31 characters which is the documented maximum length. True - maximum field name length in a structure is 63 characters which works for MATLAB 7.6+.  
- **do_compression** [bool, optional] Whether or not to compress matrices on write. Default is False.
- **oned_as** [{‘row’, ‘column’}, optional] If ‘column’, write 1-D NumPy arrays as column vectors. If ‘row’, write 1-D NumPy arrays as row vectors.
Examples

```python
from scipy.io import savemat
a = np.arange(20)
mdic = {'a': a, 'label': 'experiment'}
savemat("matlab_matrix.mat", mdic)
```

**scipy.io.whosmat**

`scipy.io.whosmat(file_name, appendmat=True, **kwargs)`

List variables inside a MATLAB file.

**Parameters**

- `file_name` [str] Name of the mat file (do not need .mat extension if appendmat==True) Can also pass open file-like object.
- `appendmat` [bool, optional] True to append the .mat extension to the end of the given filename, if not already present. Default is True.
- `byte_order` [str or None, optional] None by default, implying byte order guessed from mat file. Otherwise can be one of (‘native’, ‘=’, ‘little’, ‘<’, ‘BIG’, ‘>’).
- `mat_dtype` [bool, optional] If True, return arrays in same dtype as would be loaded into MATLAB (instead of the dtype with which they are saved).
- `squeeze_me` [bool, optional] Whether to squeeze unit matrix dimensions or not.
- `chars_as_strings` [bool, optional] Whether to convert char arrays to string arrays.
- `matlab_compatible` [bool, optional] Returns matrices as would be loaded by MATLAB (implies squeeze_me=False, chars_as_strings=False, mat_dtype=True, struct_as_record=True).
- `struct_as_record` [bool, optional] Whether to load MATLAB structs as NumPy record arrays, or as old-style NumPy arrays with dtype=object. Setting this flag to False replicates the behavior of SciPy version 0.7.x (returning numpy object arrays). The default setting is True, because it allows easier round-trip load and save of MATLAB files.

**Returns**

- `variables` [list of tuples] A list of tuples, where each tuple holds the matrix name (a string), its shape (tuple of ints), and its data class (a string). Possible data classes are: int8, uint8, int16, uint16, int32, uint32, int64, uint64, single, double, cell, struct, object, char, sparse, function, opaque, logical, unknown.
Notes

v4 (Level 1.0), v6 and v7 to 7.2 matfiles are supported.

You will need an HDF5 python library to read matlab 7.3 format mat files. Because SciPy does not supply one, we do not implement the HDF5 / 7.3 interface here.

New in version 0.12.0.

For low-level MATLAB reading and writing utilities, see `scipy.io.matlab`.

IDL® files

```
readsav(file_name[, idict, python_dict, ...])
```

Read an IDL .sav file.

```
scipy.io.readsav
```

```
scipy.io.readsav (file_name, idict=None, python_dict=False, uncompressed_file_name=None, verbose=False)
```

Read an IDL .sav file.

**Parameters**

- `file_name` [str] Name of the IDL save file.
- `idict` [dict, optional] Dictionary in which to insert .sav file variables.
- `python_dict` [bool, optional] By default, the object return is not a Python dictionary, but a case-insensitive dictionary with item, attribute, and call access to variables. To get a standard Python dictionary, set this option to True.
- `uncompressed_file_name` [str, optional] This option only has an effect for .sav files written with the /compress option. If a file name is specified, compressed .sav files are uncompressed to this file. Otherwise, readsav will use the `tempfile` module to determine a temporary filename automatically, and will remove the temporary file upon successfully reading it in.
- `verbose` [bool, optional] Whether to print out information about the save file, including the records read, and available variables.

**Returns**

- `idl_dict` [AttrDict or dict] If `python_dict` is set to False (default), this function returns a case-insensitive dictionary with item, attribute, and call access to variables. If `python_dict` is set to True, this function returns a Python dictionary with all variable names in lowercase. If `idict` was specified, then variables are written to the dictionary specified, and the updated dictionary is returned.

**Examples**

```
>>> from os.path import dirname, join as pjoin
>>> import scipy.io as sio
>>> from scipy.io import readsav
```

Get the filename for an example .sav file from the tests/data directory.

```
>>> data_dir = pjoin(dirname(sio.__file__), 'tests', 'data')
>>> sav_fname = pjoin(data_dir, 'array_float32_1d.sav')
```
Load the .sav file contents.

```python
>>> sav_data = readsav(sav_fname)
```

Get keys of the .sav file contents.

```python
>>> print(sav_data.keys())
dict_keys(['array1d'])
```

Access a content with a key.

```python
>>> print(sav_data['array1d'])
[0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0.

**Matrix Market files**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mminfo()</code></td>
<td>Return size and storage parameters from Matrix Market file-like 'source'.</td>
</tr>
<tr>
<td><code>mmread()</code></td>
<td>Reads the contents of a Matrix Market file-like 'source' into a matrix.</td>
</tr>
<tr>
<td><code>mmwrite()</code></td>
<td>Writes the sparse or dense array <code>a</code> to Matrix Market file-like <code>target</code>.</td>
</tr>
</tbody>
</table>

**scipy.io.mminfo**

Return size and storage parameters from Matrix Market file-like `source`.

**Parameters**

- `source` [str or file-like] Matrix Market filename (extension .mtx) or open file-like object

**Returns**

- `rows` [int] Number of matrix rows.
- `cols` [int] Number of matrix columns.
- `entries` [int] Number of non-zero entries of a sparse matrix or rows*cols for a dense matrix.
- `format` [str] Either 'coordinate' or 'array'.
- `field` [str] Either 'real', 'complex', 'pattern', or 'integer'.
- `symmetry` [str] Either 'general', 'symmetric', 'skew-symmetric', or 'hermitian'.

---

Chapter 3. SciPy API
scipy.io.mmread

scipy.io.mmread(source)

Reads the contents of a Matrix Market file-like ‘source’ into a matrix.

Parameters

- source [str or file-like] Matrix Market filename (extensions .mtx, .mtz.gz) or open file-like object.

Returns

- a [ndarray or coo_matrix] Dense or sparse matrix depending on the matrix format in the Matrix Market file.

scipy.io.mmwrite

scipy.io.mmwrite(target, a, comment='', field=None, precision=None, symmetry=None)

Writes the sparse or dense array a to Matrix Market file-like target.

Parameters

- target [str or file-like] Matrix Market filename (extension .mtx) or open file-like object.
- a [array-like] Sparse or dense 2-D array.
- comment [str, optional] Comments to be prepended to the Matrix Market file.
- precision [None or int, optional] Number of digits to display for real or complex values.
- symmetry [None or str, optional] Either ‘general’, ‘symmetric’, ‘skew-symmetric’, or ‘hermitian’. If symmetry is None the symmetry type of ‘a’ is determined by its values.

Unformatted Fortran files

| FortranFile(filename[, mode, header_dtype]) | A file object for unformatted sequential files from Fortran code. |
| FortranEOFError | Indicates that the file ended properly. |
| FortranFormattingError | Indicates that the file ended mid-record. |

scipy.io.FortranFile

class scipy.io.FortranFile(filename, mode='r', header_dtype=<class 'numpy.uint32'>)

A file object for unformatted sequential files from Fortran code.

Parameters

- filename [file or str] Open file object or filename.
- mode [‘r’, ‘w’, optional] Read-write mode, default is ‘r’.
- header_dtype [dtype, optional] Data type of the header. Size and endiness must match the input/output file.
Notes

These files are broken up into records of unspecified types. The size of each record is given at the start (although
the size of this header is not standard) and the data is written onto disk without any formatting. Fortran compilers
supporting the BACKSPACE statement will write a second copy of the size to facilitate backwards seeking.

This class only supports files written with both sizes for the record. It also does not support the subrecords used in
Intel and gfortran compilers for records which are greater than 2GB with a 4-byte header.

An example of an unformatted sequential file in Fortran would be written as:

```fortran
OPEN(1, FILE=myfilename, FORM='unformatted')
WRITE(1) myvariable
```

Since this is a non-standard file format, whose contents depend on the compiler and the endianness of the machine,
caution is advised. Files from gfortran 4.8.0 and gfortran 4.1.2 on x86_64 are known to work.

Consider using Fortran direct-access files or files from the newer Stream I/O, which can be easily read by `numpy.fromfile`.

Examples

To create an unformatted sequential Fortran file:

```python
>>> from scipy.io import FortranFile
>>> f = FortranFile('test.unf', 'w')
>>> f.write_record(np.array([1,2,3,4,5], dtype=np.int32))
>>> f.write_record(np.linspace(0,1,20).reshape((5,4)).T)
>>> f.close()
```

To read this file:

```python
>>> f = FortranFile('test.unf', 'r')
>>> print(f.read_ints(np.int32))
[1 2 3 4 5]
>>> print(f.read_reals(float).reshape((5,4), order="F"))
[[0. 0.05263158 0.10526316 0.15789474]
 [0.21052632 0.26315789 0.31578947 0.36842105]
 [0.42105263 0.47368421 0.52631579 0.57894737]
 [0.63157895 0.68421053 0.73684211 0.78947368]
 [0.84210526 0.89473684 0.94736842 1.]]
>>> f.close()
```

Or, in Fortran:

```fortran
integer :: a(5), i
double precision :: b(5,4)
open(1, file='test.unf', form='unformatted')
read(1) a
read(1) b
close(1)
write(*,*) a
do i = 1, 5
```

(continues on next page)
write(*,*), b(i,:),
end do

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>close()</td>
<td>Closes the file.</td>
</tr>
<tr>
<td>read_ints([dtype])</td>
<td>Reads a record of a given type from the file, defaulting to an integer type (INTEGER*4 in Fortran).</td>
</tr>
<tr>
<td>read_reals([dtype])</td>
<td>Reads a record of a given type from the file, defaulting to a floating point number (real*8 in Fortran).</td>
</tr>
<tr>
<td>read_record(*dtypes, **kwargs)</td>
<td>Reads a record of a given type from the file.</td>
</tr>
<tr>
<td>write_record(*items)</td>
<td>Write a record (including sizes) to the file.</td>
</tr>
</tbody>
</table>

*scipy.io.FortranFile.close*

FortranFile.close()

Closes the file. It is unsupported to call any other methods off this object after closing it. Note that this class supports the ‘with’ statement in modern versions of Python, to call this automatically.

*scipy.io.FortranFile.read_ints*

FortranFile.read_ints(dtype='i4')

Reads a record of a given type from the file, defaulting to an integer type (INTEGER*4 in Fortran).

**Parameters**

dtype [dtype, optional] Data type specifying the size and endiness of the data.

**Returns**

See also:

read_reals
read_record

*scipy.io.FortranFile.read_reals*

FortranFile.read_reals(dtype='f8')

Reads a record of a given type from the file, defaulting to a floating point number (real*8 in Fortran).

**Parameters**

dtype [dtype, optional] Data type specifying the size and endiness of the data.

**Returns**

See also:
**scipy.io.FortranFile.read_record**

*FortranFile.read_record(*dtypes, **kwargs)*

Reads a record of a given type from the file.

**Parameters**

* *dtypes*  
  [dtypes, optional] Data type(s) specifying the size and endiness of the data.

**Returns**

* data  

**Raises**

* FortranEOFError  
  To signal that no further records are available

* FortranFormattingError  
  To signal that the end of the file was encountered part-way through a record

**See also:**

* read_reals
* read_ints

**Notes**

If the record contains a multidimensional array, you can specify the size in the dtype. For example:

```plaintext
INTEGER var(5,4)
```

can be read with:

```plaintext
read_record('(4,5)i4').T
```

Note that this function does **not** assume the file data is in Fortran column major order, so you need to (i) swap the order of dimensions when reading and (ii) transpose the resulting array.

Alternatively, you can read the data as a 1-D array and handle the ordering yourself. For example:

```plaintext
read_record('i4').reshape(5, 4, order='F')
```

For records that contain several variables or mixed types (as opposed to single scalar or array types), give them as separate arguments:

```plaintext
double precision :: a
integer :: b
write(1) a, b
record = f.read_record('<f4', '<i4')
a = record[0]  # first number
b = record[1]  # second number
```
and if any of the variables are arrays, the shape can be specified as the third item in the relevant dtype:

```python
double precision :: a
integer :: b(3,4)
write(1) a, b

record = f.read_record('<f4', np.dtype(['<i4', (4, 3)]))

a = record[0]
b = record[1].T
```

NumPy also supports a short syntax for this kind of type:

```python
record = f.read_record('<f4', '(3,3)<i4')
```

### scipy.io.FortranFile.write_record

**FortranFile.write_record(*items)**

Write a record (including sizes) to the file.

**Parameters**

*items [array_like] The data arrays to write.

**Notes**

Writes data items to a file:

```python
write_record(a.T, b.T, c.T, ...)
write(1) a, b, c, ...
```

Note that data in multidimensional arrays is written in row-major order — to make them read correctly by Fortran programs, you need to transpose the arrays yourself when writing them.

### scipy.io.FortranEOFErrorexception

**scipy.io.FortranEOFErrorexception**

Indicates that the file ended properly.

This error descends from TypeError because the code used to raise TypeError (and this was the only way to know that the file had ended) so users might have `except TypeError:`.

**errno**

POSIX exception code

**filename**

exception filename

**filename2**

second exception filename

**strerror**

exception strerror

**with_traceback()**

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
scipy.io.FortranFormattingError

Exception `scipy.io.FortranFormattingError` indicates that the file ended mid-record.

Descends from TypeError for backward compatibility.

- `errno` : POSIX exception code
- `filename` : exception filename
- `filename2` : second exception filename
- `strerror` : exception strerror

`with_traceback()`:
```
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

Netcdf

```python
netcdf_file(filename[, mode, mmap, version, ...])
A file object for NetCDF data.
```

```python
netcdf_variable(data, typecode, size, shape, ...)
A data object for netcdf files.
```

scipy.io.netcdf_file

```python
class scipy.io.netcdf_file(filename, mode='r', mmap=None, version=1, maskandscale=False)
A file object for NetCDF data.
```

A `netcdf_file` object has two standard attributes: `dimensions` and `variables`. The values of both are dictionaries, mapping dimension names to their associated lengths and variable names to variables, respectively. Application programs should never modify these dictionaries.

All other attributes correspond to global attributes defined in the NetCDF file. Global file attributes are created by assigning to an attribute of the `netcdf_file` object.

**Parameters**

- `filename` : [string or file-like] string -> filename
- `mode` : [‘r’, ‘w’, ‘a’], optional] read-write-append mode, default is ‘r’
- `mmap` : [None or bool, optional] Whether to mmap `filename` when reading. Default is True when `filename` is a file name, False when `filename` is a file-like object. Note that when mmap is in use, data arrays returned refer directly to the mmapped data on disk, and the file cannot be closed as long as references to it exist.
- `version` : [{1, 2}, optional] version of netcdf to read / write, where 1 means *Classic format* and 2 means *64-bit offset format*. Default is 1. See here for more info.
- `maskandscale` : [bool, optional] Whether to automatically scale and/or mask data based on attributes. Default is False.
Notes

The major advantage of this module over other modules is that it doesn’t require the code to be linked to the NetCDF libraries. This module is derived from pupynere.

NetCDF files are a self-describing binary data format. The file contains metadata that describes the dimensions and variables in the file. More details about NetCDF files can be found here. There are three main sections to a NetCDF data structure:

1. Dimensions
2. Variables
3. Attributes

The dimensions section records the name and length of each dimension used by the variables. The variables would then indicate which dimensions it uses and any attributes such as data units, along with containing the data values for the variable. It is good practice to include a variable that is the same name as a dimension to provide the values for that axes. Lastly, the attributes section would contain additional information such as the name of the file creator or the instrument used to collect the data.

When writing data to a NetCDF file, there is often the need to indicate the ‘record dimension’. A record dimension is the unbounded dimension for a variable. For example, a temperature variable may have dimensions of latitude, longitude and time. If one wants to add more temperature data to the NetCDF file as time progresses, then the temperature variable should have the time dimension flagged as the record dimension.

In addition, the NetCDF file header contains the position of the data in the file, so access can be done in an efficient manner without loading unnecessary data into memory. It uses the mmap module to create Numpy arrays mapped to the data on disk, for the same purpose.

Note that when netcdf_file is used to open a file with mmap=True (default for read-only), arrays returned by it refer to data directly on the disk. The file should not be closed, and cannot be cleanly closed when asked, if such arrays are alive. You may want to copy data arrays obtained from mmapped Netcdf file if they are to be processed after the file is closed, see the example below.

Examples

To create a NetCDF file:

```python
>>> from scipy.io import netcdf_file
>>> f = netcdf_file('simple.nc', 'w')
>>> f.history = 'Created for a test'
>>> f.createDimension('time', 10)
>>> time = f.createVariable('time', 'i', ('time',))
>>> time[:] = np.arange(10)
>>> time.units = 'days since 2008-01-01'
>>> f.close()
```

Note the assignment of arange(10) to time[:]. Exposing the slice of the time variable allows for the data to be set in the object, rather than letting arange(10) overwrite the time variable.

To read the NetCDF file we just created:

```python
>>> from scipy.io import netcdf_file
>>> f = netcdf_file('simple.nc', 'r')
>>> print(f.history)
b'Created for a test'
```

(continues on next page)
NetCDF files, when opened read-only, return arrays that refer directly to memory-mapped data on disk:

```python
>>> data = time[:,]
```

If the data is to be processed after the file is closed, it needs to be copied to main memory:

```python
>>> data = time[:].copy()
>>> f.close()
>>> data.mean()
4.5
```

A NetCDF file can also be used as context manager:

```python
>>> from scipy.io import netcdf_file
>>> with netcdf_file('simple.nc', 'r') as f:
...     print(f.history)
'b'Created for a test'
```

## Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>close()</code></td>
<td>Closes the NetCDF file.</td>
</tr>
<tr>
<td><code>createDimension(name, length)</code></td>
<td>Adds a dimension to the Dimension section of the NetCDF data structure.</td>
</tr>
<tr>
<td><code>createVariable(name, type, dimensions)</code></td>
<td>Create an empty variable for the <code>netcdf_file</code> object, specifying its data type and the dimensions it uses.</td>
</tr>
<tr>
<td><code>flush()</code></td>
<td>Perform a sync-to-disk flush if the <code>netcdf_file</code> object is in write mode.</td>
</tr>
<tr>
<td><code>sync()</code></td>
<td>Perform a sync-to-disk flush if the <code>netcdf_file</code> object is in write mode.</td>
</tr>
</tbody>
</table>

```python
scipy.io.netcdf_file.close
netcdf_file.close()
```

Closes the NetCDF file.
scipy.io.netcdf_file.createDimension

netcdf_file.createDimension(name, length)
Adds a dimension to the Dimension section of the NetCDF data structure.

Note that this function merely adds a new dimension that the variables can reference. The values for the
dimension, if desired, should be added as a variable using createVariable, referring to this dimension.

Parameters

- name [str] Name of the dimension (Eg. 'lat' or 'time').
- length [int] Length of the dimension.

See also:

createVariable

scipy.io.netcdf_file.createVariable

netcdf_file.createVariable(name, type, dimensions)
Create an empty variable for the netcdf_file object, specifying its data type and the dimensions it uses.

Parameters

- name [str] Name of the new variable.
- type [dtype or str] Data type of the variable.
- dimensions [sequence of str] List of the dimension names used by the variable, in the desired order.

Returns

- variable [netcdf_variable] The newly created netcdf_variable object. This object has also
  been added to the netcdf_file object as well.

See also:

createDimension

Notes

Any dimensions to be used by the variable should already exist in the NetCDF data structure or should be
created by createDimension prior to creating the NetCDF variable.

scipy.io.netcdf_file.flush

netcdf_file.flush()
Perform a sync-to-disk flush if the netcdf_file object is in write mode.

See also:

sync

Identical function
**scipy.io.netcdf_file.sync**

```python
cdf_file.sync()
```

Perform a sync-to-disk flush if the `netcdf_file` object is in write mode.

See also:

- `sync`

Identical function

**scipy.io.netcdf_variable**

**class scipy.io.netcdf_variable** (data, typecode, size, shape, dimensions, attributes=None, maskandscale=False)

A data object for netcdf files.

`netcdf_variable` objects are constructed by calling the method `netcdf_file.createVariable` on the `netcdf_file` object. `netcdf_variable` objects behave much like array objects defined in numpy, except that their data resides in a file. Data is read by indexing and written by assigning to an indexed subset; the entire array can be accessed by the index `[:]` or (for scalars) by using the methods `getValue` and `assign-Value`. `netcdf_variable` objects also have attribute `shape` with the same meaning as for arrays, but the shape cannot be modified. There is another read-only attribute `dimensions`, whose value is the tuple of dimension names.

All other attributes correspond to variable attributes defined in the NetCDF file. Variable attributes are created by assigning to an attribute of the `netcdf_variable` object.

**Parameters**

- **data** [array_like] The data array that holds the values for the variable. Typically, this is initialized as empty, but with the proper shape.
- **typecode** [dtype character code] Desired data-type for the data array.
- **size** [int] Desired element size for the data array.
- **shape** [sequence of ints] The shape of the array. This should match the lengths of the variable’s dimensions.
- **dimensions** [sequence of strings] The names of the dimensions used by the variable. Must be in the same order of the dimension lengths given by `shape`.
- **attributes** [dict, optional] Attribute values (any type) keyed by string names. These attributes become attributes for the netcdf_variable object.
- **maskandscale** [bool, optional] Whether to automatically scale and/or mask data based on attributes. Default is False.

See also:

- `isrec`, `shape`

**Attributes**

- **dimensions** [list of str] List of names of dimensions used by the variable object.
- **isrec**, `shape` Properties
Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assignValue(value)</code></td>
<td>Assign a scalar value to a <code>netcdf_variable</code> of length one.</td>
</tr>
<tr>
<td><code>getValue()</code></td>
<td>Retrieve a scalar value from a <code>netcdf_variable</code> of length one.</td>
</tr>
<tr>
<td><code>itemsize()</code></td>
<td>Return the itemsize of the variable.</td>
</tr>
<tr>
<td><code>typecode()</code></td>
<td>Return the typecode of the variable.</td>
</tr>
</tbody>
</table>

**scipy.io.netcdf_variable.assignValue**

```python
netcdf_variable.assignValue(value)
```

Assign a scalar value to a `netcdf_variable` of length one.

**Parameters**

- `value` [scalar] Scalar value (of compatible type) to assign to a length-one netcdf variable. This value will be written to file.

**Raises**

- `ValueError` If the input is not a scalar, or if the destination is not a length-one netcdf variable.

**scipy.io.netcdf_variable.getValue**

```python
netcdf_variable.getValue()
```

Retrieve a scalar value from a `netcdf_variable` of length one.

**Raises**

- `ValueError` If the netcdf variable is an array of length greater than one, this exception will be raised.

**scipy.io.netcdf_variable.itemsize**

```python
netcdf_variable.itemsize()
```

Return the itemsize of the variable.

**Returns**

- `itemsize` [int] The element size of the variable (e.g., 8 for float64).

**scipy.io.netcdf_variable.typecode**

```python
netcdf_variable.typecode()
```

Return the typecode of the variable.

**Returns**

- `typecode` [char] The character typecode of the variable (e.g., 'i' for int).
Harwell-Boeing files

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>hb_read</em></td>
<td>Read HB-format file.</td>
</tr>
<tr>
<td><em>hb_write</em></td>
<td>Write HB-format file.</td>
</tr>
</tbody>
</table>

**scipy.io.hb_read**

**scipy.io.hb_read(path_or_open_file)**

Read HB-format file.

**Parameters**

- **path_or_open_file**: [path-like or file-like] If a file-like object, it is used as-is. Otherwise, it is opened before reading.

**Returns**

- **data**: [scipy.sparse.csc_matrix instance] The data read from the HB file as a sparse matrix.

**Notes**

At the moment not the full Harwell-Boeing format is supported. Supported features are:

- assembled, non-symmetric, real matrices
- integer for pointer/indices
- exponential format for float values, and int format

**Examples**

We can read and write a harwell-boeing format file:

```python
>>> from scipy.io.harwell_boeing import hb_read, hb_write
>>> from scipy.sparse import csr_matrix, eye
>>> data = csr_matrix(eye(3))  # create a sparse matrix
>>> hb_write("data.hb", data)  # write a hb file
>>> print(hb_read("data.hb"))  # read a hb file
(0, 0) 1.0
(1, 1) 1.0
(2, 2) 1.0
```

**scipy.io.hb_write**

**scipy.io.hb_write(path_or_open_file, m, hb_info=None)**

Write HB-format file.

**Parameters**

- **path_or_open_file**: [path-like or file-like] If a file-like object, it is used as-is. Otherwise, it is opened before writing.
- **m**: [sparse-matrix] the sparse matrix to write
- **hb_info**: [HBInfo] contains the meta-data for write

**Returns**
None

**Notes**

At the moment not the full Harwell-Boeing format is supported. Supported features are:

- assembled, non-symmetric, real matrices
- integer for pointer/indices
- exponential format for float values, and int format

**Examples**

We can read and write a harwell-boeing format file:

```python
>>> from scipy.io.harwell_boeing import hb_read, hb_write
>>> from scipy.sparse import csr_matrix, eye

>>> data = csr_matrix(eye(3))  # create a sparse matrix
>>> hb_write("data.hb", data)  # write a hb file

>>> print(hb_read("data.hb"))  # read a hb file
(0, 0) 1.0
(1, 1) 1.0
(2, 2) 1.0
```

**Wav sound files** *(scipy.io.wavfile)*

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>read</code></td>
<td>Open a WAV file.</td>
</tr>
<tr>
<td><code>write</code></td>
<td>Write a NumPy array as a WAV file.</td>
</tr>
</tbody>
</table>

**scipy.io.wavfile.read**

`scipy.io.wavfile.read` *(filename, mmap=False)*

Open a WAV file.

Return the sample rate (in samples/sec) and data from an LPCM WAV file.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>filename</code></td>
<td>[string or open file handle] Input WAV file.</td>
</tr>
<tr>
<td><code>mmap</code></td>
<td>[bool, optional] Whether to read data as memory-mapped (default: False). Not compatible with some bit depths; see Notes. Only to be used on real files. New in version 0.12.0.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>rate</code></td>
<td>[int] Sample rate of WAV file.</td>
</tr>
<tr>
<td><code>data</code></td>
<td>[numpy array] Data read from WAV file. Data-type is determined from the file; see Notes. Data is 1-D for 1-channel WAV, or 2-D of shape (Nsamples, Nchannels) otherwise. If a file-like input without a C-like file descriptor (e.g., <code>io.BytesIO</code>) is passed, this will not be writeable.</td>
</tr>
</tbody>
</table>
Notes

Common data types: [1]

<table>
<thead>
<tr>
<th>WAV format</th>
<th>Min</th>
<th>Max</th>
<th>NumPy dtype</th>
</tr>
</thead>
<tbody>
<tr>
<td>32-bit floating-point</td>
<td>-1.0</td>
<td>+1.0</td>
<td>float32</td>
</tr>
<tr>
<td>32-bit integer PCM</td>
<td>-2147483648</td>
<td>+2147483647</td>
<td>int32</td>
</tr>
<tr>
<td>24-bit integer PCM</td>
<td>-2147483648</td>
<td>+2147483392</td>
<td>int32</td>

<tr>
<td>16-bit integer PCM</td>
<td>-32768</td>
<td>+32767</td>
<td>int16</td>
</tr>
<tr>
<td>8-bit integer PCM</td>
<td>0</td>
<td>255</td>
<td>uint8</td>
</tr>
</tbody>
</table>

WAV files can specify arbitrary bit depth, and this function supports reading any integer PCM depth from 1 to 64 bits. Data is returned in the smallest compatible numpy int type, in left-justified format. 8-bit and lower is unsigned, while 9-bit and higher is signed.

For example, 24-bit data will be stored as int32, with the MSB of the 24-bit data stored at the MSB of the int32, and typically the least significant byte is 0x00. (However, if a file actually contains data past its specified bit depth, those bits will be read and output, too. [2])

This bit justification and sign matches WAV’s native internal format, which allows memory mapping of WAV files that use 1, 2, 4, or 8 bytes per sample (so 24-bit files cannot be memory-mapped, but 32-bit can).

IEEE float PCM in 32- or 64-bit format is supported, with or without mmap. Values exceeding [-1, +1] are not clipped.

Non-linear PCM (mu-law, A-law) is not supported.

References

[1], [2]

Examples

```python
>>> from os.path import dirname, join as pjoin
>>> from scipy.io import wavfile
>>> import scipy.io
```

Get the filename for an example .wav file from the tests/data directory.

```python
>>> data_dir = pjoin(dirname(scipy.io.__file__), 'tests', 'data')
>>> wav_fname = pjoin(data_dir, 'test-44100Hz-2ch-32bit-float-be.wav')
```

Load the .wav file contents.

```python
>>> samplerate, data = wavfile.read(wav_fname)
>>> print(f"number of channels = {data.shape[1]}")
number of channels = 2
>>> length = data.shape[0] / samplerate
>>> print(f"length = {length}s")
length = 0.01s
```

Plot the waveform.
```python
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> time = np.linspace(0., length, data.shape[0])
>>> plt.plot(time, data[:, 0], label="Left channel")
>>> plt.plot(time, data[:, 1], label="Right channel")
>>> plt.legend()
>>> plt.xlabel("Time [s]")
>>> plt.ylabel("Amplitude")
>>> plt.show()
```

### scipy.io.wavfile.write

**scipy.io.wavfile.write(filename, rate, data)**

Write a NumPy array as a WAV file.

**Parameters**

- **filename** [string or open file handle] Output wav file.
- **rate** [int] The sample rate (in samples/sec).
- **data** [ndarray] A 1-D or 2-D NumPy array of either integer or float data-type.

**Notes**

- Writes a simple uncompressed WAV file.
- To write multiple-channels, use a 2-D array of shape (Nsamples, Nchannels).
- The bits-per-sample and PCM/float will be determined by the data-type.

Common data types: [1]
### WAV format

<table>
<thead>
<tr>
<th>WAV format</th>
<th>Min</th>
<th>Max</th>
<th>NumPy dtype</th>
</tr>
</thead>
<tbody>
<tr>
<td>32-bit floating-point</td>
<td>-1.0</td>
<td>+1.0</td>
<td>float32</td>
</tr>
<tr>
<td>32-bit PCM</td>
<td>-2147483648</td>
<td>+2147483647</td>
<td>int32</td>
</tr>
<tr>
<td>16-bit PCM</td>
<td>-32768</td>
<td>+32767</td>
<td>int16</td>
</tr>
<tr>
<td>8-bit PCM</td>
<td>0</td>
<td>255</td>
<td>uint8</td>
</tr>
</tbody>
</table>

Note that 8-bit PCM is unsigned.

### References

[1]

### Examples

Create a 100Hz sine wave, sampled at 44100Hz. Write to 16-bit PCM, Mono.

```python
>>> from scipy.io.wavfile import write
>>> samplerate = 44100; fs = 100
>>> t = np.linspace(0., 1., samplerate)
>>> amplitude = np.iinfo(np.int16).max
>>> data = amplitude * np.sin(2. * np.pi * fs * t)
>>> write("example.wav", samplerate, data.astype(np.int16))
```

**Arff files (scipy.io.arff)**

- `loadarff(f)`
  - Read an arff file.
- `MetaData(rel, attr)`
  - Small container to keep useful information on a ARFF dataset.

**ArffError**

**ParseArffError**

### scipy.io.arff.loadarff

Read an arff file.

The data is returned as a record array, which can be accessed much like a dictionary of NumPy arrays. For example, if one of the attributes is called 'pressure', then its first 10 data points can be accessed from the data record array like so: `data['pressure'][0:10]`

**Parameters**

- `f` [file-like or str] File-like object to read from, or filename to open.
Returns

- `data` ([record array]) The data of the arff file, accessible by attribute names.
- `meta` ([MetaData]) Contains information about the arff file such as name and type of attributes, the relation (name of the dataset), etc.

Raises

- **ParseArffError**
  
  This is raised if the given file is not ARFF-formatted.
- **NotImplementedError**
  
  The ARFF file has an attribute which is not supported yet.

Notes

This function should be able to read most arff files. Not implemented functionality include:

- date type attributes
- string type attributes

It can read files with numeric and nominal attributes. It cannot read files with sparse data ({}) in the file. However, this function can read files with missing data (?) in the file, representing the data points as NaNs.

Examples

```python
>>> from scipy.io import arff
>>> from io import StringIO

>>> content = """...
... @relation foo
... @attribute width numeric
... @attribute height numeric
... @attribute color {red,green,blue,yellow,black}
... @data
...
...
... 5.0,3.25,blue
... 4.5,3.75,green
... 3.0,4.00,red
... """

>>> f = StringIO(content)

>>> data, meta = arff.loadarff(f)

>>> data

array([(5.0, 3.25, 'blue'), (4.5, 3.75, 'green'), (3.0, 4.0, 'red')],
dtype=[('width', '<f8'), ('height', '<f8'), ('color', '|S6')])

>>> meta

Dataset: foo
width's type is numeric
height's type is numeric
color's type is nominal, range is ('red', 'green', 'blue', 'yellow', 'black')
```
**scipy.io.arff.MetaData**

```python
class scipy.io.arff.MetaData(rel, attr)
```

Small container to keep useful information on a ARFF dataset.

Knows about attributes names and types.

**Notes**

Also maintains the list of attributes in order, i.e., doing for i in meta, where meta is an instance of MetaData, will return the different attribute names in the order they were defined.

**Examples**

```python
data, meta = loadarff('iris.arff')
# This will print the attributes names of the iris.arff dataset
for i in meta:
    print(i)
# This works too
meta.names()
# Getting attribute type
types = meta.types()
```

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>names()</strong></td>
<td>Return the list of attribute names.</td>
</tr>
<tr>
<td><strong>types()</strong></td>
<td>Return the list of attribute types.</td>
</tr>
</tbody>
</table>

**scipy.io.arff.MetaData.names**

```python
MetaData.names()
```

Return the list of attribute names.

**Returns**

- **attrnames** [list of str] The attribute names.

**scipy.io.arff.MetaData.types**

```python
MetaData.types()
```

Return the list of attribute types.

**Returns**

- **attr_types** [list of str] The attribute types.
**scipy.io.arff.ArffError**

Exception `scipy.io.arff.ArffError`

- **errno**
  POSIX exception code

- **filename**
  exception filename

- **filename2**
  second exception filename

- **strerror**
  exception strerror

  ```python
  with_traceback()}
  Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
  ```

**scipy.io.arff.ParseArffError**

Exception `scipy.io.arff.ParseArffError`

- **errno**
  POSIX exception code

- **filename**
  exception filename

- **filename2**
  second exception filename

- **strerror**
  exception strerror

  ```python
  with_traceback()}
  Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
  ```

### 3.3.10 Linear algebra (**scipy.linalg**)

Linear algebra functions.

**See also:**

`numpy.linalg` for more linear algebra functions. Note that although `scipy.linalg` imports most of them, identically named functions from `scipy.linalg` may offer more or slightly differing functionality.

</table>

**scipy.linalg.inv**

`scipy.linalg.inv(a, overwrite_a=False, check_finite=True)`

Compute the inverse of a matrix.

**Parameters**

- `a` : [array_like] Square matrix to be inverted.
- `overwrite_a` : [bool, optional] Discard data in `a` (may improve performance). Default is False.
- `check_finite` : [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**Returns**

- `ainv` : [ndarray] Inverse of the matrix `a`.

**Raises**

- `LinAlgError` : If `a` is singular.
ValueError
If a is not square, or not 2D.

Examples

```python
>>> from scipy import linalg
>>> a = np.array([[1., 2.], [3., 4.]])
>>> linalg.inv(a)
array([[-2. ,  1. ],
      [ 1.5, -0.5]])
>>> np.dot(a, linalg.inv(a))
array([[ 1.,  0.],
      [ 0.,  1.]])
```

**scipy.linalg.solve**

`scipy.linalg.solve(a, b, sym_pos=False, lower=False, overwrite_a=False, overwrite_b=False, check_finite=True, assume_a='gen', transposed=False)`

Solves the linear equation set $a \times x = b$ for the unknown $x$ for square $a$ matrix.

If the data matrix is known to be a particular type then supplying the corresponding string to `assume_a` key chooses the dedicated solver. The available options are

<table>
<thead>
<tr>
<th>Type</th>
<th>Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>generic matrix</td>
<td>'gen'</td>
</tr>
<tr>
<td>symmetric</td>
<td>'sym'</td>
</tr>
<tr>
<td>hermitian</td>
<td>'her'</td>
</tr>
<tr>
<td>positive definite</td>
<td>'pos'</td>
</tr>
</tbody>
</table>

If omitted, 'gen' is the default structure.

The datatype of the arrays define which solver is called regardless of the values. In other words, even when the complex array entries have precisely zero imaginary parts, the complex solver will be called based on the data type of the array.

**Parameters**

- **a** [(N, N) array_like] Square input data
- **b** [(N, NRHS) array_like] Input data for the right hand side.
- **sym_pos** [bool, optional] Assume $a$ is symmetric and positive definite. This key is deprecated and assume_a = 'pos' keyword is recommended instead. The functionality is the same. It will be removed in the future.
- **lower** [bool, optional] If True, only the data contained in the lower triangle of $a$. Default is to use upper triangle. (ignored for 'gen')
- **overwrite_a** [bool, optional] Allow overwriting data in $a$ (may enhance performance). Default is False.
- **overwrite_b** [bool, optional] Allow overwriting data in $b$ (may enhance performance). Default is False.
- **check_finite** [bool, optional] Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.
- **assume_a** [str, optional] Valid entries are explained above.
- **transposed** [bool, optional] If True, $a^T \times x = b$ for real matrices, raises `NotImplementedError` for complex matrices (only for True).
Returns

\[ x \]

[(N, NRHS) ndarray] The solution array.

Raises

ValueError

If size mismatches detected or input \( a \) is not square.

LinAlgError

If the matrix is singular.

LinAlgWarning

If an ill-conditioned input \( a \) is detected.

NotImplementedError

If transposed is True and input \( a \) is a complex matrix.

Notes

If the input \( b \) matrix is a 1-D array with \( N \) elements, when supplied together with an \( N \times N \) input \( a \), it is assumed as a valid column vector despite the apparent size mismatch. This is compatible with the numpy.dot() behavior and the returned result is still 1-D array.

The generic, symmetric, Hermitian and positive definite solutions are obtained via calling ?GESV, ?SYSV, ?HESV, and ?POSV routines of LAPACK respectively.

Examples

Given \( a \) and \( b \), solve for \( x \):

```python
>>> a = np.array([[3, 2, 0], [1, -1, 0], [0, 5, 1]])
>>> b = np.array([2, 4, -1])
>>> from scipy import linalg
>>> x = linalg.solve(a, b)
>>> x
array([ 2., -2.,  9.])
>>> np.dot(a, x) == b
array([ True,  True,  True], dtype=bool)
```

scipy.linalg.solve_banded

scipy.linalg.solve_banded

Solve the equation \( ax = b \) for \( x \), assuming \( a \) is banded matrix.

The matrix \( a \) is stored in \( ab \) using the matrix diagonal ordered form:

\[
ab[u + i - j, j] = a[i, j]
\]

Example of \( ab \) (shape of \( a \) is (6,6), \( u=1, l=2 \)):

```
*  a01  a12  a23  a34  a45
a10  a02  a13  a24  a35
a20  a11  a22  a33  a44  a55
a30  a21  a32  a43  a54  *
a40  a31  a42  a53  *  *
```

Parameters
(l, u) [(integer, integer)] Number of non-zero lower and upper diagonals
ab [(l + u + 1, M) array_like] Banded matrix
b [(M,) or (M, K) array_like] Right-hand side
overwrite_ab [bool, optional] Discard data in ab (may enhance performance)
overwrite_b [bool, optional] Discard data in b (may enhance performance)
check_finite [bool, optional] Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

Returns
x [(M,) or (M, K) ndarray] The solution to the system $a x = b$. Returned shape depends on the shape of $b$.

Examples
Solve the banded system $a x = b$, where:

\[
\begin{align*}
\begin{bmatrix}
5 & 2 & -1 & 0 & 0 \\
1 & 4 & 2 & -1 & 0 \\
0 & 1 & 3 & 2 & -1 \\
0 & 0 & 1 & 2 & 2 \\
0 & 0 & 0 & 1 & 1 \\
\end{bmatrix}
\end{align*}
\begin{align*}
\begin{bmatrix}
0 \\
1 \\
2 \\
2 \\
3 \\
\end{bmatrix}
\end{align*}
\]

There is one nonzero diagonal below the main diagonal (l = 1), and two above (u = 2). The diagonal banded form of the matrix is:

\[
\begin{align*}
\begin{bmatrix}
* & * & -1 & -1 & -1 \\
* & 2 & 2 & 2 & 2 \\
5 & 4 & 3 & 2 & 1 \\
1 & 1 & 1 & 1 & * \\
\end{bmatrix}
\end{align*}
\]

```python
t from scipy.linalg import solve_banded
t ab = np.array([[(0, 0, -1, -1, -1),
             (0, 2, 2, 2, 2),
             (5, 4, 3, 2, 1),
             (1, 1, 1, 1, 0)]])
t b = np.array([0, 1, 2, 2, 3])
t x = solve_banded((1, 2), ab, b)
t x
array([-2.33788136, 3.93220339, -4. , 4.3559322 , -1.3559322 ])
```
**scipy.linalg.solveh_banded**

**scipy.linalg.solveh_banded** *(ab, b, overwrite_ab=False, overwrite_b=False, lower=False, check_finite=True)*

Solve equation \( ax = b \). \( a \) is Hermitian positive-definite banded matrix.

The matrix \( a \) is stored in \( ab \) either in lower diagonal or upper diagonal ordered form:

\[
ab[u+i-j,j] == a[i,j] \quad \text{(if upper form; } i \leq j) \\
ab[i-j,j] == a[i,j] \quad \text{(if lower form; } i \geq j)
\]

Example of \( ab \) (shape of \( a \) is \((6, 6) \), \( u = 2 \)):

<table>
<thead>
<tr>
<th>upper form:</th>
<th>lower form:</th>
</tr>
</thead>
<tbody>
<tr>
<td>* * a02 a13 a24 a35</td>
<td>a00 a11 a22 a33 a44 a55</td>
</tr>
<tr>
<td>* a01 a12 a23 a34 a45</td>
<td>a10 a21 a32 a43 a54</td>
</tr>
<tr>
<td>a00 a11 a22 a33 a44 a55</td>
<td>a20 a31 a42 a53</td>
</tr>
<tr>
<td></td>
<td>*</td>
</tr>
</tbody>
</table>

Cells marked with * are not used.

**Parameters**

- \( ab \): [(\( u + 1, M \)] array_like] Banded matrix
- \( b \): [(\( M, \) or \( M, K \)] array_like] Right-hand side
- \( overwrite_ab \) [bool, optional] Discard data in \( ab \) (may enhance performance)
- \( overwrite_b \) [bool, optional] Discard data in \( b \) (may enhance performance)
- \( lower \) [bool, optional] Is the matrix in the lower form. (Default is upper form)
- \( check_finite \) [bool, optional] Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**Returns**

- \( x \): [(\( M, \) or \( M, K \)] ndarray] The solution to the system \( ax = b \). Shape of return matches shape of \( b \).

**Examples**

Solve the banded system \( A x = b \), where:

\[
A = \begin{bmatrix}
4 & 2 & -1 & 0 & 0 & 0 \\
2 & 5 & 2 & -1 & 0 & 0 \\
-1 & 2 & 6 & 2 & -1 & 0 \\
0 & -1 & 2 & 7 & 2 & -1 \\
0 & 0 & -1 & 2 & 8 & 2 \\
0 & 0 & 0 & -1 & 2 & 9
\end{bmatrix} \quad b = \begin{bmatrix}
1 \\
2 \\
2 \\
3 \\
3 \\
3
\end{bmatrix}
\]

```python
>>> from scipy.linalg import solveh_banded

ab contains the main diagonal and the nonzero diagonals below the main diagonal. That is, we use the lower form:
>>> ab = np.array([[4, 5, 6, 7, 8, 9],
...                [2, 2, 2, 2, 2, 0],
...                [-1, -1, -1, -1, 0, 0]])
>>> b = np.array([1, 2, 3, 3, 3])
>>> x = solveh_banded(ab, b, lower=True)
>>> x
array([ 0.03431373, 0.45938375, 0.05602241, 0.47759104, 0.17577031,
        0.34733894])

Solve the Hermitian banded system $Hx = b$, where:

$$
H = \begin{bmatrix}
8 & 2-1j & 0 & 0 & \vdots \\
2+1j & 5 & 1j & 0 & \vdots \\
0 & -1j & 9 & -2-1j & \vdots \\
0 & 0 & -2+1j & 6 & \vdots \\
\end{bmatrix}
$$

b = [1+1j]

In this example, we put the upper diagonals in the array $hb$:

```python
>>> hb = np.array([[0, 2-1j, 1j, -2-1j],
...                [8, 5, 9, 6]])
>>> b = np.array([1, 1+1j, 1-2j, 0])
>>> x = solveh_banded(hb, b)
>>> x
array([ 0.07318536-0.02939412j, 0.11877624+0.17696461j,
        0.10077984-0.23035393j, -0.00479904-0.09358128j])
```

`scipy.linalg.solve_circulant`

`scipy.linalg.solve_circulant`(c, b, singular='raise', tol=None, caxis=- 1, baxis=0, outaxis=0)

Solve $Cx = b$ for $x$, where $C$ is a circulant matrix.

$C$ is the circulant matrix associated with the vector $c$.

The system is solved by doing division in Fourier space. The calculation is:

```python
x = ifft(fft(b) / fft(c))
```

where `fft` and `ifft` are the fast Fourier transform and its inverse, respectively. For a large vector $c$, this is much faster than solving the system with the full circulant matrix.

**Parameters**

- **c** [array_like] The coefficients of the circulant matrix.
- **b** [array_like] Right-hand side matrix in $a x = b$.
- **singular** [str, optional] This argument controls how a near singular circulant matrix is handled. If `singular` is “raise” and the circulant matrix is near singular, a `LinAlgError` is raised. If `singular` is “ltsq”, the least squares solution is returned. Default is “raise”.
- **tol** [float, optional] If any eigenvalue of the circulant matrix has an absolute value that is less than or equal to `tol`, the matrix is considered to be near singular. If not given, `tol` is set to:

  ```
  tol = abs_eigs.max() * abs_eigs.size * np.finfo(np.float64).eps
  ```

  where `abs_eigs` is the array of absolute values of the eigenvalues of the circulant matrix.
- **caxis** [int] When $c$ has dimension greater than 1, it is viewed as a collection of circulant vectors. In this case, `caxis` is the axis of $c$ that holds the vectors of circulant coefficients.

3.3. API definition 673

baxis [int] When \( b \) has dimension greater than 1, it is viewed as a collection of vectors. In this case, \( baxis \) is the axis of \( b \) that holds the right-hand side vectors.

outaxis [int] When \( c \) or \( b \) are multidimensional, the value returned by \texttt{solve_circulant} is multidimensional. In this case, \( outaxis \) is the axis of the result that holds the solution vectors.

Returns

\( x \) [ndarray] Solution to the system \( C x = b \).

Raises

\texttt{LinAlgError}

If the circulant matrix associated with \( c \) is near singular.

See also:

circulant
circulant matrix

Notes

For a 1-D vector \( c \) with length \( m \), and an array \( b \) with shape \( (m, \ldots) \),

\texttt{solve_circulant(c, b)}

returns the same result as

\texttt{solve(circulant(c), b)}

where \texttt{solve} and \texttt{circulant} are from \texttt{scipy.linalg}.

New in version 0.16.0.

Examples

```python
>>> from scipy.linalg import solve_circulant, solve, circulant, lstsq

>>> c = np.array([2, 2, 4])
>>> b = np.array([1, 2, 3])
>>> solve_circulant(c, b)
array([ 0.75, -0.25,  0.25])
```

Compare that result to solving the system with \texttt{scipy.linalg.solve}:

```python
>>> solve(circulant(c), b)
array([ 0.75, -0.25,  0.25])
```

A singular example:

```python
>>> c = np.array([1, 1, 0, 0])
>>> b = np.array([1, 2, 3, 4])
```

Calling \texttt{solve_circulant(c, b)} will raise a \texttt{LinAlgError}. For the least square solution, use the option \texttt{singular='lstsq'}:

```python
>>> solve_circulant(c, b, singular='lstsq')
array([ 0.25,  1.25,  2.25,  1.25])
```
Compare to `scipy.linalg.lstsq`:

```python
>>> x, resid, rnk, s = lstsq(circulant(c), b)
>>> x
array([[ 0.25,  1.25,  2.25,  1.25]])
```

A broadcasting example:

Suppose we have the vectors of two circulant matrices stored in an array with shape (2, 5), and three \( b \) vectors stored in an array with shape (3, 5). For example,

```python
>>> c = np.array([[1.5, 2, 3, 0, 0], [1, 1, 4, 3, 2]])
>>> b = np.arange(15).reshape(-1, 5)
```

We want to solve all combinations of circulant matrices and \( b \) vectors, with the result stored in an array with shape (2, 3, 5). When we disregard the axes of \( c \) and \( b \) that hold the vectors of coefficients, the shapes of the collections are (2,) and (3,), respectively, which are not compatible for broadcasting. To have a broadcast result with shape (2, 3), we add a trivial dimension to \( c \): \( c[:, \text{np.newaxis}, :] \) has shape (2, 1, 5). The last dimension holds the coefficients of the circulant matrices, so when we call `solve_circulant`, we can use the default \( \text{caxis}=-1 \). The coefficients of the \( b \) vectors are in the last dimension of the array \( b \), so we use \( \text{baxis}=-1 \). If we use the default \( \text{outaxis} \), the result will have shape (5, 2, 3), so we’ll use \( \text{outaxis}=-1 \) to put the solution vectors in the last dimension.

```python
>>> x = solve_circulant(c[:, np.newaxis, :], b, baxis=-1, outaxis=-1)
```

Check by solving one pair of \( c \) and \( b \) vectors (cf. \( x[1, 1, :] \)):

```python
>>> solve_circulant(c[1], b[1, :])
array([[ 0.856,  0.758,  1.149, -0.412,  0.831]])
```

`scipy.linalg.solve_triangular`

`scipy.linalg.solve_triangular(a, b, trans=0, lower=False, unit_diagonal=False, overwrite_b=False, debug=None, check_finite=True)`

Solve the equation \( a \ x = b \) for \( x \), assuming \( a \) is a triangular matrix.

**Parameters**

- **a** 
  (M, M) array_like A triangular matrix
- **b** 
  (M,) or (M, N) array_like Right-hand side matrix in \( a \ x = b \)
- **lower** 
  [bool, optional] Use only data contained in the lower triangle of \( a \). Default is to use upper triangle.
- **trans** 
  [{0, 1, 2, ‘N’, ‘T’, ‘C’}, optional] Type of system to solve:
trans | system
---|---
0 or ‘N’ | a x = b
1 or ‘T’ | a^T x = b
2 or ‘C’ | a^H x = b

**unit_diagonal**

[bool, optional] If True, diagonal elements of \( a \) are assumed to be 1 and will not be referenced.

**overwrite_b**

[bool, optional] Allow overwriting data in \( b \) (may enhance performance)

**check_finite**

[bool, optional] Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**Returns**

\( x \)

[(M,) or (M, N) ndarray] Solution to the system \( a x = b \). Shape of return matches \( b \).

**Raises**

**LinAlgError**

If \( a \) is singular

**Notes**

New in version 0.9.0.

**Examples**

Solve the lower triangular system \( a x = b \), where:

\[
\begin{align*}
a &= \begin{bmatrix} 3 & 0 & 0 & 0 \\ 2 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 1 & 1 & 1 & 1 \end{bmatrix} \\
b &= \begin{bmatrix} 4 \\ 2 \\ 4 \\ 2 \end{bmatrix}
\end{align*}
\]

```python
>>> from scipy.linalg import solve_triangular
>>> a = np.array([[3, 0, 0, 0], [2, 1, 0, 0], [1, 0, 1, 0], [1, 1, 1, 1]])
>>> b = np.array([4, 2, 4, 2])
>>> x = solve_triangular(a, b, lower=True)
>>> x
array([ 1.33333333, -0.66666667,  2.66666667, -1.33333333])
>>> a.dot(x)  # Check the result
array([ 4.,  2.,  4.,  2.])
```
scipy.linalg.solve_toeplitz

scipy.linalg.solve_toeplitz(c_or_cr, b, check_finite=True)

Solve a Toeplitz system using Levinson Recursion

The Toeplitz matrix has constant diagonals, with \( c \) as its first column and \( r \) as its first row. If \( r \) is not given, \( r == \text{conjugate}(c) \) is assumed.

**Parameters**

- **c_or_cr**  
  [array_like or tuple of (array_like, array_like)] The vector \( c \), or a tuple of arrays \((c, r)\). Whatever the actual shape of \( c \), it will be converted to a 1-D array. If not supplied, \( r == \text{conjugate}(c) \) is assumed; in this case, if \( c[0] \) is real, the Toeplitz matrix is Hermitian. \( r[0] \) is ignored; the first row of the Toeplitz matrix is \([c[0], r[1:])\). Whatever the actual shape of \( r \), it will be converted to a 1-D array.

- **b**  
  [(M,) or (M, K) array_like] Right-hand side in \( T \cdot x = b \).

- **check_finite**  
  [bool, optional] Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (result entirely NaNs) if the inputs do contain infinities or NaNs.

**Returns**

- **x**  
  [(M,) or (M, K) ndarray] The solution to the system \( T \cdot x = b \). Shape of return matches shape of \( b \).

See also:

toeplitz

Toeplitz matrix

**Notes**

The solution is computed using Levinson-Durbin recursion, which is faster than generic least-squares methods, but can be less numerically stable.

**Examples**

Solve the Toeplitz system \( T \cdot x = b \), where:

\[
T = \begin{bmatrix}
1 & -1 & -2 & -3 \\
3 & 1 & -1 & -2 \\
6 & 3 & 1 & -1 \\
10 & 6 & 3 & 1 \\
\end{bmatrix}
\]

\[
b = \begin{bmatrix} 1 \\ 2 \\ 2 \\ 5 \end{bmatrix}
\]

To specify the Toeplitz matrix, only the first column and the first row are needed.

```python
>>> c = np.array([1, 3, 6, 10])  # First column of T
>>> r = np.array([1, -1, -2, -3])  # First row of T
>>> b = np.array([1, 2, 2, 5])
```

```python
>>> from scipy.linalg import solve_toeplitz, toeplitz
>>> x = solve_toeplitz((c, r), b)
>>> x
array([ 1.66666667, -1. , -2.66666667, 2.33333333])
```
Check the result by creating the full Toeplitz matrix and multiplying it by \( x \). We should get \( b \).

```
>>> T = toeplitz(c, r)
>>> T.dot(x)
array([ 1.,  2.,  2.,  5.])
```

**scipy.linalg.matmul_toeplitz**

*scipy.linalg.matmul_toeplitz*(\( c_{\text{or} \cr}, x, \text{check\_finite=False}, \text{workers=None} \))

Efficient Toeplitz Matrix-Matrix Multiplication using FFT

This function returns the matrix multiplication between a Toeplitz matrix and a dense matrix.

The Toeplitz matrix has constant diagonals, with \( c \) as its first column and \( r \) as its first row. If \( r \) is not given, \( r = \text{conjugate}(c) \) is assumed.

**Parameters**

- \( c_{\text{or} \cr} \) [array_like or tuple of (array_like, array_like)] The vector \( c \), or a tuple of arrays \((c, r)\). Whatever the actual shape of \( c \), it will be converted to a 1-D array. If not supplied, \( r = \text{conjugate}(c) \) is assumed; in this case, if \( c[0] \) is real, the Toeplitz matrix is Hermitian. \( r[0] \) is ignored; the first row of the Toeplitz matrix is \([c[0], r[1:]]\). Whatever the actual shape of \( r \), it will be converted to a 1-D array.
- \( x \) [(M,) or (M, K) array_like] Matrix with which to multiply.
- \( \text{check\_finite} \) [bool, optional] Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (result entirely NaNs) if the inputs do contain infinities or NaNs.
- \( \text{workers} \) [int, optional] To pass to scipy.fft.fft and ifft. Maximum number of workers to use for parallel computation. If negative, the value wraps around from \( \text{os.cpu\_count()} \). See scipy.fft.fft for more details.

**Returns**

- \( T @ x \) [(M,) or (M, K) ndarray] The result of the matrix multiplication \( T @ x \). Shape of return matches shape of \( x \).

See also:

**toeplitz**

Toeplitz matrix

**solve_toeplitz**

Solve a Toeplitz system using Levinson Recursion

**Notes**

The Toeplitz matrix is embedded in a circulant matrix and the FFT is used to efficiently calculate the matrix-matrix product.

Because the computation is based on the FFT, integer inputs will result in floating point outputs. This is unlike NumPy's `matmul`, which preserves the data type of the input.

This is partly based on the implementation that can be found in [1], licensed under the MIT license. More information about the method can be found in reference [2]. References [3] and [4] have more reference implementations in Python.

New in version 1.6.0.
References

[1], [2], [3], [4]

Examples

Multiply the Toeplitz matrix T with matrix x:

\[
\begin{bmatrix}
1 & -1 & -2 & -3 \\
3 & 1 & -1 & -2 \\
6 & 3 & 1 & -1 \\
10 & 6 & 3 & 1 \\
\end{bmatrix}
\begin{bmatrix}
1 & 10 \\
2 & 11 \\
2 & 11 \\
5 & 19 \\
\end{bmatrix}
\]

To specify the Toeplitz matrix, only the first column and the first row are needed.

```python
>>> c = np.array([1, 3, 6, 10])  # First column of T
>>> r = np.array([1, -1, -2, -3])  # First row of T
>>> x = np.array([[1, 10], [2, 11], [2, 11], [5, 19]])
```

```python
>>> from scipy.linalg import toeplitz, matmul_toeplitz
>>> matmul_toeplitz((c, r), x)
array([[-20., -80.],
       [-7., -8.],
       [ 9., 85.],
       [33., 218.]])
```

Check the result by creating the full Toeplitz matrix and multiplying it by x.

```python
>>> toeplitz(c, r) @ x
array([[-20., -80.],
       [-7., -8.],
       [ 9., 85.],
       [33., 218.]]
```

The full matrix is never formed explicitly, so this routine is suitable for very large Toeplitz matrices.

```python
>>> n = 1000000
>>> matmul_toeplitz([1] + [0]*(n-1), np.ones(n))
array([1., 1., 1., ..., 1., 1., 1.])
```

`scipy.linalg.det`

`scipy.linalg.det(a, overwrite_a=False, check_finite=True)`

Compute the determinant of a matrix

The determinant of a square matrix is a value derived arithmetically from the coefficients of the matrix.

The determinant for a 3x3 matrix, for example, is computed as follows:

```
a   b   c 
d   e   f = A
g   h   i
```

\[
det(A) = a\cdot e\cdot i + b\cdot f\cdot g + c\cdot d\cdot h - c\cdot e\cdot g - b\cdot d\cdot i - a\cdot f\cdot h
\]
Parameters

- **a** *(M, M) array_like* A square matrix.
- **overwrite_a** *(bool, optional)* Allow overwriting data in a (may enhance performance).
- **check_finite** *(bool, optional)* Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

Returns

- **det** *(float or complex)* Determinant of *a*.

Notes

The determinant is computed via LU factorization, LAPACK routine z/dgetrf.

Examples

```python
>>> from scipy import linalg
>>> a = np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]])
>>> linalg.det(a)
0.0
>>> a = np.array([[0, 2, 3], [4, 5, 6], [7, 8, 9]])
>>> linalg.det(a)
3.0
```

scipy.linalg.norm

This function is able to return one of eight different matrix norms, or one of an infinite number of vector norms (described below), depending on the value of the *ord* parameter. For tensors with rank different from 1 or 2, only *ord=None* is supported.

Parameters

- **a** *(array_like)* Input array. If *axis* is None, *a* must be 1-D or 2-D, unless *ord* is None. If both *axis* and *ord* are None, the 2-norm of *a*.ravel will be returned.
- **ord** *(int, inf, -inf, ‘fro’, ‘nuc’, None), optional* Order of the norm (see table under Notes). inf means NumPy’s inf object.
- **axis** *(int, 2-tuple of ints, None), optional* If *axis* is an integer, it specifies the axis of *a* along which to compute the vector norms. If *axis* is a 2-tuple, it specifies the axes that hold 2-D matrices, and the matrix norms of these matrices are computed. If *axis* is None then either a vector norm (when *a* is 1-D) or a matrix norm (when *a* is 2-D) is returned.
- **keepdims** *(bool, optional)* If this is set to True, the axes which are normed over are left in the result as dimensions with size one. With this option the result will broadcast correctly against the original *a*.
- **check_finite** *(bool, optional)* Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

Returns
n [float or ndarray] Norm of the matrix or vector(s).

Notes

For values of $\text{ord} \leq 0$, the result is, strictly speaking, not a mathematical 'norm', but it may still be useful for various numerical purposes.

The following norms can be calculated:

<table>
<thead>
<tr>
<th>ord</th>
<th>norm for matrices</th>
<th>norm for vectors</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Frobenius norm</td>
<td>2-norm</td>
</tr>
<tr>
<td>'fro'</td>
<td>Frobenius norm</td>
<td>–</td>
</tr>
<tr>
<td>'nuc'</td>
<td>nuclear norm</td>
<td>–</td>
</tr>
<tr>
<td>inf</td>
<td>max(sum(abs(a), axis=1))</td>
<td>max(abs(a))</td>
</tr>
<tr>
<td>-inf</td>
<td>min(sum(abs(a), axis=1))</td>
<td>min(abs(a))</td>
</tr>
<tr>
<td>0</td>
<td>–</td>
<td>sum(a != 0)</td>
</tr>
<tr>
<td>1</td>
<td>max(sum(abs(a), axis=0))</td>
<td>as below</td>
</tr>
<tr>
<td>-1</td>
<td>min(sum(abs(a), axis=0))</td>
<td>as below</td>
</tr>
<tr>
<td>2</td>
<td>2-norm (largest sing. value)</td>
<td>as below</td>
</tr>
<tr>
<td>-2</td>
<td>smallest singular value</td>
<td>as below</td>
</tr>
<tr>
<td>other</td>
<td>–</td>
<td>sum(abs(a)<strong>ord)</strong>(1./ord)</td>
</tr>
</tbody>
</table>

The Frobenius norm is given by [1]:

$$||A||_F = \left[ \sum_{i,j} abs(a_{i,j})^2 \right]^{1/2}$$

The nuclear norm is the sum of the singular values.

Both the Frobenius and nuclear norm orders are only defined for matrices.

**scipy.linalg.lstsq**

`scipy.linalg.lstsq(a, b, cond=None, overwrite_a=False, overwrite_b=False, check_finite=True, lapack_driver=None)`

Compute least-squares solution to equation $Ax = b$.

Compute a vector $x$ such that the 2-norm $|b - Ax|$ is minimized.

**Parameters**

- **a**: [(M, N) array_like] Left-hand side array
- **b**: [(M,), (M, K) array_like] Right hand side array
- **cond**: [float, optional] Cutoff for ‘small’ singular values; used to determine effective rank of $a$. Singular values smaller than $\text{cond} \times \text{largest_singular_value}$ are considered zero.
- **overwrite_a**: [bool, optional] Discard data in $a$ (may enhance performance). Default is False.
- **overwrite_b**: [bool, optional] Discard data in $b$ (may enhance performance). Default is False.
- **check_finite**: [bool, optional] Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination)
if the inputs do contain infinities or NaNs.

**lapack_driver**

[str, optional] Which LAPACK driver is used to solve the least-squares problem. Options are 'gelsd', 'gelsy', 'gelss'. Default ('gelsd') is a good choice. However, 'gelsy' can be slightly faster on many problems. 'gelss' was used historically. It is generally slow but uses less memory.

New in version 0.17.0.

**Returns**

- **x** [(N,) or (N, K) ndarray] Least-squares solution.
- **residues** [(K,) ndarray or float] Square of the 2-norm for each column in \( b - a x \), if \( M > N \) and \( \text{ndim}(A) == n \) (returns a scalar if \( b \) is 1-D). Otherwise a (0,)-shaped array is returned.
- **rank** [int] Effective rank of \( a \).
- **s** [(min(M, N),) ndarray or None] Singular values of \( a \). The condition number of \( a \) is \( s[0] / s[-1] \).

**Raises**

- **LinAlgError**
  If computation does not converge.
- **ValueError**
  When parameters are not compatible.

**See also:**

- **scipy.optimize.nnls**
  linear least squares with non-negativity constraint

**Notes**

When 'gelsy' is used as a driver, **residues** is set to a (0,)-shaped array and **s** is always None.

**Examples**

```
>>> from scipy.linalg import lstsq
>>> import matplotlib.pyplot as plt
```

Suppose we have the following data:

```
>>> x = np.array([1, 2.5, 3.5, 4, 5, 7, 8.5])
>>> y = np.array([0.3, 1.1, 1.5, 2.0, 3.2, 6.6, 8.6])
```

We want to fit a quadratic polynomial of the form \( y = a + b x^2 \) to this data. We first form the “design matrix” \( M \), with a constant column of 1s and a column containing \( x^2 \):

```
>>> M = x[:, np.newaxis]**[0, 2]
```

(continues on next page)
We want to find the least-squares solution to $M \cdot p = y$, where $p$ is a vector with length 2 that holds the parameters $a$ and $b$. 

```python
>>> p, res, rnk, s = lstsq(M, y)
>>> p
array([ 0.20925829, 0.12013861])
```

Plot the data and the fitted curve.

```python
>>> plt.plot(x, y, 'o', label='data')
>>> xx = np.linspace(0, 9, 101)
>>> yy = p[0] + p[1]*xx**2
>>> plt.plot(xx, yy, label='least squares fit, $y = a + bx^2$')
>>> plt.xlabel('x')
>>> plt.ylabel('y')
>>> plt.legend(framealpha=1, shadow=True)
>>> plt.grid(alpha=0.25)
>>> plt.show()
```

```
0 2 4 6 8
x
0
2
4
6
8
10
y
data
least squares fit, $y = a + bx^2$
```

**scipy.linalg.pinv**

`scipy.linalg.pinv(a, atol=None, rtol=None, return_rank=False, check_finite=True, cond=None, rcond=None)`

Compute the (Moore-Penrose) pseudo-inverse of a matrix.

Calculate a generalized inverse of a matrix using its singular-value decomposition $U @ S @ V$ in the economy mode and picking up only the columns/rows that are associated with significant singular values.

If $s$ is the maximum singular value of $a$, then the significance cut-off value is determined by $atol + rtol * s$. Any singular value below this value is assumed insignificant.

**Parameters**

- **a**
  - [(M, N) array_like] Matrix to be pseudo-inverted.
atol: float, optional
    Absolute threshold term, default value is 0.
    New in version 1.7.0.

rtol: float, optional
    Relative threshold term, default value is \( \max(M, N) \times \text{eps} \) where \( \text{eps} \) is the machine precision value of the datatype of \( a \).
    New in version 1.7.0.

return_rank
    [bool, optional] If True, return the effective rank of the matrix.

check_finite
    [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

cond, rcond
    [float, optional] In older versions, these values were meant to be used as atol with rtol=0. If both were given rcond overwrote cond and hence the code was not correct. Thus using these are strongly discouraged and the tolerances above are recommended instead. In fact, if provided, atol, rtol takes precedence over these keywords.
    Changed in version 1.7.0: Deprecated in favor of rtol and atol parameters above and will be removed in future versions of SciPy.
    Changed in version 1.3.0: Previously the default cutoff value was just \( \text{eps} \times f \) where \( f \) was \( 1e3 \) for single precision and \( 1e6 \) for double precision.

Returns

B   [(N, M) ndarray] The pseudo-inverse of matrix \( a \).

rank   [int] The effective rank of the matrix. Returned if return_rank is True.

Raises

LinAlgError
    If SVD computation does not converge.

Examples

```python
>>> from scipy import linalg
>>> rng = np.random.default_rng()
>>> a = rng.standard_normal((9, 6))
>>> B = linalg.pinv(a)
>>> np.allclose(a, a @ B @ a)
True
>>> np.allclose(B, B @ a @ B)
True
```

scipy.linalg.pinv2

scipy.linalg.pinv2 \((a, \text{cond}=\text{None}, \text{rcond}=\text{None}, \text{return_rank}=\text{False}, \text{check_finite}=\text{True})\)
Compute the (Moore-Penrose) pseudo-inverse of a matrix.

scipy.linalg.pinv2 is deprecated since SciPy 1.7.0, use scipy.linalg.pinv instead for better tolerance control.

Calculate a generalized inverse of a matrix using its singular-value decomposition and including all ‘large’ singular values.

Parameters

a [(M, N) array_like] Matrix to be pseudo-inverted.

cond, rcond [float or None] Cutoff for ‘small’ singular values; singular values smaller than this value are considered as zero. If both are omitted, the default value \(\max(M, N) \times \text{largest\_singular\_value} \times \text{eps}\) is used where \(\text{eps}\) is the machine precision value of the datatype of \(a\).

Changed in version 1.3.0: Previously the default cutoff value was just \(\text{eps} \times f\) where \(f\) was 1e3 for single precision and 1e6 for double precision.

return_rank [bool, optional] If True, return the effective rank of the matrix.

check_finite [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

Returns

\(B\) [(N, M) ndarray] The pseudo-inverse of matrix \(a\).

rank [int] The effective rank of the matrix. Returned if \(\text{return\_rank}\) is True.

Raises

LinAlgError

If SVD computation does not converge.

**scipy.linalg.pinvh**

scipy.linalg.pinvh \((a, \text{atol=None, rtol=None, lower=True, return\_rank=False, check\_finite=True, cond=None, rcond=None})\)

Compute the (Moore-Penrose) pseudo-inverse of a Hermitian matrix.

Calculate a generalized inverse of a complex Hermitian/real symmetric matrix using its eigenvalue decomposition and including all eigenvalues with ‘large’ absolute value.

Parameters

\(a\) [(N, N) array_like] Real symmetric or complex hermitian matrix to be pseudo-inverted

\(\text{atol}\): float, optional

Absolute threshold term, default value is 0.

New in version 1.7.0.

\(\text{rtol}\): float, optional

Relative threshold term, default value is \(N \times \text{eps}\) where \(\text{eps}\) is the machine precision value of the datatype of \(a\).

New in version 1.7.0.

\(\text{lower}\) [bool, optional] Whether the pertinent array data is taken from the lower or upper triangle of \(a\). (Default: lower)

\(\text{return\_rank}\) [bool, optional] If True, return the effective rank of the matrix.

\(\text{check\_finite}\) [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

\(\text{cond}\), \(\text{rcond}\) [float, optional] In older versions, these values were meant to be used as \(\text{atol}\) with \(\text{rtol}=0\). If both were given \(\text{rcond}\) overwrote \(\text{cond}\) and hence the code was not correct. Thus using these are strongly discouraged and the tolerances above are recommended instead. In fact, if provided, \(\text{atol}\), \(\text{rtol}\) takes precedence over these keywords.
Changed in version 1.7.0: Deprecated in favor of `rtol` and `atol` parameters above and will be removed in future versions of SciPy.
Changed in version 1.3.0: Previously the default cutoff value was just \( \texttt{eps*f} \) where \( f \) was \( 1e3 \) for single precision and \( 1e6 \) for double precision.

**Returns**

- \( B \) \((N, N)\text{ndarray}\) The pseudo-inverse of matrix \( a \).
- \( \text{rank} \) \([\text{int}]\) The effective rank of the matrix. Returned if `return_rank` is True.

**Raises**

- `LinAlgError` If eigenvalue algorithm does not converge.

**Examples**

```python
>>> from scipy.linalg import pinvh
>>> rng = np.random.default_rng()
>>> a = rng.standard_normal((9, 6))
>>> a = np.dot(a, a.T)
>>> B = pinvh(a)
>>> np.allclose(a, a @ B @ a)
True
>>> np.allclose(B, B @ a @ B)
True
```

**scipy.linalg.kron**

**scipy.linalg.kron**(*a*, *b*)

Kronecker product.

The result is the block matrix:

```
\begin{bmatrix}
    a[0,0]*b & a[0,1]*b & \ldots & a[0,-1]*b \\
    a[1,0]*b & a[1,1]*b & \ldots & a[1,-1]*b \\
    \vdots & \vdots & \ddots & \vdots \\
    a[-1,0]*b & a[-1,1]*b & \ldots & a[-1,-1]*b
\end{bmatrix}
```

**Parameters**

- \( a \) \([M, N] \text{ndarray}\) Input array
- \( b \) \([P, Q] \text{ndarray}\) Input array

**Returns**

- \( A \) \([M*P, N*Q] \text{ndarray}\) Kronecker product of \( a \) and \( b \).
Examples

```python
>>> from numpy import array
>>> from scipy.linalg import kron
>>> kron(array([[1,2],[3,4]]), array([[1,1]]))
array([[1, 1, 1, 2, 2, 2],
       [3, 3, 3, 4, 4, 4]])
```

**scipy.linalg.khatri_rao**

`scipy.linalg.khatri_rao(a, b)`

Khatri-rao product

A column-wise Kronecker product of two matrices

**Parameters**

- `a`: (n, k) array_like
  Input array
- `b`: (m, k) array_like
  Input array

**Returns**

- `c`: (n*m, k) ndarray
  Khatri-rao product of `a` and `b`.

**See also:**

- `kron`
  Kronecker product

**Notes**

The mathematical definition of the Khatri-Rao product is:

\[(A_{ij} \otimes B_{ij})_{ij}\]

which is the Kronecker product of every column of `A` and `B`, e.g.:

```python
c = np.vstack([np.kron(a[:, k], b[:, k]) for k in range(b.shape[1])]).T
```

**Examples**

```python
>>> from scipy import linalg
>>> a = np.array([[1, 2, 3], [4, 5, 6]])
>>> b = np.array([[3, 4, 5], [6, 7, 8], [2, 3, 9]])
>>> linalg.khatri_rao(a, b)
array([[ 3,  8, 15],
       [ 6, 14, 24],
       [ 2,  6, 27],
       [12, 20, 30],
       [24, 35, 48],
       [ 8, 15, 54]])
```
scipy.linalg.tril

**scipy.linalg.tril(m, k=0)**

Make a copy of a matrix with elements above the kth diagonal zeroed.

**Parameters**

- `m` : [array_like] Matrix whose elements to return
- `k` : [int, optional] Diagonal above which to zero elements. `k == 0` is the main diagonal, `k < 0` subdiagonal and `k > 0` superdiagonal.

**Returns**

- `tril` : [ndarray] Return is the same shape and type as `m`.

**Examples**

```python
>>> from scipy.linalg import tril
>>> tril([[1,2,3],[4,5,6],[7,8,9],[10,11,12]], -1)
array([[ 0, 0, 0],
       [ 4, 0, 0],
       [ 7, 8, 0],
       [10, 11, 12]])
```

scipy.linalg.triu

**scipy.linalg.triu(m, k=0)**

Make a copy of a matrix with elements below the kth diagonal zeroed.

**Parameters**

- `m` : [array_like] Matrix whose elements to return
- `k` : [int, optional] Diagonal below which to zero elements. `k == 0` is the main diagonal, `k < 0` subdiagonal and `k > 0` superdiagonal.

**Returns**

- `triu` : [ndarray] Return matrix with zeroed elements below the kth diagonal and has same shape and type as `m`.

**Examples**

```python
>>> from scipy.linalg import triu
>>> triu([[1,2,3],[4,5,6],[7,8,9],[10,11,12]], -1)
array([[ 1, 2, 3],
       [ 4, 5, 6],
       [ 0, 8, 9],
       [ 0, 0, 12]])
```
scipy.linalg.orthogonal_procrustes

scipy.linalg.orthogonal_procrustes(A, B, check_finite=True)

Compute the matrix solution of the orthogonal Procrustes problem.

Given matrices A and B of equal shape, find an orthogonal matrix R that most closely maps A to B using the algorithm given in [1].

Parameters

- A [(M, N) array_like] Matrix to be mapped.
- B [(M, N) array_like] Target matrix.
- check_finite [bool, optional] Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

Returns

- R [(N, N) ndarray] The matrix solution of the orthogonal Procrustes problem. Minimizes the Frobenius norm of (A @ R) - B, subject to R.T @ R = I.
- scale [float] Sum of the singular values of A.T @ B.

Raises

- ValueError If the input array shapes don’t match or if check_finite is True and the arrays contain Inf or NaN.

Notes

Note that unlike higher level Procrustes analyses of spatial data, this function only uses orthogonal transformations like rotations and reflections, and it does not use scaling or translation.

New in version 0.15.0.

References

[1]

Examples

```python
>>> from scipy.linalg import orthogonal_procrustes
>>> A = np.array([[ 2,  0,  1], [-2,  0,  0]])
```

Flip the order of columns and check for the anti-diagonal mapping

```python
>>> R, sca = orthogonal_procrustes(A, np.fliplr(A))

>>> R
array([[5.34384992e-17, 0.00000000e+00, 1.00000000e+00],
       [0.00000000e+00, 1.00000000e+00, 0.00000000e+00],
       [1.00000000e+00, 0.00000000e+00, -7.85941422e-17]])
```

```python
>>> sca
9.0
```
scipy.linalg.matrix_balance

`scipy.linalg.matrix_balance(A, permute=True, scale=True, separate=False, overwrite_a=False)`

Compute a diagonal similarity transformation for row/column balancing.

The balancing tries to equalize the row and column 1-norms by applying a similarity transformation such that the magnitude variation of the matrix entries is reflected to the scaling matrices.

Moreover, if enabled, the matrix is first permuted to isolate the upper triangular parts of the matrix and, again if scaling is also enabled, only the remaining subblocks are subjected to scaling.

The balanced matrix satisfies the following equality

\[ B = T^{-1}AT \]

The scaling coefficients are approximated to the nearest power of 2 to avoid round-off errors.

**Parameters**

- **A**
  - [(n, n) array_like] Square data matrix for the balancing.
- **permute**
  - [bool, optional] The selector to define whether permutation of A is also performed prior to scaling.
- **scale**
  - [bool, optional] The selector to turn on and off the scaling. If False, the matrix will not be scaled.
- **separate**
  - [bool, optional] This switches from returning a full matrix of the transformation to a tuple of two separate 1-D permutation and scaling arrays.
- **overwrite_a**
  - [bool, optional] This is passed to xGEBAL directly. Essentially, overwrites the result to the data. It might increase the space efficiency. See LAPACK manual for details. This is False by default.

**Returns**

- **B**
  - [(n, n) ndarray] Balanced matrix
- **T**
  - [(n, n) ndarray] A possibly permuted diagonal matrix whose nonzero entries are integer powers of 2 to avoid numerical truncation errors.
- **scale, perm**
  - [(n,) ndarray] If separate keyword is set to True then instead of the array T above, the scaling and the permutation vectors are given separately as a tuple without allocating the full array T.

**Notes**

This algorithm is particularly useful for eigenvalue and matrix decompositions and in many cases it is already called by various LAPACK routines.

The algorithm is based on the well-known technique of [1] and has been modified to account for special cases. See [2] for details which have been implemented since LAPACK v3.5.0. Before this version there are corner cases where balancing can actually worsen the conditioning. See [3] for such examples.

The code is a wrapper around LAPACK’s xGEBAL routine family for matrix balancing.

New in version 0.19.0.

[1], [2], [3]

Examples

```python
>>> from scipy import linalg
>>> x = np.array([[1, 2, 0], [9, 1, 0.01], [1, 2, 10*np.pi]])

>>> y, permscale = linalg.matrix_balance(x)
>>> np.abs(x).sum(axis=0) / np.abs(x).sum(axis=1)
array([3.66666667, 0.4995005 , 0.91312162])

>>> np.abs(y).sum(axis=0) / np.abs(y).sum(axis=1)
array([1.2 , 1.27041742, 0.92658316]) # may vary

>>> permscale # only powers of 2 (0.5 == 2^(-1))
array([[ 0.5, 0. , 0. ], # may vary
       [ 0. , 1. , 0. ],
       [ 0. , 0. , 1. ]])
```

scipy.linalg.subspace_angles

scipy.linalg.subspace_angles(A, B)

Compute the subspace angles between two matrices.

- **Parameters**
  - `A` : ((M, N) array_like) The first input array.
  - `B` : ((M, K) array_like) The second input array.

- **Returns**
  - `angles` : [ndarray, shape (min(N, K),)] The subspace angles between the column spaces of `A` and `B` in descending order.

See also:

- `orth`
- `svd`

Notes

This computes the subspace angles according to the formula provided in [1]. For equivalence with MATLAB and Octave behavior, use `angles[0].` New in version 1.0.
References

[1]

Examples

An Hadamard matrix, which has orthogonal columns, so we expect that the subspace angle to be \( \frac{\pi}{2} \):

```python
>>> from numpy.random import default_rng
>>> from scipy.linalg import hadamard, subspace_angles
>>> rng = default_rng()
>>> H = hadamard(4)
>>> print(H)
[[ 1  1  1  1]
 [ 1 -1  1 -1]
 [ 1  1 -1 -1]
 [ 1 -1 -1  1]]
>>> np.rad2deg(subspace_angles(H[:, :], H[:, 2:]))
array([ 90.,  90.])
```

And the subspace angle of a matrix to itself should be zero:

```python
>>> subspace_angles(H[:, :2], H[:, :2]) <= 2 * np.finfo(float).eps
array([ True,  True], dtype=bool)
```

The angles between non-orthogonal subspaces are in between these extremes:

```python
>>> x = rng.standard_normal((4, 3))
>>> np.rad2deg(subspace_angles(x[:, :2], x[:, [2]]))
array([ 55.832]) # random
```

`scipy.linalg.bandwidth`

`scipy.linalg.bandwidth(a)`

Return the lower and upper bandwidth of a 2D numeric array.

Parameters

- `a` : [ndarray] Input array of size (N, M)

Returns

- `lu` : [tuple] 2-tuple of ints indicating the lower and upper bandwidth. A zero denotes no sub- or super-diagonal on that side (triangular), and, say for N rows (N-1) means that side is full. Same example applies to the upper triangular part with (M-1).

Raises

- `TypeError` : If the dtype of the array is not supported, in particular, NumPy float16, float128 and complex256 dtypes.
Notes

This helper function simply runs over the array looking for the nonzero entries whether there exists a banded structure in the array or not. Hence, the performance depends on the density of nonzero entries and also memory-layout. Fortran- or C- contiguous arrays are handled best and otherwise suffers from extra random memory access cost.

The strategy is to look for only untested band elements in the upper and lower triangular parts separately; depending on the memory layout we can scan row-wise or column-wise. Moreover, say we are scanning rows and in the 6th row, 4th entry is nonzero then, on the succeeding rows the horizontal search is done only up to that band entries since we know that band is occupied. Therefore, a completely dense matrix scan cost is in the the order of $n$.

Examples

```python
>>> from scipy.linalg import bandwidth
>>> A = np.array([[3., 0., 0., 0., 0.],
...                [0., 4., 0., 0., 0.],
...                [0., 0., 5., 1., 0.],
...                [8., 0., 0., 6., 2.],
...                [0., 9., 0., 0., 7.]]
>>> bandwidth(A)
(3, 1)
```

`scipy.linalg.issymmetric`

`scipy.linalg.issymmetric(a, atol=None, rtol=None)`

Check if a square 2D array is symmetric.

Parameters

- `a` [ndarray] Input array of size (N, N).
- `atol` [float, optional] Absolute error bound
- `rtol` [float, optional] Relative error bound

Returns

- `sym` [bool] Returns True if the array symmetric.

Raises

`TypeError`

If the dtype of the array is not supported, in particular, NumPy float16, float128 and complex256 dtypes for exact comparisons.

See also:

`ishermitian`

Check if a square 2D array is Hermitian
Notes

For square empty arrays the result is returned True by convention. Complex valued arrays are tested for symmetric-
ity and not for being Hermitian (see examples)

The diagonal of the array is not scanned. Thus if there are infs, NaNs or similar problematic entries on the diagonal,
they will be ignored. However, \texttt{numpy.inf} will be treated as a number, that is to say \texttt{[[1, inf], [inf, 2]]} will return True. On the other hand \texttt{numpy.NaN} is never symmetric, say, \texttt{[[1, nan], [nan, 2]]} will return False.

When \texttt{atol} and/or \texttt{rtol} are set to, then the comparison is performed by \texttt{numpy.allclose} and the tolerance
values are passed to it. Otherwise an exact comparison against zero is performed by internal functions. Hence
performance can improve or degrade depending on the size and dtype of the array. If one of \texttt{atol} or \texttt{rtol} given
the other one is automatically set to zero.

Examples

```python
>>> from scipy.linalg import issymmetric
>>> A = np.arange(9).reshape(3, 3)
>>> A = A + A.T
>>> issymmetric(A)
True
>>> Ac = np.array([[1. + 1.j, 3.j], [3.j, 2.]])
>>> issymmetric(Ac)  # not Hermitian but symmetric
True
```

\texttt{scipy.linalg.ishermitian}

\texttt{scipy.linalg.ishermitian}(a, atol=None, rtol=None)

Check if a square 2D array is Hermitian.

Parameters

\begin{itemize}
  \item \texttt{a} [ndarray] Input array of size (N, N)
  \item \texttt{atol} [float, optional] Absolute error bound
  \item \texttt{rtol} [float, optional] Relative error bound
\end{itemize}

Returns

\begin{itemize}
  \item \texttt{her} [bool] Returns True if the array Hermitian.
\end{itemize}

Raises

\texttt{TypeError}

If the dtype of the array is not supported, in particular, NumPy float16, float128 and com-
plex256 dtypes.

See also:

\texttt{issymmetric}

Check if a square 2D array is symmetric
Notes

For square empty arrays the result is returned True by convention.

`numpy.inf` will be treated as a number, that is to say `[[1, inf], [inf, 2]]` will return True. On the other hand `numpy.NaN` is never symmetric, say, `[[1, nan], [nan, 2]]` will return False.

When atol and/or rtol are set to , then the comparison is performed by `numpy.allclose` and the tolerance values are passed to it. Otherwise an exact comparison against zero is performed by internal functions. Hence performance can improve or degrade depending on the size and dtype of the array. If one of atol or rtol given the other one is automatically set to zero.

Examples

```python
>>> from scipy.linalg import ishermitian
>>> A = np.arange(9).reshape(3, 3)
>>> A = A + A.T
>>> ishermitian(A)
True
>>> A = np.array([[1., 2. + 3.j], [2. - 3.j, 4.]])
>>> ishermitian(A)
True
>>> Ac = np.array([[1. + 1.j, 3.j], [3.j, 2.]])
>>> ishermitian(Ac)  # not Hermitian but symmetric
False
>>> Af = np.array([[0, 1 + 1j], [1 - (1+1e-12)*1j, 0]])
>>> ishermitian(Af)
False
>>> ishermitian(Af, atol=5e-11)  # almost hermitian with atol
True
```

`scipy.linalg.LinAlgError`

exception `scipy.linalg.LinAlgError`

Generic Python-exception-derived object raised by linalg functions.

General purpose exception class, derived from Python's exception.Exception class, programatically raised in linalg functions when a Linear Algebra-related condition would prevent further correct execution of the function.

Parameters

None

Examples

```python
>>> from numpy import linalg as LA
>>> LA.inv(np.zeros((2,2)))
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "...linalg.py", line 350,
    in inv return wrap(solve(a, identity(a.shape[0], dtype=a.dtype)))
  File "...linalg.py", line 249,
    in solve
... linalg.LinAlgError: singular matrix
```

(continues on next page)
raise LinAlgError('Singular matrix')

```python
with_traceback()
    Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

**scipy.linalg.LinAlgWarning**

```python
exception scipy.linalg.LinAlgWarning
    The warning emitted when a linear algebra related operation is close to fail conditions of the algorithm or loss of accuracy is expected.
```

```python
with_traceback()
    Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

### Eigenvalue Problems

### Parameters

- **a**
  - Type: `(M, M) array_like` 
  - Description: A complex or real matrix whose eigenvalues and eigenvectors will be computed.

- **b**
  - Type: `(M, M) array_like, optional` 
  - Description: Right-hand side matrix in a generalized eigenvalue problem. Default is None, identity matrix is assumed.

- **left**
  - Type: `[bool, optional]` 
  - Description: Whether to calculate and return left eigenvectors. Default is False.

---

**3.3. API Definition**

```
with_traceback()
    Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```
right [bool, optional] Whether to calculate and return right eigenvectors. Default is True.

overwrite_a [bool, optional] Whether to overwrite a; may improve performance. Default is False.

overwrite_b [bool, optional] Whether to overwrite b; may improve performance. Default is False.

check_finite [bool, optional] Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

homogeneous_eigvals [bool, optional] If True, return the eigenvalues in homogeneous coordinates. In this case \( w \) is a (2, M) array so that:

\[
w[1,i] \ a \ vr[:,i] = w[0,i] \ b \ vr[:,i]
\]

Default is False.

Returns

- \( w \) [(M,) or (2, M) double or complex ndarray] The eigenvalues, each repeated according to its multiplicity. The shape is (M,) unless homogeneous_eigvals=True.
- \( vl \) [(M, M) double or complex ndarray] The normalized left eigenvector corresponding to the eigenvalue \( w[i] \) is the column \( vl[:,i] \). Only returned if left=True.
- \( vr \) [(M, M) double or complex ndarray] The normalized right eigenvector corresponding to the eigenvalue \( w[i] \) is the column \( vr[:,i] \). Only returned if right=True.

Raises

LinAlgError

If eigenvalue computation does not converge.

See also:

- eigvals
eigenvalues of general arrays
- eigh
  Eigenvalues and right eigenvectors for symmetric/Hermitian arrays.
- eig_banded
eigenvalues and right eigenvectors for symmetric/Hermitian band matrices
- eigh_tridiagonal
eigenvalues and right eigenvectors for symmetric/Hermitian tridiagonal matrices

Examples

```python
>>> from scipy import linalg
>>> a = np.array([[0., -1.], [1., 0.]])
>>> linalg.eigvals(a)
array([0.+1.j, 0.-1.j])

>>> b = np.array([[0., 1.], [1., 1.]])
>>> linalg.eigvals(a, b)
array([1.+0.j, -1.+0.j])
```
```python
cp = np.array([[3., 0., 0.], [0., 8., 0.], [0., 0., 7.]])

w1, vr1 = linalg.eigvals(c, homogeneous_eigvals=True)
array([[3.+0.j, 8.+0.j, 7.+0.j],
       [1.+0.j, 1.+0.j, 1.+0.j]])

w2, vr2 = linalg.eig(c, left=True, right=False)[1]  # normalized left eigenvector
array([[-0.70710678+0.j, -0.70710678-0.j],
       [-0. +0.70710678j, -0. -0.70710678j]])

w3, vr3 = linalg.eig(c, left=False, right=True)[1]  # normalized right eigenvector
array([[0.70710678+0.j, 0.70710678-0.j],
       [0. -0.70710678j, 0. +0.70710678j]])
```

### scipy.linalg.eigvals

**scipy.linalg.eigvals** *(a, b=None, overwrite_a=False, check_finite=True, homogeneous_eigvals=False)*

Compute eigenvalues from an ordinary or generalized eigenvalue problem.

**Parameters**

- **a** *(M, M) array_like* A complex or real matrix whose eigenvalues and eigenvectors will be computed.
- **b** *(M, M) array_like, optional* Right-hand side matrix in a generalized eigenvalue problem. If omitted, identity matrix is assumed.
- **overwrite_a** *(bool, optional)* Whether to overwrite data in a (may improve performance)
- **check_finite** *(bool, optional)* Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.
- **homogeneous_eigvals** *(bool, optional)* If True, return the eigenvalues in homogeneous coordinates. In this case \( w \) is a (2, M) array so that:

\[
\begin{align*}
  w[1,i] \cdot a \cdot vr[:,i] &= w[0,i] \cdot b \cdot vr[:,i] \\
\end{align*}
\]

Default is False.

**Returns**

- **w** *(M,) or (2, M) double or complex ndarray* The eigenvalues, each repeated according to its multiplicity but not in any specific order. The shape is (M,) unless homogeneous_eigvals=True.

**Raises**

- **LinAlgError**

  If eigenvalue computation does not converge

**See also:**

**eig**

Eigenvalues and right eigenvectors of general arrays.

**eigvalsh**

Eigenvalues of symmetric or Hermitian arrays.

**eigvals_banded**

Eigenvalues for symmetric/Hermitian band matrices.

**eigvalsh_tridiagonal**

Eigenvalues of symmetric/Hermitian tridiagonal matrices.

## Examples

```python
>>> from scipy import linalg
>>> a = np.array([[0., -1.], [1., 0.]])
>>> linalg.eigvals(a)
array([0.+1.j, 0.-1.j])

>>> b = np.array([[0., 1.], [1., 1.]])
>>> linalg.eigvals(a, b)
array([ 1.+0.j, -1.+0.j])

>>> a = np.array([[3., 0., 0.], [0., 8., 0.], [0., 0., 7.]])
>>> linalg.eigvals(a, homogeneous_eigvals=True)
array([[3.+0.j, 8.+0.j, 7.+0.j],
       [1.+0.j, 1.+0.j, 1.+0.j]])
```

### scipy.linalg.eigh

```python
scipy.linalg.eigh(a, b=None, lower=True, eigvals_only=False, overwrite_a=False, overwrite_b=False, turbo=True, eigvals=None, type=1, check_finite=True, subset_by_index=None, subset_by_value=None, driver=None)
```

Solve a standard or generalized eigenvalue problem for a complex Hermitian or real symmetric matrix.

Find eigenvalues array `w` and optionally eigenvectors array `v` of array `a`, where `b` is positive definite such that for every eigenvalue `λ` (i-th entry of `w`) and its eigenvector `vᵢ` (i-th column of `v`) satisfies:

\[
a vᵢ = \lambda b vᵢ
\]

In the standard problem, `b` is assumed to be the identity matrix.

**Parameters**

- `a` : {(M, M) array_like} A complex Hermitian or real symmetric matrix whose eigenvalues and eigenvectors will be computed.
- `b` : {(M, M) array_like, optional} A complex Hermitian or real symmetric definite positive matrix in. If omitted, identity matrix is assumed.
- `lower` : {bool, optional} Whether the pertinent array data is taken from the lower or upper triangle of `a` and, if applicable, `b`. (Default: lower)

eigvals_only
[bool, optional] Whether to calculate only eigenvalues and no eigenvectors. (Default: both are calculated)

subset_by_index
[iterable, optional] If provided, this two-element iterable defines the start and the end indices of the desired eigenvalues (ascending order and 0-indexed). To return only the second smallest to fifth smallest eigenvalues, \([1, 4]\) is used. \([n-3, n-1]\) returns the largest three. Only available with “evr”, “evx”, and “gvx” drivers. The entries are directly converted to integers via \(\text{int}()\).

subset_by_value
[iterable, optional] If provided, this two-element iterable defines the half-open interval \((a, b]\) that, if any, only the eigenvalues between these values are returned. Only available with “evr”, “evx”, and “gvx” drivers. Use \(\text{np.inf}\) for the unconstrained ends.

driver: str, optional
Defines which LAPACK driver should be used. Valid options are “ev”, “evd”, “evr”, “evx” for standard problems and “gv”, “gvd”, “gvx” for generalized (where \(b\) is not None) problems. See the Notes section. The default for standard problems is “evr”. For generalized problems, “gvd” is used for full set, and “gvx” for subset requested cases.

type
[int, optional] For the generalized problems, this keyword specifies the problem type to be solved for \(w\) and \(v\) (only takes 1, 2, 3 as possible inputs):

\[
\begin{align*}
1 & \Rightarrow \ a \ @ \ v = w @ b @ v \\
2 & \Rightarrow a @ b @ v = w @ v \\
3 & \Rightarrow b @ a @ v = w @ v
\end{align*}
\]

This keyword is ignored for standard problems.

overwrite_a
[bool, optional] Whether to overwrite data in \(a\) (may improve performance). Default is False.

overwrite_b
[bool, optional] Whether to overwrite data in \(b\) (may improve performance). Default is False.

check_finite
[bool, optional] Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

turbo
[bool, optional] Deprecated since v1.5.0, use `driver=gvd` keyword instead. Use divide and conquer algorithm (faster but expensive in memory, only for generalized eigenvalue problem and if full set of eigenvalues are requested.). Has no significant effect if eigenvectors are not requested.

eigvals
[tuple (lo, hi), optional] Deprecated since v1.5.0, use “subset_by_index” keyword instead. Indexes of the smallest and largest (in ascending order) eigenvalues and corresponding eigenvectors to be returned: 0 <= lo <= hi <= M-1. If omitted, all eigenvalues and eigenvectors are returned.

Returns

\(w\) [(N,) ndarray] The N (1<=N<=M) selected eigenvalues, in ascending order, each repeated according to its multiplicity.

\(v\) [(M, N) ndarray] (if eigvals_only == False)

Raises

LinAlgError
If eigenvalue computation does not converge, an error occurred, or \(b\) matrix is not definite positive. Note that if input matrices are not symmetric or Hermitian, no error will be reported but results will be wrong.

See also:
\textbf{eigvalsh}

eigenvalues of symmetric or Hermitian arrays

\textbf{eig}

eigenvalues and right eigenvectors for non-symmetric arrays

\textbf{eigh_tridiagonal}

eigenvalues and right eigenvectors for symmetric/Hermitian tridiagonal matrices

\textbf{Notes}

This function does not check the input array for being Hermitian/symmetric in order to allow for representing arrays with only their upper/lower triangular parts. Also, note that even though not taken into account, finiteness check applies to the whole array and unaffected by “lower” keyword.

This function uses LAPACK drivers for computations in all possible keyword combinations, prefixed with \textit{sy} if arrays are real and \textit{he} if complex, e.g., a float array with “evr” driver is solved via “syevr”, complex arrays with “gvx” driver problem is solved via “hegvx” etc.

As a brief summary, the slowest and the most robust driver is the classical $<$\textit{sy/he}$>$\textit{ev} which uses symmetric QR. $<$\textit{sy/he}$>$\textit{evr} is seen as the optimal choice for the most general cases. However, there are certain occasions that $<$\textit{sy/he}$>$\textit{evd} computes faster at the expense of more memory usage. $<$\textit{sy/he}$>$\textit{evx}, while still being faster than $<$\textit{sy/he}$>$\textit{ev}, often performs worse than the rest except when very few eigenvalues are requested for large arrays though there is still no performance guarantee.

For the generalized problem, normalization with respect to the given type argument:

\begin{verbatim}
  type 1 and 3 :   v.conj().T @ a @ v = w
  type 2 :        inv(v).conj().T @ a @ inv(v) = w
  type 1 or 2 :   v.conj().T @ b @ v = I
  type 3 :        v.conj().T @ inv(b) @ v = I
\end{verbatim}

\textbf{Examples}

\begin{verbatim}
>>> from scipy.linalg import eigh
>>> A = np.array([[6, 3, 1, 5], [3, 0, 5, 1], [1, 5, 6, 2], [5, 1, 2, 2]])
>>> w, v = eigh(A)
>>> np.allclose(A @ v - v @ np.diag(w), np.zeros((4, 4)))
True

Request only the eigenvalues

>>> w = eigh(A, eigvals_only=True)

Request eigenvalues that are less than 10.

>>> A = np.array([[34, -4, -10, -7, 2],
>>>               [-4, 7, 2, 12, 0],
>>>               [-10, 2, 44, 2, -19],
>>>               [-7, 12, 2, 79, -34],
>>>               [2, 0, -19, -34, 29]])
\end{verbatim}
Request the largest second eigenvalue and its eigenvector

```python
>>> w, v = eigh(A, subset_by_index=[1, 1])
>>> w
array([9.11938152])
>>> v.shape  # only a single column is returned
(5, 1)
```

3.3. API definition  703
three. Only available with “evr”, “evx”, and “gvx” drivers. The entries are directly converted to integers via int().

subset_by_value
[iterable, optional] If provided, this two-element iterable defines the half-open interval \((a, b]\) that, if any, only the eigenvalues between these values are returned. Only available with “evr”, “evx”, and “gvx” drivers. Use np.inf for the unconstrained ends.

driver: str, optional
Defines which LAPACK driver should be used. Valid options are “ev”, “evd”, “evr”, “evx” for standard problems and “gv”, “gvd”, “gvx” for generalized (where b is not None) problems. See the Notes section of scipy.linalg.eigh.

turbo
[bool, optional] Depreciated by “driver=gvd” option. Has no significant effect for eigenvalue computations since no eigenvectors are requested. Deprecated since version 1.5.0.

eigvals
[tuple(lo, hi), optional] Depreciated by “subset_by_index” keyword. Indexes of the smallest and largest (in ascending order) eigenvalues and corresponding eigenvectors to be returned: \(0 <= lo <= hi <= M-1\). If omitted, all eigenvalues and eigenvectors are returned. Deprecated since version 1.5.0.

Returns

w
[(N,) ndarray] The \(1 \leq N \leq M\) selected eigenvalues, in ascending order, each repeated according to its multiplicity.

Raises

LinAlgError
If eigenvalue computation does not converge, an error occurred, or b matrix is not definite positive. Note that if input matrices are not symmetric or Hermitian, no error will be reported but results will be wrong.

See also:

eigh
eigenvalues and right eigenvectors for symmetric/Hermitian arrays
eigvals
eigenvalues of general arrays
eigvals_banded
eigenvalues for symmetric/Hermitian band matrices
eigvalsh_tridiagonal
eigenvalues of symmetric/Hermitian tridiagonal matrices

Notes

This function does not check the input array for being Hermitian/symmetric in order to allow for representing arrays with only their upper/lower triangular parts.

This function serves as a one-liner shorthand for scipy.linalg.eigh with the option eigvals_only=True to get the eigenvalues and not the eigenvectors. Here it is kept as a legacy convenience. It might be beneficial to use the main function to have full control and to be a bit more pythonic.
Examples

For more examples see `scipy.linalg.eigh`.

```python
>>> from scipy.linalg import eigvalsh
>>> A = np.array([[6, 3, 1, 5], [3, 0, 5, 1], [1, 5, 6, 2], [5, 1, 2, 2]])
>>> w = eigvalsh(A)
>>> w
array([-3.74637491, -0.76263923, 6.08502336, 12.42399079])
```

`scipy.linalg.eig_banded`

Solve real symmetric or complex Hermitian band matrix eigenvalue problem.

Find eigenvalues \(w\) and optionally right eigenvectors \(v\) of \(a\):

\[
a v[:,i] = w[i] v[:,i] \\
v.H v = identity
\]

The matrix \(a\) is stored in \(a\_band\) either in lower diagonal or upper diagonal ordered form:

\[
a\_band[u+i-j,j] == a[i,j] (if upper form; i <= j) \quad a\_band[i-j,j] == a[i,j] (if lower form; i >= j)
\]

where \(u\) is the number of bands above the diagonal.

Example of \(a\_band\) (shape of \(a\) is (6,6), \(u=2\)):

```
upper form:
*   *   a02 a13 a24 a35
*   a01 a12 a23 a34 a45
a00 a11 a22 a33 a44 a55

lower form:
a00 a11 a22 a33 a44 a55
a10 a21 a32 a43 a54 *
a20 a31 a42 a53 *
```

Cells marked with * are not used.

**Parameters**

- `a_band`: \([u+1, M]\) array_like The bands of the \(M\) by \(M\) matrix \(a\).
- `lower`: bool, optional. Is the matrix in the lower form. (Default is upper form)
- `eigvals_only`: bool, optional. Compute only the eigenvalues and no eigenvectors. (Default: calculate also eigenvectors)
- `overwrite_a_band`: bool, optional. Discard data in \(a\_band\) (may enhance performance)
- `select`: \({'a', 'v', 'i'}\), optional. Which eigenvalues to calculate

<table>
<thead>
<tr>
<th>select</th>
<th>calculated</th>
</tr>
</thead>
<tbody>
<tr>
<td>'a'</td>
<td>All eigenvalues</td>
</tr>
<tr>
<td>'v'</td>
<td>Eigenvalues in the interval ((\text{min}, \text{max}))</td>
</tr>
<tr>
<td>'i'</td>
<td>Eigenvalues with indices (\text{min} &lt;= i &lt;= \text{max})</td>
</tr>
</tbody>
</table>
select_range
[(min, max), optional] Range of selected eigenvalues

max_ev
[int, optional] For select=='v', maximum number of eigenvalues expected. For other values
of select, has no meaning.
In doubt, leave this parameter untouched.

check_finite
[bool, optional] Whether to check that the input matrix contains only finite numbers. Dis-
abling may give a performance gain, but may result in problems (crashes, non-termination)
if the inputs do contain infinities or NaNs.

Returns
w
[(M,) ndarray] The eigenvalues, in ascending order, each repeated according to its multiplic-
ity.

v
[(M, M) float or complex ndarray] The normalized eigenvector corresponding to the eigen-
value w[i] is the column v[:,i].

Raises
LinAlgError
If eigenvalue computation does not converge.

eigh_tridiagonal

Examples

```python
>>> from scipy.linalg import eig_banded
>>> A = np.array([[1, 5, 2, 0], [5, 2, 5, 2], [2, 5, 3, 5], [0, 2, 5, 4]])
>>> Ab = np.array([[1, 2, 3, 4], [5, 5, 5, 0], [2, 2, 0, 0]])
>>> w, v = eig_banded(Ab, lower=True)
>>> np.allclose(A @ v - v @ np.diag(w), np.zeros((4, 4)))
True
>>> w = eig_banded(Ab, lower=True, eigvals_only=True)
>>> w
array([-4.26200532, -2.22987175, 3.95222349, 12.53965359])

Request only the eigenvalues between [-3, 4]

```
scipy.linalg.eigvals_banded

scipy.linalg.eigvals_banded(a_band, lower=False, overwrite_a_band=False, select='a',
select_range=None, check_finite=True)

Solve real symmetric or complex Hermitian band matrix eigenvalue problem.

Find eigenvalues w of a:

```
a v[:,i] = w[i] v[:,i]
v.H v = identity
```

The matrix a is stored in `a_band` either in lower diagonal or upper diagonal ordered form:

```
a_band[u + i - j, j] == a[i,j] (if upper form; i <= j)
a_band[i - j, j] == a[i,j] (if lower form; i >= j)
```

where `u` is the number of bands above the diagonal.

Example of `a_band` (shape of a is (6,6), `u`=2):

```
upper form:
*   *   a02 a13 a24 a35
* a01 a12 a23 a34 a45
a00 a11 a22 a33 a44 a55

lower form:
a00 a11 a22 a33 a44 a55
a10 a21 a32 a43 a54 *
a20 a31 a42 a53 * *
```

Cells marked with * are not used.

**Parameters**

- **a_band** [(u+1, M) array_like] The bands of the M by M matrix a.
- **lower** [bool, optional] Is the matrix in the lower form. (Default is upper form)
- **overwrite_a_band** [bool, optional] Discard data in `a_band` (may enhance performance)
- **select** [‘a’, ‘v’, ‘i’], optional] Which eigenvalues to calculate

<table>
<thead>
<tr>
<th>select</th>
<th>calculated</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘a’</td>
<td>All eigenvalues</td>
</tr>
<tr>
<td>‘v’</td>
<td>Eigenvalues in the interval (min, max)</td>
</tr>
<tr>
<td>‘i’</td>
<td>Eigenvalues with indices min &lt;= i &lt;= max</td>
</tr>
</tbody>
</table>

- **select_range** [(min, max), optional] Range of selected eigenvalues
- **check_finite** [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**Returns**

- **w** [(M,) ndarray] The eigenvalues, in ascending order, each repeated according to its multiplicity.

**Raises**

- **LinAlgError** If eigenvalue computation does not converge.

**eigvalsh_tridiagonal**
eigenvalues of symmetric/Hermitian tridiagonal matrices

**eigvals**
eigenvalues of general arrays

**eigh**
eigenvalues and right eigenvectors for symmetric/Hermitian arrays

**eig**
eigenvalues and right eigenvectors for non-symmetric arrays

**Examples**

```python
>>> from scipy.linalg import eigvals_banded
>>> A = np.array([[1, 5, 2, 0], [5, 2, 5, 2], [2, 5, 3, 5], [0, 2, 5, 4]])
>>> Ab = np.array([[1, 2, 3, 4], [5, 5, 5, 0], [2, 2, 0, 0]])
>>> w = eigvals_banded(Ab, lower=True)
>>> w
array([-4.26200532, -2.22987175, 3.95222349, 12.53965359])
```

**scipy.linalg.eigh_tridiagonal**

Solve eigenvalue problem for a real symmetric tridiagonal matrix.

Find eigenvalues $w$ and optionally right eigenvectors $v$ of $a$:

```python
a v[:,i] = w[i] v[:,i]
v.H v = identity
```

For a real symmetric matrix $a$ with diagonal elements $d$ and off-diagonal elements $e$.

**Parameters**

- **d** [ndarray, shape (ndim,)] The diagonal elements of the array.
- **e** [ndarray, shape (ndim-1,)] The off-diagonal elements of the array.
- **select** [{‘a’, ‘v’, ‘i’}, optional] Which eigenvalues to calculate

<table>
<thead>
<tr>
<th>select</th>
<th>calculated</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘a’</td>
<td>All eigenvalues</td>
</tr>
<tr>
<td>‘v’</td>
<td>Eigenvalues in the interval (min, max)</td>
</tr>
<tr>
<td>‘i’</td>
<td>Eigenvalues with indices min &lt;= i &lt;= max</td>
</tr>
</tbody>
</table>

- **select_range** [(min, max), optional] Range of selected eigenvalues
**check_finite**

[bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**tol**

[float] The absolute tolerance to which each eigenvalue is required (only used when ‘stebz’ is the lapack_driver). An eigenvalue (or cluster) is considered to have converged if it lies in an interval of this width. If <= 0. (default), the value \( \text{eps}^* |a| \) is used where eps is the machine precision, and \( |a| \) is the 1-norm of the matrix \( a \).

**lapack_driver**

[str] LAPACK function to use, can be ‘auto’, ‘stemr’, ‘stebz’, ‘sterf’, or ‘stev’. When ‘auto’ (default), it will use ‘stemr’ if select='a' and ‘stebz’ otherwise. When ‘stebz’ is used to find the eigenvalues and eigvals_only=False, then a second LAPACK call (to ?STEIN) is used to find the corresponding eigenvectors. ‘sterf’ can only be used when eigvals_only=True and select='a'. ‘stev’ can only be used when select='a'.

**Returns**

**w**

[(M,) ndarray] The eigenvalues, in ascending order, each repeated according to its multiplicity.

**v**

[(M, M) ndarray] The normalized eigenvector corresponding to the eigenvalue \( w[i] \) is the column \( v[:,i] \).

**Raises**

LinAlgError

If eigenvalue computation does not converge.

eigenvalues and right eigenvectors for non-symmetric arrays

*eigh*

eigenvalues and right eigenvectors for symmetric/Hermitian arrays

*eig_banded*

eigenvalues and right eigenvectors for symmetric/Hermitian band matrices

**Notes**

This function makes use of LAPACK S/DSTEMR routines.
Examples

```python
>>> from scipy.linalg import eigh_tridiagonal
>>> d = 3*np.ones(4)
>>> e = -1*np.ones(3)
>>> w, v = eigh_tridiagonal(d, e)
>>> A = np.diag(d) + np.diag(e, k=1) + np.diag(e, k=-1)
```

```python
>>> np.allclose(A @ v - v @ np.diag(w), np.zeros((4, 4)))
True
```

**scipy.linalg.eigvalsh_tridiagonal**

Solve eigenvalue problem for a real symmetric tridiagonal matrix.

Find eigenvalues $w$ of $a$:

```python
a v[:,i] = w[i] v[:,i]
v.H v = identity
```

For a real symmetric matrix $a$ with diagonal elements $d$ and off-diagonal elements $e$.

**Parameters**

- **d** : [ndarray, shape (ndim,)] The diagonal elements of the array.
- **e** : [ndarray, shape (ndim-1,)] The off-diagonal elements of the array.
- **select** : ['a', 'v', 'i'], optional] Which eigenvalues to calculate
  - 'a': All eigenvalues
  - 'v': Eigenvalues in the interval (min, max)
  - 'i': Eigenvalues with indices min <= i <= max
- **select_range** : [(min, max), optional] Range of selected eigenvalues
- **check_finite** : [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.
- **tol** : [float] The absolute tolerance to which each eigenvalue is required (only used when lapack_driver='stebz'). An eigenvalue (or cluster) is considered to have converged if it lies in an interval of this width. If <= 0. (default), the value \( \text{eps} \cdot |a| \) is used where \( \text{eps} \) is the machine precision, and \( |a| \) is the 1-norm of the matrix $a$.
- **lapack_driver** : [str] LAPACK function to use, can be ‘auto’, ‘stemr’, ‘stebz’, ‘sterf’, or ‘stev’. When ‘auto’ (default), it will use ‘stemr’ if `select='a'` and ‘stebz’ otherwise. ‘sterf’ and ‘stev’ can only be used when select='a'.

**Returns**

- **w** : [(M,) ndarray] The eigenvalues, in ascending order, each repeated according to its multiplicity.

**Raises**

- **LinAlgError**
  
  If eigenvalue computation does not converge.

eigh_tridiagonal
eigenvalues and right eigenvectors for symmetric/Hermitian tridiagonal matrices

Examples

```python
>>> from scipy.linalg import eigvalsh_tridiagonal, eigvalsh
>>> d = 3*np.ones(4)
>>> e = -1*np.ones(3)
>>> w = eigvalsh_tridiagonal(d, e)
>>> A = np.diag(d) + np.diag(e, k=1) + np.diag(e, k=-1)
>>> w2 = eigvalsh(A)  # Verify with other eigenvalue routines
>>> np.allclose(w - w2, np.zeros(4))
True
```

Decompositions

- `lu(a[, permute_l, overwrite_a, check_finite])`: Compute pivoted LU decomposition of a matrix.
- `lu_factor(a[, overwrite_a, check_finite])`: Compute pivoted LU decomposition of a matrix.
- `lu_solve(lu_and_piv, b[, trans, ...])`: Solve an equation system, $a x = b$, given the LU factorization of $a$.
- `svd(a[, full_matrices, compute_uv, ...])`: Singular Value Decomposition.
- `svdvals(a[, overwrite_a, check_finite])`: Compute singular values of a matrix.
- `diagsvd(s, M, N)`: Construct the sigma matrix in SVD from singular values and size $M, N$.
- `orth(A[, rcond])`: Construct an orthonormal basis for the range of $A$ using SVD.
- `null_space(A[, rcond])`: Construct an orthonormal basis for the null space of $A$ using SVD.
- `ldl(A[, lower, hermitian, overwrite_a, ...])`: Computes the LDLt or Bunch-Kaufman factorization of a symmetric/Hermitian matrix.
- `cholesky(a[, lower, overwrite_a, check_finite])`: Compute the Cholesky decomposition of a matrix.
- `cholesky_banded(ab[, overwrite_ab, lower, ...])`: Cholesky decompose a banded Hermitian positive-definite matrix.
- `cho_factor(a[, lower, overwrite_a, check_finite])`: Compute the Cholesky decomposition of a matrix, to use in `cho_solve`.
- `cho_solve(c_and_lower, b[, overwrite_b, ...])`: Solve the linear equations $A x = b$, given the Cholesky factorization of $A$.
- `cho_solve_banded(cb_and_lower, b[, ...])`: Solve the linear equations $A x = b$, given the Cholesky factorization of the banded Hermitian $A$.
- `polar(a[, side])`: Compute the polar decomposition.
- `qr(a[, overwrite_a, lwork, mode, pivoting, ...])`: Compute QR decomposition of a matrix.
- `qr_multiply(a, c[, mode, pivoting, ...])`: Calculate the QR decomposition and multiply Q with a matrix.
- `qr_update(Q, R, u, v[, overwrite_qruv, ...])`: Rank-k QR update.
- `qr_delete(Q, R, k, int p=1[, which, ...])`: QR downdate on row or column deletions.
- `qr_insert(Q, R, u, k[, which, rcond, ...])`: QR update on row or column insertions.
- `rq(a[, overwrite_a, lwork, mode, check_finite])`: Compute RQ decomposition of a matrix.

scipy.linalg.lu

**scipy.linalg.lu** (a, permute_l=False, overwrite_a=False, check_finite=True)

Compute pivoted LU decomposition of a matrix.

The decomposition is:

\[
A = PLU
\]

where \( P \) is a permutation matrix, \( L \) lower triangular with unit diagonal elements, and \( U \) upper triangular.

**Parameters**

- **a** [\((M, N)\) array_like] Array to decompose
- **permute_l** [bool, optional] Perform the multiplication \( P*L \) (Default: do not permute)
- **overwrite_a** [bool, optional] Whether to overwrite data in \( a \) (may improve performance)
- **check_finite** [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**Returns**

- (If **permute_l** \( \equiv \) False)
  - **p** [\((M, M)\) ndarray] Permutation matrix
  - **l** [\((M, K)\) ndarray] Lower triangular or trapezoidal matrix with unit diagonal. \( K = \text{min}(M, N) \)
  - **u** [\((K, N)\) ndarray] Upper triangular or trapezoidal matrix
- (If **permute_l** \( \equiv \) True)
  - **pl** [\((M, K)\) ndarray] Permutated \( L \) matrix. \( K = \text{min}(M, N) \)
  - **u** [\((K, N)\) ndarray] Upper triangular or trapezoidal matrix

**Notes**

This is a LU factorization routine written for SciPy.
Examples

```python
>>> from scipy.linalg import lu
>>> A = np.array([[2, 5, 8, 7], [5, 2, 2, 8], [7, 5, 6, 6], [5, 4, 4, 8]])
>>> p, l, u = lu(A)
>>> np.allclose(A - p @ l @ u, np.zeros((4, 4)))
True
```

`scipy.linalg.lu_factor`

`scipy.linalg.lu_factor(a, overwrite_a=False, check_finite=True)`  
Compute pivoted LU decomposition of a matrix.

The decomposition is:

\[ A = P L U \]

where \( P \) is a permutation matrix, \( L \) lower triangular with unit diagonal elements, and \( U \) upper triangular.

**Parameters**

- `a` : [(M, M) array_like] Matrix to decompose
- `overwrite_a` : [bool, optional] Whether to overwrite data in \( A \) (may increase performance)
- `check_finite` : [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**Returns**

- `lu` : [(N, N) ndarray] Matrix containing \( U \) in its upper triangle, and \( L \) in its lower triangle. The unit diagonal elements of \( L \) are not stored.
- `piv` : [(N,) ndarray] Pivot indices representing the permutation matrix \( P \): row \( i \) of matrix was interchanged with row \( \text{piv}[i] \).

**See also:**

`lu_solve`

solve an equation system using the LU factorization of a matrix

**Notes**

This is a wrapper to the *GETRF routines from LAPACK.

**Examples**

```python
>>> from scipy.linalg import lu_factor
>>> A = np.array([[2, 5, 8, 7], [5, 2, 2, 8], [7, 5, 6, 6], [5, 4, 4, 8]])
>>> lu, piv = lu_factor(A)
>>> piv
array([2, 2, 3, 3], dtype=int32)
```

Convert LAPACK’s `piv` array to NumPy index and test the permutation

```python
>>> piv_py = [2, 0, 3, 1]
>>> L, U = np.tril(lu, k=-1) + np.eye(4), np.triu(lu)
>>> np.allclose(A[piv_py] - L @ U, np.zeros((4, 4)))
True
```

**scipy.linalg.lu_solve**

**scipy.linalg.lu_solve** *(lu_and_piv, b, trans=0, overwrite_b=False, check_finite=True)*

Solve an equation system, \( ax = b \), given the LU factorization of \( a \)

**Parameters**

- *(lu, piv)*  
  Factorization of the coefficient matrix \( a \), as given by \( \text{lu_factor} \)
- *b*  
  Right-hand side
- *trans*  
  Type of system to solve:

<table>
<thead>
<tr>
<th>trans</th>
<th>system</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>( ax = b )</td>
</tr>
<tr>
<td>1</td>
<td>( a^T x = b )</td>
</tr>
<tr>
<td>2</td>
<td>( a^H x = b )</td>
</tr>
</tbody>
</table>

- *overwrite_b*  
  Whether to overwrite data in \( b \) (may increase performance)
- *check_finite*  
  Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**Returns**

- *x*  
  Solution to the system

**See also:**

**lu_factor**

LU factorize a matrix

**Examples**

```python
>>> from scipy.linalg import lu_factor, lu_solve
>>> A = np.array([[2, 5, 8, 7], [5, 2, 2, 8], [7, 5, 6, 6], [5, 4, 4, 8]])
>>> b = np.array([1, 1, 1, 1])
>>> lu, piv = lu_factor(A)
>>> x = lu_solve((lu, piv), b)
>>> np.allclose(A @ x - b, np.zeros((4,)))
True
```
scipy.linalg.svd

scipy.linalg.svd(a, full_matrices=True, compute_uv=True, overwrite_a=False, check_finite=True, lapack_driver='gesdd')

Singular Value Decomposition.

Factorizes the matrix $a$ into two unitary matrices $U$ and $V_h$, and a 1-D array $s$ of singular values (real, non-negative) such that $a == U @ S @ V_h$, where $S$ is a suitably shaped matrix of zeros with main diagonal $s$.

Parameters

- **a** [(M, N) array_like] Matrix to decompose.
- **full_matrices** [bool, optional] If True (default), $U$ and $V_h$ are of shape $(M, M), (N, N)$. If False, the shapes are $(M, K)$ and $(K, N)$, where $K = \min(M, N)$.
- **compute_uv** [bool, optional] Whether to compute also $U$ and $V_h$ in addition to $s$. Default is True.
- **overwrite_a** [bool, optional] Whether to overwrite $a$; may improve performance. Default is False.
- **check_finite** [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.
- **lapack_driver** [{'gesdd', 'gesvd'}, optional] Whether to use the more efficient divide-and-conquer approach ('gesdd') or general rectangular approach ('gesvd') to compute the SVD. MATLAB and Octave use the 'gesvd' approach. Default is 'gesdd'.

New in version 0.18.

Returns

- **U** [ndarray] Unitary matrix having left singular vectors as columns. Of shape $(M, M)$ or $(M, K)$, depending on full_matrices.
- **s** [ndarray] The singular values, sorted in non-increasing order. Of shape $(K,)$, with $K = \min(M, N)$.
- **Vh** [ndarray] Unitary matrix having right singular vectors as rows. Of shape $(N, N)$ or $(K, N)$ depending on full_matrices.

For compute_uv=False, only $s$ is returned.

Raises

- **LinAlgError**

If SVD computation does not converge.

See also:

- **svdvals**

  Compute singular values of a matrix.

- **diagsvd**

  Construct the Sigma matrix, given the vector $s$.
Examples

```python
>>> from scipy import linalg
>>> from numpy.random import default_rng
>>> rng = default_rng()
>>> m, n = 9, 6
>>> a = rng.standard_normal((m, n)) + 1.j*rng.standard_normal((m, n))
>>> U, s, Vh = linalg.svd(a)
>>> U.shape, s.shape, Vh.shape
((9, 9), (6,), (6, 6))
```

Reconstruct the original matrix from the decomposition:

```python
>>> sigma = np.zeros((m, n))
>>> for i in range(min(m, n)):
...     sigma[i, i] = s[i]
>>> a1 = np.dot(U, np.dot(sigma, Vh))
>>> np.allclose(a, a1)
True
```

Alternatively, use `full_matrices=False` (notice that the shape of `U` is then `(m, n)` instead of `(m, m)`):

```python
>>> U, s, Vh = linalg.svd(a, full_matrices=False)
>>> U.shape, s.shape, Vh.shape
((9, 6), (6,), (6, 6))
>>> S = np.diag(s)
>>> np.allclose(a, np.dot(U, np.dot(S, Vh)))
True
```

`scipy.linalg.svdvals`

`scipy.linalg.svdvals(a, overwrite_a=False, check_finite=True)`

Compute singular values of a matrix.

**Parameters**

- `a` ([M, N] array_like) Matrix to decompose.
- `overwrite_a` [bool, optional] Whether to overwrite `a`; may improve performance. Default is False.
- `check_finite` [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**Returns**

- `s` [(min(M, N),) ndarray] The singular values, sorted in decreasing order.

**Raises**

- `LinAlgError` If SVD computation does not converge.
See also:

**svd**

Compute the full singular value decomposition of a matrix.

**diagsvd**

Construct the Sigma matrix, given the vector $s$.

Notes

`svdvals(a)` only differs from `svd(a, compute_uv=False)` by its handling of the edge case of empty `a`, where it returns an empty sequence:

```python
>>> a = np.empty((0, 2))
>>> from scipy.linalg import svdvals
>>> svdvals(a)
array([], dtype=float64)
```

Examples

```python
>>> from scipy.linalg import svdvals
>>> m = np.array([[1.0, 0.0],
...                [2.0, 3.0],
...                [1.0, 1.0],
...                [0.0, 2.0],
...                [1.0, 0.0]])
>>> svdvals(m)
array([ 4.28091555, 1.63516424])
```

We can verify the maximum singular value of $m$ by computing the maximum length of $m \cdot u$ over all the unit vectors $u$ in the (x,y) plane. We approximate “all” the unit vectors with a large sample. Because of linearity, we only need the unit vectors with angles in $[0, \pi]$.

```python
>>> t = np.linspace(0, np.pi, 2000)
>>> u = np.array([np.cos(t), np.sin(t)])
>>> np.linalg.norm(m.dot(u), axis=0).max()
4.2809152422538475
```

$p$ is a projection matrix with rank 1. With exact arithmetic, its singular values would be $[1, 0, 0, 0]$.

```python
>>> v = np.array([0.1, 0.3, 0.9, 0.3])
>>> p = np.outer(v, v)
>>> svdvals(p)
array([ 1.00000000e+00, 2.02021698e-17, 1.56692500e-17,
       8.15115104e-34])
```

The singular values of an orthogonal matrix are all 1. Here, we create a random orthogonal matrix by using the `rvs()` method of `scipy.stats.ortho_group`.

```python
>>> from scipy.stats import ortho_group
>>> orth = ortho_group.rvs(4)
```
scipy.linalg.diagsvd

scipy.linalg.diagsvd(s, M, N)

Construct the sigma matrix in SVD from singular values and size M, N.

Parameters

- `s` ((M,) or (N,) array_like) Singular values
- `M` [int] Size of the matrix whose singular values are s.
- `N` [int] Size of the matrix whose singular values are s.

Returns

- `S` [(M, N) ndarray] The S-matrix in the singular value decomposition

See also:

- `svd`
  Singular value decomposition of a matrix
- `svdvals`
  Compute singular values of a matrix.

Examples

```python
>>> from scipy.linalg import diagsvd
>>> vals = np.array([1, 2, 3])  # The array representing the computed svd
>>> diagsvd(vals, 3, 4)
array([[1, 0, 0, 0],
       [0, 2, 0, 0],
       [0, 0, 3, 0]])
>>> diagsvd(vals, 4, 3)
array([[1, 0, 0],
       [0, 2, 0],
       [0, 0, 3],
       [0, 0, 0]])
```

scipy.linalg.orth

scipy.linalg.orth(A, rcond=None)

Construct an orthonormal basis for the range of A using SVD.

Parameters

- `A` [(M, N) array_like] Input array
- `rcond` [float, optional] Relative condition number. Singular values s smaller than rcond \* max(s) are considered zero. Default: floating point eps \* max(M,N).

Returns

- `Q` [(M, K) ndarray] Orthonormal basis for the range of A. K = effective rank of A, as determined by rcond
See also:

**svd**

Singular value decomposition of a matrix

**null_space**

Matrix null space

**Examples**

```python
>>> from scipy.linalg import orth
>>> A = np.array([[2, 0], [0, 5]]) # rank 2 array
>>> orth(A)
array([[0., 1.],
       [1., 0.]])
>>> orth(A.T)
array([[0., 1.],
       [1., 0.],
       [0., 0.]])
```

`scipy.linalg.null_space`

`scipy.linalg.null_space(A, rcond=None)`

Construct an orthonormal basis for the null space of A using SVD

**Parameters**

- **A** [(M, N) array_like] Input array
- **rcond** [float, optional] Relative condition number. Singular values s smaller than `rcond * max(s)` are considered zero. Default: floating point eps * max(M,N).

**Returns**

- **Z** [(N, K) ndarray] Orthonormal basis for the null space of A. K = dimension of effective null space, as determined by rcond

See also:

**svd**

Singular value decomposition of a matrix

**orth**

Matrix range
Examples

1-D null space:

```python
>>> from scipy.linalg import null_space
>>> A = np.array([[1, 1], [1, 1]])
>>> ns = null_space(A)
>>> ns * np.sign(ns[0, 0])  # Remove the sign ambiguity of the vector
array([[ 0.70710678],
       [-0.70710678]])
```

2-D null space:

```python
>>> from numpy.random import default_rng
>>> rng = default_rng()
>>> B = rng.random((3, 5))
>>> Z = null_space(B)
>>> Z.shape
(5, 2)
>>> np.allclose(B.dot(Z), 0)
True
```

The basis vectors are orthonormal (up to rounding error):

```python
>>> Z.T.dot(Z)
array([[ 1.00000000e+00, 6.92087741e-17],
       [ 6.92087741e-17, 1.00000000e+00]])
```

scipy.linalg.ldl

`scipy.linalg.ldl(A, lower=True, hermitian=True, overwrite_a=False, check_finite=True)`

Computes the LDL or Bunch-Kaufman factorization of a symmetric/ hermitian matrix.

This function returns a block diagonal matrix \( D \) consisting blocks of size at most 2x2 and also a possibly permuted unit lower triangular matrix \( L \) such that the factorization \( A = L D L^H \) or \( A = L D L^T \) holds. If \( lower \) is False then (again possibly permuted) upper triangular matrices are returned as outer factors.

The permutation array can be used to triangularize the outer factors simply by a row shuffle, i.e., \( \text{lu}[\text{perm}, :] \) is an upper/lower triangular matrix. This is also equivalent to multiplication with a permutation matrix \( P \cdot \text{dot}(\text{lu}) \), where \( P \) is a column-permuted identity matrix \( I[:, \text{perm}] \).

Depending on the value of the boolean lower, only upper or lower triangular part of the input array is referenced. Hence, a triangular matrix on entry would give the same result as if the full matrix is supplied.

**Parameters**

- **A** [array_like] Square input array
- **lower** [bool, optional] This switches between the lower and upper triangular outer factors of the factorization. Lower triangular (lower=True) is the default.
- **hermitian** [bool, optional] For complex-valued arrays, this defines whether \( A = A \cdot \text{conj}() \cdot \text{T} \) or \( A = A \cdot \text{T} \) is assumed. For real-valued arrays, this switch has no effect.
- **overwrite_a** [bool, optional] Allow overwriting data in \( A \) (may enhance performance). The default is False.
- **check_finite**
[bool, optional] Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**Returns**

- **lu** [ndarray] The (possibly) permuted upper/lower triangular outer factor of the factorization.
- **d** [ndarray] The block diagonal multiplier of the factorization.
- **perm** [ndarray] The row-permutation index array that brings lu into triangular form.

**Raises**

- **ValueError**
  If input array is not square.
- **ComplexWarning**
  If a complex-valued array with nonzero imaginary parts on the diagonal is given and hermitian is set to True.

**See also:**

````
cholesky, lu
````

**Notes**

This function uses ?SYTRF routines for symmetric matrices and ?HETRF routines for Hermitian matrices from LAPACK. See [1] for the algorithm details.

Depending on the `lower` keyword value, only lower or upper triangular part of the input array is referenced. Moreover, this keyword also defines the structure of the outer factors of the factorization.

New in version 1.1.0.

**References**

[1]

**Examples**

Given an upper triangular array `a` that represents the full symmetric array with its entries, obtain `l`, ‘d’ and the permutation vector `perm`:

```
>>> import numpy as np
>>> from scipy.linalg import ldl
>>> a = np.array([[2, -1, 3], [0, 2, 0], [0, 0, 1]])
>>> lu, d, perm = ldl(a, lower=0)  # Use the upper part
>>> lu
array([[ 0. , 0. , 1. ],
       [ 0. , 1. , -0.5],
       [ 1. , 1. , 1.5]])
>>> d
array([[-5. , 0. , 0. ],
       [ 0. , 1.5, 0. ],
       [ 0. , 0. , 2. ]])
>>> perm
```

(continues on next page)
array([2, 1, 0])

```python
>>> lu[perm, :]
array([[ 1. , 1. , 1.5],
       [ 0. , 1. , -0.5],
       [ 0. , 0. , 1. ]])
```

```python
>>> lu.dot(d).dot(lu.T)
array([[ 2., -1., 3.],
       [-1., 2., 0.],
       [ 3., 0., 1.]])
```

### scipy.linalg.cholesky

(scipy.linalg.cholesky (a, lower=False, overwrite_a=False, check_finite=True)

Compute the Cholesky decomposition of a matrix.

Returns the Cholesky decomposition, $A = L L^*$ or $A = U^* U$ of a Hermitian positive-definite matrix $A$.

**Parameters**

- **a** : [(M, M) array_like] Matrix to be decomposed
- **lower** : [bool, optional] Whether to compute the upper- or lower-triangular Cholesky factorization. Default is upper-triangular.
- **overwrite_a** : [bool, optional] Whether to overwrite data in $a$ (may improve performance).
- **check_finite** : [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**Returns**

- **c** : [(M, M) ndarray] Upper- or lower-triangular Cholesky factor of $a$.

**Raises**

- **LinAlgError** [if decomposition fails.]

### Examples

```python
>>> from scipy.linalg import cholesky
>>> a = np.array([[1,-2j],[2j,5]])
>>> L = cholesky(a, lower=True)
>>> L
array([[ 1.+0.j, 0.+0.j],
       [ 0.+2.j, 1.+0.j]])
>>> L @ L.conj().T
array([[ 1.+0.j, 0.-2.j],
       [ 0.+2.j, 5.+0.j]])
```
scipy.linalg.cholesky_banded

scipy.linalg.cholesky_banded(ab, overwrite_ab=False, lower=False, check_finite=True)

Cholesky decompose a banded Hermitian positive-definite matrix

The matrix a is stored in ab either in lower-diagonal or upper-diagonal ordered form:

<table>
<thead>
<tr>
<th>i-j</th>
<th>j</th>
<th>ab[i,j]</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>if upper form; i &lt;= j</td>
</tr>
<tr>
<td></td>
<td></td>
<td>if lower form; i &gt;= j</td>
</tr>
</tbody>
</table>

Example of ab (shape of a is (6,6), u=2):

```
upper form:
*   *   a02  a13  a24  a35
*  a01  a12  a23  a34  a45
a00  a11  a22  a33  a44  a55

lower form:
a00  a11  a22  a33  a44  a55
a10  a21  a32  a43  a54 *
*   a20  a31  a42  a53 *
```

Parameters

- **ab**
  ([u + 1, M] array_like) Banded matrix
- **overwrite_ab**
  [bool, optional] Discard data in ab (may enhance performance)
- **lower**
  [bool, optional] Is the matrix in the lower form. (Default is upper form)
- **check_finite**
  [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

Returns

- **c**
  ([u + 1, M] ndarray) Cholesky factorization of a, in the same banded format as ab

See also:

- **cho_solve_banded**
  Solve a linear set equations, given the Cholesky factorization of a banded Hermitian.

Examples

```python
>>> from scipy.linalg import cholesky_banded
>>> from numpy import allclose, zeros, diag
>>> Ab = np.array([[[0, 0, 1j, 2, 3 j], [0, -1, -2, 3, 4], [9, 8, 7, 6, 9]]
>>> A = np.diag(Ab[0, 2: ], k=2) + np.diag(Ab[1, 1: ], k=1)
>>> A = A + A.conj().T + np.diag(Ab[2, :])
>>> c = cholesky_banded(A)
>>> C = np.diag(c[0, 2: ], k=2) + np.diag(c[1, 1: ], k=1) + np.diag(c[2, :])
>>> np.allclose(C.conj().T @ C - A, np.zeros((5, 5)))
True
```
scipy.linalg.cho_factor

**scipy.linalg.cho_factor**(*a*, *lower=False*, *overwrite_a=False*, *check_finite=True*)

Compute the Cholesky decomposition of a matrix, to use in cho_solve.

Returns a matrix containing the Cholesky decomposition, \( A = L L^* \) or \( A = U^* U \) of a Hermitian positive-definite matrix \( a \). The return value can be directly used as the first parameter to cho_solve.

**Warning:** The returned matrix also contains random data in the entries not used by the Cholesky decomposition. If you need to zero these entries, use the function `cholesky` instead.

**Parameters**

- **a** [(M, M) array_like] Matrix to be decomposed
- **lower** [bool, optional] Whether to compute the upper or lower triangular Cholesky factorization (Default: upper-triangular)
- **overwrite_a** [bool, optional] Whether to overwrite data in a (may improve performance)
- **check_finite** [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**Returns**

- **c** [(M, M) ndarray] Matrix whose upper or lower triangle contains the Cholesky factor of \( a \). Other parts of the matrix contain random data.
- **lower** [bool] Flag indicating whether the factor is in the lower or upper triangle

**Raises**

- LinAlgError
  
  Raised if decomposition fails.

**See also:**

- **cho_solve**

  Solve a linear set equations using the Cholesky factorization of a matrix.

**Examples**

```python
>>> from scipy.linalg import cho_factor
>>> A = np.array([[9, 3, 1, 5], [3, 7, 5, 1], [1, 5, 9, 2], [5, 1, 2, 6]])
>>> c, low = cho_factor(A)
>>> c
array([[3.    , 1.    , 0.33333333, 1.66666667],
       [3.    , 2.44948974, 1.90515869, -0.27216553],
       [1.    , 5.    , 2.29330749, 0.8559528 ],
       [5.    , 1.    , 2.    , 1.55418563]])
>>> np.allclose(np.triu(c).T @ np.triu(c) - A, np.zeros((4, 4)))
True
```
scipy.linalg.cho_solve

`scipy.linalg.cho_solve(c_and_lower, b, overwrite_b=False, check_finite=True)`

Solve the linear equations \( A x = b \), given the Cholesky factorization of \( A \).

**Parameters**

- `(c, lower)`  
  [tuple, (array, bool)] Cholesky factorization of \( A \), as given by `cho_factor`.
- `b`  
  [array] Right-hand side.
- `overwrite_b`  
  [bool, optional] Whether to overwrite data in \( b \) (may improve performance).
- `check_finite`  
  [bool, optional] Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**Returns**

- `x`  
  [array] The solution to the system \( A x = b \).

**Examples**

```python
>>> from scipy.linalg import cho_factor, cho_solve
>>> A = np.array([[9, 3, 1, 5], [3, 7, 5, 1], [1, 5, 9, 2], [5, 1, 2, 6]])
>>> c, low = cho_factor(A)
>>> x = cho_solve((c, low), [1, 1, 1, 1])
>>> np.allclose(A @ x - [1, 1, 1, 1], np.zeros(4))
True
```

scipy.linalg.cho_solve_banded

`scipy.linalg.cho_solve_banded(cb_and_lower, b, overwrite_b=False, check_finite=True)`

Solve the linear equations \( A x = b \), given the Cholesky factorization of the banded Hermitian \( A \).

**Parameters**

- `(cb, lower)`  
  [tuple, (ndarray, bool)] \( cb \) is the Cholesky factorization of \( A \), as given by `cholesky_banded`. `lower` must be the same value that was given to `cholesky_banded`.
- `b`  
  [array_like] Right-hand side.
- `overwrite_b`  
  [bool, optional] If True, the function will overwrite the values in \( b \).
- `check_finite`  
  [bool, optional] Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**Returns**

- `x`  
  [array] The solution to the system \( A x = b \).

**Examples**

```python
>>> from scipy.linalg import cho_factor, cho_solve
>>> A = np.array([[9, 3, 1, 5], [3, 7, 5, 1], [1, 5, 9, 2], [5, 1, 2, 6]])
>>> c, low = cho_factor(A)
>>> x = cho_solve((c, low), [1, 1, 1, 1])
>>> np.allclose(A @ x - [1, 1, 1, 1], np.zeros(4))
True
```
cholesky_banded

Cholesky factorization of a banded matrix

Notes

New in version 0.8.0.

Examples

```python
>>> from scipy.linalg import cholesky_banded, cho_solve_banded
>>> Ab = np.array([[0, 0, 1j, 2, 3j], [0, -1, -2, 3, 4], [9, 8, 7, 6, 9]])
>>> A = np.diag(Ab[0,2:], k=2) + np.diag(Ab[1,1:], k=1)
>>> A = A + A.conj().T + np.diag(Ab[2,:])
>>> c = cholesky_banded(Ab)
>>> x = cho_solve_banded((c, False), np.ones(5))
>>> np.allclose(A @ x - np.ones(5), np.zeros(5))
True
```

scipy.linalg.polar

```python
scipy.linalg.polar(a, side='right')
```

Compute the polar decomposition.

Returns the factors of the polar decomposition [1] \( u \) and \( p \) such that \( a = up \) (if \( side \) is “right”) or \( a = pu \) (if \( side \) is “left”), where \( p \) is positive semidefinite. Depending on the shape of \( a \), either the rows or columns of \( u \) are orthonormal. When \( a \) is a square array, \( u \) is a square unitary array. When \( a \) is not square, the “canonical polar decomposition” [2] is computed.

Parameters

- **a**
  - (m, n) array_like The array to be factored.
- **side**
  - {'left', 'right'}, optional Determines whether a right or left polar decomposition is computed. If \( side \) is “right”, then \( a = up \). If \( side \) is “left”, then \( a = pu \). The default is “right”.

Returns

- **u**
  - (m, n) ndarray If \( a \) is square, then \( u \) is unitary. If \( m > n \), then the columns of \( a \) are orthonormal, and if \( m < n \), then the rows of \( u \) are orthonormal.
- **p**
  - ndarray \( p \) is Hermitian positive semidefinite. If \( a \) is nonsingular, \( p \) is positive definite. The shape of \( p \) is (n, n) or (m, m), depending on whether \( side \) is “right” or “left”, respectively.

References

[1], [2]
Examples

```python
>>> from scipy.linalg import polar
>>> a = np.array([[1, -1], [2, 4]])
>>> u, p = polar(a)
>>> u
array([[ 0.85749293, -0.51449576],
       [ 0.51449576, 0.85749293]])
>>> p
array([[ 1.88648444, 1.2004901 ],
       [ 1.2004901 , 3.94446746]])

A non-square example, with m < n:

```python
>>> b = np.array([[0.5, 1, 2], [1.5, 3, 4]])
>>> u, p = polar(b)
>>> u
array([[-0.21196618, 0.39378971, -0.42393237, 0.88054056],
       [ 0.39378971, 0.78757942, 0.4739708 ]])
>>> p
array([[ 0.48470147, 0.96940295, 1.15122648],
       [ 0.96940295, 1.9388059 , 2.30245295],
       [ 1.15122648, 2.30245295, 3.65696431]])

```python
>>> u.dot(p)  # Verify the decomposition.
array([[ 0.5, 1. , 2. ],
       [ 1.5, 3. , 4. ]])
>>> u.T.dot(u)  # The rows of u are orthonormal.
array([[ 1.00000000e+00, -2.07353665e-17],
       [ -2.07353665e-17, 1.00000000e+00]])
```

Another non-square example, with m > n:

```python
>>> c = b.T
>>> u, p = polar(c)
>>> u
array([[-0.21196618, 0.39378971, -0.42393237, 0.88054056],
       [ 0.42393237, 0.78757942, 0.4739708 ]])
>>> p
array([[ 1.23116567, 1.93241587],
       [ 1.93241587, 4.84930602]])

```python
>>> u.dot(p)  # Verify the decomposition.
array([[ 0.5, 1.5],
       [ 1. , 3. ],
       [ 2. , 4. ]])
>>> u.T.dot(u)  # The columns of u are orthonormal.
array([[ 1.00000000e+00, -1.26363763e-16],
       [ -1.26363763e-16, 1.00000000e+00]])
```

3.3. API definition
scipy.linalg.qr

scipy.linalg.qr (a, overwrite_a=False, lwork=None, mode='full', pivoting=False, check_finite=True)

Compute QR decomposition of a matrix.

Calculate the decomposition $A = QR$ where $Q$ is unitary/orthogonal and $R$ upper triangular.

Parameters

- **a** [(M, N) array_like] Matrix to be decomposed
- **overwrite_a** [bool, optional] Whether data in $a$ is overwritten (may improve performance if overwrite_a is set to True by reusing the existing input data structure rather than creating a new one.)
- **lwork** [int, optional] Work array size, lwork >= a.shape[1]. If None or -1, an optimal size is computed.
- **mode** [{'full', 'r', 'economic', 'raw'}, optional] Determines what information is to be returned: either both $Q$ and $R$ ('full', default), only $R$ ('r') or both $Q$ and $R$ but computed in economy-size ('economic', see Notes). The final option 'raw' (added in SciPy 0.11) makes the function return two matrices $(Q, TAU)$ in the internal format used by LAPACK.
- **pivoting** [bool, optional] Whether or not factorization should include pivoting for rank-revealing qr decomposition. If pivoting, compute the decomposition $A P = QR$ as above, but where $P$ is chosen such that the diagonal of $R$ is non-increasing.
- **check_finite** [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

Returns

- **Q** [float or complex ndarray] Of shape (M, M), or (M, K) for mode='economic'. Not returned if mode='r'.
- **R** [float or complex ndarray] Of shape (M, N), or (K, N) for mode='economic'. K = min(M, N).
- **P** [int ndarray] Of shape (N,) for pivoting=True. Not returned if pivoting=False.

Raises

LinAlgError

Raised if decomposition fails.

Notes

This is an interface to the LAPACK routines dgeqrf, zgeqrf, dorgqr, zungqr, dgeqp3, and zgeqp3.

If mode=economic, the shapes of Q and R are (M, K) and (K, N) instead of (M, M) and (M, N), with K=min(M, N).

Examples

```python
>>> from scipy import linalg
>>> rng = np.random.default_rng()
>>> a = rng.standard_normal((9, 6))
```
```python
>>> q, r = linalg.qr(a)
>>> np.allclose(a, np.dot(q, r))
True
>>> q.shape, r.shape
((9, 9), (9, 6))

>>> r2 = linalg.qr(a, mode='r')
>>> np.allclose(r, r2)
True

>>> q3, r3 = linalg.qr(a, mode='economic')
>>> q3.shape, r3.shape
((9, 9), (9, 6))

>>> q4, r4, p4 = linalg.qr(a, pivoting=True)
>>> np.allclose(a[:, p4], np.dot(q4, r4))
True
>>> q4.shape, r4.shape, p4.shape
((9, 9), (9, 6), (6,))

>>> q5, r5, p5 = linalg.qr(a, mode='economic', pivoting=True)
>>> q5.shape, r5.shape, p5.shape
((9, 6), (6, 6), (6,))
```

**scipy.linalg.qr_multiply**

`scipy.linalg.qr_multiply(a, c, mode='right', pivoting=False, conjugate=False, overwrite_a=False, overwrite_c=False)`

Calculate the QR decomposition and multiply Q with a matrix.

Calculate the decomposition \( A = Q R \) where Q is unitary/orthogonal and R upper triangular. Multiply Q with a vector or a matrix c.

**Parameters**

- **a** [(M, N), array_like] Input array
- **c** [array_like] Input array to be multiplied by q.
- **mode** [{'left', 'right'}, optional] Q @ c is returned if mode is 'left', c @ Q is returned if mode is 'right'. The shape of c must be appropriate for the matrix multiplications, if mode is 'left', min(a.shape) == c.shape[0], if mode is 'right', a.shape[0] == c.shape[1].
- **pivoting** [bool, optional] Whether or not factorization should include pivoting for rank-revealing qr decomposition, see the documentation of qr.
- **conjugate** [bool, optional] Whether Q should be complex-conjugated. This might be faster than explicit conjugation.
- **overwrite_a** [bool, optional] Whether data in a is overwritten (may improve performance)
- **overwrite_c** [bool, optional] Whether data in c is overwritten (may improve performance). If this is used, c must be big enough to keep the result, i.e. c.shape[0] = a.shape[0] if mode is 'left'.
Returns

CQ  [ndarray] The product of Q and c.
R  [(K, N), ndarray] R array of the resulting QR factorization where K = min(M, N).
P  [(N,) ndarray] Integer pivot array. Only returned when pivoting=True.

Raises

LinAlgError
Raised if QR decomposition fails.

Notes

This is an interface to the LAPACK routines ?GEQRF, ?ORMQR, ?UNMQR, and ?GEQP3.
New in version 0.11.0.

Examples

```python
>>> from scipy.linalg import qr_multiply, qr
>>> A = np.array([[1, 3, 3], [2, 3, 2], [2, 3, 3], [1, 3, 2]])
>>> qc, r1, piv1 = qr_multiply(A, 2*np.eye(4), pivoting=1)
>>> qc
array([[-1.,  1., -1.],
       [-1., -1.,  1.],
       [-1., -1., -1.],
       [-1.,  1.,  1.]]);
>>> r1
array([[-6., -3., -5.],
       [ 0., -1., -1.11022302e-16],
       [ 0.,  0., -1.]]);
>>> piv1
array([1, 0, 2], dtype=int32)
>>> q2, r2, piv2 = qr(A, mode='economic', pivoting=1)
>>> np.allclose(2*q2 - qc, np.zeros((4, 3)))
True
```

scipy.linalg.qr_update

scipy.linalg.qr_update(Q, R, u, v, overwrite_qruv=False, check_finite=True)

Rank-k QR update

If A = QR is the QR factorization of A, return the QR factorization of A + u v**T for real A or A + u v**H for complex A.

Parameters

Q  [(M, M) or (M, N) array_like] Unitary/orthogonal matrix from the qr decomposition of A.
R  [(M, N) or (N, N) array_like] Upper triangular matrix from the qr decomposition of A.
u  [(M,) or (M, k) array_like] Left update vector
v  [(N,) or (N, k) array_like] Right update vector
overwrite_qruv  [bool, optional] If True, consume Q, R, u, and v, if possible, while performing the update, otherwise make copies as necessary. Defaults to False.
check_finite

[bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs. Default is True.

Returns

Q1 [ndarray] Updated unitary/orthogonal factor
R1 [ndarray] Updated upper triangular factor

See also:

qr, qr_multiply, qr_delete, qr_insert

Notes

This routine does not guarantee that the diagonal entries of R1 are real or positive.

New in version 0.16.0.

[1], [2], [3]

Examples

```python
>>> from scipy import linalg
>>> a = np.array([[ 3., -2., -2.],
...                [ 6., -9., -3.],
...                [ -3., 10.,  1.],
...                [ 6., -7.,  4.],
...                [ 7.,  8., -6.]])
>>> q, r = linalg.qr(a)
```

Given this q, r decomposition, perform a rank 1 update.

```python
>>> u = np.array([7., -2., 4., 3., 5.])
>>> v = np.array([1., 3., -5.])
>>> q_up, r_up = linalg.qr_update(q, r, u, v, False)
>>> q_up
array([[ 0.54073807,  0.18645997,  0.81707661, -0.02136616,  0.06902409],
        [ 0.21629523, -0.63257324,  0.06567893,  0.34125904, -0.65749222],
        [ 0.05407381,  0.64757787, -0.12781284, -0.20031219, -0.72198188],
        [ 0.48666426, -0.30466718, -0.27487277, -0.77079214,  0.0256951],
        [ 0.64888568,  0.23001 , -0.4859845 ,  0.49883891,  0.20253783]])
```

```python
>>> r_up
array([[ 18.49324201,  24.11691794, -44.98940746],
        [ 0. ,  31.95894662, -27.40998201],
        [ 0. ,  0. ,  9.25179414],
        [ 0. ,  0. ,  0. ],
        [ 0. ,  0. ,  0. ]])
```

The update is equivalent, but faster than the following.

```python
>>> a_up = a + np.outer(u, v)
>>> q_direct, r_direct = linalg.qr(a_up)

Check that we have equivalent results:
```n
```python
>>> np.allclose(np.dot(q_up, r_up), a_up)
True

And the updated Q is still unitary:
```n
```python
>>> np.allclose(np.dot(q_up.T, q_up), np.eye(5))
True

Updating economic (reduced, thin) decompositions is also possible:
```n
```python
>>> qe, re = linalg.qr(a, mode='economic')
>>> qe_up, re_up = linalg.qr_update(qe, re, u, v, False)
>>> qe_up
array([[ 0.54073807, 0.18645997, 0.81707661], # may vary (signs)
       [ 0.21629523, -0.63257324, 0.06567893],
       [ 0.05407381, 0.64757787, -0.12781284],
       [ 0.48666426, -0.30466718, -0.27487277],
       [ 0.64888568, 0.23001 , -0.4859845 ]])
>>> re_up
array([[ 18.49324201, 24.11691794, -44.98940746], # may vary (signs)
       [ 0. , 31.95894662, -27.40998201],
       [ 0. , 0. , -9.25451794]])
>>> np.allclose(np.dot(qe_up, re_up), a_up)
True
>>> np.allclose(np.dot(qe_up.T, qe_up), np.eye(3))
True

Similarly to the above, perform a rank 2 update.
```n
```python
>>> u2 = np.array([[ 7. , -1.],
                 [-2. ,  4.],
                 [ 4. ,  2.],
                 [ 3. , -6.],
                 [ 5. ,  3.]])
>>> v2 = np.array([[ 1. ,  2.],
                 [ 3. ,  4.],
                 [ 5. ,  2.]])
>>> q_up2, r_up2 = linalg.qr_update(q, r, u2, v2, False)
>>> q_up2
array([[-0.33626508, -0.03477253, 0.61956287, -0.64352987, -0.29618884], # may vary (signs)
       [-0.50439762, 0.58319694, -0.43010077, -0.33395279, 0.33008064],
       [-0.21016568, -0.63123106, 0.0582249 , -0.13675572, 0.73163206],
       [ 0.12609941, 0.49694436, 0.64590024, 0.31191919, 0.47187344],
       [-0.75659643, -0.11517748, 0.10284903, 0.5986227 , -0.21299983]])
>>> r_up2
array([[ 23.79075451, -41.1084062 ,  24.71548348], # may vary (signs)
       [ 0. , -33.83931057, 11.02226551],
       [...]])
```

(continues on next page)
This update is also a valid qr decomposition of \( A + U V^T \).

```python
>>> a_up2 = a + np.dot(u2, v2.T)
>>> np.allclose(a_up2, np.dot(q_up2, r_up2))
True
>>> np.allclose(np.dot(q_up2.T, q_up2), np.eye(5))
True
```

**scipy.linalg.qr_delete**

scipy.linalg.qr_delete \((Q, R, k, int p=1, which='row', overwrite_qr=False, check_finite=True)\)

QR downdate on row or column deletions

If \( A = Q R \) is the QR factorization of \( A \), return the QR factorization of \( A \) where \( p \) rows or columns have been removed starting at row or column \( k \).

**Parameters**

- \( Q \) [(M, M) or (M, N) array_like] Unitary/orthogonal matrix from QR decomposition.
- \( R \) [(M, N) or (N, N) array_like] Upper triangular matrix from QR decomposition.
- \( k \) [int] Index of the first row or column to delete.
- \( p \) [int, optional] Number of rows or columns to delete, defaults to 1.
- \( which: \{\text{'row'}, \text{'col'}\} \), optional
  - Determines if rows or columns will be deleted, defaults to 'row'
- \( overwrite_qr \) [bool, optional] If True, consume \( Q \) and \( R \), overwriting their contents with their downdated versions, and returning appropriately sized views. Defaults to False.
- \( check_finite \) [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs. Default is True.

**Returns**

- \( Q1 \) [ndarray] Updated unitary/orthogonal factor
- \( R1 \) [ndarray] Updated upper triangular factor

**See also:**

- \( qr, qr\_multiply, qr\_insert, qr\_update \)

**Notes**

This routine does not guarantee that the diagonal entries of \( R1 \) are positive.

New in version 0.16.0.

Examples

```python
>>> from scipy import linalg
>>> a = np.array([[ 3., -2., -2.],
...                [ 6., -9., -3.],
...                [-3., 10.,  1.],
...                [ 6., -7.,  4.],
...                [ 7.,  8., -6.]])
>>> q, r = linalg.qr(a)

Given this QR decomposition, update q and r when 2 rows are removed.

```python
>>> q1, r1 = linalg.qr_delete(q, r, 2, 2, 'row', False)
>>> q1
array([[ 0.30942637, 0.15347579, 0.93845645],  # may vary (signs)
        [ 0.61885275, 0.71680171, -0.32127338],
        [ 0.72199487, -0.68017681, -0.12681844]])

```python
>>> r1
array([[ 9.69535971, -0.4125685 , -6.80738023],  # may vary (signs)
        [ 0. , -12.19958144,  1.62370412],
        [ 0. ,  0. , -0.15218213]])

```python
The update is equivalent, but faster than the following.

```python
>>> a1 = np.delete(a, slice(2,4), 0)
>>> a1
array([[ 3., -2., -2.],
        [ 6., -9., -3.],
        [ 7.,  8., -6.]])
>>> q_direct, r_direct = linalg.qr(a1)

Check that we have equivalent results:

```python
>>> np.dot(q1, r1)
array([[ 3., -2., -2.],
        [ 6., -9., -3.],
        [ 7.,  8., -6.]]))
>>> np.allclose(np.dot(q1, r1), a1)
True

And the updated Q is still unitary:

```python
>>> np.allclose(np.dot(q1.T, q1), np.eye(3))
True
```
scipy.linalg.qr_insert

scipy.linalg.qr_insert (Q, R, u, k, which='row', rcond=None, overwrite_qru=False, check_finite=True)

QR update on row or column insertions

If \( A = Q R \) is the QR factorization of \( A \), return the QR factorization of \( A \) where rows or columns have been inserted starting at row or column \( k \).

**Parameters**

- **Q**
  - ([M, M] array_like) Unitary/orthogonal matrix from the QR decomposition of \( A \).
- **R**
  - ([M, N] array_like) Upper triangular matrix from the QR decomposition of \( A \).
- **u**
  - ([N,], (p, N), (M,), or (M, P) array_like) Rows or columns to insert
- **k**
  - [int] Index before which \( u \) is to be inserted.
- **which**: {'row', 'col'}, optional
  - Determines if rows or columns will be inserted, defaults to 'row'
- **rcond**
  - [float] Lower bound on the reciprocal condition number of \( Q \) augmented with \( \frac{u}{|u|} \)
  - Only used when updating economic mode (thin, (M,N) (N,N)) decompositions. If None, machine precision is used. Defaults to None.
- **overwrite_qru**
  - [bool, optional] If True, consume Q, R, and u, if possible, while performing the update, otherwise make copies as necessary. Defaults to False.
- **check_finite**
  - [bool, optional] Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs. Default is True.

**Returns**

- **Q1**
  - [ndarray] Updated unitary/orthogonal factor
- **R1**
  - [ndarray] Updated upper triangular factor

**Raises**

- **LinAlgError**
  - If updating a (M,N) (N,N) factorization and the reciprocal condition number of \( Q \) augmented with \( u/|u| \) is smaller than rcond.

**See also:**

- qr, qr_multiply, qr_delete, qr_update

**Notes**

This routine does not guarantee that the diagonal entries of \( R1 \) are positive.

New in version 0.16.0.

       [ 0.         ,  0.         , -6.13010256],
       [ 0.         ,  0.         ,  0.        ],
       [ 0.         ,  0.         ,  0.        ]])
```

The update is equivalent, but faster than the following.

```python
>>> a1 = np.insert(a, 2, u, 0)
>>> a1
array([[ 3., -2., -2.],
       [ 6., -7.,  4.],
       [ 6., -9., -3.],
       [-3., 10.,  1.],
       [ 7.,  8., -6.]])
>>> q_direct, r_direct = linalg qr(a1)
```

Check that we have equivalent results:

```python
>>> np.dot(q1, r1)
array([[ 3., -2., -2.],
       [ 6., -7.,  4.],
       [ 6., -9., -3.],
       [-3., 10.,  1.],
       [ 7.,  8., -6.]])
```

```python
>>> np.allclose(np.dot(q1, r1), a1)
True
```
And the updated Q is still unitary:

```python
>>> np.allclose(np.dot(q1.T, q1), np.eye(5))
True
```

**scipy.linalg.rq**

**scipy.linalg.rq** *(a, overwrite_a=False, lwork=None, mode='full', check_finite=True)*

Compute RQ decomposition of a matrix.

Calculate the decomposition \( A = R \cdot Q \) where Q is unitary/orthogonal and R upper triangular.

**Parameters**

- **a** ([M, N] array_like) Matrix to be decomposed
- **overwrite_a** [bool, optional] Whether data in a is overwritten (may improve performance)
- **lwork** [int, optional] Work array size, lwork >= a.shape[1]. If None or -1, an optimal size is computed.
- **mode** [{'full', 'r', 'economic'}, optional] Determines what information is to be returned: either both Q and R ('full', default), only R ('r') or both Q and R but computed in economy-size ('economic', see Notes).
- **check_finite** [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**Returns**

- **R** [float or complex ndarray] Of shape (M, N) or (M, K) for mode='economic'. K = min(M, N).
- **Q** [float or complex ndarray] Of shape (N, N) or (K, N) for mode='economic'. Not returned if mode='r'.

**Raises**

- **LinAlgError** If decomposition fails.

**Notes**

This is an interface to the LAPACK routines sgerqf, dgerqf, cgerqf, zgerqf, sorgqr, dorgrq, cungrq and zungrq. If mode=economic, the shapes of Q and R are (K, N) and (M, K) instead of (N,N) and (M,N), with K=min(M, N).

**Examples**

```python
>>> from scipy import linalg
>>> rng = np.random.default_rng()
>>> a = rng.standard_normal((6, 9))
>>> r, q = linalg.rq(a)
>>> np.allclose(a, r @ q)
True
>>> r.shape, q.shape
((6, 9), (9, 9))
```

(continues on next page)
scipy.linalg.qz

scipy.linalg.qz (A, B, output='real', lwork=None, sort=None, overwrite_a=False, overwrite_b=False, check_finite=True)

QZ decomposition for generalized eigenvalues of a pair of matrices.

The QZ, or generalized Schur, decomposition for a pair of n-by-n matrices (A,B) is:

\[
(A, B) = (Q \cdot AA \cdot Z^*, Q \cdot BB \cdot Z^*)
\]

where AA, BB is in generalized Schur form if BB is upper-triangular with non-negative diagonal and AA is upper-triangular, or for real QZ decomposition (output='real') block upper triangular with 1x1 and 2x2 blocks. In this case, the 1x1 blocks correspond to real generalized eigenvalues and 2x2 blocks are ‘standardized’ by making the corresponding elements of BB have the form:

\[
\begin{bmatrix}
a & 0 \\
0 & b
\end{bmatrix}
\]

and the pair of corresponding 2x2 blocks in AA and BB will have a complex conjugate pair of generalized eigenvalues. If (output='complex') or A and B are complex matrices, Z' denotes the conjugate-transpose of Z. Q and Z are unitary matrices.

Parameters

**A**
- [(N, N) array_like] 2-D array to decompose

**B**
- [(N, N) array_like] 2-D array to decompose

**output**
- [{'real', 'complex'}, optional] Construct the real or complex QZ decomposition for real matrices. Default is 'real'.

**lwork**
- [int, optional] Work array size. If None or -1, it is automatically computed.

**sort**
- [{None, callable, 'lhp', 'rhp', 'iuc', 'ouc'}, optional] NOTE: THIS INPUT IS DISABLED FOR NOW. Use ordqz instead.

Specifies whether the upper eigenvalues should be sorted. A callable may be passed that, given a eigenvalue, returns a boolean denoting whether the eigenvalue should be sorted to the top-left (True). For real matrix pairs, the sort function takes three real arguments (alphar, alphai, beta). The eigenvalue \(x = (\text{alphar} + \text{alphai} \cdot 1j)/\beta\). For complex matrix pairs or output='complex', the sort function takes two complex arguments (alpha, beta). The eigenvalue \(x = (alpha/beta)\). Alternatively, string parameters may be used:

- 'lhp' Left-hand plane \((x.\text{real} < 0.0)\)
- 'rhp' Right-hand plane \((x.\text{real} > 0.0)\)
- 'iuc' Inside the unit circle \((x*x.\text{conjugate()} < 1.0)\)
- 'ouc' Outside the unit circle \((x*x.\text{conjugate()} > 1.0)\)

Defaults to None (no sorting).

**overwrite_a**
- [bool, optional] Whether to overwrite data in a (may improve performance)

**overwrite_b**
- [bool, optional] Whether to overwrite data in b (may improve performance)
check_finite

[bool, optional] If true checks the elements of A and B are finite numbers. If false does no checking and passes matrix through to underlying algorithm.

Returns

AA [(N, N) ndarray] Generalized Schur form of A.
BB [(N, N) ndarray] Generalized Schur form of B.
Q [(N, N) ndarray] The left Schur vectors.
Z [(N, N) ndarray] The right Schur vectors.

See also:

ordqz

Notes

Q is transposed versus the equivalent function in Matlab.
New in version 0.11.0.

Examples

```python
>>> from scipy import linalg
>>> rng = np.random.default_rng()
>>> A = np.arange(9).reshape((3, 3))
>>> B = rng.standard_normal((3, 3))
>>> AA, BB, Q, Z = linalg.qz(A, B)
>>> AA

       [  0.00000000e+00,   0.00000000e+00,   1.76304656]])
>>> Q
array([[  0.10356118,   0.90697763,  -0.40824829],
       [  0.48575095,   0.31205664,   0.81649658],
       [  0.86794072,  -0.28286434,  -0.40824829]])
>>> Z
array([[  0.78900531,   0.16010775,  -0.59315776],
       [-0.21754047,  -0.83009894,  -0.51343148],
       [  0.57458399,  -0.53413598,   0.62012256]])
```
scipy.linalg.ordqz

**scipy.linalg.ordqz** (A, B, sort=’lhp’, output=’real’, overwrite_a=False, overwrite_b=False, check_finite=True)

QZ decomposition for a pair of matrices with reordering.

**Parameters**

- **A** [(N, N) array_like] 2-D array to decompose
- **B** [(N, N) array_like] 2-D array to decompose
- **sort** [{callable, ‘lhp’, ‘rhp’, ‘iuc’, ‘ouc’}, optional] Specifies whether the upper eigenvalues should be sorted. A callable may be passed that, given an ordered pair (alpha, beta) representing the eigenvalue \( x = \frac{\alpha}{\beta} \), returns a boolean denoting whether the eigenvalue should be sorted to the top-left (True). For the real matrix pairs beta is real while alpha can be complex, and for complex matrix pairs both alpha and beta can be complex. The callable must be able to accept a NumPy array. Alternatively, string parameters may be used:
  - ‘lhp’ Left-hand plane (x.real < 0.0)
  - ‘rhp’ Right-hand plane (x.real > 0.0)
  - ‘iuc’ Inside the unit circle (x*x.conjugate() < 1.0)
  - ‘ouc’ Outside the unit circle (x*x.conjugate() > 1.0)

With the predefined sorting functions, an infinite eigenvalue (i.e., alpha != 0 and beta = 0) is considered to lie in neither the left-hand nor the right-hand plane, but it is considered to lie outside the unit circle. For the eigenvalue (alpha, beta) = (0, 0), the predefined sorting functions all return False.

- **output** [str {‘real’,’complex’}, optional] Construct the real or complex QZ decomposition for real matrices. Default is ‘real’.

- **overwrite_a** [bool, optional] If True, the contents of A are overwritten.

- **overwrite_b** [bool, optional] If True, the contents of B are overwritten.

- **check_finite** [bool, optional] If true checks the elements of A and B are finite numbers. If false does no checking and passes matrix through to underlying algorithm.

**Returns**

- **AA** [(N, N) ndarray] Generalized Schur form of A.
- **BB** [(N, N) ndarray] Generalized Schur form of B.
- **alpha** [(N,) ndarray] alpha = alphar + alphai * 1j. See notes.
- **beta** [(N,) ndarray] See notes.
- **Q** [(N, N) ndarray] The left Schur vectors.
- **Z** [(N, N) ndarray] The right Schur vectors.

**See also:**

qz
Notes

On exit, \((\text{ALPHAR}(j) + \text{ALPHAI}(j)\cdot i)/\text{BETA}(j), j=1,\ldots,N\), will be the generalized eigenvalues. \(\text{ALPHAR}(j) + \text{ALPHAI}(j)\cdot i\) and \(\text{BETA}(j), j=1,\ldots,N\) are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A,B) were further reduced to triangular form using complex unitary transformations. If ALPHAI(j) is zero, then the jth eigenvalue is real; if positive, then the jth and (j+1)st eigenvalues are a complex conjugate pair, with \(\text{ALPHAI}(j+1)\) negative.

New in version 0.17.0.

Examples

```python
>>> from scipy.linalg import ordqz
>>> A = np.array([[2, 5, 8, 7], [5, 2, 2, 8], [7, 5, 6, 6], [5, 4, 4, 8]])
>>> B = np.array([[0, 6, 0, 0], [5, 0, 2, 1], [5, 2, 6, 6], [4, 7, 7, 7]])
>>> AA, BB, alpha, beta, Q, Z = ordqz(A, B, sort='lhp')
```

Since we have sorted for left half plane eigenvalues, negatives come first

```python
>>> (alpha/beta).real < 0
array([ True, True, False, False], dtype=bool)
```

SciPy.linalg.schur

SciPy.linalg.schur(a, output='real', lwork=None, overwrite_a=False, sort=None, check_finite=True)

Compute Schur decomposition of a matrix.

The Schur decomposition is:

\[
A = Z T Z^\mathsf{H}
\]

where \(Z\) is unitary and \(T\) is either upper-triangular, or for real Schur decomposition (output='real'), quasi-upper triangular. In the quasi-triangular form, 2x2 blocks describing complex-valued eigenvalue pairs may extrude from the diagonal.

Parameters

- **a** [(M, M) array_like] Matrix to decompose
- **output** [{‘real’, ‘complex’}, optional] Construct the real or complex Schur decomposition (for real matrices).
- **lwork** [int, optional] Work array size. If None or -1, it is automatically computed.
- **overwrite_a** [bool, optional] Whether to overwrite data in a (may improve performance).
- **sort** [{None, callable, ‘lhp’, ‘rhp’, ‘iuc’, ‘ouc’}, optional] Specifies whether the upper eigenvalues should be sorted. A callable may be passed that, given an eigenvalue, returns a boolean denoting whether the eigenvalue should be sorted to the top-left (True). Alternatively, string parameters may be used:

  - ‘lhp’ Left-hand plane \((x.\text{real} < 0.0)\)
  - ‘rhp’ Right-hand plane \((x.\text{real} > 0.0)\)
  - ‘iuc’ Inside the unit circle \((x^*x.\text{conjugate()} <= 1.0)\)
  - ‘ouc’ Outside the unit circle \((x^*x.\text{conjugate()} > 1.0)\)

Defaults to None (no sorting).
check_finite

[bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

Returns

\( T \) [(M, M) ndarray] Schur form of A. It is real-valued for the real Schur decomposition.

\( Z \) [(M, M) ndarray] An unitary Schur transformation matrix for A. It is real-valued for the real Schur decomposition.

\( sdim \) [int] If and only if sorting was requested, a third return value will contain the number of eigenvalues satisfying the sort condition.

Raises

LinAlgError

Error raised under three conditions:
1. The algorithm failed due to a failure of the QR algorithm to compute all eigenvalues.
2. If eigenvalue sorting was requested, the eigenvalues could not be reordered due to a failure to separate eigenvalues, usually because of poor conditioning.
3. If eigenvalue sorting was requested, roundoff errors caused the leading eigenvalues to no longer satisfy the sorting condition.

See also:

rsf2csf

Convert real Schur form to complex Schur form

Examples

```python
>>> from scipy.linalg import schur, eigvals
>>> A = np.array([[0, 2, 2], [0, 1, 2], [1, 0, 1]])
>>> T, Z = schur(A)
>>> T
array([[ 2.65896708, 1.42440458, -1.92933439],
       [ 0. , -0.32948354, -0.49063704],
       [ 0. , 1.31178921, -0.32948354]])
>>> Z
array([[0.72711591, -0.60156188, 0.33079564],
       [0.52839428, 0.79801892, 0.28976765],
       [0.43829436, 0.03590414, -0.89811411]])
```

```python
>>> T2, Z2 = schur(A, output='complex')
>>> T2
array([[ 2.65896708, -1.22839825+1.32378589j, 0.42590089+1.51937378j],
       [ 0. , -0.32948354+0.80225456j, -0.59877807+0.56192146j],
       [ 0. , 0. , -0.32948354-0.80225456j]])
>>> eigvals(T2)
array([2.65896708, -0.32948354+0.80225456j, -0.32948354-0.80225456j])
```

An arbitrary custom eig-sorting condition, having positive imaginary part, which is satisfied by only one eigenvalue

```
>>> T3, Z3, sdim = schur(A, output='complex', sort=lambda x: x.imag > 0)
>>> sdim
1
```

**scipy.linalg.rsfs2csf**

`scipy.linalg.rsfs2csf(T, Z, check_finite=True)`

Convert real Schur form to complex Schur form.

Convert a quasi-diagonal real-valued Schur form to the upper-triangular complex-valued Schur form.

**Parameters**

- `T`: [(M, M) array_like] Real Schur form of the original array
- `Z`: [(M, M) array_like] Schur transformation matrix
- `check_finite`: [bool, optional] Whether to check that the input arrays contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**Returns**

- `T`: [(M, M) ndarray] Complex Schur form of the original array
- `Z`: [(M, M) ndarray] Schur transformation matrix corresponding to the complex form

**Examples**

```python
>>> from scipy.linalg import schur, rsfs2csf
>>> A = np.array([[0, 2, 2], [0, 1, 2], [1, 0, 1]])
>>> T, Z = schur(A)
>>> T
array([[ 2.65896708,  1.42440458, -1.92933439],
       [ 0.          , -0.32948354, -0.49063704],
       [ 0.          ,  1.31178921, -0.32948354]])
>>> Z
array([[ 0.72711591,  0.28220393,  0.51319638],
       [ 0.52839428,  0.24720268, -0.68795175],
       [ 0.43829436,  0.03590414, -0.03063006]])
>>> T2, Z2 = rsfs2csf(T, Z)
>>> T2
array([[2.65896708+0.j, -1.64592781+0.74316418j, -1.21516887+1.00660462j],
       [0.+0.j, -0.32948354+8.02254558e-01j, -0.82115218-2.77555756e-17j],
       [0.+0.j, 0.+0.j, -0.32948354-0.802254558j]])
>>> Z2
array([[0.72711591+0.j, 0.28220393-0.31385693j, 0.51319638-0.17258824j],
       [0.52839428+0.j, 0.24720268+0.41635578j, -0.68795175-0.15118243j],
       [0.43829436+0.j, -0.76618703+0.01873251j, -0.03063006+0.46857912j]])
```

(continues on next page)
scipy.linalg.hessenberg

The Hessenberg decomposition is:

\[ A = Q H Q^H \]

where \( Q \) is unitary/orthogonal and \( H \) has only zero elements below the first sub-diagonal.

### Parameters

- **a** : [(M, M) array_like] Matrix to bring into Hessenberg form.
- **calc_q** : [bool, optional] Whether to compute the transformation matrix. Default is False.
- **overwrite_a** : [bool, optional] Whether to overwrite \( a \); may improve performance. Default is False.
- **check_finite** : [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

### Returns

- **H** : [(M, M) ndarray] Hessenberg form of \( a \).
- **Q** : [(M, M) ndarray] Unitary/orthogonal similarity transformation matrix \( A = Q H Q^H \). Only returned if calc_q=True.

### Examples

```python
>>> from scipy.linalg import hessenberg
>>> A = np.array([[2, 5, 8, 7], [5, 2, 2, 8], [7, 5, 6, 6], [5, 4, 4, 8]])
>>> H, Q = hessenberg(A, calc_q=True)
>>> H
array([[ 2.00000000e+00, -1.16584387e+01,  1.42005301e+00,  2.53490660e+00],
       [-9.94987437e+00,  1.45353535e+01, -5.31022304e+00,  2.43081618e+00],
       [ 0.00000000e+00, -1.83299243e+00,  3.89699617e-01, -5.15270341e-01],
       [ 0.00000000e+00,  0.00000000e+00, -3.83189513e+00,  1.07494686e+00]])
```

```python
>>> np.allclose(Q @ H @ Q.conj().T - A, np.zeros((4, 4)))
True
```

scipy.linalg.cdf2rdf

Converts complex eigenvalues \( w \) and eigenvectors \( v \) to real eigenvalues in a block diagonal form \( w_r \) and the associated real eigenvectors \( v_r \), such that:

\[ v_r @ w_r = X @ v_r \]

continues to hold, where \( X \) is the original array for which \( w \) and \( v \) are the eigenvalues and eigenvectors.

New in version 1.1.0.

### Parameters

w

[(…, M) array_like] Complex or real eigenvalues, an array or stack of arrays. Conjugate pairs must not be interleaved, else the wrong result will be produced. So [1+1j, 1, 1-1j] will give a correct result, but [1+1j, 2+1j, 1-1j, 2-1j] will not.

v

[(…, M) array_like] Complex or real eigenvectors, a square array or stack of square arrays.

Returns

wr

[(…, M, M) ndarray] Real diagonal block form of eigenvalues

vr

[(…, M, M) ndarray] Real eigenvectors associated with wr

See also:

eig

Eigenvalues and right eigenvectors for non-symmetric arrays

rsf2csf

Convert real Schur form to complex Schur form

Notes

w, v must be the eigenstructure for some real matrix X. For example, obtained by w, v = scipy.linalg.eig(X) or w, v = numpy.linalg.eig(X) in which case X can also represent stacked arrays.

New in version 1.1.0.

Examples

```python
>>> X = np.array([[1, 2, 3], [0, 4, 5], [0, -5, 4]])
>>> X
array([[ 1.,  2.,  3.],
       [ 0.,  4.,  5.],
       [ 0., -5.,  4.]])
```

```python
>>> from scipy import linalg
>>> w, v = linalg.eig(X)
>>> w
array([[ 1.+0.j,  4.+5.j,  4.-5.j]])
>>> v
array([[ 1.00000+0.j , -0.01906-0.40016j, -0.01906+0.40016j],
        [ 0.00000+0.j ,  0.00000-0.64788j,  0.00000+0.64788j],
        [ 0.00000+0.j ,  0.64788+0.j ,  0.64788-0.j ]])
```

```python
>>> wr, vr = linalg.cdf2rdf(w, v)
>>> wr
array([[ 1.,  0.,  0.],
       [ 0.,  4.,  5.],
       [ 0., -5.,  4.]])
>>> vr
array([[ 1. ,  0.40016, -0.01906],
        [ 0. ,  0.64788,  0.  ],
        [ 0. ,  0. ,  0.64788]])
```
scipy.linalg.cossin

`scipy.linalg.cossin(X, p=None, q=None, separate=False, swap_sign=False, compute_u=True, compute_vh=True)`

Compute the cosine-sine (CS) decomposition of an orthogonal/unitary matrix.

X is an \((m, m)\) orthogonal/unitary matrix, partitioned as the following where upper left block has the shape of \((p, q)\):

\[
\begin{bmatrix}
X_{11} & X_{12} \\
X_{21} & X_{22}
\end{bmatrix} =
\begin{bmatrix}
U_{11} & U_{12} \\
U_{21} & U_{22}
\end{bmatrix} \begin{bmatrix}
I & 0 & 0 & 0 \\
0 & C & 0 & -S \\
0 & 0 & 0 & -I \\
0 & S & 0 & C
\end{bmatrix} \begin{bmatrix}
V_{11} & V_{12} \\
V_{21} & V_{22}
\end{bmatrix}
\]

\(U_1, U_2, V_1, V_2\) are square orthogonal/unitary matrices of dimensions \((p, p)\), \((m-p, m-p)\), \((q, q)\), and \((m-q, m-q)\) respectively, and \(C\) and \(S\) are \((r, r)\) nonnegative diagonal matrices satisfying \(C^2 + S^2 = I\) where \(r = \min(p, m-p, q, m-q)\).

Moreover, the rank of the identity matrices are \(\min(p, q) - r, \min(p, m-q) - r, \min(m-p, q) - r, \) and \(\min(m-p, m-q) - r\) respectively.

X can be supplied either by itself and block specifications \(p, q\) or its subblocks in an iterable from which the shapes would be derived. See the examples below.

**Parameters**

- **X** [array_like, iterable] complex unitary or real orthogonal matrix to be decomposed, or iterable of subblocks \(X_{11}, X_{12}, X_{21}, X_{22}\), when \(p, q\) are omitted.
- **p** [int, optional] Number of rows of the upper left block \(X_{11}\), used only when \(X\) is given as an array.
- **q** [int, optional] Number of columns of the upper left block \(X_{11}\), used only when \(X\) is given as an array.
- **separate** [bool, optional] if True, the low level components are returned instead of the matrix factors, i.e. \((u_1, u_2), \theta, (v_{1h}, v_{2h})\) instead of \(u, cs, vh\).
- **swap_sign** [bool, optional] if True, the \(-S, -I\) block will be the bottom left, otherwise (by default) they will be in the upper right block.
- **compute_u** [bool, optional] if False, \(u\) won’t be computed and an empty array is returned.
- **compute_vh** [bool, optional] if False, \(vh\) won’t be computed and an empty array is returned.

**Returns**

\[ \text{.ndarray} \] When `compute_u=True`, contains the block diagonal orthogonal/unitary matrix consisting of the blocks \( U_1 (p \times p) \) and \( U_2 (m-p \times m-p) \) orthogonal/unitary matrices. If `separate=True`, this contains the tuple of \( (U_1, U_2) \).

\[ \text{.ndarray} \] The cosine-sine factor with the structure described above. If `separate=True`, this contains the theta array containing the angles in radians.

\[ \text{.ndarray} \] When `compute_vh=True`, contains the block diagonal orthogonal/unitary matrix consisting of the blocks \( V_1H (q \times q) \) and \( V_2H (m-q \times m-q) \) orthogonal/unitary matrices. If `separate=True`, this contains the tuple of \( (V_1H, V_2H) \).

References

[1]

Examples

```python
>>> from scipy.linalg import cossin
>>> from scipy.stats import unitary_group
>>> x = unitary_group.rvs(4)
>>> u, cs, vdh = cossin(x, p=2, q=2)
>>> np.allclose(x, u @ cs @ vdh)
True
```

Same can be entered via subblocks without the need of \( p \) and \( q \). Also let’s skip the computation of \( u \)

```python
>>> ue, cs, vdh = cossin((x[:2, :2], x[2:, 2:]), x[2:, 2:], x[2:, 2:], x[2:, 2:]), ...
    compute_u=False)
>>> print(ue)
[]
>>> np.allclose(x, u @ cs @ vdh)
True
```

```python
scipy.linalg.expm
```

**scipy.linalg.expm**

Compute the matrix exponential using Pade approximation.

**Parameters**

- \(A\) 
  - [(N, N) array_like or sparse matrix] Matrix to be exponentiated.

**Returns**

- \(expm\) 
  - [(N, N) ndarray] Matrix exponential of \(A\).

**References**

[1]

**Examples**

```python
>>> from scipy.linalg import expm, sinm, cosm
```

Matrix version of the formula \(\exp(0) = 1\):

```python
>>> expm(np.zeros((2,2)))
array([[ 1., 0.],
       [ 0., 1.]])
```

Euler’s identity \((\exp(i\theta) = \cos(\theta) + i\sin(\theta))\) applied to a matrix:

```python
>>> a = np.array([[1.0, 2.0], [-1.0, 3.0]])
>>> expm(1j*a)
array([[ 0.42645930+1.89217551j, -2.13721484-0.97811252j],
       [ 1.06860742+0.48905626j, -1.71075555+0.91406299j]])
>>> cosm(a) + 1j*sinm(a)
array([[ 0.42645930+1.89217551j, -2.13721484-0.97811252j],
       [ 1.06860742+0.48905626j, -1.71075555+0.91406299j]])
```
**scipy.linalg.logm**

`scipy.linalg.logm(A, disp=True)`

Compute matrix logarithm.

The matrix logarithm is the inverse of expm: \( \expm(\logm(A)) = A \)

**Parameters**

- **A** [(N, N) array_like] Matrix whose logarithm to evaluate
- **disp** [bool, optional] Print warning if error in the result is estimated large instead of returning estimated error. (Default: True)

**Returns**

- **logm** [(N, N) ndarray] Matrix logarithm of \( A \)
- **errest** [float] (if disp == False) 1-norm of the estimated error, \( ||\text{err}||_1 / ||A||_1 \)

**References**

[1], [2], [3]

**Examples**

```python
d>>> from scipy.linalg import logm, expm
d>>> a = np.array([[1.0, 3.0], [1.0, 4.0]])
d>>> b = logm(a)
d>>> b
array([[-1.02571087, 2.05142174],
       [0.68380725, 1.02571087]])
d>>> expm(b)  # Verify expm(logm(a)) returns a
array([[ 1.,  3.],
       [ 1.,  4.]])
```

**scipy.linalg.cosm**

`scipy.linalg.cosm(A)`

Compute the matrix cosine.

This routine uses expm to compute the matrix exponentials.

**Parameters**

- **A** [(N, N) array_like] Input array

**Returns**

- **cosm** [(N, N) ndarray] Matrix cosine of \( A \)
Examples

```python
>>> from scipy.linalg import expm, sinm, cosm
```

Euler's identity (exp(i*theta) = cos(theta) + i*sin(theta)) applied to a matrix:

```python
>>> a = np.array([[1.0, 2.0], [-1.0, 3.0]])
>>> expm(1j*a)
array([[ 0.42645930+1.89217551j, -2.13721484-0.97811252j],
       [ 1.06860742+0.48905626j, -1.71075555+0.91406299j]])
>>> cosm(a) + 1j*sinm(a)
array([[ 0.42645930+1.89217551j, -2.13721484-0.97811252j],
       [ 1.06860742+0.48905626j, -1.71075555+0.91406299j]])
```

**scipy.linalg.sinm**

```python
scipy.linalg.sinm(A)
```

Compute the matrix sine.

This routine uses expm to compute the matrix exponentials.

**Parameters**

- `A` : (N, N) array_like
  - Input array.

**Returns**

- `sinm` : (N, N) ndarray
  - Matrix sine of A

**Examples**

```python
>>> from scipy.linalg import expm, sinm, cosm
```

Euler's identity (exp(i*theta) = cos(theta) + i*sin(theta)) applied to a matrix:

```python
>>> a = np.array([[1.0, 2.0], [-1.0, 3.0]])
>>> expm(1j*a)
array([[ 0.42645930+1.89217551j, -2.13721484-0.97811252j],
       [ 1.06860742+0.48905626j, -1.71075555+0.91406299j]])
>>> cosm(a) + 1j*sinm(a)
array([[ 0.42645930+1.89217551j, -2.13721484-0.97811252j],
       [ 1.06860742+0.48905626j, -1.71075555+0.91406299j]])
```

**scipy.linalg.tanm**

```python
scipy.linalg.tanm(A)
```

Compute the matrix tangent.

This routine uses expm to compute the matrix exponentials.

**Parameters**

- `A` : (N, N) array_like
  - Input array.

**Returns**

- `tanm` : (N, N) ndarray
  - Matrix tangent of A
**Examples**

```python
>>> from scipy.linalg import tanm, sinm, cosm
>>> a = np.array([[1.0, 3.0], [1.0, 4.0]])
>>> t = tanm(a)
>>> t
array([[-2.00876993, -8.41880636],
       [-2.80626879, -10.42757629]])
```

Verify `tanm(a) = sinm(a).dot(inv(cosm(a)))`

```python
>>> s = sinm(a)
>>> c = cosm(a)
>>> s.dot(np.linalg.inv(c))
array([[-2.00876993, -8.41880636],
       [-2.80626879, -10.42757629]])
```

**scipy.linalg.coshm**

`scipy.linalg.coshm(A)`

Compute the hyperbolic matrix cosine.

This routine uses `expm` to compute the matrix exponentials.

**Parameters**

- `A` : [(N, N) array_like] Input array.

**Returns**

- `coshm` : [(N, N) ndarray] Hyperbolic matrix cosine of `A`

**Examples**

```python
>>> from scipy.linalg import tanhm, sinhm, coshm
>>> a = np.array([[1.0, 3.0], [1.0, 4.0]])
>>> c = coshm(a)
>>> c
array([[ 11.24592233, 38.76236492],
       [12.92078831, 50.00828725]])
```

Verify `tanhm(a) = sinhm(a).dot(inv(coshm(a)))`

```python
>>> t = tanhm(a)
>>> s = sinhm(a)
>>> t - s.dot(np.linalg.inv(c))
array([[ 2.72004641e-15,  4.55191440e-15],
       [0.00000000e+00, -5.55111512e-16]])
```
scipy.linalg.sinhm

**scipy.linalg.sinhm(A)**

Compute the hyperbolic matrix sine.

This routine uses expm to compute the matrix exponentials.

**Parameters**

- **A** : *(N, N) array_like* Input array.

**Returns**

- **sinhm** : *(N, N) ndarray* Hyperbolic matrix sine of A

**Examples**

```python
>>> from scipy.linalg import tanhm, sinhm, coshm
>>> a = np.array([[1.0, 3.0], [1.0, 4.0]])
>>> s = sinhm(a)
>>> s
array([[ 10.57300653,  39.28826594],
       [ 13.09608865,  49.86127247]])
```

Verify \( \text{tanhm}(a) = \text{sinhm}(a).dot(\text{inv}(\text{coshm}(a))) \)

```python
>>> t = tanhm(a)
>>> c = coshm(a)
>>> t - s.dot(np.linalg.inv(c))
array([[ 2.72004641e-15,  4.55191440e-15],
       [ 0.00000000e+00, -5.55111512e-16]])
```

scipy.linalg.tanhm

**scipy.linalg.tanhm(A)**

Compute the hyperbolic matrix tangent.

This routine uses expm to compute the matrix exponentials.

**Parameters**

- **A** : *(N, N) array_like* Input array

**Returns**

- **tanhm** : *(N, N) ndarray* Hyperbolic matrix tangent of A

**Examples**

```python
>>> from scipy.linalg import tanhm, sinhm, coshm
>>> a = np.array([[1.0, 3.0], [1.0, 4.0]])
>>> t = tanhm(a)
>>> t
array([[ 0.3428582 ,  0.51987926],
       [ 0.17329309,  0.86273746]])
```

Verify \( \text{tanhm}(a) = \text{sinhm}(a).dot(\text{inv}(\text{coshm}(a))) \)
```python
>>> s = sinhm(a)
>>> c = coshm(a)
>>> t = s.dot(np.linalg.inv(c))
array([[ 2.72004641e-15, 4.55191440e-15],
       [ 0.00000000e+00, -5.55111512e-16]])
```

**scipy.linalg.signm**

`scipy.linalg.signm(A, disp=True)`

Matrix sign function.

Extension of the scalar `sign(x)` to matrices.

**Parameters**

- `A` [(N, N) array_like] Matrix at which to evaluate the sign function
- `disp` [bool, optional] Print warning if error in the result is estimated large instead of returning estimated error. (Default: True)

**Returns**

- `signm` [(N, N) ndarray] Value of the sign function at A
- `errest` [float] (if `disp` == False)
  
  1-norm of the estimated error, \(||err\|_1 / ||A||_1\)

**Examples**

```python
>>> from scipy.linalg import signm, eigvals
>>> a = [[1,2,3], [1,2,1], [1,1,1]]
>>> eigvals(a)
array([ 4.12488542+0.j, -0.76155718+0.j, 0.63667176+0.j])
>>> eigvals(signm(a))
array([ -1.+0.j,  1.+0.j,  1.+0.j])
```

**scipy.linalg.sqrtm**

`scipy.linalg.sqrtm(A, disp=True, blocksize=64)`

Matrix square root.

**Parameters**

- `A` [(N, N) array_like] Matrix whose square root to evaluate
- `disp` [bool, optional] Print warning if error in the result is estimated large instead of returning estimated error. (Default: True)
- `blocksize` [integer, optional] If the blocksize is not degenerate with respect to the size of the input array, then use a blocked algorithm. (Default: 64)

**Returns**

- `sqrtm` [(N, N) ndarray] Value of the sqrt function at A
- `errest` [float] (if `disp` == False)
  
  Frobenius norm of the estimated error, \(||err||_F / ||A||_F\)
References

[1]

Examples

```python
>>> from scipy.linalg import sqrtm
>>> a = np.array([[1.0, 3.0], [1.0, 4.0]])
>>> r = sqrtm(a)
>>> r
array([[ 0.75592895,  1.13389342],
       [ 0.37796447,  1.88982237]])
>>> r.dot(r)
array([[ 1.,  3.],
       [ 1.,  4.]])
```

**scipy.linalg.funm**

`scipy.linalg.funm(A, func, disp=True)`

Evaluate a matrix function specified by a callable.

Returns the value of matrix-valued function \( \mathcal{F} \) at \( A \). The function \( \mathcal{F} \) is an extension of the scalar-valued function \( \mathcal{f} \) to matrices.

**Parameters**

- **A** [(N, N) array_like] Matrix at which to evaluate the function
- **func** [callable] Callable object that evaluates a scalar function \( \mathcal{f} \). Must be vectorized (e.g. using `vectorize`).
- **disp** [bool, optional] Print warning if error in the result is estimated large instead of returning estimated error. (Default: True)

**Returns**

- **funm** [(N, N) ndarray] Value of the matrix function specified by \( \mathcal{f} \) evaluated at \( A \)
- **errest** [float] (if \( \text{disp} = \text{False} \))
  1-norm of the estimated error, \( ||\text{err}||_1 / ||A||_1 \)

**Notes**

This function implements the general algorithm based on Schur decomposition (Algorithm 9.1.1. in [1]).

If the input matrix is known to be diagonalizable, then relying on the eigendecomposition is likely to be faster. For example, if your matrix is Hermitian, you can do

```python
>>> from scipy.linalg import eigh
>>> def funm_herm(a, func, check_finite=False):
...     w, v = eigh(a, check_finite=check_finite)
...     ## if you further know that your matrix is positive semidefinite,
...     ## you can optionally guard against precision errors by doing
...     # w = np.maximum(w, 0)
...     w = func(w)
...     return (v * w).dot(v.conj().T)
```
References

[1]

Examples

```python
>>> from scipy.linalg import funm
>>> a = np.array([[1.0, 3.0], [1.0, 4.0]])
>>> funm(a, lambda x: x*x)
array([[ 4., 15.],
    [ 5., 19.]]
>>> a.dot(a)
array([[ 4., 15.],
    [ 5., 19.]]
```

`scipy.linalg.expm_frechet`

`scipy.linalg.expm_frechet (A, E, method=None, compute_expm=True, check_finite=True)`

Frechet derivative of the matrix exponential of `A` in the direction `E`.

**Parameters**

- `A` : [(N, N) array_like] Matrix of which to take the matrix exponential.
- `E` : [(N, N) array_like] Matrix direction in which to take the Frechet derivative.
- `method` : [str, optional] Choice of algorithm. Should be one of
  - `SPS` (default)
  - `blockEnlarge`
- `compute_expm` : [bool, optional] Whether to compute also `expm_A` in addition to `expm_frechet_AE`. Default is True.
- `check_finite` : [bool, optional] Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**Returns**

For `compute_expm = False`, only `expm_frechet_AE` is returned.

See also:

- `expm`
  
  Compute the exponential of a matrix.
Notes

This section describes the available implementations that can be selected by the `method` parameter. The default method is `SPS`.

Method `blockEnlarge` is a naive algorithm.

Method `SPS` is Scaling-Pade-Squaring [1]. It is a sophisticated implementation which should take only about 3/8 as much time as the naive implementation. The asymptotics are the same.

New in version 0.13.0.

References

[1]

Examples

```python
>>> import scipy.linalg
>>> rng = np.random.default_rng()
>>> A = rng.standard_normal((3, 3))
>>> E = rng.standard_normal((3, 3))
>>> expm_A, expm_frechet_AE = scipy.linalg.expm_frechet(A, E)
>>> expm_A.shape, expm_frechet_AE.shape
((3, 3), (3, 3))
```

```python
>>> import scipy.linalg
>>> rng = np.random.default_rng()
>>> A = rng.standard_normal((3, 3))
>>> E = rng.standard_normal((3, 3))
>>> expm_A, expm_frechet_AE = scipy.linalg.expm_frechet(A, E)
>>> M = np.zeros((6, 6))
>>> M[:3, :3] = A; M[:3, 3:] = E; M[3:, :3] = A
>>> expm_M = scipy.linalg.expm(M)
>>> np.allclose(expm_A, expm_M[:3, :3])
True
>>> np.allclose(expm_frechet_AE, expm_M[:3, 3:])
True
```

`scipy.linalg.expm_cond`

`scipy.linalg.expm_cond` *(A, check_finite=True)*

Relative condition number of the matrix exponential in the Frobenius norm.

**Parameters**

- **A** *(2-D array_like)* Square input matrix with shape (N, N).
- **check_finite** *(bool, optional)* Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

**Returns**

- **kappa** *(float)* The relative condition number of the matrix exponential in the Frobenius norm.
See also:

**expm**

Compute the exponential of a matrix.

**expm_frechet**

Compute the Frechet derivative of the matrix exponential.

**Notes**

A faster estimate for the condition number in the 1-norm has been published but is not yet implemented in SciPy. New in version 0.14.0.

**Examples**

```python
>>> from scipy.linalg import expm_cond
>>> A = np.array([[-0.3, 0.2, 0.6], [0.6, 0.3, -0.1], [-0.7, 1.2, 0.9]])
>>> k = expm_cond(A)
>>> k
1.7787805864469866
```

**scipy.linalg.fractional_matrix_power**

`scipy.linalg.fractional_matrix_power(A, t)`

Compute the fractional power of a matrix.

Proceeds according to the discussion in section (6) of [1].

**Parameters**

- **A** : [(N, N) array_like] Matrix whose fractional power to evaluate.
- **t** : [float] Fractional power.

**Returns**

- **X** : [(N, N) array_like] The fractional power of the matrix.

**References**

[1]

**Examples**

```python
>>> from scipy.linalg import fractional_matrix_power
>>> a = np.array([[1.0, 3.0], [1.0, 4.0]])
>>> b = fractional_matrix_power(a, 0.5)
>>> b
array([[ 0.75592895, 1.13389342],
       [ 0.37796447, 1.88982237]])
>>> np.dot(b, b)  # Verify square root
array([[ 1., 3.],
       [ 1., 4.]])
```
Matrix Equation Solvers

- `solve_sylvester(a, b, q)`: Computes a solution (X) to the Sylvester equation $AX + XB = Q$.
- `solve_continuous_are(a, b, q, r[, e, s,...])`: Solves the continuous-time algebraic Riccati equation (CARE).
- `solve_discrete_are(a, b, q, r[, e, s, balanced])`: Solves the discrete-time algebraic Riccati equation (DARE).
- `solve_continuous_lyapunov(a, q)`: Solves the continuous Lyapunov equation $AX + XA^H = Q$.
- `solve_discrete_lyapunov(a, q[, method])`: Solves the discrete Lyapunov equation $AXA^H - X + Q = 0$.

**scipy.linalg.solve_sylvester**

`scipy.linalg.solve_sylvester(a, b, q)`

Computes a solution (X) to the Sylvester equation $AX + XB = Q$.

**Parameters**

- `a` - [(M, M) array_like] Leading matrix of the Sylvester equation
- `b` - [(N, N) array_like] Trailing matrix of the Sylvester equation
- `q` - [(M, N) array_like] Right-hand side

**Returns**

- `x` - [(M, N) ndarray] The solution to the Sylvester equation.

**Raises**

- `LinAlgError` If solution was not found

**Notes**

Computes a solution to the Sylvester matrix equation via the Bartels-Stewart algorithm. The A and B matrices first undergo Schur decompositions. The resulting matrices are used to construct an alternative Sylvester equation $(RY + YS^T = F)$ where the R and S matrices are in quasi-triangular form (or, when R, S or F are complex, triangular form). The simplified equation is then solved using `*TRSYL` from LAPACK directly.

New in version 0.11.0.

**Examples**

Given $a$, $b$, and $q$ solve for $x$:

```python
>>> from scipy import linalg
>>> a = np.array([[-3, -2, 0], [-1, -1, 3], [3, -5, -1]])
>>> b = np.array([[1]])
>>> q = np.array([[1],[2],[3]])
>>> x = linalg.solve_sylvester(a, b, q)
>>> x
array([[ 0.0625],
        [-0.5625],
        [ 0.6875]])
```

(continues on next page)
```python
>>> np.allclose(a.dot(x) + x.dot(b), q)
True
```

**scipy.linalg.solve_continuous_are**

scipy.linalg.solve_continuous_are(a, b, q, r, e=None, s=None, balanced=True)

Solves the continuous-time algebraic Riccati equation (CARE).

The CARE is defined as

\[ AXA^H - A^HXBR^{-1}B^HX + Q = 0 \]

The limitations for a solution to exist are:

- All eigenvalues of \( A \) on the right half plane, should be controllable.
- The associated hamiltonian pencil (See Notes), should have eigenvalues sufficiently away from the imaginary axis.

Moreover, if \( e \) or \( s \) is not precisely None, then the generalized version of CARE

\[ E^HXA + A^HXE - (E^HXB + S)R^{-1}(B^HXE + S^H) + Q = 0 \]

is solved. When omitted, \( e \) is assumed to be the identity and \( s \) is assumed to be the zero matrix with sizes compatible with \( a \) and \( b \), respectively.

**Parameters**

- a: [(M, M) array_like] Square matrix
- b: [(M, N) array_like] Input
- q: [(M, M) array_like] Input
- r: [(N, N) array_like] Nonsingular square matrix
- e: [(M, M) array_like, optional] Nonsingular square matrix
- s: [(M, N) array_like, optional] Input
- balanced: [bool, optional] The boolean that indicates whether a balancing step is performed on the data. The default is set to True.

**Returns**

- x: [(M, M) ndarray] Solution to the continuous-time algebraic Riccati equation.

**Raises**

- LinAlgError
  For cases where the stable subspace of the pencil could not be isolated. See Notes section and the references for details.

**See also:**

solve_discrete_are

Solves the discrete-time algebraic Riccati equation
Notes

The equation is solved by forming the extended hamiltonian matrix pencil, as described in [1], \( H - \lambda J \) given by the block matrices

\[
\begin{bmatrix}
 A & 0 & B \\
-\lambda^* & -A^H & -S \\
 S^H & B^H & R
\end{bmatrix}
\begin{bmatrix}
 E & 0 & 0 \\
 0 & E^H & 0 \\
 0 & 0 & 0
\end{bmatrix}
\]

and using a QZ decomposition method.

In this algorithm, the fail conditions are linked to the symmetry of the product \( U_2 U_1^{-1} \) and condition number of \( U_1 \). Here, \( U \) is the 2m-by-m matrix that holds the eigenvectors spanning the stable subspace with 2-m rows and partitioned into two m-row matrices. See [1] and [2] for more details.

In order to improve the QZ decomposition accuracy, the pencil goes through a balancing step where the sum of absolute values of \( H \) and \( J \) entries (after removing the diagonal entries of the sum) is balanced following the recipe given in [3].

New in version 0.11.0.

References

[1], [2], [3]

Examples

Given \( a, b, q, \) and \( r \) solve for \( x \):

```python
>>> from scipy import linalg
>>> a = np.array([[4, 3], [-4.5, -3.5]])
>>> b = np.array([[1], [-1]])
>>> q = np.array([[9, 6], [6, 4.]]).T
>>> r = 1
>>> x = linalg.solve_continuous_are(a, b, q, r)
>>> x
array([[ 21.72792206,  14.48528137],
       [ 14.48528137,   9.65485425]])
>>> np.allclose(a.T.dot(x) + x.dot(a)-x.dot(b).dot(b.T).dot(x), -q)
True
```

Scipy.solve_discrete_are

Scipy.solve_discrete_are \((a, b, q, r, e=None, s=None, balanced=True)\)

Solves the discrete-time algebraic Riccati equation (DARE).

The DARE is defined as

\[
A^H X A - X - (A^H X B)(R + B^H X B)^{-1}(B^H X A) + Q = 0
\]

The limitations for a solution to exist are:

- All eigenvalues of \( A \) outside the unit disc, should be controllable.
- The associated symplectic pencil (See Notes), should have eigenvalues sufficiently away from the unit circle.
Moreover, if \( e \) and \( s \) are not both precisely `None`, then the generalized version of DARE

\[
A^H X A - E^H X E - (A^H X B + S)(R + B^H X B)^{-1}(B^H X A + S^H) + Q = 0
\]

is solved. When omitted, \( e \) is assumed to be the identity and \( s \) is assumed to be the zero matrix.

**Parameters**

- `a` [(M, M) array_like] Square matrix
- `b` [(M, N) array_like] Input
- `q` [(M, M) array_like] Input
- `r` [(N, N) array_like] Square matrix
- `e` [(M, M) array_like, optional] Nonsingular square matrix
- `s` [(M, N) array_like, optional] Input
- `balanced` [bool] The boolean that indicates whether a balancing step is performed on the data. The default is set to True.

**Returns**

- `x` [(M, M) ndarray] Solution to the discrete algebraic Riccati equation.

**Raises**

- `LinAlgError` For cases where the stable subspace of the pencil could not be isolated. See Notes section and the references for details.

**See also:**

- `solve_continuous_are` Solves the continuous algebraic Riccati equation

**Notes**

The equation is solved by forming the extended symplectic matrix pencil, as described in [1], \( H - \lambda J \) given by the block matrices

\[
\begin{bmatrix}
A & 0 & B \\
-Q & E^H & -S \\
S^H & 0 & R
\end{bmatrix} \lambda^2 \begin{bmatrix}
E & 0 & B \\
0 & A^H & 0 \\
0 & -B^H & 0
\end{bmatrix}
\]

and using a QZ decomposition method.

In this algorithm, the fail conditions are linked to the symmetry of the product \( U_2 U_1^{-1} \) and condition number of \( U_1 \). Here, \( U \) is the 2m-by-m matrix that holds the eigenvectors spanning the stable subspace with 2-m rows and partitioned into two m-row matrices. See [1] and [2] for more details.

In order to improve the QZ decomposition accuracy, the pencil goes through a balancing step where the sum of absolute values of \( H \) and \( J \) rows/cols (after removing the diagonal entries) is balanced following the recipe given in [3]. If the data has small numerical noise, balancing may amplify their effects and some clean up is required.

New in version 0.11.0.
Examples

Given $a$, $b$, $q$, and $r$ solve for $x$:

```python
>>> from scipy import linalg as la
>>> a = np.array([[0, 1], [0, -1]])
>>> b = np.array([[1, 0], [2, 1]])
>>> q = np.array([[-4, -4], [-4, 7]])
>>> r = np.array([[9, 3], [3, 1]])
>>> x = la.solve_discrete_are(a, b, q, r)
>>> x
array([[-4., -4.],
[-4., 7.]]
>>> R = la.solve(r + b.T.dot(x).dot(b), b.T.dot(x).dot(a))
```

```python
>>> np.allclose(a.T.dot(x).dot(a) - x - a.T.dot(x).dot(b).dot(R), -q)
True
```

scipy.linalg.solve_continuous_lyapunov

scipy.linalg.solve_continuous_lyapunov($a$, $q$)

Solves the continuous Lyapunov equation $AX + XA^H = Q$.

Uses the Bartels-Stewart algorithm to find $X$.

Parameters

- $a$ [array_like] A square matrix
- $q$ [array_like] Right-hand side square matrix

Returns

- $x$ [ndarray] Solution to the continuous Lyapunov equation

See also:

solve_discrete_lyapunov

computes the solution to the discrete-time Lyapunov equation

solve_sylvester

computes the solution to the Sylvester equation

Notes

The continuous Lyapunov equation is a special form of the Sylvester equation, hence this solver relies on LAPACK routine 'TRSYL'.

New in version 0.11.0.
Examples

Given $a$ and $q$ solve for $x$:

```python
>>> from scipy import linalg
>>> a = np.array([[-3, -2, 0], [-1, -1, 0], [0, -5, -1]])
>>> b = np.array([2, 4, -1])
>>> q = np.eye(3)
>>> x = linalg.solve_continuous_lyapunov(a, q)
>>> x
array([[ -0.75 ,   0.875 ,  -3.75 ],
       [  0.875 ,  -1.375 ,   5.3125],
       [ -3.75 ,   5.3125 , -27.0625]])
>>> np.allclose(a.dot(x) + x.dot(a.T), q)
True
```

`scipy.linalg.solve_discrete_lyapunov`

`scipy.linalg.solve_discrete_lyapunov(a, q, method=None)`

Solves the discrete Lyapunov equation $AXA^H - X + Q = 0$.

**Parameters**

- **a** ([M, M] array_like) Square matrices corresponding to $A$ and $Q$ in the equation above respectively. Must have the same shape.
- **q** ([M, M] array_like) Square matrices corresponding to $A$ and $Q$ in the equation above respectively. Must have the same shape.
- **method** ([‘direct’, ‘bilinear’], optional) Type of solver. If not given, chosen to be direct if $M$ is less than 10 and bilinear otherwise.

**Returns**

- **x** [ndarray] Solution to the discrete Lyapunov equation

**See also:**

`solve_continuous_lyapunov`

computes the solution to the continuous-time Lyapunov equation

**Notes**

This section describes the available solvers that can be selected by the ‘method’ parameter. The default method is *direct* if $M$ is less than 10 and *bilinear* otherwise.

Method *direct* uses a direct analytical solution to the discrete Lyapunov equation. The algorithm is given in, for example, [1]. However, it requires the linear solution of a system with dimension $M^2$ so that performance degrades rapidly for even moderately sized matrices.

Method *bilinear* uses a bilinear transformation to convert the discrete Lyapunov equation to a continuous Lyapunov equation $(BX + XB' = -C)$ where $B = (A - I)(A + I)^{-1}$ and $C = 2(A' + I)^{-1}Q(A + I)^{-1}$. The continuous equation can be efficiently solved since it is a special case of a Sylvester equation. The transformation algorithm is from Popov (1964) as described in [2].

New in version 0.11.0.
References

[1], [2]

Examples

Given $a$ and $q$ solve for $x$:

```python
>>> from scipy import linalg
>>> a = np.array([[0.2, 0.5], [0.7, -0.9]])
>>> q = np.eye(2)
>>> x = linalg.solve_discrete_lyapunov(a, q)
>>> x
array([[ 0.70872893,  1.43518822],
       [ 1.43518822, -2.4266315 ]])
>>> np.allclose(a.dot(x).dot(a.T)-x, -q)
True
```

Sketches and Random Projections

```python
clarkson_woodruff_transform(input_matrix, ...
Applies a Clarkson-Woodruff Transform/sketch to the input matrix.

scipy.linalg.clarkson_woodruff_transform
Applies a Clarkson-Woodruff Transform/sketch to the input matrix.

Given an input_matrix $A$ of size $(n, d)$, compute a matrix $A'$ of size (sketch_size, d) so that

$$\|Ax\| \approx \|A'x\|$$

with high probability via the Clarkson-Woodruff Transform, otherwise known as the CountSketch matrix.

Parameters

- **input_matrix**: array_like
  Input matrix, of shape $(n, d)$.
- **sketch_size**: int
  Number of rows for the sketch.
- **seed**
  [[None, int, numpy.random.Generator],
   numpy.random.RandomState], optional
  If `seed` is None (or `np.random`), the `numpy.random.RandomState` singleton is used. If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already a `Generator` or `RandomState` instance then that instance is used.

Returns

- **A'**: [array_like] Sketch of the input matrix $A$, of size $(sketch_size, d)$.
Notes

To make the statement

$$\|Ax\| \approx \|A'x\|$$

precise, observe the following result which is adapted from the proof of Theorem 14 of [2] via Markov’s Inequality. If we have a sketch size $sketch\_size=k$ which is at least

$$k \geq \frac{2}{\epsilon^2 \delta}$$

Then for any fixed vector $x$,

$$\|Ax\| = (1 \pm \epsilon)\|A'x\|$$

with probability at least one minus delta.

This implementation takes advantage of sparsity: computing a sketch takes time proportional to $A.nnz$. Data $A$ which is in scipy.sparse.csc_matrix format gives the quickest computation time for sparse input.

```python
>>> from scipy import linalg
>>> from scipy import sparse
>>> rng = np.random.default_rng()
>>> n_rows, n_columns, sketch_n_rows = 15000, 100, 0.01, 200
>>> A = sparse.rand(n_rows, n_columns, density=density, format='csc')
>>> B = sparse.rand(n_rows, n_columns, density=density, format='csr')
>>> C = sparse.rand(n_rows, n_columns, density=density, format='coo')
>>> D = rng.standard_normal((n_rows, n_columns))
>>> SA = linalg.clarkson_woodruff_transform(A, sketch_n_rows) # fastest
>>> SB = linalg.clarkson_woodruff_transform(B, sketch_n_rows) # fast
>>> SC = linalg.clarkson_woodruff_transform(C, sketch_n_rows) # slower
>>> SD = linalg.clarkson_woodruff_transform(D, sketch_n_rows) # slowest
```

That said, this method does perform well on dense inputs, just slower on a relative scale.

References

[1], [2]

Examples

Given a big dense matrix $A$:

```python
>>> from scipy import linalg
>>> n_rows, n_columns, sketch_n_rows = 15000, 100, 200
>>> rng = np.random.default_rng()
>>> A = rng.standard_normal((n_rows, n_columns))
>>> sketch = linalg.clarkson_woodruff_transform(A, sketch_n_rows)
>>> sketch.shape
(200, 100)
>>> norm_A = np.linalg.norm(A)
>>> norm_sketch = np.linalg.norm(sketch)
```
Now with high probability, the true norm $\|A\|$ is close to the sketched norm $\|\text{sketch}\|$ in absolute value.

Similarly, applying our sketch preserves the solution to a linear regression of $\min ||Ax - b||$.

```python
>>> from scipy import linalg
>>> n_rows, n_columns, sketch_n_rows = 15000, 100, 200
>>> rng = np.random.default_rng()
>>> A = rng.standard_normal((n_rows, n_columns))
>>> b = rng.standard_normal(n_rows)
>>> x = np.linalg.lstsq(A, b, rcond=None)
>>> Ab = np.hstack((A, b.reshape(-1, 1)))
>>> SAb = linalg.clarkson_woodruff_transform(Ab, sketch_n_rows)
>>> SA, Sb = SAb[:, :-1], SAb[:, -1]
>>> x_sketched = np.linalg.lstsq(SA, Sb, rcond=None)
```

As with the matrix norm example, $\text{np.linalg.norm}(A @ x - b)$ is close to $\text{np.linalg.norm}(A @ x_{\text{sketched}} - b)$ with high probability.

#### scipy.linalg.block_diag

scipy.linalg.block_diag(*arrs)

Create a block diagonal matrix from provided arrays.

Given the inputs $A$, $B$ and $C$, the output will have these arrays arranged on the diagonal:

```python
[[A, 0, 0],
 [0, B, 0],
 [0, 0, C]]
```

**Parameters**

$A$, $B$, $C$, ...
Input arrays. A 1-D array or array_like sequence of length $n$ is treated as a 2-D array with shape $(1, n)$.

**Returns**

- **D** [ndarray] Array with $A$, $B$, $C$, … on the diagonal. $D$ has the same dtype as $A$.

**Notes**

If all the input arrays are square, the output is known as a block diagonal matrix.

Empty sequences (i.e., array-likes of zero size) will not be ignored. Noteworthy, both $[]$ and $[[[]]]$ are treated as matrices with shape $(1, 0)$.

**Examples**

```python
>>> from scipy.linalg import block_diag
>>> A = [[1, 0],
      ..., [0, 1]]
>>> B = [[3, 4, 5],
      ..., [6, 7, 8]]
>>> C = [[7]]
>>> P = np.zeros((2, 0), dtype='int32')
>>> block_diag(A, B, C)
array([[1, 0, 0, 0, 0, 0],
       [0, 1, 0, 0, 0, 0],
       [0, 0, 3, 4, 5, 0],
       [0, 0, 6, 7, 8, 0],
       [0, 0, 0, 0, 0, 7]])
>>> block_diag(A, P, B, C)
array([[1, 0, 0, 0, 0, 0],
       [0, 1, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0],
       [0, 0, 3, 4, 5, 0],
       [0, 0, 6, 7, 8, 0],
       [0, 0, 0, 0, 0, 7]])
>>> block_diag(1.0, [2, 3], [[4, 5], [6, 7]])
array([[ 1., 0., 0., 0.],
       [ 0., 2., 3., 0.],
       [ 0., 0., 4., 5.],
       [ 0., 0., 6., 7.]])
```

**scipy.linalg.circulant**

`scipy.linalg.circulant(c)`

Construct a circulant matrix.

**Parameters**

- **c** [(N,) array_like] 1-D array, the first column of the matrix.

**Returns**

- **A** [(N, N) ndarray] A circulant matrix whose first column is $c$.  

---

3.3. API definition 767
See also:

*toeplitz*

Toeplitz matrix

*hankel*

Hankel matrix

*solve_circulant*

Solve a circulant system.

Notes

New in version 0.8.0.

Examples

```python
>>> from scipy.linalg import circulant
>>> circulant([1, 2, 3])
array([[1, 3, 2],
      [2, 1, 3],
      [3, 2, 1]])
```

**scipy.linalg.companion**

`scipy.linalg.companion(a)`

Create a companion matrix.

Create the companion matrix [1] associated with the polynomial whose coefficients are given in \(a\).

Parameters

- \(a\) : [(N,) array_like] 1-D array of polynomial coefficients. The length of \(a\) must be at least two, and \(a[0]\) must not be zero.

Returns

- \(c\) : [(N-1, N-1) ndarray] The first row of \(c\) is \(-a[1:] / a[0]\), and the first sub-diagonal is all ones. The data-type of the array is the same as the data-type of \(1.0 * a[0]\).

Raises

- ValueError

If any of the following are true: a) \(a.n\text{dim} \neq 1\); b) \(a.size < 2\); c) \(a[0] == 0\).
Notes

New in version 0.8.0.

References

[1]

Examples

```python
>>> from scipy.linalg import companion
>>> companion([1, -10, 31, -30])
array([[ 10., -31., 30.],
       [ 1.,  0.,  0.],
       [ 0.,  1.,  0.]])
```

**scipy.linalg.convolution_matrix**

*scipy.linalg.convolution_matrix*(a, n, mode='full')

Construct a convolution matrix.

Constructs the Toeplitz matrix representing one-dimensional convolution [1]. See the notes below for details.

**Parameters**

- **a** [(m,) array_like] The 1-D array to convolve.
- **n** [int] The number of columns in the resulting matrix. It gives the length of the input to be convolved with *a*. This is analogous to the length of *v* in `numpy.convolve(a, v)`.
- **mode** [str] This is analogous to *mode* in `numpy.convolve(v, a, mode)`. It must be one of ('full', 'valid', 'same'). See below for how *mode* determines the shape of the result.

**Returns**

- **A** [(k, n) ndarray] The convolution matrix whose row count *k* depends on *mode*:

```plaintext
+-------+--------------------------------------------------+
|       |                                                 |
| mode  | k                                                |
|-------+--------------------------------------------------|
| 'full'| m + n - 1                                       |
| 'same'| max(m, n)                                        |
| 'valid'| max(m, n) - min(m, n) + 1                        |
+-------+--------------------------------------------------+
```

See also:

- **toeplitz**

  Toeplitz matrix

---

3.3. API definition 769
Notes

The code:

```
A = convolution_matrix(a, n, mode)
```

creates a Toeplitz matrix $A$ such that $A @ v$ is equivalent to using `convolve(a, v, mode)`. The returned array always has $n$ columns. The number of rows depends on the specified `mode`, as explained above.

In the default ‘full’ mode, the entries of $A$ are given by:

```
A[i, j] == (a[i-j] if (0 <= (i-j) < m) else 0)
```

where $m = \text{len}(a)$. Suppose, for example, the input array is $[x, y, z]$. The convolution matrix has the form:

```
[x, 0, 0, ..., 0, 0]
[y, x, 0, ..., 0, 0]
[z, y, x, ..., 0, 0]
... 
[0, 0, 0, ..., x, 0]
[0, 0, 0, ..., y, x]
[0, 0, 0, ..., z, y]
[0, 0, 0, ..., 0, z]
```

In ‘valid’ mode, the entries of $A$ are given by:

```
A[i, j] == (a[i-j+m-1] if (0 <= (i-j+m-1) < m) else 0)
```

This corresponds to a matrix whose rows are the subset of those from the ‘full’ case where all the coefficients in $a$ are contained in the row. For input $[x, y, z]$, this array looks like:

```
[z, y, x, 0, 0, ..., 0, 0, 0]
[0, z, y, x, 0, ..., 0, 0, 0]
[0, 0, z, y, x, ..., 0, 0, 0]
... 
[0, 0, 0, 0, 0, ..., x, 0, 0]
[0, 0, 0, 0, 0, ..., y, x, 0]
[0, 0, 0, 0, 0, ..., z, y, x]
```

In the ‘same’ mode, the entries of $A$ are given by:

```
d = (m - 1) // 2
A[i, j] == (a[i-j+d] if (0 <= (i-j+d) < m) else 0)
```

The typical application of the ‘same’ mode is when one has a signal of length $n$ (with $n$ greater than `len(a)`), and the desired output is a filtered signal that is still of length $n$.

For input $[x, y, z]$, this array looks like:

```
[y, x, 0, 0, ..., 0, 0, 0]
[z, y, x, 0, ..., 0, 0, 0]
[0, z, y, x, ..., 0, 0, 0]
[0, 0, z, y, ..., 0, 0, 0]
... 
```
New in version 1.5.0.

References

[1]

Examples

```python
>>> from scipy.linalg import convolution_matrix
>>> A = convolution_matrix([-1, 4, -2], 5, mode='same')
>>> A
array([[ 4, -1,  0,  0,  0],
       [-2,  4, -1,  0,  0],
       [ 0, -2,  4, -1,  0],
       [ 0,  0, -2,  4, -1],
       [ 0,  0,  0, -2,  4]])
```

Compare multiplication by A with the use of `numpy.convolve`.

```python
>>> x = np.array([1, 2, 0, -3, 0.5])
>>> A @ x
array([ 2. ,  6. , -1. , -12.5,   8. ])
```

Verify that A @ x produced the same result as applying the convolution function.

```python
>>> np.convolve([-1, 4, -2], x, mode='same')
array([ 2. ,  6. , -1. , -12.5,   8. ])
```

For comparison to the case mode='same' shown above, here are the matrices produced by mode='full' and mode='valid' for the same coefficients and size.

```python
>>> convolution_matrix([-1, 4, -2], 5, mode='full')
array([[-1, 0, 0, 0, 0],
      [ 4, -1, 0, 0, 0],
      [-2,  4, -1, 0, 0],
      [ 0, -2,  4, -1, 0],
      [ 0,  0, -2,  4, -1],
      [ 0,  0,  0, -2,  4]])
```

```python
>>> convolution_matrix([-1, 4, -2], 5, mode='valid')
array([[-2,  4, -1,  0,  0],
      [ 0, -2,  4, -1,  0],
      [ 0,  0, -2,  4, -1]])
```
**scipy.linalg.dft**

`scipy.linalg.dft(n, scale=None)`

Discrete Fourier transform matrix.

Create the matrix that computes the discrete Fourier transform of a sequence [1]. The nth primitive root of unity used to generate the matrix is \( \exp(-2\pi i/n) \), where \( i = \sqrt{-1} \).

**Parameters**

- **n** [int] Size the matrix to create.
- **scale** [str, optional] Must be None, ‘sqrtn’, or ‘n’. If `scale` is ‘sqrtn’, the matrix is divided by \( \sqrt{n} \). If `scale` is ‘n’, the matrix is divided by \( n \). If `scale` is None (the default), the matrix is not normalized, and the return value is simply the Vandermonde matrix of the roots of unity.

**Returns**

- **m** [(n, n) ndarray] The DFT matrix.

**Notes**

When `scale` is None, multiplying a vector by the matrix returned by `dft` is mathematically equivalent to (but much less efficient than) the calculation performed by `scipy.fft.fft`.

New in version 0.14.0.

**References**

[1]

**Examples**

```python
>>> from scipy.linalg import dft
>>> np.set_printoptions(precision=2, suppress=True)  # for compact output
>>> m = dft(5)
>>> m
array([[ 1. +0.j , 1. +0.j , 1. +0.j , 1. +0.j , 1. +0.j ],
        [ 1. +0.j , 0.31-0.95j, -0.81-0.59j, -0.81+0.59j, 0.31+0.95j],
        [ 1. +0.j , -0.81-0.59j, 0.31+0.95j, 0.31-0.95j, -0.81+0.59j],
        [ 1. +0.j , -0.81+0.59j, 0.31+0.95j, 0.31-0.95j, -0.81-0.59j],
        [ 1. +0.j , 0.31+0.95j, -0.81+0.59j, -0.81-0.59j, 0.31-0.95j]])
>>> x = np.array([1, 2, 3, 0, 3])
>>> m @ x  # Compute the DFT of x
array([ 9. +0.j , 0.12-0.81j, -2.12+3.44j, -2.12-3.44j, 0.12+0.81j])
```

Verify that \( m \@ x \) is the same as `fft(x)`.

```python
>>> from scipy.fft import fft
>>> fft(x)  # Same result as m @ x
array([ 9. +0.j , 0.12-0.81j, -2.12+3.44j, -2.12-3.44j, 0.12+0.81j])
```
scipy.linalg.fiedler

scipy.linalg.fiedler(a)

Returns a symmetric Fiedler matrix

Given a sequence of numbers \( a \), Fiedler matrices have the structure \( F[i, j] = \text{np.abs}(a[i] - a[j]) \), and hence zero diagonals and nonnegative entries. A Fiedler matrix has a dominant positive eigenvalue and other eigenvalues are negative. Although not valid generally, for certain inputs, the inverse and the determinant can be derived explicitly as given in [1].

**Parameters**

- \( a \) [(n,) array_like] coefficient array

**Returns**

- \( F \) [(n, n) ndarray]

**See also:**

circulant, toeplitz

**Notes**

New in version 1.3.0.

**References**

[1]

**Examples**

```python
from scipy.linalg import det, inv, fiedler
a = [1, 4, 12, 45, 77]
n = len(a)
A = fiedler(a)

A

array([[ 0, 3, 11, 44, 76],
       [ 3, 0, 8, 41, 73],
       [11, 8, 0, 33, 65],
       [44, 41, 33, 0, 32],
       [76, 73, 65, 32, 0]])
```

The explicit formulas for determinant and inverse seem to hold only for monotonically increasing/decreasing arrays. Note the tridiagonal structure and the corners.

```python
Ai = inv(A)
Ai[np.abs(Ai) < 1e-12] = 0. # cleanup the numerical noise for display
Ai

array([[ -0.16008772,  0.16666667,  0. ,   , 0.00657895],
       [ 0.16666667,  -0.22916667,  0.0625,  0.,    ],
       [ 0. ,   , 0.0625,  -0.07765152, 0.01515152, 0. ],
       [ 0. ,   , 0.,    , 0.01515152, -0.03077652, 0.015625 ],
       [ 0.00657895,  0. ,   , 0. ,    , 0.015625 , -0.00904605]])
```

(continues on next page)

3.3. API definition 773
scipy.linalg.fiedler_companion

scipy.linalg.fiedler_companion(a)
Returns a Fiedler companion matrix

Given a polynomial coefficient array \(a\), this function forms a pentadiagonal matrix with a special structure whose eigenvalues coincides with the roots of \(a\).

Parameters

- \(a\) : \([\text{N}, \text{array_like}]\) 1-D array of polynomial coefficients in descending order with a nonzero leading coefficient. For \(N < 2\), an empty array is returned.

Returns

- \(c\) : \([\text{N-1, N-1} \text{ndarray}]\) Resulting companion matrix

See also:

- companion

Notes

Similar to companion the leading coefficient should be nonzero. In the case the leading coefficient is not 1, other coefficients are rescaled before the array generation. To avoid numerical issues, it is best to provide a monic polynomial.

New in version 1.3.0.

References

[1]

Examples

```python
>>> from scipy.linalg import fiedler_companion, eigvals
>>> p = np.poly(np.arange(1, 9, 2))  # [1., -16., 86., -176., 105.]
>>> fc = fiedler_companion(p)
>>> fc
array([[ 16.,  -86.,   1.,   0.],
       [  1.,   0.,   0.,   0.],
       [  0.,  176.,   0., -105.],
       [  0.,   1.,   0.,   0.]])
>>> eigvals(fc)
array([[7.+0.j,  5.+0.j,  3.+0.j,  1.+0.j]])
```
**scipy.linalg.hadamard**

### scipy.linalg.hadamard(n, dtype=<class 'int'>)

Construct an Hadamard matrix.

Constructs an n-by-n Hadamard matrix, using Sylvester's construction. n must be a power of 2.

**Parameters**

- **n** (int) The order of the matrix. n must be a power of 2.
- **dtype** (dtype, optional) The data type of the array to be constructed.

**Returns**

- **H** [(n, n) ndarray] The Hadamard matrix.

**Notes**

New in version 0.8.0.

**Examples**

```python
>>> from scipy.linalg import hadamard
>>> hadamard(2, dtype=complex)
array([[ 1.+0.j,  1.+0.j],
       [ 1.+0.j, -1.-0.j]])
>>> hadamard(4)
array([[ 1,  1,  1,  1],
       [ 1, -1,  1, -1],
       [ 1,  1, -1, -1],
       [ 1, -1, -1,  1]])
```

**scipy.linalg.hankel**

### scipy.linalg.hankel(c, r=None)

Construct a Hankel matrix.

The Hankel matrix has constant anti-diagonals, with c as its first column and r as its last row. If r is not given, then r = zeros_like(c) is assumed.

**Parameters**

- **c** [array_like] First column of the matrix. Whatever the actual shape of c, it will be converted to a 1-D array.
- **r** [array_like, optional] Last row of the matrix. If None, r = zeros_like(c) is assumed. r[0] is ignored; the last row of the returned matrix is [c[-1], r[1:]]. Whatever the actual shape of r, it will be converted to a 1-D array.

**Returns**

- **A** [(len(c), len(r)) ndarray] The Hankel matrix. Dtype is the same as (c[0] + r[0]). dtype.

**See also:**

- **toeplitz**

Toeplitz matrix

3.3. API definition 775
circulant

    circulant matrix

Examples

```python
>>> from scipy.linalg import hankel
>>> hankel([1, 17, 99])
array([[1, 17, 99],
       [17, 99,  0],
       [99,  0,  0]])
>>> hankel([1,2,3,4], [4,7,7,8,9])
array([[1, 2, 3, 4, 7],
       [2, 3, 4, 7, 7],
       [3, 4, 7, 7, 8],
       [4, 7, 7, 8, 9]])
```

scipy.linalg.helmert

scipy.linalg.helmert(n, full=False)

Create an Helmert matrix of order n.

This has applications in statistics, compositional or simplicial analysis, and in Aitchison geometry.

Parameters

- **n** [int] The size of the array to create.
- **full** [bool, optional] If True the (n, n) ndarray will be returned. Otherwise the submatrix that does not include the first row will be returned. Default: False.

Returns

- **M** [ndarray] The Helmert matrix. The shape is (n, n) or (n-1, n) depending on the `full` argument.

Examples

```python
>>> from scipy.linalg import helmert
>>> helmert(5, full=True)
array([[0.4472136 , 0.4472136 , 0.4472136 , 0.4472136 , 0.4472136 ],
       [0.70710678, -0.70710678, 0. , 0. , 0. ],
       [0.40824829, 0.40824829, -0.81649658, 0. , 0. ],
       [0.28867513, 0.28867513, 0.28867513, -0.8660254 , 0. ],
       [0.2236068 , 0.2236068 , 0.2236068 , 0.2236068 , -0.89442719]])
```

scipy.linalg.hilbert

scipy.linalg.hilbert(n)

Create a Hilbert matrix of order n.

Returns the n by n array with entries $h[i,j] = 1 / (i + j + 1)$.

Parameters

- **n** [int] The size of the array to create.

Returns

- **h** [(n, n) ndarray] The Hilbert matrix.
See also:

```python
>>> from scipy.linalg import hilbert
>>> hilbert(3)
```

array([[ 1. , 0.5 , 0.33333333],
       [ 0.5 , 0.33333333, 0.25 ],
       [ 0.33333333, 0.25 , 0.2 ]])

```python
scipy.linalg.invhilbert
```

`scipy.linalg.invhilbert(n, exact=False)`

Compute the inverse of the Hilbert matrix of order `n`.

The entries in the inverse of a Hilbert matrix are integers. When `n` is greater than 14, some entries in the inverse exceed the upper limit of 64 bit integers. The `exact` argument provides two options for dealing with these large integers.

**Parameters**

- `n` [int] The order of the Hilbert matrix.
- `exact` [bool, optional] If False, the data type of the array that is returned is np.float64, and the array is an approximation of the inverse. If True, the array is the exact integer inverse array. To represent the exact inverse when `n` > 14, the returned array is an object array of long integers. For `n` <= 14, the exact inverse is returned as an array with data type np.int64.

**Returns**

- `invh` [(n, n)ndarray] The data type of the array is np.float64 if `exact` is False. If `exact` is True, the data type is either np.int64 (for `n` <= 14) or object (for `n` > 14). In the latter case, the objects in the array will be long integers.

See also:

```python
hilbert
```

Create a Hilbert matrix.
Notes

New in version 0.10.0.

Examples

```python
>>> from scipy.linalg import invhilbert
>>> invhilbert(4)
array([[ 16., -120.,  240., -140.],
       [ -120.,  1200., -2700.,  1680.],
       [  240., -2700.,  6480., -4200.],
       [ -140.,  1680., -4200.,  2800.]])
>>> invhilbert(4, exact=True)
array([[ 16, -120,  240, -140],
       [ -120,  1200, -2700,  1680],
       [  240, -2700,  6480, -4200],
       [ -140,  1680, -4200,  2800]], dtype=int64)
>>> invhilbert(16)[7,7]
4.2475099528537506e+19
>>> invhilbert(16, exact=True)[7,7]
42475099528537378560
```

**scipy.linalg.leslie**

`scipy.linalg.leslie(f, s)`

Create a Leslie matrix.

Given the length n array of fecundity coefficients f and the length n-1 array of survival coefficients s, return the associated Leslie matrix.

**Parameters**

- **f** [(N,) array_like] The “fecundity” coefficients.
- **s** [(N-1,) array_like] The “survival” coefficients, has to be 1-D. The length of s must be one less than the length of f, and it must be at least 1.

**Returns**

- **L** [(N, N) ndarray] The array is zero except for the first row, which is f, and the first sub-diagonal, which is s. The data-type of the array will be the data-type of f[0]+s[0].

**Notes**

New in version 0.8.0.

The Leslie matrix is used to model discrete-time, age-structured population growth [1] [2]. In a population with n age classes, two sets of parameters define a Leslie matrix: the n “fecundity coefficients”, which give the number of offspring per-capita produced by each age class, and the n - 1 “survival coefficients”, which give the per-capita survival rate of each age class.
References

[1], [2]

Examples

```python
>>> from scipy.linalg import leslie
>>> leslie([0.1, 2.0, 1.0, 0.1], [0.2, 0.8, 0.7])
array([[ 0.1,  2. ,  1. ,  0.1],
       [ 0.2,  0. ,  0. ,  0. ],
       [ 0. ,  0.8,  0. ,  0. ],
       [ 0. ,  0. ,  0.7,  0. ]])
```

scipy.linalg.pascal

`scipy.linalg.pascal(n, kind='symmetric', exact=True)`

Returns the n x n Pascal matrix.

The Pascal matrix is a matrix containing the binomial coefficients as its elements.

**Parameters**

- `n` [int] The size of the matrix to create; that is, the result is an n x n matrix.
- `kind` [str, optional] Must be one of 'symmetric', 'lower', or 'upper'. Default is 'symmetric'.
- `exact` [bool, optional] If exact is True, the result is either an array of type numpy.uint64 (if n < 35) or an object array of Python long integers. If exact is False, the coefficients in the matrix are computed using `scipy.special.comb` with exact=False. The result will be a floating point array, and the values in the array will not be the exact coefficients, but this version is much faster than exact=True.

**Returns**

See also:

- `invpascal`

Notes

See https://en.wikipedia.org/wiki/Pascal_matrix for more information about Pascal matrices.

New in version 0.11.0.

Examples

```python
>>> from scipy.linalg import pascal
>>> pascal(4)
array([[ 1,  1,  1,  1],
       [ 1,  2,  3,  4],
       [ 1,  3,  6, 10],
       [ 1,  4, 10, 20]], dtype=uint64)
```

(continues on next page)

>>> pascal(50)[-1, -1]
25477612258980856902730428600
>>> from scipy.special import comb
>>> comb(98, 49, exact=True)
25477612258980856902730428600

scipy.linalg.invpascal

scipy.linalg.invpascal(n, kind='symmetric', exact=True)

Returns the inverse of the n x n Pascal matrix.

The Pascal matrix is a matrix containing the binomial coefficients as its elements.

Parameters

- n [int] The size of the matrix to create; that is, the result is an n x n matrix.
- kind [str, optional] Must be one of 'symmetric', 'lower', or 'upper'. Default is 'symmetric'.
- exact [bool, optional] If exact is True, the result is either an array of type numpy.int64 (if n <= 35) or an object array of Python integers. If exact is False, the coefficients in the matrix are computed using scipy.special.comb with exact=False. The result will be a floating point array, and for large n, the values in the array will not be the exact coefficients.

Returns

- invp [(n, n) ndarray] The inverse of the Pascal matrix.

See also:

- pascal

Notes

New in version 0.16.0.

References

[1], [2]

Examples

```python
>>> from scipy.linalg import invpascal, pascal
>>> invp = invpascal(5)
>>> invp
array([[-5, -10,  10,   5,   1],
       [-10,  30, -35,  19,  -4],
       [  5, -35,  46, -27,   6],
       [-5,  19, -27,  17,  -4],
       [  1, - 4,   6,  -4,   1]])
```
```python
>>> p = pascal(5)
>>> p.dot(invp)
array([[ 1.,  0.,  0.,  0.,  0.],
       [ 0.,  1.,  0.,  0.,  0.],
       [ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  0.,  0.,  1.,  0.],
       [ 0.,  0.,  0.,  0.,  1.]])
```

An example of the use of `kind` and `exact`:

```python
>>> invpascal(5, kind='lower', exact=False)
array([[-1.,  1., -0.,  0., -0.],
       [ 1., -2.,  1., -0.,  0.],
       [-1.,  3., -3.,  1., -0.],
       [ 1., -4.,  6., -4.,  1.]]
```

**scipy.linalg.toeplitz**

`scipy.linalg.toeplitz(c, r=None)`

Construct a Toeplitz matrix.

The Toeplitz matrix has constant diagonals, with `c` as its first column and `r` as its first row. If `r` is not given, `r == conjugate(c)` is assumed.

**Parameters**

- `c` [array_like] First column of the matrix. Whatever the actual shape of `c`, it will be converted to a 1-D array.
- `r` [array_like, optional] First row of the matrix. If `None`, `r = conjugate(c)` is assumed; in this case, if `c[0]` is real, the result is a Hermitian matrix. `r[0]` is ignored; the first row of the returned matrix is `[c[0], r[1:]]`. Whatever the actual shape of `r`, it will be converted to a 1-D array.

**Returns**

- `A` [array_like, (len(c), len(r)) ndarray] The Toeplitz matrix. Dtype is the same as `(c[0] + r[0])`. 

**See also:**

- `circulant`
  - circulant matrix
- `hankel`
  - Hankel matrix
- `solve_toeplitz`
  - Solve a Toeplitz system.
Notes

The behavior when \( c \) or \( r \) is a scalar, or when \( c \) is complex and \( r \) is None, was changed in version 0.8.0. The behavior in previous versions was undocumented and is no longer supported.

Examples

```python
>>> from scipy.linalg import toeplitz
>>> toeplitz([1, 2, 3], [1, 4, 5, 6])
array([[1, 4, 5, 6],
       [2, 1, 4, 5],
       [3, 2, 1, 4]])
>>> toeplitz([1+0j, 2+3j, 4-1j])
array([[ 1.+0.j, 2.-3.j, 4.+1.j],
       [ 2.+3.j, 1.+0.j, 2.-3.j],
       [ 4.-1.j, 2.+3.j, 1.+0.j]])
```

cipy.linalg.tri

```
cipy.linalg.tri(N, M=None, k=0, dtype=None)

Construct (N, M) matrix filled with ones at and below the kth diagonal.

The matrix has \( A[i,j] == 1 \) for \( j <= i + k \)

Parameters

- \( N \) [int] The size of the first dimension of the matrix.
- \( M \) [int or None, optional] The size of the second dimension of the matrix. If \( M \) is None, \( M = N \) is assumed.
- \( k \) [int, optional] Number of subdiagonal below which matrix is filled with ones. \( k = 0 \) is the main diagonal, \( k < 0 \) subdiagonal and \( k > 0 \) superdiagonal.
- \( dtype \) [dtype, optional] Data type of the matrix.

Returns

- tri [(N, M) ndarray] Tri matrix.

Examples

```python
>>> from scipy.linalg import tri
>>> tri(3, 5, 2, dtype=int)
array([[1, 1, 1, 0, 0],
       [1, 1, 1, 1, 0],
       [1, 1, 1, 1, 1]])
>>> tri(3, 5, -1, dtype=int)
array([[0, 0, 0, 0, 0],
       [1, 0, 0, 0, 0],
       [1, 1, 0, 0, 0]])
```
Low-level routines

<table>
<thead>
<tr>
<th>function</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>get_blas_funcs(names[, arrays, dtype, ilp64])</td>
<td>Return available BLAS function objects from names.</td>
</tr>
<tr>
<td>get_lapack_funcs(names[, arrays, dtype, ilp64])</td>
<td>Return available LAPACK function objects from names.</td>
</tr>
<tr>
<td>find_best_blas_type([arrays, dtype])</td>
<td>Find best-matching BLAS/LAPACK type.</td>
</tr>
</tbody>
</table>

scipy.linalg.get_blas_funcs

scipy.linalg.get_blas_funcs(names, arrays=(), dtype=None, ilp64=False)

Return available BLAS function objects from names.

Parameters:
- **names**: [str or sequence of str] Name(s) of BLAS functions without type prefix.
- **arrays**: [sequence of ndarrays, optional] Arrays can be given to determine optimal prefix of BLAS routines. If not given, double-precision routines will be used, otherwise the most generic type in arrays will be used.
- **dtype**: [str or dtype, optional] Data-type specifier. Not used if arrays is non-empty.
- **ilp64**: [{True, False, ‘preferred’}, optional] Whether to return ILP64 routine variant. Choosing ‘preferred’ returns ILP64 routine if available, and otherwise the 32-bit routine. Default: False

Returns:
- **funcs**: [list] List containing the found function(s).

Notes

This routine automatically chooses between Fortran/C interfaces. Fortran code is used whenever possible for arrays with column major order. In all other cases, C code is preferred.

In BLAS, the naming convention is that all functions start with a type prefix, which depends on the type of the principal matrix. These can be one of {‘s’, ‘d’, ‘c’, ‘z’} for the NumPy types {float32, float64, complex64, complex128} respectively. The code and the dtype are stored in attributes *typecode* and *dtype* of the returned functions.

Examples

```python
>>> import scipy.linalg as LA
>>> rng = np.random.default_rng()
>>> a = rng.random((3,2))
>>> x_gemv = LA.get_blas_funcs('gemv', (a,))
>>> x_gemv.typecode
'd'
>>> x_gemv = LA.get_blas_funcs('gemv', (a*1j,))
>>> x_gemv.typecode
'z'
```
scipy.linalg.get_lapack_funcs

`scipy.linalg.get_lapack_funcs(names, arrays=(), dtype=None, ilp64=False)`

Return available LAPACK function objects from names.

Arrays are used to determine the optimal prefix of LAPACK routines.

**Parameters**

- `names` [str or sequence of str] Name(s) of LAPACK functions without type prefix.
- `arrays` [sequence of ndarrays, optional] Arrays can be given to determine optimal prefix of LAPACK routines. If not given, double-precision routines will be used, otherwise the most generic type in arrays will be used.
- `dtype` [str or dtype, optional] Data-type specifier. Not used if `arrays` is non-empty.
- `ilp64` [{True, False, 'preferred'}, optional] Whether to return ILP64 routine variant. Choosing ‘preferred’ returns ILP64 routine if available, and otherwise the 32-bit routine. Default: False

**Returns**

- `funcs` [list] List containing the found function(s).

**Notes**

This routine automatically chooses between Fortran/C interfaces. Fortran code is used whenever possible for arrays with column major order. In all other cases, C code is preferred.

In LAPACK, the naming convention is that all functions start with a type prefix, which depends on the type of the principal matrix. These can be one of {'s', 'd', 'c', 'z'} for the NumPy types {float32, float64, complex64, complex128} respectively, and are stored in attribute `typecode` of the returned functions.

**Examples**

Suppose we would like to use ‘?lange’ routine which computes the selected norm of an array. We pass our array in order to get the correct ‘lange’ flavor.

```python
>>> import scipy.linalg as LA
>>> rng = np.random.default_rng()
>>> a = rng.random((3,2))
>>> x_lange = LA.get_lapack_funcs('lange', (a,))
>>> x_lange.typecode
'd'
>>> x_lange = LA.get_lapack_funcs('lange', (a*1j,))
>>> x_lange.typecode
'z'
```

Several LAPACK routines work best when its internal WORK array has the optimal size (big enough for fast computation and small enough to avoid waste of memory). This size is determined also by a dedicated query to the function which is often wrapped as a standalone function and commonly denoted as `##_lwork`. Below is an example for `?sysv`

```python
>>> import scipy.linalg as LA
>>> rng = np.random.default_rng()
>>> a = rng.random((1000, 1000))
>>> b = rng.random((1000, 1)) * 1j
```
>>> # We pick up zsyyv and zsysv_lwork due to b array
... xsysv, xlwork = LA.get_lapack_funcs(("sysv", 'sysv_lwork'), (a, b))
>>> opt_lwork, _ = xlwork(a.shape[0]) # returns a complex for 'z' prefix
>>> udut, ipiv, x, info = xsysv(a, b, lwork=int(opt_lwork.real))

scipy.linalg.find_best_blas_type

scipy.linalg.find_best_blas_type(arrays=(), dtype=None)
Find best-matching BLAS/LAPACK type.

Parameters
arrays [sequence of ndarrays, optional] Arrays can be given to determine optimal prefix of BLAS routines. If not given, double-precision routines will be used, otherwise the most generic type in arrays will be used.
dtype [str or dtype, optional] Data-type specifier. Not used if arrays is non-empty.

Returns
prefix [str] BLAS/LAPACK prefix character.
dtype [dtype] Inferred Numpy data type.
prefer_fortran [bool] Whether to prefer Fortran order routines over C order.

Examples

>>> import scipy.linalg.blas as bla
>>> rng = np.random.default_rng()
>>> a = rng.random((10,15))
>>> b = np.asfortranarray(a) # Change the memory layout order
>>> bla.find_best_blas_type((a,))
('d', dtype('float64'), False)
>>> bla.find_best_blas_type((a*1j,))
('z', dtype('complex128'), False)
>>> bla.find_best_blas_type((b,))
('d', dtype('float64'), True)

scipy.linalg.cython_blas – Low-level BLAS functions for Cython
scipy.linalg.cython_lapack – Low-level LAPACK functions for Cython
3.3.11 Low-level BLAS functions (scipy.linalg.blas)

This module contains low-level functions from the BLAS library.

New in version 0.12.0.

Note: The common overwrite_<>() option in many routines, allows the input arrays to be overwritten to avoid extra memory allocation. However this requires the array to satisfy two conditions which are memory order and the data type to match exactly the order and the type expected by the routine.

As an example, if you pass a double precision float array to any S... routine which expects single precision arguments, f2py will create an intermediate array to match the argument types and overwriting will be performed on that intermediate array.

Similarly, if a C-contiguous array is passed, f2py will pass a FORTRAN-contiguous array internally. Please make sure that these details are satisfied. More information can be found in the f2py documentation.

Warning: These functions do little to no error checking. It is possible to cause crashes by mis-using them, so prefer using the higher-level routines in scipy.linalg.

</tbody>
</table>

scipy.linalg.blas.get_blas_funcs

scipy.linalg.blas.get_blas_funcs(names, arrays=(), dtype=None, ilp64=False)

Return available BLAS function objects from names.

Parameters

- names: [str or sequence of str] Name(s) of BLAS functions without type prefix.
- arrays: [sequence of ndarrays, optional] Arrays can be given to determine optimal prefix of BLAS routines. If not given, double-precision routines will be used, otherwise the most generic type in arrays will be used.
- dtype: [str or dtype, optional] Data-type specifier. Not used if arrays is non-empty.
- ilp64: [{'True, False, 'preferred'}, optional] Whether to return ILP64 routine variant. Choosing 'preferred' returns ILP64 routine if available, and otherwise the 32-bit routine. Default: False

Returns

- funcs: [list] List containing the found function(s).
Notes

This routine automatically chooses between Fortran/C interfaces. Fortran code is used whenever possible for arrays with column major order. In all other cases, C code is preferred.

In BLAS, the naming convention is that all functions start with a type prefix, which depends on the type of the principal matrix. These can be one of {‘s’, ‘d’, ‘c’, ‘z’} for the NumPy types {float32, float64, complex64, complex128} respectively. The code and the dtype are stored in attributes \texttt{typecode} and \texttt{dtype} of the returned functions.

Examples

```python
>>> import scipy.linalg as LA
>>> rng = np.random.default_rng()
>>> a = rng.random((3,2))
>>> x_gemv = LA.get_blas_funcs('gemv', (a,))
>>> x_gemv.typecode
'd'
>>> x_gemv = LA.get_blas_funcs('gemv', (a*1j,))
>>> x_gemv.typecode
'z'
```

\texttt{scipy.linalg.blas.find\_best\_blas\_type}

\texttt{scipy.linalg.blas.find\_best\_blas\_type(arrays=(), dtype=None)}

Find best-matching BLAS/LAPACK type.

Arrays are used to determine the optimal prefix of BLAS routines.

Parameters

- \texttt{arrays} [sequence of ndarrays, optional] Arrays can be given to determine optimal prefix of BLAS routines. If not given, double-precision routines will be used, otherwise the most generic type in arrays will be used.
- \texttt{dtype} [str or dtype, optional] Data-type specifier. Not used if \texttt{arrays} is non-empty.

Returns

- \texttt{prefix} [str] BLAS/LAPACK prefix character.
- \texttt{dtype} [dtype] Inferred Numpy data type.
- \texttt{prefer_fortran} [bool] Whether to prefer Fortran order routines over C order.

Examples

```python
>>> import scipy.linalg.blas as bla
>>> rng = np.random.default_rng()
>>> a = rng.random((10,15))
>>> b = np.asfortranarray(a)  # Change the memory layout order
>>> bla.find_best_blas_type((a,))
('d', dtype('float64'), False)
>>> bla.find_best_blas_type((a*1j,))
('z', dtype('complex128'), False)
>>> bla.find_best_blas_type((b,))
('d', dtype('float64'), True)
```
## BLAS Level 1 functions

- **caxpy**(*x*, *y*, [n, a, offx, incx, offy, incy])  
  Wrapper for caxpy.

- **dcopy**(*x*, *y*, [n, offx, incx, offy, incy])  
  Wrapper for dcopy.

- **ddot**(*x*, *y*, [n, offx, incx, offy, incy])  
  Wrapper for ddot.

- **dnrm2**(*x*, [n, offx, incx])  
  Wrapper for dnrm2.

- **drot**  
  Wrapper for drot.

- **drotg**(*a*, *b*)  
  Wrapper for drotg.

- **drotm**  
  Wrapper for drotm.

- **drotmg**(*d1*, *d2*, *x1*, *y1*)  
  Wrapper for drotmg.

- **dscal**(*a*, *x*, [n, offx, incx])  
  Wrapper for dscal.

- **dswap**(*x*, *y*, [n, offx, incx, offy, incy])  
  Wrapper for dswap.

- **sdasum**(*x*, [n, offx, incx])  
  Wrapper for sdasum.

- **dscale**(*a*, *x*, [n, offx, incx, overwrite_x])  
  Wrapper for dscale.

- **dswap**(*x*, *y*, [n, offx, incx, offy, incy])  
  Wrapper for dswap.

- **sdot**(*x*, *y*, [n, offx, incx, offy, incy])  
  Wrapper for sdot.

- **sdotg**(*a*, *b*)  
  Wrapper for sdotg.

- **sdotm**  
  Wrapper for sdotm.

- **sdotmg**(*d1*, *d2*, *x1*, *y1*)  
  Wrapper for sdotmg.

- **sscal**(*a*, *x*, [n, offx, incx])  
  Wrapper for sscale.

- **sswap**(*x*, *y*, [n, offx, incx, offy, incy])  
  Wrapper for sswap.

- **szaxpy**(*x*, *y*, [n, offx, incx, offy, incy])  
  Wrapper for szaxpy.

- **zcpxy**(*x*, *y*, [n, offx, incx, offy, incy])  
  Wrapper for zcopy.

- **zdscal**(*a*, *x*, [n, offx, incx, overwrite_x])  
  Wrapper for zdscal.

- **zsrot**(*a*, *b*)  
  Wrapper for zrotg.

- **zscal**(*a*, *x*, [n, offx, incx])  
  Wrapper for zscal.

- **zswap**(*x*, *y*, [n, offx, incx, offy, incy])  
  Wrapper for zswap.
scipy.linalg.blas.caxpy

scipy.linalg.blas.caxpy (x, y[, n, a, offx, incx, offy, incy]) = <fortran object>

Wrapper for caxpy.

Parameters

x : [input rank-1 array('F') with bounds (*)]
y : [input rank-1 array('F') with bounds (*)]

Returns

z : [rank-1 array('F') with bounds (*) and y storage]

Other Parameters

n : [input int, optional] Default: (len(x)-offx)/abs(incx)
a : [input complex, optional] Default: (1.0, 0.0)
offx : [input int, optional] Default: 0
incx : [input int, optional] Default: 1
offy : [input int, optional] Default: 0
incy : [input int, optional] Default: 1

scipy.linalg.blas.ccopy

scipy.linalg.blas.ccopy (x, y[, n, offx, incx, offy, incy]) = <fortran object>

Wrapper for ccopy.

Parameters

x : [input rank-1 array('F') with bounds (*)]
y : [input rank-1 array('F') with bounds (*)]

Returns

y : [rank-1 array('F') with bounds (*)]

Other Parameters

n : [input int, optional] Default: (len(x)-offx)/abs(incx)
offx : [input int, optional] Default: 0
incx : [input int, optional] Default: 1
offy : [input int, optional] Default: 0
incy : [input int, optional] Default: 1

scipy.linalg.blas.cdotc

scipy.linalg.blas.cdotc (x, y[, n, offx, incx, offy, incy]) = <fortran cdotc>

Wrapper for cdotc.

Parameters

x : [input rank-1 array('F') with bounds (*)]
y : [input rank-1 array('F') with bounds (*)]

Returns

xy : [complex]

Other Parameters

n : [input int, optional] Default: (len(x)-offx)/abs(incx)
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1
offy [input int, optional] Default: 0
incy [input int, optional] Default: 1

scipy.linalg.blas.cdotu

scipy.linalg.blas.cdotu(x, y[, n, offx, incx, offy, incy]) = <fortran cdotu>
Wrapper for cdotu.

Parameters
x [input rank-1 array('F') with bounds (*)]
y [input rank-1 array('F') with bounds (*)]

Returns
xy [complex]

Other Parameters
n [input int, optional] Default: (len(x)-offx)/abs(incx)
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1
offy [input int, optional] Default: 0
incy [input int, optional] Default: 1

scipy.linalg.blas.crotg

scipy.linalg.blas.crotg(a, b) = <fortran object>
Wrapper for crotg.

Parameters
a [input complex]
b [input complex]

Returns
c [complex]
s [complex]

scipy.linalg.blas.cscal

scipy.linalg.blas.cscal(a, x[, n, offx, incx]) = <fortran object>
Wrapper for cscal.

Parameters
a [input complex]
x [input rank-1 array('F') with bounds (*)]

Returns
x [rank-1 array('F') with bounds (*)]

Other Parameters
n [input int, optional] Default: (len(x)-offx)/abs(incx)
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1
scipy.linalg.blas.csrot

```
scipy.linalg.blas.csrot(x, y, c[, n, offx, incx, offy, incy, overwrite_x, overwrite_y]) = <fortran object>
```

Wrapper for csrot.

**Parameters**

- **x** [input rank-1 array('F') with bounds (*)]
- **y** [input rank-1 array('F') with bounds (*)]
- **c** [input float]
- **s** [input float]

**Returns**

- **x** [rank-1 array('F') with bounds (*)]
- **y** [rank-1 array('F') with bounds (*)]

**Other Parameters**

- **n** [input int, optional] Default: (len(x)-1-offx)/abs(incx)+1
- **overwrite_x** [input int, optional] Default: 0
- **offx** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1
- **overwrite_y** [input int, optional] Default: 0
- **offy** [input int, optional] Default: 0
- **incy** [input int, optional] Default: 1

scipy.linalg.blas.csscal

```
scipy.linalg.blas.csscal(a, x[, n, offx, incx, overwrite_x]) = <fortran object>
```

Wrapper for csscal.

**Parameters**

- **a** [input float]
- **x** [input rank-1 array('F') with bounds (*)]

**Returns**

- **x** [rank-1 array('F') with bounds (*)]

**Other Parameters**

- **n** [input int, optional] Default: (len(x)-offx)/abs(incx)
- **overwrite_x** [input int, optional] Default: 0
- **offx** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1
scipy.linalg.blas.cswap

scipy.linalg.blas.cswap(x, y[, n, offx, incx, offy, incy]) = <fortran object>

Wrapper for cswap.

Parameters

- x [input rank-1 array('F') with bounds (*)]
- y [input rank-1 array('F') with bounds (*)]

Returns

- x [rank-1 array('F') with bounds (*)]
- y [rank-1 array('F') with bounds (*)]

Other Parameters

- n [input int, optional] Default: (len(x)-offx)/abs(incx)
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offy [input int, optional] Default: 0
- incy [input int, optional] Default: 1

scipy.linalg.blas.dasum

scipy.linalg.blas.dasum(x[, n, offx, incx]) = <fortran dasum>

Wrapper for dasum.

Parameters

- x [input rank-1 array('d') with bounds (*)]

Returns

- s [float]

Other Parameters

- n [input int, optional] Default: (len(x)-offx)/abs(incx)
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1

scipy.linalg.blas.daxpy

scipy.linalg.blas.daxpy(x, y[, n, a, offx, incx, offy, incy]) = <fortran object>

Wrapper for daxpy.

Parameters

- x [input rank-1 array('d') with bounds (*)]
- y [input rank-1 array('d') with bounds (*)]

Returns

- z [rank-1 array('d') with bounds (*) and y storage]

Other Parameters

- n [input int, optional] Default: (len(x)-offx)/abs(incx)
- a [input float, optional] Default: 1.0
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offy [input int, optional] Default: 0
- incy [input int, optional] Default: 1
scipy.linalg.blas.dcopy

scipy.linalg.blas.dcopy(x[, y, n, offx, incx, offy, incy]) = <fortran object>
Wrapper for dcopy.

Parameters
x [input rank-1 array('d') with bounds (*)]
y [input rank-1 array('d') with bounds (*)]

Returns
y [rank-1 array('d') with bounds (*)]

Other Parameters
n [input int, optional] Default: (len(x)-offx)/abs(incx)
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1
offy [input int, optional] Default: 0
incy [input int, optional] Default: 1

scipy.linalg.blas.ddot

scipy.linalg.blas.ddot(x[, y, n, offx, incx, offy, incy]) = <fortran ddot>
Wrapper for ddot.

Parameters
x [input rank-1 array('d') with bounds (*)]
y [input rank-1 array('d') with bounds (*)]

Returns
xy [float]

Other Parameters
n [input int, optional] Default: (len(x)-offx)/abs(incx)
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1
offy [input int, optional] Default: 0
incy [input int, optional] Default: 1

scipy.linalg.blas.dnrm2

scipy.linalg.blas.dnrm2(x[, n, offx, incx]) = <fortran dnrm2>
Wrapper for dnrm2.

Parameters
x [input rank-1 array('d') with bounds (*)]

Returns
n2 [float]

Other Parameters
n [input int, optional] Default: (len(x)-offx)/abs(incx)
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1
scipy.linalg.blas.drot

```
scipy.linalg.blas.drot (x, y, c, s[, n, offx, incx, offy, incy, overwrite_x, overwrite_y]) = <fortran object>
```

Wrapper for drot.

**Parameters**

- `x` [input rank-1 array('d') with bounds (*)]
- `y` [input rank-1 array('d') with bounds (*)]
- `c` [input float]
- `s` [input float]

**Returns**

- `x` [rank-1 array('d') with bounds (*)]
- `y` [rank-1 array('d') with bounds (*)]

**Other Parameters**

- `n` [input int, optional] Default: (len(x)-1-offx)/abs(incx)+1
- `overwrite_x` [input int, optional] Default: 0
- `offx` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
- `overwrite_y` [input int, optional] Default: 0
- `offy` [input int, optional] Default: 0
- `incy` [input int, optional] Default: 1

scipy.linalg.blas.drotg

```
scipy.linalg.blas.drotg (a, b) = <fortran object>
```

Wrapper for drotg.

**Parameters**

- `a` [input float]
- `b` [input float]

**Returns**

- `c` [float]
- `s` [float]

scipy.linalg.blas.drotm

```
scipy.linalg.blas.drotm (x, y, param[, n, offx, incx, offy, incy, overwrite_x, overwrite_y]) = <fortran object>
```

Wrapper for drotm.

**Parameters**

- `x` [input rank-1 array('d') with bounds (*)]
- `y` [input rank-1 array('d') with bounds (*)]
- `param` [input rank-1 array('d') with bounds (5)]

**Returns**

- `x` [rank-1 array('d') with bounds (*)]
- `y` [rank-1 array('d') with bounds (*)]

**Other Parameters**

3.3. API definition

- **n** [input int, optional] Default: (len(x)-offx)/abs(incx)
- **overwrite_x** [input int, optional] Default: 0
- **offx** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1
- **overwrite_y** [input int, optional] Default: 0
- **offy** [input int, optional] Default: 0
- **incy** [input int, optional] Default: 1

### scipy.linalg.blas.drotmg

**scipy.linalg.blas.drotmg**(d1, d2, x1, y1) = <fortran object>

Wrapper for drotmg.

**Parameters**

- **d1** [input float]
- **d2** [input float]
- **x1** [input float]
- **y1** [input float]

**Returns**

- **param** [rank-1 array('d') with bounds (5)]

### scipy.linalg.blas.dscal

**scipy.linalg.blas.dscal**(a, x[, n, offx, incx]) = <fortran object>

Wrapper for dscal.

**Parameters**

- **a** [input float]
- **x** [input rank-1 array('d') with bounds (*)]

**Returns**

- **x** [rank-1 array('d') with bounds (*)]

**Other Parameters**

- **n** [input int, optional] Default: (len(x)-offx)/abs(incx)
- **offx** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1

### scipy.linalg.blas.dswap

**scipy.linalg.blas.dswap**(x, y[, n, offx, incx, offy, incy]) = <fortran object>

Wrapper for dswap.

**Parameters**

- **x** [input rank-1 array('d') with bounds (*)]
- **y** [input rank-1 array('d') with bounds (*)]

**Returns**

- **x** [rank-1 array('d') with bounds (*)]
- **y** [rank-1 array('d') with bounds (*)]

**Other Parameters**

```
scipy.linalg.blas.dzasum
scipy.linalg.blas.dzasum(x[, n, offx, incx]) = <fortran dzasum>
Wrapper for dzasum.

Parameters

x         [input rank-1 array('D') with bounds (*)]

Returns

s         [float]

Other Parameters

n         [input int, optional] Default: (len(x)-offx)/abs(incx)
offx      [input int, optional] Default: 0
incx      [input int, optional] Default: 1

scipy.linalg.blas.dznrm2
scipy.linalg.blas.dznrm2(x[, n, offx, incx]) = <fortran dznrm2>
Wrapper for dznrm2.

Parameters

x         [input rank-1 array('D') with bounds (*)]

Returns

n2        [float]

Other Parameters

n         [input int, optional] Default: (len(x)-offx)/abs(incx)
offx      [input int, optional] Default: 0
incx      [input int, optional] Default: 1

scipy.linalg.blas.icamax
scipy.linalg.blas.icamax(x[, n, offx, incx]) = <fortran object>
Wrapper for icamax.

Parameters

x         [input rank-1 array('F') with bounds (*)]

Returns

k         [int]

Other Parameters

n         [input int, optional] Default: (len(x)-offx)/abs(incx)
offx      [input int, optional] Default: 0
incx      [input int, optional] Default: 1
```
scipy.linalg.blas.idamax

scipy.linalg.blas.idamax(x[, n, offx, incx]) = <fortran object>
Wrapper for idamax.

Parameters
x [input rank-1 array('d') with bounds (*)]

Returns
k [int]

Other Parameters
n [input int, optional] Default: (len(x)-offx)/abs(incx)
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1

scipy.linalg.blas.isamax

scipy.linalg.blas.isamax(x[, n, offx, incx]) = <fortran object>
Wrapper for isamax.

Parameters
x [input rank-1 array('f') with bounds (*)]

Returns
k [int]

Other Parameters
n [input int, optional] Default: (len(x)-offx)/abs(incx)
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1

scipy.linalg.blas.izamax

scipy.linalg.blas.izamax(x[, n, offx, incx]) = <fortran object>
Wrapper for izamax.

Parameters
x [input rank-1 array('D') with bounds (*)]

Returns
k [int]

Other Parameters
n [input int, optional] Default: (len(x)-offx)/abs(incx)
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1
scipy.linalg.blas.sasum

scipy.linalg.blas.sasum(x[, n, offx, incx]) = <fortran sasum>
Wrapper for sasum.

Parameters

x [input rank-1 array('f') with bounds (*)]

Returns

s [float]

Other Parameters

n [input int, optional] Default: (len(x)-offx)/abs(incx)
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1

scipy.linalg.blas.saxpy

scipy.linalg.blas.saxpy(x[, y, n, a, offx, incx, offy, incy]) = <fortran object>
Wrapper for saxpy.

Parameters

x [input rank-1 array('f') with bounds (*)]
y [input rank-1 array('f') with bounds (*)]

Returns

z [rank-1 array('f') with bounds (*) and y storage]

Other Parameters

n [input int, optional] Default: (len(x)-offx)/abs(incx)
a [input float, optional] Default: 1.0
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1
offy [input int, optional] Default: 0
incy [input int, optional] Default: 1

scipy.linalg.blas.scasum

scipy.linalg.blas.scasum(x[, n, offx, incx]) = <fortran scasum>
Wrapper for scasum.

Parameters

x [input rank-1 array('F') with bounds (*)]

Returns

s [float]

Other Parameters

n [input int, optional] Default: (len(x)-offx)/abs(incx)
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1
scipy.linalg.blas.scnrm2

scipy.linalg.blas.scnrm2(x[, n, offx, incx]) = <fortran scnrm2>
Wrapper for scnrm2.

Parameters
x   [input rank-1 array('F') with bounds (*)]

Returns
n2  [float]

Other Parameters
n   [input int, optional] Default: (len(x)-offx)/abs(incx)
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1

scipy.linalg.blas.scopy

scipy.linalg.blas.scopy (x[, y, n, offx, incx, offy, incy]) = <fortran object>
Wrapper for scopy.

Parameters
x   [input rank-1 array('F') with bounds (*)]
y   [input rank-1 array('F') with bounds (*)]

Returns
y   [rank-1 array('f') with bounds (*)]

Other Parameters
n   [input int, optional] Default: (len(x)-offx)/abs(incx)
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1
offy [input int, optional] Default: 0
incy [input int, optional] Default: 1

scipy.linalg.blas.sdot

scipy.linalg.blas.sdot (x[, y, n, offx, incx, offy, incy]) = <fortran sdot>
Wrapper for sdot.

Parameters
x   [input rank-1 array('F') with bounds (*)]
y   [input rank-1 array('F') with bounds (*)]

Returns
xy  [float]

Other Parameters
n   [input int, optional] Default: (len(x)-offx)/abs(incx)
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1
offy [input int, optional] Default: 0
incy [input int, optional] Default: 1

scipy.linalg.blas.snrm2

scipy.linalg.blas.snrm2(x[, n, offx, incx]) = <fortran snrm2>

Wrapper for snrm2.

Parameters

x [input rank-1 array('f') with bounds (*)]

Returns

n2 [float]

Other Parameters

n [input int, optional] Default: (len(x)-offx)/abs(incx)
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1

scipy.linalg.blas.srot

scipy.linalg.blas.srot(x, y, c, s[, n, offx, incx, offy, incy, overwrite_x, overwrite_y]) = <fortran object>

Wrapper for srot.

Parameters

x [input rank-1 array('f') with bounds (*)]
y [input rank-1 array('f') with bounds (*)]
c [input float]
s [input float]

Returns

x [rank-1 array('f') with bounds (*)]
y [rank-1 array('f') with bounds (*)]

Other Parameters

n [input int, optional] Default: (len(x)-1-offx)/abs(incx)+1
overwrite_x [input int, optional] Default: 0
offx [input int, optional] Default: 0
incx [input int, optional] Default: 1
overwrite_y [input int, optional] Default: 0
offy [input int, optional] Default: 0
incy [input int, optional] Default: 1

scipy.linalg.blas.srotg

scipy.linalg.blas.srotg(a, b) = <fortran object>

Wrapper for srotg.

Parameters

a [input float]
b [input float]

Returns

c [float]
s [float]

scipy.linalg.blas.srotm

```python
scipy.linalg.blas.srotm(x, y, param[, n, offx, incx, offy, incy, overwrite_x, overwrite_y]) = <fortran object>
```

Wrapper for srotm.

**Parameters**

- **x** [input rank-1 array('f') with bounds (*)]
- **y** [input rank-1 array('f') with bounds (*)]
- **param** [input rank-1 array('f') with bounds (5)]

**Returns**

- **x** [rank-1 array('f') with bounds (*)]
- **y** [rank-1 array('f') with bounds (*)]

**Other Parameters**

- **n** [input int, optional] Default: (len(x)-offx)/abs(incx)
- **overwrite_x** [input int, optional] Default: 0
- **offx** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1
- **overwrite_y** [input int, optional] Default: 0
- **offy** [input int, optional] Default: 0
- **incy** [input int, optional] Default: 1

scipy.linalg.blas.srotmg

```python
scipy.linalg.blas.srotmg(d1, d2, x1, y1) = <fortran object>
```

Wrapper for srotmg.

**Parameters**

- **d1** [input float]
- **d2** [input float]
- **x1** [input float]
- **y1** [input float]

**Returns**

- **param** [rank-1 array('f') with bounds (5)]

scipy.linalg.blas.sscal

```python
scipy.linalg.blas.sscal(a, x[, n, offx, incx]) = <fortran object>
```

Wrapper for sscal.

**Parameters**

- **a** [input float]
- **x** [input rank-1 array('f') with bounds (*)]

**Returns**

- **x** [rank-1 array('f') with bounds (*)]

**Other Parameters**

- **n** [input int, optional] Default: (len(x)-offx)/abs(incx)
- **offx** [input int, optional] Default: 0
incx  [input int, optional] Default: 1

scipy.linalg.blas.sswap

scipy.linalg.blas.sswap(x[, n, offx, incx, offy, incy]) = <fortran object>

Wrapper for sswap.

Parameters

x  [input rank-1 array('f') with bounds (*)]
y  [input rank-1 array('f') with bounds (*)]

Returns

x  [rank-1 array('f') with bounds (*)]
y  [rank-1 array('f') with bounds (*)]

Other Parameters

n  [input int, optional] Default: (len(x)-offx)/abs(incx)
offx  [input int, optional] Default: 0
incx  [input int, optional] Default: 1
offy  [input int, optional] Default: 0
incy  [input int, optional] Default: 1

scipy.linalg.blas.zaxpy

scipy.linalg.blas.zaxpy(x[, n, a, offx, incx, offy, incy]) = <fortran object>

Wrapper for zaxpy.

Parameters

x  [input rank-1 array('D') with bounds (*)]
y  [input rank-1 array('D') with bounds (*)]

Returns

z  [rank-1 array('D') with bounds (*) and y storage]

Other Parameters

n  [input int, optional] Default: (len(x)-offx)/abs(incx)
a  [input complex, optional] Default: (1.0, 0.0)
offx  [input int, optional] Default: 0
incx  [input int, optional] Default: 1
offy  [input int, optional] Default: 0
incy  [input int, optional] Default: 1

scipy.linalg.blas.zcopy

scipy.linalg.blas.zcopy(x[, n, offx, incx, offy, incy]) = <fortran object>

Wrapper for zcopy.

Parameters

x  [input rank-1 array('D') with bounds (*)]
y  [input rank-1 array('D') with bounds (*)]

Returns

y  [rank-1 array('D') with bounds (*)]

Other Parameters
scipy.linalg.blas.zdotc

Wrapper for `zdotc`.

**Parameters**

- `x` [input rank-1 array('D') with bounds (*)]
- `y` [input rank-1 array('D') with bounds (*)]

**Returns**

- `xy` [complex]

**Other Parameters**

- `n` [input int, optional] Default: (len(x)-offx)/abs(incx)
- `offx` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
- `offy` [input int, optional] Default: 0
- `incy` [input int, optional] Default: 1

scipy.linalg.blas.zdotu

Wrapper for `zdotu`.

**Parameters**

- `x` [input rank-1 array('D') with bounds (*)]
- `y` [input rank-1 array('D') with bounds (*)]

**Returns**

- `xy` [complex]

**Other Parameters**

- `n` [input int, optional] Default: (len(x)-offx)/abs(incx)
- `offx` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
- `offy` [input int, optional] Default: 0
- `incy` [input int, optional] Default: 1

scipy.linalg.blas.zdrot

Wrapper for `zdrot`.

**Parameters**

- `x` [input rank-1 array('D') with bounds (*)]
- `y` [input rank-1 array('D') with bounds (*)]
- `c` [input float]
- `s` [input float]
Returns

\[ x \quad \text{[rank-1 array('D') with bounds (*)]} \]
\[ y \quad \text{[rank-1 array('D') with bounds (*)]} \]

Other Parameters

\[ n \quad \text{[input int, optional] Default: (len(x)-1-offx)/abs(incx)+1} \]
\[ \text{overwrite}_x \quad \text{[input int, optional] Default: 0} \]
\[ \text{offx} \quad \text{[input int, optional] Default: 0} \]
\[ \text{incx} \quad \text{[input int, optional] Default: 1} \]
\[ \text{overwrite}_y \quad \text{[input int, optional] Default: 0} \]
\[ \text{offy} \quad \text{[input int, optional] Default: 0} \]
\[ \text{incy} \quad \text{[input int, optional] Default: 1} \]

`scipy.linalg.blas.zdscal`

`scipy.linalg.blas.zdscal(a, x[, n, offx, incx, overwrite_x]) = <fortran object>`

Wrapper for `zdscal`.

Parameters

\[ a \quad \text{[input float]} \]
\[ x \quad \text{[input rank-1 array('D') with bounds (*)]} \]

Returns

\[ x \quad \text{[rank-1 array('D') with bounds (*)]} \]

Other Parameters

\[ n \quad \text{[input int, optional] Default: (len(x)-offx)/abs(incx)} \]
\[ \text{overwrite}_x \quad \text{[input int, optional] Default: 0} \]
\[ \text{offx} \quad \text{[input int, optional] Default: 0} \]
\[ \text{incx} \quad \text{[input int, optional] Default: 1} \]

`scipy.linalg.blas.zrotg`

`scipy.linalg.blas.zrotg(a, b) = <fortran object>`

Wrapper for `zrotg`.

Parameters

\[ a \quad \text{[input complex]} \]
\[ b \quad \text{[input complex]} \]

Returns

\[ c \quad \text{[complex]} \]
\[ s \quad \text{[complex]} \]
scipy.linalg.blas.zscal

```python
scipy.linalg.blas.zscal(a, x[, n, offx, incx]) = <fortran object>
```

Wrapper for zscal.

**Parameters**

- `a` [input complex]
- `x` [input rank-1 array('D') with bounds (*)]

**Returns**

- `x` [rank-1 array('D') with bounds (*)]

**Other Parameters**

- `n` [input int, optional] Default: (len(x)-offx)/abs(incx)
- `offx` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1

scipy.linalg.blas.zswap

```python
scipy.linalg.blas.zswap(x, y[, n, offx, incx, offy, incy]) = <fortran object>
```

Wrapper for zswap.

**Parameters**

- `x` [input rank-1 array('D') with bounds (*)]
- `y` [input rank-1 array('D') with bounds (*)]

**Returns**

- `x` [rank-1 array('D') with bounds (*)]
- `y` [rank-1 array('D') with bounds (*)]

**Other Parameters**

- `n` [input int, optional] Default: (len(x)-offx)/abs(incx)
- `offx` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
- `offy` [input int, optional] Default: 0
- `incy` [input int, optional] Default: 1

**BLAS Level 2 functions**

- `sgbmv(...)` Wrapper for sgbmv.
- `sgemv(...)` Wrapper for sgemv.
- `sger(...)` Wrapper for sger.
- `ssbmv(...)` Wrapper for ssbmv.
- `sspr(n, alpha, x, ap[, incx, offx, lower, overwrite_ap])` Wrapper for sspr.
- `sspr2(...)` Wrapper for sspr2.
- `ssymv(...)` Wrapper for ssymv.
- `ssyr(alpha, x[, lower, incx, offx, n, a, overwrite_a])` Wrapper for ssyr.
- `ssyr2(...)` Wrapper for ssyr2.
- `stbmv(...)` Wrapper for stbmv.
- `stpsv(...)` Wrapper for stpsv.
- `strmv(...)` Wrapper for strmv.
- `strsv(...)` Wrapper for strsv.

scipy.linalg.blas.sgbmv

scipy.linalg.blas.sgbmv(m, n, kl, ku, alpha, a, x[, incx, offx, beta, y, incy, offy, trans, overwrite_y]) = <fortran object>

Wrapper for sgbmv.

Parameters

- m [input int]
- n [input int]
- kl [input int]
- ku [input int]
- alpha [input float]
- a [input rank-2 array('f') with bounds (lda,n)]
- x [input rank-1 array('f') with bounds (*)]

Returns

- yout [rank-1 array('f') with bounds (ly) and y storage]

Other Parameters

- incx [input int, optional] Default: 1
- offx [input int, optional] Default: 0
- beta [input float, optional] Default: 0.0
- y [input rank-1 array('f') with bounds (ly)]
- overwrite_y [input int, optional] Default: 0
- incy [input int, optional] Default: 1
- offy [input int, optional] Default: 0
- trans [input int, optional] Default: 0

scipy.linalg.blas.sgemv

scipy.linalg.blas.sgemv(alpha, a, x[, beta, y, offx, incx, offy, incy, trans, overwrite_y]) = <fortran object>

Wrapper for sgemv.

Parameters

- alpha [input float]
- a [input rank-2 array('f') with bounds (m,n)]
- x [input rank-1 array('f') with bounds (*)]

Returns

- y [rank-1 array('f') with bounds (ly)]

Other Parameters

- beta [input float, optional] Default: 0.0
- y [input rank-1 array('f') with bounds (ly)]
- overwrite_y [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offx [input int, optional] Default: 0
- incy [input int, optional] Default: 1
- trans [input int, optional] Default: 0
scipy.linalg.blas.sger

scipy.linalg.blas.sger (alpha, x, y[, incx, incy, a, overwrite_x, overwrite_y, overwrite_a]) = <fortran object>

Wrapper for sger.

Parameters

alpha [input float]
x [input rank-1 array('f') with bounds (m)]
y [input rank-1 array('f') with bounds (n)]

Returns

a [rank-2 array('f') with bounds (m,n)]

Other Parameters

overwrite_x [input int, optional] Default: 1
incx [input int, optional] Default: 1
overwrite_y [input int, optional] Default: 1
incy [input int, optional] Default: 1
a [input rank-2 array('f') with bounds (m,n), optional] Default: 0.0
overwrite_a [input int, optional] Default: 0

scipy.linalg.blas.ssbmv

scipy.linalg.blas.ssbmv (k, alpha, a, x[, incx, offx, beta, y, incy, offy, lower, overwrite_y]) = <fortran object>

Wrapper for ssbmv.

Parameters

k [input int]
alpha [input float]
a [input rank-2 array('f') with bounds (lda,n)]
x [input rank-1 array('f') with bounds (*)]

Returns

yout [rank-1 array('f') with bounds (ly) and y storage]

Other Parameters

incx [input int, optional] Default: 1
offx [input int, optional] Default: 0
beta [input float, optional] Default: 0.0
y [input rank-1 array('f') with bounds (ly)]
overwrite_y [input int, optional] Default: 0
incy [input int, optional] Default: 1
offy [input int, optional] Default: 1
lower [input int, optional] Default: 0
scipy.linalg.blas.sspr

scipy.linalg.blas.sspr(n, alpha, x, ap[, incx, offx, lower, overwrite_ap]) = <fortran object>

Wrapper for sspr.

Parameters

n [input int]
alpha [input float]
x [input rank-1 array('f') with bounds (*)]
ap [input rank-1 array('f') with bounds (*)]

Returns

apu [rank-1 array('f') with bounds (*) and ap storage]

Other Parameters

incx [input int, optional] Default: 1
offx [input int, optional] Default: 0
overwrite_ap [input int, optional] Default: 0
lower [input int, optional] Default: 0

scipy.linalg.blas.sspr2

scipy.linalg.blas.sspr2(n, alpha, x, y, ap[, incx, offx, incy, offy, lower, overwrite_ap]) = <fortran object>

Wrapper for sspr2.

Parameters

n [input int]
alpha [input float]
x [input rank-1 array('f') with bounds (*)]
y [input rank-1 array('f') with bounds (*)]
ap [input rank-1 array('f') with bounds (*)]

Returns

apu [rank-1 array('f') with bounds (*) and ap storage]

Other Parameters

incx [input int, optional] Default: 1
offx [input int, optional] Default: 0
incy [input int, optional] Default: 1
offy [input int, optional] Default: 0
overwrite_ap [input int, optional] Default: 0
lower [input int, optional] Default: 0
**scipy.linalg.blas.ssymv**

scipy.linalg.blas.ssymv(alpha, a, x[, beta, y, offx, incx, offy, incy, lower, overwrite_y]) = <fortran object>

Wrapper for ssymv.

**Parameters**
- **alpha** [input float]
- **a** [input rank-2 array('f') with bounds (n,n)]
- **x** [input rank-1 array('f') with bounds (*)]

**Returns**
- **y** [rank-1 array('f') with bounds (ly)]

**Other Parameters**
- **beta** [input float, optional] Default: 0.0
- **y** [input rank-1 array('f') with bounds (ly)]
- **overwrite_y** [input int, optional] Default: 0
- **offx** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1
- **offy** [input int, optional] Default: 0
- **incy** [input int, optional] Default: 1
- **lower** [input int, optional] Default: 0

**scipy.linalg.blas.ssyr**

scipy.linalg.blas.ssyr(alpha, x[, lower, incx, offx, n, a, overwrite_a]) = <fortran object>

Wrapper for ssyr.

**Parameters**
- **alpha** [input float]
- **x** [input rank-1 array('f') with bounds (*)]

**Returns**
- **a** [rank-2 array('f') with bounds (n,n)]

**Other Parameters**
- **lower** [input int, optional] Default: 0
- **incx** [input int, optional] Default: 1
- **offx** [input int, optional] Default: 0
- **n** [input int, optional] Default: (len(x)-1-offx)/abs(incx)+1
- **a** [input rank-2 array('f') with bounds (n,n)]
- **overwrite_a** [input int, optional] Default: 0
scipy.linalg.blas.syr2

scipy.linalg.blas.syr2(alpha, x, y[, lower, incx, offx, incy, offy, n, a, overwrite_a]) = <fortran object>

Wrapper for syr2.

Parameters
- alpha [input float]
- x [input rank-1 array('f') with bounds (*)]
- y [input rank-1 array('f') with bounds (*)]

Returns
- a [rank-2 array('f') with bounds (n,n)]

Other Parameters
- lower [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offx [input int, optional] Default: 0
- incy [input int, optional] Default: 1
- offy [input int, optional] Default: 0
- n [input int, optional] Default: ((len(x)-1-offx)/abs(incx)+1 <=(len(y)-1-offy)/abs(incy)+1 ?(len(x)-1-offx)/abs(incx)+1 :len(y)-1-offy)/abs(incy)+1)
- a [input rank-2 array('f') with bounds (n,n)]
- overwrite_a [input int, optional] Default: 0

scipy.linalg.blas.stbmv

scipy.linalg.blas.stbmv(k, a, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>

Wrapper for stbmv.

Parameters
- k [input int]
- a [input rank-2 array('f') with bounds (lda,n)]
- x [input rank-1 array('f') with bounds (*)]

Returns
- xout [rank-1 array('f') with bounds (*) and x storage]

Other Parameters
- overwrite_x [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offx [input int, optional] Default: 0
- lower [input int, optional] Default: 0
- trans [input int, optional] Default: 0
- diag [input int, optional] Default: 0
scipy.linalg.blas.stpsv

scipy.linalg.blas.stpsv \( (n, ap, x[, \text{incx, offx, lower, trans, diag, overwrite}_x]) \) = <fortran object>
Wrapper for stpsv.

Parameters

- \( n \) [input int]
- \( ap \) [input rank-1 array('f') with bounds (*)]
- \( x \) [input rank-1 array('f') with bounds (*)]

Returns

- \( xout \) [rank-1 array('f') with bounds (*) and x storage]

Other Parameters

- overwrite_x [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offx [input int, optional] Default: 0
- lower [input int, optional] Default: 0
- trans [input int, optional] Default: 0
- diag [input int, optional] Default: 0

scipy.linalg.blas.strmv

scipy.linalg.blas.strmv \( (a, x[, \text{offx, incx, lower, trans, diag, overwrite}_x]) \) = <fortran object>
Wrapper for strmv.

Parameters

- \( a \) [input rank-2 array('f') with bounds (n,n)]
- \( x \) [input rank-1 array('f') with bounds (*)]

Returns

- \( x \) [rank-1 array('f') with bounds (*)]

Other Parameters

- overwrite_x [input int, optional] Default: 0
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- lower [input int, optional] Default: 0
- trans [input int, optional] Default: 0
- diag [input int, optional] Default: 0

scipy.linalg.blas.strsv

scipy.linalg.blas.strsv \( (a, x[, \text{incx, offx, lower, trans, diag, overwrite}_x]) \) = <fortran object>
Wrapper for strsv.

Parameters

- \( a \) [input rank-2 array('f') with bounds (n,n)]
- \( x \) [input rank-1 array('f') with bounds (*)]

Returns

- \( xout \) [rank-1 array('f') with bounds (*) and x storage]

Other Parameters
overwrite_x
   [input int, optional] Default: 0
incx
   [input int, optional] Default: 1
offx
   [input int, optional] Default: 0
lower
   [input int, optional] Default: 0
trans
   [input int, optional] Default: 0
diag
   [input int, optional] Default: 0

scipy.linalg.blas.dgbmv

scipy.linalg.blas.dgbmv(m, n, kl, ku, alpha, a, x[, incx, offx, beta, y, incy, offy, trans, overwrite_y]) =
   <fortran object>

Wrapper for dgbmv.

Parameters

m  [input int]
n  [input int]
kl [input int]
ku [input int]
alpha  [input float]
a  [input rank-2 array('d') with bounds (lda,n)]
x  [input rank-1 array('d') with bounds (*)]

Returns

yout  [rank-1 array('d') with bounds (ly) and y storage]

Other Parameters

incx  [input int, optional] Default: 1
offx  [input int, optional] Default: 0
beta  [input float, optional] Default: 0.0
y    [input rank-1 array('d') with bounds (ly)]
overwrite_y
   [input int, optional] Default: 0
incy  [input int, optional] Default: 1
offy  [input int, optional] Default: 0
trans [input int, optional] Default: 0

scipy.linalg.blas.dgemv

scipy.linalg.blas.dgemv(alpha, a, x[, beta, y, offx, incx, offy, incy, trans, overwrite_y]) = <fortran object>

Wrapper for dgemv.

Parameters

alpha  [input float]
a  [input rank-2 array('d') with bounds (m,n)]
x  [input rank-1 array('d') with bounds (*)]

Returns

y  [rank-1 array('d') with bounds (ly)]

Other Parameters

beta  [input float, optional] Default: 0.0
y    [input rank-1 array('d') with bounds (ly)]

3.3. API definition
**overwrite_y**
[input int, optional] Default: 0

**offx**
[input int, optional] Default: 0

**incx**

**offy**
[input int, optional] Default: 0

**incy**
[input int, optional] Default: 1

**trans**
[input int, optional] Default: 0

---

**scipy.linalg.blas.dger**

```python
scipy.linalg.blas.dger(alpha, x, y[, incx, incy, a, overwrite_x, overwrite_y, overwrite_a]) = <fortran object>
```

Wrapper for `dger`.

**Parameters**

- **alpha**
  [input float]

- **x**
  [input rank-1 array('d') with bounds (m)]

- **y**
  [input rank-1 array('d') with bounds (n)]

**Returns**

- **a**
  [rank-2 array('d') with bounds (m,n)]

**Other Parameters**

- **overwrite_x**
  [input int, optional] Default: 1

- **incx**
  [input int, optional] Default: 1

- **overwrite_y**
  [input int, optional] Default: 1

- **incy**
  [input int, optional] Default: 1

- **a**
  [input rank-2 array('d') with bounds (m,n), optional] Default: 0.0

- **overwrite_a**
  [input int, optional] Default: 0

---

**scipy.linalg.blas.dsbmv**

```python
scipy.linalg.blas.dsbmv(k, alpha, a, x[, incx, offx, beta, y, incy, offy, lower, overwrite_y]) = <fortran object>
```

Wrapper for `dsbmv`.

**Parameters**

- **k**
  [input int]

- **alpha**
  [input float]

- **a**
  [input rank-2 array('d') with bounds (lda,n)]

- **x**
  [input rank-1 array('d') with bounds (*)]

**Returns**

- **yout**
  [rank-1 array('d') with bounds (ly) and y storage]

**Other Parameters**

- **incx**
  [input int, optional] Default: 1

- **offx**
  [input int, optional] Default: 0

- **beta**
  [input float, optional] Default: 0.0

- **y**
  [input rank-1 array('d') with bounds (ly)]

- **overwrite_y**
  [input int, optional] Default: 0

---

814 Chapter 3. SciPy API

**scipy.linalg.blas.dspr**

```python
scipy.linalg.blas.dspr(n, alpha, x, ap[, incx, offx, lower, overwrite_ap]) = <fortran object>
```

*Wrapper for dspr.*

**Parameters**

- **n**  [input int]
- **alpha**  [input float]
- **x**  [input rank-1 array('d') with bounds (*)]
- **ap**  [input rank-1 array('d') with bounds (*)]

**Returns**

- **ap**  [rank-1 array('d') with bounds (*) and ap storage]

**Other Parameters**

- **incx**  [input int, optional] Default: 1
- **offx**  [input int, optional] Default: 0
- **overwrite_ap**  [input int, optional] Default: 0
- **lower**  [input int, optional] Default: 0

**scipy.linalg.blas.dspr2**

```python
scipy.linalg.blas.dspr2(n, alpha, x, y, ap[, incx, offx, incy, offy, lower, overwrite_ap]) = <fortran object>
```

*Wrapper for dspr2.*

**Parameters**

- **n**  [input int]
- **alpha**  [input float]
- **x**  [input rank-1 array('d') with bounds (*)]
- **y**  [input rank-1 array('d') with bounds (*)]
- **ap**  [input rank-1 array('d') with bounds (*)]

**Returns**

- **ap**  [rank-1 array('d') with bounds (*) and ap storage]

**Other Parameters**

- **incx**  [input int, optional] Default: 1
- **offx**  [input int, optional] Default: 0
- **incy**  [input int, optional] Default: 1
- **offy**  [input int, optional] Default: 0
- **overwrite_ap**  [input int, optional] Default: 0
- **lower**  [input int, optional] Default: 0

3.3. API definition 815
scipy.linalg.blas.dsymv

\[ \text{dsymv}(\alpha, a, x[, \beta, y, \text{offx}, \text{incy}, \text{lower}, \text{overwrite}_y]) = \text{<fortran object>} \]

Wrapper for dsymv.

**Parameters**
- \( \alpha \) [input float]
- \( a \) [input rank-2 array('d') with bounds (n,n)]
- \( x \) [input rank-1 array('d') with bounds (*)]

**Returns**
- \( y \) [rank-1 array('d') with bounds (ly)]

**Other Parameters**
- \( \beta \) [input float, optional] Default: 0.0
- \( y \) [input rank-1 array('d') with bounds (ly)]
- \( \text{overwrite}_y \) [input int, optional] Default: 0
- \( \text{offx} \) [input int, optional] Default: 0
- \( \text{incy} \) [input int, optional] Default: 1
- \( \text{offy} \) [input int, optional] Default: 0
- \( \text{lower} \) [input int, optional] Default: 0

scipy.linalg.blas.dsyr

\[ \text{dsyr}(\alpha, x[, \text{lower}, \text{incx}, \text{offx}, n, a, \text{overwrite}_a]) = \text{<fortran object>} \]

Wrapper for dsyr.

**Parameters**
- \( \alpha \) [input float]
- \( x \) [input rank-1 array('d') with bounds (*)]

**Returns**
- \( a \) [rank-2 array('d') with bounds (n,n)]

**Other Parameters**
- \( \text{lower} \) [input int, optional] Default: 0
- \( \text{incx} \) [input int, optional] Default: 1
- \( \text{offx} \) [input int, optional] Default: 0
- \( n \) [input int, optional] Default: \((\text{len}(x)-1-\text{offx})/\text{abs(incx)}+1\)
- \( a \) [input rank-2 array('d') with bounds (n,n)]
- \( \text{overwrite}_a \) [input int, optional] Default: 0
scipy.linalg.blas.dsy2

```python
scipy.linalg.blas.dsy2(alpha, x, y, lower, incx, offx, incy, offy, n, a, overwrite_a) = <fortran object>
```

Wrapper for dsyr2.

**Parameters**

- `alpha` : input float
- `x` : input rank-1 array('d') with bounds (*)
- `y` : input rank-1 array('d') with bounds (*)

**Returns**

- `a` : rank-2 array('d') with bounds (n,n)

**Other Parameters**

- `lower` : input int, optional, Default: 0
- `incx` : input int, optional, Default: 1
- `offx` : input int, optional, Default: 0
- `incy` : input int, optional, Default: 1
- `offy` : input int, optional, Default: 0
- `n` : input int, optional, Default: ((len(x)-1-offx)/abs(incx)+1 <=(len(y)-1-offy)/abs(incy)+1
  ?(len(x)-1-offx)/abs(incx)+1 :(len(y)-1-offy)/abs(incy)+1)
- `a` : input rank-2 array('d') with bounds (n,n)
- `overwrite_a` : input int, optional, Default: 0

scipy.linalg.blas.dtbmv

```python
scipy.linalg.blas.dtbmv(k, a, x, incx, offx, lower, trans, diag, overwrite_x) = <fortran object>
```

Wrapper for dtbmv.

**Parameters**

- `k` : input int
- `a` : input rank-2 array('d') with bounds (lda,n)
- `x` : input rank-1 array('d') with bounds (*)

**Returns**

- `xout` : rank-1 array('d') with bounds (*) and x storage

**Other Parameters**

- `overwrite_x` : input int, optional, Default: 0
- `incx` : input int, optional, Default: 1
- `offx` : input int, optional, Default: 0
- `lower` : input int, optional, Default: 0
- `trans` : input int, optional, Default: 0
- `diag` : input int, optional, Default: 0
scipy.linalg.blas.dtpsv

scipy.linalg.blas.dtpsv(n, ap, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>

Wrapper for dtpsv.

Parameters

- n [input int]
- ap [input rank-1 array('d') with bounds (*)]
- x [input rank-1 array('d') with bounds (*)]

Returns

- xout [rank-1 array('d') with bounds (*) and x storage]

Other Parameters

- overwrite_x [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offx [input int, optional] Default: 0
- lower [input int, optional] Default: 0
- trans [input int, optional] Default: 0
- diag [input int, optional] Default: 0

scipy.linalg.blas.dtrmv

scipy.linalg.blas.dtrmv(a, x[, offx, incx, lower, trans, diag, overwrite_x]) = <fortran object>

Wrapper for dtrmv.

Parameters

- a [input rank-2 array('d') with bounds (n,n)]
- x [input rank-1 array('d') with bounds (*)]

Returns

- x [rank-1 array('d') with bounds (*)]

Other Parameters

- overwrite_x [input int, optional] Default: 0
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- lower [input int, optional] Default: 0
- trans [input int, optional] Default: 0
- diag [input int, optional] Default: 0

scipy.linalg.blas.dtrsv

scipy.linalg.blas.dtrsv(a, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>

Wrapper for dtrsv.

Parameters

- a [input rank-2 array('d') with bounds (n,n)]
- x [input rank-1 array('d') with bounds (*)]

Returns

- xout [rank-1 array('d') with bounds (*) and x storage]

Other Parameters
overwrite_x
    [input int, optional] Default: 0
incx
    [input int, optional] Default: 1
offx
    [input int, optional] Default: 0
lower
    [input int, optional] Default: 0
trans
    [input int, optional] Default: 0
diag
    [input int, optional] Default: 0

scipy.linalg.blas.cgbmv

scipy.linalg.blas.cgbmv (m, n, kl, ku, alpha, a, x[, incx, offx, beta, y, incy, offy, trans, overwrite_y]) =
<fortran object>

Wrapper for cgbmv.

Parameters

m
    [input int]
n
    [input int]
kl
    [input int]
ku
    [input int]
alpha
    [input complex]
a
    [input rank-2 array('F') with bounds (lda,n)]
x
    [input rank-1 array('F') with bounds (*)]

Returns

yout
    [rank-1 array('F') with bounds (ly) and y storage]

Other Parameters

incx
    [input int, optional] Default: 1
offx
    [input int, optional] Default: 0
beta
    [input complex, optional] Default: (0.0, 0.0)
y
    [input rank-1 array('F') with bounds (ly)]
overwrite_y
    [input int, optional] Default: 0
incy
    [input int, optional] Default: 1
offy
    [input int, optional] Default: 0
trans
    [input int, optional] Default: 0

scipy.linalg.blas.cgemv

scipy.linalg.blas.cgemv (alpha, a, x[, beta, y, offx, incx, offy, incy, trans, overwrite_y]) = <fortran object>

Wrapper for cgemv.

Parameters

alpha
    [input complex]
a
    [input rank-2 array('F') with bounds (m,n)]
x
    [input rank-1 array('F') with bounds (*)]

Returns

y
    [rank-1 array('F') with bounds (ly)]

Other Parameters

beta
    [input complex, optional] Default: (0.0, 0.0)
y
    [input rank-1 array('F') with bounds (ly)]
overwrite_y
  [input int, optional] Default: 0
offx
  [input int, optional] Default: 0
incx
  [input int, optional] Default: 1
offy
  [input int, optional] Default: 0
incy
  [input int, optional] Default: 1
trans
  [input int, optional] Default: 0

scipy.linalg.blas.cgerc

scipy.linalg.blas.cgerc(alpha, x[, inx, incy, a, overwrite_x, overwrite_y, overwrite_a]) =
<fortran object>

Wrapper for cgerc.

Parameters
  alpha [input complex]
x [input rank-1 array('F') with bounds (m)]
y [input rank-1 array('F') with bounds (n)]

Returns
  a [rank-2 array('F') with bounds (m,n)]

Other Parameters
  overwrite_x
    [input int, optional] Default: 1
  incx
    [input int, optional] Default: 1
  overwrite_y
    [input int, optional] Default: 1
  incy
    [input int, optional] Default: 1
  a
    [input rank-2 array('F') with bounds (m,n), optional] Default: (0.0,0.0)
  overwrite_a
    [input int, optional] Default: 0

scipy.linalg.blas.cgeru

scipy.linalg.blas.cgeru(alpha, x[, inx, incy, a, overwrite_x, overwrite_y, overwrite_a]) =
<fortran object>

Wrapper for cgeru.

Parameters
  alpha [input complex]
x [input rank-1 array('F') with bounds (m)]
y [input rank-1 array('F') with bounds (n)]

Returns
  a [rank-2 array('F') with bounds (m,n)]

Other Parameters
  overwrite_x
    [input int, optional] Default: 1
  incx
    [input int, optional] Default: 1
  overwrite_y
    [input int, optional] Default: 1
  incy
    [input int, optional] Default: 1
  a
    [input rank-2 array('F') with bounds (m,n), optional] Default: (0.0,0.0)
overwrite_a
        [input int, optional] Default: 0

scipy.linalg.blas.chbmv

scipy.linalg.blas.chbmv (k, alpha, a, x[, incx, offx, beta, y, incy, offy, lower, overwrite_y]) = <fortran object>

Wrapper for chbmv.

Parameters

- k [input int]
- alpha [input complex]
- a [input rank-2 array('F') with bounds (lda,n)]
- x [input rank-1 array('F') with bounds (*)]

Returns

- yout [rank-1 array('F') with bounds (ly) and y storage]

Other Parameters

- incx [input int, optional] Default: 1
- offx [input int, optional] Default: 0
- beta [input complex, optional] Default: (0.0, 0.0)
- y [input rank-1 array('F') with bounds (ly)]
- overwrite_y [input int, optional] Default: 0
- incy [input int, optional] Default: 1
- offy [input int, optional] Default: 0
- lower [input int, optional] Default: 0

scipy.linalg.blas.chemv

scipy.linalg.blas.chemv (alpha, a, x[, beta, y, offx, incx, offy, incy, lower, overwrite_y]) = <fortran object>

Wrapper for chemv.

Parameters

- alpha [input complex]
- a [input rank-2 array('F') with bounds (n,n)]
- x [input rank-1 array('F') with bounds (*)]

Returns

- y [rank-1 array('F') with bounds (ly)]

Other Parameters

- beta [input complex, optional] Default: (0.0, 0.0)
- y [input rank-1 array('F') with bounds (ly)]
- overwrite_y [input int, optional] Default: 0
- offx [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offy [input int, optional] Default: 0
- incy [input int, optional] Default: 1
- lower [input int, optional] Default: 0

3.3. API definition
scipy.linalg.blas.cher

scipy.linalg.blas.cher(alpha, x[, lower, incx, offx, n, a, overwrite_a]) = <fortran object>

Wrapper for cher.

Parameters

  alpha [input complex]
  x [input rank-1 array('F') with bounds (*)]

Returns

  a [rank-2 array('F') with bounds (n,n)]

Other Parameters

  lower [input int, optional] Default: 0
  incx [input int, optional] Default: 1
  offx [input int, optional] Default: 0
  n [input int, optional] Default: (len(x)-1-offx)/abs(incx)+1
  a [input rank-2 array('F') with bounds (n,n)]
  overwrite_a [input int, optional] Default: 0

scipy.linalg.blas.cher2

scipy.linalg.blas.cher2(alpha, x, y[, lower, incx, offx, incy, offy, n, a, overwrite_a]) = <fortran object>

Wrapper for cher2.

Parameters

  alpha [input complex]
  x [input rank-1 array('F') with bounds (*)]
  y [input rank-1 array('F') with bounds (*)]

Returns

  a [rank-2 array('F') with bounds (n,n)]

Other Parameters

  lower [input int, optional] Default: 0
  incx [input int, optional] Default: 1
  offx [input int, optional] Default: 0
  incy [input int, optional] Default: 1
  offy [input int, optional] Default: 0
  n [input int, optional] Default: 
  a [input rank-2 array('F') with bounds (n,n)]
  overwrite_a [input int, optional] Default: 0
scipy.linalg.blas.chpmv

scipy.linalg.blas.chpmv \( (n, \alpha, ap, x[, incx, offx, beta, y, incy, offy, lower, overwrite_y]) \) =

<fortran object>

Wrapper for chpmv.

**Parameters**

- **n** [input int]
- **alpha** [input complex]
- **ap** [input rank-1 array('F') with bounds (*)]
- **x** [input rank-1 array('F') with bounds (*)]

**Returns**

- **y** [rank-1 array('F') with bounds (ly) and y storage]

**Other Parameters**

- **incx** [input int, optional] Default: 1
- **offx** [input int, optional] Default: 0
- **beta** [input complex, optional] Default: (0.0, 0.0)
- **y** [input rank-1 array('F') with bounds (ly)]
- **overwrite_y** [input int, optional] Default: 0
- **incy** [input int, optional] Default: 1
- **offy** [input int, optional] Default: 0
- **lower** [input int, optional] Default: 0

scipy.linalg.blas.chpr

scipy.linalg.blas.chpr \( (n, \alpha, x, ap[, incx, offx, lower, overwrite_ap]) \) = <fortran object>

Wrapper for chpr.

**Parameters**

- **n** [input int]
- **alpha** [input float]
- **x** [input rank-1 array('F') with bounds (*)]
- **ap** [input rank-1 array('F') with bounds (*)]

**Returns**

- **ap** [rank-1 array('F') with bounds (*) and ap storage]

**Other Parameters**

- **incx** [input int, optional] Default: 1
- **offx** [input int, optional] Default: 0
- **overwrite_ap** [input int, optional] Default: 0
- **lower** [input int, optional] Default: 0
**scipy.linalg.blas.chpr2**

`scipy.linalg.blas.chpr2(n, alpha, x, y, ap[, incx, offx, incy, offy, lower, overwrite_ap]) = <fortran object>`

Wrapper for chpr2.

**Parameters**

- `n` [input int]
- `alpha` [input complex]
- `x` [input rank-1 array('F') with bounds (*)]
- `y` [input rank-1 array('F') with bounds (*)]
- `ap` [input rank-1 array('F') with bounds (*)]

**Returns**

- `apu` [rank-1 array('F') with bounds (*) and ap storage]

**Other Parameters**

- `incx` [input int, optional] Default: 1
- `offx` [input int, optional] Default: 0
- `incy` [input int, optional] Default: 1
- `offy` [input int, optional] Default: 0
- `overwrite_ap` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0

**scipy.linalg.blas.ctbmv**

`scipy.linalg.blas.ctbmv(k, a, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>`

Wrapper for ctbmv.

**Parameters**

- `k` [input int]
- `a` [input rank-2 array('F') with bounds (lda,n)]
- `x` [input rank-1 array('F') with bounds (*)]

**Returns**

- `xout` [rank-1 array('F') with bounds (*) and x storage]

**Other Parameters**

- `overwrite_x` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
- `offx` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
- `trans` [input int, optional] Default: 0
- `diag` [input int, optional] Default: 0
scipy.linalg.blas.ctbsv

\[ \text{scipy.linalg.blas.ctbsv}(k, a, x[, incx, offx, lower, trans, diag, overwrite_x]) = \text{<fortran object>} \]

Wrapper for ctbsv.

Parameters
- \( k \) [input int]
- \( a \) [input rank-2 array('F') with bounds (lda,n)]
- \( x \) [input rank-1 array('F') with bounds (*)]

Returns
- \( xout \) [rank-1 array('F') with bounds (*) and x storage]

Other Parameters
- \( overwrite_x \) [input int, optional] Default: 0
- \( incx \) [input int, optional] Default: 1
- \( offx \) [input int, optional] Default: 0
- \( lower \) [input int, optional] Default: 0
- \( trans \) [input int, optional] Default: 0
- \( diag \) [input int, optional] Default: 0

scipy.linalg.blas.ctpmv

\[ \text{scipy.linalg.blas.ctpmv}(n, ap, x[, incx, offx, lower, trans, diag, overwrite_x]) = \text{<fortran object>} \]

Wrapper for ctpmv.

Parameters
- \( n \) [input int]
- \( ap \) [input rank-1 array('F') with bounds (*)]
- \( x \) [input rank-1 array('F') with bounds (*)]

Returns
- \( xout \) [rank-1 array('F') with bounds (*) and x storage]

Other Parameters
- \( overwrite_x \) [input int, optional] Default: 0
- \( incx \) [input int, optional] Default: 1
- \( offx \) [input int, optional] Default: 0
- \( lower \) [input int, optional] Default: 0
- \( trans \) [input int, optional] Default: 0
- \( diag \) [input int, optional] Default: 0

scipy.linalg.blas.ctpsv

\[ \text{scipy.linalg.blas.ctpsv}(n, ap, x[, incx, offx, lower, trans, diag, overwrite_x]) = \text{<fortran object>} \]

Wrapper for ctpsv.

Parameters
- \( n \) [input int]
- \( ap \) [input rank-1 array('F') with bounds (*)]
- \( x \) [input rank-1 array('F') with bounds (*)]

Returns
\[
x_{\text{out}} \quad \text{[rank-1 array('F') with bounds (*) and x storage]}
\]

**Other Parameters**

- `overwrite_x` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
- `offx` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
- `trans` [input int, optional] Default: 0
- `diag` [input int, optional] Default: 0

\[\text{scipy.linalg.blas.ctrmv}\]

\[\text{scipy.linalg.blas.ctrmv}(a, x[, \text{offx, incx, lower, trans, diag, overwrite}_x]) = <\text{fortran object}>\]

Wrapper for `ctrmv`.

**Parameters**

- `a` [input rank-2 array('F') with bounds (n,n)]
- `x` [input rank-1 array('F') with bounds (*)]

**Returns**

- `x` [rank-1 array('F') with bounds (*)]

**Other Parameters**

- `overwrite_x` [input int, optional] Default: 0
- `offx` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
- `lower` [input int, optional] Default: 0
- `trans` [input int, optional] Default: 0
- `diag` [input int, optional] Default: 0

\[\text{scipy.linalg.blas.ctrsv}\]

\[\text{scipy.linalg.blas.ctrsv}(a, x[, \text{incx, offx, lower, trans, diag, overwrite}_x]) = <\text{fortran object}>\]

Wrapper for `ctrsv`.

**Parameters**

- `a` [input rank-2 array('F') with bounds (n,n)]
- `x` [input rank-1 array('F') with bounds (*)]

**Returns**

- `x_{\text{out}}` [rank-1 array('F') with bounds (*) and x storage]

**Other Parameters**

- `overwrite_x` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
- `offx` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
- `trans` [input int, optional] Default: 0
- `diag` [input int, optional] Default: 0

**scipy.linalg.blas.csyr**

`scipy.linalg.blas.csyr(alpha, x[, lower, incx, offx, n, a, overwrite_a]) = <fortran object>`

Wrapper for csyr.

**Parameters**

- `alpha` [input complex]
- `x` [input rank-1 array('F') with bounds (*)]

**Returns**

- `a` [rank-2 array('F') with bounds (n,n)]

**Other Parameters**

- `lower` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1
- `offx` [input int, optional] Default: 0
- `n` [input int, optional] Default: (len(x)-1-offx)/abs(incx)+1
- `a` [input rank-2 array('F') with bounds (n,n)]
- `overwrite_a` [input int, optional] Default: 0

**scipy.linalg.blas.zgbmv**

`scipy.linalg.blas.zgbmv(m, n, kl, ku, alpha, a, x[, incx, offx, beta, y, incy, offy, trans, overwrite_y]) = <fortran object>`

Wrapper for zgbmv.

**Parameters**

- `m` [input int]
- `n` [input int]
- `kl` [input int]
- `ku` [input int]
- `alpha` [input complex]
- `a` [input rank-2 array('D') with bounds (lda,n)]
- `x` [input rank-1 array('D') with bounds (*)]

**Returns**

- `yout` [rank-1 array('D') with bounds (ly) and y storage]

**Other Parameters**

- `incx` [input int, optional] Default: 1
- `offx` [input int, optional] Default: 0
- `beta` [input complex, optional] Default: (0.0, 0.0)
- `y` [input rank-1 array('D') with bounds (ly)]
- `overwrite_y` [input int, optional] Default: 0
- `incy` [input int, optional] Default: 1
- `offy` [input int, optional] Default: 0
- `trans` [input int, optional] Default: 0
scipy.linalg.blas.zgemv

scipy.linalg.blas.zgemv (alpha, a, x[, beta, y, offx, incx, offy, incy, trans, overwrite_y]) = <fortran object>

Wrapper for zgemv.

Parameters

alpha    [input complex]
a        [input rank-2 array(‘D’) with bounds (m,n)]
x        [input rank-1 array(‘D’) with bounds (*)]

Returns

y        [rank-1 array(‘D’) with bounds (ly)]

Other Parameters

beta    [input complex, optional] Default: (0.0, 0.0)
y    [input rank-1 array(‘D’) with bounds (ly)]
overwrite_y    [input int, optional] Default: 0
offx    [input int, optional] Default: 0
incx    [input int, optional] Default: 1
offy    [input int, optional] Default: 0
incy    [input int, optional] Default: 1
trans    [input int, optional] Default: 0

scipy.linalg.blas.zgerc

scipy.linalg.blas.zgerc (alpha, x, y[, incx, incy, a, overwrite_x, overwrite_y, overwrite_a]) = <fortran object>

Wrapper for zgerc.

Parameters

alpha    [input complex]
x    [input rank-1 array(‘D’) with bounds (m)]
y    [input rank-1 array(‘D’) with bounds (n)]

Returns

a        [rank-2 array(‘D’) with bounds (m,n)]

Other Parameters

overwrite_x    [input int, optional] Default: 1
incx    [input int, optional] Default: 1
overwrite_y    [input int, optional] Default: 1
incy    [input int, optional] Default: 1
a    [input rank-2 array(‘D’) with bounds (m,n), optional] Default: (0.0,0.0)
overwrite_a    [input int, optional] Default: 0
scipy.linalg.blas.zgeru

scipy.linalg.blas.zgeru(alpha, x, y[, incx,incy, a,overwrite_x, overwrite_y, overwrite_a]) = <fortran object>

Wrapper for zgeru.

Parameters

- **alpha** [input complex]
- **x** [input rank-1 array('D') with bounds (m)]
- **y** [input rank-1 array('D') with bounds (n)]

Returns

- **a** [rank-2 array('D') with bounds (m,n)]

Other Parameters

- **overwrite_x** [input int, optional] Default: 1
- **incx** [input int, optional] Default: 1
- **overwrite_y** [input int, optional] Default: 1
- **incy** [input int, optional] Default: 1
- **a** [input rank-2 array('D') with bounds (m,n), optional] Default: (0.0,0.0)
- **overwrite_a** [input int, optional] Default: 0

scipy.linalg.blas.zhbmv

scipy.linalg.blas.zhbmv(k, alpha, a, x[, incx, offx, beta, y, incy, offy, lower, overwrite_y]) = <fortran object>

Wrapper for zhbmv.

Parameters

- **k** [input int]
- **alpha** [input complex]
- **a** [input rank-2 array('D') with bounds (lda,n)]
- **x** [input rank-1 array('D') with bounds (*)]

Returns

- **yout** [rank-1 array('D') with bounds (ly) and y storage]

Other Parameters

- **incx** [input int, optional] Default: 1
- **offx** [input int, optional] Default: 0
- **beta** [input complex, optional] Default: (0.0, 0.0)
- **incy** [input int, optional] Default: 1
- **offy** [input int, optional] Default: 1
- **lower** [input int, optional] Default: 0
scipy.linalg.blas.zhemv

scipy.linalg.blas.zhemv(alpha, a, x[, beta, y, offx, incx, offy, incy, lower, overwrite_y]) = <fortran object>

Wrapper for zhemv.

Parameters

alpha [input complex]
a [input rank-2 array(‘D’) with bounds (n,n)]
x [input rank-1 array(‘D’) with bounds (*)]

Returns

y [rank-1 array(‘D’) with bounds (ly)]

Other Parameters

beta [input complex, optional] Default: (0.0, 0.0)
y [input rank-1 array(‘D’) with bounds (ly)]
overwrite_y [input int, optional] Default: 0
offx [input int, optional] Default: 0
incy [input int, optional] Default: 1
offy [input int, optional] Default: 0
lower [input int, optional] Default: 0

scipy.linalg.blas.zher

scipy.linalg.blas.zher(alpha, x[, lower, incx, offx, n, a, overwrite_a]) = <fortran object>

Wrapper for zher.

Parameters

alpha [input complex]
x [input rank-1 array(‘D’) with bounds (*)]

Returns

a [rank-2 array(‘D’) with bounds (n,n)]

Other Parameters

lower [input int, optional] Default: 0
incy [input int, optional] Default: 1
offx [input int, optional] Default: 0
n [input int, optional] Default: (len(x)-1-offx)/abs(incx)+1
a [input rank-2 array(‘D’) with bounds (n,n)]
overwrite_a [input int, optional] Default: 0
scipy.linalg.blas.zher2

scipy.linalg.blas.zher2(alpha, x, y[, lower, incx, offx, incy, offy, n, a, overwrite_a]) = <fortran object>

Wrapper for zher2.

Parameters

- alpha [input complex]
- x [input rank-1 array(‘D’) with bounds (*)]
- y [input rank-1 array(‘D’) with bounds (*)]

Returns

- a [rank-2 array(‘D’) with bounds (n,n)]

Other Parameters

- lower [input int, optional] Default: 0
- incx [input int, optional] Default: 1
- offx [input int, optional] Default: 0
- incy [input int, optional] Default: 1
- offy [input int, optional] Default: 0
- n [input int, optional] Default: ((len(x)-1-offx)/abs(incx)+1 <=(len(y)-1-offy)/abs(incy)+1 ?(len(x)-1-offx)/abs(incx)+1 :len(y)-1-offy)/abs(incy)+1
- a [input rank-2 array(‘D’) with bounds (n,n)]
- overwrite_a [input int, optional] Default: 0

scipy.linalg.blas.zhpmv

scipy.linalg.blas.zhpmv(n, alpha, ap, x[, incx, offx, beta, y, incy, offy, lower, overwrite_y]) = <fortran object>

Wrapper for zhpmv.

Parameters

- n [input int]
- alpha [input complex]
- ap [input rank-1 array(‘D’) with bounds (*)]
- x [input rank-1 array(‘D’) with bounds (*)]

Returns

- yout [rank-1 array(‘D’) with bounds (ly) and y storage]

Other Parameters

- incx [input int, optional] Default: 1
- offx [input int, optional] Default: 0
- beta [input complex, optional] Default: (0.0, 0.0)
- y [input rank-1 array(‘D’) with bounds (ly)]
- overwrite_y [input int, optional] Default: 0
- incy [input int, optional] Default: 0
- offy [input int, optional] Default: 1
- lower [input int, optional] Default: 0
scipy.linalg.blas.zhpr

**scipy.linalg.blas.zhpr** \( n, \alpha, x, ap[, \text{incx, offx, lower, overwrite_ap}] \) = <fortran object>

Wrapper for `zhpr`.

**Parameters**

- **n** [input int]
- **alpha** [input float]
- **x** [input rank-1 array('D') with bounds (*)]
- **ap** [input rank-1 array('D') with bounds (*)]

**Returns**

- **ap** [rank-1 array('D') with bounds (*) and ap storage]

**Other Parameters**

- **incx** [input int, optional] Default: 1
- **offx** [input int, optional] Default: 0
- **overwrite_ap** [input int, optional] Default: 0
- **lower** [input int, optional] Default: 0

scipy.linalg.blas.zhpr2

**scipy.linalg.blas.zhpr2** \( n, \alpha, x, y, ap[, \text{incx, offx, incy, offy, lower, overwrite_ap}] \) = <fortran object>

Wrapper for `zhpr2`.

**Parameters**

- **n** [input int]
- **alpha** [input float]
- **x** [input rank-1 array('D') with bounds (*)]
- **y** [input rank-1 array('D') with bounds (*)]
- **ap** [input rank-1 array('D') with bounds (*)]

**Returns**

- **ap** [rank-1 array('D') with bounds (*) and ap storage]

**Other Parameters**

- **incx** [input int, optional] Default: 1
- **offx** [input int, optional] Default: 0
- **incy** [input int, optional] Default: 1
- **offy** [input int, optional] Default: 0
- **overwrite_ap** [input int, optional] Default: 0
- **lower** [input int, optional] Default: 0
scipy.linalg.blas.ztbmv

scipy.linalg.blas.ztbmv (k, a, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>
Wrapper for ztbmv.

Parameters

k [input int]
a [input rank-2 array('D') with bounds (lda,n)]
x [input rank-1 array('D') with bounds (*)]

Returns

xout [rank-1 array('D') with bounds (*) and x storage]

Other Parameters

overwrite_x [input int, optional] Default: 0
incx [input int, optional] Default: 1
offx [input int, optional] Default: 0
lower [input int, optional] Default: 0
trans [input int, optional] Default: 0
diag [input int, optional] Default: 0

scipy.linalg.blas.ztbsv

scipy.linalg.blas.ztbsv (k, a, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>
Wrapper for ztbsv.

Parameters

k [input int]
a [input rank-2 array('D') with bounds (lda,n)]
x [input rank-1 array('D') with bounds (*)]

Returns

xout [rank-1 array('D') with bounds (*) and x storage]

Other Parameters

overwrite_x [input int, optional] Default: 0
incx [input int, optional] Default: 1
offx [input int, optional] Default: 0
lower [input int, optional] Default: 0
trans [input int, optional] Default: 0
diag [input int, optional] Default: 0

scipy.linalg.blas.ztpmv

scipy.linalg.blas.ztpmv (n, ap, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>
Wrapper for ztpmv.

Parameters

n [input int]
ap [input rank-1 array('D') with bounds (*)]
x [input rank-1 array('D') with bounds (*)]

Returns

xout [rank-1 array('D') with bounds (*) and x storage]

Other Parameters

overwrite_x
[input int, optional] Default: 0

incx [input int, optional] Default: 1

offx [input int, optional] Default: 0

lower [input int, optional] Default: 0

trans [input int, optional] Default: 0

diag [input int, optional] Default: 0

scipy.linalg.blas.ztrmv

scipy.linalg.blas.ztrmv(a, x[, offx, incx, lower, trans, diag, overwrite_x]) = <fortran object>
Wrapper for ztrmv.

Parameters

a [input rank-2 array('D') with bounds (n,n)]

x [input rank-1 array('D') with bounds (*)]

Returns

x [rank-1 array('D') with bounds (*)]

Other Parameters

overwrite_x
[input int, optional] Default: 0

offx [input int, optional] Default: 0

incx [input int, optional] Default: 1

lower [input int, optional] Default: 0

trans [input int, optional] Default: 0

diag [input int, optional] Default: 0

scipy.linalg.blas.ztrsv

scipy.linalg.blas.ztrsv(a, x[, incx, offx, lower, trans, diag, overwrite_x]) = <fortran object>
Wrapper for ztrsv.

Parameters

a [input rank-2 array('D') with bounds (n,n)]

x [input rank-1 array('D') with bounds (*)]

Returns

xout [rank-1 array('D') with bounds (*) and x storage]

Other Parameters

overwrite_x
[input int, optional] Default: 0

incx [input int, optional] Default: 1

offx [input int, optional] Default: 0

lower [input int, optional] Default: 0

trans [input int, optional] Default: 0

diag [input int, optional] Default: 0
scipy.linalg.blas.zsyr

\[ \text{zsyr}(\alpha, x[, \text{lower}, \text{incx}, \text{offx}, n, a, \text{overwrite}_a]) = \langle\text{fortran object}\rangle \]

Wrapper for \text{zsyr}.

**Parameters**

- \(\alpha\) [input complex]
- \(x\) [input rank-1 array('D') with bounds (*)]

**Returns**

- \(a\) [rank-2 array('D') with bounds (n,n)]

**Other Parameters**

- \(\text{lower}\) [input int, optional] Default: 0
- \(\text{incx}\) [input int, optional] Default: 1
- \(\text{offx}\) [input int, optional] Default: 0
- \(n\) [input int, optional] Default: (len(x)-1-offx)/abs(incx)+1
- \(a\) [input rank-2 array('D') with bounds (n,n)]
- \(\text{overwrite}_a\) [input int, optional] Default: 0

**scipy.linalg.blas.sgemm**

```python
scipy.linalg.blas.sgemm(alpha, a, b[, beta, c, trans_a, trans_b, overwrite_c]) = <fortran object>
```

Wrapper for `sgemm`.

**Parameters**
- `alpha` [input float]
- `a` [input rank-2 array('f') with bounds (lda,ka)]
- `b` [input rank-2 array('f') with bounds (ldb,kb)]

**Returns**
- `c` [rank-2 array('f') with bounds (m,n)]

**Other Parameters**
- `beta` [input float, optional] Default: 0.0
- `c` [input rank-2 array('f') with bounds (m,n)]
- `overwrite_c` [input int, optional] Default: 0
- `trans_a` [input int, optional] Default: 0
- `trans_b` [input int, optional] Default: 0

**scipy.linalg.blas.ssymm**

```python
scipy.linalg.blas.ssymm(alpha, a, b[, beta, c, side, lower, overwrite_c]) = <fortran object>
```

Wrapper for `ssymm`.

**Parameters**
- `alpha` [input float]
- `a` [input rank-2 array('f') with bounds (lda,ka)]
- `b` [input rank-2 array('f') with bounds (ldb,kb)]

**Returns**
- `c` [rank-2 array('f') with bounds (m,n)]

**Other Parameters**
- `beta` [input float, optional] Default: 0.0
- `c` [input rank-2 array('f') with bounds (m,n)]
- `overwrite_c` [input int, optional] Default: 0
- `side` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
scipy.linalg.blas.syr2k

`scipy.linalg.blas.syr2k(alpha, a[, beta, c, trans, lower, overwrite_c]) = <fortran object>`

Wrapper for `syr2k`.

**Parameters**

- **alpha**: [input float]
- **a**: [input rank-2 array('f') with bounds (lda,ka)]
- **b**: [input rank-2 array('f') with bounds (ldb,kb)]

**Returns**

- **c**: [rank-2 array('f') with bounds (n,n)]

**Other Parameters**

- **beta**: [input float, optional] Default: 0.0
- **c**: [input rank-2 array('f') with bounds (n,n)]
- **overwrite_c**: [input int, optional] Default: 0
- **trans**: [input int, optional] Default: 0
- **lower**: [input int, optional] Default: 0

scipy.linalg.blas.syrk

`scipy.linalg.blas.syrk(alpha, a[, beta, c, trans, lower, overwrite_c]) = <fortran object>`

Wrapper for `syrk`.

**Parameters**

- **alpha**: [input float]
- **a**: [input rank-2 array('f') with bounds (lda,ka)]

**Returns**

- **c**: [rank-2 array('f') with bounds (n,n)]

**Other Parameters**

- **beta**: [input float, optional] Default: 0.0
- **c**: [input rank-2 array('f') with bounds (n,n)]
- **overwrite_c**: [input int, optional] Default: 0
- **trans**: [input int, optional] Default: 0
- **lower**: [input int, optional] Default: 0

scipy.linalg.blas.strmm

`scipy.linalg.blas.strmm(alpha, a[, side, lower, trans_a, diag, overwrite_b]) = <fortran object>`

Wrapper for `strmm`.

**Parameters**

- **alpha**: [input float]
- **a**: [input rank-2 array('f') with bounds (lda,k)]
- **b**: [input rank-2 array('f') with bounds (ldb,n)]

**Returns**

- **b**: [rank-2 array('f') with bounds (ldb,n)]

**Other Parameters**
overwrite_b
   [input int, optional] Default: 0
side  [input int, optional] Default: 0
lower [input int, optional] Default: 0
trans_a [input int, optional] Default: 0
diag  [input int, optional] Default: 0

scipy.linalg.blas.strsm

scipy.linalg.blas.strsm(alpha, a, b[, side, lower, trans_a, diag, overwrite_b]) = <fortran object>
Wrapper for strsm.

Parameters
alpha [input float]
a [input rank-2 array('f') with bounds (lda,*)]
b [input rank-2 array('f') with bounds (ldb,n)]

Returns
x [rank-2 array('f') with bounds (ldb,n) and b storage]

Other Parameters
overwrite_b
   [input int, optional] Default: 0
side  [input int, optional] Default: 0
lower [input int, optional] Default: 0
trans_a [input int, optional] Default: 0
diag  [input int, optional] Default: 0

scipy.linalg.blas.dgemm

scipy.linalg.blas.dgemm(alpha, a, b[, beta, c, trans_a, trans_b, overwrite_c]) = <fortran object>
Wrapper for dgemm.

Parameters
alpha [input float]
a [input rank-2 array('d') with bounds (lda,ka)]
b [input rank-2 array('d') with bounds (ldb,kb)]

Returns
c [rank-2 array('d') with bounds (m,n)]

Other Parameters
beta [input float, optional] Default: 0.0
c [input rank-2 array('d') with bounds (m,n)]
overwrite_c
   [input int, optional] Default: 0
trans_a [input int, optional] Default: 0
trans_b [input int, optional] Default: 0
scipy.linalg.blas.dsymm

scipy.linalg.blas.dsymm(alpha, a, b[, beta, c, side, lower, overwrite_c]) = <fortran object>

Wrapper for dsymm.

Parameters

alpha [input float]
a [input rank-2 array('d') with bounds (lda,ka)]
b [input rank-2 array('d') with bounds (ldb,kb)]

Returns

c [rank-2 array('d') with bounds (m,n)]

Other Parameters

beta [input float, optional] Default: 0.0

scipy.linalg.blas.dsyrk

scipy.linalg.blas.dsyrk(alpha, a[, beta, c, trans, lower, overwrite_c]) = <fortran object>

Wrapper for dsyrk.

Parameters

alpha [input float]
a [input rank-2 array('d') with bounds (lda,ka)]

Returns

c [rank-2 array('d') with bounds (n,n)]

Other Parameters

beta [input float, optional] Default: 0.0

trans [input int, optional] Default: 0

lower [input int, optional] Default: 0
\[ \text{beta} \quad \text{[input float, optional] Default: 0.0} \]
\[ c \quad \text{[input rank-2 array('d') with bounds (n,n)]} \]
\[ \text{overwrite}_c \quad \text{[input int, optional] Default: 0} \]
\[ \text{trans} \quad \text{[input int, optional] Default: 0} \]
\[ \text{lower} \quad \text{[input int, optional] Default: 0} \]

**scipy.linalg.blas.dtrmm**

\[ \text{scipy.linalg.blas.dtrmm}(\alpha, a, b[, \text{side}, \text{lower}, \text{trans}_a, \text{diag}, \text{overwrite}_b]) = \text{<fortran object>} \]

Wrapper for \texttt{dtrmm}.

**Parameters**

\[ \alpha \quad \text{[input float]} \]
\[ a \quad \text{[input rank-2 array('d') with bounds (lda,k)]} \]
\[ b \quad \text{[input rank-2 array('d') with bounds (ldb,n)]} \]

**Returns**

\[ b \quad \text{[rank-2 array('d') with bounds (ldb,n)]} \]

**Other Parameters**

\[ \text{overwrite}_b \quad \text{[input int, optional] Default: 0} \]
\[ \text{side} \quad \text{[input int, optional] Default: 0} \]
\[ \text{lower} \quad \text{[input int, optional] Default: 0} \]
\[ \text{trans}_a \quad \text{[input int, optional] Default: 0} \]
\[ \text{diag} \quad \text{[input int, optional] Default: 0} \]

**scipy.linalg.blas.dtrsm**

\[ \text{scipy.linalg.blas.dtrsm}(\alpha, a, b[, \text{side}, \text{lower}, \text{trans}_a, \text{diag}, \text{overwrite}_b]) = \text{<fortran object>} \]

Wrapper for \texttt{dtrsm}.

**Parameters**

\[ \alpha \quad \text{[input float]} \]
\[ a \quad \text{[input rank-2 array('d') with bounds (lda,*)]} \]
\[ b \quad \text{[input rank-2 array('d') with bounds (ldb,n)]} \]

**Returns**

\[ x \quad \text{[rank-2 array('d') with bounds (ldb,n) and b storage]} \]

**Other Parameters**

\[ \text{overwrite}_b \quad \text{[input int, optional] Default: 0} \]
\[ \text{side} \quad \text{[input int, optional] Default: 0} \]
\[ \text{lower} \quad \text{[input int, optional] Default: 0} \]
\[ \text{trans}_a \quad \text{[input int, optional] Default: 0} \]
\[ \text{diag} \quad \text{[input int, optional] Default: 0} \]
scipy.linalg.blas.cgemm

Wrapper for cgemm.

Parameters

- alpha [input complex]
- a [input rank-2 array('F') with bounds (lda,ka)]
- b [input rank-2 array('F') with bounds (ldb,kb)]

Returns

- c [rank-2 array('F') with bounds (m,n)]

Other Parameters

- beta [input complex, optional] Default: (0.0, 0.0)
- c [input rank-2 array('F') with bounds (m,n)]
- overwrite_c [input int, optional] Default: 0
- trans_a [input int, optional] Default: 0
- trans_b [input int, optional] Default: 0

scipy.linalg.blas.chemm

Wrapper for chemm.

Parameters

- alpha [input complex]
- a [input rank-2 array('F') with bounds (lda,ka)]
- b [input rank-2 array('F') with bounds (ldb,kb)]

Returns

- c [rank-2 array('F') with bounds (m,n)]

Other Parameters

- beta [input complex, optional] Default: (0.0, 0.0)
- c [input rank-2 array('F') with bounds (m,n)]
- overwrite_c [input int, optional] Default: 0
- side [input int, optional] Default: 0
- lower [input int, optional] Default: 0

scipy.linalg.blas.cher2k

Wrapper for cher2k.

Parameters

- alpha [input complex]
- a [input rank-2 array('F') with bounds (lda,ka)]
- b [input rank-2 array('F') with bounds (ldb,kb)]

Returns

- c [rank-2 array('F') with bounds (n,n)]

Other Parameters
scipy.linalg.blas.cherk

scipy.linalg.blas.cherk(alpha, a[, beta, c, trans, lower, overwrite_c]) = <fortran object>
Wrapper for cherk.

Parameters

alpha [input complex]
a [input rank-2 array('F') with bounds (lda,ka)]

Returns
c [rank-2 array('F') with bounds (n,n)]

Other Parameters

beta [input complex, optional] Default: (0.0, 0.0)
c [input rank-2 array('F') with bounds (n,n)]
overwrite_c [input int, optional] Default: 0
trans [input int, optional] Default: 0
lower [input int, optional] Default: 0

scipy.linalg.blas.csymm

scipy.linalg.blas.csymm(alpha, a[, beta, c, side, lower, overwrite_c]) = <fortran object>
Wrapper for csymm.

Parameters

alpha [input complex]
a [input rank-2 array('F') with bounds (lda,ka)]
b [input rank-2 array('F') with bounds (ldb,kb)]

Returns
c [rank-2 array('F') with bounds (m,n)]

Other Parameters

beta [input complex, optional] Default: (0.0, 0.0)
c [input rank-2 array('F') with bounds (m,n)]
overwrite_c [input int, optional] Default: 0
side [input int, optional] Default: 0
lower [input int, optional] Default: 0
scipy.linalg.blas.csyr2k

scipy.linalg.blas.csyr2k(alpha, a[, beta, c, trans, lower, overwrite_c]) = <fortran object>

Wrapper for csyr2k.

Parameters

alpha [input complex]
a [input rank-2 array('F') with bounds (lda,ka)]
b [input rank-2 array('F') with bounds (ldb,kb)]

Returns

c [rank-2 array('F') with bounds (n,n)]

Other Parameters

beta [input complex, optional] Default: (0.0, 0.0)
c [input rank-2 array('F') with bounds (n,n)]
overwrite_c [input int, optional] Default: 0
trans [input int, optional] Default: 0
lower [input int, optional] Default: 0

scipy.linalg.blas.csyrk

scipy.linalg.blas.csyrk(alpha, a[, beta, c, trans, lower, overwrite_c]) = <fortran object>

Wrapper for csyrk.

Parameters

alpha [input complex]
a [input rank-2 array('F') with bounds (lda,ka)]

Returns

c [rank-2 array('F') with bounds (n,n)]

Other Parameters

beta [input complex, optional] Default: (0.0, 0.0)
c [input rank-2 array('F') with bounds (n,n)]
overwrite_c [input int, optional] Default: 0
trans [input int, optional] Default: 0
lower [input int, optional] Default: 0

scipy.linalg.blas.ctrmn

scipy.linalg.blas.ctrmn(alpha, a[, side, lower, trans_a, diag, overwrite_b]) = <fortran object>

Wrapper for ctrmm.

Parameters

alpha [input complex]
a [input rank-2 array('F') with bounds (lda,k)]
b [input rank-2 array('F') with bounds (ldb,n)]

Returns

b [rank-2 array('F') with bounds (ldb,n)]

Other Parameters
overwrite_b  
    [input int, optional] Default: 0
side  
    [input int, optional] Default: 0
lower  
    [input int, optional] Default: 0
trans_a  
    [input int, optional] Default: 0
diag  
    [input int, optional] Default: 0

scipy.linalg.blas ctrsm

scipy.linalg.blas.ctrsm(alpha, a[, side, lower, trans_a, diag, overwrite_b]) = <fortran object>
Wrapper for ctzsm.

Parameters

alpha  
    [input complex]
a  
    [input rank-2 array('F') with bounds (lda,*)]
b  
    [input rank-2 array('F') with bounds (ldb,n)]

Returns

x  
    [rank-2 array('F') with bounds (ldb,n) and b storage]

Other Parameters

overwrite_b  
    [input int, optional] Default: 0
side  
    [input int, optional] Default: 0
lower  
    [input int, optional] Default: 0
trans_a  
    [input int, optional] Default: 0
diag  
    [input int, optional] Default: 0

scipy.linalg.blas zgemm

scipy.linalg.blas.zgemm(alpha, a[, beta, c, trans_a, trans_b, overwrite_c]) = <fortran object>
Wrapper for zgemm.

Parameters

alpha  
    [input complex]
a  
    [input rank-2 array('D') with bounds (lda,ka)]
b  
    [input rank-2 array('D') with bounds (ldb,kb)]

Returns

c  
    [rank-2 array('D') with bounds (m,n)]

Other Parameters

beta  
    [input complex, optional] Default: (0.0, 0.0)
c  
    [input rank-2 array('D') with bounds (m,n)]
overwrite_c  
    [input int, optional] Default: 0
trans_a  
    [input int, optional] Default: 0
trans_b  
    [input int, optional] Default: 0
scipy.linalg.blas.zhemm

Wrapper for zhemm.

Parameters

- **alpha** [input complex]
- **a** [input rank-2 array('D') with bounds (lda,ka)]
- **b** [input rank-2 array('D') with bounds (ldb,kb)]

Returns

- **c** [rank-2 array('D') with bounds (m,n)]

Other Parameters

- **beta** [input complex, optional] Default: (0.0, 0.0)
- **c** [input rank-2 array('D') with bounds (m,n)]
- **overwrite_c** [input int, optional] Default: 0
- **side** [input int, optional] Default: 0
- **lower** [input int, optional] Default: 0

scipy.linalg.blas.zher2k

Wrapper for zher2k.

Parameters

- **alpha** [input complex]
- **a** [input rank-2 array('D') with bounds (lda,ka)]
- **b** [input rank-2 array('D') with bounds (ldb,kb)]

Returns

- **c** [rank-2 array('D') with bounds (n,n)]

Other Parameters

- **beta** [input complex, optional] Default: (0.0, 0.0)
- **c** [input rank-2 array('D') with bounds (n,n)]
- **overwrite_c** [input int, optional] Default: 0
- **trans** [input int, optional] Default: 0
- **lower** [input int, optional] Default: 0

scipy.linalg.blas.zherk

Wrapper for zherk.

Parameters

- **alpha** [input complex]
- **a** [input rank-2 array('D') with bounds (lda,ka)]

Returns

- **c** [rank-2 array('D') with bounds (n,n)]

Other Parameters
scipy.linalg.blas.zsymm

scipy.linalg.blas.zsymm(alpha, a, b[, beta, c, side, lower, overwrite_c]) = <fortran object>

Wrapper for zsymm.

Parameters

alpha [input complex]

a [input rank-2 array('D') with bounds (lda,ka)]

b [input rank-2 array('D') with bounds (ldb,kb)]

Returns

c [rank-2 array('D') with bounds (m,n)]

Other Parameters

beta [input complex, optional] Default: (0.0, 0.0)

c [input rank-2 array('D') with bounds (m,n)]

overwrite_c [input int, optional] Default: 0

side [input int, optional] Default: 0

lower [input int, optional] Default: 0

scipy.linalg.blas.zsyr2k

scipy.linalg.blas.zsyr2k(alpha, a, b[, beta, c, trans, lower, overwrite_c]) = <fortran object>

Wrapper for zsyr2k.

Parameters

alpha [input complex]

a [input rank-2 array('D') with bounds (lda,ka)]

b [input rank-2 array('D') with bounds (ldb,kb)]

Returns

c [rank-2 array('D') with bounds (n,n)]

Other Parameters

beta [input complex, optional] Default: (0.0, 0.0)

c [input rank-2 array('D') with bounds (n,n)]

overwrite_c [input int, optional] Default: 0

trans [input int, optional] Default: 0

lower [input int, optional] Default: 0
scipy.linalg.blas.zsyrk

`scipy.linalg.blas.zsyrk(alpha[, beta, c, trans, lower, overwrite_c]) = <fortran object>`

Wrapper for zsyrk.

**Parameters**

- `alpha` [input complex]
- `a` [input rank-2 array('D') with bounds (lda,ka)]

**Returns**

- `c` [rank-2 array('D') with bounds (n,n)]

**Other Parameters**

- `beta` [input complex, optional] Default: (0.0, 0.0)
- `c` [input rank-2 array('D') with bounds (n,n)]
- `overwrite_c` [input int, optional] Default: 0
- `trans` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0

scipy.linalg.blas.ztrmm

`scipy.linalg.blas.ztrmm(alpha, a[, b, side, lower, trans_a, diag, overwrite_b]) = <fortran object>`

Wrapper for ztrmm.

**Parameters**

- `alpha` [input complex]
- `a` [input rank-2 array('D') with bounds (lda,k)]
- `b` [input rank-2 array('D') with bounds (ldb,n)]

**Returns**

- `b` [rank-2 array('D') with bounds (ldb,n)]

**Other Parameters**

- `overwrite_b` [input int, optional] Default: 0
- `side` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
- `trans_a` [input int, optional] Default: 0
- `diag` [input int, optional] Default: 0

scipy.linalg.blas.ztrsm

`scipy.linalg.blas.ztrsm(alpha, a, b[, side, lower, trans_a, diag, overwrite_b]) = <fortran object>`

Wrapper for ztrsm.

**Parameters**

- `alpha` [input complex]
- `a` [input rank-2 array('D') with bounds (lda,*)]
- `b` [input rank-2 array('D') with bounds (ldb,n)]

**Returns**

- `x` [rank-2 array('D') with bounds (ldb,n) and b storage]

**Other Parameters**

3.3. API definition 847
3.3.12 Low-level LAPACK functions (scipy.linalg.lapack)

This module contains low-level functions from the LAPACK library.

The \texttt{gegv} family of routines have been removed from LAPACK 3.6.0 and have been deprecated in SciPy 0.17.0. They will be removed in a future release.

New in version 0.12.0.

\textbf{Note:} The common \texttt{overwrite_<>} option in many routines, allows the input arrays to be overwritten to avoid extra memory allocation. However this requires the array to satisfy two conditions which are memory order and the data type to match exactly the order and the type expected by the routine.

As an example, if you pass a double precision float array to any routine which expects single precision arguments, \texttt{f2py} will create an intermediate array to match the argument types and overwriting will be performed on that intermediate array.

Similarly, if a C-contiguous array is passed, \texttt{f2py} will pass a FORTRAN-contiguous array internally. Please make sure that these details are satisfied. More information can be found in the \texttt{f2py} documentation.

\textbf{Warning:} These functions do little to no error checking. It is possible to cause crashes by mis-using them, so prefer using the higher-level routines in \texttt{scipy.linalg}.

Finding functions

\begin{verbatim}
scipy.linalg.lapack.get_lapack_funcs(names[, arrays, dtype, ilp64])

Return available LAPACK function objects from names.

scipy.linalg.lapack.get_lapack_funcs(names, arrays=(), dtype=None, ilp64=False)

Return available LAPACK function objects from names.

Arrays are used to determine the optimal prefix of LAPACK routines.

Parameters

names [str or sequence of str] Name(s) of LAPACK functions without type prefix.

arrays [sequence of ndarrays, optional] Arrays can be given to determine optimal prefix of LAPACK routines. If not given, double-precision routines will be used, otherwise the most generic type in arrays will be used.

dtype [str or dtype, optional] Data-type specifier. Not used if arrays is non-empty.

ilp64 [{True, False, 'preferred'}, optional] Whether to return ILP64 routine variant. Choosing 'preferred' returns ILP64 routine if available, and otherwise the 32-bit routine. Default: False

Returns

..."
\end{verbatim}
**Notes**

This routine automatically chooses between Fortran/C interfaces. Fortran code is used whenever possible for arrays with column major order. In all other cases, C code is preferred.

In LAPACK, the naming convention is that all functions start with a type prefix, which depends on the type of the principal matrix. These can be one of {'s', 'd', 'c', 'z'} for the NumPy types {float32, float64, complex64, complex128} respectively, and are stored in attribute `typecode` of the returned functions.

**Examples**

Suppose we would like to use ‘?lange’ routine which computes the selected norm of an array. We pass our array in order to get the correct ‘lange’ flavor.

```python
>>> import scipy.linalg as LA
>>> rng = np.random.default_rng()
>>> a = rng.random((3,2))
>>> x_lange = LA.get_lapack_funcs('lange', (a,))
>>> x_lange.typecode
'd'
>>> x_lange = LA.get_lapack_funcs('lange', (a*1j,))
>>> x_lange.typecode
'z'
```

Several LAPACK routines work best when its internal WORK array has the optimal size (big enough for fast computation and small enough to avoid waste of memory). This size is determined also by a dedicated query to the function which is often wrapped as a standalone function and commonly denoted as `##_lwork`. Below is an example for `zsysv`.

```python
>>> import scipy.linalg as LA
>>> rng = np.random.default_rng()
>>> a = rng.random((1000,1000))
>>> b = rng.random((1000,1)) * 1j
>>> # We pick up zsysv and zsysv_lwork due to b array
... xsysv, xlwork = LA.get_lapack_funcs(('sysv', 'sysv_lwork'), (a, b))
>>> opt_lwork, _ = xlwork(a.shape[0])  # returns a complex for 'z' prefix
>>> udut, ipiv, x, info = xsysv(a, b, lwork=int(opt_lwork.real))
```

**All functions**

- `sgbsv(kl,ku,ab,b,[overwrite_ab,overwrite_b])`  Wrapper for `sgbsv`.
- `dgbsv(kl,ku,ab,b,[overwrite_ab,overwrite_b])`  Wrapper for `dgbsv`.
- `cgbsv(kl,ku,ab,b,[overwrite_ab,overwrite_b])`  Wrapper for `cgbsv`.
- `zgbsv(kl,ku,ab,b,[overwrite_ab,overwrite_b])`  Wrapper for `zgbsv`.
- `sgbtrf(ab,kl,ku,[m,n,ldab,overwrite_ab])`  Wrapper for `sgbtrf`.
- `dgbtrf(ab,kl,ku,[m,n,ldab,overwrite_ab])`  Wrapper for `dgbtrf`.
- `cgbtrf(ab,kl,ku,[m,n,ldab,overwrite_ab])`  Wrapper for `cgbtrf`.
- `zgbtrf(ab,kl,ku,[m,n,ldab,overwrite_ab])`  Wrapper for `zgbtrf`.

**scipy.linalg.lapack.sgbsv**

`scipy.linalg.lapack.sgbsv(kl, ku, ab[, overwrite_ab, overwrite_b])` = <fortran object>

Wrapper for `sgbsv`.

**Parameters**

- `kl` [input int]
- `ku` [input int]
- `ab` [input rank-2 array('f') with bounds (1 + 2 * kl + ku,n)]
- `b` [input rank-2 array('f') with bounds (n,nrhs)]

**Returns**

- `lub` [rank-2 array('f') with bounds (1 + 2 * kl + ku,n) and ab storage]
- `piv` [rank-1 array('i') with bounds (n)]
- `x` [rank-2 array('f') with bounds (n,nrhs) and b storage]
- `info` [int]

**Other Parameters**

- `overwrite_ab` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0

---

3.3. API definition 861

scipy.linalg.lapack.dgbsv

scipy.linalg.lapack.dgbsv(kl, ku, ab[, overwrite_ab, overwrite_b]) = <fortran object>
Wrapper for dgbsv.

Parameters
kl [input int]
ku [input int]
ab [input rank-2 array('d') with bounds (1 + 2 * kl + ku,n)]
b [input rank-2 array('d') with bounds (n,nrhs)]

Returns
lub [rank-2 array('d') with bounds (1 + 2 * kl + ku,n) and ab storage]
piv [rank-1 array('i') with bounds (n)]
x [rank-2 array('d') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters
overwrite_ab [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.cgbsv

scipy.linalg.lapack.cgbsv(kl, ku, ab[, overwrite_ab, overwrite_b]) = <fortran object>
Wrapper for cgbsv.

Parameters
kl [input int]
ku [input int]
ab [input rank-2 array('F') with bounds (1 + 2 * kl + ku,n)]
b [input rank-2 array('F') with bounds (n,nrhs)]

Returns
lub [rank-2 array('F') with bounds (1 + 2 * kl + ku,n) and ab storage]
piv [rank-1 array('i') with bounds (n)]
x [rank-2 array('F') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters
overwrite_ab [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
scipy.linalg.lapack.zgbsv

`scipy.linalg.lapack.zgbsv(kl, ku, ab[, overwrite_ab, overwrite_b]) = <fortran object>`

Wrapper for zgbsv.

**Parameters**

- **kl** [input int]
- **ku** [input int]
- **ab** [input rank-2 array('D') with bounds (1 + 2 * kl + ku, n)]
- **b** [input rank-2 array('D') with bounds (n, nrhs)]

**Returns**

- **lub** [rank-2 array('D') with bounds (1 + 2 * kl + ku, n) and ab storage]
- **piv** [rank-1 array('i') with bounds (n)]
- **x** [rank-2 array('D') with bounds (n, nrhs) and b storage]
- **info** [int]

**Other Parameters**

- **overwrite_ab**
  - [input int, optional] Default: 0
- **overwrite_b**
  - [input int, optional] Default: 0

scipy.linalg.lapack.sgbtrf

`scipy.linalg.lapack.sgbtrf(ab, kl, ku[, m, n, ldab, overwrite_ab]) = <fortran object>`

Wrapper for sgbtrf.

**Parameters**

- **ab** [input rank-2 array('F') with bounds (ldab, n)]
- **kl** [input int]
- **ku** [input int]

**Returns**

- **lu** [rank-2 array('F') with bounds (ldab, n) and ab storage]
- **ipiv** [rank-1 array('i') with bounds (MIN(m, n))]
- **info** [int]

**Other Parameters**

- **m** [input int, optional] Default: shape(ab, 1)
- **n** [input int, optional] Default: shape(ab, 1)
- **overwrite_ab**
  - [input int, optional] Default: 0
- **ldab** [input int, optional] Default: max(shape(ab, 0), 1)
scipy.linalg.lapack.dgbtrf

scipy.linalg.lapack.dgbtrf(ab, kl, ku[, m, n, ldab, overwrite_ab]) = <fortran object>

Wrapper for dgbtrf.

Parameters

- **ab**: [input rank-2 array('d') with bounds (ldab,n)]
- **kl**: [input int]
- **ku**: [input int]

Returns

- **lu**: [rank-2 array('d') with bounds (ldab,n) and ab storage]
- **ipiv**: [rank-1 array('i') with bounds (MIN(m, n))]
- **info**: [int]

Other Parameters

- **m**: [input int, optional] Default: shape(ab,1)
- **n**: [input int, optional] Default: shape(ab,1)
- **overwrite_ab**: [input int, optional] Default: 0
- **ldab**: [input int, optional] Default: max(shape(ab,0),1)

scipy.linalg.lapack.cgbtrf

scipy.linalg.lapack.cgbtrf(ab, kl, ku[, m, n, ldab, overwrite_ab]) = <fortran object>

Wrapper for cgbtrf.

Parameters

- **ab**: [input rank-2 array('F') with bounds (ldab,n)]
- **kl**: [input int]
- **ku**: [input int]

Returns

- **lu**: [rank-2 array('F') with bounds (ldab,n) and ab storage]
- **ipiv**: [rank-1 array('i') with bounds (MIN(m, n))]
- **info**: [int]

Other Parameters

- **m**: [input int, optional] Default: shape(ab,1)
- **n**: [input int, optional] Default: shape(ab,1)
- **overwrite_ab**: [input int, optional] Default: 0
- **ldab**: [input int, optional] Default: max(shape(ab,0),1)

scipy.linalg.lapack.zgbtrf

scipy.linalg.lapack.zgbtrf(ab, kl, ku[, m, n, ldab, overwrite_ab]) = <fortran object>

Wrapper for zgbtrf.

Parameters

- **ab**: [input rank-2 array('D') with bounds (ldab,n)]
- **kl**: [input int]
- **ku**: [input int]

Returns

- **lu**: [rank-2 array('D') with bounds (ldab,n) and ab storage]
- **ipiv**: [rank-1 array('i') with bounds (MIN(m, n))]
- **info**: [int]

Other Parameters

- **m**: [input int, optional] Default: shape(ab,1)
- **n**: [input int, optional] Default: shape(ab,1)
- **overwrite_ab**: [input int, optional] Default: 0
- **ldab**: [input int, optional] Default: max(shape(ab,0),1)

lu [rank-2 array('D') with bounds (ldab,n) and ab storage]
ipiv [rank-1 array('i') with bounds (MIN(m, n))]
info [int]

Other Parameters
m [input int, optional] Default: shape(ab,1)
n [input int, optional] Default: shape(ab,1)
overwrite_ab [input int, optional] Default: 0
ldab [input int, optional] Default: max(shape(ab,0),1)

scipy.linalg.lapack.sgbtrs

scipy.linalg.lapack.sgbtrs(ab, kl, ku, b, ipiv[, trans, n, ldab, ldb, overwrite_b]) = <fortran object>
Wrapper for sgbtrs.

Parameters
ab [input rank-2 array('f') with bounds (ldab,n)]
kl [input int]
ku [input int]
b [input rank-2 array('f') with bounds (ldb,nrhs)]
ipiv [input rank-1 array('i') with bounds (n)]

Returns
x [rank-2 array('f') with bounds (ldb,nrhs) and b storage]
info [int]

Other Parameters
overwrite_b [input int, optional] Default: 0
trans [input int, optional] Default: 0
n [input int, optional] Default: shape(ab,1)
ldab [input int, optional] Default: shape(ab,0)
ldb [input int, optional] Default: shape(b,0)

scipy.linalg.lapack.dgbtrs

scipy.linalg.lapack.dgbtrs(ab, kl, ku, b, ipiv[, trans, n, ldab, ldb, overwrite_b]) = <fortran object>
Wrapper for dgbtrs.

Parameters
ab [input rank-2 array('d') with bounds (ldab,n)]
kl [input int]
ku [input int]
b [input rank-2 array('d') with bounds (ldb,nrhs)]
ipiv [input rank-1 array('i') with bounds (n)]

Returns
x [rank-2 array('d') with bounds (ldb,nrhs) and b storage]
info [int]

Other Parameters
overwrite_b
    [input int, optional] Default: 0
trans
    [input int, optional] Default: 0
n
    [input int, optional] Default: shape(ab,1)
l nab
    [input int, optional] Default: shape(ab,0)
l db
    [input int, optional] Default: shape(b,0)

scipy.linalg.lapack.cgbtrs
scipy.linalg.lapack.cgbtrs(ab, kl, ku, b, ipiv[, trans, n, ldab, ldb, overwrite_b]) = <fortran object>
Wrapper for cgbtrs.

Parameters
ab
    [input rank-2 array('F') with bounds (ldab,n)]
kl
    [input int]
ku
    [input int]
b
    [input rank-2 array('F') with bounds (ldb, nrhs)]
ipiv
    [input rank-1 array('i') with bounds (n)]

Returns
x
    [rank-2 array('F') with bounds (ldb, nrhs) and b storage]
info
    [int]

Other Parameters
overwrite_b
    [input int, optional] Default: 0
trans
    [input int, optional] Default: 0
n
    [input int, optional] Default: shape(ab,1)
l nab
    [input int, optional] Default: shape(ab,0)
l db
    [input int, optional] Default: shape(b,0)

scipy.linalg.lapack.zgbtrs
scipy.linalg.lapack.zgbtrs(ab, kl, ku, b, ipiv[, trans, n, ldab, ldb, overwrite_b]) = <fortran object>
Wrapper for zgbtrs.

Parameters
ab
    [input rank-2 array('D') with bounds (ldab,n)]
kl
    [input int]
ku
    [input int]
b
    [input rank-2 array('D') with bounds (ldb, nrhs)]
ipiv
    [input rank-1 array('i') with bounds (n)]

Returns
x
    [rank-2 array('D') with bounds (ldb, nrhs) and b storage]
info
    [int]

Other Parameters
overwrite_b
    [input int, optional] Default: 0
trans
    [input int, optional] Default: 0
n
    [input int, optional] Default: shape(ab,1)
l nab
    [input int, optional] Default: shape(ab,0)
**scipy.linalg.lapack.sgebal**

```python
scipy.linalg.lapack.sgebal(a[, scale, permute, overwrite_a]) = <fortran object>
```

Wrapper for sgebal.

**Parameters**
- `a` [input rank-2 array('f') with bounds (m,n)]

**Returns**
- `ba` [rank-2 array('f') with bounds (m,n) and a storage]
- `lo` [int]
- `hi` [int]
- `pivscale` [rank-1 array('f') with bounds (n)]
- `info` [int]

**Other Parameters**
- `scale` [input int, optional] Default: 0
- `permute` [input int, optional] Default: 0
- `overwrite_a` [input int, optional] Default: 0

**scipy.linalg.lapack.dgebal**

```python
scipy.linalg.lapack.dgebal(a[, scale, permute, overwrite_a]) = <fortran object>
```

Wrapper for dgebal.

**Parameters**
- `a` [input rank-2 array('d') with bounds (m,n)]

**Returns**
- `ba` [rank-2 array('d') with bounds (m,n) and a storage]
- `lo` [int]
- `hi` [int]
- `pivscale` [rank-1 array('d') with bounds (n)]
- `info` [int]

**Other Parameters**
- `scale` [input int, optional] Default: 0
- `permute` [input int, optional] Default: 0
- `overwrite_a` [input int, optional] Default: 0

**scipy.linalg.lapack.cgebal**

```python
scipy.linalg.lapack.cgebal(a[, scale, permute, overwrite_a]) = <fortran object>
```

Wrapper for cgebal.

**Parameters**
- `a` [input rank-2 array('F') with bounds (m,n)]

**Returns**
- `ba` [rank-2 array('F') with bounds (m,n) and a storage]
- `lo` [int]
**SciPy Reference Guide, Release 1.8.0**

- `hi` [int]
- ` pivscale` [rank-1 array('f') with bounds (n)]
- ` info` [int]

**Other Parameters**
- `scale` [input int, optional] Default: 0
- `permut` e [input int, optional] Default: 0
- `overwrite_a` [input int, optional] Default: 0

**scipy.linalg.lapack.zgebal**

`scipy.linalg.lapack.zgebal(a[, scale, permute, overwrite_a]) = <fortran object>`

Wrapper for zgebal.

**Parameters**
- `a` [input rank-2 array('D') with bounds (m,n)]

**Returns**
- `ba` [rank-2 array('D') with bounds (m,n) and a storage]
- `lo` [int]
- `hi` [int]
- ` pivscale` [rank-1 array('d') with bounds (n)]
- ` info` [int]

**Other Parameters**
- `scale` [input int, optional] Default: 0
- `permut` e [input int, optional] Default: 0
- `overwrite_a` [input int, optional] Default: 0

**scipy.linalg.lapack.sgecon**

`scipy.linalg.lapack.sgecon(a, anorm[, norm]) = <fortran object>`

Wrapper for sgecon.

**Parameters**
- `a` [input rank-2 array('f') with bounds (n,n)]
- `anorm` [input float]

**Returns**
- `rcond` [float]
- `info` [int]

**Other Parameters**
- `norm` [input string(len=1), optional] Default: ‘1’
scipy.linalg.lapack.dgecon

scipy.linalg.lapack.dgecon(a, anorm[, norm]) = <fortran object>
Wrapper for dgecon.

Parameters

- a [input rank-2 array('d') with bounds (n,n)]
- anorm [input float]

Returns

- rcond [float]
- info [int]

Other Parameters

- norm [input string(len=1), optional] Default: ‘1’

scipy.linalg.lapack.cgecon

scipy.linalg.lapack.cgecon(a, anorm[, norm]) = <fortran object>
Wrapper for cgecon.

Parameters

- a [input rank-2 array('F') with bounds (n,n)]
- anorm [input float]

Returns

- rcond [float]
- info [int]

Other Parameters

- norm [input string(len=1), optional] Default: ‘1’

scipy.linalg.lapack.zgecon

scipy.linalg.lapack.zgecon(a, anorm[, norm]) = <fortran object>
Wrapper for zgecon.

Parameters

- a [input rank-2 array('D') with bounds (n,n)]
- anorm [input float]

Returns

- rcond [float]
- info [int]

Other Parameters

- norm [input string(len=1), optional] Default: ‘1’
scipy.linalg.lapack.sgeequ

scipy.linalg.lapack.sgeequ(a) = <fortran object>
Wrapper for sgeequ.

Parameters
a [input rank-2 array('f') with bounds (m,n)]

Returns
r [rank-1 array('f') with bounds (m)]
c [rank-1 array('f') with bounds (n)]
rowcnd [float]
colcnd [float]
amax [float]
info [int]

scipy.linalg.lapack.dgeequ

scipy.linalg.lapack.dgeequ(a) = <fortran object>
Wrapper for dgeequ.

Parameters
a [input rank-2 array('d') with bounds (m,n)]

Returns
r [rank-1 array('d') with bounds (m)]
c [rank-1 array('d') with bounds (n)]
rowcnd [float]
colcnd [float]
amax [float]
info [int]

scipy.linalg.lapack.cgeequ

scipy.linalg.lapack.cgeequ(a) = <fortran object>
Wrapper for cgeequ.

Parameters
a [input rank-2 array('F') with bounds (m,n)]

Returns
r [rank-1 array('f') with bounds (m)]
c [rank-1 array('f') with bounds (n)]
rowcnd [float]
colcnd [float]
amax [float]
info [int]
### scipy.linalg.lapack.zgeequ

**scipy.linalg.lapack.zgeequ**

\[
\text{scipy.linalg.lapack.zgeequ}(a) = \text{<fortran object>}
\]

Wrapper for zgeequ.

**Parameters**

- **a**
  - [input rank-2 array('D') with bounds (m,n)]

**Returns**

- **r**
  - [rank-1 array('d') with bounds (m)]
- **c**
  - [rank-1 array('d') with bounds (n)]
- **rowcnd**
  - [float]
- **colcnd**
  - [float]
- **amax**
  - [float]
- **info**
  - [int]

### scipy.linalg.lapack.sgeequb

**scipy.linalg.lapack.sgeequb**

\[
\text{scipy.linalg.lapack.sgeequb}(a) = \text{<fortran object>}
\]

Wrapper for sgeequb.

**Parameters**

- **a**
  - [input rank-2 array('f') with bounds (m,n)]

**Returns**

- **r**
  - [rank-1 array('f') with bounds (m)]
- **c**
  - [rank-1 array('f') with bounds (n)]
- **rowcnd**
  - [float]
- **colcnd**
  - [float]
- **amax**
  - [float]
- **info**
  - [int]

### scipy.linalg.lapack.dgeequb

**scipy.linalg.lapack.dgeequb**

\[
\text{scipy.linalg.lapack.dgeequb}(a) = \text{<fortran object>}
\]

Wrapper for dgeequb.

**Parameters**

- **a**
  - [input rank-2 array('d') with bounds (m,n)]

**Returns**

- **r**
  - [rank-1 array('d') with bounds (m)]
- **c**
  - [rank-1 array('d') with bounds (n)]
- **rowcnd**
  - [float]
- **colcnd**
  - [float]
- **amax**
  - [float]
- **info**
  - [int]
scipy.linalg.lapack.cgeequb

scipy.linalg.lapack.<fortran object> = cgeequb(a)

Wrapper for cgeequb.

Parameters

- **a** [input rank-2 array('F') with bounds (m,n)]

Returns

- **r** [rank-1 array('f') with bounds (m)]
- **c** [rank-1 array('F') with bounds (n)]
- **rowcnd** [float]
- **colcnd** [float]
- **amax** [float]
- **info** [int]

scipy.linalg.lapack.zgeequb

scipy.linalg.lapack.<fortran object> = zgeequb(a)

Wrapper for zgeequb.

Parameters

- **a** [input rank-2 array('D') with bounds (m,n)]

Returns

- **r** [rank-1 array('d') with bounds (m)]
- **c** [rank-1 array('D') with bounds (n)]
- **rowcnd** [float]
- **colcnd** [float]
- **amax** [float]
- **info** [int]

scipy.linalg.lapack.sgees

scipy.linalg.lapack.<fortran object> = sgees(sselect, a, compute_v, sort_t, lwork, sselect_extra_args, overwrite_a)

Wrapper for sgees.

Parameters

- **sselect** [call-back function]
- **a** [input rank-2 array('F') with bounds (n,n)]

Returns

- **t** [rank-2 array('F') with bounds (n,n) and a storage]
- **sdim** [int]
- **wr** [rank-1 array('F') with bounds (n)]
- **wi** [rank-1 array('F') with bounds (n)]
- **vs** [rank-2 array('F') with bounds (ldvs,n)]
- **work** [rank-1 array('F') with bounds (MAX(lwork, 1))]
- **info** [int]

Other Parameters

- **compute_v** [input int, optional] Default: 1
- **sort_t** [input int, optional] Default: 0
**Notes**

Call-back functions:

```python
def sselect(arg1, arg2):
    return sselect
```

**scipy.linalg.lapack.dgees**

```python
scipy.linalg.lapack.dgees(dselect, a[, compute_v, sort_t, lwork, dselect_extra_args, overwrite_a]) =
<fortran object>
```

Wrapper for dgees.

**Parameters**

- `dselect` [call-back function]
- `a` [input rank-2 array('d') with bounds (n,n)]

**Returns**

- `t` [rank-2 array('d') with bounds (n,n) and a storage]
- `sdim` [int]
- `wr` [rank-1 array('d') with bounds (n)]
- `wi` [rank-1 array('d') with bounds (n)]
- `vs` [rank-2 array('d') with bounds (ldvs,n)]
- `work` [rank-1 array('d') with bounds (MAX(lwork, 1))]  
- `info` [int]

**Other Parameters**

- `compute_v` [input int, optional] Default: 1
- `sort_t` [input int, optional] Default: 0
- `dselect_extra_args` [input tuple, optional] Default: ()
- `overwrite_a` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: max(3*n,1)
Notes

Call-back functions:

```python
def dselect(arg1, arg2):
    return dselect
```

Required arguments:
- `arg1`: `input float`
- `arg2`: `input float`

Return objects:
- `dselect`: `int`

`scipy.linalg.lapack.cgees`

`scipy.linalg.lapack.cgees(cselect, a[, compute_v, sort_t, lwork, cselect_extra_args, overwrite_a]) = <fortran object>`

Wrapper for `cgees`.

**Parameters**
- `cselect`: [call-back function]
- `a`: [input rank-2 array('F') with bounds (n,n)]

**Returns**
- `t`: [rank-2 array('F') with bounds (n,n) and a storage]
- `sdim`: [int]
- `w`: [rank-1 array('F') with bounds (n)]
- `vs`: [rank-2 array('F') with bounds (ldvs,n)]
- `work`: [rank-1 array('F') with bounds (MAX(lwork,1))]`]
- `info`: [int]

**Other Parameters**
- `compute_v`: [input int, optional] Default: 1
- `sort_t`: [input int, optional] Default: 0
- `cselect_extra_args`: [input tuple, optional] Default: ()
- `overwrite_a`: [input int, optional] Default: 0
- `lwork`: [input int, optional] Default: max(3*n,1)

**Notes**

Call-back functions:

```python
def cselect(arg):
    return cselect
```

Required arguments:
- `arg`: `input complex`

Return objects:
- `cselect`: `int`
scipy.linalg.lapack.zgees

scipy.linalg.lapack.zgees(zselect, a[, compute_v, sort_t, lwork, zselect_extra_args, overwrite_a]) =
<fortran object>

Wrapper for zgees.

Parameters

zselect [call-back function]
a [input rank-2 array('D') with bounds (n,n)]

Returns

[rank-2 array('D') with bounds (n,n) and a storage]
sdim [int]
w [rank-1 array('D') with bounds (n)]
vs [rank-2 array('D') with bounds (ldvs,n)]
work [rank-1 array('D') with bounds (MAX(lwork, 1))]
info [int]

Other Parameters

compute_v [input int, optional] Default: 1
sort_t [input int, optional] Default: 0
zselect_extra_args [input tuple, optional] Default: ()
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)

Notes

Call-back functions:

```python
def zselect(arg):
    return zselect
```

Required arguments:
- arg : input complex

Return objects:
- zselect : int

scipy.linalg.lapack.sgeev

scipy.linalg.lapack.sgeev(a[, compute_vl, compute_vr, lwork, overwrite_a]) = <fortran object>

Wrapper for sgeev.

Parameters

a [input rank-2 array('F') with bounds (n,n)]

Returns

[rank-1 array('F') with bounds (n)]
wi [rank-1 array('F') with bounds (n)]
vl [rank-2 array('F') with bounds (ldvl,n)]
vr [rank-2 array('F') with bounds (ldvr,n)]
info [int]

Other Parameters
compute_vl  
[input int, optional] Default: 1
compute_vr  
[input int, optional] Default: 1
overwrite_a  
[input int, optional] Default: 0
lwork  
[input int, optional] Default: max(4*n,1)

scipy.linalg.lapack.dgeev

scipy.linalg.lapack.dgeev(a[, compute_vl, compute_vr, lwork, overwrite_a]) = <fortran object>

Wrapper for dgeev.

Parameters
a  [input rank-2 array('d') with bounds (n,n)]

Returns
wr  [rank-1 array('d') with bounds (n)]
wi  [rank-1 array('d') with bounds (n)]
vl  [rank-2 array('d') with bounds (ldvl,n)]
vr  [rank-2 array('d') with bounds (ldvr,n)]
info  [int]

Other Parameters
compute_vl  
[input int, optional] Default: 1
compute_vr  
[input int, optional] Default: 1
overwrite_a  
[input int, optional] Default: 0
lwork  
[input int, optional] Default: max(4*n,1)

scipy.linalg.lapack.cgeev

scipy.linalg.lapack.cgeev(a[, compute_vl, compute_vr, lwork, overwrite_a]) = <fortran object>

Wrapper for cgeev.

Parameters
a  [input rank-2 array('F') with bounds (n,n)]

Returns
w  [rank-1 array('F') with bounds (n)]
vl  [rank-2 array('F') with bounds (ldvl,n)]
vr  [rank-2 array('F') with bounds (ldvr,n)]
info  [int]

Other Parameters
compute_vl  
[input int, optional] Default: 1
compute_vr  
[input int, optional] Default: 1
overwrite_a  
[input int, optional] Default: 0
lwork  
[input int, optional] Default: max(2*n,1)
scipy.linalg.lapack.zgeev

Wrapper for zgeev.

Parameters

- \( a \) [input rank-2 array('D') with bounds (n,n)]

Returns

- \( w \) [rank-1 array('D') with bounds (n)]
- \( vl \) [rank-2 array('D') with bounds (ldvl,n)]
- \( vr \) [rank-2 array('D') with bounds (ldvr,n)]
- \( info \) [int]

Other Parameters

- \( compute_vl \) [input int, optional] Default: 1
- \( compute_vr \) [input int, optional] Default: 1
- \( overwrite_a \) [input int, optional] Default: 0
- \( lwork \) [input int, optional] Default: max(2*n,1)

scipy.linalg.lapack.sgeev_lwork

Wrapper for sgeev_lwork.

Parameters

- \( n \) [input int]

Returns

- \( work \) [float]
- \( info \) [int]

Other Parameters

- \( compute_vl \) [input int, optional] Default: 1
- \( compute_vr \) [input int, optional] Default: 1

scipy.linalg.lapack.dgeev_lwork

Wrapper for dgeev_lwork.

Parameters

- \( n \) [input int]

Returns

- \( work \) [float]
- \( info \) [int]

Other Parameters
compute_vl  
  [input int, optional] Default: 1
compute_vr  
  [input int, optional] Default: 1

scipy.linalg.lapack.cgeev_lwork

scipy.linalg.lapack.cgeev_lwork(n[, compute_vl, compute_vr]) = <fortran object>
Wrapper for cgeev_lwork.

Parameters
n  [input int]

Returns
work  [complex]
info  [int]

Other Parameters
compute_vl  
  [input int, optional] Default: 1
compute_vr  
  [input int, optional] Default: 1

scipy.linalg.lapack.zgeev_lwork

scipy.linalg.lapack.zgeev_lwork(n[, compute_vl, compute_vr]) = <fortran object>
Wrapper for zgeev_lwork.

Parameters
n  [input int]

Returns
work  [complex]
info  [int]

Other Parameters
compute_vl  
  [input int, optional] Default: 1
compute_vr  
  [input int, optional] Default: 1

scipy.linalg.lapack.sgegv

scipy.linalg.lapack.sgegv(*args, **kwds)
sgegv is deprecated! The *gegv family of routines has been deprecated in LAPACK 3.6.0 in favor of the *ggev family of routines. The corresponding wrappers will be removed from SciPy in a future release.
alphar,alphai,beta,vl,vr,info = sgegv(a,b,[compute_vl,compute_vr,lwork,overwrite_a,overwrite_b])
Wrapper for sgegv.

Parameters
a  [input rank-2 array('f') with bounds (n,n)]
b  [input rank-2 array('f') with bounds (n,n)]

Returns
alphar [rank-1 array('f') with bounds (n)]
alphai [rank-1 array('f') with bounds (n)]
beta [rank-1 array('f') with bounds (n)]
vl [rank-2 array('f') with bounds (ldvl,n)]
vr [rank-2 array('f') with bounds (ldvr,n)]
info [int]

Other Parameters

compute_vl [input int, optional] Default: 1
compute_vr [input int, optional] Default: 1
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
lwork [input int, optional] Default: max(8*n,1)

scipy.linalg.lapack.dgegv

scipy.linalg.lapack.dgegv(*args, **kwds)
dgegv is deprecated! The *gegv family of routines has been deprecated in LAPACK 3.6.0 in favor of the *ggev family of routines. The corresponding wrappers will be removed from SciPy in a future release.

alphar,alphai,beta,vl,vr,info = dgegv(a,b,[compute_vl,compute_vr,lwork,overwrite_a,overwrite_b])

Wrapper for dgegv.

Parameters

a [input rank-2 array('d') with bounds (n,n)]
b [input rank-2 array('d') with bounds (n,n)]

Returns

alphar [rank-1 array('d') with bounds (n)]
alphai [rank-1 array('d') with bounds (n)]
beta [rank-1 array('d') with bounds (n)]
vl [rank-2 array('d') with bounds (ldvl,n)]
vr [rank-2 array('d') with bounds (ldvr,n)]
info [int]

Other Parameters

compute_vl [input int, optional] Default: 1
compute_vr [input int, optional] Default: 1
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
lwork [input int, optional] Default: max(8*n,1)
scipy.linalg.lapack.cgegv

scipy.linalg.lapack.cgegv(*args, **kwds)

cgegv is deprecated! The *gegv family of routines has been deprecated in LAPACK 3.6.0 in favor of the *ggev family of routines. The corresponding wrappers will be removed from SciPy in a future release.

alpha, beta, vl, vr, info = cgegv(a, b, [compute_vl, compute_vr, lwork, overwrite_a, overwrite_b])

Wrapper for cgegv.

Parameters

a [input rank-2 array('F') with bounds (n,n)]
b [input rank-2 array('F') with bounds (n,n)]

Returns

alpha [rank-1 array('F') with bounds (n)]
beta [rank-1 array('F') with bounds (n)]
vl [rank-2 array('F') with bounds (ldvl,n)]
vr [rank-2 array('F') with bounds (ldvr,n)]
info [int]

Other Parameters

compute_vl [input int, optional] Default: 1
compute_vr [input int, optional] Default: 1
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
lwork [input int, optional] Default: max(2*n,1)

scipy.linalg.lapack.zgegv

scipy.linalg.lapack.zgegv(*args, **kwds)

zgegv is deprecated! The *gegv family of routines has been deprecated in LAPACK 3.6.0 in favor of the *ggev family of routines. The corresponding wrappers will be removed from SciPy in a future release.

alpha, beta, vl, vr, info = zgegv(a, b, [compute_vl, compute_vr, lwork, overwrite_a, overwrite_b])

Wrapper for zgegv.

Parameters

a [input rank-2 array('D') with bounds (n,n)]
b [input rank-2 array('D') with bounds (n,n)]

Returns

alpha [rank-1 array('D') with bounds (n)]
beta [rank-1 array('D') with bounds (n)]
vl [rank-2 array('D') with bounds (ldvl,n)]
vr [rank-2 array('D') with bounds (ldvr,n)]
info [int]

Other Parameters

compute_vl [input int, optional] Default: 1
compute_vr  
  [input int, optional] Default: 1
overwrite_a  
  [input int, optional] Default: 0
overwrite_b  
  [input int, optional] Default: 0
lwork  
  [input int, optional] Default: max(2*n,1)

scipy.linalg.lapack.sgehrd

scipy.linalg.lapack.sgehrd(a[, lo, hi, lwork, overwrite_a]) = <fortran object>
Wrapper for sgehrd.

Parameters

  a  [input rank-2 array('f') with bounds (n,n)]

Returns

  ht  [rank-2 array('f') with bounds (n,n) and a storage]
  tau  [rank-1 array('f') with bounds (-1 + n)]
  info  [int]

Other Parameters

  lo  [input int, optional] Default: 0
  hi  [input int, optional] Default: n-1
  overwrite_a  
    [input int, optional] Default: 0
  lwork  [input int, optional] Default: MAX(n,1)

scipy.linalg.lapack.dgehrd

scipy.linalg.lapack.dgehrd(a[, lo, hi, lwork, overwrite_a]) = <fortran object>
Wrapper for dgehrd.

Parameters

  a  [input rank-2 array('d') with bounds (n,n)]

Returns

  ht  [rank-2 array('d') with bounds (n,n) and a storage]
  tau  [rank-1 array('d') with bounds (-1 + n)]
  info  [int]

Other Parameters

  lo  [input int, optional] Default: 0
  hi  [input int, optional] Default: n-1
  overwrite_a  
    [input int, optional] Default: 0
  lwork  [input int, optional] Default: MAX(n,1)
scipy.linalg.lapack.cgehrd

scipy.linalg.lapack.cgehrd(a\[lo, hi, lwork, overwrite_a\]) = <fortran object>
Wrapper for cgehrd.

Parameters

- a [input rank-2 array('F') with bounds (n,n)]

Returns

- h (rank-2 array('F') with bounds (n,n) and a storage]
- tau [rank-1 array('F') with bounds (-1 + n)]
- info [int]

Other Parameters

- lo [input int, optional] Default: 0
- hi [input int, optional] Default: n-1
- overwrite_a [input int, optional] Default: 0
- lwork [input int, optional] Default: MAX(n,1)

scipy.linalg.lapack.zgehrd

scipy.linalg.lapack.zgehrd(a\[lo, hi, lwork, overwrite_a\]) = <fortran object>
Wrapper for zgehrd.

Parameters

- a [input rank-2 array('D') with bounds (n,n)]

Returns

- h (rank-2 array('D') with bounds (n,n) and a storage]
- tau [rank-1 array('D') with bounds (-1 + n)]
- info [int]

Other Parameters

- lo [input int, optional] Default: 0
- hi [input int, optional] Default: n-1
- overwrite_a [input int, optional] Default: 0
- lwork [input int, optional] Default: MAX(n,1)

scipy.linalg.lapack.sgehrd_lwork

scipy.linalg.lapack.sgehrd_lwork(n\[lo, hi\]) = <fortran object>
Wrapper for sgehrd_lwork.

Parameters

- n [input int]

Returns

- work [float]
- info [int]

Other Parameters

- lo [input int, optional] Default: 0
- hi [input int, optional] Default: n-1
scipy.linalg.lapack.dgehrd_lwork

Wrapper for dgehrd_lwork.

Parameters
n [input int]

Returns
work [float]
info [int]

Other Parameters
lo [input int, optional] Default: 0
hi [input int, optional] Default: n-1

scipy.linalg.lapack.cgehrd_lwork

Wrapper for cgehrd_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

Other Parameters
lo [input int, optional] Default: 0
hi [input int, optional] Default: n-1

scipy.linalg.lapack.zgehrd_lwork

Wrapper for zgehrd_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

Other Parameters
lo [input int, optional] Default: 0
hi [input int, optional] Default: n-1
scipy.linalg.lapack.sgejsv

```
scipy.linalg.lapack.sgejsv(a, joba, jobu, jobv, jobr, jobt, jobp, lwork, overwrite_a) = <fortran object>
```

Wrapper for sgejsv.

**Parameters**

- **a** [input rank-2 array('f') with bounds (lda,n)]

**Returns**

- **sva** [rank-1 array('f') with bounds (n)]
- **u** [rank-2 array('f') with bounds (((jobt == 0)&&(jobu == 3)?0:m),((jobt == 0)&&(jobu == 3)?0:m:n))]
- **v** [rank-2 array('f') with bounds (((jobt == 0)&&(jobv == 3)?0:ldv),((jobt == 0)&&(jobv == 3)?0:n))]
- **workout** [rank-1 array('f') with bounds (7)]
- **iworkout** [rank-1 array('i') with bounds (3)]
- **info** [int]

**Other Parameters**

- **joba** [input int, optional] Default: 4
- **jobu** [input int, optional] Default: 0
- **jobv** [input int, optional] Default: 0
- **jobr** [input int, optional] Default: 1
- **jobt** [input int, optional] Default: 0
- **jobp** [input int, optional] Default: 1
- **overwrite_a** [input int, optional] Default: 0
- **lwork** [input int, optional] Default: \(\max(6*n+2*n*n, \max(2*m+n, \max(4*n+n*n, \max(2*n+n*n+6, 7))))\)

scipy.linalg.lapack.dgejsv

```
scipy.linalg.lapack.dgejsv(a, joba, jobu, jobv, jobr, jobt, jobp, lwork, overwrite_a) = <fortran object>
```

Wrapper for dgejsv.

**Parameters**

- **a** [input rank-2 array('d') with bounds (lda,n)]

**Returns**

- **sva** [rank-1 array('d') with bounds (n)]
- **u** [rank-2 array('d') with bounds (((jobt == 0)&&(jobu == 3)?0:m),((jobt == 0)&&(jobu == 3)?0:m:n))]
- **v** [rank-2 array('d') with bounds (((jobt == 0)&&(jobv == 3)?0:ldv),((jobt == 0)&&(jobv == 3)?0:n))]
- **workout** [rank-1 array('f') with bounds (7)]
- **iworkout** [rank-1 array('i') with bounds (3)]
- **info** [int]

**Other Parameters**

- **joba** [input int, optional] Default: 4
- **jobu** [input int, optional] Default: 0
- **jobv** [input int, optional] Default: 0
- **jobr** [input int, optional] Default: 1

jobt   [input int, optional] Default: 0
jobp   [input int, optional] Default: 1
overwrite_a
       [input int, optional] Default: 0
lwork  [input int, optional] Default: \(\max(6n+2n^2n, \max(2m+n, \max(4n+n^2, \max(2n+n^2n+6, 7))))\)

\texttt{scipy.linalg.lapack.sgels}

\texttt{scipy.linalg.lapack.sgels(a, b[, trans, lwork, overwrite_a, overwrite_b]) = <fortran object>}

Wrapper for \texttt{sgels}.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{a} [input rank-2 array('f') with bounds (m,n)]
  \item \texttt{b} [input rank-2 array('f') with bounds (MAX(m,n),nrhs)]
\end{itemize}

\textbf{Returns}

\begin{itemize}
  \item \texttt{lqr} [rank-2 array('f') with bounds (m,n) and a storage]
  \item \texttt{x} [rank-2 array('f') with bounds (MAX(m,n),nrhs) and b storage]
  \item \texttt{info} [int]
\end{itemize}

\textbf{Other Parameters}

\begin{itemize}
  \item \texttt{trans} [input string(len=1), optional] Default: 'N'
  \item \texttt{overwrite_a} [input int, optional] Default: 0
  \item \texttt{overwrite_b} [input int, optional] Default: 0
  \item \texttt{lwork} [input int, optional] Default: MAX(MIN(m,n)+MAX(MIN(m,n),nrhs),1)
\end{itemize}

\texttt{scipy.linalg.lapack.dgels}

\texttt{scipy.linalg.lapack.dgels(a, b[, trans, lwork, overwrite_a, overwrite_b]) = <fortran object>}

Wrapper for \texttt{dgels}.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{a} [input rank-2 array('d') with bounds (m,n)]
  \item \texttt{b} [input rank-2 array('d') with bounds (MAX(m,n),nrhs)]
\end{itemize}

\textbf{Returns}

\begin{itemize}
  \item \texttt{lqr} [rank-2 array('d') with bounds (m,n) and a storage]
  \item \texttt{x} [rank-2 array('d') with bounds (MAX(m,n),nrhs) and b storage]
  \item \texttt{info} [int]
\end{itemize}

\textbf{Other Parameters}

\begin{itemize}
  \item \texttt{trans} [input string(len=1), optional] Default: 'N'
  \item \texttt{overwrite_a} [input int, optional] Default: 0
  \item \texttt{overwrite_b} [input int, optional] Default: 0
  \item \texttt{lwork} [input int, optional] Default: MAX(MIN(m,n)+MAX(MIN(m,n),nrhs),1)
\end{itemize}
scipy.linalg.lapack.cgels

**scipy.linalg.lapack.cgels** *(a, b[, trans, lwork, overwrite_a, overwrite_b]) = <fortran object>*

Wrapper for cgels.

**Parameters**
- a [input rank-2 array('F') with bounds (m,n)]
- b [input rank-2 array('F') with bounds (MAX(m, n),nrhs)]

**Returns**
- lqr [rank-2 array('F') with bounds (m,n) and a storage]
- x [rank-2 array('F') with bounds (MAX(m, n),nrhs) and b storage]
- info [int]

**Other Parameters**
- trans [input string(len=1), optional] Default: ‘N’
- overwrite_a [input int, optional] Default: 0
- overwrite_b [input int, optional] Default: 0
- lwork [input int, optional] Default: MAX(MIN(m,n)+MAX(MIN(m,n),nrhs),1)

scipy.linalg.lapack.zgels

**scipy.linalg.lapack.zgels** *(a, b[, trans, lwork, overwrite_a, overwrite_b]) = <fortran object>*

Wrapper for zgels.

**Parameters**
- a [input rank-2 array('D') with bounds (m,n)]
- b [input rank-2 array('D') with bounds (MAX(m, n),nrhs)]

**Returns**
- lqr [rank-2 array('D') with bounds (m,n) and a storage]
- x [rank-2 array('D') with bounds (MAX(m, n),nrhs) and b storage]
- info [int]

**Other Parameters**
- trans [input string(len=1), optional] Default: ‘N’
- overwrite_a [input int, optional] Default: 0
- overwrite_b [input int, optional] Default: 0
- lwork [input int, optional] Default: MAX(MIN(m,n)+MAX(MIN(m,n),nrhs),1)

scipy.linalg.lapack.sgels_lwork

**scipy.linalg.lapack.sgels_lwork** *(m, n, nrhs[, trans]) = <fortran object>*

Wrapper for sgels_lwork.

**Parameters**
- m [input int]
- n [input int]
- nrhs [input int]

**Returns**
work [float]
info [int]

Other Parameters
trans [input string(len=1), optional] Default: ‘N’

scipy.linalg.lapack.dgels_lwork

scipy.linalg.lapack.dgels_lwork(m, n, nrhs[, trans]) = <fortran object>
Wrapper for dgels_lwork.

Parameters
m [input int]
n [input int]
nrhs [input int]

Returns
work [float]
info [int]

Other Parameters
trans [input string(len=1), optional] Default: ‘N’

scipy.linalg.lapack.cgels_lwork

scipy.linalg.lapack.cgels_lwork(m, n, nrhs[, trans]) = <fortran object>
Wrapper for cgels_lwork.

Parameters
m [input int]
n [input int]
nrhs [input int]

Returns
work [complex]
info [int]

Other Parameters
trans [input string(len=1), optional] Default: ‘N’

scipy.linalg.lapack.zgels_lwork

scipy.linalg.lapack.zgels_lwork(m, n, nrhs[, trans]) = <fortran object>
Wrapper for zgels_lwork.

Parameters
m [input int]
n [input int]
nrhs [input int]

Returns
work [complex]
info [int]

Other Parameters
trans [input string(len=1), optional] Default: ‘N’

scipy.linalg.lapack.sgelsd

scipy.linalg.lapack.sgelsd(a, b, lwork, size_iwork[, cond, overwrite_a, overwrite_b]) = fortran object

Wrapper for sgelsd.

Parameters

a [input rank-2 array('f') with bounds (m,n)]
b [input rank-2 array('f') with bounds (maxmn,nrhs)]
lwork [input int]
size_iwork [input int]

Returns

x [rank-2 array('f') with bounds (maxmn,nrhs) and b storage]
s [rank-1 array('f') with bounds (minmn)]
rank [int]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
cond [input float, optional] Default: -1.0

scipy.linalg.lapack.dgelsd

scipy.linalg.lapack.dgelsd(a, b, lwork, size_iwork[, cond, overwrite_a, overwrite_b]) = fortran object

Wrapper for dgelsd.

Parameters

a [input rank-2 array('d') with bounds (m,n)]
b [input rank-2 array('d') with bounds (maxmn,nrhs)]
lwork [input int]
size_iwork [input int]

Returns

x [rank-2 array('d') with bounds (maxmn,nrhs) and b storage]
s [rank-1 array('d') with bounds (minmn)]
rank [int]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
cond [input float, optional] Default: -1.0
**scipy.linalg.lapack.cgelsd**

```python
scipy.linalg.lapack.cgelsd(a, b, lwork, size_rwork, size_iwork[, cond, overwrite_a, overwrite_b]) =
<fortran object>
```

Wrapper for cgelsd.

**Parameters**

- `a` [input rank-2 array('F') with bounds (m,n)]
- `b` [input rank-2 array('F') with bounds (maxmn,nrhs)]
- `lwork` [input int]
- `size_rwork` [input int]
- `size_iwork` [input int]

**Returns**

- `x` [rank-2 array('F') with bounds (maxmn,nrhs) and b storage]
- `s` [rank-1 array('f') with bounds (minmn)]
- `rank` [int]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0
- `cond` [input float, optional] Default: -1.0

**scipy.linalg.lapack.zgelsd**

```python
scipy.linalg.lapack.zgelsd(a, b, lwork, size_rwork, size_iwork[, cond, overwrite_a, overwrite_b]) =
<fortran object>
```

Wrapper for zgelsd.

**Parameters**

- `a` [input rank-2 array('D') with bounds (m,n)]
- `b` [input rank-2 array('D') with bounds (maxmn,nrhs)]
- `lwork` [input int]
- `size_rwork` [input int]
- `size_iwork` [input int]

**Returns**

- `x` [rank-2 array('D') with bounds (maxmn,nrhs) and b storage]
- `s` [rank-1 array('d') with bounds (minmn)]
- `rank` [int]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0
- `cond` [input float, optional] Default: -1.0

---

3.3. API definition 889
**scipy.linalg.lapack.sgelsl_work**

Wrapper for *sgelsl_work*.

**Parameters**
- \( m \) [input int]
- \( n \) [input int]
- \( nrhs \) [input int]

**Returns**
- work [float]
- iwork [int]
- info [int]

**Other Parameters**
- cond [input float, optional] Default: -1.0
- lwork [input int, optional] Default: -1

**scipy.linalg.lapack.dgelsl_work**

Wrapper for *dgelsl_work*.

**Parameters**
- \( m \) [input int]
- \( n \) [input int]
- \( nrhs \) [input int]

**Returns**
- work [float]
- iwork [int]
- info [int]

**Other Parameters**
- cond [input float, optional] Default: -1.0
- lwork [input int, optional] Default: -1

**scipy.linalg.lapack.cgelssl_work**

Wrapper for *cgelssl_work*.

**Parameters**
- \( m \) [input int]
- \( n \) [input int]
- \( nrhs \) [input int]

**Returns**
- work [complex]
- rwork [float]
- iwork [int]
- info [int]

**Other Parameters**
**cond**  [input float, optional] Default: -1.0

**lwork**  [input int, optional] Default: -1

**scipy.linalg.lapack.zgelsd_lwork**

```python
scipy.linalg.lapack.zgelsd_lwork(m, n, nrhs, cond, lwork) = <fortran object>
```

Wrapper for zgelsd_lwork.

### Parameters

- **m**  [input int]
- **n**  [input int]
- **nrhs**  [input int]

### Returns

- **work**  [complex]
- **rwork**  [float]
- **iwork**  [int]
- **info**  [int]

### Other Parameters

- **cond**  [input float, optional] Default: -1.0
- **lwork**  [input int, optional] Default: -1

**scipy.linalg.lapack.sgelss**

```python
scipy.linalg.lapack.sgelss(a, b, cond, lwork, overwrite_a, overwrite_b) = <fortran object>
```

Wrapper for sgelss.

### Parameters

- **a**  [input rank-2 array('f') with bounds (m,n)]
- **b**  [input rank-2 array('f') with bounds (maxmn,nrhs)]

### Returns

- **v**  [rank-2 array('f') with bounds (m,n) and a storage]
- **x**  [rank-2 array('f') with bounds (maxmn,nrhs) and b storage]
- **s**  [rank-1 array('f') with bounds (minmn)]
- **rank**  [int]
- **work**  [rank-1 array('f') with bounds (MAX(lwork, 1))]
- **info**  [int]

### Other Parameters

- **overwrite_a**  [input int, optional] Default: 0
- **overwrite_b**  [input int, optional] Default: 0
- **cond**  [input int, optional] Default: 0
- **lwork**  [input int, optional] Default: max(3*minmn+MAX(2*minmn,MAX(maxmn,nrhs)),1)
scipy.linalg.lapack.dgelss

scipy.linalg.lapack.dgelss(a[, cond, lwork, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for dgelss.

Parameters

a [input rank-2 array('d') with bounds (m,n)]
b [input rank-2 array('d') with bounds (maxmn,nrhs)]

Returns

v [rank-2 array('d') with bounds (m,n) and a storage]
x [rank-2 array('d') with bounds (maxmn,nrhs) and b storage]
s [rank-1 array('d') with bounds (minmn)]
rank [int]
work [rank-1 array('d') with bounds (MAX(lwork, 1))]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
cond [input float, optional] Default: -1.0
lwork [input int, optional] Default: max(3*minmn+MAX(2*minmn,MAX(maxmn,nrhs)),1)

scipy.linalg.lapack.cgelss

scipy.linalg.lapack.cgelss(a[, cond, lwork, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for cgelss.

Parameters

a [input rank-2 array('F') with bounds (m,n)]
b [input rank-2 array('F') with bounds (maxmn,nrhs)]

Returns

v [rank-2 array('F') with bounds (m,n) and a storage]
x [rank-2 array('F') with bounds (maxmn,nrhs) and b storage]
s [rank-1 array('f') with bounds (minmn)]
rank [int]
work [rank-1 array('F') with bounds (MAX(lwork, 1))]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
cond [input float, optional] Default: -1.0
lwork [input int, optional] Default: max(2*minmn+MAX(maxmn,nrhs),1)
scipy.linalg.lapack.zgelss

scipy.linalg.lapack.zgelss(a, b[, cond, lwork, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for zgelss.

Parameters

- `a` [input rank-2 array('D') with bounds (m,n)]
- `b` [input rank-2 array('D') with bounds (maxmn,nrhs)]

Returns

- `v` [rank-2 array('D') with bounds (m,n) and a storage]
- `x` [rank-2 array('D') with bounds (maxmn,nrhs) and b storage]
- `s` [rank-1 array('d') with bounds (minmn)]
- `rank` [int]
- `work` [rank-1 array('D') with bounds (MAX(lwork, 1))]
- `info` [int]

Other Parameters

- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0
- `cond` [input float, optional] Default: -1.0
- `lwork` [input int, optional] Default: max(2*minmn+MAX(maxmn,nrhs),1)

scipy.linalg.lapack.sgelss_lwork

scipy.linalg.lapack.sgelss_lwork(m, n, nrhs[, cond, lwork]) = <fortran object>

Wrapper for sgelss_lwork.

Parameters

- `m` [input int]
- `n` [input int]
- `nrhs` [input int]

Returns

- `work` [float]
- `info` [int]

Other Parameters

- `cond` [input float, optional] Default: -1.0
- `lwork` [input int, optional] Default: -1

scipy.linalg.lapack.dgelss_lwork

scipy.linalg.lapack.dgelss_lwork(m, n, nrhs[, cond, lwork]) = <fortran object>

Wrapper for dgelss_lwork.

Parameters

- `m` [input int]
- `n` [input int]
- `nrhs` [input int]

Returns

- `work` [float]
info [int]

**Other Parameters**

**cond** [input float, optional] Default: -1.0

**lwork** [input int, optional] Default: -1

### scipy.linalg.lapack.cgelss_lwork

```python
c scipy.linalg.lapack.cgelss_lwork(m, n, nrhs[, cond, lwork]) = <fortran object>
```

Wrapper for `cgelss_lwork`.

**Parameters**

**m** [input int]

**n** [input int]

**nrhs** [input int]

**Returns**

**work** [complex]

**info** [int]

**Other Parameters**

**cond** [input float, optional] Default: -1.0

**lwork** [input int, optional] Default: -1

### scipy.linalg.lapack.zgelss_lwork

```python
c scipy.linalg.lapack.zgelss_lwork(m, n, nrhs[, cond, lwork]) = <fortran object>
```

Wrapper for `zgelss_lwork`.

**Parameters**

**m** [input int]

**n** [input int]

**nrhs** [input int]

**Returns**

**work** [complex]

**info** [int]

**Other Parameters**

**cond** [input float, optional] Default: -1.0

**lwork** [input int, optional] Default: -1

### scipy.linalg.lapack.sgelsy

```python
c scipy.linalg.lapack.sgelsy(a, b, jptv, cond, lwork[, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for `sgelsy`.

**Parameters**

**a** [input rank-2 array('f') with bounds (m,n)]

**b** [input rank-2 array('f') with bounds (maxmn,nrhs)]

**jptv** [input rank-1 array('i') with bounds (n)]

**cond** [input float]

**lwork** [input int]

**Returns**
Other Parameters

 overwrite_a
 [input int, optional] Default: 0
 overwrite_b
 [input int, optional] Default: 0

 scipy.linalg.lapack.dgelsy

 scipy.linalg.lapack.dgelsy(a, b, jptv, cond, lwork[, overwrite_a, overwrite_b]) = <fortran object>

 Wrapper for dgelsy.

 Parameters

 a [input rank-2 array('d') with bounds (m,n)]
b [input rank-2 array('d') with bounds (maxmn,nrhs)]
jptv [input rank-1 array('i') with bounds (n)]
cond [input float]
lwork [input int]

 Returns

 v [rank-2 array('d') with bounds (m,n) and a storage]
x [rank-2 array('d') with bounds (maxmn,nrhs) and b storage]
j [rank-1 array('i') with bounds (n) and jptv storage]
rank [int]
info [int]

 Other Parameters

 overwrite_a
 [input int, optional] Default: 0
 overwrite_b
 [input int, optional] Default: 0

 scipy.linalg.lapack.cgelsy

 scipy.linalg.lapack.cgelsy(a, b, jptv, cond, lwork[, overwrite_a, overwrite_b]) = <fortran object>

 Wrapper for cgelsy.

 Parameters

 a [input rank-2 array('F') with bounds (m,n)]
b [input rank-2 array('F') with bounds (maxmn,nrhs)]
jptv [input rank-1 array('i') with bounds (n)]
cond [input float]
lwork [input int]

 Returns

 v [rank-2 array('F') with bounds (m,n) and a storage]
x [rank-2 array('F') with bounds (maxmn,nrhs) and b storage]
j [rank-1 array('i') with bounds (n) and jptv storage]
rank [int]
info [int]

Other Parameters
overwrite_a
[input int, optional] Default: 0
overwrite_b
[input int, optional] Default: 0

scipy.linalg.lapack.zgelsy
scipy.linalg.lapack.zgelsy(a, b, jptv, cond, lwork[, overwrite_a, overwrite_b]) = <fortran object>
Wrapper for zgelsy.

Parameters
a [input rank-2 array('D') with bounds (m,n)]
b [input rank-2 array('D') with bounds (maxmn,nrhs)]
jptv [input rank-1 array('i') with bounds (n)]
cond [input float]
lwork [input int]

Returns
v [rank-2 array('D') with bounds (m,n) and a storage]
x [rank-2 array('D') with bounds (maxmn,nrhs) and b storage]
j [rank-1 array('i') with bounds (n) and jptv storage]
r
rank [int]
info [int]

Other Parameters
overwrite_a
[input int, optional] Default: 0
overwrite_b
[input int, optional] Default: 0

scipy.linalg.lapack.sgelsy_lwork
scipy.linalg.lapack.sgelsy_lwork(m, n, nrhs, cond[, lwork]) = <fortran object>
Wrapper for sgelsy_lwork.

Parameters
m [input int]
n [input int]
nrhs [input int]
cond [input float]

Returns
work [float]
info [int]

Other Parameters
lwork [input int, optional] Default: -1
scipy.linalg.lapack.dgelsy_lwork

scipy.linalg.lapack.dgelsy_lwork(m, n, nrhs, cond[, lwork]) = <fortran object>
Wrapper for dgelsy_lwork.

Parameters
- m [input int]
- n [input int]
- nrhs [input int]
- cond [input float]

Returns
- work [float]
- info [int]

Other Parameters
- lwork [input int, optional] Default: -1

scipy.linalg.lapack.cgelsy_lwork

scipy.linalg.lapack.cgelsy_lwork(m, n, nrhs, cond[, lwork]) = <fortran object>
Wrapper for cgelsy_lwork.

Parameters
- m [input int]
- n [input int]
- nrhs [input int]
- cond [input float]

Returns
- work [complex]
- info [int]

Other Parameters
- lwork [input int, optional] Default: -1

scipy.linalg.lapack.zgelsy_lwork

scipy.linalg.lapack.zgelsy_lwork(m, n, nrhs, cond[, lwork]) = <fortran object>
Wrapper for zgelsy_lwork.

Parameters
- m [input int]
- n [input int]
- nrhs [input int]
- cond [input float]

Returns
- work [complex]
- info [int]

Other Parameters
- lwork [input int, optional] Default: -1

3.3. API definition
scipy.linalg.lapack.sgeqp3

```python
scipy.linalg.lapack.sgeqp3(a[, lwork, overwrite_a]) = <fortran object>
```

Wrapper for sgeqp3.

**Parameters**

- `a` [input rank-2 array('f') with bounds (m,n)]

**Returns**

- `qr` [rank-2 array('f') with bounds (m,n) and a storage]
- `jpvt` [rank-1 array('i') with bounds (n)]
- `tau` [rank-1 array('f') with bounds (MIN(m,n))]
- `work` [rank-1 array('f') with bounds (MAX(lwork, 1))]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: max(3*(n+1),1)

scipy.linalg.lapack.dgeqp3

```python
scipy.linalg.lapack.dgeqp3(a[, lwork, overwrite_a]) = <fortran object>
```

Wrapper for dgeqp3.

**Parameters**

- `a` [input rank-2 array('d') with bounds (m,n)]

**Returns**

- `qr` [rank-2 array('d') with bounds (m,n) and a storage]
- `jpvt` [rank-1 array('i') with bounds (n)]
- `tau` [rank-1 array('d') with bounds (MIN(m,n))]
- `work` [rank-1 array('d') with bounds (MAX(lwork, 1))]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: max(3*(n+1),1)

scipy.linalg.lapack.cgeqp3

```python
scipy.linalg.lapack.cgeqp3(a[, lwork, overwrite_a]) = <fortran object>
```

Wrapper for cgeqp3.

**Parameters**

- `a` [input rank-2 array('F') with bounds (m,n)]

**Returns**

- `qr` [rank-2 array('F') with bounds (m,n) and a storage]
- `jpvt` [rank-1 array('i') with bounds (n)]
- `tau` [rank-1 array('F') with bounds (MIN(m,n))]
- `work` [rank-1 array('F') with bounds (MAX(lwork, 1))]
- `info` [int]

**Other Parameters**
overwrite_a
  [input int, optional] Default: 0
lwork  [input int, optional] Default: max(3*(n+1),1)

scipy.linalg.lapack.zgeqp3

scipy.linalg.lapack.zgeqp3(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for zgeqp3.

Parameters
  a  [input rank-2 array('D') with bounds (m,n)]

Returns
  qr [rank-2 array('D') with bounds (m,n) and a storage]
  jpvt [rank-1 array('i') with bounds (n)]
  tau [rank-1 array('D') with bounds (MIN(m, n))]
  work [rank-1 array('D') with bounds (MAX(lwork, 1))]
  info [int]

Other Parameters
  overwrite_a
    [input int, optional] Default: 0
  lwork  [input int, optional] Default: max(3*(n+1),1)

scipy.linalg.lapack.sgeqrf

scipy.linalg.lapack.sgeqrf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for sgeqrf.

Parameters
  a  [input rank-2 array('f') with bounds (m,n)]

Returns
  qr [rank-2 array('f') with bounds (m,n) and a storage]
  tau [rank-1 array('f') with bounds (MIN(m, n))]
  work [rank-1 array('f') with bounds (MAX(lwork, 1))]
  info [int]

Other Parameters
  overwrite_a
    [input int, optional] Default: 0
  lwork  [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.dgeqrf

scipy.linalg.lapack.dgeqrf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for dgeqrf.

Parameters
  a  [input rank-2 array('d') with bounds (m,n)]

Returns
  qr [rank-2 array('d') with bounds (m,n) and a storage]
  tau [rank-1 array('d') with bounds (MIN(m, n))]
  work [rank-1 array('d') with bounds (MAX(lwork, 1))]

3.3. API definition
info [int]

Other Parameters

overwrite_a
    [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.cgeqrf

scipy.linalg.lapack.cgeqrf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for cgeqrf.

Parameters

a [input rank-2 array('F') with bounds (m,n)]

Returns

qr [rank-2 array('F') with bounds (m,n) and a storage]
tau [rank-1 array('F') with bounds (MIN(m, n))]
work [rank-1 array('F') with bounds (MAX(lwork, 1))]
info [int]

Other Parameters

overwrite_a
    [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.zgeqrf

scipy.linalg.lapack.zgeqrf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for zgeqrf.

Parameters

a [input rank-2 array('D') with bounds (m,n)]

Returns

qr [rank-2 array('D') with bounds (m,n) and a storage]
tau [rank-1 array('D') with bounds (MIN(m, n))]
work [rank-1 array('D') with bounds (MAX(lwork, 1))]
info [int]

Other Parameters

overwrite_a
    [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)
scipy.linalg.lapack.sgeqrf_lwork

scipy.linalg.lapack.sgeqrf_lwork(m, n) = <fortran object>
Wrapper for sgeqrf_lwork.

Parameters
- m [input int]
- n [input int]

Returns
- work [float]
- info [int]

scipy.linalg.lapack.dgeqrf_lwork

scipy.linalg.lapack.dgeqrf_lwork(m, n) = <fortran object>
Wrapper for dgeqrf_lwork.

Parameters
- m [input int]
- n [input int]

Returns
- work [float]
- info [int]

scipy.linalg.lapack.cgeqrf_lwork

scipy.linalg.lapack.cgeqrf_lwork(m, n) = <fortran object>
Wrapper for cgeqrf_lwork.

Parameters
- m [input int]
- n [input int]

Returns
- work [complex]
- info [int]

scipy.linalg.lapack.zgeqrf_lwork

scipy.linalg.lapack.zgeqrf_lwork(m, n) = <fortran object>
Wrapper for zgeqrf_lwork.

Parameters
- m [input int]
- n [input int]

Returns
- work [complex]
- info [int]
scipy.linalg.lapack.sgeqrfp

scipy.linalg.lapack.sgeqrfp(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for sgeqrfp.

Parameters
a  [input rank-2 array('f') with bounds (m,n)]

Returns
qr  [rank-2 array('f') with bounds (m,n) and a storage]
tau [rank-1 array('f') with bounds (MIN(m, n))]
info [int]

Other Parameters
overwrite_a
    [input int, optional] Default: 0
lwork  [input int, optional] Default: MAX(1, n)

scipy.linalg.lapack.dgeqrfp

scipy.linalg.lapack.dgeqrfp(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for dgeqrfp.

Parameters
a  [input rank-2 array('d') with bounds (m,n)]

Returns
qr  [rank-2 array('d') with bounds (m,n) and a storage]
tau [rank-1 array('d') with bounds (MIN(m, n))]
info [int]

Other Parameters
overwrite_a
    [input int, optional] Default: 0
lwork  [input int, optional] Default: MAX(1, n)

scipy.linalg.lapack.cgeqrfp

scipy.linalg.lapack.cgeqrfp(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for cgeqrfp.

Parameters
a  [input rank-2 array('F') with bounds (m,n)]

Returns
qr  [rank-2 array('F') with bounds (m,n) and a storage]
tau [rank-1 array('F') with bounds (MIN(m, n))]
info [int]

Other Parameters
overwrite_a
    [input int, optional] Default: 0
lwork  [input int, optional] Default: MAX(1, n)
scipy.linalg.lapack.zgeqrfp

scipy.linalg.lapack.zgeqrfp(a[, lwork, overwrite_a]) = <fortran object>

Wrapper for zgeqrfp.

Parameters

- a [input rank-2 array('D') with bounds (m,n)]

Returns

- qr [rank-2 array('D') with bounds (m,n) and a storage]
- tau [rank-1 array('D') with bounds (MIN(m, n))]
- info [int]

Other Parameters

- overwrite_a [input int, optional] Default: 0
- lwork [input int, optional] Default: MAX(1, n)

scipy.linalg.lapack.sgeqrfp_lwork

scipy.linalg.lapack.sgeqrfp_lwork(m, n) = <fortran object>

Wrapper for sgeqrfp_lwork.

Parameters

- m [input int]
- n [input int]

Returns

- work [float]
- info [int]

scipy.linalg.lapack.dgeqrfp_lwork

scipy.linalg.lapack.dgeqrfp_lwork(m, n) = <fortran object>

Wrapper for dgeqrfp_lwork.

Parameters

- m [input int]
- n [input int]

Returns

- work [float]
- info [int]

scipy.linalg.lapack.cgeqrfp_lwork

scipy.linalg.lapack.cgeqrfp_lwork(m, n) = <fortran object>

Wrapper for cgeqrfp_lwork.

Parameters

- m [input int]
- n [input int]

Returns

- work [complex]
- info [int]
**scipy.linalg.lapack.zgeqrfp_lwork**

scipy.linalg.lapack.zgeqrfp_lwork(m, n) = <fortran object>

Wrapper for zgeqrfp_lwork.

*Parameters*

- m [input int]
- n [input int]

*Returns*

- work [complex]
- info [int]

**scipy.linalg.lapack.sgerqf**

scipy.linalg.lapack.sgerqf(a[, lwork, overwrite_a]) = <fortran object>

Wrapper for sgerqf.

*Parameters*

- a [input rank-2 array('f') with bounds (m,n)]

*Returns*

- qr [rank-2 array('f') with bounds (m,n) and a storage]
- tau [rank-1 array('f') with bounds (MIN(m, n))]
- work [rank-1 array('f') with bounds (MAX(lwork, 1))]
- info [int]

*Other Parameters*

- overwrite_a [input int, optional] Default: 0
- lwork [input int, optional] Default: max(3*m,1)

**scipy.linalg.lapack.dgerqf**

scipy.linalg.lapack.dgerqf(a[, lwork, overwrite_a]) = <fortran object>

Wrapper for dgerqf.

*Parameters*

- a [input rank-2 array('d') with bounds (m,n)]

*Returns*

- qr [rank-2 array('d') with bounds (m,n) and a storage]
- tau [rank-1 array('d') with bounds (MIN(m, n))]
- work [rank-1 array('d') with bounds (MAX(lwork, 1))]
- info [int]

*Other Parameters*

- overwrite_a [input int, optional] Default: 0
- lwork [input int, optional] Default: max(3*m,1)
scipy.linalg.lapack.cgerqf

scipy.linalg.lapack.cgerqf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for cgerqf.

Parameters

a   [input rank-2 array('F') with bounds (m,n)]

Returns

qr  [rank-2 array('F') with bounds (m,n) and a storage]
    tau [rank-1 array('F') with bounds (MIN(m,n))]
    work [rank-1 array('F') with bounds (MAX(lwork, 1))]
    info [int]

Other Parameters

overwrite_a
    [input int, optional] Default: 0
lwork   [input int, optional] Default: max(3*m,1)

scipy.linalg.lapack.zgerqf

scipy.linalg.lapack.zgerqf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for zgerqf.

Parameters

a   [input rank-2 array('D') with bounds (m,n)]

Returns

qr  [rank-2 array('D') with bounds (m,n) and a storage]
    tau [rank-1 array('D') with bounds (MIN(m, n))]
    work [rank-1 array('D') with bounds (MAX(lwork, 1))]
    info [int]

Other Parameters

overwrite_a
    [input int, optional] Default: 0
lwork   [input int, optional] Default: max(3*m,1)

scipy.linalg.lapack.sgesdd

scipy.linalg.lapack.sgesdd(a[, compute_uv, full_matrices, lwork, overwrite_a]) = <fortran object>
Wrapper for sgesdd.

Parameters

a   [input rank-2 array('f') with bounds (m,n)]

Returns

u   [rank-2 array('f') with bounds (u0,u1)]
    s  [rank-1 array('f') with bounds (mnmn)]
    vt [rank-2 array('f') with bounds (vt0,vt1)]
    info [int]

Other Parameters

overwrite_a
[input int, optional] Default: 0

compute_uv
[input int, optional] Default: 1

full_matrices
[input int, optional] Default: 1

lwork
[input int, optional] Default: max((compute_uv?4*minmn*minmn+MAX(m,n)+9*minmn:MAX(14*minmn+4,10*minmn+2+25*(25+8))+MAX(m,n)),1)

scipy.linalg.lapack.dgesdd
scipy.linalg.lapack.
dgesdd (a[, compute_uv, full_matrices, lwork, overwrite_a]) = <fortran object>

Wrapper for dgesdd.

Parameters

a
[input rank-2 array('d') with bounds (m,n)]

Returns

u
[rank-2 array('d') with bounds (u0,u1)]
s
[rank-1 array('d') with bounds (minmn)]
vt
[rank-2 array('d') with bounds (vt0,vt1)]
info
[int]

Other Parameters

overwrite_a
[input int, optional] Default: 0

compute_uv
[input int, optional] Default: 1

full_matrices
[input int, optional] Default: 1

lwork
[input int, optional] Default: max((compute_uv?4*minmn*minmn+MAX(m,n)+9*minmn:MAX(14*minmn+4,10*minmn+2+25*(25+8))+MAX(m,n)),1)

scipy.linalg.lapack.cgesdd
scipy.linalg.lapack.
cgesdd (a[, compute_uv, full_matrices, lwork, overwrite_a]) = <fortran object>

Wrapper for cgesdd.

Parameters

a
[input rank-2 array('F') with bounds (m,n)]

Returns

u
[rank-2 array('F') with bounds (u0,u1)]
s
[rank-1 array('F') with bounds (minmn)]
vt
[rank-2 array('F') with bounds (vt0,vt1)]
info
[int]

Other Parameters

overwrite_a
[input int, optional] Default: 0

compute_uv
[input int, optional] Default: 1

full_matrices
[input int, optional] Default: 1

lwork
[input int, optional] Default: max((compute_uv?2*minmn*minmn+MAX(m,n)+2*minmn:2*minmn+MAX(m,n)),1)
**scipy.linalg.lapack.zgesdd**

```python
scipy.linalg.lapack.zgesdd(a[, compute_uv, full_matrices, lwork, overwrite_a]) = <fortran object>
```

Wrapper for zgesdd.

**Parameters**
- `a` [input rank-2 array('D') with bounds (m,n)]

**Returns**
- `u` [rank-2 array('D') with bounds (u0,u1)]
- `s` [rank-1 array('d') with bounds (minmn)]
- `vt` [rank-2 array('D') with bounds (vt0,vt1)]
- `info` [int]

**Other Parameters**
- `overwrite_a` [input int, optional] Default: 0
- `compute_uv` [input int, optional] Default: 1
- `full_matrices` [input int, optional] Default: 1
- `lwork` [input int, optional] Default: max((compute_uv?2*minmn*minmn+MAX(m,n)+2*minmn:2*minmn+MAX(m,n)),1)

**scipy.linalg.lapack.sgesdd_lwork**

```python
scipy.linalg.lapack.sgesdd_lwork(m, n[, compute_uv, full_matrices]) = <fortran object>
```

Wrapper for sgesdd_lwork.

**Parameters**
- `m` [input int]
- `n` [input int]

**Returns**
- `work` [float]
- `info` [int]

**Other Parameters**
- `compute_uv` [input int, optional] Default: 1
- `full_matrices` [input int, optional] Default: 1

**scipy.linalg.lapack.dgesdd_lwork**

```python
scipy.linalg.lapack.dgesdd_lwork(m, n[, compute_uv, full_matrices]) = <fortran object>
```

Wrapper for dgesdd_lwork.

**Parameters**
- `m` [input int]
- `n` [input int]

**Returns**
- `work` [float]
- `info` [int]
**Other Parameters**

- `compute_uv`  
  [input int, optional] Default: 1
- `full_matrices`  
  [input int, optional] Default: 1

`scipy.linalg.lapack.cgesdd_lwork`

```python
scipy.linalg.lapack.cgesdd_lwork(m, n[, compute_uv, full_matrices]) = <fortran object>
```

**Wrapper** for `cgesdd_lwork`.

**Parameters**

- `m`  
  [input int]
- `n`  
  [input int]

**Returns**

- `work`  
  [complex]
- `info`  
  [int]

**Other Parameters**

- `compute_uv`  
  [input int, optional] Default: 1
- `full_matrices`  
  [input int, optional] Default: 1

`scipy.linalg.lapack.zgesdd_lwork`

```python
scipy.linalg.lapack.zgesdd_lwork(m, n[, compute_uv, full_matrices]) = <fortran object>
```

**Wrapper** for `zgesdd_lwork`.

**Parameters**

- `m`  
  [input int]
- `n`  
  [input int]

**Returns**

- `work`  
  [complex]
- `info`  
  [int]

**Other Parameters**

- `compute_uv`  
  [input int, optional] Default: 1
- `full_matrices`  
  [input int, optional] Default: 1

`scipy.linalg.lapack.sgesv`

```python
scipy.linalg.lapack.sgesv(a, b[, overwrite_a, overwrite_b]) = <fortran object>
```

**Wrapper** for `sgesv`.

**Parameters**

- `a`  
  [input rank-2 array(‘f’) with bounds (n,n)]
- `b`  
  [input rank-2 array(‘f’) with bounds (n,nrhs)]

**Returns**

- `lu`  
  [rank-2 array(‘f’) with bounds (n,n) and a storage]
Other Parameters

overwrite_a
[input int, optional] Default: 0
overwrite_b
[input int, optional] Default: 0

scipy.linalg.lapack.dgesv

scipy.linalg.lapack.dgesv(a, b[, overwrite_a, overwrite_b]) = <fortran object>
Wrapper for dgesv.

Parameters

a       [input rank-2 array('d') with bounds (n,n)]
b       [input rank-2 array('d') with bounds (n, nrhs)]

Returns

lu      [rank-2 array('d') with bounds (n,n) and a storage]
piv     [rank-1 array('i') with bounds (n)]
x       [rank-2 array('d') with bounds (n, nrhs) and b storage]
info    [int]

Other Parameters

overwrite_a
[input int, optional] Default: 0
overwrite_b
[input int, optional] Default: 0

scipy.linalg.lapack.cgesv

scipy.linalg.lapack.cgesv(a, b[, overwrite_a, overwrite_b]) = <fortran object>
Wrapper for cgesv.

Parameters

a       [input rank-2 array('F') with bounds (n,n)]
b       [input rank-2 array('F') with bounds (n, nrhs)]

Returns

lu      [rank-2 array('F') with bounds (n,n) and a storage]
piv     [rank-1 array('i') with bounds (n)]
x       [rank-2 array('F') with bounds (n, nrhs) and b storage]
info    [int]

Other Parameters

overwrite_a
[input int, optional] Default: 0
overwrite_b
[input int, optional] Default: 0

3.3. API definition
scipy.linalg.lapack.zgesv

scipy.linalg.lapack.zgesv(a, b[, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for zgesv.

Parameters

- a [input rank-2 array('D') with bounds (n,n)]
- b [input rank-2 array('D') with bounds (n,nrhs)]

Returns

- lu [rank-2 array('D') with bounds (n,n) and a storage]
- piv [rank-1 array('i') with bounds (n)]
- x [rank-2 array('D') with bounds (n,nrhs) and b storage]
- info [int]

Other Parameters

- overwrite_a [input int, optional] Default: 0
- overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.sgesvd

scipy.linalg.lapack.sgesvd(a[, compute_uv, full_matrices, lwork, overwrite_a]) = <fortran object>

Wrapper for sgesvd.

Parameters

- a [input rank-2 array('f') with bounds (m,n)]

Returns

- u [rank-2 array('f') with bounds (u0,u1)]
- s [rank-1 array('f') with bounds (minmn)]
- vt [rank-2 array('f') with bounds (vt0,vt1)]
- info [int]

Other Parameters

- overwrite_a [input int, optional] Default: 0
- compute_uv [input int, optional] Default: 1
- full_matrices [input int, optional] Default: 1
- lwork [input int, optional] Default: max(MAX(3*minmn+MAX(m,n),5*minmn),1)
scipy.linalg.lapack.dgesvd

scipy.linalg.lapack.dgesvd(a[, compute_uv, full_matrices, lwork, overwrite_a]) = <fortran object>

Wrapper for dgesvd.

Parameters

- a [input rank-2 array('d') with bounds (m,n)]

Returns

- u [rank-2 array('d') with bounds (u0,u1)]
- s [rank-1 array('d') with bounds (minmn)]
- vt [rank-2 array('d') with bounds (vt0,vt1)]
- info [int]

Other Parameters

- overwrite_a [input int, optional] Default: 0
- compute_uv [input int, optional] Default: 1
- full_matrices [input int, optional] Default: 1
- lwork [input int, optional] Default: max(MAX(3*minmn+MAX(m,n),5*minmn),1)

scipy.linalg.lapack.cgesvd

scipy.linalg.lapack.cgesvd(a[, compute_uv, full_matrices, lwork, overwrite_a]) = <fortran object>

Wrapper for cgesvd.

Parameters

- a [input rank-2 array('F') with bounds (m,n)]

Returns

- u [rank-2 array('F') with bounds (u0,u1)]
- s [rank-1 array('f') with bounds (minmn)]
- vt [rank-2 array('F') with bounds (vt0,vt1)]
- info [int]

Other Parameters

- overwrite_a [input int, optional] Default: 0
- compute_uv [input int, optional] Default: 1
- full_matrices [input int, optional] Default: 1
- lwork [input int, optional] Default: MAX(2*minmn+MAX(m,n),1)
scipy.linalg.lapack.zgesvd

`scipy.linalg.lapack.zgesvd(a[, compute_uv, full_matrices, lwork, overwrite_a]) = <fortran object>`

Wrapper for zgesvd.

**Parameters**
- `a` [input rank-2 array('D') with bounds (m,n)]

**Returns**
- `u` [rank-2 array('D') with bounds (u0,u1)]
- `s` [rank-1 array('d') with bounds (minmn)]
- `vt` [rank-2 array('D') with bounds (vt0,vt1)]
- `info` [int]

**Other Parameters**
- `overwrite_a` [input int, optional] Default: 0
- `compute_uv` [input int, optional] Default: 1
- `full_matrices` [input int, optional] Default: 1
- `lwork` [input int, optional] Default: MAX(2*minmn+MAX(m,n),1)

scipy.linalg.lapack.sgesvd_lwork

`scipy.linalg.lapack.sgesvd_lwork(m, n[, compute_uv, full_matrices]) = <fortran object>`

Wrapper for sgesvd_lwork.

**Parameters**
- `m` [input int]
- `n` [input int]

**Returns**
- `work` [float]
- `info` [int]

**Other Parameters**
- `compute_uv` [input int, optional] Default: 1
- `full_matrices` [input int, optional] Default: 1

scipy.linalg.lapack.dgesvd_lwork

`scipy.linalg.lapack.dgesvd_lwork(m, n[, compute_uv, full_matrices]) = <fortran object>`

Wrapper for dgesvd_lwork.

**Parameters**
- `m` [input int]
- `n` [input int]

**Returns**
- `work` [float]
- `info` [int]
**Other Parameters**

- `compute_uv`  
  [input int, optional] Default: 1

- `full_matrices`  
  [input int, optional] Default: 1

`scipy.linalg.lapack.cgesvd_lwork`

**scipy.linalg.lapack.cgesvd_lwork**

`scipy.linalg.lapack.cgesvd_lwork(m, n[, compute_uv, full_matrices]) = <fortran object>`

Wrapper for `cgesvd_lwork`.

**Parameters**

- `m`  
  [input int]

- `n`  
  [input int]

**Returns**

- `work`  
  [complex]

- `info`  
  [int]

**Other Parameters**

- `compute_uv`  
  [input int, optional] Default: 1

- `full_matrices`  
  [input int, optional] Default: 1

`scipy.linalg.lapack.zgesvd_lwork`

**scipy.linalg.lapack.zgesvd_lwork**

`scipy.linalg.lapack.zgesvd_lwork(m, n[, compute_uv, full_matrices]) = <fortran object>`

Wrapper for `zgesvd_lwork`.

**Parameters**

- `m`  
  [input int]

- `n`  
  [input int]

**Returns**

- `work`  
  [complex]

- `info`  
  [int]

**Other Parameters**

- `compute_uv`  
  [input int, optional] Default: 1

- `full_matrices`  
  [input int, optional] Default: 1

`scipy.linalg.lapack.sgesvx`

**scipy.linalg.lapack.sgesvx**

`scipy.linalg.lapack.sgesvx(a, b[, fact, trans, af, ipiv, equed, r, c, overwrite_a, overwrite_b]) = <fortran object>`

Wrapper for `sgesvx`.

**Parameters**

- `a`  
  [input rank-2 array('f') with bounds (n,n)]

- `b`  
  [input rank-2 array('f') with bounds (n,nrhs)]

**Returns**
as [rank-2 array('f') with bounds (n,n) and a storage]
lu [rank-2 array('f') with bounds (n,n) and af storage]
ipiv [rank-1 array('i') with bounds (n)]
equed [string(len=1)]
rs [rank-1 array('f') with bounds (n) and r storage]
cs [rank-1 array('f') with bounds (n) and c storage]
bs [rank-2 array('f') with bounds (n,nrhs) and b storage]
x [rank-2 array('f') with bounds (n,nrhs)]
rcond [float]
ferr [rank-1 array('f') with bounds (nrhs)]
berr [rank-1 array('f') with bounds (nrhs)]
info [int]

Other Parameters
fact [input string(len=1), optional] Default: ‘E’
trans [input string(len=1), optional] Default: ‘N’
overwrite_a [input int, optional] Default: 0
af [input rank-2 array('f') with bounds (n,n)]
ipiv [input rank-1 array('i') with bounds (n)]
equed [input string(len=1), optional] Default: ‘B’
r [input rank-1 array('f') with bounds (n)]
c [input rank-1 array('f') with bounds (n)]
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.dgesvx
scipy.linalg.lapack.dgesvx(a, b[, fact, trans, af, ipiv, equed, r, c, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for dgesvx.

Parameters
a [input rank-2 array('d') with bounds (n,n)]
b [input rank-2 array('d') with bounds (n,nrhs)]

Returns
as [rank-2 array('d') with bounds (n,n) and a storage]
lu [rank-2 array('d') with bounds (n,n) and af storage]
ipiv [rank-1 array('i') with bounds (n)]
equed [string(len=1)]
rs [rank-1 array('d') with bounds (n) and r storage]
cs [rank-1 array('d') with bounds (n) and c storage]
bs [rank-2 array('d') with bounds (n,nrhs) and b storage]
x [rank-2 array('d') with bounds (n,nrhs)]
rcond [float]
ferr [rank-1 array('d') with bounds (nrhs)]
berr [rank-1 array('d') with bounds (nrhs)]
info [int]

Other Parameters
fact [input string(len=1), optional] Default: ‘E’
trans [input string(len=1), optional] Default: ‘N’
overwrite_a
  [input int, optional] Default: 0
af  [input rank-2 array('d') with bounds (n,n)]
ipiv  [input rank-1 array('i') with bounds (n)]
equed  [input string(len=1), optional] Default: ‘B’
r  [input rank-1 array('d') with bounds (n)]
c  [input rank-1 array('d') with bounds (n)]
overwrite_b
  [input int, optional] Default: 0

scipy.linalg.lapack.cgesvx

scipy.linalg.lapack.cgesvx(a, b[, fact, trans, af, ipiv, equed, r, c, overwrite_a, overwrite_b]) =
<fortran object>

Wrapper for cgesvx.

Parameters

a  [input rank-2 array('F') with bounds (n,n)]
b  [input rank-2 array('F') with bounds (n,nrhs)]

Returns

as  [rank-2 array('F') with bounds (n,n) and a storage]
lu  [rank-2 array('F') with bounds (n,n) and af storage]
ipiv  [rank-1 array('i') with bounds (n)]
equed  [string(len=1)]
rs  [rank-1 array('f') with bounds (n) and r storage]
cs  [rank-1 array('f') with bounds (n) and c storage]
bs  [rank-2 array('F') with bounds (n,nrhs) and b storage]
x  [rank-2 array('F') with bounds (n,nrhs)]
rcond  [float]
ferr  [rank-1 array('f') with bounds (nrhs)]
berr  [rank-1 array('f') with bounds (nrhs)]
info  [int]

Other Parameters

fact  [input string(len=1), optional] Default: ‘E’
trans  [input string(len=1), optional] Default: ‘N’
overwrite_a
  [input int, optional] Default: 0
af  [input rank-2 array('F') with bounds (n,n)]
ipiv  [input rank-1 array('i') with bounds (n)]
equed  [input string(len=1), optional] Default: ‘B’
r  [input rank-1 array('f') with bounds (n)]
c  [input rank-1 array('f') with bounds (n)]
overwrite_b
  [input int, optional] Default: 0
**scipy.linalg.lapack.zgesvx**

```python
scipy.linalg.lapack.zgesvx(a, b[, fact, trans, af, ipiv, equed, r, c, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for zgesvx.

**Parameters**

- `a` [input rank-2 array('D') with bounds (n,n)]
- `b` [input rank-2 array('D') with bounds (n,nrhs)]

**Returns**

- `as` [rank-2 array('D') with bounds (n,n) and a storage]
- `lu` [rank-2 array('D') with bounds (n,n) and af storage]
- `ipiv` [rank-1 array('i') with bounds (n)]
- `equed` [string(len=1)]
- `rs` [rank-1 array('d') with bounds (n) and r storage]
- `cs` [rank-1 array('d') with bounds (n) and c storage]
- `bs` [rank-2 array('D') with bounds (n,nrhs) and b storage]
- `x` [rank-2 array('D') with bounds (n,nrhs)]
- `rcond` [float]
- `ferr` [rank-1 array('d') with bounds (nrhs)]
- `berr` [rank-1 array('d') with bounds (nrhs)]
- `info` [int]

**Other Parameters**

- `fact` [input string(len=1), optional] Default: 'E'
- `trans` [input string(len=1), optional] Default: 'N'
- `overwrite_a` [input int, optional] Default: 0
- `af` [input rank-2 array('D') with bounds (n,n)]
- `ipiv` [input rank-1 array('i') with bounds (n)]
- `equed` [input string(len=1), optional] Default: 'B'
- `r` [input rank-1 array('d') with bounds (n)]
- `c` [input rank-1 array('d') with bounds (n)]
- `overwrite_b` [input int, optional] Default: 0

**scipy.linalg.lapack.sgetrf**

```python
scipy.linalg.lapack.sgetrf(a[, overwrite_a]) = <fortran object>
```

Wrapper for sgetrf.

**Parameters**

- `a` [input rank-2 array('F') with bounds (m,n)]

**Returns**

- `lu` [rank-2 array('F') with bounds (m,n) and a storage]
- `piv` [rank-1 array('i') with bounds (MIN(m, n))]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0
**scipy.linalg.lapack.dgetrf**

`scipy.linalg.lapack.dgetrf(a[, overwrite_a]) = <fortran object>`

Wrapper for dgetrf.

**Parameters**

- `a` [input rank-2 array('d') with bounds (m,n)]

**Returns**

- `lu` [rank-2 array('d') with bounds (m,n) and a storage]
- `piv` [rank-1 array('i') with bounds (MIN(m,n))]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0

**scipy.linalg.lapack.cgetrf**

`scipy.linalg.lapack.cgetrf(a[, overwrite_a]) = <fortran object>`

Wrapper for cgetrf.

**Parameters**

- `a` [input rank-2 array('F') with bounds (m,n)]

**Returns**

- `lu` [rank-2 array('F') with bounds (m,n) and a storage]
- `piv` [rank-1 array('i') with bounds (MIN(m,n))]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0

**scipy.linalg.lapack.zgetrf**

`scipy.linalg.lapack.zgetrf(a[, overwrite_a]) = <fortran object>`

Wrapper for zgetrf.

**Parameters**

- `a` [input rank-2 array('D') with bounds (m,n)]

**Returns**

- `lu` [rank-2 array('D') with bounds (m,n) and a storage]
- `piv` [rank-1 array('i') with bounds (MIN(m,n))]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0

---

**3.3. API definition**

scipy.linalg.lapack.sgetc2

scipy.linalg.lapack.sgetc2(a[, overwrite_a]) = <fortran object>
Wrapper for sgetc2.

Parameters
   a
      [input rank-2 array('f') with bounds (n,n)]

Returns
   lu
      [rank-2 array('f') with bounds (n,n) and a storage]
   ipiv
      [rank-1 array('i') with bounds (n)]
   jpiv
      [rank-1 array('i') with bounds (n)]
   info
      [int]

Other Parameters
   overwrite_a
      [input int, optional] Default: 0

scipy.linalg.lapack.dgetc2

scipy.linalg.lapack.dgetc2(a[, overwrite_a]) = <fortran object>
Wrapper for dgetc2.

Parameters
   a
      [input rank-2 array('d') with bounds (n,n)]

Returns
   lu
      [rank-2 array('d') with bounds (n,n) and a storage]
   ipiv
      [rank-1 array('i') with bounds (n)]
   jpiv
      [rank-1 array('i') with bounds (n)]
   info
      [int]

Other Parameters
   overwrite_a
      [input int, optional] Default: 0

scipy.linalg.lapack.cgetc2

scipy.linalg.lapack.cgetc2(a[, overwrite_a]) = <fortran object>
Wrapper for cgetc2.

Parameters
   a
      [input rank-2 array('F') with bounds (n,n)]

Returns
   lu
      [rank-2 array('F') with bounds (n,n) and a storage]
   ipiv
      [rank-1 array('i') with bounds (n)]
   jpiv
      [rank-1 array('i') with bounds (n)]
   info
      [int]

Other Parameters
   overwrite_a
      [input int, optional] Default: 0
scipy.linalg.lapack.zgetc2

\[
\text{scipy.linalg.lapack.zgetc2}(a[, \text{overwrite}_a]) = \text{<fortran object>}
\]
Wrapper for zgetc2.

**Parameters**

- \(a\) [input rank-2 array('D') with bounds (n,n)]

**Returns**

- \(lu\) [rank-2 array('D') with bounds (n,n) and a storage]
- \(\text{ipiv}\) [rank-1 array('I') with bounds (n)]
- \(\text{j piv}\) [rank-1 array('I') with bounds (n)]
- \(\text{info}\) [int]

**Other Parameters**

- \(\text{overwrite}_a\) [input int, optional] Default: 0

scipy.linalg.lapack.sgetri

\[
\text{scipy.linalg.lapack.sgetri}(\text{lu}, \text{piv}[\text{, lwork, overwrite}_\text{lu}]) = \text{<fortran object>}
\]
Wrapper for sgetri.

**Parameters**

- \(\text{lu}\) [input rank-2 array('F') with bounds (n,n)]
- \(\text{piv}\) [input rank-1 array('I') with bounds (n)]

**Returns**

- \(\text{inv}_a\) [rank-2 array('F') with bounds (n,n) and lu storage]
- \(\text{info}\) [int]

**Other Parameters**

- \(\text{overwrite}_\text{lu}\) [input int, optional] Default: 0
- \(\text{lwork}\) [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.dgetri

\[
\text{scipy.linalg.lapack.dgetri}(\text{lu}, \text{piv}[\text{, lwork, overwrite}_\text{lu}]) = \text{<fortran object>}
\]
Wrapper for dgetri.

**Parameters**

- \(\text{lu}\) [input rank-2 array('D') with bounds (n,n)]
- \(\text{piv}\) [input rank-1 array('I') with bounds (n)]

**Returns**

- \(\text{inv}_a\) [rank-2 array('D') with bounds (n,n) and lu storage]
- \(\text{info}\) [int]

**Other Parameters**

- \(\text{overwrite}_\text{lu}\) [input int, optional] Default: 0
- \(\text{lwork}\) [input int, optional] Default: max(3*n,1)
scipy.linalg.lapack.cgetri

scipy.linalg.lapack.cgetri (lu, piv[, lwork, overwrite_lu]) = <fortran object>
Wrapper for cgetri.

Parameters

lu [input rank-2 array('F') with bounds (n,n)]
piv [input rank-1 array('i') with bounds (n)]

Returns

inv_a [rank-2 array('F') with bounds (n,n) and lu storage]
info [int]

Other Parameters

overwrite_lu [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.zgetri

scipy.linalg.lapack.zgetri (lu, piv[, lwork, overwrite_lu]) = <fortran object>
Wrapper for zgetri.

Parameters

lu [input rank-2 array('D') with bounds (n,n)]
piv [input rank-1 array('i') with bounds (n)]

Returns

inv_a [rank-2 array('D') with bounds (n,n) and lu storage]
info [int]

Other Parameters

overwrite_lu [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.sgetri_lwork

scipy.linalg.lapack.sgetri_lwork (n) = <fortran object>
Wrapper for sgetri_lwork.

Parameters

n [input int]

Returns

work [float]
info [int]
scipy.linalg.lapack.dgetri_lwork

scipy.linalg.lapack.dgetri_lwork(n) = <fortran object>
Wrapper for dgetri_lwork.

Parameters
n [input int]

Returns
work [float]
info [int]

scipy.linalg.lapack.cgetri_lwork

scipy.linalg.lapack.cgetri_lwork(n) = <fortran object>
Wrapper for cgetri_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

scipy.linalg.lapack.zgetri_lwork

scipy.linalg.lapack.zgetri_lwork(n) = <fortran object>
Wrapper for zgetri_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

scipy.linalg.lapack.sgetrs

scipy.linalg.lapack.sgetrs(lu, piv, b[, trans, overwrite_b]) = <fortran object>
Wrapper for sgetrs.

Parameters
lu [input rank-2 array('f') with bounds (n,n)]
piv [input rank-1 array('i') with bounds (n)]
b [input rank-2 array('f') with bounds (n,nrhs)]

Returns
x [rank-2 array('f') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters
overwrite_b [input int, optional] Default: 0
trans [input int, optional] Default: 0

scipy.linalg.lapack.dgetrs

Wrapper for dgetrs.

Parameters

- lu [input rank-2 array('d') with bounds (n,n)]
- piv [input rank-1 array('i') with bounds (n)]
- b [input rank-2 array('d') with bounds (n,nrhs)]

Returns

- x [rank-2 array('d') with bounds (n,nrhs) and b storage]
- info [int]

Other Parameters

- overwrite_b [input int, optional] Default: 0
- trans [input int, optional] Default: 0

scipy.linalg.lapack.cgetrs

Wrapper for cgetrs.

Parameters

- lu [input rank-2 array('F') with bounds (n,n)]
- piv [input rank-1 array('i') with bounds (n)]
- b [input rank-2 array('F') with bounds (n,nrhs)]

Returns

- x [rank-2 array('F') with bounds (n,nrhs) and b storage]
- info [int]

Other Parameters

- overwrite_b [input int, optional] Default: 0
- trans [input int, optional] Default: 0

scipy.linalg.lapack.zgetrs

Wrapper for zgetrs.

Parameters

- lu [input rank-2 array('D') with bounds (n,n)]
- piv [input rank-1 array('i') with bounds (n)]
- b [input rank-2 array('D') with bounds (n,nrhs)]

Returns

- x [rank-2 array('D') with bounds (n,nrhs) and b storage]
- info [int]

Other Parameters

- overwrite_b [input int, optional] Default: 0
trans [input int, optional] Default: 0

**scipy.linalg.lapack.sgesc2**

`scipy.linalg.lapack.sgesc2(lu, rhs, ipiv[, overwrite_rhs]) = <fortran object>`

Wrapper for `sgesc2`.

**Parameters**

- `lu` [input rank-2 array('f') with bounds (n,n)]
- `rhs` [input rank-1 array('f') with bounds (n)]
- `ipiv` [input rank-1 array('i') with bounds (n)]
- `jpiv` [input rank-1 array('i') with bounds (n)]

**Returns**

- `x` [rank-1 array('f') with bounds (n) and rhs storage]
- `scale` [float]

**Other Parameters**

- `overwrite_rhs` [input int, optional] Default: 0

**scipy.linalg.lapack.dgesc2**

`scipy.linalg.lapack.dgesc2(lu, rhs, ipiv[, overwrite_rhs]) = <fortran object>`

Wrapper for `dgesc2`.

**Parameters**

- `lu` [input rank-2 array('d') with bounds (n,n)]
- `rhs` [input rank-1 array('d') with bounds (n)]
- `ipiv` [input rank-1 array('i') with bounds (n)]
- `jpiv` [input rank-1 array('i') with bounds (n)]

**Returns**

- `x` [rank-1 array('d') with bounds (n) and rhs storage]
- `scale` [float]

**Other Parameters**

- `overwrite_rhs` [input int, optional] Default: 0

**scipy.linalg.lapack.cgesc2**

`scipy.linalg.lapack.cgesc2(lu, rhs, ipiv[, overwrite_rhs]) = <fortran object>`

Wrapper for `cgesc2`.

**Parameters**

- `lu` [input rank-2 array('F') with bounds (n,n)]
- `rhs` [input rank-1 array('F') with bounds (n)]
- `ipiv` [input rank-1 array('i') with bounds (n)]
- `jpiv` [input rank-1 array('i') with bounds (n)]

**Returns**

- `x` [rank-1 array('F') with bounds (n) and rhs storage]
- `scale` [float]

**Other Parameters**
overwrite_rhs
   [input int, optional] Default: 0

scipy.linalg.lapack.zgesc2

scipy.linalg.lapack.zgesc2 (lu, rhs, ipiv[, overwrite_rhs]) = <fortran object>
Wrapper for zgesc2.

Parameters
   lu    [input rank-2 array('D') with bounds (n,n)]
   rhs   [input rank-1 array('D') with bounds (n)]
   ipiv  [input rank-1 array('i') with bounds (n)]
   jpiv  [input rank-1 array('i') with bounds (n)]

Returns
   x    [rank-1 array('D') with bounds (n) and rhs storage]
   scale [float]

Other Parameters
   overwrite_rhs
      [input int, optional] Default: 0

scipy.linalg.lapack.sgges

scipy.linalg.lapack.sgges (sselect, a[, jobvsl, jobvsr, sort_t, ldvsl, ldvsr, lwork, sselect_extra_args, overwrite_a, overwrite_b]) = <fortran object>
Wrapper for sgges.

Parameters
   sselect    [call-back function]
   a    [input rank-2 array('f') with bounds (lda,n)]
   b    [input rank-2 array('f') with bounds (ldb,n)]

Returns
   a    [rank-2 array('f') with bounds (lda,n)]
   b    [rank-2 array('f') with bounds (ldb,n)]
   sdim  [int]
   alphar [rank-1 array('f') with bounds (n)]
   alphai [rank-1 array('f') with bounds (n)]
   beta  [rank-1 array('f') with bounds (n)]
   vsl   [rank-2 array('f') with bounds (ldvsl,n)]
   vsr   [rank-2 array('f') with bounds (ldvsr,n)]
   work  [rank-1 array('f') with bounds (MAX(lwork, 1))]
   info  [int]

Other Parameters
   jobvsl   [input int, optional] Default: 1
   jobvsr   [input int, optional] Default: 1
   sort_t   [input int, optional] Default: 0
   sselect_extra_args
      [input tuple, optional] Default: ()
   overwrite_a
      [input int, optional] Default: 0
   overwrite_b
      [input int, optional] Default: 0

ldvsl [input int, optional] Default: ((jobvsl==1)?n:1)
ldvsr [input int, optional] Default: ((jobvsr==1)?n:1)
lwork [input int, optional] Default: max(8*n+16,1)

Notes

Call-back functions:

```python
def sselect(alphar, alphai, beta):
    return sselect
```

Required arguments:
- alphar : input float
- alphai : input float
- beta : input float

Return objects:
- sselect : int

scipy.linalg.lapack.dgges

scipy.linalg.lapack.dgges (dselect, a[, , jobvsl, jobvsr, sort_t, ldvsl, ldvsr, lwork, dselect_extra_args,
overwrite_a, overwrite_b]) = <fortran object>

Wrapper for dgges.

Parameters

- dselect [call-back function]
- a [input rank-2 array('d') with bounds (lda,n)]
- b [input rank-2 array('d') with bounds (ldb,n)]

Returns

- a [rank-2 array('d') with bounds (lda,n)]
- b [rank-2 array('d') with bounds (ldb,n)]
- sdim [int]
- alphar [rank-1 array('d') with bounds (n)]
- alphai [rank-1 array('d') with bounds (n)]
- beta [rank-1 array('d') with bounds (n)]
- vsl [rank-2 array('d') with bounds (ldvsl,n)]
- vsr [rank-2 array('d') with bounds (ldvsr,n)]
- work [rank-1 array('d') with bounds (MAX(lwork, 1))] =
- info [int]

Other Parameters

- jobvsl [input int, optional] Default: 1
- jobvsr [input int, optional] Default: 1
- sort_t [input int, optional] Default: 0
- dselect_extra_args [input tuple, optional] Default: ()
- overwrite_a [input int, optional] Default: 0
- overwrite_b [input int, optional] Default: 0
- ldvsl [input int, optional] Default: ((jobvsl==1)?n:1)
- ldvsr [input int, optional] Default: ((jobvsr==1)?n:1)
- lwork [input int, optional] Default: max(8*n+16,1)

3.3. API definition 925
Notes

Call-back functions:

```python
def dselect(alphar, alphai, beta):
    return dselect
```

Required arguments:
- `alphar` : input float
- `alphai` : input float
- `beta` : input float

Return objects:
- `dselect` : int

`scipy.linalg.lapack.cgges`

`scipy.linalg.lapack.cgges(cselect, a, b, jobvsl, jobvsr, sort_t, ldvsl, ldvsr, lwork, cselect_extra_args, overwrite_a, overwrite_b) = <fortran object>`

Wrapper for cgges.

**Parameters**
- `cselect` [call-back function]
- `a` [input rank-2 array('F') with bounds (lda,n)]
- `b` [input rank-2 array('F') with bounds (ldb,n)]

**Returns**
- `a` [rank-2 array('F') with bounds (lda,n)]
- `b` [rank-2 array('F') with bounds (ldb,n)]
- `sdim` [int]
- `alpha` [rank-1 array('F') with bounds (n)]
- `beta` [rank-1 array('F') with bounds (n)]
- `vsl` [rank-2 array('F') with bounds (ldvsl,n)]
- `vsr` [rank-2 array('F') with bounds (ldvsr,n)]
- `work` [rank-1 array('F') with bounds (MAX(lwork, 1))]  
- `info` [int]

**Other Parameters**
- `jobvsl` [input int, optional] Default: 1
- `jobvsr` [input int, optional] Default: 1
- `sort_t` [input int, optional] Default: 0
- `cselect_extra_args` [input tuple, optional] Default: ()
- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0
- `ldvsl` [input int, optional] Default: ((jobvsl==1)?n:1)
- `ldvsr` [input int, optional] Default: ((jobvsr==1)?n:1)
- `lwork` [input int, optional] Default: max(2*n,1)`
Notes

Call-back functions:

```python
def cselect(alpha, beta):
    return cselect
```

Required arguments:
- `alpha`: input complex
- `beta`: input complex

Return objects:
- `cselect`: int

**scipy.linalg.lapack.zgges**

Wrapper for `zgges`.

**Parameters**
- `zselect` [call-back function]
- `a` [input rank-2 array (D') with bounds (lda,n)]
- `b` [input rank-2 array (D') with bounds (ldb,n)]

**Returns**
- `a` [rank-2 array (D') with bounds (lda,n)]
- `b` [rank-2 array (D') with bounds (ldb,n)]
- `sdim` [int]
- `alpha` [rank-1 array (D') with bounds (n)]
- `beta` [rank-1 array (D') with bounds (n)]
- `vsl` [rank-2 array (D') with bounds (ldvsl,n)]
- `vsr` [rank-2 array (D') with bounds (ldvsr,n)]
- `work` [rank-1 array (D') with bounds (MAX(lwork, 1))]  
- `info` [int]

**Other Parameters**
- `jobvsl` [input int, optional] Default: 1
- `jobvsr` [input int, optional] Default: 1
- `sort_t` [input int, optional] Default: 0
- `zselect_extra_args` [input tuple, optional] Default: ()
- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0
- `ldvsl` [input int, optional] Default: ((jobvsl==1)?n:1)
- `ldvsr` [input int, optional] Default: ((jobvsr==1)?n:1)
- `lwork` [input int, optional] Default: max(2*n,1)
Notes

Call-back functions:

```python
def zselect(alpha, beta):
    return zselect
```

**Required arguments:**
- `alpha`: input complex
- `beta`: input complex

**Return objects:**
- `zselect`: int

### scipy.linalg.lapack.sgev

```python
scipy.linalg.lapack.sgev(a, b[, compute_vl, compute_vr, lwork, overwrite_a, overwrite_b]) =
<fortran object>
```

Wrapper for `sgev`.

**Parameters**
- `a` [input rank-2 array('f') with bounds (n,n)]
- `b` [input rank-2 array('f') with bounds (n,n)]

**Returns**
- `alphar` [rank-1 array('f') with bounds (n)]
- `alphai` [rank-1 array('f') with bounds (n)]
- `beta` [rank-1 array('f') with bounds (n)]
- `vl` [rank-2 array('f') with bounds (ldvl,n)]
- `vr` [rank-2 array('f') with bounds (ldvr,n)]
- `work` [rank-1 array('f') with bounds (MAX(lwork, 1))] (default: `lwork`)
- `info` [int]

**Other Parameters**
- `compute_vl` [input int, optional] Default: 1
- `compute_vr` [input int, optional] Default: 1
- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: max(8*n,1)

### scipy.linalg.lapack.dgev

```python
scipy.linalg.lapack.dgev(a, b[, compute_vl, compute_vr, lwork, overwrite_a, overwrite_b]) =
<fortran object>
```

Wrapper for `dgev`.

**Parameters**
- `a` [input rank-2 array('d') with bounds (n,n)]
- `b` [input rank-2 array('d') with bounds (n,n)]

**Returns**
- `alphar` [rank-1 array('d') with bounds (n)]
- `alphai` [rank-1 array('d') with bounds (n)]
Other Parameters

compute_vl
[input int, optional] Default: 1

compute_vr
[input int, optional] Default: 1

overwrite_a
[input int, optional] Default: 0

overwrite_b
[input int, optional] Default: 0

lwork
[input int, optional] Default: max(2*n,1)

scipy.linalg.lapack.cggev

scipy.linalg.lapack.cggev(a, b[, compute_vl, compute_vr, lwork, overwrite_a, overwrite_b]) =
<fortran object>

Wrapper for cggev.

Parameters

a
[input rank-2 array('F') with bounds (n,n)]

b
[input rank-2 array('F') with bounds (n,n)]

Returns

alpha
[rank-1 array('F') with bounds (n)]

beta
[rank-1 array('F') with bounds (n)]

vl
[rank-2 array('F') with bounds (ldvl,n)]

vr
[rank-2 array('F') with bounds (ldvr,n)]

work
[rank-1 array('F') with bounds (MAX(lwork, 1))]

info
[int]

Other Parameters

compute_vl
[input int, optional] Default: 1

compute_vr
[input int, optional] Default: 1

overwrite_a
[input int, optional] Default: 0

overwrite_b
[input int, optional] Default: 0

lwork
[input int, optional] Default: max(2*n,1)
scipy.linalg.lapack.zggev

scipy.linalg.lapack.zggev(a, b[, compute_vl, compute_vr, lwork, overwrite_a, overwrite_b]) =

<fortran object>

Wrapper for zggev.

Parameters

- **a** [input rank-2 array('D') with bounds (n,n)]
- **b** [input rank-2 array('D') with bounds (n,n)]

Returns

- **alpha** [rank-1 array('D') with bounds (n)]
- **beta** [rank-1 array('D') with bounds (n)]
- **vl** [rank-2 array('D') with bounds (ldvl,n)]
- **vr** [rank-2 array('D') with bounds (ldvr,n)]
- **work** [rank-1 array('D') with bounds (MAX(lwork, 1))]  
- **info** [int]

Other Parameters

- **compute_vl** [input int, optional] Default: 1
- **compute_vr** [input int, optional] Default: 1
- **overwrite_a** [input int, optional] Default: 0
- **overwrite_b** [input int, optional] Default: 0
- **lwork** [input int, optional] Default: max(2*n,1)

scipy.linalg.lapack.sgglse

scipy.linalg.lapack.sgglse(a, b, c, d[, lwork, overwrite_a, overwrite_b, overwrite_c, overwrite_d]) =

<fortran object>

Wrapper for sgglse.

Parameters

- **a** [input rank-2 array('f') with bounds (m,n)]
- **b** [input rank-2 array('f') with bounds (p,n)]
- **c** [input rank-1 array('f') with bounds (m)]
- **d** [input rank-1 array('f') with bounds (p)]

Returns

- **t** [rank-2 array('f') with bounds (m,n) and a storage]
- **r** [rank-2 array('f') with bounds (p,n) and b storage]
- **res** [rank-1 array('f') with bounds (m) and c storage]
- **x** [rank-1 array('f') with bounds (n)]
- **info** [int]

Other Parameters

- **overwrite_a** [input int, optional] Default: 0
- **overwrite_b** [input int, optional] Default: 0
- **overwrite_c** [input int, optional] Default: 0
overwrite_d
   [input int, optional] Default: 0
lwork   [input int, optional] Default: max(m+n+p,1)

scipy.linalg.lapack.dgglse

scipy.linalg.lapack.dgglse(a, b, c, d[, lwork, overwrite_a, overwrite_b, overwrite_c, overwrite_d]) =
   <fortran object>

Wrapper for dgglse.

Parameters
   a   [input rank-2 array('d') with bounds (m,n)]
   b   [input rank-2 array('d') with bounds (p,n)]
   c   [input rank-1 array('d') with bounds (m)]
   d   [input rank-1 array('d') with bounds (p)]

Returns
   t   [rank-2 array('d') with bounds (m,n) and a storage]
   r   [rank-2 array('d') with bounds (p,n) and b storage]
   res [rank-1 array('d') with bounds (m) and c storage]
   x   [rank-1 array('d') with bounds (n)]
   info [int]

Other Parameters
   overwrite_a
      [input int, optional] Default: 0
   overwrite_b
      [input int, optional] Default: 0
   overwrite_c
      [input int, optional] Default: 0
   overwrite_d
      [input int, optional] Default: 0
   lwork   [input int, optional] Default: max(m+n+p,1)

scipy.linalg.lapack.cgglse

scipy.linalg.lapack.cgglse(a, b, c, d[, lwork, overwrite_a, overwrite_b, overwrite_c, overwrite_d]) =
   <fortran object>

Wrapper for cgglse.

Parameters
   a   [input rank-2 array('F') with bounds (m,n)]
   b   [input rank-2 array('F') with bounds (p,n)]
   c   [input rank-1 array('F') with bounds (m)]
   d   [input rank-1 array('F') with bounds (p)]

Returns
   t   [rank-2 array('F') with bounds (m,n) and a storage]
   r   [rank-2 array('F') with bounds (p,n) and b storage]
   res [rank-1 array('F') with bounds (m) and c storage]
   x   [rank-1 array('F') with bounds (n)]
   info [int]

Other Parameters

 overwrite_a
   [input int, optional] Default: 0
 overwrite_b
   [input int, optional] Default: 0
 overwrite_c
   [input int, optional] Default: 0
 overwrite_d
   [input int, optional] Default: 0
 lwork
   [input int, optional] Default: max(m+n+p,1)

scipy.linalg.lapack.zgglse

scipy.linalg.lapack.zgglse(a, b, c, d[, lwork, overwrite_a, overwrite_b, overwrite_c, overwrite_d]) =
<fortran object>

Wrapper for zgglse.

Parameters
 a
   [input rank-2 array('D') with bounds (m,n)]
 b
   [input rank-2 array('D') with bounds (p,n)]
 c
   [input rank-1 array('D') with bounds (m)]
 d
   [input rank-1 array('D') with bounds (p)]

Returns
 t
   [rank-2 array('D') with bounds (m,n) and a storage]
 r
   [rank-2 array('D') with bounds (p,n) and b storage]
 res
   [rank-1 array('D') with bounds (m) and c storage]
 x
   [rank-1 array('D') with bounds (n)]
 info
   [int]

Other Parameters
 overwrite_a
   [input int, optional] Default: 0
 overwrite_b
   [input int, optional] Default: 0
 overwrite_c
   [input int, optional] Default: 0
 overwrite_d
   [input int, optional] Default: 0
 lwork
   [input int, optional] Default: max(m+n+p,1)

scipy.linalg.lapack.sgglse_lwork

scipy.linalg.lapack.sgglse_lwork(m, n, p) = <fortran object>

Wrapper for sgglse_lwork.

Parameters
 m
   [input int]
 n
   [input int]
 p
   [input int]

Returns
 work
   [float]
 info
   [int]
scipy.linalg.lapack.dgglse_lwork

scipy.linalg.lapack.dgglse_lwork(m, n, p) = <fortran object>
Wrapper for dgglse_lwork.

Parameters
m [input int]
n [input int]
p [input int]

Returns
work [float]
info [int]

scipy.linalg.lapack.cgglse_lwork

scipy.linalg.lapack.cgglse_lwork(m, n, p) = <fortran object>
Wrapper for cgglse_lwork.

Parameters
m [input int]
n [input int]
p [input int]

Returns
work [complex]
info [int]

scipy.linalg.lapack.zgglse_lwork

scipy.linalg.lapack.zgglse_lwork(m, n, p) = <fortran object>
Wrapper for zgglse_lwork.

Parameters
m [input int]
n [input int]
p [input int]

Returns
work [complex]
info [int]

scipy.linalg.lapack.sgtsv

scipy.linalg.lapack.sgtsv(dl, d, du[, overwrite_dl, overwrite_d, overwrite_du, overwrite_b]) = <fortran object>
Wrapper for sgtsv.

Parameters
dl [input rank-1 array('f') with bounds (-1 + n)]
d [input rank-1 array('f') with bounds (n)]
du [input rank-1 array('f') with bounds (-1 + n)]
b [input rank-2 array('f') with bounds (n,nrhs)]

Returns
du2 [rank-1 array('f') with bounds (-1 + n) and dl storage]

```python
d [rank-1 array('f') with bounds (n)]
du [rank-1 array('f') with bounds (-1 + n)]
x [rank-2 array('f') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters
overwrite_dl [input int, optional] Default: 0
overwrite_d [input int, optional] Default: 0
overwrite_du [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.dgtsv
scipy.linalg.lapack.dgtsv (dl, d, du, b[, overwrite_dl, overwrite_d, overwrite_du, overwrite_b]) =
<fortran object>
Wrapper for dgtsv.

Parameters
dl [input rank-1 array('d') with bounds (-1 + n)]
d [input rank-1 array('d') with bounds (n)]
du [input rank-1 array('d') with bounds (-1 + n)]
b [input rank-2 array('d') with bounds (n,nrhs)]

Returns
du2 [rank-1 array('d') with bounds (-1 + n) and dl storage]
d [rank-1 array('d') with bounds (n)]
du [rank-1 array('d') with bounds (-1 + n)]
x [rank-2 array('d') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters
overwrite_dl [input int, optional] Default: 0
overwrite_d [input int, optional] Default: 0
overwrite_du [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.cgtsv
scipy.linalg.lapack.cgtsv (dl, d, du, b[, overwrite_dl, overwrite_d, overwrite_du, overwrite_b]) =
<fortran object>
Wrapper for cgtsv.

Parameters
dl [input rank-1 array('F') with bounds (-1 + n)]
d [input rank-1 array('F') with bounds (n)]
du [input rank-1 array('F') with bounds (-1 + n)]
b [input rank-2 array('F') with bounds (n,nrhs)]
```

934 Chapter 3. SciPy API
Returns

du2 [rank-1 array('F') with bounds (-1 + n) and dl storage]
d [rank-1 array('F') with bounds (n)]
du [rank-1 array('F') with bounds (-1 + n)]
x [rank-2 array('F') with bounds (n, nrhs) and b storage]
info [int]

Other Parameters

overwrite_dl
[ input int, optional] Default: 0
overwrite_d
[ input int, optional] Default: 0
overwrite_du
[ input int, optional] Default: 0
overwrite_b
[ input int, optional] Default: 0

scipy.linalg.lapack.zgtsv

scipy.linalg.lapack.zgtsv(dl, d, du, b[, overwrite_dl, overwrite_d, overwrite_du, overwrite_b]) =
<fortran object>

Wrapper for zgtsv.

Parameters

dl [input rank-1 array('D') with bounds (-1 + n)]
d [input rank-1 array('D') with bounds (n)]
du [input rank-1 array('D') with bounds (-1 + n)]
b [input rank-2 array('D') with bounds (n, nrhs)]

Returns

du2 [rank-1 array('D') with bounds (-1 + n) and dl storage]
d [rank-1 array('D') with bounds (n)]
du [rank-1 array('D') with bounds (-1 + n)]
x [rank-2 array('D') with bounds (n, nrhs) and b storage]
info [int]

Other Parameters

overwrite_dl
[ input int, optional] Default: 0
overwrite_d
[ input int, optional] Default: 0
overwrite_du
[ input int, optional] Default: 0
overwrite_b
[ input int, optional] Default: 0
scipy.linalg.lapack.sgtsvx

scipy.linalg.lapack.sgtsvx(dl, d, du, b[, fact, trans, dlf, df, duf, du2, ipiv]) = <fortran object>

Wrapper for sgtsvx.

Parameters

dl [input rank-1 array('f') with bounds (MAX(0, -1 + n))]
d [input rank-1 array('f') with bounds (n)]
du [input rank-1 array('f') with bounds (MAX(0, -1 + n))]
b [input rank-2 array('f') with bounds (ldb,nrhs)]

Returns
dl [rank-1 array('f') with bounds (MAX(0, -1 + n))]
df [rank-1 array('f') with bounds (n)]
duf [rank-1 array('f') with bounds (MAX(0, -1 + n))]
du2 [rank-1 array('f') with bounds (MAX(0, -2 + n))]
ipiv [rank-1 array('i') with bounds (n)]
x [rank-2 array('f') with bounds (ldx,nrhs)]
rcond [float]
ferr [rank-1 array('f') with bounds (nrhs)]
berr [rank-1 array('f') with bounds (nrhs)]
info [int]

Other Parameters

fact [input string(len=1), optional] Default: 'N'
trans [input string(len=1), optional] Default: 'N'
dlf [input rank-1 array('f') with bounds (MAX(0, -1 + n))]
df [input rank-1 array('f') with bounds (n)]
duf [input rank-1 array('f') with bounds (MAX(0, -1 + n))]
du2 [input rank-1 array('f') with bounds (MAX(0, -2 + n))]

scipy.linalg.lapack.dgtsvx

scipy.linalg.lapack.dgtsvx(dl, d, du, b[, fact, trans, dlf, df, duf, du2, ipiv]) = <fortran object>

Wrapper for dgtsvx.

Parameters

dl [input rank-1 array('d') with bounds (MAX(0, -1 + n))]
d [input rank-1 array('d') with bounds (n)]
du [input rank-1 array('d') with bounds (MAX(0, -1 + n))]
b [input rank-2 array('d') with bounds (ldb,nrhs)]

Returns
dl [rank-1 array('d') with bounds (MAX(0, -1 + n))]
df [rank-1 array('d') with bounds (n)]
duf [rank-1 array('d') with bounds (MAX(0, -1 + n))]
du2 [rank-1 array('d') with bounds (MAX(0, -2 + n))]
ipiv [rank-1 array('i') with bounds (n)]
x [rank-2 array('d') with bounds (ldx,nrhs)]
rcond [float]
ferr [rank-1 array('d') with bounds (nrhs)]
berr [rank-1 array('d') with bounds (nrhs)]
info [int]
Other Parameters

- **fact**: [input string(len=1), optional] Default: 'N'
- **trans**: [input string(len=1), optional] Default: 'N'
- **dlf**: [input rank-1 array('d') with bounds (MAX(0, -1 + n))]
- **df**: [input rank-1 array('d') with bounds (n)]
- **duf**: [input rank-1 array('d') with bounds (MAX(0, -1 + n))]
- **du2**: [input rank-1 array('d') with bounds (MAX(0, -2 + n))]
- **ipiv**: [input rank-1 array('i') with bounds (n)]

**scipy.linalg.lapack.cgtsvx**

```python
scipy.linalg.lapack.cgtsvx(dl, d, du, b[, fact, trans, dlf, df, duf, du2, ipiv]) = <fortran object>
```

Wrapper for cgtsvx.

Parameters

- **dl**: [input rank-1 array('F') with bounds (MAX(0, -1 + n))]
- **d**: [input rank-1 array('F') with bounds (n)]
- **du**: [input rank-1 array('F') with bounds (MAX(0, -1 + n))]
- **b**: [input rank-2 array('F') with bounds (ldb,nrhs)]

Returns

- **dlf**: [rank-1 array('F') with bounds (MAX(0, -1 + n))]
- **df**: [rank-1 array('F') with bounds (n)]
- **duf**: [rank-1 array('F') with bounds (MAX(0, -1 + n))]
- **du2**: [rank-1 array('F') with bounds (MAX(0, -2 + n))]
- **ipiv**: [rank-1 array('i') with bounds (n)]
- **x**: [rank-2 array('F') with bounds (ldx,nrhs)]
- **rcond**: [float]
- **ferr**: [rank-1 array('f') with bounds (nrhs)]
- **berr**: [rank-1 array('f') with bounds (nrhs)]
- **info**: [int]

Other Parameters

- **fact**: [input string(len=1), optional] Default: 'N'
- **trans**: [input string(len=1), optional] Default: 'N'
- **dlf**: [input rank-1 array('F') with bounds (MAX(0, -1 + n))]
- **df**: [input rank-1 array('F') with bounds (n)]
- **duf**: [input rank-1 array('F') with bounds (MAX(0, -1 + n))]
- **du2**: [input rank-1 array('F') with bounds (MAX(0, -2 + n))]
- **ipiv**: [input rank-1 array('i') with bounds (n)]

**scipy.linalg.lapack.zgtsvx**

```python
scipy.linalg.lapack.zgtsvx(dl, d, du, b[, fact, trans, dlf, df, duf, du2, ipiv]) = <fortran object>
```

Wrapper for zgtsvx.

Parameters

- **dl**: [input rank-1 array('D') with bounds (MAX(0, -1 + n))]
- **d**: [input rank-1 array('D') with bounds (n)]
- **du**: [input rank-1 array('D') with bounds (MAX(0, -1 + n))]
- **b**: [input rank-2 array('D') with bounds (ldb,nrhs)]

Returns

- **dlf**: [rank-1 array('D') with bounds (MAX(0, -1 + n))]

3.3. API definition

```
scipy.linalg.lapack.chbevd
scipy.linalg.lapack.chbevd(ab[, compute_v, lower, ldab, lrwork, liwork, overwrite_ab]) = <fortran object>
```

Wrapper for chbevd.

**Parameters**

- `ab` [input rank-2 array('F') with bounds (ldab,n)]

**Returns**

- `w` [rank-1 array('f') with bounds (n)]
- `z` [rank-2 array('F') with bounds (ldz,ldz)]
- `info` [int]

**Other Parameters**

- `overwrite_ab` [input int, optional] Default: 1
- `compute_v` [input int, optional] Default: 1
- `lower` [input int, optional] Default: 0
- `ldab` [input int, optional] Default: shape(ab,0)
- `lrwork` [input int, optional] Default: (compute_v?1+5*n+2*n*n:n)
- `liwork` [input int, optional] Default: (compute_v?3+5*n:1)

```
scipy.linalg.lapack.zhbevd
scipy.linalg.lapack.zhbevd(ab[, compute_v, lower, ldab, lrwork, liwork, overwrite_ab]) = <fortran object>
```

Wrapper for zhbevd.

**Parameters**

- `ab` [input rank-2 array('D') with bounds (ldab,n)]

**Returns**

- `w` [rank-1 array('d') with bounds (n)]
- `z` [rank-2 array('D') with bounds (ldz,ldz)]

---

**df** [rank-1 array('D') with bounds (n)]

**duf** [rank-1 array('D') with bounds (MAX(0, -1 + n))]

**du2** [rank-1 array('D') with bounds (MAX(0, -2 + n))]

**ipiv** [rank-1 array('i') with bounds (n)]

**x** [rank-2 array('D') with bounds (ldx,nrhs)]

**rcond** [float]

**ferr** [rank-1 array('d') with bounds (nrhs)]

**berr** [rank-1 array('d') with bounds (nrhs)]

**info** [int]

**Other Parameters**

- `fact` [input string(len=1), optional] Default: 'N'
- `trans` [input string(len=1), optional] Default: 'N'
- `dlf` [input rank-1 array('D') with bounds (MAX(0, -1 + n))]
- `df` [input rank-1 array('D') with bounds (n)]
- `duf` [input rank-1 array('D') with bounds (MAX(0, -1 + n))]
- `du2` [input rank-1 array('D') with bounds (MAX(0, -2 + n))]
- `ipiv` [input rank-1 array('i') with bounds (n)]
info [int]

Other Parameters

overwrite_ab
  [input int, optional] Default: 1

compute_v
  [input int, optional] Default: 1

lower
  [input int, optional] Default: 0

ldab
  [input int, optional] Default: shape(ab,0)

lrwork
  [input int, optional] Default: (compute_v?1+5*n+2*n*n:n)

liwork
  [input int, optional] Default: (compute_v?3+5*n:1)

scipy.linalg.lapack.chbevx

scipy.linalg.lapack.chbevx(ab, vl, vu, il, iu[, ldab, compute_v, range, lower, abstol, mmax, overwrite_ab]) = <fortran object>

Wrapper for chbevx.

Parameters

ab
  [input rank-2 array(‘F’) with bounds (ldab,n)]

vl
  [input float]

vu
  [input float]

il
  [input int]

iu
  [input int]

Returns

w
  [rank-1 array(‘f’) with bounds (n)]

z
  [rank-2 array(‘F’) with bounds (ldz,mmax)]

m
  [int]

ifail
  [rank-1 array(‘i’) with bounds ((compute_v?n:1))]

info
  [int]

Other Parameters

overwrite_ab
  [input int, optional] Default: 1

ldab
  [input int, optional] Default: shape(ab,0)

compute_v
  [input int, optional] Default: 1

range
  [input int, optional] Default: 0

lower
  [input int, optional] Default: 0

abstol
  [input float, optional] Default: 0.0

mmax
  [input int, optional] Default: (compute_v?(range==2?(iu-il+1):n):1)

scipy.linalg.lapack.zhbevx

scipy.linalg.lapack.zhbevx(ab, vl, vu, il, iu[, ldab, compute_v, range, lower, abstol, mmax, overwrite_ab]) = <fortran object>

Wrapper for zhbevx.

Parameters

ab
  [input rank-2 array(‘D’) with bounds (ldab,n)]

vl
  [input float]

vu
  [input float]

il
  [input int]

iu
  [input int]
Returns

\[ w \quad \text{[rank-1 array('d') with bounds (n)]} \]
\[ z \quad \text{[rank-2 array('D') with bounds (ldz,mmax)]} \]
\[ m \quad \text{[int]} \]
\[ ifail \quad \text{[rank-1 array('i') with bounds ((compute_v?n:1))]} \]
\[ info \quad \text{[int]} \]

Other Parameters

\[
\begin{align*}
\text{overwrite_ab} & \quad \text{[input int, optional] Default: 1} \\
\text{ldab} & \quad \text{[input int, optional] Default: shape(ab,0)} \\
\text{compute_v} & \quad \text{[input int, optional] Default: 1} \\
\text{range} & \quad \text{[input int, optional] Default: 0} \\
\text{lower} & \quad \text{[input int, optional] Default: 0} \\
\text{abstol} & \quad \text{[input float, optional] Default: 0.0} \\
\text{mmax} & \quad \text{[input int, optional] Default: (compute_v?(range==2?(iu-il+1):n):1)}
\end{align*}
\]

\text{scipy.linalg.lapack.checon}

\text{scipy.linalg.lapack.checon(a, ipiv, anorm[, lower])} = <fortran object>

Wrapper for checon.

Parameters

\[
\begin{align*}
\text{a} & \quad \text{[input rank-2 array('F') with bounds (n,n)]} \\
\text{ipiv} & \quad \text{[input rank-1 array('i') with bounds (n)]} \\
\text{anorm} & \quad \text{[input float]} \\
\end{align*}
\]

Returns

\[ rcond \quad \text{[float]} \]
\[ info \quad \text{[int]} \]

Other Parameters

\[ lower \quad \text{[input int, optional] Default: 0} \]

\text{scipy.linalg.lapack.zhecon}

\text{scipy.linalg.lapack.zhecon(a, ipiv, anorm[, lower])} = <fortran object>

Wrapper for zhecon.

Parameters

\[
\begin{align*}
\text{a} & \quad \text{[input rank-2 array('D') with bounds (n,n)]} \\
\text{ipiv} & \quad \text{[input rank-1 array('i') with bounds (n)]} \\
\text{anorm} & \quad \text{[input float]} \\
\end{align*}
\]

Returns

\[ rcond \quad \text{[float]} \]
\[ info \quad \text{[int]} \]

Other Parameters

\[ lower \quad \text{[input int, optional] Default: 0} \]
scipy.linalg.lapack.chee qub

scipy.linalg.lapack.chee qub(a[, lower]) = <fortran object>
Wrapper for cheequb.

Parameters
  a [input rank-2 array('F') with bounds (lda,n)]

Returns
  s [rank-1 array('f') with bounds (n)]
  scond [float]
  amax [float]
  info [int]

Other Parameters
  lower [input int, optional] Default: 0

scipy.linalg.lapack.zheequb

scipy.linalg.lapack.zheequb(a[, lower]) = <fortran object>
Wrapper for zheequb.

Parameters
  a [input rank-2 array('D') with bounds (lda,n)]

Returns
  s [rank-1 array('d') with bounds (n)]
  scond [float]
  amax [float]
  info [int]

Other Parameters
  lower [input int, optional] Default: 0

scipy.linalg.lapack.cheev

scipy.linalg.lapack.cheev(a[, compute_v, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for cheev.

Parameters
  a [input rank-2 array('F') with bounds (n,n)]

Returns
  w [rank-1 array('f') with bounds (n)]
  v [rank-2 array('F') with bounds (n,n) and a storage]
  info [int]

Other Parameters
  compute_v [input int, optional] Default: 1
  lower [input int, optional] Default: 0
  overwrite_a [input int, optional] Default: 0
  lwork [input int, optional] Default: max(2*n-1,1)
scipy.linalg.lapack.zheev

scipy.linalg.lapack.zheev(a[;, compute_v, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for zheev.

Parameters

a [input rank-2 array('D') with bounds (n,n)]

Returns

w [rank-1 array('d') with bounds (n)]
v [rank-2 array('D') with bounds (n,n) and a storage]
info [int]

Other Parameters

compute_v [input int, optional] Default: 1
lower [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(2*n-1,1)

scipy.linalg.lapack.cheev_lwork

scipy.linalg.lapack.cheev_lwork(n[; lower]) = <fortran object>
Wrapper for cheev_lwork.

Parameters

n [input int]

Returns

work [complex]
info [int]

Other Parameters

lower [input int, optional] Default: 0

scipy.linalg.lapack.zheev_lwork

scipy.linalg.lapack.zheev_lwork(n[; lower]) = <fortran object>
Wrapper for zheev_lwork.

Parameters

n [input int]

Returns

work [complex]
info [int]

Other Parameters

lower [input int, optional] Default: 0
scipy.linalg.lapack.cheevd

scipy.linalg.lapack.cheevd(a[, compute_v, lower, lwork, liwork, lrwork, overwrite_a]) = <fortran object>

Wrapper for cheevd.

Parameters

- **a** [input rank-2 array('F') with bounds (n,n)]

Returns

- **w** [rank-1 array('f') with bounds (n)]
- **v** [rank-2 array('F') with bounds (n,n) and a storage]
- **info** [int]

Other Parameters

- **compute_v** [input int, optional] Default: 1
- **lower** [input int, optional] Default: 0
- **overwrite_a** [input int, optional] Default: 0
- **lwork** [input int, optional] Default: max((compute_v?2*n+n*n:n+1),1)
- **liwork** [input int, optional] Default: (compute_v?3+5*n:1)
- **lrwork** [input int, optional] Default: (compute_v?1+5*n+2*n*n:n)

scipy.linalg.lapack.zheevd

scipy.linalg.lapack.zheevd(a[, compute_v, lower, lwork, liwork, lrwork, overwrite_a]) = <fortran object>

Wrapper for zheevd.

Parameters

- **a** [input rank-2 array('D') with bounds (n,n)]

Returns

- **w** [rank-1 array('d') with bounds (n)]
- **v** [rank-2 array('D') with bounds (n,n) and a storage]
- **info** [int]

Other Parameters

- **compute_v** [input int, optional] Default: 1
- **lower** [input int, optional] Default: 0
- **overwrite_a** [input int, optional] Default: 0
- **lwork** [input int, optional] Default: max((compute_v?2*n+n*n:n+1),1)
- **liwork** [input int, optional] Default: (compute_v?3+5*n:1)
- **lrwork** [input int, optional] Default: (compute_v?1+5*n+2*n*n:n)
**scipy.linalg.lapack.cheevd_lwork**

*scipy.linalg.lapack.cheevd_lwork(n[, compute_v, lower]) = <fortran object>*

Wrapper for `cheevd_lwork`.

**Parameters**

- n [input int]

**Returns**

- work [complex]
- iwork [int]
- rwork [float]
- info [int]

**Other Parameters**

- compute_v [input int, optional] Default: 1
- lower [input int, optional] Default: 0

**scipy.linalg.lapack.zheevd_lwork**

*scipy.linalg.lapack.zheevd_lwork(n[, compute_v, lower]) = <fortran object>*

Wrapper for `zheevd_lwork`.

**Parameters**

- n [input int]

**Returns**

- work [complex]
- iwork [int]
- rwork [float]
- info [int]

**Other Parameters**

- compute_v [input int, optional] Default: 1
- lower [input int, optional] Default: 0

**scipy.linalg.lapack.cheevr**

*scipy.linalg.lapack.cheevr(a[, compute_v, range, lower, vl, vu, il, iu, abstol, lwork, lrwork, liwork, overwrite_a]) = <fortran object>*

Wrapper for `cheevr`.

**Parameters**

- a [input rank-2 array('F') with bounds (n,n)]

**Returns**

- w [rank-1 array('f') with bounds (n)]
- z [rank-2 array('F') with bounds ((compute_v?MAX(0, n):0),(compute_v?(*range == 'I'?1 - il + iu:MAX(1, n)):0))]
- m [int]
- isuppz [rank-1 array('i') with bounds (2 * max(1, n))]
- info [int]

**Other Parameters**
scipy.linalg.lapack.zheevr

scipy.linalg.lapack.zheevr(a[, compute_v, range, lower, vl, vu, il, iu, abstol, lwork, lrwork, liwork, overwrite_a]) = <fortran object>

Wrapper for zheevr.

Parameters

- **a** [input rank-2 array('D') with bounds (n,n)]

Returns

- **w** [rank-1 array('d') with bounds (n)]
- **z** [rank-2 array('D') with bounds ((compute_v?MAX(0, n):0),(compute_v?(*range == 'I'?1 - il + iu:MAX(1, n)):0))]
- **m** [int]
- **isuppz** [rank-1 array('i') with bounds (2 * max(1, n))]
- **info** [int]

Other Parameters

- **compute_v** [input int, optional] Default 1
- **range** [input string(len=1), optional] Default 'A'
- **lower** [input int, optional] Default 0
- **overwrite_a** [input int, optional] Default 0
- **vl** [input float, optional] Default 0.0
- **vu** [input float, optional] Default 1.0
- **il** [input int, optional] Default 1
- **iu** [input int, optional] Default n
- **abstol** [input int, optional] Default 0.0
- **lwork** [input int, optional] Default max(2*n,1)
- **lrwork** [input int, optional] Default max(24*n,1)
- **liwork** [input int, optional] Default max(1,10*n)
scipy.linalg.lapack.cheevr_lwork

scipy.linalg.lapack.cheevr_lwork(n[, lower]) = <fortran object>

Wrapper for cheevr_lwork.

Parameters

n [input int]

Returns

work [complex]
rwork [float]
iwork [int]
info [int]

Other Parameters

lower [input int, optional] Default: 0

scipy.linalg.lapack.zheevr_lwork

scipy.linalg.lapack.zheevr_lwork(n[, lower]) = <fortran object>

Wrapper for zheevr_lwork.

Parameters

n [input int]

Returns

work [complex]
rwork [float]
iwork [int]
info [int]

Other Parameters

lower [input int, optional] Default: 0

scipy.linalg.lapack.cheevx

scipy.linalg.lapack.cheevx(a[, compute_v, range, lower, vl, vu, il, iu, abstol, lwork, overwrite_a]) = <fortran object>

Wrapper for cheevx.

Parameters

a [input rank-2 array('F') with bounds (n,n)]

Returns

w [rank-1 array('f') with bounds (n)]
z [rank-2 array('F') with bounds (compute_v * n,(compute_v?(*range == 'I'? 1 - il + iu:MAX(1, n)):0))]
m [int]
ifail [rank-1 array('i') with bounds (compute_v * n)]
info [int]

Other Parameters

compute_v [input int, optional] Default 1
range [input string(len=1), optional] Default 'A'
\[ \text{lower} \quad \text{[input int, optional]} \quad \text{Default: 0} \]
\[ \text{overwrite_a} \quad \text{[input int, optional]} \quad \text{Default: 0} \]
\[ \text{vl} \quad \text{[input float, optional]} \quad \text{Default: 0.0} \]
\[ \text{vu} \quad \text{[input float, optional]} \quad \text{Default: 1.0} \]
\[ \text{il} \quad \text{[input int, optional]} \quad \text{Default: 1} \]
\[ \text{iu} \quad \text{[input int, optional]} \quad \text{Default: } n \]
\[ \text{abstol} \quad \text{[input float, optional]} \quad \text{Default: 0.0} \]
\[ \text{lwork} \quad \text{[input int, optional]} \quad \text{Default: max(2*n, 1)} \]

`scipy.linalg.lapack.zheevx`

\[ \text{scipy.linalg.lapack.zheevx}(a[, \text{compute_v, range, lower, vl, vu, il, iu, abstol, lwork, overwrite_a}]) = <\text{fortran object}> \]

Wrapper for zheevx.

**Parameters**

\[ a \quad \text{[input rank-2 array('D') with bounds (n, n)]} \]

**Returns**

\[ w \quad \text{[rank-1 array('d') with bounds (n)]} \]
\[ z \quad \text{[rank-2 array('D') with bounds (compute_v * n, (compute_v?(*range == 'I'? 1 - il + iu:MAX(1, n)):0))]} \]
\[ m \quad \text{[int]} \]
\[ ifail \quad \text{[rank-1 array('i') with bounds (compute_v * n)]} \]
\[ info \quad \text{[int]} \]

**Other Parameters**

\[ \text{compute_v} \quad \text{[input int, optional]} \quad \text{Default: 1} \]
\[ \text{range} \quad \text{[input string(len=1), optional]} \quad \text{Default: 'A'} \]
\[ \text{lower} \quad \text{[input int, optional]} \quad \text{Default: 0} \]
\[ \text{overwrite_a} \quad \text{[input int, optional]} \quad \text{Default: 0} \]
\[ \text{vl} \quad \text{[input float, optional]} \quad \text{Default: 0.0} \]
\[ \text{vu} \quad \text{[input float, optional]} \quad \text{Default: 1.0} \]
\[ \text{il} \quad \text{[input int, optional]} \quad \text{Default: 1} \]
\[ \text{iu} \quad \text{[input int, optional]} \quad \text{Default: } n \]
\[ \text{abstol} \quad \text{[input float, optional]} \quad \text{Default: 0.0} \]
\[ \text{lwork} \quad \text{[input int, optional]} \quad \text{Default: max(2*n, 1)} \]

`scipy.linalg.lapack.cheevx_lwork`

\[ \text{scipy.linalg.lapack.cheevx_lwork}(n[, \text{lower}]) = <\text{fortran object}> \]

Wrapper for cheevx_lwork.

**Parameters**

\[ n \quad \text{[input int]} \]

**Returns**

\[ \text{work} \quad \text{[complex]} \]
\[ \text{info} \quad \text{[int]} \]

**Other Parameters**

\[ \text{lower} \quad \text{[input int, optional]} \quad \text{Default: 0} \]
scipy.linalg.lapack.zheevx_lwork

scipy.linalg.lapack.zheevx_lwork(n[, lower]) = <fortran object>
Wrapper for zheevx_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.chegst

scipy.linalg.lapack.chegst(a, b[, itype, lower, overwrite_a]) = <fortran object>
Wrapper for chegst.

Parameters
a [input rank-2 array('F') with bounds (n,n)]
b [input rank-2 array('F') with bounds (n,n)]

Returns
c [rank-2 array('F') with bounds (n,n) and a storage]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
itype [input int, optional] Default: 1
lower [input int, optional] Default: 0

scipy.linalg.lapack.zhegst

scipy.linalg.lapack.zhegst(a, b[, itype, lower, overwrite_a]) = <fortran object>
Wrapper for zhegst.

Parameters
a [input rank-2 array('D') with bounds (n,n)]
b [input rank-2 array('D') with bounds (n,n)]

Returns
c [rank-2 array('D') with bounds (n,n) and a storage]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
itype [input int, optional] Default: 1
lower [input int, optional] Default: 0

**scipy.linalg.lapack.chegv**

`scipy.linalg.lapack.chegv(a, b[, itype, jobz, uplo, lwork, overwrite_a, overwrite_b]) = <fortran object>`

Wrapper for `chegv`.

**Parameters**

- `a` [input rank-2 array('F') with bounds (n,n)]
- `b` [input rank-2 array('F') with bounds (n,n)]

**Returns**

- `w` [rank-1 array('f') with bounds (n)]
- `v` [rank-2 array('F') with bounds (n,n) and a storage]
- `info` [int]

**Other Parameters**

- `itype` [input int, optional] Default: 1
- `jobz` [input string(len=1), optional] Default: ‘V’
- `uplo` [input string(len=1), optional] Default: ‘L’
- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: max(2*n-1,1)

**scipy.linalg.lapack.zhegv**

`scipy.linalg.lapack.zhegv(a, b[, itype, jobz, uplo, lwork, overwrite_a, overwrite_b]) = <fortran object>`

Wrapper for `zhegv`.

**Parameters**

- `a` [input rank-2 array('D') with bounds (n,n)]
- `b` [input rank-2 array('D') with bounds (n,n)]

**Returns**

- `w` [rank-1 array('d') with bounds (n)]
- `v` [rank-2 array('D') with bounds (n,n) and a storage]
- `info` [int]

**Other Parameters**

- `itype` [input int, optional] Default: 1
- `jobz` [input string(len=1), optional] Default: ‘V’
- `uplo` [input string(len=1), optional] Default: ‘L’
- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: max(2*n-1,1)
scipy.linalg.lapack.chegv_lwork

scipy.linalg.lapack.chegv_lwork($n[, uplo]) = <fortran object>

Wrapper for chegv_lwork.

Parameters

$n$ [input int]

Returns

work [complex]
info [int]

Other Parameters

$uplo$ [input string(len=1), optional] Default: ‘L’

scipy.linalg.lapack.zhegv_lwork

scipy.linalg.lapack.zhegv_lwork($n[, uplo]) = <fortran object>

Wrapper for zhegv_lwork.

Parameters

$n$ [input int]

Returns

work [complex]
info [int]

Other Parameters

$uplo$ [input string(len=1), optional] Default: ‘L’

scipy.linalg.lapack.chegvd

scipy.linalg.lapack.chegvd($a, b[, itype, jobz, uplo, lwork, lrwork, liwork, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for chegvd.

Parameters

$a$ [input rank-2 array('F') with bounds ($n$, $n$)]
$b$ [input rank-2 array('F') with bounds ($n$, $n$)]

Returns

$w$ [rank-1 array('f') with bounds ($n$)]
$v$ [rank-2 array('F') with bounds ($n$, $n$) with a storage]
info [int]

Other Parameters

$itype$ [input int, optional] Default 1
$jobz$ [input string(len=1), optional] Default ‘V’
$uplo$ [input string(len=1), optional] Default ‘L’
$overwrite_a$ [input int, optional] Default 0
$overwrite_b$ [input int, optional] Default 0
$lwork$ [input int, optional] Default max((*jobz=='N'?n+1:n*2*n+5*n+1),1)
$lrwork$ [input int, optional] Default $max((*jobz=='N'?2*n*n+5*n+1,1$)

liwork  [input int, optional] Default (*jobz==’N’?1:5*n+3)

scipy.linalg.lapack.zhegvd

scipy.linalg.lapack.zhegvd(a, b[, itype, jobz, uplo, lwork, lrwork, liwork, overwrite_a, overwrite_b]) =
<fortran object>

Wrapper for zhegvd.

Parameters

- **a** [input rank-2 array(‘D’) with bounds (n,n)]
- **b** [input rank-2 array(‘D’) with bounds (n,n)]

Returns

- **w** [rank-1 array(‘d’) with bounds (n)]
- **v** [rank-2 array(‘D’) with bounds (n,n) with a storage]
- **info** [int]

Other Parameters

- **itype** [input int, optional] Default 1
- **jobz** [input string(len=1), optional] Default ’V’
- **uplo** [input string(len=1), optional] Default ’L’
- **overwrite_a** [input int, optional] Default 0
- **overwrite_b** [input int, optional] Default 0
- **lwork** [input int, optional] Default (*jobz==’N’?n+1:n*(n+2))
- **lrwork** [input int, optional] Default max((*jobz==’N’?n:2*n*n+5*n+1),1)
- **liwork** [input int, optional] Default (*jobz==’N’?1:5*n+3)

scipy.linalg.lapack.chegvx

scipy.linalg.lapack.chegvx(a, b[, itype, jobz, range, uplo, vl, vu, il, iu, abstol, lwork, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for chegvx.

Parameters

- **a** [input rank-2 array(‘F’) with bounds (n,n)]
- **b** [input rank-2 array(‘F’) with bounds (n,n)]

Returns

- **w** [rank-1 array(‘f’) with bounds (n)]
- **z** [rank-2 array(‘F’) with bounds ((jobz[0]=='V'?MAX(0,n):0),(jobz[0]=='V'(range[0]==’I’?il-1:il+iu:MAX(1, n)):0))]
- **m** [int]
- **ifail** [rank-1 array(‘i’) with bounds ((jobz[0]=='N’?0:n))]
- **info** [int]

Other Parameters

- **itype** [input int, optional] Default: 1
- **jobz** [input string(len=1), optional] Default: ’V’
- **range** [input string(len=1), optional] Default: ’A’
- **uplo** [input string(len=1), optional] Default: ’L’
- **overwrite_a** [input int, optional] Default: 0
overwrite_b
    [input int, optional] Default: 0
vl
    [input float, optional] Default: 0.0
vu
    [input float, optional] Default: 1.0
il
    [input int, optional] Default: 1
iu
    [input int, optional] Default: n
abstol
    [input float, optional] Default: 0.0
lwork
    [input int, optional] Default: max(2*n,1)

scipy.linalg.lapack.zhegvx

scipy.linalg.lapack.zhegvx(a, b[, itype, jobz, range, uplo, vl, vu, il, iu, abstol, lwork, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for zhegvx.

Parameters

a
    [input rank-2 array('D') with bounds (n,n)]
b
    [input rank-2 array('D') with bounds (n,n)]

Returns

w
    [rank-1 array('d') with bounds (n)]
z
    [rank-2 array('D') with bounds ((jobz[0] == 'V'?MAX(0,n):0),(jobz[0] == 'V'?(range[0] == 'I'?1-il+iu:MAX(1,n)):0))]
m
    [int]
ifail
    [rank-1 array('i') with bounds ((jobz[0] == 'N'?0:n))]
info
    [int]

Other Parameters

itype
    [input int, optional] Default: 1
jobz
    [input string(len=1), optional] Default: 'V'
range
    [input string(len=1), optional] Default: 'A'
uplo
    [input string(len=1), optional] Default: 'L'
overwrite_a
    [input int, optional] Default: 0
overwrite_b
    [input int, optional] Default: 0
vl
    [input float, optional] Default: 0.0
vu
    [input float, optional] Default: 1.0
il
    [input int, optional] Default: 1
iu
    [input int, optional] Default: n
abstol
    [input float, optional] Default: 0.0
lwork
    [input int, optional] Default: max(2*n,1)

scipy.linalg.lapack.chegvx_lwork

scipy.linalg.lapack.chegvx_lwork(n[, uplo]) = <fortran object>

Wrapper for chegvx_lwork.

Parameters

n
    [input int]

Returns

work
    [complex]
info
    [int]
**Other Parameters**

uplo  [input string(len=1), optional] Default: ‘L’

**scipy.linalg.lapack.zhegvx_lwork**

scipy.linalg.lapack.zhegvx_lwork(n[, uplo]) = <fortran object>

**Wrapper for zhegvx_lwork**

**Parameters**

n  [input int]

**Returns**

work  [complex]
info  [int]

**Other Parameters**

uplo  [input string(len=1), optional] Default: ‘L’

**scipy.linalg.lapack.chesv**

scipy.linalg.lapack.chesv(a[, b[, lwork, lower, overwrite_a, overwrite_b]]) = <fortran object>

**Wrapper for chesv**

**Parameters**

a  [input rank-2 array('F') with bounds (n,n)]
b  [input rank-2 array('F') with bounds (n,nrhs)]

**Returns**

uduh  [rank-2 array('F') with bounds (n,n) and a storage]
ipiv  [rank-1 array('i') with bounds (n)]
x  [rank-2 array('F') with bounds (n,nrhs) and b storage]
info  [int]

**Other Parameters**

overwrite_a  [input int, optional] Default: 0
overwrite_b  [input int, optional] Default: 0
lwork  [input int, optional] Default: max(n,1)
lower  [input int, optional] Default: 0

**scipy.linalg.lapack.zhesv**

scipy.linalg.lapack.zhesv(a[, b[, lwork, lower, overwrite_a, overwrite_b]]) = <fortran object>

**Wrapper for zhesv**

**Parameters**

a  [input rank-2 array('D') with bounds (n,n)]
b  [input rank-2 array('D') with bounds (n,nrhs)]

**Returns**

uduh  [rank-2 array('D') with bounds (n,n) and a storage]
ipiv  [rank-1 array('i') with bounds (n)]
x  [rank-2 array('D') with bounds (n,nrhs) and b storage]
info  [int]
Other Parameters

overwrite_a
[input int, optional] Default: 0

overwrite_b
[input int, optional] Default: 0

lwork
[input int, optional] Default: max(n,1)

lower
[input int, optional] Default: 0

scipy.linalg.lapack.chesv_lwork

scipy.linalg.lapack.chesv_lwork(n[, lower]) = <fortran object>
Wrapper for chesv_lwork.

Parameters

n [input int]

Returns

work [complex]
info [int]

Other Parameters

lower [input int, optional] Default: 0

scipy.linalg.lapack.zhesv_lwork

scipy.linalg.lapack.zhesv_lwork(n[, lower]) = <fortran object>
Wrapper for zhesv_lwork.

Parameters

n [input int]

Returns

work [complex]
info [int]

Other Parameters

lower [input int, optional] Default: 0

scipy.linalg.lapack.chesvx

scipy.linalg.lapack.chesvx(a, b[, af, ipiv, lwork, factored, lower, overwrite_a, overwrite_b]) = <fortran object>
Wrapper for chesvx.

Parameters

a [input rank-2 array('F') with bounds (n,n)]
b [input rank-2 array('F') with bounds (n,nrhs)]

Returns

uduh [rank-2 array('F') with bounds (n,n) and af storage]

ipiv [rank-1 array('i') with bounds (n)]
x [rank-2 array('F') with bounds (n,nrhs)]
rcond [float]
ferr [rank-1 array('f') with bounds (nrhs)]
berr [rank-1 array('f') with bounds (nrhs)]
info [int]

Other Parameters

overwrite_a
   [input int, optional] Default: 0
af [input rank-2("F") with bounds (n,n)]
ipiv [input rank-1 array(‘i’) with bounds (n)]
overwrite_b
   [input int, optional] Default: 0
lwork [input int, optional] Default: max(2*n,1)
factored [input int, optional] Default: 0
lower [input int, optional] Default: 0

scipy.linalg.lapack.zhesvx

scipy.linalg.lapack.zhesvx(a, b[, af, ipiv, lwork, factored, lower, overwrite_a, overwrite_b]) =
<fortran object>

Wrapper for zhesvx.

Parameters

a [input rank-2("D") with bounds (n,n)]
b [input rank-2("D") with bounds (n, nrhs)]

Returns

uduh [rank-2("D") with bounds (n,n) and af storage]
ipiv [rank-1 array(‘i’) with bounds (n)]
x [rank-2("D") with bounds (n, nrhs)]
rcond [float]
ferr [rank-1 array(‘d’) with bounds (nrhs)]
berr [rank-1 array(‘d’) with bounds (nrhs)]
info [int]

Other Parameters

overwrite_a
   [input int, optional] Default: 0
af [input rank-2("D") with bounds (n,n)]
ipiv [input rank-1 array(‘i’) with bounds (n)]
overwrite_b
   [input int, optional] Default: 0
lwork [input int, optional] Default: max(2*n,1)
factored [input int, optional] Default: 0
lower [input int, optional] Default: 0

scipy.linalg.lapack.chesvx_lwork

scipy.linalg.lapack.chesvx_lwork(n[, lower]) = <fortran object>

Wrapper for chesvx_lwork.

Parameters

n [input int]

Returns

work [complex]
info [int]
Other Parameters

lower [input int, optional] Default: 0

scipy.linalg.lapack.zhesvx_lwork

scipy.linalg.lapack.zhesvx_lwork(n[.lower]) = <fortran object>
Wrapper for zhesvx_lwork.

Parameters

n [input int]

Returns

work [complex]
info [int]

Other Parameters

lower [input int, optional] Default: 0

scipy.linalg.lapack.chetrd

scipy.linalg.lapack.chetrd(a[, lower, overwrite_a]) = <fortran object>
Wrapper for chetrd.

Parameters

a [input rank-2 array('F') with bounds (lda,n)]

Returns

c [rank-2 array('F') with bounds (lda,n) and a storage]
d [rank-1 array('F') with bounds (n)]
e [rank-1 array('F') with bounds (-1 + n)]
tau [rank-1 array('F') with bounds (-1 + n)]
info [int]

Other Parameters

lower [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: MAX(n,1)

scipy.linalg.lapack.zhetrd

scipy.linalg.lapack.zhetrd(a[, lower, overwrite_a]) = <fortran object>
Wrapper for zhetrd.

Parameters

a [input rank-2 array('D') with bounds (lda,n)]

Returns

c [rank-2 array('D') with bounds (lda,n) and a storage]
d [rank-1 array('D') with bounds (n)]
e [rank-1 array('D') with bounds (-1 + n)]
tau [rank-1 array('D') with bounds (-1 + n)]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: MAX(n,1)

scipy.linalg.lapack.chetrd_lwork

scipy.linalg.lapack.chetrd_lwork(n[, lower]) = <fortran object>
Wrapper for chetrd_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.zhetrd_lwork

scipy.linalg.lapack.zhetrd_lwork(n[, lower]) = <fortran object>
Wrapper for zhetrd_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.chetrf

scipy.linalg.lapack.chetrf(a[, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for chetrf.

Parameters
a [input rank-2 array('F') with bounds (n,n)]

Returns
ldu [rank-2 array('F') with bounds (n,n) and a storage]
ipiv [rank-1 array('I') with bounds (n)]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(n,1)

3.3. API definition
scipy.linalg.lapack.zhetrf

scipy.linalg.lapack.zhetrf(a[, lower, lwork, overwrite_a]) = <fortran object>

Wrapper for zhetrf.

Parameters
   a      [input rank-2 array('D') with bounds (n,n)]

Returns
   ldu    [rank-2 array('D') with bounds (n,n) and a storage]
   ipiv   [rank-1 array('i') with bounds (n)]
   info   [int]

Other Parameters
   lower  [input int, optional] Default: 0
   overwrite_a  [input int, optional] Default: 0
   lwork  [input int, optional] Default: max(n,1)

scipy.linalg.lapack.chetrf_lwork

scipy.linalg.lapack.chetrf_lwork(n[, lower]) = <fortran object>

Wrapper for chetrf_lwork.

Parameters
   n      [input int]

Returns
   work   [complex]
   info   [int]

Other Parameters
   lower  [input int, optional] Default: 0

scipy.linalg.lapack.zhetrf_lwork

scipy.linalg.lapack.zhetrf_lwork(n[, lower]) = <fortran object>

Wrapper for zhetrf_lwork.

Parameters
   n      [input int]

Returns
   work   [complex]
   info   [int]

Other Parameters
   lower  [input int, optional] Default: 0
scipy.linalg.lapack.chfrk

scipy.linalg.lapack.chfrk \( (n, k, \alpha, a, \beta[, \text{transr}, \text{uplo}, \text{trans}, \text{overwrite}_c]) \) = <fortran object>

Wrapper for chfrk.

**Parameters**

\- \( n \) [input int]
\- \( k \) [input int]
\- \( \alpha \) [input float]
\- \( a \) [input rank-2 array('F') with bounds (lda,ka)]
\- \( \beta \) [input float]
\- \( c \) [input rank-1 array('F') with bounds (nt)]

**Returns**

\( c'out \) [rank-1 array('F') with bounds (nt) and c storage]

**Other Parameters**

\- \( \text{transr} \) [input string(len=1), optional] Default: ‘N’
\- \( \text{uplo} \) [input string(len=1), optional] Default: ‘U’
\- \( \text{trans} \) [input string(len=1), optional] Default: ‘N’
\- \( \text{overwrite}_c \) [input int, optional] Default: 0

scipy.linalg.lapack.zhfrk

scipy.linalg.lapack.zhfrk \( (n, k, \alpha, a, \beta[, \text{transr}, \text{uplo}, \text{trans}, \text{overwrite}_c]) \) = <fortran object>

Wrapper for zhfrk.

**Parameters**

\- \( n \) [input int]
\- \( k \) [input int]
\- \( \alpha \) [input float]
\- \( a \) [input rank-2 array('D') with bounds (lda,ka)]
\- \( \beta \) [input float]
\- \( c \) [input rank-1 array('D') with bounds (nt)]

**Returns**

\( c'out \) [rank-1 array('D') with bounds (nt) and c storage]

**Other Parameters**

\- \( \text{transr} \) [input string(len=1), optional] Default: ‘N’
\- \( \text{uplo} \) [input string(len=1), optional] Default: ‘U’
\- \( \text{trans} \) [input string(len=1), optional] Default: ‘N’
\- \( \text{overwrite}_c \) [input int, optional] Default: 0
scipy.linalg.lapack.slamch

scipy.linalg.lapack.slamch(cmach) = <fortran slamch>
Wrapper for slamch.

Parameters

   cmach [input string(len=1)]

Returns

   slamch [float]

scipy.linalg.lapack.dlamch

scipy.linalg.lapack.dlamch(cmach) = <fortran dlamch>
Wrapper for dlamch.

Parameters

   cmach [input string(len=1)]

Returns

   dlamch [float]

scipy.linalg.lapack.slange

scipy.linalg.lapack.slange(norm, a) = <fortran slange>
Wrapper for slange.

Parameters

   norm [input string(len=1)]
   a [input rank-2 array('f') with bounds (m,n)]

Returns

   n2 [float]

scipy.linalg.lapack.dlange

scipy.linalg.lapack.dlange(norm, a) = <fortran dlange>
Wrapper for dlange.

Parameters

   norm [input string(len=1)]
   a [input rank-2 array('d') with bounds (m,n)]

Returns

   n2 [float]

scipy.linalg.lapack.clange

scipy.linalg.lapack.clange(norm, a) = <fortran clange>
Wrapper for clange.

Parameters

   norm [input string(len=1)]
   a [input rank-2 array('F') with bounds (m,n)]

Returns

   n2 [float]
### scipy.linalg.lapack.zlange

**Wrapper for zlange.**

**Parameters**

- `norm` [input string(len=1)]
- `a` [input rank-2 array('D') with bounds (m,n)]

**Returns**

- `n2` [float]

### scipy.linalg.lapack.slarf

**Wrapper for slarf.**

**Parameters**

- `v` [input rank-1 array('f') with bounds ((side[0] == ‘L’?1 - abs(incv) + m * abs(incv):1 - abs(incv) + n * abs(incv)))]
- `tau` [input float]
- `c` [input rank-2 array('f') with bounds (m,n)]
- `work` [input rank-1 array('f') with bounds (lwork)]

**Returns**

- `c` [rank-2 array('f') with bounds (m,n)]

**Other Parameters**

- `side` [input string(len=1), optional] Default: ‘L’
- `incv` [input int, optional] Default: 1
- `overwrite_c` [input int, optional] Default: 0

### scipy.linalg.lapack.dlarf

**Wrapper for dlarf.**

**Parameters**

- `v` [input rank-1 array('d') with bounds ((side[0] == ‘L’?1 - abs(incv) + m * abs(incv):1 - abs(incv) + n * abs(incv)))]
- `tau` [input float]
- `c` [input rank-2 array('d') with bounds (m,n)]
- `work` [input rank-1 array('d') with bounds (lwork)]

**Returns**

- `c` [rank-2 array('d') with bounds (m,n)]

**Other Parameters**

- `side` [input string(len=1), optional] Default: ‘L’
- `incv` [input int, optional] Default: 1
- `overwrite_c` [input int, optional] Default: 0
scipy.linalg.lapack.clarf

scipy.linalg.lapack.clarf(v, tau, c, work[, side, incv, overwrite_c]) = <fortran object>

Wrapper for clarf.

Parameters

- v [input rank-1 array('F') with bounds ((side[0] == 'L'?1 - abs(incv) + m * abs(incv):1 - abs(incv) + n * abs(incv)))]
- tau [input complex]
- c [input rank-2 array('F') with bounds (m,n)]
- work [input rank-1 array('F') with bounds (lwork)]

Returns

- c [rank-2 array('F') with bounds (m,n)]

Other Parameters

- side [input string(len=1), optional] Default: 'L'
- incv [input int, optional] Default: 1
- overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.zlarf

scipy.linalg.lapack.zlarf(v, tau, c, work[, side, incv, overwrite_c]) = <fortran object>

Wrapper for zlarf.

Parameters

- v [input rank-1 array('D') with bounds ((side[0] == 'L'?1 - abs(incv) + m * abs(incv):1 - abs(incv) + n * abs(incv)))]
- tau [input complex]
- c [input rank-2 array('D') with bounds (m,n)]
- work [input rank-1 array('D') with bounds (lwork)]

Returns

- c [rank-2 array('D') with bounds (m,n)]

Other Parameters

- side [input string(len=1), optional] Default: 'L'
- incv [input int, optional] Default: 1
- overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.slarfg

scipy.linalg.lapack.slarfg(n, alpha, x[, incx, overwrite_x]) = <fortran object>

Wrapper for slarfg.

Parameters

- n [input int]
- alpha [input float]
- x [input rank-1 array('F') with bounds (lx)]

Returns

- alpha [float]
- x [rank-1 array('F') with bounds (lx)]
tau  [float]

Other Parameters

overwrite_x  [input int, optional] Default: 0
incx  [input int, optional] Default: 1

scipy.linalg.lapack.dlarfg

scipy.linalg.lapack.dlarfg(n, alpha, x[, incx, overwrite_x]) = <fortran object>
Wrapper for dlarfg.

Parameters

n  [input int]
alpha  [input float]
x  [input rank-1 array('d') with bounds (lx)]

Returns

alpha  [float]
x  [rank-1 array('d') with bounds (lx)]
tau  [float]

Other Parameters

overwrite_x  [input int, optional] Default: 0
incx  [input int, optional] Default: 1

scipy.linalg.lapack.clarfg

scipy.linalg.lapack.clarfg(n, alpha, x[, incx, overwrite_x]) = <fortran object>
Wrapper for clarfg.

Parameters

n  [input int]
alpha  [input complex]
x  [input rank-1 array('F') with bounds (lx)]

Returns

alpha  [complex]
x  [rank-1 array('F') with bounds (lx)]
tau  [complex]

Other Parameters

overwrite_x  [input int, optional] Default: 0
incx  [input int, optional] Default: 1
**scipy.linalg.lapack.zlarfg**

```python
scipy.linalg.lapack.zlarfg(n, alpha, x[, incx, overwrite_x]) = <fortran object>
```

Wrapper for zlarfg.

**Parameters**

- `n` [input int]
- `alpha` [input complex]
- `x` [input rank-1 array(‘D’) with bounds (lx)]

**Returns**

- `alpha` [complex]
- `x` [rank-1 array(‘D’) with bounds (lx)]
- `tau` [complex]

**Other Parameters**

- `overwrite_x` [input int, optional] Default: 0
- `incx` [input int, optional] Default: 1

**scipy.linalg.lapack.slartg**

```python
scipy.linalg.lapack.slartg(f, g) = <fortran object>
```

Wrapper for slartg.

**Parameters**

- `f` [input float]
- `g` [input float]

**Returns**

- `cs` [float]
- `sn` [float]
- `r` [float]

**scipy.linalg.lapack.dlartg**

```python
scipy.linalg.lapack.dlartg(f, g) = <fortran object>
```

Wrapper for dlartg.

**Parameters**

- `f` [input float]
- `g` [input float]

**Returns**

- `cs` [float]
- `sn` [float]
- `r` [float]
scipy.linalg.lapack.clartg

\[
\text{scipy.linalg.lapack.clartg}(f, g) = \langle \text{fortran object} \rangle
\]

Wrapper for clartg.

**Parameters**

- \( f \) [input complex]
- \( g \) [input complex]

**Returns**

- \( cs \) [float]
- \( sn \) [complex]
- \( r \) [complex]

scipy.linalg.lapack.zlartg

\[
\text{scipy.linalg.lapack.zlartg}(f, g) = \langle \text{fortran object} \rangle
\]

Wrapper for zlartg.

**Parameters**

- \( f \) [input complex]
- \( g \) [input complex]

**Returns**

- \( cs \) [float]
- \( sn \) [complex]
- \( r \) [complex]

scipy.linalg.lapack.slasd4

\[
\text{scipy.linalg.lapack.slasd4}(i, d, z[, rho]) = \langle \text{fortran object} \rangle
\]

Wrapper for slasd4.

**Parameters**

- \( i \) [input int]
- \( d \) [input rank-1 array('f') with bounds (n)]
- \( z \) [input rank-1 array('f') with bounds (n)]

**Returns**

- \( \text{delta} \) [rank-1 array('f') with bounds (n)]
- \( \text{sigma} \) [float]
- \( \text{work} \) [rank-1 array('f') with bounds (n)]
- \( \text{info} \) [int]

**Other Parameters**

- \( \text{rho} \) [input float, optional] Default: 1.0
scipy.linalg.lapack.dlasd4

scipy.linalg.lapack.dlasd4(i, d[, z[, rho]]) = <fortran object>

Wrapper for dlasd4.

Parameters

- i [input int]
- d [input rank-1 array('d') with bounds (n)]
- z [input rank-1 array('d') with bounds (n)]

Returns

- delta [rank-1 array('d') with bounds (n)]
- sigma [float]
- work [rank-1 array('d') with bounds (n)]
- info [int]

Other Parameters

- rho [input float, optional] Default: 1.0

scipy.linalg.lapack.slaswp

scipy.linalg.lapack.slaswp(a, piv[, k1, k2, off, inc, overwrite_a]) = <fortran object>

Wrapper for slaswp.

Parameters

- a [input rank-2 array('f') with bounds (nrows,n)]
- piv [input rank-1 array('i') with bounds (npiv)]

Returns

- a [rank-2 array('f') with bounds (nrows,n)]

Other Parameters

- overwrite_a [input int, optional] Default: 0
- k1 [input int, optional] Default: 0
- k2 [input int, optional] Default: npiv-1
- off [input int, optional] Default: 0
- inc [input int, optional] Default: 1

scipy.linalg.lapack.dlaswp

scipy.linalg.lapack.dlaswp(a, piv[, k1, k2, off, inc, overwrite_a]) = <fortran object>

Wrapper for dlaswp.

Parameters

- a [input rank-2 array('d') with bounds (nrows,n)]
- piv [input rank-1 array('i') with bounds (npiv)]

Returns

- a [rank-2 array('d') with bounds (nrows,n)]

Other Parameters

- overwrite_a [input int, optional] Default: 0
- k1 [input int, optional] Default: 0
`scipy.linalg.lapack.claswp`

`scipy.linalg.lapack.claswp(a, piv[, k1, k2, off, inc, overwrite_a]) = <fortran object>`

Wrapper for `claswp`.

**Parameters**

- **a** [input rank-2 array('F') with bounds (nrows,n)]
- **piv** [input rank-1 array('i') with bounds (npiv)]

**Returns**

- **a** [rank-2 array('F') with bounds (nrows,n)]

**Other Parameters**

- **overwrite_a** [input int, optional] Default: 0
- **k1** [input int, optional] Default: 0
- **k2** [input int, optional] Default: npiv-1
- **off** [input int, optional] Default: 0
- **inc** [input int, optional] Default: 1

`scipy.linalg.lapack.zlaswp`

`scipy.linalg.lapack.zlaswp(a, piv[, k1, k2, off, inc, overwrite_a]) = <fortran object>`

Wrapper for `zlaswp`.

**Parameters**

- **a** [input rank-2 array('D') with bounds (nrows,n)]
- **piv** [input rank-1 array('i') with bounds (npiv)]

**Returns**

- **a** [rank-2 array('D') with bounds (nrows,n)]

**Other Parameters**

- **overwrite_a** [input int, optional] Default: 0
- **k1** [input int, optional] Default: 0
- **k2** [input int, optional] Default: npiv-1
- **off** [input int, optional] Default: 0
- **inc** [input int, optional] Default: 1

`scipy.linalg.lapack.slauum`

`scipy.linalg.lapack.slauum(c[, lower, overwrite_c]) = <fortran object>`

Wrapper for `slauum`.

**Parameters**

- **c** [input rank-2 array('f') with bounds (n,n)]

**Returns**

- **a** [rank-2 array('f') with bounds (n,n) and c storage]
- **info** [int]
Other Parameters

overwrite_c
  [input int, optional] Default: 0
lower  [input int, optional] Default: 0

scipy.linalg.lapack.dlauum

scipy.linalg.lapack.dlauum(c[, lower, overwrite_c]) = <fortran object>
Wrapper for dlauum.

Parameters

c  [input rank-2 array('d') with bounds (n,n)]

Returns

a  [rank-2 array('d') with bounds (n,n) and c storage]
info [int]

Other Parameters

overwrite_c
  [input int, optional] Default: 0
lower  [input int, optional] Default: 0

scipy.linalg.lapack.clauum

scipy.linalg.lapack.clauum(c[, lower, overwrite_c]) = <fortran object>
Wrapper for clauum.

Parameters

c  [input rank-2 array('F') with bounds (n,n)]

Returns

a  [rank-2 array('F') with bounds (n,n) and c storage]
info [int]

Other Parameters

overwrite_c
  [input int, optional] Default: 0
lower  [input int, optional] Default: 0

scipy.linalg.lapack.zlauum

scipy.linalg.lapack.zlauum(c[, lower, overwrite_c]) = <fortran object>
Wrapper for zlauum.

Parameters

c  [input rank-2 array('D') with bounds (n,n)]

Returns

a  [rank-2 array('D') with bounds (n,n) and c storage]
info [int]

Other Parameters

overwrite_c
  [input int, optional] Default: 0
lower  [input int, optional] Default: 0
**scipy.linalg.lapack.sorcsd**

**scipy.linalg.lapack.sorcsd** \((x11, x12, x21, x22[, compute_u1, compute_u2, compute_v1t, compute_v2t, trans, signs, lwork, overwrite_x11, overwrite_x12, overwrite_x21, overwrite_x22]) = <fortran object>

Wrapper for sorcsd.

**Parameters**

- **x11** [input rank-2 array('f') with bounds (p,q)]
- **x12** [input rank-2 array('f') with bounds (p,mmq)]
- **x21** [input rank-2 array('f') with bounds (mmp,q)]
- **x22** [input rank-2 array('f') with bounds (mmp,mmq)]

**Returns**

- **cs11** [rank-2 array('f') with bounds (p,q) and x11 storage]
- **cs12** [rank-2 array('f') with bounds (p,mmq) and x12 storage]
- **cs21** [rank-2 array('f') with bounds (mmp,q) and x21 storage]
- **cs22** [rank-2 array('f') with bounds (mmp,mmq) and x22 storage]
- **theta** [rank-1 array('f') with bounds (min(min(p,mmp),min(q,mmq)))]
- **u1** [rank-2 array('f') with bounds ((compute_u1?p:0),(compute_u1?p:0))]
- **u2** [rank-2 array('f') with bounds ((compute_u2?mmp:0),(compute_u2?mmp:0))]
- **v1t** [rank-2 array('f') with bounds ((compute_v1t?q:0),(compute_v1t?q:0))]
- **v2t** [rank-2 array('f') with bounds ((compute_v2t?mmq:0),(compute_v2t?mmq:0))]
- **info** [int]

**Other Parameters**

- **compute_u1** [input int, optional] Default: 1
- **compute_u2** [input int, optional] Default: 1
- **compute_v1t** [input int, optional] Default: 1
- **compute_v2t** [input int, optional] Default: 1
- **trans** [input int, optional] Default: 0
- **signs** [input int, optional] Default: 0
- **overwrite_x11** [input int, optional] Default: 0
- **overwrite_x12** [input int, optional] Default: 0
- **overwrite_x21** [input int, optional] Default: 0
- **overwrite_x22** [input int, optional] Default: 0
- **lwork** [input int, optional] Default: \(2+2*m+5*\text{MAX}(1,q-1)+4*\text{MAX}(1,q)+8*q\)
scipy.linalg.lapack.dorcsd

scipy.linalg.lapack.dorcsd(x11, x12, x21, x22[, compute_u1, compute_u2, compute_v1t, compute_v2t, trans, signs, lwork, overwrite_x11, overwrite_x12, overwrite_x21, overwrite_x22]) = <fortran object>

Wrapper for dorcsd.

Parameters

- x11  [input rank-2 array('d') with bounds (p,q)]
- x12  [input rank-2 array('d') with bounds (p,mmq)]
- x21  [input rank-2 array('d') with bounds (mmp,q)]
- x22  [input rank-2 array('d') with bounds (mmp,mmq)]

Returns

- cs11  [rank-2 array('d') with bounds (p,q) and x11 storage]
- cs12  [rank-2 array('d') with bounds (p,mmq) and x12 storage]
- cs21  [rank-2 array('d') with bounds (mmp,q) and x21 storage]
- cs22  [rank-2 array('d') with bounds (mmp,mmq) and x22 storage]
- theta [rank-1 array('d') with bounds (min(min(p,mmp), min(q, mmq)))]
- u1    [rank-2 array('d') with bounds ((compute_u1?p:0),(compute_u1?p:0))]
- u2    [rank-2 array('d') with bounds ((compute_u2?mmp:0),(compute_u2?mmp:0))]
- v1t   [rank-2 array('d') with bounds ((compute_v1t?q:0),(compute_v1t?q:0))]
- v2t   [rank-2 array('d') with bounds ((compute_v2t?mmq:0),(compute_v2t?mmq:0))]
- info  [int]

Other Parameters

- compute_u1 [input int, optional] Default: 1
- compute_u2 [input int, optional] Default: 1
- compute_v1t [input int, optional] Default: 1
- compute_v2t [input int, optional] Default: 1
- trans [input int, optional] Default: 0
- signs [input int, optional] Default: 0
- overwrite_x11 [input int, optional] Default: 0
- overwrite_x12 [input int, optional] Default: 0
- overwrite_x21 [input int, optional] Default: 0
- overwrite_x22 [input int, optional] Default: 0
- lwork [input int, optional] Default: 2+2*m+5*MAX(1,q-1)+4*MAX(1,q)+8*q
scipy.linalg.lapack.sorcsd_lwork

scipy.linalg.lapack.sorcsd_lwork(m, p, q) = <fortran object>
Wrapper for sorcsd_lwork.

Parameters
m [input int]
p [input int]
q [input int]

Returns
work [float]
info [int]

scipy.linalg.lapack.dorcsd_lwork

scipy.linalg.lapack.dorcsd_lwork(m, p, q) = <fortran object>
Wrapper for dorcsd_lwork.

Parameters
m [input int]
p [input int]
q [input int]

Returns
work [float]
info [int]

scipy.linalg.lapack.sorghr

scipy.linalg.lapack.sorghr(a, tau[, lo, hi, lwork, overwrite_a]) = <fortran object>
Wrapper for sorghr.

Parameters
a [input rank-2 array('f') with bounds (n,n)]
tau [input rank-1 array('f') with bounds (-1 + n)]

Returns
ht [rank-2 array('f') with bounds (n,n) and a storage]
info [int]

Other Parameters
lo [input int, optional] Default: 0
hi [input int, optional] Default: n-1
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(hi-lo,1)
scipy.linalg.lapack.dorghr

Wrapper for dorghr.

Parameters

- a [input rank-2 array('d') with bounds (n,n)]
- tau [input rank-1 array('d') with bounds (-1 + n)]

Returns

- ht [rank-2 array('d') with bounds (n,n) and a storage]
- info [int]

Other Parameters

- lo [input int, optional] Default: 0
- hi [input int, optional] Default: n-1
- overwrite_a [input int, optional] Default: 0
- lwork [input int, optional] Default: max(hi-lo,1)

scipy.linalg.lapack.sorghr_lwork

Wrapper for sorghr_lwork.

Parameters

- n [input int]

Returns

- work [float]
- info [int]

Other Parameters

- lo [input int, optional] Default: 0
- hi [input int, optional] Default: n-1

scipy.linalg.lapack.dorghr_lwork

Wrapper for dorghr_lwork.

Parameters

- n [input int]

Returns

- work [float]
- info [int]

Other Parameters

- lo [input int, optional] Default: 0
- hi [input int, optional] Default: n-1
scipy.linalg.lapack.sorgqr

scipy.linalg.lapack.sorgqr(a, tau[, lwork, overwrite_a]) = <fortran object>

Wrapper for sorgqr.

Parameters
a [input rank-2 array('f') with bounds (m,n)]
tau [input rank-1 array('f') with bounds (k)]

Returns
q [rank-2 array('f') with bounds (m,n) and a storage]
work [rank-1 array('f') with bounds (MAX(lwork, 1))]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.dorgqr

scipy.linalg.lapack.dorgqr(a, tau[, lwork, overwrite_a]) = <fortran object>

Wrapper for dorgqr.

Parameters
a [input rank-2 array('d') with bounds (m,n)]
tau [input rank-1 array('d') with bounds (k)]

Returns
q [rank-2 array('d') with bounds (m,n) and a storage]
work [rank-1 array('d') with bounds (MAX(lwork, 1))]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.sorgrq

scipy.linalg.lapack.sorgrq(a, tau[, lwork, overwrite_a]) = <fortran object>

Wrapper for sorgrq.

Parameters
a [input rank-2 array('f') with bounds (m,n)]
tau [input rank-1 array('f') with bounds (k)]

Returns
q [rank-2 array('f') with bounds (m,n) and a storage]
work [rank-1 array('f') with bounds (MAX(lwork, 1))]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0

lwork [input int, optional] Default: max(3*m,1)

scipy.linalg.lapack.dorgrq

scipy.linalg.lapack.dorgrq(a, tau[, lwork, overwrite_a]) = <fortran object>
Wrapper for dorgrq.

Parameters

a [input rank-2 array('d') with bounds (m,n)]
tau [input rank-1 array('d') with bounds (k)]

Returns

q [rank-2 array('d') with bounds (m,n) and a storage]
work [rank-1 array('d') with bounds (MAX(lwork, 1))]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*m,1)

scipy.linalg.lapack.sormqr

scipy.linalg.lapack.sormqr(side, trans, a, tau, c[, lwork[, overwrite_c]]) = <fortran object>
Wrapper for sormqr.

Parameters

side [input string(len=1)]
trans [input string(len=1)]
a [input rank-2 array('f') with bounds (lda,k)]
tau [input rank-1 array('f') with bounds (k)]
c [input rank-2 array('f') with bounds (ldc,n)]
lwork [input int]

Returns

cq [rank-2 array('f') with bounds (ldc,n) and c storage]
work [rank-1 array('f') with bounds (MAX(lwork, 1))]
info [int]

Other Parameters

overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.dormqr

scipy.linalg.lapack.dormqr(side, trans, a, tau, c[, lwork[, overwrite_c]]) = <fortran object>
Wrapper for dormqr.

Parameters

side [input string(len=1)]
trans [input string(len=1)]
a [input rank-2 array('d') with bounds (lda,k)]
tau [input rank-1 array('d') with bounds (k)]
c [input rank-2 array('d') with bounds (ldc,n)]
lwork [input int]

Returns

- `cq` [rank-2 array('d') with bounds (ldc,n) and c storage]
- `work` [rank-1 array('d') with bounds (MAX(lwork, 1))]
- `info` [int]

Other Parameters

- `overwrite_c` [input int, optional] Default: 0

`scipy.linalg.lapack.sormrz`

`scipy.linalg.lapack.sormrz(a, tau, c[, side, trans, lwork, overwrite_c]) = <fortran object>`

Wrapper for `sormrz`.

Parameters

- `a` [input rank-2 array('f') with bounds (k,nt)]
- `tau` [input rank-1 array('f') with bounds (k)]
- `c` [input rank-2 array('f') with bounds (m,n)]

Returns

- `cq` [rank-2 array('f') with bounds (m,n) and c storage]
- `info` [int]

Other Parameters

- `side` [input string(len=1), optional] Default: ‘L’
- `trans` [input string(len=1), optional] Default: ‘N’
- `overwrite_c` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: MAX((side[0]=='L'?n:m),1)

`scipy.linalg.lapack.dormrz`

`scipy.linalg.lapack.dormrz(a, tau, c[, side, trans, lwork, overwrite_c]) = <fortran object>`

Wrapper for `dormrz`.

Parameters

- `a` [input rank-2 array('d') with bounds (k,nt)]
- `tau` [input rank-1 array('d') with bounds (k)]
- `c` [input rank-2 array('d') with bounds (m,n)]

Returns

- `cq` [rank-2 array('d') with bounds (m,n) and c storage]
- `info` [int]

Other Parameters

- `side` [input string(len=1), optional] Default: ‘L’
- `trans` [input string(len=1), optional] Default: ‘N’
- `overwrite_c` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: MAX((side[0]=='L'?n:m),1)
scipy.linalg.lapack.sormrz_lwork

scipy.linalg.lapack.sormrz_lwork(m, n[, side, trans]) = <fortran object>
Wrapper for sormrz_lwork.

Parameters
m [input int]
n [input int]

Returns
work [float]
info [int]

Other Parameters
side [input string(len=1), optional] Default: ‘L’
trans [input string(len=1), optional] Default: ‘N’

scipy.linalg.lapack.dormrz_lwork

scipy.linalg.lapack.dormrz_lwork(m, n[, side, trans]) = <fortran object>
Wrapper for dormrz_lwork.

Parameters
m [input int]
n [input int]

Returns
work [float]
info [int]

Other Parameters
side [input string(len=1), optional] Default: ‘L’
trans [input string(len=1), optional] Default: ‘N’

scipy.linalg.lapack.spbsv

scipy.linalg.lapack.spbsv(ab, b[, lower, ldab, overwrite_ab, overwrite_b]) = <fortran object>
Wrapper for spbsv.

Parameters
ab [input rank-2 array('f') with bounds (ldab,n)]
b [input rank-2 array('f') with bounds (ldb,nrhs)]

Returns
c [rank-2 array('f') with bounds (ldab,n) and ab storage]
x [rank-2 array('f') with bounds (ldb,nrhs) and b storage]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_ab [input int, optional] Default: 0
ldab [input int, optional] Default: shape(ab,0)
overwrite_b [input int, optional] Default: 0
scipy.linalg.lapack.dpbsv

Wrapper for dpbsv.

Parameters

- **ab** [input rank-2 array('d') with bounds (ldab,n)]
- **b** [input rank-2 array('d') with bounds (ldb,nrhs)]

Returns

- **c** [rank-2 array('d') with bounds (ldab,n) and ab storage]
- **x** [rank-2 array('d') with bounds (ldb,nrhs) and b storage]
- **info** [int]

Other Parameters

- **lower** [input int, optional] Default: 0
- **overwrite_ab** [input int, optional] Default: 0
- **ldab** [input int, optional] Default: shape(ab,0)
- **overwrite_b** [input int, optional] Default: 0

scipy.linalg.lapack.cpbsv

Wrapper for cpbsv.

Parameters

- **ab** [input rank-2 array('F') with bounds (ldab,n)]
- **b** [input rank-2 array('F') with bounds (ldb,nrhs)]

Returns

- **c** [rank-2 array('F') with bounds (ldab,n) and ab storage]
- **x** [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
- **info** [int]

Other Parameters

- **lower** [input int, optional] Default: 0
- **overwrite_ab** [input int, optional] Default: 0
- **ldab** [input int, optional] Default: shape(ab,0)
- **overwrite_b** [input int, optional] Default: 0

scipy.linalg.lapack.zpbsv

Wrapper for zpbsv.

Parameters

- **ab** [input rank-2 array('D') with bounds (ldab,n)]
- **b** [input rank-2 array('D') with bounds (ldb,nrhs)]

Returns

- **c** [rank-2 array('D') with bounds (ldab,n) and ab storage]

\[
x \quad \text{[rank-2 array('D') with bounds (ldb,nrhs) and b storage]}
\]
\[
info \quad \text{[int]}
\]

Other Parameters

\[
lower \quad \text{[input int, optional] Default: 0}
\]
\[
overwrite_ab \quad \text{[input int, optional] Default: 0}
\]
\[
ldab \quad \text{[input int, optional] Default: shape(ab,0)}
\]
\[
overwrite_b \quad \text{[input int, optional] Default: 0}
\]

`scipy.linalg.lapack.spbtrf`

\[
\text{scipy.linalg.lapack.spbtrf}(ab[, lower, ldab, overwrite_ab]) = \text{<fortran object>}
\]

Wrapper for `spbtrf`.

Parameters

\[
ab \quad \text{[input rank-2 array('f') with bounds (ldab,n)]}
\]

Returns

\[
c \quad \text{[rank-2 array('f') with bounds (ldab,n) and ab storage]}
\]
\[
info \quad \text{[int]}
\]

Other Parameters

\[
lower \quad \text{[input int, optional] Default: 0}
\]
\[
overwrite_ab \quad \text{[input int, optional] Default: 0}
\]
\[
ldab \quad \text{[input int, optional] Default: shape(ab,0)}
\]

`scipy.linalg.lapack.dpbtrf`

\[
\text{scipy.linalg.lapack.dpbtrf}(ab[, lower, ldab, overwrite_ab]) = \text{<fortran object>}
\]

Wrapper for `dpbtrf`.

Parameters

\[
ab \quad \text{[input rank-2 array('d') with bounds (ldab,n)]}
\]

Returns

\[
c \quad \text{[rank-2 array('d') with bounds (ldab,n) and ab storage]}
\]
\[
info \quad \text{[int]}
\]

Other Parameters

\[
lower \quad \text{[input int, optional] Default: 0}
\]
\[
overwrite_ab \quad \text{[input int, optional] Default: 0}
\]
\[
ldab \quad \text{[input int, optional] Default: shape(ab,0)}
\]
scipy.linalg.lapack.cpbtrf

scipy.linalg.lapack.cpbtrf(ab[, lower, ldab, overwrite_ab]) = <fortran object>

Wrapper for cpbtrf.

Parameters

ab [input rank-2 array('F') with bounds (ldab,n)]

Returns

c [rank-2 array('F') with bounds (ldab,n) and ab storage]
info [int]

Other Parameters

lower [input int, optional] Default: 0
overwrite_ab [input int, optional] Default: 0
ldab [input int, optional] Default: shape(ab,0)

scipy.linalg.lapack.zpbtrf

scipy.linalg.lapack.zpbtrf(ab[, lower, ldab, overwrite_ab]) = <fortran object>

Wrapper for zpbtrf.

Parameters

ab [input rank-2 array('D') with bounds (ldab,n)]

Returns

c [rank-2 array('D') with bounds (ldab,n) and ab storage]
info [int]

Other Parameters

lower [input int, optional] Default: 0
overwrite_ab [input int, optional] Default: 0
ldab [input int, optional] Default: shape(ab,0)

scipy.linalg.lapack.spbtrs

scipy.linalg.lapack.spbtrs(ab, b[, lower, ldab, overwrite_b]) = <fortran object>

Wrapper for spbtrs.

Parameters

ab [input rank-2 array('f') with bounds (ldab,n)]
b [input rank-2 array('f') with bounds (ldb,nrhs)]

Returns

x [rank-2 array('f') with bounds (ldb,nrhs) and b storage]
info [int]

Other Parameters

lower [input int, optional] Default: 0
ldab [input int, optional] Default: shape(ab,0)
overwrite_b [input int, optional] Default: 0
scipy.linalg.lapack.dpbtrs

Wrapper for dpbtrs.

Parameters

- \( ab \) [input rank-2 array('d') with bounds (ldab,n)]
- \( b \) [input rank-2 array('d') with bounds (ldb,nrhs)]

Returns

- \( x \) [rank-2 array('d') with bounds (ldb,nrhs) and b storage]
- \( info \) [int]

Other Parameters

- lower [input int, optional] Default: 0
- ldab [input int, optional] Default: shape(ab,0)
- overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.cpbtrs

Wrapper for cpbtrs.

Parameters

- \( ab \) [input rank-2 array('F') with bounds (ldab,n)]
- \( b \) [input rank-2 array('F') with bounds (ldb,nrhs)]

Returns

- \( x \) [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
- \( info \) [int]

Other Parameters

- lower [input int, optional] Default: 0
- ldab [input int, optional] Default: shape(ab,0)
- overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.zpbtrs

Wrapper for zpbtrs.

Parameters

- \( ab \) [input rank-2 array('D') with bounds (ldab,n)]
- \( b \) [input rank-2 array('D') with bounds (ldb,nrhs)]

Returns

- \( x \) [rank-2 array('D') with bounds (ldb,nrhs) and b storage]
- \( info \) [int]

Other Parameters

- lower [input int, optional] Default: 0
- ldab [input int, optional] Default: shape(ab,0)
**overwrite_b**

[input int, optional] Default: 0

**scipy.linalg.lapack.spftrf**

```python
scipy.linalg.lapack.spftrf (n, a[, transr, uplo, overwrite_a]) = <fortran object>
```

Wrapper for `spftrf`.

**Parameters**

- **n** [input int]
- **a** [input rank-1 array('f') with bounds (nt)]

**Returns**

- **achol** [rank-1 array('f') with bounds (nt) and a storage]
- **info** [int]

**Other Parameters**

- **transr** [input string(len=1), optional] Default: ‘N’
- **uplo** [input string(len=1), optional] Default: ‘U’
- **overwrite_a** [input int, optional] Default: 0

**scipy.linalg.lapack.dpftrf**

```python
scipy.linalg.lapack.dpftrf (n, a[, transr, uplo, overwrite_a]) = <fortran object>
```

Wrapper for `dpftrf`.

**Parameters**

- **n** [input int]
- **a** [input rank-1 array('d') with bounds (nt)]

**Returns**

- **achol** [rank-1 array('d') with bounds (nt) and a storage]
- **info** [int]

**Other Parameters**

- **transr** [input string(len=1), optional] Default: ‘N’
- **uplo** [input string(len=1), optional] Default: ‘U’
- **overwrite_a** [input int, optional] Default: 0

**scipy.linalg.lapack.cpftrf**

```python
scipy.linalg.lapack.cpftrf (n, a[, transr, uplo, overwrite_a]) = <fortran object>
```

Wrapper for `cpftrf`.

**Parameters**

- **n** [input int]
- **a** [input rank-1 array('F') with bounds (nt)]

**Returns**

- **achol** [rank-1 array('F') with bounds (nt) and a storage]
- **info** [int]

**Other Parameters**
transr [input string(len=1), optional] Default: ‘N’
uplo [input string(len=1), optional] Default: ‘U’
overwrite_a [input int, optional] Default: 0

scipy.linalg.lapack.zpftrf

scipy.linalg.lapack.zpftrf(n, a[, transr, uplo, overwrite_a]) = <fortran object>
Wrapper for zpftrf.

Parameters

n [input int]
a [input rank-1 array('D') with bounds (nt)]

Returns

achol [rank-1 array('D') with bounds (nt) and a storage]
info [int]

Other Parameters

transr [input string(len=1), optional] Default: ‘N’
uplo [input string(len=1), optional] Default: ‘U’
overwrite_a [input int, optional] Default: 0

scipy.linalg.lapack.spftri

scipy.linalg.lapack.spftri(n, a[, transr, uplo, overwrite_a]) = <fortran object>
Wrapper for spftri.

Parameters

n [input int]
a [input rank-1 array('f') with bounds (nt)]

Returns

ainv [rank-1 array('f') with bounds (nt) and a storage]
info [int]

Other Parameters

transr [input string(len=1), optional] Default: ‘N’
uplo [input string(len=1), optional] Default: ‘U’
overwrite_a [input int, optional] Default: 0

scipy.linalg.lapack.dpftri

scipy.linalg.lapack.dpftri(n, a[, transr, uplo, overwrite_a]) = <fortran object>
Wrapper for dpftri.

Parameters

n [input int]
a [input rank-1 array('d') with bounds (nt)]

Returns

ainv [rank-1 array('d') with bounds (nt) and a storage]
info [int]
Other Parameters

transr  [input string(len=1), optional] Default: 'N'
uplo    [input string(len=1), optional] Default: 'U'
overwrite_a  [input int, optional] Default: 0

scipy.linalg.lapack.cpftri

scipy.linalg.lapack.cpftri(n, a[, transr, uplo, overwrite_a]) = <fortran object>
Wrapper for cpftri.

Parameters

n     [input int]
a     [input rank-1 array('F') with bounds (nt)]

Returns

ainv  [rank-1 array('F') with bounds (nt) and a storage]
info  [int]

Other Parameters

transr  [input string(len=1), optional] Default: 'N'
uplo    [input string(len=1), optional] Default: 'U'
overwrite_a  [input int, optional] Default: 0

scipy.linalg.lapack.zpftri

scipy.linalg.lapack.zpftri(n, a[, transr, uplo, overwrite_a]) = <fortran object>
Wrapper for zpftri.

Parameters

n     [input int]
a     [input rank-1 array('D') with bounds (nt)]

Returns

ainv  [rank-1 array('D') with bounds (nt) and a storage]
info  [int]

Other Parameters

transr  [input string(len=1), optional] Default: 'N'
uplo    [input string(len=1), optional] Default: 'U'
overwrite_a  [input int, optional] Default: 0

scipy.linalg.lapack.spftrs

scipy.linalg.lapack.spftrs(n, a, b[, transr, uplo, overwrite_b]) = <fortran object>
Wrapper for spftrs.

Parameters

n     [input int]
a     [input rank-1 array('F') with bounds (nt)]
b     [input rank-2 array('F') with bounds (ldb,nhrs)]

Returns
scipy.linalg.lapack.dpftrs

```
scipy.linalg.lapack.dpftrs(n, a, b[, transr, uplo, overwrite_b]) = <fortran object>
```

Wrapper for dpftrs.

**Parameters**

- `n` [input int]
- `a` [input rank-1 array('d') with bounds (nt)]
- `b` [input rank-2 array('d') with bounds (ldb,nhrs)]

**Returns**

- `x` [rank-2 array('d') with bounds (ldb,nhrs) and b storage]
- `info` [int]

**Other Parameters**

- `transr` [input string(len=1), optional] Default: ‘N’
- `uplo` [input string(len=1), optional] Default: ‘U’
- `overwrite_b` [input int, optional] Default: 0

scipy.linalg.lapack.cpftrs

```
scipy.linalg.lapack.cpftrs(n, a, b[, transr, uplo, overwrite_b]) = <fortran object>
```

Wrapper for cpftrs.

**Parameters**

- `n` [input int]
- `a` [input rank-1 array('F') with bounds (nt)]
- `b` [input rank-2 array('F') with bounds (ldb,nhrs)]

**Returns**

- `x` [rank-2 array('F') with bounds (ldb,nhrs) and b storage]
- `info` [int]

**Other Parameters**

- `transr` [input string(len=1), optional] Default: ‘N’
- `uplo` [input string(len=1), optional] Default: ‘U’
- `overwrite_b` [input int, optional] Default: 0
scipy.linalg.lapack.zpftrs

scipy.linalg.lapack.zpftrs(n, a, b, transr, uplo, overwrite_b) = <fortran object>

Wrapper for zpftrs.

Parameters

n [input int]
a [input rank-1 array('D') with bounds (nt)]
b [input rank-2 array('D') with bounds (ldb,nhrs)]

Returns

x [rank-2 array('D') with bounds (ldb,nhrs) and b storage]
info [int]

Other Parameters

transr [input string(len=1), optional] Default: ‘N’
uplo [input string(len=1), optional] Default: ‘U’
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.spocon

scipy.linalg.lapack.spocon(a, anorm, uplo) = <fortran object>

Wrapper for spocon.

Parameters

a [input rank-2 array('f') with bounds (n,n)]
anorm [input float]

Returns

rcond [float]
info [int]

Other Parameters

uplo [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.dpocon

scipy.linalg.lapack.dpocon(a, anorm, uplo) = <fortran object>

Wrapper for dpocon.

Parameters

a [input rank-2 array('d') with bounds (n,n)]
anorm [input float]

Returns

rcond [float]
info [int]

Other Parameters

uplo [input string(len=1), optional] Default: ‘U’
**scipy.linalg.lapack.cpocon**

`scipy.linalg.lapack.cpocon(a, anorm[, uplo]) = <fortran object>`

Wrapper for `cpocon`.

**Parameters**

- `a` [input rank-2 array('F') with bounds (n,n)]
- `anorm` [input float]

**Returns**

- `rcond` [float]
- `info` [int]

**Other Parameters**

- `uplo` [input string(len=1), optional] Default: 'U'

**scipy.linalg.lapack.zpocon**

`scipy.linalg.lapack.zpocon(a, anorm[, uplo]) = <fortran object>`

Wrapper for `zpocon`.

**Parameters**

- `a` [input rank-2 array('D') with bounds (n,n)]
- `anorm` [input float]

**Returns**

- `rcond` [float]
- `info` [int]

**Other Parameters**

- `uplo` [input string(len=1), optional] Default: 'U'

**scipy.linalg.lapack.spstrf**

`scipy.linalg.lapack.spstrf(a[, tol, lower, overwrite_a]) = <fortran object>`

Wrapper for `spstrf`.

**Parameters**

- `a` [input rank-2 array('f') with bounds (n,n)]

**Returns**

- `c` [rank-2 array('f') with bounds (n,n) and a storage]
- `piv` [rank-1 array('i') with bounds (n)]
- `rank_c` [int]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0
- `tol` [input float, optional] Default: -1.0
- `lower` [input int, optional] Default: 0
scipy.linalg.lapack.dpstrf

scipy.linalg.lapack.dpstrf \( a\[,, tol, lower, overwrite_a \] \) = <fortran object>

Wrapper for dpstrf.

Parameters

- \( a \) [input rank-2 array('d') with bounds (n,n)]

Returns

- \( c \) [rank-2 array('d') with bounds (n,n) and a storage]
- \( piv \) [rank-1 array('i') with bounds (n)]
- \( rank_c \) [int]
- \( info \) [int]

Other Parameters

- \( overwrite_a \) [input int, optional] Default: 0
- \( tol \) [input float, optional] Default: -1.0
- \( lower \) [input int, optional] Default: 0

scipy.linalg.lapack.cpstrf

scipy.linalg.lapack.cpstrf \( a\[,, tol, lower, overwrite_a \] \) = <fortran object>

Wrapper for cpstrf.

Parameters

- \( a \) [input rank-2 array('F') with bounds (n,n)]

Returns

- \( c \) [rank-2 array('F') with bounds (n,n) and a storage]
- \( piv \) [rank-1 array('i') with bounds (n)]
- \( rank_c \) [int]
- \( info \) [int]

Other Parameters

- \( overwrite_a \) [input int, optional] Default: 0
- \( tol \) [input float, optional] Default: -1.0
- \( lower \) [input int, optional] Default: 0

scipy.linalg.lapack.zpstrf

scipy.linalg.lapack.zpstrf \( a\[,, tol, lower, overwrite_a \] \) = <fortran object>

Wrapper for zpstrf.

Parameters

- \( a \) [input rank-2 array('D') with bounds (n,n)]

Returns

- \( c \) [rank-2 array('D') with bounds (n,n) and a storage]
- \( piv \) [rank-1 array('i') with bounds (n)]
- \( rank_c \) [int]
- \( info \) [int]

Other Parameters
**overwrite_a**
[input int, optional] Default: 0

**tol**
[input float, optional] Default: -1.0

**lower**
[input int, optional] Default: 0

---

**scipy.linalg.lapack.spstf2**

```python
scipy.linalg.lapack.spstf2(a[, tol, lower, overwrite_a]) = <fortran object>
```

Wrapper for spstf2.

**Parameters**

- **a**
  [input rank-2 array('f') with bounds (n,n)]

**Returns**

- **c**
  [rank-2 array('f') with bounds (n,n) and a storage]
- **piv**
  [rank-1 array('i') with bounds (n)]
- **rank_c**
  [int]
- **info**
  [int]

**Other Parameters**

- **overwrite_a**
  [input int, optional] Default: 0
- **tol**
  [input float, optional] Default: -1.0
- **lower**
  [input int, optional] Default: 0

---

**scipy.linalg.lapack.dpstf2**

```python
scipy.linalg.lapack.dpstf2(a[, tol, lower, overwrite_a]) = <fortran object>
```

Wrapper for dpstf2.

**Parameters**

- **a**
  [input rank-2 array('d') with bounds (n,n)]

**Returns**

- **c**
  [rank-2 array('d') with bounds (n,n) and a storage]
- **piv**
  [rank-1 array('i') with bounds (n)]
- **rank_c**
  [int]
- **info**
  [int]

**Other Parameters**

- **overwrite_a**
  [input int, optional] Default: 0
- **tol**
  [input float, optional] Default: -1.0
- **lower**
  [input int, optional] Default: 0
scipy.linalg.lapack.cpstf2

scipy.linalg.lapack.cpstf2(a[, tol, lower, overwrite_a]) = <fortran object>
Wrapper for cpstf2.

Parameters

- a [input rank-2 array('F') with bounds (n,n)]

Returns

- c [rank-2 array('F') with bounds (n,n) and a storage]
- piv [rank-1 array('i') with bounds (n)]
- rank_c [int]
- info [int]

Other Parameters

- overwrite_a [input int, optional] Default: 0
- tol [input float, optional] Default: -1.0
- lower [input int, optional] Default: 0

scipy.linalg.lapack.zpstf2

scipy.linalg.lapack.zpstf2(a[, tol, lower, overwrite_a]) = <fortran object>
Wrapper for zpstf2.

Parameters

- a [input rank-2 array('D') with bounds (n,n)]

Returns

- c [rank-2 array('D') with bounds (n,n) and a storage]
- piv [rank-1 array('i') with bounds (n)]
- rank_c [int]
- info [int]

Other Parameters

- overwrite_a [input int, optional] Default: 0
- tol [input float, optional] Default: -1.0
- lower [input int, optional] Default: 0

scipy.linalg.lapack.sposv

scipy.linalg.lapack.sposv(a, b[, lower, overwrite_a, overwrite_b]) = <fortran object>
Wrapper for sposv.

Parameters

- a [input rank-2 array('f') with bounds (n,n)]
- b [input rank-2 array('f') with bounds (n,nrhs)]

Returns

- c [rank-2 array('f') with bounds (n,n) and a storage]
- x [rank-2 array('f') with bounds (n,nrhs) and b storage]
- info [int]

Other Parameters

3.3. API definition
overwrite_a  
  [input int, optional] Default: 0
overwrite_b  
  [input int, optional] Default: 0
lower  
  [input int, optional] Default: 0

scipy.linalg.lapack.dposv

Wrapper for dposv.

Parameters

a  
  [input rank-2 array('d') with bounds (n,n)]
b  
  [input rank-2 array('d') with bounds (n, nrhs)]

Returns

c  
  [rank-2 array('d') with bounds (n,n) and a storage]
x  
  [rank-2 array('d') with bounds (n, nrhs) and b storage]
info  
  [int]

Other Parameters

overwrite_a  
  [input int, optional] Default: 0
overwrite_b  
  [input int, optional] Default: 0
lower  
  [input int, optional] Default: 0

scipy.linalg.lapack.cposv

Wrapper for cposv.

Parameters

a  
  [input rank-2 array('F') with bounds (n,n)]
b  
  [input rank-2 array('F') with bounds (n, nrhs)]

Returns

c  
  [rank-2 array('F') with bounds (n,n) and a storage]
x  
  [rank-2 array('F') with bounds (n, nrhs) and b storage]
info  
  [int]

Other Parameters

overwrite_a  
  [input int, optional] Default: 0
overwrite_b  
  [input int, optional] Default: 0
lower  
  [input int, optional] Default: 0
**scipy.linalg.lapack.zposv**

```python
scipy.linalg.lapack.zposv(a, b[, lower, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for zposv.

**Parameters**

- `a` [input rank-2 array('D') with bounds (n,n)]
- `b` [input rank-2 array('D') with bounds (n,nrhs)]

**Returns**

- `c` [rank-2 array('D') with bounds (n,n) and a storage]
- `x` [rank-2 array('D') with bounds (n,nrhs) and b storage]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0

**scipy.linalg.lapack.sposvx**

```python
scipy.linalg.lapack.sposvx(a, b[, fact, af, equed, s, lower, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for sposvx.

**Parameters**

- `a` [input rank-2 array('f') with bounds (n,n)]
- `b` [input rank-2 array('f') with bounds (n,nrhs)]

**Returns**

- `a_s` [rank-2 array('f') with bounds (n,n) and a storage]
- `lu` [rank-2 array('f') with bounds (n,n) and af storage]
- `equed` [string(len=1)]
- `s` [rank-1 array('f') with bounds (n)]
- `b_s` [rank-2 array('f') with bounds (n,nrhs) and b storage]
- `x` [rank-2 array('f') with bounds (n,nrhs)]
- `rcond` [float]
- `ferr` [rank-1 array('f') with bounds (nrhs)]
- `berr` [rank-1 array('f') with bounds (nrhs)]
- `info` [int]

**Other Parameters**

- `fact` [input string(len=1), optional] Default: ‘E’
- `overwrite_a` [input int, optional] Default: 0
- `af` [input rank-2 array('f') with bounds (n,n)]
- `equed` [input string(len=1), optional] Default: ‘Y’
- `s` [input rank-1 array('f') with bounds (n)]
- `overwrite_b` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
### scipy.linalg.lapack.dposvx

**scipy.linalg.lapack.dposvx**

```python
scipy.linalg.lapack.dposvx(a, b[, fact, af, equed, s, lower, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for dposvx.

**Parameters**

- `a` : [input rank-2 array('d') with bounds (n,n)]
- `b` : [input rank-2 array('d') with bounds (n,nrhs)]

**Returns**

- `a_s` : [rank-2 array('d') with bounds (n,n) and a storage]
- `lu` : [rank-2 array('d') with bounds (n,n) and af storage]
- `equed` : [string(len=1)]
- `s` : [rank-1 array('d') with bounds (n)]
- `b_s` : [rank-2 array('d') with bounds (n,nrhs) and b storage]
- `x` : [rank-2 array('d') with bounds (n,nrhs)]
- `rcond` : [float]
- `ferr` : [rank-1 array('d') with bounds (nrhs)]
- `berr` : [rank-1 array('d') with bounds (nrhs)]
- `info` : [int]

**Other Parameters**

- `fact` : [input string(len=1), optional] Default: 'E'
- `overwrite_a` : [input int, optional] Default: 0
- `af` : [input rank-2 array('d') with bounds (n,n)]
- `equed` : [input string(len=1), optional] Default: 'Y'
- `s` : [input rank-1 array('d') with bounds (n)]
- `overwrite_b` : [input int, optional] Default: 0
- `lower` : [input int, optional] Default: 0

---

### scipy.linalg.lapack.cposvx

**scipy.linalg.lapack.cposvx**

```python
scipy.linalg.lapack.cposvx(a, b[, fact, af, equed, s, lower, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for cposvx.

**Parameters**

- `a` : [input rank-2 array('F') with bounds (n,n)]
- `b` : [input rank-2 array('F') with bounds (n,nrhs)]

**Returns**

- `a_s` : [rank-2 array('F') with bounds (n,n) and a storage]
- `lu` : [rank-2 array('F') with bounds (n,n) and af storage]
- `equed` : [string(len=1)]
- `s` : [rank-1 array('f') with bounds (n)]
- `b_s` : [rank-2 array('F') with bounds (n,nrhs) and b storage]
- `x` : [rank-2 array('F') with bounds (n,nrhs)]
- `rcond` : [float]
- `ferr` : [rank-1 array('f') with bounds (nrhs)]
- `berr` : [rank-1 array('f') with bounds (nrhs)]
- `info` : [int]
**Other Parameters**

- **fact**  
  [input string(len=1), optional] Default: ‘E’
- **overwrite_a**  
  [input int, optional] Default: 0
- **af**  
  [input rank-2 array('F') with bounds (n,n)]
- **equed**  
  [input string(len=1), optional] Default: ‘Y’
- **s**  
  [input rank-1 array('f') with bounds (n)]
- **overwrite_b**  
  [input int, optional] Default: 0
- **lower**  
  [input int, optional] Default: 0

```python
scipy.linalg.lapack.zposvx
```

Wrapper for zposvx.

**Parameters**

- **a**  
  [input rank-2 array('D') with bounds (n,n)]
- **b**  
  [input rank-2 array('D') with bounds (n,nrhs)]

**Returns**

- **a_s**  
  [rank-2 array('D') with bounds (n,n) and a storage]
- **lu**  
  [rank-2 array('D') with bounds (n,n) and af storage]
- **equed**  
  [string(len=1)]
- **s**  
  [rank-1 array('d') with bounds (n)]
- **b_s**  
  [rank-2 array('D') with bounds (n,nrhs) and b storage]
- **x**  
  [rank-2 array('D') with bounds (n,nrhs)]
- **rcond**  
  [float]
- **ferr**  
  [rank-1 array('d') with bounds (nrhs)]
- **berr**  
  [rank-1 array('d') with bounds (nrhs)]
- **info**  
  [int]

**Other Parameters**

- **fact**  
  [input string(len=1), optional] Default: ‘E’
- **overwrite_a**  
  [input int, optional] Default: 0
- **af**  
  [input rank-2 array('D') with bounds (n,n)]
- **equed**  
  [input string(len=1), optional] Default: ‘Y’
- **s**  
  [input rank-1 array('d') with bounds (n)]
- **overwrite_b**  
  [input int, optional] Default: 0
- **lower**  
  [input int, optional] Default: 0
scipy.linalg.lapack.spotrf

scipy.linalg.lapack.spotrf(a[, lower, clean, overwrite_a]) = <fortran object>

Wrapper for spotrf.

Parameters

a    [input rank-2 array('f') with bounds (n,n)]

Returns

c    [rank-2 array('f') with bounds (n,n) and a storage]
info    [int]

Other Parameters

overwrite_a    [input int, optional] Default: 0
lower    [input int, optional] Default: 0
clean    [input int, optional] Default: 1

scipy.linalg.lapack.dpotrf

scipy.linalg.lapack.dpotrf(a[, lower, clean, overwrite_a]) = <fortran object>

Wrapper for dpotrf.

Parameters

a    [input rank-2 array('d') with bounds (n,n)]

Returns

c    [rank-2 array('d') with bounds (n,n) and a storage]
info    [int]

Other Parameters

overwrite_a    [input int, optional] Default: 0
lower    [input int, optional] Default: 0
clean    [input int, optional] Default: 1

scipy.linalg.lapack.cpotrf

scipy.linalg.lapack.cpotrf(a[, lower, clean, overwrite_a]) = <fortran object>

Wrapper for cpotrf.

Parameters

a    [input rank-2 array('F') with bounds (n,n)]

Returns

c    [rank-2 array('F') with bounds (n,n) and a storage]
info    [int]

Other Parameters

overwrite_a    [input int, optional] Default: 0
lower    [input int, optional] Default: 0
clean    [input int, optional] Default: 1
scipy.linalg.lapack.zpotrf

scipy.linalg.lapack.zpotrf(a[, lower, clean, overwrite_a]) = <fortran object>

Wrapper for zpotrf.

Parameters
a [input rank-2 array('D') with bounds (n,n)]

Returns
c [rank-2 array('D') with bounds (n,n) and a storage]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
lower [input int, optional] Default: 0
clean [input int, optional] Default: 1

scipy.linalg.lapack.spotri

scipy.linalg.lapack.spotri(c[, lower, overwrite_c]) = <fortran object>

Wrapper for spotri.

Parameters
c [input rank-2 array('f') with bounds (n,n)]

Returns
inv_a [rank-2 array('f') with bounds (n,n) and c storage]
info [int]

Other Parameters
overwrite_c [input int, optional] Default: 0
lower [input int, optional] Default: 0

scipy.linalg.lapack.dpotri

scipy.linalg.lapack.dpotri(c[, lower, overwrite_c]) = <fortran object>

Wrapper for dpotri.

Parameters
c [input rank-2 array('d') with bounds (n,n)]

Returns
inv_a [rank-2 array('d') with bounds (n,n) and c storage]
info [int]

Other Parameters
overwrite_c [input int, optional] Default: 0
lower [input int, optional] Default: 0
scipy.linalg.lapack.cpotri

```python
scipy.linalg.lapack.cpotri(c[, lower, overwrite_c]) = <fortran object>
```

Wrapper for cpotri.

**Parameters**

- `c` [input rank-2 array('F') with bounds (n,n)]

**Returns**

- `inv_a` [rank-2 array('F') with bounds (n,n) and c storage]
- `info` [int]

**Other Parameters**

- `overwrite_c` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0

scipy.linalg.lapack.zpotri

```python
scipy.linalg.lapack.zpotri(c[, lower, overwrite_c]) = <fortran object>
```

Wrapper for zpotri.

**Parameters**

- `c` [input rank-2 array('D') with bounds (n,n)]

**Returns**

- `inv_a` [rank-2 array('D') with bounds (n,n) and c storage]
- `info` [int]

**Other Parameters**

- `overwrite_c` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0

scipy.linalg.lapack.spotrs

```python
scipy.linalg.lapack.spotrs(c, b[, lower, overwrite_b]) = <fortran object>
```

Wrapper for spotrs.

**Parameters**

- `c` [input rank-2 array('f') with bounds (n,n)]
- `b` [input rank-2 array('f') with bounds (n,nrhs)]

**Returns**

- `x` [rank-2 array('f') with bounds (n,nrhs) and b storage]
- `info` [int]

**Other Parameters**

- `overwrite_b` [input int, optional] Default: 0
- `lower` [input int, optional] Default: 0
scipy.linalg.lapack.dpotrs

scipy.linalg.lapack.dpotrs(c, b[, lower, overwrite_b]) = <fortran object>
Wrapper for dpotrs.

Parameters

  c [input rank-2 array('d') with bounds (n,n)]
  b [input rank-2 array('d') with bounds (n,nrhs)]

Returns

  x [rank-2 array('d') with bounds (n,nrhs) and b storage]
  info [int]

Other Parameters

  overwrite_b [input int, optional] Default: 0
  lower [input int, optional] Default: 0

scipy.linalg.lapack.cpotrs

scipy.linalg.lapack.cpotrs(c, b[, lower, overwrite_b]) = <fortran object>
Wrapper for cpotrs.

Parameters

  c [input rank-2 array('F') with bounds (n,n)]
  b [input rank-2 array('F') with bounds (n,nrhs)]

Returns

  x [rank-2 array('F') with bounds (n,nrhs) and b storage]
  info [int]

Other Parameters

  overwrite_b [input int, optional] Default: 0
  lower [input int, optional] Default: 0

scipy.linalg.lapack.zpotrs

scipy.linalg.lapack.zpotrs(c, b[, lower, overwrite_b]) = <fortran object>
Wrapper for zpotrs.

Parameters

  c [input rank-2 array('D') with bounds (n,n)]
  b [input rank-2 array('D') with bounds (n,nrhs)]

Returns

  x [rank-2 array('D') with bounds (n,nrhs) and b storage]
  info [int]

Other Parameters

  overwrite_b [input int, optional] Default: 0
  lower [input int, optional] Default: 0
scipy.linalg.lapack.sppcon

scipy.linalg.lapack.sppcon\( (n, ap, anorm[, lower]) \) = <fortran object>
Wrapper for sppcon.

Parameters

- n: [input int]
- ap: [input rank-1 array('f') with bounds (L)]
- anorm: [input float]

Returns

- rcond: [float]
- info: [int]

Other Parameters

- lower: [input int, optional] Default: 0

scipy.linalg.lapack.dppcon

scipy.linalg.lapack.dppcon\( (n, ap, anorm[, lower]) \) = <fortran object>
Wrapper for dppcon.

Parameters

- n: [input int]
- ap: [input rank-1 array('d') with bounds (L)]
- anorm: [input float]

Returns

- rcond: [float]
- info: [int]

Other Parameters

- lower: [input int, optional] Default: 0

scipy.linalg.lapack.cppcon

scipy.linalg.lapack.cppcon\( (n, ap, anorm[, lower]) \) = <fortran object>
Wrapper for cppcon.

Parameters

- n: [input int]
- ap: [input rank-1 array('F') with bounds (L)]
- anorm: [input float]

Returns

- rcond: [float]
- info: [int]

Other Parameters

- lower: [input int, optional] Default: 0
scipy.linalg.lapack.zppcon

scipy.linalg.lapack.zppcon(n, ap, anorm[, lower]) = <fortran object>

Wrapper for zppcon.

Parameters
- n [input int]
- ap [input rank-1 array('D') with bounds (L)]
- anorm [input float]

Returns
- rcond [float]
- info [int]

Other Parameters
- lower [input int, optional] Default: 0

scipy.linalg.lapack.sppsv

scipy.linalg.lapack.sppsv(n, ap, b[, lower, overwrite_b]) = <fortran object>

Wrapper for sppsv.

Parameters
- n [input int]
- ap [input rank-1 array('F') with bounds (L)]
- b [input rank-2 array('F') with bounds (ldb,nrhs)]

Returns
- x [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
- info [int]

Other Parameters
- lower [input int, optional] Default: 0
- overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.dppsv

scipy.linalg.lapack.dppsv(n, ap, b[, lower, overwrite_b]) = <fortran object>

Wrapper for dppsv.

Parameters
- n [input int]
- ap [input rank-1 array('D') with bounds (L)]
- b [input rank-2 array('D') with bounds (ldb,nrhs)]

Returns
- x [rank-2 array('D') with bounds (ldb,nrhs) and b storage]
- info [int]

Other Parameters
- lower [input int, optional] Default: 0
- overwrite_b [input int, optional] Default: 0
scipy.linalg.lapack.cppsv

scipy.linalg.lapack.cppsv(n, ap[, lower, overwrite_b]) = <fortran object>
Wrapper for cppsv.

Parameters

n [input int]
ap [input rank-1 array('F') with bounds (L)]
b [input rank-2 array('F') with bounds (ldb,nrhs)]

Returns

x [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
info [int]

Other Parameters

lower [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.zppsv

scipy.linalg.lapack.zppsv(n, ap[, lower, overwrite_b]) = <fortran object>
Wrapper for zppsv.

Parameters

n [input int]
ap [input rank-1 array('D') with bounds (L)]
b [input rank-2 array('D') with bounds (ldb,nrhs)]

Returns

x [rank-2 array('D') with bounds (ldb,nrhs) and b storage]
info [int]

Other Parameters

lower [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.spptrf

scipy.linalg.lapack.spptrf(n, ap[, lower, overwrite_ap]) = <fortran object>
Wrapper for spptrf.

Parameters

n [input int]
ap [input rank-1 array('f') with bounds (L)]

Returns

ul [rank-1 array('f') with bounds (L) and ap storage]
info [int]

Other Parameters

lower [input int, optional] Default: 0
overwrite_ap [input int, optional] Default: 0
scipy.linalg.lapack.dpptrf

Wrapper for dpptrf.

Parameters

- n [input int]
- ap [input rank-1 array('d') with bounds (L)]

Returns

- ul [rank-1 array('d') with bounds (L) and ap storage]
- info [int]

Other Parameters

- lower [input int, optional] Default: 0
- overwrite_ap [input int, optional] Default: 0

scipy.linalg.lapack.cpptrf

Wrapper for cpptrf.

Parameters

- n [input int]
- ap [input rank-1 array('F') with bounds (L)]

Returns

- ul [rank-1 array('F') with bounds (L) and ap storage]
- info [int]

Other Parameters

- lower [input int, optional] Default: 0
- overwrite_ap [input int, optional] Default: 0

scipy.linalg.lapack.zpptrf

Wrapper for zpptrf.

Parameters

- n [input int]
- ap [input rank-1 array('D') with bounds (L)]

Returns

- ul [rank-1 array('D') with bounds (L) and ap storage]
- info [int]

Other Parameters

- lower [input int, optional] Default: 0
- overwrite_ap [input int, optional] Default: 0
scipy.linalg.lapack.spptri

scipy.linalg.lapack.spptri(\( n, ap[, lower, overwrite_ap] \)) = <fortran object>

Wrapper for spptri.

Parameters
\( n \) [input int]
\( ap \) [input rank-1 array('f') with bounds (L)]

Returns
\( uli \) [rank-1 array('f') with bounds (L) and ap storage]
\( info \) [int]

Other Parameters
\( lower \) [input int, optional] Default: 0
\( overwrite_ap \) [input int, optional] Default: 0

scipy.linalg.lapack.dpptri

scipy.linalg.lapack.dpptri(\( n, ap[, lower, overwrite_ap] \)) = <fortran object>

Wrapper for dpptri.

Parameters
\( n \) [input int]
\( ap \) [input rank-1 array('d') with bounds (L)]

Returns
\( uli \) [rank-1 array('d') with bounds (L) and ap storage]
\( info \) [int]

Other Parameters
\( lower \) [input int, optional] Default: 0
\( overwrite_ap \) [input int, optional] Default: 0

scipy.linalg.lapack.cpptri

scipy.linalg.lapack.cpptri(\( n, ap[, lower, overwrite_ap] \)) = <fortran object>

Wrapper for cpptri.

Parameters
\( n \) [input int]
\( ap \) [input rank-1 array('F') with bounds (L)]

Returns
\( uli \) [rank-1 array('F') with bounds (L) and ap storage]
\( info \) [int]

Other Parameters
\( lower \) [input int, optional] Default: 0
\( overwrite_ap \) [input int, optional] Default: 0
scipy.linalg.lapack.zpptri

scipy.linalg.lapack.zpptri(n, ap[, lower, overwrite_ap]) = <fortran object>
Wrapper for zpptri.

Parameters
n [input int]
ap [input rank-1 array('D') with bounds (L)]

Returns
ul [rank-1 array('D') with bounds (L) and ap storage]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_ap [input int, optional] Default: 0

scipy.linalg.lapack.spptrs

scipy.linalg.lapack.spptrs(n, ap, b[, lower, overwrite_b]) = <fortran object>
Wrapper for spptrs.

Parameters
n [input int]
ap [input rank-1 array('f') with bounds (L)]
b [input rank-2 array('f') with bounds (ldb, nrhs)]

Returns
x [rank-2 array('f') with bounds (ldb, nrhs) and b storage]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.dpptrs

scipy.linalg.lapack.dpptrs(n, ap, b[, lower, overwrite_b]) = <fortran object>
Wrapper for dpptrs.

Parameters
n [input int]
ap [input rank-1 array('d') with bounds (L)]
b [input rank-2 array('d') with bounds (ldb, nrhs)]

Returns
x [rank-2 array('d') with bounds (ldb, nrhs) and b storage]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
scipy.linalg.lapack.cpptrs

scipy.linalg.lapack.cpptrs(n, ap[, lower, overwrite_b]) = <fortran object>
Wrapper for cpptrs.

Parameters

n [input int]
ap [input rank-1 array('F') with bounds (L)]
b [input rank-2 array('F') with bounds (ldb,nrhs)]

Returns

x [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
info [int]

Other Parameters

lower [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.zpptrs

scipy.linalg.lapack.zpptrs(n, ap[, lower, overwrite_b]) = <fortran object>
Wrapper for zpptrs.

Parameters

n [input int]
ap [input rank-1 array('D') with bounds (L)]
b [input rank-2 array('D') with bounds (ldb,nrhs)]

Returns

x [rank-2 array('D') with bounds (ldb,nrhs) and b storage]
info [int]

Other Parameters

lower [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.sptsv

scipy.linalg.lapack.sptsv(d, e, b[, overwrite_d, overwrite_e, overwrite_b]) = <fortran object>
Wrapper for sptsv.

Parameters

d [input rank-1 array('f') with bounds (n)]
e [input rank-1 array('f') with bounds (-1 + n)]
b [input rank-2 array('f') with bounds (n,nrhs)]

Returns

d [rank-1 array('f') with bounds (n)]
du [rank-1 array('f') with bounds (-1 + n) and e storage]
x [rank-2 array('f') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters
overwrite_d
[input int, optional] Default: 0

overwrite_e
[input int, optional] Default: 0

overwrite_b
[input int, optional] Default: 0

scipy.linalg.lapack.dptsv

scipy.linalg.lapack.dptsv\( d, e, b[, overwrite_d, overwrite_e, overwrite_b] \) = <fortran object>

Wrapper for dptsv.

Parameters

d [input rank-1 array('d') with bounds (n)]
e [input rank-1 array('d') with bounds (-1 + n)]
b [input rank-2 array('d') with bounds (n,nrhs)]

Returns

d [rank-1 array('d') with bounds (n)]
du [rank-1 array('d') with bounds (-1 + n) and e storage]
x [rank-2 array('d') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters

overwrite_d
[input int, optional] Default: 0

overwrite_e
[input int, optional] Default: 0

overwrite_b
[input int, optional] Default: 0

scipy.linalg.lapack.cptsv

scipy.linalg.lapack.cptsv\( d, e, b[, overwrite_d, overwrite_e, overwrite_b] \) = <fortran object>

Wrapper for cptsv.

Parameters

d [input rank-1 array('f') with bounds (n)]
e [input rank-1 array('F') with bounds (-1 + n)]
b [input rank-2 array('F') with bounds (n,nrhs)]

Returns

d [rank-1 array('f') with bounds (n)]
du [rank-1 array('F') with bounds (-1 + n) and e storage]
x [rank-2 array('F') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters

overwrite_d
[input int, optional] Default: 0

overwrite_e
[input int, optional] Default: 0

overwrite_b
[input int, optional] Default: 0
scipy.linalg.lapack.zptsv

scipy.linalg.lapack.zptsv(d, e, b[, overwrite_d, overwrite_e, overwrite_b]) = <fortran object>

Wrapper for zptsv.

Parameters

- **d** [input rank-1 array('d') with bounds (n)]
- **e** [input rank-1 array('D') with bounds (-1 + n)]
- **b** [input rank-2 array('D') with bounds (n,nrhs)]

Returns

- **d** [rank-1 array('d') with bounds (n)]
- **du** [rank-1 array('D') with bounds (-1 + n) and e storage]
- **x** [rank-2 array('D') with bounds (n,nrhs) and b storage]
- **info** [int]

Other Parameters

- **overwrite_d** [input int, optional] Default: 0
- **overwrite_e** [input int, optional] Default: 0
- **overwrite_b** [input int, optional] Default: 0

scipy.linalg.lapack.sptsvx

scipy.linalg.lapack.sptsvx(d, e, b[, fact, df, ef]) = <fortran object>

Wrapper for sptsvx.

Parameters

- **d** [input rank-1 array('f') with bounds (n)]
- **e** [input rank-1 array('f') with bounds (max(0, -1 + n))]
- **b** [input rank-2 array('f') with bounds (ldb,nrhs)]

Returns

- **df** [rank-1 array('f') with bounds (n)]
- **ef** [rank-1 array('f') with bounds (max(0, -1 + n))]
- **x** [rank-2 array('f') with bounds (ldx,nrhs)]
- **rcond** [float]
- **ferr** [rank-1 array('f') with bounds (nrhs)]
- **berr** [rank-1 array('f') with bounds (nrhs)]
- **info** [int]

Other Parameters

- **fact** [input string(len=1), optional] Default: ‘N’
- **df** [input rank-1 array('f') with bounds (n)]
- **ef** [input rank-1 array('f') with bounds (max(0, -1 + n))]

Chapter 3. SciPy API
**scipy.linalg.lapack.dptsvx**

```python
scipy.linalg.lapack.dptsvx(d, e, b[, fact, df, ef]) = <fortran object>
```

Wrapper for dptsvx.

**Parameters**
- `d` [input rank-1 array('d') with bounds (n)]
- `e` [input rank-1 array('d') with bounds (max(0, -1 + n))]
- `b` [input rank-2 array('d') with bounds (ldb,nrhs)]

**Returns**
- `df` [rank-1 array('d') with bounds (n)]
- `ef` [rank-1 array('d') with bounds (max(0, -1 + n))]
- `x` [rank-2 array('d') with bounds (ldx,nrhs)]
- `rcond` [float]
- `ferr` [rank-1 array('d') with bounds (nrhs)]
- `berr` [rank-1 array('d') with bounds (nrhs)]
- `info` [int]

**Other Parameters**
- `fact` [input string(len=1), optional] Default: ‘N’
- `df` [input rank-1 array('d') with bounds (n)]
- `ef` [input rank-1 array('d') with bounds (max(0, -1 + n))]

**scipy.linalg.lapack.cptsvx**

```python
scipy.linalg.lapack.cptsvx(d, e, b[, fact, df, ef]) = <fortran object>
```

Wrapper for cptsvx.

**Parameters**
- `d` [input rank-1 array('f') with bounds (n)]
- `e` [input rank-1 array('F') with bounds (max(0, -1 + n))]
- `b` [input rank-2 array('F') with bounds (ldb,nrhs)]

**Returns**
- `df` [rank-1 array('f') with bounds (n)]
- `ef` [rank-1 array('F') with bounds (max(0, -1 + n))]
- `x` [rank-2 array('F') with bounds (ldx,nrhs)]
- `rcond` [float]
- `ferr` [rank-1 array('f') with bounds (nrhs)]
- `berr` [rank-1 array('f') with bounds (nrhs)]
- `info` [int]

**Other Parameters**
- `fact` [input string(len=1), optional] Default: ‘N’
- `df` [input rank-1 array('f') with bounds (n)]
- `ef` [input rank-1 array('F') with bounds (max(0, -1 + n))]
scipy.linalg.lapack.zptsvx

```python
scipy.linalg.lapack.zptsvx(d, e, b[, fact, df, ef]) = <fortran object>

Wrapper for zptsvx.
```

Parameters
- `d` [input rank-1 array('d') with bounds (n)]
- `e` [input rank-1 array('D') with bounds (max(0, -1 + n))]
- `b` [input rank-2 array('D') with bounds (ldb,nrhs)]

Returns
- `df` [rank-1 array('d') with bounds (n)]
- `ef` [rank-1 array('D') with bounds (max(0, -1 + n))]
- `x` [rank-2 array('D') with bounds (ldx,nrhs)]
- `rcond` [float]
- `ferr` [rank-1 array('d') with bounds (nrhs)]
- `berr` [rank-1 array('d') with bounds (nrhs)]
- `info` [int]

Other Parameters
- `fact` [input string(len=1), optional] Default: ‘N’
- `df` [input rank-1 array('d') with bounds (n)]
- `ef` [input rank-1 array('D') with bounds (max(0, -1 + n))]

scipy.linalg.lapack.spttrf

```python
scipy.linalg.lapack.spttrf(d, e[, overwrite_d, overwrite_e]) = <fortran object>

Wrapper for spttrf.
```

Parameters
- `d` [input rank-1 array('f') with bounds (n)]
- `e` [input rank-1 array('f') with bounds ((n>0?-1+n:0))]

Returns
- `d` [rank-1 array('f') with bounds (n)]
- `e` [rank-1 array('f') with bounds ((n>0?-1+n:0))]
- `info` [int]

Other Parameters
- `overwrite_d` [input int, optional] Default: 0
- `overwrite_e` [input int, optional] Default: 0

scipy.linalg.lapack.dpttrf

```python
scipy.linalg.lapack.dpttrf(d, e[, overwrite_d, overwrite_e]) = <fortran object>

Wrapper for dpttrf.
```

Parameters
- `d` [input rank-1 array('d') with bounds (n)]
- `e` [input rank-1 array('d') with bounds ((n>0?-1+n:0))]

Returns
- `d` [rank-1 array('d') with bounds (n)]

```
e [rank-1 array('d') with bounds ((n > 0?-1 + n:0))]
info [int]

Other Parameters
overwrite_d
    [input int, optional] Default: 0
overwrite_e
    [input int, optional] Default: 0

scipy.linalg.lapack.cpttrf
scipy.linalg.lapack.cpttrf (d, e[, overwrite_d, overwrite_e]) = <fortran object>
Wrapper for cpttrf.

Parameters
    d [input rank-1 array('f') with bounds (n)]
    e [input rank-1 array('F') with bounds ((n > 0?-1 + n:0))]

Returns
    d [rank-1 array('f') with bounds (n)]
    e [rank-1 array('F') with bounds ((n > 0?-1 + n:0))]
    info [int]

Other Parameters
overwrite_d
    [input int, optional] Default: 0
overwrite_e
    [input int, optional] Default: 0

scipy.linalg.lapack.zpttrf
scipy.linalg.lapack.zpttrf (d, e[, overwrite_d, overwrite_e]) = <fortran object>
Wrapper for zpttrf.

Parameters
    d [input rank-1 array('d') with bounds (n)]
    e [input rank-1 array('D') with bounds ((n > 0?-1 + n:0))]

Returns
    d [rank-1 array('d') with bounds (n)]
    e [rank-1 array('D') with bounds ((n > 0?-1 + n:0))]
    info [int]

Other Parameters
overwrite_d
    [input int, optional] Default: 0
overwrite_e
    [input int, optional] Default: 0
```
scipy.linalg.lapack.spttrs

```python
scipy.linalg.lapack.spttrs(d, e, b[, overwrite_b]) = <fortran object>
```

Wrapper for `spttrs`.

**Parameters**

- `d` [input rank-1 array('f') with bounds (n)]
- `e` [input rank-1 array('f') with bounds ((n > 0?-1+n:0))]
- `b` [input rank-2 array('f') with bounds (ldb,nrhs)]

**Returns**

- `x` [rank-2 array('f') with bounds (ldb,nrhs) and b storage]
- `info` [int]

**Other Parameters**

- `overwrite_b` [input int, optional] Default: 0

scipy.linalg.lapack.dpttrs

```python
scipy.linalg.lapack.dpttrs(d, e, b[, overwrite_b]) = <fortran object>
```

Wrapper for `dpttrs`.

**Parameters**

- `d` [input rank-1 array('d') with bounds (n)]
- `e` [input rank-1 array('d') with bounds ((n > 0?-1+n:0))]
- `b` [input rank-2 array('d') with bounds (ldb,nrhs)]

**Returns**

- `x` [rank-2 array('d') with bounds (ldb,nrhs) and b storage]
- `info` [int]

**Other Parameters**

- `overwrite_b` [input int, optional] Default: 0

scipy.linalg.lapack.cpttrs

```python
scipy.linalg.lapack.cpttrs(d, e, b[, lower, overwrite_b]) = <fortran object>
```

Wrapper for `cpttrs`.

**Parameters**

- `d` [input rank-1 array('f') with bounds (n)]
- `e` [input rank-1 array('F') with bounds ((n > 0?-1+n:0))]
- `b` [input rank-2 array('F') with bounds (ldb,nrhs)]

**Returns**

- `x` [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
- `info` [int]

**Other Parameters**

- `lower` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0
**scipy.linalg.lapack.zpttrs**

```python
scipy.linalg.lapack.zpttrs(d, e, b[, lower, overwrite_b]) = <fortran object>
```

Wrapper for zpttrs.

**Parameters**

- `d` [input rank-1 array('d') with bounds (n)]
- `e` [input rank-1 array('D') with bounds ((n > 0?-1+n:0))]
- `b` [input rank-2 array('D') with bounds (ldb,nrhs)]

**Returns**

- `x` [rank-2 array('D') with bounds (ldb,nrhs) and b storage]
- `info` [int]

**Other Parameters**

- `lower` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0

---

**scipy.linalg.lapack.spteqr**

```python
scipy.linalg.lapack.spteqr(d, e, z[, compute_z, overwrite_d, overwrite_e, overwrite_z]) = <fortran object>
```

Wrapper for spteqr.

**Parameters**

- `d` [input rank-1 array('f') with bounds (n)]
- `e` [input rank-1 array('f') with bounds ((n > 0?-1+n:0))]
- `z` [input rank-2 array('f') with bounds ((compute_z == 0?shape(z, 0):max(1, n)),(compute_z == 0?shape(z, 1):n))]

**Returns**

- `d` [rank-1 array('f') with bounds (n)]
- `e` [rank-1 array('f') with bounds ((n > 0?-1+n:0))]
- `z` [rank-2 array('f') with bounds ((compute_z == 0?shape(z, 0):max(1, n)),(compute_z == 0?shape(z, 1):n))]
- `info` [int]

**Other Parameters**

- `compute_z` [input int, optional] Default: 0
- `overwrite_d` [input int, optional] Default: 0
- `overwrite_e` [input int, optional] Default: 0
- `overwrite_z` [input int, optional] Default: 0
scipy.linalg.lapack.dpteqr

scipy.linalg.lapack.dpteqr\( (d, e, z[, compute_z, overwrite_d, overwrite_e, overwrite_z]) \) = <fortran object>

Wrapper for dpteqr.

**Parameters**
- d [input rank-1 array('d') with bounds (n)]
- e [input rank-1 array('d') with bounds ((n > 0? -1 + n:0))]
- z [input rank-2 array('d') with bounds ((compute_z == 0?shape(z, 0):max(1, n)),(compute_z == 0?shape(z, 1):n))]

**Returns**
- d [rank-1 array('d') with bounds (n)]
- e [rank-1 array('d') with bounds ((n > 0? -1 + n:0))]
- z [rank-2 array('d') with bounds ((compute_z == 0?shape(z, 0):max(1, n)),(compute_z == 0?shape(z, 1):n))]
- info [int]

**Other Parameters**
- compute_z [input int, optional] Default: 0
- overwrite_d [input int, optional] Default: 0
- overwrite_e [input int, optional] Default: 0
- overwrite_z [input int, optional] Default: 0

scipy.linalg.lapack.cpteqr

scipy.linalg.lapack.cpteqr\( (d, e, z[, compute_z, overwrite_d, overwrite_e, overwrite_z]) \) = <fortran object>

Wrapper for cpteqr.

**Parameters**
- d [input rank-1 array('f') with bounds (n)]
- e [input rank-1 array('f') with bounds ((n > 0? -1 + n:0))]
- z [input rank-2 array('F') with bounds ((compute_z == 0?shape(z, 0):max(1, n)),(compute_z == 0?shape(z, 1):n))]

**Returns**
- d [rank-1 array('f') with bounds (n)]
- e [rank-1 array('f') with bounds ((n > 0? -1 + n:0))]
- z [rank-2 array('F') with bounds ((compute_z == 0?shape(z, 0):max(1, n)),(compute_z == 0?shape(z, 1):n))]
- info [int]

**Other Parameters**
- compute_z [input int, optional] Default: 0
- overwrite_d [input int, optional] Default: 0
- overwrite_e [input int, optional] Default: 0
**overwrite_z**
[input int, optional] Default: 0

**scipy.linalg.lapack.zpteqr**

```python
scipy.linalg.lapack.zpteqr(d, e, z[, compute_z, overwrite_d, overwrite_e, overwrite_z]) = <fortran object>
```

Wrapper for zpteqr.

**Parameters**

- **d**  
  [input rank-1 array('d') with bounds (n)]
- **e**  
  [input rank-1 array('d') with bounds ((n > 0? -1 + n:0))]
- **z**  
  [input rank-2 array('D') with bounds ((compute_z == 0?shape(z, 0):max(1, n)),(compute_z == 0?shape(z, 1):n))]

**Returns**

- **d**  
  [rank-1 array('d') with bounds (n)]
- **e**  
  [rank-1 array('d') with bounds ((n > 0? -1 + n:0))]
- **z**  
  [rank-2 array('D') with bounds ((compute_z == 0?shape(z, 0):max(1, n)),(compute_z == 0?shape(z, 1):n))]
- **info**  
  [int]

**Other Parameters**

- **compute_z**  
  [input int, optional] Default: 0
- **overwrite_d**  
  [input int, optional] Default: 0
- **overwrite_e**  
  [input int, optional] Default: 0
- **overwrite_z**  
  [input int, optional] Default: 0

**scipy.linalg.lapack.crot**

```python
scipy.linalg.lapack.crot(x, y, c[, s, n, offx, incx, offy, incy, overwrite_x, overwrite_y]) = <fortran object>
```

Wrapper for crot.

**Parameters**

- **x**  
  [input rank-1 array('F') with bounds (lx)]
- **y**  
  [input rank-1 array('F') with bounds (ly)]
- **c**  
  [input float]
- **s**  
  [input complex]

**Returns**

- **x**  
  [rank-1 array('F') with bounds (lx)]
- **y**  
  [rank-1 array('F') with bounds (ly)]

**Other Parameters**

- **n**  
  [input int, optional] Default: (lx-1-offx)/abs(incx)+1
- **overwrite_x**  
  [input int, optional] Default: 0
- **offx**  
  [input int, optional] Default: 0
- **incy**  
  [input int, optional] Default: 1
scipy.linalg.lapack.zrot

\[
\text{scipy.linalg.lapack.zrot}(x, y, c, s, n, offx, incx, offy, incy, overwrite_x, overwrite_y) = <\text{fortran object}>
\]

Wrapper for zrot.

**Parameters**

- \(x\) [input rank-1 array('D') with bounds (lx)]
- \(y\) [input rank-1 array('D') with bounds (ly)]
- \(c\) [input float]
- \(s\) [input complex]

**Returns**

- \(x\) [rank-1 array('D') with bounds (lx)]
- \(y\) [rank-1 array('D') with bounds (ly)]

**Other Parameters**

- \(n\) [input int, optional] Default: \((lx-1-offx)/abs(incx)+1\)
- \(overwrite_x\) [input int, optional] Default: 0
- \(offx\) [input int, optional] Default: 0
- \(incx\) [input int, optional] Default: 1
- \(overwrite_y\) [input int, optional] Default: 0
- \(offy\) [input int, optional] Default: 0
- \(incy\) [input int, optional] Default: 1

scipy.linalg.lapack.ssbev

\[
\text{scipy.linalg.lapack.ssbev}(ab[, compute_v, lower, ldab, overwrite_ab]) = <\text{fortran object}>
\]

Wrapper for ssbev.

**Parameters**

- \(ab\) [input rank-2 array('f') with bounds (ldab,n)]

**Returns**

- \(w\) [rank-1 array('f') with bounds (n)]
- \(z\) [rank-2 array('f') with bounds (ldz,ldz)]
- \(info\) [int]

**Other Parameters**

- \(overwrite_ab\) [input int, optional] Default: 1
- \(compute_v\) [input int, optional] Default: 1
- \(lower\) [input int, optional] Default: 0
- \(ldab\) [input int, optional] Default: shape(ab,0)
scipy.linalg.lapack.dsbev

scipy.linalg.lapack.dsbev(ab[, compute_v, lower, ldab, overwrite_ab]) = <fortran object>

Wrapper for dsbev.

Parameters

ab [input rank-2 array('d') with bounds (ldab,n)]

Returns

w [rank-1 array('d') with bounds (n)]

z [rank-2 array('d') with bounds (ldz,ldz)]

info [int]

Other Parameters

overwrite_ab [input int, optional] Default: 1

compute_v [input int, optional] Default: 1

lower [input int, optional] Default: 0

ldab [input int, optional] Default: shape(ab,0)

scipy.linalg.lapack.ssbevd

scipy.linalg.lapack.ssbevd(ab[, compute_v, lower, ldab, liwork, overwrite_ab]) = <fortran object>

Wrapper for ssbevd.

Parameters

ab [input rank-2 array('f') with bounds (ldab,n)]

Returns

w [rank-1 array('f') with bounds (n)]

z [rank-2 array('f') with bounds (ldz,ldz)]

info [int]

Other Parameters

overwrite_ab [input int, optional] Default: 1

compute_v [input int, optional] Default: 1

lower [input int, optional] Default: 0

ldab [input int, optional] Default: shape(ab,0)

liwork [input int, optional] Default: (compute_v?3+5*n:1)

scipy.linalg.lapack.dsbevd

scipy.linalg.lapack.dsbevd(ab[, compute_v, lower, ldab, liwork, overwrite_ab]) = <fortran object>

Wrapper for dsbevd.

Parameters

ab [input rank-2 array('d') with bounds (ldab,n)]

Returns

w [rank-1 array('d') with bounds (n)]

z [rank-2 array('d') with bounds (ldz,ldz)]

info [int]

Other Parameters

overwrite_ab

[input int, optional] Default: 1

compute_v

[input int, optional] Default: 1

lower

[input int, optional] Default: 0

ldab

[input int, optional] Default: shape(ab,0)

liwork

[input int, optional] Default: (compute_v?3+5*n:1)

**scipy.linalg.lapack.ssbevx**

scipy.linalg.lapack.ssbevx

Wrapper for ssbevx.

Parameters

ab [input rank-2 array('f') with bounds (ldab,n)]

vl [input float]

vu [input float]

il [input int]

iu [input int]

Returns

w [rank-1 array('f') with bounds (n)]

z [rank-2 array('f') with bounds (ldz,mmax)]

m [int]

ifail [rank-1 array('i') with bounds ((compute_v?n:1))]

info [int]

Other Parameters

overwrite_ab

[input int, optional] Default: 1

ldab

[input int, optional] Default: shape(ab,0)

compute_v

[input int, optional] Default: 1

range

[input int, optional] Default: 0

lower

[input int, optional] Default: 0

abstol

[input float, optional] Default: 0.0

mmax

[input int, optional] Default: (compute_v?(range==2?(iu-il+1):n):1)

**scipy.linalg.lapack.dsbevx**

scipy.linalg.lapack.dsbevx

Wrapper for dsbevx.

Parameters

ab [input rank-2 array('d') with bounds (ldab,n)]

vl [input float]

vu [input float]

il [input int]

iu [input int]
Returns

- \( w \) [rank-1 array('d') with bounds (n)]
- \( z \) [rank-2 array('d') with bounds (ldz,mmax)]
- \( m \) [int]
- ifail [rank-1 array('i') with bounds ((compute_v?n:1))]  
- info [int]

Other Parameters

- overwrite_ab [input int, optional] Default: 1
- ldab [input int, optional] Default: shape(ab,0)
- compute_v [input int, optional] Default: 1
- range [input int, optional] Default: 0
- lower [input int, optional] Default: 0
- abstol [input float, optional] Default: 0.0

scipy.linalg.lapack.ssfrk

```
scipy.linalg.lapack.ssfrk(n, k, alpha, a, beta, c[, transr, uplo, trans, overwrite_c]) = <fortran object>
```

Wrapper for ssfrk.

Parameters

- \( n \) [input int]
- \( k \) [input int]
- \( \alpha \) [input float]
- \( a \) [input rank-2 array('f') with bounds (lda,ka)]
- \( \beta \) [input float]
- \( c \) [input rank-1 array('f') with bounds (nt)]

Returns

- \( cout \) [rank-1 array('f') with bounds (nt) and c storage]

Other Parameters

- transr [input string(len=1), optional] Default: 'N'
- uplo [input string(len=1), optional] Default: 'U'
- trans [input string(len=1), optional] Default: 'N'
- overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.dsfrk

```
scipy.linalg.lapack.dsfrk(n, k, alpha, a, beta, c[, transr, uplo, trans, overwrite_c]) = <fortran object>
```

Wrapper for dsfrk.

Parameters

- \( n \) [input int]
- \( k \) [input int]
- \( \alpha \) [input float]
- \( a \) [input rank-2 array('d') with bounds (lda,ka)]
- \( \beta \) [input float]
c

[input rank-1 array('d') with bounds (nt)]

Returns

cout

[rank-1 array('d') with bounds (nt) and c storage]

Other Parameters

transr

[in] string(len=1), optional Default: 'N'

uplo

[in] string(len=1), optional Default: 'U'

trans

[in] string(len=1), optional Default: 'N'

overwrite_c

[input int, optional] Default: 0

scipy.linalg.lapack.sstebz

scipy.linalg.lapack.sstebz(d, e, range, vl, vu, il, iu, tol, order) = <fortran object>

Wrapper for sstebz.

Parameters

d

[rank-1 array('f') with bounds (n)]

e

[rank-1 array('f') with bounds (-1 + n)]

range

[rank-1 array('f') with bounds (-1 + n)]

vl

[rank-1 array('f') with bounds (-1 + n)]

vu

[rank-1 array('f') with bounds (-1 + n)]

il

[rank-1 array('f') with bounds (-1 + n)]

iu

[rank-1 array('f') with bounds (-1 + n)]

tol

[rank-1 array('f') with bounds (-1 + n)]

order

[rank-1 array('f') with bounds (-1 + n)]

Returns

m

[rank-1 array('f') with bounds (-1 + n)]

w

[rank-1 array('f') with bounds (-1 + n)]

iblock

[rank-1 array('f') with bounds (-1 + n)]

isplit

[rank-1 array('f') with bounds (-1 + n)]

info

[rank-1 array('f') with bounds (-1 + n)]

scipy.linalg.lapack.dstebz

scipy.linalg.lapack.dstebz(d, e, range, vl, vu, il, iu, tol, order) = <fortran object>

Wrapper for dstebz.

Parameters

d

[rank-1 array('d') with bounds (n)]

e

[rank-1 array('d') with bounds (n)]

range

[rank-1 array('d') with bounds (n)]

vl

[rank-1 array('d') with bounds (n)]

vu

[rank-1 array('d') with bounds (n)]

il

[rank-1 array('d') with bounds (n)]

iu

[rank-1 array('d') with bounds (n)]

tol

[rank-1 array('d') with bounds (n)]

order

[rank-1 array('d') with bounds (n)]

Returns

m

[rank-1 array('d') with bounds (n)]

w

[rank-1 array('d') with bounds (n)]

iblock

[rank-1 array('d') with bounds (n)]
isplit [rank-1 array('i') with bounds (n)]
info [int]

scipy.linalg.lapack.sstein

scipy.linalg.lapack.sstein (d, e, w, iblock, isplit) = <fortran object>
Wrapper for sstein.

Parameters

  d [input rank-1 array('f') with bounds (n)]
  e [input rank-1 array('f') with bounds (-1 + n)]
  w [input rank-1 array('f') with bounds (m)]
  iblock [input rank-1 array('i') with bounds (n)]
  isplit [input rank-1 array('i') with bounds (n)]

Returns

  z [rank-2 array('f') with bounds (ldz,m)]
  info [int]

scipy.linalg.lapack.dstein

scipy.linalg.lapack.dstein (d, e, w, iblock, isplit) = <fortran object>
Wrapper for dstein.

Parameters

  d [input rank-1 array('d') with bounds (n)]
  e [input rank-1 array('d') with bounds (-1 + n)]
  w [input rank-1 array('d') with bounds (m)]
  iblock [input rank-1 array('i') with bounds (n)]
  isplit [input rank-1 array('i') with bounds (n)]

Returns

  z [rank-2 array('d') with bounds (ldz,m)]
  info [int]

scipy.linalg.lapack.sstemr

scipy.linalg.lapack.sstemr (d, e, range, vl, vu, il, iu, compute_v, lwork, liwork, overwrite_d) = <fortran object>
Wrapper for sstemr.

Parameters

  d [input rank-1 array('f') with bounds (n)]
  e [input rank-1 array('f') with bounds (n)]
  range [input int]
  vl [input float]
  vu [input float]
  il [input int]
  iu [input int]

Returns

  m [int]
  w [rank-1 array('f') with bounds (n)]
  z [rank-2 array('f') with bounds (n,n)]
  info [int]

**Other Parameters**

overwrite_d
[input int, optional] Default: 0

compute_v
[input int, optional] Default: 1

lwork
[input int, optional] Default: max((compute_v?18*n:12*n),1)

liwork
[input int, optional] Default: (compute_v?10*n:8*n)

```
scipy.linalg.lapack.dstemr
d, e, range, vl, vu, il, iu[, compute_v, lwork, liwork, overwrite_d]
```

Wrapper for dstemr.

**Parameters**

d [input rank-1 array('d') with bounds (n)]
e [input rank-1 array('d') with bounds (n)]
range [input int]
vl [input float]
vu [input float]
il [input int]
iu [input int]

**Returns**

m [int]
w [rank-1 array('d') with bounds (n)]
z [rank-2 array('d') with bounds (n,n)]
info [int]

**Other Parameters**

overwrite_d
[input int, optional] Default: 0

compute_v
[input int, optional] Default: 1

lwork
[input int, optional] Default: max((compute_v?18*n:12*n),1)

liwork
[input int, optional] Default: (compute_v?10*n:8*n)

```
scipy.linalg.lapack.sstemr_lwork
d, e, range, vl, vu, il, iu[, compute_v, overwrite_d, overwrite_e]
```

Wrapper for sstemr_lwork.

**Parameters**

d [input rank-1 array('f') with bounds (n)]
e [input rank-1 array('f') with bounds (n)]
range [input int]
vl [input float]
vu [input float]
il [input int]
iu [input int]

**Returns**

work [float]

iwork [int]
info [int]

Other Parameters
overwrite_d
[input int, optional] Default: 0
overwrite_e
[input int, optional] Default: 0
compute_v
[input int, optional] Default: 1

scipy.linalg.lapack.dstemr_lwork

scipy.linalg.lapack.dstemr_lwork(d, e, range, vl, vu, il, iu[, compute_v, overwrite_d, overwrite_e]) = <fortran object>

Wrapper for dstemr_lwork.

Parameters
d [input rank-1 array('d') with bounds (n)]
e [input rank-1 array('d') with bounds (n)]
range [input int]
vl [input float]
vu [input float]
il [input int]
iu [input int]

Returns
work [float]
iwork [int]
info [int]

Other Parameters
overwrite_d
[input int, optional] Default: 0
overwrite_e
[input int, optional] Default: 0
compute_v
[input int, optional] Default: 1

scipy.linalg.lapack.ssterf

scipy.linalg.lapack.ssterf(d, e[, overwrite_d, overwrite_e]) = <fortran object>

Wrapper for ssterf.

Parameters
d [input rank-1 array('f') with bounds (n)]
e [input rank-1 array('f') with bounds (-1 + n)]

Returns
vals [rank-1 array('f') with bounds (n) and d storage]
info [int]

Other Parameters
overwrite_d
[input int, optional] Default: 0

3.3. API definition 1021
overwrite_e
[input int, optional] Default: 0

scipy.linalg.lapack.dsterf

scipy.linalg.lapack.dsterf(d, e[, overwrite_d, overwrite_e]) = <fortran object>
Wrapper for dsterf.

Parameters

d [input rank-1 array('d') with bounds (n)]
e [input rank-1 array('d') with bounds (-1 + n)]

Returns

vals [rank-1 array('d') with bounds (n) and d storage]
info [int]

Other Parameters

overwrite_d [input int, optional] Default: 0
overwrite_e [input int, optional] Default: 0

scipy.linalg.lapack.sstev

scipy.linalg.lapack.sstev(d, e[, compute_v, overwrite_d, overwrite_e]) = <fortran object>
Wrapper for sstev.

Parameters

d [input rank-1 array('f') with bounds (n)]
e [input rank-1 array('f') with bounds (MAX(-1 + n, 1))]

Returns

vals [rank-1 array('f') with bounds (n) and d storage]
z [rank-2 array('f') with bounds (ldz,(compute_v?n:1))]
info [int]

Other Parameters

overwrite_d [input int, optional] Default: 0
overwrite_e [input int, optional] Default: 0
compute_v [input int, optional] Default: 1

scipy.linalg.lapack.dstev

scipy.linalg.lapack.dstev(d, e[, compute_v, overwrite_d, overwrite_e]) = <fortran object>
Wrapper for dstev.

Parameters

d [input rank-1 array('d') with bounds (n)]
e [input rank-1 array('d') with bounds (MAX(-1 + n, 1))]

Returns

vals [rank-1 array('d') with bounds (n) and d storage]
z  [rank-2 array('d') with bounds (ldz,(compute_v?=n:1))]  
info  [int]

Other Parameters

overwrite_d  [input int, optional] Default: 0  
overwrite_e  [input int, optional] Default: 0  
compute_v  [input int, optional] Default: 1

scipy.linalg.lapack.ssycon

scipy.linalg.lapack.ssycon(a, ipiv, anorm[, lower]) = <fortran object>  
Wrapper for ssycon.

Parameters

a  [input rank-2 array('f') with bounds (n,n)]  
ipiv  [input rank-1 array('i') with bounds (n)]  
anorm  [input float]

Returns

rcond  [float]  
info  [int]

Other Parameters

lower  [input int, optional] Default: 0

scipy.linalg.lapack.dsycon

scipy.linalg.lapack.dsycon(a, ipiv, anorm[, lower]) = <fortran object>  
Wrapper for dsycon.

Parameters

a  [input rank-2 array('d') with bounds (n,n)]  
ipiv  [input rank-1 array('i') with bounds (n)]  
anorm  [input float]

Returns

rcond  [float]  
info  [int]

Other Parameters

lower  [input int, optional] Default: 0
**scipy.linalg.lapack.csycon**

scipy.linalg.lapack.csycon(a, ipiv, anorm[, lower]) = <fortran object>

Wrapper for csycon.

**Parameters**

- **a** [input rank-2 array('F') with bounds (n,n)]
- **ipiv** [input rank-1 array('i') with bounds (n)]
- **anorm** [input float]

**Returns**

- **rcond** [float]
- **info** [int]

**Other Parameters**

- **lower** [input int, optional] Default: 0

**scipy.linalg.lapack.zsycon**

scipy.linalg.lapack.zsycon(a, ipiv, anorm[, lower]) = <fortran object>

Wrapper for zsycon.

**Parameters**

- **a** [input rank-2 array('D') with bounds (n,n)]
- **ipiv** [input rank-1 array('i') with bounds (n)]
- **anorm** [input float]

**Returns**

- **rcond** [float]
- **info** [int]

**Other Parameters**

- **lower** [input int, optional] Default: 0

**scipy.linalg.lapack.ssyconv**

scipy.linalg.lapack.ssyconv(a, ipiv[, lower, way, overwrite_a]) = <fortran object>

Wrapper for ssyconv.

**Parameters**

- **a** [input rank-2 array('f') with bounds (n,n)]
- **ipiv** [input rank-1 array('i') with bounds (n)]

**Returns**

- **a** [rank-2 array('f') with bounds (n,n)]
- **e** [rank-1 array('f') with bounds (n)]
- **info** [int]

**Other Parameters**

- **lower** [input int, optional] Default: 0
- **way** [input int, optional] Default: 0
- **overwrite_a** [input int, optional] Default: 0
scipy.linalg.lapack.dsyconv

```python
scipy.linalg.lapack.dsyconv(a, ipiv[, lower, way, overwrite_a]) = <fortran object>
```
Wrapper for dsyconv.

**Parameters**
- `a`: [input rank-2 array('d') with bounds (n,n)]
- `ipiv`: [input rank-1 array('i') with bounds (n)]

**Returns**
- `a`: [rank-2 array('d') with bounds (n,n)]
- `e`: [rank-1 array('d') with bounds (n)]
- `info`: [int]

**Other Parameters**
- `lower`: [input int, optional] Default: 0
- `way`: [input int, optional] Default: 0
- `overwrite_a`: [input int, optional] Default: 0

---

scipy.linalg.lapack.csyconv

```python
scipy.linalg.lapack.csyconv(a, ipiv[, lower, way, overwrite_a]) = <fortran object>
```
Wrapper for csyconv.

**Parameters**
- `a`: [input rank-2 array('F') with bounds (n,n)]
- `ipiv`: [input rank-1 array('i') with bounds (n)]

**Returns**
- `a`: [rank-2 array('F') with bounds (n,n)]
- `e`: [rank-1 array('F') with bounds (n)]
- `info`: [int]

**Other Parameters**
- `lower`: [input int, optional] Default: 0
- `way`: [input int, optional] Default: 0
- `overwrite_a`: [input int, optional] Default: 0

---

scipy.linalg.lapack.zsyconv

```python
scipy.linalg.lapack.zsyconv(a, ipiv[, lower, way, overwrite_a]) = <fortran object>
```
Wrapper for zsyconv.

**Parameters**
- `a`: [input rank-2 array('D') with bounds (n,n)]
- `ipiv`: [input rank-1 array('i') with bounds (n)]

**Returns**
- `a`: [rank-2 array('D') with bounds (n,n)]
- `e`: [rank-1 array('D') with bounds (n)]
- `info`: [int]

**Other Parameters**
lower [input int, optional] Default: 0
way [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0

**scipy.linalg.lapack.ssyequb**

scipy.linalg.lapack.ssyequb(a[, lower]) = <fortran object>
Wrapper for ssyequb.

Parameters

a [input rank-2 array('f') with bounds (lda,n)]

Returns

s [rank-1 array('f') with bounds (n)]
scond [float]
amax [float]
info [int]

Other Parameters

lower [input int, optional] Default: 0

**scipy.linalg.lapack.dsyequb**

scipy.linalg.lapack.dsyequb(a[, lower]) = <fortran object>
Wrapper for dsyequb.

Parameters

a [input rank-2 array('d') with bounds (lda,n)]

Returns

s [rank-1 array('d') with bounds (n)]
scond [float]
amax [float]
info [int]

Other Parameters

lower [input int, optional] Default: 0

**scipy.linalg.lapack.csyequb**

scipy.linalg.lapack.csyequb(a[, lower]) = <fortran object>
Wrapper for csyequb.

Parameters

a [input rank-2 array('F') with bounds (lda,n)]

Returns

s [rank-1 array('f') with bounds (n)]
scond [float]
amax [float]
info [int]

Other Parameters

lower [input int, optional] Default: 0
scipy.linalg.lapack.zsyequb

`scipy.linalg.lapack.zsyequb(a[, lower]) = <fortran object>`

Wrapper for zsyequb.

**Parameters**

- `a` : input rank-2 array('D') with bounds (lda,n)

**Returns**

- `s` : rank-1 array('d') with bounds (n)
- `scond` : float
- `amax` : float
- `info` : int

**Other Parameters**

- `lower` : input int, optional [default: 0]

scipy.linalg.lapack.ssyev

`scipy.linalg.lapack.ssyev(a[, compute_v, lower, lwork, overwrite_a]) = <fortran object>`

Wrapper for ssyev.

**Parameters**

- `a` : input rank-2 array('f') with bounds (n,n)

**Returns**

- `w` : rank-1 array('f') with bounds (n)
- `v` : rank-2 array('f') with bounds (n,n) and a storage
- `info` : int

**Other Parameters**

- `compute_v` : input int, optional [default: 1]
- `lower` : input int, optional [default: 0]
- `overwrite_a` : input int, optional [default: 0]
- `lwork` : input int, optional [default: max(3*n-1,1)]

scipy.linalg.lapack.dsyev

`scipy.linalg.lapack.dsyev(a[, compute_v, lower, lwork, overwrite_a]) = <fortran object>`

Wrapper for dsyev.

**Parameters**

- `a` : input rank-2 array('d') with bounds (n,n)

**Returns**

- `w` : rank-1 array('d') with bounds (n)
- `v` : rank-2 array('d') with bounds (n,n) and a storage
- `info` : int

**Other Parameters**

- `compute_v` : input int, optional [default: 1]
- `lower` : input int, optional [default: 0]
overwrite_a
   [input int, optional] Default: 0
lwork   [input int, optional] Default: max(3*n-1,1)

scipy.linalg.lapack.ssyev_lwork
scipy.linalg.lapack.ssyev_lwork(n[, lower]) = <fortran object>
Wrapper for ssyev_lwork.

Parameters
   n   [input int]

Returns
   work   [float]
   info   [int]

Other Parameters
   lower   [input int, optional] Default: 0

scipy.linalg.lapack.dsyev_lwork
scipy.linalg.lapack.dsyev_lwork(n[, lower]) = <fortran object>
Wrapper for dsyev_lwork.

Parameters
   n   [input int]

Returns
   work   [float]
   info   [int]

Other Parameters
   lower   [input int, optional] Default: 0

scipy.linalg.lapack.ssyevd
scipy.linalg.lapack.ssyevd(a[, compute_v, lower, lwork, liwork, overwrite_a]) = <fortran object>
Wrapper for ssyevd.

Parameters
   a   [input rank-2 array('f') with bounds (n,n)]

Returns
   w   [rank-1 array('f') with bounds (n)]
   v   [rank-2 array('f') with bounds (n,n) and a storage]
   info   [int]

Other Parameters
   compute_v   [input int, optional] Default: 1
   lower   [input int, optional] Default: 0
   overwrite_a   [input int, optional] Default: 0
   lwork   [input int, optional] Default: max((compute_v?1+6*n+2*n*n:2*n+1),1)
liwork [input int, optional] Default: (compute_v?3+5*n:1)

scipy.linalg.lapack.dsyevd

scipy.linalg.lapack.dsyevd\(a, compute_v, lower, lwork, liwork, overwrite_a\) = <fortran object>

Wrapper for dsyevd.

Parameters

\(a\) [input rank-2 array('d') with bounds (n,n)]

Returns

\(w\) [rank-1 array('d') with bounds (n)]
\(v\) [rank-2 array('d') with bounds (n,n) and a storage]
\(info\) [int]

Other Parameters

\(compute_v\) [input int, optional] Default: 1
\(lower\) [input int, optional] Default: 0
\(overwrite_a\) [input int, optional] Default: 0
\(lwork\) [input int, optional] Default: max((compute_v?1+6*n+2*n*n:2*n+1),1)
\(liwork\) [input int, optional] Default: (compute_v?3+5*n:1)

scipy.linalg.lapack.ssyevd_lwork

scipy.linalg.lapack.ssyevd_lwork\(n, compute_v, lower\) = <fortran object>

Wrapper for ssyevd_lwork.

Parameters

\(n\) [input int]

Returns

\(work\) [float]
\(iwork\) [int]
\(info\) [int]

Other Parameters

\(compute_v\) [input int, optional] Default: 1
\(lower\) [input int, optional] Default: 0

scipy.linalg.lapack.dsyevd_lwork

scipy.linalg.lapack.dsyevd_lwork\(n, compute_v, lower\) = <fortran object>

Wrapper for dsyevd_lwork.

Parameters

\(n\) [input int]

Returns

\(work\) [float]
\(iwork\) [int]
\(info\) [int]
**Other Parameters**

- **compute_v**
  - [input int, optional] Default: 1
- **lower**
  - [input int, optional] Default: 0

### scipy.linalg.lapack.ssyevr

```python
scipy.linalg.lapack.ssyevr(a[, compute_v, range, lower, vl, il, ilu, abstol, lwork, liwork, overwrite_a])
```

Wrapper for **ssyevr**.

**Parameters**

- **a**
  - [input rank-2 array('f') with bounds (n,n)]

**Returns**

- **w**
  - [rank-1 array('f') with bounds (n)]
- **z**
  - [rank-2 array('f') with bounds ((compute_v?MAX(0, n):0),(compute_v?(*range == 'I'?1 - il + ilu:MAX(I, n)):0))]
- **m**
  - [int]
- **isuppz**
  - [rank-1 array('i') with bounds ((compute_v?2 * (*range == 'A' || (*range == 1 + 'I' && il - ilu == n)?n:0):0))]
- **info**
  - [int]

**Other Parameters**

- **compute_v**
  - [input int, optional] Default 1
- **range**
  - [input string(len=1), optional] Default 'A'
- **lower**
  - [input int, optional] Default 0
- **overwrite_a**
  - [input int, optional] Default 0
- **vl**
  - [input float, optional] Default 0.0
- **vu**
  - [input float, optional] Default 1.0
- **il**
  - [input int, optional] Default 1
- **iu**
  - [input int, optional] Default n
- **abstol**
  - [input float, optional] Default 0.0
- **lwork**
  - [input int, optional] Default max(26*n,1)
- **liwork**
  - [input int, optional] Default max(1,10*n)

### scipy.linalg.lapack.dsyevr

```python
scipy.linalg.lapack.dsyevr(a[, compute_v, range, lower, vl, il, ilu, abstol, lwork, liwork, overwrite_a])
```

Wrapper for **dsyevr**.

**Parameters**

- **a**
  - [input rank-2 array('d') with bounds (n,n)]

**Returns**

- **w**
  - [rank-1 array('d') with bounds (n)]
- **z**
  - [rank-2 array('d') with bounds ((compute_v?MAX(0, n):0),(compute_v?(*range == 'I'?1 - il + ilu:MAX(I, n)):0))]
- **m**
  - [int]
- **isuppz**
  - [rank-1 array('i') with bounds ((compute_v?2 * (*range == 'A' || (*range == 1 + 'I' && il - ilu == n)?n:0):0))]

**Other Parameters**

- **compute_v**
  - [input int, optional] Default 1
- **range**
  - [input string(len=1), optional] Default 'A'
- **lower**
  - [input int, optional] Default 0
- **overwrite_a**
  - [input int, optional] Default 0
- **vl**
  - [input float, optional] Default 0.0
- **vu**
  - [input float, optional] Default 1.0
- **il**
  - [input int, optional] Default 1
- **iu**
  - [input int, optional] Default n
- **abstol**
  - [input float, optional] Default 0.0
- **lwork**
  - [input int, optional] Default max(26*n,1)
- **liwork**
  - [input int, optional] Default max(1,10*n)
Other Parameters

compute_v
    [input int, optional] Default: 1
range
    [input string(len=1), optional] Default: 'A'
lower
    [input int, optional] Default: 0
overwrite_a
    [input int, optional] Default: 0
vl
    [input float, optional] Default: 0.0
vu
    [input float, optional] Default: 1.0
il
    [input int, optional] Default: 1
iu
    [input int, optional] Default: n
abstol
    [input float, optional] Default: 0.0
lwork
    [input int, optional] Default: max(26*n, 1)
lwork
    [input int, optional] Default: max(1, 10*n)

scipy.linalg.lapack.ssyevr_lwork

scipy.linalg.lapack.ssyevr_lwork(n[, lower]) = <fortran object>
Wrapper for ssyevr_lwork.

Parameters

n
    [input int]

Returns

work
    [float]
iwork
    [int]
info
    [int]

Other Parameters

lower
    [input int, optional] Default: 0

scipy.linalg.lapack.dsyevr_lwork

scipy.linalg.lapack.dsyevr_lwork(n[, lower]) = <fortran object>
Wrapper for dsyevr_lwork.

Parameters

n
    [input int]

Returns

work
    [float]
iwork
    [int]
info
    [int]

Other Parameters

lower
    [input int, optional] Default: 0
scipy.linalg.lapack.ssyevx

scipy.linalg.lapack.ssyevx(a[, compute_v, range, lower, vl, vu, il, iu, abstol, lwork, overwrite_a]) = <fortran object>

Wrapper for ssyevx.

Parameters

a [input rank-2 array('f') with bounds (n,n)]

Returns

w [rank-1 array('f') with bounds (n)]
z [rank-2 array('f') with bounds ((compute_v?MAX(0, n):0), (compute_v?(*range == 'I'?1 - il + iu:MAX(1, n)):0))]
m [int]
ifail [rank-1 array('i') with bounds ((compute_v?n:0))]
info [int]

Other Parameters

compute_v [input int, optional] Default 1
range [input string(len=1), optional] Default 'A'
lower [input int, optional] Default 0
overwrite_a [input int, optional] Default 0
vl [input float, optional] Default 0.0
vu [input float, optional] Default 1.0
il [input int, optional] Default 1
iu [input int, optional] Default n
abstol [input float, optional] Default 0.0
lwork [input int, optional] Default max(8*n,1)

scipy.linalg.lapack.dsyevx

scipy.linalg.lapack.dsyevx(a[, compute_v, range, lower, vl, vu, il, iu, abstol, lwork, overwrite_a]) = <fortran object>

Wrapper for dsyevx.

Parameters

a [input rank-2 array('d') with bounds (n,n)]

Returns

w [rank-1 array('d') with bounds (n)]
z [rank-2 array('d') with bounds ((compute_v?MAX(0, n):0), (compute_v?(*range == 'I'?1 - il + iu:MAX(1, n)):0))]
m [int]
ifail [rank-1 array('i') with bounds ((compute_v?n:0))]
info [int]

Other Parameters

compute_v [input int, optional] Default 1
range [input string(len=1), optional] Default 'A'
lower [input int, optional] Default 0
overwrite_a [input int, optional] Default 0
### scipy.linalg.lapack.ssyevx_lwork

```python
scipy.linalg.lapack.ssyevx_lwork(n[, lower]) = <fortran object>
```

Wrapper for `ssyevx_lwork`.

#### Parameters
- **n** ([input int])

#### Returns
- **work** ([float])
- **info** ([int])

#### Other Parameters
- **lower** ([input int, optional]) Default: 0

### scipy.linalg.lapack.dsyevx_lwork

```python
scipy.linalg.lapack.dsyevx_lwork(n[, lower]) = <fortran object>
```

Wrapper for `dsyevx_lwork`.

#### Parameters
- **n** ([input int])

#### Returns
- **work** ([float])
- **info** ([int])

#### Other Parameters
- **lower** ([input int, optional]) Default: 0

### scipy.linalg.lapack.ssygst

```python
scipy.linalg.lapack.ssygst(a, b[, itype, lower, overwrite_a]) = <fortran object>
```

Wrapper for `ssygst`.

#### Parameters
- **a** ([input rank-2 array('f') with bounds (n,n)])
- **b** ([input rank-2 array('f') with bounds (n,n)])

#### Returns
- **c** ([rank-2 array('f') with bounds (n,n) and a storage])
- **info** ([int])

#### Other Parameters
- **overwrite_a** ([input int, optional]) Default: 0
- **itype** ([input int, optional]) Default: 1
- **lower** ([input int, optional]) Default: 0
scipy.linalg.lapack.dsygst

```python
scipy.linalg.lapack.dsygst(a, b[, itype, lower, overwrite_a]) = <fortran object>
```

Wrapper for dsysgst.

**Parameters**

- `a` : [input rank-2 array('d') with bounds (n,n)]
- `b` : [input rank-2 array('d') with bounds (n,n)]

**Returns**

- `c` : [rank-2 array('d') with bounds (n,n) and a storage]
- `info` : [int]

**Other Parameters**

- `overwrite_a` : [input int, optional] Default: 0
- `itype` : [input int, optional] Default: 1
- `lower` : [input int, optional] Default: 0

scipy.linalg.lapack.ssygv

```python
scipy.linalg.lapack.ssygv(a, b[, itype, jobz, uplo, lwork, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for ssygv.

**Parameters**

- `a` : [input rank-2 array('f') with bounds (n,n)]
- `b` : [input rank-2 array('f') with bounds (n,n)]

**Returns**

- `w` : [rank-1 array('f') with bounds (n)]
- `v` : [rank-2 array('f') with bounds (n,n) and a storage]
- `info` : [int]

**Other Parameters**

- `itype` : [input int, optional] Default: 1
- `jobz` : [input string(len=1), optional] Default: 'V'
- `uplo` : [input string(len=1), optional] Default: 'L'
- `overwrite_a` : [input int, optional] Default: 0
- `overwrite_b` : [input int, optional] Default: 0
- `lwork` : [input int, optional] Default: max(3*n-1,1)

scipy.linalg.lapack.dsygv

```python
scipy.linalg.lapack.dsygv(a, b[, itype, jobz, uplo, lwork, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for dsygv.

**Parameters**

- `a` : [input rank-2 array('d') with bounds (n,n)]
- `b` : [input rank-2 array('d') with bounds (n,n)]

**Returns**

- [ ]

w [rank-1 array('d') with bounds (n)]
v [rank-2 array('d') with bounds (n,n) and a storage]
info [int]

Other Parameters
itype [input int, optional] Default: 1
jobz [input string(len=1), optional] Default: 'V'
uplo [input string(len=1), optional] Default: 'L'
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n-1,1)

scipy.linalg.lapack.ssygv_lwork

scipy.linalg.lapack.ssygv_lwork(n[, uplo]) = <fortran object>
Wrapper for ssygv_lwork.

Parameters
n [input int]

Returns
work [float]
info [int]

Other Parameters
uplo [input string(len=1), optional] Default: 'L'

scipy.linalg.lapack.dsygv_lwork

scipy.linalg.lapack.dsygv_lwork(n[, uplo]) = <fortran object>
Wrapper for dsygv_lwork.

Parameters
n [input int]

Returns
work [float]
info [int]

Other Parameters
uplo [input string(len=1), optional] Default: 'L'

scipy.linalg.lapack.ssygvd

scipy.linalg.lapack.ssygvd(a[, b, itype, jobz, uplo, lwork, overwrite_a, overwrite_b]) =
<fortran object>

Wrapper for ssygvd.

Parameters
a [input rank-2 array('f') with bounds (n,n)]
b [input rank-2 array('f') with bounds (n,n)]

Returns

w  [rank-1 array('f') with bounds (n)]
v  [rank-2 array('f') with bounds (n, n) with a storage]
info  [int]

Other Parameters
itype  [input int, optional] Default 1
jobz  [input string(len=1), optional] Default 'V'
uplo  [input string(len=1), optional] Default 'L'
overwrite_a  [input int, optional] Default 0
overwrite_b  [input int, optional] Default 0
lwork  [input int, optional] Default (*jobz=='N'?2*n+1:1+6*n+2*n*n)
liwork  [input int, optional] Default (*jobz=='N'?1:5*n+3)

scipy.linalg.lapack.dsygvd

scipy.linalg.lapack.dsygvd(a, b, itype, jobz, uplo, lwork, liwork, overwrite_a, overwrite_b) = <fortran object>
Wrapper for dsygvd.

Parameters
a  [input rank-2 array('d') with bounds (n, n)]
b  [input rank-2 array('d') with bounds (n, n)]

Returns
w  [rank-1 array('d') with bounds (n)]
v  [rank-2 array('d') with bounds (n, n) with a storage]
info  [int]

Other Parameters
itype  [input int, optional] Default 1
jobz  [input string(len=1), optional] Default 'V'
uplo  [input string(len=1), optional] Default 'L'
overwrite_a  [input int, optional] Default 0
overwrite_b  [input int, optional] Default 0
lwork  [input int, optional] Default (*jobz=='N'?2*n+1:1+6*n+2*n*n)
liwork  [input int, optional] Default (*jobz=='N'?1:5*n+3)

scipy.linalg.lapack.ssygvx

scipy.linalg.lapack.ssygvx(a, b, itype, jobz, range, uplo, vl, vu, il, ii, abstol, lwork, overwrite_a, overwrite_b) = <fortran object>
Wrapper for ssygvx.

Parameters
a  [input rank-2 array('f') with bounds (n, n)]
b  [input rank-2 array('f') with bounds (n, n)]

Returns
w  [rank-1 array('f') with bounds (n)]
z  [rank-2 array('f') with bounds (jobz[0] == 'V'?MAX(0, n):0),(jobz[0] == 'V'?(range[0] == 'T'?1 - il + ii:MAX(1, n)):0))]

m [int]
ifar [rank-1 array('i') with bounds ((jobz[0] == ‘N’?0:n))]
info [int]

Other Parameters

itype [input int, optional] Default: 1
jobz [input string(len=1), optional] Default: ‘V’
range [input string(len=1), optional] Default: ‘A’
uplo [input string(len=1), optional] Default: ‘L’
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
vl [input float, optional] Default: 0.0
vu [input float, optional] Default: 1.0
il [input int, optional] Default: 1
iu [input int, optional] Default: n
abstol [input float, optional] Default: 0.0
lwork [input int, optional] Default: max(8*n,1)

scipy.linalg.lapack.dsygvx

scipy.linalg.lapack.dsygvx(a, b, itype, jobz, range, uplo, vl, vu, il, iu, abstol, lwork, overwrite_a, overwrite_b) = <fortran object>

Wrapper for dsygvx.

Parameters

a [input rank-2 array('d') with bounds (n,n)]
b [input rank-2 array('d') with bounds (n,n)]

Returns

w [rank-1 array('d') with bounds (n)]
z [rank-2 array('d') with bounds ((jobz[0] == ‘V’?MAX(0, n):0),(jobz[0] == ‘V’?(range[0] == ‘I’?1-il+iu:MAX(1,n)):0))]
m [int]
ifar [rank-1 array('i') with bounds ((jobz[0] == ‘N’?0:n))]
info [int]

Other Parameters

itype [input int, optional] Default: 1
jobz [input string(len=1), optional] Default: ‘V’
range [input string(len=1), optional] Default: ‘A’
uplo [input string(len=1), optional] Default: ‘L’
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
vl [input float, optional] Default: 0.0
vu [input float, optional] Default: 1.0
il [input int, optional] Default: 1
iu [input int, optional] Default: n
abstol [input float, optional] Default: 0.0
lwork [input int, optional] Default: max(8*n,1)
scipy.linalg.lapack.ssygvx_lwork

scipy.linalg.lapack.ssygvx_lwork(n, uplo) = <fortran object>

Wrapper for ssygvx_lwork.

Parameters
- n [input int]

Returns
- work [float]
- info [int]

Other Parameters
- uplo [input string(len=1), optional] Default: 'L'

scipy.linalg.lapack.dsygvx_lwork

scipy.linalg.lapack.dsygvx_lwork(n, uplo) = <fortran object>

Wrapper for dsygvx_lwork.

Parameters
- n [input int]

Returns
- work [float]
- info [int]

Other Parameters
- uplo [input string(len=1), optional] Default: 'L'

scipy.linalg.lapack.ssysv

scipy.linalg.lapack.ssysv(a, b[, lwork, lower, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for ssysv.

Parameters
- a [input rank-2 array('f') with bounds (n,n)]
- b [input rank-2 array('f') with bounds (n, nrhs)]

Returns
- udut [rank-2 array('f') with bounds (n,n) and a storage]
- ipiv [rank-1 array('i') with bounds (n)]
- x [rank-2 array('f') with bounds (n, nrhs) and b storage]
- info [int]

Other Parameters
- overwrite_a [input int, optional] Default: 0
- overwrite_b [input int, optional] Default: 0
- lwork [input int, optional] Default: max(n,1)
- lower [input int, optional] Default: 0
scipy.linalg.lapack.dsysv

scipy.linalg.lapack.dsysv(a, b[, lwork, lower, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for dsyev.

Parameters

a [input rank-2 array('d') with bounds (n,n)]
b [input rank-2 array('d') with bounds (n,nrhs)]

Returns

udut [rank-2 array('d') with bounds (n,n) and a storage]
ipiv [rank-1 array('i') with bounds (n)]
x [rank-2 array('d') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
lwork [input int, optional] Default: max(n,1)
lower [input int, optional] Default: 0

scipy.linalg.lapack.csysv

scipy.linalg.lapack.csysv(a, b[, lwork, lower, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for csysv.

Parameters

a [input rank-2 array('F') with bounds (n,n)]
b [input rank-2 array('F') with bounds (n,nrhs)]

Returns

udut [rank-2 array('F') with bounds (n,n) and a storage]
ipiv [rank-1 array('i') with bounds (n)]
x [rank-2 array('F') with bounds (n,nrhs) and b storage]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
lwork [input int, optional] Default: max(n,1)
lower [input int, optional] Default: 0
scipy.linalg.lapack.zsysv

`scipy.linalg.lapack.zsysv(a, b[, lwork, lower, overwrite_a, overwrite_b]) = <fortran object>`

Wrapper for zsysv.

**Parameters**

- `a` [input rank-2 array('D') with bounds (n,n)]
- `b` [input rank-2 array('D') with bounds (n,nrhs)]

**Returns**

- `udut` [rank-2 array('D') with bounds (n,n) and a storage]
- `ipiv` [rank-1 array('i') with bounds (n)]
- `x` [rank-2 array('D') with bounds (n,nrhs) and b storage]
- `info` [int]

**Other Parameters**

- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: max(n,1)
- `lower` [input int, optional] Default: 0

scipy.linalg.lapack.ssysv_lwork

`scipy.linalg.lapack.ssysv_lwork(n[, lower]) = <fortran object>`

Wrapper for ssysv_lwork.

**Parameters**

- `n` [input int]

**Returns**

- `work` [float]
- `info` [int]

**Other Parameters**

- `lower` [input int, optional] Default: 0

scipy.linalg.lapack.dsysv_lwork

`scipy.linalg.lapack.dsysv_lwork(n[, lower]) = <fortran object>`

Wrapper for dsysv_lwork.

**Parameters**

- `n` [input int]

**Returns**

- `work` [float]
- `info` [int]

**Other Parameters**

- `lower` [input int, optional] Default: 0
scipy.linalg.lapack.csysv_lwork

```
scipy.linalg.lapack.csysv_lwork(n[, lower]) = <fortran object>
```

Wrapper for csysv_lwork.

**Parameters**

- **n** [input int]

**Returns**

- **work** [complex]
- **info** [int]

**Other Parameters**

- **lower** [input int, optional] Default: 0

scipy.linalg.lapack.zsysv_lwork

```
scipy.linalg.lapack.zsysv_lwork(n[, lower]) = <fortran object>
```

Wrapper for zsysv_lwork.

**Parameters**

- **n** [input int]

**Returns**

- **work** [complex]
- **info** [int]

**Other Parameters**

- **lower** [input int, optional] Default: 0

scipy.linalg.lapack.ssysvx

```
scipy.linalg.lapack.ssysvx(a, b[, af, ipiv, lwork, factored, lower, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for ssyevx.

**Parameters**

- **a** [input rank-2 array('f') with bounds (n,n)]
- **b** [input rank-2 array('f') with bounds (n,nrhs)]

**Returns**

- **a_s** [rank-2 array('f') with bounds (n,n) and a storage]
- **udut** [rank-2 array('f') with bounds (n,n) and af storage]
- **ipiv** [rank-1 array('i') with bounds (n)]
- **b_s** [rank-2 array('f') with bounds (n,nrhs) and b storage]
- **x** [rank-2 array('f') with bounds (n,nrhs)]
- **rcond** [float]
- **ferr** [rank-1 array('f') with bounds (nrhs)]
- **berr** [rank-1 array('f') with bounds (nrhs)]
- **info** [int]

**Other Parameters**

- **overwrite_a** [input int, optional] Default: 0
- **af** [input rank-2 array('f') with bounds (n,n)]

scipy.linalg.lapack.dsysvx

scipy.linalg.lapack.dsysvx(a, b[, af, ipiv, lwork, factored, lower, overwrite_a, overwrite_b]) =<fortran object>

Wrapper for dsyevx.

Parameters
a [input rank-2 array('d') with bounds (n,n)]
b [input rank-2 array('d') with bounds (n,nrhs)]

Returns
a_s [rank-2 array('d') with bounds (n,n) and a storage]
udut [rank-2 array('d') with bounds (n,n) and af storage]
 ipiv [rank-1 array('i') with bounds (n)]
b_s [rank-2 array('d') with bounds (n,nrhs) and b storage]
x [rank-2 array('d') with bounds (n,nrhs)]
rcond [float]
ferr [rank-1 array('d') with bounds (nrhs)]
berr [rank-1 array('d') with bounds (nrhs)]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
af [input rank-2 array('d') with bounds (n,n)]
ipiv [input rank-1 array('i') with bounds (n)]
overwrite_b [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)
factored [input int, optional] Default: 0
lower [input int, optional] Default: 0

scipy.linalg.lapack.csysvx

scipy.linalg.lapack.csysvx(a, b[, af, ipiv, lwork, factored, lower, overwrite_a, overwrite_b]) =<fortran object>

Wrapper for csysvx.

Parameters
a [input rank-2 array('F') with bounds (n,n)]
b [input rank-2 array('F') with bounds (n,nrhs)]

Returns
a_s [rank-2 array('F') with bounds (n,n) and a storage]
udut [rank-2 array('F') with bounds (n,n) and af storage]
 ipiv [rank-1 array('i') with bounds (n)]
b_s [rank-2 array('F') with bounds (n,nrhs) and b storage]
x [rank-2 array('F') with bounds (n,nrhs)]
rcond [float]
ferr [rank-1 array('d') with bounds (nrhs)]
berr [rank-1 array('d') with bounds (nrhs)]
info [int]

Other Parameters
overwrite_a [input int, optional] Default: 0
af [input rank-2 array('d') with bounds (n,n)]
ipiv [input rank-1 array('i') with bounds (n)]
overwrite_b [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)
factored [input int, optional] Default: 0
lower [input int, optional] Default: 0
rcond  [float]
ferr  [rank-1 array('f') with bounds (nrhs)]
berr  [rank-1 array('f') with bounds (nrhs)]
info  [int]

Other Parameters

overwrite_a
   [input int, optional] Default: 0
af  [input rank-2 array('F') with bounds (n,n)]
ipiv  [input rank-1 array('i') with bounds (n)]

overwrite_b
   [input int, optional] Default: 0
lwork  [input int, optional] Default: max(3*n,1)
factored  [input int, optional] Default: 0
lower  [input int, optional] Default: 0

scipy.linalg.lapack.zsysvx

scipy.linalg.lapack.zsysvx(a, b[, af, ipiv, lwork, factored, lower, overwrite_a, overwrite_b]) =

<fortran object>

Wrapper for zsysvx.

Parameters

a  [input rank-2 array('D') with bounds (n,n)]
b  [input rank-2 array('D') with bounds (n,nrhs)]

Returns

a_s  [rank-2 array('D') with bounds (n,n) and a storage]
udut  [rank-2 array('D') with bounds (n,n) and af storage]
ipiv  [rank-1 array('i') with bounds (n)]
b_s  [rank-2 array('D') with bounds (n,nrhs) and b storage]
x  [rank-2 array('D') with bounds (n,nrhs)]
rcond  [float]
ferr  [rank-1 array('d') with bounds (nrhs)]
berr  [rank-1 array('d') with bounds (nrhs)]
info  [int]

Other Parameters

overwrite_a
   [input int, optional] Default: 0
af  [input rank-2 array('D') with bounds (n,n)]
ipiv  [input rank-1 array('i') with bounds (n)]

overwrite_b
   [input int, optional] Default: 0
lwork  [input int, optional] Default: max(3*n,1)
factored  [input int, optional] Default: 0
lower  [input int, optional] Default: 0
scipy.linalg.lapack.ssysvx_lwork

Wrapper for ssysvx_lwork.

Parameters

- **n** [input int]

Returns

- **work** [float]
- **info** [int]

Other Parameters

- **lower** [input int, optional] Default: 0

scipy.linalg.lapack.dsysvx_lwork

Wrapper for dsysvx_lwork.

Parameters

- **n** [input int]

Returns

- **work** [float]
- **info** [int]

Other Parameters

- **lower** [input int, optional] Default: 0

scipy.linalg.lapack.csysvx_lwork

Wrapper for csysvx_lwork.

Parameters

- **n** [input int]

Returns

- **work** [complex]
- **info** [int]

Other Parameters

- **lower** [input int, optional] Default: 0

scipy.linalg.lapack.zsysvx_lwork

Wrapper for zsysvx_lwork.

Parameters

- **n** [input int]

Returns

- **work** [complex]
- **info** [int]
Other Parameters

- lower [input int, optional] Default: 0

**scipy.linalg.lapack.ssytf2**

```python
scipy.linalg.lapack.ssytf2(a[, lower, overwrite_a]) = <fortran object>
```

Wrapper for ssytf2.

**Parameters**

- a [input rank-2 array('f') with bounds (n,n)]

**Returns**

- ldu [rank-2 array('f') with bounds (n,n) and a storage]
- ipiv [rank-1 array('i') with bounds (n)]
- info [int]

Other Parameters

- lower [input int, optional] Default: 0
- overwrite_a [input int, optional] Default: 0

**scipy.linalg.lapack.dsytf2**

```python
scipy.linalg.lapack.dsytf2(a[, lower, overwrite_a]) = <fortran object>
```

Wrapper for dsytf2.

**Parameters**

- a [input rank-2 array('d') with bounds (n,n)]

**Returns**

- ldu [rank-2 array('d') with bounds (n,n) and a storage]
- ipiv [rank-1 array('i') with bounds (n)]
- info [int]

Other Parameters

- lower [input int, optional] Default: 0
- overwrite_a [input int, optional] Default: 0

**scipy.linalg.lapack.csytf2**

```python
scipy.linalg.lapack.csytf2(a[, lower, overwrite_a]) = <fortran object>
```

Wrapper for csytf2.

**Parameters**

- a [input rank-2 array('F') with bounds (n,n)]

**Returns**

- ldu [rank-2 array('F') with bounds (n,n) and a storage]
- ipiv [rank-1 array('i') with bounds (n)]
- info [int]

Other Parameters

- lower [input int, optional] Default: 0
overwrite_a
    [input int, optional] Default: 0

scipy.linalg.lapack.zsytf2

scipy.linalg.lapack.zsytf2(a[, lower, overwrite_a]) = <fortran object>
Wrapper for zsytf2.

Parameters
    a      [input rank-2 array('D') with bounds (n,n)]

Returns
    ldu    [rank-2 array('D') with bounds (n,n) and a storage]
    ipiv   [rank-1 array('i') with bounds (n)]
    info   [int]

Other Parameters
    lower  [input int, optional] Default: 0
    overwrite_a [input int, optional] Default: 0

scipy.linalg.lapack.ssytrd

scipy.linalg.lapack.ssytrd(a[, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for ssytrd.

Parameters
    a      [input rank-2 array('f') with bounds (lda,n)]

Returns
    c      [rank-2 array('f') with bounds (lda,n) and a storage]
    d      [rank-1 array('f') with bounds (n)]
    e      [rank-1 array('f') with bounds (-1 + n)]
    tau    [rank-1 array('f') with bounds (-1 + n)]
    info   [int]

Other Parameters
    lower  [input int, optional] Default: 0
    overwrite_a [input int, optional] Default: 0
    lwork  [input int, optional] Default: MAX(n,1)

scipy.linalg.lapack.dsytrd

scipy.linalg.lapack.dsytrd(a[, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for dsytrd.

Parameters
    a      [input rank-2 array('d') with bounds (lda,n)]

Returns
    c      [rank-2 array('d') with bounds (lda,n) and a storage]
    d      [rank-1 array('d') with bounds (n)]
    e      [rank-1 array('d') with bounds (-1 + n)]
    tau    [rank-1 array('d') with bounds (-1 + n)]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: MAX(n,1)

scipy.linalg.lapack.ssytrd_lwork

scipy.linalg.lapack.ssytrd_lwork(n[, lower]) = <fortran object>
Wrapper for ssytrd_lwork.

Parameters
n [input int]

Returns
work [float]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.dsytrd_lwork

scipy.linalg.lapack.dsytrd_lwork(n[, lower]) = <fortran object>
Wrapper for dsytrd_lwork.

Parameters
n [input int]

Returns
work [float]
info [int]

Other Parameters
lower [input int, optional] Default: 0

scipy.linalg.lapack.ssytrf

scipy.linalg.lapack.ssytrf(a[, lower, lwork, overwrite_a]) = <fortran object>
Wrapper for ssytrf.

Parameters
a [input rank-2 array('f') with bounds (n,n)]

Returns
ldu [rank-2 array('f') with bounds (n,n) and a storage]
ipiv [rank-1 array('i') with bounds (n)]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0

3.3. API definition

lwork [input int, optional] Default: max(n,1)

scipy.linalg.lapack.dsytrf

scipy.linalg.lapack.dsytrf(a[[], lower, lwork, overwrite_a]] = <fortran object>
Wrapper for dsytrf.

Parameters
a [input rank-2 array('d') with bounds (n,n)]

Returns
ldu [rank-2 array('d') with bounds (n,n) and a storage]
ipiv [rank-1 array('i') with bounds (n)]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(n,1)

scipy.linalg.lapack.csytrf

scipy.linalg.lapack.csytrf(a[[], lower, lwork, overwrite_a]] = <fortran object>
Wrapper for csytrf.

Parameters
a [input rank-2 array('F') with bounds (n,n)]

Returns
ldu [rank-2 array('F') with bounds (n,n) and a storage]
ipiv [rank-1 array('i') with bounds (n)]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(n,1)

scipy.linalg.lapack.zsytrf

scipy.linalg.lapack.zsytrf(a[[], lower, lwork, overwrite_a]] = <fortran object>
Wrapper for zsytrf.

Parameters
a [input rank-2 array('D') with bounds (n,n)]

Returns
ldu [rank-2 array('D') with bounds (n,n) and a storage]
ipiv [rank-1 array('i') with bounds (n)]
info [int]

Other Parameters
lower [input int, optional] Default: 0
overwrite_a
    [input int, optional] Default: 0
lwork
    [input int, optional] Default: max(n,1)

scipy.linalg.lapack.ssytrf_lwork

scipy.linalg.lapack.ssytrf_lwork(n[, lower]) = <fortran object>
Wrapper for ssytrf_lwork.

Parameters
    n       [input int]

Returns
    work    [float]
    info    [int]

Other Parameters
    lower   [input int, optional] Default: 0

scipy.linalg.lapack.dsytrf_lwork

scipy.linalg.lapack.dsytrf_lwork(n[, lower]) = <fortran object>
Wrapper for dsytrf_lwork.

Parameters
    n       [input int]

Returns
    work    [float]
    info    [int]

Other Parameters
    lower   [input int, optional] Default: 0

scipy.linalg.lapack.csytrf_lwork

scipy.linalg.lapack.csytrf_lwork(n[, lower]) = <fortran object>
Wrapper for csytrf_lwork.

Parameters
    n       [input int]

Returns
    work    [complex]
    info    [int]

Other Parameters
    lower   [input int, optional] Default: 0
scipy.linalg.lapack.zsytrf_lwork

scipy.linalg.lapack.zsytrf_lwork(n[, lower]) = <fortran object>

Wrapper for zsytrf_lwork.

Parameters
  n [input int]

Returns
  work [complex]
  info [int]

Other Parameters
  lower [input int, optional] Default: 0

scipy.linalg.lapack.stbtrs

scipy.linalg.lapack.stbtrs(ab, b[, uplo, trans, diag, overwrite_b]) = <fortran object>

Wrapper for stbtrs.

Parameters
  ab [input rank-2 array('f') with bounds (ldab,n)]
  b [input rank-2 array('f') with bounds (ldb,nrhs)]

Returns
  x [rank-2 array('f') with bounds (ldb,nrhs) and b storage]
  info [int]

Other Parameters
  uplo [input string(len=1), optional] Default: ‘U’
  trans [input string(len=1), optional] Default: ‘N’
  diag [input string(len=1), optional] Default: ‘N’
  overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.dtbtrs

scipy.linalg.lapack.dtbtrs(ab, b[, uplo, trans, diag, overwrite_b]) = <fortran object>

Wrapper for dtbtrs.

Parameters
  ab [input rank-2 array('d') with bounds (ldab,n)]
  b [input rank-2 array('d') with bounds (ldb,nrhs)]

Returns
  x [rank-2 array('d') with bounds (ldb,nrhs) and b storage]
  info [int]

Other Parameters
  uplo [input string(len=1), optional] Default: ‘U’
  trans [input string(len=1), optional] Default: ‘N’
  diag [input string(len=1), optional] Default: ‘N’
  overwrite_b [input int, optional] Default: 0
scipy.linalg.lapack.ctbtrs

scipy.linalg.lapack.ctbtrs(ab, b[, uplo, trans, diag, overwrite_b]) = <fortran object>

Wrapper for ctbtrs.

Parameters

- ab [input rank-2 array('F') with bounds (ldab,n)]
- b [input rank-2 array('F') with bounds (ldb,nrhs)]

Returns

- x [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
- info [int]

Other Parameters

- uplo [input string(len=1), optional] Default: ‘U’
- trans [input string(len=1), optional] Default: ‘N’
- diag [input string(len=1), optional] Default: ‘N’
- overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.ztbtrs

scipy.linalg.lapack.ztbtrs(ab, b[, uplo, trans, diag, overwrite_b]) = <fortran object>

Wrapper for ztbtrs.

Parameters

- ab [input rank-2 array('D') with bounds (ldab,n)]
- b [input rank-2 array('D') with bounds (ldb,nrhs)]

Returns

- x [rank-2 array('D') with bounds (ldb,nrhs) and b storage]
- info [int]

Other Parameters

- uplo [input string(len=1), optional] Default: ‘U’
- trans [input string(len=1), optional] Default: ‘N’
- diag [input string(len=1), optional] Default: ‘N’
- overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.stfsm

scipy.linalg.lapack.stfsm(alpha, a[, transr, side, uplo, trans, diag, overwrite_b]) = <fortran object>

Wrapper for stfsm.

Parameters

- alpha [input float]
- a [input rank-1 array('f') with bounds (nt)]
- b [input rank-2 array('f') with bounds (m,n)]

Returns

- x [rank-2 array('f') with bounds (m,n) and b storage]

Other Parameters
transr [input string(len=1), optional] Default: ‘N’
side [input string(len=1), optional] Default: ‘L’
uplo [input string(len=1), optional] Default: ‘U’
trans [input string(len=1), optional] Default: ‘N’
diag [input string(len=1), optional] Default: ‘N’
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.dtfsm

scipy.linalg.lapack.dtfsm(alpha, a, b[, transr, side, uplo, trans, diag, overwrite_b]) = <fortran object>

Wrapper for dtfsm.

Parameters

alpha [input float]
a [input rank-1 array('d') with bounds (nt)]
b [input rank-2 array('d') with bounds (m,n)]

Returns

x [rank-2 array('d') with bounds (m,n) and b storage]

Other Parameters

ctrans [input string(len=1), optional] Default: ‘N’
side [input string(len=1), optional] Default: ‘L’
uplo [input string(len=1), optional] Default: ‘U’
trans [input string(len=1), optional] Default: ‘N’
diag [input string(len=1), optional] Default: ‘N’
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.ctfsm

scipy.linalg.lapack.ctfsm(alpha, a, b[, transr, side, uplo, trans, diag, overwrite_b]) = <fortran object>

Wrapper for ctfsm.

Parameters

alpha [input complex]
a [input rank-1 array('F') with bounds (nt)]
b [input rank-2 array('F') with bounds (m,n)]

Returns

x [rank-2 array('F') with bounds (m,n) and b storage]

Other Parameters

ctrans [input string(len=1), optional] Default: ‘N’
side [input string(len=1), optional] Default: ‘L’
uplo [input string(len=1), optional] Default: ‘U’
trans [input string(len=1), optional] Default: ‘N’
diag [input string(len=1), optional] Default: ‘N’
overwrite_b [input int, optional] Default: 0

**scipy.linalg.lapack.ztfsm**

scipy.linalg.lapack.ztfsm(alpha, a, b[, transr, side, uplo, trans, diag, overwrite_b]) = <fortran object>

Wrapper for ztfsm.

**Parameters**

- **alpha** [input complex]
- **a** [input rank-1 array(D) with bounds (nt)]
- **b** [input rank-2 array(D) with bounds (m,n)]

**Returns**

- **x** [rank-2 array(D) with bounds (m,n) and b storage]

**Other Parameters**

- **transr** [input string(len=1), optional] Default: 'N'
- **side** [input string(len=1), optional] Default: 'L'
- **uplo** [input string(len=1), optional] Default: 'U'
- **trans** [input string(len=1), optional] Default: 'N'
- **diag** [input string(len=1), optional] Default: 'N'
- **overwrite_b** [input int, optional] Default: 0

**scipy.linalg.lapack.stfttp**

scipy.linalg.lapack.stfttp(n, arf[, transr, uplo]) = <fortran object>

Wrapper for stfttp.

**Parameters**

- **n** [input int]
- **arf** [input rank-1 array(F) with bounds (nt)]

**Returns**

- **ap** [rank-1 array(F) with bounds (nt)]
- **info** [int]

**Other Parameters**

- **transr** [input string(len=1), optional] Default: 'N'
- **uplo** [input string(len=1), optional] Default: 'U'

**scipy.linalg.lapack.dtfttp**

scipy.linalg.lapack.dtfttp(n, arf[, transr, uplo]) = <fortran object>

Wrapper for dtfttp.

**Parameters**

- **n** [input int]
- **arf** [input rank-1 array(D) with bounds (nt)]

**Returns**

- **ap** [rank-1 array(D) with bounds (nt)]
- **info** [int]

**Other Parameters**

- **transr** [input string(len=1), optional] Default: 'N'
**uplo** [input string(len=1), optional] Default: ‘U’

### scipy.linalg.lapack.ctfttp

**scipy.linalg.lapack.ctfttp**

```python
scipy.linalg.lapack.ctfttp(n, arf[, transr, uplo]) = <fortran object>
```

Wrapper for `ctfttp`.

**Parameters**

- **n** [input int]
- **arf** [input rank-1 array('F') with bounds (nt)]

**Returns**

- **ap** [rank-1 array('F') with bounds (nt)]
- **info** [int]

**Other Parameters**

- **transr** [input string(len=1), optional] Default: ‘N’
- **uplo** [input string(len=1), optional] Default: ‘U’

### scipy.linalg.lapack.ztfttp

**scipy.linalg.lapack.ztfttp**

```python
scipy.linalg.lapack.ztfttp(n, arf[, transr, uplo]) = <fortran object>
```

Wrapper for `ztfttp`.

**Parameters**

- **n** [input int]
- **arf** [input rank-1 array('D') with bounds (nt)]

**Returns**

- **ap** [rank-1 array('D') with bounds (nt)]
- **info** [int]

**Other Parameters**

- **transr** [input string(len=1), optional] Default: ‘N’
- **uplo** [input string(len=1), optional] Default: ‘U’

### scipy.linalg.lapack.stfttr

**scipy.linalg.lapack.stfttr**

```python
scipy.linalg.lapack.stfttr(n, arf[, transr, uplo]) = <fortran object>
```

Wrapper for `stfttr`.

**Parameters**

- **n** [input int]
- **arf** [input rank-1 array('f') with bounds (nt)]

**Returns**

- **a** [rank-2 array('f') with bounds (lda,n)]
- **info** [int]

**Other Parameters**

- **transr** [input string(len=1), optional] Default: ‘N’
- **uplo** [input string(len=1), optional] Default: ‘U’
scipy.linalg.lapack.dfttr

scipy.linalg.lapack.dfttr(n, arf[, transr, uplo]) = <fortran object>
Wrapper for dfttr.

Parameters

n [input int]
arf [input rank-1 array('d') with bounds (nt)]

Returns

a [rank-2 array('d') with bounds (lda,n)]
info [int]

Other Parameters

transr [input string(len=1), optional] Default: 'N'
uplo [input string(len=1), optional] Default: 'U'

scipy.linalg.lapack.ctfttr

scipy.linalg.lapack.ctfttr(n, arf[, transr, uplo]) = <fortran object>
Wrapper for ctfttr.

Parameters

n [input int]
arf [input rank-1 array('F') with bounds (nt)]

Returns

a [rank-2 array('F') with bounds (lda,n)]
info [int]

Other Parameters

transr [input string(len=1), optional] Default: 'N'
uplo [input string(len=1), optional] Default: 'U'

scipy.linalg.lapack.ztfttr

scipy.linalg.lapack.ztfttr(n, arf[, transr, uplo]) = <fortran object>
Wrapper for ztfttr.

Parameters

n [input int]
arf [input rank-1 array('D') with bounds (nt)]

Returns

a [rank-2 array('D') with bounds (lda,n)]
info [int]

Other Parameters

transr [input string(len=1), optional] Default: 'N'
uplo [input string(len=1), optional] Default: 'U'
scipy.linalg.lapack.stgexc

scipy.linalg.lapack.stgexc(a, b, q, z, ifst, ilst[, lwork, overwrite_a, overwrite_b, overwrite_q, overwrite_z]), = <fortran object>

Wrapper for stgexc.

Parameters

a [input rank-2 array(‘f’) with bounds (lda,n)]
b [input rank-2 array(‘f’) with bounds (ldb,n)]
q [input rank-2 array(‘f’) with bounds (ldq,n)]
z [input rank-2 array(‘f’) with bounds (ldz,n)]
ifst [input int]
ilst [input int]

Returns

a [rank-2 array(‘f’) with bounds (lda,n)]
b [rank-2 array(‘f’) with bounds (ldb,n)]
q [rank-2 array(‘f’) with bounds (ldq,n)]
z [rank-2 array(‘f’) with bounds (ldz,n)]
work [rank-1 array(‘f’) with bounds (MAX(lwork, 1))]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
overwrite_q [input int, optional] Default: 0
overwrite_z [input int, optional] Default: 0
lwork [input int, optional] Default: max(4*n+16,1)

scipy.linalg.lapack.dtgexc

scipy.linalg.lapack.dtgexc(a, b, q, z, ifst, ilst[, lwork, overwrite_a, overwrite_b, overwrite_q, overwrite_z]), = <fortran object>

Wrapper for dtgexc.

Parameters

a [input rank-2 array(‘d’) with bounds (lda,n)]
b [input rank-2 array(‘d’) with bounds (ldb,n)]
q [input rank-2 array(‘d’) with bounds (ldq,n)]
z [input rank-2 array(‘d’) with bounds (ldz,n)]
ifst [input int]
ilst [input int]

Returns

a [rank-2 array(‘d’) with bounds (lda,n)]
b [rank-2 array(‘d’) with bounds (ldb,n)]
q [rank-2 array(‘d’) with bounds (ldq,n)]
z [rank-2 array(‘d’) with bounds (ldz,n)]
work [rank-1 array(‘d’) with bounds (MAX(lwork, 1))]
info [int]
Other Parameters

overwrite_a
[input int, optional] Default: 0
overwrite_b
[input int, optional] Default: 0
overwrite_q
[input int, optional] Default: 0
overwrite_z
[input int, optional] Default: 0
lwork
[input int, optional] Default: \(\max(4n+16,1)\)

scipy.linalg.lapack.ctgexc

\[
\text{scipy.linalg.lapack.ctgexc}(a, b, q, z, ifst, ilst[, overwrite_a, overwrite_b, overwrite_q, overwrite_z]) =<\text{fortran object}>
\]

Wrapper for \texttt{ctgexc}.

Parameters

\begin{itemize}
  \item \(a\) [input rank-2 array('F') with bounds (lda,n)]
  \item \(b\) [input rank-2 array('F') with bounds (ldb,n)]
  \item \(q\) [input rank-2 array('F') with bounds (ldq,n)]
  \item \(z\) [input rank-2 array('F') with bounds (ldz,n)]
  \item \(ifst\) [input int]
  \item \(ilst\) [input int]
\end{itemize}

Returns

\begin{itemize}
  \item \(a\) [rank-2 array('F') with bounds (lda,n)]
  \item \(b\) [rank-2 array('F') with bounds (ldb,n)]
  \item \(q\) [rank-2 array('F') with bounds (ldq,n)]
  \item \(z\) [rank-2 array('F') with bounds (ldz,n)]
  \item \(info\) [int]
\end{itemize}

Other Parameters

overwrite_a
[input int, optional] Default: 0
overwrite_b
[input int, optional] Default: 0
overwrite_q
[input int, optional] Default: 0
overwrite_z
[input int, optional] Default: 0

scipy.linalg.lapack.ztgexc

\[
\text{scipy.linalg.lapack.ztgexc}(a, b, q, z, ifst, ilst[, overwrite_a, overwrite_b, overwrite_q, overwrite_z]) =<\text{fortran object}>
\]

Wrapper for \texttt{ztgexc}.

Parameters

\begin{itemize}
  \item \(a\) [input rank-2 array('D') with bounds (lda,n)]
  \item \(b\) [input rank-2 array('D') with bounds (ldb,n)]
  \item \(q\) [input rank-2 array('D') with bounds (ldq,n)]
  \item \(z\) [input rank-2 array('D') with bounds (ldz,n)]
  \item \(ifst\) [input int]
\end{itemize}
ialst [input int]

Returns

a [rank-2 array('D') with bounds (lda,n)]
b [rank-2 array('D') with bounds (ldb,n)]
q [rank-2 array('D') with bounds (ldq,n)]
z [rank-2 array('D') with bounds (ldz,n)]
info [int]

Other Parameters

overwrite_a
[input int, optional] Default: 0
overwrite_b
[input int, optional] Default: 0
overwrite_q
[input int, optional] Default: 0
overwrite_z
[input int, optional] Default: 0

scipy.linalg.lapack.stgsen

scipy.linalg.lapack.stgsen(select, a, b, q, z[, ijob, wantq, wantz, lwork, liwork, overwrite_a, overwrite_b, overwrite_q, overwrite_z]) = <fortran object>

Wrapper for stgsen.

Parameters

select [input rank-1 array('i') with bounds (n)]
a [input rank-2 array('f') with bounds (n,n)]
b [input rank-2 array('f') with bounds (n,n)]
q [input rank-2 array('f') with bounds (n,n)]
z [input rank-2 array('f') with bounds (n,n)]

Returns

as [rank-2 array('f') with bounds (n,n) and a storage]
bs [rank-2 array('f') with bounds (n,n) and b storage]
alphar [rank-1 array('f') with bounds (n)]
alphai [rank-1 array('f') with bounds (n)]
beta [rank-1 array('f') with bounds (n)]
qs [rank-2 array('f') with bounds (n,n) and q storage]
zs [rank-2 array('f') with bounds (n,n) and z storage]
m [int]
pl [float]
pr [float]
dif [rank-1 array('f') with bounds (2)]
info [int]

Other Parameters

ijob [input int, optional] Default: 4
wantq [input int, optional] Default: 1
wantz [input int, optional] Default: 1
overwrite_a
[input int, optional] Default: 0
overwrite_b
[input int, optional] Default: 0
overwrite_q
  [input int, optional] Default: 0
overwrite_z
  [input int, optional] Default: 0
lwork  [input int, optional] Default: 4*n+16
liwork [input int, optional] Default: n+6

**scipy.linalg.lapack.dtgsen**

**Wrapper for dtgsen.**

**Parameters**

- **select**  [input rank-1 array('i') with bounds (n)]
- **a**  [input rank-2 array('d') with bounds (n,n)]
- **b**  [input rank-2 array('d') with bounds (n,n)]
- **q**  [input rank-2 array('d') with bounds (n,n)]
- **z**  [input rank-2 array('d') with bounds (n,n)]

**Returns**

- **as**  [rank-2 array('d') with bounds (n,n) and a storage]
- **bs**  [rank-2 array('d') with bounds (n,n) and b storage]
- **alphar**  [rank-1 array('d') with bounds (n)]
- **alphai**  [rank-1 array('d') with bounds (n)]
- **beta**  [rank-1 array('d') with bounds (n)]
- **qs**  [rank-2 array('d') with bounds (n,n) and q storage]
- **zs**  [rank-2 array('d') with bounds (n,n) and z storage]
- **m**  [int]
- **pl**  [float]
- **pr**  [float]
- **dif**  [rank-1 array('d') with bounds (2)]
- **info**  [int]

**Other Parameters**

- **ijob**  [input int, optional] Default: 4
- **wantq**  [input int, optional] Default: 1
- **wantz**  [input int, optional] Default: 1
- **overwrite_a**  [input int, optional] Default: 0
- **overwrite_b**  [input int, optional] Default: 0
- **overwrite_q**  [input int, optional] Default: 0
- **overwrite_z**  [input int, optional] Default: 0
- **lwork**  [input int, optional] Default: 4*n+16
- **liwork**  [input int, optional] Default: n+6

scipy.linalg.lapack.ctgsen

scipy.linalg.lapack.ctgsen (select, a, b, q, z, ijob, wantq, wantz, lwork, liwork, overwrite_a, overwrite_b, overwrite_q, overwrite_z) = <fortran object>

Wrapper for ctgsen.

Parameters

select [input rank-1 array('i') with bounds (n)]
a [input rank-2 array('F') with bounds (n,n)]
b [input rank-2 array('F') with bounds (n,n)]
q [input rank-2 array('F') with bounds (n,n)]
z [input rank-2 array('F') with bounds (n,n)]

Returns

as [rank-2 array('F') with bounds (n,n) and storage]
bs [rank-2 array('F') with bounds (n,n) and b storage]
alpha [rank-1 array('F') with bounds (n)]
beta [rank-1 array('F') with bounds (n)]
qs [rank-2 array('F') with bounds (n,n) and q storage]
zs [rank-2 array('F') with bounds (n,n) and z storage]
m [int]
pl [float]
pr [float]
dif [rank-1 array('F') with bounds (2)]
info [int]

Other Parameters

ijob [input int, optional] Default: 4
wantq [input int, optional] Default: 1
wantz [input int, optional] Default: 1
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
overwrite_q [input int, optional] Default: 0
overwrite_z [input int, optional] Default: 0
lwork [input int, optional] Default: (ijob==0?1:n+2)
liwork [input int, optional] Default: (ijob==0?1:n+2)

scipy.linalg.lapack.ztgsen

scipy.linalg.lapack.ztgsen (select, a, b, q, z, ijob, wantq, wantz, lwork, liwork, overwrite_a, overwrite_b, overwrite_q, overwrite_z) = <fortran object>

Wrapper for ztgsen.

Parameters

select [input rank-1 array('i') with bounds (n)]
a [input rank-2 array('D') with bounds (n,n)]
b [input rank-2 array('D') with bounds (n,n)]
q [input rank-2 array('D') with bounds (n,n)]
z [input rank-2 array('D') with bounds (n,n)]

Returns
as [rank-2 array('D') with bounds (n,n) and a storage]
bs [rank-2 array('D') with bounds (n,n) and b storage]
alpha [rank-1 array('D') with bounds (n)]
beta [rank-1 array('D') with bounds (n)]
qs [rank-2 array('D') with bounds (n,n) and q storage]
zs [rank-2 array('D') with bounds (n,n) and z storage]
m [int]
pl [float]
pr [float]
dif [rank-1 array('d') with bounds (2)]
info [int]

Other Parameters

ijob [input int, optional] Default: 4
wantq [input int, optional] Default: 1
wantz [input int, optional] Default: 1
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
overwrite_q [input int, optional] Default: 0
overwrite_z [input int, optional] Default: 0
lwork [input int, optional] Default: (ijob==0?1:n+2)
lwork [input int, optional] Default: (ijob==0?1:n+2)

scipy.linalg.lapack.stgsen_lwork

scipy.linalg.lapack.stgsen_lwork (select, a[:, ijob]) = <fortran object>

Parameters

select [input rank-1 array('i') with bounds (n)]
a [input rank-2 array('f') with bounds (n,n)]

Returns

work [float]
iwork [int]
info [int]

Other Parameters

ijob [input int, optional] Default: 4

scipy.linalg.lapack.dtgsen_lwork

scipy.linalg.lapack.dtgsen_lwork (select, a[:, ijob]) = <fortran object>

Parameters

select [input rank-1 array('i') with bounds (n)]
a [input rank-2 array('d') with bounds (n,n)]

Returns

work [float]

iwork [int]
info [int]

Other Parameters
ijob [input int, optional] Default: 4

scipy.linalg.lapack.ctgsen_lwork
scipy.linalg.lapack.ctgsen_lwork (select, a, b[, ijob]) = <fortran object>
Wrapper for cttgsen_lwork.

Parameters
select [input rank-1 array('i') with bounds (n)]
a [input rank-2 array('F') with bounds (n,n)]
b [input rank-2 array('F') with bounds (n,n)]

Returns
work [complex]
iwork [int]
info [int]

Other Parameters
ijob [input int, optional] Default: 4

scipy.linalg.lapack.ztgsen_lwork
scipy.linalg.lapack.ztgsen_lwork (select, a, b[, ijob]) = <fortran object>
Wrapper for zttgsen_lwork.

Parameters
select [input rank-1 array('i') with bounds (n)]
a [input rank-2 array('D') with bounds (n,n)]
b [input rank-2 array('D') with bounds (n,n)]

Returns
work [complex]
iwork [int]
info [int]

Other Parameters
ijob [input int, optional] Default: 4

scipy.linalg.lapack.stpttf
scipy.linalg.lapack.stpttf (n, ap[, transr, uplo]) = <fortran object>
Wrapper for stpttf.

Parameters
n [input int]
ap [input rank-1 array('f') with bounds (nt)]

Returns
arf [rank-1 array('f') with bounds (nt)]
info [int]

Other Parameters
transr  [input string(len=1), optional] Default: ‘N’
uplo   [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.dtpttf

scipy.linalg.lapack.dtpttf (n, ap[, transr, uplo]) = <fortran object>
Wrapper for dtpttf.

Parameters
n        [input int]
ap       [input rank-1 array('d') with bounds (nt)]

Returns
arf     [rank-1 array('d') with bounds (nt)]
info    [int]

Other Parameters
transr  [input string(len=1), optional] Default: ‘N’
uplo    [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.ctpttf

scipy.linalg.lapack.ctpttf (n, ap[, transr, uplo]) = <fortran object>
Wrapper for ctpttf.

Parameters
n        [input int]
ap       [input rank-1 array('F') with bounds (nt)]

Returns
arf     [rank-1 array('F') with bounds (nt)]
info    [int]

Other Parameters
transr  [input string(len=1), optional] Default: ‘N’
uplo    [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.ztpttf

scipy.linalg.lapack.ztpttf (n, ap[, transr, uplo]) = <fortran object>
Wrapper for ztpttf.

Parameters
n        [input int]
ap       [input rank-1 array('D') with bounds (nt)]

Returns
arf     [rank-1 array('D') with bounds (nt)]
info    [int]

Other Parameters
transr  [input string(len=1), optional] Default: ‘N’
uplo    [input string(len=1), optional] Default: ‘U’
scipy.linalg.lapack.stpttr

`scipy.linalg.lapack.stpttr(n, ap[, uplo]) = <fortran object>`

Wrapper for stpttr.

**Parameters**

- `n` [input int]
- `ap` [input rank-1 array('f') with bounds (nt)]

**Returns**

- `a` [rank-2 array('f') with bounds (n,n)]
- `info` [int]

**Other Parameters**

- `uplo` [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.dtpttr

`scipy.linalg.lapack.dtpttr(n, ap[, uplo]) = <fortran object>`

Wrapper for dtpttr.

**Parameters**

- `n` [input int]
- `ap` [input rank-1 array('d') with bounds (nt)]

**Returns**

- `a` [rank-2 array('d') with bounds (n,n)]
- `info` [int]

**Other Parameters**

- `uplo` [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.ctpttr

`scipy.linalg.lapack.ctpttr(n, ap[, uplo]) = <fortran object>`

Wrapper for ctpttr.

**Parameters**

- `n` [input int]
- `ap` [input rank-1 array('F') with bounds (nt)]

**Returns**

- `a` [rank-2 array('F') with bounds (n,n)]
- `info` [int]

**Other Parameters**

- `uplo` [input string(len=1), optional] Default: ‘U’
scipy.linalg.lapack.ztpttr

scipy.linalg.lapack.ztpttr(n, ap[, uplo]) = <fortran object>

Wrapper for ztpttr.

Parameters

n [input int]
ap [input rank-1 array('D') with bounds (nt)]

Returns

a [rank-2 array('D') with bounds (n,n)]
info [int]

Other Parameters

uplo [input string(len=1), optional] Default: 'U'

scipy.linalg.lapack.strsyl

scipy.linalg.lapack.strsyl(a, b, c[, trana, tranb, isgn, overwrite_c]) = <fortran object>

Wrapper for strsyl.

Parameters

a [input rank-2 array('f') with bounds (m,m)]
b [input rank-2 array('f') with bounds (n,n)]
c [input rank-2 array('f') with bounds (m,n)]

Returns

x [rank-2 array('f') with bounds (m,n) and c storage]
scale [float]
info [int]

Other Parameters

trana [input string(len=1), optional] Default: 'N'
tranb [input string(len=1), optional] Default: 'N'
isgn [input int, optional] Default: 1
overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.dtrsyl

scipy.linalg.lapack.dtrsyl(a, b, c[, trana, tranb, isgn, overwrite_c]) = <fortran object>

Wrapper for dtrsyl.

Parameters

a [input rank-2 array('d') with bounds (m,m)]
b [input rank-2 array('d') with bounds (n,n)]
c [input rank-2 array('d') with bounds (m,n)]

Returns

x [rank-2 array('d') with bounds (m,n) and c storage]
scale [float]
info [int]

Other Parameters

trana [input string(len=1), optional] Default: 'N'
scipy.linalg.lapack.ctrsyl

scipy.linalg.lapack.ctrsyl(a, b, c[, trana, tranb, isgn, overwrite_c]) = <fortran object>

Wrapper for ctrsyl.

Parameters

- a [input rank-2 array('F') with bounds (m,m)]
- b [input rank-2 array('F') with bounds (n,n)]
- c [input rank-2 array('F') with bounds (m,n)]

Returns

- x [rank-2 array('F') with bounds (m,n) and c storage]
- scale [float]
- info [int]

Other Parameters

- trana [input string(len=1), optional] Default: ‘N’
- tranb [input string(len=1), optional] Default: ‘N’
- isgn [input int, optional] Default: 1
- overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.ztrsyl

scipy.linalg.lapack.ztrsyl(a, b, c[, trana, tranb, isgn, overwrite_c]) = <fortran object>

Wrapper for ztrsyl.

Parameters

- a [input rank-2 array('D') with bounds (m,m)]
- b [input rank-2 array('D') with bounds (n,n)]
- c [input rank-2 array('D') with bounds (m,n)]

Returns

- x [rank-2 array('D') with bounds (m,n) and c storage]
- scale [float]
- info [int]

Other Parameters

- trana [input string(len=1), optional] Default: ‘N’
- tranb [input string(len=1), optional] Default: ‘N’
- isgn [input int, optional] Default: 1
- overwrite_c [input int, optional] Default: 0
scipy.linalg.lapack.strtri

Wrapper for _strtri_.

Parameters

- c [input rank-2 array('f') with bounds (n,n)]

Returns

- inv_c [rank-2 array('f') with bounds (n,n) and c storage]
- info [int]

Other Parameters

- overwrite_c [input int, optional] Default: 0
- lower [input int, optional] Default: 0
- unitdiag [input int, optional] Default: 0

scipy.linalg.lapack.dtrtri

Wrapper for _dtrtri_.

Parameters

- c [input rank-2 array('d') with bounds (n,n)]

Returns

- inv_c [rank-2 array('d') with bounds (n,n) and c storage]
- info [int]

Other Parameters

- overwrite_c [input int, optional] Default: 0
- lower [input int, optional] Default: 0
- unitdiag [input int, optional] Default: 0

scipy.linalg.lapack.ctrtri

Wrapper for _ctrtri_.

Parameters

- c [input rank-2 array('F') with bounds (n,n)]

Returns

- inv_c [rank-2 array('F') with bounds (n,n) and c storage]
- info [int]

Other Parameters

- overwrite_c [input int, optional] Default: 0
- lower [input int, optional] Default: 0
- unitdiag [input int, optional] Default: 0
scipy.linalg.lapack.ztrtri

scipy.linalg.lapack.ztrtri(c[, lower, unitdiag, overwrite_c]) = <fortran object>

Wrapper for ztrtri.

Parameters
- c [input rank-2 array('D') with bounds (n,n)]

Returns
- inv_c [rank-2 array('D') with bounds (n,n) and c storage]
- info [int]

Other Parameters
- overwrite_c [input int, optional] Default: 0
- lower [input int, optional] Default: 0
- unitdiag [input int, optional] Default: 0

scipy.linalg.lapack.strtrs

scipy.linalg.lapack.strtrs(a, b[, lower, trans, unitdiag, lda, overwrite_b]) = <fortran object>

Wrapper for strtrs.

Parameters
- a [input rank-2 array('f') with bounds (lda,n)]
- b [input rank-2 array('f') with bounds (ldb,nrhs)]

Returns
- x [rank-2 array('f') with bounds (ldb,nrhs) and b storage]
- info [int]

Other Parameters
- lower [input int, optional] Default: 0
- trans [input int, optional] Default: 0
- unitdiag [input int, optional] Default: 0
- lda [input int, optional] Default: shape(a,0)
- overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.dtrtrs

scipy.linalg.lapack.dtrtrs(a, b[, lower, trans, unitdiag, lda, overwrite_b]) = <fortran object>

Wrapper for dtrtrs.

Parameters
- a [input rank-2 array('d') with bounds (lda,n)]
- b [input rank-2 array('d') with bounds (ldb,nrhs)]

Returns
- x [rank-2 array('d') with bounds (ldb,nrhs) and b storage]
- info [int]

Other Parameters
- lower [input int, optional] Default: 0
- trans [input int, optional] Default: 0

unitdiag  [input int, optional] Default: 0
lda   [input int, optional] Default: shape(a,0)
overwrite_b   [input int, optional] Default: 0

**scipy.linalg.lapack.ctrtrs**

**scipy.linalg.lapack.ctrtrs**(a, b[, lower, trans, unitdiag, lda, overwrite_b]) = <fortran object>

Wrapper for ctrtrs.

**Parameters**

- a   [input rank-2 array('F') with bounds (lda,n)]
- b   [input rank-2 array('F') with bounds (ldb,nrhs)]

**Returns**

- x   [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
- info   [int]

**Other Parameters**

- lower   [input int, optional] Default: 0
- trans   [input int, optional] Default: 0
- unitdiag   [input int, optional] Default: 0
- lda   [input int, optional] Default: shape(a,0)
- overwrite_b   [input int, optional] Default: 0

**scipy.linalg.lapack.ztrtrs**

**scipy.linalg.lapack.ztrtrs**(a, b[, lower, trans, unitdiag, lda, overwrite_b]) = <fortran object>

Wrapper for ztrtrs.

**Parameters**

- a   [input rank-2 array('D') with bounds (lda,n)]
- b   [input rank-2 array('D') with bounds (ldb,nrhs)]

**Returns**

- x   [rank-2 array('D') with bounds (ldb,nrhs) and b storage]
- info   [int]

**Other Parameters**

- lower   [input int, optional] Default: 0
- trans   [input int, optional] Default: 0
- unitdiag   [input int, optional] Default: 0
- lda   [input int, optional] Default: shape(a,0)
- overwrite_b   [input int, optional] Default: 0
scipy.linalg.lapack.strttf

```python
scipy.linalg.lapack.strttf(a[, transr, uplo]) = <fortran object>
```

Wrapper for strttf.

**Parameters**

- `a` [input rank-2 array('f') with bounds (lda,n)]

**Returns**

- `arf` [rank-1 array('f') with bounds ((n + n * n) / 2)]
- `info` [int]

**Other Parameters**

- `transr` [input string(len=1), optional] Default: ‘N’
- `uplo` [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.dtrttf

```python
scipy.linalg.lapack.dtrttf(a[, transr, uplo]) = <fortran object>
```

Wrapper for dtrttf.

**Parameters**

- `a` [input rank-2 array('d') with bounds (lda,n)]

**Returns**

- `arf` [rank-1 array('d') with bounds ((n + n * n) / 2)]
- `info` [int]

**Other Parameters**

- `transr` [input string(len=1), optional] Default: ‘N’
- `uplo` [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.ctrttf

```python
scipy.linalg.lapack.ctrttf(a[, transr, uplo]) = <fortran object>
```

Wrapper for ctrttf.

**Parameters**

- `a` [input rank-2 array('F') with bounds (lda,n)]

**Returns**

- `arf` [rank-1 array('F') with bounds ((n + n * n) / 2)]
- `info` [int]

**Other Parameters**

- `transr` [input string(len=1), optional] Default: ‘N’
- `uplo` [input string(len=1), optional] Default: ‘U’
scipy.linalg.lapack.ztrttf

scipy.linalg.lapack.ztrttf(a[, transr, uplo]) = <fortran object>
Wrapper for ztrttf.

    Parameters
    a       [input rank-2 array('D') with bounds (lda,n)]

    Returns
    arf     [rank-1 array('D') with bounds ((n + n * n) / 2)]
    info    [int]

    Other Parameters
    transr       [input string(len=1), optional] Default: ‘N’
    uplo         [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.strttp

scipy.linalg.lapack.strttp(a[, uplo]) = <fortran object>
Wrapper for strttp.

    Parameters
    a       [input rank-2 array('f') with bounds (lda,n)]

    Returns
    ap      [rank-1 array('f') with bounds ((n + n * n) / 2)]
    info    [int]

    Other Parameters
    uplo     [input string(len=1), optional] Default: ‘U’

scipy.linalg.lapack.dtrttp

scipy.linalg.lapack.dtrttp(a[, uplo]) = <fortran object>
Wrapper for dtrttp.

    Parameters
    a       [input rank-2 array('d') with bounds (lda,n)]

    Returns
    ap      [rank-1 array('d') with bounds ((n + n * n) / 2)]
    info    [int]

    Other Parameters
    uplo     [input string(len=1), optional] Default: ‘U’
scipy.linalg.lapack.crrtt

scipy.linalg.lapack.crrtt(a[[], uplo]) = <fortran object>
Wrapper for crrtt.

Parameters
   a [input rank-2 array('F') with bounds (lda,n)]

Returns
   ap [rank-1 array('F') with bounds ((n + n * n) / 2)]
   info [int]

Other Parameters
   uplo [input string(len=1), optional] Default: 'U'

scipy.linalg.lapack.ztrtt

scipy.linalg.lapack.ztrtt(a[[], uplo]) = <fortran object>
Wrapper for ztrtt.

Parameters
   a [input rank-2 array('D') with bounds (lda,n)]

Returns
   ap [rank-1 array('D') with bounds ((n + n * n) / 2)]
   info [int]

Other Parameters
   uplo [input string(len=1), optional] Default: 'U'

scipy.linalg.lapack.stzrzf

scipy.linalg.lapack.stzrzf(a[[], lwork, overwrite_a]) = <fortran object>
Wrapper for stzrzf.

Parameters
   a [input rank-2 array('f') with bounds (m,n)]

Returns
   rz [rank-2 array('f') with bounds (m,n) and a storage]
   tau [rank-1 array('f') with bounds (m)]
   info [int]

Other Parameters
   overwrite_a [input int, optional] Default: 0
   lwork [input int, optional] Default: MAX(m,1)
scipy.linalg.lapack.dtzrzf

scipy.linalg.lapack.dtzrzf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for dtzrzf.

Parameters
a        [input rank-2 array('d') with bounds (m,n)]

Returns
rz       [rank-2 array('d') with bounds (m,n) and a storage]
tau      [rank-1 array('d') with bounds (m)]
info     [int]

Other Parameters
overwrite_a
          [input int, optional] Default: 0
lwork     [input int, optional] Default: MAX(m,1)

scipy.linalg.lapack.ctzrzf

scipy.linalg.lapack.ctzrzf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for ctzrzf.

Parameters
a        [input rank-2 array('F') with bounds (m,n)]

Returns
rz       [rank-2 array('F') with bounds (m,n) and a storage]
tau      [rank-1 array('F') with bounds (m)]
info     [int]

Other Parameters
overwrite_a
          [input int, optional] Default: 0
lwork     [input int, optional] Default: MAX(m,1)

scipy.linalg.lapack.ztzrzf

scipy.linalg.lapack.ztzrzf(a[, lwork, overwrite_a]) = <fortran object>
Wrapper for ztzrzf.

Parameters
a        [input rank-2 array('D') with bounds (m,n)]

Returns
rz       [rank-2 array('D') with bounds (m,n) and a storage]
tau      [rank-1 array('D') with bounds (m)]
info     [int]

Other Parameters
overwrite_a
          [input int, optional] Default: 0
lwork     [input int, optional] Default: MAX(m,1)
scipy.linalg.lapack.stzrzf_lwork

Wrapper for stzrzf_lwork.

Parameters

- m [input int]
- n [input int]

Returns

- work [float]
- info [int]

scipy.linalg.lapack.dtzrzf_lwork

Wrapper for dtzrzf_lwork.

Parameters

- m [input int]
- n [input int]

Returns

- work [float]
- info [int]

scipy.linalg.lapack.ctzrzf_lwork

Wrapper for ctzrzf_lwork.

Parameters

- m [input int]
- n [input int]

Returns

- work [complex]
- info [int]

scipy.linalg.lapack.ztzrzf_lwork

Wrapper for ztzrzf_lwork.

Parameters

- m [input int]
- n [input int]

Returns

- work [complex]
- info [int]
scipy.linalg.lapack.cunghr

scipy.linalg.lapack.cunghr(a, tau[, lo, hi, lwork, overwrite_a]) = <fortran object>

Wrapper for cunghr.

Parameters
a [input rank-2 array('F') with bounds (n,n)]
tau [input rank-1 array('F') with bounds (-1 + n)]

Returns
ht [rank-2 array('F') with bounds (n,n) and a storage]
info [int]

Other Parameters
lo [input int, optional] Default: 0
hi [input int, optional] Default: n-1
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(hi-lo,1)

scipy.linalg.lapack.zunghr

scipy.linalg.lapack.zunghr(a, tau[, lo, hi, lwork, overwrite_a]) = <fortran object>

Wrapper for zunghr.

Parameters
a [input rank-2 array('D') with bounds (n,n)]
tau [input rank-1 array('D') with bounds (-1 + n)]

Returns
ht [rank-2 array('D') with bounds (n,n) and a storage]
info [int]

Other Parameters
lo [input int, optional] Default: 0
hi [input int, optional] Default: n-1
overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(hi-lo,1)

scipy.linalg.lapack.cunghr_lwork

scipy.linalg.lapack.cunghr_lwork(n[, lo, hi]) = <fortran object>

Wrapper for cunghr_lwork.

Parameters
n [input int]

Returns
work [complex]
info [int]

Other Parameters
lo [input int, optional] Default: 0
hi [input int, optional] Default: n-1
scipy.linalg.lapack.zunghr_lwork

scipy.linalg.lapack.zunghr_lwork(n[, lo, hi]) = <fortran object>

Wrapper for zunghr_lwork.

Parameters

n [input int]

Returns

work [complex]
info [int]

Other Parameters

lo [input int, optional] Default: 0
hi [input int, optional] Default: n-1

scipy.linalg.lapack.cungqr

scipy.linalg.lapack.cungqr(a, tau[, lwork, overwrite_a]) = <fortran object>

Wrapper for cungqr.

Parameters

a [input rank-2 array('F') with bounds (m,n)]
tau [input rank-1 array('F') with bounds (k)]

Returns

q [rank-2 array('F') with bounds (m,n) and a storage]
work [rank-1 array('F') with bounds (MAX(lwork, 1))]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)

scipy.linalg.lapack.zungqr

scipy.linalg.lapack.zungqr(a, tau[, lwork, overwrite_a]) = <fortran object>

Wrapper for zungqr.

Parameters

a [input rank-2 array('D') with bounds (m,n)]
tau [input rank-1 array('D') with bounds (k)]

Returns

q [rank-2 array('D') with bounds (m,n) and a storage]
work [rank-1 array('D') with bounds (MAX(lwork, 1))]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*n,1)
scipy.linalg.lapack.cungrq

scipy.linalg.lapack.cungrq(a, tau[, lwork, overwrite_a]) = <fortran object>

Wrapper for cungrq.

Parameters

a [input rank-2 array('F') with bounds (m,n)]
tau [input rank-1 array('F') with bounds (k)]

Returns

q [rank-2 array('F') with bounds (m,n) and a storage]
work [rank-1 array('F') with bounds (MAX(lwork, 1))]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*m,1)

scipy.linalg.lapack.zungrq

scipy.linalg.lapack.zungrq(a, tau[, lwork, overwrite_a]) = <fortran object>

Wrapper for zungrq.

Parameters

a [input rank-2 array('D') with bounds (m,n)]
tau [input rank-1 array('D') with bounds (k)]

Returns

q [rank-2 array('D') with bounds (m,n) and a storage]
work [rank-1 array('D') with bounds (MAX(lwork, 1))]
info [int]

Other Parameters

overwrite_a [input int, optional] Default: 0
lwork [input int, optional] Default: max(3*m,1)

scipy.linalg.lapack.cunmqr

scipy.linalg.lapack.cunmqr(side, trans, a, tau, c[, lwork[, overwrite_c]]) = <fortran object>

Wrapper for cunmqr.

Parameters

side [input string(len=1)]
trans [input string(len=1)]
a [input rank-2 array('F') with bounds (lda,k)]
tau [input rank-1 array('F') with bounds (k)]
c [input rank-2 array('F') with bounds (ldc,n)]
lwork [input int]

Returns

cq [rank-2 array('F') with bounds (ldc,n) and c storage]
work [rank-1 array('F') with bounds (MAX(lwork, 1))]
info [int]

3.3. API definition
**Other Parameters**

overwrite_c  
[input int, optional] Default: 0

scipy.linalg.lapack.zunmqr

scipy.linalg.lapack.zunmqr (side, trans, a, tau, c, lwork[, overwrite_c]) = <fortran object>  
Wrapper for zunmqr.

**Parameters**

- side  
[input string(len=1)]
- trans  
[input string(len=1)]
- a  
[input rank-2 array('D') with bounds (lda,k)]
- tau  
[input rank-1 array('D') with bounds (k)]
- c  
[input rank-2 array('D') with bounds (ldc,n)]
- lwork  
[input int]

**Returns**

- cq  
[rank-2 array('D') with bounds (ldc,n) and c storage]
- work  
[rank-1 array('D') with bounds (MAX(lwork, 1))]
- info  
[int]

**Other Parameters**

overwrite_c  
[input int, optional] Default: 0

scipy.linalg.lapack.sgeqrt

scipy.linalg.lapack.sgeqrt (nb, a[, overwrite_a]) = <fortran object>  
Wrapper for sgeqrt.

**Parameters**

- nb  
[input int]
- a  
[input rank-2 array('f') with bounds (m,n)]

**Returns**

- a  
[rank-2 array('f') with bounds (m,n)]
- t  
[rank-2 array('f') with bounds (nb,MIN(m,n))]
- info  
[int]

**Other Parameters**

overwrite_a  
[input int, optional] Default: 0

scipy.linalg.lapack.dgeqrt

scipy.linalg.lapack.dgeqrt (nb, a[, overwrite_a]) = <fortran object>  
Wrapper for dgeqrt.

**Parameters**

- nb  
[input int]
- a  
[input rank-2 array('d') with bounds (m,n)]

**Returns**

- a  
[rank-2 array('d') with bounds (m,n)]

```
```

```
Other Parameters
overwrite_a
[input int, optional] Default: 0
```

```
scipy.linalg.lapack.cgeqrt
scipy.linalg.lapack.cgeqrt (nb, a[, overwrite_a]) = <fortran object>
Wrapper for cgeqrt.
Parameters
nb [input int]
a [input rank-2 array('F') with bounds (m,n)]
Returns
a [rank-2 array('F') with bounds (m,n)]
t [rank-2 array('F') with bounds (nb,MIN(m,n))]
info [int]
Other Parameters
overwrite_a
[input int, optional] Default: 0
```

```
scipy.linalg.lapack.zgeqrt
scipy.linalg.lapack.zgeqrt (nb, a[, overwrite_a]) = <fortran object>
Wrapper for zgeqrt.
Parameters
nb [input int]
a [input rank-2 array('D') with bounds (m,n)]
Returns
a [rank-2 array('D') with bounds (m,n)]
t [rank-2 array('D') with bounds (nb,MIN(m,n))]
info [int]
Other Parameters
overwrite_a
[input int, optional] Default: 0
```

```
scipy.linalg.lapack.sgemqrt
scipy.linalg.lapack.sgemqrt (v, t, c[, side, trans, overwrite_c]) = <fortran object>
Wrapper for sgemqrt.
Parameters
v [input rank-2 array('f') with bounds ((side[0] == 'L'?m:n),k)]
t [input rank-2 array('f') with bounds (nb,k)]
c [input rank-2 array('f') with bounds (m,n)]
Returns
c [rank-2 array('f') with bounds (m,n)]
```

3.3. API definition

info [int]

Other Parameters
side [input string(len=1), optional] Default: ‘L’
trans [input string(len=1), optional] Default: ‘N’
overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.dgemqrt

scipy.linalg.lapack.dgemqrt(v, t[, side, trans, overwrite_c]) = <fortran object>

Wrapper for dgemqrt.

Parameters
v [input rank-2 array('d') with bounds ((side[0]=='L'?m:n),k)]
t [input rank-2 array('d') with bounds (nb,k)]
c [input rank-2 array('d') with bounds (m,n)]

Returns
c [rank-2 array('d') with bounds (m,n)]
info [int]

Other Parameters
side [input string(len=1), optional] Default: ‘L’
trans [input string(len=1), optional] Default: ‘N’
overwrite_c [input int, optional] Default: 0

scipy.linalg.lapack.cgemqrt

scipy.linalg.lapack.cgemqrt(v, t[, side, trans, overwrite_c]) = <fortran object>

Wrapper for cgemqrt.

Parameters
v [input rank-2 array('F') with bounds ((side[0]=='L'?m:n),k)]
t [input rank-2 array('F') with bounds (nb,k)]
c [input rank-2 array('F') with bounds (m,n)]

Returns
c [rank-2 array('F') with bounds (m,n)]
info [int]

Other Parameters
side [input string(len=1), optional] Default: ‘L’
trans [input string(len=1), optional] Default: ‘N’
overwrite_c [input int, optional] Default: 0
scipy.linalg.lapack.zgemqrt

`scipy.linalg.lapack.zgemqrt(v, t, c[, side, trans, overwrite_c]) = <fortran object>`

Wrapper for zgemqrt.

**Parameters**

- `v` [input rank-2 array('D') with bounds ((side[0] == 'L'?m:n),k)]
- `t` [input rank-2 array('D') with bounds (nb,k)]
- `c` [input rank-2 array('D') with bounds (m,n)]

**Returns**

- `c` [rank-2 array('D') with bounds (m,n)]
- `info` [int]

**Other Parameters**

- `side` [input string(len=1), optional] Default: 'L'
- `trans` [input string(len=1), optional] Default: 'N'
- `overwrite_c` [input int, optional] Default: 0

scipy.linalg.lapack.sgttrf

`scipy.linalg.lapack.sgttrf(dl, d, du[, overwrite_dl, overwrite_d, overwrite_du]) = <fortran object>`

Wrapper for sgttrf.

**Parameters**

- `dl` [input rank-1 array('f') with bounds (-1 + n)]
- `d` [input rank-1 array('f') with bounds (n)]
- `du` [input rank-1 array('f') with bounds (-1 + n)]

**Returns**

- `dl` [rank-1 array('f') with bounds (-1 + n)]
- `d` [rank-1 array('f') with bounds (n)]
- `du` [rank-1 array('f') with bounds (-1 + n)]
- `du2` [rank-1 array('f') with bounds (-2 + n)]
- `ipiv` [rank-1 array('i') with bounds (n)]
- `info` [int]

**Other Parameters**

- `overwrite_dl` [input int, optional] Default: 0
- `overwrite_d` [input int, optional] Default: 0
- `overwrite_du` [input int, optional] Default: 0
**scipy.linalg.lapack.dgttrf**

```python
scipy.linalg.lapack.dgttrf(dl, d, du[, overwrite_dl, overwrite_d, overwrite_du]) = <fortran object>
```

Wrapper for `dgttrf`.

**Parameters**
- `dl` [input rank-1 array('d') with bounds (-1 + n)]
- `d` [input rank-1 array('d') with bounds (n)]
- `du` [input rank-1 array('d') with bounds (-1 + n)]

**Returns**
- `dl` [rank-1 array('d') with bounds (-1 + n)]
- `d` [rank-1 array('d') with bounds (n)]
- `du` [rank-1 array('d') with bounds (-1 + n)]
- `du2` [rank-1 array('d') with bounds (-2 + n)]
- `ipiv` [rank-1 array('i') with bounds (n)]
- `info` [int]

**Other Parameters**
- `overwrite_dl` [input int, optional] Default: 0
- `overwrite_d` [input int, optional] Default: 0
- `overwrite_du` [input int, optional] Default: 0

**scipy.linalg.lapack.cgttrf**

```python
scipy.linalg.lapack.cgttrf(dl, d, du[, overwrite_dl, overwrite_d, overwrite_du]) = <fortran object>
```

Wrapper for `cgttrf`.

**Parameters**
- `dl` [input rank-1 array('F') with bounds (-1 + n)]
- `d` [input rank-1 array('F') with bounds (n)]
- `du` [input rank-1 array('F') with bounds (-1 + n)]

**Returns**
- `dl` [rank-1 array('F') with bounds (-1 + n)]
- `d` [rank-1 array('F') with bounds (n)]
- `du` [rank-1 array('F') with bounds (-1 + n)]
- `du2` [rank-1 array('F') with bounds (-2 + n)]
- `ipiv` [rank-1 array('i') with bounds (n)]
- `info` [int]

**Other Parameters**
- `overwrite_dl` [input int, optional] Default: 0
- `overwrite_d` [input int, optional] Default: 0
- `overwrite_du` [input int, optional] Default: 0
scipy.linalg.lapack.zgttrf

```python
scipy.linalg.lapack.zgttrf(dl, d, du[, overwrite_dl, overwrite_d, overwrite_du]) = <fortran object>
```

Wrapper for zgttrf.

**Parameters**

- **dl** [input rank-1 array('D') with bounds (-1 + n)]
- **d** [input rank-1 array('D') with bounds (n)]
- **du** [input rank-1 array('D') with bounds (-1 + n)]

**Returns**

- **dl** [rank-1 array('D') with bounds (-1 + n)]
- **d** [rank-1 array('D') with bounds (n)]
- **du** [rank-1 array('D') with bounds (-1 + n)]
- **du2** [rank-1 array('D') with bounds (-2 + n)]
- **ipiv** [rank-1 array('i') with bounds (n)]
- **info** [int]

**Other Parameters**

- **overwrite_dl** [input int, optional] Default: 0
- **overwrite_d** [input int, optional] Default: 0
- **overwrite_du** [input int, optional] Default: 0

scipy.linalg.lapack.sgttrs

```python
scipy.linalg.lapack.sgttrs(dl, d, du, du2, ipiv, b[, trans, overwrite_b]) = <fortran object>
```

Wrapper for sgttrs.

**Parameters**

- **dl** [input rank-1 array('F') with bounds (-1 + n)]
- **d** [input rank-1 array('F') with bounds (n)]
- **du** [input rank-1 array('F') with bounds (-1 + n)]
- **du2** [input rank-1 array('F') with bounds (-2 + n)]
- **ipiv** [input rank-1 array('i') with bounds (n)]
- **b** [input rank-2 array('F') with bounds (ldb,nrhs)]

**Returns**

- **x** [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
- **info** [int]

**Other Parameters**

- **trans** [input string(len=1), optional] Default: 'N'
- **overwrite_b** [input int, optional] Default: 0
scipy.linalg.lapack.dgttrs

Wrapper for dgttrs.

Parameters

dl [input rank-1 array('d') with bounds (-1 + n)]
d [input rank-1 array('d') with bounds (n)]
du [input rank-1 array('d') with bounds (-1 + n)]
du2 [input rank-1 array('d') with bounds (-2 + n)]
ippiv [input rank-1 array('i') with bounds (n)]
b [input rank-2 array('d') with bounds (ldb,nrhs)]

Returns

x [rank-2 array('d') with bounds (ldb,nrhs) and b storage]
info [int]

Other Parameters

trans [input string(len=1), optional] Default: ‘N’
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.cgttrs

Wrapper for cgttrs.

Parameters

dl [input rank-1 array('F') with bounds (-1 + n)]
d [input rank-1 array('F') with bounds (n)]
du [input rank-1 array('F') with bounds (-1 + n)]
du2 [input rank-1 array('F') with bounds (-2 + n)]
ippiv [input rank-1 array('i') with bounds (n)]
b [input rank-2 array('F') with bounds (ldb,nrhs)]

Returns

x [rank-2 array('F') with bounds (ldb,nrhs) and b storage]
info [int]

Other Parameters

trans [input string(len=1), optional] Default: ‘N’
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.zgttrs

Wrapper for zgttrs.

Parameters

dl [input rank-1 array('D') with bounds (-1 + n)]
d [input rank-1 array('D') with bounds (n)]
du [input rank-1 array('D') with bounds (-1 + n)]
du2 [input rank-1 array('D') with bounds (-2 + n)]
ippiv [input rank-1 array('i') with bounds (n)]

b

Returns

x

info

Other Parameters

trans

overwrite_b

scipy.linalg.lapack.stpqrt

scipy.linalg.lapack.stpqrt (l, nb, a, b[, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for stpqrt.

Parameters

l

nb

a

b

Returns

a

b

t

info

Other Parameters

overwrite_a

overwrite_b

scipy.linalg.lapack.dtpqrt

scipy.linalg.lapack.dtpqrt (l, nb, a, b[, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for dtpqrt.

Parameters

l

nb

a

b

Returns

a

b

t

info

Other Parameters

overwrite_a

overwrite_b

3.3. API definition 1085
overwrite_b
  [input int, optional] Default: 0

**scipy.linalg.lapack.ctpqrt**

```python
scipy.linalg.lapack.ctpqrt(l, nb, a[, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for ctpqrt.

**Parameters**

- **l** [input int]
- **nb** [input int]
- **a** [input rank-2 array('F') with bounds (n,n)]
- **b** [input rank-2 array('F') with bounds (m,n)]

**Returns**

- **a** [rank-2 array('F') with bounds (n,n)]
- **b** [rank-2 array('F') with bounds (m,n)]
- **t** [rank-2 array('F') with bounds (nb,n)]
- **info** [int]

**Other Parameters**

- **overwrite_a** [input int, optional] Default: 0
- **overwrite_b** [input int, optional] Default: 0

**scipy.linalg.lapack.ztpqrt**

```python
scipy.linalg.lapack.ztpqrt(l, nb, a[, overwrite_a, overwrite_b]) = <fortran object>
```

Wrapper for ztpqrt.

**Parameters**

- **l** [input int]
- **nb** [input int]
- **a** [input rank-2 array('D') with bounds (n,n)]
- **b** [input rank-2 array('D') with bounds (m,n)]

**Returns**

- **a** [rank-2 array('D') with bounds (n,n)]
- **b** [rank-2 array('D') with bounds (m,n)]
- **t** [rank-2 array('D') with bounds (nb,n)]
- **info** [int]

**Other Parameters**

- **overwrite_a** [input int, optional] Default: 0
- **overwrite_b** [input int, optional] Default: 0
scipy.linalg.lapack.stpmqrt

scipy.linalg.lapack.stpmqrt(l, v, t, a, b[, side, trans, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for stpmqrt.

Parameters
l [input int]
v [input rank-2 array('f') with bounds ((side[0] == 'L'?m:n),k)]
t [input rank-2 array('f') with bounds (nb,k)]
a [input rank-2 array('f') with bounds ((side[0] == 'L'?k:m),(side[0] == 'L'?n:k))]
b [input rank-2 array('f') with bounds (m,n)]

Returns
a [rank-2 array('f') with bounds ((side[0] == 'L'?k:m),(side[0] == 'L'?n:k))]
b [rank-2 array('f') with bounds (m,n)]
info [int]

Other Parameters
side [input string(len=1), optional] Default: 'L'
trans [input string(len=1), optional] Default: 'N'
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0

scipy.linalg.lapack.dtpmqrt

scipy.linalg.lapack.dtpmqrt(l, v, t, a, b[, side, trans, overwrite_a, overwrite_b]) = <fortran object>

Wrapper for dtpmqrt.

Parameters
l [input int]
v [input rank-2 array('d') with bounds ((side[0] == 'L'?m:n),k)]
t [input rank-2 array('d') with bounds (nb,k)]
a [input rank-2 array('d') with bounds ((side[0] == 'L'?k:m),(side[0] == 'L'?n:k))]
b [input rank-2 array('d') with bounds (m,n)]

Returns
a [rank-2 array('d') with bounds ((side[0] == 'L'?k:m),(side[0] == 'L'?n:k))]
b [rank-2 array('d') with bounds (m,n)]
info [int]

Other Parameters
side [input string(len=1), optional] Default: 'L'
trans [input string(len=1), optional] Default: 'N'
overwrite_a [input int, optional] Default: 0
overwrite_b [input int, optional] Default: 0
`scipy.linalg.lapack.ctpmqrt`  
`scipy.linalg.lapack.ctpmqrt(l, v, t, a[, side, trans, overwrite_a, overwrite_b]) = <fortran object>`  
Wrapper for `ctpmqrt`.

**Parameters**
- `l` [input int]  
  [input rank-2 array('F') with bounds ((side[0] == 'L'?'m:n',k))]
- `v` [input rank-2 array('F') with bounds (nb,k)]
- `t` [input rank-2 array('F') with bounds ((side[0] == 'L'?'k:m),(side[0] == 'L'?'n:k))]
- `a` [input rank-2 array('F') with bounds (m,n)]
- `b` [input rank-2 array('F') with bounds ((side[0] == 'L'?'m:n',k))]

**Returns**
- `a` [rank-2 array('F') with bounds ((side[0] == 'L'?'k:m),(side[0] == 'L'?'n:k))]
- `b` [rank-2 array('F') with bounds (m,n)]
- `info` [int]

**Other Parameters**
- `side` [input string(len=1), optional] Default: 'L'
- `trans` [input string(len=1), optional] Default: 'N'
- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0

`scipy.linalg.lapack.ztpmqrt`  
`scipy.linalg.lapack.ztpmqrt(l, v, t, a[, side, trans, overwrite_a, overwrite_b]) = <fortran object>`  
Wrapper for `ztpmqrt`.

**Parameters**
- `l` [input int]  
  [input rank-2 array('F') with bounds ((side[0] == 'L'?'m:n',k))]
- `v` [input rank-2 array('D') with bounds (nb,k)]
- `t` [input rank-2 array('D') with bounds ((side[0] == 'L'?'k:m),(side[0] == 'L'?'n:k))]
- `a` [input rank-2 array('D') with bounds (m,n)]
- `b` [input rank-2 array('D') with bounds ((side[0] == 'L'?'m:n',k))]

**Returns**
- `a` [rank-2 array('D') with bounds ((side[0] == 'L'?'k:m),(side[0] == 'L'?'n:k))]
- `b` [rank-2 array('D') with bounds (m,n)]
- `info` [int]

**Other Parameters**
- `side` [input string(len=1), optional] Default: 'L'
- `trans` [input string(len=1), optional] Default: 'N'
- `overwrite_a` [input int, optional] Default: 0
- `overwrite_b` [input int, optional] Default: 0
scipy.linalg.lapack.cuncsd

scipy.linalg.lapack.cuncsd(x11, x12, x21, x22[, compute_u1, compute_u2, compute_v1t, compute_v2t, trans, signs, lwork, lrwork, overwrite_x11, overwrite_x12, overwrite_x21, overwrite_x22]) = <fortran object>

Wrapper for cuncsd.

**Parameters**

- **x11**: [input rank-2 array('F') with bounds (p,q)]
- **x12**: [input rank-2 array('F') with bounds (p,mmq)]
- **x21**: [input rank-2 array('F') with bounds (mmp,q)]
- **x22**: [input rank-2 array('F') with bounds (mmp,mmq)]

**Returns**

- **cs11**: [rank-2 array('F') with bounds (p,q) and x11 storage]
- **cs12**: [rank-2 array('F') with bounds (p,mmq) and x12 storage]
- **cs21**: [rank-2 array('F') with bounds (mmp,q) and x21 storage]
- **cs22**: [rank-2 array('F') with bounds (mmp,mmq) and x22 storage]
- **theta**: [rank-1 array('f') with bounds (min(min(p,mmp),min(q,mmq)))]
- **u1**: [rank-2 array('F') with bounds ((compute_u1?p:0),(compute_u1?p:0))]
- **u2**: [rank-2 array('F') with bounds ((compute_u2?mmp:0),(compute_u2?mmp:0))]
- **v1t**: [rank-2 array('F') with bounds ((compute_v1t?q:0),(compute_v1t?q:0))]
- **v2t**: [rank-2 array('F') with bounds ((compute_v2t?mmq:0),(compute_v2t?mmq:0))]
- **info**: [int]

**Other Parameters**

- **compute_u1**: [input int, optional] Default: 1
- **compute_u2**: [input int, optional] Default: 1
- **compute_v1t**: [input int, optional] Default: 1
- **compute_v2t**: [input int, optional] Default: 1
- **trans**: [input int, optional] Default: 0
- **signs**: [input int, optional] Default: 0
- **overwrite_x11**: [input int, optional] Default: 0
- **overwrite_x12**: [input int, optional] Default: 0
- **overwrite_x21**: [input int, optional] Default: 0
- **overwrite_x22**: [input int, optional] Default: 0
- **lwork**: [input int, optional] Default: 2*m+MAX(1,MAX(mmp,mmq))+1
- **lrwork**: [input int, optional] Default: 5*MAX(1,q-1)+4*MAX(1,q)+8*q+1
scipy.linalg.lapack.zuncsd

Wrapper for zuncsd.

Parameters

- **x11**: [input rank-2 array('D') with bounds (p,q)]
- **x12**: [input rank-2 array('D') with bounds (p,mmq)]
- **x21**: [input rank-2 array('D') with bounds (mmp,q)]
- **x22**: [input rank-2 array('D') with bounds (mmp,mmq)]

Returns

- **cs11**: [rank-2 array('D') with bounds (p,q) and x11 storage]
- **cs12**: [rank-2 array('D') with bounds (p,mmq) and x12 storage]
- **cs21**: [rank-2 array('D') with bounds (mmp,q) and x21 storage]
- **cs22**: [rank-2 array('D') with bounds (mmp,mmq) and x22 storage]
- **theta**: [rank-1 array('d') with bounds (min(min(p,mmp), min(q, mmq)))]
- **u1**: [rank-2 array('d') with bounds ((compute_u1?p:0),(compute_u1?p:0))]
- **u2**: [rank-2 array('D') with bounds ((compute_u2?mmp:0),(compute_u2?mmp:0))]
- **v1t**: [rank-2 array('D') with bounds ((compute_v1t?q:0),(compute_v1t?q:0))]
- **v2t**: [rank-2 array('D') with bounds ((compute_v2t?mmq:0),(compute_v2t?mmq:0))]
- **info**: [int]

Other Parameters

- **compute_u1**: [input int, optional] Default: 1
- **compute_u2**: [input int, optional] Default: 1
- **compute_v1t**: [input int, optional] Default: 1
- **compute_v2t**: [input int, optional] Default: 1
- **trans**: [input int, optional] Default: 0
- **signs**: [input int, optional] Default: 0
- **overwrite_x11**: [input int, optional] Default: 0
- **overwrite_x12**: [input int, optional] Default: 0
- **overwrite_x21**: [input int, optional] Default: 0
- **overwrite_x22**: [input int, optional] Default: 0
- **lwork**: [input int, optional] Default: 2*m+MAX(1,MAX(mmp,mmq))+1
- **lrwork**: [input int, optional] Default: 5*MAX(1,q-1)+4*MAX(1,q)+8*q+1
scipy.linalg.lapack.cunmzd

scipy.linalg.lapack.cunmzd(a, tau[, side, trans, overwrite_c]) = <fortran object>
Wrapper for cunmzd.

Parameters
a [input rank-2 array('F') with bounds (k,nt)]
tau [input rank-1 array('F') with bounds (k)]
c [input rank-2 array('F') with bounds (m,n)]
side [input string(len=1), optional] Default: 'L'
trans [input string(len=1), optional] Default: 'N'
overwrite_c [input int, optional] Default: 0
lwork [input int, optional] Default: MAX((side[0]=='L'?n:m),1)

scipy.linalg.lapack.zunmzd

scipy.linalg.lapack.zunmzd(a, tau[, side, trans, overwrite_c]) = <fortran object>
Wrapper for zunmzd.

Parameters
a [input rank-2 array('F') with bounds (k,nt)]
tau [input rank-1 array('F') with bounds (k)]
c [input rank-2 array('F') with bounds (m,n)]
side [input string(len=1), optional] Default: 'L'
trans [input string(len=1), optional] Default: 'N'
overwrite_c [input int, optional] Default: 0
lwork [input int, optional] Default: MAX((side[0]=='L'?n:m),1)
scipy.linalg.lapack.zunmrz

Wrapper for zunmrz.

**Parameters**

- `a` [input rank-2 array('D') with bounds (k,nt)]
- `tau` [input rank-1 array('D') with bounds (k)]
- `c` [input rank-2 array('D') with bounds (m,n)]

**Returns**

- `cq` [rank-2 array('D') with bounds (m,n) and c storage]
- `info` [int]

**Other Parameters**

- `side` [input string(len=1), optional] Default: 'L'
- `trans` [input string(len=1), optional] Default: 'N'
- `overwrite_c` [input int, optional] Default: 0
- `lwork` [input int, optional] Default: MAX((side[0]=='L'?n:m),1)

scipy.linalg.lapack.cunmrz_lwork

Wrapper for cunmrz_lwork.

**Parameters**

- `m` [input int]
- `n` [input int]

**Returns**

- `work` [complex]
- `info` [int]

**Other Parameters**

- `side` [input string(len=1), optional] Default: 'L'
- `trans` [input string(len=1), optional] Default: 'N'

scipy.linalg.lapack.zunmrz_lwork

Wrapper for zunmrz_lwork.

**Parameters**

- `m` [input int]
- `n` [input int]

**Returns**

- `work` [complex]
- `info` [int]

**Other Parameters**

- `side` [input string(len=1), optional] Default: 'L'
- `trans` [input string(len=1), optional] Default: 'N'
```python
scipy.linalg.lapack.ilaver

scipy.linalg.lapack.ilaver = <fortran object>

Wrapper for ilaver.

Returns

- major [int]

3.3.13 BLAS Functions for Cython

Usable from Cython via:

```python
cimport scipy.linalg.cython_blas
```

These wrappers do not check for alignment of arrays. Alignment should be checked before these wrappers are used.

Raw function pointers (Fortran-style pointer arguments):

- caxpy
- ccopy
- cdotc
- cdotu
- cgbmv
- cgemm
- cgemv
- cgerc
- cgeru

3.3.14 LAPACK functions for Cython

Usable from Cython via:

```python
cimport scipy.linalg.cython_lapack
```

This module provides Cython-level wrappers for all primary routines included in LAPACK 3.4.0 except for zcgesv since its interface is not consistent from LAPACK 3.4.0 to 3.6.0. It also provides some of the fixed-api auxiliary routines.

These wrappers do not check for alignment of arrays. Alignment should be checked before these wrappers are used.

Raw function pointers (Fortran-style pointer arguments):
• cbbcsd
• cbdsqr
• cgbbrd
• cgbbcon

3.3.15 Interpolative matrix decomposition (scipy.linalg.interpolative)

New in version 0.13.

An interpolative decomposition (ID) of a matrix $A \in \mathbb{C}^{m \times n}$ of rank $k \leq \min\{m, n\}$ is a factorization

$$A \Pi = [A\Pi_1 \ A\Pi_2] = A\Pi_1 [I \ T],$$

where $\Pi = [\Pi_1, \Pi_2]$ is a permutation matrix with $\Pi_1 \in \{0, 1\}^{n \times k}$, i.e., $A\Pi_2 = A\Pi_1 T$. This can equivalently be written as $A = BP$, where $B = A\Pi_1$ and $P = [I, T]\Pi^T$ are the skeleton and interpolation matrices, respectively.

If $A$ does not have exact rank $k$, then there exists an approximation in the form of an ID such that $A = BP + E$, where $\|E\| \sim \sigma_{k+1}$ is on the order of the $(k + 1)$-th largest singular value of $A$. Note that $\sigma_{k+1}$ is the best possible error for a rank-$k$ approximation and, in fact, is achieved by the singular value decomposition (SVD) $A \approx U S V^*$, where $U \in \mathbb{C}^{m \times k}$ and $V \in \mathbb{C}^{n \times k}$ have orthonormal columns and $S = \text{diag}(\sigma_i) \in \mathbb{C}^{k \times k}$ is diagonal with nonnegative entries.

The principal advantages of using an ID over an SVD are that:

• it is cheaper to construct;
• it preserves the structure of $A$; and
• it is more efficient to compute with in light of the identity submatrix of $P$.

**scipy.linalg.interpolative.interp_decomp**

**scipy.linalg.interpolative.interp_decomp(A, eps_or_k, rand=True)**

Compute ID of a matrix.

An ID of a matrix $A$ is a factorization defined by a rank $k$, a column index array $idx$, and interpolation coefficients $proj$ such that:

\[
\text{numpy.dot}(A[:,idx[:k]], proj) = A[:,idx[k:]]
\]

The original matrix can then be reconstructed as:

\[
\text{numpy.hstack}([A[:,idx[:k]], \text{numpy.dot}(A[:,idx[:k]], proj)])[:,\text{numpy.argsort}(idx)]
\]

or via the routine `reconstruct_matrix_from_id`. This can equivalently be written as:

\[
\text{numpy.dot}(A[:,idx[:k]], \\
\quad \text{numpy.hstack}([\text{numpy.eye}(k), proj])[:,\text{np.argsort}(idx)])
\]

in terms of the skeleton and interpolation matrices:

$B = A[:,idx[:k]]$

and:

$P = \text{numpy.hstack}([\text{numpy.eye}(k), proj])[:,\text{np.argsort}(idx)]$

respectively. See also `reconstruct_interp_matrix` and `reconstruct_skel_matrix`.

The ID can be computed to any relative precision or rank (depending on the value of $eps_or_k$). If a precision is specified ($eps_or_k < 1$), then this function has the output signature:

$k, idx, proj = \text{interp_decomp}(A, eps_or_k)$

Otherwise, if a rank is specified ($eps_or_k >= 1$), then the output signature is:

$idx, proj = \text{interp_decomp}(A, eps_or_k)$

**Parameters**

- **A** [numpy.ndarray or scipy.sparse.linalg.LinearOperator with rmatvec] Matrix to be factored.
- **eps_or_k** [float or int] Relative error (if $eps_or_k < 1$) or rank (if $eps_or_k >= 1$) of approximation.
- **rand** [bool, optional] Whether to use random sampling if $A$ is of type numpy.ndarray (randomized algorithms are always used if $A$ is of type scipy.sparse.linalg.LinearOperator).

**Returns**

- **k** [int] Rank required to achieve specified relative precision if $eps_or_k < 1$.
- **idx** [numpy.ndarray] Column index array.
- **proj** [numpy.ndarray] Interpolation coefficients.
scipy.linalg.interpolative.reconstruct_matrix_from_id

scipy.linalg.interpolative.reconstruct_matrix_from_id(B, idx, proj)

Reconstruct matrix from its ID.

A matrix $A$ with skeleton matrix $B$ and ID indices and coefficients $idx$ and $proj$, respectively, can be reconstructed as:

$$\text{numpy.hstack}([B, \text{numpy.dot}(B, \text{proj})])[::\text{numpy.argsort}(idx)]$$

See also \texttt{reconstruct_interp_matrix} and \texttt{reconstruct_skel_matrix}.

Parameters

- **B** ([\texttt{numpy.ndarray}]) Skeleton matrix.
- **idx** ([\texttt{numpy.ndarray}]) Column index array.
- **proj** ([\texttt{numpy.ndarray}]) Interpolation coefficients.

Returns

- **numpy.ndarray** Reconstructed matrix.

scipy.linalg.interpolative.reconstruct_interp_matrix

scipy.linalg.interpolative.reconstruct_interp_matrix(idx, proj)

Reconstruct interpolation matrix from ID.

The interpolation matrix can be reconstructed from the ID indices and coefficients $idx$ and $proj$, respectively, as:

$$P = \text{numpy.hstack}([\text{numpy.eye}(\text{proj.shape}[0]), \text{proj})[::\text{numpy.argsort}(idx)]$$

The original matrix can then be reconstructed from its skeleton matrix $B$ via:

$$\text{numpy.dot}(B, P)$$

See also \texttt{reconstruct_matrix_from_id} and \texttt{reconstruct_skel_matrix}.

Parameters

- **idx** ([\texttt{numpy.ndarray}]) Column index array.
- **proj** ([\texttt{numpy.ndarray}]) Interpolation coefficients.

Returns

- **numpy.ndarray** Interpolation matrix.

scipy.linalg.interpolative.reconstruct_skel_matrix

scipy.linalg.interpolative.reconstruct_skel_matrix(A, k, idx)

Reconstruct skeleton matrix from ID.

The skeleton matrix can be reconstructed from the original matrix $A$ and its ID rank and indices $k$ and $idx$, respectively, as:

$$B = A[:, idx[:k]]$$

The original matrix can then be reconstructed via:

$$\text{numpy.hstack}([B, \text{numpy.dot}(B, \text{proj})])[::\text{numpy.argsort}(idx)]$$
See also `reconstruct_matrix_from_id` and `reconstruct_interp_matrix`.

**Parameters**

- `k` [int] Rank of ID.
- `idx` [numpy.ndarray] Column index array.

**Returns**

- `numpy.ndarray` Skeleton matrix.

```python
scipy.linalg.interpolative.id_to_svd

scipy.linalg.interpolative.id_to_svd(B, idx, proj)

Convert ID to SVD.

The SVD reconstruction of a matrix with skeleton matrix $B$ and ID indices and coefficients $idx$ and $proj$, respectively, is:

```python
U, S, V = id_to_svd(B, idx, proj)
A = numpy.dot(U, numpy.dot(numpy.diag(S), V.conj().T))
```

See also `svd`.

**Parameters**

- `idx` [numpy.ndarray] Column index array.
- `proj` [numpy.ndarray] Interpolation coefficients.

**Returns**

- `U` [numpy.ndarray] Left singular vectors.
- `S` [numpy.ndarray] Singular values.
- `V` [numpy.ndarray] Right singular vectors.

```python
scipy.linalg.interpolative.svd

scipy.linalg.interpolative.svd(A, eps_or_k, rand=True)

Compute SVD of a matrix via an ID.

An SVD of a matrix $A$ is a factorization:

```python
A = numpy.dot(U, numpy.dot(numpy.diag(S), V.conj().T))
```

where $U$ and $V$ have orthonormal columns and $S$ is nonnegative.

The SVD can be computed to any relative precision or rank (depending on the value of $eps_or_k$).

See also `interp_decomp` and `id_to_svd`.

**Parameters**

- `A` [numpy.ndarray or scipy.sparse.linalg.LinearOperator] Matrix to be factored, given as either a `numpy.ndarray` or a `scipy.sparse.linalg.LinearOperator` with the `matvec` and `rmatvec` methods (to apply the matrix and its adjoint).
- `eps_or_k` [float or int] Relative error (if $eps_or_k < 1$) or rank (if $eps_or_k >= 1$) of approximation.
- `rand` [bool, optional] Whether to use random sampling if $A$ is of type `numpy.ndarray` (randomized algorithms are always used if $A$ is of type `scipy.sparse.linalg.LinearOperator`).
Returns

U [numpy.ndarray] Left singular vectors.
S [numpy.ndarray] Singular values.
V [numpy.ndarray] Right singular vectors.

scipy.linalg.interpolative.estimate_spectral_norm

scipy.linalg.interpolative.estimate_spectral_norm(A, its=20)
Estimates spectral norm of a matrix by the randomized power method.

Parameters

A [scipy.sparse.linalg.LinearOperator] Matrix given as a scipy.sparse.linalg.LinearOperator with the matvec and rmatvec methods (to apply the matrix and its adjoint).
its [int, optional] Number of power method iterations.

Returns

float Spectral norm estimate.

scipy.linalg.interpolative.estimate_spectral_norm_diff

scipy.linalg.interpolative.estimate_spectral_norm_diff(A, B, its=20)
Estimates spectral norm of the difference of two matrices by the randomized power method.

Parameters

A [scipy.sparse.linalg.LinearOperator] First matrix given as a scipy.sparse.linalg.LinearOperator with the matvec and rmatvec methods (to apply the matrix and its adjoint).
B [scipy.sparse.linalg.LinearOperator] Second matrix given as a scipy.sparse.linalg.LinearOperator with the matvec and rmatvec methods (to apply the matrix and its adjoint).
its [int, optional] Number of power method iterations.

Returns

float Spectral norm estimate of matrix difference.

scipy.linalg.interpolative.estimate_rank

scipy.linalg.interpolative.estimate_rank(A, eps)
Estimates matrix rank to a specified relative precision using randomized methods.

The matrix A can be given as either a numpy.ndarray or a scipy.sparse.linalg.LinearOperator, with different algorithms used for each case. If A is of type numpy.ndarray, then the output rank is typically about 8 higher than the actual numerical rank.

Parameters

A [numpy.ndarray or scipy.sparse.linalg.LinearOperator] Matrix whose rank is to be estimated, given as either a numpy.ndarray or a scipy.sparse.linalg.LinearOperator with the rmatvec method (to apply the matrix adjoint).
eps [float] Relative error for numerical rank definition.

Returns

int Estimated matrix rank.

Support functions:
**SciPy Reference Guide, Release 1.8.0**

<table>
<thead>
<tr>
<th><code>seed([seed])</code></th>
<th>Seed the internal random number generator used in this ID package.</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>rand(*shape)</code></td>
<td>Generate standard uniform pseudorandom numbers via a very efficient lagged Fibonacci method.</td>
</tr>
</tbody>
</table>

**scipy.linalg.interpolative.seed**

`scipy.linalg.interpolative.seed(seed=None)`

Seed the internal random number generator used in this ID package.

The generator is a lagged Fibonacci method with 55-element internal state.

**Parameters**

- `seed` ([int, sequence, ‘default’, optional] If ‘default’, the random seed is reset to a default value. If `seed` is a sequence containing 55 floating-point numbers in range [0, 1], these are used to set the internal state of the generator. If the value is an integer, the internal state is obtained from `numpy.random.RandomState` (MT19937) with the integer used as the initial seed. If `seed` is omitted (None), `numpy.random.rand` is used to initialize the generator.

**scipy.linalg.interpolative.rand**

`scipy.linalg.interpolative.rand(*shape)`

Generate standard uniform pseudorandom numbers via a very efficient lagged Fibonacci method.

This routine is used for all random number generation in this package and can affect ID and SVD results.

**Parameters**

- `shape` Shape of output array

**References**

This module uses the ID software package [R5a82238cdab4-1] by Martinsson, Rokhlin, Shkolnisky, and Tygert, which is a Fortran library for computing IDs using various algorithms, including the rank-revealing QR approach of [R5a82238cdab4-2] and the more recent randomized methods described in [R5a82238cdab4-3], [R5a82238cdab4-4], and [R5a82238cdab4-5]. This module exposes its functionality in a way convenient for Python users. Note that this module does not add any functionality beyond that of organizing a simpler and more consistent interface.

We advise the user to consult also the documentation for the ID package.

**Tutorial**

**Initializing**

The first step is to import `scipy.linalg.interpolative` by issuing the command:

```bash
>>> import scipy.linalg.interpolative as sli
```

Now let’s build a matrix. For this, we consider a Hilbert matrix, which is well know to have low rank:

```python
>>> from scipy.linalg import hilbert
>>> n = 1000
>>> A = hilbert(n)
```

We can also do this explicitly via:
```python
>>> import numpy as np
>>> n = 1000
>>> A = np.empty((n, n), order='F')
>>> for j in range(n):
...    for i in range(m):
...        A[i,j] = 1. / (i + j + 1)
```

Note the use of the flag `order='F'` in `numpy.empty`. This instantiates the matrix in Fortran-contiguous order and is important for avoiding data copying when passing to the backend.

We then define multiplication routines for the matrix by regarding it as a `scipy.sparse.linalg.LinearOperator`:

```python
>>> from scipy.sparse.linalg import aslinearoperator
>>> L = aslinearoperator(A)
```

This automatically sets up methods describing the action of the matrix and its adjoint on a vector.

### Computing an ID

We have several choices of algorithm to compute an ID. These fall largely according to two dichotomies:

1. how the matrix is represented, i.e., via its entries or via its action on a vector; and
2. whether to approximate it to a fixed relative precision or to a fixed rank.

We step through each choice in turn below.

In all cases, the ID is represented by three parameters:

1. a rank \( k \);
2. an index array \( \text{idx} \); and
3. interpolation coefficients \( \text{proj} \).

The ID is specified by the relation \( \text{np.dot}(A[:, \text{idx}[k:]], \text{proj}) = A[:, \text{idx}[k:]] \).

### From matrix entries

We first consider a matrix given in terms of its entries.

To compute an ID to a fixed precision, type:

```python
>>> k, idx, proj = sli.interp_decomp(A, eps)
```

where \( \text{eps} < 1 \) is the desired precision.

To compute an ID to a fixed rank, use:

```python
>>> idx, proj = sli.interp_decomp(A, k)
```

where \( k \geq 1 \) is the desired rank.

Both algorithms use random sampling and are usually faster than the corresponding older, deterministic algorithms, which can be accessed via the commands:

```python
>>> k, idx, proj = sli.interp_decomp(A, eps, rand=False)
```

and:

3.3. API definition
>>> idx, proj = sli.interp_decomp(A, k, rand=False)

respectively.

From matrix action

Now consider a matrix given in terms of its action on a vector as a `scipy.sparse.linalg.LinearOperator`.

To compute an ID to a fixed precision, type:

```python
>>> k, idx, proj = sli.interp_decomp(L, eps)
```

To compute an ID to a fixed rank, use:

```python
>>> idx, proj = sli.interp_decomp(L, k)
```

These algorithms are randomized.

Reconstructing an ID

The ID routines above do not output the skeleton and interpolation matrices explicitly but instead return the relevant information in a more compact (and sometimes more useful) form. To build these matrices, write:

```python
>>> B = sli.reconstruct_skel_matrix(A, k, idx)
```

for the skeleton matrix and:

```python
>>> P = sli.reconstruct_interp_matrix(idx, proj)
```

for the interpolation matrix. The ID approximation can then be computed as:

```python
>>> C = np.dot(B, P)
```

This can also be constructed directly using:

```python
>>> C = sli.reconstruct_matrix_from_id(B, idx, proj)
```

without having to first compute \( P \).

Alternatively, this can be done explicitly as well using:

```python
>>> B = A[:,idx[:k]]
>>> P = np.hstack([np.eye(k), proj])[:,np.argsort(idx)]
>>> C = np.dot(B, P)
```

Computing an SVD

An ID can be converted to an SVD via the command:

```python
>>> U, S, V = sli.id_to_svd(B, idx, proj)
```

The SVD approximation is then:

```python
>>> C = np.dot(U, np.dot(np.diag(S), np.dot(V.conj().T)))
```
The SVD can also be computed “fresh” by combining both the ID and conversion steps into one command. Following the various ID algorithms above, there are correspondingly various SVD algorithms that one can employ.

From matrix entries

We consider first SVD algorithms for a matrix given in terms of its entries.

To compute an SVD to a fixed precision, type:

```
>>> U, S, V = sli.svd(A, eps)
```

To compute an SVD to a fixed rank, use:

```
>>> U, S, V = sli.svd(A, k)
```

Both algorithms use random sampling; for the deterministic versions, issue the keyword `rand=False` as above.

From matrix action

Now consider a matrix given in terms of its action on a vector.

To compute an SVD to a fixed precision, type:

```
>>> U, S, V = sli.svd(L, eps)
```

To compute an SVD to a fixed rank, use:

```
>>> U, S, V = sli.svd(L, k)
```

Utility routines

Several utility routines are also available.

To estimate the spectral norm of a matrix, use:

```
>>> snorm = sli.estimate_spectral_norm(A)
```

This algorithm is based on the randomized power method and thus requires only matrix-vector products. The number of iterations to take can be set using the keyword `its` (default: `its=20`). The matrix is interpreted as a `scipy.sparse.linalg.LinearOperator`, but it is also valid to supply it as a `numpy.ndarray`, in which case it is trivially converted using `scipy.sparse.linalg.aslinearoperator`.

The same algorithm can also estimate the spectral norm of the difference of two matrices $A_1$ and $A_2$ as follows:

```
>>> diff = sli.estimate_spectral_norm_diff(A1, A2)
```

This is often useful for checking the accuracy of a matrix approximation.

Some routines in `scipy.linalg.interpolative` require estimating the rank of a matrix as well. This can be done with either:

```
>>> k = sli.estimate_rank(A, eps)
```

or:
>>> k = sli.estimate_rank(L, eps)

depending on the representation. The parameter \texttt{eps} controls the definition of the numerical rank.

Finally, the random number generation required for all randomized routines can be controlled via \texttt{scipy.linalg.interpolative.seed}. To reset the seed values to their original values, use:

```python
>>> sli.seed('default')
```

To specify the seed values, use:

```python
>>> sli.seed(s)
```

where \texttt{s} must be an integer or array of 55 floats. If an integer, the array of floats is obtained by using \texttt{numpy.random.rand} with the given integer seed.

To simply generate some random numbers, type:

```python
>>> sli.rand(n)
```

where \texttt{n} is the number of random numbers to generate.

**Remarks**

The above functions all automatically detect the appropriate interface and work with both real and complex data types, passing input arguments to the proper backend routine.

### 3.3.16 Miscellaneous routines (scipy.misc)

Various utilities that don’t have another home.

<table>
<thead>

**scipy.misc.ascent**

\texttt{scipy.misc.ascent()}  
Get an 8-bit grayscale bit-depth, 512 x 512 derived image for easy use in demos

The image is derived from \texttt{accent-to-the-top.jpg} at \url{http://www.public-domain-image.com/people-public-domain-images-pictures/}

**Parameters**

- None

**Returns**

- \texttt{ascent} [ndarray] convenient image to use for testing and demonstration
```python
>>> import scipy.misc
>>> ascent = scipy.misc.ascent()
>>> ascent.shape
(512, 512)
>>> ascent.max()
255

>>> import matplotlib.pyplot as plt
>>> plt.gray()
>>> plt.imshow(ascent)
>>> plt.show()
```

### scipy.misc.central_diff_weights

**scipy.misc.central_diff_weights** (*Np, ndiv=1*)

Return weights for an Np-point central derivative.

Assumes equally-spaced function points.

If weights are in the vector w, then derivative is \( w[0] * f(x-h_0*\text{dx}) + \ldots + w[-1] * f(x+h_0*\text{dx}) \)

**Parameters**

- **Np** [int] Number of points for the central derivative.
- **ndiv** [int, optional] Number of divisions. Default is 1.

**Returns**

Notes

Can be inaccurate for a large number of points.

References

[1]

Examples

We can calculate a derivative value of a function.

```python
>>> from scipy.misc import central_diff_weights
>>> def f(x):
...     return 2 * x**2 + 3
>>> x = 3.0  # derivative point
>>> h = 0.1  # differential step
>>> Np = 3   # point number for central derivative
>>> weights = central_diff_weights(Np)  # weights for first derivative
>>> vals = [f(x + (i - Np/2) * h) for i in range(Np)]
>>> sum(w * v for (w, v) in zip(weights, vals)) / h
11.79999999999998
```

This value is close to the analytical solution: f'(x) = 4x, so f'(3) = 12

**scipy.misc.derivative**

`scipy.misc.derivative(func, x0, dx=1.0, n=1, args=(), order=3)`

Find the nth derivative of a function at a point.

Given a function, use a central difference formula with spacing `dx` to compute the nth derivative at `x0`.

**Parameters**

- `func` [function] Input function.
- `x0` [float] The point at which the nth derivative is found.
- `dx` [float, optional] Spacing.
- `n` [int, optional] Order of the derivative. Default is 1.
- `args` [tuple, optional] Arguments
- `order` [int, optional] Number of points to use, must be odd.

**Notes**

Decreasing the step size too small can result in round-off error.
Examples

```python
>>> from scipy.misc import derivative
>>> def f(x):
...     return x**3 + x**2
>>> derivative(f, 1.0, dx=1e-6)
4.9999999999217337
```

**scipy.misc.face**

`scipy.misc.face(gray=False)`

Get a 1024 x 768, color image of a raccoon face.

raccoon-procyon-lotor.jpg at http://www.public-domain-image.com

**Parameters**

- `gray` [bool, optional] If True return 8-bit grey-scale image, otherwise return a color image

**Returns**

- `face` [ndarray] image of a raccoon face

Examples

```python
>>> import scipy.misc
>>> face = scipy.misc.face()
>>> face.shape
(768, 1024, 3)
>>> face.max()
255
>>> face.dtype
dtype('uint8')
```

```python
>>> import matplotlib.pyplot as plt
>>> plt.gray()
>>> plt.imshow(face)
>>> plt.show()
```

**scipy.misc.electrocardiogram**

`scipy.misc.electrocardiogram()`

Load an electrocardiogram as an example for a 1-D signal.

The returned signal is a 5 minute long electrocardiogram (ECG), a medical recording of the heart’s electrical activity, sampled at 360 Hz.

**Returns**

- `ecg` [ndarray] The electrocardiogram in millivolt (mV) sampled at 360 Hz.
Notes

The provided signal is an excerpt (19:35 to 24:35) from the record 208 (lead MLII) provided by the MIT-BIH Arrhythmia Database [1] on PhysioNet [2]. The excerpt includes noise induced artifacts, typical heartbeats as well as pathological changes.

New in version 1.1.0.

References

[1], [2]

Examples

```python
>>> from scipy.misc import electrocardiogram
>>> ecg = electrocardiogram()
>>> ecg
array([-0.245, -0.215, -0.185, ..., -0.405, -0.395, -0.385])
>>> ecg.shape, ecg.mean(), ecg.std()
((108000,), -0.16510875, 0.5992473991177294)
```

As stated the signal features several areas with a different morphology. E.g., the first few seconds show the electrical activity of a heart in normal sinus rhythm as seen below.

```python
>>> import matplotlib.pyplot as plt
>>> fs = 360
>>> time = np.arange(ecg.size) / fs
>>> plt.plot(time, ecg)
>>> plt.xlabel("time in s")
>>> plt.ylabel("ECG in mV")
>>> plt.xlim(9, 10.2)
>>> plt.ylim(-1, 1.5)
>>> plt.show()
```
After second 16, however, the first premature ventricular contractions, also called extrasystoles, appear. These have a different morphology compared to typical heartbeats. The difference can easily be observed in the following plot.

```python
>>> plt.plot(time, ecg)
>>> plt.xlabel("time in s")
>>> plt.ylabel("ECG in mV")
>>> plt.xlim(46.5, 50)
>>> plt.ylim(-2, 1.5)
>>> plt.show()
```

At several points large artifacts disturb the recording, e.g.:

```python
>>> plt.plot(time, ecg)
>>> plt.xlabel("time in s")
>>> plt.ylabel("ECG in mV")
```
Finally, examining the power spectrum reveals that most of the biosignal is made up of lower frequencies. At 60 Hz the noise induced by the mains electricity can be clearly observed.

```python
>>> from scipy.signal import welch
>>> f, Pxx = welch(ecg, fs=fs, nperseg=2048, scaling="spectrum")
>>> plt.plot(f, Pxx)
>>> plt.xlabel("Frequency in Hz")
>>> plt.ylabel("Power spectrum of the ECG in mV**2")
>>> plt.xlim(f[[0, -1]])
>>> plt.show()
```
### 3.3.17 Multidimensional image processing (scipy.ndimage)

This package contains various functions for multidimensional image processing.

**scipy.ndimage.convolve**

`scipy.ndimage.convolve (input, weights, output=None, mode='reflect', cval=0.0, origin=0)`

Multidimensional convolution.

The array is convolved with the given kernel.

**Parameters**

- **input** [array_like] The input array.
- **weights** [array_like] Array of weights, same number of dimensions as input.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘reflect’. Behavior for each valid value is as follows:
'reflect' (d c b a | a b c d | d c b a)
   The input is extended by reflecting about the edge of the last pixel. This mode
   is also sometimes referred to as half-sample symmetric.

'constant' (k k k k | a b c d | k k k k)
   The input is extended by filling all values beyond the edge with the same constant
   value, defined by the cval parameter.

'nearest' (a a a a | a b c d | d d d d)
   The input is extended by replicating the last pixel.

'mirror' (d c b | a b c d | c b a)
   The input is extended by reflecting about the center of the last pixel. This mode
   is also sometimes referred to as whole-sample symmetric.

'wrap' (a b c d | a b c d | a b c d)
   The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

'grid-mirror'
   This is a synonym for 'reflect'.

'grid-constant'
   This is a synonym for 'constant'.

'grid-wrap'
   This is a synonym for 'wrap'.

cval [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0
origin [int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A
   value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter
to the left, and negative ones to the right. By passing a sequence of origins with length equal
to the number of dimensions of the input array, different shifts can be specified along each
axis.

Returns

result [ndarray] The result of convolution of input with weights.

See also:

correlate
   Correlate an image with a kernel.

Notes

Each value in result is \( C_i = \sum_j I_{i+k-j} W_j \), where \( W \) is the weights kernel, \( j \) is the N-D spatial index over \( W \), \( I \) is
   the input and \( k \) is the coordinate of the center of \( W \), specified by origin in the input parameters.

Examples

Perhaps the simplest case to understand is mode='constant', cval=0.0, because in this case borders (i.e.,
where the weights kernel, centered on any one value, extends beyond an edge of input) are treated as zeros.

```python
>>> a = np.array([[1, 2, 0, 0],
                ... [5, 3, 0, 4],
                ... [0, 0, 0, 7],
                ... [9, 3, 0, 0]])
>>> k = np.array([[1,1],[1,0],[0,0]])
>>> from scipy import ndimage
>>> ndimage.convolve(a, k, mode='constant', cval=0.0)
```
(continues on next page)
array(
    [[11, 10, 7, 4],
     [10, 3, 11, 11],
     [15, 12, 14, 7],
     [12, 3, 7, 0]]
)

Setting cval=1.0 is equivalent to padding the outer edge of input with 1.0's (and then extracting only the original region of the result).

```python
>>> ndimage.convolve(a, k, mode='constant', cval=1.0)
array(
    [[13, 11, 8, 7],
     [11, 3, 11, 14],
     [16, 12, 14, 10],
     [15, 6, 10, 5]]
)
```

With mode='reflect' (the default), outer values are reflected at the edge of input to fill in missing values.

```python
>>> b = np.array([[2, 0, 0],
                 ... [1, 0, 0],
                 ... [0, 0, 0]])
>>> k = np.array([[0, 1, 0],
                ... [0, 1, 0],
                ... [0, 1, 0]])
>>> ndimage.convolve(b, k, mode='reflect')
array(
    [[5, 0, 0],
     [3, 0, 0],
     [1, 0, 0]])
```

This includes diagonally at the corners.

```python
>>> k = np.array([[1,0,0],[0,1,0],[0,0,1]])
>>> ndimage.convolve(b, k)
array(
    [[4, 2, 0],
     [3, 2, 0],
     [1, 1, 0]])
```

With mode='nearest', the single nearest value in to an edge in input is repeated as many times as needed to match the overlapping weights.

```python
>>> c = np.array([[2, 0, 1],
                 ... [1, 0, 0],
                 ... [0, 0, 0]])
>>> k = np.array([[0, 1, 0],
                ... [0, 1, 0],
                ... [0, 1, 0],
                ... [0, 1, 0],
                ... [0, 1, 0]])
>>> ndimage.convolve(c, k, mode='nearest')
array(
    [[7, 0, 3],
     [5, 0, 2],
     [3, 0, 1]])
```
scipy.ndimage.convolve1d

**scipy.ndimage.convolve1d** *(input, weights, axis=-1, output=None, mode='reflect', cval=0.0, origin=0)*

Calculate a 1-D convolution along the given axis.

The lines of the array along the given axis are convolved with the given weights.

**Parameters**

<table>

<td>[int, optional] Controls the placement of the filter on the input array's pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right.</td>
</tr>
</tbody>
</table>

**Returns**

**convolve1d**

[ndarray] Convolved array with same shape as input
Examples

```python
>>> from scipy.ndimage import convolve1d
>>> convolve1d([2, 8, 0, 4, 1, 9, 9, 0], weights=[1, 3])
array([14, 24,  4, 13, 12, 36, 27,  0])
```

`scipy.ndimage.correlate`

`scipy.ndimage.correlate` (input, weights, output=None, mode='reflect', cval=0.0, origin=0)

Multidimensional correlation.

The array is correlated with the given kernel.

**Parameters**

- **input** [array_like] The input array.
- **weights** [ndarray] array of weights, same number of dimensions as input
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** ['reflect', 'constant', 'nearest', 'mirror', 'wrap'], optional] The `mode` parameter determines how the input array is extended beyond its boundaries. Default is 'reflect'. Behavior for each valid value is as follows:
  - **reflect** (d c b a \mid a b c d \mid d c b a)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - **constant** (k k k k \mid a b c d \mid k k k k)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
  - **nearest** (a a a a \mid a b c d \mid d d d d)
    The input is extended by replicating the last pixel.
  - **mirror** (d c b \mid a b c d \mid c b a)
    The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - **wrap** (a b c d \mid a b c d \mid a b c d)
    The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:
- **grid-mirror**
  This is a synonym for 'reflect'.
- **grid-constant**
  This is a synonym for 'constant'.
- **grid-wrap**
  This is a synonym for 'wrap'.

- **cval** [scalar, optional] Value to fill past edges of input if `mode` is 'constant'. Default is 0.0.
- **origin** [int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

**Returns**

- **result** [ndarray] The result of correlation of `input` with `weights`.

See also:
**convolve**

Convolve an image with a kernel.

**Examples**

Correlation is the process of moving a filter mask often referred to as kernel over the image and computing the sum of products at each location.

```python
>>> from scipy.ndimage import correlate
>>> input_img = np.arange(25).reshape(5,5)
>>> print(input_img)
[[ 0  1  2  3  4]
 [ 5  6  7  8  9]
 [10 11 12 13 14]
 [15 16 17 18 19]
 [20 21 22 23 24]]
```

Define a kernel (weights) for correlation. In this example, it is for sum of center and up, down, left and right next elements.

```python
>>> weights = [[0, 1, 0],
             ..., [1, 1, 1],
             ..., [0, 1, 0]]
```

We can calculate a correlation result: For example, element [2,2] is $7 + 11 + 12 + 13 + 17 = 60$.

```python
>>> correlate(input_img, weights)
array([[ 6, 10, 15, 20, 24],
       [ 26, 30, 35, 40, 44],
       [ 51, 55, 60, 65, 69],
       [ 76, 80, 85, 90, 94],
       [ 96, 100, 105, 110, 114]])
```

**scipy.ndimage.correlate1d**

*scipy.ndimage.correlate1d*(input, weights, axis=-1, output=None, mode='reflect', cval=0.0, origin=0)

Calculate a 1-D correlation along the given axis.

The lines of the array along the given axis are correlated with the given weights.

**Parameters**

- **input** [array_like] The input array.
- **weights** [array] 1-D sequence of numbers.
- **axis** [int, optional] The axis of input along which to calculate. Default is -1.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is 'reflect'. Behavior for each valid value is as follows:
  - **‘reflect’** (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.

- **nearest** (a a a a | a b c d | d d d d)
  The input is extended by replicating the last pixel.

- **mirror** (d c b | a b c d | c b a)
  The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

- **wrap** (a b c d | a b c d | a b c d)
  The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

- **grid-mirror**
  This is a synonym for ‘reflect’.

- **grid-constant**
  This is a synonym for ‘constant’.

- **grid-wrap**
  This is a synonym for ‘wrap’.

**Examples**

```python
>>> from scipy.ndimage import correlate1d
>>> correlate1d([2, 8, 0, 4, 1, 9, 9, 0], weights=[1, 3])
array([ 8, 26, 8, 12, 7, 28, 36, 9])
```

**scipy.ndimage.gaussian_filter**

Multidimensional Gaussian filter.

**Parameters**

- **input** [array_like] The input array.
- **sigma** [scalar or sequence of scalars] Standard deviation for Gaussian kernel. The standard deviations of the Gaussian filter are given for each axis as a sequence, or as a single number, in which case it is equal for all axes.
- **order** [int or sequence of ints, optional] The order of the filter along each axis is given as a sequence of integers, or as a single number. An order of 0 corresponds to convolution with a Gaussian kernel. A positive order corresponds to convolution with that derivative of a Gaussian.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [str or sequence, optional] The `mode` parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:
  - **reflect** (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

`constant` \((k\ k\ k\ |\ a\ b\ c\ d\ |\ k\ k\ k\)\)

The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.

`nearest` \((a\ a\ a\ |\ a\ b\ c\ d\ |\ d\ d\ d\)\)

The input is extended by replicating the last pixel.

`mirror` \((d\ c\ b\ |\ a\ b\ c\ d\ |\ c\ b\ a\)\)

The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

`wrap` \((a\ b\ c\ d\ |\ a\ b\ c\ d\ |\ a\ b\ c\ d\)\)

The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

`grid-constant`

This is a synonym for ‘constant’.

`grid-mirror`

This is a synonym for ‘reflect’.

`grid-wrap`

This is a synonym for ‘wrap’.

`cval` [scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0.

`truncate` [float] Truncate the filter at this many standard deviations. Default is 4.0.

Returns

gaussian_filter

```
[ndarray] Returned array of same shape as input.
```

Notes

The multidimensional filter is implemented as a sequence of 1-D convolution filters. The intermediate arrays are stored in the same data type as the output. Therefore, for output types with a limited precision, the results may be imprecise because intermediate results may be stored with insufficient precision.

Examples

```python
>>> from scipy.ndimage import gaussian_filter
>>> a = np.arange(50, step=2).reshape((5, 5))
>>> a
array([[ 0,  2,  4,  6,  8],
       [10, 12, 14, 16, 18],
       [20, 22, 24, 26, 28],
       [30, 32, 34, 36, 38],
       [40, 42, 44, 46, 48]])
>>> gaussian_filter(a, sigma=1)
array([[ 4,  6,  8,  9, 11],
       [10, 12, 14, 15, 17],
       [20, 22, 24, 25, 27],
       [29, 31, 33, 34, 36],
       [35, 37, 39, 40, 42]])
```
```python
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = gaussian_filter(ascent, sigma=5)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```

---

**scipy.ndimage.gaussian_filter1d**

`scipy.ndimage.gaussian_filter1d(input, sigma, axis=-1, order=0, output=None, mode='reflect', cval=0.0, truncate=4.0)`

1-D Gaussian filter.

**Parameters**

- `input` ([array_like]) The input array.
- `sigma` ([scalar]) Standard deviation for Gaussian kernel.
- `axis` ([int, optional]) The axis of `input` along which to calculate. Default is `-1`.
- `order` ([int, optional]) An order of 0 corresponds to convolution with a Gaussian kernel. A positive order corresponds to convolution with that derivative of a Gaussian.
- `output` ([array or dtype, optional]) The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as `input` will be created.
- `mode` ([{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional]) The `mode` parameter determines how the input array is extended beyond its boundaries. Default is 'reflect'. Behavior for each valid value is as follows:
  - **reflect** (`d c b a | a b c d | d c b a`)  
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - **constant** (`k k k k | a b c d | k k k k`)  
    The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
  - **nearest** (`a a a a | a b c d | d d d d`)  
    The input is extended by replicating the last pixel.
'mirror' (d c b \ a b c d \ c b a)
    The input is extended by reflecting about the center of the last pixel. This mode
    is also sometimes referred to as whole-sample symmetric.

'wrap' (a b c d \ a b c d \ a b c d)
    The input is extended by wrapping around to the opposite edge.
For consistency with the interpolation functions, the following mode names can also be used:

'grid-mirror'
    This is a synonym for 'reflect'.

'grid-constant'
    This is a synonym for 'constant'.

'grid-wrap'
    This is a synonym for 'wrap'.

```
cval     [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
truncated [float, optional] Truncate the filter at this many standard deviations. Default is 4.0.
```

**Returns**

gaussian_filter1d
    [ndarray]

**Examples**

```python
>>> from scipy.ndimage import gaussian_filter1d
>>> gaussian_filter1d([1.0, 2.0, 3.0, 4.0, 5.0], 1)
array([ 1.42704095, 2.06782203, 3. , 3.93217797, 4.57295905])
>>> gaussian_filter1d([1.0, 2.0, 3.0, 4.0, 5.0], 4)
array([ 2.91948343, 2.95023502, 3. , 3.04976498, 3.08051657])
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
>>> x = rng.standard_normal(101).cumsum()
>>> y3 = gaussian_filter1d(x, 3)
>>> y6 = gaussian_filter1d(x, 6)
>>> plt.plot(x, 'k', label='original data')
>>> plt.plot(y3, '--', label='filtered, sigma=3')
>>> plt.plot(y6, ':', label='filtered, sigma=6')
>>> plt.legend()
>>> plt.grid()
>>> plt.show()
```

scipy.ndimage.gaussian_gradient_magnitude

```
scipy.ndimage.gaussian_gradient_magnitude (input, sigma, output=None, mode='reflect', cval=0.0,
**kwargs)
```

Multidimensional gradient magnitude using Gaussian derivatives.

**Parameters**

- **input**
  - [array_like] The input array.

- **sigma**
  - [scalar or sequence of scalars] The standard deviations of the Gaussian filter are given for each axis as a sequence, or as a single number, in which case it is equal for all axes.

- **output**
  - [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

- **mode**
  - [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the
number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:

- ‘reflect’ (*d* *c* *b* *a* | *a* *b* *c* *d* | *d* *c* *b* *a*)
  The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

- ‘constant’ (*k* *k* *k* *k* | *a* *b* *c* *d* | *k* *k* *k* *k*)
  The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.

- ‘nearest’ (*a* *a* *a* *a* | *a* *b* *c* *d* | *d* *d* *d* *d*)
  The input is extended by replicating the last pixel.

- ‘mirror’ (*d* *c* *b* | *a* *b* *c* *d* | *c* *b* *a*)
  The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

- ‘wrap’ (*a* *b* *c* *d* | *a* *b* *c* *d* | *a* *b* *c* *d*)
  The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

- ‘grid-constant’
  This is a synonym for ‘constant’.

- ‘grid-mirror’
  This is a synonym for ‘reflect’.

- ‘grid-wrap’
  This is a synonym for ‘wrap’.

`cval` [scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0.

Extra keyword arguments will be passed to `gaussian_filter()`.

**Returns**

- `gaussian_gradient_magnitude` [ndarray] Filtered array. Has the same shape as `input`.
Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.gaussian_gradient_magnitude(ascent, sigma=5)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```

scipy.ndimage.gaussian_laplace

scipy.ndimage.gaussian_laplace(input, sigma, output=None, mode='reflect', cval=0.0, **kwargs)

Multidimensional Laplace filter using Gaussian second derivatives.

**Parameters**

- **input** [array_like] The input array.
- **sigma** [scalar or sequence of scalars] The standard deviations of the Gaussian filter are given for each axis as a sequence, or as a single number, in which case it is equal for all axes.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:
  - **‘reflect’** (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - **‘constant’** (k k k | a b c d | k k k k)

![](image.png)
The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.

- **‘nearest’** (a a a a | a b c d | d d d d)
  - The input is extended by replicating the last pixel.

- **‘mirror’** (d c b | a b c d | c b a)
  - The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

- **‘wrap’** (a b c d | a b c d | a b c d)
  - The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

- **‘grid-constant’**
  - This is a synonym for ‘constant’.

- **‘grid-mirror’**
  - This is a synonym for ‘reflect’.

- **‘grid-wrap’**
  - This is a synonym for ‘wrap’.

- **`cval`** [scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0.

Extra keyword arguments will be passed to `gaussian_filter()`.

### Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> ascent = misc.ascent()

>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side

>>> result = ndimage.gaussian_laplace(ascent, sigma=1)
>>> ax1.imshow(result)

>>> result = ndimage.gaussian_laplace(ascent, sigma=3)
>>> ax2.imshow(result)
>>> plt.show()
```

#### scipy.ndimage.generic_filter

`scipy.ndimage.generic_filter(input, function, size=None, footprint=None, output=None, mode='reflect', cval=0.0, origin=0, extra_arguments=(), extra_keywords=None)`

Calculate a multidimensional filter using the given function.

At each element the provided function is called. The input values within the filter footprint at that element are passed to the function as a 1-D array of double values.

**Parameters**

- **input** [array_like] The input array.
- **function** [[callable, scipy.LowLevelCallable]] Function to apply at each element.
- **size** [scalar or tuple, optional] See footprint, below. Ignored if footprint is given.
- **footprint** [array, optional] Either size or footprint must be defined. size gives the shape that is taken from the input array, at every element position, to define the input to the filter function. footprint is a boolean array that specifies (implicitly) a shape, but also which of the elements
within this shape will get passed to the filter function. Thus size=(n,m) is equivalent to footprint=np.ones((n,m)). We adjust size to the number of dimensions of the input array, so that, if the input array is shape (10,10,10), and size is 2, then the actual size used is (2,2,2). When footprint is given, size is ignored.

**output**  
[array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

**mode**  
[{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is 'reflect'. Behavior for each valid value is as follows:

- **reflect** (d c b a | a b c d | d c b a)  
The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

- **constant** (k k k k | a b c d | k k k k)  
The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.

- **nearest** (a a a a | a b c d | d d d d)  
The input is extended by replicating the last pixel.

- **mirror** (d c b | a b c d | c b a)  
The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

- **wrap** (a b c d | a b c d | a b c d)  
The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

- **grid-mirror**  
  This is a synonym for ‘reflect’.

- **grid-constant**  
  This is a synonym for ‘constant’.

- **grid-wrap**  
  This is a synonym for ‘wrap’.

**cval**  
[scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

**origin**  
[int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal
to the number of dimensions of the input array, different shifts can be specified along each axis.

extra_arguments
[sequence, optional] Sequence of extra positional arguments to pass to the passed function.

extra_keywords
[dict, optional] Dict of extra keyword arguments to pass to the passed function.

Notes

This function also accepts low-level callback functions with one of the following signatures and wrapped in `scipy.LowLevelCallable`:

```python
int callback(double *buffer, npy_intp filter_size,
             double *return_value, void *user_data)
int callback(double *buffer, intptr_t filter_size,
             double *return_value, void *user_data)
```

The calling function iterates over the elements of the input and output arrays, calling the callback function at each element. The elements within the footprint of the filter at the current element are passed through the `buffer` parameter, and the number of elements within the footprint through `filter_size`. The calculated value is returned in `return_value`. `user_data` is the data pointer provided to `scipy.LowLevelCallable` as-is.

The callback function must return an integer error status that is zero if something went wrong and one otherwise. If an error occurs, you should normally set the python error status with an informative message before returning, otherwise a default error message is set by the calling function.

In addition, some other low-level function pointer specifications are accepted, but these are for backward compatibility only and should not be used in new code.

`scipy.ndimage.generic_filter1d`

`scipy.ndimage.generic_filter1d` can be used to apply a 1-D filter along a given axis.

```python
scipy.ndimage.generic_filter1d(input, function, filter_size, axis=-1, output=None, mode='reflect', cval=0.0, origin=0, extra_arguments=(), extra_keywords=None)
```

Calculate a 1-D filter along the given axis.

`generic_filter1d` iterates over the lines of the array, calling the given function at each line. The arguments of the line are the input line, and the output line. The input and output lines are 1-D double arrays. The input line is extended appropriately according to the filter size and origin. The output line must be modified in-place with the result.

**Parameters**

- `input` [array_like] The input array.
- `function` [{callable, scipy.LowLevelCallable}] Function to apply along given axis.
- `filter_size` [scalar] Length of the filter.
- `axis` [int, optional] The axis of `input` along which to calculate. Default is -1.
- `output` [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- `mode` [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The `mode` parameter determines how the input array is extended beyond its boundaries. Default is ‘reflect’. Behavior for each valid value is as follows:
  - ‘reflect’ (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.

The input is extended by replicating the last pixel.

The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

The input is extended by wrapping around to the opposite edge. For consistency with the interpolation functions, the following mode names can also be used:

This is a synonym for ‘reflect’.

This is a synonym for ‘constant’.

This is a synonym for ‘wrap’.

cval [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

origin [int, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right.

extra_arguments [sequence, optional] Sequence of extra positional arguments to pass to passed function.

extra_keywords [dict, optional] dict of extra keyword arguments to pass to passed function.

Notes

This function also accepts low-level callback functions with one of the following signatures and wrapped in `scipy.LowLevelCallable`:

```c
int function(double *input_line, npy_intp input_length, 
              double *output_line, npy_intp output_length, 
              void *user_data)

int function(double *input_line, intptr_t input_length, 
              double *output_line, intptr_t output_length, 
              void *user_data)
```

The calling function iterates over the lines of the input and output arrays, calling the callback function at each line. The current line is extended according to the border conditions set by the calling function, and the result is copied into the array that is passed through `input_line`. The length of the input line (after extension) is passed through `input_length`. The callback function should apply the filter and store the result in the array passed through `output_line`. The length of the output line is passed through `output_length`. `user_data` is the data pointer provided to `scipy.LowLevelCallable` as-is.

The callback function must return an integer error status that is zero if something went wrong and one otherwise. If an error occurs, you should normally set the python error status with an informative message before returning, otherwise a default error message is set by the calling function.

In addition, some other low-level function pointer specifications are accepted, but these are for backward compatibility only and should not be used in new code.
scipy.ndimage.generic_gradient_magnitude

**scipy.ndimage.generic_gradient_magnitude** *(input, derivative, output=None, mode='reflect', cval=0.0, extra_arguments=(), extra_keywords=None)*

Gradient magnitude using a provided gradient function.

**Parameters**

- **input** [array_like] The input array.
- **derivative** [callable] Callable with the following signature:

  ```
  derivative(input, axis, output, mode, cval, 
  *extra_arguments, **extra_keywords)
  ```

  See `extra_arguments`, `extra_keywords` below. `derivative` can assume that `input` and `output` are ndarrays. Note that the output from `derivative` is modified inplace; be careful to copy important inputs before returning them.

- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

- **mode** [str or sequence, optional] The `mode` parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:
  
  - 'reflect' *(d c b a | a b c d | d c b a)*
    
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

  - 'constant' *(k k k k | a b c d | k k k k)*
    
    The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.

  - 'nearest' *(a a a a | a b c d | d d d d)*
    
    The input is extended by replicating the last pixel.

  - 'mirror' *(d c b | a b c d | c b a)*
    
    The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

  - 'wrap' *(a b c d | a b c d | a b c d)*
    
    The input is extended by wrapping around to the opposite edge.

  For consistency with the interpolation functions, the following mode names can also be used:

  - 'grid-constant'
    
    This is a synonym for 'constant'.

  - 'grid-mirror'
    
    This is a synonym for 'reflect'.

  - 'grid-wrap'
    
    This is a synonym for 'wrap'.

- **cval** [scalar, optional] Value to fill past edges of input if `mode` is 'constant'. Default is 0.0.

- **extra_keywords** [dict, optional] dict of extra keyword arguments to pass to passed function.

- **extra_arguments** [sequence, optional] Sequence of extra positional arguments to pass to passed function.
**scipy.ndimage.generic_laplace**

`scipy.ndimage.generic_laplace(input, derivative2, output=None, mode='reflect', cval=0.0, extra_arguments=(), extra_keywords=None)`

N-D Laplace filter using a provided second derivative function.

**Parameters**

- `input` [array_like] The input array.
- `derivative2` [callable] Callable with the following signature:
  ```python
derivative2(input, axis, output, mode, cval, *extra_arguments, **extra_keywords)
```
  See `extra_arguments`, `extra_keywords` below.
- `output` [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- `mode` [str or sequence, optional] The `mode` parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:
  - ‘reflect’ (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - ‘constant’ (k k k k | a b c d | k k k k)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
  - ‘nearest’ (a a a a | a b c d | d d d d)
    The input is extended by replicating the last pixel.
  - ‘mirror’ (d c b | a b c d | c b a)
    The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - ‘wrap’ (a b c d | a b c d | a b c d)
    The input is extended by wrapping around to the opposite edge.
  For consistency with the interpolation functions, the following mode names can also be used:
  - ‘grid-constant’
    This is a synonym for ‘constant’.
  - ‘grid-mirror’
    This is a synonym for ‘reflect’.
  - ‘grid-wrap’
    This is a synonym for ‘wrap’.
- `cval` [scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0.
- `extra_keywords` [dict, optional] dict of extra keyword arguments to pass to passed function.
- `extra_arguments` [sequence, optional] Sequence of extra positional arguments to pass to passed function.
scipy.ndimage.laplace

scipy.ndimage.laplace(input, output=None, mode='reflect', cval=0.0)

N-D Laplace filter based on approximate second derivatives.

**Parameters**

- **input** [array_like] The input array.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:
  - 'reflect' (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - 'constant' (k k k k | a b c d | k k k k)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - 'nearest' (a a a a | a b c d | d d d d)
    The input is extended by replicating the last pixel.
  - 'mirror' (d c b a | a b c d | c b a)
    The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - 'wrap' (a b c d | a b c d | a b c d)
    The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:
- 'grid-constant'
  This is a synonym for 'constant'.
- 'grid-mirror'
  This is a synonym for 'reflect'.
- 'grid-wrap'
  This is a synonym for 'wrap'.
- **cval** [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.

**Examples**

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.laplace(ascent)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```
**scipy.ndimage.maximum_filter**

`scipy.ndimage.maximum_filter(input, size=None, footprint=None, output=None, mode='reflect', cval=0.0, origin=0)`

Calculate a multidimensional maximum filter.

**Parameters**

- `input` [array_like] The input array.
- `size` [scalar or tuple, optional] See footprint, below. Ignored if footprint is given.
- `footprint` [array, optional] Either `size` or `footprint` must be defined. `size` gives the shape that is taken from the input array, at every element position, to define the input to the filter function. `footprint` is a boolean array that specifies (implicitly) a shape, but also which of the elements within this shape will get passed to the filter function. Thus `size=(n,m)` is equivalent to `footprint=np.ones((n,m))`. We adjust `size` to the number of dimensions of the input array, so that, if the input array is shape `(10,10,10)`, and `size` is 2, then the actual size used is `(2,2,2)`. When `footprint` is given, `size` is ignored.
- `output` [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- `mode` [str or sequence, optional] The `mode` parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:
  - `'reflect'` (d b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - `'constant'` (k k k k | a b c d | k k k k)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
  - `'nearest'` (a a a a | a b c d | d d d d)
    The input is extended by replicating the last pixel.
  - `'mirror'` (d c b | a b c d | c b a)
    The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - `'wrap'` (a b c d | a b c d | a b c d)
    The input is extended by wrapping around to the opposite edge.
For consistency with the interpolation functions, the following mode names can also be used:

- **grid-constant**
  - This is a synonym for ‘constant’.
- **grid-mirror**
  - This is a synonym for ‘reflect’.
- **grid-wrap**
  - This is a synonym for ‘wrap’.

**cval**
- [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

**origin**
- [int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

**Returns**

- **maximum_filter**
  - [ndarray] Filtered array. Has the same shape as input.

**Notes**

A sequence of modes (one per axis) is only supported when the footprint is separable. Otherwise, a single mode string must be provided.

**Examples**

```python
>>> from scipy import ndimage, misc
generate a test image

>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(121) # left side
>>> asct = misc.ascent()
>>> result = ndimage.maximum_filter(asct, size=20)
>>> ax1.imshow(asct)
>>> ax2.imshow(result)
>>> plt.show()
```

**scipy.ndimage.maximum_filter1d**

`scipy.ndimage.maximum_filter1d(input, size, axis=-1, output=None, mode='reflect', cval=0.0, origin=0)`

Calculate a 1-D maximum filter along the given axis.

The lines of the array along the given axis are filtered with a maximum filter of given size.

**Parameters**

- **input**
  - [array_like] The input array.
- **size**
  - [int] Length along which to calculate the 1-D maximum.
- **axis**
  - [int, optional] The axis of input along which to calculate. Default is -1.
- **output**
  - [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode**
  - [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘reflect’. Behavior for each valid value is as follows:
The `maximum1d` function takes an input array and applies a maximum filter to it. This filter is used to enhance edges and details in the image. The function can be applied in 2D or 3D, and it supports various modes of boundary treatment:

- **'reflect'** \((d c b a | a b c d | d c b a)\)
  The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

- **'constant'** \((k k k k | a b c d | k k k k)\)
  The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.

- **'nearest'** \((a a a a | a b c d | d d d d)\)
  The input is extended by replicating the last pixel.

- **'mirror'** \((d c b | a b c d | c b a)\)
  The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

- **'wrap'** \((a b c d | a b c d | a b c d)\)
  The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

- **'grid-mirror'**
  This is a synonym for 'reflect'.

- **'grid-constant'**
  This is a synonym for 'constant'.

- **'grid-wrap'**
  This is a synonym for 'wrap'.

- **cval** [scalar, optional] Value to fill past edges of input if `mode` is 'constant'. Default is 0.0.

- **origin** [int, optional] Controls the placement of the filter on the input array's pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right.

**Returns**

- **maximum1d** [ndarray, None] Maximum-filtered array with same shape as input. None if `output` is not provided.
Notes

This function implements the MAXLIST algorithm [1], as described by Richard Harter [2], and has a guaranteed \( O(n) \) performance, \( n \) being the input length, regardless of filter size.

[1], [2]

Examples

```python
>>> from scipy.ndimage import maximum_filter1d
>>> maximum_filter1d([2, 8, 0, 4, 1, 9, 9, 0], size=3)
array([8, 8, 8, 4, 9, 9, 9, 9])
```

scipy.ndimage.median_filter

scipy.ndimage.median_filter (input, size=None, footprint=None, output=None, mode='reflect', cval=0.0, origin=0)

Calculate a multidimensional median filter.

Parameters

- **input** [array_like] The input array.
- **size** [scalar or tuple, optional] See footprint, below. Ignored if footprint is given.
- **footprint** [array, optional] Either size or footprint must be defined. size gives the shape that is taken from the input array, at every element position, to define the input to the filter function. footprint is a boolean array that specifies (implicitly) a shape, but also which of the elements within this shape will get passed to the filter function. Thus size=(n,m) is equivalent to footprint=np.ones((n,m)). We adjust size to the number of dimensions of the input array, so that, if the input array is shape (10,10,10), and size is 2, then the actual size used is (2,2,2). When footprint is given, size is ignored.
- **output** [array or dtypes, optional] The array in which to place the output, or the dtypes of the returned array. By default an array of the same dtype as input will be created.
- **mode** [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘reflect’. Behavior for each valid value is as follows:

  - ‘reflect’ (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - ‘constant’ (k k k k | a b c d | k k k k)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - ‘nearest’ (a a a a | a b c d | d d d d)
    The input is extended by replicating the last pixel.
  - ‘mirror’ (d c b | a b c d | c b a)
    The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - ‘wrap’ (a b c d | a b c d | a b c d)
    The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

  - ‘grid-mirror’
    This is a synonym for ‘reflect’.
`grid-constant`  
This is a synonym for ‘constant’.

`grid-wrap`  
This is a synonym for ‘wrap’.

cval  
[scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0.

origin  
[int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

Returns  

median_filter  
[ndarray] Filtered array. Has the same shape as `input`.

`scipy.signal.medfilt2d`

Notes  

For 2-dimensional images with `uint8`, `float32` or `float64` dtypes the specialised function `scipy.signal.medfilt2d` may be faster. It is however limited to constant mode with `cval=0`.

Examples  

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.median_filter(ascent, size=20)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```
input array, so that, if the input array is shape (10,10,10), and size is 2, then the actual size used is (2,2,2). When footprint is given, size is ignored.

output [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

mode [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:

‘reflect’ (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

‘constant’ (k k k k | a b c d | k k k k)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.

‘nearest’ (a a a a | a b c d | d d d d)
    The input is extended by replicating the last pixel.

‘mirror’ (d c b | a b c d | c b a)
    The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

‘wrap’ (a b c d | a b c d | a b c d)
    The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

‘grid-constant’
    This is a synonym for ‘constant’.

‘grid-mirror’
    This is a synonym for ‘reflect’.

‘grid-wrap’
    This is a synonym for ‘wrap’.

cval [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

origin [int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.
Returns

minimum_filter

[array] Filtered array. Has the same shape as input.

Notes

A sequence of modes (one per axis) is only supported when the footprint is separable. Otherwise, a single mode string must be provided.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.minimum_filter(ascent, size=20)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```
scipy.ndimage.minimum_filter1d

`scipy.ndimage.minimum_filter1d(input, size, axis=-1, output=None, mode='reflect', cval=0.0, origin=0)`

Calculate a 1-D minimum filter along the given axis.

The lines of the array along the given axis are filtered with a minimum filter of given size.

**Parameters**

- `input` [array_like] The input array.
- `size` [int] Length along which to calculate 1D minimum
- `axis` [int, optional] The axis of `input` along which to calculate. Default is -1.
- `output` [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- `mode` [{‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’}, optional] The `mode` parameter determines how the input array is extended beyond its boundaries. Default is ‘reflect’. Behavior for each valid value is as follows:
  - ‘reflect’ (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - ‘constant’ (k k k k | a b c d | k k k k)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
  - ‘nearest’ (a a a a | a b c d | d d d d)
    The input is extended by replicating the last pixel.
  - ‘mirror’ (d c b | a b c d | c b a)
    The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - ‘wrap’ (a b c d | a b c d | a b c d)
    The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:
- ‘grid-mirror’
  This is a synonym for ‘reflect’.
- ‘grid-constant’
  This is a synonym for ‘constant’.
- ‘grid-wrap’
  This is a synonym for ‘wrap’.
- `cval` [scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0.
- `origin` [int, optional] Controls the placement of the filter on the input array's pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right.

**Notes**

This function implements the MINLIST algorithm [1], as described by Richard Harter [2], and has a guaranteed O(n) performance, n being the `input` length, regardless of filter size.
scipy.ndimage.percentile_filter

scipy.ndimage.percentile_filter(input, percentile, size=None, footprint=None, output=None, mode='reflect', cval=0.0, origin=0)
