Calculate a multidimensional percentile filter.

Parameters

- **input** [array_like] The input array.
- **percentile** [scalar] The percentile parameter may be less than zero, i.e., percentile = -20 equals percentile = 80
- **size** [scalar or tuple, optional] See footprint, below. Ignored if footprint is given.
- **footprint** [array, optional] Either size or footprint must be defined. size gives the shape that is taken from the input array, at every element position, to define the input to the filter function. footprint is a boolean array that specifies (implicitly) a shape, but also which of the elements within this shape will get passed to the filter function. Thus size=(n,m) is equivalent to footprint=np.ones((n,m)). We adjust size to the number of dimensions of the input array, so that, if the input array is shape (10,10,10), and size is 2, then the actual size used is (2,2,2). When footprint is given, size is ignored.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘reflect’. Behavior for each valid value is as follows:
  - ‘reflect’ (d c b a | a b c d | d c b a)
    - The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - ‘constant’ (k k k k | a b c d | k k k k)
    - The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - ‘nearest’ (a a a a | a b c d | d d d d)
    - The input is extended by replicating the last pixel.
  - ‘mirror’ (d c b | a b c d | c b a)
    - The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - ‘wrap’ (a b c d | a b c d | a b c d)
    - The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:
- **grid-mirror**
  - This is a synonym for ‘reflect’.
- **grid-constant**
  - This is a synonym for ‘constant’.
- **grid-wrap**
  - This is a synonym for ‘wrap’.
**cval**
[scalar, optional] Value to fill past edges of input if *mode* is ‘constant’. Default is 0.0.

**origin**
[int or sequence, optional] Controls the placement of the filter on the input array's pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

**Returns**

**percentile_filter**

[ndarray] Filtered array. Has the same shape as *input*.

**Examples**

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.percentile_filter(ascent, percentile=20, size=20)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```
Calculate a Prewitt filter.

Parameters

- **input** [array_like] The input array.
- **axis** [int, optional] The axis of `input` along which to calculate. Default is -1.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [str or sequence, optional] The `mode` parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is ‘reflect’. The valid values and their behavior is as follows:
  - ‘reflect’ (*d c b a | a b c d | d c b a*)
    - The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - ‘constant’ (*k k k k | a b c d | k k k k*)
    - The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
  - ‘nearest’ (*a a a a | a b c d | d d d d*)
    - The input is extended by replicating the last pixel.
  - ‘mirror’ (*d c b | a b c d | c b a*)
    - The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - ‘wrap’ (*a b c d | a b c d | a b c d*)
    - The input is extended by wrapping around to the opposite edge.
For consistency with the interpolation functions, the following mode names can also be used:
  - ‘grid-constant’
    - This is a synonym for ‘constant’.
  - ‘grid-mirror’
    - This is a synonym for ‘reflect’.
  - ‘grid-wrap’
    - This is a synonym for ‘wrap’.
- **cval** [scalar, optional] Value to fill past edges of input if `mode` is ‘constant’. Default is 0.0.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.prewitt(ascent)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```
scipy.ndimage.rank_filter

scipy.ndimage.rank_filter(input, rank, size=None, footprint=None, output=None, mode='reflect', cval=0.0, origin=0)

Calculate a multidimensional rank filter.

Parameters

input [array_like] The input array.
rank [int] The rank parameter may be less then zero, i.e., rank = -1 indicates the largest element.
size [scalar or tuple, optional] See footprint, below. Ignored if footprint is given.
footprint [array, optional] Either size or footprint must be defined. size gives the shape that is taken from the input array, at every element position, to define the input to the filter function. footprint is a boolean array that specifies (implicitly) a shape, but also which of the elements within this shape will get passed to the filter function. Thus size=(n,m) is equivalent to footprint=np.ones((n,m)). We adjust size to the number of dimensions of the input array, so that, if the input array is shape (10,10,10), and size is 2, then the actual size used is (2,2,2). When footprint is given, size is ignored.
output [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
mode [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘reflect’. Behavior for each valid value is as follows:

‘reflect’ (d c b a \mid a b c d \mid d c b a)
The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

‘constant’ (k k k k \mid a b c d \mid k k k k)
The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.

‘nearest’ (a a a a \mid a b c d \mid d d d d)
The input is extended by replicating the last pixel.

‘mirror’ (d c b \mid a b c d \mid c b a)
The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

‘wrap’ (a b c d \mid a b c d \mid a b c d)
The input is extended by wrapping around to the opposite edge.
For consistency with the interpolation functions, the following mode names can also be used:

‘grid-mirror’
This is a synonym for ‘reflect’.

‘grid-constant’
This is a synonym for ‘constant’.

‘grid-wrap’
This is a synonym for ‘wrap’.

cval [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.
origin [int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

Returns

rank_filter [ndarray] Filtered array. Has the same shape as input.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.rank_filter(ascent, rank=42, size=20)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```
scipy.ndimage.sobel

scipy.ndimage.sobel(input, axis=-1, output=None, mode='reflect', cval=0.0)

Calculate a Sobel filter.

Parameters

- **input** [array_like] The input array.
- **axis** [int, optional] The axis of input along which to calculate. Default is -1.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **mode** [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:
  - **reflect** (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - **constant** (k k k k | a b c d | k k k k)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.
  - **nearest** (a a a a | a b c d | d d d d)
    The input is extended by replicating the last pixel.
  - **mirror** (d c b | a b c d | c b a)
    The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - **wrap** (a b c d | a b c d | a b c d)
    The input is extended by wrapping around to the opposite edge.
For consistency with the interpolation functions, the following mode names can also be used:
  - **grid-constant**
    This is a synonym for 'constant'.
  - **grid-mirror**
    This is a synonym for 'reflect'.
  - **grid-wrap**
    This is a synonym for 'wrap'.
- **cval** [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.sobel(ascent)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```
scipy.ndimage.uniform_filter

scipy.ndimage.uniform_filter (input, size=3, output=None, mode='reflect', cval=0.0, origin=0)

Multidimensional uniform filter.

Parameters

input [array_like] The input array.

size [int or sequence of ints, optional] The sizes of the uniform filter are given for each axis as a sequence, or as a single number, in which case the size is equal for all axes.

output [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

mode [str or sequence, optional] The mode parameter determines how the input array is extended when the filter overlaps a border. By passing a sequence of modes with length equal to the number of dimensions of the input array, different modes can be specified along each axis. Default value is 'reflect'. The valid values and their behavior is as follows:

- 'reflect' (d c b a | a b c d | d c b a)
  The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

- 'constant' (k k k k | a b c d | k k k k)
  The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter.

- 'nearest' (a a a a | a b c d | d d d d)
  The input is extended by replicating the last pixel.

- 'mirror' (d c b | a b c d | c b a)
  The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

- 'wrap' (a b c d | a b c d | a b c d)
  The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

- 'grid-constant'
  This is a synonym for 'constant'.

- 'grid-mirror'
  This is a synonym for 'reflect'.

- 'grid-wrap'
  This is a synonym for 'wrap'.
cval  [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

origin  [int or sequence, optional] Controls the placement of the filter on the input array’s pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right. By passing a sequence of origins with length equal to the number of dimensions of the input array, different shifts can be specified along each axis.

Returns
uniform_filter
[ndarray] Filtered array. Has the same shape as input.

Notes
The multidimensional filter is implemented as a sequence of 1-D uniform filters. The intermediate arrays are stored in the same data type as the output. Therefore, for output types with a limited precision, the results may be imprecise because intermediate results may be stored with insufficient precision.

Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.gray()  # show the filtered result in grayscale
>>> ax1 = fig.add_subplot(121)  # left side
>>> ax2 = fig.add_subplot(122)  # right side
>>> ascent = misc.ascent()
>>> result = ndimage.uniform_filter(ascent, size=20)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result)
>>> plt.show()
```

---

3.3. API definition

1189
scipy.ndimage.uniform_filter1d

scipy.ndimage.uniform_filter1d(input, size=1, axis=-1, output=None, mode='reflect', cval=0.0, origin=0)

Calculate a 1-D uniform filter along the given axis.

The lines of the array along the given axis are filtered with a uniform filter of given size.

**Parameters**

- `input` ([array_like]) The input array.
- `size` [int] length of uniform filter
- `axis` [int, optional] The axis of `input` along which to calculate. Default is -1.
- `output` [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- `mode` [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The `mode` parameter determines how the input array is extended beyond its boundaries. Default is 'reflect'. Behavior for each valid value is as follows:
  - 'reflect' (d c b a | a b c d | d c b a)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - 'constant' (k k k k | a b c d | k k k k)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter.
  - 'nearest' (a a a a | a b c d | d d d d)
    The input is extended by replicating the last pixel.
  - 'mirror' (d c b | a b c d | c b a)
    The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
  - 'wrap' (a b c d | a b c d | a b c d)
    The input is extended by wrapping around to the opposite edge.

For consistency with the interpolation functions, the following mode names can also be used:

- 'grid-mirror'
  This is a synonym for 'reflect'.
- 'grid-constant'
  This is a synonym for 'constant'.
- 'grid-wrap'
  This is a synonym for 'wrap'.

- `cval` [scalar, optional] Value to fill past edges of input if `mode` is 'constant'. Default is 0.0.
- `origin` [int, optional] Controls the placement of the filter on the input array's pixels. A value of 0 (the default) centers the filter over the pixel, with positive values shifting the filter to the left, and negative ones to the right.

**Examples**

```python
>>> from scipy.ndimage import uniform_filter1d
>>> uniform_filter1d([2, 8, 0, 4, 1, 9, 9, 0], size=3)
array([4, 3, 4, 1, 4, 6, 6, 3])
```
Fourier filters

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>

<td>Multidimensional Fourier shift filter.</td>
</tr>
<tr>
<td><code>fourier_uniform</code></td>
<td>Multidimensional uniform fourier filter.</td>
</tr>
</tbody>
</table>

**scipy.ndimage.fourier_ellipsoid**

The array is multiplied with the fourier transform of an ellipsoid of given sizes.

**Parameters**

- `input` [array_like]: The input array.
- `size` [float or sequence]: The size of the box used for filtering. If a float, `size` is the same for all axes. If a sequence, `size` has to contain one value for each axis.
- `n` [int, optional]: If `n` is negative (default), then the input is assumed to be the result of a complex fft. If `n` is larger than or equal to zero, the input is assumed to be the result of a real fft, and `n` gives the length of the array before transformation along the real transform direction.
- `axis` [int, optional]: The axis of the real transform.
- `output` [ndarray, optional]: If given, the result of filtering the input is placed in this array. None is returned in this case.

**Returns**

- `fourier_ellipsoid` [ndarray]: The filtered input.

**Notes**

This function is implemented for arrays of rank 1, 2, or 3.

**Examples**

```python
>>> from scipy import ndimage, misc
>>> import numpy.fft
>>> import matplotlib.pyplot as plt
>>> fig, (ax1, ax2) = plt.subplots(1, 2)
>>> plt.gray() # show the filtered result in grayscale
>>> ascent = misc.ascent()
>>> input_ = numpy.fft.fft2(ascent)
>>> result = ndimage.fourier_ellipsoid(input_, size=20)
>>> result = numpy.fft.ifft2(result)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result.real) # the imaginary part is an artifact
>>> plt.show()
```
scipy.ndimage.fourier_gaussian

scipy.ndimage.fourier_gaussian(input, sigma, n=-1, axis=-1, output=None)

Multidimensional Gaussian fourier filter.

The array is multiplied with the fourier transform of a Gaussian kernel.

Parameters

- **input** [array_like] The input array.
- **sigma** [float or sequence] The sigma of the Gaussian kernel. If a float, sigma is the same for all axes. If a sequence, sigma has to contain one value for each axis.
- **n** [int, optional] If n is negative (default), then the input is assumed to be the result of a complex fft. If n is larger than or equal to zero, the input is assumed to be the result of a real fft, and n gives the length of the array before transformation along the real transform direction.
- **axis** [int, optional] The axis of the real transform.
- **output** [ndarray, optional] If given, the result of filtering the input is placed in this array. None is returned in this case.

Returns

fourier_gaussian [ndarray] The filtered input.

Examples

```python
>>> from scipy import ndimage, misc
>>> import numpy.fft
>>> import matplotlib.pyplot as plt
>>> fig, (ax1, ax2) = plt.subplots(1, 2)
>>> plt.gray()  # show the filtered result in grayscale
>>> ascent = misc.ascent()
>>> input_ = numpy.fft.fft2(ascent)
>>> result = ndimage.fourier_gaussian(input_, sigma=4)
>>> result = numpy.fft.ifft2(result)
```

(continues on next page)
scipy.ndimage.fourier_shift

scipy.ndimage.fourier_shift(input, shift, n=-1, axis=-1, output=None)
Multidimensional Fourier shift filter.

The array is multiplied with the Fourier transform of a shift operation.

Parameters

- **input** [array_like] The input array.
- **shift** [float or sequence] The size of the box used for filtering. If a float, `shift` is the same for all axes. If a sequence, `shift` has to contain one value for each axis.
- **n** [int, optional] If `n` is negative (default), then the input is assumed to be the result of a complex fft. If `n` is larger than or equal to zero, the input is assumed to be the result of a real fft, and `n` gives the length of the array before transformation along the real transform direction.
- **axis** [int, optional] The axis of the real transform.
- **output** [ndarray, optional] If given, the result of shifting the input is placed in this array. None is returned in this case.

Returns

- **fourier_shift** [ndarray] The shifted input.
Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> import numpy.fft

>>> fig, (ax1, ax2) = plt.subplots(1, 2)
>>> plt.gray()  # show the filtered result in grayscale
>>> ascent = misc.ascent()
>>> input_ = numpy.fft.fft2(ascent)
>>> result = ndimage.fourier_shift(input_, shift=200)
>>> result = numpy.fft.ifft2(result)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result.real)  # the imaginary part is an artifact
>>> plt.show()
```

scipy.ndimage.fourier_uniform

scipy.ndimage.fourier_uniform(input, size, n=-1, axis=-1, output=None)

Multidimensional uniform fourier filter.

The array is multiplied with the Fourier transform of a box of given size.

**Parameters**

- `input` [array_like] The input array.
- `size` [float or sequence] The size of the box used for filtering. If a float, `size` is the same for all axes. If a sequence, `size` has to contain one value for each axis.
- `n` [int, optional] If n is negative (default), then the input is assumed to be the result of a complex fft. If n is larger than or equal to zero, the input is assumed to be the result of a real fft, and `n` gives the length of the array before transformation along the real transform direction.
- `axis` [int, optional] The axis of the real transform.
- `output` [ndarray, optional] If given, the result of filtering the input is placed in this array. None is returned in this case.

**Returns**
fourier_uniform
[ndarray] The filtered input.

Examples

```python
>>> from scipy import ndimage, misc
>>> import numpy.fft
>>> import matplotlib.pyplot as plt
>>> fig, (ax1, ax2) = plt.subplots(1, 2)
>>> plt.gray()  # show the filtered result in grayscale
>>> ascent = misc.ascent()
>>> input_ = numpy.fft.fft2(ascent)
>>> result = ndimage.fourier_uniform(input_, size=20)
>>> result = numpy.fft.ifft2(result)
>>> ax1.imshow(ascent)
>>> ax2.imshow(result.real)  # the imaginary part is an artifact
>>> plt.show()
```

</tbody>
</table>
scipy.ndimage.affine_transform

scipy.ndimage.affine_transform(input, matrix, offset=0.0, output_shape=None, output=None, order=3, mode='constant', cval=0.0, prefilter=True)

Apply an affine transformation.

Given an output image pixel index vector \( \mathbf{o} \), the pixel value is determined from the input image at position
\[
\text{np.dot(matrix, } \mathbf{o} \text{) + offset}.
\]

This does ‘pull’ (or ‘backward’) resampling, transforming the output space to the input to locate data. Affine transformations are often described in the ‘push’ (or ‘forward’) direction, transforming input to output. If you have a matrix for the ‘push’ transformation, use its inverse (numpy.linalg.inv) in this function.

**Parameters**

- **input** [array_like] The input array.
- **matrix** [ndarray] The inverse coordinate transformation matrix, mapping output coordinates to input coordinates. If \( \text{ndim} \) is the number of dimensions of \( \text{input} \), the given matrix must have one of the following shapes:
  - \((\text{ndim}, \text{ndim})\): the linear transformation matrix for each output coordinate.
  - \((\text{ndim},)\): assume that the 2-D transformation matrix is diagonal, with the diagonal specified by the given value. A more efficient algorithm is then used that exploits the separability of the problem.
  - \((\text{ndim} + 1, \text{ndim} + 1)\): assume that the transformation is specified using homogeneous coordinates [1]. In this case, any value passed to \text{offset} is ignored.
  - \((\text{ndim}, \text{ndim} + 1)\): as above, but the bottom row of a homogeneous transformation matrix is always \([0, 0, \ldots, 1]\), and may be omitted.
- **offset** [float or sequence, optional] The offset into the array where the transform is applied. If a float, \text{offset} is the same for each axis. If a sequence, \text{offset} should contain one value for each axis.
- **output_shape** [tuple of ints, optional] Shape tuple.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **order** [int, optional] The order of the spline interpolation, default is 3. The order has to be in the range 0-5.
- **mode** ['reflect', 'grid-mirror', 'constant', 'grid-constant', 'nearest', 'mirror', 'grid-wrap', 'wrap'], optional] The \text{mode} parameter determines how the input array is extended beyond its boundaries. Default is 'constant'. Behavior for each valid value is as follows (see additional plots and details on boundary modes):
  - **reflect** \((d \quad c \quad b \quad a \quad | \quad a \quad b \quad c \quad d \quad | \quad d \quad c \quad b \quad a)\)
    The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
  - **grid-mirror**
    This is a synonym for 'reflect'.
  - **constant** \((k \quad k \quad k \quad | \quad a \quad b \quad c \quad d \quad | \quad k \quad k \quad k \quad k)\)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the \text{cval} parameter. No interpolation is performed beyond the edges of the input.
  - **grid-constant** \((k \quad k \quad k \quad | \quad a \quad b \quad c \quad d \quad | \quad k \quad k \quad k \quad)\)
    The input is extended by filling all values beyond the edge with the same constant value, defined by the \text{cval} parameter. Interpolation occurs for samples outside the input’s extent as well.
The input is extended by replicating the last pixel.

- **'mirror'** (d c b | a b c d | c b a)
  The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

- **'grid-wrap'** (a b c d | a b c d | a b c d)
  The input is extended by wrapping around to the opposite edge.

- **'wrap'** (d b c d | a b c d | b c a b)
  The input is extended by wrapping around to the opposite edge, but in a way such that the last point and initial point exactly overlap. In this case it is not well defined which sample will be chosen at the point of overlap.

**cval** [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.

**prefilter** [bool, optional] Determines if the input array is prefiltered with `spline_filter` before interpolation. The default is True, which will create a temporary `float64` array of filtered values if order > 1. If setting this to False, the output will be slightly blurred if order > 1, unless the input is prefiltered, i.e. it is the result of calling `spline_filter` on the original input.

**Returns**

- affine_transform [ndarray] The transformed input.

**Notes**

The given matrix and offset are used to find for each point in the output the corresponding coordinates in the input by an affine transformation. The value of the input at those coordinates is determined by spline interpolation of the requested order. Points outside the boundaries of the input are filled according to the given mode.

Changed in version 0.18.0: Previously, the exact interpretation of the affine transformation depended on whether the matrix was supplied as a 1-D or a 2-D array. If a 1-D array was supplied to the matrix parameter, the output pixel value at index \( o \) was determined from the input image at position \( \text{matrix} \times (o + \text{offset}) \).

For complex-valued input, this function transforms the real and imaginary components independently.

New in version 1.6.0: Complex-valued support added.

**References**

[1]

`scipy.ndimage.geometric_transform`

`scipy.ndimage.geometric_transform(input, mapping, output_shape=None, output=None, order=3, mode='constant', cval=0.0, prefilter=True, extra_arguments=(), extra_keywords={})`

Apply an arbitrary geometric transform.

The given mapping function is used to find, for each point in the output, the corresponding coordinates in the input. The value of the input at those coordinates is determined by spline interpolation of the requested order.

**Parameters**

- input [array_like] The input array.
- mapping [{callable, `scipy.LowLevelCallable`}] A callable object that accepts a tuple of length equal to the output array rank, and returns the corresponding input coordinates as a tuple of length equal to the input array rank.
output_shape

tuple of ints, optional] Shape tuple.

output
[array or dtype, optional] The array in which to place the output, or the dtype of the returned
array. By default an array of the same dtype as input will be created.

order
[int, optional] The order of the spline interpolation, default is 3. The order has to be in the
range 0-5.

mode
[['reflect','grid-mirror','constant','grid-constant','nearest','mirror','grid-wrap','wrap'], optional] The mode parameter determines how the input array is extended beyond its bound-
daries. Default is 'constant'. Behavior for each valid value is as follows (see additional plots
and details on boundary modes):

'reflect' (d c b a | a b c d | d c b a)
The input is extended by reflecting about the edge of the last pixel. This mode
is also sometimes referred to as half-sample symmetric.

'grid-mirror'
This is a synonym for 'reflect'.

'constant' (k k k k | a b c d | k k k k)
The input is extended by filling all values beyond the edge with the same constant
value, defined by the cval parameter. No interpolation is performed beyond the
edges of the input.

'grid-constant' (k k k k | a b c d | k k k k)
The input is extended by filling all values beyond the edge with the same constant
value, defined by the cval parameter. Interpolation occurs for samples outside
the input's extent as well.

'nearest' (a a a a | a b c d | d d d d)
The input is extended by replicating the last pixel.

'mirror' (d c b | a b c d | c b a)
The input is extended by reflecting about the center of the last pixel. This mode
is also sometimes referred to as whole-sample symmetric.

'grid-wrap' (a b c d | a b c d | a b c d)
The input is extended by wrapping around to the opposite edge.

'wrap' (d b c d | a b c d | b c a b)
The input is extended by wrapping around to the opposite edge, but in a way
such that the last point and initial point exactly overlap. In this case it is not well
defined which sample will be chosen at the point of overlap.

cval
[scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.

prefilter
[bool, optional] Determines if the input array is prefiltered with spline_filter before
interpolation. The default is True, which will create a temporary float64 array of filtered
values if order > 1. If setting this to False, the output will be slightly blurred if order > 1,
unless the input is prefiltered, i.e., it is the result of calling spline_filter on the original
input.

eextra_arguments
[tuple, optional] Extra arguments passed to mapping.

eextra_keywords
[dict, optional] Extra keywords passed to mapping.

Returns

output [ndarray] The filtered input.

See also:

map_coordinates, affine_transform, spline_filter1d
Notes

This function also accepts low-level callback functions with one the following signatures and wrapped in `scipy.LowLevelCallable`:

```python
int mapping(npy_intp *output_coordinates, double *input_coordinates, int output_rank, int input_rank, void *user_data)
int mapping(intptr_t *output_coordinates, double *input_coordinates, int output_rank, int input_rank, void *user_data)
```

The calling function iterates over the elements of the output array, calling the callback function at each element. The coordinates of the current output element are passed through `output_coordinates`. The callback function must return the coordinates at which the input must be interpolated in `input_coordinates`. The rank of the input and output arrays are given by `input_rank` and `output_rank` respectively. `user_data` is the data pointer provided to `scipy.LowLevelCallable` as-is.

The callback function must return an integer error status that is zero if something went wrong and one otherwise. If an error occurs, you should normally set the Python error status with an informative message before returning, otherwise a default error message is set by the calling function.

In addition, some other low-level function pointer specifications are accepted, but these are for backward compatibility only and should not be used in new code.

For complex-valued `input`, this function transforms the real and imaginary components independently.

New in version 1.6.0: Complex-valued support added.

Examples

```python
>>> import numpy as np
>>> from scipy.ndimage import geometric_transform
>>> a = np.arange(12.).reshape((4, 3))
>>> def shift_func(output_coords):
...     return (output_coords[0] - 0.5, output_coords[1] - 0.5)
...
>>> geometric_transform(a, shift_func)
array([[ 0. , 0. , 0. ],
       [ 0. , 1.362, 2.738],
       [ 0. , 4.812, 6.187],
       [ 0. , 8.263, 9.637]])
>>> b = [1, 2, 3, 4, 5]
>>> def shift_func(output_coords):
...     return (output_coords[0] - 3,)
...
>>> geometric_transform(b, shift_func, mode='constant')
array([0, 0, 0, 1, 2])
>>> geometric_transform(b, shift_func, mode='nearest')
array([1, 1, 1, 1, 2])
>>> geometric_transform(b, shift_func, mode='reflect')
array([3, 2, 1, 1, 2])
>>> geometric_transform(b, shift_func, mode='wrap')
array([2, 3, 4, 1, 2])
```
scipy.ndimage.map_coordinates

**scipy.ndimage.map_coordinates** *(input, coordinates, output=None, order=3, mode='constant', cval=0.0, prefilter=True)*

Map the input array to new coordinates by interpolation.

The array of coordinates is used to find, for each point in the output, the corresponding coordinates in the input. The value of the input at those coordinates is determined by spline interpolation of the requested order.

The shape of the output is derived from that of the coordinate array by dropping the first axis. The values of the array along the first axis are the coordinates in the input array at which the output value is found.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>input</strong></td>
<td>[array_like] The input array.</td>
</tr>
<tr>
<td><strong>coordinates</strong></td>
<td>[array_like] The coordinates at which <strong>input</strong> is evaluated.</td>
</tr>
<tr>
<td><strong>output</strong></td>
<td>[array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.</td>
</tr>
<tr>
<td><strong>order</strong></td>
<td>[int, optional] The order of the spline interpolation, default is 3. The order has to be in the range 0-5.</td>
</tr>
</tbody>
</table>
| **mode** | [{}{'reflect', 'grid-mirror', 'constant', 'grid-constant', 'nearest', 'mirror', 'grid-wrap', 'wrap'}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is 'constant'. Behavior for each valid value is as follows (see additional plots and details on boundary modes):
- **reflect** *(d c b a | a b c d | d c b a)*
  The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.
- **grid-mirror**
  This is a synonym for 'reflect'.
- **constant** *(k k k k | a b c d | k k k k)*
  The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter. No interpolation is performed beyond the edges of the input.
- **grid-constant** *(k k k k | a b c d | k k k k)*
  The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter. Interpolation occurs for samples outside the input’s extent as well.
- **nearest** *(a a a a | a b c d | d d d d)*
  The input is extended by replicating the last pixel.
- **mirror** *(d c b | a b c d | c b a)*
  The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.
- **grid-wrap** *(a b c d | a b c d | a b c d)*
  The input is extended by wrapping around to the opposite edge.
- **wrap** *(d b c d | a b c d | b c a b)*
  The input is extended by wrapping around to the opposite edge, but in a way such that the last point and initial point exactly overlap. In this case it is not well defined which sample will be chosen at the point of overlap. |
| **cval** | [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0. |
| **prefilter** | [bool, optional] Determines if the input array is prefiltered with **spline_filter** before interpolation. The default is True, which will create a temporary float64 array of filtered values if order > 1. If setting this to False, the output will be slightly blurred if order > 1, unless the input is prefiltered, i.e. it is the result of calling **spline_filter** on the original input. |

**Returns**
map_coordinates

[ndarray] The result of transforming the input. The shape of the output is derived from that of coordinates by dropping the first axis.

See also:

spline_filter, geometric_transform, scipy.interpolate

Notes

For complex-valued input, this function maps the real and imaginary components independently.

New in version 1.6.0: Complex-valued support added.

Examples

```python
>>> from scipy import ndimage
>>> a = np.arange(12.).reshape((4, 3))
>>> a
array([[ 0.,  1.,  2.],
       [ 3.,  4.,  5.],
       [ 6.,  7.,  8.],
       [ 9., 10., 11.]])
>>> ndimage.map_coordinates(a, [[0.5, 2], [0.5, 1]], order=1)
array([2., 7.])
```

Above, the interpolated value of a[0.5, 0.5] gives output[0], while a[2, 1] is output[1].

```python
>>> inds = np.array([[0.5, 2], [0.5, 4]])
>>> ndimage.map_coordinates(a, inds, order=1, cval=-33.3)
array([ 2. , -33.3])
>>> ndimage.map_coordinates(a, inds, order=1, mode='nearest')
array([ 2.,  8.])
>>> ndimage.map_coordinates(a, inds, order=1, cval=0, output=bool)
array([ True, False], dtype=bool)
```

scipy.ndimage.rotate

scipy.ndimage.rotate(input, angle, axes=(1, 0), reshape=True, output=None, order=3, mode='constant', cval=0.0, prefilter=True)

Rotate an array.

The array is rotated in the plane defined by the two axes given by the axes parameter using spline interpolation of the requested order.

Parameters

- **input** [array_like] The input array.
- **angle** [float] The rotation angle in degrees.
- **axes** [tuple of 2 ints, optional] The two axes that define the plane of rotation. Default is the first two axes.
- **reshape** [bool, optional] If reshape is true, the output shape is adapted so that the input array is contained completely in the output. Default is True.
- **output** [array or dtye, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
order [int, optional] The order of the spline interpolation, default is 3. The order has to be in the range 0-5.

mode [{‘reflect’, ‘grid-mirror’, ‘constant’, ‘grid-constant’, ‘nearest’, ‘mirror’, ‘grid-wrap’, ‘wrap’}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘constant’. Behavior for each valid value is as follows (see additional plots and details on boundary modes):

‘reflect’ (d c b a | a b c d | d c b a)
   The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

‘grid-mirror’
   This is a synonym for ‘reflect’.

‘constant’ (k k k k | a b c d | k k k k)
   The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter. No interpolation is performed beyond the edges of the input.

‘grid-constant’ (k k k k | a b c d | k k k k)
   The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter. Interpolation occurs for samples outside the input’s extent as well.

‘nearest’ (a a a a | a b c d | d d d d)
   The input is extended by replicating the last pixel.

‘mirror’ (d c b a | a b c d | c b a)
   The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

‘grid-wrap’ (a b c d | a b c d | a b c d)
   The input is extended by wrapping around to the opposite edge.

‘wrap’ (d b c d | a b c d | b c a b)
   The input is extended by wrapping around to the opposite edge, but in a way such that the last point and initial point exactly overlap. In this case it is not well defined which sample will be chosen at the point of overlap.

cval [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

prefilter [bool, optional] Determines if the input array is prefiltered with spline_filter before interpolation. The default is True, which will create a temporary float64 array of filtered values if order > 1. If setting this to False, the output will be slightly blurred if order > 1, unless the input is prefiltered, i.e. it is the result of calling spline_filter on the original input.

Returns

rotate [ndarray] The rotated input.

Notes

For complex-valued input, this function rotates the real and imaginary components independently.

New in version 1.6.0: Complex-valued support added.
Examples

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure(figsize=(10, 3))
>>> ax1, ax2, ax3 = fig.subplots(1, 3)
>>> img = misc.ascent()
>>> img_45 = ndimage.rotate(img, 45, reshape=False)
>>> full_img_45 = ndimage.rotate(img, 45, reshape=True)
>>> ax1.imshow(img, cmap='gray')
>>> ax1.set_axis_off()
>>> ax2.imshow(img_45, cmap='gray')
>>> ax2.set_axis_off()
>>> ax3.imshow(full_img_45, cmap='gray')
>>> ax3.set_axis_off()
>>> fig.set_tight_layout(True)
>>> plt.show()
```

```python
>>> print(img.shape)
(512, 512)
>>> print(img_45.shape)
(512, 512)
>>> print(full_img_45.shape)
(724, 724)
```

### scipy.ndimage.shift

**scipy.ndimage.shift** *(input, shift, output=None, order=3, mode='constant', cval=0.0, prefilter=True)*

Shift an array.

The array is shifted using spline interpolation of the requested order. Points outside the boundaries of the input are filled according to the given mode.

**Parameters**

- **input** [array_like] The input array.
- **shift** [float or sequence] The shift along the axes. If a float, *shift* is the same for each axis. If a sequence, *shift* should contain one value for each axis.
- **output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.
- **order** [int, optional] The order of the spline interpolation, default is 3. The order has to be in the range 0-5.
mode  [[‘reflect’, ‘grid-mirror’, ‘constant’, ‘grid-constant’, ‘nearest’, ‘mirror’, ‘grid-wrap’, ‘wrap’}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is ‘constant’. Behavior for each valid value is as follows (see additional plots and details on boundary modes):

‘reflect’ (d c b a | a b c d | d c b a)
The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

‘grid-mirror’
This is a synonym for ‘reflect’.

‘constant’ (k k k k | a b c d | k k k k)
The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter. No interpolation is performed beyond the edges of the input.

‘grid-constant’ (k k k k | a b c d | k k k k)
The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter. Interpolation occurs for samples outside the input’s extent as well.

‘nearest’ (a a a a | a b c d | d d d d)
The input is extended by replicating the last pixel.

‘mirror’ (d c b | a b c d | c b a)
The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

‘grid-wrap’ (a b c d | a b c d | a b c d)
The input is extended by wrapping around to the opposite edge.

‘wrap’ (d b c d | a b c d | b c a b)
The input is extended by wrapping around to the opposite edge, but in a way such that the last point and initial point exactly overlap. In this case it is not well defined which sample will be chosen at the point of overlap.

cval [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.

prefilter [bool, optional] Determines if the input array is prefiltered with spline_filter before interpolation. The default is True, which will create a temporary float64 array of filtered values if order > 1. If setting this to False, the output will be slightly blurred if order > 1, unless the input is prefiltered, i.e. it is the result of calling spline_filter on the original input.

Returns

shift [ndarray] The shifted input.

Notes

For complex-valued input, this function shifts the real and imaginary components independently.

New in version 1.6.0: Complex-valued support added.
scipy.ndimage.spline_filter

`scipy.ndimage.spline_filter` *(input, order=3, output=<class 'numpy.float64'>, mode='mirror')*

Multidimensional spline filter.

For more details, see `spline_filter1d`.

See also:

`spline_filter1d`

Calculate a 1-D spline filter along the given axis.

Notes

The multidimensional filter is implemented as a sequence of 1-D spline filters. The intermediate arrays are stored in the same data type as the output. Therefore, for output types with a limited precision, the results may be imprecise because intermediate results may be stored with insufficient precision.

For complex-valued `input`, this function processes the real and imaginary components independently.

New in version 1.6.0: Complex-valued support added.

Examples

We can filter an image using multidimensional splines:

```python
>>> from scipy.ndimage import spline_filter
>>> import matplotlib.pyplot as plt
>>> orig_img = np.eye(20)  # create an image
>>> orig_img[10, :] = 1.0
>>> sp_filter = spline_filter(orig_img, order=3)
>>> f, ax = plt.subplots(1, 2, sharex=True)
>>> for ind, data in enumerate([orig_img, "original image"],
...                            [sp_filter, "spline filter"]):
...    ax[ind].imshow(data[0], cmap='gray_r')
...    ax[ind].set_title(data[1])
>>> plt.tight_layout()
>>> plt.show()
```

scipy.ndimage.spline_filter1d

`scipy.ndimage.spline_filter1d` *(input, order=3, axis=-1, output=<class 'numpy.float64'>, mode='mirror')*

Calculate a 1-D spline filter along the given axis.

The lines of the array along the given axis are filtered by a spline filter. The order of the spline must be >= 2 and <= 5.

Parameters

- `input` [array_like] The input array.
- `order` [int, optional] The order of the spline, default is 3.
- `axis` [int, optional] The axis along which the spline filter is applied. Default is the last axis.
- `output` [ndarray or dtype, optional] The array in which to place the output, or the dtype of the returned array. Default is `numpy.float64`.  

3.3. API definition 1205
The `mode` parameter determines how the input array is extended beyond its boundaries. Default is 'mirror'. Behavior for each valid value is as follows (see additional plots and details on boundary modes):

- **'reflect'** \((d c b a | a b c d | d c b a)\)
  The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

- **'grid-mirror'**
  This is a synonym for 'reflect'.

- **'constant'** \((k k k k | a b c d | k k k k)\)
  The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter. No interpolation is performed beyond the edges of the input.

- **'grid-constant'** \((k k k k | a b c d | k k k k)\)
  The input is extended by filling all values beyond the edge with the same constant value, defined by the `cval` parameter. Interpolation occurs for samples outside the input’s extent as well.

- **'nearest'** \((a a a a | a b c d | d d d d)\)
  The input is extended by replicating the last pixel.

- **'mirror'** \((d c b | a b c d | c b a)\)
  The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

- **'grid-wrap'** \((a b c d | a b c d | a b c d)\)
  The input is extended by wrapping around to the opposite edge.

- **'wrap'** \((d b c d | a b c d | b c a b)\)
  The input is extended by wrapping around to the opposite edge, but in a way such that the last point and initial point exactly overlap. In this case it is not well defined which sample will be chosen at the point of overlap.

**Returns**

spline_filter1d

[ndarray] The filtered input.

See also:
**spline_filter**

Multidimensional spline filter.

**Notes**

All of the interpolation functions in *ndimage* do spline interpolation of the input image. If using B-splines of order > 1, the input image values have to be converted to B-spline coefficients first, which is done by applying this 1-D filter sequentially along all axes of the input. All functions that require B-spline coefficients will automatically filter their inputs, a behavior controllable with the `prefilter` keyword argument. For functions that accept a `mode` parameter, the result will only be correct if it matches the `mode` used when filtering.

For complex-valued input, this function processes the real and imaginary components independently.

New in version 1.6.0: Complex-valued support added.

**Examples**

We can filter an image using 1-D spline along the given axis:

```python
>>> from scipy.ndimage import spline_filter1d
>>> import matplotlib.pyplot as plt
>>> orig_img = np.eye(20)  # create an image
>>> orig_img[10, :] = 1.0
>>> sp_filter_axis_0 = spline_filter1d(orig_img, axis=0)
>>> sp_filter_axis_1 = spline_filter1d(orig_img, axis=1)
>>> f, ax = plt.subplots(1, 3, sharex=True)
>>> for ind, data in enumerate([orig_img, "original image"],
                                 [sp_filter_axis_0, "spline filter (axis=0)"],
                                 [sp_filter_axis_1, "spline filter (axis=1)"])):
...    ax[ind].imshow(data[0], cmap='gray_r')
...    ax[ind].set_title(data[1])
>>> plt.tight_layout()
>>> plt.show()
```
scipy.ndimage.zoom

**scipy.ndimage.zoom** *(input, zoom, output=None, order=3, mode='constant', cval=0.0, prefilter=True, *, grid_mode=False)*

Zoom an array.

The array is zoomed using spline interpolation of the requested order.

**Parameters**

**input** [array_like] The input array.

**zoom** [float or sequence] The zoom factor along the axes. If a float, zoom is the same for each axis. If a sequence, zoom should contain one value for each axis.

**output** [array or dtype, optional] The array in which to place the output, or the dtype of the returned array. By default an array of the same dtype as input will be created.

**order** [int, optional] The order of the spline interpolation, default is 3. The order has to be in the range 0-5.

**mode** [{'reflect', 'grid-mirror', 'constant', 'grid-constant', 'nearest', 'mirror', 'grid-wrap', 'wrap'}, optional] The mode parameter determines how the input array is extended beyond its boundaries. Default is 'constant'. Behavior for each valid value is as follows (see additional plots and details on boundary modes):

- **reflect** (d c b a | a b c d | d c b a)
  
The input is extended by reflecting about the edge of the last pixel. This mode is also sometimes referred to as half-sample symmetric.

- **grid-mirror**
  
  This is a synonym for 'reflect'.

- **constant** (k k k k | a b c d | k k k k)
  
The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter. No interpolation is performed beyond the edges of the input.

- **grid-constant** (k k k k | a b c d | k k k k)
  
The input is extended by filling all values beyond the edge with the same constant value, defined by the cval parameter. Interpolation occurs for samples outside the input's extent as well.

- **nearest** (a a a a | a b c d | d d d d)
  
The input is extended by replicating the last pixel.

- **mirror** (d c b | a b c d | c b a)
  
The input is extended by reflecting about the center of the last pixel. This mode is also sometimes referred to as whole-sample symmetric.

- **grid-wrap** (a b c d | a b c d | a b c d)
  
The input is extended by wrapping around to the opposite edge.

- **wrap** (d b c d | a b c d | b c a b)
  
The input is extended by wrapping around to the opposite edge, but in a way such that the last point and initial point exactly overlap. In this case it is not well defined which sample will be chosen at the point of overlap.

**cval** [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.

**prefilter** [bool, optional] Determines if the input array is prefiltered with spline_filter before interpolation. The default is True, which will create a temporary float64 array of filtered values if order > 1. If setting this to False, the output will be slightly blurred if order > 1, unless the input is prefiltered, i.e. it is the result of calling spline_filter on the original input.

**grid_mode** [bool, optional] If False, the distance from the pixel centers is zoomed. Otherwise, the distance including the full pixel extent is used. For example, a 1d signal of length 5 is considered to have length 4 when grid_mode is False, but length 5 when grid_mode is True. See the following visual illustration:
The starting point of the arrow in the diagram above corresponds to coordinate location 0 in each mode.

**Returns**

**zoom** [ndarray] The zoomed input.

**Notes**

For complex-valued `input`, this function zooms the real and imaginary components independently.

New in version 1.6.0: Complex-valued support added.

**Examples**

```python
>>> from scipy import ndimage, misc
>>> import matplotlib.pyplot as plt

>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(121) # left side
>>> ax2 = fig.add_subplot(122) # right side
>>> ascent = misc.ascent()
>>> result = ndimage.zoom(ascent, 3.0)
>>> ax1.imshow(ascent, vmin=0, vmax=255)
>>> ax2.imshow(result, vmin=0, vmax=255)
>>> plt.show()
```
>>> print(ascent.shape)
(512, 512)

>>> print(result.shape)
(1536, 1536)

**scipy.ndimage.center_of_mass**

`scipy.ndimage.center_of_mass(input, labels=None, index=None)`

Calculate the center of mass of the values of an array at labels.

**Parameters**

- **input**  
  [ndarray] Data from which to calculate center-of-mass. The masses can either be positive or negative.
- **labels**  
  [ndarray, optional] Labels for objects in `input`, as generated by `ndimage.label`. Only used with `index`. Dimensions must be the same as `input`.
- **index**  
  [int or sequence of ints, optional] Labels for which to calculate centers-of-mass. If not specified, the combined center of mass of all labels greater than zero will be calculated. Only used with `labels`. 
Returns

center_of_mass  
[tuple, or list of tuples] Coordinates of centers-of-mass.

Examples

```python
>>> a = np.array([[0, 0, 0, 0],
                ...               [0, 1, 1, 0],
                ...               [0, 1, 1, 0],
                ...               [0, 1, 1, 0]])
>>> from scipy import ndimage
>>> ndimage.center_of_mass(a)
(2.0, 1.5)
```

Calculation of multiple objects in an image

```python
>>> b = np.array([[0, 1, 0, 0],
                ...               [0, 0, 0, 0],
                ...               [0, 0, 1, 1],
                ...               [0, 0, 1, 1]])
>>> lbl = ndimage.label(b)[0]
>>> ndimage.center_of_mass(b, lbl, [1, 2])
[(0.33333333333333331, 1.3333333333333333), (3.5, 2.5)]
```

Negative masses are also accepted, which can occur for example when bias is removed from measured data due to random noise.

```python
>>> c = np.array([[-1, 0, 0, 0],
                ...               [0, -1, -1, 0],
                ...               [0, 1, -1, 0],
                ...               [0, 1, 1, 0]])
>>> ndimage.center_of_mass(c)
(-4.0, 1.0)
```

If there are division by zero issues, the function does not raise an error but rather issues a RuntimeWarning before returning inf and/or NaN.

```python
>>> d = np.array([-1, 1])
>>> ndimage.center_of_mass(d)
(inf,)
```

**scipy.ndimage.extrema**

scipy.ndimage.extrema(input, labels=None, index=None)

Calculate the minimums and maximums of the values of an array at labels, along with their positions.

Parameters

- **input** [ndarray] N-D image data to process.
- **labels** [ndarray, optional] Labels of features in input. If not None, must be same shape as input.
- **index** [int or sequence of ints, optional] Labels to include in output. If None (default), all values where non-zero labels are used.

Returns
minimums, maximums
[ int or ndarray] Values of minimums and maximums in each feature.

min_positions, max_positions
[tuple or list of tuples] Each tuple gives the N-D coordinates of the corresponding minimum or maximum.

See also:
maximum, minimum, maximum_position, minimum_position, center_of_mass

Examples

```python
>>> a = np.array([[1, 2, 0, 0],
...                [5, 3, 0, 4],
...                [0, 0, 0, 7],
...                [9, 3, 0, 0]])
>>> from scipy import ndimage
>>> ndimage.extrema(a)
(0, 9, (0, 2), (3, 0))
```

Features to process can be specified using labels and index:

```python
>>> lbl, nlbl = ndimage.label(a)
>>> ndimage.extrema(a, lbl, index=np.arange(1, nlbl+1))
(array([1, 4, 3]),
 array([5, 7, 9]),
 [(0, 0), (1, 3), (3, 1)],
 [(1, 0), (2, 3), (3, 0)])
```

If no index is given, non-zero labels are processed:

```python
>>> ndimage.extrema(a, lbl)
(1, 9, (0, 0), (3, 0))
```

scipy.ndimage.find_objects

scipy.ndimage.find_objects (input, max_label=0)
Find objects in a labeled array.

Parameters

- input [ndarray of ints] Array containing objects defined by different labels. Labels with value 0 are ignored.
- max_label [int, optional] Maximum label to be searched for in input. If max_label is not given, the positions of all objects are returned.

Returns

- object_slices [list of tuples] A list of tuples, with each tuple containing N slices (with N the dimension of the input array). Slices correspond to the minimal parallelepiped that contains the object. If a number is missing, None is returned instead of a slice.

See also:

label, center_of_mass
Notes

This function is very useful for isolating a volume of interest inside a 3-D array, that cannot be “seen through”.

Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((6, 6), dtype=int)
>>> a[2:4, 2:4] = 1
>>> a[4, 4] = 1
>>> a[:, 3] = 2
>>> a[0, 5] = 3
>>> a
array([[2, 2, 2, 0, 0, 3],
       [2, 2, 2, 0, 0, 0],
       [0, 0, 1, 1, 0, 0],
       [0, 0, 1, 1, 0, 0],
       [0, 0, 0, 0, 1, 0],
       [0, 0, 0, 0, 0, 0]])
>>> ndimage.find_objects(a)
[(slice(2, 5, None), slice(2, 5, None)), (slice(0, 2, None), slice(0, 3, None)), (slice(0, 1, None), slice(5, 6, None))]
>>> ndimage.find_objects(a, max_label=2)
[(slice(2, 5, None), slice(2, 5, None)), (slice(0, 2, None), slice(0, 3, None))]
>>> ndimage.find_objects(a == 1, max_label=2)
[(slice(2, 5, None), slice(2, 5, None)), None]
```

```python
>>> loc = ndimage.find_objects(a)[0]
>>> a[loc]
array([[1, 1, 0],
       [1, 1, 0],
       [0, 0, 1]])
```

scipy.ndimage.histogram

`scipy.ndimage.histogram` (`input`, `min`, `max`, `bins`, `labels=None`, `index=None`)  
Calculate the histogram of the values of an array, optionally at labels.

Histogram calculates the frequency of values in an array within bins determined by `min`, `max`, and `bins`. The `labels` and `index` keywords can limit the scope of the histogram to specified sub-regions within the array.

**Parameters**

- `input` : [array_like] Data for which to calculate histogram.
- `min, max` : [int] Minimum and maximum values of range of histogram bins.
- `bins` : [int] Number of bins.
- `labels` : [array_like, optional] Labels for objects in `input`. If not None, must be same shape as `input`.
- `index` : [int or sequence of ints, optional] Label or labels for which to calculate histogram. If None, all values where label is greater than zero are used.

**Returns**

- `hist` : [ndarray] Histogram counts.
Examples

```python
>>> a = np.array([[ 0. , 0.2146, 0.5962, 0. ],
...                 [ 0. , 0.7778, 0. , 0. ],
...                 [ 0. , 0. , 0. , 0. ],
...                 [ 0. , 0. , 0.7181, 0.2787],
...                 [ 0. , 0. , 0.6573, 0.3094]],
...                 ...
>>> from scipy import ndimage
>>> ndimage.histogram(a, 0, 1, 10)
array([13, 0, 2, 1, 0, 1, 1, 2, 0, 0])

With labels and no indices, non-zero elements are counted:

```python
>>> lbl, nlbl = ndimage.label(a)
>>> ndimage.histogram(a, 0, 1, 10, lbl)
array([0, 0, 2, 1, 0, 1, 1, 2, 0, 0])
```

Indices can be used to count only certain objects:

```python
>>> ndimage.histogram(a, 0, 1, 10, lbl, 2)
array([0, 0, 1, 1, 0, 0, 1, 1, 0, 0])
```

scipy.ndimage.label

scipy.ndimage.label(input, structure=None, output=None)

Label features in an array.

Parameters

- **input**: [array_like] An array-like object to be labeled. Any non-zero values in input are counted as features and zero values are considered the background.
- **structure**: [array_like, optional] A structuring element that defines feature connections. structure must be centrosymmetric (see Notes). If no structuring element is provided, one is automatically generated with a squared connectivity equal to one. That is, for a 2-D input array, the default structuring element is:

  ```
  [[0,1,0],
   [1,1,1],
   [0,1,0]]
  ```

- **output**: [(None, data-type, array_like), optional] If output is a data type, it specifies the type of the resulting labeled feature array. If output is an array-like object, then output will be updated with the labeled features from this function. This function can operate in-place, by passing output=input. Note that the output must be able to store the largest label, or this function will raise an Exception.

Returns

- **label**: [ndarray or int] An integer ndarray where each unique feature in input has a unique label in the returned array.
- **num_features**: [int] How many objects were found.

See also:
**find_objects**

generate a list of slices for the labeled features (or objects); useful for finding features’ position or dimensions

**Notes**

A centrosymmetric matrix is a matrix that is symmetric about the center. See [1] for more information.

The *structure* matrix must be centrosymmetric to ensure two-way connections. For instance, if the *structure* matrix is not centrosymmetric and is defined as:

```
[[0,1,0],
 [1,1,0],
 [0,0,0]]
```

and the *input* is:

```
[[1,2],
 [0,3]]
```

then the structure matrix would indicate the entry 2 in the input is connected to 1, but 1 is not connected to 2.

**References**

[1]

**Examples**

Create an image with some features, then label it using the default (cross-shaped) structuring element:

```python
>>> from scipy.ndimage import label, generate_binary_structure
>>> a = np.array([[0,0,1,1,0],[0,0,1,0,0],
...                [1,1,0,0,1],[0,0,0,1,0]])
>>> labeled_array, num_features = label(a)
```

Each of the 4 features are labeled with a different integer:

```python
>>> num_features
4
>>> labeled_array
array([[0, 0, 1, 1, 0],
        [0, 0, 1, 0, 0],
        [2, 2, 0, 0, 3],
        [0, 0, 4, 0, 0]])
```

Generate a structuring element that will consider features connected even if they touch diagonally:

```python
>>> s = generate_binary_structure(2,2)
```

or,
Label the image using the new structuring element:

```
>>> labeled_array, num_features = label(a, structure=s)
```

Show the 2 labeled features (note that features 1, 3, and 4 from above are now considered a single feature):

```
>>> num_features
2
>>> labeled_array
array([[0, 0, 1, 1, 0, 0],
       [0, 0, 0, 1, 0, 0],
       [2, 2, 0, 0, 1, 0],
       [0, 0, 0, 1, 0, 0]])
```

### scipy.ndimage.labeled_comprehension

**scipy.ndimage.labeled_comprehension**

`scipy.ndimage.labeled_comprehension(input, labels, index, func, out_dtype, default, pass_positions=False)`

Roughly equivalent to `func(input[labels == i]) for i in index`.

Sequentially applies an arbitrary function (that works on array_like input) to subsets of an N-D image array specified by `labels` and `index`. The option exists to provide the function with positional parameters as the second argument.

**Parameters**

- `input` [array_like] Data from which to select `labels` to process.
- `labels` [array_like or None] Labels to objects in `input`. If not None, array must be same shape as `input`. If None, `func` is applied to raveled `input`.
- `index` [int, sequence of ints or None] Subset of `labels` to which to apply `func`. If a scalar, a single value is returned. If None, `func` is applied to all non-zero values of `labels`.
- `func` [callable] Python function to apply to `labels` from `input`.
- `out_dtype` [dtype] Dtype to use for `result`.
- `default` [int, float or None] Default return value when a element of `index` does not exist in `labels`.
- `pass_positions` [bool, optional] If True, pass linear indices to `func` as a second argument. Default is False.

**Returns**

- `result` [ndarray] Result of applying `func` to each of `labels` to `input` in `index`.

### Examples

```
>>> a = np.array([[1, 2, 0, 0],
...                [5, 3, 0, 4],
...                [0, 0, 0, 7],
...                [9, 3, 0, 0]])
>>> from scipy import ndimage
>>> lbl, nlbl = ndimage.label(a)
>>> lbs = np.arange(1, nlbl+1)
>>> ndimage.labeled_comprehension(a, lbl, lbs, np.mean, float, 0)
array([ 2.75,  5.5,  6.  ])
```
Falling back to default:

```python
>>> lbls = np.arange(1, nlbl+2)
>>> ndimage.labeled_comprehension(a, lbl, lbls, np.mean, float, -1)
array([ 2.75, 5.5, 6., -1. ])
```

Passing positions:

```python
>>> def fn(val, pos):
...     print("fn says: %s : %s" % (val, pos))
...     return (val.sum()) if (pos.sum() % 2 == 0) else (-val.sum())
...
>>> ndimage.labeled_comprehension(a, lbl, lbls, fn, float, 0, True)
fn says: [1 2 5 3] : [0 1 4 5]
fn says: [4 7] : [ 7 11]
fn says: [9 3] : [12 13]
array([ 11., 11., -12., 0.])
```

**scipy.ndimage.maximum**

**scipy.ndimage.maximum**(input, labels=None, index=None)

Calculate the maximum of the values of an array over labeled regions.

**Parameters**

- `input` [array_like] Array_like of values. For each region specified by `labels`, the maximal values of `input` over the region is computed.
- `labels` [array_like, optional] An array of integers marking different regions over which the maximum value of `input` is to be computed. `labels` must have the same shape as `input`. If `labels` is not specified, the maximum over the whole array is returned.
- `index` [array_like, optional] A list of region labels that are taken into account for computing the maxima. If `index` is None, the maximum over all elements where `labels` is non-zero is returned.

**Returns**

- `output` [float or list of floats] List of maxima of `input` over the regions determined by `labels` and whose index is in `index`. If `index` or `labels` are not specified, a float is returned: the maximal value of `input` if `labels` is None, and the maximal value of elements where `labels` is greater than zero if `index` is None.

**See also:**

- `label`, `minimum`, `median`, `maximum_position`, `extrema`, `sum`, `mean`, `variance`, `standard_deviation`
Notes

The function returns a Python list and not a NumPy array, use `np.array` to convert the list to an array.

Examples

```python
>>> a = np.arange(16).reshape((4,4))
>>> a
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11],
       [12, 13, 14, 15]])
>>> labels = np.zeros_like(a)
>>> labels[:2,:2] = 1
>>> labels[2:, 1:3] = 2
>>> labels
array([[1, 1, 0, 0],
       [1, 1, 0, 0],
       [0, 2, 2, 0],
       [0, 2, 2, 0]])
>>> from scipy import ndimage
>>> ndimage.maximum(a)
15.0
>>> ndimage.maximum(a, labels=labels, index=[1,2])
[5.0, 14.0]
>>> ndimage.maximum(a, labels=labels)
14.0

>>> b = np.array([[1, 2, 0, 0],
                 ... [5, 3, 0, 4],
                 ... [0, 0, 0, 7],
                 ... [9, 3, 0, 0]])
>>> labels, labels_nb = ndimage.label(b)
>>> labels
array([[1, 1, 0, 0],
       [1, 1, 0, 2],
       [0, 0, 2, 0],
       [0, 2, 2, 0]])
>>> ndimage.maximum(b, labels=labels, index=np.arange(1, labels_nb + 1))
[5.0, 7.0, 9.0]
```

**scipy.ndimage.maximum_position**

`scipy.ndimage.maximum_position(input, labels=None, index=None)`

Find the positions of the maximums of the values of an array at labels.

For each region specified by `labels`, the position of the maximum value of `input` within the region is returned.

**Parameters**

- **input** [array_like] Array_like of values.
- **labels** [array_like, optional] An array of integers marking different regions over which the position of the maximum value of `input` is to be computed. `labels` must have the same shape as `input`. If `labels` is not specified, the location of the first maximum over the whole array is returned.
The `labels` argument only works when `index` is specified.

**index**

[array_like, optional] A list of region labels that are taken into account for finding the location of the maxima. If `index` is None, the first maximum over all elements where `labels` is non-zero is returned.

The `index` argument only works when `labels` is specified.

**Returns**

**output**

[list of tuples of ints] List of tuples of ints that specify the location of maxima of `input` over the regions determined by `labels` and whose index is in `index`.

If `index` or `labels` are not specified, a tuple of ints is returned specifying the location of the first maximal value of `input`.

See also:

`label`, `minimum`, `median`, `maximum_position`, `extrema`, `sum`, `mean`, `variance`, `standard_deviation`

**Examples**

```python
>>> from scipy import ndimage
>>> a = np.array([[1, 2, 0, 0],
...                [5, 3, 0, 4],
...                [0, 0, 0, 7],
...                [9, 3, 0, 0]])
>>> ndimage.maximum_position(a)
(3, 0)
```

Features to process can be specified using `labels` and `index`:

```python
>>> lbl = np.array([[0, 1, 2, 3],
...                 [0, 1, 2, 3],
...                 [0, 1, 2, 3],
...                 [0, 1, 2, 3]])
>>> ndimage.maximum_position(a, lbl, 1)
(1, 1)
```

If no index is given, non-zero `labels` are processed:

```python
>>> ndimage.maximum_position(a, lbl)
(2, 3)
```

If there are no maxima, the position of the first element is returned:

```python
>>> ndimage.maximum_position(a, lbl, 2)
(0, 2)
```
scipy.ndimage.mean

**(input, labels=None, index=None)**

Calculate the mean of the values of an array at labels.

**Parameters**

- **input**: [array_like] Array on which to compute the mean of elements over distinct regions.
- **labels**: [array_like, optional] Array of labels of same shape, or broadcastable to the same shape as input. All elements sharing the same label form one region over which the mean of the elements is computed.
- **index**: [int or sequence of ints, optional] Labels of the objects over which the mean is to be computed. Default is None, in which case the mean for all values where label is greater than 0 is calculated.

**Returns**

- **out**: [list] Sequence of same length as index, with the mean of the different regions labeled by the labels in index.

See also:

variance, standard_deviation, minimum, maximum, sum, label

**Examples**

```python
>>> from scipy import ndimage
>>> a = np.arange(25).reshape((5,5))
>>> labels = np.zeros_like(a)
>>> labels[3:5,3:5] = 1
>>> index = np.unique(labels)
>>> labels
array([[0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0],
       [0, 0, 1, 1, 1],
       [0, 0, 1, 1, 1]])
>>> index
array([0, 1])
>>> ndimage.mean(a, labels=labels, index=index)
[10.285714285714286, 21.0]
```

scipy.ndimage.median

**(input, labels=None, index=None)**

Calculate the median of the values of an array over labeled regions.

**Parameters**

- **input**: [array_like] Array_like of values. For each region specified by labels, the median value of input over the region is computed.
- **labels**: [array_like, optional] An array_like of integers marking different regions over which the median value of input is to be computed. labels must have the same shape as input. If labels is not specified, the median over the whole array is returned.
- **index**: [array_like, optional] A list of region labels that are taken into account for computing the medians. If index is None, the median over all elements where labels is non-zero is returned.
Returns

median  [float or list of floats] List of medians of input over the regions determined by labels and whose index is in index. If index or labels are not specified, a float is returned: the median value of input if labels is None, and the median value of elements where labels is greater than zero if index is None.

See also:

label, minimum, maximum, extrema, sum, mean, variance, standard_deviation

Notes

The function returns a Python list and not a NumPy array, use np.array to convert the list to an array.

Examples

```python
>>> from scipy import ndimage
>>> a = np.array([[1, 2, 0, 1],
... [5, 3, 0, 4],
... [0, 0, 0, 7],
... [9, 3, 0, 0]])
>>> labels, labels_nb = ndimage.label(a)
>>> labels
array([[1, 1, 0, 2],
       [1, 1, 0, 2],
       [0, 0, 0, 2],
       [3, 3, 0, 0]])
>>> ndimage.median(a, labels=labels, index=np.arange(1, labels_nb + 1))
[2.5, 4.0, 6.0]
>>> ndimage.median(a)
1.0
>>> ndimage.median(a, labels=labels)
3.0
```

```
scipy.ndimage.minimum
```

scipy.ndimage.minimum(input, labels=None, index=None)

Calculate the minimum of the values of an array over labeled regions.

Parameters

- **input**  [array_like] Array_like of values. For each region specified by labels, the minimal values of input over the region is computed.
- **labels**  [array_like, optional] An array_like of integers marking different regions over which the minimum value of input is to be computed. labels must have the same shape as input. If labels is not specified, the minimum over the whole array is returned.
- **index**  [array_like, optional] A list of region labels that are taken into account for computing the minima. If index is None, the minimum over all elements where labels is non-zero is returned.

Returns

- **minimum**  [float or list of floats] List of minima of input over the regions determined by labels and whose index is in index. If index or labels are not specified, a float is returned: the minimal_value.
value of \texttt{input} if \texttt{labels} is None, and the minimal value of elements where \texttt{labels} is greater than zero if \texttt{index} is None.

See also:

\texttt{label, maximum, median, minimum\_position, extrema, sum, mean, variance standard\_deviation}

Notes

The function returns a Python list and not a NumPy array, use \texttt{np.array} to convert the list to an array.

Examples

```python
>>> from scipy import ndimage
>>> a = np.array([[1, 2, 0, 0],
...                [5, 3, 0, 4],
...                [0, 0, 0, 7],
...                [9, 3, 0, 0]])
>>> labels, labels_nb = ndimage.label(a)
>>> labels
array([[1, 1, 0, 0],
       [1, 1, 0, 2],
       [0, 0, 0, 2],
       [3, 3, 0, 0]])
>>> ndimage.minimum(a, labels=labels, index=np.arange(1, labels_nb + 1))
[1.0, 4.0, 3.0]
>>> ndimage.minimum(a)
0.0
>>> ndimage.minimum(a, labels=labels)
1.0
```

\texttt{scipy.ndimage.minimum\_position}

\texttt{scipy.ndimage.minima\_position}(\texttt{input}, \texttt{labels=\textit{None}}, \texttt{index=\textit{None}})

Find the positions of the minimums of the values of an array at labels.

**Parameters**

- \texttt{input} [\texttt{array\_like}] Array_like of values.
- \texttt{labels} [\texttt{array\_like}, \texttt{optional}] An array of integers marking different regions over which the position of the minimum value of \texttt{input} is to be computed. \texttt{labels} must have the same shape as \texttt{input}. If \texttt{labels} is not specified, the location of the first minimum over the whole array is returned. The \texttt{labels} argument only works when \texttt{index} is specified.
- \texttt{index} [\texttt{array\_like}, \texttt{optional}] A list of region labels that are taken into account for finding the location of the minima. If \texttt{index} is None, the first minimum over all elements where \texttt{labels} is non-zero is returned. The \texttt{index} argument only works when \texttt{labels} is specified.

**Returns**

- \texttt{output} [\texttt{list of tuples of ints}] Tuple of ints or list of tuples of ints that specify the location of minima of \texttt{input} over the regions determined by \texttt{labels} and whose index is in \texttt{index}. 

If \textit{index} or \textit{labels} are not specified, a tuple of ints is returned specifying the location of the first minimal value of \textit{input}.

See also:

\texttt{label}, \texttt{minimum}, \texttt{median}, \texttt{maximum_position}, \texttt{extrema}, \texttt{sum}, \texttt{mean}, \texttt{variance}

\texttt{standard_deviation}

\textbf{Examples}

```python
>>> a = np.array([[10, 20, 30],
...                [40, 80, 100],
...                [1, 100, 200]])
>>> b = np.array([[1, 2, 0, 1],
...                [5, 3, 0, 4],
...                [0, 0, 0, 7],
...                [9, 3, 0, 0]])

>>> from scipy import ndimage

>>> ndimage.minimum_position(a)
(2, 0)
>>> ndimage.minimum_position(b)
(0, 2)
```

Features to process can be specified using \textit{labels} and \textit{index}:

```python
>>> label, pos = ndimage.label(a)
>>> ndimage.minimum_position(a, label, index=np.arange(1, pos+1))
[(2, 0)]

>>> label, pos = ndimage.label(b)
>>> ndimage.minimum_position(b, label, index=np.arange(1, pos+1))
[(0, 0), (0, 3), (3, 1)]
```

\texttt{scipy.ndimage.standard_deviation}

\texttt{scipy.ndimage.standard_deviation (input, labels=None, index=None)}

Calculate the standard deviation of the values of an N-D image array, optionally at specified sub-regions.

\textbf{Parameters}

\begin{itemize}
    \item \texttt{input} [array_like] N-D image data to process.
    \item \texttt{labels} [array_like, optional] Labels to identify sub-regions in \textit{input}. If not None, must be same shape as \textit{input}.
    \item \texttt{index} [int or sequence of ints, optional] \textit{labels} to include in output. If None (default), all values where \textit{labels} is non-zero are used.
\end{itemize}

\textbf{Returns}

\begin{itemize}
    \item \texttt{standard_deviation} [float or ndarray] Values of standard deviation, for each sub-region if \textit{labels} and \textit{index} are specified.
\end{itemize}

See also:
label, variance, maximum, minimum, extrema

Examples

```python
>>> a = np.array([[1, 2, 0, 0],
...                [5, 3, 0, 4],
...                [0, 0, 0, 7],
...                [9, 3, 0, 0]])
>>> from scipy import ndimage
>>> ndimage.standard_deviation(a)
2.7585095613392387

Features to process can be specified using labels and index:

```python
>>> lbl, nlbl = ndimage.label(a)
>>> ndimage.standard_deviation(a, lbl, index=np.arange(1, nlbl+1))
aarray([ 1.479, 1.5 , 3. ])
```  
If no index is given, non-zero labels are processed:

```python
>>> ndimage.standard_deviation(a, lbl)
2.4874685927665499

scipy.ndimage.sum_labels

scipy.ndimage.sum_labels (input, labels=None, index=None)
Calculate the sum of the values of the array.

Parameters

- input [array_like] Values of input inside the regions defined by labels are summed together.
- labels [array_like of ints, optional] Assign labels to the values of the array. Has to have the same shape as input.
- index [array_like, optional] A single label number or a sequence of label numbers of the objects to be measured.

Returns

- sum [ndarray or scalar] An array of the sums of values of input inside the regions defined by labels with the same shape as index. If ‘index’ is None or scalar, a scalar is returned.

See also:

mean, median

Examples

```python
>>> from scipy import ndimage
>>> input = [0, 1, 2, 3]
>>> labels = [1, 1, 2, 2]
>>> ndimage.sum(input, labels, index=[1, 2])
1.0, 5.0
>>> ndimage.sum(input, labels, index=1)
1
```  
(continues on next page)
scipy.ndimage.variance

**scipy.ndimage.variance** (*input*, *labels=None*, *index=None*)

Calculate the variance of the values of an N-D image array, optionally at specified sub-regions.

**Parameters**

- **input**  
  [array_like] Nd-image data to process.

- **labels**  
  [array_like, optional] Labels defining sub-regions in *input*. If not None, must be same shape as *input*.

- **index**  
  [int or sequence of ints, optional] *labels* to include in output. If None (default), all values where *labels* is non-zero are used.

**Returns**

- **variance**  
  [float or ndarray] Values of variance, for each sub-region if *labels* and *index* are specified.

**See also:**

*label, standard_deviation, maximum, minimum, extrema*

**Examples**

```python
>>> a = np.array([[1, 2, 0, 0],
...                [5, 3, 0, 4],
...                [0, 0, 0, 7],
...                [9, 3, 0, 0]])
>>> from scipy import ndimage
>>> ndimage.variance(a)
7.609375
```

Features to process can be specified using *labels* and *index*:

```python
>>> lbl, nlbl = ndimage.label(a)
>>> ndimage.variance(a, lbl, index=np.arange(1, nlbl+1))
array([ 2.1875, 2.25 , 9.   ])
```

If no index is given, all non-zero *labels* are processed:

```python
>>> ndimage.variance(a, lbl)
6.1875
```
scipy.ndimage.watershed_ift

**scipy.ndimage.watershed_ift** *(input, markers, structure=None, output=None)*

Apply watershed from markers using image foresting transform algorithm.

**Parameters**

- **input** [array_like] Input.
- **markers** [array_like] Markers are points within each watershed that form the beginning of the process. Negative markers are considered background markers which are processed after the other markers.
- **structure** [structure element, optional] A structuring element defining the connectivity of the object can be provided. If None, an element is generated with a squared connectivity equal to one.
- **output** [ndarray, optional] An output array can optionally be provided. The same shape as input.

**Returns**

- **watershed_ift** [ndarray] Output. Same shape as input.

### `scipy.ndimage.binary_closing`

#### `scipy.ndimage.binary_closing`

Multidimensional binary closing with the given structuring element.

The *closing* of an input image by a structuring element is the *erosion* of the *dilation* of the image by the structuring element.

**Parameters**

- **input** [array_like] Binary array_like to be closed. Non-zero (True) elements form the subset to be closed.
- **structure** [array_like, optional] Structuring element used for the closing. Non-zero elements are considered True. If no structuring element is provided an element is generated with a square connectivity equal to one (i.e., only nearest neighbors are connected to the center, diagonally-connected elements are not considered neighbors).
- **iterations** [int, optional] The dilation step of the closing, then the erosion step are each repeated `iterations` times (one, by default). If iterations is less than 1, each operations is repeated until the result does not change anymore. Only an integer of iterations is accepted.
- **output** [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.
- **origin** [int or tuple of ints, optional] Placement of the filter, by default 0.
- **mask** [array_like, optional] If a mask is given, only those elements with a True value at the corresponding mask element are modified at each iteration. New in version 1.1.0.
- **border_value** [int (cast to 0 or 1), optional] Value at the border in the output array. New in version 1.1.0.
- **brute_force** [boolean, optional] Memory condition: if False, only the pixels whose value was changed in the last iteration are tracked as candidates to be updated in the current iteration; if true all pixels are considered as candidates for update, regardless of what happened in the previous iteration. False by default. New in version 1.1.0.

**Returns**

- **binary_closing** [ndarray of bools] Closing of the input by the structuring element.

**See also:**

- `grey_closing`
- `binary_opening`
- `binary_dilation`
- `binary_erosion`
- `generate_binary_structure`
Notes

Closing \[1\] is a mathematical morphology operation \[2\] that consists in the succession of a dilation and an erosion of the input with the same structuring element. Closing therefore fills holes smaller than the structuring element. Together with opening (binary_opening), closing can be used for noise removal.

[1], [2]

Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((5, 5), dtype=int)
>>> a[1:-1, 1:-1] = 1; a[2, 2] = 0
>>> a
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 0, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
>>> # Closing removes small holes
>>> ndimage.binary_closing(a).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
>>> # Closing is the erosion of the dilation of the input
>>> ndimage.binary_dilation(a).astype(int)
array([[0, 1, 1, 1, 0],
       [1, 1, 1, 1, 1],
       [1, 1, 1, 1, 1],
       [0, 1, 1, 1, 0]])
>>> ndimage.binary_erosion(ndimage.binary_dilation(a)).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
```
In addition to removing holes, closing can also coarsen boundaries with fine hollows.

```python
>>> ndimage.binary_closing(a).astype(int)
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 0, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
```

```python
>>> ndimage.binary_closing(a, structure=np.ones((2,2))).astype(int)
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
```

`scipy.ndimage.binary_dilation`

*scipy.ndimage.binary_dilation* (*input*, *structure=None*, *iterations=1*, *mask=None*, *output=None*, *border_value=0*, *origin=0*, *brute_force=False*)

Multidimensional binary dilation with the given structuring element.

**Parameters**

- **input** [array_like] Binary array_like to be dilated. Non-zero (True) elements form the subset to be dilated.
- **structure** [array_like, optional] Structuring element used for the dilation. Non-zero elements are considered True. If no structuring element is provided an element is generated with a square connectivity equal to one.
- **iterations** [int, optional] The dilation is repeated *iterations* times (one, by default). If iterations is less than 1, the dilation is repeated until the result does not change anymore. Only an integer of iterations is accepted.
- **mask** [array_like, optional] If a mask is given, only those elements with a True value at the corresponding mask element are modified at each iteration.
- **output** [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.
- **border_value** [int (cast to 0 or 1), optional] Value at the border in the output array.
- **origin** [int or tuple of ints, optional] Placement of the filter, by default 0.
- **brute_force** [boolean, optional] Memory condition: if False, only the pixels whose value was changed in the last iteration are tracked as candidates to be updated (dilated) in the current iteration; if True all pixels are considered as candidates for dilation, regardless of what happened in the previous iteration. False by default.

**Returns**

- **binary_dilation** [ndarray of bools] Dilation of the input by the structuring element.

grey_dilation, binary_erosion, binary_closing, binary_opening

generate_binary_structure

Notes

Dilation [1] is a mathematical morphology operation [2] that uses a structuring element for expanding the shapes in an image. The binary dilation of an image by a structuring element is the locus of the points covered by the structuring element, when its center lies within the non-zero points of the image.

Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((5, 5))
>>> a[2, 2] = 1
>>> a
array([[0. , 0. , 0. , 0. , 0. ],
       [0. , 0. , 0. , 0. , 0. ],
       [0. , 0. , 1. , 0. , 0. ],
       [0. , 0. , 0. , 0. , 0. ],
       [0. , 0. , 0. , 0. , 0. ]])
>>> ndimage.binary_dilation(a)
array([[False, False, False, False, False],
       [False, False, True, False, False],
       [False, True, True, True, False],
       [False, False, True, False, False],
       [False, False, False, False, False]], dtype=bool)
>>> ndimage.binary_dilation(a).astype(a.dtype)
array([[0. , 0. , 0. , 0. , 0. ],
       [0. , 0. , 1. , 0. , 0. ],
       [0. , 1. , 1. , 1. , 0. ],
       [0. , 0. , 1. , 0. , 0. ],
       [0. , 0. , 0. , 0. , 0. ]])
>>> # 3x3 structuring element with connectivity 1, used by default
>>> struct1 = ndimage.generate_binary_structure(2, 1)
>>> struct1
array([[False, True, False],
       [True, True, True],
       [False, True, False]], dtype=bool)
>>> # 3x3 structuring element with connectivity 2
>>> struct2 = ndimage.generate_binary_structure(2, 2)
>>> struct2
array([[ True, True, True],
       [True, True, True],
       [ True, True, True]], dtype=bool)
```

(continues on next page)
```python
>>> ndimage.binary_dilation(a, structure=struct1).astype(a.dtype)
array([[ 0., 0., 0., 0., 0.],
[ 0., 0., 1., 0., 0.],
[ 0., 1., 1., 1., 0.],
[ 0., 0., 1., 0., 0.],
[ 0., 0., 0., 0., 0.]]
>>> ndimage.binary_dilation(a, structure=struct2).astype(a.dtype)
array([[ 0., 0., 0., 0., 0.],
[ 0., 1., 1., 1., 0.],
[ 0., 1., 1., 1., 0.],
[ 0., 1., 1., 1., 0.],
[ 0., 0., 0., 0., 0.]]
>>> ndimage.binary_dilation(a, structure=struct1, 
... iterations=2).astype(a.dtype)
array([[ 0., 0., 1., 0., 0.],
[ 0., 1., 1., 1., 0.],
[ 1., 1., 1., 1., 1.],
[ 0., 1., 1., 1., 0.],
[ 0., 0., 1., 0., 0.]]
```

**scipy.ndimage.binary_erosion**

Multidimensional binary erosion with a given structuring element.

Binary erosion is a mathematical morphology operation used for image processing.

**Parameters**

- **input** [array_like] Binary image to be eroded. Non-zero (True) elements form the subset to be eroded.
- **structure** [array_like, optional] Structuring element used for the erosion. Non-zero elements are considered True. If no structuring element is provided, an element is generated with a square connectivity equal to one.
- **iterations** [int, optional] The erosion is repeated iterations times (one, by default). If iterations is less than 1, the erosion is repeated until the result does not change anymore.
- **mask** [array_like, optional] If a mask is given, only those elements with a True value at the corresponding mask element are modified at each iteration.
- **output** [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.
- **border_value** [int (cast to 0 or 1), optional] Value at the border in the output array.
- **origin** [int or tuple of ints, optional] Placement of the filter, by default 0.
- **brute_force** [boolean, optional] Memory condition: if False, only the pixels whose value was changed in the last iteration are tracked as candidates to be updated (eroded) in the current iteration; if True all pixels are considered as candidates for erosion, regardless of what happened in the previous iteration. False by default.

**Returns**

- **binary_erosion** [ndarray of bools] Erosion of the input by the structuring element.

grey_erosion, binary_dilation, binary_closing, binary_opening

generate_binary_structure

Notes

Erosion [1] is a mathematical morphology operation [2] that uses a structuring element for shrinking the shapes in an image. The binary erosion of an image by a structuring element is the locus of the points where a superimposition of the structuring element centered on the point is entirely contained in the set of non-zero elements of the image.

Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((7,7), dtype=int)
>>> a[1:6, 2:5] = 1
>>> a
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
>>> ndimage.binary_erosion(a).astype(a.dtype)
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 1, 0, 0, 0],
       [0, 0, 0, 1, 0, 0, 0],
       [0, 0, 0, 1, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
>>> ndimage.binary_erosion(a, structure=np.ones((5,5))).astype(a.dtype)
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],

       [0, 0, 0, 0, 0, 0, 0]])
```
**scipy.ndimage.binary_fill_holes**

**scipy.ndimage.binary_fill_holes**(*input*, *structure=None, output=None, origin=0)

Fill the holes in binary objects.

**Parameters**

- **input** [array_like] N-D binary array with holes to be filled
- **structure** [array_like, optional] Structuring element used in the computation; large-size elements make computations faster but may miss holes separated from the background by thin regions. The default element (with a square connectivity equal to one) yields the intuitive result where all holes in the input have been filled.
- **output** [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.
- **origin** [int, tuple of ints, optional] Position of the structuring element.

**Returns**

- **out** [ndarray] Transformation of the initial image *input* where holes have been filled.

**See also:**

- *binary_dilation*, *binary_propagation*, *label*

**Notes**

The algorithm used in this function consists in invading the complementary of the shapes in *input* from the outer boundary of the image, using binary dilations. Holes are not connected to the boundary and are therefore not invaded. The result is the complementary subset of the invaded region.

- [1]

**Examples**

```python
>>> from scipy import ndimage
>>> a = np.zeros((5, 5), dtype=int)
>>> a[1:4, 1:4] = 1
>>> a[2,2] = 0
>>> a
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 0, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
>>> ndimage.binary_fill_holes(a).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 1],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
>>> # Too big structuring element
```

(continues on next page)
>>> ndimage.binary_fill_holes(a, structure=np.ones((5,5))).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 0, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])

scipy.ndimage.binary_hit_or_miss

scipy.ndimage.binary_hit_or_miss(input, structure1=None, structure2=None, output=None, origin1=0, origin2=None)

Multidimensional binary hit-or-miss transform.

The hit-or-miss transform finds the locations of a given pattern inside the input image.

**Parameters**

- **input** [array_like (cast to bools)] Binary image where a pattern is to be detected.
- **structure1** [array_like (cast to bools), optional] Part of the structuring element to be fitted to the foreground (non-zero elements) of input. If no value is provided, a structure of square connectivity 1 is chosen.
- **structure2** [array_like (cast to bools), optional] Second part of the structuring element that has to miss completely the foreground. If no value is provided, the complementary of structure1 is taken.
- **output** [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.
- **origin1** [int or tuple of ints, optional] Placement of the first part of the structuring element structure1, by default 0 for a centered structure.
- **origin2** [int or tuple of ints, optional] Placement of the second part of the structuring element structure2, by default 0 for a centered structure. If a value is provided for origin1 and not for origin2, then origin2 is set to origin1.

**Returns**

- **binary_hit_or_miss** [ndarray] Hit-or-miss transform of input with the given structuring element (structure1, structure2).

Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((7,7), dtype=int)
>>> a
array([[0, 0, 0, 0, 0, 0, 0],
        [0, 1, 0, 0, 0, 0, 0],
        [0, 0, 1, 1, 0, 0, 0],
        [0, 0, 1, 1, 0, 0, 0],
        [0, 0, 0, 0, 1, 1, 0],
        [0, 0, 0, 0, 1, 1, 0],
        [0, 0, 0, 0, 0, 0, 0]], dtype=int)
>>> structure1 = np.array([[[1, 0, 0],
                            [0, 1, 1],
                            [0, 1, 1]]])
>>> structure1
array([[[1, 0, 0],
        [0, 1, 1],
        [0, 1, 1]]])
>>> # Find the matches of structure1 in the array a
>>> ndimage.binary_hit_or_miss(a, structure1=structure1).astype(int)
array([[0, 0, 0, 0, 0, 0, 0],
        [0, 0, 0, 0, 0, 0, 0],
        [0, 0, 1, 0, 0, 0, 0],
        [0, 0, 0, 0, 0, 0, 0],
        [0, 0, 0, 0, 1, 0, 0],
        [0, 0, 0, 0, 0, 1, 0],
        [0, 0, 0, 0, 0, 0, 0]], dtype=int)
>>> # Change the origin of the filter
>>> # origin1=1 is equivalent to origin1=(1,1) here
>>> ndimage.binary_hit_or_miss(a, structure1=structure1, \... origin1=1).astype(int)
array([[0, 0, 0, 0, 0, 0, 0],
        [0, 0, 0, 0, 0, 0, 0],
        [0, 0, 0, 0, 0, 0, 0],
        [0, 0, 0, 0, 0, 0, 0],
        [0, 0, 0, 0, 0, 0, 0],
        [0, 0, 0, 0, 0, 0, 0],
        [0, 0, 0, 0, 0, 0, 0]], dtype=int)
```

`scipy.ndimage.binary_opening`

`scipy.ndimage.binary_opening` *(input, structure=None, iterations=1, output=None, origin=0, mask=None, border_value=0, brute_force=False)*

Multidimensional binary opening with the given structuring element.

The opening of an input image by a structuring element is the *dilation* of the *erosion* of the image by the structuring element.

**Parameters**

- **input** [array_like] Binary array_like to be opened. Non-zero (True) elements form the subset to be opened.
- **structure** [array_like, optional] Structuring element used for the opening. Non-zero elements are considered True. If no structuring element is provided an element is generated with a square
connectivity equal to one (i.e., only nearest neighbors are connected to the center, diagonally-connected elements are not considered neighbors).

**iterations**
[int, optional] The erosion step of the opening, then the dilation step are each repeated *iterations* times (one, by default). If *iterations* is less than 1, each operation is repeated until the result does not change anymore. Only an integer of iterations is accepted.

**output**
[ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.

**origin**
[int or tuple of ints, optional] Placement of the filter, by default 0.

**mask**
[array_like, optional] If a mask is given, only those elements with a True value at the corresponding mask element are modified at each iteration. New in version 1.1.0.

**border_value**
[int (cast to 0 or 1), optional] Value at the border in the output array. New in version 1.1.0.

**brute_force**
[boolean, optional] Memory condition: if False, only the pixels whose value was changed in the last iteration are tracked as candidates to be updated in the current iteration; if true all pixels are considered as candidates for update, regardless of what happened in the previous iteration. False by default. New in version 1.1.0.

**Returns**

**binary_opening**
[ndarray of bools] Opening of the input by the structuring element.

grey_opening, binary_closing, binary_erosion, binary_dilation

generate_binary_structure

Notes

Opening [1] is a mathematical morphology operation [2] that consists in the succession of an erosion and a dilation of the input with the same structuring element. Opening, therefore, removes objects smaller than the structuring element.

Together with closing (binary_closing), opening can be used for noise removal.

Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((5, 5), dtype=int)
>>> a[1:4, 1:4] = 1; a[4, 4] = 1
>>> a
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]], dtype=int32)
```
>>> # Opening removes small objects
>>> ndimage.binary_opening(a, structure=np.ones((3,3))).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])

>>> # Opening can also smooth corners
>>> ndimage.binary_opening(a).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 1, 0, 0],
       [0, 0, 0, 0, 0]])

>>> # Opening is the dilation of the erosion of the input
>>> ndimage.binary_erosion(a).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0],
       [0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0]])

>>> ndimage.binary_dilation(ndimage.binary_erosion(a)).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 1, 0, 0],
       [0, 0, 0, 0, 0]])

scipy.ndimage.binary_propagation

scipy.ndimage.binary_propagation(input, structure=None, mask=None, output=None, border_value=0, origin=0)

Multidimensional binary propagation with the given structuring element.

Parameters

- **input** [array_like] Binary image to be propagated inside mask.
- **structure** [array_like, optional] Structuring element used in the successive dilations. The output may depend on the structuring element, especially if mask has several connex components. If no structuring element is provided, an element is generated with a squared connectivity equal to one.
- **mask** [array_like, optional] Binary mask defining the region into which input is allowed to propagate.
- **output** [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.
- **border_value** [int (cast to 0 or 1), optional] Value at the border in the output array.
- **origin** [int or tuple of ints, optional] Placement of the filter, by default 0.

Returns

- **binary_propagation** [ndarray] Binary propagation of input inside mask.
Notes

This function is functionally equivalent to calling binary_dilation with the number of iterations less than one: iterative dilation until the result does not change anymore.

The succession of an erosion and propagation inside the original image can be used instead of an opening for deleting small objects while keeping the contours of larger objects untouched.

Examples

```python
>>> from scipy import ndimage
>>> input = np.zeros((8, 8), dtype=int)
>>> input[2, 2] = 1
>>> mask = np.zeros((8, 8), dtype=int)
>>> input
array([[0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0]])
>>> mask
array([[0, 0, 0, 0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 0, 0, 0, 1, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 1, 1],
       [0, 0, 0, 0, 0, 0, 1, 1]])
>>> ndimage.binary_propagation(input, mask=mask).astype(int)
array([[0, 0, 0, 0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0]])
>>> ndimage.binary_propagation(input, mask=mask, 
... structure=np.ones((3, 3))).astype(int)
array([[0, 0, 0, 0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0],
       [0, 1, 1, 1, 0, 0, 0, 0]],)
```
```python
>>> # Comparison between opening and erosion+propagation

       [0, 0, 1, 1, 1, 0],
       [0, 0, 0, 1, 0, 0],
       [0, 0, 0, 0, 0, 0]])
>>> b = ndimage.binary_erosion(a)
>>> b.astype(int)
array([[0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0],
       [0, 0, 0, 1, 0, 0],
       [0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0]])
>>> ndimage.binary_propagation(b, mask=a).astype(int)
array([[0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0],
       [0, 0, 1, 1, 1, 0],
       [0, 0, 1, 1, 1, 0],
       [0, 0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0, 0]])
```

**scipy.ndimage.black_tophat**

scipy.ndimage.black_tophat (input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)

Multidimensional black tophat filter.

**Parameters**

- **input** [array_like] Input.
- **size** [tuple of ints, optional] Shape of a flat and full structuring element used for the filter. Optional if footprint or structure is provided.
- **footprint** [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the black tophat filter.
- **structure** [array of ints, optional] Structuring element used for the filter. structure may be a non-flat structuring element.
output [array, optional] An array used for storing the output of the filter may be provided.
mode [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The mode parameter determines how the array borders are handled, where \( cval \) is the value when mode is equal to 'constant'. Default is 'reflect'

cval [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
origin [scalar, optional] The origin parameter controls the placement of the filter. Default 0

Returns

black_tophat [ndarray] Result of the filter of input with structure.

white_tophat, grey_opening, grey_closing

Examples

Change dark peak to bright peak and subtract background.

```python
>>> from scipy.ndimage import generate_binary_structure, black_tophat
>>> square = generate_binary_structure(rank=2, connectivity=3)
>>> dark_on_gray = np.array([[7, 6, 6, 6, 7],
...                           [6, 4, 0, 4, 6],
...                           ...
...                           [6, 5, 4, 5, 6],
...                           ...
...                           [7, 6, 6, 6, 7]])
>>> black_tophat(input=dark_on_gray, structure=square)
array([[0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0],
       [0, 1, 5, 1, 0],
       [0, 0, 1, 0, 0],
       [0, 0, 0, 0, 0]])
```

scipy.ndimage.distance_transform_bf

scipy.ndimage.distance_transform_bf(input, metric='euclidean', sampling=None, return_distances=True, return_indices=False, distances=None, indices=None)

Distance transform function by a brute force algorithm.

This function calculates the distance transform of the input, by replacing each foreground (non-zero) element, with its shortest distance to the background (any zero-valued element).

In addition to the distance transform, the feature transform can be calculated. In this case the index of the closest background element to each foreground element is returned in a separate array.

Parameters

input [array_like] Input
metric [{'euclidean', 'taxicab', 'chessboard'}, optional] 'cityblock' and 'manhattan' are also valid, and map to 'taxicab'. The default is 'euclidean'.
sampling [float, or sequence of float, optional] This parameter is only used when metric is 'euclidean'. Spacing of elements along each dimension. If a sequence, must be of length equal to the input rank; if a single number, this is used for all axes. If not specified, a grid spacing of unity is implied.
return_distances
[bool, optional] Whether to calculate the distance transform. Default is True.

return_indices
[bool, optional] Whether to calculate the feature transform. Default is False.

distances
[ndarray, optional] An output array to store the calculated distance transform, instead of returning it. return_distances must be True. It must be the same shape as input, and of type float64 if metric is 'euclidean'; uint32 otherwise.

indices
[int32 ndarray, optional] An output array to store the calculated feature transform, instead of returning it. return_indices must be True. Its shape must be (input.ndim,) + input.shape.

Returns

distances
[ndarray, optional] The calculated distance transform. Returned only when return_distances is True and distances is not supplied. It will have the same shape as the input array.

indices
[int32 ndarray, optional] The calculated feature transform. It has an input-shaped array for each dimension of the input. See distance_transform_edt documentation for an example. Returned only when return_indices is True and indices is not supplied.

Notes
This function employs a slow brute force algorithm, see also the function distance_transform_cdt for more efficient taxicab and chessboard algorithms.

scipy.ndimage.distance_transform_cdt

Distance transform for chamfer type of transforms.

In addition to the distance transform, the feature transform can be calculated. In this case the index of the closest background element to each foreground element is returned in a separate array.

Parameters

input
[array_like] Input

metric
[['chessboard', 'taxicab'] or array_like, optional] The metric determines the type of chamfering that is done. If the metric is equal to 'taxicab' a structure is generated using generate_binary_structure with a squared distance equal to 1. If the metric is equal to 'chessboard', a metric is generated using generate_binary_structure with a squared distance equal to the dimensionality of the array. These choices correspond to the common interpretations of the 'taxicab' and the 'chessboard' distance metrics in two dimensions. A custom metric may be provided, in the form of a matrix where each dimension has a length of three. 'cityblock' and 'manhattan' are also valid, and map to 'taxicab'. The default is 'chessboard'.

return_distances
[bool, optional] Whether to calculate the distance transform. Default is True.

return_indices
[bool, optional] Whether to calculate the feature transform. Default is False.

distances
[int32 ndarray, optional] An output array to store the calculated distance transform, instead of returning it. return_distances must be True. It must be the same shape as input.

indices
[int32 ndarray, optional] An output array to store the calculated feature transform, instead of returning it. return_indices must be True. Its shape must be (input.ndim,) + input.shape.

Returns

distances
[int32 ndarray, optional] The calculated distance transform. Returned only when return_distances is True, and distances is not supplied. It will have the same shape as the input array.
indices [int32 ndarray, optional] The calculated feature transform. It has an input-shaped array for each dimension of the input. See distance_transform_edt documentation for an example. Returned only when return_indices is True, and indices is not supplied.

**scipy.ndimage.distance_transform_edt**

scipy.ndimage.distance_transform_edt (input, sampling=None, return_distances=True, return_indices=False, distances=None, indices=None)

Exact Euclidean distance transform.

In addition to the distance transform, the feature transform can be calculated. In this case the index of the closest background element to each foreground element is returned in a separate array.

**Parameters**

- **input** [array_like] Input data to transform. Can be any type but will be converted into binary: 1 wherever input equates to True, 0 elsewhere.
- **sampling** [float, or sequence of float, optional] Spacing of elements along each dimension. If a sequence, must be of length equal to the input rank; if a single number, this is used for all axes. If not specified, a grid spacing of unity is implied.
- **return_distances** [bool, optional] Whether to calculate the distance transform. Default is True.
- **return_indices** [bool, optional] Whether to calculate the feature transform. Default is False.
- **distances** [float64 ndarray, optional] An output array to store the calculated distance transform, instead of returning it. return_distances must be True. It must be the same shape as input.
- **indices** [int32 ndarray, optional] An output array to store the calculated feature transform, instead of returning it. return_indices must be True. Its shape must be (input.ndim,) + input.shape.

**Returns**

- **distances** [float64 ndarray, optional] The calculated distance transform. Returned only when return_distances is True and distances is not supplied. It will have the same shape as the input array.
- **indices** [int32 ndarray, optional] The calculated feature transform. It has an input-shaped array for each dimension of the input. See example below. Returned only when return_indices is True and indices is not supplied.

**Notes**

The Euclidean distance transform gives values of the Euclidean distance:

\[ y_i = \sqrt{\sum_{i} (x[i] - b[i])^2} \]

where b[i] is the background point (value 0) with the smallest Euclidean distance to input points x[i], and n is the number of dimensions.
Examples

```python
>>> from scipy import ndimage
>>> a = np.array([[0,1,1,1],
...                [0,0,1,1],
...                [0,1,1,1],
...                [0,1,1,0],
...                [0,1,0,0]])
>>> ndimage.distance_transform_edt(a)
array([[ 0. , 1. , 1.4142, 2.2361, 3. ],
       [ 0. , 0. , 1. , 2. , 2. ],
       [ 0. , 1. , 1.4142, 1.4142, 1. ],
       [ 0. , 1. , 1.4142, 1. , 0. ],
       [ 0. , 1. , 1. , 0. , 0. ]])
```

With a sampling of 2 units along x, 1 along y:

```python
>>> ndimage.distance_transform_edt(a, sampling=[2,1])
array([[ 0. , 1. , 2. , 2.8284, 3.6056],
       [ 0. , 0. , 1. , 2. , 3. ],
       [ 0. , 1. , 2. , 2.2361, 2. ],
       [ 0. , 1. , 2. , 1. , 0. ],
       [ 0. , 1. , 1. , 0. , 0. ]])
```

Asking for indices as well:

```python
>>> edt, inds = ndimage.distance_transform_edt(a, return_indices=True)
>>> inds
array([[[0, 0, 1, 1, 3],
        [1, 1, 1, 3],
        [2, 2, 1, 3],
        [3, 3, 4, 3],
        [4, 4, 4, 4]],
       [[0, 0, 1, 4],
        [0, 1, 1, 4],
        [0, 0, 1, 4],
        [0, 0, 3, 4],
        [0, 0, 3, 4]]])
```

With arrays provided for inplace outputs:

```python
>>> indices = np.zeros(((np.ndim(a),) + a.shape), dtype=np.int32)
>>> ndimage.distance_transform_edt(a, return_indices=True, indices=indices)
array([[ 0. , 1. , 1.4142, 2.2361, 3. ],
       [ 0. , 0. , 1. , 2. , 2. ],
       [ 0. , 1. , 1.4142, 1.4142, 1. ],
       [ 0. , 1. , 1.4142, 1. , 0. ],
       [ 0. , 1. , 1. , 0. , 0. ]])
>>> indices
array([[[0, 0, 1, 1, 3],
        [1, 1, 1, 3],
        [2, 2, 1, 3],
        [2, 2, 1, 3],
        [2, 2, 1, 3]],
       [[0, 0, 1, 4],
        [0, 1, 1, 4],
        [0, 0, 1, 4],
        [0, 0, 3, 4],
        [0, 0, 3, 4]]])
```

scipy.ndimage.generate_binary_structure

scipy.ndimage.generate_binary_structure(rank, connectivity)

Generate a binary structure for binary morphological operations.

Parameters

- **rank** [int] Number of dimensions of the array to which the structuring element will be applied, as returned by `np.ndim`.
- **connectivity** [int] `connectivity` determines which elements of the output array belong to the structure, i.e., are considered as neighbors of the central element. Elements up to a squared distance of `connectivity` from the center are considered neighbors. `connectivity` may range from 1 (no diagonal elements are neighbors) to `rank` (all elements are neighbors).

Returns

- **output** [ndarray of bools] Structuring element which may be used for binary morphological operations, with `rank` dimensions and all dimensions equal to 3.

See also:

- `iterate_structure`, `binary_dilation`, `binary_erosion`

Notes

generate_binary_structure can only create structuring elements with dimensions equal to 3, i.e., minimal dimensions. For larger structuring elements, that are useful e.g., for eroding large objects, one may either use `iterate_structure`, or create directly custom arrays with numpy functions such as `numpy.ones`.

Examples

```python
>>> from scipy import ndimage
>>> struct = ndimage.generate_binary_structure(2, 1)
>>> struct
array([[False,  True, False],
       [ True,  True,  True],
       [False,  True, False]], dtype=bool)
>>> a = np.zeros((5,5))
>>> a[2, 2] = 1
>>> a
array([[ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.]])
```
>>> b = ndimage.binary_dilation(a, structure=struct).astype(a.dtype)
>>> b
array([[ 0.,  0.,  0.,  0.,  0.],
        [ 0.,  1.,  0.,  0.,  0.],
        [ 0.,  1.,  1.,  1.,  0.],
        [ 0.,  0.,  0.,  0.,  0.],
        [ 0.,  0.,  0.,  0.,  0.]])
>>> ndimage.binary_dilation(b, structure=struct).astype(a.dtype)
array([[ 0.,  0.,  1.,  0.,  0.],
        [ 0.,  1.,  1.,  1.,  0.],
        [ 1.,  1.,  1.,  1.,  1.],
        [ 0.,  1.,  1.,  1.,  0.],
        [ 0.,  0.,  1.,  0.,  0.]]
>>> struct = ndimage.generate_binary_structure(2, 2)
>>> struct
array([[ True,  True,  True],
        [ True,  True,  True],
        [ True,  True,  True]], dtype=bool)
>>> struct = ndimage.generate_binary_structure(3, 1)
>>> struct # no diagonal elements
array([[[False, False, False],
        [False,  True, False],
        [False, False, False]],
        [[False,  True, False],
        [ True,  True,  True],
        [False,  True, False]],
        [[False, False, False],
        [False,  True, False],
        [False, False, False]], dtype=bool)

scipy.ndimage.grey_closing

scipy.ndimage.grey_closing(input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)

Multidimensional grayscale closing.

A grayscale closing consists in the succession of a grayscale dilation, and a grayscale erosion.

Parameters

- **input** [array_like] Array over which the grayscale closing is to be computed.
- **size** [tuple of ints] Shape of a flat and full structuring element used for the grayscale closing. Optional if footprint or structure is provided.
- **footprint** [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the grayscale closing.
- **structure** [array of ints, optional] Structuring element used for the grayscale closing. structure may be a non-flat structuring element.
- **output** [array, optional] An array used for storing the output of the closing may be provided.
- **mode** [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The mode parameter determines how the array borders are handled, where cval is the value when mode is equal to ‘constant’. Default is ‘reflect’
- **cval** [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.
- **origin** [scalar, optional] The origin parameter controls the placement of the filter. Default 0

3.3. API definition
Returns

grey_closing
   [ndarray] Result of the grayscale closing of input with structure.

See also:

binary_closing, grey_dilation, grey_erosion, grey_opening

generate_binary_structure

Notes

The action of a grayscale closing with a flat structuring element amounts to smoothen deep local minima, whereas
binary closing fills small holes.

[1]

Examples

```python
>>> from scipy import ndimage
>>> a = np.arange(36).reshape((6,6))
>>> a[3,3] = 0
>>> a
array([[ 0,  1,  2,  3,  4,  5],
       [ 6,  7,  8,  9, 10, 11],
       [12, 13, 14, 15, 16, 17],
       [18, 19, 20,  0, 22, 23],
       [24, 25, 26, 27, 28, 29],
       [30, 31, 32, 33, 34, 35]])
>>> ndimage.grey_closing(a, size=(3,3))
array([[ 7,  7,  8,  9, 10, 11],
       [ 7,  7,  8,  9, 10, 11],
       [13, 13, 14, 15, 16, 17],
       [19, 19, 20,  0, 22, 23],
       [25, 25, 26, 27, 28, 29],
       [31, 31, 32, 33, 34, 35]])
>>> # Note that the local minimum a[3,3] has disappeared
```

scipy.ndimage.grey_dilation

Calculate a greyscale dilation, using either a structuring element, or a footprint corresponding to a flat structuring
element.

Grayscale dilation is a mathematical morphology operation. For the simple case of a full and flat structuring element,
it can be viewed as a maximum filter over a sliding window.

Parameters

- `input` [array_like] Array over which the grayscale dilation is to be computed.
size [tuple of ints] Shape of a flat and full structuring element used for the grayscale dilation. Optional if footprint or structure is provided.
footprint [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the grayscale dilation. Non-zero values give the set of neighbors of the center over which the maximum is chosen.
structure [array of ints, optional] Structuring element used for the grayscale dilation. structure may be a non-flat structuring element.
output [array, optional] An array used for storing the output of the dilation may be provided.
mode ['reflect','constant','nearest','mirror','wrap'], optional] The mode parameter determines how the array borders are handled, where cval is the value when mode is equal to 'constant'. Default is 'reflect'
cval [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
origin [scalar, optional] The origin parameter controls the placement of the filter. Default 0

Returns
grey_dilation [ndarray] Grayscale dilation of input.

See also:

binary_dilation, grey_erosion, grey_closing, grey_opening
generate_binary_structure, maximum_filter

Notes

The grayscale dilation of an image input by a structuring element s defined over a domain E is given by:

\[(input+s)(x) = \max\ \{input(y)+s(x-y), \text{for } y \text{ in } E\}\]

In particular, for structuring elements defined as \(s(y) = 0\) for \(y \text{ in } E\), the grayscale dilation computes the maximum of the input image inside a sliding window defined by E.

Grayscale dilation [1] is a mathematical morphology operation [2].

Examples

```python
>>> from scipy import ndimage
>>> a = np.zeros((7,7), dtype=int)
>>> a[2:5, 2:5] = 1
>>> a[4, 4] = 2; a[2, 3] = 3
>>> a
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 3, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 2, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
```

(continues on next page)
```python
>>> ndimage.grey_dilation(a, size=(3,3))
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 1, 3, 3, 3, 1, 0],
       [0, 1, 3, 3, 3, 1, 0],
       [0, 1, 3, 3, 2, 0],
       [0, 1, 1, 2, 2, 0],
       [0, 1, 1, 2, 2, 0],
       [0, 0, 0, 0, 0, 0]])
```
```python
>>> ndimage.grey_dilation(a, footprint=np.ones((3,3)))
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 1, 3, 3, 3, 1, 0],
       [0, 1, 3, 3, 3, 1, 0],
       [0, 1, 3, 3, 2, 0],
       [0, 1, 1, 2, 2, 0],
       [0, 1, 1, 2, 2, 0],
       [0, 0, 0, 0, 0, 0]])
```
```python
>>> s = ndimage.generate_binary_structure(2,1)
```
```python
>>> s
array([[False,  True, False],
       [ True,  True,  True],
       [False,  True, False]], dtype=bool)
```
```python
>>> ndimage.grey_dilation(a, footprint=s)
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 3, 1, 0, 0],
       [0, 1, 3, 3, 1, 0],
       [0, 1, 1, 2, 2, 0],
       [0, 1, 1, 2, 2, 0],
       [0, 0, 1, 2, 1, 0],
       [0, 0, 0, 0, 0, 0]])
```
```python
>>> ndimage.grey_dilation(a, size=(3,3), structure=np.ones((3,3)))
array([[1, 1, 1, 1, 1, 1, 1],
       [1, 2, 4, 4, 4, 2, 1],
       [1, 2, 4, 4, 4, 2, 1],
       [1, 2, 4, 4, 4, 3, 1],
       [1, 2, 2, 3, 3, 3, 1],
       [1, 2, 2, 3, 3, 3, 1],
       [1, 1, 1, 1, 1, 1, 1]])
```

**scipy.ndimage.grey_erosion**

`scipy.ndimage.grey_erosion` *(input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)*

Calculate a greyscale erosion, using either a structuring element, or a footprint corresponding to a flat structuring element.

Grayscale erosion is a mathematical morphology operation. For the simple case of a full and flat structuring element, it can be viewed as a minimum filter over a sliding window.

**Parameters**

- `input` [array_like] Array over which the grayscale erosion is to be computed.
- `size` [tuple of ints] Shape of a flat and full structuring element used for the grayscale erosion. Optional if `footprint` or `structure` is provided.
- `footprint` [array of ints, optional] Positions of non-infinite elements of a flat structuring element used
for the grayscale erosion. Non-zero values give the set of neighbors of the center over which the minimum is chosen.

**structure**
[array of ints, optional] Structuring element used for the grayscale erosion. *structure* may be a non-flat structuring element.

**output**
[array, optional] An array used for storing the output of the erosion may be provided.

**mode**
[{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The *mode* parameter determines how the array borders are handled, where *cval* is the value when mode is equal to 'constant'. Default is 'reflect'

**cval**
[scalar, optional] Value to fill past edges of input if *mode* is 'constant'. Default is 0.0.

**origin**
[scalar, optional] The *origin* parameter controls the placement of the filter. Default 0

**Returns**

output  [ndarray] Grayscale erosion of *input*.

See also:

*binary_erosion*, *grey_dilation*, *grey_opening*, *grey_closing*

*generate_binary_structure*, *minimum_filter*

**Notes**

The grayscale erosion of an image input by a structuring element *s* defined over a domain *E* is given by:

\[(\text{input}+s)(x) = \min \{\text{input}(y) - s(x-y), \text{for } y \in E\}\]

In particular, for structuring elements defined as *s*(y) = 0 for y in E, the grayscale erosion computes the minimum of the input image inside a sliding window defined by E.

Grayscale erosion [1] is a *mathematical morphology* operation [2].

[1], [2]

**Examples**

```python
>>> from scipy import ndimage
>>> a = np.zeros((7,7), dtype=int)
>>> a[1:6, 1:6] = 3
>>> a[4,4] = 2; a[2,3] = 1
>>> a
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 3, 3, 3, 3, 3, 0],
       [0, 3, 3, 1, 3, 3, 0],
       [0, 3, 3, 3, 3, 3, 0],
       [0, 3, 3, 3, 2, 3, 0],
       [0, 3, 3, 3, 3, 3, 0],
       [0, 0, 0, 0, 0, 0, 0]])
>>> ndimage.grey_erosion(a, size=(3,3))
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       (continues on next page)
```
scipy.ndimage.grey_opening

scipy.ndimage.grey_opening(input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)

Multidimensional grayscale opening.

A grayscale opening consists in the succession of a grayscale erosion, and a grayscale dilation.

Parameters

- **input**: [array_like] Array over which the grayscale opening is to be computed.
- **size**: [tuple of ints] Shape of a flat and full structuring element used for the grayscale opening. Optional if footprint or structure is provided.
- **footprint**: [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the grayscale opening.
- **structure**: [array of ints, optional] Structuring element used for the grayscale opening. structure may be a non-flat structuring element.
- **output**: [array, optional] An array used for storing the output of the opening may be provided.
- **mode**: [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The mode parameter determines how the array borders are handled, where cval is the value when mode is equal to 'constant'. Default is 'reflect'
- **cval**: [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0.
- **origin**: [scalar, optional] The origin parameter controls the placement of the filter. Default 0

Returns

- **grey_opening**: [ndarray] Result of the grayscale opening of input with structure.

See also:

- binary_opening, grey_dilation, grey_erosion, grey_closing
- generate_binary_structure
Notes

The action of a grayscale opening with a flat structuring element amounts to smoothen high local maxima, whereas binary opening erases small objects.

References

[1]

Examples

```python
>>> from scipy import ndimage
>>> a = np.arange(36).reshape((6, 6))
>>> a[3, 3] = 50
>>> a
array([[ 0,  1,  2,  3,  4,  5],
       [ 6,  7,  8,  9, 10, 11],
       [12, 13, 14, 15, 16, 17],
       [18, 19, 20, 50, 22, 23],
       [24, 25, 26, 27, 28, 29],
       [30, 31, 32, 33, 34, 35]])
>>> ndimage.grey_opening(a, size=(3, 3))
array([[ 0,  1,  2,  3,  4,  4],
       [ 6,  7,  8,  9, 10, 10],
       [12, 13, 14, 15, 16, 16],
       [18, 19, 20, 22, 22, 22],
       [24, 25, 26, 27, 28, 28],
       [24, 25, 26, 27, 28, 28]])
>>> # Note that the local maximum a[3,3] has disappeared
```

**scipy.ndimage.iterate_structure**

scipy.ndimage.iterate_structure(structure, iterations, origin=None)

Iterate a structure by dilating it with itself.

**Parameters**

- **structure** [array_like] Structuring element (an array of bools, for example), to be dilated with itself.
- **iterations** [int] number of dilations performed on the structure with itself
- **origin** [optional] If origin is None, only the iterated structure is returned. If not, a tuple of the iterated structure and the modified origin is returned.

**Returns**

- **iterate_structure** [ndarray of bools] A new structuring element obtained by dilating structure (iterations - 1) times with itself.

See also:

- **generate_binary_structure**
Examples

```python
>>> from scipy import ndimage
>>> struct = ndimage.generate_binary_structure(2, 1)
>>> struct.astype(int)
array([[0, 1, 0],
       [1, 1, 1],
       [0, 1, 0]])
```

```python
>>> ndimage.iterate_structure(struct, 2).astype(int)
array([[0, 0, 0, 1, 0, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 1, 1, 1, 1, 1, 0],
       [1, 1, 1, 1, 1, 1, 1],
       [0, 1, 1, 1, 1, 1, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 0, 1, 0, 0, 0]])
```

```python
>>> ndimage.iterate_structure(struct, 3).astype(int)
array([[0, 0, 0, 1, 0, 0, 0, 0],
       [0, 0, 0, 1, 1, 0, 0, 0],
       [0, 0, 1, 1, 1, 1, 0, 0],
       [0, 1, 1, 1, 1, 1, 1, 1],
       [1, 1, 1, 1, 1, 1, 1, 1],
       [0, 1, 1, 1, 1, 1, 1, 0],
       [0, 0, 1, 1, 1, 1, 0, 0],
       [0, 0, 0, 1, 0, 0, 0, 0]])
```

scipy.ndimage.morphological_gradient

scipy.ndimage.morphological_gradient (input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)

Multidimensional morphological gradient.

The morphological gradient is calculated as the difference between a dilation and an erosion of the input with a given structuring element.

Parameters

- **input** [array_like] Array over which to compute the morphological gradient.
- **size** [tuple of ints] Shape of a flat and full structuring element used for the mathematical morphology operations. Optional if footprint or structure is provided. A larger size yields a more blurred gradient.
- **footprint** [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the morphology operations. Larger footprints give a more blurred morphological gradient.
- **structure** [array of ints, optional] Structuring element used for the morphology operations. structure may be a non-flat structuring element.
- **output** [array, optional] An array used for storing the output of the morphological gradient may be provided.
- **mode** ['reflect', 'constant', 'nearest', 'mirror', 'wrap'], optional] The mode parameter determines how the array borders are handled, where cval is the value when mode is equal to 'constant'. Default is 'reflect'
- **cval** [scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0
- **origin** [scalar, optional] The origin parameter controls the placement of the filter. Default 0

Returns

- **morphological_gradient** [ndarray] Morphological gradient of input.

See also:
grey_dilation, grey_erosion, gaussian_gradient_magnitude

Notes

For a flat structuring element, the morphological gradient computed at a given point corresponds to the maximal difference between elements of the input among the elements covered by the structuring element centered on the point.

scipy.ndimage.morphological_laplace

**scipy.ndimage.morphological_laplace** *(input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)*

Multidimensional morphological laplace.

**Parameters**

- **input** [array_like] Input.
- **size** [int or sequence of ints, optional] See structure.
- **footprint** [bool or ndarray, optional] See structure.
- **structure** [structure, optional] Either size, footprint, or the structure must be provided.
- **output** [ndarray, optional] An output array can optionally be provided.
- **mode** [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The mode parameter determines how the array borders are handled. For ‘constant’ mode, values beyond borders are set to be cval. Default is ‘reflect’.
- **cval** [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0
- **origin** [origin, optional] The origin parameter controls the placement of the filter.

**Returns**

- **morphological_laplace** [ndarray] Output

**scipy.ndimage.white_tophat**

**scipy.ndimage.white_tophat** *(input, size=None, footprint=None, structure=None, output=None, mode='reflect', cval=0.0, origin=0)*

Multidimensional white tophat filter.

**Parameters**

- **input** [array_like] Input.
- **size** [tuple of ints] Shape of a flat and full structuring element used for the filter. Optional if footprint or structure is provided.
- **footprint** [array of ints, optional] Positions of elements of a flat structuring element used for the white tophat filter.
- **structure** [array of ints, optional] Structuring element used for the filter. structure may be a non-flat structuring element.
- **output** [array, optional] An array used for storing the output of the filter may be provided.
- **mode** [‘reflect’, ‘constant’, ‘nearest’, ‘mirror’, ‘wrap’], optional] The mode parameter determines how the array borders are handled, where cval is the value when mode is equal to ‘constant’. Default is ‘reflect’.
- **cval** [scalar, optional] Value to fill past edges of input if mode is ‘constant’. Default is 0.0.
- **origin** [scalar, optional] The origin parameter controls the placement of the filter. Default is 0.

**Returns**

- **output** [ndarray] Result of the filter of input with structure.

**See also:**

- **black_tophat**
Examples

Subtract gray background from a bright peak.

```python
>>> from scipy.ndimage import generate_binary_structure, white_tophat
>>> square = generate_binary_structure(rank=2, connectivity=3)
>>> bright_on_gray = np.array([[2, 3, 3, 2],
                              [3, 4, 5, 4, 3],
                              [3, 5, 9, 5, 3],
                              [3, 4, 5, 4, 3],
                              [2, 3, 3, 2]])
>>> white_tophat(input=bright_on_gray, structure=square)
array([[0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0],
       [0, 1, 5, 1, 0],
       [0, 0, 1, 0, 0],
       [0, 0, 0, 0, 0]])
```

scipy.odr.Data

class scipy.odr.Data(x, y=None, we=None, wd=None, fix=None, meta={})

The data to fit.

Parameters

x [array_like] Observed data for the independent variable of the regression

y [array_like, optional] If array-like, observed data for the dependent variable of the regression. A scalar input implies that the model to be used on the data is implicit.

we [array_like, optional] If we is a scalar, then that value is used for all data points (and all dimensions of the response variable). If we is a rank-1 array of length q (the dimensionality of the response variable), then this vector is the diagonal of the covariant weighting matrix for all data points. If we is a rank-1 array of length n (the number of data points), then the i'th element is the weight for the i'th response variable observation (single-dimensional only). If we is a rank-2 array of shape (q, q), then this is the full covariant weighting matrix broadcast to each observation. If we is a rank-2 array of shape (q, n), then we[:,i] is the diagonal of the covariant weighting matrix for the i'th observation. If we is a rank-3 array of shape (q, q, n), then we[:,:,i] is the full specification of the covariant weighting matrix for each observation. If the fit is implicit, then only a positive scalar value is used.

wd [array_like, optional] If wd is a scalar, then that value is used for all data points (and all dimensions of the input variable). If wd = 0, then the covariant weighting matrix for each observation is set to the identity matrix (so each dimension of each observation has the same weight). If wd is a rank-1 array of length m (the dimensionality of the input variable), then this vector is the diagonal of the covariant weighting matrix for all data points. If wd is a rank-1 array of length n (the number of data points), then the i'th element is the weight for the i'th input variable observation (single-dimensional only). If wd is a rank-2 array of shape (m, m), then this is the full covariant weighting matrix broadcast to each observation. If wd is a rank-2 array of shape (m, n), then wd[:,i] is the diagonal of the covariant weighting matrix for the i'th observation. If wd is a rank-3 array of shape (m, m, n), then wd[:,:,i] is the full specification of the covariant weighting matrix for each observation.

fix [array_like of ints, optional] The fix argument is the same as ifixx in the class ODR. It is an array of integers with the same shape as data.x that determines which input observations are treated as fixed. One can use a sequence of length m (the dimensionality of the input observations) to fix some dimensions for all observations. A value of 0 fixes the observation, a value > 0 makes it free.

Notes

Each argument is attached to the member of the instance of the same name. The structures of x and y are described in the Model class docstring. If y is an integer, then the Data instance can only be used to fit with implicit models where the dimensionality of the response is equal to the specified value of y.

The we argument weights the effect a deviation in the response variable has on the fit. The wd argument weights the effect a deviation in the input variable has on the fit. To handle multidimensional inputs and responses easily, the structure of these arguments has the n'th dimensional axis first. These arguments heavily use the structured arguments feature of ODRPACK to conveniently and flexibly support all options. See the ODRPACK User's Guide for a full explanation of how these weights are used in the algorithm. Basically, a higher value of the weight for a particular data point makes a deviation at that point more detrimental to the fit.
## Methods

| set_meta(**kwds) | Update the metadata dictionary with the keywords and data provided by keywords. |

### scipy.odr.Data.set_meta

Data.set_meta(**kwds)

Update the metadata dictionary with the keywords and data provided by keywords.

### Examples

```py
data.set_meta(lab="Ph 7; Lab 26", title="Ag110 + Ag108 Decay")
```

### scipy.odr.RealData

**class scipy.odr.RealData**(x, y=None, sx=None, sy=None, covx=None, covy=None, fix=None, meta={})

The data, with weightings as actual standard deviations and/or covariances.

**Parameters**

- **x** [array_like] Observed data for the independent variable of the regression
- **y** [array_like, optional] If array-like, observed data for the dependent variable of the regression. A scalar input implies that the model to be used on the data is implicit.
- **sx** [array_like, optional] Standard deviations of \( x \) \( sx \) are standard deviations of \( x \) and are converted to weights by dividing 1.0 by their squares.
- **sy** [array_like, optional] Standard deviations of \( y \) \( sy \) are standard deviations of \( y \) and are converted to weights by dividing 1.0 by their squares.
- **covx** [array_like, optional] Covariance of \( x \ \text{covx} \) is an array of covariance matrices of \( x \) and are converted to weights by performing a matrix inversion on each observation’s covariance matrix.
- **covy** [array_like, optional] Covariance of \( y \ \text{covy} \) is an array of covariance matrices and are converted to weights by performing a matrix inversion on each observation’s covariance matrix.
- **fix** [array_like, optional] The argument and member fix is the same as Data.fix and ODR.ifixx: It is an array of integers with the same shape as \( x \) that determines which input observations are treated as fixed. One can use a sequence of length \( m \) (the dimensionality of the input observations) to fix some dimensions for all observations. A value of 0 fixes the observation, a value > 0 makes it free.
- **meta** [dict, optional] Free-form dictionary for metadata.

**Notes**

The weights \( wd \) and \( we \) are computed from provided values as follows:

- \( sx \) and \( sy \) are converted to weights by dividing 1.0 by their squares. For example, \( wd = 1./\text{numpy.power}(\text{sx}', 2) \).
- \( \text{covx} \) and \( \text{covy} \) are arrays of covariance matrices and are converted to weights by performing a matrix inversion on each observation’s covariance matrix. For example, \( \text{we}[i] = \text{numpy.linalg.inv(\text{covy}[i])} \).

These arguments follow the same structured argument conventions as \( wd \) and we only restricted by their natures: \( sx \) and \( sy \) can’t be rank-3, but \( \text{covx} \) and \( \text{covy} \) can be.
Only set either *sx* or *covx* (not both). Setting both will raise an exception. Same with *sy* and *covy*.

Methods

```
set_meta(**kwds)  Update the metadata dictionary with the keywords and
data provided by keywords.
```

**scipy.odr.RealData.set_meta**

```
RealData.set_meta(**kwds)
Update the metadata dictionary with the keywords and data provided by keywords.
```

**Examples**

```
data.set_meta(lab="Ph 7; Lab 26", title="Ag110 + Ag108 Decay")
```

**scipy.odr.Model**

class scipy.odr.Model (fcn, fjacb=None, fjacd=None, extra_args=None, estimate=None, implicit=0, meta=None)

The `Model` class stores information about the function you wish to fit.

It stores the function itself, at least, and optionally stores functions which compute the Jacobians used during fitting. Also, one can provide a function that will provide reasonable starting values for the fit parameters possibly given the set of data.

**Parameters**

- **fcn** [function] `fcn(beta, x) -> y`
- **fjacb** [function] Jacobian of `fcn` wrt the fit parameters `beta`. `fjacb(beta, x) -> @f_i(x,B)/@B_j`
- **fjacd** [function] Jacobian of `fcn` wrt the (possibly multidimensional) input variable. `fjacd(beta, x) -> @f_i(x,B)/@x_j`
- **extra_args** [tuple, optional] If specified, `extra_args` should be a tuple of extra arguments to pass to `fcn`, `fjacb`, and `fjacd`. Each will be called by `apply(fcn, (beta, x) + extra_args)`
- **estimate** [array_like of rank-1] Provides estimates of the fit parameters from the data `estimate(data) -> estbeta`
- **implicit** [boolean] If `TRUE`, specifies that the model is implicit; i.e *fcn*(beta, x) ≈ 0 and there is no y data to fit against
- **meta** [dict, optional] freeform dictionary of metadata for the model

**Notes**

Note that the `fcn`, `fjacb`, and `fjacd` operate on NumPy arrays and return a NumPy array. The `estimate` object takes an instance of the `Data` class.

Here are the rules for the shapes of the argument and return arrays of the callback functions:

- **x** if the input data is single-dimensional, then x is rank-1 array; i.e., x = array([1, 2, 3, ...]); x.shape = (n,) If the input data is multi-dimensional, then x is a rank-2 array; i.e., x = array([[1, 2, ...], [2, 4, ...]]); x.shape = (m, n). In all cases, it has the same shape as the input data array passed to `odr`. `m` is the dimensionality of the input data, `n` is the number of observations.
y  if the response variable is single-dimensional, then y is a rank-1 array, i.e., \( y = \text{array}([2, 4, \ldots]) \); \( y.\text{shape} = (n,). \) If the response variable is multi-dimensional, then y is a rank-2 array, i.e., \( y = \text{array}([[2, 4, \ldots], [3, 6, \ldots]]) \); \( y.\text{shape} = (q, n) \) where \( q \) is the dimensionality of the response variable.

beta  rank-1 array of length \( p \) where \( p \) is the number of parameters; i.e. \( \beta = \text{array}([B_1, B_2, \ldots, B_p]) \)

fjacb  if the response variable is multi-dimensional, then the return array's shape is \( (q, p, n) \) such that \( \text{fjacb}(x, \beta)[l,k,i] = \frac{d f_l(X,B)}{d B_k} \) evaluated at the \( i \)th data point. If \( q == 1 \), then the return array is only rank-2 and with shape \( (p, n) \).

fjacd  as with fjacb, only the return array's shape is \( (q, m, n) \) such that \( \text{fjacd}(x, \beta)[l,j,i] = \frac{d f_l(X,B)}{d X_j} \) at the \( i \)th data point. If \( q == 1 \), then the return array's shape is \( (m, n) \). If \( m == 1 \), the shape is \( (n,) \). If \( m == q == 1 \), the shape is \( (n,) \).

Methods

```python
set_meta(**kwds)  Update the metadata dictionary with the keywords and data provided here.
```

```python
scipy.odr.Model.set_meta
```

```python
Model.set_meta(**kwds)
```

Update the metadata dictionary with the keywords and data provided here.

Examples

```python
set_meta(name="Exponential", equation="y = a \exp(b \times) + c")
```

```python
scipy.odr.ODR
```

```python
class scipy.odr.ODR (data, model, beta0=None, delta0=None,ifixb=None,ifixx=None, job=None, iprint=None, errfile=None, rptfile=None, ndigit=None, taufac=None, sstol=None, partol=None, maxit=None, stpb=None, stpd=None, sclb=None, scld=None, work=None, iwork=None, overwrite=False)
```

The ODR class gathers all information and coordinates the running of the main fitting routine.

Members of instances of the ODR class have the same names as the arguments to the initialization routine.

Parameters

```python
data  [Data class instance] instance of the Data class
model  [Model class instance] instance of the Model class
```

Other Parameters

```python
beta0  [array_like of rank-1] a rank-1 sequence of initial parameter values. Optional if model provides an “estimate” function to estimate these values.
```
delta0  [array_like of floats of rank-1, optional] a (double-precision) float array to hold the initial values of the errors in the input variables. Must be same shape as data.x

ifixb  [array_like of ints of rank-1, optional] sequence of integers with the same length as beta0 that determines which parameters are held fixed. A value of 0 fixes the parameter, a value > 0 makes the parameter free.

ifixx  [array_like of ints with same shape as data.x, optional] an array of integers with the same shape as data.x that determines which input observations are treated as fixed. One can use a sequence of length m (the dimensionality of the input observations) to fix some dimensions for all observations. A value of 0 fixes the observation, a value > 0 makes it free.

erfile  [str, optional] string with the filename to print ODRPACK errors to. If the file already exists, an error will be thrown. The overwrite argument can be used to prevent this. Do Not Open This File Yourself!

rptfile  [str, optional] string with the filename to print ODRPACK summaries to. If the file already exists, an error will be thrown. The overwrite argument can be used to prevent this. Do Not Open This File Yourself!

ndigit  [int, optional] integer specifying the number of reliable digits in the computation of the function.

taufac  [float, optional] float specifying the initial trust region. The default value is 1. The initial trust region is equal to taufac times the length of the first computed Gauss-Newton step. taufac must be less than 1.

sstol  [float, optional] float specifying the tolerance for convergence based on the relative change in the sum-of-squares. The default value is eps**(1/2) where eps is the smallest value such that 1 + eps > 1 for double precision computation on the machine. sstol must be less than 1.

partol  [float, optional] float specifying the tolerance for convergence based on the relative change in the estimated parameters. The default value is eps**(2/3) for explicit models and eps**(1/3) for implicit models. partol must be less than 1.

maxit  [int, optional] integer specifying the maximum number of iterations to perform. For first runs, maxit is the total number of iterations performed and defaults to 50. For restarts, maxit is the number of additional iterations to perform and defaults to 10.

stpb  [array_like, optional] sequence (len(stpb) == len(beta0)) of relative step sizes to compute finite difference derivatives wrt the parameters.

stdp  [optional] array (stdp.shape == data.x.shape or stdp.shape == (m,)) of relative step sizes to compute finite difference derivatives wrt the input variable errors. If stdp is a rank-1 array with length m (the dimensionality of the input variable), then the values are broadcast to all observations.

sclb  [array_like, optional] sequence (len(stpb) == len(beta0)) of scaling factors for the parameters. The purpose of these scaling factors are to scale all of the parameters to around unity. Normally appropriate scaling factors are computed if this argument is not specified. Specify them yourself if the automatic procedure goes awry.

scld  [array_like, optional] array (scld.shape == data.x.shape or scld.shape == (m,)) of scaling factors for the errors in the input variables. Again, these factors are automatically computed if you do not provide them. If scld.shape == (m,), then the scaling factors are broadcast to all observations.

work  [ndarray, optional] array to hold the double-valued working data for ODRPACK. When restarting, takes the value of self.output.work.

iwork  [ndarray, optional] array to hold the integer-valued working data for ODRPACK. When restarting, takes the value of self.output.iwork.
overwrite  [bool, optional] If it is True, output files defined by *errfile* and *rptfile* are overwritten. The default is False.

**Attributes**

- **data**  [Data] The data for this fit
- **model**  [Model] The model used in fit
- **output**  [Output] An instance if the Output class containing all of the returned data from an invocation of ODR.run() or ODR.restart()

**Methods**

- **restart([iter])**  
  Restarts the run with *iter* more iterations.

- **run()**  
  Run the fitting routine with all of the information given and with *full_output=1*.

- **set_iprint([init, so_init, iter, so_iter, ...])**  
  Set the iprint parameter for the printing of computation reports.

- **set_job([fit_type, deriv, var_calc, ...])**  
  Sets the ”job” parameter is a hopefully comprehensible way.

**scipy.odr.ODR.restart**

ODR.restart (*iter=None*)  
Restarts the run with *iter* more iterations.

**Parameters**

- **iter**  [int, optional] ODRPACK’s default for the number of new iterations is 10.

**Returns**

- **output**  [Output instance] This object is also assigned to the attribute .output.

**scipy.odr.ODR.run**

ODR.run()  
Run the fitting routine with all of the information given and with *full_output=1*.

**Returns**

- **output**  [Output instance] This object is also assigned to the attribute .output.

**scipy.odr.ODR.set_iprint**

ODR.set_iprint (*init=None, so_init=None, iter=None, so_iter=None, iter_step=None, final=None, so_final=None*)  
Set the iprint parameter for the printing of computation reports.

If any of the arguments are specified here, then they are set in the iprint member. If iprint is not set manually or with this method, then ODRPACK defaults to no printing. If no filename is specified with the member rptfile, then ODRPACK prints to stdout. One can tell ODRPACK to print to stdout in addition to the specified filename by setting the so_* arguments to this function, but one cannot specify to print to stdout but not a file since one can do that by not specifying a rptfile filename.
There are three reports: initialization, iteration, and final reports. They are represented by the arguments init, iter, and final respectively. The permissible values are 0, 1, and 2 representing “no report”, “short report”, and “long report” respectively.

The argument iter_step (0 <= iter_step <= 9) specifies how often to make the iteration report; the report will be made for every iter_step'th iteration starting with iteration one. If iter_step == 0, then no iteration report is made, regardless of the other arguments.

If the rptfile is None, then any so_* arguments supplied will raise an exception.

**scipy.odr.ODR.set_job**

**ODR.set_job** (*fit_type=None, deriv=None, var_calc=None, del_init=None, restart=None*)

Sets the “job” parameter in a hopefully comprehensible way.

If an argument is not specified, then the value is left as is. The default value from class initialization is for all of these options set to 0.

**Parameters**

- **fit_type**
  - [0, 1, 2] int: 0 -> explicit ODR
    - 1 -> implicit ODR
    - 2 -> ordinary least-squares

- **deriv**
  - [0, 1, 2, 3] int: 0 -> forward finite differences
    - 1 -> central finite differences
    - 2 -> user-supplied derivatives (Jacobians) with results checked by ODRPACK
    - 3 -> user-supplied derivatives, no checking

- **var_calc**
  - [0, 1, 2] int:
    - 0 -> calculate asymptotic covariance matrix and fit parameter uncertainties (V_B, s_B) using derivatives recomputed at the final solution
    - 1 -> calculate V_B and s_B using derivatives from last iteration
    - 2 -> do not calculate V_B and s_B

- **del_init**
  - [0, 1] int: 0 -> initial input variable offsets set to 0
    - 1 -> initial offsets provided by user in variable “work”

- **restart**
  - [0, 1] int: 0 -> fit is not a restart
    - 1 -> fit is a restart

**Notes**

The permissible values are different from those given on pg. 31 of the ODRPACK User’s Guide only in that one cannot specify numbers greater than the last value for each variable.

If one does not supply functions to compute the Jacobians, the fitting procedure will change deriv to 0, finite differences, as a default. To initialize the input variable offsets by yourself, set del_init to 1 and put the offsets into the “work” variable correctly.
scipy.odr.Output

class scipy.odr.Output (output)

The Output class stores the output of an ODR run.

Notes

Takes one argument for initialization, the return value from the function odr. The attributes listed as “optional” above are only present if odr was run with full_output=1.

Attributes

beta [ndarray] Estimated parameter values, of shape (q,).
sd_beta [ndarray] Standard deviations of the estimated parameters, of shape (p,).
cov_beta [ndarray] Covariance matrix of the estimated parameters, of shape (p,p).
delta [ndarray, optional] Array of estimated errors in input variables, of same shape as x.
eps [ndarray, optional] Array of estimated errors in response variables, of same shape as y.
xplus [ndarray, optional] Array of x + delta.
y [ndarray, optional] Array y = fcn(x + delta).
res_var [float, optional] Residual variance.
sum_square [float, optional] Sum of squares error.
sum_square_delta [float, optional] Sum of squares of delta error.
sum_square_eps [float, optional] Sum of squares of eps error.
inv_condnum [float, optional] Inverse condition number (cf. ODRPACK UG p. 77).
rel_error [float, optional] Relative error in function values computed within fcn.
work [ndarray, optional] Final work array.
work_ind [dict, optional] Indices into work for drawing out values (cf. ODRPACK UG p. 83).
info [int, optional] Reason for returning, as output by ODRPACK (cf. ODRPACK UG p. 38).
stopreason [list of str, optional] info interpreted into English.

Methods

pprint() Pretty-print important results.

scipy.odr.Output.pprint

Output.pprint () Pretty-print important results.

scipy.odr.odr

`scipy.odr.odr(fcn, beta0, y, x, we=None, wd=None, fjacb=None, fjacd=None, extra_args=None,ifixx=None, ifixb=None, job=0, iprint=0, errfile=None, rptfile=None, ndigit=0, taufac=0.0, sstol=-1.0, partol=-1.0, maxit=-1, stpb=None, stdp=None, sclb=None, scld=None, work=None, iwork=None, full_output=0)`

Low-level function for ODR.

See also:

ODR

The ODR class gathers all information and coordinates the running of the main fitting routine.

Model

The Model class stores information about the function you wish to fit.

Data

The data to fit.

RealData

Data with weights as actual std. devs and/or covariances.

Notes

This is a function performing the same operation as the ODR, Model, and Data classes together. The parameters of this function are explained in the class documentation.

scipy.odr.OdrWarning

exception `scipy.odr.OdrWarning`

Warning indicating that the data passed into ODR will cause problems when passed into ‘odr’ that the user should be aware of.

```python
with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

scipy.odr.OdrError

exception `scipy.odr.OdrError`

Exception indicating an error in fitting.

This is raised by odr if an error occurs during fitting.

```python
with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

scipy.odr.OdrStop

exception `scipy.odr.OdrStop`

Exception stopping fitting.

You can raise this exception in your objective function to tell odr to stop fitting.

```python
with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```
scipy.odr.polynomial

scipy.odr.polynomial(order)
Factory function for a general polynomial model.

Parameters

order [int or sequence] If an integer, it becomes the order of the polynomial to fit. If a sequence of numbers, then these are the explicit powers in the polynomial. A constant term (power 0) is always included, so don’t include 0. Thus, polynomial(n) is equivalent to polynomial(range(1, n+1)).

Returns

Examples

We can fit an input data using orthogonal distance regression (ODR) with a polynomial model:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy import odr
>>> x = np.linspace(0.0, 5.0)
>>> y = np.sin(x)
>>> poly_model = odr.polynomial(3)  # using third order polynomial model
>>> data = odr.Data(x, y)
>>> odr_obj = odr.ODR(data, poly_model)
>>> output = odr_obj.run()  # running ODR fitting
>>> poly = np.poly1d(output.beta[::-1])
>>> poly_y = poly(x)
>>> plt.plot(x, y, label="input data")
>>> plt.plot(x, poly_y, label="polynomial ODR")
>>> plt.legend()
>>> plt.show()
```
**scipy.odr.exponential**

*scipy.odr.exponential* = `<scipy.odr._models._ExponentialModel object>

Exponential model

This model is defined by $y = \beta_0 + e^{\beta_1 x}$

**Examples**

We can calculate orthogonal distance regression with an exponential model:

```python
>>> from scipy import odr
>>> x = np.linspace(0.0, 5.0)
>>> y = -10.0 + np.exp(0.5 * x)
>>> data = odr.Data(x, y)
>>> odr_obj = odr.ODR(data, odr.exponential)
>>> output = odr_obj.run()
>>> print(output.beta)
[-10.  0.5]
```

**scipy.odr.multilinear**

*scipy.odr.multilinear* = `<scipy.odr._models._MultilinearModel object>

Arbitrary-dimension linear model

This model is defined by $y = \beta_0 + \sum_{i=1}^{m} \beta_i x_i$

**Examples**

We can calculate orthogonal distance regression with an arbitrary dimensional linear model:

```python
>>> from scipy import odr
>>> x = np.linspace(0.0, 5.0)
>>> y = 10.0 + 5.0 * x
>>> data = odr.Data(x, y)
>>> odr_obj = odr.ODR(data, odr.multilinear)
>>> output = odr_obj.run()
>>> print(output.beta)
[10.  5.]
```

**scipy.odr.unilinear**

*scipy.odr.unilinear* = `<scipy.odr._models._UnilinearModel object>

Univariate linear model

This model is defined by $y = \beta_0 x + \beta_1$
Examples

We can calculate orthogonal distance regression with an unlinear model:

```python
>>> from scipy import odr
>>> x = np.linspace(0.0, 5.0)
>>> y = 1.0 * x + 2.0
>>> data = odr.Data(x, y)
>>> odr_obj = odr.ODR(data, odr.unilinear)
>>> output = odr_obj.run()
>>> print(output.beta)
[1. 2.]
```

scipy.odr.quadratic

```
scipy.odr.quadratic = <scipy.odr._models._QuadraticModel object>
```

Quadratic model

This model is defined by $y = \beta_0 x^2 + \beta_1 x + \beta_2$

Examples

We can calculate orthogonal distance regression with a quadratic model:

```python
>>> from scipy import odr
>>> x = np.linspace(0.0, 5.0)
>>> y = 1.0 * x ** 2 + 2.0 * x + 3.0
>>> data = odr.Data(x, y)
>>> odr_obj = odr.ODR(data, odr.quadratic)
>>> output = odr_obj.run()
>>> print(output.beta)
[1. 2. 3.]
```

Usage information

Introduction

Why Orthogonal Distance Regression (ODR)? Sometimes one has measurement errors in the explanatory (a.k.a., “independent”) variable(s), not just the response (a.k.a., “dependent”) variable(s). Ordinary Least Squares (OLS) fitting procedures treat the data for explanatory variables as fixed, i.e., not subject to error of any kind. Furthermore, OLS procedures require that the response variables be an explicit function of the explanatory variables; sometimes making the equation explicit is impractical and/or introduces errors. ODR can handle both of these cases with ease, and can even reduce to the OLS case if that is sufficient for the problem.

ODRPACK is a FORTRAN-77 library for performing ODR with possibly non-linear fitting functions. It uses a modified trust-region Levenberg-Marquardt-type algorithm [1] to estimate the function parameters. The fitting functions are provided by Python functions operating on NumPy arrays. The required derivatives may be provided by Python functions as well, or may be estimated numerically. ODRPACK can do explicit or implicit ODR fits, or it can do OLS. Input and output variables may be multidimensional. Weights can be provided to account for different variances of the observations, and even covariances between dimensions of the variables.

The `scipy.odr` package offers an object-oriented interface to ODRPACK, in addition to the low-level `odr` function.

Additional background information about ODRPACK can be found in the ODRPACK User’s Guide, reading which is recommended.
Basic usage

1. Define the function you want to fit against:

```python
def f(B, x):
    '''Linear function y = m*x + b'''
    # B is a vector of the parameters.
    # x is an array of the current x values.
    # x is in the same format as the x passed to Data or RealData.
    #
    return B[0]*x + B[1]
```

2. Create a Model:

```python
linear = Model(f)
```

3. Create a Data or RealData instance:

```python
mydata = Data(x, y, wd=1./power(sx, 2), we=1./power(sy, 2))
```

or, when the actual covariances are known:

```python
mydata = RealData(x, y, sx=sx, sy=sy)
```

4. Instantiate ODR with your data, model and initial parameter estimate:

```python
myodr = ODR(mydata, linear, beta0=[1., 2.])
```

5. Run the fit:

```python
myoutput = myodr.run()
```

6. Examine output:

```python
myoutput.pprint()
```

3.3.19 Optimization and root finding (scipy.optimize)

SciPy optimize provides functions for minimizing (or maximizing) objective functions, possibly subject to constraints. It includes solvers for nonlinear problems (with support for both local and global optimization algorithms), linear programming, constrained and nonlinear least-squares, root finding, and curve fitting.

Common functions and objects, shared across different solvers, are:

| `show_options([solver, method, disp])` | Show documentation for additional options of optimization solvers. |
| `OptimizeResult` | Represents the optimization result. |
| `OptimizeWarning` | |
scipy.optimize.show_options

scipy.optimize.show_options(solver=None, method=None, disp=True)

Show documentation for additional options of optimization solvers.

These are method-specific options that can be supplied through the options dict.

Parameters

- **solver** [str] Type of optimization solver. One of 'minimize', 'minimize_scalar', 'root', 'root_scalar', 'linprog', or 'quadratic_assignment'.
- **method** [str, optional] If not given, shows all methods of the specified solver. Otherwise, show only the options for the specified method. Valid values corresponds to methods’ names of respective solver (e.g., 'BFGS' for 'minimize').
- **disp** [bool, optional] Whether to print the result rather than returning it.

Returns

- **text** Either None (for disp=True) or the text string (disp=False)

Notes

The solver-specific methods are:

- **scipy.optimize.minimize**
  - Nelder-Mead
  - Powell
  - CG
  - BFGS
  - Newton-CG
  - L-BFGS-B
  - TNC
  - COBYLA
  - SLSQP
  - dogleg
  - trust-ncg

- **scipy.optimize.root**
  - hybr
  - lm
  - broyden1
  - broyden2
  - anderson
  - linearmixing
  - diagbroyden
  - excitingmixing
  - krylov
• df-sane

```
scipy.optimize.minimize_scalar
• brent
• golden
• bounded

scipy.optimize.root_scalar
• bisect
• brentq
• brent
• ridder

• highs-ipm

```
scipy.optimize.quadratic_assignment
• faq
• 2opt
```

**Examples**

We can print documentations of a solver in stdout:

```python
>>> from scipy.optimize import show_options
>>> show_options(solver="minimize")
...```

Specifying a method is possible:

```python
>>> show_options(solver="minimize", method="Nelder-Mead")
...
```

We can also get the documentations as a string:

```python
>>> show_options(solver="minimize", method="Nelder-Mead", disp=False)
Minimization of scalar function of one or more variables using the ...
```
scipy.optimize.OptimizeResult

class scipy.optimize.OptimizeResult

Represents the optimization result.

Notes

OptimizeResult may have additional attributes not listed here depending on the specific solver being used. Since this class is essentially a subclass of dict with attribute accessors, one can see which attributes are available using the OptimizeResult.keys method.

Attributes

- **x** [ndarray] The solution of the optimization.
- **success** [bool] Whether or not the optimizer exited successfully.
- **status** [int] Termination status of the optimizer. Its value depends on the underlying solver. Refer to message for details.
- **message** [str] Description of the cause of the termination.
- **fun, jac, hess**: ndarray
  Values of objective function, its Jacobian and its Hessian (if available). The Hessians may be approximations, see the documentation of the function in question.
- **hess_inv** [object] Inverse of the objective function’s Hessian; may be an approximation. Not available for all solvers. The type of this attribute may be either np.ndarray or scipy.sparse.linalg.LinearOperator.
- **nfev, njev, nhev** [int] Number of evaluations of the objective functions and of its Jacobian and Hessian.
- **nit** [int] Number of iterations performed by the optimizer.
- **maxcv** [float] The maximum constraint violation.

Methods

- **__getitem__**
  x.__getitem__(y) <=> x[y]
- **__len__** (/)
  Return len(self).
- **clear**
- **copy**
- **fromkeys**(iterable[, value])
  Create a new dictionary with keys from iterable and values set to value.
- **get**(key[, default])
  Return the value for key if key is in the dictionary, else default.
- **items**
- **keys**
- **pop**(key[, default])
  If the key is not found, return the default if given; otherwise, raise a KeyError.
- **popitem**(/) Remove and return a (key, value) pair as a 2-tuple.
- **setdefault**(key[, default])
  Insert key with a value of default if key is not in the dictionary.

Table 121 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>update()</code></td>
<td>If <code>E</code> is present and has a <code>.keys()</code> method, then does: for <code>k</code> in <code>E</code>: <code>D[k] = E[k]</code> If <code>E</code> is present and lacks a <code>.keys()</code> method, then does: for <code>k, v</code> in <code>E</code>: <code>D[k] = v</code> In either case, this is followed by: for <code>k</code> in <code>F</code>: <code>D[k] = F[k]</code></td>
</tr>
</tbody>
</table>

`values()`

```python
scipy.optimize.OptimizeResult.__getitem__
```

OptimizeResult.__getitem__(y) \(\Rightarrow x[y]\)

```python
scipy.optimize.OptimizeResult.__len__
```

Return `len(self)`.

```python
scipy.optimize.OptimizeResult.clear
```

OptimizeResult.clear() \(\Rightarrow\) None. Remove all items from `D`.

```python
scipy.optimize.OptimizeResult.copy
```

OptimizeResult.copy() \(\Rightarrow\) a shallow copy of `D`.

```python
scipy.optimize.OptimizeResult.fromkeys
```

Create a new dictionary with keys from `iterable` and values set to `value`.

```python
scipy.optimize.OptimizeResult.get
```

OptimizeResult.get(key, default=None) \(\Rightarrow\) Return the value for `key` if `key` is in the dictionary, else `default`.

```python
scipy.optimize.OptimizeResult.items
```

OptimizeResult.items() \(\Rightarrow\) a set-like object providing a view on `D`'s items

```python
scipy.optimize.OptimizeResult.keys
```

OptimizeResult.keys() \(\Rightarrow\) a set-like object providing a view on `D`'s keys

```python
scipy.optimize.OptimizeResult.pop
```

OptimizeResult.pop(key, default=\(<unrepresentable>\), ...) \(\Rightarrow\) If the key is not found, return the default if given; otherwise, raise a `KeyError`.

```python
scipy.optimize.OptimizeResult.popitem
```

OptimizeResult.popitem() \(\Rightarrow\) Remove and return a `(key, value)` pair as a 2-tuple. Pairs are returned in LIFO (last-in, first-out) order. Raises `KeyError` if the dict is empty.
**scipy.optimize.OptimizeResult.setdefault**

OptimizeResult.setdefault(key, default=None, /)

Insert key with a value of default if key is not in the dictionary.

Return the value for key if key is in the dictionary, else default.

**scipy.optimize.OptimizeResult.update**

OptimizeResult.update([E], **F) → None. Update D from dict/iterable E and F.

If E is present and has a .keys() method, then does: for k in E: D[k] = E[k] If E is present and lacks a .keys() method, then does: for k, v in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]

**scipy.optimize.OptimizeResult.values**

OptimizeResult.values() → an object providing a view on D's values

**scipy.optimize.OptimizeWarning**

exception scipy.optimize.OptimizeWarning

with_traceback() → Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

**Optimization**

**Scalar functions optimization**

<table>
<thead>
<tr>
<th>minimize_scalar(fun[, bracket, bounds, ...])</th>
<th>Minimization of scalar function of one variable.</th>
</tr>
</thead>
</table>

**scipy.optimize.minimize_scalar**

scipy.optimize.minimize_scalar (fun, bracket=None, bounds=None, args=(), method='brent', tol=None, options=None)

Minimization of scalar function of one variable.

**Parameters**

| fun [callable] Objective function. Scalar function, must return a scalar. |
| bracket [sequence, optional] For methods ‘brent’ and ‘golden’, bracket defines the bracketing interval and can either have three items (a, b, c) so that a < b < c and fun(b) < fun(a), fun(c) or two items a and c which are assumed to be a starting interval for a downhill bracket search (see bracket); it doesn’t always mean that the obtained solution will satisfy a <= x <= c. |
| bounds [sequence, optional] For method ‘bounded’, bounds is mandatory and must have two items corresponding to the optimization bounds. |
| args [tuple, optional] Extra arguments passed to the objective function. |
| method [str or callable, optional] Type of solver. Should be one of: |

| Brent |
| Bound |
| Golden |

* custom - a callable object (added in version 0.14.0), see below

See the ‘Notes’ section for details of each solver.

| tol [float, optional] Tolerance for termination. For detailed control, use solver-specific options. |

3.3. API definition 1273
maxiter  [int] Maximum number of iterations to perform.
disp     [bool] Set to True to print convergence messages.

See show_options for solver-specific options.

Returns
res      [OptimizeResult] The optimization result represented as an OptimizeResult object. Important attributes are: x the solution array, success a Boolean flag indicating if the optimizer exited successfully and message which describes the cause of the termination. See OptimizeResult for a description of other attributes.

See also:

minimize

Interface to minimization algorithms for scalar multivariate functions

show_options

Additional options accepted by the solvers

Notes

This section describes the available solvers that can be selected by the ‘method’ parameter. The default method is Brent.

Method Brent uses Brent’s algorithm to find a local minimum. The algorithm uses inverse parabolic interpolation when possible to speed up convergence of the golden section method.

Method Golden uses the golden section search technique. It uses analog of the bisection method to decrease the bracketed interval. It is usually preferable to use the Brent method.

Method Bounded can perform bounded minimization. It uses the Brent method to find a local minimum in the interval x1 < xopt < x2.

Custom minimizers

It may be useful to pass a custom minimization method, for example when using some library frontend to minimize_scalar. You can simply pass a callable as the method parameter.

The callable is called as method(fun, args, **kwargs, **options) where kwargs corresponds to any other parameters passed to minimize (such as bracket, tol, etc.), except the options dict, which has its contents also passed as method parameters pair by pair. The method shall return an OptimizeResult object.

The provided method callable must be able to accept (and possibly ignore) arbitrary parameters; the set of parameters accepted by minimize may expand in future versions and then these parameters will be passed to the method. You can find an example in the scipy.optimize tutorial.

New in version 0.11.0.
Examples

Consider the problem of minimizing the following function.

```python
>>> def f(x):
...     return (x - 2) * x * (x + 2)**2
```

Using the *Brent* method, we find the local minimum as:

```python
>>> from scipy.optimize import minimize_scalar
>>> res = minimize_scalar(f)
>>> res.x
1.28077640403
```

Using the *Bounded* method, we find a local minimum with specified bounds as:

```python
>>> res = minimize_scalar(f, bounds=(-3, -1), method='bounded')
>>> res.x
-2.0000002026
```

The *minimize_scalar* function supports the following methods:

*minimize_scalar(method='brent')*

```python
scipy.optimize.minimize_scalar (fun, args=(), method='brent', tol=None, options={'func': None, 'brack': None, 'xtol': 1.48e-08, 'maxiter': 500, 'disp': 0})
```

See also:

For documentation for the rest of the parameters, see *scipy.optimize.minimize_scalar*

**Options**

- `maxiter` [int] Maximum number of iterations to perform.
- `xtol` [float] Relative error in solution `xopt` acceptable for convergence.
- `disp` int, optional

If non-zero, print messages.

0: no message printing. 1: non-convergence notification messages only. 2: print a message on convergence too. 3: print iteration results.

**Notes**

Uses inverse parabolic interpolation when possible to speed up convergence of golden section method.
minimize_scalar(method='bounded')

```python
scipy.optimize.minimize_scalar (fun, bounds=None, args=(), method='bounded', tol=None,
                                options={'func': None, 'xatol': 1e-05, 'maxiter': 500, 'disp': 0})
```

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize_scalar`

**Options**

- `maxiter` [int] Maximum number of iterations to perform.
- `disp` int, optional
  - If non-zero, print messages.
    - 0: no message printing. 1: non-convergence notification messages only. 2: print a message on convergence too. 3: print iteration results.
- `xatol` [float] Absolute error in solution `xopt` acceptable for convergence.

minimize_scalar(method='golden')

```python
scipy.optimize.minimize_scalar (fun, args=(), method='golden', tol=None, options={'func': None, 'brack': None, 'xtol': 1.4901161193847656e-08, 'maxiter': 5000, 'disp': 0})
```

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize_scalar`

**Options**

- `xtol` [float] Relative error in solution `xopt` acceptable for convergence.
- `maxiter` [int] Maximum number of iterations to perform.
- `disp` int, optional
  - If non-zero, print messages.
    - 0: no message printing. 1: non-convergence notification messages only. 2: print a message on convergence too. 3: print iteration results.

Local (multivariate) optimization

**minimize**(fun, x0[, args, method, jac, hess, ...]) Minimization of scalar function of one or more variables.

`scipy.optimize.minimize`

```python
scipy.optimize.minimize (fun, x0, args=(), method=None, jac=None, hess=None, hessp=None,
                         bounds=None, constraints=(), tol=None, callback=None, options=None)
```

Minimization of scalar function of one or more variables.

**Parameters**

- `fun` [callable] The objective function to be minimized.
  - `fun(x, *args) -> float`
  - where `x` is an 1-D array with shape (n,) and `args` is a tuple of the fixed parameters needed to completely specify the function.
- `x0` [ndarray, shape (n,)] Initial guess. Array of real elements of size (n,), where n is the number of independent variables.
args [tuple, optional] Extra arguments passed to the objective function and its derivatives (fun, jac and hess functions).

method [str or callable, optional] Type of solver. Should be one of
- ‘Nelder-Mead’ (see here)
- ‘Powell’ (see here)
- ‘CG’ (see here)
- ‘BFGS’ (see here)
- ‘Newton-CG’ (see here)
- ‘L-BFGS-B’ (see here)
- ‘TNC’ (see here)
- ‘COBYLA’ (see here)
- ‘SLSQP’ (see here)
- ‘trust-constr’ (see here)
- ‘dogleg’ (see here)
- ‘trust-neg’ (see here)
- ‘trust-exact’ (see here)
- ‘trust-krylov’ (see here)
- custom - a callable object (added in version 0.14.0), see below for description.

If not given, chosen to be one of BFGS, L-BFGS-B, SLSQP, depending on whether or not the problem has constraints or bounds.

jac [{callable, ‘2-point’, ‘3-point’, ‘cs’, bool}, optional] Method for computing the gradient vector. Only for CG, BFGS, Newton-CG, L-BFGS-B, TNC, SLSQP, dogleg, trust-neg, trust-krylov, trust-exact and trust-constr. If it is a callable, it should be a function that returns the gradient vector:

\[ \text{fun}(x, *\text{args}) \rightarrow \text{array_like, shape (n,)} \]

where \( x \) is an array with shape (n,) and \( \text{args} \) is a tuple with the fixed parameters. If \( \text{fun} \) is a Boolean and is True, \( \text{fun} \) is assumed to return a tuple \((f, g)\) containing the objective function and the gradient. Methods ‘Newton-CG’, ‘trust-neg’, ‘dogleg’, ‘trust-exact’, and ‘trust-krylov’ require that either a callable be supplied, or that \( \text{fun} \) return the objective and gradient. If None or False, the gradient will be estimated using 2-point finite difference estimation with an absolute step size. Alternatively, the keywords \{‘2-point’, ‘3-point’, ‘cs’\} can be used to select a finite difference scheme for numerical estimation of the gradient with a relative step size. These finite difference schemes obey any specified bounds.

\[ \text{fun}(x, *\text{args}) \rightarrow \{\text{LinearOperator, spmatrix, array}\}, (n, n) \]

where \( x \) is a (n,) ndarray and \( \text{args} \) is a tuple with the fixed parameters. The keywords \{‘2-point’, ‘3-point’, ‘cs’\} can also be used to select a finite difference scheme for numerical estimation of the hessian. Alternatively, objects implementing the HessianUpdateStrategy interface can be used to approximate the Hessian. Available quasi-Newton methods implementing this interface are:
- BFGS;
- SR1.

hessp [callable, optional] Hessian of objective function times an arbitrary vector \( p \). Only for Newton-CG, trust-neg, trust-krylov, trust-constr. Only one of hess or hessp needs to be given. If \( \text{hess} \) is provided, then \( \text{hessp} \) will be ignored. \( \text{hessp} \) must compute the Hessian times an arbitrary vector:

\[ \text{fun}(x, p, *\text{args}) \rightarrow \text{ndarray shape (n,)} \]

where \( x \) is a (n,) ndarray, \( p \) is an arbitrary vector with dimension (n,) and \( \text{args} \) is a tuple with the fixed parameters.

bounds [sequence or Bounds, optional] Bounds on variables for Nelder-Mead, L-BFGS-B, TNC, SLSQP, Powell, and trust-constr methods. There are two ways to specify the bounds:
1. Instance of `Bounds` class.
2. Sequence of `(min, max)` pairs for each element in `x`. None is used to specify no bound.

**constraints**

```
[({Constraint, dict} or List of {Constraint, dict}, optional] Constraints definition. Only for
COBYLA, SLSQP and trust-constr.
Constraints for ‘trust-constr’ are defined as a single object or a list of objects specifying con-
straints to the optimization problem. Available constraints are:

- LinearConstraint
- NonlinearConstraint
```

Constraints for COBYLA, SLSQP are defined as a list of dictionaries. Each dictionary with
fields:

- `fun` [callable] The function defining the constraint.
- `jac` [callable, optional] The Jacobian of `fun` (only for SLSQP).
- `args` [sequence, optional] Extra arguments to be passed to the function and Jacob-

Equality constraint means that the constraint function result is to be zero whereas inequality
means that it is to be non-negative. Note that COBYLA only supports inequality constraints.

**tol** [float, optional] Tolerance for termination. When `tol` is specified, the selected minimization
algorithm sets some relevant solver-specific tolerance(s) equal to `tol`. For detailed control,
use solver-specific options.

**options** [dict, optional] A dictionary of solver options. All methods accept the following generic
options:

- `maxiter` [int] Maximum number of iterations to perform. Depending on the method
each iteration may use several function evaluations.
- `disp` [bool] Set to True to print convergence messages.

For method-specific options, see `show_options`.

**callback** [callable, optional] Called after each iteration. For ‘trust-constr’ it is a callable with the sig-
nature:

```
callback(xk, OptimizeResult state) -> bool
```

where `xk` is the current parameter vector, and `state` is an `OptimizeResult` object,
with the same fields as the ones from the return. If callback returns True the algorithm
execution is terminated. For all the other methods, the signature is:

```
callback(xk)
```

where `xk` is the current parameter vector.

**Returns**

- `res` [OptimizeResult] The optimization result represented as an `OptimizeResult` object. Im-
portant attributes are: `x` the solution array, `success` a Boolean flag indicating if the opti-
mizer exited successfully and `message` which describes the cause of the termination. See
`OptimizeResult` for a description of other attributes.

Interface to minimization algorithms for scalar univariate functions

Additional options accepted by the solvers
Notes

This section describes the available solvers that can be selected by the ‘method’ parameter. The default method is BFGS.

Unconstrained minimization

Method **CG** uses a nonlinear conjugate gradient algorithm by Polak and Ribiere, a variant of the Fletcher-Reeves method described in [5] pp.120-122. Only the first derivatives are used.

Method **BFGS** uses the quasi-Newton method of Broyden, Fletcher, Goldfarb, and Shanno (BFGS) [5] pp. 136. It uses the first derivatives only. BFGS has proven good performance even for non-smooth optimizations. This method also returns an approximation of the Hessian inverse, stored as `hess_inv` in the `OptimizeResult` object.

Method **Newton-CG** uses a Newton-CG algorithm [5] pp. 168 (also known as the truncated Newton method). It uses a CG method to compute the search direction. See also `TNC` method for a box-constrained minimization with a similar algorithm. Suitable for large-scale problems.

Method **dogleg** uses the dog-leg trust-region algorithm [5] for unconstrained minimization. This algorithm requires the gradient and Hessian; furthermore the Hessian is required to be positive definite.

Method **trust-ncg** uses the Newton conjugate gradient trust-region algorithm [5] for unconstrained minimization. This algorithm requires the gradient and either the Hessian or a function that computes the product of the Hessian with a given vector. Suitable for large-scale problems.

Method **trust-krylov** uses the Newton GLTR trust-region algorithm [14], [15] for unconstrained minimization. This algorithm requires the gradient and either the Hessian or a function that computes the product of the Hessian with a given vector. Suitable for large-scale problems. On indefinite problems it requires usually less iterations than the `trust-ncg` method and is recommended for medium and large-scale problems.

Method **trust-exact** is a trust-region method for unconstrained minimization in which quadratic subproblems are solved almost exactly [13]. This algorithm requires the gradient and the Hessian (which is not required to be positive definite). It is, in many situations, the Newton method to converge in fewer iterations and the most recommended for small and medium-size problems.

Bound-Constrained minimization

Method **Nelder-Mead** uses the Simplex algorithm [1], [2]. This algorithm is robust in many applications. However, if numerical computation of derivative can be trusted, other algorithms using the first and/or second derivatives information might be preferred for their better performance in general.

Method **L-BFGS-B** uses the L-BFGS-B algorithm [6], [7] for bound constrained minimization.

Method **Powell** is a modification of Powell’s method [3], [4] which is a conjugate direction method. It performs sequential one-dimensional minimizations along each vector of the directions set (`direc` field in `options` and `info`), which is updated at each iteration of the main minimization loop. The function need not be differentiable, and no derivatives are taken. If bounds are not provided, then an unbounded line search will be used. If bounds are provided and the initial guess is within the bounds, then every function evaluation throughout the minimization procedure will be within the bounds. If bounds are provided, the initial guess is outside the bounds, and `direc` is full rank (default has full rank), then some function evaluations during the first iteration may be outside the bounds, but every function evaluation after the first iteration will be within the bounds. If `direc` is not full rank, then some parameters may not be optimized and the solution is not guaranteed to be within the bounds.

Method **TNC** uses a truncated Newton algorithm [5], [8] to minimize a function with variables subject to bounds. This algorithm uses gradient information; it is also called Newton Conjugate-Gradient. It differs from the `Newton-CG` method described above as it wraps a C implementation and allows each variable to be given upper and lower bounds.
Method **COBYLA** uses the Constrained Optimization BY Linear Approximation (COBYLA) method \[9\], \[10\], \[11\]. The algorithm is based on linear approximations to the objective function and each constraint. The method wraps a FORTRAN implementation of the algorithm. The constraints functions ‘fun’ may return either a single number or an array or list of numbers.

Method **SLSQP** uses Sequential Least SQuares Programming to minimize a function of several variables with any combination of bounds, equality and inequality constraints. The method wraps the SLSQP Optimization subroutine originally implemented by Dieter Kraft \[12\]. Note that the wrapper handles infinite values in bounds by converting them into large floating values.

Method **trust-constr** is a trust-region algorithm for constrained optimization. It switches between two implementations depending on the problem definition. It is the most versatile constrained minimization algorithm implemented in SciPy and the most appropriate for large-scale problems. For equality constrained problems it is an implementation of Byrd-Omojokun Trust-Region SQP method described in \[17\] and in \[5\], p. 549. When inequality constraints are imposed as well, it switches to the trust-region interior point method described in \[16\]. This interior point algorithm, in turn, solves inequality constraints by introducing slack variables and solving a sequence of equality-constrained barrier problems for progressively smaller values of the barrier parameter. The previously described equality constrained SQP method is used to solve the subproblems with increasing levels of accuracy as the iterate gets closer to a solution.

**Finite-Difference Options**

For Method **trust-constr** the gradient and the Hessian may be approximated using three finite-difference schemes: (‘2-point’, ‘3-point’, ‘cs’). The scheme ‘cs’ is, potentially, the most accurate but it requires the function to correctly handle complex inputs and to be differentiable in the complex plane. The scheme ‘3-point’ is more accurate than ‘2-point’ but requires twice as many operations. If the gradient is estimated via finite-differences the Hessian must be estimated using one of the quasi-Newton strategies.

**Custom minimizers**

It may be useful to pass a custom minimization method, for example when using a frontend to this method such as scipy.optimize.basinhopping or a different library. You can simply pass a callable as the method parameter.

The callable is called as method(fun, x0, args, **kwargs, **options) where kwargs corresponds to any other parameters passed to minimize (such as callback, hess, etc.), except the options dict, which has its contents also passed as method parameters pair by pair. Also, if jac has been passed as a bool type, jac and fun are mangled so that fun returns just the function values and jac is converted to a function returning the Jacobian. The method shall return an OptimizeResult object.

The provided method callable must be able to accept (and possibly ignore) arbitrary parameters; the set of parameters accepted by minimize may expand in future versions and then these parameters will be passed to the method. You can find an example in the scipy.optimize tutorial.

New in version 0.11.0.

Examples

Let us consider the problem of minimizing the Rosenbrock function. This function (and its respective derivatives) is implemented in rosen (resp. rosen_der, rosen_hess) in the scipy.optimize.

```python
>>> from scipy.optimize import minimize, rosen, rosen_der
```

A simple application of the Nelder-Mead method is:

```python
>>> x0 = [1.3, 0.7, 0.8, 1.9, 1.2]
>>> res = minimize(rosen, x0, method='Nelder-Mead', tol=1e-6)
>>> res.x
array([ 1., 1., 1., 1., 1.])
```

Now using the BFGS algorithm, using the first derivative and a few options:

```python
>>> res = minimize(rosen, x0, method='BFGS', jac=rosen_der, ...     options={'gtol': 1e-6, 'disp': True})
Optimization terminated successfully.
Current function value: 0.000000
Iterations: 26
Function evaluations: 31
Gradient evaluations: 31
>>> res.x
array([ 1., 1., 1., 1., 1.])
>>> print(res.message)
Optimization terminated successfully.
>>> res.hess_inv
array([[ 0.00749589, 0.01255155, 0.02396251, 0.04750988, 0.09495377],
       [ 0.01255155, 0.02510441, 0.04794055, 0.09502834, 0.18996269],
       [ 0.02396251, 0.04794055, 0.09631614, 0.19092151, 0.38165151],
       [ 0.04750988, 0.09502834, 0.19092151, 0.38341252, 0.7664427 ],
       [ 0.09495377, 0.18996269, 0.38165151, 0.7664427, 1.53713523]])
```

Next, consider a minimization problem with several constraints (namely Example 16.4 from [5]). The objective function is:

```python
>>> fun = lambda x: (x[0] - 1)**2 + (x[1] - 2.5)**2
```

There are three constraints defined as:

```python
>>> cons = [{'type': 'ineq', 'fun': lambda x: x[0] - 2 * x[1] + 2},
          {'type': 'ineq', 'fun': lambda x: -x[0] - 2 * x[1] + 6},
          {'type': 'ineq', 'fun': lambda x: -x[0] + 2 * x[1] + 2})
```

And variables must be positive, hence the following bounds:

```python
>>> bnds = ((0, None), (0, None))
```
The optimization problem is solved using the SLSQP method as:

```python
>>> res = minimize(fun, (2, 0), method='SLSQP', bounds=bnds,
                    constraints=cons)
```

It should converge to the theoretical solution (1.4, 1.7).

The `minimize` function supports the following methods:

**minimize(method='Nelder-Mead')**

```python
scipy.optimize.minimize (fun, x0, args=(), method='Nelder-Mead', bounds=None, tol=None, callback=None,
                         options={'func': None, 'maxiter': None, 'maxfev': None, 'disp': False, 'return_all':
                          False, 'initial_simplex': None, 'xatol': 0.0001, 'fatol': 0.0001, 'adaptive': False})
```

Minimization of scalar function of one or more variables using the Nelder-Mead algorithm.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

**Options**

- `disp` [bool] Set to True to print convergence messages.
- `maxiter`, `maxfev` [int] Maximum allowed number of iterations and function evaluations. Will default to \(N \times 200\), where \(N\) is the number of variables, if neither `maxiter` or `maxfev` is set. If both `maxiter` and `maxfev` are set, minimization will stop at the first reached.
- `return_all` [bool, optional] Set to True to return a list of the best solution at each of the iterations.
- `initial_simplex` [array_like of shape (N + 1, N)] Initial simplex. If given, overrides `x0`. `initial_simplex[j, :]` should contain the coordinates of the jth vertex of the N+1 vertices in the simplex, where N is the dimension.
- `xatol` [float, optional] Absolute error in xopt between iterations that is acceptable for convergence.
- `fatol` [number, optional] Absolute error in func(xopt) between iterations that is acceptable for convergence.
- `bounds` [sequence or `Bounds`, optional] Bounds on variables. There are two ways to specify the bounds:
  1. Instance of `Bounds` class.
  2. Sequence of (min, max) pairs for each element in x. None is used to specify no bound. Note that this just clips all vertices in simplex based on the bounds.

**References**

**minimize**(*method*='Powell')

```python
scipy.optimize.minimize(fun, x0, args=(), method='Powell', bounds=None, tol=None, callback=None,
                         options={'func': None, 'xtol': 0.0001, 'ftol': 0.0001, 'maxiter': None, 'maxfev': None, 'disp': False, 'direc': None, 'return_all': False})
```

Minimization of scalar function of one or more variables using the modified Powell algorithm.

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

**Options**

- `disp` [bool] Set to True to print convergence messages.
- `xtol` [float] Relative error in solution `xopt` acceptable for convergence.
- `ftol` [float] Relative error in `fun(xopt)` acceptable for convergence.
- `maxiter`, `maxfev` [int] Maximum allowed number of iterations and function evaluations. Will default to `N*1000`, where `N` is the number of variables, if neither `maxiter` or `maxfev` is set. If both `maxiter` and `maxfev` are set, minimization will stop at the first reached.
- `direc` [ndarray] Initial set of direction vectors for the Powell method.
- `return_all` [bool, optional] Set to True to return a list of the best solution at each of the iterations.
- `bounds` [Bounds] If bounds are not provided, then an unbounded line search will be used. If bounds are provided and the initial guess is within the bounds, then every function evaluation throughout the minimization procedure will be within the bounds. If bounds are provided, the initial guess is outside the bounds, and `direc` is full rank (or left to default), then some function evaluations during the first iteration may be outside the bounds, but every function evaluation after the first iteration will be within the bounds. If `direc` is not full rank, then some parameters may not be optimized and the solution is not guaranteed to be within the bounds.
- `return_all` [bool, optional] Set to True to return a list of the best solution at each of the iterations.

**minimize**(*method*='CG')

```python
scipy.optimize.minimize(fun, x0, args=(), method='CG', jac=None, tol=None, callback=None,
                        options={'gtol': 1e-05, 'norm': inf, 'eps': 1.4901161193847656e-08, 'maxiter': None, 'disp': False, 'return_all': False, 'finite_diff_rel_step': None})
```

Minimization of scalar function of one or more variables using the conjugate gradient algorithm.

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

**Options**

- `disp` [bool] Set to True to print convergence messages.
- `maxiter` [int] Maximum number of iterations to perform.
- `gtol` [float] Gradient norm must be less than `gtol` before successful termination.
- `norm` [float] Order of norm (Inf is max, -Inf is min).
- `eps` [float or ndarray] If `jac` is `None` the absolute step size used for numerical approximation of the jacobian via forward differences.
- `return_all` [bool, optional] Set to True to return a list of the best solution at each of the iterations.
- `finite_diff_rel_step` [None or array_like, optional] If `jac` in `[2-point', '3-point', 'cs']` the relative step size to use for numerical approximation of the jacobian. The absolute step size is computed as `h = rel_step * sign(x0) * max(1, abs(x0))`, possibly adjusted to fit into the
bounds. For method='3-point' the sign of $h$ is ignored. If None (default) then step is selected automatically.

**minimize(method='BFGS')**

```python
scipy.optimize.minimize (fun, x0, args=(), method='BFGS', jac=None, tol=None, callback=None,
options={'gtol': 1e-05, 'norm': inf, 'eps': 1.4901161193847656e-08, 'maxiter':
None, 'disp': False, 'return_all': False, 'finite_diff_rel_step': None})
```

Minimization of scalar function of one or more variables using the BFGS algorithm.

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

**Options**

- **disp** [bool] Set to True to print convergence messages.
- **maxiter** [int] Maximum number of iterations to perform.
- **gtol** [float] Gradient norm must be less than gtol before successful termination.
- **norm** [float] Order of norm (Inf is max, -Inf is min).
- **eps** [float or ndarray] If jac is None the absolute step size used for numerical approximation of the jacobian via forward differences.
- **return_all** [bool, optional] Set to True to return a list of the best solution at each of the iterations.
- **finite_diff_rel_step** [None or array_like, optional] If jac in ['2-point', '3-point', 'cs'] the relative step size to use for numerical approximation of the jacobian. The absolute step size is computed as $h = rel_step * sign(x0) * max(1, abs(x0))$, possibly adjusted to fit into the bounds. For method='3-point' the sign of $h$ is ignored. If None (default) then step is selected automatically.

**minimize(method='Newton-CG')**

```python
scipy.optimize.minimize (fun, x0, args=(), method='Newton-CG', jac=None, hess=None, hessp=None,
tol=None, callback=None, options={'xtol': 1e-05, 'eps': 1.4901161193847656e-08,
'maxiter': None, 'disp': False, 'return_all': False})
```

Minimization of scalar function of one or more variables using the Newton-CG algorithm.

Note that the jac parameter (Jacobian) is required.

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

**Options**

- **disp** [bool] Set to True to print convergence messages.
- **xtol** [float] Average relative error in solution $xopt$ acceptable for convergence.
- **maxiter** [int] Maximum number of iterations to perform.
- **eps** [float or ndarray] If hessp is approximated, use this value for the step size.
- **return_all** [bool, optional] Set to True to return a list of the best solution at each of the iterations.
minimize(method='L-BFGS-B')

scipy.optimize.minimize (fun, x0, args=(), method='L-BFGS-B', jac=None, bounds=None, tol=None,
callback=None, options={'disp': None, 'maxcor': 10, 'ftol': 2.220446049250313e-09, 'gtol': 1e-05, 'eps': 1e-08, 'maxfun': 15000, 'maxiter': 15000, 'iprint': -1, 'maxls': 20, 'finite_diff_rel_step': None})

Minimize a scalar function of one or more variables using the L-BFGS-B algorithm.

See also:

For documentation for the rest of the parameters, see scipy.optimize.minimize

Options

disp [None or int] If disp is None (the default), then the supplied version of iprint is used. If disp is not None, then it overrides the supplied version of iprint with the behaviour you outlined.

maxcor [int] The maximum number of variable metric corrections used to define the limited memory matrix. (The limited memory BFGS method does not store the full hessian but uses this many terms in an approximation to it.)

ftol [float] The iteration stops when \( (f^k - f^{k+1}) / \max\{\|f^k\|,\|f^{k+1}\|,1\} \leq f_{tol} \).

gtol [float] The iteration will stop when \( \max\{|\text{proj g}_i| \mid i = 1, \ldots, n\} \leq g_{tol} \)

eps [float or ndarray] If jac is None the absolute step size used for numerical approximation of the jacobian via forward differences.

maxfun [int] Maximum number of function evaluations.

maxiter [int] Maximum number of iterations.

iprint [int, optional] Controls the frequency of output. iprint < 0 means no output; iprint = 0 print only one line at the last iteration; 0 < iprint < 99 print also f and \|g\| every iprint iterations; iprint = 99 print details of every iteration except n-vectors; iprint = 100 print also the changes of active set and final x; iprint > 100 print details of every iteration including x and g.

callback [callable, optional] Called after each iteration, as callback(xk), where xk is the current parameter vector.

maxls [int, optional] Maximum number of line search steps (per iteration). Default is 20.

finite_diff_rel_step [None or array_like, optional] If jac in ['2-point', '3-point', 'cs'] the relative step size to use for numerical approximation of the jacobian. The absolute step size is computed as \( h = \text{rel_step} \ast \text{sign}(x0) \ast \max(1, \text{abs}(x0)) \), possibly adjusted to fit into the bounds. For method='3-point' the sign of h is ignored. If None (default) then step is selected automatically.

Notes

The option ftol is exposed via the scipy.optimize.minimize interface, but calling scipy.optimize.fmin_l_bfgs_b directly exposes factr. The relationship between the two is ftol = factr * numpy.finfo(float).eps. I.e., factr multiplies the default machine floating-point precision to arrive at ftol.

3.3. API definition 1285
minimize(method='TNC')

```python
scipy.optimize.minimize (fun, x0, args=(), method='TNC', jac=None, bounds=None, tol=None,
callback=None, options={'eps': 1e-08, 'scale': None, 'offset': None, 'mesg_num':
'None', 'maxCGit': -1, 'maxiter': None, 'eta': -1, 'stepmx': 0, 'accuracy': 0, 'minfev':
0, 'ftol': -1, 'xtol': -1, 'gtol': -1, 'rescale': -1, 'disp': False, 'finite_diff_rel_step':
'None', 'maxfun': None})
```

Minimize a scalar function of one or more variables using a truncated Newton (TNC) algorithm.

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

**Options**

- **eps** [float or ndarray] If `jac is None` the absolute step size used for numerical approximation of the jacobian via forward differences.
- **scale** [list of floats] Scaling factors to apply to each variable. If None, the factors are up-low for interval bounded variables and 1+|x| fo the others. Defaults to None.
- **offset** [float] Value to subtract from each variable. If None, the offsets are (up+low)/2 for interval bounded variables and x for the others.
- **disp** [bool] Set to True to print convergence messages.
- **maxCGit** [int] Maximum number of hessian*vector evaluations per main iteration. If maxCGit == 0, the direction chosen is -gradient if maxCGit < 0, maxCGit is set to max(1, min(50,n/2)). Defaults to -1.
- **maxiter** [int, optional] Maximum number of function evaluations. This keyword is deprecated in favor of `maxfun`. Only if `maxfun` is None is this keyword used.
- **eta** [float] Severity of the line search. If < 0 or > 1, set to 0.25. Defaults to -1.
- **stepmx** [float] Maximum step for the line search. May be increased during call. If too small, it will be set to 10.0. Defaults to 0.
- **accuracy** [float] Relative precision for finite difference calculations. If <= machine_precision, set to sqrt(machine_precision). Defaults to 0.
- **minfev** [float] Minimum function value estimate. Defaults to 0.
- **ftol** [float] Precision goal for the value of f in the stopping criterion. If ftol < 0.0, ftol is set to 0.0 defaults to -1.
- **xtol** [float] Precision goal for the value of x in the stopping criterion (after applying x scaling factors). If xtol < 0.0, xtol is set to sqrt(machine_precision). Defaults to -1.
- **gtol** [float] Precision goal for the value of the projected gradient in the stopping criterion (after applying x scaling factors). If gtol < 0.0, gtol is set to 1e-2 * sqrt(accuracy). Setting it to 0.0 is not recommended. Defaults to -1.
- **rescale** [float] Scaling factor (in log10) used to trigger f value rescaling. If 0, rescale at each iteration. If a large value, never rescale. If < 0, rescale is set to 1.3.
- **finite_diff_rel_step** [None or array_like, optional] If `jac in [2-point,'3-point','cs']` the relative step size to use for numerical approximation of the jacobian. The absolute step size is computed as h = rel_step * sign(x0) * max(1, abs(x0)), possibly adjusted to fit into the bounds. For method='3-point' the sign of h is ignored. If None (default) then step is selected automatically.
- **maxfun** [int] Maximum number of function evaluations. If None, `maxfun` is set to max(100, 10*len(x0)). Defaults to None.
minimize(method='COBYLA')

```python
c scipy.optimize.minimize( fun, x0, args=(), method='COBYLA', constraints=(), tol=None, callback=None, options={'rhobeg': 1.0, 'maxiter': 1000, 'disp': False, 'catol': 0.0002})
```

Minimize a scalar function of one or more variables using the Constrained Optimization BY Linear Approximation (COBYLA) algorithm.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

**Options**

- **rhobeg** [float] Reasonable initial changes to the variables.
- **tol** [float] Final accuracy in the optimization (not precisely guaranteed). This is a lower bound on the size of the trust region.
- **disp** [bool] Set to True to print convergence messages. If False, `verbosity` is ignored as set to 0.
- **maxiter** [int] Maximum number of function evaluations.
- **catol** [float] Tolerance (absolute) for constraint violations
- **callback** [callable, optional] Called after each iteration, as `callback(x)`, where `x` is the current parameter vector.

minimize(method='SLSQP')

```python
c scipy.optimize.minimize( fun, x0, args=(), method='SLSQP', jac=None, bounds=None, constraints=(), tol=None, callback=None, options={'func': None, 'maxiter': 100, 'ftol': 1e-06, 'iprint': 1, 'disp': False, 'eps': 1.4901161193847656e-08, 'finite_diff_rel_step': None})
```

Minimize a scalar function of one or more variables using Sequential Least Squares Programming (SLSQP).

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

**Options**

- **ftol** [float] Precision goal for the value of f in the stopping criterion.
- **eps** [float] Step size used for numerical approximation of the Jacobian.
- **disp** [bool] Set to True to print convergence messages. If False, `verbosity` is ignored and set to 0.
- **maxiter** [int] Maximum number of iterations.
- **finite_diff_rel_step** [None or array_like, optional] If `jac` in ['2-point', '3-point', 'cs'] the relative step size to use for numerical approximation of `jac`. The absolute step size is computed as `h = rel_step * sign(x0) * max(1, abs(x0))`, possibly adjusted to fit into the bounds. For `method='3-point'` the sign of `h` is ignored. If None (default) then step is selected automatically.
```
minimize(method='trust-constr')
```

`scipy.optimize.minimize (fun, x0, args=(), method='trust-constr', hess=None, hessp=None, bounds=None, constraints=(), tol=None, callback=None, options={'grad': None, 'xtol': 1e-08, 'gtol': 1e-08, 'barrier_tol': 1e-08, 'sparse_jacobian': None, 'maxiter': 1000, 'verbose': 0, 'finite_diff_rel_step': None, 'initial_constr_penalty': 1.0, 'initial_tr_radius': 1.0, 'initial_barrier_parameter': 0.1, 'initial_barrier_tolerance': 0.1, 'factorization_method': None, 'disp': False})`

Minimize a scalar function subject to constraints.

**Parameters**

- `gtol` [float, optional] Tolerance for termination by the norm of the Lagrangian gradient. The algorithm will terminate when both the infinity norm (i.e., max abs value) of the Lagrangian gradient and the constraint violation are smaller than `gtol`. Default is 1e-8.

- `xtol` [float, optional] Tolerance for termination by the change of the independent variable. The algorithm will terminate when `tr_radius < xtol`, where `tr_radius` is the radius of the trust region used in the algorithm. Default is 1e-8.

- `barrier_tol` [float, optional] Threshold on the barrier parameter for the algorithm termination. When inequality constraints are present, the algorithm will terminate only when the barrier parameter is less than `barrier_tol`. Default is 1e-8.

- `sparse_jacobian` [[bool, None], optional] Determines how to represent Jacobians of the constraints. If bool, then Jacobians of all the constraints will be converted to the corresponding format. If None (default), then Jacobians won’t be converted, but the algorithm can proceed only if they all have the same format.

- `initial_tr_radius`: float, optional
  Initial trust radius. The trust radius gives the maximum distance between solution points in consecutive iterations. It reflects the trust the algorithm puts in the local approximation of the optimization problem. For an accurate local approximation the trust-region should be large and for an approximation valid only close to the current point it should be a small one. The trust radius is automatically updated throughout the optimization process, with `initial_tr_radius` being its initial value. Default is 1 (recommended in [1], p. 19).

- `initial_constr_penalty` [float, optional] Initial constraints penalty parameter. The penalty parameter is used for balancing the requirements of decreasing the objective function and satisfying the constraints. It is used for defining the merit function: `merit_function(x) = fun(x) + constr_penalty * constr_norm_l2(x), where constr_norm_l2(x)` is the l2 norm of a vector containing all the constraints. The merit function is used for accepting or rejecting trial points and `constr_penalty` weights the two conflicting goals of reducing objective function and constraints. The penalty is automatically updated throughout the optimization process, with `initial_constr_penalty` being its initial value. Default is 1 (recommended in [1], p. 19).

- `initial_barrier_parameter, initial_barrier_tolerance`: float, optional
  Initial barrier parameter and initial tolerance for the barrier subproblem. Both are used only when inequality constraints are present. For dealing with optimization problems `min_x f(x)` subject to inequality constraints `c(x) <= 0` the algorithm introduces slack variables, solving the problem `min_(x,s) f(x) + barrier_parameter*sum(ln(s))` subject to the equality constraints `c(x) + s = 0` instead of the original problem. This subproblem is solved for decreasing values of `barrier_parameter` and with decreasing tolerances for the termination, starting with `initial_barrier_parameter` for the barrier parameter and `initial_barrier_tolerance` for the barrier tolerance. Default is 0.1 for both values (recommended in [1] p. 19). Also note that `barrier_parameter` and `barrier_tolerance` are updated with the same prefactor.
factorization_method
[string or None, optional] Method to factorize the Jacobian of the constraints. Use None (default) for the auto selection or one of:
• ‘NormalEquation’ (requires scikit-sparse)
• ‘AugmentedSystem’
• ‘QRFactorization’
• ‘SVDFactorization’
The methods ‘NormalEquation’ and ‘AugmentedSystem’ can be used only with sparse constraints. The projections required by the algorithm will be computed using, respectively, the normal equation and the augmented system approaches explained in [1]. ‘NormalEquation’ computes the Cholesky factorization of $A \ A^T$ and ‘AugmentedSystem’ performs the LU factorization of an augmented system. They usually provide similar results. ‘AugmentedSystem’ is used by default for sparse matrices.
The methods ‘QRFactorization’ and ‘SVDFactorization’ can be used only with dense constraints. They compute the required projections using, respectively, QR and SVD factorizations. The ‘SVDFactorization’ method can cope with Jacobian matrices with deficient row rank and will be used whenever other factorization methods fail (which may imply the conversion of sparse matrices to a dense format when required). By default, ‘QRFactorization’ is used for dense matrices.

finite_diff_rel_step
[None or array_like, optional] Relative step size for the finite difference approximation.

maxiter
[int, optional] Maximum number of algorithm iterations. Default is 1000.

verbose
[[0, 1, 2], optional] Level of algorithm’s verbosity:
• 0 (default) : work silently.
• 1 : display a termination report.
• 2 : display progress during iterations.
• 3 : display progress during iterations (more complete report).

disp
[bool, optional] If True (default), then verbose will be set to 1 if it was 0.

Returns

`OptimizeResult` with the fields documented below. Note the following:

1. All values corresponding to the constraints are ordered as they were passed to the solver. And values corresponding to bounds constraints are put after other constraints.
2. All numbers of function, Jacobian or Hessian evaluations correspond to numbers of actual Python function calls. It means, for example, that if a Jacobian is estimated by finite differences, then the number of Jacobian evaluations will be zero and the number of function evaluations will be incremented by all calls during the finite difference estimation.

x
[ndarray, shape (n,)] Solution found.

optimality
[float] Infinity norm of the Lagrangian gradient at the solution.

constr_violation
[float] Maximum constraint violation at the solution.

fun
[float] Objective function at the solution.

grad
[ndarray, shape (n,)] Gradient of the objective function at the solution.

lagrangian_grad
[ndarray, shape (n,)] Gradient of the Lagrangian function at the solution.

nit
[int] Total number of iterations.
nfev
[integer] Number of the objective function evaluations.
njev
[integer] Number of the objective function gradient evaluations.
nhev
[integer] Number of the objective function Hessian evaluations.
cg_niter
[int] Total number of the conjugate gradient method iterations.

method
[['equality_constrained_sqp', 'tr_interior_point']] Optimization method used.

constr
[list of ndarray] List of constraint values at the solution.
jac [list of {ndarray, sparse matrix}] List of the Jacobian matrices of the constraints at the solution.

v [list of ndarray] List of the Lagrange multipliers for the constraints at the solution. For an inequality constraint a positive multiplier means that the upper bound is active, a negative multiplier means that the lower bound is active and if a multiplier is zero it means the constraint is not active.

constr_nfev [list of int] Number of constraint evaluations for each of the constraints.

constr_njev [list of int] Number of Jacobian matrix evaluations for each of the constraints.

constr_nhev [list of int] Number of Hessian evaluations for each of the constraints.

tr_radius [float] Radius of the trust region at the last iteration.

constr_penalty [float] Penalty parameter at the last iteration, see initial_constr_penalty.

barrier_tolerance [float] Tolerance for the barrier subproblem at the last iteration. Only for problems with inequality constraints.

barrier_parameter [float] Barrier parameter at the last iteration. Only for problems with inequality constraints.

execution_time [float] Total execution time.

status [0, 1, 2, 3] Termination status:
• 0: The maximum number of function evaluations is exceeded.
• 1: gtol termination condition is satisfied.
• 2: xtol termination condition is satisfied.
• 3: callback function requested termination.

cg_stop_cond [int] Reason for CG subproblem termination at the last iteration:
• 0: CG subproblem not evaluated.
• 1: Iteration limit was reached.
• 2: Reached the trust-region boundary.
• 3: Negative curvature detected.
• 4: Tolerance was satisfied.

References

[1]

minimize(method='dogleg')

scipy.optimize.minimize (fun, x0, args=(), method='dogleg', jac=None, hess=None, tol=None, callback=None, options={})

Minimization of scalar function of one or more variables using the dog-leg trust-region algorithm.

See also:

For documentation for the rest of the parameters, see scipy.optimize.minimize

Options

initial_trust_radius [float] Initial trust-region radius.
max_trust_radius
[float] Maximum value of the trust-region radius. No steps that are longer than this value will be proposed.

eta
[float] Trust region related acceptance stringency for proposed steps.

gtol
[float] Gradient norm must be less than gtol before successful termination.

minimize(method='trust-ncg')

scipy.optimize.minimize (fun, x0, args=(), method='trust-ncg', jac=None, hess=None, hessp=None, tol=None, callback=None, options={})

Minimization of scalar function of one or more variables using the Newton conjugate gradient trust-region algorithm.

See also:
For documentation for the rest of the parameters, see scipy.optimize.minimize

Options

initial_trust_radius
[float] Initial trust-region radius.

max_trust_radius
[float] Maximum value of the trust-region radius. No steps that are longer than this value will be proposed.

eta
[float] Trust region related acceptance stringency for proposed steps.

gtol
[float] Gradient norm must be less than gtol before successful termination.

minimize(method='trust-krylov')

scipy.optimize.minimize (fun, x0, args=(), method='trust-krylov', jac=None, hess=None, hessp=None, tol=None, callback=None, options={'inexact': True})

Minimization of a scalar function of one or more variables using a nearly exact trust-region algorithm that only requires matrix vector products with the hessian matrix.

New in version 1.0.0.

See also:
For documentation for the rest of the parameters, see scipy.optimize.minimize

Options

inexact [bool, optional] Accuracy to solve subproblems. If True requires less nonlinear iterations, but more vector products.
minimize(method='trust-exact')

```python
scipy.optimize.minimize (fun, x0, args=(), method='trust-exact', jac=None, hess=None, tol=None,
callback=None, options={})
```

Minimization of scalar function of one or more variables using a nearly exact trust-region algorithm.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.minimize`

**Options**

- `initial_tr_radius` [float] Initial trust-region radius.
- `max_tr_radius` [float] Maximum value of the trust-region radius. No steps that are longer than this value will be proposed.
- `eta` [float] Trust region related acceptance stringency for proposed steps.
- `gtol` [float] Gradient norm must be less than `gtol` before successful termination.

Constraints are passed to `minimize` function as a single object or as a list of objects from the following classes:

<table>
<thead>
<tr>
<th>NonlinearConstraint</th>
<th>LinearConstraint</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>scipy.optimize.NonlinearConstraint</code></td>
<td><code>scipy.optimize.LinearConstraint</code></td>
</tr>
</tbody>
</table>

```python
class scipy.optimize.NonlinearConstraint (fun, lb, ub[, jac, ...])
```

Nonlinear constraint on the variables.

The constraint has the general inequality form:

\[
\text{lb} \leq \text{fun}(x) \leq \text{ub}
\]

Here the vector of independent variables \(x\) is passed as `ndarray` of shape (n,) and `fun` returns a vector with m components.

It is possible to use equal bounds to represent an equality constraint or infinite bounds to represent a one-sided constraint.

**Parameters**

- `fun` [callable] The function defining the constraint. The signature is `fun(x) -> array_like, shape (m,)`.
- `lb, ub` [array_like] Lower and upper bounds on the constraint. Each array must have the shape (m,) or be a scalar, in the latter case a bound will be the same for all components of the constraint. Use `np.inf` with an appropriate sign to specify a one-sided constraint. Set components of `lb` and `ub` equal to represent an equality constraint. Note that you can mix constraints of different types: interval, one-sided or equality, by setting different components of `lb` and `ub` as necessary.
jac  [{callable, ‘2-point’, ‘3-point’, ‘cs’}, optional] Method of computing the Jacobian matrix (an m-by-n matrix, where element (i, j) is the partial derivative of f[i] with respect to x[j]). The keywords {‘2-point’, ‘3-point’, ‘cs’} select a finite difference scheme for the numerical estimation. A callable must have the following signature: jac(x) -> {ndarray, sparse matrix}, shape (m, n). Default is ‘2-point’.

hess  [{callable, ‘2-point’, ‘3-point’, ‘cs’, HessianUpdateStrategy, None}, optional] Method for computing the Hessian matrix. The keywords {‘2-point’, ‘3-point’, ‘cs’} select a finite difference scheme for numerical estimation. Alternatively, objects implementing HessianUpdateStrategy interface can be used to approximate the Hessian. Currently available implementations are:

• BFGS (default option)
• SR1

A callable must return the Hessian matrix of dot(fun, v) and must have the following signature: hess(x, v) -> {LinearOperator, sparse matrix, array_like}, shape (n, n). Here v is ndarray with shape (m,) containing Lagrange multipliers.

keep_feasible
[array_like of bool, optional] Whether to keep the constraint components feasible throughout iterations. A single value set this property for all components. Default is False. Has no effect for equality constraints.

finite_diff_rel_step: None or array_like, optional
Relative step size for the finite difference approximation. Default is None, which will select a reasonable value automatically depending on a finite difference scheme.

finite_diff_jac_sparsity: {None, array_like, sparse matrix}, optional
Defines the sparsity structure of the Jacobian matrix for finite difference estimation, its shape must be (m, n). If the Jacobian has only few non-zero elements in each row, providing the sparsity structure will greatly speed up the computations. A zero entry means that a corresponding element in the Jacobian is identically zero. If provided, forces the use of ‘lsmr’ trust-region solver. If None (default) then dense differencing will be used.

Notes
Finite difference schemes {‘2-point’, ‘3-point’, ‘cs’} may be used for approximating either the Jacobian or the Hessian. We, however, do not allow its use for approximating both simultaneously. Hence whenever the Jacobian is estimated via finite-differences, we require the Hessian to be estimated using one of the quasi-Newton strategies.

The scheme ‘cs’ is potentially the most accurate, but requires the function to correctly handles complex inputs and be analytically continuable to the complex plane. The scheme ‘3-point’ is more accurate than ‘2-point’ but requires twice as many operations.

Examples
Constrain x[0] < sin(x[1]) + 1.9

```python
>>> from scipy.optimize import NonlinearConstraint
>>> con = lambda x: x[0] - np.sin(x[1])
>>> nlc = NonlinearConstraint(con, -np.inf, 1.9)
```
**scipy.optimize.LinearConstraint**

```python
class scipy.optimize.LinearConstraint(A, lb, ub, keep_feasible=False)
```

Linear constraint on the variables.

The constraint has the general inequality form:

\[ lb \leq A \cdot x \leq ub \]

Here the vector of independent variables \( x \) is passed as ndarray of shape \((n,)\) and the matrix \( A \) has shape \((m, n)\).

It is possible to use equal bounds to represent an equality constraint or infinite bounds to represent a one-sided constraint.

**Parameters**

- **A** [{array_like, sparse matrix}, shape (m, n)] Matrix defining the constraint.
- **lb**, **ub** [array_like] Lower and upper bounds on the constraint. Each array must have the shape \((m,)\) or be a scalar, in the latter case a bound will be the same for all components of the constraint. Use `np.inf` with an appropriate sign to specify a one-sided constraint. Set components of \( lb \) and \( ub \) equal to represent an equality constraint. Note that you can mix constraints of different types: interval, one-sided or equality, by setting different components of \( lb \) and \( ub \) as necessary.
- **keep_feasible** [array_like of bool, optional] Whether to keep the constraint components feasible throughout iterations. A single value set this property for all components. Default is False. Has no effect for equality constraints.

Simple bound constraints are handled separately and there is a special class for them:

```python
Bounds(lb, ub[, keep_feasible])
```

**Boundsconstraint on the variables.**

**scipy.optimize.Bounds**

```python
class scipy.optimize.Bounds(lb, ub, keep_feasible=False)
```

Bounds constraint on the variables.

The constraint has the general inequality form:

\[ lb \leq x \leq ub \]

It is possible to use equal bounds to represent an equality constraint or infinite bounds to represent a one-sided constraint.

**Parameters**

- **lb**, **ub** [array_like] Lower and upper bounds on independent variables. Each array must have the same size as \( x \) or be a scalar, in which case a bound will be the same for all the variables. Set components of \( lb \) and \( ub \) equal to fix a variable. Use `np.inf` with an appropriate sign to disable bounds on all or some variables. Note that you can mix constraints of different types: interval, one-sided or equality, by setting different components of \( lb \) and \( ub \) as necessary.
- **keep_feasible** [array_like of bool, optional] Whether to keep the constraint components feasible throughout iterations. A single value set this property for all components. Default is False. Has no effect for equality constraints.
Quasi-Newton strategies implementing `HessianUpdateStrategy` interface can be used to approximate the Hessian in `minimize` function (available only for the ‘trust-constr’ method). Available quasi-Newton methods implementing this interface are:

<table>
<thead>
<tr>
<th>QN Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>BFGS</strong></td>
<td>Broyden-Fletcher-Goldfarb-Shanno (BFGS) Hessian update strategy.</td>
</tr>
<tr>

<td>Symmetric-rank-1 Hessian update strategy.</td>
</tr>
</tbody>
</table>

### scipy.optimize.BFGS

**class** scipy.optimize.BFGS

Broyden-Fletcher-Goldfarb-Shanno (BFGS) Hessian update strategy.

**Parameters**

- **exception_strategy**
  
  [{'skip_update', 'damp_update'}, optional] Define how to proceed when the curvature condition is violated. Set it to ‘skip_update’ to just skip the update. Or, alternatively, set it to ‘damp_update’ to interpolate between the actual BFGS result and the unmodified matrix. Both exceptions strategies are explained in [1], p.536-537.

- **min_curvature**
  
  [float] This number, scaled by a normalization factor, defines the minimum curvature $\text{dot}(\delta_{\text{grad}}, \delta_{\text{x}})$ allowed to go unaffected by the exception strategy. By default is equal to $1e^{-8}$ when `exception_strategy` = ‘skip_update’ and equal to 0.2 when `exception_strategy` = 'damp_update'.

- **init_scale**
  
  [{float, ‘auto’}] Matrix scale at first iteration. At the first iteration the Hessian matrix or its inverse will be initialized with $\text{init_scale}*\text{np.eye}(n)$, where $n$ is the problem dimension. Set it to ‘auto’ in order to use an automatic heuristic for choosing the initial scale. The heuristic is described in [1], p.143. By default uses ‘auto’.

**Notes**

The update is based on the description in [1], p.140.

scipy.optimize.BFGS.dot

BFGS.dot \((p)\)
Compute the product of the internal matrix with the given vector.

**Parameters**
- \(p\) [array_like] 1-D array representing a vector.

**Returns**
- \(Hp\) [array] 1-D represents the result of multiplying the approximation matrix by vector \(p\).

scipy.optimize.BFGS.get_matrix

BFGS.get_matrix()
Return the current internal matrix.

**Returns**
- \(M\) [ndarray, shape (n, n)] Dense matrix containing either the Hessian or its inverse (depending on how \(approx\_type\) was defined).

scipy.optimize.BFGS.initialize

BFGS.initialize \((n, approx\_type)\)
Initialize internal matrix.
Allocate internal memory for storing and updating the Hessian or its inverse.

**Parameters**
- \(n\) [int] Problem dimension.
- \(approx\_type\) [{'hess', 'inv_hess}] Selects either the Hessian or the inverse Hessian. When set to ‘hess’ the Hessian will be stored and updated. When set to ‘inv_hess’ its inverse will be used instead.

scipy.optimize.BFGS.update

BFGS.update \((\delta_x, \delta_grad)\)
Update internal matrix.
Update Hessian matrix or its inverse (depending on how ‘approx_type’ is defined) using information about the last evaluated points.

**Parameters**
- \(\delta_x\) [ndarray] The difference between two points the gradient function have been evaluated at: \(\delta_x = x2 - x1\).  
- \(\delta_grad\) [ndarray] The difference between the gradients: \(\delta_grad = \text{grad}(x2) - \text{grad}(x1)\).
scipy.optimize.SR1

class scipy.optimize.SR1(min_denominator=1e-08, init_scale='auto')
Symmetric-rank-1 Hessian update strategy.

Parameters

min_denominator [float] This number, scaled by a normalization factor, defines the minimum denominator magnitude allowed in the update. When the condition is violated we skip the update. By default uses 1e-8.

init_scale [float, ‘auto’], optional Matrix scale at first iteration. At the first iteration the Hessian matrix or its inverse will be initialized with init_scale*np.eye(n), where n is the problem dimension. Set it to ‘auto’ in order to use an automatic heuristic for choosing the initial scale. The heuristic is described in [1], p.143. By default uses ‘auto’.

Notes

The update is based on the description in [1], p.144-146.

References

[1]

Methods

dot(p) Compute the product of the internal matrix with the given vector.

get_matrix() Return the current internal matrix.

initialize(n, approx_type) Initialize internal matrix.

update(delta_x, delta_grad) Update internal matrix.

scipy.optimize.SR1.dot

SR1.dot(p)
Compute the product of the internal matrix with the given vector.

Parameters

p [array_like] 1-D array representing a vector.

Returns

Hp [array] 1-D represents the result of multiplying the approximation matrix by vector p.
scipy.optimize.SR1.get_matrix

SR1.get_matrix()
Return the current internal matrix.

Returns

M [ndarray, shape (n, n)] Dense matrix containing either the Hessian or its inverse (depending on how approx_type was defined).

scipy.optimize.SR1.initialize

SR1.initialize(n, approx_type)
Initialize internal matrix.

Allocate internal memory for storing and updating the Hessian or its inverse.

Parameters

n [int] Problem dimension.
approx_type
    [‘hess’, ‘inv_hess’] Selects either the Hessian or the inverse Hessian. When set to ‘hess’ the Hessian will be stored and updated. When set to ‘inv_hess’ its inverse will be used instead.

scipy.optimize.SR1.update

SR1.update(delta_x, delta_grad)
Update internal matrix.

Update Hessian matrix or its inverse (depending on how ‘approx_type’ is defined) using information about the last evaluated points.

Parameters

delta_x [ndarray] The difference between two points the gradient function have been evaluated at: delta_x = x2 - x1.
delta_grad [ndarray] The difference between the gradients: delta_grad = grad(x2) - grad(x1).

Global optimization

basinhopping(func, x0[, niter, T, stepsize, ...]) Find the global minimum of a function using the basin-hopping algorithm.
brute(func, ranges[, args, Ns, full_output, ...]) Minimize a function over a given range by brute force.
differential_evolution(func, bounds[, args, ...]) Finds the global minimum of a multivariate function.
shgo(func, bounds[, args, constraints, n, ...]) Finds the global minimum of a function using SHG optimization.
dual_annealing(func, bounds[, args, ...]) Find the global minimum of a function using Dual Annealing.
Find the global minimum of a function using the basin-hopping algorithm.

Basin-hopping is a two-phase method that combines a global stepping algorithm with local minimization at each step. Designed to mimic the natural process of energy minimization of clusters of atoms, it works well for similar problems with “funnel-like, but rugged” energy landscapes [5].

As the step-taking, step acceptance, and minimization methods are all customizable, this function can also be used to implement other two-phase methods.

**Parameters**

- **func** [callable f(x, *args)] Function to be optimized. args can be passed as an optional item in the dict `minimizer_kwargs`
- **x0** [array_like] Initial guess.
- **niter** [integer, optional] The number of basin-hopping iterations. There will be a total of niter + 1 runs of the local minimizer.
- **T** [float, optional] The “temperature” parameter for the accept or reject criterion. Higher “temperatures” mean that larger jumps in function value will be accepted. For best results T should be comparable to the separation (in function value) between local minima.
- **stepsize** [float, optional] Maximum step size for use in the random displacement.
- **minimizer_kwargs** [dict, optional] Extra keyword arguments to be passed to the local minimizer scipy.optimize.minimize() Some important options could be:
  - **method** [str] The minimization method (e.g. "L-BFGS-B")
  - **args** [tuple] Extra arguments passed to the objective function (func) and its derivatives (Jacobian, Hessian).
- **take_step** [callable take_step(x), optional] Replace the default step-taking routine with this routine. The default step-taking routine is a random displacement of the coordinates, but other step-taking algorithms may be better for some systems. `take_step` can optionally have the attribute `take_step.stepsize`. If this attribute exists, then basinhopping will adjust `take_step.stepsize` in order to try to optimize the global minimum search.
- **accept_test** [callable, accept_test(f_new=f_new, x_new=x_new, f_old=f_old, x_old=x_old), optional] Define a test which will be used to judge whether or not to accept the step. This will be used in addition to the Metropolis test based on “temperature” T. The acceptable return values are True, False, or "force accept". If any of the tests return False then the step is rejected. If the latter, then this will override any other tests in order to accept the step. This can be used, for example, to forcefully escape from a local minimum that basinhopping is trapped in.
- **callback** [callable, callback(x, f, accept), optional] A callback function which will be called for all minima found. x and f are the coordinates and function value of the trial minimum, and accept is whether or not that minimum was accepted. This can be used, for example, to save the lowest N minima found. Also, callback can be used to specify a user defined stop criterion by optionally returning True to stop the basinhopping routine.
- **interval** [integer, optional] interval for how often to update the stepsize
- **disp** [bool, optional] Set to True to print status messages
- **niter_success** [integer, optional] Stop the run if the global minimum candidate remains the same for this number of iterations.
- **seed** [{None, int, numpy.random.Generator}]
numpy.random.RandomState}, optional
If seed is None (or np.random), the numpy.random.RandomState singleton is used.
If seed is an int, a new RandomState instance is used, seeded with seed. If seed is already
a Generator or RandomState instance then that instance is used. Specify seed for
repeatable minimizations. The random numbers generated with this seed only affect the
default Metropolis accept_test and the default take_step. If you supply your own take_step
and accept_test, and these functions use random number generation, then those functions are
responsible for the state of their random number generator.

target_accept_rate
[float, optional] The target acceptance rate that is used to adjust the stepsize. If the current
acceptance rate is greater than the target, then the stepsize is increased. Otherwise, it is
decreased. Range is (0, 1). Default is 0.5.
New in version 1.8.0.

stepwise_factor
[float, optional] The stepsize is multiplied or divided by this stepwise factor upon each update.
Range is (0, 1). Default is 0.9.
New in version 1.8.0.

Returns
res [OptimizeResult] The optimization result represented as a OptimizeResult object. Im-
portant attributes are: x the solution array, fun the value of the function at the solution, and
message which describes the cause of the termination. The OptimizeResult object
returned by the selected minimizer at the lowest minimum is also contained within this ob-
ject and can be accessed through the lowest_optimization_result attribute. See
OptimizeResult for a description of other attributes.

See also:

minimize
The local minimization function called once for each basinhopping step. minimizer_kwarggs is passed to
this routine.

Notes
Basin-hopping is a stochastic algorithm which attempts to find the global minimum of a smooth scalar function of
one or more variables [1] [2] [3] [4]. The algorithm in its current form was described by David Wales and Jonathan
The algorithm is iterative with each cycle composed of the following features
1) random perturbation of the coordinates
2) local minimization
3) accept or reject the new coordinates based on the minimized function value
The acceptance test used here is the Metropolis criterion of standard Monte Carlo algorithms, although there are
many other possibilities [3].
This global minimization method has been shown to be extremely efficient for a wide variety of problems in physics
and chemistry. It is particularly useful when the function has many minima separated by large barriers. See the
Cambridge Cluster Database http://www-wales.ch.cam.ac.uk/CCD.html for databases of molecular systems that
have been optimized primarily using basin-hopping. This database includes minimization problems exceeding 300
degrees of freedom.
See the free software program GMIN (http://www-wales.ch.cam.ac.uk/GMIN) for a Fortran implementation of basin-hopping. This implementation has many different variations of the procedure described above, including more advanced step taking algorithms and alternate acceptance criterion.

For stochastic global optimization there is no way to determine if the true global minimum has actually been found. Instead, as a consistency check, the algorithm can be run from a number of different random starting points to ensure the lowest minimum found in each example has converged to the global minimum. For this reason, basinhopping will by default simply run for the number of iterations niter and return the lowest minimum found. It is left to the user to ensure that this is in fact the global minimum.

Choosing stepsize: This is a crucial parameter in basinhopping and depends on the problem being solved. The step is chosen uniformly in the region from x0-stepsize to x0+stepsize, in each dimension. Ideally, it should be comparable to the typical separation (in argument values) between local minima of the function being optimized. basinhopping will, by default, adjust stepsize to find an optimal value, but this may take many iterations. You will get quicker results if you set a sensible initial value for stepsize.

Choosing T: The parameter T is the “temperature” used in the Metropolis criterion. Basin hopping steps are always accepted if func(xnew) < func(xold). Otherwise, they are accepted with probability:

\[
\exp\left(\frac{-\text{func}(x_{\text{new}}) - \text{func}(x_{\text{old}})}{T}\right)
\]

So, for best results, T should be comparable to the typical difference (in function values) between local minima. (The height of “walls” between local minima is irrelevant.) If T is 0, the algorithm becomes Monotonic Basin-Hopping, in which all steps that increase energy are rejected. New in version 0.12.0.

[1], [2], [3], [4], [5]

Examples

The following example is a 1-D minimization problem, with many local minima superimposed on a parabola.

```python
>>> from scipy.optimize import basinhopping
>>> func = lambda x: np.cos(14.5 * x - 0.3) + (x + 0.2) * x
>>> x0=[1.]
```

Basinhopping, internally, uses a local minimization algorithm. We will use the parameter `minimizer_kwargs` to tell basinhopping which algorithm to use and how to set up that minimizer. This parameter will be passed to `scipy.optimize.minimize()`.

```python
>>> minimizer_kwargs = {"method": "BFGS"}
>>> ret = basinhopping(func, x0, minimizer_kwargs=minimizer_kwargs,
...   niter=200)
>>> print("global minimum: x = %4f, f(x0) = %4f" % (ret.x, ret.fun))
global minimum: x = -0.1951, f(x0) = -1.0009
```

Next consider a 2-D minimization problem. Also, this time, we will use gradient information to significantly speed up the search.
```python
>>> def func2d(x):
...     f = np.cos(14.5 * x[0] - 0.3) + (x[1] + 0.2) * x[1] + (x[0] + 0.2) * x[0]
...     df = np.zeros(2)
...     df[0] = -14.5 * np.sin(14.5 * x[0] - 0.3) + 2. * x[0] + 0.2
...     df[1] = 2. * x[1] + 0.2
...     return f, df

We'll also use a different local minimization algorithm. Also, we must tell the minimizer that our function returns both energy and gradient (Jacobian).

```python
>>> minimizer_kwargs = {"method":"L-BFGS-B", "jac":True}
>>> x0 = [1.0, 1.0]
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...     niter=200)
>>> print("global minimum: x = [%s, %s], f(x0) = %.4f" % (ret.x[0],
...     ret.x[1],
...     ret.fun))
```
```
global minimum: x = [-0.1951, -0.1000], f(x0) = -1.0109
```

Here is an example using a custom step-taking routine. Imagine you want the first coordinate to take larger steps than the rest of the coordinates. This can be implemented like so:

```python
>>> class MyTakeStep:
...     def __init__(self, stepsize=0.5):
...         self.stepsize = stepsize
...         self.rng = np.random.default_rng()
...     def __call__(self, x):
...         s = self.stepsize
...         x[0] += self.rng.uniform(-2.*s, 2.*s)
...         x[1:] += self.rng.uniform(-s, s, x[1:].shape)
...         return x

Since MyTakeStep.stepsize exists basinhopping will adjust the magnitude of stepsize to optimize the search. We'll use the same 2-D function as before

```python
>>> mytakestep = MyTakeStep()
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...     niter=200, take_step=mymakestep)
>>> print("global minimum: x = [%s, %s], f(x0) = %.4f" % (ret.x[0],
...     ret.x[1],
...     ret.fun))
```
```
global minimum: x = [-0.1951, -0.1000], f(x0) = -1.0109
```

Now, let's do an example using a custom callback function which prints the value of every minimum found

```python
>>> def print_fun(x, f, accepted):
...     print("at minimum %.4f accepted %d" % (f, int(accepted)))
```
```
We'll run it for only 10 basinhopping steps this time.

```python
>>> rng = np.random.default_rng()
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...     niter=10, callback=print_fun, seed=rng)
```
```
at minimum 0.4159 accepted 1
at minimum -0.4317 accepted 1
at minimum -1.0109 accepted 1
at minimum -0.9073 accepted 1
at minimum -0.4317 accepted 0
at minimum -0.1021 accepted 1
at minimum -0.7425 accepted 1
at minimum -0.9073 accepted 1
at minimum -0.4317 accepted 0
at minimum -0.7425 accepted 1
at minimum -0.9073 accepted 1
The minimum at -1.0109 is actually the global minimum, found already on the 8th iteration.

Now let's implement bounds on the problem using a custom accept_test:

```python
class MyBounds:
    ...  def __init__(self, xmax=[1.1, 1.1], xmin=[-1.1, -1.1]):
        self.xmax = np.array(xmax)
        self.xmin = np.array(xmin)
    ...  def __call__(self, **kwargs):
        x = kwargs['x_new']
        tmax = bool(np.all(x < self.xmax))
        tmin = bool(np.all(x >= self.xmin))
        return tmax and tmin
```

```python
mybounds = MyBounds()
ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
                   niter=10, accept_test=mybounds)
```

**scipy.optimize.brute**

`scipy.optimize.brute(func, ranges, args=(), Ns=20, full_output=0, finish=<function fmin>, disp=False, workers=1)`

Minimize a function over a given range by brute force.

Uses the “brute force” method, i.e., computes the function’s value at each point of a multidimensional grid of points, to find the global minimum of the function.

The function is evaluated everywhere in the range with the datatype of the first call to the function, as enforced by the `vectorize` NumPy function. The value and type of the function evaluation returned when `full_output=True` are affected in addition by the `finish` argument (see Notes).

The brute force approach is inefficient because the number of grid points increases exponentially - the number of grid points to evaluate is Ns ** len(x). Consequently, even with coarse grid spacing, even moderately sized problems can take a long time to run, and/or run into memory limitations.

**Parameters**

- **func** [callable] The objective function to be minimized. Must be in the form `f(x, *args)`, where `x` is the argument in the form of a 1-D array and `args` is a tuple of any additional fixed parameters needed to completely specify the function.
ranges [tuple] Each component of the ranges tuple must be either a “slice object” or a range tuple of the form (low, high). The program uses these to create the grid of points on which the objective function will be computed. See Note 2 for more detail.

args [tuple, optional] Any additional fixed parameters needed to completely specify the function.

Ns [int, optional] Number of grid points along the axes, if not otherwise specified. See Note 2.

full_output [bool, optional] If True, return the evaluation grid and the objective function’s values on it.

finish [callable, optional] An optimization function that is called with the result of brute force minimization as initial guess. finish should take func and the initial guess as positional arguments, and take args as keyword arguments. It may additionally take full_output and/or disp as keyword arguments. Use None if no “polishing” function is to be used. See Notes for more details.

disp [bool, optional] Set to True to print convergence messages from the finish callable.

workers [int or map-like callable, optional] If workers is an int the grid is subdivided into workers sections and evaluated in parallel (uses multiprocessing.Pool). Supply -1 to use all cores available to the Process. Alternatively supply a map-like callable, such as multiprocessing.Pool.map for evaluating the grid in parallel. This evaluation is carried out as workers(func, iterable). Requires that func be pickleable.

New in version 1.3.0.

Returns

x0 [ndarray] A 1-D array containing the coordinates of a point at which the objective function had its minimum value. (See Note 1 for which point is returned.)
fval [float] Function value at the point x0. (Returned when full_output is True.)
grid [tuple] Representation of the evaluation grid. It has the same length as x0. (Returned when full_output is True.)
Jout [ndarray] Function values at each point of the evaluation grid, i.e., Jout = func(*grid). (Returned when full_output is True.)

See also:

basinhopping, differential_evolution

Notes

Note 1: The program finds the gridpoint at which the lowest value of the objective function occurs. If finish is None, that is the point returned. When the global minimum occurs within (or not very far outside) the grid’s boundaries, and the grid is fine enough, that point will be in the neighborhood of the global minimum.

However, users often employ some other optimization program to “polish” the gridpoint values, i.e., to seek a more precise (local) minimum near brute’s best gridpoint. The brute function’s finish option provides a convenient way to do that. Any polishing program used must take brute’s output as its initial guess as a positional argument, and take brute’s input values for args as keyword arguments, otherwise an error will be raised. It may additionally take full_output and/or disp as keyword arguments.

brute assumes that the finish function returns either an OptimizeResult object or a tuple in the form: (xmin, Jmin, ..., statuscode), where xmin is the minimizing value of the argument, Jmin is the minimum value of the objective function, “...” may be some other returned values (which are not used by brute), and statuscode is the status code of the finish program.

Note that when finish is not None, the values returned are those of the finish program, not the gridpoint ones. Consequently, while brute confines its search to the input grid points, the finish program’s results usually will not coincide with any gridpoint, and may fall outside the grid’s boundary. Thus, if a minimum only needs to be found over the provided grid points, make sure to pass in finish=None.
Note 2: The grid of points is a `numpy.mgrid` object. For `brute` the *ranges* and *Ns* inputs have the following effect. Each component of the *ranges* tuple can be either a slice object or a two-tuple giving a range of values, such as (0, 5). If the component is a slice object, `brute` uses it directly. If the component is a two-tuple range, `brute` internally converts it to a slice object that interpolates *Ns* points from its low-value to its high-value, inclusive.

**Examples**

We illustrate the use of `brute` to seek the global minimum of a function of two variables that is given as the sum of a positive-definite quadratic and two deep “Gaussian-shaped” craters. Specifically, define the objective function \( f \) as the sum of three other functions, \( f = f_1 + f_2 + f_3 \). We suppose each of these has a signature \((z, *params)\), where \( z = (x, y) \), and \( params \) and the functions are as defined below.

```python
>>> params = (2, 3, 7, 8, 9, 10, 44, -1, 2, 26, 1, -2, 0.5)
>>> def f1(z, *params):
... x, y = z
... a, b, c, d, e, f, g, h, i, j, k, l, scale = params
... return (a * x**2 + b * x * y + c * y**2 + d*x + e*y + f)
```

```python
>>> def f2(z, *params):
... x, y = z
... a, b, c, d, e, f, g, h, i, j, k, l, scale = params
... return (-g*np.exp(-((x-h)**2 + (y-i)**2) / scale))
```

```python
>>> def f3(z, *params):
... x, y = z
... a, b, c, d, e, f, g, h, i, j, k, l, scale = params
... return (-j*np.exp(-((x-k)**2 + (y-l)**2) / scale))
```

```python
>>> def f(z, *params):
... return f1(z, *params) + f2(z, *params) + f3(z, *params)
```

Thus, the objective function may have local minima near the minimum of each of the three functions of which it is composed. To use `fmin` to polish its gridpoint result, we may then continue as follows:

```python
>>> rranges = (slice(-4, 4, 0.25), slice(-4, 4, 0.25))
>>> from scipy import optimize
>>> resbrute = optimize.brute(f, rranges, args=params, full_output=True,
... finish=optimize.fmin)
>>> resbrute[0] # global minimum
array([-1.05665192, 1.80834843])
>>> resbrute[1] # function value at global minimum
-3.4085818767
```

Note that if `finish` had been set to None, we would have gotten the gridpoint \([-1.0 1.75]\) where the rounded function value is -2.892.
scipy.optimize.differential_evolution

scipy.optimize.differential_evolution(func, bounds, args=(), strategy='best1bin', maxiter=1000, popsize=15, tol=0.01, mutation=(0.5, 1), recombination=0.7, seed=None, callback=None, disp=False, polish=True, init='latinhypercube', atol=0, updating='immediate', workers=1, constraints=(), x0=None)

Finds the global minimum of a multivariate function.

Differential Evolution is stochastic in nature (does not use gradient methods) to find the minimum, and can search large areas of candidate space, but often requires larger numbers of function evaluations than conventional gradient-based techniques.

The algorithm is due to Storn and Price [1].

**Parameters**

- **func** [callable] The objective function to be minimized. Must be in the form \( f(x, *args) \), where \( x \) is the argument in the form of a 1-D array and \( args \) is a tuple of any additional fixed parameters needed to completely specify the function.

- **bounds** [sequence or Bounds] Bounds for variables. There are two ways to specify the bounds:
  1. Instance of Bounds class.
  2. (min, max) pairs for each element in \( x \), defining the finite lower and upper bounds for the optimizing argument of \( func \). It is required to have \( \text{len(bounds)} == \text{len(x)} \). \( \text{len(bounds)} \) is used to determine the number of parameters in \( x \).

- **args** [tuple, optional] Any additional fixed parameters needed to completely specify the objective function.

- **strategy** [str, optional] The differential evolution strategy to use. Should be one of:
  - 'best1bin'
  - 'best1exp'
  - 'rand1exp'
  - 'randtobest1exp'
  - 'currenttobest1exp'
  - 'best2exp'
  - 'rand2exp'
  - 'randtobest1bin'
  - 'currenttobest1bin'
  - 'best2bin'
  - 'rand2bin'
  - 'rand1bin'
  The default is 'best1bin'.

- **maxiter** [int, optional] The maximum number of generations over which the entire population is evolved. The maximum number of function evaluations (with no polishing) is: \((\text{maxiter} + 1) * \text{popsize} * \text{len(x)}\)

- **popsize** [int, optional] A multiplier for setting the total population size. The population has \( \text{popsize} * \text{len(x)} \) individuals. This keyword is overridden if an initial population is supplied via the \( \text{init} \) keyword. When using \( \text{init} = \text{'sobol'} \) the population size is calculated as the next power of 2 after \( \text{popsize} * \text{len(x)} \).

- **tol** [float, optional] Relative tolerance for convergence, the solving stops when \( \text{np.std(pop)} \leq \text{atol} + \text{tol} * \text{np.abs(np.mean(population_energies))} \), where and \( \text{atol} \) and \( \text{tol} \) are the absolute and relative tolerance respectively.

- **mutation** [float or tuple(float, float), optional] The mutation constant. In the literature this is also known as differential weight, being denoted by \( F \). If specified as a float it should be in the range \([0, 2]\). If specified as a tuple \((\text{min, max})\) dithering is employed. Dithering randomly changes the mutation constant on a generation by generation basis. The mutation constant for that generation is taken from \( U[\text{min, max}] \). Dithering can help speed convergence...
significantly. Increasing the mutation constant increases the search radius, but will slow down convergence.

**recombination**

[float, optional] The recombination constant, should be in the range [0, 1]. In the literature this is also known as the crossover probability, being denoted by CR. Increasing this value allows a larger number of mutants to progress into the next generation, but at the risk of population stability.

**seed**

[[None, int, numpy.random.Generator,]
numpy.random.RandomState], optional

If `seed` is None (or `np.random`), the `numpy.random.RandomState` singleton is used. If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already a `Generator` or `RandomState` instance then that instance is used. Specify `seed` for repeatable minimizations.

**disp**

[bool, optional] Prints the evaluated `func` at every iteration.

**callback**

[callable, callback(xk, convergence=val), optional] A function to follow the progress of the minimization. `xk` is the best solution found so far. `val` represents the fractional value of the population convergence. When `val` is greater than one the function halts. If callback returns `True`, then the minimization is halted (any polishing is still carried out).

**polish**

[bool, optional] If True (default), then `scipy.optimize.minimize` with the L-BFGS-B method is used to polish the best population member at the end, which can improve the minimization slightly. If a constrained problem is being studied then the `trust-constr` method is used instead.

**init**

[str or array-like, optional] Specify which type of population initialization is performed. Should be one of:

- ‘latinhypercube’
- ‘sobol’
- ‘halton’
- ‘random’

array specifying the initial population. The array should have shape (M, len(x)), where M is the total population size and len(x) is the number of parameters. `init` is clipped to `bounds` before use.

The default is ‘latinhypercube’. Latin Hypercube sampling tries to maximize coverage of the available parameter space.

‘sobol’ and ‘halton’ are superior alternatives and maximize even more the parameter space. ‘sobol’ will enforce an initial population size which is calculated as the next power of 2 after `popsize * len(x)`.

‘halton’ has no requirements but is a bit less efficient. See `scipy.stats.qmc` for more details.

‘random’ initializes the population randomly - this has the drawback that clustering can occur, preventing the whole of parameter space being covered. Use of an array to specify a population could be used, for example, to create a tight bunch of initial guesses in an location where the solution is known to exist, thereby reducing time for convergence.

**atol**

[float, optional] Absolute tolerance for convergence, the solving stops when \( \text{np.std(pop)} \leq \text{atol} + \text{tol} \times \text{np.abs(np.mean(population_energies))} \), where and `atol` and `tol` are the absolute and relative tolerance respectively.

**updating**

[{'immediate', 'deferred'}, optional] If 'immediate', the best solution vector is continuously updated within a single generation [4]. This can lead to faster convergence as trial vectors can take advantage of continuous improvements in the best solution. With 'deferred', the best solution vector is updated once per generation. Only 'deferred' is compatible with parallelization, and the `workers` keyword can over-ride this option.

New in version 1.2.0.

**workers**

[int or map-like callable, optional] If `workers` is an int the population is subdivided into `workers` sections and evaluated in parallel (uses `multiprocessing.Pool`). Supply -1 to use all available CPU cores. Alternatively supply a map-like callable, such as `multiprocessing.Pool.map` for evaluating the population in parallel. This evaluation is carried out as
workers(func, iterable). This option will override the updating keyword to updating='deferred' if workers != 1. Requires that func be pickleable.
New in version 1.2.0.

constraints

[[NonLinearConstraint, LinearConstraint, Bounds]] Constraints on the solver, over and above those applied by the bounds kw. Uses the approach by Lampinen [5].
New in version 1.4.0.

x0

[None or array-like, optional] Provides an initial guess to the minimization. Once the population has been initialized this vector replaces the first (best) member. This replacement is done even if init is given an initial population.
New in version 1.7.0.

Returns

res [OptimizeResult] The optimization result represented as a OptimizeResult object. Important attributes are: x the solution array, success a Boolean flag indicating if the optimizer exited successfully and message which describes the cause of the termination. See OptimizeResult for a description of other attributes. If polish was employed, and a lower minimum was obtained by the polishing, then OptimizeResult also contains the jac attribute. If the eventual solution does not satisfy the applied constraints success will be False.

Notes

Differential evolution is a stochastic population based method that is useful for global optimization problems. At each pass through the population the algorithm mutates each candidate solution by mixing with other candidate solutions to create a trial candidate. There are several strategies [2] for creating trial candidates, which suit some problems more than others. The ‘best1bin’ strategy is a good starting point for many systems. In this strategy two members of the population are randomly chosen. Their difference is used to mutate the best member (the ‘best’ in ‘best1bin’), b0, so far:

\[
b' = b_0 + \text{mutation} \times (\text{population}[\text{rand0}] - \text{population}[\text{rand1}])
\]

A trial vector is then constructed. Starting with a randomly chosen ith parameter the trial is sequentially filled (in modulo) with parameters from b’ or the original candidate. The choice of whether to use b’ or the original candidate is made with a binomial distribution (the ‘bin’ in ‘best1bin’) - a random number in [0, 1) is generated. If this number is less than the recombination constant then the parameter is loaded from b’, otherwise it is loaded from the original candidate. The final parameter is always loaded from b’. Once the trial candidate is built its fitness is assessed. If the trial is better than the original candidate then it takes its place. If it is also better than the best overall candidate it also replaces that. To improve your chances of finding a global minimum use higher popsize values, with higher mutation and (dithering), but lower recombination values. This has the effect of widening the search radius, but slowing convergence. By default the best solution vector is updated continuously within a single iteration (updating='immediate'). This is a modification [4] of the original differential evolution algorithm which can lead to faster convergence as trial vectors can immediately benefit from improved solutions. To use the original Storn and Price behaviour, updating the best solution once per iteration, set updating='deferred'.
New in version 0.15.0.

Examples

Let us consider the problem of minimizing the Rosenbrock function. This function is implemented in `rosen` in `scipy.optimize`.

```python
>>> from scipy.optimize import rosen, differential_evolution
>>> bounds = [(0, 2), (0, 2), (0, 2), (0, 2), (0, 2)]
>>> result = differential_evolution(rosen, bounds)
>>> result.x, result.fun
(array([1., 1., 1., 1., 1.]), 1.9216496320061384e-19)
```

Now repeat, but with parallelization.

```python
>>> bounds = [(0, 2), (0, 2), (0, 2), (0, 2), (0, 2)]
>>> result = differential_evolution(rosen, bounds, updating='deferred',
...                                workers=2)
>>> result.x, result.fun
(array([1., 1., 1., 1., 1.]), 1.9216496320061384e-19)
```

Let’s try and do a constrained minimization

```python
>>> from scipy.optimize import NonlinearConstraint, Bounds
>>> def constr_f(x):
...     return np.array(x[0] + x[1])
... # the sum of x[0] and x[1] must be less than 1.9
>>> nlc = NonlinearConstraint(constr_f, -np.inf, 1.9)
>>> # specify limits using a `Bounds` object.
>>> bounds = Bounds([0., 0.], [2., 2.])
>>> result = differential_evolution(rosen, bounds, constraints=(nlc),
...                                 seed=1)
>>> result.x, result.fun
(array([0.96633867, 0.93363577]), 0.0011361355854792312)
```

Next find the minimum of the Ackley function (https://en.wikipedia.org/wiki/Test_functions_for_optimization).

```python
>>> from scipy.optimize import differential_evolution
>>> import numpy as np
>>> def ackley(x):
...     arg1 = -0.2 * np.sqrt(0.5 * (x[0] ** 2 + x[1] ** 2))
...     arg2 = 0.5 * (np.cos(2. * np.pi * x[0]) + np.cos(2. * np.pi *
...                  -x[1]))
...     return -20. * np.exp(arg1) - np.exp(arg2) + 20. + np.e
>>> bounds = [(-5, 5), (-5, 5)]
>>> result = differential_evolution(ackley, bounds)
>>> result.x, result.fun

```
scipy.optimize.shgo

**scipy.optimize.shgo** *(func, bounds, args=(), constraints=(), n=None, iters=1, callback=None, minimizer_kwargs=(), options=(), sampling_method='simplicial')*

Finds the global minimum of a function using SHG optimization.

SHGO stands for “simplicial homology global optimization”.

**Parameters**

- **func** [callable] The objective function to be minimized. Must be in the form \( f(x, \ *args) \), where \( x \) is the argument in the form of a 1-D array and \( args \) is a tuple of any additional fixed parameters needed to completely specify the function.

- **bounds** [sequence] Bounds for variables. \((min, \ max)\) pairs for each element in \( x \), defining the lower and upper bounds for the optimizing argument of \( func \). It is required to have \( \text{len}(\text{bounds}) = \text{len}(x) \). \( \text{len}(\text{bounds}) \) is used to determine the number of parameters in \( x \). Use \( \text{None} \) for one of \( \text{min} \) or \( \text{max} \) when there is no bound in that direction. By default bounds are \((\text{None}, \text{None})\).

- **args** [tuple, optional] Any additional fixed parameters needed to completely specify the objective function.

- **constraints** [dict or sequence of dict, optional] Constraints definition. Function(s) \( \mathbb{R}^n \) in the form:

  \[
  g(x) >= 0 \text{ applied as } g : \mathbb{R}^n \rightarrow \mathbb{R}^m \\
  h(x) == 0 \text{ applied as } h : \mathbb{R}^n \rightarrow \mathbb{R}^p
  \]

  Each constraint is defined in a dictionary with fields:

  - **fun** [callable] The function defining the constraint.
  - **jac** [callable, optional] The Jacobian of \( \text{fun} \) (only for SLSQP).
  - **args** [sequence, optional] Extra arguments to be passed to the function and Jacobian.

  Equality constraint means that the constraint function result is to be zero whereas inequality means that it is to be non-negative. Note that COBYLA only supports inequality constraints.

  **Note:** Only the COBYLA and SLSQP local minimize methods currently support constraint arguments. If the constraints sequence used in the local optimization problem is not defined in minimizer_kwargs and a constrained method is used then the global constraints will be used. (Defining a constraints sequence in minimizer_kwargs means that constraints will not be added so if equality constraints and so forth need to be added then the inequality functions in constraints need to be added to minimizer_kwargs too).

- **n** [int, optional] Number of sampling points used in the construction of the simplicial complex. Note that this argument is only used for sobol and other arbitrary sampling_methods. In case of sobol, it must be a power of 2: \( n=2^m \), and the argument will automatically be converted to the next higher power of 2. Default is 100 for sampling_method='simplicial' and 128 for sampling_method='sobol'.

- **iters** [int, optional] Number of iterations used in the construction of the simplicial complex. Default is 1.

- **callback** [callable, optional] Called after each iteration, as \( \text{callback}(xk) \), where \( xk \) is the current parameter vector.

- **minimizer_kwargs** [dict, optional] Extra keyword arguments to be passed to the minimizer scipy.optimize.minimize Some important options could be:

  - **method** [str] The minimization method, the default is SLSQP.

- **args** [tuple] Extra arguments passed to the objective function (`func`) and its derivatives (Jacobian, Hessian).
- **options** [dict, optional] Note that by default the tolerance is specified as `{ftol: 1e-12}`

**options** [dict, optional] A dictionary of solver options. Many of the options specified for the global routine are also passed to the `scipy.optimize.minimize` routine. The options that are also passed to the local routine are marked with “(L)”.

Stopping criteria, the algorithm will terminate if any of the specified criteria are met. However, the default algorithm does not require any to be specified:

- **maxfev** [int (L)] Maximum number of function evaluations in the feasible domain. (Note only methods that support this option will terminate the routine at precisely exact specified value. Otherwise the criterion will only terminate during a global iteration)
- **f_min** Specify the minimum objective function value, if it is known.
- **f_tol** [float] Precision goal for the value of f in the stopping criterion. Note that the global routine will also terminate if a sampling point in the global routine is within this tolerance.
- **maxiter** [int] Maximum number of iterations to perform.
- **maxev** [int] Maximum number of sampling evaluations to perform (includes searching in infeasible points).
- **maxtime** [float] Maximum processing runtime allowed
- **minhgrd** [int] Minimum homology group rank differential. The homology group of the objective function is calculated (approximately) during every iteration. The rank of this group has a one-to-one correspondence with the number of locally convex subdomains in the objective function (after adequate sampling points each of these subdomains contain a unique global minimum). If the difference in the hgr is 0 between iterations for `maxhgrd` specified iterations the algorithm will terminate.

Objective function knowledge:

- **symmetry** [bool] Specify True if the objective function contains symmetric variables. The search space (and therefore performance) is decreased by O(n!).
- **jac** [bool or callable, optional] Jacobian (gradient) of objective function. Only for CG, BFGS, Newton-CG, L-BFGS-B, TNC, SLSQP, dogleg, trust-ncg. If `jac` is a boolean and is True, `fun` is assumed to return the gradient along with the objective function. If False, the gradient will be estimated numerically. `jac` can also be a callable returning the gradient of the objective. In this case, it must accept the same arguments as `fun`. (Passed to `scipy.optimize.minimize` automatically)

- **hess**, **hessp** [callable, optional] Hessian (matrix of second-order derivatives) of objective function or Hessian of objective function times an arbitrary vector p. Only for Newton-CG, dogleg, trust-ncg. Only one of `hessp` or `hess` needs to be given. If `hess` is provided, then `hessp` will be ignored. If neither `hess` nor `hessp` is provided, then the Hessian product will be approximated using finite differences on `jac`. `hessp` must compute the Hessian times an arbitrary vector. (Passed to `scipy.optimize.minimize` automatically)

Algorithm settings:

- **minimize_every_iter** [bool] If True then promising global sampling points will be passed to a local minimization routine every iteration. If False then only the final minimizer pool will be run. Defaults to False.
- **local_iter** [int] Only evaluate a few of the best minimizer pool candidates every iteration. If False all potential points are passed to the local minimization routine.
If True then any sampling points generated which are outside will the feasible domain will be saved and given an objective function value of $\text{inf}$. If False then these points will be discarded. Using this functionality could lead to higher performance with respect to function evaluations before the global minimum is found, specifying False will use less memory at the cost of a slight decrease in performance. Defaults to True.

Feedback:

- **disp**
  - [bool (L)] Set to True to print convergence messages.

**sampling_method**

[str or function, optional] Current built in sampling method options are halton, sobol and simplicial. The default simplicial provides the theoretical guarantee of convergence to the global minimum in finite time. halton and sobol method are faster in terms of sampling point generation at the cost of the loss of guaranteed convergence. It is more appropriate for most “easier” problems where the convergence is relatively fast. User defined sampling functions must accept two arguments of $n$ sampling points of dimension $\text{dim}$ per call and output an array of sampling points with shape $n \times \text{dim}$.

**Returns**

- **res**
  - [OptimizeResult] The optimization result represented as a OptimizeResult object. Important attributes are: $x$ the solution array corresponding to the global minimum, $\text{fun}$ the function output at the global solution, $\text{xl}$ an ordered list of local minima solutions, $\text{funl}$ the function output at the corresponding local solutions, success a Boolean flag indicating if the optimizer exited successfully, $\text{message}$ which describes the cause of the termination, nfev the total number of objective function evaluations including the sampling calls, nlfev the total number of objective function evaluations culminating from all local search optimizations, nit number of iterations performed by the global routine.

**Notes**

Global optimization using simplicial homology global optimization [1]. Appropriate for solving general purpose NLP and blackbox optimization problems to global optimality (low-dimensional problems).

In general, the optimization problems are of the form:

\[
\begin{align*}
\text{minimize } f(x) \text{ subject to } \\
g_i(x) & \geq 0, \quad i = 1, \ldots, m \\
h_j(x) & = 0, \quad j = 1, \ldots, p
\end{align*}
\]

where $x$ is a vector of one or more variables. $f(x)$ is the objective function $\mathbb{R}^n \rightarrow \mathbb{R}$, $g_i(x)$ are the inequality constraints, and $h_j(x)$ are the equality constraints.

Optionally, the lower and upper bounds for each element in $x$ can also be specified using the `bounds` argument.

While most of the theoretical advantages of SHGO are only proven for when $f(x)$ is a Lipschitz smooth function, the algorithm is also proven to converge to the global optimum for the more general case where $f(x)$ is non-continuous, non-convex and non-smooth, if the default sampling method is used [1].

The local search method may be specified using the `minimizer_kwargs` parameter which is passed on to scipy.optimize.minimize. By default, the SLSQP method is used. In general, it is recommended to use the SLSQP or COBYLA local minimization if inequality constraints are defined for the problem since the other methods do not use constraints.

The halton and sobol method points are generated using scipy.stats.qmc. Any other QMC method could be used.

[1], [2], [3], [4]

Examples

First consider the problem of minimizing the Rosenbrock function, rosen:

```python
>>> from scipy.optimize import rosen, shgo
>>> bounds = [(0, 2), (0, 2), (0, 2), (0, 2), (0, 2)]
>>> result = shgo(rosen, bounds)
>>> result.x, result.fun
(array([1., 1., 1., 1., 1.]), 2.920392374190081e-18)
```

Note that bounds determine the dimensionality of the objective function and is therefore a required input, however you can specify empty bounds using `None` or objects like `np.inf` which will be converted to large float numbers.

```python
>>> bounds = [(None, None), ]*4
>>> result = shgo(rosen, bounds)
>>> result.x
array([0.99999951, 0.99999804, 0.99999511, 0.9999882 ])
```

Next, we consider the Eggholder function, a problem with several local minima and one global minimum. We will demonstrate the use of arguments and the capabilities of `shgo`. (https://en.wikipedia.org/wiki/Test_functions_for_optimization)

```python
>>> def eggholder(x):
...     return -((x[1] + 47.0) * np.sin(np.sqrt(abs(x[0] / 2.0 + (x[1] + 47.0))))
...     - x[0] * np.sin(np.sqrt(abs(x[0] - (x[1] + 47.0))))
...     )

>>> bounds = [(-512, 512), (-512, 512)]
```

`shgo` has built-in low discrepancy sampling sequences. First, we will input 64 initial sampling points of the Sobol' sequence:

```python
>>> result = shgo(eggholder, bounds, n=64, sampling_method='sobol')
>>> result.x, result.fun
(array([512. ,  404.23180824]), -959.6406627208397)
```

`shgo` also has a return for any other local minima that was found, these can be called using:

```python
>>> result.xl
array([[ 512.0,  404.23180824],
       [ 283.0759062 , -487.12565635],
       [-294.66820039, -462.01964031],
       [-105.87688911,  423.15323845],
       [-242.97926 ,  274.38030925],
       [-506.25823477,  6.3131022 ],
       [-408.71980731, -156.10116949],
       [ 150.23207937,  301.31376595],
       [ 91.00920901, -391.283763 ]],
      (continues on next page)
These results are useful in applications where there are many global minima and the values of other global minima are desired or where the local minima can provide insight into the system (for example morphologies in physical chemistry [4]).

If we want to find a larger number of local minima, we can increase the number of sampling points or the number of iterations. We’ll increase the number of sampling points to 64 and the number of iterations from the default of 1 to 3. Using simplicial this would have given us $64 \times 3 = 192$ initial sampling points.

```python
>>> result_2 = shgo(eggholder, bounds, n=64, iters=3, sampling_method='sobol')
>>> len(result.xl), len(result_2.xl)
(12, 20)
```

Note the difference between, e.g., $n=192$, iters=1 and $n=64$, iters=3. In the first case the promising points contained in the minimiser pool are processed only once. In the latter case it is processed every 64 sampling points for a total of 3 times.

To demonstrate solving problems with non-linear constraints consider the following example from Hock and Schittkowski problem 73 (cattle-feed) [3]:

Minimize: $f = 24.55 \times x_1 + 26.75 \times x_2 + 39 \times x_3 + 40.50 \times x_4$

Subject to:

\[
\begin{align*}
2.3 \times x_1 + 5.6 \times x_2 + 11.1 \times x_3 + 1.3 \times x_4 & - 5 & \geq 0, \\
12 \times x_1 + 11.9 \times x_2 + 41.8 \times x_3 + 52.1 \times x_4 & - 21 & \geq 0, \\
-1.645 \times \sqrt{0.28 \times x_1^{**2} + 0.19 \times x_2^{**2} + \\
20.5 \times x_3^{**2} + 0.62 \times x_4^{**2}} & \geq 0, \\
1 & \geq x_i \geq 0 \text{ for all } i
\end{align*}
\]

The approximate answer given in [3] is:

\[f([0.6355216, -0.12e-11, 0.3127019, 0.05177655]) = 29.894378\]
... - 1.645 * np.sqrt(0.28*x[0]**2 + 0.19*x[1]**2
... + 20.5*x[2]**2 + 0.62*x[3]**2)
... ) # >=0

... >>> def h1(x):

... >>> cons = ({'type': 'ineq', 'fun': g1},
...           {'type': 'ineq', 'fun': g2},
...           {'type': 'eq', 'fun': h1})

... >>> bounds = [(0, 1.0),]*4

... >>> res = shgo(f, bounds, iters=3, constraints=cons)

... >>> res

    fun: 29.894378159142136
    funl: array([29.89437816])
    message: 'Optimization terminated successfully.'
    nfev: 114
    nit: 3
    nlfev: 35
    nlhev: 0
    nljev: 5
    success: True
              17765506e-02])
                17765506e-02]])

... g1(res.x), g2(res.x), h1(res.x)

**scipy.optimize.dual_annealing**

`scipy.optimize.dual_annealing` *(func, bounds, args=(), maxiter=1000, minimizer_kwags=None, initial_temp=5230.0, restart_temp_ratio=2e-05, visit=2.62, accept=- 5.0, maxfun=1000000.0, seed=None, no_local_search=False, callback=None, x0=None, local_search_options=None)*

Find the global minimum of a function using Dual Annealing.

**Parameters**

- **func** [callable] The objective function to be minimized. Must be in the form `f(x, *args)`, where `x` is the argument in the form of a 1-D array and `args` is a tuple of any additional fixed parameters needed to completely specify the function.

- **bounds** [sequence, shape (n, 2)] Bounds for variables. `(min, max)` pairs for each element in `x`, defining bounds for the objective function parameter.

- **args** [tuple, optional] Any additional fixed parameters needed to completely specify the objective function.

- **maxiter** [int, optional] The maximum number of global search iterations. Default value is 1000.

- **minimizer_kwags** [dict, optional] Extra keyword arguments to be passed to the local minimizer (`minimize`). Some important options could be: `method` for the minimizer method to use and `args` for objective function additional arguments.
**initial_temp**

[float, optional] The initial temperature, use higher values to facilitates a wider search of the energy landscape, allowing dual_annealing to escape local minima that it is trapped in. Default value is 5230. Range is (0.01, 5e4].

**restart_temp_ratio**

[float, optional] During the annealing process, temperature is decreasing, when it reaches \(\text{initial_temp} \times \text{restart_temp_ratio}\), the reannealing process is triggered. Default value of the ratio is 2e-5. Range is (0, 1).

**visit**

[float, optional] Parameter for visiting distribution. Default value is 2.62. Higher values give the visiting distribution a heavier tail, this makes the algorithm jump to a more distant region. The value range is (1, 3).

**accept**

[float, optional] Parameter for acceptance distribution. It is used to control the probability of acceptance. The lower the acceptance parameter, the smaller the probability of acceptance. Default value is -5.0 with a range (-1e4, -5].

**maxfun**

[int, optional] Soft limit for the number of objective function calls. If the algorithm is in the middle of a local search, this number will be exceeded, the algorithm will stop just after the local search is done. Default value is 1e7.

**seed**

[[None, int, numpy.random.Generator],
numpy.random.RandomState], optional

If `seed` is None (or `np.random`), the `numpy.random.RandomState` singleton is used. If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already a `Generator` or `RandomState` instance then that instance is used. Specify `seed` for repeatable minimizations. The random numbers generated with this seed only affect the visiting distribution function and new coordinates generation.

**no_local_search**

[bool, optional] If `no_local_search` is set to True, a traditional Generalized Simulated Annealing will be performed with no local search strategy applied.

**callback**

[callable, optional] A callback function with signature `callback(x, f, context)`, which will be called for all minima found. \(x\) and \(f\) are the coordinates and function value of the latest minimum found, and `context` has value in \([0, 1, 2]\), with the following meaning:
- 0: minimum detected in the annealing process.
- 1: detection occurred in the local search process.
- 2: detection done in the dual annealing process.

If the callback implementation returns True, the algorithm will stop.

**x0**

[ndarray, shape(n,), optional] Coordinates of a single N-D starting point.

**local_search_options**

[dict, optional] Backwards compatible flag for `minimizer_options`, only one of these should be supplied.

**Returns**

[OptimizeResult] The optimization result represented as a `OptimizeResult` object. Important attributes are: `x` the solution array, `fun` the value of the function at the solution, and `message` which describes the cause of the termination. See `OptimizeResult` for a description of other attributes.
Notes

This function implements the Dual Annealing optimization. This stochastic approach derived from [3] combines the generalization of CSA (Classical Simulated Annealing) and FSA (Fast Simulated Annealing) [1] [2] coupled to a strategy for applying a local search on accepted locations [4]. An alternative implementation of this same algorithm is described in [5] and benchmarks are presented in [6]. This approach introduces an advanced method to refine the solution found by the generalized annealing process. This algorithm uses a distorted Cauchy-Lorentz visiting distribution, with its shape controlled by the parameter $q_v$

$$g_{qv}(\Delta x(t)) \propto \frac{[T_{qv}(t)]^{\frac{D}{3-qv}}}{\left[1 + (q_v - 1) \frac{(\Delta x(t))^2}{[T_{qv}(t)]^{\frac{D}{3-qv}}} \right]^{rac{1}{q_v-1} + \frac{D}{2}}}$$

Where $t$ is the artificial time. This visiting distribution is used to generate a trial jump distance $\Delta x(t)$ of variable $x(t)$ under artificial temperature $T_{qv}(t)$.

From the starting point, after calling the visiting distribution function, the acceptance probability is computed as follows:

$$p_{qa} = \min\{1, \left[1 - (1 - q_a)\beta \Delta E\right]^{\frac{1}{1-q_a}}\}$$

Where $q_a$ is a acceptance parameter. For $q_a < 1$, zero acceptance probability is assigned to the cases where

$$[1 - (1 - q_a)\beta \Delta E] < 0$$

The artificial temperature $T_{qv}(t)$ is decreased according to

$$T_{qv}(t) = T_{qv}(1) \frac{2^{q_v-1} - 1}{(1 + t)^{q_v-1} - 1}$$

Where $q_v$ is the visiting parameter.

New in version 1.2.0.

Examples

The following example is a 10-D problem, with many local minima. The function involved is called Rastrigin (https://en.wikipedia.org/wiki/Rastrigin_function)

```python
>>> from scipy.optimize import dual_annealing
>>> func = lambda x: np.sum(x**2 - 10*np.cos(2*np.pi*x)) + 10*np.size(x)
>>> lw = [-5.12] * 10
>>> up = [5.12] * 10
>>> ret = dual_annealing(func, bounds=list(zip(lw, up)))
>>> ret.x
array([-4.26437714e-09, -3.91699361e-09, -1.86149218e-09, -3.97165720e-09,
        -6.29151648e-09, -6.53145322e-09, -3.93616815e-09, -6.55623025e-09,
        -6.05775280e-09, -5.00668935e-09]) # random
>>> ret.fun
0.000000
```
Least-squares and curve fitting

Nonlinear least-squares

**least_squares** *(fun, x0[, jac, bounds, ...])* Solve a nonlinear least-squares problem with bounds on the variables.

```python
scipy.optimize.least_squares
```

Solve a nonlinear least-squares problem with bounds on the variables.

Given the residuals `f(x)` (an m-D real function of n real variables) and the loss function `rho(s)` (a scalar function), `least_squares` finds a local minimum of the cost function `F(x)`:

\[
\text{minimize } F(x) = 0.5 \sum_{i=0}^{m-1} \rho(f_i(x)^2)
\]

subject to \(lb \leq x \leq ub\)

The purpose of the loss function `rho(s)` is to reduce the influence of outliers on the solution.

**Parameters**

- `fun` [callable] Function which computes the vector of residuals, with the signature `fun(x, *args, **kwargs)`, i.e., the minimization proceeds with respect to its first argument. The argument `x` passed to this function is an array of shape (n,) (never a scalar, even for n=1). It must allocate and return a 1-D array_like of shape (m,) or a scalar. If the argument `x` is complex or the function `fun` returns complex residuals, it must be wrapped in a real function of real arguments, as shown at the end of the Examples section.

- `x0` [array_like with shape (n,) or float] Initial guess on independent variables. If float, it will be treated as a 1-D array with one element.

- `jac` [12-point', '3-point', 'cs', callable], optional] Method of computing the Jacobian matrix (an m-by-n matrix, where element (i, j) is the partial derivative of f[i] with respect to x[j]). The keywords select a finite difference scheme for numerical estimation. The scheme '3-point' is more accurate, but requires twice as many operations as '2-point' (default). The scheme 'cs' uses complex steps, and while potentially the most accurate, it is applicable only when `fun` correctly handles complex inputs and can be analytically continued to the complex plane. Method 'lm' always uses the '2-point' scheme. If callable, it is used as `jac(x, *args, **kwargs)` and should return a good approximation (or the exact value) for the Jacobian as an array_like (np.atleast_2d is applied), a sparse matrix (csr_matrix preferred for performance) or a `scipy.sparse.linalg.LinearOperator`.

- `bounds` [2-tuple of array_like, optional] Lower and upper bounds on independent variables. Defaults to no bounds. Each array must match the size of `x0` or be a scalar, in the latter case a bound will be the same for all variables. Use `np.inf` with an appropriate sign to disable bounds on all or some variables.

  - 'trf': Trust Region Reflective algorithm, particularly suitable for large sparse problems with bounds. Generally robust method.
  - 'dogbox': dogleg algorithm with rectangular trust regions, typical use case is small problems with bounds. Not recommended for problems with rank-deficient Jacobian.
- `'lm'`: Levenberg-Marquardt algorithm as implemented in MINPACK. Doesn’t handle bounds and sparse Jacobians. Usually the most efficient method for small unconstrained problems.

Default is ‘trf’. See Notes for more information.

**ftol**
[float or None, optional] Tolerance for termination by the change of the cost function. Default is 1e-8. The optimization process is stopped when \( dF < \text{ftol} \times F \), and there was an adequate agreement between a local quadratic model and the true model in the last step. If None and ‘method’ is not ‘lm’, the termination by this condition is disabled. If ‘method’ is ‘lm’, this tolerance must be higher than machine epsilon.

**xtol**
[float or None, optional] Tolerance for termination by the change of the independent variables. Default is 1e-8. The exact condition depends on the method used:
- For ‘trf’ and ‘dogbox’: \( \|dx\| < \text{xtol} \times (\|x\| + \|dx\|) \).
- For ‘lm’: \( \text{Delta} < \text{xtol} \times \|x\| \), where \( \text{Delta} \) is a trust-region radius and \( x \) is the value of \( x \) scaled according to \( x\_\text{scale} \) parameter (see below).

If None and ‘method’ is not ‘lm’, the termination by this condition is disabled. If ‘method’ is ‘lm’, this tolerance must be higher than machine epsilon.

**gtol**
[float or None, optional] Tolerance for termination by the norm of the gradient. Default is 1e-8. The exact condition depends on a method used:
- For ‘trf’: \( \|g\_\text{scaled}\| < \text{gtol} \), where \( g\_\text{scaled} \) is the value of the gradient scaled to account for the presence of the bounds [STIR].
- For ‘dogbox’: \( \|g\_\text{free}\| < \text{gtol} \), where \( g\_\text{free} \) is the gradient with respect to the variables which are not in the optimal state on the boundary.
- For ‘lm’: the maximum absolute value of the cosine of angles between columns of the Jacobian and the residual vector is less than \( \text{gtol} \), or the residual vector is zero.

If None and ‘method’ is not ‘lm’, the termination by this condition is disabled. If ‘method’ is ‘lm’, this tolerance must be higher than machine epsilon.

**x_scale**
[array_like or ‘jac’, optional] Characteristic scale of each variable. Setting \( x\_\text{scale} \) is equivalent to reformulating the problem in scaled variables \( x\_s = x / x\_\text{scale} \). An alternative view is that the size of a trust region along jth dimension is proportional to \( x\_\text{scale}[j] \). Improved convergence may be achieved by setting \( x\_\text{scale} \) such that a step of a given size along any of the scaled variables has a similar effect on the cost function. If set to ‘jac’, the scale is iteratively updated using the inverse norms of the columns of the Jacobian matrix (as described in [JJMore]).

**loss**
[str or callable, optional] Determines the loss function. The following keyword values are allowed:
- ‘linear’ (default): \( \rho(z) = z \). Gives a standard least-squares problem.
- ‘soft_l1’: \( \rho(z) = 2 \times ((1 + z)^{0.5} - 1) \). The smooth approximation of \( l_1(\text{absolute value}) \) loss. Usually a good choice for robust least squares.
- ‘huber’: \( \rho(z) = z \) if \( z \leq 1 \) else \( 2z^{0.5} - 1 \). Works similarly to ‘soft_l1’.
- ‘cauchy’: \( \rho(z) = \ln(1 + z) \). Severely weakens outliers influence, but may cause difficulties in optimization process.
- ‘arctan’: \( \rho(z) = \arctan(z) \). Limits a maximum loss on a single residual, has properties similar to ‘cauchy’.

If callable, it must take a 1-D ndarray \( z=f\star2 \) and return an array_like with shape (3, m) where row 0 contains function values, row 1 contains first derivatives and row 2 contains second derivatives. Method ‘lm’ supports only ‘linear’ loss.

**f_scale**
[float, optional] Value of soft margin between inlier and outlier residuals, default is 1.0. The loss function is evaluated as follows \( \rho_\text{f}(f\star2) = C\star2 \times \rho_\text{f}(f\star2 / C\star2) \), where \( C \) is \( f\_\text{scale} \), and \( \rho_\text{f} \) is determined by \( \text{loss} \) parameter. This parameter has no effect with \( \text{loss}='\text{linear}' \), but for other \( \text{loss} \) values it is of crucial importance.

**max_nfev**
[None or int, optional] Maximum number of function evaluations before the termination. If None (default), the value is chosen automatically:
- For ‘trf’ and ‘dogbox’: 100 * n.
• For ‘lm’: $100 \times n$ if \texttt{jac} is callable and $100 \times n \times (n + 1)$ otherwise (because ‘lm’ counts function calls in Jacobian estimation).

**diff_step**

[None or array_like, optional] Determines the relative step size for the finite difference approximation of the Jacobian. The actual step is computed as $x \times \texttt{diff_step}$. If None (default), then \texttt{diff_step} is taken to be a conventional “optimal” power of machine epsilon for the finite difference scheme used [NR].

**tr_solver**

  • ‘exact’ is suitable for not very large problems with dense Jacobian matrices. The computational complexity per iteration is comparable to a singular value decomposition of the Jacobian matrix.
  
  • ‘lsmr’ is suitable for problems with sparse and large Jacobian matrices. It uses the iterative procedure \texttt{scipy.sparse.linalg.lsmr} for finding a solution of a linear least-squares problem and only requires matrix-vector product evaluations.

If None (default), the solver is chosen based on the type of Jacobian returned on the first iteration.

**tr_options**

[dict, optional] Keyword options passed to trust-region solver.

  • \texttt{tr_solver=’exact’}: \texttt{tr_options} are ignored.
  
  • \texttt{tr_solver=’lsmr’}: options for \texttt{scipy.sparse.linalg.lsmr}. Additionally, method=’trf’ supports ‘regularize’ option (bool, default is True), which adds a regularization term to the normal equation, which improves convergence if the Jacobian is rank-deficient [Byrd] (eq. 3.4).

**jac_sparsity**

[[None, array_like, sparse matrix], optional] Defines the sparsity structure of the Jacobian matrix for finite difference estimation, its shape must be (m, n). If the Jacobian has only few non-zero elements in each row, providing the sparsity structure will greatly speed up the computations [Curtis]. A zero entry means that a corresponding element in the Jacobian is identically zero. If provided, forces the use of ‘lsmr’ trust-region solver. If None (default), then dense differencing will be used. Has no effect for ‘lm’ method.

**verbose**

[[0, 1, 2], optional] Level of algorithm’s verbosity:

  • 0 (default): work silently.
  
  • 1: display a termination report.
  
  • 2: display progress during iterations (not supported by ‘lm’ method).

**args, kwargs**

[tuple and dict, optional] Additional arguments passed to \texttt{fun} and \texttt{jac}. Both empty by default. The calling signature is \texttt{fun(x, *args, **kwargs)} and the same for \texttt{jac}.

**Returns**

[OptimizeResult] \texttt{OptimizeResult} with the following fields defined:

  • \texttt{x} [ndarray, shape (n,)] Solution found.
  
  • \texttt{cost} [float] Value of the cost function at the solution.
  
  • \texttt{fun} [ndarray, shape (m,)] Vector of residuals at the solution.
  
  • \texttt{jac} [ndarray, sparse matrix or LinearOperator, shape (m, n)] Modified Jacobian matrix at the solution, in the sense that $J^T J$ is a Gauss-Newton approximation of the Hessian of the cost function. The type is the same as the one used by the algorithm.
  
  • \texttt{grad} [ndarray, shape (m,)] Gradient of the cost function at the solution.
  
  • \texttt{optimality} [float] First-order optimality measure. In unconstrained problems, it is always the uniform norm of the gradient. In constrained problems, it is the quantity which was compared with \texttt{gtol} during iterations.
  
  • \texttt{active_mask} [ndarray of int, shape (n,)] Each component shows whether a corresponding constraint is active (that is, whether a variable is at the bound):

    • 0: a constraint is not active.
-1: a lower bound is active.
1: an upper bound is active.

Might be somewhat arbitrary for ‘trf’ method as it generates a sequence of strictly feasible iterates and *active_mask* is determined within a tolerance threshold.

**nfew**
[int] Number of function evaluations done. Methods ‘trf’ and ‘dogbox’ do not count function calls for numerical Jacobian approximation, as opposed to ‘lm’ method.

**njev**
[int or None] Number of Jacobian evaluations done. If numerical Jacobian approximation is used in ‘lm’ method, it is set to None.

**status**
[int] The reason for algorithm termination:
-1: improper input parameters status returned from MINPACK.
0: the maximum number of function evaluations is exceeded.
1: *gtol* termination condition is satisfied.
2: *ftol* termination condition is satisfied.
3: *xtol* termination condition is satisfied.
4: Both *ftol* and *xtol* termination conditions are satisfied.

**message**
[str] Verbal description of the termination reason.

**success**
[bool] True if one of the convergence criteria is satisfied (*status > 0*).

See also:

**leastsq**
A legacy wrapper for the MINPACK implementation of the Levenberg-Marquadt algorithm.

**curve_fit**
Least-squares minimization applied to a curve-fitting problem.

Notes

Method ‘lm’ (Levenberg-Marquardt) calls a wrapper over least-squares algorithms implemented in MINPACK (lmder, lmdif). It runs the Levenberg-Marquardt algorithm formulated as a trust-region type algorithm. The implementation is based on paper [JJMore], it is very robust and efficient with a lot of smart tricks. It should be your first choice for unconstrained problems. Note that it doesn’t support bounds. Also, it doesn’t work when m < n.

Method ‘trf’ (Trust Region Reflective) is motivated by the process of solving a system of equations, which constitute the first-order optimality condition for a bound-constrained minimization problem as formulated in [STIR]. The algorithm iteratively solves trust-region subproblems augmented by a special diagonal quadratic term and with trust-region shape determined by the distance from the bounds and the direction of the gradient. This enhancements help to avoid making steps directly into bounds and efficiently explore the whole space of variables. To further improve convergence, the algorithm considers search directions reflected from the bounds. To obey theoretical requirements, the algorithm keeps iterates strictly feasible. With dense Jacobians trust-region subproblems are solved by an exact method very similar to the one described in [JJMore] (and implemented in MINPACK). The difference from the MINPACK implementation is that a singular value decomposition of a Jacobian matrix is done once per iteration, instead of a QR decomposition and series of Givens rotation eliminations. For large sparse Jacobians a 2-D subspace approach of solving trust-region subproblems is used [STIR], [Byrd]. The subspace is spanned by a scaled gradient and an approximate Gauss-Newton solution delivered by *scipy.sparse.linalg.lsmr*. When no constraints are imposed the algorithm is very similar to MINPACK and has generally comparable performance. The algorithm works quite robust in unbounded and bounded problems, thus it is chosen as a default algorithm.

Method ‘dogbox’ operates in a trust-region framework, but considers rectangular trust regions as opposed to conventional ellipsoids [Vogl]. The intersection of a current trust region and initial bounds is again rectangular, so on each iteration a quadratic minimization problem subject to bound constraints is solved approximately by Powell's
dogleg method [NumOpt]. The required Gauss-Newton step can be computed exactly for dense Jacobians or approximately by scipy.sparse.linalg.lsmr for large sparse Jacobians. The algorithm is likely to exhibit slow convergence when the rank of Jacobian is less than the number of variables. The algorithm often outperforms ‘trf’ in bounded problems with a small number of variables.

Robust loss functions are implemented as described in [BA]. The idea is to modify a residual vector and a Jacobian matrix on each iteration such that computed gradient and Gauss-Newton Hessian approximation match the true gradient and Hessian approximation of the cost function. Then the algorithm proceeds in a normal way, i.e., robust loss functions are implemented as a simple wrapper over standard least-squares algorithms.

New in version 0.17.0.

[STIR], [NR], [Byrd], [Curtis], [JJMore], [Voglis], [NumOpt], [BA]

Examples

In this example we find a minimum of the Rosenbrock function without bounds on independent variables.

```python
>>> def fun_rosenbrock(x):
...     return np.array([10 * (x[1] - x[0])**2, (1 - x[0])])
```

Notice that we only provide the vector of the residuals. The algorithm constructs the cost function as a sum of squares of the residuals, which gives the Rosenbrock function. The exact minimum is at \( x = [1.0, 1.0] \).

```python
>>> from scipy.optimize import least_squares
>>> x0_rosenbrock = np.array([2, 2])
>>> res_1 = least_squares(fun_rosenbrock, x0_rosenbrock)
>>> res_1.x
array([ 1.,  1.])
>>> res_1.cost
9.8669242910846867e-30
>>> res_1.optimality
8.8928864934219529e-14
```

We now constrain the variables, in such a way that the previous solution becomes infeasible. Specifically, we require that \( x[1] \geq 1.5 \), and \( x[0] \) left unconstrained. To this end, we specify the `bounds` parameter to `least_squares` in the form `bounds=([-np.inf, 1.5], np.inf)`.

We also provide the analytic Jacobian:

```python
>>> def jac_rosenbrock(x):
...     return np.array([
...         [-20 * x[0], 10],
...         [-1, 0]])
```

Putting this all together, we see that the new solution lies on the bound:

```python
>>> res_2 = least_squares(fun_rosenbrock, x0_rosenbrock, jac_rosenbrock, ...
...                        bounds=([-np.inf, 1.5], np.inf))
>>> res_2.x
array([ 1.22437075,  1.5])
>>> res_2.cost
```

(continues on next page)
Now we solve a system of equations (i.e., the cost function should be zero at a minimum) for a Broyden tridiagonal vector-valued function of 100000 variables:

```python
>>> def fun_broyden(x):
...     f = (3 - x) * x + 1
...     f[1:] = x[:-1]
...     f[1:] = 2 * x[1:
...     return f
```

The corresponding Jacobian matrix is sparse. We tell the algorithm to estimate it by finite differences and provide the sparsity structure of Jacobian to significantly speed up this process.

```python
>>> from scipy.sparse import lil_matrix
>>> def sparsity_broyden(n):
...     sparsity = lil_matrix((n, n), dtype=int)
...     i = np.arange(n)
...     sparsity[i, i] = 1
...     i = np.arange(1, n)
...     sparsity[i, i - 1] = 1
...     i = np.arange(n - 1)
...     sparsity[i, i + 1] = 1
...     return sparsity
... >>> n = 100000
>>> x0_broyden = -np.ones(n)
>>> res_3 = least_squares(fun_broyden, x0_broyden,
...                         ... jac_sparsity=sparsity_broyden(n))
>>> res_3.cost
4.5687069299604613e-23
>>> res_3.optimality
1.1650454296851518e-11
```

Let’s also solve a curve fitting problem using robust loss function to take care of outliers in the data. Define the model function as $y = a + b \times \exp(c \times t)$, where $t$ is a predictor variable, $y$ is an observation and $a$, $b$, $c$ are parameters to estimate.

First, define the function which generates the data with noise and outliers, define the model parameters, and generate data:

```python
>>> from numpy.random import default_rng
>>> rng = default_rng()
>>> def gen_data(t, a, b, c, noise=0., n_outliers=0, seed=None):
...     rng = default_rng(seed)
...     y = a + b * np.exp(t * c)
...     error = noise * rng.standard_normal(t.size)
...     outliers = rng.integers(0, t.size, n_outliers)
```
...   error[outliers] *= 10
...   return y + error
...
>>> a = 0.5
>>> b = 2.0
>>> c = -1
>>> t_min = 0
>>> t_max = 10
>>> n_points = 15
...
>>> t_train = np.linspace(t_min, t_max, n_points)
>>> y_train = gen_data(t_train, a, b, c, noise=0.1, n_outliers=3)

Define function for computing residuals and initial estimate of parameters.

```python
>>> def fun(x, t, y):
...     return x[0] + x[1] * np.exp(x[2] * t) - y
... >>> x0 = np.array([1.0, 1.0, 0.0])
```

Compute a standard least-squares solution:

```python
>>> res_lsq = least_squares(fun, x0, args=(t_train, y_train))
```

Now compute two solutions with two different robust loss functions. The parameter `f_scale` is set to 0.1, meaning that inlier residuals should not significantly exceed 0.1 (the noise level used).

```python
>>> res_soft_l1 = least_squares(fun, x0, loss='soft_l1', f_scale=0.1,
...                               args=(t_train, y_train))
>>> res_log = least_squares(fun, x0, loss='cauchy', f_scale=0.1,
...                          args=(t_train, y_train))
```

And, finally, plot all the curves. We see that by selecting an appropriate loss we can get estimates close to optimal even in the presence of strong outliers. But keep in mind that generally it is recommended to try 'soft_l1' or 'huber' losses first (if at all necessary) as the other two options may cause difficulties in optimization process.

```python
>>> t_test = np.linspace(t_min, t_max, n_points * 10)
>>> y_true = gen_data(t_test, a, b, c)
>>> y_lsq = gen_data(t_test, *res_lsq.x)
>>> y_soft_l1 = gen_data(t_test, *res_soft_l1.x)
>>> y_log = gen_data(t_test, *res_log.x)
...
>>> import matplotlib.pyplot as plt
>>> plt.plot(t_train, y_train, 'o')
>>> plt.plot(t_test, y_true, 'k', linewidth=2, label='true')
>>> plt.plot(t_test, y_lsq, label='linear loss')
>>> plt.plot(t_test, y_soft_l1, label='soft_l1 loss')
>>> plt.plot(t_test, y_log, label='cauchy loss')
>>> plt.xlabel("t")
>>> plt.ylabel("y")
>>> plt.legend()
>>> plt.show()
```
In the next example, we show how complex-valued residual functions of complex variables can be optimized with `least_squares()`. Consider the following function:

```python
>>> def f(z):
...    return z - (0.5 + 0.5j)
```

We wrap it into a function of real variables that returns real residuals by simply handling the real and imaginary parts as independent variables:

```python
>>> def f_wrap(x):
...    fx = f(x[0] + 1j*x[1])
...    return np.array([fx.real, fx.imag])
```

Thus, instead of the original m-D complex function of n complex variables we optimize a 2m-D real function of 2n real variables:

```python
>>> from scipy.optimize import least_squares
>>> res_wrapped = least_squares(f_wrap, (0.1, 0.1), bounds=([0, 0], [1,␣-1]))
>>> z = res_wrapped.x[0] + res_wrapped.x[1]*1j
>>> z
(0.49999999999925893+0.49999999999925893j)
```

**Linear least-squares**

- `nnls(A, b[, maxiter])`: Solve \( \text{argmin}_x \| Ax - b \|_2 \) for \( x \geq 0 \).
- `lsq_linear(A, b[, bounds, method, tol, ...])`: Solve a linear least-squares problem with bounds on the variables.
scipy.optimize.nnls

scipy.optimize.nnls (A, b, maxiter=None)
Solve argmin_x || Ax - b ||_2 for x>=0. This is a wrapper for a FORTRAN non-negative least squares solver.

Parameters
b           [ndarray] Right-hand side vector.
maxiter: int, optional
Maximum number of iterations, optional. Default is 3 * A.shape[1].

Returns
x           [ndarray] Solution vector.
rnorm       [float] The residual, || Ax-b ||_2.

See also:

lsq_linear
Linear least squares with bounds on the variables

Notes
The FORTRAN code was published in the book below. The algorithm is an active set method. It solves the KKT (Karush-Kuhn-Tucker) conditions for the non-negative least squares problem.

References

Examples

```python
>>> from scipy.optimize import nnls
...
>>> A = np.array([[1, 0], [1, 0], [0, 1]])
>>> b = np.array([2, 1, 1])
>>> nnls(A, b)
(array([1.5, 1.]), 0.7071067811865475)

>>> b = np.array([-1, -1, -1])
>>> nnls(A, b)
(array([0., 0.]), 1.7320508075688772)
```
scipy.optimize.lsq_linear

scipy.optimize.lsq_linear(A, b, bounds=(- inf, inf), method='trf', tol=1e-10, lsmr_tol=None, max_iter=None, verbose=0)

Solve a linear least-squares problem with bounds on the variables.

Given a m-by-n design matrix A and a target vector b with m elements, *lsq_linear* solves the following optimization problem:

\[
\begin{align*}
\text{minimize} & \quad 0.5 \times ||A x - b||^2 \\
\text{subject to} & \quad lb \leq x \leq ub
\end{align*}
\]

This optimization problem is convex, hence a found minimum (if iterations have converged) is guaranteed to be global.

**Parameters**

- **A** [array_like, sparse matrix of LinearOperator, shape (m, n)] Design matrix. Can be *scipy.sparse.linalg.LinearOperator*.
- **b** [array_like, shape (m,)] Target vector.
- **bounds** [2-tuple of array_like, optional] Lower and upper bounds on independent variables. Defaults to no bounds. Each array must have shape (n,) or be a scalar, in the latter case a bound will be the same for all variables. Use np.inf with an appropriate sign to disable bounds on all or some variables.
- **method** ['trf' or 'bvls', optional] Method to perform minimization.
  - 'trf' : Trust Region Reflective algorithm adapted for a linear least-squares problem. This is an interior-point-like method and the required number of iterations is weakly correlated with the number of variables.
  - 'bvls' : Bounded-variable least-squares algorithm. This is an active set method, which requires the number of iterations comparable to the number of variables. Can't be used when A is sparse or LinearOperator.
  Default is 'trf'.
- **tol** [float, optional] Tolerance parameter. The algorithm terminates if a relative change of the cost function is less than tol on the last iteration. Additionally, the first-order optimality measure is considered:
  - method='trf' terminates if the uniform norm of the gradient, scaled to account for the presence of the bounds, is less than tol.
  - method='bvls' terminates if Karush-Kuhn-Tucker conditions are satisfied within tol tolerance.
- **lsq_solver** [[None, 'exact', 'lsmr'], optional] Method of solving unbounded least-squares problems throughout iterations:
  - 'exact' : Use dense QR or SVD decomposition approach. Can't be used when A is sparse or LinearOperator.
  - 'lsmr' : Use *scipy.sparse.linalg.lsmr* iterative procedure which requires only matrix-vector product evaluations. Can't be used with method='bvls'.
  If None (default), the solver is chosen based on type of A.
- **lsmr_tol** [None, float or 'auto', optional] Tolerance parameters 'atol' and 'btol' for *scipy.sparse.linalg.lsmr* If None (default), it is set to $1e-2 \times tol$. If 'auto', the tolerance will be adjusted based on the optimality of the current iterate, which can speed up the optimization process, but is not always reliable.
- **max_iter** [None or int, optional] Maximum number of iterations before termination. If None (default), it is set to 100 for method='trf' or to the number of variables for method='bvls' (not counting iterations for 'bvls' initialization).
- **verbose** [0, 1, 2], optional] Level of algorithm's verbosity:
  - 0 : work silently (default).
• 1: display a termination report.
• 2: display progress during iterations.

Returns

OptimizeResult with the following fields defined:

x [ndarray, shape (n,)] Solution found.
cost [float] Value of the cost function at the solution.
fun [ndarray, shape (m,)] Vector of residuals at the solution.
optimality [float] First-order optimality measure. The exact meaning depends on method, refer to the description of tol parameter.
active_mask [ndarray of int, shape (n,)] Each component shows whether a corresponding constraint is active (that is, whether a variable is at the bound):
• 0: a constraint is not active.
• -1: a lower bound is active.
• 1: an upper bound is active.

Might be somewhat arbitrary for the trf method as it generates a sequence of strictly feasible iterates and active_mask is determined within a tolerance threshold.
nit [int] Number of iterations. Zero if the unconstrained solution is optimal.
status [int] Reason for algorithm termination:
• -1: the algorithm was not able to make progress on the last iteration.
• 0: the maximum number of iterations is exceeded.
• 1: the first-order optimality measure is less than tol.
• 2: the relative change of the cost function is less than tol.
• 3: the unconstrained solution is optimal.
message [str] Verbal description of the termination reason.
success [bool] True if one of the convergence criteria is satisfied (status > 0).

See also:

nnls
Linear least squares with non-negativity constraint.

least_squares
Nonlinear least squares with bounds on the variables.

Notes

The algorithm first computes the unconstrained least-squares solution by numpy.linalg.lstsq or scipy.sparse.linalg.lsmr depending on lsqlin solver. This solution is returned as optimal if it lies within the bounds.

Method ‘trf’ runs the adaptation of the algorithm described in [STIR] for a linear least-squares problem. The iterations are essentially the same as in the nonlinear least-squares algorithm, but as the quadratic function model is always accurate, we don’t need to track or modify the radius of a trust region. The line search (backtracking) is used as a safety net when a selected step does not decrease the cost function. Read more detailed description of the algorithm in scipy.optimize.least_squares.

Method ‘bvls’ runs a Python implementation of the algorithm described in [BVLS]. The algorithm maintains active and free sets of variables, on each iteration chooses a new variable to move from the active set to the free set and then solves the unconstrained least-squares problem on free variables. This algorithm is guaranteed to give an accurate solution eventually, but may require up to n iterations for a problem with n variables. Additionally, an ad-hoc initialization procedure is implemented, that determines which variables to set free or active initially. It takes some number of iterations before actual BVLS starts, but can significantly reduce the number of further iterations.

Examples

In this example, a problem with a large sparse matrix and bounds on the variables is solved.

```python
>>> from scipy.sparse import rand
>>> from scipy.optimize import lsq_linear
>>> rng = np.random.default_rng()
... >>> m = 20000
... >>> n = 10000
... >>> A = rand(m, n, density=1e-4, random_state=rng)
>>> b = rng.standard_normal(m)
... >>> lb = rng.standard_normal(n)
>>> ub = lb + 1
... >>> res = lsq_linear(A, b, bounds=(lb, ub), lsmr_tol='auto', verbose=1)
# may vary
The relative change of the cost function is less than `tol'.
Number of iterations 16, initial cost 1.5039e+04, final cost 1.1112e+04,
first-order optimality 4.66e-08.
```

Curve fitting

```
curve_fit(f, xdata, ydata[, p0, sigma, ...])
```

Use non-linear least squares to fit a function, f, to data.

**scipy.optimize.curve_fit**

```
scipy.optimize.curve_fit (f, xdata, ydata, p0=None, sigma=None, absolute_sigma=False,
                        check_finite=True, bounds=(- inf, inf), method=None, jac=None, **kwags)
```

Use non-linear least squares to fit a function, f, to data.

Assumes ydata = f(xdata, *params) + eps.

**Parameters**

- **f** [callable] The model function, f(x, ...). It must take the independent variable as the first argument and the parameters to fit as separate remaining arguments.
- **xdata** [array_like or object] The independent variable where the data is measured. Should usually be an M-length sequence or an (k,M)-shaped array for functions with k predictors, but can actually be any object.
- **ydata** [array_like] The dependent data, a length M array - nominally f(xdata, ...).
- **p0** [array_like, optional] Initial guess for the parameters (length N). If None, then the initial values will all be 1 (if the number of parameters for the function can be determined using introspection, otherwise a `ValueError` is raised).
- **sigma** [None or M-length sequence or MxM array, optional] Determines the uncertainty in ydata. If we define residuals as r = ydata - f(xdata, *popt), then the interpretation of sigma depends on its number of dimensions:
• A 1-D sigma should contain values of standard deviations of errors in ydata. In this case, the optimized function is \( \text{chisq} = \sum((r / \sigma) ** 2) \).
• A 2-D sigma should contain the covariance matrix of errors in ydata. In this case, the optimized function is \( \text{chisq} = r.T \odot \text{inv}(\sigma) \odot r \).

New in version 0.19.
None (default) is equivalent of 1-D sigma filled with ones.

absolute_sigma
[bool, optional] If True, sigma is used in an absolute sense and the estimated parameter covariance pcov reflects these absolute values.
If False (default), only the relative magnitudes of the sigma values matter. The returned parameter covariance matrix pcov is based on scaling sigma by a constant factor. This constant is set by demanding that the reduced chisq for the optimal parameters popt when using the scaled sigma equals unity. In other words, sigma is scaled to match the sample variance of the residuals after the fit. Default is False. Mathematically, \( \text{pcov(absolute_sigma=False)} = \text{pcov(absolute_sigma=True)} \times \frac{\text{chisq(popt)}}{(M-N)} \)

check_finite
[bool, optional] If True, check that the input arrays do not contain nans of infs, and raise a ValueError if they do. Setting this parameter to False may silently produce nonsensical results if the input arrays do contain nans. Default is True.

bounds
[2-tuple of array_like, optional] Lower and upper bounds on parameters. Defaults to no bounds. Each element of the tuple must be either an array with the length equal to the number of parameters, or a scalar (in which case the bound is taken to be the same for all parameters). Use np.inf with an appropriate sign to disable bounds on all or some parameters.
New in version 0.17.

method
[{'lm', 'trf', 'dogbox'}, optional] Method to use for optimization. See least_squares for more details. Default is 'lm' for unconstrained problems and 'trf' if bounds are provided. The method 'lm' won't work when the number of observations is less than the number of variables, use 'trf' or 'dogbox' in this case.
New in version 0.17.

jac
[callable, string or None, optional] Function with signature \( \text{jac}(x, \ldots) \) which computes the Jacobian matrix of the model function with respect to parameters as a dense array_like structure. It will be scaled according to provided sigma. If None (default), the Jacobian will be estimated numerically. String keywords for ‘trf’ and ‘dogbox’ methods can be used to select a finite difference scheme, see least_squares.
New in version 0.18.

kwags
Keyword arguments passed to leastsq for method='lm' or least_squares otherwise.

Returns

popt
[array] Optimal values for the parameters so that the sum of the squared residuals of \( f(xdata, *\text{popt}) - ydata \) is minimized.

pcov
[2-D array] The estimated covariance of popt. The diagonals provide the variance of the parameter estimate. To compute one standard deviation errors on the parameters use \( \text{perr} = \text{np.sqrt(np.diag(pcov))} \).

How the sigma parameter affects the estimated covariance depends on absolute_sigma argument, as described above.
If the Jacobian matrix at the solution doesn’t have a full rank, then ‘lm’ method returns a matrix filled with np.inf, on the other hand ‘trf’ and ‘dogbox’ methods use Moore-Penrose pseudoinverse to compute the covariance matrix.

Raises

ValueError
if either ydata or xdata contain NaNs, or if incompatible options are used.

**RuntimeError**
if the least-squares minimization fails.

**OptimizeWarning**
if covariance of the parameters cannot be estimated.

See also:

**least_squares**
Minimize the sum of squares of nonlinear functions.

**scipy.stats.linregress**
Calculate a linear least squares regression for two sets of measurements.

Notes
With method='lm', the algorithm uses the Levenberg-Marquardt algorithm through leastsq. Note that this algorithm can only deal with unconstrained problems.

Box constraints can be handled by methods ‘trf’ and ‘dogbox’. Refer to the docstring of least_squares for more information.

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.optimize import curve_fit

>>> def func(x, a, b, c):
    ...
    return a * np.exp(-b * x) + c

Define the data to be fit with some noise:

```python
>>> xdata = np.linspace(0, 4, 50)
>>> y = func(xdata, 2.5, 1.3, 0.5)
>>> rng = np.random.default_rng()
>>> y_noise = 0.2 * rng.normal(size=xdata.size)
>>> ydata = y + y_noise
>>> plt.plot(xdata, ydata, 'b-', label='data')
```

Fit for the parameters a, b, c of the function func:

```python
>>> popt, pcov = curve_fit(func, xdata, ydata)
>>> popt
array([2.56274217, 1.37268521, 0.47427475])
>>> plt.plot(xdata, func(xdata, *popt), 'r-', label='fit: a=%5.3f, b=%5.3f, c=%5.3f' % tuple(popt))
```

Constrain the optimization to the region of 0 <= a <= 3, 0 <= b <= 1 and 0 <= c <= 0.5:

```python
>>> popt, pcov = curve_fit(func, xdata, ydata, bounds=(0, [3., 1., 0.5]))
>>> popt
array([2.43736712, 1. , 0.34463856])
```
```python
>>> plt.plot(xdata, func(xdata, *popt), 'g--',
... label='fit: a=%5.3f, b=%5.3f, c=%5.3f' % tuple(popt))

>>> plt.xlabel('x')
>>> plt.ylabel('y')
>>> plt.legend()
>>> plt.show()
```

Root finding

Scalar functions

- `root_scalar(f, args, method, bracket, ...)`: Find a root of a scalar function.
- `brentq(f, a, b, args, xtol, rtol, maxiter, ...)`: Find a root of a function in a bracketing interval using Brent's method.
- `brenth(f, a, b, args, xtol, rtol, maxiter, ...)`: Find a root of a function in a bracketing interval using Brent's method with hyperbolic extrapolation.
- `ridder(f, a, b, args, xtol, rtol, maxiter, ...)`: Find a root of a function in an interval using Ridder's method.
- `bisect(f, a, b, args, rtol, maxiter, ...)`: Find root of a function within an interval using bisection.
- `newton(func, x0[, fprime, args, tol, ...])`: Find a zero of a real or complex function using the Newton-Raphson (or secant or Halley's) method.
- `toms748(f, a, b[, args, k, xtol, rtol, ...])`: Find a zero using TOMS Algorithm 748 method.
- `RootResults(result, iterations, ...)`: Represents the root finding result.
scipy.optimize.root_scalar

scipy.optimize.root_scalar \(f, \) \(args=(), \) \(method=None, \) \(bracket=None, \) \(fprime=None, \) \(fprime2=None, \) \(x0=None, \) \(x1=None, \) \(xtol=None, \) \(rtol=None, \) \(maxiter=None, \) \(options=None\)

Find a root of a scalar function.

**Parameters**

- \(f\) [callable] A function to find a root of.
- \(args\) [tuple, optional] Extra arguments passed to the objective function and its derivative(s).
- \(method\) [str, optional] Type of solver. Should be one of:
  - ‘bisect’ (see here)
  - ‘brentq’ (see here)
  - ‘brenth’ (see here)
  - ‘ridder’ (see here)
  - ‘toms748’ (see here)
  - ‘newton’ (see here)
  - ‘secant’ (see here)
  - ‘halley’ (see here)

- \(bracket\): A sequence of 2 floats, optional
  An interval bracketing a root. \(f(x, *args)\) must have different signs at the two endpoints.

- \(x0\) [float, optional] Initial guess.
- \(x1\) [float, optional] A second guess.

- \(fprime\) [bool or callable, optional] If \(fprime\) is a boolean and is True, \(f\) is assumed to return the value of the objective function and of the derivative. \(fprime\) can also be a callable returning the derivative of \(f\). In this case, it must accept the same arguments as \(f\).

- \(fprime2\) [bool or callable, optional] If \(fprime2\) is a boolean and is True, \(f\) is assumed to return the value of the objective function and of the first and second derivatives. \(fprime2\) can also be a callable returning the second derivative of \(f\). In this case, it must accept the same arguments as \(f\).

- \(xtol\) [float, optional] Tolerance (absolute) for termination.
- \(rtol\) [float, optional] Tolerance (relative) for termination.
- \(maxiter\) [int, optional] Maximum number of iterations.
- \(options\) [dict, optional] A dictionary of solver options. E.g., \(k\), see \(show_options()\) for details.

**Returns**

- \(sol\) [RootResults] The solution represented as a \(RootResults\) object. Important attributes are: \(root\) the solution, \(converged\) a boolean flag indicating if the algorithm exited successfully and \(flag\) which describes the cause of the termination. See \(RootResults\) for a description of other attributes.

See also:

- \(show_options\)
  Additional options accepted by the solvers
- \(root\)
  Find a root of a vector function.
Notes

This section describes the available solvers that can be selected by the 'method' parameter.

The default is to use the best method available for the situation presented. If a bracket is provided, it may use one of the bracketing methods. If a derivative and an initial value are specified, it may select one of the derivative-based methods. If no method is judged applicable, it will raise an Exception.

Examples

Find the root of a simple cubic

```python
>>> from scipy import optimize
>>> def f(x):
...     return (x**3 - 1)  # only one real root at x = 1

>>> def fprime(x):
...     return 3*x**2
```

The `brentq` method takes as input a bracket

```python
>>> sol = optimize.root_scalar(f, bracket=[0, 3], method='brentq')
>>> sol.root, sol.iterations, sol.function_calls
(1.0, 10, 11)
```

The `newton` method takes as input a single point and uses the derivative(s)

```python
>>> sol = optimize.root_scalar(f, x0=0.2, fprime=fprime, method='newton')
>>> sol.root, sol.iterations, sol.function_calls
(1.0, 11, 22)
```

The function can provide the value and derivative(s) in a single call.

```python
>>> def f_p_pp(x):
...     return (x**3 - 1), 3*x**2, 6*x

>>> sol = optimize.root_scalar(f_p_pp, x0=0.2, fprime=True, method='newton')
>>> sol.root, sol.iterations, sol.function_calls
(1.0, 11, 11)
```

```python
>>> sol = optimize.root_scalar(f_p_pp, x0=0.2, fprime=True, fprime2=True, method='halley')
>>> sol.root, sol.iterations, sol.function_calls
(1.0, 7, 8)
```
Find a root of a function in a bracketing interval using Brent’s method.

Uses the classic Brent’s method to find a zero of the function \( f \) on the sign changing interval \([a, b]\). Generally considered the best of the rootfinding routines here. It is a safe version of the secant method that uses inverse quadratic extrapolation. Brent’s method combines root bracketing, interval bisection, and inverse quadratic interpolation. It is sometimes known as the van Wijngaarden-Dekker-Brent method. Brent (1973) claims convergence is guaranteed for functions computable within \([a, b]\).

[Brent1973] provides the classic description of the algorithm. Another description can be found in a recent edition of Numerical Recipes, including [PressEtal1992]. A third description is at http://mathworld.wolfram.com/BrentsMethod.html. It should be easy to understand the algorithm just by reading our code. Our code diverges a bit from standard presentations: we choose a different formula for the extrapolation step.

**Parameters**

- **f**    
  [function] Python function returning a number. The function \( f \) must be continuous, and \( f(a) \) and \( f(b) \) must have opposite signs.

- **a**    
  [scalar] One end of the bracketing interval \([a, b]\).

- **b**    
  [scalar] The other end of the bracketing interval \([a, b]\).

- **xtol**    
  [number, optional] The computed root \( x_0 \) will satisfy \( \text{np.allclose}(x, x_0, \text{atol}=\text{xtol}, \text{rtol}=\text{rtol}) \), where \( x \) is the exact root. The parameter must be nonnegative. For nice functions, Brent’s method will often satisfy the above condition with \( \text{xtol}/2 \) and \( \text{rtol}/2 \). [Brent1973]

- **rtol**    
  [number, optional] The computed root \( x_0 \) will satisfy \( \text{np.allclose}(x, x_0, \text{atol}=\text{xtol}, \text{rtol}=\text{rtol}) \), where \( x \) is the exact root. The parameter cannot be smaller than its default value of \( 4*\text{np.finfo(float).eps} \). For nice functions, Brent’s method will often satisfy the above condition with \( \text{xtol}/2 \) and \( \text{rtol}/2 \). [Brent1973]

- **maxiter**    
  [int, optional] If convergence is not achieved in \( \text{maxiter} \) iterations, an error is raised. Must be \( \geq 0 \).

- **args**    
  [tuple, optional] Containing extra arguments for the function \( f \). \( f \) is called by \( \text{apply}(f, (x)+\text{args}) \).

- **full_output**    
  [bool, optional] If \( \text{full_output} \) is False, the root is returned. If \( \text{full_output} \) is True, the return value is \( (x, r) \), where \( x \) is the root, and \( r \) is a \text{RootResults} object.

- **disp**    
  [bool, optional] If True, raise RuntimeError if the algorithm didn’t converge. Otherwise, the convergence status is recorded in any \text{RootResults} return object.

**Returns**

- **x0**    
  [float] Zero of \( f \) between \( a \) and \( b \).

- **r**    
  [\text{RootResults} (present if \text{full_output} = True)] Object containing information about the convergence. In particular, \( r.converged \) is True if the routine converged.
Notes

$f$ must be continuous. $f(a)$ and $f(b)$ must have opposite signs.

Related functions fall into several classes:

Examples

```python
>>> def f(x):
...     return (x**2 - 1)

>>> from scipy import optimize

>>> root = optimize.brentq(f, -2, 0)
>>> root
-1.0

>>> root = optimize.brentq(f, 0, 2)
>>> root
1.0
```
scipy.optimize.brenth

```python
scipy.optimize.brenth(f, a, b, args=(), xtol=2e-12, rtol=8.881784197001252e-16, maxiter=100,
                        full_output=False, disp=True)
```

Find a root of a function in a bracketing interval using Brent’s method with hyperbolic extrapolation.

A variation on the classic Brent routine to find a zero of the function \( f \) between the arguments \( a \) and \( b \) that uses hyperbolic extrapolation instead of inverse quadratic extrapolation. Bus & Dekker (1975) guarantee convergence for this method, claiming that the upper bound of function evaluations here is 4 or 5 times lesser than that for bisection. \( f(a) \) and \( f(b) \) cannot have the same signs. Generally, on a par with the brent routine, but not as heavily tested. It is a safe version of the secant method that uses hyperbolic extrapolation. The version here is by Chuck Harris, and implements Algorithm M of [BusAndDekker1975], where further details (convergence properties, additional remarks and such) can be found.

**Parameters**

- \( f \) [function] Python function returning a number. \( f \) must be continuous, and \( f(a) \) and \( f(b) \) must have opposite signs.
- \( a \) [scalar] One end of the bracketing interval \([a,b]\).
- \( b \) [scalar] The other end of the bracketing interval \([a,b]\).
- \( xtol \) [number, optional] The computed root \( x_0 \) will satisfy \( \text{np.allclose}(x, x_0, atol=xtol, rtol=rtol) \), where \( x \) is the exact root. The parameter must be nonnegative. As with \( \text{brentq} \), for nice functions the method will often satisfy the above condition with \( xtol/2 \) and \( rtol/2 \).
- \( rtol \) [number, optional] The computed root \( x_0 \) will satisfy \( \text{np.allclose}(x, x_0, atol=xtol, rtol=rtol) \), where \( x \) is the exact root. The parameter cannot be smaller than its default value of \( 4*\text{np.finfo(float).eps} \). As with \( \text{brentq} \), for nice functions the method will often satisfy the above condition with \( xtol/2 \) and \( rtol/2 \).
- \( maxiter \) [int, optional] If convergence is not achieved in \( maxiter \) iterations, an error is raised. Must be \( \geq 0 \).
- \( args \) [tuple, optional] Containing extra arguments for the function \( f \). \( f \) is called by \( \text{apply}(f, (x)+args) \).
- \( full_output \) [bool, optional] If \( full_output \) is False, the root is returned. If \( full_output \) is True, the return value is \( (x, r) \), where \( x \) is the root, and \( r \) is a \( \text{RootResults} \) object.
- \( disp \) [bool, optional] If True, raise RuntimeError if the algorithm didn't converge. Otherwise, the convergence status is recorded in any \( \text{RootResults} \) return object.

**Returns**

- \( x_0 \) [float] Zero of \( f \) between \( a \) and \( b \).
- \( r \) [RootResults (present if \( full_output = True \))] Object containing information about the convergence. In particular, \( r.converged \) is True if the routine converged.

scipy.optimize.ridder

scipy.optimize.ridder(f, a, b, args=(), xtol=2e-12, rtol=8.881784197001252e-16, maxiter=100,
    full_output=False, disp=True)

Find a root of a function in an interval using Ridder's method.

Parameters

- f [function] Python function returning a number. f must be continuous, and f(a) and f(b) must have opposite signs.
- a [scalar] One end of the bracketing interval [a,b].
- b [scalar] The other end of the bracketing interval [a,b].
- xtol [number, optional] The computed root x0 will satisfy np.allclose(x, x0, atol=xtol, rtol=rtol), where x is the exact root. The parameter must be non-negative.
rtol  
[number, optional] The computed root $x_0$ will satisfy $\text{np.allclose}(x, x_0, atol=xtol, rtol=rtol)$, where $x$ is the exact root. The parameter cannot be smaller than its default value of $4*\text{np.finfo(float).eps}$.

maxiter  
[int, optional] If convergence is not achieved in $\text{maxiter}$ iterations, an error is raised. Must be $\geq 0$.

args  
[tuple, optional] Containing extra arguments for the function $f$. $f$ is called by $\text{apply}(f, (x)+\text{args})$.

full_output  
[bool, optional] If $\text{full_output}$ is False, the root is returned. If $\text{full_output}$ is True, the return value is $(x, r)$, where $x$ is the root, and $r$ is a $\text{RootResults}$ object.

disp  
[bool, optional] If True, raise RuntimeError if the algorithm didn’t converge. Otherwise, the convergence status is recorded in any $\text{RootResults}$ return object.

Returns

$x_0$  
[float] Zero of $f$ between $a$ and $b$.

$r$  
[$\text{RootResults}$ (present if $\text{full_output} = \text{True}$)] Object containing information about the convergence. In particular, $r.converged$ is True if the routine converged.

brentq, brent, bisect, newton

1-D root-finding

fixed_point

scalar fixed-point finder

Notes

Uses [Ridders1979] method to find a zero of the function $f$ between the arguments $a$ and $b$. Ridders’ method is faster than bisection, but not generally as fast as the Brent routines. [Ridders1979] provides the classic description and source of the algorithm. A description can also be found in any recent edition of Numerical Recipes.

The routine used here diverges slightly from standard presentations in order to be a bit more careful of tolerance.

References

[Ridders1979]

Examples

```python
>>> def f(x):
...    return (x**2 - 1)

>>> from scipy import optimize

>>> root = optimize.ridder(f, 0, 2)
>>> root
1.0
```
```python
>>> root = optimize.ridder(f, -2, 0)
>>> root
-1.0
```

**scipy.optimize.bisect**

`scipy.optimize.bisect(f, a, b, args=(), tol=1e-12, rtol=8.881784197001252e-16, maxiter=100, full_output=False, disp=True)`

Find root of a function within an interval using bisection.

Basic bisection routine to find a zero of the function `f` between the arguments `a` and `b`. `f(a)` and `f(b)` cannot have the same signs. Slow but sure.

**Parameters**

- **f** [function] Python function returning a number. `f` must be continuous, and `f(a)` and `f(b)` must have opposite signs.
- **a** [scalar] One end of the bracketing interval `[a, b]`.
- **b** [scalar] The other end of the bracketing interval `[a, b]`.
- **xtol** [number, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root. The parameter must be non-negative.
- **rtol** [number, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root. The parameter cannot be smaller than its default value of `4*np.finfo(float).eps`.
- **maxiter** [int, optional] If convergence is not achieved in `maxiter` iterations, an error is raised. Must be >= 0.
- **args** [tuple, optional] Containing extra arguments for the function `f`. `f` is called by `apply(f, (x)+args)`.
- **full_output** [bool, optional] If `full_output` is False, the root is returned. If `full_output` is True, the return value is `(x, r)`, where `x` is the root, and `r` is a `RootResults` object.
- **disp** [bool, optional] If True, raise `RuntimeError` if the algorithm didn’t converge. Otherwise, the convergence status is recorded in a `RootResults` return object.

**Returns**

- **x0** [float] Zero of `f` between `a` and `b`.
- **r** [RootResults (present if full_output = True)] Object containing information about the convergence. In particular, `r.converged` is True if the routine converged.

Examples

```python
>>> def f(x):
...     return (x**2 - 1)

>>> from scipy import optimize

>>> root = optimize.bisect(f, 0, 2)
>>> root
1.0

>>> root = optimize.bisect(f, -2, 0)
>>> root
-1.0
```

**scipy.optimize.newton**

`scipy.optimize.newton` *(func, x0, fprime=None, args=(), tol=1.48e-08, maxiter=50, fprime2=None, x1=None, rtol=0.0, full_output=False, disp=True)*

Find a zero of a real or complex function using the Newton-Raphson (or secant or Halley’s) method.

Find a zero of the scalar-valued function `func` given a nearby scalar starting point `x0`. The Newton-Raphson method is used if the derivative `fprime` of `func` is provided, otherwise the secant method is used. If the second order derivative `fprime2` of `func` is also provided, then Halley’s method is used.

If `x0` is a sequence with more than one item, `newton` returns an array: the zeros of the function from each (scalar) starting point in `x0`. In this case, `func` must be vectorized and return a sequence or array of the same shape as its first argument. If `fprime` (`fprime2`) is given, then its return must also have the same shape: each element is the first (second) derivative of `func` with respect to its only variable evaluated at each element of its first argument.

`newton` is for finding roots of a scalar-valued functions of a single variable. For problems involving several variables, see `root`.

**Parameters**

- **func** [callable] The function whose zero is wanted. It must be a function of a single variable of the form `f(x, a, b, c...)`, where `a, b, c...` are extra arguments that can be passed in the `args` parameter.
- **x0** [float, sequence, or ndarray] An initial estimate of the zero that should be somewhere near the actual zero. If not scalar, then `func` must be vectorized and return a sequence or array of the same shape as its first argument.
- **fprime** [callable, optional] The derivative of the function when available and convenient. If it is None (default), then the secant method is used.
- **args** [tuple, optional] Extra arguments to be used in the function call.
- **tol** [float, optional] The allowable error of the zero value. If `func` is complex-valued, a larger `tol` is recommended as both the real and imaginary parts of `x` contribute to `|x - x0|`.
- **maxiter** [int, optional] Maximum number of iterations.
- **fprime2** [callable, optional] The second order derivative of the function when available and convenient. If it is None (default), then the normal Newton-Raphson or the secant method is used. If it is not None, then Halley’s method is used.
- **x1** [float, optional] Another estimate of the zero that should be somewhere near the actual zero. Used if `fprime` is not provided.
- **rtol** [float, optional] Tolerance (relative) for termination.
full_output
[bool, optional] If full_output is False (default), the root is returned. If True and \(x0\) is scalar, the return value is \((x, r)\), where \(x\) is the root and \(r\) is a RootResults object. If True and \(x0\) is non-scalar, the return value is \((x, converged, zero_der)\) (see Returns section for details).

disp
[bool, optional] If True, raise a RuntimeError if the algorithm didn’t converge, with the error message containing the number of iterations and current function value. Otherwise, the convergence status is recorded in a RootResults return object. Ignored if \(x0\) is not scalar. Note: this has little to do with displaying, however, the 'disp' keyword cannot be renamed for backwards compatibility.

Returns

root
[float, sequence, or ndarray] Estimated location where function is zero.

r
[RootResults, optional] Present if full_output=True and \(x0\) is scalar. Object containing information about the convergence. In particular, r.converged is True if the routine converged.

converged
[ndarray of bool, optional] Present if full_output=True and \(x0\) is non-scalar. For vector functions, indicates which elements converged successfully.

zero_der
[ndarray of bool, optional] Present if full_output=True and \(x0\) is non-scalar. For vector functions, indicates which elements had a zero derivative.

interface to root solvers for multi-input, multi-output functions

Notes

The convergence rate of the Newton-Raphson method is quadratic, the Halley method is cubic, and the secant method is sub-quadratic. This means that if the function is well-behaved the actual error in the estimated zero after the \(n\)th iteration is approximately the square (cube for Halley) of the error after the \((n-1)\)th step. However, the stopping criterion used here is the step size and there is no guarantee that a zero has been found. Consequently, the result should be verified. Safer algorithms are brentq, brent, ridder, and bisection, but they all require that the root first be bracketed in an interval where the function changes sign. The brentq algorithm is recommended for general use in one dimensional problems when such an interval has been found.

When newton is used with arrays, it is best suited for the following types of problems:

- The initial guesses, \(x0\), are all relatively the same distance from the roots.
- Some or all of the extra arguments, \(args\), are also arrays so that a class of similar problems can be solved together.
- The size of the initial guesses, \(x0\), is larger than \(O(100)\) elements. Otherwise, a naive loop may perform as well or better than a vector.
Examples

```python
>>> from scipy import optimize
>>> import matplotlib.pyplot as plt

>>> def f(x):
...     return (x**3 - 1)  # only one real root at x = 1

fprime is not provided, use the secant method:

```python
>>> root = optimize.newton(f, 1.5)
>>> root
1.0000000000000016
>>> root = optimize.newton(f, 1.5, fprime=lambda x: 6 * x)
>>> root
1.0000000000000016
```

Only fprime is provided, use the Newton-Raphson method:

```python
>>> root = optimize.newton(f, 1.5, fprime=lambda x: 3 * x**2)
>>> root
1.0
```

Both fprime2 and fprime are provided, use Halley's method:

```python
>>> root = optimize.newton(f, 1.5, fprime=lambda x: 3 * x**2,
...                         fprime2=lambda x: 6 * x)
>>> root
1.0
```

When we want to find zeros for a set of related starting values and/or function parameters, we can provide both of those as an array of inputs:

```python
>>> f = lambda x, a: x**3 - a
>>> fder = lambda x, a: 3 * x**2
>>> rng = np.random.default_rng()
>>> x = rng.standard_normal(100)
>>> a = np.arange(-50, 50)
>>> vec_res = optimize.newton(f, x, fprime=fder, args=(a,), maxiter=200)

The above is the equivalent of solving for each value in (x, a) separately in a for-loop, just faster:

```python
>>> loop_res = [optimize.newton(f, x0, fprime=fder, args=(a0,),
...                          maxiter=200)
...             for x0, a0 in zip(x, a)]
>>> np.allclose(vec_res, loop_res)
True
```

Plot the results found for all values of a:

```python
>>> analytical_result = np.sign(a) * np.abs(a)**(1/3)
>>> fig, ax = plt.subplots()
>>> ax.plot(a, analytical_result, 'o')
>>> ax.plot(a, vec_res, '.')
```

(continues on next page)

```python
>>> ax.set_xlabel('$a$')
>>> ax.set_ylabel('$x$ where $f(x, a)=0$')
>>> plt.show()
```

```
40  
20  
0 20 40
```

```latex
40
20
0
20
40
```

scipy.optimize.toms748

```python
scipy.optimize.toms748(f, a, b, args=(), k=1, xtol=2e-12, rtol=8.881784197001252e-16, maxiter=100, full_output=False, disp=True)
```

Find a zero using TOMS Algorithm 748 method.

Implements the Algorithm 748 method of Alefeld, Potro and Shi to find a zero of the function \( f \) on the interval \([a, b]\), where \( f(a) \) and \( f(b) \) must have opposite signs.

It uses a mixture of inverse cubic interpolation and “Newton-quadratic” steps. [APS1995].

**Parameters**

- **f** [function] Python function returning a scalar. The function \( f \) must be continuous, and \( f(a) \) and \( f(b) \) have opposite signs.
- **a** [scalar,] lower boundary of the search interval
- **b** [scalar,] upper boundary of the search interval
- **args** [tuple, optional] containing extra arguments for the function \( f \). \( f \) is called by \( f(x, *args) \).
- **k** [int, optional] The number of Newton quadratic steps to perform each iteration. \( k \geq 1 \).
- **xtol** [scalar, optional] The computed root \( x_0 \) will satisfy \( \text{np.allclose}(x, x_0, \text{atol}=\text{xtol}, \text{rtol}=\text{rtol}) \), where \( x \) is the exact root. The parameter must be non-negative.
- **rtol** [scalar, optional] The computed root \( x_0 \) will satisfy \( \text{np.allclose}(x, x_0, \text{atol}=\text{xtol}, \text{rtol}=\text{rtol}) \), where \( x \) is the exact root.
- **maxiter** [int, optional] If convergence is not achieved in \( \text{maxiter} \) iterations, an error is raised. Must be \( \geq 0 \).
- **full_output** [bool, optional] If \( \text{full_output} \) is False, the root is returned. If \( \text{full_output} \) is True, the return value is \((x, r)\), where \( x \) is the root, and \( r \) is a \textit{RootResults} object.
disp [bool, optional] If True, raise RuntimeError if the algorithm didn’t converge. Otherwise, the convergence status is recorded in the RootResults return object.

Returns

x0 [float] Approximate Zero of f
r [RootResults (present if full_output = True)] Object containing information about the convergence. In particular, r.converged is True if the routine converged.

brentq, brent, ridder, bisect, newton
fsolve

find zeroes in N dimensions.

Notes

f must be continuous. Algorithm 748 with k=2 is asymptotically the most efficient algorithm known for finding roots of a four times continuously differentiable function. In contrast with Brent’s algorithm, which may only decrease the length of the enclosing bracket on the last step, Algorithm 748 decreases it each iteration with the same asymptotic efficiency as it finds the root.

For easy statement of efficiency indices, assume that f has 4 continuous derivatives. For k=1, the convergence order is at least 2.7, and with about asymptotically 2 function evaluations per iteration, the efficiency index is approximately 1.65. For k=2, the order is about 4.6 with asymptotically 3 function evaluations per iteration, and the efficiency index 1.66. For higher values of k, the efficiency index approaches the kth root of (3k−2), hence k=1 or k=2 are usually appropriate.

Examples

```python
>>> def f(x):
...     return (x**3 - 1)  # only one real root at x = 1
>>> from scipy import optimize
>>> root, results = optimize.toms748(f, 0, 2, full_output=True)
>>> root
1.0
>>> results
    converged: True
    flag: 'converged'
    function_calls: 11
    iterations: 5
    root: 1.0
```
scipy.optimize.RootResults

class scipy.optimize.RootResults(root, iterations, function_calls, flag)

Represents the root finding result.

Attributes

   root [float] Estimated root location.
   iterations [int] Number of iterations needed to find the root.
   function_calls [int] Number of times the function was called.
   converged [bool] True if the routine converged.
   flag [str] Description of the cause of termination.

The root_scalar function supports the following methods:

root_scalar(method='brentq')

scipy.optimize.root_scalar(args=(), method='brentq', x0=None, options={})

See also:

For documentation for the rest of the parameters, see scipy.optimize.root_scalar

Options

   args [tuple, optional] Extra arguments passed to the objective function.
   xtol [float, optional] Tolerance (absolute) for termination.
   rtol [float, optional] Tolerance (relative) for termination.
   maxiter [int, optional] Maximum number of iterations.
   options: dict, optional
     Specifies any method-specific options not covered above.

root_scalar(method='brenth')

scipy.optimize.root_scalar(args=(), method='brenth', x0=None, options={})

See also:

For documentation for the rest of the parameters, see scipy.optimize.root_scalar

Options

   args [tuple, optional] Extra arguments passed to the objective function.
   xtol [float, optional] Tolerance (absolute) for termination.
   rtol [float, optional] Tolerance (relative) for termination.
   maxiter [int, optional] Maximum number of iterations.
   options: dict, optional
     Specifies any method-specific options not covered above.
root_scalar(method='bisect')

```python
scipy.optimize.root_scalar (args=(), method='bisect', x0=None, options={})
```

See also:

For documentation for the rest of the parameters, see `scipy.optimize.root_scalar`

**Options**

- **args** [tuple, optional] Extra arguments passed to the objective function.
- **xtol** [float, optional] Tolerance (absolute) for termination.
- **rtol** [float, optional] Tolerance (relative) for termination.
- **maxiter** [int, optional] Maximum number of iterations.
- **x0** [float, required] Initial guess.
- **x1** [float, required] A second guess.
- **options**: dict, optional
  Specifies any method-specific options not covered above.

root_scalar(method='halley')

```python
scipy.optimize.root_scalar (args=(), method='halley', x0=None, options={})
```

See also:

For documentation for the rest of the parameters, see `scipy.optimize.root_scalar`

**Options**

- **args** [tuple, optional] Extra arguments passed to the objective function and its derivatives.
- **xtol** [float, optional] Tolerance (absolute) for termination.
- **rtol** [float, optional] Tolerance (relative) for termination.
- **maxiter** [int, optional] Maximum number of iterations.
- **x0** [float, required] Initial guess.
- **fprime** [bool or callable, required] If fprime is a boolean and is True, f is assumed to return the value of derivative along with the objective function. fprime can also be a callable returning the derivative of f. In this case, it must accept the same arguments as f.
- **fprime2** [bool or callable, required] If fprime2 is a boolean and is True, f is assumed to return the value of 1st and 2nd derivatives along with the objective function. fprime2 can also be a callable returning the 2nd derivative of f. In this case, it must accept the same arguments as f.
options: dict, optional

Specifies any method-specific options not covered above.

The table below lists situations and appropriate methods, along with asymptotic convergence rates per iteration (and per function evaluation) for successful convergence to a simple root(*). Bisection is the slowest of them all, adding one bit of accuracy for each function evaluation, but is guaranteed to converge. The other bracketing methods all (eventually) increase the number of accurate bits by about 50% for every function evaluation. The derivative-based methods, all built on newton, can converge quite quickly if the initial value is close to the root. They can also be applied to functions defined on (a subset of) the complex plane.

See also:

- scipy.optimize.cython_optimize – Typed Cython versions of zeros functions

Fixed point finding:

\[
\text{fixed_point}(\text{func, x0[, args, xtol, maxiter, ...]})
\]

Find a fixed point of the function.

scipy.optimize.fixed_point

\[
\text{scipy.optimize.fixed_point}(\text{func, x0[, args=(), xtol=1e-08, maxiter=500, method='del2'})
\]

Find a fixed point of the function.

Given a function of one or more variables and a starting point, find a fixed point of the function: i.e., where \( \text{func}(x0) = x0 \).

**Parameters**

- func [function] Function to evaluate.
- x0 [array_like] Fixed point of function.
- args [tuple, optional] Extra arguments to func.
- xtol [float, optional] Convergence tolerance, defaults to 1e-08.
- maxiter [int, optional] Maximum number of iterations, defaults to 500.
method  [[“del2”, “iteration”], optional] Method of finding the fixed-point, defaults to “del2”, which uses Steffensen’s Method with Aitken’s $\text{Del}^2$ convergence acceleration [1]. The “iteration” method simply iterates the function until convergence is detected, without attempting to accelerate the convergence.

References

[1]

Examples

```python
>>> from scipy import optimize
>>> def func(x, c1, c2):
...     return np.sqrt(c1/(x+c2))
>>> c1 = np.array([10, 12.])
>>> c2 = np.array([3, 5.])
>>> optimize.fixed_point(func, [1.2, 1.3], args=(c1,c2))
array([ 1.4920333 , 1.37228132])
```

Multidimensional

```python
root(fun, x0[, args, method, jac, tol, ...]) Find a root of a vector function.
```

```python
scipy.optimize.root (fun, x0, args=(), method='hybr', jac=None, tol=None, callback=None, options=None)  Find a root of a vector function.
```

Parameters

- **fun** [callable] A vector function to find a root of.
- **x0** [ndarray] Initial guess.
- **args** [tuple, optional] Extra arguments passed to the objective function and its Jacobian.
- **method** [str, optional] Type of solver. Should be one of:
  - ‘hybr’ (see here)
  - ‘lm’ (see here)
  - ‘broyden1’ (see here)
  - ‘broyden2’ (see here)
  - ‘anderson’ (see here)
  - ‘linearmixing’ (see here)
  - ‘diagbroyden’ (see here)
  - ‘excitingmixing’ (see here)
  - ‘krylov’ (see here)
  - ‘df-sane’ (see here)
- **jac** [bool or callable, optional] If `jac` is a Boolean and is True, `fun` is assumed to return the value of Jacobian along with the objective function. If False, the Jacobian will be estimated numerically. `jac` can also be a callable returning the Jacobian of `fun`. In this case, it must accept the same arguments as `fun`.
- **tol** [float, optional] Tolerance for termination. For detailed control, use solver-specific options.
callback [function, optional] Optional callback function. It is called on every iteration as \( \text{callback}(x, f) \) where \( x \) is the current solution and \( f \) the corresponding residual. For all methods but 'hybr' and 'lm'.

options [dict, optional] A dictionary of solver options. E.g., \( \text{xtol} \) or \( \text{maxiter} \), see \texttt{show_options()} for details.

Returns

\( \text{sol} \) [\texttt{OptimizeResult}] The solution represented as a \texttt{OptimizeResult} object. Important attributes are: \( x \) the solution array, \( \text{success} \) a Boolean flag indicating if the algorithm exited successfully and \( \text{message} \) which describes the cause of the termination. See \texttt{OptimizeResult} for a description of other attributes.

See also:

\texttt{show_options}

Additional options accepted by the solvers

Notes

This section describes the available solvers that can be selected by the 'method' parameter. The default method is \( \text{hybr} \).

Method \( \text{hybr} \) uses a modification of the Powell hybrid method as implemented in MINPACK [1].

Method \( \text{lm} \) solves the system of nonlinear equations in a least squares sense using a modification of the Levenberg-Marquardt algorithm as implemented in MINPACK [1].

Method \( \text{df-sane} \) is a derivative-free spectral method. [3]

Methods \( \text{broyden1}, \text{broyden2}, \text{anderson}, \text{linearmixing}, \text{diagbroyden}, \text{excitingmixing}, \text{krylov} \) are inexact Newton methods, with backtracking or full line searches [2]. Each method corresponds to a particular Jacobian approximations.

- Method \( \text{broyden1} \) uses Broyden's first Jacobian approximation, it is known as Broyden's good method.
- Method \( \text{broyden2} \) uses Broyden's second Jacobian approximation, it is known as Broyden's bad method.
- Method \( \text{anderson} \) uses (extended) Anderson mixing.
- Method \( \text{Krylov} \) uses Krylov approximation for inverse Jacobian. It is suitable for large-scale problem.
- Method \( \text{diagbroyden} \) uses diagonal Broyden Jacobian approximation.
- Method \( \text{linearmixing} \) uses a scalar Jacobian approximation.
- Method \( \text{excitingmixing} \) uses a tuned diagonal Jacobian approximation.

\textbf{Warning:} The algorithms implemented for methods \( \text{diagbroyden}, \text{linearmixing} \) and \( \text{excitingmixing} \) may be useful for specific problems, but whether they will work may depend strongly on the problem.

New in version 0.11.0.

Examples

The following functions define a system of nonlinear equations and its jacobian.

```python
>>> def fun(x):
...    return [x[0] + 0.5 * (x[0] - x[1])**3 - 1.0,
...            0.5 * (x[1] - x[0])**3 + x[1]]

>>> def jac(x):
...    return np.array([[(1 + 1.5 * (x[0] - x[1])**2,
...                       -1.5 * (x[0] - x[1])**2],
...                      [-1.5 * (x[1] - x[0])**2,
...                       1 + 1.5 * (x[1] - x[0])**2]])
```

A solution can be obtained as follows.

```python
>>> from scipy import optimize
>>> sol = optimize.root(fun, [0, 0], jac=jac, method='hybr')
>>> sol.x
array([[ 0.8411639, 0.1588361]])
```

Large problem

Suppose that we needed to solve the following integrodifferential equation on the square \([0, 1] \times [0, 1]\):

\[
\nabla^2 P = 10 \left( \int_0^1 \int_0^1 \cosh(P) \, dx \, dy \right)^2
\]

with \(P(x, 1) = 1\) and \(P = 0\) elsewhere on the boundary of the square.

The solution can be found using the `method='krylov'` solver:

```python
>>> from scipy import optimize
>>> # parameters
>>> nx, ny = 75, 75
>>> hx, hy = 1. / (nx-1), 1. / (ny-1)

>>> P_left, P_right = 0, 0
>>> P_top, P_bottom = 1, 0

>>> def residual(P):
...    d2x = np.zeros_like(P)
...    d2y = np.zeros_like(P)
...    d2x[1:-1] = (P[2:] - 2*P[1:-1] + P[:-2]) / hx/hx
...    d2x[0] = (P[1] - 2*P[0] + P_left)/hx/hx
...    d2x[-1] = (P_right - 2*P[-1] + P[-2])/hx/hx
...    d2y[:1:-1] = (P[:,2:] - 2*P[:,1:-1] + P[:,:-2])/hy/hy

(continues on next page)
The root function supports the following methods:

**root(method='hybr')**

`scipy.optimize.root` supports the following methods:

```
scipy.optimize.root (fun, x0, args=(), method='hybr', jac=None, tol=None, callback=None, options={})
```

Find the roots of a multivariate function using MINPACK’s hybrd and hybrj routines (modified Powell method).

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.root`

**Options**

- **col_deriv** [bool] Specify whether the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).
xtol

[float] The calculation will terminate if the relative error between two consecutive iterates is at most $\times tol$.

maxfev

[int] The maximum number of calls to the function. If zero, then $100 \times (N+1)$ is the maximum where $N$ is the number of elements in $x_0$.

band

[tuple] If set to a two-sequence containing the number of sub- and super-diagonals within the band of the Jacobi matrix, the Jacobi matrix is considered banded (only for fprime=None).

eps

[float] A suitable step length for the forward-difference approximation of the Jacobian (for fprime=None). If $\varepsilon$ is less than the machine precision, it is assumed that the relative errors in the functions are of the order of the machine precision.

factor

[float] A parameter determining the initial step bound ($\text{factor} \times || \text{diag} \times x||$). Should be in the interval $(0.1, 100)$.

diag

[sequence] $N$ positive entries that serve as scale factors for the variables.

root(method='lm')

scipy.optimize.root (fun, x0, args=(), method='lm', jac=None, tol=None, callback=None,
options={'col_deriv': 0, 'xtol': 1.49012e-08, 'ftol': 1.49012e-08, 'gtol': 0.0, 'maxiter': 0,
'eps': 0.0, 'factor': 100, 'diag': None})

Solve for least squares with Levenberg-Marquardt

See also:

For documentation for the rest of the parameters, see scipy.optimize.root

Options

col_deriv [bool] non-zero to specify that the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).

ftol [float] Relative error desired in the sum of squares.

xtol [float] Relative error desired in the approximate solution.

gtol [float] Orthogonality desired between the function vector and the columns of the Jacobian.

maxiter [int] The maximum number of calls to the function. If zero, then $100 \times (N+1)$ is the maximum where $N$ is the number of elements in $x_0$.

epsfcn [float] A suitable step length for the forward-difference approximation of the Jacobian (for Dfun=None). If epsfcn is less than the machine precision, it is assumed that the relative errors in the functions are of the order of the machine precision.

factor [float] A parameter determining the initial step bound ($\text{factor} \times || \text{diag} \times x||$). Should be in the interval $(0.1, 100)$.

diag [sequence] $N$ positive entries that serve as scale factors for the variables.

root(method='broyden1')

scipy.optimize.root (fun, x0, args=(), method='broyden1', tol=None, callback=None, options={})

For documentation for the rest of the parameters, see scipy.optimize.root

Options

nit [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

disp [bool, optional] Print status to stdout on every iteration.
maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.

ftol [float, optional] Relative tolerance for the residual. If omitted, not used.
fatol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

xtol [float, optional] Relative minimum step size. If omitted, not used.
xatol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search [{None, ‘armijo’ (default), ‘wolfe’}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

jac_options [dict, optional] Options for the respective Jacobian approximation.

alpha [float, optional] Initial guess for the Jacobian is (-1/alpha).

reduction_method [str or tuple, optional] Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form (method, param1, param2, ...) that gives the name of the method and values for additional parameters.

Methods available:

- **restart** Drop all matrix columns. Has no extra parameters.
- **simple** Drop oldest matrix column. Has no extra parameters.
- **svd** Keep only the most significant SVD components. Extra parameters:
  - **to_retain** Number of SVD components to retain when rank reduction is done. Default is max_rank - 2.

max_rank [int, optional] Maximum rank for the Broyden matrix. Default is infinity (i.e., no rank reduction).

**Examples**

```python
>>> def func(x):
...     return np.cos(x) + x[:-1] - [1, 2, 3, 4]
...
>>> from scipy import optimize
>>> res = optimize.root(func, [1, 1, 1, 1], method='broyden1', tol=1e-14)
>>> x = res.x
>>> x
array([4.04674914, 3.91158389, 2.71791677, 1.61756251])
>>> np.cos(x) + x[:-1]
array([1., 2., 3., 4.])
```

**Options**

- `nit` [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- `disp` [bool, optional] Print status to stdout on every iteration.
- `maxiter` [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.
- `ftol` [float, optional] Relative tolerance for the residual. If omitted, not used.
- `fatol` [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- `xtol` [float, optional] Relative minimum step size. If omitted, not used.
- `xatol` [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- `tol_norm` [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
- `line_search` [{None, ‘armijo’ (default), ‘wolfe’}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.
- `jac_options` [dict, optional] Options for the respective Jacobian approximation.
- `alpha` [float, optional] Initial guess for the Jacobian is (-1/alpha).
- `M` [float, optional] Number of previous vectors to retain. Defaults to 5.
- `w0` [float, optional] Regularization parameter for numerical stability. Compared to unity, good values of the order of 0.01.

root(method='linearmixing')

- **ftol**  [float, optional] Relative tolerance for the residual. If omitted, not used.

fatol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

xtol [float, optional] Relative minimum step size. If omitted, not used.

xatol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search [{None, ‘armijo’ (default), ‘wolfe’}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

jac_options [dict, optional] Options for the respective Jacobian approximation.
   alpha [float, optional] Initial Jacobian approximation is (-1/alpha).
   alphamax [float, optional] The entries of the diagonal Jacobian are kept in the range [alpha, alphamax].

root(method='krylov')

scipy.optimize.root (fun, x0, args=(), method='krylov', tol=None, callback=None, options={})

See also:
For documentation for the rest of the parameters, see scipy.optimize.root

Options

disp [bool, optional] Print status to stdout on every iteration.

maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, NoConvergence is raised.

ftol [float, optional] Relative tolerance for the residual. If omitted, not used.

fatol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

xtol [float, optional] Relative minimum step size. If omitted, not used.

xatol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search [{None, ‘armijo’ (default), ‘wolfe’}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

jac_options [dict, optional] Options for the respective Jacobian approximation.
   rdiff [float, optional] Relative step size to use in numerical differentiation.
   method [{‘lgmres’, ‘gmres’, ‘bicgstab’, ‘cgs’, ‘minres’} or function] Krylov method to use to approximate the Jacobian. Can be a string, or a function implementing the same interface as the iterative solvers in scipy.sparse.linalg. The default is scipy.sparse.linalg.lgmres.
   inner_M [LinearOperator or InverseJacobian] Preconditioner for the inner Krylov iteration. Note that you can use also inverse Jacobians as (adaptive) preconditioners. For example,
```python
>>> jac = BroydenFirst()
>>> kjac = KrylovJacobian(inner_M=jac.inverse).
```

If the preconditioner has a method named 'update', it will be called as update(x, f) after each nonlinear step, with x giving the current point, and f the current function value.

- **inner_tol**, **inner_maxiter**, ...
  Parameters to pass on to the “inner” Krylov solver. See `scipy.sparse.linalg.gmres` for details.

- **outer_k** [int, optional] Size of the subspace kept across LGMRES nonlinear iterations. See `scipy.sparse.linalg.lgmres` for details.

### `root(method='df-sane')`

`scipy.optimize.root` *(fun, x0, args=(), method='df-sane', tol=None, callback=None, options={'func': None, 'ftol': 1e-08, 'fatol': 1e-300, 'maxfev': 1000, 'fnorm': None, 'disp': False, 'M': 10, 'eta_strategy': None, 'sigma_eps': 1e-10, 'sigma_0': 1.0, 'line_search': 'cruz'})`

Solve nonlinear equation with the DF-SANE method

See also:

For documentation for the rest of the parameters, see `scipy.optimize.root`

#### Options

- **ftol** [float, optional] Relative norm tolerance.
- **fatol** [float, optional] Absolute norm tolerance. Algorithm terminates when ||func(x)|| < fatol + ftol ||func(x_0)||.
- **f_norm** [callable, optional] Norm to use in the convergence check. If None, 2-norm is used.
- **maxfev** [int, optional] Maximum number of function evaluations.
- **disp** [bool, optional] Whether to print convergence process to stdout.
- **eta_strategy** [callable, optional] Choice of the eta_k parameter, which gives slack for growth of \[||F||^2\]. Called as eta_k = eta_strategy(k, x, F) with k the iteration number, x the current iterate and F the current residual. Should satisfy eta_k > 0 and sum(eta, k=0..inf) < inf. Default: \[||F||^2 / (1 + k)^2\].
- **sigma_eps** [float, optional] The spectral coefficient is constrained to sigma_eps < sigma < 1/sigma_eps. Default: 1e-10
- **sigma_0** [float, optional] Initial spectral coefficient. Default: 1.0
- **M** [int, optional] Number of iterates to include in the nonmonotonic line search. Default: 10
- **line_search** ['cruz', 'cheng'] Type of line search to employ. 'cruz' is the original one defined in [Martinez & Raydan, Math. Comp. 75, 1429 (2006)], 'cheng' is a modified search defined in [Cheng & Li. IMA J. Numer. Anal. 29, 814 (2009)]. Default: 'cruz'

[1], [2], [3]

Linear programming

\texttt{linprog}(c[, A\_ub, b\_ub, A\_eq, b\_eq, bounds, ...])  
Linear programming: minimize a linear objective function subject to linear equality and inequality constraints.

\texttt{scipy.optimize.linprog}

\texttt{scipy.optimize.linprog}(c, A\_ub=\texttt{None}, b\_ub=\texttt{None}, A\_eq=\texttt{None}, b\_eq=\texttt{None}, bounds=\texttt{None},  
\texttt{method=}'interior-point', callback=\texttt{None}, options=\texttt{None}, x0=\texttt{None})

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints.

Linear programming solves problems of the following form:

$$\min_{x} c^T x$$

such that

\[ A\_ub x \leq b\_ub, \]
\[ A\_eq x = b\_eq, \]
\[ l \leq x \leq u, \]

where \( x \) is a vector of decision variables; \( c, b\_ub, b\_eq, l, \) and \( u \) are vectors; and \( A\_ub \) and \( A\_eq \) are matrices.

Alternatively, that's:

minimize:

\[ c \_ A \_ x \]

such that:

\[ A\_ub \_ A \_ x \leq b\_ub \]
\[ A\_eq \_ A \_ x = b\_eq \]
\[ l \_ A \_ x \_ ub \]

Note that by default \( lb = 0 \) and \( ub = \texttt{None} \) unless specified with \texttt{bounds}.

**Parameters**

- \( c \) [1-D array] The coefficients of the linear objective function to be minimized.
- \( A\_ub \) [2-D array, optional] The inequality constraint matrix. Each row of \( A\_ub \) specifies the coefficients of a linear inequality constraint on \( x \).
- \( b\_ub \) [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of \( A\_ub \_ A \_ x \).
- \( A\_eq \) [2-D array, optional] The equality constraint matrix. Each row of \( A\_eq \) specifies the coefficients of a linear equality constraint on \( x \).
- \( b\_eq \) [1-D array, optional] The equality constraint vector. Each element of \( A\_eq \_ A \_ x \) must equal the corresponding element of \( b\_eq \).
- \texttt{bounds} [sequence, optional] A sequence of (min, max) pairs for each element in \( x \), defining the minimum and maximum values of that decision variable. Use \texttt{None} to indicate that there is no bound. By default, bounds are (0, \texttt{None}) (all decision variables are non-negative). If a single tuple (min, max) is provided, then \texttt{min} and \texttt{max} will serve as bounds for all decision variables.
method [str, optional] The algorithm used to solve the standard form problem. 'highs-ds', 'highs-ipm', 'highs', 'interior-point' (default), 'revised simplex', and 'simplex' (legacy) are supported.

callback [callable, optional] If a callback function is provided, it will be called at least once per iteration of the algorithm. The callback function must accept a single scipy.optimize.OptimizeResult consisting of the following fields:

- **x** [1-D array] The current solution vector.
- **fun** [float] The current value of the objective function \( c \cdot x \).
- **success** [bool] True when the algorithm has completed successfully.
- **slack** [1-D array] The (nominally positive) values of the slack, \( b_{ub} - A_{ub} \cdot x \).
- **con** [1-D array] The (nominally zero) residuals of the equality constraints, \( b_{eq} - A_{eq} \cdot x \).
- **phase** [int] The phase of the algorithm being executed.
- **status** [int] An integer representing the status of the algorithm.

  - 0: Optimization proceeding nominally.
  - 1: Iteration limit reached.
  - 2: Problem appears to be infeasible.
  - 3: Problem appears to be unbounded.
  - 4: Numerical difficulties encountered.
- **nit** [int] The current iteration number.
- **message** [str] A string descriptor of the algorithm status.

Callback functions are not currently supported by the HiGHS methods.

options [dict, optional] A dictionary of solver options. All methods accept the following options:

- **maxiter** [int] Maximum number of iterations to perform. Default: see method-specific documentation.
- **disp** [bool] Set to True to print convergence messages. Default: False.
- **presolve** [bool] Set to False to disable automatic presolve. Default: True.

All methods except the HiGHS solvers also accept:

- **tol** [float] A tolerance which determines when a residual is “close enough” to zero to be considered exactly zero.
- **autoscale** [bool] Set to True to automatically perform equilibration. Consider using this option if the numerical values in the constraints are separated by several orders of magnitude. Default: False.
- **rr** [bool] Set to False to disable automatic redundancy removal. Default: True.
- **rr_method** [string] Method used to identify and remove redundant rows from the equality constraint matrix after presolve. For problems with dense input, the available methods for redundancy removal are:

  - **SVD**: Repeatedly performs singular value decomposition on the matrix, detecting redundant rows based on nonzeros in the left singular vectors that correspond with zero singular values. May be fast when the matrix is nearly full rank.
  - **pivot**: Uses the algorithm presented in [5] to identify redundant rows.
  - **ID**: Uses a randomized interpolative decomposition. Identifies columns of the matrix transpose not used in a full-rank interpolative decomposition of the matrix.
  - **None**: Uses “svd” if the matrix is nearly full rank, that is, the difference between the matrix rank and the number of rows is less than five. If not, uses “pivot”. The behavior of this default is subject to change without prior notice.

Default: None. For problems with sparse input, this option is ignored, and the pivot-based algorithm presented in [5] is used.

For method-specific options, see show_options('linprog').
\[ x_0 \] [1-D array, optional] Guess values of the decision variables, which will be refined by the optimization algorithm. This argument is currently used only by the ‘revised simplex’ method, and can only be used if \( x_0 \) represents a basic feasible solution.

**Returns**

\[ \text{res} \] [OptimizeResult] A scipy.optimize.OptimizeResult consisting of the fields:

\[ x \] [1-D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.

\[ \text{fun} \] [float] The optimal value of the objective function \( c \odot x \).

\[ \text{slack} \] [1-D array] The (nominally positive) values of the slack variables, \( b_{\text{ub}} - A_{\text{ub}} \odot x \).

\[ \text{con} \] [1-D array] The (nominally zero) residuals of the equality constraints, \( b_{\text{eq}} - A_{\text{eq}} \odot x \).

\[ \text{success} \] [bool] True when the algorithm succeeds in finding an optimal solution.

\[ \text{status} \] [int] An integer representing the exit status of the algorithm.

0 : Optimization terminated successfully.
1 : Iteration limit reached.
2 : Problem appears to be infeasible.
3 : Problem appears to be unbounded.
4 : Numerical difficulties encountered.

\[ \text{nit} \] [int] The total number of iterations performed in all phases.

\[ \text{message} \] [str] A string descriptor of the exit status of the algorithm.

**See also:**

show_options

Additional options accepted by the solvers.

**Notes**

This section describes the available solvers that can be selected by the ‘method’ parameter.

‘highs-ds’ and ‘highs-ipm’ are interfaces to the HiGHS simplex and interior-point method solvers [13], respectively. ‘highs’ chooses between the two automatically. These are the fastest linear programming solvers in SciPy, especially for large, sparse problems; which of these two is faster is problem-dependent. ‘interior-point’ is the default as it was the fastest and most robust method before the recent addition of the HiGHS solvers. ‘revised simplex’ is more accurate than interior-point for the problems it solves. ‘simplex’ is the legacy method and is included for backwards compatibility and educational purposes.

Method highs-ds is a wrapper of the C++ high performance dual revised simplex implementation (HSOL) [13], [14]. Method highs-ipm is a wrapper of a C++ implementation of an interior-point method [13]; it features a crossover routine, so it is as accurate as a simplex solver. Method highs chooses between the two automatically. For new code involving linprog, we recommend explicitly choosing one of these three method values.

New in version 1.6.0.

Method interior-point uses the primal-dual path following algorithm as outlined in [4]. This algorithm supports sparse constraint matrices and is typically faster than the simplex methods, especially for large, sparse problems. Note, however, that the solution returned may be slightly less accurate than those of the simplex methods and will not, in general, correspond with a vertex of the polytope defined by the constraints.

New in version 1.0.0.

Method revised simplex uses the revised simplex method as described in [9], except that a factorization [11] of the basis matrix, rather than its inverse, is efficiently maintained and used to solve the linear systems at each iteration of the algorithm.
New in version 1.3.0.

Method `simplex` uses a traditional, full-tableau implementation of Dantzig’s simplex algorithm [1], [2] (not the Nelder-Mead simplex). This algorithm is included for backwards compatibility and educational purposes.

New in version 0.15.0.

Before applying `interior-point`, `revised simplex`, or `simplex`, a presolve procedure based on [8] attempts to identify trivial infeasibilities, trivial unboundedness, and potential problem simplifications. Specifically, it checks for:

- rows of zeros in $A_{eq}$ or $A_{ub}$, representing trivial constraints;
- columns of zeros in $A_{eq}$ and $A_{ub}$, representing unconstrained variables;
- column singletons in $A_{eq}$, representing fixed variables; and
- column singletons in $A_{ub}$, representing simple bounds.

If presolve reveals that the problem is unbounded (e.g. an unconstrained and unbounded variable has negative cost) or infeasible (e.g., a row of zeros in $A_{eq}$ corresponds with a nonzero in $b_{eq}$), the solver terminates with the appropriate status code. Note that presolve terminates as soon as any sign of unboundedness is detected; consequently, a problem may be reported as unbounded when in reality the problem is infeasible (but infeasibility has not been detected yet). Therefore, if it is important to know whether the problem is actually infeasible, solve the problem again with option `presolve=False`.

If neither infeasibility nor unboundedness are detected in a single pass of the presolve, bounds are tightened where possible and fixed variables are removed from the problem. Then, linearly dependent rows of the $A_{eq}$ matrix are removed, (unless they represent an infeasibility) to avoid numerical difficulties in the primary solve routine. Note that rows that are nearly linearly dependent (within a prescribed tolerance) may also be removed, which can change the optimal solution in rare cases. If this is a concern, eliminate redundancy from your problem formulation and run with option `rr=False` or `presolve=False`.

Several potential improvements can be made here: additional presolve checks outlined in [8] should be implemented, the presolve routine should be run multiple times (until no further simplifications can be made), and more of the efficiency improvements from [5] should be implemented in the redundancy removal routines.

After presolve, the problem is transformed to standard form by converting the (tightened) simple bounds to upper bound constraints, introducing non-negative slack variables for inequality constraints, and expressing unbounded variables as the difference between two non-negative variables. Optionally, the problem is automatically scaled via equilibration [12]. The selected algorithm solves the standard form problem, and a postprocessing routine converts the result to a solution to the original problem.

Examples

Consider the following problem:

$$
\min_{x_0, x_1} -x_0 + 4x_1
$$

such that

$$
-3x_0 + x_1 \leq 6,
-2x_0 + x_1 \geq -4,
-x_0 \geq -3.
$$

The problem is not presented in the form accepted by `linprog`. This is easily remedied by converting the “greater than” inequality constraint to a “less than” inequality constraint by multiplying both sides by a factor of $-1$. Note
also that the last constraint is really the simple bound $-3 \leq x_1 \leq \infty$. Finally, since there are no bounds on $x_0$, we must explicitly specify the bounds $-\infty \leq x_0 \leq \infty$, as the default is for variables to be non-negative. After collecting coefficients into arrays and tuples, the input for this problem is:

```python
>>> c = [-1, 4]
>>> A = [[-3, 1], [1, 2]]
>>> b = [6, 4]
>>> x0_bounds = (None, None)
>>> x1_bounds = (-3, None)
>>> from scipy.optimize import linprog
>>> res = linprog(c, A_ub=A, b_ub=b, bounds=[x0_bounds, x1_bounds])
```

Note that the default method for `linprog` is ‘interior-point’, which is approximate by nature.

```python
>>> print(res)
con: array([], dtype=float64)
fun: -21.99999984082494 # may vary
message: 'Optimization terminated successfully.'
nit: 6 # may vary
slack: array([ 3.8999997e+01, 8.46872439e-08]) # may vary
status: 0
success: True
x: array([ 9.99999989, -2.99999999]) # may vary
```

If you need greater accuracy, try ‘revised simplex’.

```python
>>> res = linprog(c, A_ub=A, b_ub=b, bounds=[x0_bounds, x1_bounds],
... method='revised simplex')
>>> print(res)
con: array([], dtype=float64)
fun: -22.0 # may vary
message: 'Optimization terminated successfully.'
nit: 1 # may vary
slack: array([39., 0.]) # may vary
status: 0
success: True
x: array([10., -3.]) # may vary
```

You can use the `options` parameter, e.g., to restrict the maximum number of iterations.

```python
>>> res = linprog(c, A_ub=A, b_ub=b, bounds=[x0_bounds, x1_bounds],
... options={'maxiter': 4})
>>> print(res)
con: array([], dtype=float64)
fun: -21.35207150630407 # may vary

The `linprog` function supports the following methods:
linprog(method='simplex')

```python
scipy.optimize.linprog(c, A_ub=None, b_ub=None, A_eq=None, b_eq=None, bounds=None,
                       method='simplex', callback=None, options={'maxiter': 5000, 'disp': False, 'presolve': True, 'tol': 1e-12, 'autoscale': False, 'rr': True, 'bland': False}, x0=None)
```

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using the tableau-based simplex method.

Linear programming solves problems of the following form:

\[
\min_{x} \quad c^T x \\
\text{subject to} \quad A_{ub} x \leq b_{ub}, \quad A_{eq} x = b_{eq}, \quad l \leq x \leq u,
\]

where \( x \) is a vector of decision variables; \( c, b_{ub}, b_{eq}, l, \) and \( u \) are vectors; and \( A_{ub} \) and \( A_{eq} \) are matrices.

Alternatively, that's:

minimize:

\[
c @ x
\]

such that:

\[
A_{ub} @ x \leq b_{ub} \\
A_{eq} @ x = b_{eq} \\
lb \leq x \leq ub
\]

Note that by default \( lb = 0 \) and \( ub = None \) unless specified with `bounds`.

**Parameters**

- **c** [1-D array] The coefficients of the linear objective function to be minimized.
- **A_ub** [2-D array, optional] The inequality constraint matrix. Each row of \( A_{ub} \) specifies the coefficients of a linear inequality constraint on \( x \).
- **b_ub** [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of \( A_{ub} @ x \).
- **A_eq** [2-D array, optional] The equality constraint matrix. Each row of \( A_{eq} \) specifies the coefficients of a linear equality constraint on \( x \).
- **b_eq** [1-D array, optional] The equality constraint vector. Each element of \( A_{eq} @ x \) must equal the corresponding element of \( b_{eq} \).
- **bounds** [sequence, optional] A sequence of \((\text{min}, \text{max})\) pairs for each element in \( x \), defining the minimum and maximum values of that decision variable. Use None to indicate that there is no bound. By default, bounds are \((0, None)\) (all decision variables are non-negative). If a single tuple \((\text{min}, \text{max})\) is provided, then \text{min} and \text{max} will serve as bounds for all decision variables.
- **method** [str] This is the method-specific documentation for 'simplex', 'highs', 'highs-ds', 'highs-ipm', 'interior-point' (default), and 'revised simplex' are also available.
- **callback** [callable, optional] Callback function to be executed once per iteration.

**Returns**

- **res** [OptimizeResult] A `scipy.optimize.OptimizeResult` consisting of the fields:
  - **x** [1-D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.
  - **fun** [float] The optimal value of the objective function \( c @ x \).
slack [1-D array] The (nominally positive) values of the slack variables, \( b_{ub} - A_{ub} @ x \).

con [1-D array] The (nominally zero) residuals of the equality constraints, \( b_{eq} - A_{eq} @ x \).

success [bool] True when the algorithm succeeds in finding an optimal solution.

status [int] An integer representing the exit status of the algorithm.
0 : Optimization terminated successfully.
1 : Iteration limit reached.
2 : Problem appears to be infeasible.
3 : Problem appears to be unbounded.
4 : Numerical difficulties encountered.

nit [int] The total number of iterations performed in all phases.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.linprog`

**Options**

maxiter [int (default: 5000)] The maximum number of iterations to perform in either phase.

disp [bool (default: False)] Set to True if indicators of optimization status are to be printed to the console each iteration.

presolve [bool (default: True)] Presolve attempts to identify trivial infeasibilities, identify trivial unboundedness, and simplify the problem before sending it to the main solver. It is generally recommended to keep the default setting True; set to False if presolve is to be disabled.

tol [float (default: 1e-12)] The tolerance which determines when a solution is “close enough” to zero in Phase 1 to be considered a basic feasible solution or close enough to positive to serve as an optimal solution.

autoscale [bool (default: False)] Set to True to automatically perform equilibration. Consider using this option if the numerical values in the constraints are separated by several orders of magnitude.

rr [bool (default: False)] Set to False to disable automatic redundancy removal.

bland [bool] If True, use Bland’s anti-cycling rule [3] to choose pivots to prevent cycling. If False, choose pivots which should lead to a converged solution more quickly. The latter method is subject to cycling (non-convergence) in rare instances.

unknown_options [dict] Optional arguments not used by this particular solver. If unknown_options is non-empty a warning is issued listing all unused options.

**References**

[1], [2], [3]

**linprog(method='interior-point')**

`scipy.optimize.linprog(c, A_ub=None, b_ub=None, A_eq=None, b_eq=None, bounds=None, method='interior-point', callback=None, options={'maxiter': 1000, 'disp': False, 'presolve': True, 'tol': 1e-08, 'autoscale': False, 'rr': True, 'alpha0': 0.99995, 'beta': 0.1, 'sparse': False, 'lssq': False, 'sym_pos': True, 'cholesky': True, 'pc': True, 'ip': False, 'permc_spec': 'MMD_AT_PLUS_A'}, x0=None)`

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using the interior-point method of [4].
Linear programming solves problems of the following form:

\[
\min_x \ c^T x \\
\text{such that } A_{ub} x \leq b_{ub}, \\
A_{eq} x = b_{eq}, \\
l \leq x \leq u,
\]

where \( x \) is a vector of decision variables; \( c, b_{ub}, b_{eq}, l, \) and \( u \) are vectors; and \( A_{ub} \) and \( A_{eq} \) are matrices.

Alternatively, that's:

minimize:

\[
c \cdot x
\]

such that:

\[
A_{ub} \cdot x \leq b_{ub} \\
A_{eq} \cdot x = b_{eq} \\
lb \leq x \leq ub
\]

Note that by default \( lb = 0 \) and \( ub = None \) unless specified with \( bounds \).

**Parameters**

- \( c \) [1-D array] The coefficients of the linear objective function to be minimized.
- \( A_{ub} \) [2-D array, optional] The inequality constraint matrix. Each row of \( A_{ub} \) specifies the coefficients of a linear inequality constraint on \( x \).
- \( b_{ub} \) [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of \( A_{ub} \cdot x \).
- \( A_{eq} \) [2-D array, optional] The equality constraint matrix. Each row of \( A_{eq} \) specifies the coefficients of a linear equality constraint on \( x \).
- \( b_{eq} \) [1-D array, optional] The equality constraint vector. Each element of \( A_{eq} \cdot x \) must equal the corresponding element of \( b_{eq} \).
- \( bounds \) [sequence, optional] A sequence of \((\text{min}, \text{max})\) pairs for each element in \( x \), defining the minimum and maximum values of that decision variable. Use None to indicate that there is no bound. By default, bounds are \((0, None)\) (all decision variables are non-negative). If a single tuple \((\text{min}, \text{max})\) is provided, then \text{min} and \text{max} will serve as bounds for all decision variables.
- \( method \) [str] This is the method-specific documentation for 'interior-point'. 'highs', 'highs-ds', 'highs-ipm', 'revised simplex', and 'simplex' (legacy) are also available.
- \( callback \) [callable, optional] Callback function to be executed once per iteration.

**Returns**

- \( res \) [OptimizeResult] A scipy.optimize.OptimizeResult consisting of the fields:
  - \( x \) [1-D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.
  - \( fun \) [float] The optimal value of the objective function \( c \cdot x \).
  - \( slack \) [1-D array] The (nominally positive) values of the slack variables, \( b_{ub} - A_{ub} \cdot x \).
  - \( con \) [1-D array] The (nominally zero) residuals of the equality constraints, \( b_{eq} - A_{eq} \cdot x \).
  - \( success \) [bool] True when the algorithm succeeds in finding an optimal solution.
  - \( status \) [int] An integer representing the exit status of the algorithm. 0: Optimization terminated successfully. 1: Iteration limit reached.
2: Problem appears to be infeasible.
3: Problem appears to be unbounded.
4: Numerical difficulties encountered.

**message** [str] A string descriptor of the exit status of the algorithm.

**nit** [int] The total number of iterations performed in all phases.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.linprog`

### Options

**maxiter** [int (default: 1000)] The maximum number of iterations of the algorithm.

**disp** [bool (default: False)] Set to `True` if indicators of optimization status are to be printed to the console each iteration.

**presolve** [bool (default: True)] Presolve attempts to identify trivial infeasibilities, identify trivial unboundedness, and simplify the problem before sending it to the main solver. It is generally recommended to keep the default setting `True`; set to `False` if presolve is to be disabled.

**tol** [float (default: 1e-8)] Termination tolerance to be used for all termination criteria; see [4] Section 4.5.

**autoscale** [bool (default: False)] Set to `True` to automatically perform equilibration. Consider using this option if the numerical values in the constraints are separated by several orders of magnitude.

**rr** [bool (default: True)] Set to `False` to disable automatic redundancy removal.

**alpha0** [float (default: 0.99995)] The maximal step size for Mehrota's predictor-corrector search direction; see \( \beta_3 \) of [4] Table 8.1.

**beta** [float (default: 0.1)] The desired reduction of the path parameter \( \mu \) (see [6]) when Mehrota's predictor-corrector is not in use (uncommon).

**sparse** [bool (default: False)] Set to `True` if the problem is to be treated as sparse after presolve. If either \( A_{eq} \) or \( A_{ub} \) is a sparse matrix, this option will automatically be set `True`, and the problem will be treated as sparse even during presolve. If your constraint matrices contain mostly zeros and the problem is not very small (less than about 100 constraints or variables), consider setting `True` or providing \( A_{eq} \) and \( A_{ub} \) as sparse matrices.

**lstsq** [bool (default: False)] Set to `True` if the problem is expected to be very poorly conditioned. This should always be left `False` unless severe numerical difficulties are encountered. Leave this at the default unless you receive a warning message suggesting otherwise.

**sym_pos** [bool (default: True)] Leave `True` if the problem is expected to yield a well conditioned symmetric positive definite normal equation matrix (almost always). Leave this at the default unless you receive a warning message suggesting otherwise.

**cholesky** [bool (default: True)] Set to `True` if the normal equations are to be solved by explicit Cholesky decomposition followed by explicit forward/backward substitution. This is typically faster for problems that are numerically well-behaved.

**pc** [bool (default: True)] Leave `True` if the predictor-corrector method of Mehrota is to be used. This is almost always (if not always) beneficial.

**ip** [bool (default: False)] Set to `True` if the improved initial point suggestion due to [4] Section 4.3 is desired. Whether this is beneficial or not depends on the problem.

**perm_spec** [str (default: ‘MMD_AT_PLUS_A’)] (Has effect only with sparse = True, lstsq = False, sym_pos = True, and no SuiteSparse.) A matrix is factorized in each iteration of the algorithm. This option specifies how to permute the columns of the matrix for sparsity preservation. Acceptable values are:
- **NATURAL:** natural ordering.
- **MMD_ATA:** minimum degree ordering on the structure of \( A^T A \).
- **MMD_AT_PLUS_A:** minimum degree ordering on the structure of \( A^T + A \).
- **COLAMD:** approximate minimum degree column ordering.
This option can impact the convergence of the interior point algorithm; test different values to determine which performs best for your problem. For more information, refer to scipy.sparse.linalg.splu.

unknown_options

[dict] Optional arguments not used by this particular solver. If unknown_options is non-empty a warning is issued listing all unused options.

Notes

This method implements the algorithm outlined in [4] with ideas from [8] and a structure inspired by the simpler methods of [6].

The primal-dual path following method begins with initial ‘guesses’ of the primal and dual variables of the standard form problem and iteratively attempts to solve the (nonlinear) Karush-Kuhn-Tucker conditions for the problem with a gradually reduced logarithmic barrier term added to the objective. This particular implementation uses a homogeneous self-dual formulation, which provides certificates of infeasibility or unboundedness where applicable.

The default initial point for the primal and dual variables is that defined in [4] Section 4.4 Equation 8.22. Optionally (by setting initial point option ip=True), an alternate (potentially improved) starting point can be calculated according to the additional recommendations of [4] Section 4.4.

A search direction is calculated using the predictor-corrector method (single correction) proposed by Mehrota and detailed in [4] Section 4.1. (A potential improvement would be to implement the method of multiple corrections described in [4] Section 4.2.) In practice, this is accomplished by solving the normal equations, [4] Section 5.1 Equations 8.31 and 8.32, derived from the Newton equations [4] Section 5 Equations 8.25 (compare to [4] Section 4 Equations 8.6-8.8). The advantage of solving the normal equations rather than 8.25 directly is that the matrices involved are symmetric positive definite, so Cholesky decomposition can be used rather than the more expensive LU factorization.

With default options, the solver used to perform the factorization depends on third-party software availability and the conditioning of the problem.

For dense problems, solvers are tried in the following order:
1. scipy.linalg.cho_factor
2. scipy.linalg.solve with option sym_pos=True
3. scipy.linalg.solve with option sym_pos=False
4. scipy.linalg.lstsq

For sparse problems:
1. sksparse.cholmod.cholesky (if scikit-sparse and SuiteSparse are installed)
2. scipy.sparse.linalg.factorized (if scikit-umfpack and SuiteSparse are installed)
3. scipy.sparse.linalg.splu (which uses SuperLU distributed with SciPy)
4. scipy.sparse.linalg.lsqr

If the solver fails for any reason, successively more robust (but slower) solvers are attempted in the order indicated. Attempting, failing, and re-starting factorization can be time consuming, so if the problem is numerically challenging, options can be set to bypass solvers that are failing. Setting cholesky=False skips to solver 2, sym_pos=False skips to solver 3, and lstsq=True skips to solver 4 for both sparse and dense problems.

Potential improvements for combatting issues associated with dense columns in otherwise sparse problems are outlined in [4] Section 5.3 and [10] Section 4.1-4.2; the latter also discusses the alleviation of accuracy issues associated with the substitution approach to free variables.
After calculating the search direction, the maximum possible step size that does not activate the non-negativity constraints is calculated, and the smaller of this step size and unity is applied (as in [4] Section 4.1.) [4] Section 4.3 suggests improvements for choosing the step size.

The new point is tested according to the termination conditions of [4] Section 4.5. The same tolerance, which can be set using the tol option, is used for all checks. (A potential improvement would be to expose the different tolerances to be set independently.) If optimality, unboundedness, or infeasibility is detected, the solve procedure terminates; otherwise it repeats.

Whereas the top level linprog module expects a problem of form:

Minimize:

\[ c @ x \]

Subject to:

\[
\begin{align*}
A_{ub} @ x & \leq b_{ub} \\
A_{eq} @ x & = b_{eq} \\
lb & \leq x \leq ub \\
\end{align*}
\]

where \( lb = 0 \) and \( ub = None \) unless set in bounds. The problem is automatically converted to the form:

Minimize:

\[ c @ x \]

Subject to:

\[
\begin{align*}
A @ x & = b \\
x & \geq 0 \\
\end{align*}
\]

for solution. That is, the original problem contains equality, upper-bound and variable constraints whereas the method specific solver requires equality constraints and variable non-negativity. linprog converts the original problem to standard form by converting the simple bounds to upper bound constraints, introducing non-negative slack variables for inequality constraints, and expressing unbounded variables as the difference between two non-negative variables. The problem is converted back to the original form before results are reported.

\]

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using the revised simplex method.

Linear programming solves problems of the following form:

\[
\begin{align*}
\min_x c^T x \\
\text{such that } & A_{ub}x \leq b_{ub}, \\
& A_{eq}x = b_{eq}, \\
& l \leq x \leq u,
\end{align*}
\]
where \( x \) is a vector of decision variables; \( c, b_{ub}, b_{eq}, l, \) and \( u \) are vectors; and \( A_{ub} \) and \( A_{eq} \) are matrices.

Alternatively, that’s:

\[
\begin{align*}
\text{minimize:} & & c \cdot x \\
\text{subject to:} & & A_{ub} \cdot x \leq b_{ub} \\
& & A_{eq} \cdot x = b_{eq} \\
& & l \leq x \leq u
\end{align*}
\]

Note that by default \( l_b = 0 \) and \( u_b = \text{None} \) unless specified with bounds.

### Parameters

- **c** [1-D array] The coefficients of the linear objective function to be minimized.
- **A_ub** [2-D array, optional] The inequality constraint matrix. Each row of \( A_{ub} \) specifies the coefficients of a linear inequality constraint on \( x \).
- **b_ub** [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of \( A_{ub} \cdot x \).
- **A_eq** [2-D array, optional] The equality constraint matrix. Each row of \( A_{eq} \) specifies the coefficients of a linear equality constraint on \( x \).
- **b_eq** [1-D array, optional] The equality constraint vector. Each element of \( A_{eq} \cdot x \) must equal the corresponding element of \( b_{eq} \).
- **bounds** [sequence, optional] A sequence of \((\min, \max)\) pairs for each element in \( x \), defining the minimum and maximum values of that decision variable. Use None to indicate that there is no bound. By default, bounds are \((0, \text{None})\) (all decision variables are non-negative). If a single tuple \((\min, \max)\) is provided, then \( \min \) and \( \max \) will serve as bounds for all decision variables.
- **method** [str] This is the method-specific documentation for ‘revised simplex’. ‘highs’, ‘highs-ds’, ‘highs-ipm’, ‘interior-point’ (default), and ‘simplex’ (legacy) are also available.
- **callback** [callable, optional] Callback function to be executed once per iteration.
- **x0** [1-D array, optional] Guess values of the decision variables, which will be refined by the optimization algorithm. This argument is currently used only by the ‘revised simplex’ method, and can only be used if \( x0 \) represents a basic feasible solution.

### Returns

- **res** [OptimizeResult] A scipy.optimize.OptimizeResult consisting of the fields:
  - **x** [1-D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.
  - **fun** [float] The optimal value of the objective function \( c \cdot x \).
  - **slack** [1-D array] The (nominally positive) values of the slack variables, \( b_{ub} - A_{ub} \cdot x \).
  - **con** [1-D array] The (nominally zero) residuals of the equality constraints, \( b_{eq} - A_{eq} \cdot x \).
  - **success** [bool] True when the algorithm succeeds in finding an optimal solution.
  - **status** [int] An integer representing the exit status of the algorithm.
    - 0: Optimization terminated successfully.
    - 1: Iteration limit reached.
    - 2: Problem appears to be infeasible.
    - 3: Problem appears to be unbounded.
    - 4: Numerical difficulties encountered.
    - 5: Problem has no constraints; turn presolve on.
6: Invalid guess provided.

**message** [str] A string descriptor of the exit status of the algorithm.

**nit** [int] The total number of iterations performed in all phases.

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.linprog`

**Options**

- **maxiter** [int (default: 5000)] The maximum number of iterations to perform in either phase.
- **disp** [bool (default: False)] Set to `True` if indicators of optimization status are to be printed to the console each iteration.
- **presolve** [bool (default: True)] Presolve attempts to identify trivial infeasibilities, identify trivial unboundedness, and simplify the problem before sending it to the main solver. It is generally recommended to keep the default setting `True`; set to `False` if presolve is to be disabled.
- **tol** [float (default: 1e-12)] The tolerance which determines when a solution is “close enough” to zero in Phase 1 to be considered a basic feasible solution or close enough to positive to serve as an optimal solution.
- **autoscale** [bool (default: False)] Set to `True` to automatically perform equilibration. Consider using this option if the numerical values in the constraints are separated by several orders of magnitude.
- **rr** [bool (default: True)] Set to `False` to disable automatic redundancy removal.
- **maxupdate** [int (default: 10)] The maximum number of updates performed on the LU factorization. After this many updates is reached, the basis matrix is factorized from scratch.
- **mast** [bool (default: False)] Minimize Amortized Solve Time. If enabled, the average time to solve a linear system using the basis factorization is measured. Typically, the average solve time will decrease with each successive solve after initial factorization, as factorization takes much more time than the solve operation (and updates). Eventually, however, the updated factorization becomes sufficiently complex that the average solve time begins to increase. When this is detected, the basis is refactorized from scratch. Enable this option to maximize speed at the risk of nondeterministic behavior. Ignored if `maxupdate` is 0.
- **pivot** ["mrc" or “bland” (default: “mrc”)] Pivot rule: Minimum Reduced Cost (“mrc”) or Bland’s rule (“bland”). Choose Bland’s rule if iteration limit is reached and cycling is suspected.
- **unknown_options** [dict] Optional arguments not used by this particular solver. If `unknown_options` is non-empty a warning is issued listing all unused options.

**Notes**

Method *revised simplex* uses the revised simplex method as described in [9], except that a factorization [11] of the basis matrix, rather than its inverse, is efficiently maintained and used to solve the linear systems at each iteration of the algorithm.

'primal_feasibility_tolerance': None, 'ipm_optimality_tolerance': None}, x0=None)
```

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using the HiGHS interior point solver.

Linear programming solves problems of the following form:

\[
\min_x \ c^T x \\
\text{such that } A_{ub} x \leq b_{ub}, \\
A_{eq} x = b_{eq}, \\
l \leq x \leq u,
\]

where \( x \) is a vector of decision variables; \( c, b_{ub}, b_{eq}, l, \) and \( u \) are vectors; and \( A_{ub} \) and \( A_{eq} \) are matrices.

Alternatively, that’s:

\[
\minimize \ c \odot x \\
\text{such that } A_{ub} \odot x \leq b_{ub} \\
A_{eq} \odot x = b_{eq} \\
lb \leq x \leq ub
\]

Note that by default \( lb = 0 \) and \( ub = None \) unless specified with \textit{bounds}.

Parameters

- **c** [1-D array] The coefficients of the linear objective function to be minimized.
- **A_ub** [2-D array, optional] The inequality constraint matrix. Each row of \( A_{ub} \) specifies the coefficients of a linear inequality constraint on \( x \).
- **b_ub** [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of \( A_{ub} @ x \).
- **A_eq** [2-D array, optional] The equality constraint matrix. Each row of \( A_{eq} \) specifies the coefficients of a linear equality constraint on \( x \).
- **b_eq** [1-D array, optional] The equality constraint vector. Each element of \( A_{eq} @ x \) must equal the corresponding element of \( b_{eq} \).
- **bounds** [sequence, optional] A sequence of (\textit{min}, \textit{max}) pairs for each element in \( x \), defining the minimum and maximum values of that decision variable. Use \textit{None} to indicate that there is no bound. By default, bounds are (0, None) (all decision variables are non-negative). If a single tuple (\textit{min}, \textit{max}) is provided, then \textit{min} and \textit{max} will serve as bounds for all decision variables.
- **method** [str] This is the method-specific documentation for ‘highs-ipm’. ‘highs-ipm’, ‘highs-ds’, ‘interior-point’ (default), ‘revised simplex’, and ‘simplex’ (legacy) are also available.

Returns

- **res** [OptimizeResult] A \texttt{scipy.optimize.OptimizeResult} consisting of the fields:

- **x** [1D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.
- **fun** [float] The optimal value of the objective function \( c \odot x \).
- **slack** [1D array] The (nominally positive) values of the slack, \( b_{ub} - A_{ub} \odot x \).
- **con** [1D array] The (nominally zero) residuals of the equality constraints, \( b_{eq} - A_{eq} \odot x \).
- **success** [bool] True when the algorithm succeeds in finding an optimal solution.
- **status** [int] An integer representing the exit status of the algorithm.
  - 0: Optimization terminated successfully.
  - 1: Iteration or time limit reached.
  - 2: Problem appears to be infeasible.
  - 3: Problem appears to be unbounded.
  - 4: The HiGHS solver ran into a problem.
- **message** [str] A string descriptor of the exit status of the algorithm.
- **nit** [int] The total number of iterations performed. For the HiGHS interior-point method, this does not include crossover iterations.
- **crossover_nit** [int] The number of primal/dual pushes performed during the crossover routine for the HiGHS interior-point method.
- **ineqlin** [OptimizeResult] Solution and sensitivity information corresponding to the inequality constraints, \( b_{ub} \).
  - **residual** [np.ndarray] The (nominally positive) values of the slack variables, \( b_{ub} - A_{ub} \odot x \). This quantity is also commonly referred to as “slack”.
  - **marginals** [np.ndarray] The sensitivity (partial derivative) of the objective function with respect to the right-hand side of the inequality constraints, \( b_{ub} \).
- **eqlin** [OptimizeResult] Solution and sensitivity information corresponding to the equality constraints, \( b_{eq} \).
  - **residual** [np.ndarray] The (nominally zero) residuals of the equality constraints, \( b_{eq} - A_{eq} \odot x \).
  - **marginals** [np.ndarray] The sensitivity (partial derivative) of the objective function with respect to the right-hand side of the equality constraints, \( b_{eq} \).
- **lower, upper** [OptimizeResult] Solution and sensitivity information corresponding to the lower and upper bounds on decision variables, \( bounds \).
  - **residual** [np.ndarray] The (nominally positive) values of the quantity \( x - lb \) (lower) or \( ub - x \) (upper).
  - **marginals** [np.ndarray] The sensitivity (partial derivative) of the objective function with respect to the lower and upper bounds.

*See also:*

For documentation for the rest of the parameters, see `scipy.optimize.linprog`

**Options**

- **maxiter** [int] The maximum number of iterations to perform in either phase. For ‘highs-ipm’, this does not include the number of crossover iterations. Default is the largest possible value for an int on the platform.
- **disp** [bool (default: False)] Set to True if indicators of optimization status are to be printed to the console during optimization.

3.3. API definition 1375

presolve  [bool (default: True)] Presolve attempts to identify trivial infeasibilities, identify trivial unboundedness, and simplify the problem before sending it to the main solver. It is generally recommended to keep the default setting True; set to False if presolve is to be disabled.

time_limit  [float] The maximum time in seconds allotted to solve the problem; default is the largest possible value for a double on the platform.

dual_feasibility_tolerance  [double (default: 1e-07)] The minimum of this and primal_feasibility_tolerance is used for the feasibility tolerance of 'highs-ipm'.

primal_feasibility_tolerance  [double (default: 1e-07)] The minimum of this and dual_feasibility_tolerance is used for the feasibility tolerance of 'highs-ipm'.

ipm_optimality_tolerance  [double (default: 1e-08)] Optimality tolerance for 'highs-ipm'. Minimum allowable value is 1e-12.

unknown_options  [dict] Optional arguments not used by this particular solver. If unknown_options is non-empty, a warning is issued listing all unused options.

Notes

Method 'highs-ipm' is a wrapper of a C++ implementation of an interior-point method [13]; it features a crossover routine, so it is as accurate as a simplex solver. Method 'highs-ds' is a wrapper of the C++ high performance dual revised simplex implementation (HSOL) [13], [14]. Method 'highs' chooses between the two automatically. For new code involving linprog, we recommend explicitly choosing one of these three method values instead of 'interior-point' (default), 'revised simplex', and 'simplex' (legacy).

The result fields ineqlin, eqlin, lower, and upper all contain marginals, or partial derivatives of the objective function with respect to the right-hand side of each constraint. These partial derivatives are also referred to as “Lagrange multipliers”, “dual values”, and “shadow prices”. The sign convention of marginals is opposite that of Lagrange multipliers produced by many nonlinear solvers.

linprog(method='highs-ds')

scipy.optimize.linprog(c, A_ub=None, b_ub=None, A_eq=None, b_eq=None, bounds=None, method='highs-ds', callback=None, options={'maxiter': None, 'disp': False, 'presolve': True, 'time_limit': None, 'dual_feasibility_tolerance': None, 'primal_feasibility_tolerance': None, 'simplex_dual_edge_weight_strategy': None}, x0=None)

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using the HiGHS dual simplex solver.

Linear programming solves problems of the following form:

\[
\min_x \ c^T x \\
\text{such that } A_{ub} x \leq b_{ub}, \quad A_{eq} x = b_{eq}, \quad l \leq x \leq u,
\]

where \( x \) is a vector of decision variables; \( c, b_{ub}, b_{eq}, l, \) and \( u \) are vectors; and \( A_{ub} \) and \( A_{eq} \) are matrices.
Alternatively, that’s:

```
minimize:
```

\[ c \odot x \]

such that:

\[
A_{ub} \odot x \leq b_{ub} \\
A_{eq} \odot x = b_{eq} \\
lb \leq x \leq ub
\]

Note that by default \( lb = 0 \) and \( ub = \text{None} \) unless specified with \textit{bounds}.

### Parameters

- \( c \) [1-D array] The coefficients of the linear objective function to be minimized.
- \( A_{ub} \) [2-D array, optional] The inequality constraint matrix. Each row of \( A_{ub} \) specifies the coefficients of a linear inequality constraint on \( x \).
- \( b_{ub} \) [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of \( A_{ub} \odot x \).
- \( A_{eq} \) [2-D array, optional] The equality constraint matrix. Each row of \( A_{eq} \) specifies the coefficients of a linear equality constraint on \( x \).
- \( b_{eq} \) [1-D array, optional] The equality constraint vector. Each element of \( A_{eq} \odot x \) must equal the corresponding element of \( b_{eq} \).
- \textit{bounds} [sequence, optional] A sequence of \((\text{min}, \text{max})\) pairs for each element in \( x \), defining the minimum and maximum values of that decision variable. Use \text{None} to indicate that there is no bound. By default, bounds are \((0, \text{None})\) (all decision variables are non-negative). If a single tuple \((\text{min}, \text{max})\) is provided, then \text{min} and \text{max} will serve as bounds for all decision variables.
- \textit{method} [str] This is the method-specific documentation for ‘highs-ds’, ‘highs’, ‘highs-ipm’, ‘interior-point’ (default), ‘revised simplex’, and ‘simplex’ (legacy) are also available.

### Returns

- \textit{res} [OptimizeResult] A \texttt{scipy.optimize.OptimizeResult} consisting of the fields:
  - \textit{x} [1D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.
  - \textit{fun} [float] The optimal value of the objective function \( c \odot x \).
  - \textit{slack} [1D array] The (nominally positive) values of the slack, \( b_{ub} - A_{ub} \odot x \).
  - \textit{con} [1D array] The (nominally zero) residuals of the equality constraints, \( b_{eq} - A_{eq} \odot x \).
  - \textit{success} [bool] \text{True} when the algorithm succeeds in finding an optimal solution.
  - \textit{status} [int] An integer representing the exit status of the algorithm.
    - 0 : Optimization terminated successfully.
    - 1 : Iteration or time limit reached.
    - 2 : Problem appears to be infeasible.
    - 3 : Problem appears to be unbounded.
    - 4 : The HiGHS solver ran into a problem.
  - \textit{message} [str] A string descriptor of the exit status of the algorithm.
  - \textit{nit} [int] The total number of iterations performed. This includes iterations in all phases.
  - \textit{crossover_nit} [int] This is always 0 for the HiGHS simplex method. For the HiGHS interior-point method, this is the number of primal/dual pushes performed during the crossover routine.
ineqlin  [OptimizeResult] Solution and sensitivity information corresponding to the inequality constraints, $b_{ub}$. A dictionary consisting of the fields:

residual  [np.ndarray] The (nominally positive) values of the slack variables, $b_{ub} - A_{ub} \times x$. This quantity is also commonly referred to as "slack".

marginals  [np.ndarray] The sensitivity (partial derivative) of the objective function with respect to the right-hand side of the inequality constraints, $b_{ub}$.

eqlin  [OptimizeResult] Solution and sensitivity information corresponding to the equality constraints, $b_{eq}$. A dictionary consisting of the fields:

residual  [np.ndarray] The (nominally zero) residuals of the equality constraints, $b_{eq} - A_{eq} \times x$.

marginals  [np.ndarray] The sensitivity (partial derivative) of the objective function with respect to the right-hand side of the equality constraints, $b_{eq}$.

lower, upper  [OptimizeResult] Solution and sensitivity information corresponding to the lower and upper bounds on decision variables, $bounds$.

residual  [np.ndarray] The (nominally positive) values of the quantity $x - lb$ (lower) or $ub - x$ (upper).

marginals  [np.ndarray] The sensitivity (partial derivative) of the objective function with respect to the lower and upper bounds $bounds$.

See also:

For documentation for the rest of the parameters, see scipy.optimize.linprog

### Options

- **maxiter**  [int] The maximum number of iterations to perform in either phase. Default is the largest possible value for an int on the platform.

- **disp**  [bool (default: False)] Set to True if indicators of optimization status are to be printed to the console during optimization.

- **presolve**  [bool (default: True)] Presolve attempts to identify trivial infeasibilities, identify trivial unboundedness, and simplify the problem before sending it to the main solver. It is generally recommended to keep the default setting True; set to False if presolve is to be disabled.

- **time_limit**  [float] The maximum time in seconds allotted to solve the problem; default is the largest possible value for a double on the platform.

- **dual_feasibility_tolerance**  [double (default: 1e-07)] Dual feasibility tolerance for 'highs-ds'.

- **primal_feasibility_tolerance**  [double (default: 1e-07)] Primal feasibility tolerance for 'highs-ds'.

- **simplex_dual_edge_weight_strategy**  [str (default: None)] Strategy for simplex dual edge weights. The default, None, automatically selects one of the following.

  - 'dantzig' uses Dantzig's original strategy of choosing the most negative reduced cost.
  - 'devex' uses the strategy described in [15].
  - 'steepest' uses the exact steepest edge strategy as described in [16].
  - 'steepest-devex' begins with the exact steepest edge strategy until the computation is too costly or inexact and then switches to the devex method.

  Currently, None always selects 'steepest-devex', but this may change as new options become available.

- **unknown_options**  [dict] Optional arguments not used by this particular solver. If unknown_options is non-empty, a warning is issued listing all unused options.
Notes

Method ‘highs-ds’ is a wrapper of the C++ high performance dual revised simplex implementation (HSOL) [13], [14]. Method ‘highs-ipm’ is a wrapper of a C++ implementation of an interior-point method [13]: it features a crossover routine, so it is as accurate as a simplex solver. Method ‘highs’ chooses between the two automatically.

For new code involving `linprog`, we recommend explicitly choosing one of these three method values instead of ‘interior-point’ (default), ‘revised simplex’, and ‘simplex’ (legacy).

The result fields `ineqlin`, `eqlin`, `lower`, and `upper` all contain marginals, or partial derivatives of the objective function with respect to the right-hand side of each constraint. These partial derivatives are also referred to as “Lagrange multipliers”, “dual values”, and “shadow prices”. The sign convention of marginals is opposite that of Lagrange multipliers produced by many nonlinear solvers.

`linprog(method='highs')`

```python
scipy.optimize.linprog(c, A_ub=None, b_ub=None, A_eq=None, b_eq=None, bounds=None, method='highs', callback=None, options={'maxiter': None, 'disp': False, 'presolve': True, 'time_limit': None, 'dual_feasibility_tolerance': None, 'primal_feasibility_tolerance': None, 'ipm_optimality_tolerance': None, 'simplex_dual_edge_weight_strategy': None}, x0=None)
```

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using one of the HiGHS solvers.

Linear programming solves problems of the following form:

\[
\min_x \; c^T x \\
\text{such that} \; A_{ub} x \leq b_{ub}, \\
\quad A_{eq} x = b_{eq}, \\
\quad l \leq x \leq u,
\]

where \( x \) is a vector of decision variables; \( c, b_{ub}, b_{eq}, l, \) and \( u \) are vectors; and \( A_{ub} \) and \( A_{eq} \) are matrices.

Alternatively, that’s:

minimize:

\[
c @ x
\]

such that:

\[
A_{ub} @ x \; \leq \; b_{ub} \\
A_{eq} @ x \; = \; b_{eq} \\
lb \; \leq \; x \; \leq \; ub
\]

Note that by default \( lb = 0 \) and \( ub = None \) unless specified with \( bounds \).

Parameters

- `c` : [1-D array] The coefficients of the linear objective function to be minimized.
- `b_ub` : [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of `A_ub @ x`.

3.3. API definition 1379

A_eq  [2-D array, optional] The equality constraint matrix. Each row of \( A_{eq} \) specifies the coefficients of a linear equality constraint on \( x \).

b_eq  [1-D array, optional] The equality constraint vector. Each element of \( A_{eq} @ x \) must equal the corresponding element of \( b_{eq} \).

bounds  [sequence, optional] A sequence of \((\text{min}, \text{max})\) pairs for each element in \( x \), defining the minimum and maximum values of that decision variable. Use \text{None} to indicate that there is no bound. By default, bounds are \((0, \text{None})\) (all decision variables are non-negative). If a single tuple \((\text{min}, \text{max})\) is provided, then \text{min} and \text{max} will serve as bounds for all decision variables.

method  [str] This is the method-specific documentation for ‘highs’, which chooses automatically between ‘highs-ds’ and ‘highs-ipm’. ‘interior-point’ (default), ‘revised simplex’, and ‘simplex’ (legacy) are also available.

Returns

res  [OptimizerResult] A \texttt{scipy.optimize.OptimizeResult} consisting of the fields:

\( x \)  [1D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.

\( \text{fun} \)  [float] The optimal value of the objective function \( c @ x \).

\( \text{slack} \)  [1D array] The (nominally positive) values of the slack, \( b_{ub} - A_{ub} @ x \).

\( \text{con} \)  [1D array] The (nominally zero) residuals of the equality constraints, \( b_{eq} - A_{eq} @ x \).

\( \text{success} \)  [bool] True when the algorithm succeeds in finding an optimal solution.

\( \text{status} \)  [int] An integer representing the exit status of the algorithm.

0 : Optimization terminated successfully.

1 : Iteration or time limit reached.

2 : Problem appears to be infeasible.

3 : Problem appears to be unbounded.

4 : The HiGHS solver ran into a problem.

\( \text{message} \)  [str] A string descriptor of the exit status of the algorithm.

\( \text{nit} \)  [int] The total number of iterations performed. For the HiGHS simplex method, this includes iterations in all phases. For the HiGHS interior-point method, this does not include crossover iterations.

\( \text{crossover_nit} \)  [int] The number of primal/dual pushes performed during the crossover routine for the HiGHS interior-point method. This is 0 for the HiGHS simplex method.

ineqlin  [OptimizerResult] Solution and sensitivity information corresponding to the inequality constraints, \( b_{ub} \). A dictionary consisting of the fields:

\( \text{residual} \)  [np.ndarray] The (nominally positive) values of the slack variables, \( b_{ub} - A_{ub} @ x \). This quantity is also commonly referred to as “slack”.

\( \text{marginals} \)  [np.ndarray] The sensitivity (partial derivative) of the objective function with respect to the right-hand side of the inequality constraints, \( b_{ub} \).

eqlin  [OptimizerResult] Solution and sensitivity information corresponding to the equality constraints, \( b_{eq} \). A dictionary consisting of the fields:

\( \text{residual} \)  [np.ndarray] The (nominally zero) residuals of the equality constraints, \( b_{eq} - A_{eq} @ x \).

\( \text{marginals} \)  [np.ndarray] The sensitivity (partial derivative) of the objective function with respect to the right-hand side of the equality constraints, \( b_{eq} \).

lower, upper  [OptimizerResult] Solution and sensitivity information corresponding to the lower and upper bounds on decision variables, \textit{bounds}. 

1380 Chapter 3. SciPy API
residual \([\text{npt.array}]\) The (nominally positive) values of the quantity \(x - lb\) (lower) or \(ub - x\) (upper).

marginals \([\text{npt.array}]\) The sensitivity (partial derivative) of the objective function with respect to the lower and upper bounds.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.linprog`

Options

maxiter \([\text{int}]\) The maximum number of iterations to perform in either phase. For ‘highs-ipm’, this does not include the number of crossover iterations. Default is the largest possible value for an int on the platform.

disp \([\text{bool (default: False)}]\) Set to True if indicators of optimization status are to be printed to the console during optimization.

presolve \([\text{bool (default: True)}]\) Presolve attempts to identify trivial infeasibilities, identify trivial unboundedness, and simplify the problem before sending it to the main solver. It is generally recommended to keep the default setting True; set to False if presolve is to be disabled.

time_limit \([\text{float}]\) The maximum time in seconds allotted to solve the problem; default is the largest possible value for a double on the platform.

dual_feasibility_tolerance \([\text{double (default: 1e-07)}]\) Dual feasibility tolerance for ‘highs-ds’. The minimum of this and primal_feasibility_tolerance is used for the feasibility tolerance of ‘highs-ipm’.

primal_feasibility_tolerance \([\text{double (default: 1e-07)}]\) Primal feasibility tolerance for ‘highs-ds’. The minimum of this and dual_feasibility_tolerance is used for the feasibility tolerance of ‘highs-ipm’.

ipm_optimality_tolerance \([\text{double (default: 1e-08)}]\) Optimality tolerance for ‘highs-ipm’. Minimum allowable value is 1e-12.

simplex_dual_edge_weight_strategy \([\text{str (default: None)}]\) Strategy for simplex dual edge weights. The default, None, automatically selects one of the following.

'dantzig' uses Dantzig’s original strategy of choosing the most negative reduced cost.
'develx' uses the strategy described in [15].
'steepest' uses the exact steepest edge strategy as described in [16].
'steepest-devex' begins with the exact steepest edge strategy until the computation is too costly or inexact and then switches to the develx method.
Currently, None always selects 'steepest-devex', but this may change as new options become available.

unknown_options \([\text{dict}]\) Optional arguments not used by this particular solver. If unknown_options is non-empty, a warning is issued listing all unused options.

Notes

Method ‘highs-ds’ is a wrapper of the C++ high performance dual revised simplex implementation (HSOL) [13], [14]. Method ‘highs-ipm’ is a wrapper of a C++ implementation of an interior-point method [13]; it features a crossover routine, so it is as accurate as a simplex solver. Method ‘highs’ chooses between the two automatically. For new code involving linprog, we recommend explicitly choosing one of these three method values instead of ‘interior-point’ (default), ‘revised simplex’, and ‘simplex’ (legacy).

The result fields ineqlin, eqlin, lower, and upper all contain marginals, or partial derivatives of the objective function with respect to the right-hand side of each constraint. These partial derivatives are also referred to as “Lagrange
multipliers”, “dual values”, and “shadow prices”. The sign convention of marginals is opposite that of Lagrange multipliers produced by many nonlinear solvers.

References

[13], [14], [15], [16]

The simplex, interior-point, and revised simplex methods support callback functions, such as:

\begin{verbatim}
linprog_verbose_callback(res) A sample callback function demonstrating the linprog callback interface.
\end{verbatim}

\begin{verbatim}
scipy.optimize.linprog_verbose_callback(res)
A sample callback function demonstrating the linprog callback interface. This callback produces detailed output to sys.stdout before each iteration and after the final iteration of the simplex algorithm.
\end{verbatim}

Parameters

- \texttt{res}:
  A \texttt{scipy.optimize.OptimizeResult} consisting of the following fields:
  - \texttt{x}:
    [1-D array] The independent variable vector which optimizes the linear programming problem.
  - \texttt{fun}:
    [float] Value of the objective function.
  - \texttt{success}:
    [bool] True if the algorithm succeeded in finding an optimal solution.
  - \texttt{slack}:
    [1-D array] The values of the slack variables. Each slack variable corresponds to an inequality constraint. If the slack is zero, then the corresponding constraint is active.
  - \texttt{con}:
    [1-D array] The (nominally zero) residuals of the equality constraints, that is, \( \mathbf{b} - \mathbf{A}_{eq} \mathbf{x} \).
  - \texttt{phase}:
    [int] The phase of the optimization being executed. In phase 1 a basic feasible solution is sought and the T has an additional row representing an alternate objective function.
  - \texttt{status}:
    [int] An integer representing the exit status of the optimization:

\begin{verbatim}
0 : Optimization terminated successfully
1 : Iteration limit reached
2 : Problem appears to be infeasible
3 : Problem appears to be unbounded
4 : Serious numerical difficulties encountered
\end{verbatim}

- \texttt{nit}:
  [int] The number of iterations performed.
- \texttt{message}:
  [str] A string descriptor of the exit status of the optimization.

Assignment problems

\begin{verbatim}
linear_sum_assignment(cost_matrix[, maximize])
Solve the linear sum assignment problem.
\end{verbatim}

\begin{verbatim}
quadratic_assignment(A, B[, method, options])
Approximates solution to the quadratic assignment problem and the graph matching problem.
\end{verbatim}
scipy.optimize.linear_sum_assignment

```python
scipy.optimize.linear_sum_assignment(cost_matrix, maximize=False)
```

Solve the linear sum assignment problem.

**Parameters**

- `cost_matrix`
  - [array] The cost matrix of the bipartite graph.

- `maximize`
  - [bool (default: False)] Calculates a maximum weight matching if true.

**Returns**

- `row_ind, col_ind`
  - [array] An array of row indices and one of corresponding column indices giving the optimal assignment. The cost of the assignment can be computed as `cost_matrix[row_ind, col_ind].sum()`. The row indices will be sorted; in the case of a square cost matrix they will be equal to `numpy.arange(cost_matrix.shape[0])`.

**See also:**

- `scipy.sparse.csgraph.min_weight_full_bipartite_matching` for sparse inputs

**Notes**

The linear sum assignment problem \[1\] is also known as minimum weight matching in bipartite graphs. A problem instance is described by a matrix $C$, where each $C[i,j]$ is the cost of matching vertex $i$ of the first partite set (a “worker”) and vertex $j$ of the second set (a “job”). The goal is to find a complete assignment of workers to jobs of minimal cost.

Formally, let $X$ be a boolean matrix where $X[i,j] = 1$ iff row $i$ is assigned to column $j$. Then the optimal assignment has cost

$$\min \sum_i \sum_j C_{i,j} X_{i,j}$$

where, in the case where the matrix $X$ is square, each row is assigned to exactly one column, and each column to exactly one row.

This function can also solve a generalization of the classic assignment problem where the cost matrix is rectangular. If it has more rows than columns, then not every row needs to be assigned to a column, and vice versa.

This implementation is a modified Jonker-Volgenant algorithm with no initialization, described in ref. \[2\].

New in version 0.17.0.

Examples

```python
>>> cost = np.array([[4, 1, 3], [2, 0, 5], [3, 2, 2]])
>>> from scipy.optimize import linear_sum_assignment
>>> row_ind, col_ind = linear_sum_assignment(cost)
>>> col_ind
array([1, 0, 2])
>>> cost[row_ind, col_ind].sum()
5
```

`scipy.optimize.quadratic_assignment`

`scipy.optimize.quadratic_assignment(A, B, method='faq', options=None)`

Approximates solution to the quadratic assignment problem and the graph matching problem.

Quadratic assignment solves problems of the following form:

\[
\min_{P} \text{trace}(A^T P B P^T)
\]

s.t. \(P \in \mathcal{P}\)

where \(\mathcal{P}\) is the set of all permutation matrices, and \(A\) and \(B\) are square matrices.

Graph matching tries to maximize the same objective function. This algorithm can be thought of as finding the alignment of the nodes of two graphs that minimizes the number of induced edge disagreements, or, in the case of weighted graphs, the sum of squared edge weight differences.

Note that the quadratic assignment problem is NP-hard. The results given here are approximations and are not guaranteed to be optimal.

Parameters

- **A** [2-D array, square] The square matrix \(A\) in the objective function above.
- **B** [2-D array, square] The square matrix \(B\) in the objective function above.
- **method** [str in {'faq', '2opt'} (default: 'faq')] The algorithm used to solve the problem. 'faq' (default) and '2opt' are available.
- **options** [dict, optional] A dictionary of solver options. All solvers support the following:
  - **maximize** [bool (default: False)] Maximizes the objective function if True.
  - **partial_match** [2-D array of integers, optional (default: None)] Fixes part of the matching. Also known as a “seed” [2]. Each row of `partial_match` specifies a pair of matched nodes: node `partial_match[i, 0]` of \(A\) is matched to node `partial_match[i, 1]` of \(B\). The array has shape \((m, 2)\), where \(m\) is not greater than the number of nodes, \(n\).
  - **rng** [{None, int, numpy.random.Generator, numpy.random.RandomState}, optional]
    If `seed` is None (or `np.random`), the `numpy.random.RandomState` singleton is used. If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already a `Generator` or `RandomState` instance then that instance is used.

Returns

- **res** [OptimizeResult] `OptimizeResult` containing the following fields.
  - **col_ind** [1-D array] Column indices corresponding to the best permutation found of the nodes of \(B\).
fun [float] The objective value of the solution.
nit [int] The number of iterations performed during optimization.

Notes

The default method 'faq' uses the Fast Approximate QAP algorithm [1]; it typically offers the best combination of speed and accuracy. Method '2opt' can be computationally expensive, but may be a useful alternative, or it can be used to refine the solution returned by another method.

References

[1], [2], [3]

Examples

```python
>>> from scipy.optimize import quadratic_assignment
>>> A = np.array([[0, 80, 150, 170], [80, 0, 130, 100],
...     [150, 130, 0, 120], [170, 100, 120, 0]])
>>> B = np.array([[0, 5, 2, 7], [0, 0, 3, 8],
...     [0, 0, 0, 3], [0, 0, 0, 0]])
>>> res = quadratic_assignment(A, B)
>>> print(res)
 col_ind: array([0, 3, 2, 1])
 fun: 3260
 nit: 9
```

The see the relationship between the returned col_ind and fun, use col_ind to form the best permutation matrix found, then evaluate the objective function \( f(P) = \text{trace}(A^T P B P^T) \).

```python
>>> perm = res['col_ind']
>>> P = np.eye(len(A), dtype=int)[perm]
>>> fun = np.trace(A.T @ P @ B @ P.T)
>>> print(fun)
3260
```

Alternatively, to avoid constructing the permutation matrix explicitly, directly permute the rows and columns of the distance matrix.

```python
>>> fun = np.trace(A.T @ B[perm][:, perm])
>>> print(fun)
3260
```

Although not guaranteed in general, quadratic_assignment happens to have found the globally optimal solution.

```python
>>> from itertools import permutations
>>> perm_opt, fun_opt = None, np.inf
>>> for perm in permutations([0, 1, 2, 3]):
...     perm = np.array(perm)
...     fun = np.trace(A.T @ B[perm][:, perm])
...     if fun < fun_opt:
```

(continues on next page)
Here is an example for which the default method, ‘faq’, does not find the global optimum.

```python
>>> A = np.array([[0, 5, 8, 6], [5, 0, 5, 1],
...                [8, 5, 0, 2], [6, 1, 2, 0]])
>>> B = np.array([[0, 1, 8, 4], [1, 0, 5, 2],
...                [8, 5, 0, 5], [4, 2, 5, 0]])
>>> res = quadratic_assignment(A, B)
>>> print(res)
  col_ind: array([1, 0, 3, 2])
  fun: 178
  nit: 13
```

If accuracy is important, consider using ‘2opt’ to refine the solution.

```python
>>> guess = np.array([np.arange(len(A)), res.col_ind]).T
>>> res = quadratic_assignment(A, B, method='2opt',
...                            options={'partial_guess': guess})
>>> print(res)
  col_ind: array([1, 2, 3, 0])
  fun: 176
  nit: 17
```

The `quadratic_assignment` function supports the following methods:

### `quadratic_assignment(method='faq')`

The function `scipy.optimize.quadratic_assignment` solves the Quadratic Assignment Problem (QAP) and the Graph Matching Problem (GMP) using the Fast Approximate QAP Algorithm (FAQ) [1].

Quadratic assignment solves problems of the following form:

\[
\min_P \ \text{trace}(A^T P B P^T) \\
\text{s.t. } P \in \mathcal{P}
\]

where \( \mathcal{P} \) is the set of all permutation matrices, and \( A \) and \( B \) are square matrices.

Graph matching tries to maximize the same objective function. This algorithm can be thought of as finding the alignment of the nodes of two graphs that minimizes the number of induced edge disagreements, or, in the case of weighted graphs, the sum of squared edge weight differences.

Note that the quadratic assignment problem is NP-hard. The results given here are approximations and are not guaranteed to be optimal.

**Parameters**

- **A** [2-D array, square] The square matrix \( A \) in the objective function above.
- **B** [2-D array, square] The square matrix \( B \) in the objective function above.
method [str in {'faq', '2opt'} (default: 'faq')] The algorithm used to solve the problem. This is the method-specific documentation for 'faq'. '2opt' is also available.

Returns

res [OptimizeResult] OptimizeResult containing the following fields.

- col_ind [1-D array] Column indices corresponding to the best permutation found of the nodes of $B$.
- fun [float] The objective value of the solution.
- nit [int] The number of Frank-Wolfe iterations performed.

See also:

For documentation for the rest of the parameters, see scipy.optimize.quadratic_assignment

Options

- maximize [bool (default: False)] Maximizes the objective function if True.
- partial_match [2-D array of integers, optional (default: None)] Fixes part of the matching. Also known as a “seed” [2].
  Each row of partial_match specifies a pair of matched nodes: node partial_match[i, 0] of $A$ is matched to node partial_match[i, 1] of $B$. The array has shape $(m, 2)$, where $m$ is not greater than the number of nodes, $n$.
- rng [None, int, numpy.random.Generator, numpy.random.RandomState], optional
  If seed is None (or np.random), the numpy.random.RandomState singleton is used.
  If seed is an int, a new RandomState instance is used, seeded with seed. If seed is already a Generator or RandomState instance then that instance is used.
- P0 [2-D array, “barycenter”, or “randomized” (default: “barycenter”)] Initial position. Must be a doubly-stochastic matrix [3].
  If the initial position is an array, it must be a doubly stochastic matrix of size $m' \times m'$ where $m' = n - m$.
  If "barycenter" (default), the initial position is the barycenter of the Birkhoff polytope (the space of doubly stochastic matrices). This is a $m' \times m'$ matrix with all entries equal to $1/m'$.
  If "randomized" the initial search position is $P_0 = (J + K)/2$, where $J$ is the barycenter and $K$ is a random doubly stochastic matrix.
- shuffle_input [bool (default: False)] Set to True to resolve degenerate gradients randomly. For non-degenerate gradients this option has no effect.
- maxiter [int, positive (default: 30)] Integer specifying the max number of Frank-Wolfe iterations performed.
- tol [float (default: 0.03)] Tolerance for termination. Frank-Wolfe iteration terminates when $\frac{||P_i - P_{i+1}||_F}{\sqrt{m'}} \leq tol$, where $i$ is the iteration number.
Notes

The algorithm may be sensitive to the initial permutation matrix (or search “position”) due to the possibility of several local minima within the feasible region. A barycenter initialization is more likely to result in a better solution than a single random initialization. However, calling `quadratic_assignment` several times with different random initializations may result in a better optimum at the cost of longer total execution time.

References

[1], [2], [3]

Examples

As mentioned above, a barycenter initialization often results in a better solution than a single random initialization.

```python
>>> from numpy.random import default_rng
>>> rng = default_rng()
>>> n = 15
>>> A = rng.random((n, n))
>>> B = rng.random((n, n))
>>> res = quadratic_assignment(A, B)  # FAQ is default method
>>> print(res.fun)
46.871483385480545  # may vary

>>> options = {"P0": "randomized"}  # use randomized initialization
>>> res = quadratic_assignment(A, B, options=options)
>>> print(res.fun)
47.224831071310625  # may vary
```

However, consider running from several randomized initializations and keeping the best result.

```python
>>> res = min([quadratic_assignment(A, B, options=options)
... for i in range(30)], key=lambda x: x.fun)
>>> print(res.fun)
46.671852533681516  # may vary
```

The ‘2-opt’ method can be used to further refine the results.

```python
>>> options = {"partial_guess": np.array([np.arange(n), res.col_ind]).T}
>>> res = quadratic_assignment(A, B, method="2opt", options=options)
>>> print(res.fun)
46.47160735721583  # may vary
```
quadratic_assignment(method='2opt')

scipy.optimize.quadratic_assignment (A, B, method='2opt', options={'maximize': False, 'rng': None, 'partial_match': None, 'partial_guess': None})

Solve the quadratic assignment problem (approximately).

This function solves the Quadratic Assignment Problem (QAP) and the Graph Matching Problem (GMP) using the 2-opt algorithm [1].

Quadratic assignment solves problems of the following form:

\[
\min_P \text{trace}(A^T B P P^T) \\
\text{s.t. } P \in \mathcal{P}
\]

where \( \mathcal{P} \) is the set of all permutation matrices, and \( A \) and \( B \) are square matrices.

Graph matching tries to maximize the same objective function. This algorithm can be thought of as finding the alignment of the nodes of two graphs that minimizes the number of induced edge disagreements, or, in the case of weighted graphs, the sum of squared edge weight differences.

Note that the quadratic assignment problem is NP-hard. The results given here are approximations and are not guaranteed to be optimal.

Parameters

- **A**: [2-D array, square] The square matrix \( A \) in the objective function above.
- **B**: [2-D array, square] The square matrix \( B \) in the objective function above.
- **method** [str in {'faq', '2opt'} (default: 'faq')] The algorithm used to solve the problem. This is the method-specific documentation for '2opt'. 'faq' is also available.

Returns

- **res** [OptimizeResult] OptimizerResult containing the following fields.
  - **col_ind** [1-D array] Column indices corresponding to the best permutation found of the nodes of \( B \).
  - **fun** [float] The objective value of the solution.
  - **nit** [int] The number of iterations performed during optimization.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.quadratic_assignment`

Options

- **maximize** [bool (default: False)] Maximizes the objective function if True.
- **rng** [[None, int, numpy.random.Generator], numpy.random.RandomState], optional
  - If `seed` is None (or `np.random`), the `numpy.random.RandomState` singleton is used.
  - If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already a `Generator` or `RandomState` instance then that instance is used.
- **partial_match** [2-D array of integers, optional (default: None)] Fixes part of the matching. Also known as a "seed" [2].
  - Each row of `partial_match` specifies a pair of matched nodes: node `partial_match[i, 0]` of \( A \) is matched to node `partial_match[i, 1]` of \( B \). The array has shape \((m, 2)\), where \( m \) is not greater than the number of nodes, \( n \).
- **partial_guess** [2-D array of integers, optional (default: None)] A guess for the matching between the two matrices. Unlike `partial_match`, `partial_guess` does not fix the indices; they are still free to be optimized.
Each row of `partial_guess` specifies a pair of matched nodes: node `partial_guess[i, 0]` of `A` is matched to node `partial_guess[i, 1]` of `B`. The array has shape `(m, 2)`, where `m` is not greater than the number of nodes, `n`.

**Notes**

This is a greedy algorithm that works similarly to bubble sort: beginning with an initial permutation, it iteratively swaps pairs of indices to improve the objective function until no such improvements are possible.

**Utilities**

**Finite-difference approximation**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>approx_fprime</code></td>
<td>Finite-difference approximation of the gradient of a scalar function.</td>
</tr>
<tr>
<td><code>check_grad</code></td>
<td>Check the correctness of a gradient function by comparing it against a (forward) finite-difference approximation of the gradient.</td>
</tr>
</tbody>
</table>

**scipy.optimize.approx_fprime**

`scipy.optimize.approx_fprime(xk, f, epsilon=1.4901161193847656e-08, *args)`

Finite-difference approximation of the gradient of a scalar function.

**Parameters**

- `xk` [array_like] The coordinate vector at which to determine the gradient of `f`.
- `f` [callable] The function of which to determine the gradient (partial derivatives). Should take `xk` as first argument, other arguments to `f` can be supplied in `*args`. Should return a scalar, the value of the function at `xk`.
- `epsilon` [{float, array_like}, optional] Increment to `xk` to use for determining the function gradient. If a scalar, uses the same finite difference delta for all partial derivatives. If an array, should contain one value per element of `xk`. Defaults to `sqrt(np.finfo(float).eps)`, which is approximately `1.49e-08`.
- `*args` [args, optional] Any other arguments that are to be passed to `f`.

**Returns**

**See also:**

- `check_grad` Check correctness of gradient function against approx_fprime.
Notes

The function gradient is determined by the forward finite difference formula:

\[
\frac{f(x_k[i] + \epsilon[i]) - f(x_k[i])}{\epsilon[i]}
\]

The main use of `approx_fprime` is in scalar function optimizers like `fmin_bfgs`, to determine numerically the Jacobian of a function.

Examples

```python
>>> from scipy import optimize
>>> def func(x, c0, c1):
...    "Coordinate vector `x` should be an array of size two."
...    return c0 * x[0]**2 + c1*x[1]**2

>>> x = np.ones(2)
>>> c0, c1 = (1, 200)
>>> eps = np.sqrt(np.finfo(float).eps)
>>> optimize.approx_fprime(x, func, [eps, np.sqrt(200) * eps], c0, c1)
array([ 2. , 400.00004198])
```

`scipy.optimize.check_grad`

`scipy.optimize.check_grad` (func, grad, x0, *args, epsilon=1.4901161193847656e-08, direction='all', seed=None)

Check the correctness of a gradient function by comparing it against a (forward) finite-difference approximation of the gradient.

Parameters

- **func** ([callable func(x0, *args)]) Function whose derivative is to be checked.
- **grad** ([callable grad(x0, *args)]) Gradient of `func`.
- **x0** ([ndarray]) Points to check `grad` against forward difference approximation of grad using `func`.
- **args** ([*args, optional]) Extra arguments passed to `func` and `grad`.
- **epsilon** ([float, optional]) Step size used for the finite difference approximation. It defaults to `sqrt(np.finfo(float).eps)`, which is approximately 1.49e-08.
- **direction** ([str, optional]) If set to 'random', then gradients along a random vector are used to check `grad` against forward difference approximation using `func`. By default it is 'all', in which case, all the one hot direction vectors are considered to check `grad`.
- **seed** ([None, int, numpy.random.Generator])
  - `numpy.random.RandomState`, optional
  - If `seed` is None (or `np.random`), the `numpy.random.RandomState` singleton is used. If `seed` is an int, a new RandomState instance is used, seeded with `seed`. If `seed` is already a Generator or RandomState instance then that instance is used. Specify `seed` for reproducing the return value from this function. The random numbers generated with this seed affect the random vector along which gradients are computed to check `grad`. Note that `seed` is only used when `direction` argument is set to 'random'.

Returns
err [float] The square root of the sum of squares (i.e., the 2-norm) of the difference between
grad(x0, *args) and the finite difference approximation of grad using func at the
points x0.

See also:
approx_fprime

Examples

```python
>>> def func(x):
...     return x[0]**2 - 0.5 * x[1]**3
>>> def grad(x):
...     return [2 * x[0], -1.5 * x[1]**2]
>>> from scipy.optimize import check_grad
>>> check_grad(func, grad, [1.5, -1.5])
2.9802322387695312e-08 # may vary
>>> rng = np.random.default_rng()
>>> check_grad(func, grad, [1.5, -1.5],
...             direction='random', seed=rng)
2.9802322387695312e-08
```

Line search

<table>
<thead>
<tr>
<th>bracket(func[, xa, xb, args, grow_limit, ...])</th>
<th>Bracket the minimum of the function.</th>
</tr>
</thead>
<tbody>
<tr>
<td>line_search(f, myfprime, xk, pk[, gfk,...])</td>
<td>Find alpha that satisfies strong Wolfe conditions.</td>
</tr>
</tbody>
</table>

scipy.optimize.bracket

scipy.optimize.bracket (func, xa=0.0, xb=1.0, args=(), grow_limit=110.0, maxiter=1000)
Bracket the minimum of the function.

Given a function and distinct initial points, search in the downhill direction (as defined by the initial points) and return new points xa, xb, xc that bracket the minimum of the function f(xa) > f(xb) < f(xc). It doesn’t always mean that obtained solution will satisfy xa<=x<=xb.

Parameters

- **func** [callable f(x,*args)] Objective function to minimize.
- **xa, xb** [float, optional] Bracketing interval. Defaults xa to 0.0, and xb to 1.0.
- **args** [tuple, optional] Additional arguments (if present), passed to func.
- **grow_limit** [float, optional] Maximum grow limit. Defaults to 110.0
- **maxiter** [int, optional] Maximum number of iterations to perform. Defaults to 1000.

Returns

- **xa, xb, xc** [float] Bracket.
- **fa, fb, fc** [float] Objective function values in bracket.
- **funcalls** [int] Number of function evaluations made.
Examples

This function can find a downward convex region of a function:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.optimize import bracket
>>> def f(x):
...     return 10*x**2 + 3*x + 5
>>> x = np.linspace(-2, 2)
>>> y = f(x)
>>> x, xb, xc, fa, fb, fc, funcalls = bracket(f, xa=init_xa, xb=init_xb)
>>> plt.axvline(x=init_xa, color="k", linestyle="--")
>>> plt.axvline(x=init_xb, color="k", linestyle="--")
>>> plt.plot(x, y, "-k")
>>> plt.plot(xa, fa, "bx")
>>> plt.plot(xb, fb, "rx")
>>> plt.plot(xc, fc, "bx")
>>> plt.show()
```

**scipy.optimize.line_search**

`scipy.optimize.line_search(f, myfprime, xk, pk, gfk=None, old_fval=None, old_old_fval=None, args=(), c1=0.0001, c2=0.9, amax=None, extra_condition=None, maxiter=10)`

Find alpha that satisfies strong Wolfe conditions.

**Parameters**

- `f` ([callable f(x,*args)]) Objective function.
- `myfprime` ([callable f'(x,*args)]) Objective function gradient.
- `xk` ([ndarray]) Starting point.
- `pk` ([ndarray]) Search direction.
- `gfk` ([ndarray, optional]) Gradient value for x=xk (xk being the current parameter estimate). Will be recomputed if omitted.
old_fval  [float, optional] Function value for x=xk. Will be recomputed if omitted.
old_old_fval
  [float, optional] Function value for the point preceding x=xk.
 args  [tuple, optional] Additional arguments passed to objective function.
c1  [float, optional] Parameter for Armijo condition rule.
c2  [float, optional] Parameter for curvature condition rule.
amax  [float, optional] Maximum step size
extra_condition  
  [callable, optional] A callable of the form `extra_condition(alpha, x, f, g)` returning a boolean. Arguments are the proposed step `alpha` and the corresponding `x`, `f` and `g` values. The line search accepts the value of `alpha` only if this callable returns `True`. If the callable returns `False` for the step length, the algorithm will continue with new iterates. The callable is only called for iterates satisfying the strong Wolfe conditions.
maxiter  [int, optional] Maximum number of iterations to perform.

**Returns**
alpha  [float or None] Alpha for which \(x_{new} = x_0 + alpha \times pk\), or None if the line search algorithm did not converge.
f = int] Number of function evaluations made.
ge = int] Number of gradient evaluations made.
new_fval  [float or None] New function value \(f(x_{new}) = f(x_0 + alpha \times pk)\), or None if the line search algorithm did not converge.
old_fval  [float] Old function value \(f(x_0)\).
new_slope  [float or None] The local slope along the search direction at the new value \(<myfprime(x_{new}), pk>\), or None if the line search algorithm did not converge.

**Notes**

**Examples**

```python
>>> from scipy.optimize import line_search

A objective function and its gradient are defined.
```n
```python
def obj_func(x):
...    return (x[0])**2+(x[1])**2
>>> def obj_grad(x):
...    return [2*x[0], 2*x[1]]

We can find alpha that satisfies strong Wolfe conditions.
```n
```python
>>> start_point = np.array([1.8, 1.7])
>>> search_gradient = np.array([-1.0, -1.0])
>>> line_search(obj_func, obj_grad, start_point, search_gradient)
(1.0, 2, 1, 1.1300000000000001, 6.13, [1.6, 1.4])
```

</tbody>
</table>

scipy.optimize.LbfgsInvHessProduct

class scipy.optimize.LbfgsInvHessProduct (*args, **kwargs)

Linear operator for the L-BFGS approximate inverse Hessian.

This operator computes the product of a vector with the approximate inverse of the Hessian of the objective function, using the L-BFGS limited memory approximation to the inverse Hessian, accumulated during the optimization.

Objects of this class implement the scipy.sparse.linalg.LinearOperator interface.

Parameters

- sk [array_like, shape=(n_corr, n)] Array of n_corr most recent updates to the solution vector. (See [1]).
- yk [array_like, shape=(n_corr, n)] Array of n_corr most recent updates to the gradient. (See [1]).

References

[1]

Attributes

- H Hermitian adjoint.
- T Transpose this linear operator.

Methods

- __call__(x) Call self as a function.
- adjoint() Hermitian adjoint.
- dot(x) Matrix-matrix or matrix-vector multiplication.
- matmat(X) Matrix-matrix multiplication.
- matvec(x) Matrix-vector multiplication.
- rmatmat(X) Adjoint matrix-matrix multiplication.
- rmatvec(x) Adjoint matrix-vector multiplication.
- todense() Return a dense array representation of this operator.
- transpose() Transpose this linear operator.
scipy.optimize.LbfgsInvHessProduct.__call__

LbfgsInvHessProduct.__call__(x)
Call self as a function.

scipy.optimize.LbfgsInvHessProduct.adjoint

LbfgsInvHessProduct.adjoint()
Hermitian adjoint.
Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.
Can be abbreviated self.H instead of self.adjoint().

Returns

scipy.optimize.LbfgsInvHessProduct.dot

LbfgsInvHessProduct.dot(x)
Matrix-matrix or matrix-vector multiplication.

Parameters
x [array_like] 1-d or 2-d array, representing a vector or matrix.

Returns
Ax [array] 1-d or 2-d array (depending on the shape of x) that represents the result of applying this linear operator on x.

scipy.optimize.LbfgsInvHessProduct.matmat

LbfgsInvHessProduct.matmat(X)
Matrix-matrix multiplication.
Performs the operation y=A*X where A is an MxN linear operator and X dense N*K matrix or ndarray.

Parameters
X [matrix, ndarray] An array with shape (N,K).

Returns
Y [matrix, ndarray] A matrix or ndarray with shape (M,K) depending on the type of the X argument.
Notes

This matmat wraps any user-specified matmat routine or overridden _matmat method to ensure that y has the correct type.

scipy.optimize.LbfgsInvHessProduct.matvec

LbfgsInvHessProduct.matvec(x)
Matrix-vector multiplication.

Performs the operation \( y = A \times x \) where \( A \) is an MxN linear operator and \( x \) is a column vector or 1-d array.

Parameters

- \( x \)
  - [matrix, ndarray]] An array with shape (N,) or (N,1).

Returns

- \( y \)
  - [matrix, ndarray]] A matrix or ndarray with shape (M,) or (M,1) depending on the type and shape of the \( x \) argument.

Notes

This matvec wraps the user-specified matvec routine or overridden _matvec method to ensure that y has the correct shape and type.

scipy.optimize.LbfgsInvHessProduct.rmatmat

LbfgsInvHessProduct.rmatmat(X)
Adjoint matrix-matrix multiplication.

Performs the operation \( y = A^H \times x \) where \( A \) is an MxN linear operator and \( x \) is a column vector or 1-d array, or 2-d array. The default implementation defers to the adjoint.

Parameters

- \( X \)
  - [matrix, ndarray]] A matrix or 2D array.

Returns

- \( Y \)
  - [matrix, ndarray]] A matrix or 2D array depending on the type of the input.

Notes

This rmatmat wraps the user-specified rmatmat routine.
**scipy.optimize.LbfgsInvHessProduct.rmatvec**

LbfgsInvHessProduct.rmatvec(x)

Adjoint matrix-vector multiplication.

Performs the operation \( y = A^H \times x \) where \( A \) is an \( M \times N \) linear operator and \( x \) is a column vector or 1-d array.

**Parameters**

- **x**
  - [matrix, ndarray] An array with shape \((M,)\) or \((M,1)\).

**Returns**

- **y**
  - [matrix, ndarray] A matrix or ndarray with shape \((N,)\) or \((N,1)\) depending on the type and shape of the \( x \) argument.

**Notes**

This rmatvec wraps the user-specified rmatvec routine or overridden \_rmatvec method to ensure that \( y \) has the correct shape and type.

**scipy.optimize.LbfgsInvHessProduct.todense**

LbfgsInvHessProduct.todense()

Return a dense array representation of this operator.

**Returns**

- **arr**
  - [ndarray, shape=(n, n)] An array with the same shape and containing the same data represented by this LinearOperator.

**scipy.optimize.LbfgsInvHessProduct.transpose**

LbfgsInvHessProduct.transpose()

Transpose this linear operator.

Returns a LinearOperator that represents the transpose of this one. Can be abbreviated self.T instead of self.transpose().

**scipy.optimize.HessianUpdateStrategy**

class scipy.optimize.HessianUpdateStrategy

Interface for implementing Hessian update strategies.

Many optimization methods make use of Hessian (or inverse Hessian) approximations, such as the quasi-Newton methods BFGS, SR1, L-BFGS. Some of these approximations, however, do not actually need to store the entire matrix or can compute the internal matrix product with a given vector in a very efficiently manner. This class serves as an abstract interface between the optimization algorithm and the quasi-Newton update strategies, giving freedom of implementation to store and update the internal matrix as efficiently as possible. Different choices of initialization and update procedure will result in different quasi-Newton strategies.

Four methods should be implemented in derived classes: initialize, update, dot and get_matrix.
Notes

Any instance of a class that implements this interface, can be accepted by the method `minimize` and used by the compatible solvers to approximate the Hessian (or inverse Hessian) used by the optimization algorithms.

Methods

<table>

### scipy.optimize.HessianUpdateStrategy.dot

`HessianUpdateStrategy.dot(p)`  
Compute the product of the internal matrix with the given vector.

**Parameters**
- `p` [array_like] 1-D array representing a vector.

**Returns**
- `Hp` [array] 1-D represents the result of multiplying the approximation matrix by vector p.

### scipy.optimize.HessianUpdateStrategy.get_matrix

`HessianUpdateStrategy.get_matrix()`  
Return current internal matrix.

**Returns**
- `H` [ndarray, shape (n, n)] Dense matrix containing either the Hessian or its inverse (depending on how `approx_type` is defined).

### scipy.optimize.HessianUpdateStrategy.initialize

`HessianUpdateStrategy.initialize(n, approx_type)`  
Initialize internal matrix.

Allocate internal memory for storing and updating the Hessian or its inverse.

**Parameters**
- `n` [int] Problem dimension.
- `approx_type` [[`'hess'`, `'inv_hess'`]] Selects either the Hessian or the inverse Hessian. When set to `hess` the Hessian will be stored and updated. When set to `inv_hess` its inverse will be used instead.
scipy.optimize.HessianUpdateStrategy.update

HessianUpdateStrategy.update(delta_x, delta_grad)
Update internal matrix.
Update Hessian matrix or its inverse (depending on how ‘approx_type’ is defined) using information about
the last evaluated points.

Parameters

delta_x: [ndarray] The difference between two points the gradient function have been evaluated
at: delta_x = x2 - x1.
delta_grad: [ndarray] The difference between the gradients: delta_grad = grad(x2) -
grad(x1).

Benchmark problems

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>

scipy.optimize.rosen

scipy.optimize.rosen(x)
The Rosenbrock function.
The function computed is:

\[
\sum(100.0 \ast (x[1:] - x[:-1]**2.0)**2.0 + (1 - x[:-1])**2.0)
\]

Parameters

x: [array_like] 1-D array of points at which the Rosenbrock function is to be computed.

Returns

f: [float] The value of the Rosenbrock function.

See also:

rosen_der, rosen_hess, rosen_hess_prod
Examples

```python
>>> from scipy.optimize import rosen
>>> X = 0.1 * np.arange(10)
>>> rosen(X)
76.56
```

For higher-dimensional input `rosen` broadcasts. In the following example, we use this to plot a 2D landscape. Note that `rosen_hess` does not broadcast in this manner.

```python
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.mplot3d import Axes3D
>>> x = np.linspace(-1, 1, 50)
>>> X, Y = np.meshgrid(x, x)
>>> ax = plt.subplot(111, projection='3d')
>>> ax.plot_surface(X, Y, rosen([X, Y]))
>>> plt.show()
```

### scipy.optimize.rosen_der

`scipy.optimize.rosen_der(x)`

The derivative (i.e. gradient) of the Rosenbrock function.

**Parameters**

- `x` : [array_like] 1-D array of points at which the derivative is to be computed.

**Returns**

- `rosen_der` : [(N,) ndarray] The gradient of the Rosenbrock function at `x`.

**See also:**

- `rosen`, `rosen_hess`, `rosen_hess_prod`
**Examples**

```python
>>> from scipy.optimize import rosen_der
>>> X = 0.1 * np.arange(9)
>>> rosen_der(X)
array([-2., 10.6, 15.6, 13.4, 6.4, -3., -12.4, -19.4, 62.])
```

`scipy.optimize.rosen_hess`

`scipy.optimize.rosen_hess(x)`

The Hessian matrix of the Rosenbrock function.

**Parameters**

- **x** [array_like] 1-D array of points at which the Hessian matrix is to be computed.

**Returns**

- **rosen_hess** [ndarray] The Hessian matrix of the Rosenbrock function at `x`.

See also:

- `rosen`, `rosen_der`, `rosen_hess_prod`

**Examples**

```python
>>> from scipy.optimize import rosen_hess
>>> X = 0.1 * np.arange(4)
>>> rosen_hess(X)
array([[-38., 0., 0., 0.],
       [ 0., 134., -40., 0.],
       [ 0., -40., 130., -80.],
       [ 0., 0., -80., 200.]])
```

`scipy.optimize.rosen_hess_prod`

`scipy.optimize.rosen_hess_prod(x, p)`

Product of the Hessian matrix of the Rosenbrock function with a vector.

**Parameters**

- **x** [array_like] 1-D array of points at which the Hessian matrix is to be computed.
- **p** [array_like] 1-D array, the vector to be multiplied by the Hessian matrix.

**Returns**

- **rosen_hess_prod** [ndarray] The Hessian matrix of the Rosenbrock function at `x` multiplied by the vector `p`.

See also:

- `rosen`, `rosen_der`, `rosen_hess`
Examples

```python
>>> from scipy.optimize import rosen_hess_prod
>>> X = 0.1 * np.arange(9)
>>> p = 0.5 * np.arange(9)
>>> rosen_hess_prod(X, p)
array([-0., 27., -10., -95., -192., -265., -278., -195., -180.])
```

Legacy functions

The functions below are not recommended for use in new scripts; all of these methods are accessible via a newer, more consistent interfaces, provided by the interfaces above.

Optimization

General-purpose multivariate methods:

- `fmin(func, x0[, args, xtol, ftol, maxiter, ...])`: Minimize a function using the downhill simplex algorithm.
- `fmin_powell(func, x0[, args, xtol, ftol, ...])`: Minimize a function using modified Powell’s method.
- `fmin_cg(f, x0[, fprime, args, gtol, norm, ...])`: Minimize a function using a nonlinear conjugate gradient algorithm.
- `fmin_bfgs(f, x0[, fprime, args, gtol, norm, ...])`: Minimize a function using the BFGS algorithm.
- `fmin_ncg(f, x0[, fprime[, fhess_p, fhess, ...]])`: Unconstrained minimization of a function using the Newton-CG method.

`scipy.optimize.fmin`

- `scipy.optimize.fmin(func, x0, args=(), xtol=0.0001, ftol=0.0001, maxiter=None, maxfun=None, full_output=0, disp=1, retall=0, callback=None, initial_simplex=None)`

Minimize a function using the downhill simplex algorithm.

This algorithm only uses function values, not derivatives or second derivatives.

**Parameters**

- `func` [callable func(x,*args)] The objective function to be minimized.
- `x0` [ndarray] Initial guess.
- `args` [tuple, optional] Extra arguments passed to func, i.e., f(x,*args).
- `xtol` [float, optional] Absolute error in xopt between iterations that is acceptable for convergence.
- `ftol` [number, optional] Absolute error in func(xopt) between iterations that is acceptable for convergence.
- `maxiter` [int, optional] Maximum number of iterations to perform.
- `maxfun` [number, optional] Maximum number of function evaluations to make.
- `full_output` [bool, optional] Set to True if fopt and warnflag outputs are desired.
- `disp` [bool, optional] Set to True to print convergence messages.
- `retall` [bool, optional] Set to True to return list of solutions at each iteration.
- `callback` [callable, optional] Called after each iteration, as callback(xk), where xk is the current parameter vector.
initial_simplex
[array_like of shape (N + 1, N), optional] Initial simplex. If given, overrides x0.
initial_simplex[j, :] should contain the coordinates of the jth vertex of the N+1
vertices in the simplex, where N is the dimension.

Returns
xopt [ndarray] Parameter that minimizes function.
fopt [float] Value of function at minimum: fopt = func(xopt).
iter [int] Number of iterations performed.
funcalls [int] Number of function calls made.
warnflag [int] 1: Maximum number of function evaluations made. 2: Maximum number of iterations
reached.
allvecs [list] Solution at each iteration.

See also:
minimize
Interface to minimization algorithms for multivariate functions. See the ‘Nelder-Mead’ method in particular.

Notes
Uses a Nelder-Mead simplex algorithm to find the minimum of function of one or more variables.
This algorithm has a long history of successful use in applications. But it will usually be slower than an algorithm
that uses first or second derivative information. In practice, it can have poor performance in high-dimensional
problems and is not robust to minimizing complicated functions. Additionally, there currently is no complete
theory describing when the algorithm will successfully converge to the minimum, or how fast it will if it does. Both
the ftol and xtol criteria must be met for convergence.

[1], [2]

Examples

```python
>>> def f(x):
    ...    return x**2

>>> from scipy import optimize

>>> minimum = optimize.fmin(f, 1)
Optimization terminated successfully.
    Current function value: 0.000000
    Iterations: 17
    Function evaluations: 34
>>> minimum[0]
-8.8817841970012523e-16
```
scipy.optimize.fmin_powell

`scipy.optimize.fmin_powell(func, x0, args=(), xtol=0.0001, ftol=0.0001, maxiter=None, maxfun=None, full_output=0, disp=1, retall=0, callback=None, direc=None)`

Minimize a function using modified Powell’s method.

This method only uses function values, not derivatives.

**Parameters**

- `func` ([callable f(x,*args)]) Objective function to be minimized.
- `x0` ([ndarray]) Initial guess.
- `args` ([tuple, optional]) Extra arguments passed to func.
- `xtol` ([float, optional]) Line-search error tolerance.
- `ftol` ([float, optional]) Relative error in `func(xopt)` acceptable for convergence.
- `maxiter` ([int, optional]) Maximum number of iterations to perform.
- `maxfun` ([int, optional]) Maximum number of function evaluations to make.
- `full_output` ([bool, optional]) If True, `fopt, xi, direc, iter, funcalls, and warnflag` are returned.
- `disp` ([bool, optional]) If True, print convergence messages.
- `retall` ([bool, optional]) If True, return a list of the solution at each iteration.
- `callback` ([callable, optional]) An optional user-supplied function, called after each iteration. Called as `callback(xk)`, where `xk` is the current parameter vector.
- `direc` ([ndarray, optional]) Initial fitting step and parameter order set as an (N, N) array, where N is the number of fitting parameters in `x0`. Defaults to step size 1.0 fitting all parameters simultaneously (`np.eye((N, N))`). To prevent initial consideration of values in a step or to change initial step size, set to 0 or desired step size in the Jth position in the Mth block, where J is the position in `x0` and M is the desired evaluation step, with steps being evaluated in index order. Step size and ordering will change freely as minimization proceeds.

**Returns**

- `xopt` ([ndarray]) Parameter which minimizes `func`.
- `fopt` ([number]) Value of function at minimum: `fopt = func(xopt)`.
- `direc` ([ndarray]) Current direction set.
- `iter` ([int]) Number of iterations.
- `funcalls` ([int]) Number of function calls made.
- `warnflag` ([int])
  - `1` : Maximum number of function evaluations.
  - `2` : Maximum number of iterations.
  - `3` : NaN result encountered.
  - `4` : The result is out of the provided bounds.
- `allvecs` ([list]) List of solutions at each iteration.

See also:

- `minimize`

Interface to unconstrained minimization algorithms for multivariate functions. See the ‘Powell’ method in particular.
Notes

Uses a modification of Powell’s method to find the minimum of a function of N variables. Powell’s method is a conjugate direction method.

The algorithm has two loops. The outer loop merely iterates over the inner loop. The inner loop minimizes over each current direction in the direction set. At the end of the inner loop, if certain conditions are met, the direction that gave the largest decrease is dropped and replaced with the difference between the current estimated x and the estimated x from the beginning of the inner-loop.

The technical conditions for replacing the direction of greatest increase amount to checking that

1. No further gain can be made along the direction of greatest increase from that iteration.
2. The direction of greatest increase accounted for a large sufficient fraction of the decrease in the function value from that iteration of the inner loop.

Examples

```python
>>> def f(x):
...     return x**2

>>> from scipy import optimize

>>> minimum = optimize.fmin_powell(f, -1)
Optimization terminated successfully.
         Current function value: 0.000000
         Iterations: 2
         Function evaluations: 18

>>> minimum
array(0.0)
```

scipy.optimize.fmin_cg

scipy.optimize.fmin_cg(f, x0, fprime=None, args=(), gtol=1e-05, norm=inf, epsilon=1.4901161193847656e-08, maxiter=None, full_output=0, disp=1, retall=0, callback=None)

Minimize a function using a nonlinear conjugate gradient algorithm.

**Parameters**

- `f` : [callable, f(x, *args)] Objective function to be minimized. Here x must be a 1-D array of the variables that are to be changed in the search for a minimum, and args are the other (fixed) parameters of f.

**x0**  
[ndarray] A user-supplied initial estimate of *xopt*, the optimal value of *x*. It must be a 1-D array of values.

**fprime**  
[callable, fprime(x, *args), optional] A function that returns the gradient of *f* at *x*. Here *x* and *args* are as described above for *f*. The returned value must be a 1-D array. Defaults to None, in which case the gradient is approximated numerically (see *epsilon*, below).

**args**  
[tuple, optional] Parameter values passed to *f* and *fprime*. Must be supplied whenever additional fixed parameters are needed to completely specify the functions *f* and *fprime*.

**gtol**  
[float, optional] Stop when the norm of the gradient is less than *gtol*.

**norm**  
[float, optional] Order to use for the norm of the gradient (-np.Inf is min, np.Inf is max).

**epsilon**  
[float or ndarray, optional] Step size(s) to use when *fprime* is approximated numerically. Can be a scalar or a 1-D array. Defaults to *sqrt(np epsilon)*, with eps the floating point machine precision. Usually *sqrt(epsei)* is about 1.5e-8.

**maxiter**  
[int, optional] Maximum number of iterations to perform. Default is 200 * len(x0).

**full_output**  
[bool, optional] If True, return *fopt*, *func_calls*, *grad_calls*, and *warnflag* in addition to *xopt*. See the Returns section below for additional information on optional return values.

**disp**  
[bool, optional] If True, return a convergence message, followed by *xopt*.

**retall**  
[bool, optional] If True, add to the returned values the results of each iteration. Called as *callback(xk)*, where *xk* is the current value of *x0*.

**callback**  
[callable, optional] An optional user-supplied function, called after each iteration. Called as *callback(xk)*, where *xk* is the current value of *x0*.

### Returns

**xopt**  
[ndarray] Parameters which minimize *f*, i.e., *f(xopt) == fopt*. Only returned if *full_output* is True.

**fopt**  
[float, optional] Minimum value found, *f(xopt)*. Only returned if *full_output* is True.

**func_calls**  
[int, optional] The number of function calls made. Only returned if *full_output* is True.

**grad_calls**  
[int, optional] The number of gradient calls made. Only returned if *full_output* is True.

**warnflag**  
[int, optional] Integer value with warning status, only returned if *full_output* is True.  
0 : Success.  
1 : The maximum number of iterations was exceeded.  
2 : Gradient and/or function calls were not changing. May indicate that precision was lost, i.e., the routine did not converge.  
3 : NaN result encountered.

**allvecs**  
[list of ndarray, optional] List of arrays, containing the results at each iteration. Only returned if *retall* is True.

**See also:**

*minimize*  
common interface to all *scipy.optimize* algorithms for unconstrained and constrained minimization of multivariate functions. It provides an alternative way to call *fmin_cg*, by specifying *method='CG'*.  

### Notes

This conjugate gradient algorithm is based on that of Polak and Ribiere [1].

Conjugate gradient methods tend to work better when:

1. *f* has a unique global minimizing point, and no local minima or other stationary points,
2. *f* is, at least locally, reasonably well approximated by a quadratic function of the variables,
3. *f* is continuous and has a continuous gradient,
4. *fprime* is not too large, e.g., has a norm less than 1000,
5. The initial guess, $x_0$, is reasonably close to $f$’s global minimizing point, $x_{opt}$.

[1]

Examples

Example 1: seek the minimum value of the expression $a \cdot u^2 + b \cdot u \cdot v + c \cdot v^2 + d \cdot u + e \cdot v + f$ for given values of the parameters and an initial guess $(u, v) = (0, 0)$.

```python
>>> args = (2, 3, 7, 8, 9, 10) # parameter values
>>> def f(x, *args):
...    u, v = x
...    a, b, c, d, e, f = args
...    return a*u**2 + b*u*v + c*v**2 + d*u + e*v + f
>>> def gradf(x, *args):
...    u, v = x
...    a, b, c, d, e, f = args
...    gu = 2*a*u + b*v + d  # u-component of the gradient
...    gv = b*u + 2*c*v + e  # v-component of the gradient
...    return np.asarray((gu, gv))
>>> x0 = np.asarray((0, 0)) # Initial guess.
>>> from scipy import optimize
>>> res1 = optimize.fmin_cg(f, x0, fprime=gradf, args=args)
Optimization terminated successfully.
Current function value: 1.617021
Iterations: 4
Function evaluations: 8
Gradient evaluations: 8
>>> res1
array([-1.80851064, -0.25531915])
```

Example 2: solve the same problem using the `minimize` function. (This `myopts` dictionary shows all of the available options, although in practice only non-default values would be needed. The returned value will be a dictionary.)

```python
>>> opts = {'maxiter': None,  # default value.
...         'disp': True,  # non-default value.
...         'gtol': 1e-5,  # default value.
...         'norm': np.inf,  # default value.
...         'eps': 1.4901161193847656e-08}  # default value.
>>> res2 = optimize.minimize(f, x0, jac=gradf, args=args,
...                           method='CG', options=opts)
Optimization terminated successfully.
Current function value: 1.617021
Iterations: 4
Function evaluations: 8
Gradient evaluations: 8
>>> res2.x  # minimum found
array([-1.80851064, -0.25531915])
```
Minimize a function using the BFGS algorithm.

**Parameters**

- **f**
  - [callable f(x, *args)] Objective function to be minimized.
- **x0**
  - [ndarray] Initial guess.
- **fprime**
  - [callable f'(x, *args), optional] Gradient of f.
- **args**
  - [tuple, optional] Extra arguments passed to f and fprime.
- **gtol**
  - [float, optional] Gradient norm must be less than gtol before successful termination.
- **norm**
  - [float, optional] Order of norm (Inf is max, -Inf is min)
- **epsilon**
  - [int or ndarray, optional] If fprime is approximated, use this value for the step size.
- **callback**
  - [callable, optional] An optional user-supplied function to call after each iteration. Called as callback(xk), where xk is the current parameter vector.
- **maxiter**
  - [int, optional] Maximum number of iterations to perform.
- **full_output**
  - [bool, optional] If True, return fopt, func_calls, grad_calls, and warnflag in addition to xopt.
- **disp**
  - [bool, optional] Print convergence message if True.
- **retall**
  - [bool, optional] Return a list of results at each iteration if True.

**Returns**

- **xopt**
  - [ndarray] Parameters which minimize f, i.e., f(xopt) == fopt.
- **fopt**
  - [float] Minimum value.
- **gopt**
  - [ndarray] Value of gradient at minimum, f'(xopt), which should be near 0.
- **Bopt**
  - [ndarray] Value of 1/f''(xopt), i.e., the inverse Hessian matrix.
- **func_calls**
  - [int] Number of function_calls made.
- **grad_calls**
  - [int] Number of gradient calls made.
- **warnflag**
  - [integer] 1: Maximum number of iterations exceeded. 2: Gradient and/or function calls not changing. 3: NaN result encountered.
- **allvecs**
  - [list] The value of xopt at each iteration. Only returned if retall is True.

**See also:**

- **minimize**

  Interface to minimization algorithms for multivariate functions. See method='BFGS' in particular.

**Notes**

Optimize the function, f, whose gradient is given by fprime using the quasi-Newton method of Broyden, Fletcher, Goldfarb, and Shanno (BFGS).

  Function evaluations: 24    # may vary
  Gradient evaluations: 8   # may vary
array([[ 2.85169950e-06, -4.61820139e-07]])

>>> def quadratic_cost_grad(x, Q):
...     return 2 * Q @ x
...
>>> fmin_bfgs(quadratic_cost, x0, quadratic_cost_grad, args=(cost_weight,))
Optimization terminated successfully.
  Current function value: 0.000000
  Iterations: 7
  Function evaluations: 8
  Gradient evaluations: 8
array([[ 2.85916637e-06, -4.54371951e-07]])
```

**scipy.optimize.fmin_ncg**

`scipy.optimize.fmin_ncg(f, x0, fprime=None, fhess_p=None, fhess=None, args=(), avextol=1e-05, epsilon=1.4901161193847656e-08, maxiter=None, full_output=0, disp=1, retall=0, callback=None)`

Unconstrained minimization of a function using the Newton-CG method.

**Parameters**

- **f**: [callable f(x, *args)](https://www.example.com) Objective function to be minimized.
- **x0**: [ndarray] Initial guess.
- **fprime**: [callable f'(x, *args)](https://www.example.com) Gradient of f.
- **fhess_p**: [callable fhess_p(x, p, *args), optional] Function which computes the Hessian of f times an arbitrary vector, p.
- **fhess**: [callable fhess(x, *args), optional] Function to compute the Hessian matrix of f.
- **args**: [tuple, optional] Extra arguments passed to f, fprime, fhess_p, and fhess (the same set of extra arguments is supplied to all of these functions).
- **epsilon**: [float or ndarray, optional] If fhess is approximated, use this value for the step size.
callback [callable, optional] An optional user-supplied function which is called after each iteration. Called as callback(xk), where xk is the current parameter vector.

avextol [float, optional] Convergence is assumed when the average relative error in the minimizer falls below this amount.

maxiter [int, optional] Maximum number of iterations to perform.

full_output [bool, optional] If True, return the optional outputs.

disp [bool, optional] If True, print convergence message.

retall [bool, optional] If True, return a list of results at each iteration.

Returns

xopt [ndarray] Parameters which minimize f, i.e., f(xopt) == fopt.
fopt [float] Value of the function at xopt, i.e., fopt = f(xopt).
fcalls [int] Number of function calls made.
gcalls [int] Number of gradient calls made.
hcalls [int] Number of Hessian calls made.
allvecs [list] The result at each iteration, if retall is True (see below).

See also:

minimize

Interface to minimization algorithms for multivariate functions. See the ‘Newton-CG’ method in particular.

Notes

Only one of fhess_p or fhess need to be given. If fhess is provided, then fhess_p will be ignored. If neither fhess nor fhess_p is provided, then the hessian product will be approximated using finite differences on fprime. fhess_p must compute the hessian times an arbitrary vector. If it is not given, finite-differences on fprime are used to compute it.

Newton-CG methods are also called truncated Newton methods. This function differs from scipy.optimize.fmin_tnc because

1. scipy.optimize.fmin_ncg is written purely in Python using NumPy

   and scipy while scipy.optimize.fmin_tnc calls a C function.

2. scipy.optimize.fmin_ncg is only for unconstrained minimization

   while scipy.optimize.fmin_tnc is for unconstrained minimization or box constrained minimization. (Box constraints give lower and upper bounds for each variable separately.)

fmin_cobyla(func, x0, cons[, args,...]) Minimize a function using the Constrained Optimization By Linear Approximation (COBYLA) method.

fmin_slsqp(func, x0[, eqcons, f_eqcons, ...]) Minimize a function using Sequential Least Squares Programming

scipy.optimize.fmin_l_bfgs_b

scipy.optimize.fmin_l_bfgs_b (func, x0, fprime=None, args=(), approx_grad=0, bounds=None, m=10, factr=10000000.0, pgtol=1e-05, epsilon=1e-08, iprint=-1, maxfun=15000, maxiter=15000, disp=None, callback=None, maxls=20)

Minimize a function func using the L-BFGS-B algorithm.

**Parameters**

- **func** [callable f(x,*args)] Function to minimize.
- **x0** [ndarray] Initial guess.
- **fprime** [callable fprime(x,*args), optional] The gradient of func. If None, then func returns the function value and the gradient (f, g = func(x, *args)), unless approx_grad is True in which case func returns only f.
- **args** [sequence, optional] Arguments to pass to func and fprime.
- **approx_grad** [bool,optional] Whether to approximate the gradient numerically (in which case func returns only the function value).
- **bounds** [list, optional] (min, max) pairs for each element in x, defining the bounds on that parameter. Use None or +inf for one of min or max when there is no bound in that direction.
- **m** [int, optional] The maximum number of variable metric corrections used to define the limited memory matrix. (The limited memory BFGS method does not store the full hessian but uses this many terms in an approximation to it.)
- **factr** [float, optional] The iteration stops when (f^k - f^(k+1))/max{|f^k|, |f^(k+1)|,1} <= factr * eps, where eps is the machine precision, which is automatically generated by the code. Typical values for factr are: 1e12 for low accuracy; 1e7 for moderate accuracy; 10.0 for extremely high accuracy. See Notes for relationship to ftol, which is exposed (instead of factr) by the scipy.optimize.minimize interface to L-BFGS-B.
- **pgtol** [float, optional] The iteration will stop when max{|proj g_i | i = 1, ..., n} <= pgtol where pg_i is the i-th component of the projected gradient.
- **epsilon** [float, optional] Step size used when approx_grad is True, for numerically calculating the gradient
- **iprint** [int, optional] Controls the frequency of output. iprint < 0 means no output; iprint = 0 print only one line at the last iteration; 0 < iprint < 99 print also f and |proj g| every iprint iterations; iprint = 99 print details of every iteration except n-vectors; iprint = 100 print also the changes of active set and final x; iprint > 100 print details of every iteration including x and g.
- **disp** [int, optional] If zero, then no output. If a positive number, then this over-rides iprint (i.e., iprint gets the value of disp).
- **maxfun** [int, optional] Maximum number of function evaluations. Note that this function may violate the limit because of evaluating gradients by numerical differentiation.
- **maxiter** [int, optional] Maximum number of iterations.
- **callback** [callable, optional] Called after each iteration, as callback(xk), where xk is the current parameter vector.
- **maxls** [int, optional] Maximum number of line search steps (per iteration). Default is 20.

**Returns**
x [array_like] Estimated position of the minimum.

f [float] Value of \textit{func} at the minimum.

d [dict] Information dictionary.
  • \text{d['warnflag']} is
    – 0 if converged,
    – 1 if too many function evaluations or too many iterations,
    – 2 if stopped for another reason, given in \text{d['task']}
  • \text{d['grad']} is the gradient at the minimum (should be 0-ish)
  • \text{d['funcalls']} is the number of function calls made.
  • \text{d['nit']} is the number of iterations.

See also:

\texttt{minimize}

Interface to minimization algorithms for multivariate functions. See the ‘L-BFGS-B’ \textit{method} in particular. Note that the \textit{ftol} option is made available via that interface, while \textit{factr} is provided via this interface, where \textit{factr} is the factor multiplying the default machine floating-point precision to arrive at \textit{ftol}: \text{ftol} = \text{factr} \times \texttt{numpy.finfo(float).eps}.

Notes

\texttt{scipy.optimize.fmin_tnc}

\texttt{scipy.optimize.fmin_tnc} (\textit{func}, \textit{x0}, \textit{fprime=None}, \textit{args=()}, \textit{approx_grad=0}, \textit{bounds=None}, \textit{epsilon=1e-08}, \textit{scale=None}, \textit{offset=None}, \textit{messages=15}, \textit{maxCGit=-1}, \textit{maxfun=None}, \textit{eta=-1}, \textit{stepmx=0}, \textit{accuracy=0}, \textit{fmin=0}, \textit{ftol=-1}, \textit{xtol=-1}, \textit{pgtol=-1}, \textit{rescale=-1}, \textit{disp=None}, \textit{callback=None})

Minimize a function with variables subject to bounds, using gradient information in a truncated Newton algorithm. This method wraps a C implementation of the algorithm.

Parameters

\textbf{func} \hspace{1em} [callable \textit{func}(\textit{x}, \ *\textit{args})] Function to minimize. Must do one of:
1. Return f and g, where f is the value of the function and g its gradient (a list of floats).
2. Return the function value but supply gradient function separately as fprime.
3. Return the function value and set approx_grad=True.
   If the function returns None, the minimization is aborted.

   x0  [array_like] Initial estimate of minimum.

   fprime  [callable fprime(x, *args), optional] Gradient of func. If None, then either func must return the function value and the gradient (f, g = func(x, *args)) or approx_grad must be True.

   args  [tuple, optional] Arguments to pass to function.

   approx_grad  [bool, optional] If true, approximate the gradient numerically.

   bounds  [list, optional] (min, max) pairs for each element in x0, defining the bounds on that parameter. Use None or +/-inf for one of min or max when there is no bound in that direction.

   epsilon  [float, optional] Used if approx_grad is True. The stepsize in a finite difference approximation for fprime.

   scale  [array_like, optional] Scaling factors to apply to each variable. If None, the factors are up-low for interval bounded variables and 1+|x| for the others. Defaults to None.

   offset  [array_like, optional] Value to subtract from each variable. If None, the offsets are (up+low)/2 for interval bounded variables and x for the others.

   messages  [int, optional] Bit mask used to select messages display during minimization values defined in the MSGS dict. Defaults to MSGS_ALL.

   disp  [int, optional] Integer interface to messages. 0 = no message, 5 = all messages

   maxCGit  [int, optional] Maximum number of hessian*vector evaluations per main iteration. If maxCGit == 0, the direction chosen is -gradient if maxCGit < 0, maxCGit is set to max(1, min(50, n/2)). Defaults to -1.

   maxfun  [int, optional] Maximum number of function evaluation. If None, maxfun is set to max(100, 10*len(x0)). Defaults to None. Note that this function may violate the limit because of evaluating gradients by numerical differentiation.

   eta  [float, optional] Severity of the line search. If < 0 or > 1, set to 0.25. Defaults to -1.

   stepmx  [float, optional] Maximum step for the line search. May be increased during call. If too small, it will be set to 10.0. Defaults to 0.

   accuracy  [float, optional] Relative precision for finite difference calculations. If <= machine_precision, set to sqrt(machine_precision). Defaults to 0.

   fmin  [float, optional] Minimum function value estimate. Defaults to 0.

   ftol  [float, optional] Precision goal for the value of f in the stopping criterion. If ftol < 0.0, ftol is set to 0.0 default to -1.

   xtol  [float, optional] Precision goal for the value of x in the stopping criterion (after applying x scaling factors). If xtol < 0.0, xtol is set to sqrt(machine_precision). Defaults to -1.

   pgtol  [float, optional] Precision goal for the value of the projected gradient in the stopping criterion (after applying x scaling factors). If pgtol < 0.0, pgtol is set to 1e-2 * sqrt(accuracy). Setting it to 0.0 is not recommended. Defaults to -1.

   rescale  [float, optional] Scaling factor (in log10) used to trigger f value rescaling. If 0, rescale at each iteration. If a large value, never rescale. If < 0, rescale is set to 1.3.

   callback  [callable, optional] Called after each iteration, as callback(xk), where xk is the current parameter vector.

**Returns**

   x  [ndarray] The solution.

   nfeval  [int] The number of function evaluations.

   rc  [int] Return code, see below

See also:

   minimize
Interface to minimization algorithms for multivariate functions. See the ‘TNC’ method in particular.

**Notes**

The underlying algorithm is truncated Newton, also called Newton Conjugate-Gradient. This method differs from scipy.optimize.fmin_ncg in that

1. it wraps a C implementation of the algorithm
2. it allows each variable to be given an upper and lower bound.

The algorithm incorporates the bound constraints by determining the descent direction as in an unconstrained truncated Newton, but never taking a step-size large enough to leave the space of feasible x’s. The algorithm keeps track of a set of currently active constraints, and ignores them when computing the minimum allowable step size. (The x’s associated with the active constraint are kept fixed.) If the maximum allowable step size is zero then a new constraint is added. At the end of each iteration one of the constraints may be deemed no longer active and removed. A constraint is considered no longer active if it is currently active but the gradient for that variable points inward from the constraint. The specific constraint removed is the one associated with the variable of largest index whose constraint is no longer active.

Return codes are defined as follows:

**scipy.optimize.fmin_cobyla**

`scipy.optimize.fmin_cobyla(func, x0, cons, args=(), consargs=None, rhoend=0.0001, maxfun=1000, disp=None, catol=0.0002, *, callback=None)`

Minimize a function using the Constrained Optimization By Linear Approximation (COBYLA) method. This method wraps a FORTRAN implementation of the algorithm.

**Parameters**

- `func` [callable] Function to minimize. In the form `func(x, *args)`.
- `x0` [ndarray] Initial guess.
- `cons` [sequence] Constraint functions; must all be >=0 (a single function if only 1 constraint). Each function takes the parameters x as its first argument, and it can return either a single number or an array or list of numbers.
- `args` [tuple, optional] Extra arguments to pass to function.
**consargs** [tuple, optional] Extra arguments to pass to constraint functions (default of None means use same extra arguments as those passed to `func`). Use () for no extra arguments.

**rhobeg** [float, optional] Reasonable initial changes to the variables.

**rhoend** [float, optional] Final accuracy in the optimization (not precisely guaranteed). This is a lower bound on the size of the trust region.

**disp** [{0, 1, 2, 3}, optional] Controls the frequency of output; 0 implies no output.

**maxfun** [int, optional] Maximum number of function evaluations.

**catol** [float, optional] Absolute tolerance for constraint violations.

**callback** [callable, optional] Called after each iteration, as `callback(x)`, where `x` is the current parameter vector.

**Returns**

- `x` [ndarray] The argument that minimises $f$.

**See also:**

`minimize`

Interface to minimization algorithms for multivariate functions. See the ‘COBYLA’ method in particular.

**Notes**

This algorithm is based on linear approximations to the objective function and each constraint. We briefly describe the algorithm.

Suppose the function is being minimized over $k$ variables. At the $j$th iteration the algorithm has $k+1$ points $v_1, \ldots, v_{(k+1)}$, an approximate solution $x_j$, and a radius $RHO_j$. (i.e., linear plus a constant) approximations to the objective function and constraint functions such that their function values agree with the linear approximation on the $k+1$ points $v_1, \ldots, v_{(k+1)}$. This gives a linear program to solve (where the linear approximations of the constraint functions are constrained to be non-negative).

However, the linear approximations are likely only good approximations near the current simplex, so the linear program is given the further requirement that the solution, which will become $x_{(j+1)}$, must be within $RHO_j$ from $x_j$. $RHO_j$ only decreases, never increases. The initial $RHO_j$ is `rhobeg` and the final $RHO_j$ is `rhoend`. In this way COBYLA’s iterations behave like a trust region algorithm.

Additionally, the linear program may be inconsistent, or the approximation may give poor improvement. For details about how these issues are resolved, as well as how the points $v_i$ are updated, refer to the source code or the references below.

**References**

Examples

Minimize the objective function \( f(x, y) = x \cdot y \) subject to the constraints \( x^2 + y^2 < 1 \) and \( y > 0 \):

```python
>>> def objective(x):
    ...    return x[0] * x[1]
    ...

>>> def constr1(x):
    ...    return 1 - (x[0]**2 + x[1]**2)
    ...

>>> def constr2(x):
    ...    return x[1]
    ...

>>> from scipy.optimize import fmin_cobyla
>>> fmin_cobyla(objective, [0.0, 0.1], [constr1, constr2], rhoend=1e-7)
array([-0.70710685, 0.70710671])
```

The exact solution is \((-\sqrt{2}/2, \sqrt{2}/2)\).

**scipy.optimize.fmin_slsqp**

Python interface function for the SLSQP Optimization subroutine originally implemented by Dieter Kraft.

**Parameters**

- **func** [callable f(x,*args)] Objective function. Must return a scalar.
- **x0** [1-D ndarray of float] Initial guess for the independent variable(s).
- **eqcons** [list, optional] A list of functions of length n such that eqcons[j](x,*args) == 0.0 in a successfully optimized problem.
- **f_eqcons** [callable f(x,*args), optional] Returns a 1-D array in which each element must equal 0.0 in a successfully optimized problem. If f_eqcons is specified, eqcons is ignored.
- **ieqcons** [list, optional] A list of functions of length n such that ieqcons[j](x,*args) >= 0.0 in a successfully optimized problem.
- **f_ieqcons** [callable f(x,*args), optional] Returns an m by n array in which each element must be greater or equal to 0.0 in a successfully optimized problem. If f_ieqcons is specified, ieqcons is ignored.
- **bounds** [list, optional] A list of tuples specifying the lower and upper bound for each independent variable [(xl0, xu0),(xl1, xu1),...]. Infinite values will be interpreted as large floating values.
- **fprime** [callable f(x,*args), optional] A function that evaluates the partial derivatives of func.
- **fprime_eqcons** [callable f(x,*args), optional] A function of the form fprime_eqcons(x0, *args) that returns the m by n array of equality constraint normals. If not provided, the normals will be approximated. The array returned by fprime_eqcons should be sized as (len(eqcons), len(x0))
- **fprime_ieqcons** [callable f(x,*args), optional] A function of the form fprime_ieqcons(x0, *args) that returns the m by n array of inequality constraint normals. If not provided, the normals will be approximated. The array returned by fprime_ieqcons should be sized as (len(ieqcons), len(x0)).
- **args** [sequence, optional] Additional arguments passed to func and fprime.
iter  [int, optional] The maximum number of iterations.
acc  [float, optional] Requested accuracy.
iprint  [int, optional] The verbosity of fmin_slsqp:
        * iprint <= 0: Silent operation
        * iprint == 1: Print summary upon completion (default)
        * iprint >= 2: Print status of each iterate and summary
disp  [int, optional] Overrides the iprint interface (preferred).
full_output  [bool, optional] If False, return only the minimizer of func (default). Otherwise, output final objective function and summary information.
epsilon  [float, optional] The step size for finite-difference derivative estimates.
callback  [callable, optional] Called after each iteration, as callback(x), where x is the current parameter vector.

Returns

callable

out  [ndarray of float] The final minimizer of func.
fx  [ndarray of float, if full_output is true] The final value of the objective function.
its  [int, if full_output is true] The number of iterations.
imode  [int, if full_output is true] The exit mode from the optimizer (see below).
smode  [string, if full_output is true] Message describing the exit mode from the optimizer.

See also:

minimize

Interface to minimization algorithms for multivariate functions. See the 'SLSQP' method in particular.

Notes

Exit modes are defined as follows

-1 : Gradient evaluation required (g & a)
0 : Optimization terminated successfully
1 : Function evaluation required (f & c)
2 : More equality constraints than independent variables
3 : More than 3*n iterations in LSQ subproblem
4 : Inequality constraints incompatible
5 : Singular matrix E in LSQ subproblem
6 : Singular matrix C in LSQ subproblem
7 : Rank-deficient equality constraint subproblem HFTI
8 : Positive directional derivative for linesearch
9 : Iteration limit reached

Examples

Examples are given in the tutorial.

Univariate (scalar) minimization methods:

fminbound(func, x1, x2[, args, xtol, ...]) Bounded minimization for scalar functions.

**scipy.optimize.fminbound**

`scipy.optimize.fminbound(func, x1, x2, args=(), xtol=1e-05, maxfun=500, full_output=0, disp=1)`

Bounded minimization for scalar functions.

**Parameters**

- `func` ([callable f(x,*args)]): Objective function to be minimized (must accept and return scalars).
- `x1`, `x2` ([float or array scalar]): The optimization bounds.
- `args` ([tuple, optional]): Extra arguments passed to function.
- `xtol` ([float, optional]): The convergence tolerance.
- `maxfun` ([int, optional]): Maximum number of function evaluations allowed.
- `full_output` ([bool, optional]): If True, return optional outputs.
- `disp` ([int, optional]): If non-zero, print messages. 0: no message printing. 1: non-convergence notification messages only. 2: print a message on convergence too. 3: print iteration results.

**Returns**

- `xopt` ([ndarray]): Parameters (over given interval) which minimize the objective function.
- `fval` ([number]): The function value at the minimum point.
- `ierr` ([int]): An error flag (0 if converged, 1 if maximum number of function calls reached).
- `numfunc` ([int]): The number of function calls made.

**See also:**

minimize_scalar

Interface to minimization algorithms for scalar univariate functions. See the ‘Bounded’ method in particular.

**Notes**

Finds a local minimizer of the scalar function `func` in the interval `x1 < xopt < x2` using Brent’s method. (See `brent` for auto-bracketing.)

**Examples**

`fminbound` finds the minimum of the function in the given range. The following examples illustrate the same

```python
>>> def f(x):
...     return x**2

>>> from scipy import optimize
```
```python
>>> minimum = optimize.fminbound(f, -1, 2)
>>> minimum
0.0
>>> minimum = optimize.fminbound(f, 1, 2)
>>> minimum
1.0000059608609866
```

**scipy.optimize.brent**

*scipy.optimize.brent*(func, args=(), brack=None, tol=1.48e-08, full_output=0, maxiter=500)

Given a function of one variable and a possible bracket, return the local minimum of the function isolated to a fractional precision of tol.

**Parameters**

- **func** *(callable f(x,*args))* Objective function.
- **args** *(tuple, optional)* Additional arguments (if present).
- **brack** *(tuple, optional)* Either a triple (xa,xb,xc) where xa<xb<xc and func(xb) < func(xa), func(xc) or a pair (xa,xb) which are used as a starting interval for a downhill bracket search (see *bracket*). Providing the pair (xa,xb) does not always mean the obtained solution will satisfy xa<=x<=xb.
- **tol** *(float, optional)* Relative error in solution xopt acceptable for convergence.
- **full_output** *(bool, optional)* If True, return all output args (xmin, fval, iter, funcalls).
- **maxiter** *(int, optional)* Maximum number of iterations in solution.

**Returns**

- **xmin** *(ndarray)* Optimum point.
- **fval** *(float)* Optimum value.
- **iter** *(int)* Number of iterations.
- **funcalls** *(int)* Number of objective function evaluations made.

**See also:**

*minimize_scalar*

Interface to minimization algorithms for scalar univariate functions. See the ‘Brent’ method in particular.

**Notes**

Uses inverse parabolic interpolation when possible to speed up convergence of golden section method.

Does not ensure that the minimum lies in the range specified by *brack*. See *fminbound*. 
Examples

We illustrate the behaviour of the function when `$brack$` is of size 2 and 3 respectively. In the case where `$brack$` is of the form `(xa,xb)`, we can see for the given values, the output need not necessarily lie in the range `(xa,xb)`.

```python
>>> def f(x):
    ...    return x**2

>>> from scipy import optimize

>>> minimum = optimize.brent(f,brack=(1,2))
>>> minimum
0.0

>>> minimum = optimize.brent(f,brack=(-1,0.5,2))
>>> minimum
-2.7755575615628914e-17
```

**scipy.optimize.golden**

`scipy.optimize.golden(func, args=(), brack=None, tol=1.4901161193847656e-08, full_output=0, maxiter=5000)`

Return the minimum of a function of one variable using golden section method.

Given a function of one variable and a possible bracketing interval, return the minimum of the function isolated to a fractional precision of `$tol$`.

**Parameters**

- `func` [callable func(x,*args)] Objective function to minimize.
- `args` [tuple, optional] Additional arguments (if present), passed to `func`.
- `brack` [tuple, optional] Triple `(a,b,c)`, where `(a<b<c)` and `func(b)` < `func(a)` and `func(c)`. If bracket consists of two numbers `(a, c)`, then they are assumed to be a starting interval for a downhill bracket search (see `bracket`); it doesn’t always mean that obtained solution will satisfy $a\leq x\leq c$.
- `tol` [float, optional] X tolerance stop criterion
- `full_output` [bool, optional] If True, return optional outputs.
- `maxiter` [int] Maximum number of iterations to perform.

**See also:**

`minimize_scalar`

Interface to minimization algorithms for scalar univariate functions. See the ‘Golden’ method in particular.
Notes

Uses analog of bisection method to decrease the bracketed interval.

Examples

We illustrate the behaviour of the function when \( brack \) is of size 2 and 3, respectively. In the case where \( brack \) is of the form \((x_a, x_b)\), we can see for the given values, the output need not necessarily lie in the range \((x_a, x_b)\).

```python
>>> def f(x):
...     return x**2
```  
```python
>>> from scipy import optimize
```  
```python
>>> minimum = optimize.golden(f, brack=(1, 2))
>>> minimum
1.571727788484873e-16
>>> minimum = optimize.golden(f, brack=(-1, 0.5, 2))
>>> minimum
-1.571727788484873e-16
```

Least-squares

\[ \text{leastsq}(\text{func}, \text{x0}, \text{args}, \text{Dfun}, \text{full_output}, ...) \] Minimize the sum of squares of a set of equations.

\[ \text{scipy.optimize.leastsq}(\text{func}, \text{x0}, \text{args}=(), \text{Dfun}=None, \text{full_output}=0, \text{col_deriv}=0, \text{ftol}=1.49012e-08, \text{xtol}=1.49012e-08, \text{gtol}=0.0, \text{maxfev}=0, \text{epsfcn}=None, \text{factor}=100, \text{diag}=None) \]
Minimize the sum of squares of a set of equations.

```python
x = arg min(sum(func(y)**2, axis=0))
      y
```

Parameters

- **func**: [callable] Should take at least one (possibly length \( N \) vector) argument and returns \( M \) floating point numbers. It must not return NaNs or fitting might fail. \( M \) must be greater than or equal to \( N \).
- **x0**: [ndarray] The starting estimate for the minimization.
- **args**: [tuple, optional] Any extra arguments to func are placed in this tuple.
- **Dfun**: [callable, optional] A function or method to compute the Jacobian of func with derivatives across the rows. If this is None, the Jacobian will be estimated.
- **full_output**: [bool, optional] non-zero to return all optional outputs.
- **col_deriv**: [bool, optional] non-zero to specify that the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).
- **ftol**: [float, optional] Relative error desired in the sum of squares.
- **xtol**: [float, optional] Relative error desired in the approximate solution.
- **gtol**: [float, optional] Orthogonality desired between the function vector and the columns of the Jacobian.
maxfev  [int, optional] The maximum number of calls to the function. If Dfun is provided, then the
default maxfev is 100*(N+1) where N is the number of elements in x0, otherwise the default
maxfev is 200*(N+1).

epsfcn  [float, optional] A variable used in determining a suitable step length for the forward-difference
approximation of the Jacobian (for Dfun=None). Normally the actual step length will be
sqrt(epsfcn)*x If epsfcn is less than the machine precision, it is assumed that the relative
errors are of the order of the machine precision.
factor  [float, optional] A parameter determining the initial step bound (factor * || diag *
x||). Should be in interval (0.1, 100).
diag  [sequence, optional] N positive entries that serve as a scale factors for the variables.

Returns

x  [ndarray] The solution (or the result of the last iteration for an unsuccessful call).
cov_x  [ndarray] The inverse of the Hessian. fjac and ipvt are used to construct an estimate of
the Hessian. A value of None indicates a singular matrix, which means the curvature in
parameters x is numerically flat. To obtain the covariance matrix of the parameters x, cov_x
must be multiplied by the variance of the residuals – see curve_fit.
infodict  [dict] a dictionary of optional outputs with the keys:
nfev  The number of function calls
fvec  The function evaluated at the output
fjac  A permutation of the R matrix of a QR factorization of the final approximate
Jacobian matrix, stored column wise. Together with ipvt, the covariance of the
estimate can be approximated.
ipvt  An integer array of length N which defines a permutation matrix, p, such that
fjac*p = q*r, where r is upper triangular with diagonal elements of nonincreasing
magnitude. Column j of p is column ipvt(j) of the identity matrix.
qtf  The vector (transpose(q) * fvec).
mesg  [str] A string message giving information about the cause of failure.
ier  [int] An integer flag. If it is equal to 1, 2, 3 or 4, the solution was found. Otherwise, the
solution was not found. In either case, the optional output variable ‘mesg’ gives more infor-
mation.

See also:

least_squares

Newer interface to solve nonlinear least-squares problems with bounds on the variables. See method==’lm’
in particular.

Notes

“leastsq” is a wrapper around MINPACK’s lmdif and lmder algorithms.
cov_x is a Jacobian approximation to the Hessian of the least squares objective function. This approximation
assumes that the objective function is based on the difference between some observed target data (ydata) and a
(non-linear) function of the parameters f(xdata, params)

```python
func(params) = ydata - f(xdata, params)
```

so that the objective function is

```
min params sum((ydata - f(xdata, params))**2, axis=0)
```

The solution, x, is always a 1-D array, regardless of the shape of x0, or whether x0 is a scalar.
### Examples

```python
>>> from scipy.optimize import leastsq
>>> def func(x):
...     return 2*(x-3)**2+1
>>> leastsq(func, 0)
(array([2.99999999]), 1)
```

### Root finding

</tbody>
</table>

#### scipy.optimize.fsolve

Find the roots of a function. Return the roots of the (non-linear) equations defined by \( \text{func}(x) = 0 \) given a starting estimate.

**Parameters**

- `func`:
  - `[callable f(x, *args)]` A function that takes at least one (possibly vector) argument, and returns a value of the same length.
- `x0`:
  - `[ndarray]` The starting estimate for the roots of \( \text{func}(x) = 0 \).
- `args`:
  - `[tuple, optional]` Any extra arguments to `func`.
- `fprime`:
  - `[callable f(x, *args), optional]` A function to compute the Jacobian of `func` with derivatives across the rows. By default, the Jacobian will be estimated.
- `full_output`:
  - `[bool, optional]` If True, return optional outputs.
- `col_deriv`:
  - `[bool, optional]` Specify whether the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).
- `xtol`:
  - `[float, optional]` The calculation will terminate if the relative error between two consecutive iterates is at most `xtol`.
- `maxfev`:
  - `[int, optional]` The maximum number of calls to the function. If zero, then \( 100 \times (N+1) \) is the maximum where \( N \) is the number of elements in `x0`.
- `band`:
  - `[tuple, optional]` If set to a two-sequence containing the number of sub- and super-diagonals within the band of the Jacobi matrix, the Jacobi matrix is considered banded (only for `fprime=None`).
- `epsfcn`:
  - `[float, optional]` A suitable step length for the forward-difference approximation of the Jacobian (for `fprime=None`). If `epsfcn` is less than the machine precision, it is assumed that the relative errors in the functions are of the order of the machine precision.
- `factor`:
  - `[float, optional]` A parameter determining the initial step bound (\( \text{factor} \times \| \text{diag} \times x \| \)). Should be in the interval \((0.1, 100)\).
- `diag`:
  - `[sequence, optional]` N positive entries that serve as a scale factors for the variables.

**Returns**

- `[sequence, optional]` N positive entries that serve as a scale factors for the variables.

x: [ndarray] The solution (or the result of the last iteration for an unsuccessful call).

infodict: [dict] A dictionary of optional outputs with the keys:
- nfev: number of function calls
- njev: number of Jacobian calls
- fvec: function evaluated at the output
- fjac: the orthogonal matrix, q, produced by the QR factorization of the final approximate Jacobian matrix, stored column wise
- r: upper triangular matrix produced by QR factorization of the same matrix
- qtf: the vector (transpose(q) * fvec)
- ier: [int] An integer flag. Set to 1 if a solution was found, otherwise refer to mesg for more information.
- mesg: [str] If no solution is found, mesg details the cause of failure.

root

Interface to root finding algorithms for multivariate functions. See the method='hybr' in particular.

Notes

fsolve is a wrapper around MINPACK's hybrd and hybrj algorithms.

Examples

Find a solution to the system of equations: \( x_0 \cos(x_1) = 4, x_1 x_0 - x_1 = 5 \).

```python
>>> from scipy.optimize import fsolve
>>> def func(x):
...    return [x[0] * np.cos(x[1]) - 4,
...            x[1] * x[0] - x[1] - 5]
>>> root = fsolve(func, [1, 1])
>>> root
array([6.50409711, 0.90841421])
>>> np.isclose(func(root), [0.0, 0.0])  # func(root) should be almost 0.0.
array([ True, True])
```

scipy.optimize.broyden1

`scipy.optimize.broyden1(F, xin, iter=None, alpha=None, reduction_method='restart', max_rank=None, verbose=False, maxiter=None, f_tol=None, f_rtol=None, x_tol=None, x_rtol=None, tol_norm=None, line_search='armijo', callback=None, **kw)`

Find a root of a function, using Broyden's first Jacobian approximation.

This method is also known as "Broyden’s good method".

**Parameters**

- F: [function(x) -> f] Function whose root to find; should take and return an array-like object.
- xin: [array_like] Initial guess for the solution
- alpha: [float, optional] Initial guess for the Jacobian is \((-1/\text{alpha})\).
reduction_method
[ str or tuple, optional] Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form (method, param1, param2, ...) that gives the name of the method and values for additional parameters.
Methods available:
• restart: drop all matrix columns. Has no extra parameters.
• simple: drop oldest matrix column. Has no extra parameters.
• svd: keep only the most significant SVD components. Takes an extra parameter, to_retain, which determines the number of SVD components to retain when rank reduction is done. Default is max_rank - 2.
max_rank
[int, optional] Maximum rank for the Broyden matrix. Default is infinity (i.e., no rank reduction).
iter
[int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
verbose
[bool, optional] Print status to stdout on every iteration.
maxiter
[int, optional] Maximum number of iterations to make. If more are needed to meet convergence, NoConvergence is raised.
f_tol
[float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
f_rtol
[float, optional] Relative tolerance for the residual. If omitted, not used.
x_tol
[float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
x_rtol
[float, optional] Relative minimum step size. If omitted, not used.
tol_norm
[function(vector)->scalar, optional] Norm to use in convergence check. Default is the maximum norm.
line_search
[None, ‘armijo’ (default), ‘wolfe’], optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.
callback
[function, optional] Optional callback function. It is called on every iteration as callback(x, f) where x is the current solution and f the corresponding residual.

Returns
sol
[ndarray] An array (of similar array type as x0) containing the final solution.

Raises
NoConvergence
When a solution was not found.

See also:
root
Interface to root finding algorithms for multivariate functions. See method=='broyden1' in particular.
Notes

This algorithm implements the inverse Jacobian Quasi-Newton update

\[ H_+ = H + (dx - H df)dx^\dagger H/(dx^\dagger H df) \]

which corresponds to Broyden’s first Jacobian update

\[ J_+ = J + (df - J dx)dx^\dagger/dx^\dagger dx \]

Examples

The following functions define a system of nonlinear equations

```python
>>> def fun(x):
    ...     return [x[0] + 0.5 * (x[0] - x[1])**3 - 1.0, 
    ...             0.5 * (x[1] - x[0])**3 + x[1]]
```

A solution can be obtained as follows.

```python
>>> from scipy import optimize
>>> sol = optimize.broyden1(fun, [0, 0])
>>> sol
array([0.84116396, 0.15883641])
```

**scipy.optimize.broyden2**

Find a root of a function, using Broyden’s second Jacobian approximation.

This method is also known as “Broyden’s bad method”.

**Parameters**

- `F` ([function(x) -> f] Function whose root to find; should take and return an array-like object.
- `xin` ([array_like] Initial guess for the solution
- `alpha` [float, optional] Initial guess for the Jacobian is \((-1/alpha)\).
- `reduction_method` [str or tuple, optional] Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form (method, param1, param2, ...) that gives the name of the method and values for additional parameters.

   Methods available:
   - restart: drop all matrix columns. Has no extra parameters.
   - simple: drop oldest matrix column. Has no extra parameters.)
• **svd**: keep only the most significant SVD components. Takes an extra parameter, `to_retain`, which determines the number of SVD components to retain when rank reduction is done. Default is `max_rank - 2`.

**max_rank** [int, optional] Maximum rank for the Broyden matrix. Default is infinity (i.e., no rank reduction).

**iter** [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

**verbose** [bool, optional] Print status to stdout on every iteration.

**maxiter** [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.

**f_tol** [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

**f_rtol** [float, optional] Relative tolerance for the residual. If omitted, not used.

**x_tol** [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

**x_rtol** [float, optional] Relative minimum step size. If omitted, not used.

**tol_norm** [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

**line_search** [None, ‘armijo’ (default), ‘wolfe’], optional Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

**callback** [function, optional] Optional callback function. It is called on every iteration as `callback(x, f)` where `x` is the current solution and `f` the corresponding residual.

**Returns**

**sol** [ndarray] An array (of similar array type as `x0`) containing the final solution.

**Raises**

`NoConvergence` When a solution was not found.

**See also:**

`root`

Interface to root finding algorithms for multivariate functions. See `method='broyden2'` in particular.

**Notes**

This algorithm implements the inverse Jacobian Quasi-Newton update

$$H_+ = H + (dx - H df)df\dagger/(df\dagger df)$$

corresponding to Broyden’s second method.
**Examples**

The following functions define a system of nonlinear equations:

```python
>>> def fun(x):
...     return [x[0] + 0.5 * (x[0] - x[1])**3 - 1.0,
...             0.5 * (x[1] - x[0])**3 + x[1]]
```

A solution can be obtained as follows.

```python
>>> from scipy import optimize
>>> sol = optimize.broyden2(fun, [0, 0])
>>> sol
array([0.84116365, 0.15883529])
```

Large-scale nonlinear solvers:

- `newton_krylov(F, xin[, iter, rdiff, method, ...])` Find a root of a function, using Krylov approximation for inverse Jacobian.
- `anderson(F, xin[, iter, alpha, w0, M, ...])` Find a root of a function, using (extended) Anderson mixing.

```python
scipy.optimize.newton_krylov
```

```python
scipy.optimize.newton_krylov(F, xin[, iter=None, rdiff=None, method='lgmres', inner_maxiter=20, inner_M=None, outer_k=10, verbose=False, maxiter=None, f_tol=None, f_rtol=None, x_tol=None, x_rtol=None, tol_norm=None, line_search='armijo', callback=None, **kw])
```

Find a root of a function, using Krylov approximation for inverse Jacobian.

This method is suitable for solving large-scale problems.

**Parameters**

- `F` [function(x) -> f] Function whose root to find; should take and return an array-like object.
- `xin` [array_like] Initial guess for the solution
- `rdiff` [float, optional] Relative step size to use in numerical differentiation.
- `method` ['lgmres', 'gmres', 'bicgstab', 'cgs', 'minres'] or function] Krylov method to use to approximate the Jacobian. Can be a string, or a function implementing the same interface as the iterative solvers in `scipy.sparse.linalg`.
- `inner_maxiter` [int, optional] Parameter to pass to the “inner” Krylov solver: maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- `inner_M` [LinearOperator or InverseJacobian] Preconditioner for the inner Krylov iteration. Note that you can use also inverse Jacobians as (adaptive) preconditioners. For example,
```python
>>> from scipy.optimize.nonlin import BroydenFirst,
    KrylovJacobian
>>> from scipy.optimize.nonlin import InverseJacobian
>>> jac = BroydenFirst()
>>> kjac = KrylovJacobian(inner_M=InverseJacobian(jac))
```

If the preconditioner has a method named 'update', it will be called as `update(x, f)` after each nonlinear step, with `x` giving the current point, and `f` the current function value.

**Parameters**

- `outer_k` [int, optional] Size of the subspace kept across LGMRES nonlinear iterations. See `scipy.sparse.linalg.lgmres` for details.

- `inner_kwargs` [kwargs] Keyword parameters for the “inner” Krylov solver (defined with `method`). Parameter names must start with the `inner_` prefix which will be stripped before passing on the inner method. See, e.g., `scipy.sparse.linalg.gmres` for details.

- `iter` [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

- `verbose` [bool, optional] Print status to stdout on every iteration.

- `maxiter` [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.

- `f_tol` [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is $6e^{-6}$.

- `f_rtol` [float, optional] Relative tolerance for the residual. If omitted, not used.

- `x_tol` [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

- `x_rtol` [float, optional] Relative minimum step size. If omitted, not used.

- `tol_norm` [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

- `line_search` [{None, ‘armijo’ (default), ‘wolfe’}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

- `callback` [function, optional] Optional callback function. It is called on every iteration as `callback(x, f)` where `x` is the current solution and `f` the corresponding residual.

**Returns**

- `sol` [ndarray] An array (of similar array type as `x0`) containing the final solution.

**Raises**

- `NoConvergence` When a solution was not found.

- `root`
  
  Interface to root finding algorithms for multivariate functions. See `method='krylov'` in particular.

- `scipy.sparse.linalg.gmres`
- `scipy.sparse.linalg.lgmres`
**Notes**

This function implements a Newton-Krylov solver. The basic idea is to compute the inverse of the Jacobian with an iterative Krylov method. These methods require only evaluating the Jacobian-vector products, which are conveniently approximated by a finite difference:

\[ Jv \approx \frac{(f(x + \omega \cdot v / |v|) - f(x))/\omega}{\omega} \]

Due to the use of iterative matrix inverses, these methods can deal with large nonlinear problems.

SciPy's `scipy.sparse.linalg` module offers a selection of Krylov solvers to choose from. The default here is `lgmres`, which is a variant of restarted GMRES iteration that reuses some of the information obtained in the previous Newton steps to invert Jacobians in subsequent steps.

For a review on Newton-Krylov methods, see for example [1], and for the LGMRES sparse inverse method, see [2].

**Examples**

The following functions define a system of nonlinear equations

```python
>>> def fun(x):
    ...     return [x[0] + 0.5 * x[1] - 1.0,
    ...              0.5 * (x[1] - x[0]) ** 2]
```

A solution can be obtained as follows.

```python
>>> from scipy import optimize
>>> sol = optimize.newton_krylov(fun, [0, 0])
>>> sol
array([0.66731771, 0.66536458])
```

**scipy.optimize.anderson**

Find a root of a function, using (extended) Anderson mixing.

The Jacobian is formed by for a ‘best’ solution in the space spanned by last M vectors. As a result, only a MxM matrix inversions and MxN multiplications are required. [Ey]

**Parameters**

- `F [function(x) -> f]` Function whose root to find; should take and return an array-like object.
- `xin [array_like]` Initial guess for the solution
- `alpha [float, optional]` Initial guess for the Jacobian is (-1/alpha).
- `M [float, optional]` Number of previous vectors to retain. Defaults to 5.
- `w0 [float, optional]` Regularization parameter for numerical stability. Compared to unity, good values of the order of 0.01.
iter  [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
verbose [bool, optional] Print status to stdout on every iteration.
maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, NoConvergence is raised.
f_tol  [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
f_rtol  [float, optional] Relative tolerance for the residual. If omitted, not used.
x_tol  [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
x_rtol [float, optional] Relative minimum step size. If omitted, not used.
tol_norm [function(vector)->scalar, optional] Norm to use in convergence check. Default is the maximum norm.
line_search [{None, 'armijo' (default), 'wolfe'}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.
callback [function, optional] Optional callback function. It is called on every iteration as callback(x, f) where x is the current solution and f the corresponding residual.

Returns

sol  [ndarray] An array (of similar array type as x0) containing the final solution.

Raises

NoConvergence

When a solution was not found.

scipy.optimize.excitingmixing(F, xin, iter=None, alpha=None, alphamax=1.0, verbose=False, maxiter=None, f_tol=None, f_rtol=None, x_tol=None, x_rtol=None, tol_norm=None, line_search='armijo', callback=None, **kw)
```

Find a root of a function, using a tuned diagonal Jacobian approximation.

The Jacobian matrix is diagonal and is tuned on each iteration.

**Warning:** This algorithm may be useful for specific problems, but whether it will work may depend strongly on the problem.

**Parameters**

- **F** [function(x) -> f] Function whose root to find; should take and return an array-like object.
- **xin** [array_like] Initial guess for the solution
- **alpha** [float, optional] Initial Jacobian approximation is (-1/alpha).
- **alphamax** [float, optional] The entries of the diagonal Jacobian are kept in the range [alpha, alphamax].
- **iter** [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- **verbose** [bool, optional] Print status to stdout on every iteration.
- **maxiter** [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.
- **f_tol** [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- **f_rtol** [float, optional] Relative tolerance for the residual. If omitted, not used.

scipy.optimize.linearmixing

scipy.optimize.linearmixing(F, xin, iter=None, alpha=None, verbose=False, maxiter=None, f_tol=None, f_rtol=None, x_tol=None, x_rtol=None, tol_norm=None, line_search='armijo', callback=None, **kw)

Find a root of a function, using a scalar Jacobian approximation.

**Warning:** This algorithm may be useful for specific problems, but whether it will work may depend strongly on the problem.

**Parameters**

- **F** [function(x) -> f] Function whose root to find; should take and return an array-like object.
- **xin** [array_like] Initial guess for the solution
- **alpha** [float, optional] The Jacobian approximation is (-1/alpha).
- **iter** [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- **verbose** [bool, optional] Print status to stdout on every iteration.
- **maxiter** [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, NoConvergence is raised.
- **f_tol** [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- **f_rtol** [float, optional] Relative tolerance for the residual. If omitted, not used.
- **x_tol** [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- **x_rtol** [float, optional] Relative minimum step size. If omitted, not used.
- **tol_norm** [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
- **line_search** [{'None', 'armijo' (default), 'wolfe'}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.
- **callback** [function, optional] Optional callback function. It is called on every iteration as callback(x, f) where x is the current solution and f the corresponding residual.

**Returns**

- **sol** [ndarray] An array (of similar array type as x0) containing the final solution.

**Raises**

- NoConvergence
  When a solution was not found.

`scipy.optimize.diagbroyden`

`scipy.optimize.diagbroyden`(F, xin=None, alpha=None, verbose=False, maxiter=None, f_tol=None, f_rtol=None, x_tol=None, x_rtol=None, tol_norm=None, line_search='armijo', callback=None, **kw)

Find a root of a function, using diagonal Broyden Jacobian approximation.

The Jacobian approximation is derived from previous iterations, by retaining only the diagonal of Broyden matrices.

**Warning:** This algorithm may be useful for specific problems, but whether it will work may depend strongly on the problem.

**Parameters**

- **F** : [function(x) -> f] Function whose root to find; should take and return an array-like object.
- **xin** : [array_like] Initial guess for the solution.
- **alpha** : [float, optional] Initial guess for the Jacobian is \((-1/alpha)\).
- **iter** : [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- **verbose** : [bool, optional] Print status to stdout on every iteration.
- **maxiter** : [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.
- **f_tol** : [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- **f_rtol** : [float, optional] Relative tolerance for the residual. If omitted, not used.
- **x_tol** : [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- **x_rtol** : [float, optional] Relative minimum step size. If omitted, not used.
- **tol_norm** : [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
- **line_search** : [{None, 'armijo' (default), 'wolfe'}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.
- **callback** : [function, optional] Optional callback function. It is called on every iteration as `callback(x, f)` where `x` is the current solution and `f` the corresponding residual.

**Returns**

- **sol** : [ndarray] An array (of similar array type as x0) containing the final solution.

**Raises**

- **NoConvergence**

When a solution was not found.

Examples

The following functions define a system of nonlinear equations

```python
>>> def fun(x):
...     return [x[0] + 0.5 * (x[0] - x[1])**3 - 1.0,
...             0.5 * (x[1] - x[0])**3 + x[1]]
```

A solution can be obtained as follows.

```python
>>> from scipy import optimize
>>> sol = optimize.diagbroyden(fun, [0, 0])
>>> sol
array([0.84116403, 0.15883384])
```

3.3.20 Cython optimize zeros API

The underlying C functions for the following root finders can be accessed directly using Cython:

- `bisect`
- `ridder`
- `brentq`
- `brenth`

The Cython API for the zeros functions is similar except there is no disp argument. Import the zeros functions using `cimport` from `scipy.optimize.cython_optimize`.

```python
from scipy.optimize.cython_optimize cimport bisect, ridder, brentq, brent
```

Callback signature

The zeros functions in `cython_optimize` expect a callback that takes a double for the scalar independent variable as the 1st argument and a user defined struct with any extra parameters as the 2nd argument.

```c
double (*callback_type)(double, void*)
```
Examples

Usage of cython_optimize requires Cython to write callbacks that are compiled into C. For more information on compiling Cython, see the Cython Documentation.

These are the basic steps:

1. Create a Cython .pyx file, for example: myexample.pyx.
2. Import the desired root finder from cython_optimize.
3. Write the callback function, and call the selected zeros function passing the callback, any extra arguments, and the other solver parameters.

   ```python
   from scipy.optimize.cython_optimize cimport brentq
   # import math from Cython
   from libc cimport math
   myargs = {'C0': 1.0, 'C1': 0.7}  # a dictionary of extra arguments
   XLO, XHI = 0.5, 1.0  # lower and upper search boundaries
   XTOL, RTOL, MITR = 1e-3, 1e-3, 10  # other solver parameters
   # user-defined struct for extra parameters
ctypedef struct test_params:
    double C0
    double C1

   # user-defined callback
cdef double f(double x, void *args):
    cdef test_params *myargs = <test_params *> args
    return myargs.C0 - math.exp(-(x - myargs.C1))

   # Cython wrapper function
cdef double brentq_wrapper_example(dict args, double xa, double xb,
                                      double xtol, double rtol, int mitr):
    # Cython automatically casts dictionary to struct
cdef test_params myargs = args
    return brentq(f, xa, xb, <test_params *> &myargs, xtol, rtol, mitr, NULL)

   # Python function
def brentq_example(args=myargs, xa=XLO, xb=XHI, xtol=XTOL, rtol=RTOL,
                       mitr=MITR):
    '''Calls Cython wrapper from Python.''
    return brentq_wrapper_example(args, xa, xb, xtol, rtol, mitr)
   ```

4. If you want to call your function from Python, create a Cython wrapper, and a Python function that calls the wrapper, or use cpdef. Then, in Python, you can import and run the example.

   ```python
   from myexample import brentq_example
   ```
x = brentq_example()
# 0.6999942848231314

5. Create a Cython .pxd file if you need to export any Cython functions.

**Full output**

The functions in `cython_optimize` can also copy the full output from the solver to a C struct that is passed as its last argument. If you don’t want the full output, just pass NULL. The full output struct must be type `zeros_full_output`, which is defined in `scipy.optimize.cython_optimize` with the following fields:

- int funcalls: number of function calls
- int iterations: number of iterations
- int error_num: error number
- double root: root of function

The root is copied by `cython_optimize` to the full output struct. An error number of -1 means a sign error, -2 means a convergence error, and 0 means the solver converged. Continuing from the previous example:

```python
from scipy.optimize import brentq, zeros_full_output

# cython brentq solver with full output
def brent_full_output_example(myargs, XLO, XHI, XTOL, RTOL, MITR):
    '''Returns full output'''
    return brentq_full_output_wrapper_example(myargs, XLO, XHI, XTOL, RTOL, MITR)

result = brent_full_output_example()
# {'error_num': 0,
#  'funcalls': 6,
#  'iterations': 5,
#  'root': 0.6999942848231314}
```
3.3.21 Signal processing (scipy.signal)

Convolution

- `convolve(in1, in2[, mode, method])` Convolves two N-dimensional arrays.
- `correlate(in1, in2[, mode, method])` Cross-correlates two N-dimensional arrays.
- `fftconvolve(in1, in2[, mode, axes])` Convolves two N-dimensional arrays using FFT.
- `oconvolve(in1, in2[, mode, axes])` Convolves two N-dimensional arrays using the overlap-add method.
- `convolve2d(in1, in2[, mode, boundary, fillvalue])` Convolves two 2-dimensional arrays.
- `correlate2d(in1, in2[, mode, boundary, ...])` Cross-correlates two 2-dimensional arrays.
- `sepfir2d(input, hrow, hcol)` Convolves with a 2-D separable FIR filter.
- `choose_conv_method(in1, in2[, mode, measure])` Finds the fastest convolution/correlation method.
- `correlation_lags(in1_len, in2_len[, mode])` Calculates the lag / displacement indices array for 1D cross-correlation.

**scipy.signal.convolve**

*scipy.signal.convolve (in1, in2, mode='full', method='auto')*

Convolves two N-dimensional arrays.

Convolve `in1` and `in2`, with the output size determined by the `mode` argument.

**Parameters**

- `in1` [array_like] First input.
- `in2` [array_like] Second input. Should have the same number of dimensions as `in1`.
- `mode` [str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:
  - `full`: The output is the full discrete linear convolution of the inputs. (Default)
  - `valid`: The output consists only of those elements that do not rely on the zero-padding. In `valid` mode, either `in1` or `in2` must be at least as large as the other in every dimension.
  - `same`: The output is the same size as `in1`, centered with respect to the ‘full’ output.
- `method` [str {'auto', 'direct', 'fft'}, optional] A string indicating which method to use to calculate the convolution:
  - `direct`: The convolution is determined directly from sums, the definition of convolution.
  - `fft`: The Fourier Transform is used to perform the convolution by calling `fftconvolve`.
  - `auto`: Automatically chooses direct or Fourier method based on an estimate of which is faster (default). See Notes for more detail.
  New in version 0.19.0.

**Returns**

- `convolve` [array] An N-dimensional array containing a subset of the discrete linear convolution of `in1` with `in2`.

**See also:**

- `numpy.polymul` performs polynomial multiplication (same operation, but also accepts poly1d objects)
- `choose_conv_method` chooses the fastest appropriate convolution method
fftconvolve

Always uses the FFT method.

oaconvolve

Uses the overlap-add method to do convolution, which is generally faster when the input arrays are large and significantly different in size.

Notes

By default, convolve and correlate use method='auto', which calls choose_conv_method to choose the fastest method using pre-computed values (choose_conv_method can also measure real-world timing with a keyword argument). Because fftconvolve relies on floating point numbers, there are certain constraints that may force method=direct (more detail in choose_conv_method docstring).

Examples

Smooth a square pulse using a Hann window:

```python
>>> from scipy import signal
>>> sig = np.repeat([0., 1., 0.], 100)
>>> win = signal.windows.hann(50)
>>> filtered = signal.convolve(sig, win, mode='same') / sum(win)
```

```python
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_win, ax_filt) = plt.subplots(3, 1, sharex=True)
>>> ax_orig.plot(sig)
>>> ax_orig.set_title('Original pulse')
>>> ax_orig.margins(0, 0.1)
>>> ax_win.plot(win)
>>> ax_win.set_title('Filter impulse response')
>>> ax_win.margins(0, 0.1)
>>> ax_filt.plot(filtered)
>>> ax_filt.set_title('Filtered signal')
>>> ax_filt.margins(0, 0.1)
>>> fig.tight_layout()
>>> fig.show()
```

scipy.signal.correlate

scipy.signal.correlate(in1, in2, mode='full', method='auto')

Cross-correlate two N-dimensional arrays.

Cross-correlate in1 and in2, with the output size determined by the mode argument.

Parameters

- **in1** [array_like] First input.
- **in2** [array_like] Second input. Should have the same number of dimensions as in1.
- **mode** [str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:
  - full: The output is the full discrete linear cross-correlation of the inputs. (Default)
  - valid: The output consists only of those elements that do not rely on the zero-padding.
  In 'valid' mode, either in1 or in2 must be at least as large as the other in every dimension.
The output is the same size as `in1`, centered with respect to the ‘full’ output.

**method** [str {‘auto’, ‘direct’, ‘fft’}, optional] A string indicating which method to use to calculate the correlation.
- **direct** The correlation is determined directly from sums, the definition of correlation.
- **fft** The Fast Fourier Transform is used to perform the correlation more quickly (only available for numerical arrays.)
- **auto** Automatically chooses direct or Fourier method based on an estimate of which is faster (default). See `convolve` Notes for more detail. New in version 0.19.0.

**Returns**
- **correlate** [array] An N-dimensional array containing a subset of the discrete linear cross-correlation of `in1` with `in2`.

See also:
- `choose_conv_method` contains more documentation on `method`.
- `correlation_lags` calculates the lag / displacement indices array for 1D cross-correlation.

**Notes**

The correlation `z` of two d-dimensional arrays `x` and `y` is defined as:

\[
z[\ldots, k, \ldots] = \text{sum}[\ldots, i_{-1}, \ldots, x[\ldots, i_{-1}, \ldots] * \text{conj}(y[\ldots, i_{-1} - k, \ldots, \ldots])]\]

This way, if `x` and `y` are 1-D arrays and `z = correlate(x, y, 'full')` then

\[
z[k] = (x * y)(k - N + 1) = \sum_{i=0}^{||x||-1} x[i]y[i+k-N+1]
\]
for \( k = 0, 1, ..., |x| + |y| - 2 \)

where \(|x|\) is the length of \(x\), \(N = \max(|x|, |y|)\), and \(y_m\) is 0 when \(m\) is outside the range of \(y\).

method='fft' only works for numerical arrays as it relies on `fftconvolve`. In certain cases (i.e., arrays of objects or when rounding integers can lose precision), method='direct' is always used.

When using “same” mode with even-length inputs, the outputs of `correlate` and `correlate2d` differ: There is a 1-index offset between them.

**Examples**

Implement a matched filter using cross-correlation, to recover a signal that has passed through a noisy channel.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()

>>> sig = np.repeat([0., 1., 1., 0., 1., 0., 0., 1.], 128)
>>> sig_noise = sig + rng.standard_normal(len(sig))
>>> corr = signal.correlate(sig_noise, np.ones(128), mode='same') / 128

>>> clock = np.arange(64, len(sig), 128)
>>> fig, (ax_orig, ax_noise, ax_corr) = plt.subplots(3, 1, sharex=True)
>>> ax_orig.plot(sig)
>>> ax_orig.set_title('Original signal')
>>> ax_noise.plot(sig_noise)
>>> ax_noise.set_title('Signal with noise')
>>> ax_corr.plot(corr)
>>> ax_corr.set_title('Cross-correlated with rectangular pulse')
>>> ax_orig.margins(0.1)
>>> fig.tight_layout()
>>> plt.show()
```

Compute the cross-correlation of a noisy signal with the original signal.

```python
>>> x = np.arange(128) / 128
>>> sig = np.sin(2 * np.pi * x)
>>> sig_noise = sig + rng.standard_normal(len(sig))
>>> corr = signal.correlate(sig_noise, sig)
>>> lags = signal.correlation_lags(len(sig), len(sig_noise))
>>> corr /= np.max(corr)

>>> fig, (ax_orig, ax_noise, ax_corr) = plt.subplots(3, 1, figsize=(4.8, 4.8))
>>> ax_orig.plot(sig)
>>> ax_orig.set_title('Original signal')
>>> ax_orig.set_xlabel('Sample Number')
>>> ax_noise.plot(sig_noise)
>>> ax_noise.set_title('Signal with noise')
```

(continues on next page)
scipy.signal.fftconvolve

scipy.signal.fftconvolve(in1, in2, mode='full', axes=None)

Convolves two N-dimensional arrays using FFT.

Convolve in1 and in2 using the fast Fourier transform method, with the output size determined by the mode argument.

This is generally much faster than convolve for large arrays (n > ~500), but can be slower when only a few output values are needed, and can only output float arrays (int or object array inputs will be cast to float).

As of v0.19, convolve automatically chooses this method or the direct method based on an estimation of which is faster.

**Parameters**

- **in1** [array_like] First input.
- **in2** [array_like] Second input. Should have the same number of dimensions as in1.
- **mode** [str {‘full’, ‘valid’, ‘same’}, optional] A string indicating the size of the output:
  - **full** The output is the full discrete linear convolution of the inputs. (Default)
  - **valid** The output consists only of those elements that do not rely on the zero-padding. In ‘valid’ mode, either in1 or in2 must be at least as large as the other in every dimension.
  - **same** The output is the same size as in1, centered with respect to the ‘full’ output.
- **axes** [int or array_like of ints or None, optional] Axes over which to compute the convolution. The default is over all axes.
Returns

- **out**: [array] An N-dimensional array containing a subset of the discrete linear convolution of `in1` with `in2`.

See also:

**convolve**

Uses the direct convolution or FFT convolution algorithm depending on which is faster.

**oaconvolve**

Uses the overlap-add method to do convolution, which is generally faster when the input arrays are large and significantly different in size.

Examples

Autocorrelation of white noise is an impulse.

```python
>>> from scipy import signal
>>> rng = np.random.default_rng()
>>> sig = rng.standard_normal(1000)
>>> autocorr = signal.fftconvolve(sig, sig[::-1], mode='full')
```

Gaussian blur implemented using FFT convolution. Notice the dark borders around the image, due to the zero-padding beyond its boundaries. The `convolve2d` function allows for other types of image boundaries, but is far slower.

```python
>>> from scipy import misc
>>> face = misc.face(gray=True)
>>> kernel = np.outer(signal.windows.gaussian(70, 8), signal.windows.gaussian(70, 8))
>>> blurred = signal.fftconvolve(face, kernel, mode='same')
```

```python
>>> fig, (ax_orig, ax_kernel, ax_blurred) = plt.subplots(3, 1, figsize=(6, 15))
>>> ax_orig.imshow(face, cmap='gray')
>>> ax_orig.set_title('Original')
>>> ax_orig.set_axis_off()
>>> ax_kernel.imshow(kernel, cmap='gray')
>>> ax_kernel.set_title('Gaussian kernel')
>>> ax_kernel.set_axis_off()
>>> ax_blurred.imshow(blurred, cmap='gray')
>>> ax_blurred.set_title('Blurred')
```

(continues on next page)
```python
>>> ax_blurred.set_axis_off()
>>> fig.show()
```

```
White noise
```

```
Autocorrelation
```

**scipy.signal.overlapadd**

`scipy.signal.overlapadd(in1, in2, mode='full', axes=None)`

Convolves two N-dimensional arrays using the overlap-add method.

Convolves `in1` and `in2` using the overlap-add method, with the output size determined by the `mode` argument.

This is generally much faster than `convolve` for large arrays (n > ~500), and generally much faster than `fftconvolve` when one array is much larger than the other, but can be slower when only a few output values are needed or when the arrays are very similar in shape, and can only output float arrays (int or object array inputs will be cast to float).

**Parameters**

- `in1` [array_like] First input.
- `in2` [array_like] Second input. Should have the same number of dimensions as `in1`.
- `mode` [str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:
  - `full` The output is the full discrete linear convolution of the inputs. (Default)
  - `valid` The output consists only of those elements that do not rely on the zero-padding. In ‘valid’ mode, either `in1` or `in2` must be at least as large as the other in every dimension.
  - `same` The output is the same size as `in1`, centered with respect to the ‘full’ output.
- `axes` [int or array_like of ints or None, optional] Axes over which to compute the convolution. The default is over all axes.

**Returns**

- `out` [array] An N-dimensional array containing a subset of the discrete linear convolution of `in1` with `in2`.

**See also:**

- `convolve`
3.3. API definition
Uses the direct convolution or FFT convolution algorithm depending on which is faster.

**fftconvolve**

An implementation of convolution using FFT.

**Notes**

New in version 1.4.0.

**References**

[1], [2]

**Examples**

Conolve a 100,000 sample signal with a 512-sample filter.

```python
>>> from scipy import signal
>>> rng = np.random.default_rng()
>>> sig = rng.standard_normal(100000)
>>> filt = signal.firwin(512, 0.01)
>>> fsig = signal.oaconvolve(sig, filt)
```

```python
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_mag) = plt.subplots(2, 1)
>>> ax_orig.plot(sig)
>>> ax_orig.set_title('White noise')
>>> ax_mag.plot(fsig)
>>> ax_mag.set_title('Filtered noise')
>>> fig.tight_layout()
>>> fig.show()
```

![White noise](image1.png)

![Filtered noise](image2.png)
scipy.signal.convolve2d

scipy.signal.convolve2d(in1, in2, mode='full', boundary='fill', fillvalue=0)

Convolves two 2-dimensional arrays.

Convolves in1 and in2 with output size determined by mode, and boundary conditions determined by boundary and fillvalue.

Parameters

- **in1** ([array_like]) First input. Should have the same number of dimensions as in1.
- **in2** ([array_like]) Second input. Should have the same number of dimensions as in1.
- **mode** ([str {‘full’, ‘valid’, ‘same’}, optional]) A string indicating the size of the output:
  - **full** The output is the full discrete linear convolution of the inputs. (Default)
  - **valid** The output consists only of those elements that do not rely on the zero-padding. In ‘valid’ mode, either in1 or in2 must be at least as large as the other in every dimension.
  - **same** The output is the same size as in1, centered with respect to the ‘full’ output.
- **boundary** ([str {‘fill’, ‘wrap’, ‘symm’}, optional]) A flag indicating how to handle boundaries:
  - **fill** Pad input arrays with fillvalue. (default)
  - **wrap** Circular boundary conditions.
  - **symm** Symmetrical boundary conditions.
- **fillvalue** ([scalar, optional]) Value to fill pad input arrays with. Default is 0.

Returns

- **out** ([ndarray]) A 2-dimensional array containing a subset of the discrete linear convolution of in1 with in2.

Examples

Compute the gradient of an image by 2D convolution with a complex Scharr operator. (Horizontal operator is real, vertical is imaginary.) Use symmetric boundary condition to avoid creating edges at the image boundaries.

```python
>>> from scipy import signal
>>> from scipy import misc
>>> ascent = misc.ascent()
>>> scharr = np.array([[[-3-3j, 0-10j, +3-3j],
                      [-10+0j, 0+0j, +10+0j],
                      [-3+3j, 0+10j, +3+3j]]]) # Gx + j*Gy
>>> grad = signal.convolve2d(ascent, scharr, boundary='symm', mode='same')

>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_mag, ax_ang) = plt.subplots(3, 1, figsize=(6, 15))
>>> ax_orig.imshow(ascent, cmap='gray')
>>> ax_orig.set_title('Original')
>>> ax_orig.set_axis_off()
>>> ax_mag.imshow(np.abs(grad), cmap='gray')
>>> ax_mag.set_title('Gradient magnitude')
>>> ax_mag.set_axis_off()
>>> ax_ang.imshow(np.angle(grad), cmap='hsv') # hsv is cyclic, like angles
>>> ax_ang.set_title('Gradient orientation')
>>> ax_ang.set_axis_off()
>>> fig.show()
```
Original

Gradient magnitude

Gradient orientation
scipy.signal.correlate2d

scipy.signal.correlate2d(in1, in2, mode='full', boundary='fill', fillvalue=0)

Cross-correlate two 2-dimensional arrays.

Cross-correlate in1 and in2 with output size determined by mode, and boundary conditions determined by boundary and fillvalue.

Parameters

in1 [array_like] First input.
in2 [array_like] Second input. Should have the same number of dimensions as in1.
mode [str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:
    full The output is the full discrete linear cross-correlation of the inputs. (Default)
    valid The output consists only of those elements that do not rely on the zero-padding. In ‘valid’ mode, either in1 or in2 must be at least as large as the other in every dimension.
    same The output is the same size as in1, centered with respect to the ‘full’ output.
boundary [str {'fill', 'wrap', 'symm'}, optional] A flag indicating how to handle boundaries:
    fill pad input arrays with fillvalue. (default)
    wrap circular boundary conditions.
    symm symmetrical boundary conditions.
fillvalue [scalar, optional] Value to fill pad input arrays with. Default is 0.

Returns
correlate2d [ndarray] A 2-dimensional array containing a subset of the discrete linear cross-correlation of in1 with in2.

Notes

When using “same” mode with even-length inputs, the outputs of correlate and correlate2d differ: There is a 1-index offset between them.

Examples

Use 2D cross-correlation to find the location of a template in a noisy image:

```python
>>> from scipy import signal
>>> from scipy import misc
>>> rng = np.random.default_rng()
>>> face = misc.face(gray=True) - misc.face(gray=True).mean()
>>> template = np.copy(face[300:365, 670:750])  # right eye
>>> template -= template.mean()
>>> face = face + rng.standard_normal(face.shape) * 50  # add noise
>>> corr = signal.correlate2d(face, template, boundary='symm', mode='same')
>>> y, x = np.unravel_index(np.argmax(corr), corr.shape)  # find the match
```

```python
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_template, ax_corr) = plt.subplots(3, 1,...  figsize=(6, 15))
>>> ax_orig.imshow(face, cmap='gray')
```
(continues on next page)
```python
>>> ax_orig.set_title('Original')
>>> ax_orig.set_axis_off()
>>> ax_template.imshow(template, cmap='gray')
>>> ax_template.set_title('Template')
>>> ax_template.set_axis_off()
>>> ax_corr.imshow(corr, cmap='gray')
>>> ax_corr.set_title('Cross-correlation')
>>> ax_corr.set_axis_off()
>>> ax_orig.plot(x, y, 'ro')
>>> fig.show()
```

**scipy.signal.sepfir2d**

`scipy.signal.sepfir2d(input, hrow, hcol)`

Convolve with a 2-D separable FIR filter.

Convolve the rank-2 input array with the separable filter defined by the rank-1 arrays hrow, and hcol. Mirror symmetric boundary conditions are assumed. This function can be used to find an image given its B-spline representation.

**Parameters**

- **input** [ndarray] The input signal. Must be a rank-2 array.
- **hrow** [ndarray] A rank-1 array defining the row direction of the filter. Must be odd-length
- **hcol** [ndarray] A rank-1 array defining the column direction of the filter. Must be odd-length

**Returns**

- **output** [ndarray] The filtered signal.

**Examples**

Examples are given in the tutorial.

**scipy.signal.choose_conv_method**

`scipy.signal.choose_conv_method(in1, in2, mode='full', measure=False)`

Find the fastest convolution/correlation method.

This primarily exists to be called during the `method='auto'` option in `convolve` and `correlate`. It can also be used to determine the value of `method` for many different convolutions of the same dtype/shape. In addition, it supports timing the convolution to adapt the value of `method` to a particular set of inputs and/or hardware.

**Parameters**

- **in1** [array_like] The first argument passed into the convolution function.
- **in2** [array_like] The second argument passed into the convolution function.
- **mode** [str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:
  - **full** The output is the full discrete linear convolution of the inputs. (Default)
  - **valid** The output consists only of those elements that do not rely on the zero-padding.
  - **same** The output is the same size as `in1`, centered with respect to the ‘full’ output.
- **measure** [bool, optional] If True, run and time the convolution of `in1` and `in2` with both methods and return the fastest. If False (default), predict the fastest method using precomputed values.

**Returns**

- **method** [str] A string indicating which convolution method is fastest, either ‘direct’ or ‘fft’
3.3. API definition

Original

Template

Cross-correlation
times : [dict, optional] A dictionary containing the times (in seconds) needed for each method. This value is only returned if measure=True.

See also:

convolve
correlate

Notes

Generally, this method is 99% accurate for 2D signals and 85% accurate for 1D signals for randomly chosen input sizes. For precision, use measure=True to find the fastest method by timing the convolution. This can be used to avoid the minimal overhead of finding the fastest method later, or to adapt the value of method to a particular set of inputs.

Experiments were run on an Amazon EC2 r5a.2xlarge machine to test this function. These experiments measured the ratio between the time required when using method='auto' and the time required for the fastest method (i.e., ratio = time_auto / min(time_fft, time_direct)). In these experiments, we found:

- There is a 95% chance of this ratio being less than 1.5 for 1D signals and a 99% chance of being less than 2.5 for 2D signals.
- The ratio was always less than 2.5/5 for 1D/2D signals respectively.
- This function is most inaccurate for 1D convolutions that take between 1 and 10 milliseconds with method='direct'. A good proxy for this (at least in our experiments) is \(1e6 \leq in1.size * in2.size \leq 1e7\).

The 2D results almost certainly generalize to 3D/4D/etc because the implementation is the same (the 1D implementation is different).

All the numbers above are specific to the EC2 machine. However, we did find that this function generalizes fairly decently across hardware. The speed tests were of similar quality (and even slightly better) than the same tests performed on the machine to tune this function's numbers (a mid-2014 15-inch MacBook Pro with 16GB RAM and a 2.5GHz Intel i7 processor).

There are cases when fftconvolve supports the inputs but this function returns direct (e.g., to protect against floating point integer precision).

New in version 0.19.

Examples

Estimate the fastest method for a given input:

```python
>>> from scipy import signal
>>> rng = np.random.default_rng()
>>> img = rng.random((32, 32))
>>> filter = rng.random((8, 8))
>>> method = signal.choose_conv_method(img, filter, mode='same')
>>> method
'fft'
```

This can then be applied to other arrays of the same dtype and shape:
>>> img2 = rng.random((32, 32))
>>> filter2 = rng.random((8, 8))
>>> corr2 = signal.correlate(img2, filter2, mode='same', method=method)
>>> conv2 = signal.convolve(img2, filter2, mode='same', method=method)

The output of this function (method) works with `correlate` and `convolve`.

### scipy.signal.correlation_lags

**scipy.signal.correlation_lags** *(in1_len, in2_len, mode='full')*

Calculates the lag / displacement indices array for 1D cross-correlation.

**Parameters**

- `in1_size` [int] First input size.
- `in2_size` [int] Second input size.
- `mode` [str {'full', 'valid', 'same'}, optional] A string indicating the size of the output. See the documentation `correlate` for more information.

**Returns**

- `lags` [array] Returns an array containing cross-correlation lag/displacement indices. Indices can be indexed with the `np.argmax` of the correlation to return the lag/displacement.

**See also:**

- `correlate`
  
  Compute the N-dimensional cross-correlation.

**Notes**

Cross-correlation for continuous functions \( f \) and \( g \) is defined as:

\[
(f * g)(\tau) \triangleq \int_{t_0}^{t_0+T} f(t) g(t + \tau) \, dt
\]

Where \( \tau \) is defined as the displacement, also known as the lag.

Cross correlation for discrete functions \( f \) and \( g \) is defined as:

\[
(f * g)[n] \triangleq \sum_{m=-\infty}^{\infty} f[m] g[m + n]
\]

Where \( n \) is the lag.

**Examples**

Cross-correlation of a signal with its time-delayed self.

```python
>>> from scipy import signal
>>> from numpy.random import default_rng
>>> rng = default_rng()
>>> x = rng.standard_normal(1000)
>>> y = np.concatenate([rng.standard_normal(100), x])
>>> correlation = signal.correlate(x, y, mode="full")
```
```python
>>> lags = signal.correlation_lags(x.size, y.size, mode="full")
>>> lag = lags[np.argmax(correlation)]
```

**B-splines**

- `bspline(x, n)`
  B-spline basis function of order n.
- `cubic(x)`
  A cubic B-spline.
- `quadratic(x)`
  A quadratic B-spline.
- `gauss_spline(x, n)`
  Gaussian approximation to B-spline basis function of order n.
- `cspline1d(signal[, lamb])`
  Compute cubic spline coefficients for rank-1 array.
- `qspline1d(signal[, lamb])`
  Compute quadratic spline coefficients for rank-1 array.
- `cspline2d(input[, lambda, precision])`
  Coefficients for 2-D cubic (3rd order) B-spline.
- `qspline2d(input[, lambda, precision])`
  Coefficients for 2-D quadratic (2nd order) B-spline.
- `cspline1d_eval(cj,newx[, dx,x0])`
  Evaluate a cubic spline at the new set of points.
- `qspline1d_eval(cj,newx[, dx,x0])`
  Evaluate a quadratic spline at the new set of points.
- `spline_filter(Iin[, lamb])`
  Smoothing spline (cubic) filtering of a rank-2 array.

### scipy.signal.bspline

**scipy.signal.bspline(x, n)**

B-spline basis function of order n.

**Parameters**

- `x` [array_like] a knot vector
- `n` [int] The order of the spline. Must be non-negative, i.e., n >= 0

**Returns**

- `res` [ndarray] B-spline basis function values

**See also:**

- `cubic`
  A cubic B-spline.
- `quadratic`
  A quadratic B-spline.

**Notes**

Uses numpy.piecewise and automatic function-generator.
Examples

We can calculate B-Spline basis function of several(157,65),(844,903)

```python
>>> from scipy.signal import bspline, cubic, quadratic
>>> bspline(0.0, 1)
1
```
```
>>> knots = [-1.0, 0.0, -1.0]
>>> bspline(knots, 2)
array([0.125, 0.75, 0.125])
```
```
>>> np.array_equal(bspline(knots, 2), quadratic(knots))
True
```
```
>>> np.array_equal(bspline(knots, 3), cubic(knots))
True
```

scipy.signal.cubic

scipy.signal.cubic(x)

A cubic B-spline.

This is a special case of `bspline`, and equivalent to `bspline(x, 3)`.

Parameters

- `x` : [array_like] a knot vector

Returns

- `res` : [ndarray] Cubic B-spline basis function values

See also:

- `bspline`
  B-spline basis function of order n

- `quadratic`
  A quadratic B-spline.

Examples

We can calculate B-Spline basis function of several orders:

```python
>>> from scipy.signal import bspline, cubic, quadratic
>>> bspline(0.0, 1)
1
```
```
>>> knots = [-1.0, 0.0, -1.0]
>>> bspline(knots, 2)
array([0.125, 0.75, 0.125])
```
scipy.signal.quadratic

scipy.signal.quadratic(x)
A quadratic B-spline.

This is a special case of bspline, and equivalent to bspline(x, 2).

Parameters

x : array_like a knot vector

Returns

res : ndarray Quadratic B-spline basis function values

See also:

bspline
B-spline basis function of order n
cubic
A cubic B-spline.

Examples

We can calculate B-Spline basis function of several orders:

```python
>>> from scipy.signal import bspline, cubic, quadratic
>>> bspline(0.0, 1)
1
```

```python
>>> knots = [-1.0, 0.0, -1.0]
>>> bspline(knots, 2)
array([0.125, 0.75, 0.125])
```

```python
>>> np.array_equal(bspline(knots, 2), quadratic(knots))
True
```

```python
>>> np.array_equal(bspline(knots, 3), cubic(knots))
True
```
**scipy.signal.gauss_spline**

`scipy.signal.gauss_spline(x, n)`

Gaussian approximation to B-spline basis function of order n.

**Parameters**

- `x` : array_like, a knot vector
- `n` : int, The order of the spline. Must be non-negative, i.e., `n >= 0`

**Returns**

- `res` : ndarray, B-spline basis function values approximated by a zero-mean Gaussian function.

**Notes**

The B-spline basis function can be approximated well by a zero-mean Gaussian function with standard-deviation equal to \( \sigma = (n + 1)/12 \) for large \( n \):

\[
\frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{x^2}{2\sigma}}
\]

**References**

[1], [2]

**Examples**

We can calculate B-Spline basis functions approximated by a gaussian distribution:

```python
>>> from scipy.signal import gauss_spline, bspline
>>> knots = np.array([-1.0, 0.0, -1.0])
>>> gauss_spline(knots, 3)
array([0.15418033, 0.6909883, 0.15418033])  # may vary
```

```python
>>> bspline(knots, 3)
array([0.16666667, 0.66666667, 0.16666667])  # may vary
```

**scipy.signal.cspline1d**

`scipy.signal.cspline1d(signal, lamb=0.0)`

Compute cubic spline coefficients for rank-1 array.

Find the cubic spline coefficients for a 1-D signal assuming mirror-symmetric boundary conditions. To obtain the signal back from the spline representation mirror-symmetric-convolve these coefficients with a length 3 FIR window \([1.0, 4.0, 1.0]/6.0\).

**Parameters**

- `signal` : ndarray, A rank-1 array representing samples of a signal.
- `lamb` : float, optional, Smoothing coefficient, default is 0.0.

**Returns**

- `c` : ndarray, Cubic spline coefficients.

See also:
cspline1d_eval

Evaluate a cubic spline at the new set of points.

Examples

We can filter a signal to reduce and smooth out high-frequency noise with a cubic spline:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import cspline1d, cspline1d_eval
>>> rng = np.random.default_rng()
>>> sig = np.repeat([0., 1., 0.], 100)
>>> sig += rng.standard_normal(len(sig)) * 0.05  # add noise
>>> time = np.linspace(0, len(sig))
>>> filtered = cspline1d_eval(cspline1d(sig), time)
>>> plt.plot(sig, label="signal")
>>> plt.plot(time, filtered, label="filtered")
>>> plt.legend()
>>> plt.show()
```

scipy.signal.qspline1d

scipy.signal.qspline1d(signal, lamb=0.0)

Compute quadratic spline coefficients for rank-1 array.

Parameters

- **signal** [ndarray] A rank-1 array representing samples of a signal.
- **lamb** [float, optional] Smoothing coefficient (must be zero for now).

Returns

- **c** [ndarray] Quadratic spline coefficients.

See also:
qspline1d_eval

Evaluate a quadratic spline at the new set of points.

Notes

Find the quadratic spline coefficients for a 1-D signal assuming mirror-symmetric boundary conditions. To obtain the signal back from the spline representation mirror-symmetric-convolve these coefficients with a length 3 FIR window [1.0, 6.0, 1.0]/8.0.

Examples

We can filter a signal to reduce and smooth out high-frequency noise with a quadratic spline:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import qspline1d, qspline1d_eval
>>> rng = np.random.default_rng()
>>> sig = np.repeat([0., 1., 0.], 100)
>>> sig += rng.standard_normal(len(sig))*0.05  # add noise
>>> time = np.linspace(0, len(sig))
>>> filtered = qspline1d_eval(qspline1d(sig), time)
>>> plt.plot(sig, label="signal")
>>> plt.plot(time, filtered, label="filtered")
>>> plt.legend()
>>> plt.show()
```
**scipy.signal.cspline2d**

`scipy.signal.cspline2d(input, lambda=0.0, precision=-1.0)`

Coefficients for 2-D cubic (3rd order) B-spline.

Return the third-order B-spline coefficients over a regularly spaced input grid for the two-dimensional input image.

**Parameters**

- **input** [ndarray] The input signal.
- **lambda** [float] Specifies the amount of smoothing in the transfer function.
- **precision** [float] Specifies the precision for computing the infinite sum needed to apply mirror-symmetric boundary conditions.

**Returns**

- **output** [ndarray] The filtered signal.

**Examples**

Examples are given *in the tutorial*.

**scipy.signal.qspline2d**

`scipy.signal.qspline2d(input, lambda=0.0, precision=-1.0)`

Coefficients for 2-D quadratic (2nd order) B-spline:

Return the second-order B-spline coefficients over a regularly spaced input grid for the two-dimensional input image.

**Parameters**

- **input** [ndarray] The input signal.
- **lambda** [float] Specifies the amount of smoothing in the transfer function.
- **precision** [float] Specifies the precision for computing the infinite sum needed to apply mirror-symmetric boundary conditions.

**Returns**

- **output** [ndarray] The filtered signal.

**Examples**

Examples are given *in the tutorial*.

**scipy.signal.cspline1d_eval**

`scipy.signal.cspline1d_eval(cj, newx, dx=1.0, x0=0)`

Evaluate a cubic spline at the new set of points.

`dx` is the old sample-spacing while `x0` was the old origin. In other-words the old-sample points (knot-points) for which the `cj` represent spline coefficients were at equally-spaced points of:

\[ \text{oldx} = x0 + j \times dx, j=0 \ldots N-1, \text{with} \ N=\text{len}(cj) \]

Edges are handled using mirror-symmetric boundary conditions.

**Parameters**

- **cj** [ndarray] cubic spline coefficients
- **newx** [ndarray] New set of points.
- **dx** [float, optional] Old sample-spacing, the default value is 1.0.
x0  [int, optional] Old origin, the default value is 0.

Returns
res  [ndarray] Evaluated a cubic spline points.

See also:

cspline1d

Compute cubic spline coefficients for rank-1 array.

Examples

We can filter a signal to reduce and smooth out high-frequency noise with a cubic spline:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import cspline1d, cspline1d_eval
>>> rng = np.random.default_rng()
>>> sig = np.repeat([0., 1., 0.], 100)
>>> sig += rng.standard_normal(len(sig))*.05  # add noise
>>> time = np.linspace(0, len(sig))
>>> filtered = cspline1d_eval(cspline1d(sig), time)
>>> plt.plot(sig, label="signal")
>>> plt.plot(time, filtered, label="filtered")
>>> plt.legend()
>>> plt.show()
```
scipy.signal.qspline1d_eval

Evaluate a quadratic spline at the new set of points.

**Parameters**

- **cj** ([ndarray]): Quadratic spline coefficients
- **newx** ([ndarray]): New set of points.
- **dx** ([float, optional]): Old sample-spacing, the default value is 1.0.
- **x0** ([int, optional]): Old origin, the default value is 0.

**Returns**

- **res** ([ndarray]): Evaluated a quadratic spline points.

**See also:**

qspline1d

Compute quadratic spline coefficients for rank-1 array.

**Notes**

- \(dx\) is the old sample-spacing while \(x0\) was the old origin. In other-words the old-sample points (knot-points) for which the \(cj\) represent spline coefficients were at equally-spaced points of:

\[
\text{oldx} = x0 + j \cdot dx \quad j=0\ldots N-1, \quad \text{with} \quad N=\text{len}(cj)
\]

Edges are handled using mirror-symmetric boundary conditions.

**Examples**

We can filter a signal to reduce and smooth out high-frequency noise with a quadratic spline:

```python
from scipy.signal import qspline1d, qspline1d_eval

rng = np.random.default_rng()
	sig = np.repeat([0., 1., 0.], 100)
	sig += rng.standard_normal(len(sig))*0.05  # add noise

time = np.linspace(0, len(sig))

filtered = qspline1d_eval(qspline1d(sig), time)

plt.plot(sig, label="signal")
plt.plot(time, filtered, label="filtered")
plt.legend()
plt.show()
```
scipy.signal.spline_filter

scipy.signal.spline_filter (lin, lmbda=5.0)

Smoothing spline (cubic) filtering of a rank-2 array.

Filter an input data set, lin, using a (cubic) smoothing spline of fall-off lmbda.

Parameters

- **lin** [array_like] input data set
- **lmbda** [float, optional] spline smoothing fall-off value, default is 5.0.

Returns

- **res** [ndarray] filtered input data

Examples

We can filter an multi dimentional signal (ex: 2D image) using cubic B-spline filter:

```python
>>> from scipy.signal import spline_filter
>>> import matplotlib.pyplot as plt
>>> orig_img = np.eye(20)  # create an image
>>> orig_img[10, :] = 1.0
>>> sp_filter = spline_filter(orig_img, lmbda=0.1)
>>> f, ax = plt.subplots(1, 2, sharex=True)
>>> for ind, data in enumerate([orig_img, "original image"],
...                            [sp_filter, "spline filter"]):
...     ax[ind].imshow(data[0], cmap='gray_r')
...     ax[ind].set_title(data[1])
>>> plt.tight_layout()
>>> plt.show()
```
Filtering

*order_filter*(a, domain, rank)  Perform an order filter on an N-D array.

*medfilt*(volume[, kernel_size])  Perform a median filter on an N-dimensional array.

*medfilt2d*(input[, kernel_size])  Median filter a 2-dimensional array.

*wiener*(im[, mysize, noise])  Implement a Wiener filter on an N-dimensional array.

*symiirorder1*(input, c0, z1[, precision])  Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of first-order sections. The second section uses a reversed sequence. This implements a system with the following transfer function and mirror-symmetric boundary conditions:

\[
\text{symiirorder2}(\text{input, r, omega[, precision]})
\]

Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of second-order sections. The second section uses a reversed sequence. This implements the following transfer function:

*lfiltic*(b, a, y[, x])  Construct initial conditions for lfilter given input and output vectors.

*lfilter_zi*(b, a)  Construct initial conditions for lfilter for step response steady-state.

*filtfilt*(b, a, x[, axis, padtype, padlen,...])  Apply a digital filter forward and backward to a signal.

*savvogel_filter*(x, window_length, polyorder[, ...])  Apply a Savitzky-Golay filter to an array.

*deconvolve*(signal, divisor)  Deconvolves divisor out of signal using inverse filtering.

*sosfilt*(sos, x[, axis, zi])  Filter data along one dimension using cascaded second-order sections.

*sosfilt_zi*(sos)  Construct initial conditions for sosfilt for step response steady-state.

*sosfiltfilt*(sos, x[, axis, padtype, padlen])  A forward-backward digital filter using cascaded second-order sections.

*hilbert*(x[, N, axis])  Compute the analytic signal, using the Hilbert transform.

*hilbert2*(x[, N])  Compute the ‘2-D’ analytic signal of x.

**scipy.signal.order_filter**

`scipy.signal.order_filter(a, domain, rank)`

Perform an order filter on an N-D array.

Perform an order filter on the array in. The domain argument acts as a mask centered over each pixel. The non-zero elements of domain are used to select elements surrounding each input pixel which are placed in a list. The list is sorted, and the output for that pixel is the element corresponding to rank in the sorted list.

**Parameters**

- **a** [ndarray] The N-dimensional input array.
- **domain** [array_like] A mask array with the same number of dimensions as $a$. Each dimension should have an odd number of elements.
- **rank** [int] A non-negative integer which selects the element from the sorted list (0 corresponds to the smallest element, 1 is the next smallest element, etc.).

**Returns**

- **out** [ndarray] The results of the order filter in an array with the same shape as $a$.

**Examples**

```python
gtir from scipy import signal
gtir x = np.arange(25).reshape(5, 5)
gtir domain = np.identity(3)
gtir x
array([[0, 1, 2, 3, 4],
       [5, 6, 7, 8, 9],
       [10, 11, 12, 13, 14],
       [15, 16, 17, 18, 19],
       [20, 21, 22, 23, 24]])
gtir signal.order_filter(x, domain, 0)
array([[0., 0., 0., 0., 0.],
       [0., 0., 1., 2., 0.],
       [0., 5., 6., 7., 0.],
       [0., 10., 11., 12., 0.],
       [0., 0., 0., 0., 0.]])
gtir signal.order_filter(x, domain, 2)
array([[6., 7., 8., 9., 4.],
       [16., 17., 18., 19., 14.],
       [21., 22., 23., 24., 19.],
       [20., 21., 22., 23., 24.]])
```
scipy.signal.medfilt

```python
scipy.signal.medfilt(volume, kernel_size=None)
```

Perform a median filter on an N-dimensional array.

Apply a median filter to the input array using a local window-size given by `kernel_size`. The array will automatically be zero-padded.

**Parameters**

- `kernel_size` [array_like, optional] A scalar or an N-length list giving the size of the median filter window in each dimension. Elements of `kernel_size` should be odd. If `kernel_size` is a scalar, then this scalar is used as the size in each dimension. Default size is 3 for each dimension.

**Returns**

- `out` [ndarray] An array the same size as input containing the median filtered result.

**Warns**

- `UserWarning` If array size is smaller than kernel size along any dimension

**See also:**

- `scipy.ndimage.median_filter`
- `scipy.signal.medfilt2d`

**Notes**

The more general function `scipy.ndimage.median_filter` has a more efficient implementation of a median filter and therefore runs much faster.

For 2-dimensional images with `uint8`, `float32` or `float64` dtypes, the specialised function `scipy.signal.medfilt2d` may be faster.

scipy.signal.medfilt2d

```python
scipy.signal.medfilt2d(input, kernel_size=3)
```

Median filter a 2-dimensional array.

Apply a median filter to the `input` array using a local window-size given by `kernel_size` (must be odd). The array is zero-padded automatically.

**Parameters**

- `input` [array_like] A 2-dimensional input array.
- `kernel_size` [array_like, optional] A scalar or a list of length 2, giving the size of the median filter window in each dimension. Elements of `kernel_size` should be odd. If `kernel_size` is a scalar, then this scalar is used as the size in each dimension. Default is a kernel of size `(3, 3)`.

**Returns**

- `out` [ndarray] An array the same size as input containing the median filtered result.

**See also:**

- `scipy.ndimage.median_filter`
Notes

This is faster than medfilt when the input dtype is uint8, float32, or float64; for other types, this falls back to medfilt; you should use scipy.ndimage.median_filter instead as it is much faster. In some situations, scipy.ndimage.median_filter may be faster than this function.

scipy.signal.wiener

scipy.signal.wiener(im, mysize=None, noise=None)

Perform a Wiener filter on an N-dimensional array.

Apply a Wiener filter to the N-dimensional array im.

Parameters

mysize [int or array_like, optional] A scalar or an N-length list giving the size of the Wiener filter window in each dimension. Elements of mysize should be odd. If mysize is a scalar, then this scalar is used as the size in each dimension.

noise [float, optional] The noise-power to use. If None, then noise is estimated as the average of the local variance of the input.

Returns

out [ndarray] Wiener filtered result with the same shape as im.

Notes

This implementation is similar to wiener2 in Matlab/Octave. For more details see [1]

References

[1]

Examples

```python
>>> from scipy.misc import face
>>> from scipy.signal import wiener
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> rng = np.random.default_rng()
>>> img = rng.random((40, 40))  # Create a random image
>>> filtered_img = wiener(img, (5, 5))  # Filter the image
>>> f, (plot1, plot2) = plt.subplots(1, 2)
>>> plot1.imshow(img)
>>> plot2.imshow(filtered_img)
>>> plt.show()
```
scipy.signal.symiirorder1

Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of first-order sections. The second section uses a reversed sequence. This implements a system with the following transfer function and mirror-symmetric boundary conditions:

\[
H(z) = \frac{c_0}{(1-z_1/z)(1 - z_1 z)}
\]

The resulting signal will have mirror symmetric boundary conditions as well.

**Parameters**

- **input** [ndarray] The input signal.
- **c0, z1** [scalar] Parameters in the transfer function.
- **precision** : Specifies the precision for calculating initial conditions of the recursive filter based on mirror-symmetric input.

**Returns**

- **output** [ndarray] The filtered signal.

scipy.signal.symiirorder2

Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of second-order sections. The second section uses a reversed sequence. This implements the following transfer function:

\[
H(z) = \frac{c s^2}{(1 - a2/z - a3/z^2)(1 - a2 z - a3 z^2)}
\]

where:
a2 = (2 r cos omega)
a3 = - r^2
cs = 1 - 2 r cos omega + r^2

**Parameters**

- **input** [ndarray] The input signal.
- **r, omega** [float] Parameters in the transfer function.
- **precision** [float] Specifies the precision for calculating initial conditions of the recursive filter based on mirror-symmetric input.

**Returns**

- **output** [ndarray] The filtered signal.

**scipy.signal.lfilter**

```python
scipy.signal.lfilter(b, a, x, axis=-1, zi=None)
```

Filter data along one-dimension with an IIR or FIR filter.

Filter a data sequence, `x`, using a digital filter. This works for many fundamental data types (including Object type). The filter is a direct form II transposed implementation of the standard difference equation (see Notes).

The function `sosfilt` (and filter design using `output='sos'`) should be preferred over `lfilter` for most filtering tasks, as second-order sections have fewer numerical problems.

**Parameters**

- **b** [array_like] The numerator coefficient vector in a 1-D sequence.
- **a** [array_like] The denominator coefficient vector in a 1-D sequence. If `a[0]` is not 1, then both `a` and `b` are normalized by `a[0]`.
- **x** [array_like] An N-dimensional input array.
- **axis** [int, optional] The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.
- **zi** [array_like, optional] Initial conditions for the filter delays. It is a vector (or array of vectors for an N-dimensional input) of length `max(len(a), len(b)) - 1`. If `zi` is None or is not given then initial rest is assumed. See `lfilter_zi` for more information.

**Returns**

- **y** [array] The output of the digital filter.
- **zf** [array, optional] If `zi` is None, this is not returned, otherwise, `zf` holds the final filter delay values.

**See also:**

- `lfilter_zi` Compute initial state (steady state of step response) for `lfilter`.
- `filtfilt` A forward-backward filter, to obtain a filter with linear phase.
- `savgol_filter` A Savitzky-Golay filter.
**sosfilt**

Filter data using cascaded second-order sections.

**sosfiltfilt**

A forward-backward filter using second-order sections.

**Notes**

The filter function is implemented as a direct II transposed structure. This means that the filter implements:

\[ -a[1]y[n-1] - \ldots - a[N]y[n-N] \]

where \( M \) is the degree of the numerator, \( N \) is the degree of the denominator, and \( n \) is the sample number. It is implemented using the following difference equations (assuming \( M = N \)):

\[
\begin{align*}
    a[0]y[n] &= b[0]x[n] + d[0][n-1] \\
    \vdots \\
    d[N-1][n] &= b[N]x[n] - a[N]y[n]
\end{align*}
\]

where \( d \) are the state variables.

The rational transfer function describing this filter in the z-transform domain is:

\[
Y(z) = \frac{-1}{b[0] + b[1]z + \ldots + b[M]z} \frac{-1}{a[0] + a[1]z + \ldots + a[N]z} X(z)
\]

**Examples**

Generate a noisy signal to be filtered:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
>>> t = np.linspace(-1, 1, 201)
>>> x = (np.sin(2*np.pi*0.75*t*(1-t) + 2.1) +
       ... 0.1*np.sin(2*np.pi*1.25*t + 1) +
       ... 0.18*np.cos(2*np.pi*3.85*t))
>>> xn = x + rng.standard_normal(len(t)) * 0.08
```

Create an order 3 lowpass butterworth filter:

```python
>>> b, a = signal.butter(3, 0.05)
```

Apply the filter to \( xn \). Use \texttt{filtfilt} to choose the initial condition of the filter:
>>> zi = signal.lfilter_zi(b, a)
>>> z, _ = signal.lfilter(b, a, xn, zi=zi*xn[0])

Apply the filter again, to have a result filtered at an order the same as filtfilt:

>>> z2, _ = signal.lfilter(b, a, z, zi=zi*z[0])

Use filtfilt to apply the filter:

>>> y = signal.filtfilt(b, a, xn)

Plot the original signal and the various filtered versions:

```python
>>> plt.figure
>>> plt.plot(t, xn,'b', alpha=0.75)
>>> plt.plot(t, z,'r--', t, z2,'r', t, y,'k', ...
... 'filtfilt'), loc='best')
>>> plt.legend(('noisy signal', 'lfilter, once', 'lfilter, twice', ...
... 'filtfilt'), loc='best')
>>> plt.grid(True)
>>> plt.show()
```

---

**scipy.signal.lfiltic**

`scipy.signal.lfiltic(b, a, y=x=None)`

Construct initial conditions for lfilter given input and output vectors.

Given a linear filter (b, a) and initial conditions on the output y and the input x, return the initial conditions on the state vector zi which is used by lfilter to generate the output given the input.

**Parameters**

- **b** [array_like] Linear filter term.
- **a** [array_like] Linear filter term.
- **y** [array_like] Initial conditions.  
  - If \( N = \text{len}(a) - 1 \), then \( y = \{y[-1], y[-2], \ldots, y[-N]\} \).  
  - If \( y \) is too short, it is padded with zeros.
x [array_like, optional] Initial conditions.  
If \( M = \text{len}(b) - 1 \), then \( x = \{x[-1], x[-2], \ldots, x[-M]\} \).  
If \( x \) is not given, its initial conditions are assumed zero.  
If \( x \) is too short, it is padded with zeros.

**Returns**

zi [ndarray] The state vector \( zi = \{z_0[-1], z_1[-1], \ldots, z_K-1[-1]\} \), where \( K = \max(M, N) \).

See also:

* `lfilter`, `lfilter_zi`

**scipy.signal.lfilter_zi**

`scipy.signal.lfilter_zi(b, a)`  
Construct initial conditions for `lfilter` for step response steady-state.

Compute an initial state \( zi \) for the `lfilter` function that corresponds to the steady state of the step response.

A typical use of this function is to set the initial state so that the output of the filter starts at the same value as the first element of the signal to be filtered.

**Parameters**

b, a [array_like (1-D)] The IIR filter coefficients. See `lfilter` for more information.

**Returns**

zi [1-D ndarray] The initial state for the filter.

See also:

* `lfilter`, `lfiltic`, `filtfilt`

**Notes**

A linear filter with order \( m \) has a state space representation \((A, B, C, D)\), for which the output \( y \) of the filter can be expressed as:

\[
\begin{align*}
    z(n+1) &= A*z(n) + B*x(n) \\
    y(n) &= C*z(n) + D*x(n)
\end{align*}
\]

where \( z(n) \) is a vector of length \( m \), \( A \) has shape \((m, m)\), \( B \) has shape \((m, 1)\), \( C \) has shape \((1, m)\) and \( D \) has shape \((1, 1)\) (assuming \( x(n) \) is a scalar). \( lfilter_zi \) solves:

\[
zi = A*z + B
\]

In other words, it finds the initial condition for which the response to an input of all ones is a constant.

Given the filter coefficients \( a \) and \( b \), the state space matrices for the transposed direct form II implementation of the linear filter, which is the implementation used by `scipy.signal.lfilter`, are:

\[
A = scipy.linalg.companion(a).T \\
B = b[1:] - a[1:]*b[0]
\]

assuming \( a[0] \) is 1.0; if \( a[0] \) is not 1, \( a \) and \( b \) are first divided by \( a[0] \).
Examples

The following code creates a lowpass Butterworth filter. Then it applies that filter to an array whose values are all 1.0; the output is also all 1.0, as expected for a lowpass filter. If the \( zi \) argument of \texttt{lfilter} had not been given, the output would have shown the transient signal.

```python
>>> from numpy import array, ones
>>> from scipy.signal import lfilter, lfilter_zi, butter
>>> b, a = butter(5, 0.25)
>>> zi = lfilter_zi(b, a)
>>> y, zo = lfilter(b, a, ones(10), zi=zi)
>>> y
array([1., 1., 1., 1., 1., 1., 1., 1., 1., 1.])
```

Another example:

```python
>>> x = array([0.5, 0.5, 0.5, 0.0, 0.0, 0.0, 0.0])
>>> y, zf = lfilter(b, a, x, zi=zi*x[0])
>>> y
array([ 0.5 , 0.5 , 0.5 , 0.49836039, 0.48610528,
        0.44399389, 0.43399389, 0.35505241])
```

Note that the \( zi \) argument to \texttt{lfilter} was computed using \texttt{lfilter_zi} and scaled by \( x[0] \). Then the output \( y \) has no transient until the input drops from 0.5 to 0.0.

\texttt{scipy.signal.filtfilt}

\texttt{scipy.signal.filtfilt}(\( b, a, x, \text{axis}=-1, \text{padtype}='\text{odd}', \text{padlen}=None, \text{method}='\text{pad}', \text{irlen}=None \))

Apply a digital filter forward and backward to a signal.

This function applies a linear digital filter twice, once forward and once backwards. The combined filter has zero phase and a filter order twice that of the original.

The function provides options for handling the edges of the signal.

The function \texttt{sosfiltfilt}(and filter design using \texttt{output='sos'}) should be preferred over \texttt{filtfilt} for most filtering tasks, as second-order sections have fewer numerical problems.

\textit{Parameters}

- \( b \) : [(\( N \)) array_like] The numerator coefficient vector of the filter.
- \( a \) : [(\( N \)) array_like] The denominator coefficient vector of the filter. If \( a[0] \) is not 1, then both \( a \) and \( b \) are normalized by \( a[0] \).
- \( x \) : [array_like] The array of data to be filtered.
- \( \text{axis} \) : [int, optional] The axis of \( x \) to which the filter is applied. Default is -1.
- \( \text{padtype} \) : [str or None, optional] Must be ‘odd’, ‘even’, ‘constant’, or None. This determines the type of extension to use for the padded signal to which the filter is applied. If \( \text{padtype} \) is None, no padding is used. The default is ‘odd’.
- \( \text{padlen} \) : [int or None, optional] The number of elements by which to extend \( x \) at both ends of \( \text{axis} \) before applying the filter. This value must be less than \( x.shape[\text{axis}] - 1 \). \( \text{padlen}=0 \) implies no padding. The default value is \( 3 * \max(\text{len}(a), \text{len}(b)) \).
- \( \text{method} \) : [str, optional] Determines the method for handling the edges of the signal, either “pad” or “gust”. When \( \text{method} \) is “pad”, the signal is padded; the type of padding is determined by \( \text{padtype} \) and \( \text{padlen} \), and \( \text{irlen} \) is ignored. When \( \text{method} \) is “gust”, Gustafsson’s method is used, and \( \text{padtype} \) and \( \text{padlen} \) are ignored.
irlen  [int or None, optional] When method is “gust”, irlen specifies the length of the impulse response of the filter. If irlen is None, no part of the impulse response is ignored. For a long signal, specifying irlen can significantly improve the performance of the filter.

Returns

\( y \)  [ndarray] The filtered output with the same shape as \( x \).

See also:

`sosfiltfilt`, `lfilter_zi`, `lfilter`, `lfiltic`, `savgol_filter`, `sosfilt`

Notes

When method is “pad”, the function pads the data along the given axis in one of three ways: odd, even or constant. The odd and even extensions have the corresponding symmetry about the end point of the data. The constant extension extends the data with the values at the end points. On both the forward and backward passes, the initial condition of the filter is found by using `lfilter_zi` and scaling it by the end point of the extended data.

When method is “gust”, Gustafsson’s method [1] is used. Initial conditions are chosen for the forward and backward passes so that the forward-backward filter gives the same result as the backward-forward filter.

The option to use Gustaffson's method was added in scipy version 0.16.0.

References

[1]

Examples

The examples will use several functions from `scipy.signal`.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

First we create a one second signal that is the sum of two pure sine waves, with frequencies 5 Hz and 250 Hz, sampled at 2000 Hz.

```python
>>> t = np.linspace(0, 1.0, 2001)
>>> xlow = np.sin(2 * np.pi * 5 * t)
>>> xhigh = np.sin(2 * np.pi * 250 * t)
>>> x = xlow + xhigh
```

Now create a lowpass Butterworth filter with a cutoff of 0.125 times the Nyquist frequency, or 125 Hz, and apply it to \( x \) with `filtfilt`. The result should be approximately \( xlow \), with no phase shift.

```python
>>> b, a = signal.butter(8, 0.125)
>>> y = signal.filtfilt(b, a, x, padlen=150)
>>> np.abs(y - xlow).max()
9.1086182074789912e-06
```

We get a fairly clean result for this artificial example because the odd extension is exact, and with the moderately long padding, the filter's transients have dissipated by the time the actual data is reached. In general, transient effects at the edges are unavoidable.
The following example demonstrates the option `method="gust"`.

First, create a filter.

```python
>>> b, a = signal.ellip(4, 0.01, 120, 0.125)  # Filter to be applied.
```

`sig` is a random input signal to be filtered.

```python
>>> rng = np.random.default_rng()
>>> n = 60
>>> sig = rng.standard_normal(n)**3 + 3*rng.standard_normal(n).cumsum()
```

Apply `filtfilt` to `sig`, once using the Gustafsson method, and once using padding, and plot the results for comparison.

```python
>>> fgust = signal.filtfilt(b, a, sig, method="gust")
>>> fpad = signal.filtfilt(b, a, sig, padlen=50)
>>> plt.plot(sig, 'k-', label='input')
>>> plt.plot(fgust, 'b-', linewidth=4, label='gust')
>>> plt.plot(fpad, 'c-', linewidth=1.5, label='pad')
>>> plt.legend(loc='best')
>>> plt.show()
```

![Plot showing input, gust, and pad signals](image)

The `irlen` argument can be used to improve the performance of Gustafsson’s method.

Estimate the impulse response length of the filter.

```python
>>> z, p, k = signal.tf2zpk(b, a)
>>> eps = 1e-9
>>> r = np.max(np.abs(p))
>>> approx_impulse_len = int(np.ceil(np.log(eps) / np.log(r)))
>>> approx_impulse_len
137
```

Apply the filter to a longer signal, with and without the `irlen` argument. The difference between `y1` and `y2` is small. For long signals, using `irlen` gives a significant performance improvement.
```python
generate code
```

### scipy.signal.savgol_filter

**scipy.signal.savgol_filter**$(x, \text{window_length}, \text{polyorder}, \text{deriv}=0, \text{delta}=1.0, \text{axis}=-1, \text{mode}='\text{interp}', \text{cval}=0.0)$

Apply a Savitzky-Golay filter to an array.

This is a 1-D filter. If $x$ has dimension greater than 1, $axis$ determines the axis along which the filter is applied.

**Parameters**

- **x** [array_like] The data to be filtered. If $x$ is not a single or double precision floating point array, it will be converted to type `numpy.float64` before filtering.
- **window_length** [int] The length of the filter window (i.e., the number of coefficients). If $mode$ is ‘interp’, $window_length$ must be less than or equal to the size of $x$.
- **polyorder** [int] The order of the polynomial used to fit the samples. $polyorder$ must be less than $window_length$.
- **deriv** [int, optional] The order of the derivative to compute. This must be a nonnegative integer. The default is 0, which means to filter the data without differentiating.
- **delta** [float, optional] The spacing of the samples to which the filter will be applied. This is only used if $deriv > 0$. Default is 1.0.
- **axis** [int, optional] The axis of the array $x$ along which the filter is to be applied. Default is -1.
- **mode** [str, optional] Must be ‘mirror’, ‘constant’, ‘nearest’, ‘wrap’ or ‘interp’. This determines the type of extension to use for the padded signal to which the filter is applied. When $mode$ is ‘constant’, the padding value is given by $cval$. See the Notes for more details on ‘mirror’, ‘constant’, ‘wrap’, and ‘nearest’. When the ‘interp’ mode is selected (the default), no extension is used. Instead, a degree $polyorder$ polynomial is fit to the last $window_length$ values of the edges, and this polynomial is used to evaluate the last $window_length // 2$ output values.
- **cval** [scalar, optional] Value to fill past the edges of the input if $mode$ is ‘constant’. Default is 0.0.

**Returns**

- **y** [ndarray, same shape as $x$] The filtered data.

**See also:**

`savgol_coeffs`

**Notes**

Details on the $mode$ options:

- **‘mirror’**:
  Repeats the values at the edges in reverse order. The value closest to the edge is not included.
- **‘nearest’**: The extension contains the nearest input value.
- **‘constant’**: The extension contains the value given by the $cval$ argument.
- **‘wrap’**: The extension contains the values from the other end of the array.
For example, if the input is [1, 2, 3, 4, 5, 6, 7, 8], and window_length is 7, the following shows the extended data for the various mode options (assuming cval is 0):

<table>
<thead>
<tr>
<th>mode</th>
<th>Ext</th>
<th>Input</th>
<th>Ext</th>
</tr>
</thead>
<tbody>
<tr>
<td>'mirror'</td>
<td>4</td>
<td>3 2 1 2 3 4 5 6 7 8</td>
<td>7 6 5</td>
</tr>
<tr>
<td>'nearest'</td>
<td>1</td>
<td>1 1 1 1 2 3 4 5 6 7 8</td>
<td>8 8 8 8</td>
</tr>
<tr>
<td>'constant'</td>
<td>0</td>
<td>0 0 0 1 2 3 4 5 6 7 8</td>
<td>0 0 0 0</td>
</tr>
<tr>
<td>'wrap'</td>
<td>6</td>
<td>7 8 1 2 3 4 5 6 7 8</td>
<td>1 2 3</td>
</tr>
</tbody>
</table>

New in version 0.14.0.

Examples

```python
>>> from scipy.signal import savgol_filter
>>> np.set_printoptions(precision=2)  # For compact display.
>>> x = np.array([2, 2, 5, 2, 1, 0, 1, 4, 9])
```

Filter with a window length of 5 and a degree 2 polynomial. Use the defaults for all other parameters.

```python
>>> savgol_filter(x, 5, 2)
array([1.66, 3.17, 3.54, 2.86, 0.66, 0.17, 1.00, 4.00, 7.97])
```

Note that the last five values in x are samples of a parabola, so when mode='interp' (the default) is used with polyorder=2, the last three values are unchanged. Compare that to, for example, mode='nearest':

```python
>>> savgol_filter(x, 5, 2, mode='nearest')
array([1.74, 3.03, 3.54, 2.86, 0.66, 0.17, 1.00, 4.60, 7.97])
```

scipy.signal.deconvolve

scipy.signal.deconvolve(signal, divisor)

Deconvolves divisor out of signal using inverse filtering.

Returns the quotient and remainder such that signal = convolve(divisor, quotient) + remainder

Parameters

- `signal` : array_like Signal data, typically a recorded signal
- `divisor` : array_like Divisor data, typically an impulse response or filter that was applied to the original signal

Returns

- `quotient` : ndarray Quotient, typically the recovered original signal
- `remainder` : ndarray Remainder

See also:

numpy.polydiv

performs polynomial division (same operation, but also accepts poly1d objects)
Examples

Deconvolve a signal that’s been filtered:

```python
>>> from scipy import signal
>>> original = [0, 1, 0, 0, 1, 1, 0, 0]
>>> impulse_response = [2, 1]
>>> recorded = signal.convolve(impulse_response, original)
>>> recorded
array([0, 2, 1, 0, 2, 3, 1, 0, 0])
>>> recovered, remainder = signal.deconvolve(recorded, impulse_response)
>>> recovered
array([ 0., 1., 0., 0., 1., 1., 0., 0.])
```

```
scipy.signal.sosfilt

scipy.signal.sosfilt(sos, x, axis=-1, zi=None)

Filter data along one dimension using cascaded second-order sections.

Filter a data sequence, `x`, using a digital IIR filter defined by `sos`.

Parameters

- **sos** [array_like] Array of second-order filter coefficients, must have shape `(n_sections, 6)`. Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.
- **x** [array_like] An N-dimensional input array.
- **axis** [int, optional] The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.
- **zi** [array_like, optional] Initial conditions for the cascaded filter delays. It is a (at least 2D) vector of shape `(n_sections, ..., 2, ...)`, where ..., 2, ... denotes the shape of `x`, but with `x.shape[axis]` replaced by 2. If `zi` is None or is not given then initial rest (i.e. all zeros) is assumed. Note that these initial conditions are not the same as the initial conditions given by `lfilter` or `lfilter_zi`.

Returns

- **y** [ndarray] The output of the digital filter.
- **zf** [ndarray, optional] If `zi` is None, this is not returned, otherwise, `zf` holds the final filter delay values.

See also:

- `zpk2sos`, `sos2zpk`, `sosfilt_zi`, `sosfiltfilt`, `sosfreqz`

Notes

The filter function is implemented as a series of second-order filters with direct-form II transposed structure. It is designed to minimize numerical precision errors for high-order filters.

New in version 0.16.0.
Examples

Plot a 13th-order filter’s impulse response using both `lfilter` and `sosfilt`, showing the instability that results from trying to do a 13th-order filter in a single stage (the numerical error pushes some poles outside of the unit circle):

```python
>>> import matplotlib.pyplot as plt
>>> from scipy import signal
>>> b, a = signal.ellip(13, 0.009, 80, 0.05, output='ba')
>>> sos = signal.ellip(13, 0.009, 80, 0.05, output='sos')
>>> x = signal.unit_impulse(700)
>>> y_tf = signal.lfilter(b, a, x)
>>> y_sos = signal.sosfilt(sos, x)
>>> plt.plot(y_tf, 'r', label='TF')
>>> plt.plot(y_sos, 'k', label='SOS')
>>> plt.legend(loc='best')
>>> plt.show()
```

`scipy.signal.sosfilt_zi`

`scipy.signal.sosfilt_zi(sos)`

Construct initial conditions for sosfilt for step response steady-state.

A typical use of this function is to set the initial state so that the output of the filter starts at the same value as the first element of the signal to be filtered.

Parameters

- **sos** [array_like] Array of second-order filter coefficients, must have shape `(n_sections, 6)`. See `sosfilt` for the SOS filter format specification.

Returns

- **zi** [ndarray] Initial conditions suitable for use with `sosfilt`, shape `(n_sections, 2)`.

See also:
sosfilt, zpk2sos

Notes

New in version 0.16.0.

Examples

Filter a rectangular pulse that begins at time 0, with and without the use of the \texttt{zi} argument of \texttt{scipy.signal.sosfilt}.

\begin{verbatim}
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> sos = signal.butter(9, 0.125, output='sos')
>>> zi = signal.sosfilt_zi(sos)
>>> x = (np.arange(250) < 100).astype(int)
>>> f1 = signal.sosfilt(sos, x)
>>> f2, zo = signal.sosfilt(sos, x, zi=zi)

>>> plt.plot(x, 'k--', label='x')
>>> plt.plot(f1, 'b', alpha=0.5, linewidth=2, label='filtered')
>>> plt.plot(f2, 'g', alpha=0.25, linewidth=4, label='filtered with zi')
>>> plt.legend(loc='best')
>>> plt.show()
\end{verbatim}

\begin{figure}
\centering
\includegraphics[width=0.5\textwidth]{example_plot.png}
\caption{Example plot showing filtered pulse with and without \texttt{zi}.
\end{figure}
scipy.signal.sosfiltfilt

scipy.signal.sosfiltfilt(sos, x, axis=-1, padtype='odd', padlen=None)
A forward-backward digital filter using cascaded second-order sections.

See `filtfilt` for more complete information about this method.

Parameters

- sos [array_like] Array of second-order filter coefficients, must have shape (n_sections, 6). Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.
- x [array_like] The array of data to be filtered.
- axis [int, optional] The axis of x to which the filter is applied. Default is -1.
- padtype [str or None, optional] Must be 'odd', 'even', 'constant', or None. This determines the type of extension to use for the padded signal to which the filter is applied. If padtype is None, no padding is used. The default is 'odd'.
- padlen [int or None, optional] The number of elements by which to extend x at both ends of axis before applying the filter. This value must be less than x.shape[axis] - 1. padlen=0 implies no padding. The default value is:

\[
3 \times (2 \times \text{len}(\text{sos}) + 1) - \min((\text{sos}[:, 2] == 0).\text{sum()}, (\text{sos}[:, 5] == 0).\text{sum}())
\]

The extra subtraction at the end attempts to compensate for poles and zeros at the origin (e.g. for odd-order filters) to yield equivalent estimates of padlen to those of `filtfilt` for second-order section filters built with `scipy.signal` functions.

Returns

- y [ndarray] The filtered output with the same shape as x.

See also:

`filtfilt`, `sosfilt`, `sosfilt_zi`, `sosfreqz`

Notes

New in version 0.18.0.

Examples

```python
>>> from scipy.signal import sosfiltfilt, butter
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()

Create an interesting signal to filter.

```python
>>> n = 201
>>> t = np.linspace(0, 1, n)
>>> x = 1 + (t < 0.5) - 0.25*t**2 + 0.05* rng.standard_normal(n)
```  
Create a lowpass Butterworth filter, and use it to filter x.

```python
>>> sos = butter(4, 0.125, output='sos')
>>> y = sosfiltfilt(sos, x)
```
For comparison, apply an 8th order filter using \texttt{sosfilt}. The filter is initialized using the mean of the first four values of \(x\).

```python
>>> from scipy.signal import sosfilt, sosfilt_zi
>>> sos8 = butter(8, 0.125, output='sos')
>>> zi = x[:4].mean() * sosfilt_zi(sos8)
>>> y2, zo = sosfilt(sos8, x, zi=zi)
```

Plot the results. Note that the phase of \(y\) matches the input, while \(y2\) has a significant phase delay.

```python
>>> plt.plot(t, x, alpha=0.5, label='x(t)')
>>> plt.plot(t, y, label='y(t)')
>>> plt.plot(t, y2, label='y2(t)')
>>> plt.legend(framealpha=1, shadow=True)
>>> plt.grid(alpha=0.25)
>>> plt.xlabel('t')
>>> plt.show()
```

\texttt{scipy.signal.hilbert}

\texttt{scipy.signal.hilbert}(\(x, N=\text{None}, axis=-1\))

Compute the analytic signal, using the Hilbert transform.

The transformation is done along the last axis by default.

\textit{Parameters}

\begin{itemize}
\item \textbf{x} [array_like] Signal data. Must be real.
\item \textbf{N} [int, optional] Number of Fourier components. Default: \(x.shape[axis]\)
\item \textbf{axis} [int, optional] Axis along which to do the transformation. Default: \(-1\).
\end{itemize}

\textit{Returns}

\begin{itemize}
\item \textbf{xa} [ndarray] Analytic signal of \(x\), of each 1-D array along \(axis\)
Notes

The analytic signal $x_a(t)$ of signal $x(t)$ is:

$$x_a = F^{-1}(F(x)2U) = x + iy$$

where $F$ is the Fourier transform, $U$ the unit step function, and $y$ the Hilbert transform of $x$. [1]

In other words, the negative half of the frequency spectrum is zeroed out, turning the real-valued signal into a complex signal. The Hilbert transformed signal can be obtained from `np.imag(hilbert(x))`, and the original signal from `np.real(hilbert(x))`.

References

[1], [2], [3]

Examples

In this example we use the Hilbert transform to determine the amplitude envelope and instantaneous frequency of an amplitude-modulated signal.

```python
>>> import numpy as np
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import hilbert, chirp

>>> duration = 1.0
>>> fs = 400.0
>>> samples = int(fs*duration)
>>> t = np.arange(samples) / fs
```

We create a chirp of which the frequency increases from 20 Hz to 100 Hz and apply an amplitude modulation.

```python
>>> signal = chirp(t, 20.0, t[-1], 100.0)
>>> signal *= (1.0 + 0.5 * np.sin(2.0*np.pi*3.0*t) )
```

The amplitude envelope is given by magnitude of the analytic signal. The instantaneous frequency can be obtained by differentiating the instantaneous phase in respect to time. The instantaneous phase corresponds to the phase angle of the analytic signal.

```python
>>> analytic_signal = hilbert(signal)
>>> amplitude_envelope = np.abs(analytic_signal)
>>> instantaneous_phase = np.unwrap(np.angle(analytic_signal))
>>> instantaneous_frequency = (np.diff(instantaneous_phase) /
...                           (2.0*np.pi) * fs)
```

```python
>>> fig, (ax0, ax1) = plt.subplots(nrows=2)
>>> ax0.plot(t, signal, label='signal')
>>> ax0.plot(t, amplitude_envelope, label='envelope')
>>> ax0.set_ylabel("time in seconds")
>>> ax0.legend()
>>> ax1.plot(t[1:], instantaneous_frequency)
>>> ax1.set_ylabel("time in seconds")
```

(continues on next page)
scipy.signal.hilbert2

scipy.signal.hilbert2(x, N=None)

Compute the ‘2-D’ analytic signal of x

Parameters

x [array_like] 2-D signal data.
N [int or tuple of two ints, optional] Number of Fourier components. Default is x.shape

Returns

xa [ndarray] Analytic signal of x taken along axes (0,1).

References

[1]

scipy.signal.decimate

scipy.signal.decimate(x, q, n=None, ftype='iir', axis=-1, zero_phase=True)

Downsample the signal after applying an anti-aliasing filter.

By default, an order 8 Chebyshev type I filter is used. A 30 point FIR filter with Hamming window is used if ftype is ‘fir’.

Parameters

x [array_like] The signal to be downsampled, as an N-dimensional array.
q [int] The downsampling factor. When using IIR downsampling, it is recommended to call decimate multiple times for downsampling factors higher than 13.
n [int, optional] The order of the filter (1 less than the length for ‘fir’). Defaults to 8 for ‘iir’ and 20 times the downsampling factor for ‘fir’.
ftype [str {'iir', 'fir'} or dlti instance, optional] If 'iir' or 'fir', specifies the type of lowpass filter. If an instance of an dlti object, uses that object to filter before downsampling.

axis [int, optional] The axis along which to decimate.

zero_phase [bool, optional] Prevent phase shift by filtering with filtfilt instead of lfilter when using an IIR filter, and shifting the outputs back by the filter’s group delay when using an FIR filter. The default value of True is recommended, since a phase shift is generally not desired. New in version 0.18.0.

Returns

y [ndarray] The down-sampled signal.

See also:

resample
Resample up or down using the FFT method.

resample_poly
Resample using polyphase filtering and an FIR filter.

Notes

The zero_phase keyword was added in 0.18.0. The possibility to use instances of dlti as ftype was added in 0.18.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Define wave parameters.

>>> wave_duration = 3
>>> sample_rate = 100
>>> freq = 2
>>> q = 5

Calculate number of samples.

>>> samples = wave_duration*sample_rate
>>> samples_decimated = int(samples/q)

Create cosine wave.

>>> x = np.linspace(0, wave_duration, samples, endpoint=False)
>>> y = np.cos(x*np.pi*freq**2)

Decimate cosine wave.

>>> ydem = signal.decimate(y, q)
>>> xnew = np.linspace(0, wave_duration, samples_decimated, endpoint=False)
```
Plot original and decimated waves.

```python
>>> plt.plot(x, y, ',-', xnew, ydem, 'o-')
>>> plt.xlabel('Time, Seconds')
>>> plt.legend(['data', 'decimated'], loc='best')
>>> plt.show()
```

**scipy.signal.detrend**

`scipy.signal.detrend`(data, axis=-1, type='linear', bp=0, overwrite_data=False)

Remove linear trend along axis from data.

**Parameters**

- **data** [array_like] The input data.
- **axis** [int, optional] The axis along which to detrend the data. By default this is the last axis (-1).
- **type** [string, {'linear', 'constant'}, optional] The type of detrending. If `type == 'linear'` (default), the result of a linear least-squares fit to `data` is subtracted from `data`. If `type == 'constant'`, only the mean of `data` is subtracted.
- **bp** [array_like of ints, optional] A sequence of break points. If given, an individual linear fit is performed for each part of `data` between two break points. Break points are specified as indices into `data`. This parameter only has an effect when `type == 'linear'`.
- **overwrite_data** [bool, optional] If True, perform in place detrending and avoid a copy. Default is False

**Returns**

- **ret** [ndarray] The detrended input data.
Examples

```python
>>> from scipy import signal
>>> from numpy.random import default_rng
>>> rng = default_rng()
>>> npoints = 1000
>>> noise = rng.standard_normal(npoints)
>>> x = 3 + 2*np.linspace(0, 1, npoints) + noise
>>> (signal.detrend(x) - noise).max()
0.06  # random
```

scipy.signal.resample

scipy.signal.resample(x, num, t=None, axis=0, window=None, domain='time')

Resample x to num samples using Fourier method along the given axis.

The resampled signal starts at the same value as x but is sampled with a spacing of len(x) / num * (spacing of x). Because a Fourier method is used, the signal is assumed to be periodic.

Parameters

- x [array_like] The data to be resampled.
- num [int] The number of samples in the resampled signal.
- t [array_like, optional] If t is given, it is assumed to be the equally spaced sample positions associated with the signal data in x.
- axis [int, optional] The axis of x that is resampled. Default is 0.
- window [array_like, callable, string, float, or tuple, optional] Specifies the window applied to the signal in the Fourier domain. See below for details.
- domain [string, optional] A string indicating the domain of the input x: time Consider the input x as time-domain (Default), freq Consider the input x as frequency-domain.

Returns

- resampled_x or (resampled_x, resampled_t) Either the resampled array, or, if t was given, a tuple containing the resampled array and the corresponding resampled positions.

See also:

decimate

Downsample the signal after applying an FIR or IIR filter.

resample_poly

Resample using polyphase filtering and an FIR filter.

Notes

The argument window controls a Fourier-domain window that tapers the Fourier spectrum before zero-padding to alleviate ringing in the resampled values for sampled signals you didn't intend to be interpreted as band-limited.

If window is a function, then it is called with a vector of inputs indicating the frequency bins (i.e. fftfreq(x.shape[axis]) ).

If window is an array of the same length as x.shape[axis] it is assumed to be the window to be applied directly in the Fourier domain (with dc and low-frequency first).

For any other type of window, the function scipy.signal.get_window is called to generate the window.
The first sample of the returned vector is the same as the first sample of the input vector. The spacing between samples is changed from $dx$ to $dx \times \frac{\text{len}(x)}{\text{num}}$.

If $t$ is not None, then it is used solely to calculate the resampled positions $\text{resampled}_t$.

As noted, $\text{resample}$ uses FFT transformations, which can be very slow if the number of input or output samples is large and prime; see $\text{scipy.fft.fft}$.

**Examples**

Note that the end of the resampled data rises to meet the first sample of the next cycle:

```python
>>> from scipy import signal

>>> x = np.linspace(0, 10, 20, endpoint=False)
>>> y = np.cos(-x**2/6.0)
>>> f = signal.resample(y, 100)
>>> xnew = np.linspace(0, 10, 100, endpoint=False)

>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'go-', xnew, f, '.-', 10, y[0], 'ro')
>>> plt.legend(['data', 'resampled'], loc='best')
>>> plt.show()
```

**scipy.signal.resample_poly**

`scipy.signal.resample_poly(x, up, down, axis=0, window=('kaiser', 5.0), padtype='constant', cval=None)`

Resample $x$ along the given axis using polyphase filtering.

The signal $x$ is upsampled by the factor $up$, a zero-phase low-pass FIR filter is applied, and then it is downsampled by the factor $down$. The resulting sample rate is $\frac{up}{down}$ times the original sample rate. By default, values beyond the boundary of the signal are assumed to be zero during the filtering step.

**Parameters**

- $x$: [array_like] The data to be resampled.
The upsampling factor.
- **down** [int] The downsampling factor.
- **axis** [int, optional] The axis of x that is resampled. Default is 0.
- **window** [string, tuple, or array_like, optional] Desired window to use to design the low-pass filter, or the FIR filter coefficients to employ. See below for details.
- **padtype** [string, optional] `constant`, `line`, `mean`, `median`, `maximum`, `minimum` or any of the other signal extension modes supported by `scipy.signal.upfirdn`. Changes assumptions on values beyond the boundary. If `constant`, assumed to be `cval` (default zero). If `line` assumed to continue a linear trend defined by the first and last points. `mean`, `median`, `maximum` and `minimum` work as in `np.pad` and assume that the values beyond the boundary are the mean, median, maximum or minimum respectively of the array along the axis. New in version 1.4.0.
- **cval** [float, optional] Value to use if `padtype='constant'`. Default is zero. New in version 1.4.0.

**Returns**

- **resampled_x** [array] The resampled array.

**See also:**

- decimate
  Downsample the signal after applying an FIR or IIR filter.
- resample
  Resample up or down using the FFT method.

**Notes**

This polyphase method will likely be faster than the Fourier method in `scipy.signal.resample` when the number of samples is large and prime, or when the number of samples is large and up and down share a large greatest common denominator. The length of the FIR filter used will depend on `max(up, down) / gcd(up, down)`, and the number of operations during polyphase filtering will depend on the filter length and down (see `scipy.signal.upfirdn` for details).

The argument **window** specifies the FIR low-pass filter design.

If **window** is an array_like it is assumed to be the FIR filter coefficients. Note that the FIR filter is applied after the upsampling step, so it should be designed to operate on a signal at a sampling frequency higher than the original by a factor of `up/gcd(up, down)`. This function’s output will be centered with respect to this array, so it is best to pass a symmetric filter with an odd number of samples if, as is usually the case, a zero-phase filter is desired.

For any other type of **window**, the functions `scipy.signal.get_window` and `scipy.signal.firwin` are called to generate the appropriate filter coefficients.

The first sample of the returned vector is the same as the first sample of the input vector. The spacing between samples is changed from `dx` to `dx * down / float(up).`
Examples

By default, the end of the resampled data rises to meet the first sample of the next cycle for the FFT method, and gets closer to zero for the polyphase method:

```python
>>> from scipy import signal

>>> x = np.linspace(0, 10, 20, endpoint=False)
>>> y = np.cos(-x**2/6.0)
>>> f_fft = signal.resample(y, 100)
>>> f_poly = signal.resample_poly(y, 100, 20)
>>> xnew = np.linspace(0, 10, 100, endpoint=False)

>>> import matplotlib.pyplot as plt
>>> plt.plot(xnew, f_fft, 'b.-', xnew, f_poly, 'r.-')
>>> plt.plot(x, y, 'ko-')
>>> plt.plot(10, y[0], 'bo', 10, 0., 'ro')  # boundaries
>>> plt.legend(['resample', 'resamp_poly', 'data'], loc='best')
>>> plt.show()
```

This default behaviour can be changed by using the padtype option:

```python
>>> N = 5
>>> x = np.linspace(0, 1, N, endpoint=False)
>>> y = 2 + x**2 - 1.7*np.sin(x) + .2*np.cos(11*x)
>>> y2 = 1 + x**3 + 0.1*np.sin(x) + .1*np.cos(11*x)
>>> Y = np.stack([y, y2], axis=-1)
>>> up = 4
>>> xr = np.linspace(0, 1, N*up, endpoint=False)
```
```python
>>> y2 = signal.resample_poly(Y, up, 1, padtype='constant')
>>> y3 = signal.resample_poly(Y, up, 1, padtype='mean')
>>> y4 = signal.resample_poly(Y, up, 1, padtype='line')

>>> import matplotlib.pyplot as plt
>>> for i in [0, 1]:
...     plt.figure()
...     plt.plot(xr, y4[:, i], 'g.', label='line')
...     plt.plot(xr, y3[:, i], 'y.', label='mean')
...     plt.plot(xr, y2[:, i], 'r.', label='constant')
...     plt.plot(x, Y[:, i], 'k-')
...     plt.legend()

>>> plt.show()
```
scipy.signal.upfirdn

scipy.signal.upfirdn(h, x, up=1, down=1, axis=-1, mode='constant', cval=0)

Upsample, FIR filter, and downsample.

**Parameters**

- `h` [array_like] 1-D FIR (finite-impulse response) filter coefficients.
- `x` [array_like] Input signal array.
- `up` [int, optional] Upsampling rate. Default is 1.
- `down` [int, optional] Downsampling rate. Default is 1.
- `axis` [int, optional] The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.
- `mode` [str, optional] The signal extension mode to use. The set {"constant", "symmetric", "reflect", "edge", "wrap") correspond to modes provided by numpy.pad. "smooth" implements a smooth extension by extending based on the slope of the last 2 points at each end of the array. "antireflect" and "antisymmetric" are anti-symmetric versions of "reflect" and "symmetric". The mode "line" extends the signal based on a linear trend defined by the first and last points along the axis.
  New in version 1.4.0.
- `cval` [float, optional] The constant value to use when mode == "constant".
  New in version 1.4.0.

**Returns**

- `y` [ndarray] The output signal array. Dimensions will be the same as `x` except for along `axis`, which will change size according to the `h`, `up`, and `down` parameters.

**Notes**

The algorithm is an implementation of the block diagram shown on page 129 of the Vaidyanathan text [1] (Figure 4.3-8d).

The direct approach of upsampling by factor of P with zero insertion, FIR filtering of length \( n \), and downsampling by factor of Q is \( O(N^*Q) \) per output sample. The polyphase implementation used here is \( O(N/P) \).

New in version 0.18.

**References**

[1]

**Examples**

Simple operations:

```python
>>> from scipy.signal import upfirdn
>>> upfirdn([1], [1, 2, 3], 3) # upsampling with zeros insertion
array([ 1., 0., 0., 2., 0., 0., 3., 0., 0.])
>>> upfirdn([1, 1, 1], [1, 2, 3], 3) # upsampling with sample-and-hold
array([ 1., 1., 1., 2., 2., 2., 3., 3., 3.])
```

(continues on next page)
```python
>>> upfirdn([.5, 1, .5], [1, 1, 1], 2)  # linear interpolation
array([0.5, 1., 1., 1., 1., 0.5, 0.])
>>> upfirdn([1], np.arange(10), 1, 3)  # decimation by 3
array([3., 6., 9.])
>>> upfirdn([.5, 1, .5], np.arange(10), 2, 3)  # linear interp, rate 2/3
array([0., 2.5, 4., 5.5, 7., 8.5, 0.])
```

Apply a single filter to multiple signals:

```python
>>> x = np.reshape(np.arange(8), (4, 2))
>>> x
array([[0, 1],
       [2, 3],
       [4, 5],
       [6, 7]])
```

Apply along the last dimension of `x`:

```python
>>> h = [1, 1]
>>> upfirdn(h, x, 2)
array([[ 0.,  0.,  1.,  1.],
       [ 2.,  2.,  3.,  3.],
       [ 4.,  4.,  5.,  5.],
       [ 6.,  6.,  7.,  7.]])
```

Apply along the 0th dimension of `x`:

```python
>>> upfirdn(h, x, 2, axis=0)
array([[ 0.,  1.],
       [ 0.,  1.],
       [ 2.,  3.],
       [ 2.,  3.],
       [ 4.,  5.],
       [ 4.,  5.],
       [ 6.,  7.],
       [ 6.,  7.]])
```

**scipy.signal.bilinear**

**scipy.signal.bilinear** *(b, a, fs=1.0)*

Return a digital IIR filter from an analog one using a bilinear transform.

Transform a set of poles and zeros from the analog s-plane to the digital z-plane using Tustin’s method, which substitutes \((z-1) / (z+1)\) for \(s\), maintaining the shape of the frequency response.

**Parameters**

- **b** [array_like] Numerator of the analog filter transfer function.
- **a** [array_like] Denominator of the analog filter transfer function.
- **fs** [float] Sample rate, as ordinary frequency (e.g., hertz). No prewarping is done in this function.

**Returns**

- **z** [ndarray] Numerator of the transformed digital filter transfer function.
- **p** [ndarray] Denominator of the transformed digital filter transfer function.

**See also:**

- `lp2lp`, `lp2hp`, `lp2bp`, `lp2bs`
- `bilinear_zpk`
Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> fs = 100
>>> bf = 2 * np.pi * np.array([7, 13])
>>> filts = signal.lti(*signal.butter(4, bf, btype='bandpass',
                              analog=True))
>>> filtz = signal.lti(*signal.bilinear(filts.num, filts.den, fs))
>>> wz, hz = signal.freqz(filtz.num, filtz.den)
>>> ws, hs = signal.freqs(filts.num, filts.den, worN=fs*wz)

>>> plt.semilogx(wz*fs/(2*np.pi), 20*np.log10(np.abs(hz).clip(1e-15)),
               label=r'$|H_z(e^{' + r'(j \omega)})|$')
>>> plt.semilogx(ws*fs/(2*np.pi), 20*np.log10(np.abs(hs).clip(1e-15)),
               label=r'$|H(j \omega)|$')
>>> plt.legend()
>>> plt.xlabel('Frequency [Hz]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.grid()
```

![Graph showing frequency response](image)

**scipy.signal.bilinear_zpk**

Return a digital IIR filter from an analog one using a bilinear transform.

Transform a set of poles and zeros from the analog s-plane to the digital z-plane using Tustin's method, which substitutes \((z-1) / (z+1)\) for \(s\), maintaining the shape of the frequency response.

**Parameters**

- **z**  
  [array_like] Zeros of the analog filter transfer function.

- **p**  
  [array_like] Poles of the analog filter transfer function.

- **k**  
  [float] System gain of the analog filter transfer function.

fs

[float] Sample rate, as ordinary frequency (e.g., hertz). No prewarping is done in this function.

Returns

z

[ndarray] Zeros of the transformed digital filter transfer function.

p

[ndarray] Poles of the transformed digital filter transfer function.

k

[float] System gain of the transformed digital filter.

lp2lp_zpk, lp2hp_zpk, lp2bp_zpk, lp2bs_zpk

bilinear

Notes

New in version 1.1.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> fs = 100
>>> bf = 2 * np.pi * np.array([7, 13])
>>> filts = signal.lti(*signal.butter(4, bf, btype='bandpass',
            analog=True,
            output='zpk'))
>>> filtz = signal.lti(*signal.bilinear_zpk(filts.zeros, filts.poles,
            filts.gain, fs))
>>> wz, hz = signal.freqz_zpk(filtz.zeros, filtz.poles, filtz.gain)
>>> ws, hs = signal.freqs_zpk(filts.zeros, filts.poles, filts.gain,
            worN=fs*wz)
>>> plt.semilogx(wz*fs/(2*np.pi), 20*np.log10(np.abs(hz).clip(1e-15)),
            label=r'$|H_z(e^{j \omega})|$')
>>> plt.semilogx(ws*fs/(2*np.pi), 20*np.log10(np.abs(hs).clip(1e-15)),
            label=r'$|H(e^{j \omega})|$')
>>> plt.legend()
>>> plt.xlabel('Frequency [Hz]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.grid()
```

scipy.signal.findfreqs

scipy.signal.findfreqs(num, den, N, kind='ba')

Find array of frequencies for computing the response of an analog filter.

Parameters

num, den

[array_like, 1-D] The polynomial coefficients of the numerator and denominator of the transfer function of the filter or LTI system, where the coefficients are ordered from highest to lowest degree. Or, the roots of the transfer function numerator and denominator (i.e., zeroes and poles).

N

[int] The length of the array to be computed.
kind [str {'ba', 'zp'}, optional] Specifies whether the numerator and denominator are specified by
their polynomial coefficients ('ba'), or their roots ('zp').

Returns

Examples

Find a set of nine frequencies that span the “interesting part” of the frequency response for the filter with the transfer
function

\[ H(s) = \frac{s}{s^2 + 8s + 25} \]

```python
>>> from scipy import signal
>>> signal.findfreqs([1, 0], [1, 8, 25], N=9)
array([ 1.00000000e-02, 3.16227766e-02, 1.00000000e-01,
        3.16227766e-01, 1.00000000e+00, 3.16227766e+00,
        1.00000000e+01, 3.16227766e+01, 1.00000000e+02])
```

scipy.signal.firls

scipy.signal.firls (numtaps, bands, desired, weight=None, nyq=None, fs=None)
FIR filter design using least-squares error minimization.

Calculate the filter coefficients for the linear-phase finite impulse response (FIR) filter which has the best approxi-
mation to the desired frequency response described by bands and desired in the least squares sense (i.e., the integral
of the weighted mean-squared error within the specified bands is minimized).

Parameters

numtaps [int] The number of taps in the FIR filter. numtaps must be odd.
bands [array_like] A monotonic nondecreasing sequence containing the band edges in Hz. All
elements must be non-negative and less than or equal to the Nyquist frequency given by nyq.
desired [array_like] A sequence the same size as bands containing the desired gain at the start and
end point of each band.
weight [array_like, optional] A relative weighting to give to each band region when solving the least squares problem. `weight` has to be half the size of `bands`.

nyq [float, optional] Deprecated. Use `fs` instead. Nyquist frequency. Each frequency in `bands` must be between 0 and `nyq` (inclusive). Default is 1.

fs [float, optional] The sampling frequency of the signal. Each frequency in `bands` must be between 0 and `fs/2` (inclusive). Default is 2.

Returns

coeffs [ndarray] Coefficients of the optimal (in a least squares sense) FIR filter.

See also:

firwin
firwin2
minimum_phase
remez

Notes

This implementation follows the algorithm given in [1]. As noted there, least squares design has multiple advantages:

1. Optimal in a least-squares sense.
2. Simple, non-iterative method.
3. The general solution can obtained by solving a linear system of equations.
4. Allows the use of a frequency dependent weighting function.

This function constructs a Type I linear phase FIR filter, which contains an odd number of `coeffs` satisfying for $n < \text{numtaps}$:

$$coeffs(n) = coeffs(\text{numtaps} - 1 - n)$$

The odd number of coefficients and filter symmetry avoid boundary conditions that could otherwise occur at the Nyquist and 0 frequencies (e.g., for Type II, III, or IV variants).

New in version 0.18.

References

[1]

Examples

We want to construct a band-pass filter. Note that the behavior in the frequency ranges between our stop bands and pass bands is unspecified, and thus may overshoot depending on the parameters of our filter:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> fig, axs = plt.subplots(2)
>>> fs = 10.0  # Hz
>>> desired = (0, 0, 1, 1, 0, 0)
```
>>> for bi, bands in enumerate(((0, 1, 2, 3, 4, 5), (0, 1, 2, 4, 4.5, ...))):
    ...
    fir_firls = signal.firls(73, bands, desired, fs=fs)
    ...
    fir_remez = signal.remez(73, bands, desired[::2], fs=fs)
    ...
    fir_firwin2 = signal.firwin2(73, bands, desired, fs=fs)
    ...

scipy.signal.firwin

scipy.signal.firwin(numtaps, cutoff, width=None, window='hamming', pass_zero=True, scale=True, nyq=None, fs=None)

FIR filter design using the window method.

This function computes the coefficients of a finite impulse response filter. The filter will have linear phase; it will be Type I if `numtaps` is odd and Type II if `numtaps` is even.

Type II filters always have zero response at the Nyquist frequency, so a ValueError exception is raised if firwin is called with `numtaps` even and having a passband whose right end is at the Nyquist frequency.

**Parameters**

- **numtaps** [int] Length of the filter (number of coefficients, i.e. the filter order + 1). `numtaps` must be odd if a passband includes the Nyquist frequency.
- **cutoff** [float or 1-D array_like] Cutoff frequency of filter (expressed in the same units as `fs`) OR an array of cutoff frequencies (that is, band edges). In the latter case, the frequencies in `cutoff` should be positive and monotonically increasing between 0 and `fs/2`. The values 0 and `fs/2` must not be included in `cutoff`.
- **width** [float or None, optional] If `width` is not None, then assume it is the approximate width of the transition region (expressed in the same units as `fs`) for use in Kaiser FIR filter design. In this case, the `window` argument is ignored.
- **window** [string or tuple of string and parameter values, optional] Desired window to use. See `scipy.signal.get_window` for a list of windows and required parameters.
- **pass_zero** [{True, False, 'bandpass', 'lowpass', 'highpass', 'bandstop'}, optional] If True, the gain at the frequency 0 (i.e., the “DC gain”) is 1. If False, the DC gain is 0. Can also be a string argument for the desired filter type (equivalent to `btype` in IIR design functions).
  New in version 1.3.0: Support for string arguments.
- **scale** [bool, optional] Set to True to scale the coefficients so that the frequency response is exactly unity at a certain frequency. That frequency is either:
  • 0 (DC) if the first passband starts at 0 (i.e. pass_zero is True)
  • `fs/2` (the Nyquist frequency) if the first passband ends at `fs/2` (i.e the filter is a single band highpass filter); center of first passband otherwise
- **nyq** [float, optional] Deprecated. Use `fs` instead. This is the Nyquist frequency. Each frequency in `cutoff` must be between 0 and `nyq`. Default is 1.
- **fs** [float, optional] The sampling frequency of the signal. Each frequency in `cutoff` must be between 0 and `fs/2`. Default is 2.

**Returns**

- **h** [(numtaps,) ndarray] Coefficients of length `numtaps` FIR filter.

**Raises**

- **ValueError**
  If any value in `cutoff` is less than or equal to 0 or greater than or equal to `fs/2`, if the values in `cutoff` are not strictly monotonically increasing, or if `numtaps` is even but a passband includes the Nyquist frequency.

**See also:**

- **firwin2**
- **firls**
- **minimum_phase**
- **remez**
Examples

Low-pass from 0 to f:

```python
>>> from scipy import signal
>>> numtaps = 3
>>> f = 0.1
>>> signal.firwin(numtaps, f)
array([ 0.06799017, 0.86401967, 0.06799017])
```

Use a specific window function:

```python
>>> signal.firwin(numtaps, f, window='nuttall')
array([ 3.56607041e-04, 9.99286786e-01, 3.56607041e-04])
```

High-pass ('stop' from 0 to f):

```python
>>> signal.firwin(numtaps, f, pass_zero=False)
array([-0.00859313, 0.98281375, -0.00859313])
```

Band-pass:

```python
>>> f1, f2 = 0.1, 0.2
>>> signal.firwin(numtaps, [f1, f2], pass_zero=False)
array([ 0.06301614, 0.88770441, 0.06301614])
```

Band-stop:

```python
>>> signal.firwin(numtaps, [f1, f2])
array([-0.00801395, 1.0160279 , -0.00801395])
```

Multi-band (passbands are [0, f1], [f2, f3] and [f4, 1]):

```python
>>> f3, f4 = 0.3, 0.4
>>> signal.firwin(numtaps, [f1, f2, f3, f4])
array([-0.01376344, 1.02752689, -0.01376344])
```

Multi-band (passbands are [f1, f2] and [f3, f4]):

```python
>>> signal.firwin(numtaps, [f1, f2, f3, f4], pass_zero=False)
array([ 0.04890915, 0.91284326, 0.04890915])
```

**scipy.signal.firwin2**

`scipy.signal.firwin2(numtaps, freq, gain, nfreqs=None, window='hamming', nyq=None, antisymmetric=False, fs=None)`

FIR filter design using the window method.

From the given frequencies `freq` and corresponding gains `gain`, this function constructs an FIR filter with linear phase and (approximately) the given frequency response.

**Parameters**

- `numtaps` : [int] The number of taps in the FIR filter. `numtaps` must be less than `nfreqs`.
- `freq` : [array_like, 1-D] The frequency sampling points. Typically 0.0 to 1.0 with 1.0 being Nyquist. The Nyquist frequency is half `fs`. The values in `freq` must be nondecreasing. A value can be
repeated once to implement a discontinuity. The first value in \( \text{freq} \) must be 0, and the last value must be \( \text{fs}/2 \). Values 0 and \( \text{fs}/2 \) must not be repeated.

**gain**
[array_like] The filter gains at the frequency sampling points. Certain constraints to gain values, depending on the filter type, are applied, see Notes for details.

**nfreqs**
[int, optional] The size of the interpolation mesh used to construct the filter. For most efficient behavior, this should be a power of 2 plus 1 (e.g., 129, 257, etc). The default is one more than the smallest power of 2 that is not less than \( \text{numtaps} \). \( \text{nfreqs} \) must be greater than \( \text{numtaps} \).

**window**
[string or (string, float) or float, or None, optional] Window function to use. Default is “hanning”. See scipy.signal.get_window for the complete list of possible values. If None, no window function is applied.

**nyq**
[float, optional] Deprecated. Use ‘\( \text{fs} \)’ instead. This is the Nyquist frequency. Each frequency in \( \text{freq} \) must be between 0 and \( \text{nyq} \). Default is 1.

**antisymmetric**
[bool, optional] Whether resulting impulse response is symmetric/antisymmetric. See Notes for more details.

**fs**
[float, optional] The sampling frequency of the signal. Each frequency in \( \text{cutoff} \) must be between 0 and \( \text{fs}/2 \). Default is 2.

**Returns**

**taps**
[ndarray] The filter coefficients of the FIR filter, as a 1-D array of length \( \text{numtaps} \).

See also:

firls
firwin
minimum_phase
remez

**Notes**

From the given set of frequencies and gains, the desired response is constructed in the frequency domain. The inverse FFT is applied to the desired response to create the associated convolution kernel, and the first \( \text{numtaps} \) coefficients of this kernel, scaled by \( \text{window} \), are returned.

The FIR filter will have linear phase. The type of filter is determined by the value of ‘\( \text{numtaps} \)’ and \( \text{antisymmetric} \) flag. There are four possible combinations:

- odd \( \text{numtaps} \), \( \text{antisymmetric} \) is False, type I filter is produced
- even \( \text{numtaps} \), \( \text{antisymmetric} \) is False, type II filter is produced
- odd \( \text{numtaps} \), \( \text{antisymmetric} \) is True, type III filter is produced
- even \( \text{numtaps} \), \( \text{antisymmetric} \) is True, type IV filter is produced

Magnitude response of all but type I filters are subjects to following constraints:

- type II – zero at the Nyquist frequency
- type III – zero at zero and Nyquist frequencies
- type IV – zero at zero frequency

New in version 0.9.0.
References

[1],[2]

Examples

A lowpass FIR filter with a response that is 1 on [0.0, 0.5], and that decreases linearly on [0.5, 1.0] from 1 to 0:

```python
>>> from scipy import signal
>>> taps = signal.firwin2(150, [0.0, 0.5, 1.0], [1.0, 1.0, 0.0])
>>> print(taps[72:78])
[-0.02286961 -0.06362756 0.57310236 0.57310236 -0.06362756 -0.02286961]
```

scipy.signal.freqs

```python
scipy.signal.freqs(b, a, worN=200, plot=None)
```

Compute frequency response of analog filter.

Given the M-order numerator \(b\) and N-order denominator \(a\) of an analog filter, compute its frequency response:

\[
H(\omega) = \frac{b[0](j\omega)^M + b[1](j\omega)^{(M-1)} + \ldots + b[M]}{a[0](j\omega)^N + a[1](j\omega)^{(N-1)} + \ldots + a[N]}
\]

Parameters

- **b** [array_like] Numerator of a linear filter.
- **a** [array_like] Denominator of a linear filter.
- **worN** [{None, int, array_like}, optional] If None, then compute at 200 frequencies around the interesting parts of the response curve (determined by pole-zero locations). If a single integer, then compute at that many frequencies. Otherwise, compute the response at the angular frequencies (e.g., rad/s) given in worN.
- **plot** [callable, optional] A callable that takes two arguments. If given, the return parameters \(w\) and \(h\) are passed to plot. Useful for plotting the frequency response inside freqs.

Returns

- **w** [ndarray] The angular frequencies at which \(h\) was computed.
- **h** [ndarray] The frequency response.

See also:

freqz

Compute the frequency response of a digital filter.
Notes

Using Matplotlib’s “plot” function as the callable for plot produces unexpected results, this plots the real part of the complex transfer function, not the magnitude. Try lambda w, h: plot(w, abs(h)).

Examples

```python
>>> from scipy.signal import freqs, iirfilter

>>> b, a = iirfilter(4, [1, 10], 1, 60, analog=True, ftype='cheby1')

>>> w, h = freqs(b, a, worN=np.logspace(-1, 2, 1000))

>>> import matplotlib.pyplot as plt
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.xlabel('Frequency')
>>> plt.ylabel('Amplitude response [dB]')
>>> plt.grid()
>>> plt.show()
```

### scipy.signal.freqs_zpk

`scipy.signal.freqs_zpk(z, p, k, worN=200)`

Compute frequency response of analog filter.

Given the zeros $z$, poles $p$, and gain $k$ of a filter, compute its frequency response:

$$H(w) = k \frac{(jw-z[0]) \cdot (jw-z[1]) \cdot \ldots \cdot (jw-z[-1])}{(jw-p[0]) \cdot (jw-p[1]) \cdot \ldots \cdot (jw-p[-1])}$$

**Parameters**

z
[array_like] Zeroes of a linear filter
p
[array_like] Poles of a linear filter
k
[scalar] Gain of a linear filter
worN
[None, int, array_like], optional] If None, then compute at 200 frequencies around the interesting parts of the response curve (determined by pole-zero locations). If a single integer, then compute at that many frequencies. Otherwise, compute the response at the angular frequencies (e.g., rad/s) given in worN.

Returns

w
[ndarray] The angular frequencies at which $h$ was computed.
h
[ndarray] The frequency response.

See also:

freqs
Compute the frequency response of an analog filter in TF form
freqz
Compute the frequency response of a digital filter in TF form
freqz_zpk
Compute the frequency response of a digital filter in ZPK form

Notes

New in version 0.19.0.

Examples

```python
>>> from scipy.signal import freqs_zpk, iirfilter
>>> z, p, k = iirfilter(4, [1, 10], 1, 60, analog=True, ftype='cheby1',
                        output='zpk')
>>> w, h = freqs_zpk(z, p, k, worN=np.logspace(-1, 2, 1000))
>>> import matplotlib.pyplot as plt
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.xlabel('Frequency')
>>> plt.ylabel('Amplitude response [dB]
''
>>> plt.grid()
>>> plt.show()
```
**scipy.signal.freqz**

`scipy.signal.freqz(b, a=1, worN=512, whole=False, plot=None, fs=6.283185307179586, include_nyquist=False)`

Compute the frequency response of a digital filter.

Given the M-order numerator $b$ and N-order denominator $a$ of a digital filter, compute its frequency response:

$$
H(e^{j\omega}) = \frac{b[0] + b[1]e^{-j\omega} + \ldots + b[M]e^{-jM\omega}}{a[0] + a[1]e^{-j\omega} + \ldots + a[N]e^{-jN\omega}}
$$

**Parameters**

- **b** [array_like] Numerator of a linear filter. If $b$ has dimension greater than 1, it is assumed that the coefficients are stored in the first dimension, and $b.shape[1:], a.shape[1:]$, and the shape of the frequencies array must be compatible for broadcasting.

- **a** [array_like] Denominator of a linear filter. If $b$ has dimension greater than 1, it is assumed that the coefficients are stored in the first dimension, and $b.shape[1:], a.shape[1:]$, and the shape of the frequencies array must be compatible for broadcasting.

- **worN** [(None, int, array_like), optional] If a single integer, then compute at that many frequencies (default is N=512). This is a convenient alternative to:

  ```python
  np.linspace(0, fs if whole else fs/2, N, endpoint=include_nyquist)
  ```

  Using a number that is fast for FFT computations can result in faster computations (see Notes).

  If an array_like, compute the response at the frequencies given. These are in the same units as $fs$.

- **whole** [bool, optional] Normally, frequencies are computed from 0 to the Nyquist frequency, $fs/2$ (upper-half of unit-circle). If *whole* is True, compute frequencies from 0 to $fs$. Ignored if *worN* is array_like.
plot  [callable] A callable that takes two arguments. If given, the return parameters \( w \) and \( h \) are passed to plot. Useful for plotting the frequency response inside \( \text{freqz} \).

fs  [float, optional] The sampling frequency of the digital system. Defaults to \( 2\pi \) radians/sample \((\text{so} \ w \ \text{is from} \ 0 \ \text{to} \ \pi)\).
New in version 1.2.0.

include_nyquist  [bool, optional] If \( \text{whole} \) is False and \( \text{worN} \) is an integer, setting \( \text{include_nyquist} \) to True will include the last frequency (Nyquist frequency) and is otherwise ignored.
New in version 1.5.0.

Returns

\( w \)  [ndarray] The frequencies at which \( h \) was computed, in the same units as \( fs \). By default, \( w \) is normalized to the range \([0, \pi)\) (radians/sample).

\( h \)  [ndarray] The frequency response, as complex numbers.

See also:

freqz_zpk
sosfreqz

Notes

Using Matplotlib’s \texttt{matplotlib.pyplot.plot} function as the callable for \( \text{plot} \) produces unexpected results, as this plots the real part of the complex transfer function, not the magnitude. Try \texttt{lambda w, h: plot(w, np.abs(h))}.

A direct computation via (R)FFT is used to compute the frequency response when the following conditions are met:

1. An integer value is given for \( \text{worN} \).
2. \( \text{worN} \) is fast to compute via FFT (i.e., \texttt{next_fast_len(worN)} equals \( \text{worN} \)).
3. The denominator coefficients are a single value \((a.\text{shape}[0] == 1)\).
4. \( \text{worN} \) is at least as long as the numerator coefficients \((\text{worN} >= b.\text{shape}[0])\).
5. If \( b.\text{ndim} > 1 \), then \( b.\text{shape}[-1] == 1 \).

For long FIR filters, the FFT approach can have lower error and be much faster than the equivalent direct polynomial calculation.

Examples

```python
>>> from scipy import signal
>>> b = signal.firwin(80, 0.5, window=('kaiser', 8))
>>> w, h = signal.freqz(b)

>>> import matplotlib.pyplot as plt
>>> fig, ax1 = plt.subplots()
>>> ax1.set_title('Digital filter frequency response')
```
Broadcasting Examples

Suppose we have two FIR filters whose coefficients are stored in the rows of an array with shape (2, 25). For this demonstration, we'll use random data:

```python
>>> rng = np.random.default_rng()
>>> b = rng.random((2, 25))
```

To compute the frequency response for these two filters with one call to `freqz`, we must pass in `b.T`, because `freqz` expects the first axis to hold the coefficients. We must then extend the shape with a trivial dimension of length 1 to allow broadcasting with the array of frequencies. That is, we pass in `b.T[..., np.newaxis]`, which has shape (25, 2, 1):

```python
>>> w, h = signal.freqz(b.T[..., np.newaxis], worN=1024)
>>> w.shape
(1024,)
>>> h.shape
(2, 1024)
```

Now, suppose we have two transfer functions, with the same numerator coefficients `b = [0.5, 0.5]`. The coefficients for the two denominators are stored in the first dimension of the 2-D array `a`:

```python
>>> w, h = signal.freqz(b.T[..., np.newaxis], worN=1024)
```
a = [ 1 1 ]
[ -0.25, -0.5 ]

```python
>>> b = np.array([0.5, 0.5])
>>> a = np.array([[1, 1], [-0.25, -0.5]])
```

Only `a` is more than 1-D. To make it compatible for broadcasting with the frequencies, we extend it with a trivial dimension in the call to `freqz`:

```python
>>> w, h = signal.freqz(b, a[...], np.newaxis, worN=1024)
>>> w.shape
(1024,)
>>> h.shape
(2, 1024)
```

**scipy.signal.freqz_zpk**

* scipy.signal.freqz_zpk(z, p, k, worN=512, whole=False, fs=6.283185307179586)

Compute the frequency response of a digital filter in ZPK form.

Given the Zeros, Poles and Gain of a digital filter, compute its frequency response:

\[ H(z) = k \frac{\prod_i(z - Z[i])}{\prod_j(z - P[j])} \]

where `k` is the gain, `Z` are the zeros and `P` are the poles.

**Parameters**

- `z` [array_like] Zeros of a linear filter
- `p` [array_like] Poles of a linear filter
- `k` [scalar] Gain of a linear filter
- `worN` [{None, int, array_like}, optional] If a single integer, then compute at that many frequencies (default is N=512). If an array_like, compute the response at the frequencies given. These are in the same units as `fs`.
- `whole` [bool, optional] Normally, frequencies are computed from 0 to the Nyquist frequency, fs/2 (upper-half of unit-circle). If `whole` is True, compute frequencies from 0 to fs. Ignored if `w` is array_like.
- `fs` [float, optional] The sampling frequency of the digital system. Defaults to 2*pi radians/sample (so `w` is from 0 to pi). New in version 1.2.0.

**Returns**

- `w` [ndarray] The frequencies at which `h` was computed, in the same units as `fs`. By default, `w` is normalized to the range [0, pi) (radians/sample).
- `h` [ndarray] The frequency response, as complex numbers.

**See also:**

- `freqs`
  - Compute the frequency response of an analog filter in TF form
- `freqs_zpk`
  - Compute the frequency response of an analog filter in ZPK form
freqz

Compute the frequency response of a digital filter in TF form

**Notes**

New in version 0.19.0.

**Examples**

Design a 4th-order digital Butterworth filter with cut-off of 100 Hz in a system with sample rate of 1000 Hz, and plot the frequency response:

```python
>>> from scipy import signal
>>> z, p, k = signal.butter(4, 100, output='zpk', fs=1000)
>>> w, h = signal.freqz_zpk(z, p, k, fs=1000)

>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(1, 1, 1)
>>> ax1.set_title('Digital filter frequency response')

>>> ax1.plot(w, 20 * np.log10(abs(h)), 'b')
>>> ax1.set_ylabel('Amplitude [dB]', color='b')
>>> ax1.set_xlabel('Frequency [Hz]')

>>> ax2 = ax1.twinx()
>>> angles = np.unwrap(np.angle(h))
>>> ax2.plot(w, angles, 'g')
>>> ax2.set_ylabel('Angle [radians]', color='g')

>>> plt.axis('tight')
>>> plt.show()
```

**scipy.signal.sosfreqz**

Compute the frequency response of a digital filter in SOS format.

Given `sos`, an array with shape (n, 6) of second order sections of a digital filter, compute the frequency response of the system function:

\[
H(z) = \frac{B_0(z) B_1(z) \cdots B^{(n-1)}(z)}{A_0(z) A_1(z) \cdots A^{(n-1)}(z)}
\]

for \(z = \exp(\omega j)\), where \(B^{(k)}(z)\) and \(A^{(k)}(z)\) are numerator and denominator of the transfer function of the \(k\)-th second order section.

**Parameters**
sos: array_like Array of second-order filter coefficients, must have shape \((n\_sections, 6)\). Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.

worN: [None, int, array_like, optional] If a single integer, then compute at that many frequencies (default is \(N=512\)). Using a number that is fast for FFT computations can result in faster computations (see Notes of freqz).

If an array_like, compute the response at the frequencies given (must be 1-D). These are in the same units as \(fs\).

whole: [bool, optional] Normally, frequencies are computed from 0 to the Nyquist frequency, \(fs/2\) (upper-half of unit-circle). If whole is True, compute frequencies from 0 to \(fs\).

fs: [float, optional] The sampling frequency of the digital system. Defaults to 2*pi radians/sample (so \(w\) is from 0 to pi).

New in version 1.2.0.

**Returns**

\(w\): [ndarray] The frequencies at which \(h\) was computed, in the same units as \(fs\). By default, \(w\) is normalized to the range [0, pi) (radians/sample).

\(h\): [ndarray] The frequency response, as complex numbers.

**See also:**

freqz, sosfilt

**Notes**

New in version 0.19.0.
Examples

Design a 15th-order bandpass filter in SOS format.

```python
>>> from scipy import signal
>>> sos = signal.ellip(15, 0.5, 60, (0.2, 0.4), btype='bandpass', output='sos')
```

Compute the frequency response at 1500 points from DC to Nyquist.

```python
>>> w, h = signal.sosfreqz(sos, worN=1500)
```

Plot the response.

```python
>>> import matplotlib.pyplot as plt
>>> plt.subplot(2, 1, 1)
>>> db = 20*np.log10(np.maximum(np.abs(h), 1e-5))
>>> plt.plot(w/np.pi, db)
>>> plt.ylim(-75, 5)
>>> plt.grid(True)
>>> plt.xticks([0, -np.pi, -0.5*np.pi, 0, 0.5*np.pi, np.pi], ...
             [r'$\pi$', r'$-\pi/2$', '0', r'$\pi/2$', r'$\pi$'])
>>> plt.ylabel('Gain [dB]')
>>> plt.title('Frequency Response')
>>> plt.subplot(2, 1, 2)
>>> plt.plot(w/np.pi, np.angle(h))
>>> plt.grid(True)
>>> plt.xticks([0, -np.pi, -0.5*np.pi, 0, 0.5*np.pi, np.pi], ...
             [r'$\pi$', r'$-\pi/2$', '0', r'$\pi/2$', r'$\pi$'])
>>> plt.yticks([-np.pi, -0.5*np.pi, 0, 0.5*np.pi, np.pi], ...
             [r'$\pi$', r'$-\pi/2$', '0', r'$\pi/2$', r'$\pi$'])
>>> plt.xlabel('Normalized frequency (1.0 = Nyquist)')
>>> plt.ylabel('Phase [rad]')
>>> plt.show()
```

If the same filter is implemented as a single transfer function, numerical error corrupts the frequency response:
```python
>>> b, a = signal.ellip(15, 0.5, 60, (0.2, 0.4), btype='bandpass',
                    output='ba')
>>> w, h = signal.freqz(b, a, worN=1500)
>>> db = 20*np.log10(np.maximum(np.abs(h), 1e-5))
>>> plt.plot(w/np.pi, db)
>>> plt.ylim(-75, 5)
>>> plt.grid(True)
>>> plt.xticks([0, -20, -40, -60])
>>> plt.ylabel('Gain [dB]')
>>> plt.title('Frequency Response')
>>> plt.plot(w/np.pi, np.angle(h))
>>> plt.grid(True)
>>> plt.yticks([-np.pi, -0.5*np.pi, 0, 0.5*np.pi, np.pi],
             [r'$\pi$', r'$\pi/2$', '0', r'$\pi/2$', r'$\pi$'])
>>> plt.xlabel('Normalized frequency (1.0 = Nyquist)')
>>> plt.show()
```

**scipy.signal.gammatone**

This function computes the coefficients of an FIR or IIR gammatone digital filter [1].

**Parameters**

- `freq` [float] Center frequency of the filter (expressed in the same units as `fs`).
- `ftype` [{'fir', 'iir'}] The type of filter the function generates. If 'fir', the function will generate an Nth order FIR gammatone filter. If 'iir', the function will generate an 8th order digital IIR filter, modeled as an 4th order gammatone filter.
- `order` [int, optional] The order of the filter. Only used when `ftype='fir'`. Default is 4 to model the human auditory system. Must be between 0 and 24.
numtaps [int, optional] Length of the filter. Only used when ftype='fir'. Default is $fs \times 0.015$ if $fs$ is greater than 1000, 15 if $fs$ is less than or equal to 1000.

fs [float, optional] The sampling frequency of the signal. freq must be between 0 and $fs/2$. Default is 2.

Returns
b, a [ndarray, ndarray] Numerator (b) and denominator (a) polynomials of the filter.

Raises
ValueError
If freq is less than or equal to 0 or greater than or equal to $fs/2$, if ftype is not ‘fir’ or ‘iir’, if order is less than or equal to 0 or greater than 24 when ftype='fir'

Examples
16-sample 4th order FIR Gammatone filter centered at 440 Hz

```python
>>> from scipy import signal
>>> b, a = signal.gammatone(440, 'fir', numtaps=16, fs=16000)
(array([0.00000000e+00, 2.22196719e-07, 1.64942101e-06, 4.99298227e-06,
   1.01993969e-05, 1.63125770e-05, 2.14648940e-05, 2.29947263e-05,
   1.76776931e-05, 2.04980537e-06, -2.72062858e-05, -7.28455299e-05,
   -1.36651076e-04, -2.19066855e-04, -3.18905076e-04, -4.33156712e-04]), [1.0])
```

IIR Gammatone filter centered at 440 Hz

```python
>>> b, a = signal.gammatone(440, 'iir', fs=16000)
>>> w, h = signal.freqz(b, a)
>>> plt.plot(w / ((2 * np.pi) / 16000), 20 * np.log10(abs(h)))
>>> plt.xscale('log')
>>> plt.title('Gammatone filter frequency response')
>>> plt.xlabel('Frequency')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(440, color='green')  # cutoff frequency
>>> plt.show()
```
scipy.signal.group_delay

**scipy.signal.group_delay** *(system, w=512, whole=False, fs=6.283185307179586)*

Compute the group delay of a digital filter.

The group delay measures by how many samples amplitude envelopes of various spectral components of a signal are delayed by a filter. It is formally defined as the derivative of continuous (unwrapped) phase:

\[
D(w) = -\frac{d}{dw} \arg H(e^{jw})
\]

**Parameters**

- **system** *(tuple of array_like (b, a))* Numerator and denominator coefficients of a filter transfer function.
- **w** *[None, int, array_like], optional]* If a single integer, then compute at that many frequencies (default is N=512).
  If an array_like, compute the delay at the frequencies given. These are in the same units as fs.
- **whole** *[bool, optional]* Normally, frequencies are computed from 0 to the Nyquist frequency, fs/2 (upper-half of unit-circle). If whole is True, compute frequencies from 0 to fs. Ignored if w is array_like.
- **fs** *[float, optional]* The sampling frequency of the digital system. Defaults to 2*pi radians/sample (so w is from 0 to pi).
  New in version 1.2.0.

**Returns**

- **w** *[ndarray]* The frequencies at which group delay was computed, in the same units as fs. By default, w is normalized to the range [0, pi) (radians/sample).
- **gd** *[ndarray]* The group delay.

**See also:**

- **freqz**
Frequency response of a digital filter

Notes

The similar function in MATLAB is called `grpdelay`.

If the transfer function $H(z)$ has zeros or poles on the unit circle, the group delay at corresponding frequencies is undefined. When such a case arises the warning is raised and the group delay is set to 0 at those frequencies.

For the details of numerical computation of the group delay refer to [1].

New in version 0.16.0.

[1]

Examples

```python
>>> from scipy import signal
>>> b, a = signal.iirdesign(0.1, 0.3, 5, 50, ftype='cheby1')
>>> w, gd = signal.group_delay((b, a))

>>> import matplotlib.pyplot as plt
>>> plt.title('Digital filter group delay')
>>> plt.plot(w, gd)
>>> plt.ylabel('Group delay [samples]')
>>> plt.xlabel('Frequency [rad/sample]')
>>> plt.show()
```

Digital filter group delay
scipy.signal.iirdesign

scipy.signal.iirdesign(wp, ws, gpass, gstop, analog=False, ftype='ellip', output='ba', fs=None)

Complete IIR digital and analog filter design.

Given passband and stopband frequencies and gains, construct an analog or digital IIR filter of minimum order for a given basic type. Return the output in numerator, denominator (‘ba’), pole-zero (‘zpk’) or second order sections (‘sos’) form.

Parameters

wp, ws [float or array like, shape (2,)] Passband and stopband edge frequencies. Possible values are scalars (for lowpass and highpass filters) or ranges (for bandpass and bandstop filters). For digital filters, these are in the same units as fs. By default, fs is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. For example:
- Lowpass: wp = 0.2, ws = 0.3
- Highpass: wp = 0.3, ws = 0.2
- Bandpass: wp = [0.2, 0.5], ws = [0.1, 0.6]
- Bandstop: wp = [0.1, 0.6], ws = [0.2, 0.5]
For analog filters, wp and ws are angular frequencies (e.g., rad/s). Note, that for bandpass and bandstop filters passband must lie strictly inside stopband or vice versa.

gpass [float] The maximum loss in the passband (dB).
gstop [float] The minimum attenuation in the stopband (dB).
analog [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.
ftype [str, optional] The type of IIR filter to design:
- Butterworth: ‘butter’
- Chebyshev I: ‘cheby1’
- Chebyshev II: ‘cheby2’
- Cauer/elliptic: ‘ellip’
- Bessel/Thomson: ‘bessel’

output [{'ba’, ‘zpk’, ‘sos’}, optional] Filter form of the output:
- second-order sections (recommended): ‘sos’
- numerator/denominator (default): ‘ba’
- pole-zero: ‘zpk’
In general the second-order sections (‘sos’) form is recommended because inferring the coefficients for the numerator/denominator form (‘ba’) suffers from numerical instabilities. For reasons of backward compatibility the default form is the numerator/denominator form (‘ba’), where the ‘b’ and the ‘a’ in ‘ba’ refer to the commonly used names of the coefficients used.
Note: Using the second-order sections form (‘sos’) is sometimes associated with additional computational costs: for data-intensive use cases it is therefore recommended to also investigate the numerator/denominator form (‘ba’).

fs [float, optional] The sampling frequency of the digital system.
New in version 1.2.0.

Returns

b, a [ndarray, ndarray] Numerator (b) and denominator (a) polynomials of the IIR filter. Only returned if output=’ba’.

z, p, k [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if output=’zpk’.
sos [ndarray] Second-order sections representation of the IIR filter. Only returned if output=’sos’.

iirfilter

General filter design using order and critical frequencies

Notes

The 'sos' output parameter was added in 0.16.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> import matplotlib.ticker

>>> wp = 0.2
>>> ws = 0.3
>>> gpass = 1
>>> gstop = 40

>>> system = signal.iirdesign(wp, ws, gpass, gstop)
>>> w, h = signal.freqz('system')

>>> fig, ax1 = plt.subplots()
>>> ax1.set_title('Digital filter frequency response')
>>> ax1.plot(w, 20 * np.log10(abs(h)), 'b')
>>> ax1.set_ylabel('Amplitude [dB]', color='b')
>>> ax1.set_xlabel('Frequency [rad/sample]')
>>> ax1.grid()
>>> ax1.set_ylim([-120, 20])

>>> ax2 = ax1.twinx()
>>> angles = np.unwrap(np.angle(h))
>>> ax2.plot(w, angles, 'g')
>>> ax2.set_ylabel('Angle (radians)', color='g')
>>> ax2.grid()
>>> ax2.axis('tight')
>>> ax2.set_ylim([-6, 1])
>>> nticks = 8
>>> ax1.yaxis.set_major_locator(matplotlib.ticker.LinearLocator(nticks))
>>> ax2.yaxis.set_major_locator(matplotlib.ticker.LinearLocator(nticks))
```
scipy.signal.iirfilter

scipy.signal.iirfilter(N, Wn=None, rp=None, rs=None, btype='band', analog=False, ftype='butter', output='ba', fs=None)

IIR digital and analog filter design given order and critical points.

Design an Nth-order digital or analog filter and return the filter coefficients.

Parameters

N : int
    The order of the filter.
Wn : array_like
    A scalar or length-2 sequence giving the critical frequencies.
For digital filters, Wn are in the same units as fs. By default, fs is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (Wn is thus in half-cycles / sample.)
For analog filters, Wn is an angular frequency (e.g., rad/s).
rp : float, optional
    For Chebyshev and elliptic filters, provides the maximum ripple in the passband. (dB)
rs : float, optional
    For Chebyshev and elliptic filters, provides the minimum attenuation in the stop band. (dB)
btype : {'bandpass', 'lowpass', 'highpass', 'bandstop'}, optional
    The type of filter. Default is 'bandpass'.
analog : bool, optional
    When True, return an analog filter, otherwise a digital filter is returned.
ftype : str, optional
    The type of IIR filter to design:
    • Butterworth : 'butter'
    • Chebyshev I : 'cheby1'
    • Chebyshev II : 'cheby2'
    • Cauer/elliptic : 'ellip'
    • Bessel/Thomson: 'bessel'
output : {'ba', 'zpk', 'sos'}, optional
    Filter form of the output:
    • second-order sections (recommended): 'sos'
    • numerator/denominator (default) : 'ba'
    • pole-zero : 'zpk'

In general the second-order sections ('sos') form is recommended because inferring the coefficients for the numerator/denominator form ('ba') suffers from numerical instabilities. For
reasons of backward compatibility the default form is the numerator/denominator form ('ba'), where the 'b' and the 'a' in 'ba' refer to the commonly used names of the coefficients used. Note: Using the second-order sections form ('sos') is sometimes associated with additional computational costs: for data-intense use cases it is therefore recommended to also investigate the numerator/denominator form ('ba').

**fs**
[float, optional] The sampling frequency of the digital system.
New in version 1.2.0.

**Returns**

- **b, a** [ndarray, ndarray] Numerator (b) and denominator (a) polynomials of the IIR filter. Only returned if output='ba'.
- **z, p, k** [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if output='zpk'.
- **sos** [ndarray] Second-order sections representation of the IIR filter. Only returned if output=='sos'.

**See also:**

- **butter**
  Filter design using order and critical points
- **cheby1, cheby2, ellip, bessel**
- **buttord**
  Find order and critical points from passband and stopband spec
- **cheblord, cheb2ord, ellipord**
- **iirdesign**
  General filter design using passband and stopband spec

**Notes**

The 'sos' output parameter was added in 0.16.0.

**Examples**

Generate a 17th-order Chebyshev II analog bandpass filter from 50 Hz to 200 Hz and plot the frequency response:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.iirfilter(17, [2*np.pi*50, 2*np.pi*200], rs=60,
...                          btype='band', analog=True, ftype='cheby2')
>>> w, h = signal.freqs(b, a, 1000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1, 1, 1)
>>> ax.semilogx(w / (2*np.pi), 20 * np.log10(np.maximum(abs(h), 1e-5)))
>>> ax.set_title('Chebyshev Type II bandpass frequency response')
>>> ax.set_xlabel('Frequency [Hz]')
>>> ax.set_ylabel('Amplitude [dB]')
>>> ax.axis((10, 1000, -100, 10))
```
Create a digital filter with the same properties, in a system with sampling rate of 2000 Hz, and plot the frequency response. (Second-order sections implementation is required to ensure stability of a filter of this order):

```python
>>> sos = signal.iirfilter(17, [50, 200], rs=60, btype='band',
...                        analog=False, ftype='cheby2', fs=2000,
...                        output='sos')
>>> w, h = signal.sosfreqz(sos, 2000, fs=2000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1, 1, 1)
>>> ax.semilogx(w, 20*np.log10(np.maximum(abs(h), 1e-5)))
>>> ax.set_title('Chebyshev Type II bandpass frequency response')
>>> ax.set_xlabel('Frequency [Hz]')
>>> ax.set_ylabel('Amplitude [dB]')
>>> ax.axis((10, 1000, -100, 10))
>>> ax.grid(which='both', axis='both')
>>> plt.show()
```

**scipy.signal.kaiser_atten**

`scipy.signal.kaiser_atten(numtaps, width)`

Compute the attenuation of a Kaiser FIR filter.

Given the number of taps $N$ and the transition width $width$, compute the attenuation $a$ in dB, given by Kaiser’s formula:

$$a = 2.285 \times (N - 1) \times \pi \times width + 7.95$$

**Parameters**

- `numtaps` [int] The number of taps in the FIR filter.
- `width` [float] The desired width of the transition region between passband and stopband (or, in general, at any discontinuity) for the filter, expressed as a fraction of the Nyquist frequency.
Chebyshev Type II bandpass frequency response

<table>

Returns

a [float] The attenuation of the ripple, in dB.

See also:

kaiserord, kaiser_beta

Examples

Suppose we want to design a FIR filter using the Kaiser window method that will have 211 taps and a transition width of 9 Hz for a signal that is sampled at 480 Hz. Expressed as a fraction of the Nyquist frequency, the width is 9/(0.5*480) = 0.0375. The approximate attenuation (in dB) is computed as follows:

```python
>>> from scipy.signal import kaiser_atten
>>> kaiser_atten(211, 0.0375)
64.48099630593983
```

scipy.signal.kaiser_beta

scipy.signal.kaiser_beta(a)

Compute the Kaiser parameter beta, given the attenuation a.

Parameters

a [float] The desired attenuation in the stopband and maximum ripple in the passband, in dB. This should be a positive number.

Returns

beta [float] The beta parameter to be used in the formula for a Kaiser window.
References

Examples

Suppose we want to design a lowpass filter, with 65 dB attenuation in the stop band. The Kaiser window parameter to be used in the window method is computed by \texttt{kaiser\_beta(65)}:

\begin{verbatim}
>>> from scipy.signal import kaiser_beta
>>> kaiser_beta(65)
6.20426
\end{verbatim}

\texttt{scipy.signal.kaiserord}

\texttt{scipy.signal.kaiserord}(\texttt{ripple, width})

Determine the filter window parameters for the Kaiser window method.

The parameters returned by this function are generally used to create a finite impulse response filter using the window method, with either \texttt{firwin} or \texttt{firwin2}.

\textit{Parameters}

\begin{itemize}
  \item \texttt{ripple} [float] Upper bound for the deviation (in dB) of the magnitude of the filter's frequency response from that of the desired filter (not including frequencies in any transition intervals). That is, if \( w \) is the frequency expressed as a fraction of the Nyquist frequency, \( A(w) \) is the actual frequency response of the filter and \( D(w) \) is the desired frequency response, the design requirement is that:
    \[
    \text{abs}(A(w) - D(w)) < 10^{-\text{ripple}/20}
    \]
    for \( 0 \leq w \leq 1 \) and \( w \) not in a transition interval.
  \item \texttt{width} [float] Width of transition region, normalized so that 1 corresponds to \( \pi \) radians / sample. That is, the frequency is expressed as a fraction of the Nyquist frequency.
\end{itemize}

\textit{Returns}

\begin{itemize}
  \item \texttt{numtaps} [int] The length of the Kaiser window.
  \item \texttt{beta} [float] The beta parameter for the Kaiser window.
\end{itemize}

See also:

\texttt{kaiser\_beta, kaiser\_atten}

Notes

There are several ways to obtain the Kaiser window:

\begin{itemize}
  \item \texttt{signal.windows.kaiser(numtaps, beta, sym=True)}
  \item \texttt{signal.get\_window(beta, numtaps)}
  \item \texttt{signal.get\_window('kaiser', beta), numtaps)}
\end{itemize}

The empirical equations discovered by Kaiser are used.
References

Examples

We will use the Kaiser window method to design a lowpass FIR filter for a signal that is sampled at 1000 Hz.
We want at least 65 dB rejection in the stop band, and in the pass band the gain should vary no more than 0.5%.

We want a cutoff frequency of 175 Hz, with a transition between the pass band and the stop band of 24 Hz. That
is, in the band [0, 163], the gain varies no more than 0.5%, and in the band [187, 500], the signal is attenuated by
at least 65 dB.

```python
>>> from scipy.signal import kaiserord, firwin, freqz
>>> import matplotlib.pyplot as plt
>>> fs = 1000.0
>>> cutoff = 175
>>> width = 24
```

The Kaiser method accepts just a single parameter to control the pass band ripple and the stop band rejection, so
we use the more restrictive of the two. In this case, the pass band ripple is 0.005, or 46.02 dB, so we will use 65
dB as the design parameter.

Use `kaiserord` to determine the length of the filter and the parameter for the Kaiser window.

```python
>>> numtaps, beta = kaiserord(65, width/(0.5*fs))
>>> numtaps
167
>>> beta
6.20426
```

Use `firwin` to create the FIR filter.

```python
>>> taps = firwin(numtaps, cutoff, window=('kaiser', beta),
...                scale=False, nyq=0.5*fs)
```

Compute the frequency response of the filter. *w* is the array of frequencies, and *h* is the corresponding complex
array of frequency responses.

```python
>>> w, h = freqz(taps, worN=8000)
>>> w *= 0.5*fs/np.pi  # Convert w to Hz.
```

Compute the deviation of the magnitude of the filter's response from that of the ideal lowpass filter. Values in the
transition region are set to `np.nan`, so they won't appear in the plot.

```python
>>> ideal = w < cutoff  # The "ideal" frequency response.
>>> deviation = np.abs(np.abs(h) - ideal)
>>> deviation[(w > cutoff - 0.5*width) & (w < cutoff + 0.5*width)] = np.nan
```

Plot the deviation. A close look at the left end of the stop band shows that the requirement for 65 dB attenuation
is violated in the first lobe by about 0.125 dB. This is not unusual for the Kaiser window method.
```python
>>> plt.plot(w, 20*np.log10(np.abs(deviation)))
>>> plt.xlim(0, 0.5*fs)
>>> plt.ylim(-90, -60)
>>> plt.grid(alpha=0.25)
>>> plt.axhline(-65, color='r', ls='--', alpha=0.3)
>>> plt.xlabel('Frequency (Hz)')
>>> plt.ylabel('Deviation from ideal (dB)')
>>> plt.title('Lowpass Filter Frequency Response')
>>> plt.show()
```

### scipy.signal.minimum_phase

`scipy.signal.minimum_phase(h, method='homomorphic', n_fft=None)`

Convert a linear-phase FIR filter to minimum phase

**Parameters**

- **h**
  - [array] Linear-phase FIR filter coefficients.

- **method**
  - [str] The method to use:
    - `'homomorphic'` (default)
      - This method works best with filters with an odd number of taps, and the resulting minimum phase filter will have a magnitude response that approximates the square root of the original filter’s magnitude response.
    - `'hilbert'`
      - This method is designed to be used with equiripple filters (e.g., from `remez`) with unity or zero gain regions.

- **n_fft**
  - [int] The number of points to use for the FFT. Should be at least a few times larger than the signal length (see Notes).

**Returns**

- **h_minimum**
  - [array] The minimum-phase version of the filter, with length `(length(h) + 1) // 2`.

**See also:**

`firwin`

In the case of the Hilbert method, the deviation from the ideal spectrum \( \epsilon \) is related to the number of stopband zeros \( n_{\text{stop}} \) and FFT length \( n_{\text{fft}} \) as:

\[
\epsilon = 2 \times \frac{n_{\text{stop}}}{n_{\text{fft}}}
\]

For example, with 100 stopband zeros and a FFT length of 2048, \( \epsilon = 0.0976 \). If we conservatively assume that the number of stopband zeros is one less than the filter length, we can take the FFT length to be the next power of 2 that satisfies \( \epsilon = 0.01 \) as:

\[
n_{\text{fft}} = 2^{\lceil \frac{\log_2(2 \times (\text{len}(h) - 1) / 0.01)\rceil}}
\]

This gives reasonable results for both the Hilbert and homomorphic methods, and gives the value used when \( n_{\text{fft}} = \text{None} \).

Alternative implementations exist for creating minimum-phase filters, including zero inversion [2] and spectral factorization [3] [4]. For more information, see:

http://dspguru.com/dsp/howtos/how-to-design-minimum-phase-fir-filters

References

[1], [2], [3], [4], [5]

Examples

Create an optimal linear-phase filter, then convert it to minimum phase:

```python
>>> from scipy.signal import remez, minimum_phase, freqz, group_delay
>>> import matplotlib.pyplot as plt
>>> freq = [0, 0.2, 0.3, 1.0]
>>> desired = [1, 0]
>>> h_linear = remez(151, freq, desired, Hz=2.)
```

Convert it to minimum phase:

```python
>>> h_min_hom = minimum_phase(h_linear, method='homomorphic')
>>> h_min_hil = minimum_phase(h_linear, method='hilbert')
```

Compare the three filters:

```python
>>> fig, axs = plt.subplots(4, figsize=(4, 8))
>>> for h, style, color in zip((h_linear, h_min_hom, h_min_hil),
... ('-', '-.', '--'), ('k', 'r', 'c')):
...     w, H = freqz(h)
...     w, gd = group_delay((h, 1))
(continues on next page)```
... w /= np.pi
... axs[0].plot(h, color=color, linestyle=style)
... axs[1].plot(w, np.abs(H), color=color, linestyle=style)
... axs[2].plot(w, 20 * np.log10(np.abs(H)), color=color, linestyle=style)
... axs[3].plot(w, gd, color=color, linestyle=style)

```python
>>> for ax in axs:
...     ax.grid(True, color='0.5')
...     ax.fill_between(freq[1:], *ax.get_ylim(), color='#ffeeaa', zorder=1)
>>> axs[0].set(xlim=[0, len(h_linear) - 1], ylabel='Amplitude', xlabel='Samples')
>>> axs[1].legend(['Linear', 'Min-Hom', 'Min-Hil'], title='Phase')
>>> for ax, ylim in zip(axs[1:], ([0, 1.1], [-150, 10], [-60, 60])):
...     ax.set(xlim=[0, 1], ylim=ylim, xlabel='Frequency')
>>> axs[1].set(ylabel='Magnitude')
>>> axs[2].set(ylabel='Magnitude (dB)')
>>> axs[3].set(ylabel='Group delay')
>>> plt.tight_layout()
```

**scipy.signal.savgol_coeffs**

(scipy.signal.savgol_coeffs (window_length, polyorder, deriv=0, delta=1.0, pos=None, use='conv')

Compute the coefficients for a 1-D Savitzky-Golay FIR filter.

**Parameters**

- **window_length**
  - [int] The length of the filter window (i.e., the number of coefficients).

- **polyorder**
  - [int] The order of the polynomial used to fit the samples. polyorder must be less than window_length.

- **deriv**
  - [int, optional] The order of the derivative to compute. This must be a nonnegative integer. The default is 0, which means to filter the data without differentiating.

- **delta**
  - [float, optional] The spacing of the samples to which the filter will be applied. This is only used if deriv > 0.

- **pos**
  - [int or None, optional] If pos is not None, it specifies evaluation position within the window. The default is the middle of the window.

- **use**
  - [str, optional] Either ‘conv’ or ‘dot’. This argument chooses the order of the coefficients. The default is ‘conv’, which means that the coefficients are ordered to be used in a convolution. With use='dot', the order is reversed, so the filter is applied by dotting the coefficients with the data set.

**Returns**

- **coeffs**
  - [1-D ndarray] The filter coefficients.

**See also:**

savgol_filter
Notes

New in version 0.14.0.

References

Examples

```python
>>> from scipy.signal import savgol_coeffs
>>> savgol_coeffs(5, 2)
array([-0.08571429, 0.34285714, 0.48571429, 0.34285714, -0.08571429])
>>> savgol_coeffs(5, 2, deriv=1)
array([ 2.00000000e-01, 1.00000000e-01, 2.07548111e-16, -1.00000000e-01,
         -2.00000000e-01])
Note that use='dot' simply reverses the coefficients.
```
```python
>>> savgol_coeffs(5, 2, pos=3)
array([0.25714286, 0.37142857, 0.34285714, 0.17142857, -0.14285714])
>>> savgol_coeffs(5, 2, pos=3, use='dot')
array([-0.25714286, -0.37142857, -0.34285714, -0.17142857, 0.14285714])
>>> savgol_coeffs(4, 2, pos=3, deriv=1, use='dot')
array([0.45, -0.85, -0.65, 1.05])
```

`x` contains data from the parabola `x = t**2`, sampled at `t = -1, 0, 1, 2, 3`. `c` holds the coefficients that will compute the derivative at the last position. When dotted with `x` the result should be 6.

```python
>>> x = np.array([1, 0, 1, 4, 9])
>>> c = savgol_coeffs(5, 2, pos=4, deriv=1, use='dot')
>>> c.dot(x)
6.0
```

`scipy.signal.remez`

`scipy.signal.remez`(numtaps, bands, desired, weight=None, Hz=None, type='bandpass', maxiter=25,
grid_density=16, fs=None)

Calculate the minimax optimal filter using the Remez exchange algorithm.

Calculate the filter-coefficients for the finite impulse response (FIR) filter whose transfer function minimizes the maximum error between the desired gain and the realized gain in the specified frequency bands using the Remez exchange algorithm.

**Parameters**

- **numtaps**  [int] The desired number of taps in the filter. The number of taps is the number of terms in the filter, or the filter order plus one.
- **bands**  [array_like] A monotonic sequence containing the band edges. All elements must be non-negative and less than half the sampling frequency as given by `fs`.
- **desired**  [array_like] A sequence half the size of bands containing the desired gain in each of the specified bands.
weight [array_like, optional] A relative weighting to give to each band region. The length of weight has to be half the length of bands.
type [{‘bandpass’, ‘differentiator’, ‘hilbert’}, optional] The type of filter:
  • ‘bandpass’: flat response in bands. This is the default.
  • ‘differentiator’: frequency proportional response in bands.
  • ‘hilbert’ [filter with odd symmetry, that is, type III] (for even order) or type IV (for odd order) linear phase filters.
maxiter [int, optional] Maximum number of iterations of the algorithm. Default is 25.
grid_density [int, optional] Grid density. The dense grid used in `remez` is of size \((\text{numtaps} + 1) \times \text{grid\_density}\). Default is 16.
fs [float, optional] The sampling frequency of the signal. Default is 1.

Returns
out [ndarray] A rank-1 array containing the coefficients of the optimal (in a minimax sense) filter.

[1], [2]

Examples
In these examples `remez` gets used creating a bandpass, bandstop, lowpass and highpass filter. The used parameters are the filter order, an array with according frequency boundaries, the desired attenuation values and the sampling frequency. Using `freqz` the corresponding frequency response gets calculated and plotted.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> def plot_response(fs, w, h, title):
...     """Utility function to plot response functions""
...     fig = plt.figure()
...     ax = fig.add_subplot(111)
...     ax.plot(0.5*fs*w/np.pi, 20*np.log10(np.abs(h)))
...     ax.set_ylim(-40, 5)
...     ax.set_xlim(0, 0.5*fs)
...     ax.grid(True)
...     ax.set_xlabel('Frequency (Hz)')
...     ax.set_ylabel('Gain (dB)')
...     ax.set_title(title)
```

This example shows a steep low pass transition according to the small transition width and high filter order:
```python
>>> fs = 22050.0  # Sample rate, Hz
>>> cutoff = 8000.0  # Desired cutoff frequency, Hz
>>> trans_width = 100  # Width of transition from pass band to stop band, in Hz
>>> numtaps = 400  # Size of the FIR filter.
>>> taps = signal.remez(numtaps, [0, cutoff, cutoff + trans_width, 0.
-5*fs], [1, 0], Hz=fs)
>>> w, h = signal.freqz(taps, [1], worN=2000)
>>> plot_response(fs, w, h, "Low-pass Filter")

This example shows a high pass filter:
```n
```python
>>> fs = 22050.0  # Sample rate, Hz
>>> cutoff = 2000.0  # Desired cutoff frequency, Hz
>>> trans_width = 250  # Width of transition from pass band to stop band, in Hz
>>> numtaps = 125  # Size of the FIR filter.
>>> taps = signal.remez(numtaps, [0, cutoff - trans_width, cutoff, 0.
-5*fs], [0, 1], Hz=fs)
>>> w, h = signal.freqz(taps, [1], worN=2000)
>>> plot_response(fs, w, h, "High-pass Filter")

For a signal sampled with 22 kHz a bandpass filter with a pass band of 2-5 kHz gets calculated using the Remez algorithm. The transition width is 260 Hz and the filter order 10:
```n
```python
>>> fs = 22000.0  # Sample rate, Hz
>>> band = [2000, 5000]  # Desired pass band, Hz
>>> trans_width = 260  # Width of transition from pass band to stop band, Hz
>>> numtaps = 10  # Size of the FIR filter.
>>> edges = [0, band[0] - trans_width, band[0], band[1],
band[1] + trans_width, 0.5*fs]
>>> taps = signal.remez(numtaps, edges, [0, 1, 0], Hz=fs)
>>> w, h = signal.freqz(taps, [1], worN=2000)
>>> plot_response(fs, w, h, "Band-pass Filter")

It can be seen that for this bandpass filter, the low order leads to higher ripple and less steep transitions. There is very low attenuation in the stop band and little overshoot in the pass band. Of course the desired gain can be better approximated with a higher filter order.

The next example shows a bandstop filter. Because of the high filter order the transition is quite steep:
```n
```python
>>> fs = 20000.0  # Sample rate, Hz
>>> band = [6000, 8000]  # Desired stop band, Hz
>>> trans_width = 200  # Width of transition from pass band to stop band, Hz
>>> numtaps = 175  # Size of the FIR filter.
>>> edges = [0, band[0] - trans_width, band[0], band[1], band[1] + trans_width, 0.5*fs]
>>> taps = signal.remez(numtaps, edges, [1, 0, 1], Hz=fs)
>>> w, h = signal.freqz(taps, [1], worN=2000)
>>> plot_response(fs, w, h, "Band-stop Filter")

3.3. API definition
```python
>>> plt.show()
```

**scipy.signal.unique_roots**

`scipy.signal.unique_roots(p, tol=0.001, rtype='min')`

Determine unique roots and their multiplicities from a list of roots.

**Parameters**

- `p` [array_like] The list of roots.
- `tol` [float, optional] The tolerance for two roots to be considered equal in terms of the distance between them. Default is $1e^{-3}$. Refer to Notes about the details on roots grouping.
  - ‘max’, ‘maximum’: pick the maximum of those roots
  - ‘min’, ‘minimum’: pick the minimum of those roots
3.3. API definition
• ‘avg’, ‘mean’: take the average of those roots
When finding minimum or maximum among complex roots they are compared first by the real part and then by the imaginary part.

**Returns**

- **unique** [ndarray] The list of unique roots.
- **multiplicity** [ndarray] The multiplicity of each root.

**Notes**

If we have 3 roots a, b, and c, such that a is close to b and b is close to c (distance is less than tol), then it doesn’t necessarily mean that a is close to c. It means that roots grouping is not unique. In this function we use “greedy” grouping going through the roots in the order they are given in the input p.

This utility function is not specific to roots but can be used for any sequence of values for which uniqueness and multiplicity has to be determined. For a more general routine, see `numpy.unique`.

**Examples**

```python
>>> from scipy import signal
>>> vals = [0, 1.3, 1.31, 2.8, 1.25, 2.2, 10.3]
>>> uniq, mult = signal.unique_roots(vals, tol=2e-2, rtype='avg')
```

Check which roots have multiplicity larger than 1:

```python
>>> uniq[mult > 1]
array([1.305])
```

**scipy.signal.residue**

`scipy.signal.residue(b, a, tol=0.001, rtype='avg')`

Compute partial-fraction expansion of b(s) / a(s).

If M is the degree of numerator b and N the degree of denominator a:

\[
H(s) = \frac{b(s)}{a(s)} = \frac{b[0] s^M + b[1] s^{M-1} + \ldots + b[M]}{a[0] s^N + a[1] s^{N-1} + \ldots + a[N]}
\]

then the partial-fraction expansion H(s) is defined as:

\[
\frac{r[0]}{(s-p[0])} + \frac{r[1]}{(s-p[1])} + \ldots + \frac{r[-1]}{(s-p[-1])} + k(s)
\]

If there are any repeated roots (closer together than tol), then H(s) has terms like:

\[
\frac{r[i]}{(s-p[i])} + \frac{r[i+1]}{(s-p[i])^2} + \ldots + \frac{r[i+n-1]}{(s-p[i])^n}
\]
This function is used for polynomials in positive powers of $s$ or $z$, such as analog filters or digital filters in controls engineering. For negative powers of $z$ (typical for digital filters in DSP), use `residuez`.

See Notes for details about the algorithm.

**Parameters**

- **b** [array_like] Numerator polynomial coefficients.
- **a** [array_like] Denominator polynomial coefficients.
- **tol** [float, optional] The tolerance for two roots to be considered equal in terms of the distance between them. Default is 1e-3. See `unique_roots` for further details.

**Returns**

- **r** [ndarray] Residues corresponding to the poles. For repeated poles, the residues are ordered to correspond to ascending by power fractions.
- **p** [ndarray] Poles ordered by magnitude in ascending order.
- **k** [ndarray] Coefficients of the direct polynomial term.

See also:

`invres`, `residuez`, `numpy.poly`, `unique_roots`

**Notes**

The “deflation through subtraction” algorithm is used for computations — method 6 in [1].

The form of partial fraction expansion depends on poles multiplicity in the exact mathematical sense. However there is no way to exactly determine multiplicity of roots of a polynomial in numerical computing. Thus you should think of the result of `residue` with given `tol` as partial fraction expansion computed for the denominator composed of the computed poles with empirically determined multiplicity. The choice of `tol` can drastically change the result if there are close poles.

**References**

[1]

`scipy.signal.residuez`

`scipy.signal.residuez` ($b, a, tol=0.001, rtype='avg'$)

Compute partial-fraction expansion of $b(z) / a(z)$.

If $M$ is the degree of numerator $b$ and $N$ the degree of denominator $a$:

$$
\frac{b(z)}{a(z)} = \frac{b[0] + b[1] z^*(-1) + \ldots + b[M] z^*(-M)}{a[0] + a[1] z^*(-1) + \ldots + a[N] z^*(-N)}
$$

then the partial-fraction expansion $H(z)$ is defined as:

$$
\begin{align*}
  r[0] & \quad r[-1] \\
  (1-p[0] z^*(-1)) & \quad (1-p[-1] z^*(-1))
\end{align*}
$$

If there are any repeated roots (closer than `tol`), then the partial fraction expansion has terms like:
This function is used for polynomials in negative powers of \( z \), such as digital filters in DSP. For positive powers, use \texttt{residue}.

See Notes of \texttt{residue} for details about the algorithm.

**Parameters**

- \( b \) [array_like] Numerator polynomial coefficients.
- \( a \) [array_like] Denominator polynomial coefficients.
- \( \textbf{tol} \) [float, optional] The tolerance for two roots to be considered equal in terms of the distance between them. Default is 1e-3. See \texttt{unique_roots} for further details.
- \( \textbf{rtype} \) ['avg', 'min', 'max'], optional] Method for computing a root to represent a group of identical roots. Default is 'avg'. See \texttt{unique_roots} for further details.

**Returns**

- \( r \) [ndarray] Residues corresponding to the poles. For repeated poles, the residues are ordered to correspond to ascending by power fractions.
- \( p \) [ndarray] Poles ordered by magnitude in ascending order.
- \( k \) [ndarray] Coefficients of the direct polynomial term.

See also:

\texttt{invresz, residue, unique_roots}

\textit{scipy.signal.invres}\n
\textit{scipy.signal.invres}(r, p, k, tol=0.001, rtype='avg')

Compute \( b(s) \) and \( a(s) \) from partial fraction expansion.

If \( M \) is the degree of numerator \( b \) and \( N \) the degree of denominator \( a \):

\[
H(s) = \frac{b(s)}{a(s)} = \frac{b[0]}{a[0]} s^{**}(M) + \frac{b[1]}{a[1]} s^{**}(M-1) + \ldots + \frac{b[M]}{a[M]}
\]

then the partial-fraction expansion \( H(s) \) is defined as:

\[
\frac{r[0]}{(s-p[0])} + \frac{r[1]}{(s-p[1])} + \ldots + \frac{r[-1]}{(s-p[-1])} + k(s)
\]

If there are any repeated roots (closer together than \( \textbf{tol} \)), then \( H(s) \) has terms like:

\[
\frac{r[i]}{(s-p[i])} + \frac{r[i+1]}{(s-p[i])} + \ldots + \frac{r[i+n-1]}{(s-p[i])} + \frac{r[i+n]}{(s-p[i])} + \ldots
\]

This function is used for polynomials in positive powers of \( s \) or \( z \), such as analog filters or digital filters in controls engineering. For negative powers of \( z \) (typical for digital filters in DSP), use \texttt{invresz}.

**Parameters**

- \( r \) [array_like] Residues corresponding to the poles. For repeated poles, the residues must be ordered to correspond to ascending by power fractions.

residue, invresz

scipy.signal.invresz

scipy.signal.invresz(r, p, k, tol=0.001, rtype='avg')

Compute \( b(z) \) and \( a(z) \) from partial fraction expansion.

If \( M \) is the degree of numerator \( b \) and \( N \) the degree of denominator \( a \):

\[
\frac{b(z)}{a(z)} = \frac{b[0] + b[1] z^{-1} + \ldots + b[M] z^{-M}}{a[0] + a[1] z^{-1} + \ldots + a[N] z^{-N}}
\]

then the partial-fraction expansion \( H(z) \) is defined as:

\[
\begin{align*}
\frac{r[0]}{1-p[0] z^{-1}} & + \frac{r[-1]}{1-p[-1] z^{-1}} \\
& \ldots \\
\end{align*}
\]

If there are any repeated roots (closer than \( tol \)), then the partial fraction expansion has terms like:

\[
\begin{align*}
\frac{r[i]}{1-p[i] z^{-1}} & + \frac{r[i+1]}{1-p[i+1] z^{-1}} & + \frac{r[i+n-1]}{1-p[i+n-1] z^{-1}} \\
& \ldots \\
\end{align*}
\]

This function is used for polynomials in negative powers of \( z \), such as digital filters in DSP. For positive powers, use \texttt{invres}.

Parameters

- \( r \) [array_like] Residues corresponding to the poles. For repeated poles, the residues must be ordered to correspond to ascending by power fractions.
- \( p \) [array_like] Poles. Equal poles must be adjacent.
- \( k \) [array_like] Coefficients of the direct polynomial term.
- \( tol \) [float, optional] The tolerance for two roots to be considered equal in terms of the distance between them. Default is 1e-3. See \texttt{unique_roots} for further details.
- \( rtype \) [{'avg', 'min', 'max'}, optional] Method for computing a root to represent a group of identical roots. Default is 'avg'. See \texttt{unique_roots} for further details.

Returns

- \( b \) [ndarray] Numerator polynomial coefficients.
- \( a \) [ndarray] Denominator polynomial coefficients.

scipy.signal.abcd_normalize

scipy.signal.abcd_normalize(A=None, B=None, C=None, D=None)
  Check state-space matrices and ensure they are 2-D.

  If enough information on the system is provided, that is, enough properly-shaped arrays are passed to the function, the missing ones are built from this information, ensuring the correct number of rows and columns. Otherwise a ValueError is raised.

  Parameters

  A, B, C, D  [array_like, optional] State-space matrices. All of them are None (missing) by default. See `ss2tf` for format.

  Returns

  Raises
**ValueError**

If not enough information on the system was provided.

**scipy.signal.band_stop_obj**

`scipy.signal.band_stop_obj(wp, ind, passb, stopb, gpass, gstop, type)`  
Band Stop Objective Function for order minimization.

Returns the non-integer order for an analog band stop filter.

**Parameters**

- `wp` [scalar] Edge of passband `passb`.
- `ind` [int, {0, 1}] Index specifying which `passb` edge to vary (0 or 1).
- `passb` [ndarray] Two element sequence of fixed passband edges.
- `stopb` [ndarray] Two element sequence of fixed stopband edges.
- `gstop` [float] Amount of attenuation in stopband in dB.
- `gpass` [float] Amount of ripple in the passband in dB.
- `type` [{‘butter’, ‘cheby’, ‘ellip’}] Type of filter.

**Returns**

- `n` [scalar] Filter order (possibly non-integer).

**scipy.signal.besselap**

`scipy.signal.besselap(N, norm='phase')`  
Return (z,p,k) for analog prototype of an Nth-order Bessel filter.

**Parameters**

- `N` [int] The order of the filter.
- `norm` [{‘phase’, ‘delay’, ‘mag’}, optional] Frequency normalization:
  - `phase` The filter is normalized such that the phase response reaches its midpoint at an angular (e.g., rad/s) cutoff frequency of 1. This happens for both low-pass and high-pass filters, so this is the “phase-matched” case. [6]  
  The magnitude response asymptotes are the same as a Butterworth filter of the same order with a cutoff of `Wn`.  
  This is the default, and matches MATLAB’s implementation.
  - `delay` The filter is normalized such that the group delay in the passband is 1 (e.g., 1 second). This is the “natural” type obtained by solving Bessel polynomials.
  - `mag` The filter is normalized such that the gain magnitude is -3 dB at angular frequency 1. This is called “frequency normalization” by Bond. [1]  
  New in version 0.18.0.

**Returns**

- `z` [ndarray] Zeros of the transfer function. Is always an empty array.
- `p` [ndarray] Poles of the transfer function.
- `k` [scalar] Gain of the transfer function. For phase-normalized, this is always 1.

**See also:**

- `bessel`  
  Filter design function using this prototype
Notes

To find the pole locations, approximate starting points are generated \([2]\) for the zeros of the ordinary Bessel polynomial \([3]\), then the Aberth-Ehrlich method \([4] [5]\) is used on the \(K_v(x)\) Bessel function to calculate more accurate zeros, and these locations are then inverted about the unit circle.

References

[1], [2], [3], [4], [5], [6]

**scipy.signal.buttap**

```python
scipy.signal.buttap(N)
```

Return \((z,p,k)\) for analog prototype of \(N\)th-order Butterworth filter.

The filter will have an angular (e.g., rad/s) cutoff frequency of 1.

See also:

**butter**

Filter design function using this prototype

**scipy.signal.cheb1ap**

```python
scipy.signal.cheb1ap(N, rp)
```

Return \((z,p,k)\) for \(N\)th-order Chebyshev type I analog lowpass filter.

The returned filter prototype has \(rp\) decibels of ripple in the passband.

The filter’s angular (e.g. rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first drops below \(-rp\).

See also:

**cheby1**

Filter design function using this prototype

**scipy.signal.cheb2ap**

```python
scipy.signal.cheb2ap(N, rs)
```

Return \((z,p,k)\) for \(N\)th-order Chebyshev type I analog lowpass filter.

The returned filter prototype has \(rs\) decibels of ripple in the stopband.

The filter’s angular (e.g. rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first reaches \(-rs\).

See also:

**cheby2**

Filter design function using this prototype
scipy.signal.cmplx_sort

scipy.signal.cmplx_sort(p)
Sort roots based on magnitude.

Parameters

p [array_like] The roots to sort, as a 1-D array.

Returns

indx [ndarray] Array of indices needed to sort the input p.

Examples

```python
>>> from scipy import signal
>>> vals = [1, 4, 1+1.j, 3]
>>> p_sorted, indx = signal.cmplx_sort(vals)
>>> p_sorted
array([1.+0.j, 1.+1.j, 3.+0.j, 4.+0.j])
>>> indx
array([0, 2, 3, 1])
```

scipy.signal.ellipap

scipy.signal.ellipap(N, rp, rs)
Return (z,p,k) of Nth-order elliptic analog lowpass filter.

The filter is a normalized prototype that has rp decibels of ripple in the passband and a stopband rs decibels down.

The filter’s angular (e.g., rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first drops below -rp.

ellip
Filter design function using this prototype

References

[1], [2]

scipy.signal.lp2bp

scipy.signal.lp2bp(b, a, wo=1.0, bw=1.0)
Transform a lowpass filter prototype to a bandpass filter.

Return an analog band-pass filter with center frequency wo and bandwidth bw from an analog low-pass filter prototype with unity cutoff frequency, in transfer function (‘ba’) representation.

Parameters

b [array_like] Numerator polynomial coefficients.
a [array_like] Denominator polynomial coefficients.
wo [float] Desired passband center, as angular frequency (e.g., rad/s). Defaults to no change.
bw [float] Desired passband width, as angular frequency (e.g., rad/s). Defaults to 1.
**Returns**

- **b** (array_like) Numerator polynomial coefficients of the transformed band-pass filter.
- **a** (array_like) Denominator polynomial coefficients of the transformed band-pass filter.

**See also:**

- `lp2lp`, `lp2hp`, `lp2bs`, `bilinear`
- `lp2bp_zpk`

**Notes**

This is derived from the s-plane substitution

\[ s \rightarrow \frac{s^2 + \omega_0^2}{s \cdot BW} \]

This is the “wideband” transformation, producing a passband with geometric (log frequency) symmetry about \( \omega_0 \).

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> lp = signal.lti([1.0], [1.0, 1.0])
>>> bp = signal.lti(signal.lp2bp(lp.num, lp.den))
>>> w, mag_lp, p_lp = lp.bode()
>>> w, mag_bp, p_bp = bp.bode(w)

>>> plt.plot(w, mag_lp, label='Lowpass')
>>> plt.plot(w, mag_bp, label='Bandpass')
>>> plt.semilogx()
>>> plt.grid()
>>> plt.xlabel('Frequency [rad/s]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.legend()
```

**scipy.signal.lp2bp_zpk**

`scipy.signal.lp2bp_zpk(z, p, k, wo=1.0, bw=1.0)`  
Transform an analog low-pass filter prototype to a bandpass filter.

Return an analog band-pass filter with center frequency \( \omega_0 \) and bandwidth \( bw \) from an analog low-pass filter prototype with unity cutoff frequency, using zeros, poles, and gain ('zpk') representation.

**Parameters**

- **z** [array_like] Zeros of the analog filter transfer function.
- **p** [array_like] Poles of the analog filter transfer function.
- **k** [float] System gain of the analog filter transfer function.
- **wo** [float] Desired passband center, as angular frequency (e.g., rad/s). Defaults to no change.
- **bw** [float] Desired passband width, as angular frequency (e.g., rad/s). Defaults to 1.
z  [ndarray] Zeros of the transformed band-pass filter transfer function.
p  [ndarray] Poles of the transformed band-pass filter transfer function.
k  [float] System gain of the transformed band-pass filter.

See also:

lp2lp_zpk, lp2hp_zpk, lp2bs_zpk, bilinear
lp2bp

Notes

This is derived from the s-plane substitution

\[ s \rightarrow \frac{s^2 + \omega_0^2}{s \cdot BW} \]

This is the “wideband” transformation, producing a passband with geometric (log frequency) symmetry about \( \omega_0 \).

New in version 1.1.0.

**scipy.signal.lp2bs**

`scipy.signal.lp2bs(b, a=1.0, wo=1.0, bw=1.0)`  

Transform a lowpass filter prototype to a bandstop filter.

Return an analog band-stop filter with center frequency \( \omega_0 \) and bandwidth \( bw \) from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

**Parameters**

- `b`  [array_like] Numerator polynomial coefficients.
- `a`  [array_like] Denominator polynomial coefficients.
- `wo`  [float] Desired stopband center, as angular frequency (e.g., rad/s). Defaults to no change.
- `bw`  [float] Desired stopband width, as angular frequency (e.g., rad/s). Defaults to 1.

**Returns**

- `b`  [array_like] Numerator polynomial coefficients of the transformed band-stop filter.
a [array_like] Denominator polynomial coefficients of the transformed band-stop filter.

See also:

lp2lp, lp2hp, lp2bp, bilinear
lp2bs_zpk

Notes

This is derived from the s-plane substitution

\[ s \rightarrow \frac{s \cdot BW}{s^2 + \omega_0^2} \]

This is the “wideband” transformation, producing a stopband with geometric (log frequency) symmetry about \( \omega_0 \).

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> lp = signal.lti([1.0], [1.0, 1.5])
>>> bs = signal.lti(signal.lp2bs(lp.num, lp.den))
>>> w, mag_lp, p_lp = lp.bode()
>>> w, mag_bs, p_bs = bs.bode(w)
>>> plt.plot(w, mag_lp, label='Lowpass')
>>> plt.plot(w, mag_bs, label='Bandstop')
>>> plt.semilogx()
>>> plt.grid()
>>> plt.xlabel('Frequency [rad/s]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.legend()
```

![Magnitude plot comparing Lowpass and Bandstop filters](image)

10^{-1} 10^0 10^1

Magnitude [dB]
scipy.signal.lp2bs_zpk

Parameters

- z: [array_like] Zeros of the analog filter transfer function.
- p: [array_like] Poles of the analog filter transfer function.
- k: [float] System gain of the analog filter transfer function.
- wo: [float] Desired stopband center, as angular frequency (e.g., rad/s). Defaults to no change.
- bw: [float] Desired stopband width, as angular frequency (e.g., rad/s). Defaults to 1.

Returns

- z: [ndarray] Zeros of the transformed band-stop filter transfer function.
- p: [ndarray] Poles of the transformed band-stop filter transfer function.
- k: [float] System gain of the transformed band-stop filter.

Notes

This is derived from the s-plane substitution

\[ s \rightarrow \frac{s \cdot BW}{s^2 + \omega_0^2} \]

This is the “wideband” transformation, producing a stopband with geometric (log frequency) symmetry about wo.

New in version 1.1.0.

scipy.signal.lp2hp

Parameters

- b: [array_like] Numerator polynomial coefficients.
- a: [array_like] Denominator polynomial coefficients.
- wo: [float] Desired cutoff, as angular frequency (e.g., rad/s). Defaults to no change.

Returns

- b: [array_like] Numerator polynomial coefficients of the transformed high-pass filter.
- a: [array_like] Denominator polynomial coefficients of the transformed high-pass filter.

Notes

This is derived from the s-plane substitution

\[ s \rightarrow \frac{s}{s^2 + \omega_0^2} \]

3.3. API definition
Notes

This is derived from the s-plane substitution

\[ s \rightarrow \frac{\omega_0}{s} \]

This maintains symmetry of the lowpass and highpass responses on a logarithmic scale.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> lp = signal.lti([1.0], [1.0, 1.0])
>>> hp = signal.lti(*signal.lp2hp(lp.num, lp.den))
>>> w, mag_lp, p_lp = lp.bode()
>>> w, mag_hp, p_hp = hp.bode(w)

>>> plt.plot(w, mag_lp, label='Lowpass')
>>> plt.plot(w, mag_hp, label='Highpass')
>>> plt.semilogx()
>>> plt.grid()
>>> plt.xlabel('Frequency [rad/s]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.legend()
```

![Magnitude vs Frequency plot](image)

- Lowpass
- Highpass
scipy.signal.lp2hp_zpk

scipy.signal.lp2hp_zpk(z, p, k, wo=1.0)

Transform a lowpass filter prototype to a highpass filter.

Return an analog high-pass filter with cutoff frequency \(\omega_0\) from an analog low-pass filter prototype with unity cutoff frequency, using zeros, poles, and gain ('zpk') representation.

**Parameters**

- \(z\) : [array_like] Zeros of the analog filter transfer function.
- \(p\) : [array_like] Poles of the analog filter transfer function.
- \(k\) : [float] System gain of the analog filter transfer function.
- \(\omega_0\) : [float] Desired cutoff, as angular frequency (e.g., rad/s). Defaults to no change.

**Returns**

- \(z\) : [ndarray] Zeros of the transformed high-pass filter transfer function.
- \(p\) : [ndarray] Poles of the transformed high-pass filter transfer function.
- \(k\) : [float] System gain of the transformed high-pass filter.

See also:

lp2lp_zpk, lp2bp_zpk, lp2bs_zpk, bilinear

lp2hp

**Notes**

This is derived from the s-plane substitution

\[ s \rightarrow \frac{\omega_0}{s} \]

This maintains symmetry of the lowpass and highpass responses on a logarithmic scale.

New in version 1.1.0.

scipy.signal.lp2lp

scipy.signal.lp2lp(b, a, wo=1.0)

Transform a lowpass filter prototype to a different frequency.

Return an analog low-pass filter with cutoff frequency \(\omega_0\) from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

**Parameters**

- \(b\) : [array_like] Numerator polynomial coefficients.
- \(a\) : [array_like] Denominator polynomial coefficients.
- \(\omega_0\) : [float] Desired cutoff, as angular frequency (e.g., rad/s). Defaults to no change.

**Returns**

- \(b\) : [array_like] Numerator polynomial coefficients of the transformed low-pass filter.
- \(a\) : [array_like] Denominator polynomial coefficients of the transformed low-pass filter.

See also:

lp2hp, lp2bp, lp2bs, bilinear

lp2lp_zpk
Notes

This is derived from the s-plane substitution

\[ s \rightarrow \frac{s}{\omega_0} \]

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> lp = signal.lti([1.0], [1.0, 1.0])
>>> lp2 = signal.lti(*signal.lp2lp(lp.num, lp.den, 2))
>>> w, mag_lp, p_lp = lp.bode()
>>> w, mag_lp2, p_lp2 = lp2.bode(w)

>>> plt.plot(w, mag_lp, label='Lowpass')
>>> plt.plot(w, mag_lp2, label='Transformed Lowpass')
>>> plt.semilogx()
>>> plt.grid()
>>> plt.xlabel('Frequency [rad/s]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.legend()
```

![Bode plot example](image.png)
**scipy.signal.lp2lp_zpk**

**scipy.signal.lp2lp_zpk** \( (z, p, k, wo=1.0) \)

Transform a lowpass filter prototype to a different frequency.

Return an analog low-pass filter with cutoff frequency \( wo \) from an analog low-pass filter prototype with unity cutoff frequency, using zeros, poles, and gain (‘zpk’) representation.

**Parameters**

- \( z \) [array_like] Zeros of the analog filter transfer function.
- \( p \) [array_like] Poles of the analog filter transfer function.
- \( k \) [float] System gain of the analog filter transfer function.
- \( wo \) [float] Desired cutoff, as angular frequency (e.g., rad/s). Defaults to no change.

**Returns**

- \( z \) [ndarray] Zeros of the transformed low-pass filter transfer function.
- \( p \) [ndarray] Poles of the transformed low-pass filter transfer function.
- \( k \) [float] System gain of the transformed low-pass filter.

See also:

- \( lp2hp_zpk \)
- \( lp2bp_zpk \)
- \( lp2bs_zpk \)
- \( bilinear \)
- \( lp2lp \)

**Notes**

This is derived from the s-plane substitution

\[
s \rightarrow \frac{s}{\omega_0}
\]

New in version 1.1.0.

**scipy.signal.normalize**

**scipy.signal.normalize** \( (b, a) \)

Normalize numerator/denominator of a continuous-time transfer function.

If values of \( b \) are too close to 0, they are removed. In that case, a BadCoefficients warning is emitted.

**Parameters**

- \( b \): array_like
  Numerator of the transfer function. Can be a 2-D array to normalize multiple transfer functions.
- \( a \): array_like
  Denominator of the transfer function. At most 1-D.

**Returns**

- \( num \): array
  The numerator of the normalized transfer function. At least a 1-D array. A 2-D array if the input \( num \) is a 2-D array.
- \( den \): 1-D array
  The denominator of the normalized transfer function.
Notes
Coefficients for both the numerator and denominator should be specified in descending exponent order (e.g., \( s^2 + 3s + 5 \) would be represented as \([1, 3, 5]\)).

\texttt{scipy.signal.butter} (\texttt{N, Wn[, btype, analog, output, fs]})
Butterworth digital and analog filter design.

Design an Nth-order digital or analog Butterworth filter and return the filter coefficients.

**Parameters**
- \texttt{N} [int] The order of the filter.
- \texttt{Wn} [array_like] The critical frequency or frequencies. For lowpass and highpass filters, \( Wn \) is a scalar; for bandpass and bandstop filters, \( Wn \) is a length-2 sequence. For a Butterworth filter, this is the point at which the gain drops to 1/sqrt(2) that of the passband (the “-3 dB point”). For digital filters, if \( fs \) is not specified, \( Wn \) units are normalized from 0 to 1, where 1 is the Nyquist frequency (\( Wn \) is thus in half cycles / sample and defined as 2\*critical frequencies / \( fs \)). If \( fs \) is specified, \( Wn \) is in the same units as \( fs \). For analog filters, \( Wn \) is an angular frequency (e.g., rad/s).
- \texttt{btype} ['lowpass', 'highpass', 'bandpass', 'bandstop'], optional The type of filter. Default is 'low-pass'.
- \texttt{analog} [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.
- \texttt{output} ['ba', 'zpk', 'sos'], optional Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba' for backwards compatibility, but 'sos' should be used for general-purpose filtering.
- \texttt{fs} [float, optional] The sampling frequency of the digital system. New in version 1.2.0.

**Returns**
- \texttt{b, a} [ndarray, ndarray] Numerator (\( b \)) and denominator (\( a \)) polynomials of the IIR filter. Only returned if \texttt{output='ba'}. 
- \texttt{z, p, k} [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if \texttt{output='zpk'}. 
- \texttt{sos} [ndarray] Second-order sections representation of the IIR filter. Only returned if \texttt{output='sos'}. 

1552 Chapter 3. SciPy API
See also:

`buttord`, `buttap`

Notes

The Butterworth filter has maximally flat frequency response in the passband. The 'sos' output parameter was added in 0.16.0.

If the transfer function form \([b, a]\) is requested, numerical problems can occur since the conversion between roots and the polynomial coefficients is a numerically sensitive operation, even for \(N >= 4\). It is recommended to work with the SOS representation.

Examples

Design an analog filter and plot its frequency response, showing the critical points:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.butter(4, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Butterworth filter frequency response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.show()
```

Generate a signal made up of 10 Hz and 20 Hz, sampled at 1 kHz.
Design a digital high-pass filter at 15 Hz to remove the 10 Hz tone, and apply it to the signal. (It’s recommended to use second-order sections format when filtering, to avoid numerical error with transfer function (ba) format):

```python
>>> t = np.linspace(0, 1, 1000, False)  # 1 second
>>> sig = np.sin(2*np.pi*10*t) + np.sin(2*np.pi*20*t)
>>> fig, (ax1, ax2) = plt.subplots(2, 1, sharex=True)
>>> ax1.plot(t, sig)
>>> ax1.set_title('10 Hz and 20 Hz sinusoids')
>>> ax1.axis([0, 1, -2, 2])

scipy.signal.buttord

scipy.signal.buttord(wp, ws, gpass, gstop, analog=False, fs=None)

Butterworth filter order selection.

Return the order of the lowest order digital or analog Butterworth filter that loses no more than `gpass` dB in the passband and has at least `gstop` dB attenuation in the stopband.

Parameters

wp, ws (float)  Passband and stopband edge frequencies.

For digital filters, these are in the same units as fs. By default, fs is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (wp and ws are thus in half-cycles / sample.) For example:

- Lowpass: wp = 0.2, ws = 0.3
- Highpass: wp = 0.3, ws = 0.2
- Bandpass: wp = [0.2, 0.5], ws = [0.1, 0.6]
• Bandstop: \( wp = [0.1, 0.6], ws = [0.2, 0.5] \)

For analog filters, \( wp \) and \( ws \) are angular frequencies (e.g., \( \text{rad/s} \)).

- \( \text{gpass} \) [float] The maximum loss in the passband (dB).
- \( \text{gstop} \) [float] The minimum attenuation in the stopband (dB).
- \( \text{analog} \) [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.
- \( \text{fs} \) [float, optional] The sampling frequency of the digital system.

New in version 1.2.0.

**Returns**

- \( \text{ord} \) [int] The lowest order for a Butterworth filter which meets specs.
- \( \text{wn} \) [ndarray or float] The Butterworth natural frequency (i.e. the “3dB frequency”). Should be used with \texttt{butter} to give filter results. If \( \text{fs} \) is specified, this is in the same units, and \( \text{fs} \) must also be passed to \texttt{butter}.

**See also:**

- \texttt{butter} Filter design using order and critical points
- \texttt{cheb1ord} Find order and critical points from passband and stopband spec
- \texttt{cheb2ord, ellipord}
- \texttt{iirfilter} General filter design using order and critical frequencies
- \texttt{iirdesign} General filter design using passband and stopband spec

### Examples

Design an analog bandpass filter with passband within 3 dB from 20 to 50 rad/s, while rejecting at least -40 dB below 14 and above 60 rad/s. Plot its frequency response, showing the passband and stopband constraints in gray.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> N, Wn = signal.buttord([20, 50], [14, 60], 3, 40, True)
>>> b, a = signal.butter(N, Wn, 'band', True)
>>> w, h = signal.freqs(b, a, np.logspace(1, 2, 500))
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Butterworth bandpass filter fit to constraints')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([1, 14, 14, 1], [-40, -40, 99, 99], '0.9', lw=0) # stop
>>> plt.fill([20, 20, 50, 50], [-99, -3, -3, -99], '0.9', lw=0) # pass
>>> plt.fill([60, 60, 1e9, 1e9], [99, -40, -40, 99], '0.9', lw=0) # stop
>>> plt.axis([10, 100, -60, 3])
>>> plt.show()
```
scipy.signal.

scipy.signal.

scipy.signal.cheyby1(N, rp, Wn, btype='low', analog=False, output='ba', fs=None)

Chebyshev type I digital and analog filter design.

Design an Nth-order digital or analog Chebyshev type I filter and return the filter coefficients.

Parameters

N [int] The order of the filter.

rp [float] The maximum ripple allowed below unity gain in the passband. Specified in decibels, as a positive number.

Wn [array_like] A scalar or length-2 sequence giving the critical frequencies. For Type I filters, this is the point in the transition band at which the gain first drops below -rp.

btype [ {'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional] The type of filter. Default is 'lowpass'.

analog [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

output [ {'ba', 'zpk', 'sos'}, optional] Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba' for backwards compatibility, but 'sos' should be used for general-purpose filtering.

Returns

b, a [ndarray, ndarray] Numerator (b) and denominator (a) polynomials of the IIR filter. Only returned if output='ba'.

z, p, k [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if output='zpk'.

sos [ndarray] Second-order sections representation of the IIR filter. Only returned if output=='sos'.

See also:
cheb1ord, cheb1ap

Notes

The Chebyshev type I filter maximizes the rate of cutoff between the frequency response’s passband and stopband, at the expense of ripple in the passband and increased ringing in the step response.

Type I filters roll off faster than Type II (cheby2), but Type II filters do not have any ripple in the passband.

The equiripple passband has N maxima or minima (for example, a 5th-order filter has 3 maxima and 2 minima). Consequently, the DC gain is unity for odd-order filters, or -rp dB for even-order filters.

The 'sos' output parameter was added in 0.16.0.

Examples

Design an analog filter and plot its frequency response, showing the critical points:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.cheby1(4, 5, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev Type I frequency response (rp=5)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.axhline(-5, color='green') # rp
>>> plt.show()
```

Generate a signal made up of 10 Hz and 20 Hz, sampled at 1 kHz
```python
>>> t = np.linspace(0, 1, 1000, False)  # 1 second
>>> sig = np.sin(2*np.pi*10*t) + np.sin(2*np.pi*20*t)
>>> fig, (ax1, ax2) = plt.subplots(2, 1, sharex=True)
>>> ax1.plot(t, sig)
>>> ax1.set_title('10 Hz and 20 Hz sinusoids')
>>> ax1.axis([0, 1, -2, 2])

Design a digital high-pass filter at 15 Hz to remove the 10 Hz tone, and apply it to the signal. (It’s recommended to use second-order sections format when filtering, to avoid numerical error with transfer function (ba) format):

```python
>>> sos = signal.cheby1(10, 1, 15, 'hp', fs=1000, output='sos')
>>> filtered = signal.sosfilt(sos, sig)
>>> ax2.plot(t, filtered)
>>> ax2.set_title('After 15 Hz high-pass filter')
>>> ax2.axis([0, 1, -2, 2])
>>> ax2.set_xlabel('Time [seconds]')
>>> plt.tight_layout()
>>> plt.show()
```

`scipy.signal.cheb1ord`

`scipy.signal.cheb1ord` ([wp, ws], gpass, gstop, analog=False, fs=None)

Chebyshev type I filter order selection.

Return the order of the lowest order digital or analog Chebyshev Type I filter that loses no more than `gpass` dB in the passband and has at least `gstop` dB attenuation in the stopband.

Parameters

- **wp, ws** [float] Passband and stopband edge frequencies.
  For digital filters, these are in the same units as `fs`. By default, `fs` is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (`wp` and `ws` are thus in half-cycles/sample.) For example:
  - Lowpass: `wp = 0.2, ws = 0.3`
  - Highpass: `wp = 0.3, ws = 0.2`
  - Bandpass: `wp = [0.2, 0.5], ws = [0.1, 0.6]`
• Bandstop: \( \text{wp} = [0.1, 0.6] \), \( \text{ws} = [0.2, 0.5] \)

For analog filters, \( \text{wp} \) and \( \text{ws} \) are angular frequencies (e.g., rad/s).

- \( \text{gpass} \) [float] The maximum loss in the passband (dB).
- \( \text{gstg} \) [float] The minimum attenuation in the stopband (dB).
- \( \text{analog} \) [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.
- \( \text{fs} \) [float, optional] The sampling frequency of the digital system.

New in version 1.2.0.

Returns

- \( \text{ord} \) [int] The lowest order for a Chebyshev type I filter that meets specs.
- \( \text{wn} \) [ndarray or float] The Chebyshev natural frequency (the “3dB frequency”) for use with \text{cheby1} to give filter results. If \( \text{fs} \) is specified, this is in the same units, and \( \text{fs} \) must also be passed to \text{cheby1}.

See also:

- \text{cheby1}
  Filter design using order and critical points

  Find order and critical points from passband and stopband spec
- \text{cheb2ord, ellipord}
- \text{iirfilter}
  General filter design using order and critical frequencies
- \text{iirdesign}
  General filter design using passband and stopband spec

Examples

Design a digital lowpass filter such that the passband is within 3 dB up to 0.2*(fs/2), while rejecting at least -40 dB above 0.3*(fs/2). Plot its frequency response, showing the passband and stopband constraints in gray.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> N, Wn = signal.cheb1ord(0.2, 0.3, 3, 40)
>>> b, a = signal.cheby1(N, 3, Wn, 'low')
>>> w, h = signal.freqz(b, a)
>>> plt.semilogx(w / np.pi, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev I lowpass filter fit to constraints')
>>> plt.xlabel('Normalized frequency')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([0.01, 0.2, 0.2, 0.01], [-3, -3, -99, -99], '0.9', lw=0) # stop
>>> plt.fill([0.3, 0.3, 2, 2], [9, -40, -40, 9], '0.9', lw=0) # pass
>>> plt.axis([0.08, 1, -60, 3])
>>> plt.show()
```
scipy.signal.cheby2

`scipy.signal.cheby2(N, rs, Wn, btype='low', analog=False, output='ba', fs=None)`

Chebyshev type II digital and analog filter design.

Design an Nth-order digital or analog Chebyshev type II filter and return the filter coefficients.

**Parameters**

- `N` [int] The order of the filter.
- `rs` [float] The minimum attenuation required in the stop band. Specified in decibels, as a positive number.
- `Wn` [array_like] A scalar or length-2 sequence giving the critical frequencies. For Type II filters, this is the point in the transition band at which the gain first reaches `-rs`. For digital filters, `Wn` are in the same units as `fs`. By default, `fs` is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (`Wn` is thus in half-cycles / sample.) For analog filters, `Wn` is an angular frequency (e.g., rad/s).
- `analog` [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.
- `output` [‘ba’, ‘zpk’, ‘sos’], optional] Type of output: numerator/denominator (‘ba’), pole-zero (‘zpk’), or second-order sections (‘sos’). Default is ‘ba’ for backwards compatibility, but ‘sos’ should be used for general-purpose filtering.

**Returns**

- `b, a` [ndarray, ndarray] Numerator (b) and denominator (a) polynomials of the IIR filter. Only returned if `output='ba'`.
- `z, p, k` [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.

See also:
cheb2ord, cheb2ap

Notes

The Chebyshev type II filter maximizes the rate of cutoff between the frequency response’s passband and stopband, at the expense of ripple in the stopband and increased ringing in the step response.

Type II filters do not roll off as fast as Type I (cheby1).

The 'sos' output parameter was added in 0.16.0.

Examples

Design an analog filter and plot its frequency response, showing the critical points:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.cheby2(4, 40, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev Type II frequency response (rs=40)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.axhline(-40, color='green') # rs
>>> plt.show()
```

Generate a signal made up of 10 Hz and 20 Hz, sampled at 1 kHz
```python
>>> t = np.linspace(0, 1, 1000, False) # 1 second
>>> sig = np.sin(2*np.pi*10*t) + np.sin(2*np.pi*20*t)
>>> fig, (ax1, ax2) = plt.subplots(2, 1, sharex=True)
>>> ax1.plot(t, sig)
>>> ax1.set_title('10 Hz and 20 Hz sinusoids')
>>> ax1.axis([0, 1, -2, 2])
Design a digital high-pass filter at 17 Hz to remove the 10 Hz tone, and apply it to the signal. (It's recommended to use second-order sections format when filtering, to avoid numerical error with transfer function (ba) format):

```python
>>> sos = signal.cheby2(12, 20, 17, 'hp', fs=1000, output='sos')
>>> filtered = signal.sosfilt(sos, sig)
>>> ax2.plot(t, filtered)
>>> ax2.set_title('After 17 Hz high-pass filter')
>>> ax2.axis([0, 1, -2, 2])
>>> ax2.set_xlabel('Time [seconds]')
>>> plt.show()
```
For analog filters, \(wp\) and \(ws\) are angular frequencies (e.g., rad/s).

**gpass** [float] The maximum loss in the passband (dB).

**gstop** [float] The minimum attenuation in the stopband (dB).

**analog** [bool, optional] When True, return an analog filter, otherwise a digital filter is returned. New in version 1.2.0.

**fs** [float, optional] The sampling frequency of the digital system.

**Returns**

**ord** [int] The lowest order for a Chebyshev type II filter that meets specs.

**wn** [ndarray or float] The Chebyshev natural frequency (the “3dB frequency”) for use with `cheby2` to give filter results. If \(fs\) is specified, this is in the same units, and \(fs\) must also be passed to `cheby2`.

  - General filter design using passband and stopband spec

### Examples

Design a digital bandstop filter which rejects -60 dB from 0.2*(fs/2) to 0.5*(fs/2), while staying within 3 dB below 0.1*(fs/2) or above 0.6*(fs/2). Plot its frequency response, showing the passband and stopband constraints in gray.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> N, Wn = signal.cheb2ord([0.1, 0.6], [0.2, 0.5], 3, 60)
>>> b, a = signal.cheby2(N, 60, Wn, 'stop')
>>> w, h = signal.freqz(b, a)
>>> plt.semilogx(w / np.pi, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev II bandstop filter fit to constraints')
>>> plt.xlabel('Normalized frequency')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([.01, .1, .1, .01], [-3, -3, -99, -99], '0.9', lw=0) # stop
>>> plt.fill([.2, .2, .5, .5], [9, -60, -60, 9], '0.9', lw=0) # pass
>>> plt.fill([.6, .6, 2, 2], [-99, -3, -99, 0.9], '0.9', lw=0) # stop
>>> plt.axis([0.06, 1, -80, 3])
>>> plt.show()
```
scipy.signal.ellip

`scipy.signal.ellip(N, rp, rs, Wn, btype='low', analog=False, output='ba', fs=None)`

Elliptic (Cauer) digital and analog filter design.

Design an Nth-order digital or analog elliptic filter and return the filter coefficients.

**Parameters**

- **N** [int] The order of the filter.
- **rp** [float] The maximum ripple allowed below unity gain in the passband. Specified in decibels, as a positive number.
- **rs** [float] The minimum attenuation required in the stop band. Specified in decibels, as a positive number.
- **Wn** [array_like] A scalar or length-2 sequence giving the critical frequencies. For elliptic filters, this is the point in the transition band at which the gain first drops below -rp.
  - For digital filters, Wn are in the same units as fs. By default, fs is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (Wn is thus in half-cycles / sample.)
  - For analog filters, Wn is an angular frequency (e.g., rad/s).
- **btype** [str] The type of filter. Default is ‘lowpass’.
- **analog** [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.
- **output** [str] Type of output: numerator/denominator (‘ba’), pole-zero (‘zpk’), or second-order sections (‘sos’). Default is ‘ba’ for backwards compatibility, but ‘sos’ should be used for general-purpose filtering.
- **fs** [float, optional] The sampling frequency of the digital system.

**Returns**

- **b, a** [ndarray, ndarray] Numerator (b) and denominator (a) polynomials of the IIR filter. Only returned if output='ba'.
- **z, p, k** [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if output='zpk'.
- **sos** [ndarray] Second-order sections representation of the IIR filter. Only returned if output=='sos'.
See also:

ellipord, ellipap

Notes

Also known as Cauer or Zolotarev filters, the elliptical filter maximizes the rate of transition between the frequency response's passband and stopband, at the expense of ripple in both, and increased ringing in the step response.

As \( rp \) approaches 0, the elliptical filter becomes a Chebyshev type II filter (cheby2). As \( rs \) approaches 0, it becomes a Chebyshev type I filter (cheby1). As both approach 0, it becomes a Butterworth filter (butter).

The equiripple passband has \( N \) maxima or minima (for example, a 5th-order filter has 3 maxima and 2 minima). Consequently, the DC gain is unity for odd-order filters, or \(-rp\) dB for even-order filters.

The 'sos' output parameter was added in 0.16.0.

Examples

Design an analog filter and plot its frequency response, showing the critical points:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.ellip(4, 5, 40, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Elliptic filter frequency response (rp=5, rs=40)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.axhline(-40, color='green') # rs
>>> plt.axhline(-5, color='green') # rp
>>> plt.show()
```

Generate a signal made up of 10 Hz and 20 Hz, sampled at 1 kHz

```python
>>> t = np.linspace(0, 1, 1000, False) # 1 second
>>> sig = np.sin(2*np.pi*10*t) + np.sin(2*np.pi*20*t)
>>> fig, (ax1, ax2) = plt.subplots(2, 1, sharex=True)
>>> ax1.plot(t, sig)
>>> ax1.set_title('10 Hz and 20 Hz sinusoids')
>>> ax1.axis([0, 1, -2, 2])
```

Design a digital high-pass filter at 17 Hz to remove the 10 Hz tone, and apply it to the signal. (It's recommended to use second-order sections format when filtering, to avoid numerical error with transfer function (ba) format):

```python
>>> sos = signal.ellip(8, 1, 100, 17, 'hp', fs=1000, output='sos')
>>> filtered = signal.sosfilt(sos, sig)
>>> ax2.plot(t, filtered)
>>> ax2.set_title('After 17 Hz high-pass filter')
```

```
**scipy.signal.ellipord**

*scipy.signal.ellipord(wp, ws, gpass, gstop, analog=False, fs=None)*

Elliptic (Cauer) filter order selection.

Return the order of the lowest order digital or analog elliptic filter that loses no more than gpass dB in the passband and has at least gstop dB attenuation in the stopband.

**Parameters**

- **wp, ws** [float]: Passband and stopband edge frequencies.
  For digital filters, these are in the same units as fs. By default, fs is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (wp and ws are thus in half-cycles / sample.) For example:
  - Lowpass: wp = 0.2, ws = 0.3
  - Highpass: wp = 0.3, ws = 0.2
  - Bandpass: wp = [0.2, 0.5], ws = [0.1, 0.6]
  - Bandstop: wp = [0.1, 0.6], ws = [0.2, 0.5]
  For analog filters, wp and ws are angular frequencies (e.g., rad/s).

- **gpass** [float]: The maximum loss in the passband (dB).

- **gstop** [float]: The minimum attenuation in the stopband (dB).

- **analog** [bool, optional]: When True, return an analog filter, otherwise a digital filter is returned.

- **fs** [float, optional]: The sampling frequency of the digital system.
  New in version 1.2.0.

**Returns**

- **ord** [int]: The lowest order for an Elliptic (Cauer) filter that meets specs.

- **wn** [ndarray or float]: The Chebyshev natural frequency (the “3dB frequency”) for use with *ellip* to give filter results. If fs is specified, this is in the same units, and fs must also be passed to *ellip*.

3.3. API definition 1567
Examples

Design an analog highpass filter such that the passband is within 3 dB above 30 rad/s, while rejecting -60 dB at 10 rad/s. Plot its frequency response, showing the passband and stopband constraints in gray.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> N, Wn = signal.ellipord(30, 10, 3, 60, True)
>>> b, a = signal.ellip(N, 3, 60, Wn, 'high', True)
>>> w, h = signal.freqs(b, a, np.logspace(0, 3, 500))
>>> plt.semilogx(w, 20 * np.log10(abs(h)));
>>> plt.title('Elliptical highpass filter fit to constraints')
>>> plt.xlabel('Frequency [radians / second]
' >>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([.1, 10, 10, .1], [1e4, 1e4, -60, -60], '0.9', lw=0) # stop
>>> plt.fill([30, 30, 1e9, 1e9], [-99, -3, -3, -99], '0.9', lw=0) # pass
>>> plt.axis([1, 300, -80, 3])
>>> plt.show()
```

Elliptical highpass filter fit to constraints

### scipy.signal.bessel

scipy.signal.bessel \((N, \text{Wn}, \text{btype}='\text{low}', \text{analog}=False, \text{output}='ba', \text{norm}='\text{phase}', \text{fs}=None)\)

Bessel/Thomson digital and analog filter design.

Design an Nth-order digital or analog Bessel filter and return the filter coefficients.

**Parameters**

N  
[int] The order of the filter.

Wn  
[array_like] A scalar or length-2 sequence giving the critical frequencies (defined by the \text{norm} parameter). For analog filters, \text{Wn} is an angular frequency (e.g., rad/s). For digital filters, \text{Wn} are in the same units as \text{fs}. By default, \text{fs} is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (\text{Wn} is thus in half-cycles / sample.)
btype  [['lowpass', 'highpass', 'bandpass', 'bandstop'], optional] The type of filter. Default is 'low-pass'.

analog  [bool, optional] When True, return an analog filter, otherwise a digital filter is returned. (See Notes.)

output  [['ba', 'zpk', 'sos'], optional] Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

norm  [['phase', 'delay', 'mag'], optional] Critical frequency normalization:

  phase  The filter is normalized such that the phase response reaches its midpoint at angular (e.g. rad/s) frequency $W_n$. This happens for both low-pass and high-pass filters, so this is the “phase-matched” case. The magnitude response asymptotes are the same as a Butterworth filter of the same order with a cutoff of $W_n$. This is the default, and matches MATLAB’s implementation.

delay  The filter is normalized such that the group delay in the passband is $1/W_n$ (e.g., seconds). This is the “natural” type obtained by solving Bessel polynomials.

mag  The filter is normalized such that the gain magnitude is -3 dB at angular frequency $W_n$. New in version 0.18.0.

Returns

b, a  [ndarray, ndarray] Numerator ($b$) and denominator ($a$) polynomials of the IIR filter. Only returned if output='ba'.

z, p, k  [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if output='zpk'.

sos  [ndarray] Second-order sections representation of the IIR filter. Only returned if output=='sos'.

Notes

Also known as a Thomson filter, the analog Bessel filter has maximally flat group delay and maximally linear phase response, with very little ringing in the step response. [1]

The Bessel is inherently an analog filter. This function generates digital Bessel filters using the bilinear transform, which does not preserve the phase response of the analog filter. As such, it is only approximately correct at frequencies below about $fs/4$. To get maximally-flat group delay at higher frequencies, the analog Bessel filter must be transformed using phase-preserving techniques.

See besselap for implementation details and references.
The 'sos' output parameter was added in 0.16.0.

References

[1]
Examples

Plot the phase-normalized frequency response, showing the relationship to the Butterworth’s cutoff frequency (green):

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.butter(4, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)), color='silver', ls='dashed')
>>> b, a = signal.bessel(4, 100, 'low', analog=True, norm='phase')
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)))

```

Bessel filter magnitude response (with Butterworth)

```

and the phase midpoint:

```python
>>> plt.figure()
>>> plt.semilogx(w, np.unwrap(np.angle(h)))
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.axhline(-np.pi, color='red') # phase midpoint
```
Plot the magnitude-normalized frequency response, showing the -3 dB cutoff:

```python
>>> b, a = signal.bessel(3, 10, 'low', analog=True, norm='mag')
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)))
>>> plt.axhline(-3, color='red')  # -3 dB magnitude
>>> plt.axvline(10, color='green')  # cutoff frequency
>>> plt.title('Magnitude-normalized Bessel filter frequency response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()
```

Plot the delay-normalized filter, showing the maximally-flat group delay at 0.1 seconds:
>>> b, a = signal.bessel(5, 1/0.1, 'low', analog=True, norm='delay')
>>> w, h = signal.freqs(b, a)
>>> plt.figure()
>>> plt.semilogx(w[1:], -np.diff(np.unwrap(np.angle(h)))/np.diff(w))
>>> plt.axhline(0.1, color='red')  # 0.1 seconds group delay
>>> plt.title('Bessel filter group delay')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Group delay [seconds]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()

scipy.signal.iirnotch

scipy.signal.iirnotch(w0, Q, fs=2.0)

Design second-order IIR notch digital filter.

A notch filter is a band-stop filter with a narrow bandwidth (high quality factor). It rejects a narrow frequency band and leaves the rest of the spectrum little changed.

**Parameters**

- **w0** [float] Frequency to remove from a signal. If `fs` is specified, this is in the same units as `fs`. By default, it is a normalized scalar that must satisfy 0 < w0 < 1, with w0 = 1 corresponding to half of the sampling frequency.
- **Q** [float] Quality factor. Dimensionless parameter that characterizes notch filter -3 dB bandwidth bw relative to its center frequency, Q = w0/bw.
- **fs** [float, optional] The sampling frequency of the digital system. New in version 1.2.0.

**Returns**

- **b, a** [ndarray, ndarray] Numerator (b) and denominator (a) polynomials of the IIR filter.

**See also:**

iirpeak
Notes

New in version 0.19.0.

References

[1]

Examples

Design and plot filter to remove the 60 Hz component from a signal sampled at 200 Hz, using a quality factor Q = 30

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> fs = 200.0  # Sample frequency (Hz)
>>> f0 = 60.0   # Frequency to be removed from signal (Hz)
>>> Q = 30.0   # Quality factor
>>> # Design notch filter
>>> b, a = signal.iirnotch(f0, Q, fs)

>>> # Frequency response
>>> freq, h = signal.freqz(b, a, fs=fs)
>>> # Plot
>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20*np.log10(abs(h)), color='blue')
>>> ax[0].set_title("Frequency Response")
>>> ax[0].set_ylabel("Amplitude (dB)", color='blue')
>>> ax[0].set_xlim([0, 100])
>>> ax[0].set_ylim([-25, 10])
>>> ax[0].grid()
>>> ax[1].plot(freq, np.unwrap(np.angle(h))*180/np.pi, color='green')
>>> ax[1].set_ylabel("Angle (degrees)", color='green')
>>> ax[1].set_xlim([0, 100])
>>> ax[1].set_xticks([-90, -60, -30, 0, 30, 60, 90])
>>> ax[1].set_yticks([-90, 90])
>>> ax[1].grid()
>>> plt.show()
```

scipy.signal.iirpeak

**scipy.signal.iirpeak** *(w0, Q, fs=2.0)*

Design second-order IIR peak (resonant) digital filter.

A peak filter is a band-pass filter with a narrow bandwidth (high quality factor). It rejects components outside a narrow frequency band.

**Parameters**

- **w0** *(float)* Frequency to be retained in a signal. If `fs` is specified, this is in the same units as `fs`. By default, it is a normalized scalar that must satisfy 0 < w0 < 1, with w0 = 1 corresponding to half of the sampling frequency.

Q [float] Quality factor. Dimensionless parameter that characterizes peak filter -3 dB bandwidth bw relative to its center frequency, \( Q = \omega_0 / \omega_b \).

Returns

b, a [ndarray, ndarray] Numerator (b) and denominator (a) polynomials of the IIR filter.

See also:

iirnotch

Notes

New in version 0.19.0.

References

[1]

Examples

Design and plot filter to remove the frequencies other than the 300 Hz component from a signal sampled at 1000 Hz, using a quality factor Q = 30

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> fs = 1000.0  # Sample frequency (Hz)
>>> f0 = 300.0  # Frequency to be retained (Hz)
>>> Q = 30.0  # Quality factor
>>> # Design peak filter
>>> b, a = signal.iirpeak(f0, Q, fs)

>>> # Frequency response
>>> freq, h = signal.freqz(b, a, fs=fs)

>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
 >>> ax[0].plot(freq, 20*np.log10(np.maximum(abs(h), 1e-5)), color='blue')
 >>> ax[0].set_title('Frequency Response')
 >>> ax[0].set_ylabel('Amplitude (dB)', color='blue')
 >>> ax[0].set_xlabel('Frequency (Hz)')
 >>> ax[0].set_xlim([0, 500])
 >>> ax[0].set_ylim([-90, 90])
 >>> ax[0].grid()

>>> ax[1].plot(freq, np.unwrap(np.angle(h)) * 180/np.pi, color='green')
 >>> ax[1].set_ylabel('Angle (degrees)', color='green')
 >>> ax[1].set_xlabel('Frequency (Hz)')
 >>> ax[1].set_xlim([0, 500])
 >>> ax[1].set_yticks([-90, -60, -30, 0, 30, 60, 90])
 >>> ax[1].set_ylim([-90, 90])
```

(continues on next page)
scipy.signal.iircomb

```python
scipy.signal.iircomb(w0, Q, ftype='notch', fs=2.0)
```

Design IIR notching or peaking digital comb filter.

A notching comb filter is a band-stop filter with a narrow bandwidth (high quality factor). It rejects a narrow frequency band and leaves the rest of the spectrum little changed.

A peaking comb filter is a band-pass filter with a narrow bandwidth (high quality factor). It rejects components outside a narrow frequency band.

**Parameters**

- **w0**  
  [float] Frequency to attenuate (notching) or boost (peaking). If `fs` is specified, this is in the same units as `fs`. By default, it is a normalized scalar that must satisfy $0 < w0 < 1$, with $w0 = 1$ corresponding to half of the sampling frequency.

- **Q**  
  [float] Quality factor. Dimensionless parameter that characterizes notch filter -3 dB bandwidth $bw$ relative to its center frequency, $Q = w0/bw$.

- **ftype**  
  [{'notch', 'peak'}] The type of comb filter generated by the function. If 'notch', then it returns a filter with notches at frequencies $0, w0, 2 * w0$, etc. If 'peak', then it returns a filter with peaks at frequencies $0.5 * w0, 1.5 * w0, 2.5 * w0$, etc. Default is 'notch'.

```python
>>> ax[1].grid()
>>> plt.show()
```
fs    [float, optional] The sampling frequency of the signal. Default is 2.0.

Returns
b, a    [ndarray, ndarray] Numerator (b) and denominator (a) polynomials of the IIR filter.

Raises
ValueError
    If \( w0 \) is less than or equal to 0 or greater than or equal to \( fs/2 \), if \( fs \) is not divisible by \( w0 \), if \( ftype \) is not ‘notch’ or ‘peak’

See also:
iirnotch
iirpeak

Notes
For implementation details, see [1]. The TF implementation of the comb filter is numerically stable even at higher orders due to the use of a single repeated pole, which won’t suffer from precision loss.

References
[1]

Examples
Design and plot notching comb filter at 20 Hz for a signal sampled at 200 Hz, using quality factor \( Q = 30 \)

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> fs = 200.0  # Sample frequency (Hz)
>>> f0 = 20.0   # Frequency to be removed from signal (Hz)
>>> Q = 30.0   # Quality factor
>>> # Design notching comb filter
>>> b, a = signal.iircomb(f0, Q, ftype='notch', fs=fs)

>>> # Frequency response
>>> freq, h = signal.freqz(b, a, fs=fs)
>>> response = abs(h)
>>> # To avoid divide by zero when graphing
>>> response[response == 0] = 1e-20

>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20*np.log10(abs(response)), color='blue')
>>> ax[0].set_title("Frequency Response")
>>> ax[0].set_ylabel("Amplitude (dB)", color='blue')
>>> ax[0].set_xlim([0, 100])
>>> ax[0].set_ylim([-30, 10])
>>> ax[0].grid()  
```
Design and plot peaking comb filter at 250 Hz for a signal sampled at 1000 Hz, using quality factor Q = 30

```python
>>> fs = 1000.0  # Sample frequency (Hz)
>>> f0 = 250.0   # Frequency to be retained (Hz)
>>> Q = 30.0    # Quality factor
>>> # Design peaking filter
>>> b, a = signal.iircomb(f0, Q, ftype='peak', fs=fs)

>>> # Frequency response
>>> freq, h = signal.freqz(b, a, fs=fs)
>>> response = abs(h)
>>> # To avoid divide by zero when graphing
```
```python
>>> response[response == 0] = 1e-20
>>> # Plot
>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20*np.log10(np.maximum(abs(h), 1e-5)), color='blue')
>>> ax[0].set_title("Frequency Response")
>>> ax[0].set_ylabel("Amplitude (dB)", color='blue')
>>> ax[0].set_xlim([0, 500])
>>> ax[0].set_ylim([-80, 10])
>>> ax[0].grid()
>>> ax[1].plot(freq, np.unwrap(np.angle(h))*180/np.pi, color='green')
>>> ax[1].set_ylabel("Angle (degrees)", color='green')
>>> ax[1].set_xlabel("Frequency (Hz)"")
>>> ax[1].set_xlim([0, 500])
>>> ax[1].set_ylim([-90, 90])
>>> ax[1].grid()
>>> plt.show()
```

**scipy.signal.lti**

```python
class scipy.signal.lti(*system)
```

Continuous-time linear time invariant system base class.

**Parameters**

- `*system` [arguments] The `lti` class can be instantiated with either 2, 3 or 4 arguments. The following gives the number of arguments and the corresponding continuous-time subclass that is created:
  - 2: `TransferFunction` (numerator, denominator)
  - 3: `ZerosPolesGain` (zeros, poles, gain)
  - 4: `StateSpace` (A, B, C, D)

Each argument can be an array or a sequence.

**See also:**

`ZerosPolesGain, StateSpace, TransferFunction, dlti`

**Notes**

`lti` instances do not exist directly. Instead, `lti` creates an instance of one of its subclasses: `StateSpace`, `TransferFunction` or `ZerosPolesGain`.

If (numerator, denominator) is passed in for `*system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g., \(s^2 + 3s + 5\) would be represented as \([1, 3, 5]\)).

Changing the value of properties that are not directly part of the current system representation (such as the zeros of a `StateSpace` system) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.
Examples

```python
from scipy import signal

>>> signal.lti(1, 2, 3, 4)
StateSpaceContinuous(
    array([[1]]),
    array([[2]]),
    array([[3]]),
    array([[4]]),
dt: None
)

Construct the transfer function \( H(s) = \frac{5(s-1)(s-2)}{(s-3)(s-4)} \):

```python
>>> signal.lti([1, 2], [3, 4], 5)
ZerosPolesGainContinuous(
    array([1, 2]),
    array([3, 4]),
    5,
    dt: None
)

Construct the transfer function \( H(s) = \frac{3s+4}{s+2} \):

```python
>>> signal.lti([3, 4], [1, 2])
TransferFunctionContinuous(
    array([3., 4.]),
    array([1., 2.]),
dt: None
)
```

Attributes

dt

Return the sampling time of the system, None for lti systems.

poles

Poles of the system.

zeros

Zeros of the system.

Methods

bode([w, n])

Calculate Bode magnitude and phase data of a continuous-time system.

freqresp([w, n])

Calculate the frequency response of a continuous-time system.

impulse([X0, T, N])

Return the impulse response of a continuous-time system.

output(U, T[, X0])

Return the response of a continuous-time system to input U.

step([X0, T, N])

Return the step response of a continuous-time system.

to_discrete(dt[, method, alpha])

Return a discretized version of the current system.
**scipy.signal.lti.bode**

```python
lti.bode(w=None, n=100)
```
Calculate Bode magnitude and phase data of a continuous-time system.

Returns a 3-tuple containing arrays of frequencies [rad/s], magnitude [dB] and phase [deg]. See `bode` for details.

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> sys = signal.TransferFunction([1], [1, 1])
>>> w, mag, phase = sys.bode()

>>> plt.figure()
>>> plt.semilogx(w, mag)  # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()
```

![Bode magnitude and phase plots](image)

**scipy.signal.lti.freqresp**

```python
lti.freqresp(w=None, n=10000)
```
Calculate the frequency response of a continuous-time system.

Returns a 2-tuple containing arrays of frequencies [rad/s] and complex magnitude. See `freqresp` for details.
scipy.signal.lti.impulse

`lti.impulse(X0=None, T=None, N=None)`
Return the impulse response of a continuous-time system. See `impulse` for details.

scipy.signal.lti.output

`lti.output(U, T, X0=None)`
Return the response of a continuous-time system to input $U$. See `lsim` for details.

scipy.signal.lti.step

`lti.step(X0=None, T=None, N=None)`
Return the step response of a continuous-time system. See `step` for details.

scipy.signal.lti.to_discrete

`lti.to_discrete(dt, method='zoh', alpha=None)`
Return a discretized version of the current system.

Parameters: See `cont2discrete` for details.

Returns

```
sys: instance of dlti
```
**scipy.signal.StateSpace**

*class scipy.signal.StateSpace(*system, **kwargs*)*

Linear Time Invariant system in state-space form.

Represents the system as the continuous-time, first order differential equation \( \dot{x} = Ax + Bu \) or the discrete-time difference equation \( x[k+1] = Ax[k] + Bu[k] \). StateSpace systems inherit additional functionality from the \( lti \), respectively the \( dlti \) classes, depending on which system representation is used.

**Parameters**

*system: arguments*

The StateSpace class can be instantiated with 1 or 4 arguments. The following gives the number of input arguments and their interpretation:

- 1: \( lti \) or \( dlti \) system: \( (StateSpace, TransferFunction \text{ or } ZerosPolesGain) \)
- 4: array_like: \( (A, B, C, D) \)

*dt: float, optional*

Sampling time [s] of the discrete-time systems. Defaults to \( None \) (continuous-time). Must be specified as a keyword argument, for example, \( dt=0.1 \).

**See also:**

\( TransferFunction, ZerosPolesGain, lti, dlti \)

\( ss2zpk, ss2tf, zpk2sos \)

**Notes**

Changing the value of properties that are not part of the StateSpace system representation (such as zeros or poles) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call \( sys = sys.to_zpk() \) before accessing/changing the zeros, poles or gain.

**Examples**

```python
>>> from scipy import signal

>>> a = np.array([[0, 1], [0, 0]])
>>> b = np.array([[0], [1]])
>>> c = np.array([[1, 0]])
>>> d = np.array([[0]])

>>> sys = signal.StateSpace(a, b, c, d)
>>> print(sys)
StateSpaceContinuous(array([[0, 1],
    [0, 0]]),
array([[0],
    [1]]),
array([[1, 0]]),
array([[0]]),
dt: None)
```
```python
>>> sys.to_discrete(0.1)
StateSpaceDiscrete(
    array([[1. , 0.1],
           [0. , 1. ]]),
    array([[0.005],
           [0.1 ]]),
    array([[1, 0]]),
    array([[0]]),
    dt: 0.1
)
```

```python
>>> a = np.array([[1, 0.1], [0, 1]])
>>> b = np.array([[0.005], [0.1]])

>>> signal.StateSpace(a, b, c, d, dt=0.1)
StateSpaceDiscrete(
    array([[1. , 0.1],
           [0. , 1. ]]),
    array([[0.005],
           [0.1 ]]),
    array([[1, 0]]),
    array([[0]]),
    dt: 0.1
)
```

### Attributes

- **A**: State matrix of the `StateSpace` system.
- **B**: Input matrix of the `StateSpace` system.
- **C**: Output matrix of the `StateSpace` system.
- **D**: Feedthrough matrix of the `StateSpace` system.
- **dt**: Return the sampling time of the system, `None` for `lti` systems.
- **poles**: Poles of the system.
- **zeros**: Zeros of the system.

### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>

</tr>
</tbody>
</table>
scipy.signal.StateSpace.__mul__

`StateSpace.__mul__(other)`

Post-multiply another system or a scalar

Handles multiplication of systems in the sense of a frequency domain multiplication. That means, given two systems $E_1(s)$ and $E_2(s)$, their multiplication, $H(s) = E_1(s) * E_2(s)$, means that applying $H(s)$ to $U(s)$ is equivalent to first applying $E_2(s)$, and then $E_1(s)$.

Notes

For SISO systems the order of system application does not matter. However, for MIMO systems, where the two systems are matrices, the order above ensures standard Matrix multiplication rules apply.

scipy.signal.StateSpace.to_ss

`StateSpace.to_ss()`

Return a copy of the current `StateSpace` system.

Returns

- `sys` [instance of `StateSpace`] The current system (copy)

scipy.signal.StateSpace.to_tf

`StateSpace.to_tf(**kwargs)`

Convert system representation to `TransferFunction`.

Parameters

- `kwargs` [dict, optional] Additional keywords passed to `ss2zpk`

Returns

- `sys` [instance of `TransferFunction`] Transfer function of the current system

scipy.signal.StateSpace.to_zpk

`StateSpace.to_zpk(**kwargs)`

Convert system representation to `ZerosPolesGain`.

Parameters

- `kwargs` [dict, optional] Additional keywords passed to `ss2zpk`

Returns

- `sys` [instance of `ZerosPolesGain`] Zeros, poles, gain representation of the current system
scipy.signal.TransferFunction

class scipy.signal.TransferFunction(*system, **kwargs)

Linear Time Invariant system class in transfer function form.

Represents the system as the continuous-time transfer function
\[ H(s) = \sum_{i=0}^{N} b[N - i]s^i / \sum_{j=0}^{M} a[M - j]s^j \]
or the discrete-time transfer function
\[ H(s) = \sum_{i=0}^{N} b[N - i]z^i / \sum_{j=0}^{M} a[M - j]z^j, \]
where \( b \) are elements of the numerator \( \text{num} \), \( a \) are elements of the denominator \( \text{den} \), and \( N = len(b) - 1, M = len(a) - 1 \). **TransferFunction** systems inherit additional functionality from the **lti**, respectively the **dlti** classes, depending on which system representation is used.

**Parameters**

*system: arguments

The **TransferFunction** class can be instantiated with 1 or 2 arguments. The following gives the number of input arguments and their interpretation:

- 1: \( \text{lti or dlti system: (StateSpace, TransferFunction or ZerosPoles-Gain)} \)
- 2: array_like: (numerator, denominator)

**dt: float, optional**

Sampling time [s] of the discrete-time systems. Defaults to None (continuous-time). Must be specified as a keyword argument, for example, \( dt=0.1 \).

See also:

**ZerosPolesGain, StateSpace, lti, dlti**

**tf2ss, tf2zpk, tf2sos**

**Notes**

Changing the value of properties that are not part of the \( \text{TransferFunction} \) system representation (such as the \( A, B, C, D \) state-space matrices) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call \( sys = sys.to_ss() \) before accessing/changing the \( A, B, C, D \) system matrices.

If (numerator, denominator) is passed in for \( *system \), coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \( s^2 + 3s + 5 \) or \( z^2 + 3z + 5 \) would be represented as \( [1, 3, 5] \) )

**Examples**

Construct the transfer function \( H(s) = \frac{s^2+3s+3}{s^2+2s+1} \).

```python
>>> from scipy import signal

>>> num = [1, 3, 3]
>>> den = [1, 2, 1]

>>> signal.TransferFunction(num, den)
TransferFunctionContinuous(
array([1., 3., 3.]),
array([1., 2., 1.]),
dt: None)
```
Construct the transfer function $H(z) = \frac{z^2 + 3z + 3}{z^2 + 2z + 1}$ with a sampling time of 0.1 seconds:

```python
>>> signal.TransferFunction(num, den, dt=0.1)
TransferFunctionDiscrete(
    array([[1., 3., 3.]],
    array([[1., 2., 1.]],
    dt: 0.1
)
```

**Attributes**
- `den`: Denominator of the `TransferFunction` system.
- `dt`: Return the sampling time of the system, `None` for `lti` systems.
- `num`: Numerator of the `TransferFunction` system.
- `poles`: Poles of the system.
- `zeros`: Zeros of the system.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>to_ss()</code></td>
<td>Convert system representation to <code>StateSpace</code>.</td>
</tr>
<tr>
<td><code>to_tf()</code></td>
<td>Return a copy of the current <code>TransferFunction</code> system.</td>
</tr>
<tr>
<td><code>to_zpk()</code></td>
<td>Convert system representation to <code>ZerosPoles-Gain</code>.</td>
</tr>
</tbody>
</table>

**scipy.signal.TransferFunction.to_ss**

`TransferFunction.to_ss()` Convert system representation to `StateSpace`.

**Returns**
- `sys` [instance of `StateSpace`] State space model of the current system

**scipy.signal.TransferFunction.to_tf**

`TransferFunction.to_tf()` Return a copy of the current `TransferFunction` system.

**Returns**
- `sys` [instance of `TransferFunction`] The current system (copy)
scipy.signal.TransferFunction.to_zpk

```python
TransferFunction.to_zpk()
```

Convert system representation to `ZerosPolesGain`.

Returns
sys
[instance of `ZerosPolesGain`] Zeros, poles, gain representation of the current system

scipy.signal.ZerosPolesGain

class scipy.signal.ZerosPolesGain(*system, **kwargs)

Linear Time Invariant system class in zeros, poles, gain form.

Represents the system as the continuous- or discrete-time transfer function $H(s) = k \prod_i (s-z[i])/\prod_j (s-p[j])$ , where $k$ is the gain, $z$ are the zeros and $p$ are the poles. `ZerosPolesGain` systems inherit additional functionality from the `lti`, respectively the `dlti` classes, depending on which system representation is used.

Parameters

*system [arguments] The `ZerosPolesGain` class can be instantiated with 1 or 3 arguments. The following gives the number of input arguments and their interpretation:
• 1: `lti` or `dlti` system: (StateSpace, TransferFunction or `ZerosPolesGain`)
• 3: array_like: (zeros, poles, gain)

dt: float, optional
Sampling time [s] of the discrete-time systems. Defaults to `None` (continuous-time). Must be specified as a keyword argument, for example, `dt=0.1`.

See also:
TransferFunction, StateSpace, `lti`, `dlti`
zpk2ss, zpk2tf, zpk2sos

Notes

Changing the value of properties that are not part of the `ZerosPolesGain` system representation (such as the $A$, $B$, $C$, $D$ state-space matrices) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_ss()` before accessing/changing the $A$, $B$, $C$, $D$ system matrices.

Examples

Construct the transfer function $H(s) = \frac{5(s-1)(s-2)}{(s-3)(s-4)}$:

```python
>>> from scipy import signal

>>> signal.ZerosPolesGain([[1, 2], [3, 4]], 5)
ZerosPolesGainContinuous(
    array([[1, 2]],
    array([[3, 4]],
    5,
```

(continues on next page)
dt: None
)

Construct the transfer function \( H(z) = \frac{5(z-1)(z-2)}{(z-3)(z-4)} \) with a sampling time of 0.1 seconds:

```python
>>> signal.ZerosPolesGain([[1, 2], [3, 4]], 5, dt=0.1)
ZerosPolesGainDiscrete(
    array([[1, 2]]),
    array([[3, 4]]),
    5,
    dt: 0.1
)
```

### Attributes

- **dt**: Return the sampling time of the system, *None* for *lti* systems.
- **gain**: Gain of the *ZerosPolesGain* system.
- **poles**: Poles of the *ZerosPolesGain* system.
- **zeros**: Zeros of the *ZerosPolesGain* system.

### Methods

- **to_ss()**: Convert system representation to *StateSpace*.
- **to_tf()**: Convert system representation to *TransferFunction*.
- **to_zpk()**: Return a copy of the current *ZerosPolesGain* system.

**scipy.signal.ZerosPolesGain.to_ss**

*ZerosPolesGain.to_ss()*

Convert system representation to *StateSpace*.

**Returns**

*sys* ([instance of *StateSpace*] State space model of the current system

**scipy.signal.ZerosPolesGain.to_tf**

*ZerosPolesGain.to_tf()*

Convert system representation to *TransferFunction*.

**Returns**

*sys* ([instance of *TransferFunction*] Transfer function of the current system
scipy.signal.ZerosPolesGain.to_zpk

ZerosPolesGain.to_zpk()

Return a copy of the current ‘ZerosPolesGain’ system.

Returns

sys [instance of ZerosPolesGain] The current system (copy)

scipy.signal.lsim

scipy.signal.lsim(system, U, T, X0=None, interp=True)

Simulate output of a continuous-time linear system.

Parameters

system [an instance of the LTI class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:

• 1: (instance of lti)
• 2: (num, den)
• 3: (zeros, poles, gain)
• 4: (A, B, C, D)

U [array_like] An input array describing the input at each time T (interpolation is assumed between given times). If there are multiple inputs, then each column of the rank-2 array represents an input. If U = 0 or None, a zero input is used.

T [array_like] The time steps at which the input is defined and at which the output is desired. Must be nonnegative, increasing, and equally spaced.

X0 [array_like, optional] The initial conditions on the state vector (zero by default).

interp [bool, optional] Whether to use linear (True, the default) or zero-order-hold (False) interpolation for the input array.

Returns

T [1D ndarray] Time values for the output.

yout [1D ndarray] System response.

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \(s^2 + 3s + 5\) would be represented as \([1, 3, 5]\)).

Examples

We’ll use lsim to simulate an analog Bessel filter applied to a signal.

```python
>>> from scipy.signal import bessel, lsim
>>> import matplotlib.pyplot as plt
```

Create a low-pass Bessel filter with a cutoff of 12 Hz.

```python
>>> b, a = bessel(N=5, Wn=2*np.pi*12, btype='lowpass', analog=True)
```

Generate data to which the filter is applied.
The input signal is the sum of three sinusoidal curves, with frequencies 4 Hz, 40 Hz, and 80 Hz. The filter should mostly eliminate the 40 Hz and 80 Hz components, leaving just the 4 Hz signal.

In a second example, we simulate a double integrator $y'' = u$, with a constant input $u = 1$. We'll use the state space representation of the integrator.
Compute the simulation, and then plot $y$. As expected, the plot shows the curve $y = 0.5t^2$.

```python
>>> tout, y, x = lsim(system, u, t)
>>> plt.plot(t, y)
>>> plt.grid(alpha=0.3)
>>> plt.xlabel('t')
>>> plt.show()
```

**scipy.signal.lsim2**

`scipy.signal.lsim2(system, U=None, T=None, X0=None, **kwargs)`  
Simulate output of a continuous-time linear system, by using the ODE solver `scipy.integrate.odeint`.

**Parameters**

- `system` ([an instance of the `lti` class or a tuple describing the system.]) The following gives the number of elements in the tuple and the interpretation:
  - 1: (instance of `lti`)
  - 2: (num, den)
  - 3: (zeros, poles, gain)
  - 4: (A, B, C, D)
- `U` ([array_like (1D or 2D), optional]) An input array describing the input at each time T. Linear interpolation is used between given times. If there are multiple inputs, then each column of the rank-2 array represents an input. If U is not given, the input is assumed to be zero.
- `T` ([array_like (1D or 2D), optional]) The time steps at which the input is defined and at which the output is desired. The default is 101 evenly spaced points on the interval [0,10.0].
- `X0` ([array_like (1D), optional]) The initial condition of the state vector. If X0 is not given, the initial conditions are assumed to be 0.
- `kwargs` ([dict]) Additional keyword arguments are passed on to the function `odeint`. See the notes below for more details.

**Returns**

- `T` ([1D ndarray]) The time values for the output.
- `yout` ([ndarray]) The response of the system.
- `xout` ([ndarray]) The time-evolution of the state-vector.
See also:

lsim

Notes

This function uses \texttt{scipy.integrate.odeint} to solve the system's differential equations. Additional keyword arguments given to \texttt{lsim2} are passed on to \texttt{odeint}. See the documentation for \texttt{scipy.integrate.odeint} for the full list of arguments.

If (num, den) is passed in for \texttt{system}, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. $s^2 + 3s + 5$ would be represented as [1, 3, 5]).

Examples

We'll use \texttt{lsim2} to simulate an analog Bessel filter applied to a signal.

```python
>>> from scipy.signal import bessel, lsim
>>> import matplotlib.pyplot as plt

Create a low-pass Bessel filter with a cutoff of 12 Hz.

```python
>>> b, a = bessel(N=5, Wn=2*np.pi*12, btype='lowpass', analog=True)
``` 

Generate data to which the filter is applied.

```python
>>> t = np.linspace(0, 1.25, 500, endpoint=False)
``` 

The input signal is the sum of three sinusoidal curves, with frequencies 4 Hz, 40 Hz, and 80 Hz. The filter should mostly eliminate the 40 Hz and 80 Hz components, leaving just the 4 Hz signal.

```python
>>> u = (np.cos(2*np.pi*4*t) + 0.6*np.sin(2*np.pi*40*t) +
... 0.5*np.cos(2*np.pi*80*t))
``` 

Simulate the filter with \texttt{lsim2}.

```python
>>> tout, yout, xout = lsim2((b, a), U=u, T=t)
``` 

Plot the result.

```python
>>> plt.plot(t, u, 'r', alpha=0.5, linewidth=1, label='input')
>>> plt.plot(tout, yout, 'k', linewidth=1.5, label='output')
>>> plt.legend(loc='best', shadow=True, framealpha=1)
>>> plt.grid(alpha=0.3)
>>> plt.xlabel('t')
>>> plt.show()
``` 

In a second example, we simulate a double integrator $y'' = u$, with a constant input $u = 1$. We'll use the state space representation of the integrator.

```python
>>> from scipy.signal import lti
>>> A = np.array([[0, 1], [0, 0]])
>>> B = np.array([[0], [1]])
```
(continued from previous page)

```python
>>> C = np.array([[1, 0]])
>>> D = 0
>>> system = lti(A, B, C, D)
```

\( t \) and \( u \) define the time and input signal for the system to be simulated.

```python
>>> t = np.linspace(0, 5, num=50)
>>> u = np.ones_like(t)
```

Compute the simulation, and then plot \( y \). As expected, the plot shows the curve \( y = 0.5t^2 \).

```python
>>> tout, y, x = lsim2(system, u, t)
>>> plt.plot(t, y)
>>> plt.grid(alpha=0.3)
>>> plt.xlabel('t')
>>> plt.show()
```

**scipy.signal.impulse**

```python
scipy.signal.impulse(system, X0=None, T=None, N=None)
```

Impulse response of continuous-time system.

**Parameters**

- `system` [an instance of the LTI class or a tuple of array_like] describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of `lti`)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
- `X0` [array_like, optional] Initial state-vector. Defaults to zero.
- `N` [int, optional] The number of time points to compute (if `T` is not given).

**Returns**
**T**  [ndarray] A 1-D array of time points.

**yout**  [ndarray] A 1-D array containing the impulse response of the system (except for singularities at zero).

**Notes**

If (num, den) is passed in for *system*, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \( s^2 + 3s + 5 \) would be represented as \([1, 3, 5]\)).

**Examples**

Compute the impulse response of a second order system with a repeated root: \( x''(t) + 2*x'(t) + x(t) = u(t) \)

```python
>>> from scipy import signal
>>> system = ([1.0], [1.0, 2.0, 1.0])
>>> t, y = signal.impulse(system)
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, y)
```

**scipy.signal.impulse2**

*scipy.signal.impulse2* (*system*, *X0=None*, *T=None*, *N=None*, **kwargs)

Impulse response of a single-input, continuous-time linear system.

**Parameters**

- **system**  [an instance of the LTI class or a tuple of array_like] describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of *lti*)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
X0 [1-D array_like, optional] The initial condition of the state vector. Default: 0 (the zero vector).
T [1-D array_like, optional] The time steps at which the input is defined and at which the output is desired. If T is not given, the function will generate a set of time samples automatically.
N [int, optional] Number of time points to compute. Default: 100.
kwarg [various types] Additional keyword arguments are passed on to the function scipy.signal.lsim2, which in turn passes them on to scipy.integrate.odeint; see the latter’s documentation for information about these arguments.

Returns

T [ndarray] The time values for the output.
yout [ndarray] The output response of the system.

See also:

impulse, lsim2, scipy.integrate.odeint

Notes

The solution is generated by calling scipy.signal.lsim2, which uses the differential equation solver scipy.integrate.odeint.

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. s^2 + 3s + 5 would be represented as [1, 3, 5]).

New in version 0.8.0.
Examples

Compute the impulse response of a second order system with a repeated root: \( x''(t) + 2x'(t) + x(t) = u(t) \)

```python
>>> from scipy import signal
>>> system = ([1.0], [1.0, 2.0, 1.0])
>>> t, y = signal.impulse2(system)
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, y)
```

scipy.signal.step

scipy.signal.step(system, X0=None, T=None, N=None)

Step response of continuous-time system.

Parameters

- **system** [an instance of the LTI class or a tuple of array_like] describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of lti)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
- **X0** [array_like, optional] Initial state-vector (default is zero).
- **T** [array_like, optional] Time points (computed if not given).
- **N** [int, optional] Number of time points to compute if T is not given.

Returns

- **T** [1D ndarray] Output time points.
- **yout** [1D ndarray] Step response of system.

See also:

scipy.signal.step2
Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \(s^2 + 3s + 5\) would be represented as \([1, 3, 5]\)).

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> lti = signal.lti([1.0], [1.0, 1.0])
>>> t, y = signal.step(lti)
>>> plt.plot(t, y)
>>> plt.xlabel('Time [s]')
>>> plt.ylabel('Amplitude')
>>> plt.title('Step response for 1. Order Lowpass')
>>> plt.grid()
```

![Step response for 1. Order Lowpass](image)

scipy.signal.step2

scipy.signal.step2(system, X0=None, T=None, N=None, **kwargs)

Step response of continuous-time system.

This function is functionally the same as `scipy.signal.step`, but it uses the function `scipy.signal.lsim2` to compute the step response.

Parameters

- **system** [an instance of the LTI class or a tuple of array_like] describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of `lti`)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
- **X0** [array_like, optional] Initial state-vector (default is zero).
- **T** [array_like, optional] Time points (computed if not given).
[N, optional] Number of time points to compute if T is not given.

[kwargs] Additional keyword arguments are passed on the function `scipy.signal.lsim2`, which in turn passes them on to `scipy.integrate.odeint`. See the documentation for `scipy.integrate.odeint` for information about these arguments.

**Returns**

[T] [1D ndarray] Output time points.

[yout] [1D ndarray] Step response of system.

**See also:**

`scipy.signal.step`

**Notes**

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. $s^2 + 3s + 5$ would be represented as `[1, 3, 5]`).

New in version 0.8.0.

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> lti = signal.lti([1.0], [1.0, 1.0])
>>> t, y = signal.step2(lti)
>>> plt.plot(t, y)
>>> plt.xlabel('Time [s]')
>>> plt.ylabel('Amplitude')
>>> plt.title('Step response for 1. Order Lowpass')
>>> plt.grid()
```

![Step response for 1. Order Lowpass](image)
scipy.signal.freqresp

scipy.signal.freqresp(system, w=None, n=10000)

Calculate the frequency response of a continuous-time system.

Parameters

- **system** [an instance of the lti class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of lti)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
- **w** [array_like, optional] Array of frequencies (in rad/s). Magnitude and phase data is calculated for every value in this array. If not given, a reasonable set will be calculated.
- **n** [int, optional] Number of frequency points to compute if w is not given. The n frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

Returns

- **w** [1D ndarray] Frequency array [rad/s]
- **H** [1D ndarray] Array of complex magnitude values

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \(s^2 + 3s + 5\) would be represented as \([1, 3, 5]\)).

Examples

Generating the Nyquist plot of a transfer function

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Construct the transfer function \(H(s) = \frac{5}{(s-1)^2}\):

```python
>>> s1 = signal.ZerosPolesGain([], [1, 1, 1], [5])
```n

```python
>>> w, H = signal.freqresp(s1)
```n
```python
>>> plt.figure()
>>> plt.plot(H.real, H.imag, "b")
>>> plt.plot(H.real, -H.imag, "r")
>>> plt.show()
```
scipy.signal.bode

scipy.signal.bode(system, w=None, n=100)

Calculate Bode magnitude and phase data of a continuous-time system.

**Parameters**

- **system** [an instance of the LTI class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of `lti`)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
- **w** [array_like, optional] Array of frequencies (in rad/s). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.
- **n** [int, optional] Number of frequency points to compute if `w` is not given. The `n` frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

**Returns**

- **w** [1D ndarray] Frequency array [rad/s]
- **mag** [1D ndarray] Magnitude array [dB]
- **phase** [1D ndarray] Phase array [deg]

**Notes**

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \(s^2 + 3s + 5\) would be represented as `[1, 3, 5]`).

New in version 0.11.0.
### Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> sys = signal.TransferFunction([1], [1, 1])
>>> w, mag, phase = signal.bode(sys)

>>> plt.figure()
>>> plt.semilogx(w, mag)  # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()
```

![Bode magnitude plot](image1.png)

**scipy.signal.dlti**

```python
class scipy.signal.dlti(*system, **kwargs)
```

Discrete-time linear time invariant system base class.

**Parameters**

*system: arguments

The `dlti` class can be instantiated with either 2, 3 or 4 arguments. The following gives the number of arguments and the corresponding discrete-time subclass that is created:

- **2**: `TransferFunction`: (numerator, denominator)
- **3**: `ZerosPolesGain`: (zeros, poles, gain)
- **4**: `StateSpace`: (A, B, C, D)

Each argument can be an array or a sequence.

**dt: float, optional**

Sampling time [s] of the discrete-time systems. Defaults to True (unspecified sampling time). Must be specified as a keyword argument, for example, `dt=0.1`.

**See also:**

`ZerosPolesGain, StateSpace, TransferFunction, lti`

**Notes**

`dlti` instances do not exist directly. Instead, `dlti` creates an instance of one of its subclasses: `StateSpace`, `TransferFunction` or `ZerosPolesGain`.

Changing the value of properties that are not directly part of the current system representation (such as the zeros of a `StateSpace` system) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.

If (numerator, denominator) is passed in for *system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g., \(z^2 + 3z + 5\) would be represented as \([1, 3, 5]\)).

New in version 0.18.0.
Examples

```python
>>> from scipy import signal

>>> signal.dlti(1, 2, 3, 4)
StateSpaceDiscrete(
    array([[1]]),
    array([[2]]),
    array([[3]]),
    array([[4]]),
dt: True
)

>>> signal.dlti(1, 2, 3, 4, dt=0.1)
StateSpaceDiscrete(
    array([[1]]),
    array([[2]]),
    array([[3]]),
    array([[4]]),
dt: 0.1
)

Construct the transfer function $H(z) = \frac{5(z-1)(z-2)}{(z-3)(z-4)}$ with a sampling time of 0.1 seconds:

```python
>>> signal.dlti([1, 2], [3, 4], 5, dt=0.1)
ZerosPolesGainDiscrete(
    array([1, 2]),
    array([3, 4]),
    5,
    dt: 0.1
)
```

Construct the transfer function $H(z) = \frac{3z+4}{1z+2}$ with a sampling time of 0.1 seconds:

```python
>>> signal.dlti([3, 4], [1, 2], dt=0.1)
TransferFunctionDiscrete(
    array([3., 4.]),
    array([1., 2.]),
    dt: 0.1
)
```

Attributes

- `dt`: Return the sampling time of the system.
- `poles`: Poles of the system.
- `zeros`: Zeros of the system.

### `scipy.signal.dlti.bode`

```python
dlti.bode (w=None, n=100)
```

Calculate Bode magnitude and phase data of a discrete-time system. Returns a 3-tuple containing arrays of frequencies [rad/s], magnitude [dB] and phase [deg]. See `dbode` for details.

### Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Construct the transfer function \( H(z) = \frac{1}{z^2 + 2z + 3} \) with sampling time 0.5s:

```python
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.5)
```  
Equivalent: `signal.dbode(sys)`

```python
>>> w, mag, phase = sys.bode()
>>> plt.figure()
>>> plt.semilogx(w, mag)  # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()
```

### `scipy.signal.dlti.freqresp`

```python
dlti.freqresp (w=None, n=10000, whole=False)
```

Calculate the frequency response of a discrete-time system. Returns a 2-tuple containing arrays of frequencies [rad/s] and complex magnitude. See `dfreqresp` for details.
3.3. API definition
**scipy.signal.dlti.impulse**

```python
dlti.impulse(x0=None, t=None, n=None)
```

Return the impulse response of the discrete-time `dlti` system. See `dimpulse` for details.

**scipy.signal.dlti.output**

```python
dlti.output(u, t, x0=None)
```

Return the response of the discrete-time system to input `u`. See `dlsim` for details.

**scipy.signal.dlti.step**

```python
dlti.step(x0=None, t=None, n=None)
```

Return the step response of the discrete-time `dlti` system. See `dstep` for details.

**scipy.signal.dlsim**

```python
scipy.signal.dlsim(system, u, t=None, x0=None)
```

Simulate output of a discrete-time linear system.

**Parameters**

- `system` [tuple of array_like or instance of `dlti`]: A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1: (instance of `dlti`)
  - 3: (num, den, dt)
  - 4: (zeros, poles, gain, dt)
  - 5: (A, B, C, D, dt)
- `u` [array_like]: An input array describing the input at each time `t` (interpolation is assumed between given times). If there are multiple inputs, then each column of the rank-2 array represents an input.
- `t` [array_like, optional]: The time steps at which the input is defined. If `t` is given, it must be the same length as `u`, and the final value in `t` determines the number of steps returned in the output.
- `x0` [array_like, optional]: The initial conditions on the state vector (zero by default).

**Returns**

- `tout` [ndarray]: Time values for the output, as a 1-D array.
- `yout` [ndarray]: System response, as a 1-D array.
- `xout` [ndarray, optional]: Time-evolution of the state-vector. Only generated if the input is a `StateSpace` system.

See also:

- `lsim`, `dstep`, `dimpulse`, `cont2discrete`
Examples

A simple integrator transfer function with a discrete time step of 1.0 could be implemented as:

```python
>>> from scipy import signal
>>> tf = ([1.0,], [1.0, -1.0, 1.0])
>>> t_in = [0.0, 1.0, 2.0, 3.0]
>>> u = np.asarray([0.0, 0.0, 1.0, 1.0])
>>> t_out, y = signal.dlsim(tf, u, t=t_in)
>>> y.T
array([[ 0.,  0.,  0.,  1.]])
```

scipy.signal.dimpulse

scipy.signal.dimpulse (system, x0=None, t=None, n=None)

Impulse response of discrete-time system.

**Parameters**

- `system`: [tuple of array_like or instance of dlti] A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1: (instance of dlti)
  - 3: (num, den, dt)
  - 4: (zeros, poles, gain, dt)
  - 5: (A, B, C, D, dt)
- `x0`: [array_like, optional] Initial state-vector. Defaults to zero.
- `n`: [int, optional] The number of time points to compute (if `t` is not given).

**Returns**

- `tout`: [ndarray] Time values for the output, as a 1-D array.
- `yout`: [tuple of ndarray] Impulse response of system. Each element of the tuple represents the output of the system based on an impulse in each input.

See also:

impulse, dstep, dlsim, cont2discrete

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> butter = signal.dlti(*signal.butter(3, 0.5))
>>> t, y = signal.dimpulse(butter, n=25)
>>> plt.step(t, np.squeeze(y))
>>> plt.grid()
>>> plt.xlabel('n [samples]')
>>> plt.ylabel('Amplitude')
```
scipy.signal.dstep

scipy.signal.dstep(system, x0=None, t=None, n=None)
Step response of discrete-time system.

Parameters

- **system** [tuple of array_like] A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1: (instance of dlti)
  - 3: (num, den, dt)
  - 4: (zeros, poles, gain, dt)
  - 5: (A, B, C, D, dt)

- **x0** [array_like, optional] Initial state-vector. Defaults to zero.

- **t** [array_like, optional] Time points. Computed if not given.

- **n** [int, optional] The number of time points to compute (if t is not given).

Returns

- **tout** [ndarray] Output time points, as a 1-D array.

- **yout** [tuple of ndarray] Step response of system. Each element of the tuple represents the output of the system based on a step response to each input.

See also:

- step, dimpulse, dlsim, cont2discrete
Examples

```python
from scipy import signal
import matplotlib.pyplot as plt

butter = signal.dlti(signal.butter(3, 0.5))
t, y = signal.dstep(butter, n=25)
plt.step(t, np.squeeze(y))
plt.grid()
plt.xlabel('n [samples]')
plt.ylabel('Amplitude')
```

### scipy.signal.dfreqresp

**scipy.signal.dfreqresp** *(system, w=None, n=10000, whole=False)*

Calculate the frequency response of a discrete-time system.

**Parameters**

- **system** [an instance of the `dlti` class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of `dlti`)
  - 2 (numerator, denominator, dt)
  - 3 (zeros, poles, gain, dt)
  - 4 (A, B, C, D, dt)
- **w** [array_like, optional] Array of frequencies (in radians/sample). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.
- **n** [int, optional] Number of frequency points to compute if `w` is not given. The `n` frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.
- **whole** [bool, optional] Normally, if ‘w’ is not given, frequencies are computed from 0 to the Nyquist frequency, pi radians/sample (upper-half of unit-circle). If `whole` is True, compute frequencies from 0 to 2*pi radians/sample.

**Returns**
\[ w \quad [1D \text{ndarray}] \text{ Frequency array [radians/sample]} \]
\[ H \quad [1D \text{ndarray}] \text{ Array of complex magnitude values} \]

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \( z^2 + 3z + 5 \) would be represented as \([1, 3, 5]\)).

New in version 0.18.0.

Examples

Generating the Nyquist plot of a transfer function

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Construct the transfer function \( H(z) = \frac{1}{z^2 + 2z + 3} \) with a sampling time of 0.05 seconds:

```python
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.05)
```

```python
>>> w, H = signal.dfreqresp(sys)

```python
>>> plt.figure()
>>> plt.plot(H.real, H.imag, "b")
>>> plt.plot(H.real, -H.imag, "r")
>>> plt.show()
```

![Nyquist plot example](image-url)
**scipy.signal.dbode**

`scipy.signal.dbode(system, w=None, n=100)`

Calculate Bode magnitude and phase data of a discrete-time system.

**Parameters**

- **system** [an instance of the LTI class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of `dlti`)
  - 2 (num, den, dt)
  - 3 (zeros, poles, gain, dt)
  - 4 (A, B, C, D, dt)
- **w** [array_like, optional] Array of frequencies (in radians/sample). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.
- **n** [int, optional] Number of frequency points to compute if w is not given. The n frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

**Returns**

- **w** [1D ndarray] Frequency array [rad/time_unit]
- **mag** [1D ndarray] Magnitude array [dB]
- **phase** [1D ndarray] Phase array [deg]

**Notes**

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \(z^2 + 3z + 5\) would be represented as [1, 3, 5]).

New in version 0.18.0.

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Construct the transfer function \(H(z) = \frac{1}{z^2 + 2z + 3}\) with a sampling time of 0.05 seconds:

```python
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.05)
```  
Equivalent: `sys.bode()`

```python
>>> w, mag, phase = signal.dbode(sys)
```

```python
>>> plt.figure()
>>> plt.semilogx(w, mag)  # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()
```

### scipy.signal.tf2zpk

**scipy.signal.tf2zpk**(b, a)

Return zero, pole, gain (z, p, k) representation from a numerator, denominator representation of a linear filter.

**Parameters**

- **b** [array_like] Numerator polynomial coefficients.
- **a** [array_like] Denominator polynomial coefficients.

**Returns**

- **z** [ndarray] Zeros of the transfer function.
- **p** [ndarray] Poles of the transfer function.
- **k** [float] System gain.

**Notes**

If some values of `b` are too close to 0, they are removed. In that case, a BadCoefficients warning is emitted.

The `b` and `a` arrays are interpreted as coefficients for positive, descending powers of the transfer function variable. So the inputs `b = [b_0, b_1, ..., b_M]` and `a = [a_0, a_1, ..., a_N]` can represent an analog filter of the form:

\[
H(s) = \frac{b_0s^M + b_1s^{(M-1)} + \cdots + b_M}{a_0s^N + a_1s^{(N-1)} + \cdots + a_N}
\]

or a discrete-time filter of the form:

\[
H(z) = \frac{b_0z^M + b_1z^{(M-1)} + \cdots + b_M}{a_0z^N + a_1z^{(N-1)} + \cdots + a_N}
\]
This “positive powers” form is found more commonly in controls engineering. If \( M \) and \( N \) are equal (which is true for all filters generated by the bilinear transform), then this happens to be equivalent to the “negative powers” discrete-time form preferred in DSP:

\[
H(z) = \frac{b_0 + b_1 z^{-1} + \cdots + b_M z^{-M}}{a_0 + a_1 z^{-1} + \cdots + a_N z^{-N}}
\]

Although this is true for common filters, remember that this is not true in the general case. If \( M \) and \( N \) are not equal, the discrete-time transfer function coefficients must first be converted to the “positive powers” form before finding the poles and zeros.

**scipy.signal.tf2sos**

`scipy.signal.tf2sos(b, a, pairing=None, *, analog=False)`

Return second-order sections from transfer function representation

**Parameters**

- **b** [array_like] Numerator polynomial coefficients.
- **a** [array_like] Denominator polynomial coefficients.
- **pairing** [[None, ‘nearest’, ‘keep_odd’, ‘minimal’], optional] The method to use to combine pairs of poles and zeros into sections. See `zpk2sos` for information and restrictions on `pairing` and `analog` arguments.
- **analog** [bool, optional] If True, system is analog, otherwise discrete. New in version 1.8.0.

**Returns**

- **sos** [ndarray] Array of second-order filter coefficients, with shape \((n\_sections, 6)\). See `sosfilt` for the SOS filter format specification.

See also:

`zpk2sos, sosfilt`

**Notes**

It is generally discouraged to convert from TF to SOS format, since doing so usually will not improve numerical precision errors. Instead, consider designing filters in ZPK format and converting directly to SOS. TF is converted to SOS by first converting to ZPK format, then converting ZPK to SOS.

New in version 0.16.0.

**scipy.signal.tf2ss**

`scipy.signal.tf2ss(num, den)`

Transfer function to state-space representation.

**Parameters**

- **num, den** [array_like] Sequences representing the coefficients of the numerator and denominator polynomials, in order of descending degree. The denominator needs to be at least as long as the numerator.

**Returns**

- **A, B, C, D** [ndarray] State space representation of the system, in controller canonical form.
Examples

Convert the transfer function:

\[
H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1}
\]

```python
>>> num = [1, 3, 3]
>>> den = [1, 2, 1]
```

to the state-space representation:

\[
\dot{x}(t) = \begin{bmatrix} -2 & -1 \\ 1 & 0 \end{bmatrix} x(t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix} u(t)
\]

\[
y(t) = \begin{bmatrix} 1 & 2 \end{bmatrix} x(t) + \begin{bmatrix} 1 \end{bmatrix} u(t)
\]

```python
>>> from scipy.signal import tf2ss
>>> A, B, C, D = tf2ss(num, den)
>>> A
array([[-2., -1.],
       [ 1.,  0.]])
>>> B
array([[ 1.],
       [ 0.]])
>>> C
array([[ 1.,  2.]])
>>> D
array([[ 1.]])
```

scipy.signal.zpk2tf

```
scipy.signal.zpk2tf(z, p, k)
```

Return polynomial transfer function representation from zeros and poles

**Parameters**

- `z` [array_like] Zeros of the transfer function.
- `p` [array_like] Poles of the transfer function.
- `k` [float] System gain.

**Returns**

- `b` [ndarray] Numerator polynomial coefficients.
- `a` [ndarray] Denominator polynomial coefficients.

scipy.signal.zpk2sos

```
scipy.signal.zpk2sos(z, p, k, pairing=None, *, analog=False)
```

Return second-order sections from zeros, poles, and gain of a system

**Parameters**

- `z` [array_like] Zeros of the transfer function.
- `p` [array_like] Poles of the transfer function.
- `k` [float] System gain.
pairing  [[None, 'nearest', 'keep_odd', 'minimal'], optional] The method to use to combine pairs of poles and zeros into sections. If analog is False and pairing is None, pairing is set to 'nearest'; if analog is True, pairing must be 'minimal', and is set to that if it is None.

analog  [bool, optional] If True, system is analog, otherwise discrete. New in version 1.8.0.

Returns
sos  [ndarray] Array of second-order filter coefficients, with shape (n_sections, 6). See sosfilt for the SOS filter format specification.

See also:
sosfilt

Notes
The algorithm used to convert ZPK to SOS format is designed to minimize errors due to numerical precision issues. The pairing algorithm attempts to minimize the peak gain of each biquadratic section. This is done by pairing poles with the nearest zeros, starting with the poles closest to the unit circle for discrete-time systems, and poles closest to the imaginary axis for continuous-time systems.

pairing='minimal' outputs may not be suitable for sosfilt, and analog=True outputs will never be suitable for sosfilt.

Algorithms
The steps in the pairing='nearest', pairing='keep_odd', and pairing='minimal' algorithms are mostly shared. The 'nearest' algorithm attempts to minimize the peak gain, while 'keep_odd' minimizes peak gain under the constraint that odd-order systems should retain one section as first order. 'minimal' is similar to 'keep_odd', but no additional poles or zeros are introduced.

The algorithm steps are as follows:

As a pre-processing step for pairing='nearest', pairing='keep_odd', add poles or zeros to the origin as necessary to obtain the same number of poles and zeros for pairing. If pairing == 'nearest' and there are an odd number of poles, add an additional pole and a zero at the origin.

The following steps are then iterated over until no more poles or zeros remain:

1. Take the (next remaining) pole (complex or real) closest to the unit circle (or imaginary axis, for analog=True) to begin a new filter section.
2. If the pole is real and there are no other remaining real poles\(^1\), add the closest real zero to the section and leave it as a first order section. Note that after this step we are guaranteed to be left with an even number of real poles, complex poles, real zeros, and complex zeros for subsequent pairing iterations.
3. Else:
   1. If the pole is complex and the zero is the only remaining real zero*, then pair the pole with the next closest zero (guaranteed to be complex). This is necessary to ensure that there will be a real zero remaining to eventually create a first-order section (thus keeping the odd order).
   2. Else pair the pole with the closest remaining zero (complex or real).
3. Proceed to complete the second-order section by adding another pole and zero to the current pole and zero in the section:
   1. If the current pole and zero are both complex, add their conjugates.

\(^1\) This conditional can only be met for specific odd-order inputs with the pairing = 'keep_odd' or 'minimal' methods.
2. Else if the pole is complex and the zero is real, add the conjugate pole and the next closest real zero.
3. Else if the pole is real and the zero is complex, add the conjugate zero and the real pole closest to those zeros.
4. Else (we must have a real pole and real zero) add the next real pole closest to the unit circle, and then add the real zero closest to that pole.

New in version 0.16.0.

Examples

Design a 6th order low-pass elliptic digital filter for a system with a sampling rate of 8000 Hz that has a pass-band corner frequency of 1000 Hz. The ripple in the pass-band should not exceed 0.087 dB, and the attenuation in the stop-band should be at least 90 dB.

In the following call to `ellip`, we could use `output='sos'`, but for this example, we'll use `output='zpk'`, and then convert to SOS format with `zpk2sos`:

```python
>>> from scipy import signal
>>> z, p, k = signal.ellip(6, 0.087, 90, 1000/(0.5*8000), output='zpk')
```

Now convert to SOS format.

```python
>>> sos = signal.zpk2sos(z, p, k)
```

The coefficients of the numerators of the sections:

```python
>>> sos[:, :3]
array([[ 0.0014154 , 0.00248707, 0.0014154 ],
       [ 1. , 0.72965193, 1. ],
       [ 1. , 0.17594966, 1. ]])
```

The symmetry in the coefficients occurs because all the zeros are on the unit circle.

The coefficients of the denominators of the sections:

```python
>>> sos[:, 3:]
array([[ 1. , -1.32543251, 0.46989499],
       [ 1. , -1.26117915, 0.6262586 ],
       [ 1. , -1.25707217, 0.86199667]])
```

The next example shows the effect of the `pairing` option. We have a system with three poles and three zeros, so the SOS array will have shape (2, 6). The means there is, in effect, an extra pole and an extra zero at the origin in the SOS representation.

```python
>>> z1 = np.array([-1, -0.5-0.5j, -0.5+0.5j])
>>> p1 = np.array([0.75, 0.8+0.1j, 0.8-0.1j])
```

With `pairing='nearest'` (the default), we obtain

```python
>>> signal.zpk2sos(z1, p1, 1)
array([[ 1. , 1. , 0.5 , 1. , -0.75, 0. ],
       [ 1. , 1. , 0. , 1. , -1.6 , 0.65]])
```
The first section has the zeros {-0.5-0.05j, -0.5+0.5j} and the poles {0, 0.75}, and the second section has the zeros {-1, 0} and poles {0.8+0.1j, 0.8-0.1j}. Note that the extra pole and zero at the origin have been assigned to different sections.

With `pairing='keep_odd'`, we obtain:

```python
>>> signal.zpk2sos(z1, p1, 1, pairing='keep_odd')
array([[ 1. , 1. , 0. , 1. , -0.75, 0. ],
       [ 1. , 1. , 0.5 , 1. , -1.6 , 0.65]])
```

The extra pole and zero at the origin are in the same section. The first section is, in effect, a first-order section.

With `pairing='minimal'`, the first-order section doesn’t have the extra pole and zero at the origin:

```python
>>> signal.zpk2sos(z1, p1, 1, pairing='minimal')
array([[ 0. , 1. , 1. , 0. , 1. , -0.75],
       [ 1. , 1. , 0.5 , 1. , -1.6 , 0.65]])
```

`sparse.signal.zpk2ss`

`sparse.signal.zpk2ss(z, p, k)`

Zero-pole-gain representation to state-space representation

**Parameters**

- `z` [sequence] Zeros and poles.
- `p` [float] System gain.
- `k` [float] System gain.

**Returns**

- `A, B, C, D` [ndarray] State space representation of the system, in controller canonical form.

`sparse.signal.ss2tf`

`sparse.signal.ss2tf(A, B, C, D, input=0)`  
State-space to transfer function.

A, B, C, D defines a linear state-space system with `p` inputs, `q` outputs, and `n` state variables.

**Parameters**

- `A` [array_like] State (or system) matrix of shape `(n, n)`
- `B` [array_like] Input matrix of shape `(n, p)`
- `C` [array_like] Output matrix of shape `(q, n)`
- `D` [array_like] Feedthrough (or feedforward) matrix of shape `(q, p)`
- `input` [int, optional] For multiple-input systems, the index of the input to use.

**Returns**

- `num` [2-D ndarray] Numerator(s) of the resulting transfer function(s). `num` has one row for each of the system’s outputs. Each row is a sequence representation of the numerator polynomial.
- `den` [1-D ndarray] Denominator of the resulting transfer function(s). `den` is a sequence representation of the denominator polynomial.
Examples

Convert the state-space representation:

\[
\begin{align*}
\dot{x}(t) &= \begin{bmatrix} -2 & -1 \\ 1 & 0 \end{bmatrix} x(t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix} u(t) \\
y(t) &= \begin{bmatrix} 1 & 2 \end{bmatrix} x(t) + \begin{bmatrix} 1 \end{bmatrix} u(t)
\end{align*}
\]

```python
>>> A = [[-2, -1], [1, 0]]
>>> B = [[1], [0]]  # 2-D column vector
>>> C = [[1, 2]]    # 2-D row vector
>>> D = 1
```
to the transfer function:

\[
H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1}
\]

```python
>>> from scipy.signal import ss2tf
>>> ss2tf(A, B, C, D)
(array([[1., 3., 3.]]), array([ 1., 2., 1.]))
```

**scipy.signal.ss2zpk**

**scipy.signal.ss2zpk** (*A*, *B*, *C*, *D*, *input*=`0`)

State-space representation to zero-pole-gain representation.

*A*, *B*, *C*, *D* defines a linear state-space system with *p* inputs, *q* outputs, and *n* state variables.

**Parameters**

- **A** : [array_like] State (or system) matrix of shape (*n*, *n*)
- **B** : [array_like] Input matrix of shape (*n*, *p*)
- **C** : [array_like] Output matrix of shape (*q*, *n*)
- **D** : [array_like] Feedthrough (or feedforward) matrix of shape (*q*, *p*)
- **input** : [int, optional] For multiple-input systems, the index of the input to use.

**Returns**

- **z** : [sequence] Zeros and poles.
- **p** : [array] Poles of the transfer function.
- **k** : [float] System gain.

**scipy.signal.sos2zpk**

**scipy.signal.sos2zpk** (*sos*)

Return zeros, poles, and gain of a series of second-order sections.

**Parameters**

- **sos** : [array_like] Array of second-order filter coefficients, must have shape (*n_sections*, 6). See *sosfilt* for the SOS filter format specification.

**Returns**

- **z** : [ndarray] Zeros of the transfer function.
- **p** : [ndarray] Poles of the transfer function.
- **k** : [float] System gain.
**Notes**

The number of zeros and poles returned will be \( n \_sections \times 2 \) even if some of these are (effectively) zero.

New in version 0.16.0.

**scipy.signal.sos2tf**

`scipy.signal.sos2tf(sos)`

Return a single transfer function from a series of second-order sections

**Parameters**

- `sos` [array_like] Array of second-order filter coefficients, must have shape \((n \_sections, 6)\). See `sosfilt` for the SOS filter format specification.

**Returns**

- `b` [ndarray] Numerator polynomial coefficients.
- `a` [ndarray] Denominator polynomial coefficients.

**Notes**

New in version 0.16.0.

**scipy.signal.cont2discrete**

`scipy.signal.cont2discrete(system, dt, method='zoh', alpha=None)`

Transform a continuous to a discrete state-space system.

**Parameters**

- `system` [a tuple describing the system or an instance of lti] The following gives the number of elements in the tuple and the interpretation:
  - 1: (instance of lti)
  - 2: (num, den)
  - 3: (zeros, poles, gain)
  - 4: (A, B, C, D)
- `dt` [float] The discretization time step.
- `method` [str, optional] Which method to use:
  - gbt: generalized bilinear transformation
  - bilinear: Tustin's approximation (“gbt” with alpha=0.5)
  - euler: Euler (or forward differencing) method (“gbt” with alpha=0)
  - backward_diff: Backwards differencing (“gbt” with alpha=1.0)
  - zoh: zero-order hold (default)
  - foh: first-order hold (versionadded: 1.3.0)
  - impulse: equivalent impulse response (versionadded: 1.3.0)
- `alpha` [float within [0, 1], optional] The generalized bilinear transformation weighting parameter, which should only be specified with method="gbt", and is ignored otherwise

**Returns**

- `sysd` [tuple containing the discrete system] Based on the input type, the output will be of the form
  - (num, den, dt) for transfer function input
  - (zeros, poles, gain, dt) for zeros-poles-gain input
  - (A, B, C, D, dt) for state-space system input
Notes

By default, the routine uses a Zero-Order Hold (zoh) method to perform the transformation. Alternatively, a
generalized bilinear transformation may be used, which includes the common Tustin's bilinear approximation, an
Euler’s method technique, or a backwards differencing technique.

The Zero-Order Hold (zoh) method is based on [1], the generalized bilinear approximation is based on [2] and [3],
the First-Order Hold (foh) method is based on [4].

References

[1], [2], [3], [4]

Examples

We can transform a continuous state-space system to a discrete one:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import cont2discrete, lti, dlti, dstep

Define a continuous state-space system.

```python
>>> A = np.array([[0, 1], [-10., -3]])
>>> B = np.array([[0], [10.]])
>>> C = np.array([[1., 0]])
>>> D = np.array([[0.]])
>>> l_system = lti(A, B, C, D)
>>> t, x = l_system.step(T=np.linspace(0, 5, 100))
>>> fig, ax = plt.subplots()
>>> ax.plot(t, x, label='Continuous', linewidth=3)
```

Transform it to a discrete state-space system using several methods.

```python
>>> dt = 0.1
>>> for method in ['zoh', 'bilinear', 'euler', 'backward_diff', 'foh',
                 'impulse']:
...    d_system = cont2discrete((A, B, C, D), dt, method=method)
...    s, x_d = dstep(d_system)
...    ax.step(s, np.squeeze(x_d), label=method, where='post')
>>> ax.axis([t[0], t[-1], x[0], 1.4])
>>> ax.legend(loc='best')
>>> fig.tight_layout()
>>> plt.show()
```
scipy.signal.place_poles

`scipy.signal.place_poles(A, B, poles, method='YT', rtol=0.001, maxiter=30)`

Compute K such that eigenvalues \((A - \text{dot}(B, K))\) = poles.

K is the gain matrix such as the plant described by the linear system \(AX + BU\) will have its closed-loop poles, i.e. the eigenvalues \(A - B*K\), as close as possible to those asked for in poles.

SISO, MISO and MIMO systems are supported.

**Parameters**

- **A, B** [ndarray] State-space representation of linear system \(AX + BU\).
- **poles** [array_like] Desired real poles and/or complex conjugates poles. Complex poles are only supported with method='YT' (default).
- **method:** {'YT', 'KNV0'}, optional
  Which method to choose to find the gain matrix K. One of:
  - ‘YT’: Yang Tits
  - ‘KNV0’: Kautsky, Nichols, Van Dooren update method 0
  See References and Notes for details on the algorithms.
- **rtol:** float, optional
  After each iteration the determinant of the eigenvectors of \(A - B*K\) is compared to its previous value, when the relative error between these two values becomes lower than \(rtol\) the algorithm stops. Default is 1e-3.
- **maxiter:** int, optional
  Maximum number of iterations to compute the gain matrix. Default is 30.

**Returns**

- **full_state_feedback** [Bunch object]
  full_state_feedback is composed of:
  - **gain_matrix** [1-D ndarray] The closed loop matrix K such as the eigenvalues of \(A-BK\) are as close as possible to the requested poles.
computed_poles

[1-D ndarray] The poles corresponding to $A - BK$ sorted as first the real poles in increasing order, then the complex conjugates in lexicographic order.

requested_poles

[1-D ndarray] The poles the algorithm was asked to place sorted as above, they may differ from what was achieved.

$X$

[2-D ndarray] The transfer matrix such as $X \times \text{diag}(\text{poles}) = (A - B*K) \times X$ (see Notes)

rtol

[float] The relative tolerance achieved on $\det(X)$ (see Notes). \text{rtol} will be NaN if it is possible to solve the system $\text{diag}(\text{poles}) = (A - B*K)$, or 0 when the optimization algorithms can’t do anything i.e when $B\.shape[1] == 1$.

nb_iter

[int] The number of iterations performed before converging. \text{nb_iter} will be NaN if it is possible to solve the system $\text{diag}(\text{poles}) = (A - B*K)$, or 0 when the optimization algorithms can’t do anything i.e when $B\.shape[1] == 1$.

Notes

The Tits and Yang (YT), [2] paper is an update of the original Kautsky et al. (KNV) paper [1]. KNV relies on rank-1 updates to find the transfer matrix $X$ such that $X \times \text{diag}(\text{poles}) = (A - B*K) \times X$, whereas YT uses rank-2 updates. This yields on average more robust solutions (see [2] pp 21-22), furthermore the YT algorithm supports complex poles whereas KNV does not in its original version. Only update method 0 proposed by KNV has been implemented here, hence the name 'KNV0'.

KNV extended to complex poles is used in Matlab’s \texttt{place} function, YT is distributed under a non-free licence by Slicot under the name \texttt{robpole}. It is unclear and undocumented how KNV0 has been extended to complex poles (Tits and Yang claim on page 14 of their paper that their method can not be used to extend KNV to complex poles), therefore only YT supports them in this implementation.

As the solution to the problem of pole placement is not unique for MIMO systems, both methods start with a tentative transfer matrix which is altered in various way to increase its determinant. Both methods have been proven to converge to a stable solution, however depending on the way the initial transfer matrix is chosen they will converge to different solutions and therefore there is absolutely no guarantee that using 'KNV0' will yield results similar to Matlab’s or any other implementation of these algorithms.

Using the default method 'YT' should be fine in most cases; 'KNV0' is only provided because it is needed by 'YT' in some specific cases. Furthermore 'YT' gives on average more robust results than 'KNV0' when $\text{abs}(\det(X))$ is used as a robustness indicator.

[2] is available as a technical report on the following URL: \url{https://hdl.handle.net/1903/5598}

References

[1], [2]
Examples

A simple example demonstrating real pole placement using both KNV and YT algorithms. This is example number 1 from section 4 of the reference KNV publication ([1]):

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> A = np.array([[ 1.380, -0.2077,  6.715, -5.676 ],
                [-0.5814, -4.290,  0,  0.6750 ],
                [ 1.067,  4.273, -6.654,  5.893 ],
                [ 0.0480,  4.273,  1.343, -2.104 ]])
>>> B = np.array([[ 0,  5.679 ],
                [ 1.136,  1.136 ],
                [ 0,  0 ],
                [-3.146,  0 ]])
>>> P = np.array([-0.2, -0.5, -5.0566, -8.6659])

Now compute K with KNV method 0, with the default YT method and with the YT method while forcing 100 iterations of the algorithm and print some results after each call.

```python
>>> fsf1 = signal.place_poles(A, B, P, method='KNV0')
>>> fsf1.gain_matrix
array([[ 0.20071427, -0.96665799,  0.24066128, -0.10279785],
       [ 0.50587268,  0.57779091,  0.51795763, -0.41991442]])
```

```python
>>> fsf2 = signal.place_poles(A, B, P)  # uses YT method
>>> fsf2.computed_poles
array([-8.6659, -5.0566, -0.5 , -0.2 ])  
```  

```python
>>> fsf3 = signal.place_poles(A, B, P, rtol=-1, maxiter=100)
>>> fsf3.X
array([[ 0.52072442+0.j, -0.08409372+0.j, -0.56847937+0.j,  0.74823657+0.j],
       [-0.04977751+0.j, -0.80872954+0.j,  0.13566234+0.j, -0.29322906+0.j],
       [-0.82266932+0.j, -0.19168026+0.j, -0.56348322+0.j, -0.43815060+0.j],
       [ 0.22267347+0.j,  0.54967577+0.j, -0.58387806+0.j, -0.40271926+0.j]])
```

The absolute value of the determinant of X is a good indicator to check the robustness of the results, both 'KNV0' and 'YT' aim at maximizing it. Below a comparison of the robustness of the results above:

```python
>>> abs(np.linalg.det(fsf1.X)) < abs(np.linalg.det(fsf2.X))
True
>>> abs(np.linalg.det(fsf2.X)) < abs(np.linalg.det(fsf3.X))
True
```

Now a simple example for complex poles:

```python
>>> A = np.array([[ 0,  7/3.,  0,  0 ],
                [ 0,  0,  0,  7/9. ],
                [ 0, -0.25,  0,  0.25 ],
                [ 0,  0, -0.25,  0.25 ]])
>>> B = np.array([[ 0,  5/3. ],
                [ 0,  0 ],
                [ 0,  0 ],
                [ 0,  0 ]])
>>> P = np.array([-0.5, -0.5, -0.5, -0.5])
```
>>> B = np.array([[0, 0],
...                [0, 0],
...                [1, 0],
...                [0, 1]])
>>> P = np.array([-3, -1, -2-1j, -2+1j]) / 3.
>>> fsf = signal.place_poles(A, B, P, method='YT')

We can plot the desired and computed poles in the complex plane:

```python
>>> t = np.linspace(0, 2*np.pi, 401)
>>> plt.plot(np.cos(t), np.sin(t), 'k--')  # unit circle
>>> plt.plot(fsf.requested_poles.real, fsf.requested_poles.imag, 'wo', label='Desired')
>>> plt.plot(fsf.computed_poles.real, fsf.computed_poles.imag, 'bx', label='Placed')
>>> plt.grid()
>>> plt.axis('image')
>>> plt.axis([-1.1, 1.1, -1.1, 1.1])
>>> plt.legend(bbox_to_anchor=(1.05, 1), loc=2, numpoints=1)
```

### Waveforms

- **chirp(t, f0, t1, f1[, method, phi, vertex_zero])**: Frequency-swept cosine generator.
- **gausspulse(t[, fc, bw, bwrl, tpr, retquad, ...])**: Return a Gaussian modulated sinusoid.
- **max_len_seq(nbits[, state, length, taps])**: Maximum length sequence (MLS) generator.
- **sawtooth(t[, width])**: Return a periodic sawtooth or triangle waveform.
- **square(t[, duty])**: Return a periodic square-wave waveform.

continues on next page
Table 166 – continued from previous page

**Parameters**
- `t` [array_like] Times at which to evaluate the waveform.
- `f0` [float] Frequency (e.g. Hz) at time t=0.
- `t1` [float] Time at which f1 is specified.
- `f1` [float] Frequency (e.g. Hz) of the waveform at time t1.
- `method` [ {'linear', 'quadratic', 'logarithmic', 'hyperbolic'}, optional ] Kind of frequency sweep. If not given, `linear` is assumed. See Notes below for more details.
- `phi` [float, optional] Phase offset, in degrees. Default is 0.
- `vertex_zero` [bool, optional] This parameter is only used when `method` is 'quadratic'. It determines whether the vertex of the parabola that is the graph of the frequency is at t=0 or t=t1.

**Returns**
- `y` [ndarray] A numpy array containing the signal evaluated at t with the requested time-varying frequency. More precisely, the function returns \( \cos(\mathrm{phase} + (\pi/180)\times\phi) \) where \( \mathrm{phase} \) is the integral (from 0 to t) of \( 2\pi f(t) \). f(t) is defined below.

**See also:**
- `sweep_poly`

**Notes**

There are four options for the `method`. The following formulas give the instantaneous frequency (in Hz) of the signal generated by `chirp()`. For convenience, the shorter names shown below may also be used.

linear, lin, li:
- \( f(t) = f0 + (f1 - f0) \times t / t1 \)

quadratic, quad, q:
- The graph of the frequency f(t) is a parabola through (0, f0) and (t1, f1). By default, the vertex of the parabola is at (0, f0). If `vertex_zero` is False, then the vertex is at (t1, f1). The formula is:
  - if `vertex_zero` is True:
    \( f(t) = f0 + (f1 - f0) \times t**2 / t1**2 \)
  - else:
    \( f(t) = f1 - (f1 - f0) \times (t1 - t)**2 / t1**2 \)
- To use a more general quadratic function, or an arbitrary polynomial, use the function `scipy.signal.sweep_poly`.

logarithmic, log, lo:

\[ f(t) = f_0 \times (f_1/f_0)^{t/t_1} \]

\( f_0 \) and \( f_1 \) must be nonzero and have the same sign.
This signal is also known as a geometric or exponential chirp.

Hyperbolic, hyp:
\[
f(t) = \frac{f_0 \times f_1 \times t_1}{(f_0 - f_1) \times t + f_1 \times t_1}
\]

\( f_0 \) and \( f_1 \) must be nonzero.

### Examples

The following will be used in the examples:

```python
>>> from scipy.signal import chirp, spectrogram
>>> import matplotlib.pyplot as plt
```

For the first example, we’ll plot the waveform for a linear chirp from 6 Hz to 1 Hz over 10 seconds:

```python
>>> t = np.linspace(0, 10, 1500)
>>> w = chirp(t, f0=6, f1=1, t1=10, method='linear')
>>> plt.plot(t, w)
>>> plt.title("Linear Chirp, f(0)=6, f(10)=1")
>>> plt.xlabel('t (sec)')
>>> plt.show()
```

For the remaining examples, we’ll use higher frequency ranges, and demonstrate the result using `scipy.signal.spectrogram`. We’ll use a 4 second interval sampled at 7200 Hz.

```python
>>> fs = 7200
>>> T = 4
>>> t = np.arange(0, int(T*fs)) / fs
```

We’ll use this function to plot the spectrogram in each example.
```python
>>> def plot_spectrogram(title, w, fs):
    ...      ff, tt, Sxx = spectrogram(w, fs=fs, nperseg=256, nfft=576)
    ...      plt.pcolormesh(tt, ff[:145], Sxx[:145], cmap='gray_r', shading='gouraud')
    ...      plt.title(title)
    ...      plt.xlabel('t (sec)')
    ...      plt.ylabel('Frequency (Hz)')
    ...      plt.grid()

Quadratic chirp from 1500 Hz to 250 Hz (vertex of the parabolic curve of the frequency is at t=0):

```python
>>> w = chirp(t, f0=1500, f1=250, t1=T, method='quadratic')
>>> plot_spectrogram(f'Quadratic Chirp, f(0)=1500, f(T)=250', w, fs)
>>> plt.show()

```

```

Quadratic chirp from 1500 Hz to 250 Hz (vertex of the parabolic curve of the frequency is at t=T):

```python
>>> w = chirp(t, f0=1500, f1=250, t1=T, method='quadratic',
            ...         vertex_zero=False)
>>> plot_spectrogram(f'Quadratic Chirp, f(0)=1500, f(T)=250
...                  (vertex_zero=False)', w, fs)
>>> plt.show()

Logarithmic chirp from 1500 Hz to 250 Hz:

```python
>>> w = chirp(t, f0=1500, f1=250, t1=T, method='logarithmic')
>>> plot_spectrogram(f'Logarithmic Chirp, f(0)=1500, f(T)=250', w, fs)
>>> plt.show()

Hyperbolic chirp from 1500 Hz to 250 Hz:

```python
>>> w = chirp(t, f0=1500, f1=250, t1=T, method='hyperbolic')
>>> plot_spectrogram(f'Hyperbolic Chirp, f(0)=1500, f(T)=250', w, fs)
>>> plt.show()
```
Quadratic Chirp, $f(0)=1500$, $f(4)=250$  
(vertex_zero=False)

Logarithmic Chirp, $f(0)=1500$, $f(4)=250$
scipy.signal.gausspulse

scipy.signal.gausspulse(t, fc=1000, bw=0.5, bwr=-6, tpr=-60, retquad=False, retenv=False)

Return a Gaussian modulated sinusoid:

\[ \exp(-a t^2) \exp(1j*2*pi*fc*t) \].

If retquad is True, then return the real and imaginary parts (in-phase and quadrature). If retenv is True, then return the envelope (unmodulated signal). Otherwise, return the real part of the modulated sinusoid.

**Parameters**

- t : [ndarray or the string 'cutoff'] Input array.
- fc : [float, optional] Center frequency (e.g. Hz). Default is 1000.
- bw : [float, optional] Fractional bandwidth in frequency domain of pulse (e.g. Hz). Default is 0.5.
- bwr : [float, optional] Reference level at which fractional bandwidth is calculated (dB). Default is -6.
- tpr : [float, optional] If t is ‘cutoff’, then the function returns the cutoff time for when the pulse amplitude falls below tpr (in dB). Default is -60.
- retquad : [bool, optional] If True, return the quadrature (imaginary) as well as the real part of the signal. Default is False.
- retenv : [bool, optional] If True, return the envelope of the signal. Default is False.

**Returns**

- yI : [ndarray] Real part of signal. Always returned.
- yQ : [ndarray] Imaginary part of signal. Only returned if retquad is True.
- yenv : [ndarray] Envelope of signal. Only returned if retenv is True.

**See also:**

scipy.signal.morlet
Examples

Plot real component, imaginary component, and envelope for a 5 Hz pulse, sampled at 100 Hz for 2 seconds:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(-1, 1, 2 * 100, endpoint=False)
>>> i, q, e = signal.gausspulse(t, fc=5, retquad=True, retenv=True)
>>> plt.plot(t, i, t, q, t, e, '--')
```

scipy.signal.max_len_seq

`scipy.signal.max_len_seq(nbits, state=None, length=None, taps=None)`

Maximum length sequence (MLS) generator.

**Parameters**

- `nbits` [int] Number of bits to use. Length of the resulting sequence will be \((2^{*nbits}) - 1\). Note that generating long sequences (e.g., greater than `nbits == 16`) can take a long time.
- `state` [array_like, optional] If array, must be of length `nbits`, and will be cast to binary (bool) representation. If None, a seed of ones will be used, producing a repeatable representation. If `state` is all zeros, an error is raised as this is invalid. Default: None.
- `length` [int, optional] Number of samples to compute. If None, the entire length \((2^{*nbits}) - 1\) is computed.
- `taps` [array_like, optional] Polynomial taps to use (e.g., [7, 6, 1] for an 8-bit sequence). If None, taps will be automatically selected (for up to `nbits == 32`).

**Returns**

- `seq` [array] Resulting MLS sequence of 0’s and 1’s.
- `state` [array] The final state of the shift register.
Notes

The algorithm for MLS generation is generically described in:

https://en.wikipedia.org/wiki/Maximum_length_sequence

The default values for taps are specifically taken from the first option listed for each value of nbits in:

New in version 0.15.0.

Examples

MLS uses binary convention:

```python
>>> from scipy.signal import max_len_seq
>>> max_len_seq(4)[0]
array([1, 1, 1, 1, 0, 1, 0, 1, 1, 0, 0, 1, 0, 0, 0], dtype=int8)
```

MLS has a white spectrum (except for DC):

```python
>>> import matplotlib.pyplot as plt
>>> from numpy.fft import fft, ifft, fftshift, fftfreq
>>> seq = max_len_seq(6)[0]*2-1  # +1 and -1
>>> spec = fft(seq)
>>> N = len(seq)
>>> plt.plot(fftshift(fftfreq(N)), fftshift(np.abs(spec)), '-.')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```

Circular autocorrelation of MLS is an impulse:
Linear autocorrelation of MLS is approximately an impulse:

```python
>>> acorr = np.correlate(seq, seq, 'full')
>>> plt.figure()
>>> plt.plot(np.arange(-N+1, N), acorr, '.-')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```

scipy.signal.sawtooth

`scipy.signal.sawtooth(t, width=1)`

Return a periodic sawtooth or triangle waveform.

The sawtooth waveform has a period $2\pi$, rises from -1 to 1 on the interval 0 to $width \cdot 2\pi$, then drops from 1 to -1 on the interval $width \cdot 2\pi$ to $2\pi$. `width` must be in the interval $[0, 1]$.

Note that this is not band-limited. It produces an infinite number of harmonics, which are aliased back and forth across the frequency spectrum.

- **Parameters**
  - `t` [array_like] Time.
  - `width` [array_like, optional] Width of the rising ramp as a proportion of the total cycle. Default is 1, producing a rising ramp, while 0 produces a falling ramp. `width = 0.5` produces a triangle wave. If an array, causes wave shape to change over time, and must be the same length as `t`.

- **Returns**
  - `y` [ndarray] Output array containing the sawtooth waveform.
Examples

A 5 Hz waveform sampled at 500 Hz for 1 second:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(0, 1, 500)
>>> plt.plot(t, signal.sawtooth(2 * np.pi * 5 * t))
```
scipy.signal.square

`scipy.signal.square(t, duty=0.5)`

Return a periodic square-wave waveform.

The square wave has a period $2\pi$, has value +1 from 0 to $2\pi \cdot \text{duty}$ and -1 from $2\pi \cdot \text{duty}$ to $2\pi$. 

duty must be in the interval [0,1].

Note that this is not band-limited. It produces an infinite number of harmonics, which are aliased back and forth across the frequency spectrum.

**Parameters**

- **t** [array_like] The input time array.
- **duty** [array_like, optional] Duty cycle. Default is 0.5 (50% duty cycle). If an array, causes wave shape to change over time, and must be the same length as t.

**Returns**

- **y** [ndarray] Output array containing the square waveform.

**Examples**

A 5 Hz waveform sampled at 500 Hz for 1 second:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(0, 1, 500, endpoint=False)
>>> plt.plot(t, signal.square(2 * np.pi * 5 * t))
>>> plt.ylim(-2, 2)
```

A pulse-width modulated sine wave:

```python
>>> plt.figure()
>>> sig = np.sin(2 * np.pi * t)
>>> pwm = signal.square(2 * np.pi * 30 * t, duty=(sig + 1)/2)
>>> plt.subplot(2, 1, 1)
>>> plt.plot(t, sig)
>>> plt.subplot(2, 1, 2)
>>> plt.plot(t, pwm)
>>> plt.ylim(-1.5, 1.5)
```

scipy.signal.sweep_poly

`scipy.signal.sweep_poly(t, poly, phi=0)`

Frequency-swept cosine generator, with a time-dependent frequency.

This function generates a sinusoidal function whose instantaneous frequency varies with time. The frequency at time $t$ is given by the polynomial $poly$.

**Parameters**

- **t** [ndarray] Times at which to evaluate the waveform.
- **poly** [1-D array_like or instance of numpy.poly1d] The desired frequency expressed as a polynomial. If poly is a list or ndarray of length n, then the elements of poly are the coefficients of the polynomial, and the instantaneous frequency is $f(t) = \text{poly}[0]*t^{(n-1)} + \text{poly}[1]*t^{(n-2)} + ... + \text{poly}[n-1]$.

If poly is an instance of numpy.poly1d, then the instantaneous frequency is $f(t) = \text{poly}(t)$.
**phi**          [float, optional] Phase offset, in degrees, Default: 0.

**Returns**

**sweep_poly**          [ndarray] A numpy array containing the signal evaluated at \( t \) with the requested time-varying frequency. More precisely, the function returns \( \cos(\text{phase} + (\pi/180)\times\phi) \), where \( \text{phase} \) is the integral (from 0 to \( t \)) of \( 2 \times \pi \times f(t) \); \( f(t) \) is defined above.

**See also:**

chirp

**Notes**

New in version 0.8.0.

If \( \text{poly} \) is a list or ndarray of length \( n \), then the elements of \( \text{poly} \) are the coefficients of the polynomial, and the instantaneous frequency is:

\[
f(t) = \text{poly}[0] t^{(n-1)} + \text{poly}[1] t^{(n-2)} + \ldots + \text{poly}[n-1]
\]

If \( \text{poly} \) is an instance of numpy.poly1d, then the instantaneous frequency is:

\[
f(t) = \text{poly}(t)
\]

Finally, the output \( s \) is:

\[
\cos(\text{phase} + (\pi/180)\times\phi)
\]

where \( \text{phase} \) is the integral from 0 to \( t \) of \( 2 \times \pi \times f(t) \), \( f(t) \) as defined above.

**Examples**

Compute the waveform with instantaneous frequency:

\[
f(t) = 0.025 t^3 - 0.36 t^2 + 1.25 t + 2
\]

over the interval \( 0 \leq t \leq 10 \).

```plaintext
>>> from scipy.signal import sweep_poly
>>> p = np.poly1d([0.025, -0.36, 1.25, 2.0])
>>> t = np.linspace(0, 10, 5001)
>>> w = sweep_poly(t, p)
```

Plot it:

```plaintext
>>> import matplotlib.pyplot as plt
>>> plt.subplot(2, 1, 1)
>>> plt.plot(t, w)
>>> plt.title("Sweep Poly with frequency "$f(t)$ = 0.025t^3 - 0.36t^2 + 1.25t + 2$")
>>> plt.subplot(2, 1, 2)
>>> plt.plot(t, p(t), 'r', label='$f(t)$')
>>> plt.legend()
>>> plt.xlabel('t')
>>> plt.tight_layout()
>>> plt.show()
```
Sweep Poly
with frequency \( f(t) = 0.025t^3 - 0.36t^2 + 1.25t + 2 \)

\[ \text{scipy.signal.unit_impulse} \]

\texttt{scipy.signal.unit_impulse}(\texttt{shape, idx=None, dtype=\texttt{class 'float'}>)
Unit impulse signal (discrete delta function) or unit basis vector.

\textit{Parameters}

- \texttt{shape} [int or tuple of int] Number of samples in the output (1-D), or a tuple that represents the shape of the output (N-D).
- \texttt{idx} [None or int or tuple of int or 'mid', optional] Index at which the value is 1. If None, defaults to the 0th element. If \texttt{idx='mid'}, the impulse will be centered at \texttt{shape // 2} in all dimensions. If an int, the impulse will be at \texttt{idx} in all dimensions.
- \texttt{dtype} [data-type, optional] The desired data-type for the array, e.g., \texttt{numpy.int8}. Default is \texttt{numpy.float64}.

\textit{Returns}

- \texttt{y} [ndarray] Output array containing an impulse signal.

\textit{Notes}

The 1D case is also known as the Kronecker delta.
New in version 0.19.0.

\textit{Examples}

An impulse at the 0th element (\( \delta[n] \)):

```python
>>> from scipy import signal
>>> signal.unit_impulse(8)
array([ 1.,  0.,  0.,  0.,  0.,  0.,  0.,  0.])
```

Impulse offset by 2 samples (\( \delta[n-2] \)):
```python
>>> signal.unit_impulse(7, 2)
array([ 0., 0., 1., 0., 0., 0., 0.])
```

2-dimensional impulse, centered:

```python
>>> signal.unit_impulse((3, 3), 'mid')
array([[ 0., 0., 0.],
       [ 0., 1., 0.],
       [ 0., 0., 0.]])
```

Impulse at (2, 2), using broadcasting:

```python
>>> signal.unit_impulse((4, 4), 2)
array([[ 0., 0., 0., 0.],
       [ 0., 0., 0., 0.],
       [ 0., 0., 1., 0.],
       [ 0., 0., 0., 0.]])
```

Plot the impulse response of a 4th-order Butterworth lowpass filter:

```python
>>> imp = signal.unit_impulse(100, 'mid')
>>> b, a = signal.butter(4, 0.2)
>>> response = signal.lfilter(b, a, imp)
>>> import matplotlib.pyplot as plt
>>> plt.plot(np.arange(-50, 50), imp)
>>> plt.plot(np.arange(-50, 50), response)
>>> plt.margins(0.1, 0.1)
>>> plt.xlabel('Time [samples]')
>>> plt.ylabel('Amplitude')
>>> plt.grid(True)
>>> plt.show()
```
Window functions

For window functions, see the `scipy.signal.windows` namespace.

In the `scipy.signal` namespace, there is a convenience function to obtain these windows by name:

```python
scipy.signal.get_window(window, Nx[, fftbins])
```

Return a window of a given length and type.

**Parameters**
- `window` [string, float, or tuple] The type of window to create. See below for more details.
- `Nx` [int] The number of samples in the window.
- `fftbins` [bool, optional] If True (default), create a “periodic” window, ready to use with `ifftshift` and be multiplied by the result of an FFT (see also `fftfreq`). If False, create a “symmetric” window, for use in filter design.

**Returns**
- `get_window` [ndarray] Returns a window of length `Nx` and type `window`

**Notes**

Window types:
- boxcar
- triang
- blackman
- hamming
- hann
- bartlett
- flattop
- parzen
- bohman
- blackmanharris
- nuttall
- barthann
- cosine
- exponential
- tukey
- taylor
- kaiser (needs beta)

- **gaussian** (needs standard deviation)
- **general_cosine** (needs weighting coefficients)
- **general_gaussian** (needs power, width)
- **general_hamming** (needs window coefficient)
- **dpss** (needs normalized half-bandwidth)
- **chebwin** (needs attenuation)

If the window requires no parameters, then *window* can be a string.

If the window requires parameters, then *window* must be a tuple with the first argument the string name of the window, and the next arguments the needed parameters.

If *window* is a floating point number, it is interpreted as the beta parameter of the *kaiser* window.

Each of the window types listed above is also the name of a function that can be called directly to create a window of that type.

### Examples

```python
>>> from scipy import signal
generate windows
>>> signal.get_window('triang', 7)
a = array([ 0.125, 0.375, 0.625, 0.875, 0.875, 0.625, 0.375])
>>> signal.get_window('kaiser', 4.0, 9)
a = array([ 0.08848053, 0.29425961, 0.56437221, 0.82160913, 0.97885093,
          0.97885093, 0.82160913, 0.56437221, 0.29425961])
>>> signal.get_window('exponential', None, 1.), 9)
a = array([ 0.011109 , 0.03019738, 0.082085 , 0.22313016, 0.60653066,
          0.60653066, 0.22313016, 0.082085 , 0.03019738])
>>> signal.get_window(4.0, 9)
a = array([ 0.08848053, 0.29425961, 0.56437221, 0.82160913, 0.97885093,
          0.97885093, 0.82160913, 0.56437221, 0.29425961])
```

### Wavelets

- **cascade(hk[, J])**
  - Return (x, phi, psi) at dyadic points $k/2^{*J}$ from filter coefficients.

- **daub(p)**
  - The coefficients for the FIR low-pass filter producing Daubechies wavelets.

- **morlet(M[, w, s, complete])**
  - Complex Morlet wavelet.

- **gqmf(hk)**
  - Return high-pass qmf filter from low-pass

- **ricker(points, a)**
  - Return a Ricker wavelet, also known as the "Mexican hat wavelet".

- **morlet2(M, s[, w])**
  - Complex Morlet wavelet, designed to work with *cwt*.

- **cwt(data, wavelet, widths[, dtype])**
  - Continuous wavelet transform.
scipy.signal.cascade

scipy.signal.cascade(hk, J=7)
Return (x, phi, psi) at dyadic points $K/2^J$ from filter coefficients.

Parameters
- **hk** [array_like] Coefficients of low-pass filter.
- **J** [int, optional] Values will be computed at grid points $K/2^J$. Default is 7.

Returns
- **x** [ndarray] The dyadic points $K/2^J$ for $K=0...N * (2^J)-1$ where $\text{len}(hk) = \text{len}(gk) = N+1$.
- **phi** [ndarray] The scaling function $\phi(x)$ at $x$: $\phi(x) = \sum(hk \times \phi(2x-k))$, where $k$ is from 0 to N.
- **psi** [ndarray, optional] The wavelet function $\psi(x)$ at $x$: $\psi(x) = \sum(gk \times \phi(2x-k))$, where $k$ is from 0 to N. $\psi$ is only returned if $gk$ is not None.

Notes
The algorithm uses the vector cascade algorithm described by Strang and Nguyen in “Wavelets and Filter Banks”. It builds a dictionary of values and slices for quick reuse. Then inserts vectors into final vector at the end.

scipy.signal.daub

scipy.signal.daub(p)
The coefficients for the FIR low-pass filter producing Daubechies wavelets.

$p\geq1$ gives the order of the zero at $f=1/2$. There are $2p$ filter coefficients.

Parameters
- **p** [int] Order of the zero at $f=1/2$, can have values from 1 to 34.

Returns
- **daub** [ndarray] Return

scipy.signal.morlet

scipy.signal.morlet(M, w=5.0, s=1.0, complete=True)
Complex Morlet wavelet.

Parameters
- **M** [int] Length of the wavelet.
- **w** [float, optional] Omega0. Default is 5
- **s** [float, optional] Scaling factor, windowed from $-s^2\times\pi$ to $+s^2\times\pi$. Default is 1.
- **complete** [bool, optional] Whether to use the complete or the standard version.

Returns
- **morlet** [((M,)) ndarray]

See also:
- **morlet2**

Implementation of Morlet wavelet, compatible with $\text{cwt}$.
scipy.signal.gausspulse

Notes

The standard version:

\[ \pi^{-0.25} \cdot \exp(1j\omega x) \cdot \exp(-0.5(x^2)) \]

This commonly used wavelet is often referred to simply as the Morlet wavelet. Note that this simplified version can cause admissibility problems at low values of \( \omega \).

The complete version:

\[ \pi^{-0.25} \cdot (\exp(1j\omega x) - \exp(-0.5(\omega^2))) \cdot \exp(-0.5(x^2)) \]

This version has a correction term to improve admissibility. For \( \omega \) greater than 5, the correction term is negligible. Note that the energy of the return wavelet is not normalised according to \( s \).

The fundamental frequency of this wavelet in Hz is given by \( f = 2s\omega r / M \) where \( r \) is the sampling rate.

Note: This function was created before cwt and is not compatible with it.

scipy.signal.qmf

scipy.signal.qmf(hk)

Return high-pass qmf filter from low-pass

Parameters

- \( hk \) [array_like] Coefficients of high-pass filter.

scipy.signal.ricker

scipy.signal.ricker(points, a)

Return a Ricker wavelet, also known as the “Mexican hat wavelet”.

It models the function:

\[ A \cdot (1 - (x/a)^2) \cdot \exp(-0.5(x/a)^2), \]

where \( A = 2/(\sqrt{3a}(\pi^{0.25})) \).

Parameters

- \( points \) [int] Number of points in vector. Will be centered around 0.
- \( a \) [scalar] Width parameter of the wavelet.

Returns

- \( vector \) [(N,) ndarray] Array of length \( points \) in shape of ricker curve.
Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> points = 100
>>> a = 4.0
>>> vec2 = signal.ricker(points, a)
>>> print(len(vec2))
100
>>> plt.plot(vec2)
>>> plt.show()
```

![Plot of the Ricker wavelet](image)

**scipy.signal.morlet2**

*scipy.signal.morlet2*(M, s, w=5)

Complex Morlet wavelet, designed to work with *cwt*.

Returns the complete version of morlet wavelet, normalised according to `s`:

\[
\exp(i \omega_0 x / s) \times \exp(-0.5(x/s)^2) \times \pi^{(-0.25)} \times \sqrt{1/s}
\]

**Parameters**

- M [int] Length of the wavelet.
- w [float, optional] Omega0. Default is 5

**Returns**

- morlet [(M,) ndarray]

**See also:**

*morlet*
Implementation of Morlet wavelet, incompatible with \texttt{cwt}

\textbf{Notes}

New in version 1.4.0.

This function was designed to work with \texttt{cwt}. Because \texttt{morlet2} returns an array of complex numbers, the \texttt{dtype} argument of \texttt{cwt} should be set to \texttt{complex128} for best results.

Note the difference in implementation with \texttt{morlet}. The fundamental frequency of this wavelet in Hz is given by:

\begin{equation}
    f = \frac{w \times fs}{2 \times s \times np.pi}
\end{equation}

where \(fs\) is the sampling rate and \(s\) is the wavelet width parameter. Similarly we can get the wavelet width parameter at \(f\):

\begin{equation}
    s = \frac{w \times fs}{2 \times f \times np.pi}
\end{equation}

\textbf{Examples}

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> M = 100
>>> s = 4.0
>>> w = 2.0
>>> wavelet = signal.morlet2(M, s, w)
>>> plt.plot(abs(wavelet))
>>> plt.show()
```

This example shows basic use of \texttt{morlet2} with \texttt{cwt} in time-frequency analysis:
```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> t, dt = np.linspace(0, 1, 200, retstep=True)
>>> fs = 1/dt
>>> w = 6.
>>> sig = np.cos(2*np.pi*(50 + 10*t)*t) + np.sin(40*np.pi*t)
>>> freq = np.linspace(1, fs/2, 100)
>>> widths = w*fs / (2*freq*np.pi)
>>> cwtm = signal.cwt(sig, signal.morlet2, widths, w=w)
>>> plt.pcolormesh(t, freq, np.abs(cwtm), cmap='viridis', shading='gouraud')
>>> plt.show()
```

**scipy.signal.cwt**

`scipy.signal.cwt(data, wavelet, widths, dtype=None, **kwargs)`  
Continuous wavelet transform.

Performs a continuous wavelet transform on `data`, using the `wavelet` function. A CWT performs a convolution with `data` using the `wavelet` function, which is characterized by a width parameter and length parameter. The `wavelet` function is allowed to be complex.

**Parameters**

- **data**  
  [(N,) ndarray] data on which to perform the transform.

- **wavelet**  
  [function] Wavelet function, which should take 2 arguments. The first argument is the number of points that the returned vector will have (len(wavelet(length,width)) == length). The second is a width parameter, defining the size of the wavelet (e.g. standard deviation of a gaussian). See `ricker`, which satisfies these requirements.

- **widths**  
  [(M,) sequence] Widths to use for transform.

- **dtype**  
  [data-type, optional] The desired data type of output. Defaults to `float64` if the output of `wavelet` is real and `complex128` if it is complex.

- **kwargs**  
  Keyword arguments passed to wavelet function.

New in version 1.4.0.
**Returns**

cwt: (M, N) ndarray
Will have shape of (len(widths), len(data)).

**Notes**

New in version 1.4.0.

For non-symmetric, complex-valued wavelets, the input signal is convolved with the time-reversed complex-conjugate of the wavelet data [1].

```python
length = min(10 * width[ii], len(data))
cwt[ii,:] = signal.convolve(data, np.conj(wavelet(length, width[ii], **kwargs))[:-1], mode='same')
```

**References**

[1]

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(-1, 1, 200, endpoint=False)
>>> sig = np.cos(2 * np.pi * 7 * t) + signal.gausspulse(t - 0.4, fc=2)
>>> widths = np.arange(1, 31)
>>> cwtmatr = signal.cwt(sig, signal.ricker, widths)
>>> plt.imshow(cwtmatr, extent=[-1, 1, 31, 1], cmap='PRGn', aspect='auto',
...           vmax=abs(cwtmatr).max(), vmin=-abs(cwtmatr).max())
>>> plt.show()
```

**scipy.signal.argrelmin**

`scipy.signal.argrelmin(data, axis=0, order=1, mode='clip')`

Calculate the relative minima of data.

**Parameters**

- **data** [ndarray] Array in which to find the relative minima.
- **axis** [int, optional] Axis over which to select from data. Default is 0.
- **order** [int, optional] How many points on each side to use for the comparison to consider comparator(n, n+x) to be True.
- **mode** [str, optional] How the edges of the vector are treated. Available options are 'wrap' (wrap around) or 'clip' (treat overflow as the same as the last (or first) element). Default 'clip'. See `numpy.take`.

**Returns**

- **extrema** [tuple of ndarrays] Indices of the minima in arrays of integers. extrema[k] is the array of indices of axis k of data. Note that the return value is a tuple even when data is 1-D.

**See also:**

- `argrelextrema`, `argrelmax`, `find_peaks`

**Notes**

This function uses `argrelextrema` with `np.less` as comparator. Therefore, it requires a strict inequality on both sides of a value to consider it a minimum. This means flat minima (more than one sample wide) are not detected. In case of 1-D `data find_peaks` can be used to detect all local minima, including flat ones, by calling it with negated `data`.

New in version 0.11.0.

**Examples**

```python
>>> from scipy.signal import argrelmin
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelmin(x)
(array([1, 5]),)
>>> y = np.array([[1, 2, 1, 2],
...                [2, 2, 0, 0],
...                [5, 3, 4, 4]])
...```
```python
>>> argrelmin(y, axis=1)
(array([0, 2]), array([2, 1]))
```

**scipy.signal.argrelmax**

`scipy.signal.argrelmax(data, axis=0, order=1, mode='clip')`

Calculate the relative maxima of `data`.

**Parameters**

- **data** [ndarray] Array in which to find the relative maxima.
- **axis** [int, optional] Axis over which to select from `data`. Default is 0.
- **order** [int, optional] How many points on each side to use for the comparison to consider \( comparator(n, n+x) \) to be True.
- **mode** [str, optional] How the edges of the vector are treated. Available options are 'wrap' (wrap around) or 'clip' (treat overflow as the same as the last (or first) element). Default 'clip'. See `numpy.take`.

**Returns**

- **extrema** [tuple of ndarrays] Indices of the maxima in arrays of integers. `extrema[k]` is the array of indices of axis `k` of `data`. Note that the return value is a tuple even when `data` is 1-D.

**See also:**

`argrelextrema`, `argrelmin`, `find_peaks`

**Notes**

This function uses `argrelextrema` with `np.greater` as comparator. Therefore, it requires a strict inequality on both sides of a value to consider it a maximum. This means flat maxima (more than one sample wide) are not detected. In case of 1-D `data` `find_peaks` can be used to detect all local maxima, including flat ones.

New in version 0.11.0.

**Examples**

```python
>>> from scipy.signal import argrelmax
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelmax(x)
(array([3, 6]),)
>>> y = np.array([[1, 2, 1, 2],
                [2, 2, 0, 0],
                [5, 3, 4, 4]])
>>> argrelmax(y, axis=1)
(array([0]), array([1]))
```
scipy.signal.argrelextrema

scipy.signal.argrelextrema(data, comparator, axis=0, order=1, mode='clip')

Calculate the relative extrema of data.

Parameters

data [ndarray] Array in which to find the relative extrema.
comparator [callable] Function to use to compare two data points. Should take two arrays as arguments.
axis [int, optional] Axis over which to select from data. Default is 0.
order [int, optional] How many points on each side to use for the comparison to consider comparator(n, n+x) to be True.
mode [str, optional] How the edges of the vector are treated. ‘wrap’ (wrap around) or ‘clip’ (treat overflow as the same as the last (or first) element). Default is ‘clip’. See numpy.take.

Returns

extrema [tuple of ndarrays] Indices of the maxima in arrays of integers. extrema[k] is the array of indices of axis k of data. Note that the return value is a tuple even when data is 1-D.

See also:

argrelmin, argrelmax

Notes

New in version 0.11.0.

Examples

```python
>>> from scipy.signal import argrelextrema
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelextrema(x, np.greater)
(array([3, 6]),)
>>> y = np.array([[1, 2, 1, 2],
                ... [2, 2, 0, 0],
                ... [5, 3, 4, 4]])
>>> argrelextrema(y, np.less, axis=1)
(array([0, 2]), array([2, 1]))
```

scipy.signal.find_peaks

scipy.signal.find_peaks(x, height=None, threshold=None, distance=None, prominence=None, width=None, wlen=None, rel_height=0.5, plateau_size=None)

Find peaks inside a signal based on peak properties.

This function takes a 1-D array and finds all local maxima by simple comparison of neighboring values. Optionally, a subset of these peaks can be selected by specifying conditions for a peak’s properties.

Parameters

x [sequence] A signal with peaks.
height [number or ndarray or sequence, optional] Required height of peaks. Either a number, None, an array matching x or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required height.
threshold [number or ndarray or sequence, optional] Required threshold of peaks, the vertical distance to its neighboring samples. Either a number, `None`, an array matching `x` or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required threshold.

distance [number, optional] Required minimal horizontal distance (>= 1) in samples between neighbouring peaks. Smaller peaks are removed first until the condition is fulfilled for all remaining peaks.

prominence [number or ndarray or sequence, optional] Required prominence of peaks. Either a number, `None`, an array matching `x` or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required prominence.

width [number or ndarray or sequence, optional] Required width of peaks in samples. Either a number, `None`, an array matching `x` or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required width.

wlen [int, optional] Used for calculation of the peaks prominences, thus it is only used if one of the arguments `prominence` or `width` is given. See argument `wlen` in `peak_prominences` for a full description of its effects.

rel_height [float, optional] Used for calculation of the peaks width, thus it is only used if `width` is given. See argument `rel_height` in `peak_widths` for a full description of its effects.

plateau_size [number or ndarray or sequence, optional] Required size of the flat top of peaks in samples. Either a number, `None`, an array matching `x` or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required plateau size. New in version 1.2.0.

Returns

peaks [ndarray] Indices of peaks in `x` that satisfy all given conditions.

properties [dict] A dictionary containing properties of the returned peaks which were calculated as intermediate results during evaluation of the specified conditions:

- `‘peak_heights’`  
  If `height` is given, the height of each peak in `x`.

- `‘left_thresholds’, ‘right_thresholds’`  
  If `threshold` is given, these keys contain a peaks vertical distance to its neighbouring samples.

- `‘prominences’, ‘right_bases’, ‘left_bases’`  
  If `prominence` is given, these keys are accessible. See `peak_prominences` for a description of their content.

- `‘width_heights’, ‘left_ips’, ‘right_ips’`  
  If `width` is given, these keys are accessible. See `peak_widths` for a description of their content.

- `‘plateau_sizes’, ‘left_edges’, ‘right_edges’`  
  If `plateau_size` is given, these keys are accessible and contain the indices of a peak’s edges (edges are still part of the plateau) and the calculated plateau sizes.
  
  New in version 1.2.0.

To calculate and return properties without excluding peaks, provide the open interval `(None, None)` as a value to the appropriate argument (excluding `distance`).

Warns

PeakPropertyWarning  
Raised if a peak’s properties have unexpected values (see `peak_prominences` and `peak_widths`).
**Warning:** This function may return unexpected results for data containing NaNs. To avoid this, NaNs should either be removed or replaced.

See also:

- `find_peaks_cwt`  
  Find peaks using the wavelet transformation.
- `peak_prominences`  
  Directly calculate the prominence of peaks.
- `peak_widths`  
  Directly calculate the width of peaks.

**Notes**

In the context of this function, a peak or local maximum is defined as any sample whose two direct neighbours have a smaller amplitude. For flat peaks (more than one sample of equal amplitude wide) the index of the middle sample is returned (rounded down in case the number of samples is even). For noisy signals the peak locations can be off because the noise might change the position of local maxima. In those cases consider smoothing the signal before searching for peaks or use other peak finding and fitting methods (like `find_peaks_cwt`).

Some additional comments on specifying conditions:

- Almost all conditions (excluding `distance`) can be given as half-open or closed intervals, e.g., 1 or `(1, None)` defines the half-open interval `[1, ∞)` while `(None, 1)` defines the interval `[−∞, 1]`. The open interval `(None, None)` can be specified as well, which returns the matching properties without exclusion of peaks.
- The border is always included in the interval used to select valid peaks.
- For several conditions the interval borders can be specified with arrays matching `x` in shape which enables dynamic constrains based on the sample position.
- The conditions are evaluated in the following order: `plateau_size`, `height`, `threshold`, `distance`, `prominence`, `width`. In most cases this order is the fastest one because faster operations are applied first to reduce the number of peaks that need to be evaluated later.
- While indices in `peaks` are guaranteed to be at least `distance` samples apart, edges of flat peaks may be closer than the allowed `distance`.
- Use `wlen` to reduce the time it takes to evaluate the conditions for `prominence` or `width` if `x` is large or has many local maxima (see `peak_prominences`).

New in version 1.1.0.
Examples

To demonstrate this function’s usage we use a signal \(x\) supplied with SciPy (see \texttt{scipy.misc.electrocardiogram}). Let’s find all peaks (local maxima) in \(x\) whose amplitude lies above 0.

\begin{verbatim}
>>> import matplotlib.pyplot as plt
>>> from scipy.misc import electrocardiogram
>>> from scipy.signal import find_peaks

>>> x = electrocardiogram()[2000:4000]
>>> peaks, _ = find_peaks(x, height=0)

>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.plot(np.zeros_like(x), "--", color="gray")
>>> plt.show()
\end{verbatim}

We can select peaks below 0 with \texttt{height=(None, 0)} or use arrays matching \(x\) in size to reflect a changing condition for different parts of the signal.

\begin{verbatim}
>>> border = np.sin(np.linspace(0, 3 * np.pi, x.size))
>>> peaks, _ = find_peaks(x, height=(-border, border))

>>> np.diff(peaks)
array([186, 180, 177, 171, 177, 169, 167, 164, 158, 162, 172])

>>> plt.plot(x)
\end{verbatim}

Another useful condition for periodic signals can be given with the \texttt{distance} argument. In this case, we can easily select the positions of QRS complexes within the electrocardiogram (ECG) by demanding a distance of at least 150 samples.

\begin{verbatim}
>>> peaks, _ = find_peaks(x, distance=150)
>>> np.diff(peaks)
array([186, 180, 177, 171, 177, 169, 167, 164, 158, 162, 172])

>>> plt.plot(x)
\end{verbatim}
Especially for noisy signals peaks can be easily grouped by their prominence (see `peak_prominences`). E.g., we can select all peaks except for the mentioned QRS complexes by limiting the allowed prominence to 0.6.

```python
>>> peaks, properties = find_peaks(x, prominence=(None, 0.6))
>>> properties['prominences'].max()
0.5049999999999999
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.show()
```

And, finally, let's examine a different section of the ECG which contains beat forms of different shape. To select
only the atypical heart beats, we combine two conditions: a minimal prominence of 1 and width of at least 20 samples.

```python
>>> x = electrocardiogram()[17000:18000]
>>> peaks, properties = find_peaks(x, prominence=1, width=20)
>>> properties["prominences"], properties["widths"]
(array([1.495, 2.3]), array([36.93773946, 39.32723577]))
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.vlines(x=peaks, ymin=x[peaks] - properties["prominences"],
...           ymax = x[peaks], color = "C1")
>>> plt.hlines(y=properties["width_heights"], xmin=properties["left_ips"],
...           xmax=properties["right_ips"], color = "C1")
>>> plt.show()
```
scipy.signal.find_peaks_cwt

```python
scipy.signal.find_peaks_cwt(vector, widths, wavelet=None, max_distances=None, gap_thresh=None, min_length=None, min_snr=1, noise_perc=10, window_size=None)
```

Find peaks in a 1-D array with wavelet transformation.

The general approach is to smooth `vector` by convolving it with `wavelet(width)` for each width in `widths`. Relative maxima which appear at enough length scales, and with sufficiently high SNR, are accepted.

**Parameters**

- `vector` [ndarray] 1-D array in which to find the peaks.
- `widths` [float or sequence] Single width or 1-D array-like of widths to use for calculating the CWT matrix. In general, this range should cover the expected width of peaks of interest.
- `wavelet` [callable, optional] Should take two parameters and return a 1-D array to convolve with `vector`. The first parameter determines the number of points of the returned wavelet array, the second parameter is the scale (width) of the wavelet. Should be normalized and symmetric. Default is the ricker wavelet.
- `max_distances` [ndarray, optional] At each row, a ridge line is only connected if the relative max at row[n] is within `max_distances[n]` from the relative max at row[n+1]. Default value is `widths/4`.
- `gap_thresh` [float, optional] If a relative maximum is not found within `max_distances`, there will be a gap. A ridge line is discontinued if there are more than `gap_thresh` points without connecting a new relative maximum. Default is the first value of the `widths` array i.e. `widths[0]`.
- `min_length` [int, optional] Minimum length a ridge line needs to be acceptable. Default is `cwt.shape[0] / 4`, i.e. 1/4-th the number of widths.
- `min_snr` [float, optional] Minimum SNR ratio. Default 1. The signal is the value of the cwt matrix at the shortest length scale (`cwt[0, loc]`), the noise is the `noise_perc`th percentile of datapoints contained within a window of `window_size` around `cwt[0, loc]`.
- `noise_perc` [float, optional] When calculating the noise floor, percentile of data points examined below which to consider noise. Calculated using `stats.scoreatpercentile`. Default is 10.

**Returns**

- `peaks_indices` [ndarray] Indices of the locations in the `vector` where peaks were found. The list is sorted.

**See also:**

- `cwt`
  - Continuous wavelet transform.
- `find_peaks`
  - Find peaks inside a signal based on peak properties.
Notes

This approach was designed for finding sharp peaks among noisy data, however with proper parameter selection it should function well for different peak shapes.

The algorithm is as follows:

1. Perform a continuous wavelet transform on vector, for the supplied widths. This is a convolution of vector with wavelet(width) for each width in widths. See cwt.
2. Identify “ridge lines” in the cwt matrix. These are relative maxima at each row, connected across adjacent rows. See identify_ridge_lines
3. Filter the ridge_lines using filter_ridge_lines.

New in version 0.11.0.

References

[1]

Examples

```python
>>> from scipy import signal
>>> xs = np.arange(0, np.pi, 0.05)
>>> data = np.sin(xs)
>>> peakind = signal.find_peaks_cwt(data, np.arange(1,10))
>>> peakind, xs[peakind], data[peakind]
([[32], array([ 1.6]), array([ 0.9995736])])
```

scipy.signal.peak_prominences

scipy.signal.peak_prominences(x, peaks, wlen=None)

Calculate the prominence of each peak in a signal.

The prominence of a peak measures how much a peak stands out from the surrounding baseline of the signal and is defined as the vertical distance between the peak and its lowest contour line.

Parameters

- **x** ([sequence]) A signal with peaks.
- **peaks** ([sequence]) Indices of peaks in x.
- **wlen** ([int, optional]) A window length in samples that optionally limits the evaluated area for each peak to a subset of x. The peak is always placed in the middle of the window therefore the given length is rounded up to the next odd integer. This parameter can speed up the calculation (see Notes).

Returns

- **prominences** ([ndarray]) The calculated prominences for each peak in peaks.
- **left_bases, right_bases** ([ndarray]) The peaks’ bases as indices in x to the left and right of each peak. The higher base of each pair is a peak’s lowest contour line.

Raises

3.3. API definition 1659
ValueError

If a value in peaks is an invalid index for x.

Warns

PeakPropertyWarning

For indices in peaks that don’t point to valid local maxima in x, the returned prominence will be 0 and this warning is raised. This also happens if wlen is smaller than the plateau size of a peak.

Warning: This function may return unexpected results for data containing NaNs. To avoid this, NaNs should either be removed or replaced.

See also:

find_peaks

Find peaks inside a signal based on peak properties.

peak_widths

Calculate the width of peaks.

Notes

Strategy to compute a peak’s prominence:

1. Extend a horizontal line from the current peak to the left and right until the line either reaches the window border (see wlen) or intersects the signal again at the slope of a higher peak. An intersection with a peak of the same height is ignored.

2. On each side find the minimal signal value within the interval defined above. These points are the peak’s bases.

3. The higher one of the two bases marks the peak’s lowest contour line. The prominence can then be calculated as the vertical difference between the peaks height itself and its lowest contour line.

Searching for the peak’s bases can be slow for large x with periodic behavior because large chunks or even the full signal need to be evaluated for the first algorithmic step. This evaluation area can be limited with the parameter wlen which restricts the algorithm to a window around the current peak and can shorten the calculation time if the window length is short in relation to x. However, this may stop the algorithm from finding the true global contour line if the peak’s true bases are outside this window. Instead, a higher contour line is found within the restricted window leading to a smaller calculated prominence. In practice, this is only relevant for the highest set of peaks in x. This behavior may even be used intentionally to calculate “local” prominences.

New in version 1.1.0.
References

[1]

Examples

```python
>>> from scipy.signal import find_peaks, peak_prominences
>>> import matplotlib.pyplot as plt

Create a test signal with two overlayed harmonics

```python
>>> x = np.linspace(0, 6 * np.pi, 1000)
>>> x = np.sin(x) + 0.6 * np.sin(2.6 * x)
``` 

Find all peaks and calculate prominences

```python
>>> peaks, _ = find_peaks(x)
>>> prominences = peak_prominences(x, peaks)[0]
>>> prominences
array([1.24159486, 0.47840168, 0.28470524, 3.10716793, 0.284603,
       0.47822491, 2.48340261, 0.47822491])
``` 

Calculate the height of each peak’s contour line and plot the results

```python
>>> contour_heights = x[peaks] - prominences
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.vlines(x=peaks, ymin=contour_heights, ymax=x[peaks])
>>> plt.show()
```

Let’s evaluate a second example that demonstrates several edge cases for one peak at index 5.
```python
>>> x = np.array([0, 1, 0, 3, 1, 3, 0, 4, 0])
>>> peaks = np.array([5])
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.show()
```

```python
>>> peak_prominences(x, peaks)
# -> (prominences, left_bases, right_bases)
(array([3.]), array([2]), array([6]))
```

Note how the peak at index 3 of the same height is not considered as a border while searching for the left base. Instead, two minima at 0 and 2 are found in which case the one closer to the evaluated peak is always chosen. On the right side, however, the base must be placed at 6 because the higher peak represents the right border to the evaluated area.

```python
>>> peak_prominences(x, peaks, wlen=3.1)
(array([2.]), array([4]), array([6]))
```

Here, we restricted the algorithm to a window from 3 to 7 (the length is 5 samples because `wlen` was rounded up to the next odd integer). Thus, the only two candidates in the evaluated area are the two neighboring samples and a smaller prominence is calculated.

**scipy.signal.peak_widths**

`scipy.signal.peak_widths(x, peaks, rel_height=0.5, prominence_data=None, wlen=None)`

Calculate the width of each peak in a signal.

This function calculates the width of a peak in samples at a relative distance to the peak’s height and prominence.

**Parameters**

- `x` [sequence] A signal with peaks.
- `peaks` [sequence] Indices of peaks in `x`.
- `rel_height` [float, optional] Chooses the relative height at which the peak width is measured as a percentage of its prominence. 1.0 calculates the width of the peak at its lowest contour line.
while 0.5 evaluates at half the prominence height. Must be at least 0. See notes for further explanation.

**prominence_data**

[tuple, optional] A tuple of three arrays matching the output of `peak_prominences` when called with the same arguments `x` and `peaks`. This data are calculated internally if not provided.

**wlen**

[int, optional] A window length in samples passed to `peak_prominences` as an optional argument for internal calculation of `prominence_data`. This argument is ignored if `prominence_data` is given.

**Returns**

- **widths** [ndarray] The widths for each peak in samples.
- **width_heights** [ndarray] The height of the contour lines at which the `widths` were evaluated.
- **left_ips, right_ips** [ndarray] Interpolated positions of left and right intersection points of a horizontal line at the respective evaluation height.

**Raises**

- **ValueError**

  If `prominence_data` is supplied but doesn’t satisfy the condition `0 <= left_base <= peak <= right_base < x.shape[0]` for each peak, has the wrong dtype, is not C-contiguous or does not have the same shape.

**Warns**

- **PeakPropertyWarning**

  Raised if any calculated width is 0. This may stem from the supplied `prominence_data` or if `rel_height` is set to 0.

---

**Warning:** This function may return unexpected results for data containing NaNs. To avoid this, NaNs should either be removed or replaced.

**See also:**

- **find_peaks**

  Find peaks inside a signal based on peak properties.

- **peak_prominences**

  Calculate the prominence of peaks.

**Notes**

The basic algorithm to calculate a peak’s width is as follows:

- Calculate the evaluation height $h_{eval}$ with the formula $h_{eval} = h_{peak} - P \cdot R$, where $h_{peak}$ is the height of the peak itself, $P$ is the peak’s prominence and $R$ a positive ratio specified with the argument `rel_height`.

- Draw a horizontal line at the evaluation height to both sides, starting at the peak’s current vertical position until the lines either intersect a slope, the signal border or cross the vertical position of the peak’s base (see `peak_prominences` for an definition). For the first case, intersection with the signal, the true intersection point is estimated with linear interpolation.
• Calculate the width as the horizontal distance between the chosen endpoints on both sides. As a consequence of this, the maximal possible width for each peak is the horizontal distance between its bases.

As shown above to calculate a peak’s width its prominence and bases must be known. You can supply these yourself with the argument prominence_data. Otherwise, they are internally calculated (see peak_prominences).

New in version 1.1.0.

Examples

```python
>>> from scipy.signal import chirp, find_peaks, peak_widths
>>> import matplotlib.pyplot as plt

Create a test signal with two overlayed harmonics

```python
>>> x = np.linspace(0, 6 * np.pi, 1000)
>>> x = np.sin(x) + 0.6 * np.sin(2.6 * x)
``` 

Find all peaks and calculate their widths at the relative height of 0.5 (contour line at half the prominence height) and 1 (at the lowest contour line at full prominence height).

```python
>>> peaks, _ = find_peaks(x)
>>> results_half = peak_widths(x, peaks, rel_height=0.5)
>>> results_half[0] # widths
array([ 64.25172825, 41.29465463, 35.46943289, 104.71586081,
        35.46729324, 41.30429622, 181.93835853, 45.37078546])
``` 

```python
>>> results_full = peak_widths(x, peaks, rel_height=1)
>>> results_full[0] # widths
array([181.9396084 , 72.99284945, 61.28657872, 373.84622694,
        61.78404617, 72.48822812, 253.09161876, 79.36860878])
``` 

Plot signal, peaks and contour lines at which the widths were calculated

```python
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.hlines(*results_half[1:], color="C2")
>>> plt.hlines(*results_full[1:], color="C3")
>>> plt.show()
``` 

Spectral analysis

- `periodogram(x[, fs, window, nfft, detrend, ...])` Estimate power spectral density using a periodogram.
- `welch(x[, fs, window, nperseg, noverlap, ...])` Estimate power spectral density using Welch’s method.
- `csd(x, y[, fs, window, nperseg, noverlap, ...])` Estimate the cross power spectral density, Pxy, using Welch’s method.
- `coherence(x, y[, fs, window, nperseg, ...])` Estimate the magnitude squared coherence estimate, Cxy, of discrete-time signals X and Y using Welch’s method.
- `spectrogram(x[, fs, window, nperseg, ...])` Compute a spectrogram with consecutive Fourier transforms.
- `lombscargle(x, y, freqs)` Computes the Lomb-Scargle periodogram.

**scipy.signal.periodogram**

Estimate power spectral density using a periodogram.

```
scipy.signal.periodogram(x, fs=1.0, window='boxcar', nfft=None, detrend='constant',
                          return_onesided=True, scaling='density', axis=-1)
```

**Parameters**

- **x** [array_like] Time series of measurement values
- **fs** [float, optional] Sampling frequency of the x time series. Defaults to 1.0.
- **window** [str or tuple or array_like, optional] Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array_like it will be used directly as the window and its length must be nperseg. Defaults to 'boxcar'.
- **nfft** [int, optional] Length of the FFT used. If `None` the length of `x` will be used.
- **detrend** [str or function or False, optional] Specifies how to detrend each segment. If `detrend` is a string, it is passed as the `type` argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If `detrend` is `False`, no detrending is done. Defaults to 'constant'.
- **return_onesided** [bool, optional] If `True`, return a one-sided spectrum for real data. If `False` return a two-sided spectrum. Defaults to `True`, but for complex data, a two-sided spectrum is always returned.
- **scaling** [['density', 'spectrum'], optional] Selects between computing the power spectral density ('density') where `Pxx` has units of V**2/Hz and computing the power spectrum ('spectrum') where `Pxx` has units of V**2, if `x` is measured in V and `fs` is measured in Hz. Defaults to 'density'.
- **axis** [int, optional] Axis along which the periodogram is computed; the default is over the last axis (i.e. `axis=-1`).

**Returns**

- **f** [ndarray] Array of sample frequencies.
- **Pxx** [ndarray] Power spectral density or power spectrum of `x`.

See also:

- **welch**
  Estimate power spectral density using Welch’s method
- **lombscargle**
  Lomb-Scargle periodogram for unevenly sampled data

3.3. API definition 1665
Notes

New in version 0.12.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()

Generate a test signal, a 2 Vrms sine wave at 1234 Hz, corrupted by 0.001 V**2/Hz of white noise sampled at 10 kHz.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2*np.sqrt(2)
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> x = amp*np.sin(2*np.pi*freq*time)
>>> x += rng.normal(scale=np.sqrt(noise_power), size=time.shape)
```  
Compute and plot the power spectral density.

```python
>>> f, Pxx_den = signal.periodogram(x, fs)
>>> plt.semilogy(f, Pxx_den)
>>> plt.xlim([1e-7, 1e2])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.show()
```  
If we average the last half of the spectral density, to exclude the peak, we can recover the noise power on the signal.
Now compute and plot the power spectrum.

```python
>>> np.mean(Pxx_den[25000:]
0.000985320699252543

The peak height in the power spectrum is an estimate of the RMS amplitude.

3.3. API definition
scipy.signal.welch

scipy.signal.welch(x, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1, average='mean')

Estimate power spectral density using Welch’s method.

Welch’s method [1] computes an estimate of the power spectral density by dividing the data into overlapping segments, computing a modified periodogram for each segment and averaging the periodograms.

Parameters

- **x** [array_like] Time series of measurement values
- **fs** [float, optional] Sampling frequency of the x time series. Defaults to 1.0.
- **window** [str or tuple or array_like, optional] Desired window to use. If window is a string or tuple, it is passed to get_window to generate the window values, which are DFT-even by default. See get_window for a list of windows and required parameters. If window is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Hann window.
- **nperseg** [int, optional] Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array_like, is set to the length of the window.
- **noverlap** [int, optional] Number of points to overlap between segments. If None, noverlap = nperseg // 2. Defaults to None.
- **nfft** [int, optional] Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is nperseg. Defaults to None.
- **detrend** [str or function or False, optional] Specifies how to detrend each segment. If detrend is a string, it is passed as the type argument to the detrend function. If it is a function, it takes a segment and returns a detrended segment. If detrend is False, no detrending is done. Defaults to 'constant'.
- **return_onesided** [bool, optional] If True, return a one-sided spectrum for real data. If False return a two-sided spectrum. Defaults to True, but for complex data, a two-sided spectrum is always returned.
- **scaling** [{ 'density', 'spectrum' }, optional] Selects between computing the power spectral density ('density') where Pxx has units of V**2/Hz and computing the power spectrum ('spectrum') where Pxx has units of V**2, if x is measured in V and fs is measured in Hz. Defaults to 'density'.
- **axis** [int, optional] Axis along which the periodogram is computed; the default is over the last axis (i.e. axis=-1).
- **average** [{ 'mean', 'median' }, optional] Method to use when averaging periodograms. Defaults to 'mean'. New in version 1.2.0.

Returns

- **f** [ndarray] Array of sample frequencies.
- **Pxx** [ndarray] Power spectral density or power spectrum of x.

See also:

- **periodogram**
  - Simple, optionally modified periodogram
- **lombscargle**
  - Lomb-Scargle periodogram for unevenly sampled data
Notes

An appropriate amount of overlap will depend on the choice of window and on your requirements. For the default Hann window an overlap of 50% is a reasonable trade off between accurately estimating the signal power, while not over counting any of the data. Narrower windows may require a larger overlap.

If `noverlap` is 0, this method is equivalent to Bartlett’s method [2].

New in version 0.12.0.

References

[1], [2]

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()

Generate a test signal, a 2 Vrms sine wave at 1234 Hz, corrupted by 0.001 V**2/Hz of white noise sampled at 10 kHz.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2*np.sqrt(2)
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> x = amp*np.sin(2*np.pi*freq*time)
>>> x += rng.normal(scale=np.sqrt(noise_power), size=time.shape)
```  
Compute and plot the power spectral density.

```python
>>> f, Pxx_den = signal.welch(x, fs, nperseg=1024)
>>> plt.semilogy(f, Pxx_den)
>>> plt.ylim([0.5e-3, 1])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.show()
```  
If we average the last half of the spectral density, to exclude the peak, we can recover the noise power on the signal.

```python
>>> np.mean(Pxx_den[256:])
0.0009924865443739191
```  
Now compute and plot the power spectrum.

```python
>>> f, Pxx_spec = signal.welch(x, fs, 'flattop', 1024, scaling='spectrum')
>>> plt.figure()
>>> plt.semilogy(f, np.sqrt(Pxx_spec))
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('Linear spectrum [V RMS]')
>>> plt.show()
```
The top graph shows the power spectral density (PSD) in $V^2/Hz$ and the bottom graph shows the linear spectrum in $V$ RMS versus frequency in Hz.
The peak height in the power spectrum is an estimate of the RMS amplitude.

```python
>>> np.sqrt(Pxx_spec.max())
2.0077340678640727
```

If we now introduce a discontinuity in the signal, by increasing the amplitude of a small portion of the signal by 50, we can see the corruption of the mean average power spectral density, but using a median average better estimates the normal behaviour.

```python
>>> f, Pxx_den = signal.welch(x, fs, nperseg=1024)
>>> f_med, Pxx_den_med = signal.welch(x, fs, nperseg=1024, average='median')
>>> plt.semilogy(f, Pxx_den, label='mean')
>>> plt.semilogy(f_med, Pxx_den_med, label='median')
>>> plt.ylim([0.5e-3, 1])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.legend()
>>> plt.show()
```

**scipy.signal.csd**

Estimate the cross power spectral density, Pxy, using Welch's method.

```python
scipy.signal.csd(x, y, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1, average='mean')
```

**Parameters**

- `x` [array_like] Time series of measurement values
- `y` [array_like] Time series of measurement values
- `fs` [float, optional] Sampling frequency of the x and y time series. Defaults to 1.0.
- `window` [str, tuple, or array_like, optional] Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array_like
it will be used directly as the window and its length must be nperseg. Defaults to a Hann window.

**nperseg**

[int, optional] Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array_like, is set to the length of the window.

**noverlap**

[int, optional] Number of points to overlap between segments. If *None*, `noverlap = nperseg // 2`. Defaults to *None*.

**nfft**

[int, optional] Length of the FFT used, if a zero padded FFT is desired. If *None*, the FFT length is `nperseg`. Defaults to *None*.

**detrend**

[str or function or *False*, optional] Specifies how to detrend each segment. If `detrend` is a string, it is passed as the *type* argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If `detrend` is *False*, no detrending is done. Defaults to 'constant'.

**return_onesided**

[bool, optional] If *True*, return a one-sided spectrum for real data. If *False* return a two-sided spectrum. Defaults to *True*, but for complex data, a two-sided spectrum is always returned.

**scaling**

[{'density', 'spectrum'}, optional] Selects between computing the cross spectral density ('density') where `Pxy` has units of V**2/Hz and computing the cross spectrum ('spectrum') where `Pxy` has units of V**2, if `x` and `y` are measured in V and `fs` is measured in Hz. Defaults to 'density'.

**axis**

[int, optional] Axis along which the CSD is computed for both inputs; the default is over the last axis (i.e. `axis=-1`).

**average**

[{'mean', 'median'}, optional] Method to use when averaging periodograms. If the spectrum is complex, the average is computed separately for the real and imaginary parts. Defaults to 'mean'.

New in version 1.2.0.

**Returns**

- **f**
  [ndarray] Array of sample frequencies.
- **Pxy**
  [ndarray] Cross spectral density or cross power spectrum of `x,y`.

See also:

- **periodogram**
  Simple, optionally modified periodogram
- **lombscargle**
  Lomb-Scargle periodogram for unevenly sampled data
- **welch**
  Power spectral density by Welch’s method. [Equivalent to `csd(x,x)`]
- **coherence**
  Magnitude squared coherence by Welch’s method.
Notes

By convention, Pxy is computed with the conjugate FFT of X multiplied by the FFT of Y.

If the input series differ in length, the shorter series will be zero-padded to match.

An appropriate amount of overlap will depend on the choice of window and on your requirements. For the default Hann window an overlap of 50% is a reasonable trade off between accurately estimating the signal power, while not over counting any of the data. Narrower windows may require a larger overlap.

New in version 0.16.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()

Generate two test signals with some common features.

```python
>>> fs = 10e3  
>>> N = 1e5  
>>> amp = 20  
>>> freq = 1234.0  
>>> noise_power = 0.001 * fs / 2  
>>> time = np.arange(N) / fs  
>>> b, a = signal.butter(2, 0.25, 'low')  
>>> x = rng.normal(scale=np.sqrt(noise_power), size=time.shape)  
>>> y = signal.lfilter(b, a, x)  
>>> x += amp*np.sin(2*np.pi*freq*time)  
>>> y += rng.normal(scale=0.1*np.sqrt(noise_power), size=time.shape)
```

Compute and plot the magnitude of the cross spectral density.

```python
>>> f, Pxy = signal.csd(x, y, fs, nperseg=1024)  
>>> plt.semilogy(f, np.abs(Pxy))  
>>> plt.xlabel('frequency [Hz]')  
>>> plt.ylabel('CSD [V**2/Hz]')  
>>> plt.show()
```
Estimate the magnitude squared coherence estimate, $C_{xy}$, of discrete-time signals $X$ and $Y$ using Welch’s method.

$$C_{xy} = \frac{|P_{xy}|^2}{P_{xx}P_{yy}}$$

where $P_{xx}$ and $P_{yy}$ are power spectral density estimates of $X$ and $Y$, and $P_{xy}$ is the cross spectral density estimate of $X$ and $Y$.

**Parameters**

- `x` [array_like] Time series of measurement values
- `y` [array_like] Time series of measurement values
- `fs` [float, optional] Sampling frequency of the `x` and `y` time series. Defaults to 1.0.
- `window` [str or tuple or array_like, optional] Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array_like it will be used directly as the window and its length must be `nperseg`. Defaults to a Hann window.
- `nperseg` [int, optional] Length of each segment. Defaults to None, but if `window` is str or tuple, is set to 256, and if `window` is array_like, is set to the length of the window.
- `noverlap` [int, optional] Number of points to overlap between segments. If `None`, `noverlap = nperseg // 2`. Defaults to `None`.
- `nfft` [int, optional] Length of the FFT used, if a zero padded FFT is desired. If `None`, the FFT length is `nperseg`. Defaults to `None`.
- `detrend` [str or function or `False`, optional] Specifies how to detrend each segment. If `detrend` is a string, it is passed as the `type` argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If `detrend` is `False`, no detrending is done. Defaults to ‘constant’.
- `axis` [int, optional] Axis along which the coherence is computed for both inputs; the default is over the last axis (i.e. `axis=-1`).

**Returns**

- `Cxy` [ndarray] Magnitude squared coherence of `x` and `y`. 

```python
scipy.signal.coherence

scipy.signal.coherence(x, y, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, detrend='constant', axis=-1)
```

Estimate the magnitude squared coherence estimate, $C_{xy}$, of discrete-time signals $X$ and $Y$ using Welch’s method.

$$C_{xy} = \frac{|P_{xy}|^2}{P_{xx}P_{yy}}$$

where $P_{xx}$ and $P_{yy}$ are power spectral density estimates of $X$ and $Y$, and $P_{xy}$ is the cross spectral density estimate of $X$ and $Y$.

**Notes**

An appropriate amount of overlap will depend on the choice of window and on your requirements. For the default Hann window an overlap of 50% is a reasonable trade off between accurately estimating the signal power, while not over counting any of the data. Narrower windows may require a larger overlap.

New in version 0.16.0.

**References**

[1], [2]

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
```

Generate two test signals with some common features.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 20
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> b, a = signal.butter(2, 0.25, 'low')
>>> x = rng.normal(scale=np.sqrt(noise_power), size=time.shape)
>>> y = signal.lfilter(b, a, x)
>>> x += amp*np.sin(2*np.pi*freq*time)
>>> y += rng.normal(scale=0.1*np.sqrt(noise_power), size=time.shape)
```

Compute and plot the coherence.

```python
>>> f, Cxy = signal.coherence(x, y, fs, nperseg=1024)
>>> plt.semilogy(f, Cxy)
>>> plt.xlabel('frequency [Hz]')
```

(continues on next page)
scipy.signal.spectrogram

scipy.signal.spectrogram(x, fs=1.0, window=('tukey', 0.25), nperseg=None, noverlap=None, nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1, mode='psd')

Compute a spectrogram with consecutive Fourier transforms.

Spectrograms can be used as a way of visualizing the change of a nonstationary signal’s frequency content over time.

Parameters

- **x**: array_like, Time series of measurement values
- **fs**: float, optional, Sampling frequency of the x time series. Defaults to 1.0.
- **window**: str or tuple or array_like, optional, Desired window to use. If window is a string or tuple, it is passed to get_window to generate the window values, which are DFT-even by default. See get_window for a list of windows and required parameters. If window is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Tukey window with shape parameter of 0.25.
- **nperseg**: int, optional, Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array_like, is set to the length of the window.
- **noverlap**: int, optional, Number of points to overlap between segments. If None, noverlap = nperseg // 8. Defaults to None.
- **nfft**: int, optional, Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is nperseg. Defaults to None.
- **detrend**: str or function or False, optional, Specifies how to detrend each segment. If detrend is a string, it is passed as the type argument to the detrend function. If it is a function, it takes a segment and returns a detrended segment. If detrend is False, no detrending is done. Defaults to ‘constant’.
- **return_onesided**: bool, optional, If True, return a one-sided spectrum for real data. If False return a two-sided spectrum. Defaults to True, but for complex data, a two-sided spectrum is always returned.
...
Examples

```python
>>> from scipy import signal
>>> from scipy.fft import fftshift
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()

Generate a test signal, a 2 Vrms sine wave whose frequency is slowly modulated around 3 kHz, corrupted by white noise of exponentially decreasing magnitude sampled at 10 kHz.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.01 * fs / 2
>>> time = np.arange(N) / float(fs)
>>> mod = 500*np.cos(2*np.pi*0.25*time)
>>> carrier = amp * np.sin(2*np.pi*3e3*time + mod)
>>> noise = rng.normal(scale=np.sqrt(noise_power), size=time.shape)
>>> noise *= np.exp(-time/5)
>>> x = carrier + noise
```

Compute and plot the spectrogram.

```python
>>> f, t, Sxx = signal.spectrogram(x, fs)
>>> plt.pcolormesh(t, f, Sxx, shading='gouraud')
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.show()
```

Note, if using output that is not one sided, then use the following:

```python
>>> f, t, Sxx = signal.spectrogram(x, fs, return_onesided=False)
>>> plt.pcolormesh(t, fftshift(f), fftshift(Sxx, axes=0), shading='gouraud')
```
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.show()
istft
Inverse Short Time Fourier Transform

check_COLA
Check whether the Constant OverLap Add (COLA) constraint is met

welch
Power spectral density by Welch’s method

spectrogram
Spectrogram by Welch’s method

csd
Cross spectral density by Welch’s method

Notes
This subroutine calculates the periodogram using a slightly modified algorithm due to Townsend [3] which allows the periodogram to be calculated using only a single pass through the input arrays for each frequency.
The algorithm running time scales roughly as O(x * freqs) or O(N^2) for a large number of samples and frequencies.

References
[1], [2], [3]

Examples

```python
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
```

First define some input parameters for the signal:

```python
>>> A = 2.
>>> w0 = 1. # rad/sec
>>> nin = 150
>>> nout = 100000
```

Randomly generate sample times:

```python
>>> x = rng.uniform(0, 10*np.pi, nin)
```

Plot a sine wave for the selected times:

```python
>>> y = A * np.cos(w0*x)
```

Define the array of frequencies for which to compute the periodogram:

```python
>>> w = np.linspace(0.01, 10, nout)
```

Calculate Lomb-Scargle periodogram:
```python
>>> import scipy.signal as signal
>>> pgram = signal.lombscargle(x, y, w, normalize=True)
```

Now make a plot of the input data:

```python
>>> fig, (ax_t, ax_w) = plt.subplots(2, 1, constrained_layout=True)
>>> ax_t.plot(x, y, 'b+')
>>> ax_t.set_xlabel('Time [s]')

Then plot the normalized periodogram:

```python
>>> ax_w.plot(w, pgram)
>>> ax_w.set_xlabel('Angular frequency [rad/s]')
>>> ax_w.set_ylabel('Normalized amplitude')
>>> plt.show()
```

### scipy.signal.vectorstrength

`scipy.signal.vectorstrength(events, period)`

Determine the vector strength of the events corresponding to the given period.

The vector strength is a measure of phase synchrony, how well the timing of the events is synchronized to a single period of a periodic signal.

If multiple periods are used, calculate the vector strength of each. This is called the “resonating vector strength”.

**Parameters**

- `events` [1D array_like] An array of time points containing the timing of the events.
- `period` [float or array_like] The period of the signal that the events should synchronize to. The period is in the same units as `events`. It can also be an array of periods, in which case the outputs are arrays of the same length.

**Returns**

- `strength` [float or 1D array] The strength of the synchronization. 1.0 is perfect synchronization and 0.0 is no synchronization. If `period` is an array, this is also an array with each element containing the vector strength at the corresponding period.
phase  [float or array] The phase that the events are most strongly synchronized to in radians. If period is an array, this is also an array with each element containing the phase for the corresponding period.

scipy.signal.stft

scipy.signal.stft(x, fs=1.0, window='hann', nperseg=256, noverlap=None, nfft=None, detrend=False, return_onesided=True, boundary='zeros', padded=True, axis=-1)

Compute the Short Time Fourier Transform (STFT).

STFTs can be used as a way of quantifying the change of a nonstationary signal’s frequency and phase content over time.

Parameters

x  [array_like] Time series of measurement values
fs  [float, optional] Sampling frequency of the x time series. Defaults to 1.0.
window  [str or tuple or array_like, optional] Desired window to use. If window is a string or tuple, it is passed to get_window to generate the window values, which are DFT-even by default. See get_window for a list of windows and required parameters. If window is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Hann window.
nperseg  [int, optional] Length of each segment. Defaults to 256.
noverlap  [int, optional] Number of points to overlap between segments. If None, noverlap = nperseg // 2. Defaults to None. When specified, the COLA constraint must be met (see Notes below).
nfft  [int, optional] Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is nperseg. Defaults to None.
detrend  [str or function or False, optional] Specifies how to detrend each segment. If detrend is a string, it is passed as the type argument to the detrend function. If it is a function, it takes a segment and returns a detrended segment. If detrend is False, no detrending is done. Defaults to False.
return_onesided  [bool, optional] If True, return a one-sided spectrum for real data. If False return a two-sided spectrum. Defaults to True, but for complex data, a two-sided spectrum is always returned.
boundary  [str or None, optional] Specifies whether the input signal is extended at both ends, and how to generate the new values, in order to center the first windowed segment on the first input point. This has the benefit of enabling reconstruction of the first input point when the employed window function starts at zero. Valid options are ['even', 'odd', 'constant', 'zeros', None]. Defaults to 'zeros', for zero padding extension. I.e. [1, 2, 3, 4] is extended to [0, 1, 2, 3, 4, 0] for nperseg=3.
padded [bool, optional] Specifies whether the input signal is zero-padded at the end to make the signal fit exactly into an integer number of window segments, so that all of the signal is included in the output. Defaults to True. Padding occurs after boundary extension, if boundary is not None, and padded is True, as is the default.

axis [int, optional] Axis along which the STFT is computed; the default is over the last axis (i.e. axis=-1).

Returns

f [ndarray] Array of sample frequencies.
t [ndarray] Array of segment times.
Zxx [ndarray] STFT of x. By default, the last axis of Zxx corresponds to the segment times.

Notes

In order to enable inversion of an STFT via the inverse STFT in istft, the signal windowing must obey the constraint of “Nonzero OverLap Add” (NOLA), and the input signal must have complete windowing coverage (i.e. (x.shape[axis] - nperseg) % (nperseg - noverlap) == 0). The padded argument may be used to accomplish this.

Given a time-domain signal $x[n]$, a window $w[n]$, and a hop size $H = nperseg - noverlap$, the windowed frame at time index $t$ is given by

$$x_t[n] = x[n]w[n - tH]$$

The overlap-add (OLA) reconstruction equation is given by

$$x[n] = \sum_t x_t[n]w[n - tH] \quad \sum_t w^2[n - tH]$$

The NOLA constraint ensures that every normalization term that appears in the denominator of the OLA reconstruction equation is nonzero. Whether a choice of window, nperseg, and noverlap satisfy this constraint can be tested with check_NOLA.
New in version 0.19.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
Generate a test signal, a 2 Vrms sine wave whose frequency is slowly modulated around 3kHz, corrupted by white noise of exponentially decreasing magnitude sampled at 10 kHz.
```

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.01 * fs / 2
>>> time = np.arange(N) / float(fs)
>>> mod = 500*np.cos(2*np.pi*0.25*time)
>>> carrier = amp * np.sin(2*np.pi*3e3*time + mod)
>>> noise = rng.normal(scale=np.sqrt(noise_power),
... size=time.shape)
>>> noise *= np.exp(-time/5)
>>> x = carrier + noise
```

Compute and plot the STFT's magnitude.
```
>>> f, t, Zxx = signal.stft(x, fs, nperseg=1000)
>>> plt.pcolormesh(t, f, np.abs(Zxx), vmin=0, vmax=amp, shading='gouraud')
>>> plt.title('STFT Magnitude')
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.show()
```

`scipy.signal.istft`

`scipy.signal.istft`(Zxx, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, input_onesided=True, boundary=True, time_axis=-1, freq_axis=-2)

Perform the inverse Short Time Fourier transform (iSTFT).

**Parameters**

- **Zxx**: [array_like] STFT of the signal to be reconstructed. If a purely real array is passed, it will be cast to a complex data type.
- **fs**: [float, optional] Sampling frequency of the time series. Defaults to 1.0.
- **window**: [str or tuple or array_like, optional] Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Hann window. Must match the window used to generate the STFT for faithful inversion.
nperseg [int, optional] Number of data points corresponding to each STFT segment. This parameter must be specified if the number of data points per segment is odd, or if the STFT was padded via nfft > nperseg. If None, the value depends on the shape of Zxx and input_onesided. If input_onesided is True, nperseg=2*(Zxx.shape[freq_axis] - 1). Otherwise, nperseg=Zxx.shape[freq_axis]. Defaults to None.

noverlap [int, optional] Number of points to overlap between segments. If None, half of the segment length. Defaults to None. When specified, the COLA constraint must be met (see Notes below), and should match the parameter used to generate the STFT. Defaults to None.

nfft [int, optional] Number of FFT points corresponding to each STFT segment. This parameter must be specified if the STFT was padded via nfft > nperseg. If None, the default values are the same as for nperseg, detailed above, with one exception: if input_onesided is True and nperseg==2*Zxx.shape[freq_axis] - 1, nfft also takes on that value. This case allows the proper inversion of an odd-length unpadded STFT using nfft=None. Defaults to None.

input_onesided [bool, optional] If True, interpret the input array as one-sided FFTs, such as is returned by stft with return_onesided=True and numpy.fft.rfft. If False, interpret the input as a two-sided FFT. Defaults to True.

boundary [bool, optional] Specifies whether the input signal was extended at its boundaries by supplying a non-None boundary argument to stft. Defaults to True.

time_axis [int, optional] Where the time segments of the STFT is located; the default is the last axis (i.e. axis=-1).

draw_onesided [int, optional] Where the frequency axis of the STFT is located; the default is the penultimate axis (i.e. axis=-2).

Returns

- t [ndarray] Array of output data times.
- x [ndarray] iSTFT of Zxx.

See also:

- stft
  Short Time Fourier Transform
- check_COLA

3.3. API definition 1685
Check whether the Constant OverLap Add (COLA) constraint is met

**check_NOLA**

Check whether the Nonzero Overlap Add (NOLA) constraint is met

**Notes**

In order to enable inversion of an STFT via the inverse STFT with *istft*, the signal windowing must obey the constraint of “nonzero overlap add” (NOLA):

\[
\sum_t w^2[n - tH] \neq 0
\]

This ensures that the normalization factors that appear in the denominator of the overlap-add reconstruction equation

\[
x[n] = \frac{\sum_t x_t[n] w[n - tH]}{\sum_t w^2[n - tH]}
\]

are not zero. The NOLA constraint can be checked with the `check_NOLA` function.

An STFT which has been modified (via masking or otherwise) is not guaranteed to correspond to a exactly realizable signal. This function implements the iSTFT via the least-squares estimation algorithm detailed in [2], which produces a signal that minimizes the mean squared error between the STFT of the returned signal and the modified STFT.

New in version 0.19.0.

**References**

[1], [2]

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
```

Generate a test signal, a 2 Vrms sine wave at 50Hz corrupted by 0.001 V**2/Hz of white noise sampled at 1024 Hz.

```python
>>> fs = 1024
>>> N = 10*fs
>>> nperseg = 512
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / float(fs)
>>> carrier = amp * np.sin(2*np.pi*50*time)
>>> noise = rng.normal(scale=np.sqrt(noise_power),
... size=time.shape)
>>> x = carrier + noise
```

Compute the STFT, and plot its magnitude

```python
>>> f, t, Zxx = signal.stft(x, fs=fs, nperseg=nperseg)
>>> plt.figure()
>>> plt.pcolormesh(t, f, np.abs(Zxx), vmin=0, vmax=amp, shading='gouraud')
>>> plt.ylim([f[1], f[-1]])
>>> plt.title('STFT Magnitude')
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.yscale('log')
>>> plt.show()
```

Zero the components that are 10% or less of the carrier magnitude, then convert back to a time series via inverse STFT

```python
>>> Zxx = np.where(np.abs(Zxx) >= amp/10, Zxx, 0)
>>> _, xrec = signal.istft(Zxx, fs)
```

Compare the cleaned signal with the original and true carrier signals.

```python
>>> plt.figure()
>>> plt.plot(time, x, time, xrec, time, carrier)
>>> plt.xlim([2, 2.1])
>>> plt.xlabel('Time [sec]')
>>> plt.ylabel('Signal')
>>> plt.legend(['Carrier + Noise', 'Filtered via STFT', 'True Carrier'])
>>> plt.show()
```

Note that the cleaned signal does not start as abruptly as the original, since some of the coefficients of the transient were also removed:

```python
>>> plt.figure()
>>> plt.plot(time, x, time, xrec, time, carrier)
>>> plt.xlim([0, 0.1])
>>> plt.xlabel('Time [sec]')
>>> plt.ylabel('Signal')
```

(continues on next page)

3.3. API definition 1687
scipy.signal.check_COLA

scipy.signal.check_COLA(window, nperseg, noverlap, tol=1e-10)
Check whether the Constant OverLap Add (COLA) constraint is met.

Parameters

- window [str or tuple or array_like] Desired window to use. If window is a string or tuple, it is passed to get_window to generate the window values, which are DFT-even by default. See get_window for a list of windows and required parameters. If window is array_like it will be used directly as the window and its length must be nperseg.
- nperseg [int] Length of each segment.
The `check_COLA` function is used to verify whether a given combination of STFT parameters satisfies the Constant Overlap Add (COLA) constraint. It takes two parameters:

- `noverlap` [int] Number of points to overlap between segments.
- `tol` [float, optional] The allowed variance of a bin's weighted sum from the median bin sum.

**Returns**

- `verdict` [bool] True if chosen combination satisfies COLA within `tol`, False otherwise

**See also:**

- `check_NOLA` Check whether the Nonzero Overlap Add (NOLA) constraint is met
- `stft` Short Time Fourier Transform
- `istft` Inverse Short Time Fourier Transform

**Notes**

In order to enable inversion of an STFT via the inverse STFT in `istft`, it is sufficient that the signal windowing obeys the constraint of “Constant Overlap Add” (COLA). This ensures that every point in the input data is equally weighted, thereby avoiding aliasing and allowing full reconstruction.

**Some examples of windows that satisfy COLA:**

- Rectangular window at overlap of 0, 1/2, 2/3, 3/4, …
- Bartlett window at overlap of 1/2, 3/4, 5/6, …
- Hann window at 1/2, 2/3, 3/4, …
- Any Blackman family window at 2/3 overlap
- Any window with `noverlap = nperseg-1`

A very comprehensive list of other windows may be found in [2], wherein the COLA condition is satisfied when the “Amplitude Flatness” is unity.

New in version 0.19.0.

**References**

[1], [2]

**Examples**

```python
>>> from scipy import signal

Confirm COLA condition for rectangular window of 75% (3/4) overlap:

```python
>>> signal.check_COLA(signal.windows.boxcar(100), 100, 75)
True
```

COLA is not true for 25% (1/4) overlap, though:
```python
>>> signal.check_COLA(signal.windows.boxcar(100), 100, 25)
False

“Symmetrical” Hann window (for filter design) is not COLA:

```python
>>> signal.check_COLA(signal.windows.hann(120, sym=True), 120, 60)
False

“Periodic” or “DFT-even” Hann window (for FFT analysis) is COLA for overlap of 1/2, 2/3, 3/4, etc.:

```python
>>> signal.check_COLA(signal.windows.hann(120, sym=False), 120, 60)
True

```python
>>> signal.check_COLA(signal.windows.hann(120, sym=False), 120, 80)
True

```python
>>> signal.check_COLA(signal.windows.hann(120, sym=False), 120, 90)
True
```

scipy.signal.check_NOLA

scipy.signal.check_NOLA(window, nperseg, noverlap, tol=1e-10)

Check whether the Nonzero Overlap Add (NOLA) constraint is met.

Parameters

- **window** [str or tuple or array_like] Desired window to use. If *window* is a string or tuple, it is passed to *get_window* to generate the window values, which are DFT-even by default. See *get_window* for a list of windows and required parameters. If *window* is array_like it will be used directly as the window and its length must be *nperseg*.
- **nperseg** [int] Length of each segment.
- **noverlap** [int] Number of points to overlap between segments.
- **tol** [float, optional] The allowed variance of a bin’s weighted sum from the median bin sum.

Returns

- **verdict** [bool] *True* if chosen combination satisfies the NOLA constraint within *tol*, *False* otherwise

See also:

- check_COLA
- check_NOLA
- stft
- Short Time Fourier Transform
- istft
- Inverse Short Time Fourier Transform
Notes

In order to enable inversion of an STFT via the inverse STFT in `istft`, the signal windowing must obey the constraint of “nonzero overlap add” (NOLA):

\[ \sum_{t} w^2[n - tH] \neq 0 \]

for all \( n \), where \( w \) is the window function, \( t \) is the frame index, and \( H \) is the hop size (\( H = nperseg - noverlap \)). This ensures that the normalization factors in the denominator of the overlap-add inversion equation are not zero. Only very pathological windows will fail the NOLA constraint.

New in version 1.2.0.

References

[1], [2]

Examples

```python
>>> from scipy import signal

Confirm NOLA condition for rectangular window of 75% (3/4) overlap:

>>> signal.check_NOLA(signal.windows.boxcar(100), 100, 75)
True

NOLA is also true for 25% (1/4) overlap:

>>> signal.check_NOLA(signal.windows.boxcar(100), 100, 25)
True

“Symmetrical” Hann window (for filter design) is also NOLA:

>>> signal.check_NOLA(signal.windows.hann(120, sym=True), 120, 60)
True

As long as there is overlap, it takes quite a pathological window to fail NOLA:

>>> w = np.ones(64, dtype="float")
>>> w[::2] = 0
>>> signal.check_NOLA(w, 64, 32)
False

If there is not enough overlap, a window with zeros at the ends will not work:

>>> signal.check_NOLA(signal.windows.hann(64), 64, 0)
False
>>> signal.check_NOLA(signal.windows.hann(64), 64, 1)
False
>>> signal.check_NOLA(signal.windows.hann(64), 64, 2)
True
```
Chirp Z-transform and Zoom FFT

</tbody>
</table>

`scipy.signal.czt`

`scipy.signal.czt(x, m=None, w=None, a=1 + 0j, *, axis=-1)`

Compute the frequency response around a spiral in the Z plane.

**Parameters**

- `x` [array] The signal to transform.
- `m` [int, optional] The number of output points desired. Default is the length of the input data.
- `w` [complex, optional] The ratio between points in each step. This must be precise or the accumulated error will degrade the tail of the output sequence. Defaults to equally spaced points around the entire unit circle.
- `a` [complex, optional] The starting point in the complex plane. Default is `1+0j`.
- `axis` [int, optional] Axis over which to compute the FFT. If not given, the last axis is used.

**Returns**

- `out` [ndarray] An array of the same dimensions as `x`, but with the length of the transformed axis set to `m`.

**See also:**

- `CZT`
  
  Class that creates a callable chirp z-transform function.

- `zoom_fft`
  
  Convenience function for partial FFT calculations.

**Notes**

The defaults are chosen such that `signal.czt(x)` is equivalent to `fft.fft(x)` and, if `m > len(x)`, that `signal.czt(x, m)` is equivalent to `fft.fft(x, m)`.

If the transform needs to be repeated, use `CZT` to construct a specialized transform function which can be reused without recomputing constants.

An example application is in system identification, repeatedly evaluating small slices of the z-transform of a system, around where a pole is expected to exist, to refine the estimate of the pole's true location. [1]
References

[1]

Examples

Generate a sinusoid:

```python
>>> f1, f2, fs = 8, 10, 200  # Hz
>>> t = np.linspace(0, 1, fs, endpoint=False)
>>> x = np.sin(2*np.pi*t*f2)
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, x)
>>> plt.axis([0, 1, -1.1, 1.1])
>>> plt.show()
```

Its discrete Fourier transform has all of its energy in a single frequency bin:

```python
>>> from scipy.fft import rfft, rfftfreq
>>> from scipy.signal import czt, czt_points
>>> plt.plot(rfftfreq(fs, 1/fs), abs(rfft(x)))
>>> plt.margins(0, 0.1)
>>> plt.show()
```

However, if the sinusoid is logarithmically-decaying:

```python
>>> x = np.exp(-t*f1) * np.sin(2*np.pi*t*f2)
>>> plt.plot(t, x)
>>> plt.axis([0, 1, -1.1, 1.1])
>>> plt.show()
```

the DFT will have spectral leakage:
While the DFT always samples the z-transform around the unit circle, the chirp z-transform allows us to sample the Z-transform along any logarithmic spiral, such as a circle with radius smaller than unity:

```python
>>> M = fs // 2  # Just positive frequencies, like rfft
>>> a = np.exp(-f1/fs)  # Starting point of the circle, radius < 1
>>> w = np.exp(-1j*np.pi/M)  # "Step size" of circle
>>> points = czt_points(M + 1, w, a)  # M + 1 to include Nyquist
>>> plt.plot(points.real, points.imag, '.')
>>> plt.gca().add_patch(plt.Circle((0,0), radius=1, fill=False, alpha=.3))
>>> plt.axis('equal'); plt.axis([-1.05, 1.05, -0.05, 1.05])
>>> plt.show()
```

With the correct radius, this transforms the decaying sinusoid (and others with the same decay rate) without spectral leakage:

```python
>>> z_vals = czt(x, M + 1, w, a)  # Include Nyquist for comparison to rfft
>>> freqs = np.angle(points)*fs/(2*np.pi)  # angle = omega, radius = sigma
>>> plt.plot(freqs, abs(z_vals))
>>> plt.margins(0, 0.1)
>>> plt.show()
```
`scipy.signal.zoom_fft`

`scipy.signal.zoom_fft(x, fn=m=, fs=2, endpoint=False, axis=-1)`

Compute the DFT of `x` only for frequencies in range `fn`.

**Parameters**

- `x` [array] The signal to transform.
- `fn` [array_like] A length-2 sequence `[f1, f2]` giving the frequency range, or a scalar, for which the range `[0, fn]` is assumed.
- `m` [int, optional] The number of points to evaluate. The default is the length of `x`.
- `fs` [float, optional] The sampling frequency. If `fs=10` represented 10 kHz, for example, then `f1` and `f2` would also be given in kHz. The default sampling frequency is 2, so `f1` and `f2` should be in the range `[0, 1]` to keep the transform below the Nyquist frequency.
- `endpoint` [bool, optional] If True, `f2` is the last sample. Otherwise, it is not included. Default is False.
- `axis` [int, optional] Axis over which to compute the FFT. If not given, the last axis is used.

**Returns**

- `out` [ndarray] The transformed signal. The Fourier transform will be calculated at the points `f1`, `f1+df`, `f1+2df`, ..., `f2`, where `df=(f2-f1)/m`.

**See also:**

- `ZoomFFT`
  
  Class that creates a callable partial FFT function.

**Notes**

The defaults are chosen such that `signal.zoom_fft(x, 2)` is equivalent to `fft.fft(x)` and, if `m > len(x)`, that `signal.zoom_fft(x, 2, m)` is equivalent to `fft.fft(x, m)`.

To graph the magnitude of the resulting transform, use:

```python
plot(linspace(f1, f2, m, endpoint=False), abs(zoom_fft(x, [f1, f2], m)))
```

If the transform needs to be repeated, use `ZoomFFT` to construct a specialized transform function which can be reused without recomputing constants.

**Examples**

To plot the transform results use something like the following:

```python
>>> from scipy.signal import zoom_fft
>>> t = np.linspace(0, 1, 1021)
>>> x = np.cos(2*np.pi*15*t) + np.sin(2*np.pi*17*t)
>>> f1, f2 = 5, 27
>>> X = zoom_fft(x, [f1, f2], len(x), fs=1021)
>>> f = np.linspace(f1, f2, len(x))
>>> import matplotlib.pyplot as plt
>>> plt.plot(f, 20*np.log10(np.abs(X)))
>>> plt.show()
```
scipy.signal.CZT

class scipy.signal.CZT(n, m=None, w=None, a=1 + 0j)

Create a callable chirp z-transform function.

Transform to compute the frequency response around a spiral. Objects of this class are callables which can compute the chirp z-transform on their inputs. This object precalculates the constant chirps used in the given transform.

Parameters

- **n** [int] The size of the signal.
- **m** [int, optional] The number of output points desired. Default is \( n \).
- **w** [complex, optional] The ratio between points in each step. This must be precise or the accumulated error will degrade the tail of the output sequence. Defaults to equally spaced points around the entire unit circle.
- **a** [complex, optional] The starting point in the complex plane. Default is \( 1+0j \).

Returns

- **f** [CZT] Callable object \( f(x, \ axis=-1) \) for computing the chirp z-transform on \( x \).

See also:

czt

Convenience function for quickly calculating CZT.

ZoomFFT

Class that creates a callable partial FFT function.
Notes

The defaults are chosen such that \( f(x) \) is equivalent to `fft.fft(x)` and, if \( m > \text{len}(x) \), that \( f(x, m) \) is equivalent to `fft.fft(x, m)`.

If \( w \) does not lie on the unit circle, then the transform will be around a spiral with exponentially-increasing radius. Regardless, angle will increase linearly.

For transforms that do lie on the unit circle, accuracy is better when using `ZoomFFT`, since any numerical error in \( w \) is accumulated for long data lengths, drifting away from the unit circle.

The chirp z-transform can be faster than an equivalent FFT with zero padding. Try it with your own array sizes to see.

However, the chirp z-transform is considerably less precise than the equivalent zero-padded FFT.

As this CZT is implemented using the Bluestein algorithm, it can compute large prime-length Fourier transforms in \( O(N \log N) \) time, rather than the \( O(N^{**2}) \) time required by the direct DFT calculation. (`scipy.fft` also uses Bluestein's algorithm'.)

(The name “chirp z-transform” comes from the use of a chirp in the Bluestein algorithm. It does not decompose signals into chirps, like other transforms with “chirp” in the name.)

References

[1], [2]

Examples

Compute multiple prime-length FFTs:

```python
>>> from scipy.signal import CZT
>>> a = np.random.rand(7)
>>> b = np.random.rand(7)
>>> c = np.random.rand(7)
>>> czt_7 = CZT(n=7)
>>> A = czt_7(a)
>>> B = czt_7(b)
>>> C = czt_7(c)
```

Display the points at which the FFT is calculated:

```python
>>> czt_7.points()
array([[ 1.00000000+0.j, 0.62348980+0.78183148j,
       -0.22252093+0.97492791j, -0.90096887+0.43388374j,
       -0.90096887-0.43388374j, -0.22252093-0.97492791j,
       0.62348980-0.78183148j]], dtype=complex)
>>> import matplotlib.pyplot as plt
>>> plt.plot(czt_7.points().real, czt_7.points().imag, 'o')
>>> plt.gca().add_patch(plt.Circle((0,0), radius=1, fill=False, alpha=.3))
>>> plt.axis('equal')
>>> plt.show()
```
### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>call</strong>(x, *[, axis])</td>
<td>Calculate the chirp z-transform of a signal.</td>
</tr>
<tr>
<td>points()</td>
<td>Return the points at which the chirp z-transform is computed.</td>
</tr>
</tbody>
</table>

#### scipy.signal.CZT.__call__

CZT.__call__(x, *[, axis=- 1])

Calculate the chirp z-transform of a signal.

**Parameters**

- **x** : [array] The signal to transform.
- **axis** : [int, optional] Axis over which to compute the FFT. If not given, the last axis is used.

**Returns**

- **out** : [ndarray] An array of the same dimensions as x, but with the length of the transformed axis set to m.

#### scipy.signal.CZT.points

CZT.points()

Return the points at which the chirp z-transform is computed.
scipy.signal.ZoomFFT

class scipy.signal.ZoomFFT(n, fn=None, *, fs=2, endpoint=False)

Create a callable zoom FFT transform function.

This is a specialization of the chirp z-transform (CZT) for a set of equally-spaced frequencies around the unit circle, used to calculate a section of the FFT more efficiently than calculating the entire FFT and truncating.

Parameters

- **n** [int] The size of the signal.
- **fn** [array_like] A length-2 sequence \([f_1, f_2]\) giving the frequency range, or a scalar, for which the range \([0, fn]\) is assumed.
- **m** [int, optional] The number of points to evaluate. Default is \(n\).
- **fs** [float, optional] The sampling frequency. If \(fs=10\) represented 10 kHz, for example, then \(f1\) and \(f2\) would also be given in kHz. The default sampling frequency is 2, so \(f1\) and \(f2\) should be in the range \([0, 1]\) to keep the transform below the Nyquist frequency.
- **endpoint** [bool, optional] If True, \(f2\) is the last sample. Otherwise, it is not included. Default is False.

Returns

- **f** [ZoomFFT] Callable object \(f(x, \text{axis}=-1)\) for computing the zoom FFT on \(x\).

See also:

zoom_fft

Convenience function for calculating a zoom FFT.

Notes

The defaults are chosen such that \(f(x, 2)\) is equivalent to \(\text{fft.fft}(x)\) and, if \(m > \text{len}(x)\), that \(f(x, 2, m)\) is equivalent to \(\text{fft.fft}(x, m)\).

Sampling frequency is \(1/dt\), the time step between samples in the signal \(x\). The unit circle corresponds to frequencies from 0 up to the sampling frequency. The default sampling frequency of 2 means that \(f1, f2\) values up to the Nyquist frequency are in the range \([0, 1]\). For \(f1, f2\) values expressed in radians, a sampling frequency of \(2*\pi\) should be used.

Remember that a zoom FFT can only interpolate the points of the existing FFT. It cannot help to resolve two separate nearby frequencies. Frequency resolution can only be increased by increasing acquisition time.

These functions are implemented using Bluestein’s algorithm (as is scipy.fft). [2]

References

[1], [2]
Examples

To plot the transform results use something like the following:

```python
>>> from scipy.signal import ZoomFFT
>>> t = np.linspace(0, 1, 1021)
>>> x = np.cos(2*np.pi*15*t) + np.sin(2*np.pi*17*t)
>>> f1, f2 = 5, 27
>>> transform = ZoomFFT(len(x), [f1, f2], len(x), fs=1021)
>>> X = transform(x)
>>> f = np.linspace(f1, f2, len(x))
>>> import matplotlib.pyplot as plt
>>> plt.plot(f, 20*np.log10(np.abs(X)))
>>> plt.show()
```

Methods

```python
scipy.signal.ZoomFFT.__call__(x, *, axis=–1)

Calculate the chirp z-transform of a signal.
```

**Parameters**

- `x` [array] The signal to transform.
- `axis` [int, optional] Axis over which to compute the FFT. If not given, the last axis is used.

**Returns**
```python
out [ndarray] An array of the same dimensions as x, but with the length of the transformed axis set to m.

scipy.signal.ZoomFFT.points

ZoomFFT.points()
Return the points at which the chirp z-transform is computed.

scipy.signal.czt_points

scipy.signal.czt_points(m, w=None, a=1 + 0j)
Return the points at which the chirp z-transform is computed.

Parameters
m [int] The number of points desired.
w [complex, optional] The ratio between points in each step. Defaults to equally spaced points around the entire unit circle.
a [complex, optional] The starting point in the complex plane. Default is 1+0j.

Returns
out [ndarray] The points in the Z plane at which CZT samples the z-transform, when called with arguments m, w, and a, as complex numbers.

See also:

CZT
Class that creates a callable chirp z-transform function.
czt
Convenience function for quickly calculating CZT.

Examples
Plot the points of a 16-point FFT:
```
>>> from scipy.signal import czt_points
>>> points = czt_points(16)
>>> import matplotlib.pyplot as plt
>>> plt.plot(points.real, points.imag, 'o')
>>> plt.gca().add_patch(plt.Circle((0,0), radius=1, fill=False, alpha=.3))
>>> plt.axis('equal')
>>> plt.show()
```
and a 91-point logarithmic spiral that crosses the unit circle:
```
>>> m, w, a = 91, 0.995*np.exp(-1j*np.pi*.05), 0.8*np.exp(1j*np.pi/6)
>>> points = czt_points(m, w, a)
>>> plt.plot(points.real, points.imag, 'o')
>>> plt.gca().add_patch(plt.Circle((0,0), radius=1, fill=False, alpha=.3))
>>> plt.axis('equal')
>>> plt.show()
```

3.3. API definition
The functions are simpler to use than the classes, but are less efficient when using the same transform on many arrays of the same length, since they repeatedly generate the same chirp signal with every call. In these cases, use the classes to create a reusable function instead.

### 3.3.22 Sparse matrices (scipy.sparse)

SciPy 2-D sparse array package for numeric data.

**Note:** This package is switching to an array interface, compatible with NumPy arrays, from the older matrix interface. We recommend that you use the array objects (bsr_array, coo_array, etc.) for all new work.

When using the array interface, please note that:

- $x \cdot y$ no longer performs matrix multiplication, but element-wise multiplication (just like with NumPy arrays). To make code work with both arrays and matrices, use $x \odot y$ for matrix multiplication.
- Operations such as `sum`, that used to produce dense matrices, now produce arrays, whose multiplication behavior differs similarly.
- Sparse arrays currently must be two-dimensional. This also means that all `slicing` operations on these objects must produce two-dimensional results, or they will result in an error. This will be addressed in a future version.

The construction utilities (`eye, kron, random, diags`, etc.) have not yet been ported, but their results can be wrapped into arrays:

```python
A = csr_array(eye(3))
```

#### scipy.sparse.bsr_array

**class** `scipy.sparse.bsr_array` *(arg1, shape=None, dtype=None, copy=False, blocksize=None)*

Block Sparse Row array

*This can be instantiated in several ways:*

- `bsr_array(D, [blocksize=(R,C)])`
  - where D is a dense array or 2-D ndarray.
- `bsr_array(S, [blocksize=(R,C)])`
  - with another sparse array S (equivalent to S.tobsr())

---

1705
bsr_array((M, N), [blocksize=(R,C), dtype])

to construct an empty array with shape (M, N) dtype is optional, defaulting to dtype='d'.

bsr_array((data, ij), [blocksize=(R,C), shape=(M, N)])

where data and ij satisfy a[ij[0, k], ij[1, k]] = data[k]

bsr_array((data, indices, indptr), [shape=(M, N)])

is the standard BSR representation where the block column indices for row i are stored in indices[indptr[i]:indptr[i+1]] and their corresponding block values are stored in data[ indptr[i]: indptr[i+1] ]. If the shape parameter is not supplied, the array dimensions are inferred from the index arrays.

Notes

Sparse arrays can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and array power.

Summary of BSR format

The Block Compressed Row (BSR) format is very similar to the Compressed Sparse Row (CSR) format. BSR is appropriate for sparse arrays with dense sub arrays like the last example below. Block arrays often arise in vector-valued finite element discretizations. In such cases, BSR is considerably more efficient than CSR and CSC for many sparse arithmetic operations.

Blocksize

The blocksize (R,C) must evenly divide the shape of the array (M,N). That is, R and C must satisfy the relationship M % R = 0 and N % C = 0.

If no blocksize is specified, a simple heuristic is applied to determine an appropriate blocksize.

Examples

```python
>>> from scipy.sparse import bsr_array

>>> bsr_array((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)

>>> row = np.array([0, 0, 1, 2, 2])
>>> col = np.array([0, 2, 2, 0, 1])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> bsr_array((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [1, 0, 2],
       [4, 5, 6]])

>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6]).repeat(4).reshape(6, 2, 2)
>>> bsr_array((data, indices, indptr), shape=(6, 6)).toarray()
array([[1, 1, 0, 0, 2, 2],
       [1, 1, 0, 0, 2, 2],
       (continues on next page)]]
```
Attributes

dtype [dtype] Data type of the array
ndim [int] Number of dimensions (this is always 2)
nnz Number of stored values, including explicit zeros.
data Data array of the array
indices BSR format index array
indptr BSR format index pointer array
blocksize Block size of the array
has_sorted_indices
Determine whether the matrix has sorted indices

Methods

__len__()
__mul__(*args, **kwargs)

arcsin() Element-wise arcsin.
arcsinh() Element-wise arcsinh.
arctan() Element-wise arctan.
arctanh() Element-wise arctanh.
argmax([axis, out]) Return indices of maximum elements along an axis.
argmin([axis, out]) Return indices of minimum elements along an axis.
asformat(format[, copy]) Return this matrix in the passed format.
asfptype() Upcast matrix to a floating point format (if necessary)
astype(dtype[, casting, copy]) Cast the matrix elements to a specified type.
ceil() Element-wise ceil.
check_format([full_check]) check whether the matrix format is valid
conjugate([copy]) Element-wise complex conjugation.
conjugate() Returns a copy of this matrix.
copy() Returns a copy of this matrix.
count_nonzero() Number of non-zero entries, equivalent to
deg2rad() Element-wise deg2rad.
diagonal([k]) Returns the kth diagonal of the matrix.
dot(other) Ordinary dot product
def2rad() Element-wise deg2rad.
ediagonal_zeroes() Remove zero elements in-place.
extpm() Element-wise expm1.
floor() Element-wise floor.
getH() Return the Hermitian transpose of this matrix.
get_shape() Get shape of a matrix.
getcol(j) Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

bsr_array.arctanh()
```

Element-wise arctanh.

See `numpy.arctanh` for more information.
scipy.sparse.bsr_array.argmax

```python
bsr_array.argmax(axis=None, out=None)
```
Return indices of maximum elements along an axis.

Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

**Parameters**

- `axis` : {-2, -1, 0, 1, None}, optional
  Axis along which the argmax is computed. If None (default), index of the maximum element in the flattened data is returned.

- `out` : [None, optional]
  This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- `ind` : [numpy.matrix or int]
  Indices of maximum elements. If matrix, its size along `axis` is 1.

scipy.sparse.bsr_array.argmin

```python
bsr_array.argmin(axis=None, out=None)
```
Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters**

- `axis` : {-2, -1, 0, 1, None}, optional
  Axis along which the argmin is computed. If None (default), index of the minimum element in the flattened data is returned.

- `out` : [None, optional]
  This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- `ind` : [numpy.matrix or int]
  Indices of minimum elements. If matrix, its size along `axis` is 1.

scipy.sparse.bsr_array.asformat

```python
bsr_array.asformat(format, copy=False)
```
Return this matrix in the passed format.

**Parameters**

- `format` : [{str, None}] The desired matrix format ("csr", "csc", "lil", "dok", "array", ...) or None for no conversion.

- `copy` : [bool, optional]
  If True, the result is guaranteed to not share data with self.

**Returns**

- `A` : [This matrix in the passed format.]
scipy.sparse.bsr_array.asfptype

bsr_array.asfptype()
   Upcast matrix to a floating point format (if necessary)

scipy.sparse.bsr_array.astype

bsr_array.astype(dtype, casting='unsafe', copy=True)
   Cast the matrix elements to a specified type.

   Parameters
   
   dtype [string or numpy dtype] Typecode or data-type to which to cast the data.
   casting [{‘no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’}, optional] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
   copy [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.

scipy.sparse.bsr_array.ceil

bsr_array.ceil()
   Element-wise ceil.

   See numpy.ceil for more information.

scipy.sparse.bsr_array.check_format

bsr_array.check_format (full_check=True)
   check whether the matrix format is valid

   Parameters:
   
   full_check:

   True - rigorous check, O(N) operations : default False - basic check, O(1) operations

scipy.sparse.bsr_array.conj

bsr_array.conj (copy=True)
   Element-wise complex conjugation.

   If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

   Parameters
   
   copy [bool, optional] If True, the result is guaranteed to not share data with self.

   Returns
A  

[The element-wise complex conjugate.]

**scipy.sparse.bsr_array.conjugate**

```python
csr_array.conjugate(copy=True)
```

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- `copy` [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

A  

[The element-wise complex conjugate.]

**scipy.sparse.bsr_array.copy**

```python
csr_array.copy()
```

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

**scipy.sparse.bsr_array.count_nonzero**

```python
csr_array.count_nonzero()
```

Number of non-zero entries, equivalent to

```python
np.count_nonzero(a.toarray())
```

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

**scipy.sparse.bsr_array.deg2rad**

```python
csr_array.deg2rad()
```

Element-wise deg2rad.

See `numpy.deg2rad` for more information.

**scipy.sparse.bsr_array.diagonal**

```python
csr_array.diagonal(k=0)
```

Returns the kth diagonal of the matrix.

**Parameters**

- `k` [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).

New in version 1.0.

See also:
**numpy.diagonal**

Equivalent numpy function.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

**scipy.sparse.bsr_array.dot**

bsr_array.dot(other)
Ordinary dot product

**Examples**

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

**scipy.sparse.bsr_array.eliminate_zeros**

bsr_array.eliminate_zeros()
Remove zero elements in-place.

**scipy.sparse.bsr_array.expm1**

bsr_array.expm1()
Element-wise expm1.

See numpy.expm1 for more information.
scipy.sparse.bsr_array.floor

bsr_array.floor()
Element-wise floor.

See numpy.floor for more information.

scipy.sparse.bsr_array.getH

bsr_array.getH()
Return the Hermitian transpose of this matrix.

See also:

numpy.matrix.getH

NumPy’s implementation of getH for matrices

scipy.sparse.bsr_array.get_shape

bsr_array.get_shape()
Get shape of a matrix.

scipy.sparse.bsr_array.getcol

bsr_array.getcol(j)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.bsr_array.getformat

bsr_array.getformat()
Format of a matrix representation as a string.

scipy.sparse.bsr_array.getmaxprint

bsr_array.getmaxprint()
Maximum number of elements to display when printed.

scipy.sparse.bsr_array.getnnz

bsr_array.getnnz(axis=None)
Number of stored values, including explicit zeros.

Parameters
axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:
count_nonzero

Number of non-zero entries

scipy.sparse.bsr_array.getrow

bsr_array.getrow(i)

Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

scipy.sparse.bsr_array.log1p

bsr_array.log1p()

Element-wise log1p.

See numpy.log1p for more information.

scipy.sparse.bsr_array.matmat

bsr_array.matmat(**kwds)

matmat is deprecated! BSR matmat is deprecated in SciPy 0.19.0. Use * operator instead.

Multiply this sparse matrix by other matrix.

scipy.sparse.bsr_array.matvec

bsr_array.matvec(**kwds)

matvec is deprecated! BSR matvec is deprecated in SciPy 0.19.0. Use * operator instead.

Multiply matrix by vector.

scipy.sparse.bsr_array.max

bsr_array.max(axis=None, out=None)

Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just
the non-zero ones.

Parameters

axis  
{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is
to compute the maximum over all the matrix elements, returning a scalar (i.e., axis =
None).

out  
[None, optional] This argument is in the signature solely for NumPy compatibility rea-
sons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amax  
[coo_matrix or scalar] Maximum of a. If axis is None, the result is a scalar value. If
axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

min

The minimum value of a sparse matrix along a given axis.
**numpy.matrix.max**

NumPy’s implementation of ‘max’ for matrices

**scipy.sparse.bsr_array.maximum**

`bsr_array.maximum(other)`

Element-wise maximum between this and another matrix.

**scipy.sparse.bsr_array.mean**

`bsr_array.mean(axis=None, dtype=None, out=None)`

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. `float64` intermediate and return values are used for integer inputs.

**Parameters**

- `axis` ([{-2, -1, 0, 1, None}] optional) Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., `axis = None`).
- `dtype` ([data-type, optional]) Type to use in computing the mean. For integer inputs, the default is `float64`; for floating point inputs, it is the same as the input `dtype`. New in version 0.18.0.
- `out` ([np.matrix, optional]) Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

**Returns**

- `m` [np.matrix]

**See also:**

**numpy.matrix.mean**

NumPy’s implementation of ‘mean’ for matrices

**scipy.sparse.bsr_array.min**

`bsr_array.min(axis=None, out=None)`

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters**

- `axis` ([{-2, -1, 0, 1, None}] optional) Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e., `axis = None`).
- `out` [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- `amin` [coo_matrix or scalar] Minimum of `a`. If `axis` is None, the result is a scalar value. If `axis` is given, the result is a sparse.coo_matrix of dimension `a.ndim - 1`. 
See also:

max

The maximum value of a sparse matrix along a given axis.

numpy.matrix.min

NumPy’s implementation of ‘min’ for matrices

scipy.sparse.bsr_array.minimum

bsr_array.minimum(other)

Element-wise minimum between this and another matrix.

scipy.sparse.bsr_array.multiply

bsr_array.multiply(other)

Point-wise multiplication by another matrix, vector, or scalar.

scipy.sparse.bsr_array.nonzero

bsr_array.nonzero()

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.bsr_array.power

bsr_array.power(n, dtype=None)

This function performs element-wise power.

Parameters

n       [n is a scalar]
dtype   [If dtype is not specified, the current dtype will be preserved.]
scipy.sparse.bsr_array.prune

bsr_array.prune()
Remove empty space after all non-zero elements.

scipy.sparse.bsr_array.rad2deg

bsr_array.rad2deg()
Element-wise rad2deg.
See numpy.rad2deg for more information.

scipy.sparse.bsr_array.reshape

bsr_array.reshape(self, shape, order='C', copy=False)
Gives a new shape to a sparse matrix without changing its data.

Parameters

- shape [length-2 tuple of ints] The new shape should be compatible with the original shape.
- order [{‘C’, ‘F’}, optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

- reshaped_matrix [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

numpy.matrix.reshape
NumPy’s implementation of ‘reshape’ for matrices

scipy.sparse.bsr_array.resize

bsr_array.resize(*shape)
Resize the matrix in-place to dimensions given by shape
Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

- shape [(int, int)] number of rows and columns in the new matrix
Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

```python
scipy.sparse.bsr_array.rint

bsr_array.rint()
Element-wise rint.
See `numpy.rint` for more information.
```

```python
scipy.sparse.bsr_array.set_shape

bsr_array.set_shape(shape)
See `reshape`.
```

```python
scipy.sparse.bsr_array.setdiag

bsr_array.setdiag(values, k=0)
Set diagonal or off-diagonal elements of the array.

Parameters

values [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.
If a scalar value is given, all of the diagonal is set to it.

k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).
```

```python
scipy.sparse.bsr_array.sign

bsr_array.sign()
Element-wise sign.
See `numpy.sign` for more information.
```
scipy.sparse.bsr_array.sin

bsr_array.sin()

Element-wise sin.

See numpy.sin for more information.

scipy.sparse.bsr_array.sinh

bsr_array.sinh()

Element-wise sinh.

See numpy.sinh for more information.

scipy.sparse.bsr_array.sort_indices

bsr_array.sort_indices()

Sort the indices of this matrix in place

scipy.sparse.bsr_array.sorted_indices

bsr_array.sorted_indices()

Return a copy of this matrix with sorted indices

scipy.sparse.bsr_array.sqrt

bsr_array.sqrt()

Element-wise sqrt.

See numpy.sqrt for more information.

scipy.sparse.bsr_array.sum

bsr_array.sum(axis=None, dtype=None, out=None)

Sum the matrix elements over a given axis.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., axis = None).

dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

New in version 0.18.0.
**Returns**

`sum_along_axis`

[np.matrix] A matrix with the same shape as `self`, with the specified axis removed.

**See also:**

`numpy.matrix.sum`

NumPy's implementation of 'sum' for matrices

**scipy.sparse.bsr_array.sum_duplicates**

`bsr_array.sum_duplicates()`  
Eliminate duplicate matrix entries by adding them together  
The is an *in place* operation

**scipy.sparse.bsr_array.tan**

`bsr_array.tan()`  
Element-wise tan.  
See `numpy.tan` for more information.

**scipy.sparse.bsr_array.tanh**

`bsr_array.tanh()`  
Element-wise tanh.  
See `numpy.tanh` for more information.

**scipy.sparse.bsr_array.toarray**

`bsr_array.toarray(order=None, out=None)`  
Return a dense ndarray representation of this matrix.

**Parameters**

- `order`  
  {{C, ‘F’}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, which provides no ordering guarantees. Cannot be specified in conjunction with the `out` argument.

- `out`  
  [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, `out` is required to be memory contiguous (either C or Fortran ordered).

**Returns**

- `arr`  
  [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed, the same object is returned after being modified in-place to contain the appropriate values.
.. py:method:: scipy.sparse.bsr_array.tobsr

   \texttt{bsr\_array.tobsr}(\texttt{blocksize=\textit{None}, \textit{copy=False}})

   Convert this matrix into Block Sparse Row Format.

   With copy=False, the data/indices may be shared between this matrix and the resultant \textit{bsr\_matrix}.

   If \textit{blocksize}=(R, C) is provided, it will be used for determining block size of the \textit{bsr\_matrix}.

.. py:method:: scipy.sparse.bsr_array.tocoo

   \texttt{bsr\_array.tocoo}(\texttt{\textit{copy=True}})

   Convert this matrix to COOrdinate format.

   When copy=False the data array will be shared between this matrix and the resultant \textit{coo\_matrix}.

.. py:method:: scipy.sparse.bsr_array.tocsc

   \texttt{bsr\_array.tocsc}(\texttt{\textit{copy=False}})

   Convert this matrix to Compressed Sparse Column format.

   With copy=False, the data/indices may be shared between this matrix and the resultant \textit{csc\_matrix}.

.. py:method:: scipy.sparse.bsr_array.tocsr

   \texttt{bsr\_array.tocsr}(\texttt{\textit{copy=False}})

   Convert this matrix to Compressed Sparse Row format.

   With copy=False, the data/indices may be shared between this matrix and the resultant \textit{csr\_matrix}.

.. py:method:: scipy.sparse.bsr_array.todense

   \texttt{bsr\_array.todense}(\texttt{\textit{order=\textit{None}, \textit{out=\textit{None}}}})

   Return a dense matrix representation of this matrix.

   Parameters

   \texttt{order} [\{'C', 'F'}, \texttt{optional}] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘\textit{None}’, which provides no ordering guarantees. Cannot be specified in conjunction with the \texttt{out} argument.

   \texttt{out} [\texttt{ndarray}, \texttt{2-D}, \texttt{optional}] If specified, uses this array (or \texttt{numpy.matrix}) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

   Returns

   \texttt{arr} [\texttt{numpy.matrix}, \texttt{2-D}] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If \texttt{out} was passed and was an array (rather than a \texttt{numpy.matrix}), it will be filled with the appropriate values and returned wrapped in a \texttt{numpy.matrix} object that shares the same memory.
scipy.sparse.bsr_array.todia

`bsr_array.todia(copy=False)`
Convert this matrix to sparse DIAgonal format.
With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.bsr_array.todok

`bsr_array.todok(copy=False)`
Convert this matrix to Dictionary Of Keys format.
With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.bsr_array.tolil

`bsr_array.tolil(copy=False)`
Convert this matrix to List of Lists format.
With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.bsr_array.trace

`bsr_array.trace(offset=0)`
Returns the sum along diagonals of the sparse matrix.

Parameters

offset [int, optional] Which diagonal to get, corresponding to elements a[i, i+offset]. Default: 0 (the main diagonal).

scipy.sparse.bsr_array.transpose

`bsr_array.transpose(axes=None, copy=False)`
Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [self with the dimensions reversed.]

See also:

`numpy.matrix.transpose`
NumPy's implementation of ‘transpose’ for matrices
scipy.sparse.bsr_array.trunc

bsr_array.trunc()
Element-wise trunc.

See numpy.trunc for more information.

scipy.sparse.coo_array

class scipy.sparse.coo_array(arg1, shape=None, dtype=None, copy=False)
A sparse array in COOrdinate format.

Also known as the ‘ijv’ or ‘triplet’ format.

This can be instantiated in several ways:

coo_array(D)
    with a dense array D

coo_array(S)
    with another sparse array S (equivalent to S.tocoo())

coo_array((M, N), [dtype])
    to construct an empty array with shape (M, N) dtype is optional, defaulting to dtype='d'.

coo_array((data, (i, j)), [shape=(M, N)])
    to construct from three arrays:
    1. data[:]: the entries of the array, in any order
    2. i[:]: the row indices of the array entries
    3. j[:]: the column indices of the array entries

    Where A[i[k], j[k]] = data[k]. When shape is not specified, it is inferred from the
    index arrays

Notes

Sparse arrays can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and
array power.

Advantages of the COO format

- facilitates fast conversion among sparse formats
- permits duplicate entries (see example)
- very fast conversion to and from CSR/CSC formats

Disadvantages of the COO format
• does not directly support:
  – arithmetic operations
  – slicing

**Intended Usage**

• COO is a fast format for constructing sparse arrays

• Once a array has been constructed, convert to CSR or CSC format for fast arithmetic and array vector operations

• By default when converting to CSR or CSC format, duplicate (i,j) entries will be summed together. This facilitates efficient construction of finite element arrays and the like. (see example)

**Examples**

```python
>>> # Constructing an empty array
>>> from scipy.sparse import coo_array
>>> coo_array((3, 4), dtype=np.int8).toarray()
array([[0., 0., 0., 0.],
       [0., 0., 0., 0.],
       [0., 0., 0., 0.]], dtype=int8)
```

```python
>>> # Constructing a array using ijv format
>>> row = np.array([0, 3, 1, 0])
>>> col = np.array([0, 3, 1, 2])
>>> data = np.array([4, 5, 7, 9])
>>> coo_array((data, (row, col)), shape=(4, 4)).toarray()
array([[4, 0, 9, 0],
       [0, 7, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 5]])
```

```python
>>> # Constructing a array with duplicate indices
>>> row = np.array([0, 0, 1, 3, 1, 0])
>>> col = np.array([0, 2, 1, 3, 1, 0])
>>> data = np.array([1, 1, 1, 1, 1, 1])
>>> coo = coo_array((data, (row, col)), shape=(4, 4))
>>> # Duplicate indices are maintained until implicitly or explicitly summed
>>> np.max(coo.data)
1
>>> coo.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

**Attributes**

- **dtype**  [dtype] Data type of the array
ndim  [int] Number of dimensions (this is always 2)
nnz  Number of stored values, including explicit zeros.
data  COO format data array of the array
row  COO format row index array of the array
col  COO format column index array of the array

Methods

__len__()  

__mul__(*args, **kwargs)  

arcsin()  Element-wise arcsin.
arcsinh()  Element-wise arcsinh.
arctan()  Element-wise arctan.
arctanh()  Element-wise arctanh.
argmax([axis, out])  Return indices of maximum elements along an axis.
argmin([axis, out])  Return indices of minimum elements along an axis.
asformat(format[, copy])  Return this matrix in the passed format.
asfptype()  Upcast matrix to a floating point format (if necessary)
astype(dtype[, casting, copy])  Cast the matrix elements to a specified type.
ceil()  Element-wise ceil.
conj([copy])  Element-wise complex conjugation.
conjugate([copy])  Element-wise complex conjugation.
copy()  Returns a copy of this matrix.
count_nonzero()  Number of non-zero entries, equivalent to
deg2rad()  Element-wise deg2rad.
diagonal([k])  Returns the kth diagonal of the matrix.
dot(other)  Ordinary dot product
eliminate_zeros()  Remove zero entries from the matrix
expm1()  Element-wise expm1.
floor()  Element-wise floor.
getH()  Return the Hermitian transpose of this matrix.
get_shape()  Get shape of a matrix.
getcol(j)  Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
getformat()  Format of a matrix representation as a string.
getmaxprint()  Maximum number of elements to display when printed.
getnnz([axis])  Number of stored values, including explicit zeros.
getrow(i)  Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
log1p()  Element-wise log1p.
max([axis, out])  Return the maximum of the matrix or maximum along an axis.
maximum(other)  Element-wise maximum between this and another matrix.
mean([axis, dtype, out])  Compute the arithmetic mean along the specified axis.
min([axis, out])  Return the minimum of the matrix or maximum along an axis.

</table>

**scipy.sparse.coo_array.__len__**

coo_array.__len__()
scipy.sparse.coo_array.__mul__

coo_array.__mul__(*args, **kwargs)

scipy.sparse.coo_array.arcsin

coo_array.arcsin()
Element-wise arcsin.

See numpy.arcsin for more information.

scipy.sparse.coo_array.arcsinh

coo_array.arcsinh()
Element-wise arcsinh.

See numpy.arcsinh for more information.

scipy.sparse.coo_array.arctan

coo_array.arctan()
Element-wise arctan.

See numpy.arctan for more information.

scipy.sparse.coo_array.arctanh

coo_array.arctanh()
Element-wise arctanh.

See numpy.arctanh for more information.

scipy.sparse.coo_array.argmax

coo_array.argmax(axis=None, out=None)
Return indices of maximum elements along an axis.
Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

Parameters

- **axis**
  - [[-2, -1, 0, 1, None], optional] Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.

- **out**
  - [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

- **ind**
  - [numpy.matrix or int] Indices of maximum elements. If matrix, its size along axis is 1.
**scipy.sparse.coo_array.argmin**

```python
coo_array.argmin(axis=None, out=None)
```

Return indices of minimum elements along an axis. Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters**

- **axis**
  - [{-2, -1, 0, 1, None}, optional] Axis along which the argmin is computed. If None (default), index of the minimum element in the flattened data is returned.
- **out**
  - [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- **ind**
  - [numpy.matrix or int] Indices of minimum elements. If matrix, its size along axis is 1.

**scipy.sparse.coo_array.asformat**

```python
coo_array.asformat(format, copy=False)
```

Return this matrix in the passed format.

**Parameters**

- **format**
  - [str, None] The desired matrix format ("csr", "csc", "lil", "dok", "array", ...) or None for no conversion.
- **copy**
  - [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- **A**
  - [This matrix in the passed format.]

**scipy.sparse.coo_array.asfptype**

```python
coo_array.asfptype()
```

Upcast matrix to a floating point format (if necessary)

**scipy.sparse.coo_array.astype**

```python
coo_array.astype(dtype, casting='unsafe', copy=True)
```

Cast the matrix elements to a specified type.

**Parameters**

- **dtype**
  - [string or numpype dtype] Typecode or data-type to which to cast the data.
- **casting**
  - ["no", "equiv", "safe", "same_kind", "unsafe"], optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.
- **copy**
  - [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.
**scipy.sparse.coo_array.ceil**

```python
coo_array.ceil()
```

Element-wise ceil.

See `numpy.ceil` for more information.

**scipy.sparse.coo_array.conj**

```python
coo_array.conj(copy=True)
```

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- `copy` [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- `A` [The element-wise complex conjugate.]

**scipy.sparse.coo_array.conjugate**

```python
coo_array.conjugate(copy=True)
```

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- `copy` [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- `A` [The element-wise complex conjugate.]

**scipy.sparse.coo_array.copy**

```python
coo_array.copy()
```

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

**scipy.sparse.coo_array.count_nonzero**

```python
coo_array.count_nonzero()
```

Number of non-zero entries, equivalent to `np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.
scipy.sparse.coo_array.deg2rad

coo_array.deg2rad()
Element-wise deg2rad.
See numpy.deg2rad for more information.

scipy.sparse.coo_array.diagonal

coo_array.diagonal(k=0)
Returns the kth diagonal of the matrix.

Parameters

- k [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
New in version 1.0.

See also:

numpy.diagonal

Equivalent numpy function.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

scipy.sparse.coo_array.dot

coo_array.dot(other)
Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([1, -3, -1], dtype=int64)
```
scipy.sparse.coo_array.eliminate_zeros

```python
coo_array.eliminate_zeros()
```
Remove zero entries from the matrix
This is an in place operation

scipy.sparse.coo_array.expm1

```python
coo_array.expm1()
```
Element-wise expm1.
See numpy.expm1 for more information.

scipy.sparse.coo_array.floor

```python
coo_array.floor()
```
Element-wise floor.
See numpy.floor for more information.

scipy.sparse.coo_array.getH

```python
coo_array.getH()
```
Return the Hermitian transpose of this matrix.
See also:

```
numpy.matrix.getH
```
NumPy's implementation of getH for matrices

scipy.sparse.coo_array.get_shape

```python
coo_array.get_shape()
```
Get shape of a matrix.

scipy.sparse.coo_array.getcol

```python
coo_array.getcol(j)
```
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
scipy.sparse.coo_array.getformat

coo_array.getformat()
Format of a matrix representation as a string.

scipy.sparse.coo_array.getmaxprint

coo_array.getmaxprint()
Maximum number of elements to display when printed.

scipy.sparse.coo_array.getnnz

coo_array.getnnz(axis=None)
Number of stored values, including explicit zeros.

Parameters
axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:
count_nonzero
Number of non-zero entries

scipy.sparse.coo_array.getrow

coo_array.getrow(i)
Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

scipy.sparse.coo_array.log1p

coo_array.log1p()
Element-wise log1p.

See numpy.log1p for more information.

scipy.sparse.coo_array.max

coo_array.max(axis=None, out=None)
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters
axis [-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e., axis = None).
out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.
Returns

amax [coo_matrix or scalar] Maximum of $a$. If $axis$ is None, the result is a scalar value. If $axis$ is given, the result is a sparse.cooc_matrix of dimension $a$.ndim - 1.

See also:

min

The minimum value of a sparse matrix along a given axis.

numpy.matrix.max

NumPy's implementation of 'max' for matrices

scipy.sparse.coo_array.maximum

coo_array.maximum(other)

Element-wise maximum between this and another matrix.

scipy.sparse.coo_array.mean

coo_array.mean(axis=None, dtype=None, out=None)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters

axis [-2, -1, 0, 1, None] optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., $axis$ = None).

dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype.

New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

New in version 0.18.0.

Returns

m [np.matrix]

See also:

numpy.matrix.mean

NumPy's implementation of 'mean' for matrices
**scipy.sparse.coo_array.min**

`coo_array.min(axis=None, out=None)`

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters**

- `axis` [-2, -1, 0, 1, None] optional
  - Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e., `axis = None`).
- `out` [None, optional]
  - This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- `amin` [coo_matrix or scalar]
  - Minimum of `a`. If `axis` is None, the result is a scalar value. If `axis` is given, the result is a sparse.coo_matrix of dimension `a.ndim - 1`.

**See also:**

- `numpy.matrix.min`
  - NumPy's implementation of 'min' for matrices

**scipy.sparse.coo_array.minimum**

`coo_array.minimum(other)`

Element-wise minimum between this and another matrix.

**scipy.sparse.coo_array.multiply**

`coo_array.multiply(other)`

Point-wise multiplication by another matrix.

**scipy.sparse.coo_array.nonzero**

`coo_array.nonzero()`

_nonzero indices_

- Returns a tuple of arrays (row, col) containing the indices of the non-zero elements of the matrix.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

**scipy.sparse.coo_array.power**

coo_array.power(n, dtype=None)

This function performs element-wise power.

**Parameters**

- **n** [n is a scalar]
- **dtype** [If dtype is not specified, the current dtype will be preserved.]

**scipy.sparse.coo_array.rad2deg**

coo_array.rad2deg()

Element-wise rad2deg.

See `numpy.rad2deg` for more information.

**scipy.sparse.coo_array.reshape**

coo_array.reshape(self, shape, order='C', copy=False)

Gives a new shape to a sparse matrix without changing its data.

**Parameters**

- **shape** [length-2 tuple of ints] The new shape should be compatible with the original shape.
- **order** ['C', 'F'], optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- **copy** [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- **reshaped_matrix** [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

- `numpy.matrix.reshape`

NumPy’s implementation of ‘reshape’ for matrices
**scipy.sparse.coo_array.resize**

```python
coo_array.resize(*shape)
```

Resize the matrix in-place to dimensions given by `shape`.

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

**Parameters**

- `shape` [(int, int)] number of rows and columns in the new matrix

**Notes**

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

**scipy.sparse.coo_array.rint**

```python
coo_array.rint()
```

Element-wise rint.

See `numpy.rint` for more information.

**scipy.sparse.coo_array.set_shape**

```python
coo_array.set_shape(shape)
```

See `reshape`.

**scipy.sparse.coo_array.setdiag**

```python
coo_array.setdiag(values, k=0)
```

Set diagonal or off-diagonal elements of the array.

**Parameters**

- `values` [array_like] New values of the diagonal elements.
  
  Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.
  
  If a scalar value is given, all of the diagonal is set to it.

- `k` [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).
scipy.sparse.coo_array.sign

coo_array.sign()
Element-wise sign.

See numpy.sign for more information.

scipy.sparse.coo_array.sin

coo_array.sin()
Element-wise sin.

See numpy.sin for more information.

scipy.sparse.coo_array.sinh

coo_array.sinh()
Element-wise sinh.

See numpy.sinh for more information.

scipy.sparse.coo_array.sqrt

coo_array.sqrt()
Element-wise sqrt.

See numpy.sqrt for more information.

scipy.sparse.coo_array.sum

coo_array.sum(axis=None, dtype=None, out=None)
Sum the matrix elements over a given axis.

Parameters

- **axis**  
  [-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., axis = None).

- **dtype**  
  [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used.

- **out**  
  [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

Returns

- **sum_along_axis**  
  [np.matrix] A matrix with the same shape as self, with the specified axis removed.

See also:
**numpy.matrix.sum**

NumPy's implementation of 'sum' for matrices

**scipy.sparse.coo_array.sum_duplicates**

coo_array.sum_duplicates()

Eliminate duplicate matrix entries by adding them together

This is an *in place* operation

**scipy.sparse.coo_array.tan**

coo_array.tan()

Element-wise tan.

See *numpy.tan* for more information.

**scipy.sparse.coo_array.tanh**

coo_array.tanh()

Element-wise tanh.

See *numpy.tanh* for more information.

**scipy.sparse.coo_array.toarray**

coo_array.toarray(order=None, out=None)

See the docstring for *spmatrix.toarray*.

**scipy.sparse.coo_array.tobsr**

coo_array.tobsr(blocksize=None, copy=False)

Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

**scipy.sparse.coo_array.tocoo**

coo_array.tocoo(copy=False)

Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.
**scipy.sparse.coo_array.tocsc**

**coo_array.tocsc** *(copy=False)*

Convert this matrix to Compressed Sparse Column format

Duplicate entries will be summed together.

**Examples**

```python
>>> from numpy import array
>>> from scipy.sparse import coo_matrix
>>> row = array([0, 0, 1, 3, 1, 0, 0])
>>> col = array([0, 2, 1, 3, 1, 0, 0])
>>> data = array([1, 1, 1, 1, 1, 1, 1])
>>> A = coo_matrix((data, (row, col)), shape=(4, 4)).tocsc()
>>> A.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

**scipy.sparse.coo_array.tocsr**

**coo_array.tocsr** *(copy=False)*

Convert this matrix to Compressed Sparse Row format

Duplicate entries will be summed together.

**Examples**

```python
>>> from numpy import array
>>> from scipy.sparse import coo_matrix
>>> row = array([0, 0, 1, 3, 1, 0, 0])
>>> col = array([0, 2, 1, 3, 1, 0, 0])
>>> data = array([1, 1, 1, 1, 1, 1, 1])
>>> A = coo_matrix((data, (row, col)), shape=(4, 4)).tocsr()
>>> A.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```
scipy.sparse.coo_array.todense

coo_array.todense(order=None, out=None)
Return a dense matrix representation of this matrix.

Parameters
  order [{‘C’, ‘F’}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, which provides no ordering guarantees. Cannot be specified in conjunction with the out argument.
  out [ndarray, 2-D, optional] If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns
  arr [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

scipy.sparse.coo_array.todia

coo_array.todia(copy=False)
Convert this matrix to sparse DIAgonal format.

    With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.coo_array.todok

coo_array.todok(copy=False)
Convert this matrix to Dictionary Of Keys format.

    With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.coo_array.tolil

coo_array.tolil(copy=False)
Convert this matrix to List of Lists format.

    With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.coo_array.trace

coo_array.trace(offset=0)
Returns the sum along diagonals of the sparse matrix.

Parameters
  offset [int, optional] Which diagonal to get, corresponding to elements a[i, i+offset]. Default: 0 (the main diagonal).
**scipy.sparse.coo_array.transpose**

`coo_array.transpose(axes=None, copy=False)`

Reverses the dimensions of the sparse matrix.

**Parameters**

- **axes** ([None, optional]) This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.
- **copy** ([bool, optional]) Indicates whether or not attributes of `self` should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- **p** `[self with the dimensions reversed.]`

**See also:**

- `numpy.matrix.transpose`
  
  NumPy's implementation of 'transpose' for matrices

**scipy.sparse.coo_array.trunc**

`coo_array.trunc()`

Element-wise trunc.

See `numpy.trunc` for more information.

**scipy.sparse.csc_array**

`class scipy.sparse.csc_array(arg1, shape=None, dtype=None, copy=False)`

Compressed Sparse Column array

This can be instantiated in several ways:

- `csc_array(D)` with a dense array or rank-2nd array `D`
- `csc_array(S)` with another sparse array `S` (equivalent to `S.tocsc()`)
- `csc_array((M, N), [dtype])` to construct an empty array with shape `(M, N)` dtype is optional, defaulting to dtype='d'.
- `csc_array((data, (row_ind, col_ind)), [shape=(M, N)])` where `data`, `row_ind` and `col_ind` satisfy the relationship `a[row_ind[k], col_ind[k]] = data[k].`
- `csc_array((data, indices, indptr), [shape=(M, N)])` is the standard CSC representation where the row indices for column `i` are stored in `indices[indptr[i]:indptr[i+1]]` and their corresponding values are stored in `data[indptr[i]:indptr[i+1]]`. If the shape parameter is not supplied, the array dimensions are inferred from the index arrays.
Notes

Sparse arrays can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and array power.

Advantages of the CSC format

• efficient arithmetic operations CSC + CSC, CSC * CSC, etc.
• efficient column slicing
• fast array vector products (CSR, BSR may be faster)

Disadvantages of the CSC format

• slow row slicing operations (consider CSR)
• changes to the sparsity structure are expensive (consider LIL or DOK)

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csc_array
>>> csc_array((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)

>>> row = np.array([0, 2, 2, 0, 1])
>>> col = np.array([0, 0, 1, 2, 2])
>>> data = np.array([1, 2, 3, 4, 5])
>>> csc_array((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 4],
       [0, 0, 5],
       [2, 3, 6]])
```

Attributes

dtype  [dtype] Data type of the array
ndim  [int] Number of dimensions (this is always 2)
nnz  Number of stored values, including explicit zeros.
data  Data array of the array
indices  CSC format index array
indptr  CSC format index pointer array
has_sorted_indices
Determine whether the matrix has sorted indices

Methods

__len__()

__mul__(*args, **kwargs)

arcsin()
Element-wise arcsin.
arcsinh()
Element-wise arccosh.
arctan()
Element-wise arctan.
arctanh()
Element-wise arctanh.
armax([axis, out])
Return indices of maximum elements along an axis.
armin([axis, out])
Return indices of minimum elements along an axis.
asformat(format[, copy])
Return this matrix in the passed format.
asfptype()
Upcast matrix to a floating point format (if necessary)
astype(dtype[, casting, copy])
Cast the matrix elements to a specified type.
ceil()
Element-wise ceil.
check_format([full_check])
check whether the matrix format is valid
conj([copy])
Element-wise complex conjugation.
conjugate([copy])
Element-wise complex conjugation.
copy()
Returns a copy of this matrix.
count_nonzero()
Number of non-zero entries, equivalent to
deg2rad()
Element-wise deg2rad.
diagonal([k])
Returns the kth diagonal of the matrix.
dot(other)
Ordinary dot product
eliminate_zeros()
Remove zero entries from the matrix
expm1()
Element-wise expm1.
floor()
Element-wise floor.
getH()
Return the Hermitian transpose of this matrix.
get_shape()
Get shape of a matrix.
getcol(i)
Returns a copy of column i of the matrix, as a (m x 1) CSC matrix (column vector).
getformat()
Format of a matrix representation as a string.
getmaxprint()
Maximum number of elements to display when printed.
getnnz([axis])
Number of stored values, including explicit zeros.
getrow(i)
Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).
log1p()
Element-wise log1p.
max([axis, out])
Return the maximum of the matrix or maximum along an axis.
maximum(other)
Element-wise maximum between this and another matrix.
mean([axis, dtype, out])
Compute the arithmetic mean along the specified axis.
min([axis, out])
Return the minimum of the matrix or maximum along an axis.
minimum(other)
Element-wise minimum between this and another matrix.
Table 177 – continued from previous page

```python
scipy.sparse.csc_array.__len__
```

csc_array.__len__()
scipy.sparse.csc_array.__mul__

csc_array.__mul__(*args, **kwargs)

scipy.sparse.csc_array.arcsin

csc_array.arcsin()
Element-wise arcsin.
See numpy.arcsin for more information.

scipy.sparse.csc_array.arcsinh

csc_array.arcsinh()
Element-wise arcsinh.
See numpy.arcsinh for more information.

scipy.sparse.csc_array.arctan

csc_array.arctan()
Element-wise arctan.
See numpy.arctan for more information.

scipy.sparse.csc_array.arctanh

csc_array.arctanh()
Element-wise arctanh.
See numpy.arctanh for more information.

scipy.sparse.csc_array.argmax

csc_array.argmax(axis=None, out=None)
Return indices of maximum elements along an axis.
Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

Parameters:
axis [[-2, -1, 0, 1, None], optional] Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.
out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns:
ind [numpy.matrix or int] Indices of maximum elements. If matrix, its size along axis is 1.
scipy.sparse.csc_array.argmin

csc_array.argmin(axis=None, out=None)
Return indices of minimum elements along an axis.
Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

Parameters
axis [{-2, -1, 0, 1, None}, optional] Axis along which the argmin is computed. If None (default), index of the minimum element in the flattened data is returned.
out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns
ind [numpy.matrix or int] Indices of minimum elements. If matrix, its size along axis is 1.

scipy.sparse.csc_array.asformat

csc_array.asformat(format, copy=False)
Return this matrix in the passed format.

Parameters
format [[str, None]] The desired matrix format ("csr", "csc", "lil", "dok", "array", ...) or None for no conversion.
copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns
A [This matrix in the passed format.]

scipy.sparse.csc_array.asfptype

csc_array.asfptype()
Upcast matrix to a floating point format (if necessary)

scipy.sparse.csc_array.astype

csc_array.astype(dtype, casting='unsafe', copy=True)
Cast the matrix elements to a specified type.

Parameters
dtype [string or numpym dtype] Typecode or data-type to which to cast the data.
casting [{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. ‘no’ means the data types should not be cast at all, ‘equiv’ means only byte-order changes are allowed, ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
copy [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.
scipy.sparse.csc_array.ceil

csc_array.ceil()  
Element-wise ceil.  
See numpy.ceil for more information.

scipy.sparse.csc_array.check_format

csc_array.check_format(full_check=True)  
check whether the matrix format is valid

Parameters

full_check [bool, optional] If True, rigorous check, O(N) operations. Otherwise basic check, O(1) operations (default True).

scipy.sparse.csc_array.conj

csc_array.conj(copy=True)  
Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.csc_array.conjugate

csc_array.conjugate(copy=True)  
Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]
**scipy.sparse.csc_array.copy**

csc_array.copy()  
Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

**scipy.sparse.csc_array.count_nonzero**

csc_array.count_nonzero()  
Number of non-zero entries, equivalent to

np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

**scipy.sparse.csc_array.deg2rad**

csc_array.deg2rad()  
Element-wise deg2rad.

See numpy.deg2rad for more information.

**scipy.sparse.csc_array.diagonal**

csc_array.diagonal(k=0)  
Returns the kth diagonal of the matrix.

**Parameters**

- k [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal). New in version 1.0.

**See also:**

- numpy.diagonal

  Equivalent numpy function.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix(([1, 2, 0], [0, 0, 3], [4, 0, 5]))
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```
scipy.sparse.csc_array.dot

csc_array.dot(other)
Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.csc_array.eliminate_zeros

csc_array.eliminate_zeros()
Remove zero entries from the matrix
This is an in place operation.

scipy.sparse.csc_array.expm1

csc_array.expm1()
Element-wise expm1.
See numpy.expm1 for more information.

scipy.sparse.csc_array.floor

csc_array.floor()
Element-wise floor.
See numpy.floor for more information.

scipy.sparse.csc_array.getH

csc_array.getH()
Return the Hermitian transpose of this matrix.
See also:

    numpy.matrix.getH
NumPy's implementation of getH for matrices
**scipy.sparse.csc_array.get_shape**

```
csc_array.get_shape()
```

Get shape of a matrix.

**scipy.sparse.csc_array.getcol**

```
csc_array.getcol(i)
```

Returns a copy of column i of the matrix, as a (m x 1) CSC matrix (column vector).

**scipy.sparse.csc_array.getformat**

```
csc_array.getformat()
```

Format of a matrix representation as a string.

**scipy.sparse.csc_array.getmaxprint**

```
csc_array.getmaxprint()
```

Maximum number of elements to display when printed.

**scipy.sparse.csc_array.getnnz**

```
csc_array.getnnz(axis=None)
```

Number of stored values, including explicit zeros.

**Parameters**

- `axis` [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

- `count_nonzero`
  
  Number of non-zero entries

**scipy.sparse.csc_array.getrow**

```
csc_array.getrow(i)
```

Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).
scipy.sparse.csc_array.log1p

csc_array.log1p()
Element-wise log1p.

See numpy.log1p for more information.

scipy.sparse.csc_array.max

csc_array.max(axis=None, out=None)
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just
the non-zero ones.

Parameters
axis [-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is
to compute the maximum over all the matrix elements, returning a scalar (i.e., axis =
None).
out [None, optional] This argument is in the signature solely for NumPy compatibility rea-
sons. Do not pass in anything except for the default value, as this argument is not used.

Returns
amax [coo_matrix or scalar] Maximum of a. If axis is None, the result is a scalar value. If
axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

min
The minimum value of a sparse matrix along a given axis.

numpy.matrix.max
NumPy's implementation of ‘max’ for matrices

scipy.sparse.csc_array.maximum

csc_array.maximum(other)
Element-wise maximum between this and another matrix.

scipy.sparse.csc_array.mean

csc_array.mean(axis=None, dtype=None, out=None)
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default,
otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters
axis [-2, -1, 0, 1, None] optional] Axis along which the mean is computed. The default is
to compute the mean of all elements in the matrix (i.e., axis = None).
dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default
is float64; for floating point inputs, it is the same as the input dtype.
New in version 0.18.0.
out  [np.matrix, optional] Alternative output matrix in which to place the result. It must have
the same shape as the expected output, but the type of the output values will be cast if
necessary.
New in version 0.18.0.

Returns

m  [np.matrix]

See also:

numpy.matrix.mean

NumPy’s implementation of ‘mean’ for matrices

scipy.sparse.csc_array.min

csc_array.min(axis=None, out=None)
Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just
the non-zero ones.

Parameters

axis  [[-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is
to compute the minimum over all the matrix elements, returning a scalar (i.e., axis =
None).

out  [None, optional] This argument is in the signature solely for NumPy compatibility rea-
sons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amin  [coo_matrix or scalar] Minimum of a. If axis is None, the result is a scalar value. If
axis is given, the result is a sparse.coo_matrix of dimension a.ndim – 1.

See also:

max

The maximum value of a sparse matrix along a given axis.

numpy.matrix.min

NumPy’s implementation of ‘min’ for matrices

scipy.sparse.csc_array.minimum

csc_array.minimum(other)
Element-wise minimum between this and another matrix.
**scipy.sparse.csc_array.multiply**

csc_array.multiply(other)

Point-wise multiplication by another matrix, vector, or scalar.

**scipy.sparse.csc_array.nonzero**

csc_array.nonzero()

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

**scipy.sparse.csc_array.power**

csc_array.power(n, dtype=None)

This function performs element-wise power.

**Parameters**

- `n` [n is a scalar]
- `dtype` [If dtype is not specified, the current dtype will be preserved.]

**scipy.sparse.csc_array.prune**

csc_array.prune()

Remove empty space after all non-zero elements.

**scipy.sparse.csc_array.rad2deg**

csc_array.rad2deg()

Element-wise rad2deg.

See numpy.rad2deg for more information.
scipy.sparse.csc_array.reshape

csc_array.reshape(self, shape, order='C', copy=False)

Gives a new shape to a sparse matrix without changing its data.

Parameters

- **shape** [length-2 tuple of ints] The new shape should be compatible with the original shape.
- **order** [{‘C’, ‘F’}, optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- **copy** [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

- **reshaped_matrix** [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

- **numpy.matrix.reshape**
  NumPy's implementation of 'reshape' for matrices

scipy.sparse.csc_array.resize

csc_array.resize(*shape)

Resize the matrix in-place to dimensions given by shape

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

- **shape** [(int, int)] number of rows and columns in the new matrix

Notes

The semantics are not identical to numpy.ndarray.resize or numpy.resize. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.
scipy.sparse.csc_array.rint

csc_array.rint()
Element-wise rint.

See numpy.rint for more information.

scipy.sparse.csc_array.set_shape

csc_array.set_shape(shape)
See reshape.

scipy.sparse.csc_array.setdiag

csc_array.setdiag(values, k=0)
Set diagonal or off-diagonal elements of the array.

Parameters
values [array_like] New values of the diagonal elements. Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored. If a scalar value is given, all of the diagonal is set to it.
k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

scipy.sparse.csc_array.sign

csc_array.sign()
Element-wise sign.

See numpy.sign for more information.

scipy.sparse.csc_array.sin

csc_array.sin()
Element-wise sin.

See numpy.sin for more information.

scipy.sparse.csc_array.sinh

csc_array.sinh()
Element-wise sinh.

See numpy.sinh for more information.
scipy.sparse.csc_array.sort_indices

csc_array.sort_indices()
Sort the indices of this matrix in place

scipy.sparse.csc_array.sorted_indices

csc_array.sorted_indices()
Return a copy of this matrix with sorted indices

scipy.sparse.csc_array.sqrt

csc_array.sqrt()
Element-wise sqrt.
See numpy.sqrt for more information.

scipy.sparse.csc_array.sum

csc_array.sum(axis=None, dtype=None, out=None)
Sum the matrix elements over a given axis.

Parameters
axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., axis = None).
dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used. New in version 0.18.0.
out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

Returns
sum_along_axis [np.matrix] A matrix with the same shape as self, with the specified axis removed.

See also:

numpy.matrix.sum
NumPy's implementation of 'sum' for matrices
**scipy.sparse.csc_array.sum_duplicates**

```python
csc_array.sum_duplicates()
```
Eliminate duplicate matrix entries by adding them together
This is an **in place** operation.

**scipy.sparse.csc_array.tan**

```python
csc_array.tan()
```
Element-wise tan.
See **numpy.tan** for more information.

**scipy.sparse.csc_array.tanh**

```python
csc_array.tanh()
```
Element-wise tanh.
See **numpy.tanh** for more information.

**scipy.sparse.csc_array.toarray**

```python
csc_array.toarray(order=None, out=None)
```
Return a dense ndarray representation of this matrix.

*Parameters*

- **order** [{‘C’, ‘F’}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ’None’, which provides no ordering guarantees. Cannot be specified in conjunction with the **out** argument.
- **out** [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, **out** is required to be memory contiguous (either C or Fortran ordered).

*Returns*

- **arr** [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If **out** was passed, the same object is returned after being modified in-place to contain the appropriate values.

**scipy.sparse.csc_array.tobsr**

```python
csc_array.tobsr(blocksize=None, copy=False)
```
Convert this matrix to Block Sparse Row format.

With **copy=False**, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When **blocksize=(R, C)** is provided, it will be used for construction of the bsr_matrix.
**scipy.sparse.csc_array.tocoo**

csc_array.tocoo(copy=True)

Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

**scipy.sparse.csc_array.tocsc**

csc_array.tocsc(copy=False)

Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

**scipy.sparse.csc_array.tocsr**

csc_array.tocsr(copy=False)

Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

**scipy.sparse.csc_array.todense**

csc_array.todense(order=None, out=None)

Return a dense matrix representation of this matrix.

**Parameters**

- **order** [{‘C’, ‘F’}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, which provides no ordering guarantees. Cannot be specified in conjunction with the out argument.

- **out** [ndarray, 2-D, optional] If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**

- **arr** [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

**scipy.sparse.csc_array.todia**

csc_array.todia(copy=False)

Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.
scipy.sparse.csc_array.todok

csc_array.todok(copy=False)
Convert this matrix to Dictionary Of Keys format.
With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.csc_array.tolil

csc_array.tolil(copy=False)
Convert this matrix to List of Lists format.
With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.csc_array.trace

csc_array.trace(offset=0)
Returns the sum along diagonals of the sparse matrix.

Parameters

offset [int, optional] Which diagonal to get, corresponding to elements a[i, i+offset]. Default: 0 (the main diagonal).

scipy.sparse.csc_array.transpose

csc_array.transpose(axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [self with the dimensions reversed.]

See also:
numpy.matrix.transpose

NumPy's implementation of 'transpose' for matrices

scipy.sparse.csc_array.trunc

csc_array.trunc() Element-wise trunc.

See numpy.trunc for more information.

scipy.sparse.csr_array

class scipy.sparse.csr_array(arg1, shape=None, dtype=None, copy=False)

Compressed Sparse Row array

This can be instantiated in several ways:

csr_array(D)
with a dense array or rank-2 ndarray D
csr_array(S)
with another sparse array S (equivalent to S.tocsr())
csr_array((M, N), [dtype])
to construct an empty array with shape (M, N) dtype is optional, defaulting to dtype='d'.
csr_array((data, (row_ind, col_ind)), [shape=(M, N)])
where data, row_ind and col_ind satisfy the relationship a[row_ind[k],
col_ind[k]] = data[k].
csr_array((data, indices, indptr), [shape=(M, N)])
is the standard CSR representation where the column indices for row i are stored in
indices[indptr[i]:indptr[i+1]] and their corresponding values are stored in
data[indptr[i]:indptr[i+1]]. If the shape parameter is not supplied, the array di-
mensions are inferred from the index arrays.

Notes

Sparse arrays can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and array power.

Advantages of the CSR format

• efficient arithmetic operations CSR + CSR, CSR * CSR, etc.
• efficient row slicing
• fast array vector products

Disadvantages of the CSR format

• slow column slicing operations (consider CSC)
• changes to the sparsity structure are expensive (consider LIL or DOK)

3.3. API definition 1761
Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_array
>>> csr_array(((3, 4), dtype=np.int8)).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```python
>>> row = np.array([0, 0, 0, 0])
>>> col = np.array([0, 1, 2, 3])
>>> data = np.array([1, 2, 3, 4])
>>> csr_array((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])
```

Duplicate entries are summed together:

```python
>>> row = np.array([0, 1, 2, 3])
>>> col = np.array([0, 1, 1, 0])
>>> data = np.array([1, 2, 3, 4])
>>> csr_array((data, (row, col)), shape=(3, 3)).toarray()
array([[9, 0, 0],
       [0, 2, 0],
       [0, 4, 0]])
```

As an example of how to construct a CSR array incrementally, the following snippet builds a term-document array from texts:

```python
>>> docs = ["hello", "world", "hello"], ["goodbye", "cruel", "world"]
>>> indptr = [0]
>>> indices = []
>>> data = []
>>> vocabulary = {}
>>> for d in docs:
...     for term in d:
...         index = vocabulary.setdefault(term, len(vocabulary))
...         indices.append(index)
...         data.append(1)
...         indptr.append(len(indices))
...     vocabary = {}
>>> csr_array((data, indices, indptr), dtype=int).toarray()
array([[2, 1, 0, 0],
       [0, 1, 1, 1]])
```
Attributes

dtype [dtype] Data type of the array
ndim [int] Number of dimensions (this is always 2)
nnz Number of stored values, including explicit zeros.
data CSR format data array of the array
indices CSR format index array of the array
indptr CSR format index pointer array of the array
has_sorted_indices Determine whether the matrix has sorted indices

Methods

__len__()  

__mul__(*args, **kwargs)  

arcsin() Element-wise arcsin.
arcsinh() Element-wise arcsinh.
arctan() Element-wise arctan.
arctanh() Element-wise arctanh.
argmax([axis, out]) Return indices of maximum elements along an axis.
argmin([axis, out]) Return indices of minimum elements along an axis.
astformat(format[, copy]) Return this matrix in the passed format.
astype(dtype[, casting, copy]) Cast the matrix elements to a specified type.
ceil() Element-wise ceil.
check_format([full_check]) check whether the matrix format is valid
conj([copy]) Element-wise complex conjugation.
conjugate([copy]) Element-wise complex conjugation.
copy() Returns a copy of this matrix.
count_nonzero() Number of non-zero entries, equivalent to
deg2rad() Element-wise deg2rad.
diagonal([k]) Returns the kth diagonal of the matrix.
dot(other) Ordinary dot product
eliminate_zeros() Remove zero entries from the matrix
expm1() Element-wise expm1.
floor() Element-wise floor.
getH() Return the Hermitian transpose of this matrix.
get_shape() Get shape of a matrix.
getcol(i) Returns a copy of column i of the matrix, as a (m x 1) CSR matrix (column vector).
getformat() Format of a matrix representation as a string.
getmaxprint() Maximum number of elements to display when printed.
getnnz([axis]) Number of stored values, including explicit zeros.
getrow(i) Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).
log1p() Element-wise log1p.

</table>
**scipy.sparse.csr_array.__len__**

csr_array.__len__()  

**scipy.sparse.csr_array.__mul__**

csr_array.__mul__(*args, **kwargs)

**scipy.sparse.csr_array.arcsin**

csr_array.arcsin()  
Element-wise arcsin.  
See numpy.arcsin for more information.

**scipy.sparse.csr_array.arcsinh**

csr_array.arcsinh()  
Element-wise arcsinh.  
See numpy.arcsinh for more information.

**scipy.sparse.csr_array.arctan**

csr_array.arctan()  
Element-wise arctan.  
See numpy.arctan for more information.

**scipy.sparse.csr_array.arctanh**

csr_array.arctanh()  
Element-wise arctanh.  
See numpy.arctanh for more information.

**scipy.sparse.csr_array.argmax**

csr_array.argmax( axis=None, out=None )  
Return indices of maximum elements along an axis. Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>axis</td>
<td>[{-2, -1, 0, 1, None}, optional] Axis along which the argmax is computed. If None (default), index of the maximum element in the flattened data is returned.</td>
</tr>
<tr>
<td>out</td>
<td>[None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.</td>
</tr>
</tbody>
</table>
Returns
ind [numpy.matrix or int] Indices of maximum elements. If matrix, its size along axis is 1.

scipy.sparse.csr_array.argmin
csr_array.argmin(axis=None, out=None)
Return indices of minimum elements along an axis.
Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

Parameters
axis [{-2, -1, 0, 1, None}, optional] Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.
out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns
ind [numpy.matrix or int] Indices of minimum elements. If matrix, its size along axis is 1.

scipy.sparse.csr_array.asformat
csr_array.asformat(format, copy=False)
Return this matrix in the passed format.

Parameters
format [{str, None}] The desired matrix format ("csr", "csc", "lil", "dok", "array", …) or None for no conversion.
copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns
A [This matrix in the passed format.]

scipy.sparse.csr_array.asfptype
csr_array.asfptype()
Upcast matrix to a floating point format (if necessary)

scipy.sparse.csr_array.astype
csr_array.astype(dtype, casting='unsafe', copy=True)
Cast the matrix elements to a specified type.

Parameters
dtype [string or numpy dtype] Typecode or data-type to which to cast the data.
**casting**

[{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.

**copy**

[bool, optional] If `copy` is False, the result might share some memory with this matrix. If `copy` is True, it is guaranteed that the result and this matrix do not share any memory.

**scipy.sparse.csr_array.ceil**

csr_array.ceil()

Element-wise ceiling.

See `numpy.ceil` for more information.

**scipy.sparse.csr_array.check_format**

csr_array.check_format (full_check=True)

check whether the matrix format is valid

**Parameters**

- **full_check** [bool, optional] If True, rigorous check, O(N) operations. Otherwise basic check, O(1) operations (default True).

**scipy.sparse.csr_array.conj**

csr_array.conj (copy=True)

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- **A** [The element-wise complex conjugate.]

**scipy.sparse.csr_array.conjugate**

csr_array.conjugate (copy=True)

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**
A [The element-wise complex conjugate.]

**scipy.sparse.csr_array.copy**

csr_array.copy()  
Returns a copy of this matrix.  
No data/indices will be shared between the returned value and current matrix.

**scipy.sparse.csr_array.count_nonzero**

csr_array.count_nonzero()  
Number of non-zero entries, equivalent to  
np.count_nonzero(a.toarray())  
Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

**scipy.sparse.csr_array.deg2rad**

csr_array.deg2rad()  
Element-wise deg2rad.  
See numpy.deg2rad for more information.

**scipy.sparse.csr_array.diagonal**

csr_array.diagonal(k=0)  
Returns the kth diagonal of the matrix.

**Parameters**

k [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0  
(the main diagonal).  
New in version 1.0.

**Examples**

```python  
>>> from scipy.sparse import csr_matrix  
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])  
>>> A.diagonal()  
array([1, 0, 5])  
>>> A.diagonal(k=1)  
array([2, 3])  
```
**scipy.sparse.csr_array.dot**

```python
csr_array.dot(other)
```

Ordinary dot product

**Examples**

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

**scipy.sparse.csr_array.eliminate_zeros**

```python
csr_array.eliminate_zeros()
```

Remove zero entries from the matrix

This is an *in place* operation.

**scipy.sparse.csr_array.expm1**

```python
csr_array.expm1()
```

Element-wise expm1.

See *numpy.expm1* for more information.

**scipy.sparse.csr_array.floor**

```python
csr_array.floor()
```

Element-wise floor.

See *numpy.floor* for more information.

**scipy.sparse.csr_array.getH**

```python
csr_array.getH()
```

Return the Hermitian transpose of this matrix.

See also:

```
numpy.matrix.getH
```

NumPy’s implementation of *getH* for matrices
scipy.sparse.csr_array.get_shape

csr_array.get_shape()
Get shape of a matrix.

scipy.sparse.csr_array.getcol

csr_array.getcol(i)
Returns a copy of column i of the matrix, as a (m x 1) CSR matrix (column vector).

scipy.sparse.csr_array.getformat

csr_array.getformat()
Format of a matrix representation as a string.

scipy.sparse.csr_array.getmaxprint

csr_array.getmaxprint()
Maximum number of elements to display when printed.

scipy.sparse.csr_array.getnnz

csr_array.getnnz(axis=None)
Number of stored values, including explicit zeros.

Parameters
axis [None, 0, or 1] Select between the number of values across the whole matrix, in each
column, or in each row.

See also:
count_nonzero
Number of non-zero entries

scipy.sparse.csr_array.getrow

csr_array.getrow(i)
Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).
scipy.sparse.csr_array.log1p

csr_array.log1p()
Element-wise log1p.

See numpy.log1p for more information.

scipy.sparse.csr_array.max

csr_array.max(axis=None, out=None)
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just
the non-zero ones.

Parameters

axis [-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is
to compute the maximum over all the matrix elements, returning a scalar (i.e., axis = None).

out [None, optional] This argument is in the signature solely for NumPy compatibility rea-
sons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amax [coo_matrix or scalar] Maximum of a. If axis is None, the result is a scalar value. If
axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

min

The minimum value of a sparse matrix along a given axis.

numpy.matrix.max

NumPy's implementation of 'max' for matrices

scipy.sparse.csr_array.maximum

csr_array.maximum(other)
Element-wise maximum between this and another matrix.

scipy.sparse.csr_array.mean

csr_array.mean(axis=None, dtype=None, out=None)
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default,
otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters

axis [-2, -1, 0, 1, None] optional] Axis along which the mean is computed. The default is
to compute the mean of all elements in the matrix (i.e., axis = None).

dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is
float64; for floating point inputs, it is the same as the input dtype.
New in version 0.18.0.
out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

m [np.matrix]

See also:

numpy.matrix.mean

NumPy’s implementation of ‘mean’ for matrices

scipy.sparse.csr_array.min

csr_array.min(axis=None, out=None)
Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e., axis = None).

out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amin [coo_matrix or scalar] Minimum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

max

The maximum value of a sparse matrix along a given axis.

numpy.matrix.min

NumPy’s implementation of ‘min’ for matrices

scipy.sparse.csr_array.minimum

csr_array.minimum(other)
Element-wise minimum between this and another matrix.
scipy.sparse.csr_array.multiply

csr_array.multiply(other)
   Point-wise multiplication by another matrix, vector, or scalar.

scipy.sparse.csr_array.nonzero

csr_array.nonzero()
   nonzero indices
   Returns a tuple of arrays (row, col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.csr_array.power

csr_array.power(n, dtype=None)
   This function performs element-wise power.

   Parameters

   n [n is a scalar]
   dtype [If dtype is not specified, the current dtype will be preserved.]

scipy.sparse.csr_array.prune

csr_array.prune()
   Remove empty space after all non-zero elements.

scipy.sparse.csr_array.rad2deg

csr_array.rad2deg()
   Element-wise rad2deg.

   See numpy.rad2deg for more information.
scipy.sparse.csr_array.reshape

csr_array.reshape(self, shape, order='C', copy=False)

Gives a new shape to a sparse matrix without changing its data.

Parameters

- **shape** [length-2 tuple of ints] The new shape should be compatible with the original shape.
- **order** [{‘C’, ‘F’}, optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- **copy** [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

- **reshaped_matrix** [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

- **numpy.matrix.reshape**

  NumPy’s implementation of ‘reshape’ for matrices

scipy.sparse.csr_array.resize

csr_array.resize(*shape)

Resize the matrix in-place to dimensions given by shape

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

- **shape** [(int, int)] number of rows and columns in the new matrix

Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.
**scipy.sparse.csr_array.rint**

csr_array.rint()

Element-wise rint.

See `numpy.rint` for more information.

**scipy.sparse.csr_array.set_shape**

csr_array.set_shape(shape)

See `reshape`.

**scipy.sparse.csr_array.setdiag**

csr_array.setdiag(values, k=0)

Set diagonal or off-diagonal elements of the array.

*Parameters*

- **values** [array_like] New values of the diagonal elements. Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored. If a scalar value is given, all of the diagonal is set to it.
- **k** [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

**scipy.sparse.csr_array.sign**

csr_array.sign()

Element-wise `sign`.

See `numpy.sign` for more information.

**scipy.sparse.csr_array.sin**

csr_array.sin()

Element-wise `sin`.

See `numpy.sin` for more information.

**scipy.sparse.csr_array.sinh**

csr_array.sinh()

Element-wise `sinh`.

See `numpy.sinh` for more information.
scipy.sparse.csr_array.sort_indices

csr_array.sort_indices()

Sort the indices of this matrix in place

scipy.sparse.csr_array.sorted_indices

csr_array.sorted_indices()

Return a copy of this matrix with sorted indices

scipy.sparse.csr_array.sqrt

csr_array.sqrt()

Element-wise sqrt.

See numpy.sqrt for more information.

scipy.sparse.csr_array.sum

csr_array.sum(axis=None, dtype=None, out=None)

Sum the matrix elements over a given axis.

Parameters

axis  [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., axis = None).

dtype  [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used.

New in version 0.18.0.

out  [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

New in version 0.18.0.

Returns

sum_along_axis  [np.matrix] A matrix with the same shape as self, with the specified axis removed.

See also:

numpy.matrix.sum

NumPy's implementation of `sum' for matrices
scipy.sparse.csr_array.sum_duplicates

csr_array.sum_duplicates()
    Eliminate duplicate matrix entries by adding them together
    This is an in place operation.

scipy.sparse.csr_array.tan

csr_array.tan()
    Element-wise tan.
    See numpy.tan for more information.

scipy.sparse.csr_array.tanh

csr_array.tanh()
    Element-wise tanh.
    See numpy.tanh for more information.

scipy.sparse.csr_array.toarray

csr_array.toarray(order=None, out=None)
    Return a dense ndarray representation of this matrix.
    Parameters
    order [{‘C’, ‘F’}, optional] Whether to store multidimensional data in
    C (row-major) or Fortran (column-major) order in memory. The default is
    ‘None’, which provides no ordering guarantees. Cannot be specified in
    conjunction with the out argument.
    out [ndarray, 2-D, optional] If specified, uses this array as the output
    buffer instead of allocating a new array to return. The provided array
    must have the same shape and dtype as the sparse matrix on which you
    are calling the method. For most sparse types, out is required to
    be memory contiguous (either C or Fortran ordered).
    Returns
    arr [ndarray, 2-D] An array with the same shape and containing the same
    data represented by the sparse matrix, with the requested memory
    order. If out was passed, the same object is returned after being
    modified in-place to contain the appropriate values.

scipy.sparse.csr_array.tobsr

csr_array.tobsr(blocksize=None, copy=True)
    Convert this matrix to Block Sparse Row format.
    With copy=False, the data/indices may be shared between this matrix
    and the resultant bsr_matrix.
    When blocksize=(R, C) is provided, it will be used for construction of
    the bsr_matrix.
**scipy.sparse.csr_array.tocoo**

```python
csr_array.tocoo(copy=True)
```
Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

**scipy.sparse.csr_array.tocsc**

```python
csr_array.tocsc(copy=False)
```
Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

**scipy.sparse.csr_array.tocsr**

```python
csr_array.tocsr(copy=False)
```
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

**scipy.sparse.csr_array.todense**

```python
csr_array.todense(order=None, out=None)
```
Return a dense matrix representation of this matrix.

**Parameters**

- **order** [{‘C’, ‘F’}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, which provides no ordering guarantees. Cannot be specified in conjunction with the out argument.

- **out** [ndarray, 2-D, optional] If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**

- **arr** [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

**scipy.sparse.csr_array.todia**

```python
csr_array.todia(copy=False)
```
Convert this matrix to sparse DIAGONal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.
scipy.sparse.csr_array.todok

`csr_array.todok(copy=False)`
Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.csr_array.tolil

`csr_array.tolil(copy=False)`
Convert this matrix to List of Lists format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.csr_array.trace

`csr_array.trace(offset=0)`
Returns the sum along diagonals of the sparse matrix.

Parameters

offset [int, optional] Which diagonal to get, corresponding to elements $a[i, i+offset]$. Default: 0 (the main diagonal).

scipy.sparse.csr_array.transpose

`csr_array.transpose(axes=None, copy=False)`
Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.

copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [self with the dimensions reversed.]

See also:

numpy.matrix.transpose
NumPy's implementation of ‘transpose’ for matrices
scipy.sparse.csr_array.trunc

csr_array.trunc()
    Element-wise trunc.
    See numpy.trunc for more information.

__getitem__

scipy.sparse.dia_array

class scipy.sparse.dia_array(arg1, shape=None, dtype=None, copy=False)
    Sparse array with DIAGONAL storage

    This can be instantiated in several ways:

    dia_array(D)
        with a dense array

    dia_array(S)
        with another sparse array S (equivalent to S.todia())

    dia_array((M, N), [dtype])
        to construct an empty array with shape (M, N), dtype is optional, defaulting to dtype=`d`

    dia_array((data, offsets), shape=(M, N))
        where the data[k,:] stores the diagonal entries for diagonal offsets[k] (See example below)

Notes

Sparse arrays can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and array power.

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import dia_array
>>> dia_array((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)

>>> data = np.array([[1, 2, 3, 4]]).repeat(3, axis=0)
>>> offsets = np.array([0, -1, 2])
>>> dia_array((data, offsets), shape=(4, 4)).toarray()
array([[1, 0, 3, 0],
       [1, 2, 0, 4],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
```
```python
>>> from scipy.sparse import dia_array
>>> n = 10
>>> ex = np.ones(n)
>>> data = np.array([ex, 2 * ex, ex])
>>> offsets = np.array([-1, 0, 1])
>>> dia_array((data, offsets), shape=(n, n)).toarray()
array([[2., 1., 0., ..., 0., 0., 0.],
       [1., 2., 1., ..., 0., 0., 0.],
       [0., 1., 2., ..., 0., 0., 0.],
       ...,
       [0., 0., 0., ..., 2., 1., 0.],
       [0., 0., 0., ..., 1., 2., 1.],
       [0., 0., 0., ..., 0., 1., 2.]])
```

**Attributes**

- `dtype` [dtype] Data type of the array
- `ndim` [int] Number of dimensions (this is always 2)
- `nnz` Number of stored values, including explicit zeros.
- `data` DIA format data array of the array
- `offsets` DIA format offset array of the array

**Methods**

- `__len__()`
- `__mul__(*args, **kwargs)`

  - `arcsin()` Element-wise arcsin.
  - `arcsinh()` Element-wise arcsinh.
  - `arctan()` Element-wise arctan.
  - `arctanh()` Element-wise arctanh.
  - `asformat(format[, copy])` Return this matrix in the passed format.
  - `asfptype()` Upcast matrix to a floating point format (if necessary)
  - `astype(dtype[, casting, copy])` Cast the matrix elements to a specified type.
  - `ceil()` Element-wise ceil.
  - `conj([copy])` Element-wise complex conjugation.
  - `conjugate([copy])` Element-wise complex conjugation.
  - `copy()` Returns a copy of this matrix.
  - `count_nonzero()` Number of non-zero entries, equivalent to
  - `deg2rad()` Element-wise deg2rad.
  - `diagonal([k])` Returns the kth diagonal of the matrix.
  - `dot(other)` Ordinary dot product
  - `expm1()` Element-wise expm1.
  - `floor()` Element-wise floor.
  - `getH()` Return the Hermitian transpose of this matrix.
  - `get_shape()` Get shape of a matrix.
  - `getcol(j)` Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

continues on next page

### 3.3. API definition
getformat()  Format of a matrix representation as a string.
getmaxprint()  Maximum number of elements to display when printed.
getnnz([axis])  Number of stored values, including explicit zeros.
getrow(i)  Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
log1p()  Element-wise log1p.
maximum(other)  Element-wise maximum between this and another matrix.
mean([axis, dtype, out])  Compute the arithmetic mean along the specified axis.
minimum(other)  Element-wise minimum between this and another matrix.
multiply(other)  Point-wise multiplication by another matrix
nonzero()  nonzero indices
power(n[, dtype])  This function performs element-wise power.
rad2deg()  Element-wise rad2deg.
reshape(self, shape[, order, copy])  Gives a new shape to a sparse matrix without changing its data.
rint()  Element-wise rint.
set_shape(shape)  See reshape.
setdiag(values[, k])  Set diagonal or off-diagonal elements of the array.
sign()  Element-wise sign.
sin()  Element-wise sin.
sinh()  Element-wise sinh.
sqrt()  Element-wise sqrt.
sum([axis, dtype, out])  Sum the matrix elements over a given axis.
tan()  Element-wise tan.
tanh()  Element-wise tanh.
todense([order, out])  Return a dense ndarray representation of this matrix.
todok([copy])  Convert this matrix to Dictionary Of Keys format.
todense([order, out])  Return a dense matrix representation of this matrix.
todok([copy])  Convert this matrix to sparse DIAgonal format.
toarray([order, out])  Convert this matrix to Block Sparse Row format.
tocsr([copy])  Convert this matrix to Compressed Sparse Row format.
toci([copy])  Convert this matrix to Compressed Sparse Column format.
trace([offset])  Returns the sum along diagonals of the sparse matrix.
transpose([axes, copy])  Reverses the dimensions of the sparse matrix.
trunc()  Element-wise trunc.
scipy.sparse.dia_array.__len__

dia_array.__len__()

scipy.sparse.dia_array.__mul__

dia_array.__mul__(*args, **kwargs)

scipy.sparse.dia_array.arcsin

dia_array.arcsin()
   Element-wise arcsin.
   See numpy.arcsin for more information.

scipy.sparse.dia_array.arcsinh

dia_array.arcsinh()
   Element-wise arcsinh.
   See numpy.arcsinh for more information.

scipy.sparse.dia_array.arctan

dia_array.arctan()
   Element-wise arctan.
   See numpy.arctan for more information.

scipy.sparse.dia_array.arctanh

dia_array.arctanh()
   Element-wise arctanh.
   See numpy.arctanh for more information.

scipy.sparse.dia_array.asformat

dia_array.asformat(format, copy=False)
   Return this matrix in the passed format.

   Parameters
   ----------
   format: [str, None]
      The desired matrix format ("csr", "csc", "lil", "dok", "array", ...) or None
      for no conversion.
   copy: [bool, optional]
      If True, the result is guaranteed to not share data with self.

   Returns
   -------
   A: [This matrix in the passed format.]
scipy.sparse.dia_array.asfptype

dia_array.asfptype()
  Upcast matrix to a floating point format (if necessary)

scipy.sparse.dia_array.astype

dia_array.astype(dtype, casting='unsafe', copy=True)
  Cast the matrix elements to a specified type.
  
  Parameters

  dtype [string or numpy dtype] Typecode or data-type to which to cast the data.

  casting [{‘no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’}, optional] Controls what kind of data casting may occur. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.

  copy [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.

scipy.sparse.dia_array.ceil

dia_array.ceil()
  Element-wise ceil.

  See numpy.ceil for more information.

scipy.sparse.dia_array.conj

dia_array.conj(copy=True)
  Element-wise complex conjugation.

  If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

  Parameters

  copy [bool, optional] If True, the result is guaranteed to not share data with self.

  Returns

  A [The element-wise complex conjugate.]
scipy.sparse.dia_array.conjugate

dia_array.conjugate(copy=True)
Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.dia_array.copy

dia_array.copy()
Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

scipy.sparse.dia_array.count_nonzero

dia_array.count_nonzero()
Number of non-zero entries, equivalent to
np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.dia_array.deg2rad

dia_array.deg2rad()
Element-wise deg2rad.

See numpy.deg2rad for more information.

scipy.sparse.dia_array.diagonal

dia_array.diagonal(k=0)
Returns the kth diagonal of the matrix.

Parameters

k [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).

New in version 1.0.

See also:

numpy.diagonal
Equivalent numpy function.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.dia_array.dot

dia_array.dot(other)

Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.dia_array.expm1

dia_array.expm1()

Element-wise expm1.

See numpy.expm1 for more information.

scipy.sparse.dia_array.floor

dia_array.floor()

Element-wise floor.

See numpy.floor for more information.

scipy.sparse.dia_array.getH

dia_array.getH()

Return the Hermitian transpose of this matrix.

See also:

    numpy.matrix.getH

    NumPy's implementation of getH for matrices
**scipy.sparse.dia_array.get_shape**

```python
dia_array.get_shape()
```
Get shape of a matrix.

**scipy.sparse.dia_array.getcol**

```python
dia_array.getcol(j)
```
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

**scipy.sparse.dia_array.getformat**

```python
dia_array.getformat()
```
Format of a matrix representation as a string.

**scipy.sparse.dia_array.getmaxprint**

```python
dia_array.getmaxprint()
```
Maximum number of elements to display when printed.

**scipy.sparse.dia_array.getnnz**

```python
dia_array.getnnz(axis=None)
```
Number of stored values, including explicit zeros.

**Parameters**

- **axis** [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

- **count_nonzero**
  Number of non-zero entries

**scipy.sparse.dia_array.getrow**

```python
dia_array.getrow(i)
```
Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
scipy.sparse.dia_array.log1p

dia_array.log1p()
   Element-wise log1p.
   See numpy.log1p for more information.

scipy.sparse.dia_array.maximum

dia_array.maximum(other)
   Element-wise maximum between this and another matrix.

scipy.sparse.dia_array.mean

dia_array.mean(axis=None, dtype=None, out=None)
   Compute the arithmetic mean along the specified axis.
   Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

   Parameters
   axis   [{-2, -1, 0, 1, None} optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., axis = None).
   dtype  [data-type, optional] Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype. New in version 0.18.0.
   out    [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

   Returns
   m  [np.matrix]

   See also:

   numpy.matrix.mean
      NumPy's implementation of 'mean' for matrices

scipy.sparse.dia_array.minimum

dia_array.minimum(other)
   Element-wise minimum between this and another matrix.
**scipy.sparse.dia_array.multiply**

`dia_array.multiply(other)`  
Point-wise multiplication by another matrix

**scipy.sparse.dia_array.nonzero**

`dia_array.nonzero()`  
nonzero indices  
Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

**scipy.sparse.dia_array.power**

`dia_array.power(n, dtype=None)`  
This function performs element-wise power.  

**Parameters**

- `n` [n is a scalar]
- `dtype` [If dtype is not specified, the current dtype will be preserved.]

**scipy.sparse.dia_array.rad2deg**

`dia_array.rad2deg()`  
Element-wise rad2deg.  

See `numpy.rad2deg` for more information.

**scipy.sparse.dia_array.reshape**

`dia_array.reshape(self, shape, order='C', copy=False)`  
Gives a new shape to a sparse matrix without changing its data.  

**Parameters**

- `shape` [length-2 tuple of ints] The new shape should be compatible with the original shape.  
- `order` [‘C’, ‘F’, optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.  
- `copy` [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.
**Returns**

`reshaped_matrix`

[sparse matrix] A sparse matrix with the given `shape`, not necessarily of the same format as the current object.

See also:

`numpy.matrix.reshape`

NumPy’s implementation of ‘reshape’ for matrices

**scipy.sparse.dia_array.resize**

dia_array.resize(*shape*)

Resize the matrix in-place to dimensions given by `shape`

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

**Parameters**

`shape`  [(int, int)] number of rows and columns in the new matrix

**Notes**

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

**scipy.sparse.dia_array.rint**

dia_array.rint()

Element-wise rint.

See `numpy.rint` for more information.

**scipy.sparse.dia_array.set_shape**

dia_array.set_shape(shape)

See `reshape`.
scipy.sparse.dia_array.setdiag
dia_array.setdiag(values, k=0)
   Set diagonal or off-diagonal elements of the array.
   Parameters
   values  [array_like] New values of the diagonal elements.
   Values may have any length. If the diagonal is longer than values, then the remaining
diagonal entries will not be set. If values are longer than the diagonal, then the remaining
values are ignored.
   If a scalar value is given, all of the diagonal is set to it.
   k       [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0
   (the main diagonal).

scipy.sparse.dia_array.sign
dia_array.sign()
   Element-wise sign.
   See numpy.sign for more information.

scipy.sparse.dia_array.sin
dia_array.sin()
   Element-wise sin.
   See numpy.sin for more information.

scipy.sparse.dia_array.sinh
dia_array.sinh()
   Element-wise sinh.
   See numpy.sinh for more information.

scipy.sparse.dia_array.sqrt
dia_array.sqrt()
   Element-wise sqrt.
   See numpy.sqrt for more information.
scipy.sparse.dia_array.sum

dia_array.sum (axis=None, dtype=None, out=None)
Sum the matrix elements over a given axis.

Parameters
axis [{-2,-1,0,1,None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., axis = None).
dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used.
out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

Returns
sum_along_axis [np.matrix] A matrix with the same shape as self, with the specified axis removed.

See also:
numpy.matrix.sum
NumPy's implementation of 'sum' for matrices

scipy.sparse.dia_array.tan

dia_array.tan()
Element-wise tan.

See numpy.tan for more information.

scipy.sparse.dia_array.tanh

dia_array.tanh()
Element-wise tanh.

See numpy.tanh for more information.

scipy.sparse.dia_array.toarray

dia_array.toarray(order=None, out=None)
Return a dense ndarray representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, which provides no ordering guarantees. Cannot be specified in conjunction with the out argument.

out [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, out is required to be memory contiguous (either C or Fortran ordered).

Returns

arr [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed, the same object is returned after being modified in-place to contain the appropriate values.

scipy.sparse.dia_array.tobsr

dia_array.tobsr(blocksize=None, copy=False)
Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

scipy.sparse.dia_array.tocoo

dia_array.tocoo(copy=False)
Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

scipy.sparse.dia_array.tocsc

dia_array.tocsc(copy=False)
Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.
**scipy.sparse.dia_array.tocsr**

dia_array.tocsr(copy=False)

Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

**scipy.sparse.dia_array.todense**

dia_array.todense(order=None, out=None)

Return a dense matrix representation of this matrix.

Parameters

- **order** [{'C', 'F'}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, which provides no ordering guarantees. Cannot be specified in conjunction with the `out` argument.
- **out** [ndarray, 2-D, optional] If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

- **arr** [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

**scipy.sparse.dia_array.todia**

dia_array.todia(copy=False)

Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

**scipy.sparse.dia_array.todok**

dia_array.todok(copy=False)

Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

**scipy.sparse.dia_array.tolil**

dia_array.tolil(copy=False)

Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.
**scipy.sparse.dia_array.trace**

dia_array.trace(offset=0)

Returns the sum along diagonals of the sparse matrix.

*Parameters*

offset [int, optional] Which diagonal to get, corresponding to elements a[i, i+offset]. Default: 0 (the main diagonal).

**scipy.sparse.dia_array.transpose**

dia_array.transpose(axes=None, copy=False)

Reverses the dimensions of the sparse matrix.

*Parameters*

axes [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

copy [bool, optional] Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

*Returns*

p [self with the dimensions reversed.]

See also:

numpy.matrix.transpose

NumPy’s implementation of ‘transpose’ for matrices

**scipy.sparse.dia_array.trunc**

dia_array.trunc()

Element-wise trunc.

See numpy.trunc for more information.

**scipy.sparse.dok_array**

class scipy.sparse.dok_array(arg1, shape=None, dtype=None, copy=False)

Dictionary Of Keys based sparse array.

This is an efficient structure for constructing sparse arrays incrementally.

*This can be instantiated in several ways:*

dok_array(D)  
with a dense array, D

dok_array(S)  
with a sparse array, S

**dok_array((M,N), [dtype])**

create the array with initial shape (M,N) dtype is optional, defaulting to dtype='d'

Notes

Sparse arrays can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and array power.

Allows for efficient O(1) access of individual elements. Duplicates are not allowed. Can be efficiently converted to a coo_array once constructed.

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import dok_array
>>> S = dok_array((5, 5), dtype=np.float32)
>>> for i in range(5):
...     for j in range(5):
...         S[i, j] = i + j  # Update element
```

Attributes

- **dtype** [dtype] Data type of the array
- **ndim** [int] Number of dimensions (this is always 2)
- **nnz** Number of stored values, including explicit zeros.

Methods

- **__len__()** Return len(self).
- **__mul__(*)** Return len(self).
- **asformat(format[, copy])** Return this matrix in the passed format.
- **asfptype()** Upcast matrix to a floating point format (if necessary)
- **astype(dtype[, casting, copy])** Cast the matrix elements to a specified type.
- **clear()**
- **conj([copy])** Element-wise complex conjugation.
- **conjugate([copy])** Element-wise complex conjugation.
- **copy()** Returns a copy of this matrix.
- **count_nonzero()** Number of non-zero entries, equivalent to
diagonal([k]) Returns the kth diagonal of the matrix.
- **dot(other)** Ordinary dot product
- **fromkeys(iterable[, value])** Create a new dictionary with keys from iterable and values set to value.
- **get(key[, default])** This overrides the dict.get method, providing type checking but otherwise equivalent functionality.
- **getH()** Return the Hermitian transpose of this matrix.

</tbody>
</table>

**3.3. API definition**

![continues on next page]
Table 180 – continued from previous page

values()

scipy.sparse.dok_array.__len__

dok_array.__len__()
    Return len(self).

scipy.sparse.dok_array.__mul__

dok_array.__mul__(*args, **kwargs)

scipy.sparse.dok_array.asformat

dok_array.asformat(format, copy=False)
    Return this matrix in the passed format.

Parameters

format   [{str, None}] The desired matrix format ("csr", "csc", "lil", "dok", "array", ...) or None for no conversion.
copy    [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A        [This matrix in the passed format.]

scipy.sparse.dok_array.asfptype

dok_array.asfptype()
    Upcast matrix to a floating point format (if necessary)

scipy.sparse.dok_array.astype

dok_array.astype(dtype, casting='unsafe', copy=True)
    Cast the matrix elements to a specified type.

Parameters

dtype   [string or numpy dtype] Typecode or data-type to which to cast the data.
casting [{‘no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’}, optional] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
copy    [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.
scipy.sparse.dok_array.clear

dok_array.clear() → None. Remove all items from D.

scipy.sparse.dok_array.conj

dok_array.conj(copy=True)
Element-wise complex conjugation.

   If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

   Parameters
   copy [bool, optional] If True, the result is guaranteed to not share data with self.

   Returns
   A [The element-wise complex conjugate.]

scipy.sparse.dok_array.conjtransp

dok_array.conjtransp()
Return the conjugate transpose.

scipy.sparse.dok_array.conjugate

dok_array.conjugate(copy=True)
Element-wise complex conjugation.

   If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

   Parameters
   copy [bool, optional] If True, the result is guaranteed to not share data with self.

   Returns
   A [The element-wise complex conjugate.]

scipy.sparse.dok_array.copy

dok_array.copy()
Returns a copy of this matrix.

   No data/indices will be shared between the returned value and current matrix.
scipy.sparse.dok_array.count_nonzero

dok_array.count_nonzero()
   Number of non-zero entries, equivalent to
       np.count_nonzero(a.toarray())

   Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data
   attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.dok_array.diagonal

dok_array.diagonal(k=0)
   Returns the kth diagonal of the matrix.

   Parameters
   k       [int, optional] Which diagonal to get, corresponding to elements a[j, i+k]. Default: 0
            (the main diagonal).
            New in version 1.0.

   See also:

   numpy.diagonal

   Equivalent numpy function.

Examples

>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])

scipy.sparse.dok_array.dot

dok_array.dot(other)
   Ordinary dot product

Examples

>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
**scipy.sparse.dok_array.fromkeys**

```python
dok_array.fromkeys(iterable, value=None, /)
```

Create a new dictionary with keys from iterable and values set to value.

**scipy.sparse.dok_array.get**

```python
dok_array.get(key, default=0.0)
```

This overrides the dict.get method, providing type checking but otherwise equivalent functionality.

**scipy.sparse.dok_array.getH**

```python
dok_array.getH()
```

Return the Hermitian transpose of this matrix.

See also:

```python
numpy.matrix.getH
```

NumPy's implementation of `getH` for matrices

**scipy.sparse.dok_array.get_shape**

```python
dok_array.get_shape()
```

Get shape of a matrix.

**scipy.sparse.dok_array.getcol**

```python
dok_array.getcol(j)
```

Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

**scipy.sparse.dok_array.getformat**

```python
dok_array.getformat()
```

Format of a matrix representation as a string.

**scipy.sparse.dok_array.getmaxprint**

```python
dok_array.getmaxprint()
```

Maximum number of elements to display when printed.
scipy.sparse.dok_array.getnnz

dok_array.getnnz(\textit{axis=None})
Number of stored values, including explicit zeros.

\textbf{Parameters}

axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

\textbf{See also:}

count_nonzero

Number of non-zero entries

scipy.sparse.dok_array.getrow

dok_array.getrow(\textit{i})
Returns a copy of row \textit{i} of the matrix, as a (1 x n) sparse matrix (row vector).

scipy.sparse.dok_array.items

dok_array.items() \rightarrow \text{a set-like object providing a view on D's items}

scipy.sparse.dok_array.keys

dok_array.keys() \rightarrow \text{a set-like object providing a view on D's keys}

scipy.sparse.dok_array.maximum

dok_array.maximum(\textit{other})
Element-wise maximum between this and another matrix.

scipy.sparse.dok_array.mean

dok_array.mean(\textit{axis=None, dtype=None, out=None})
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. \texttt{float64} intermediate and return values are used for integer inputs.

\textbf{Parameters}

axis [{-2, -1, 0, 1, None} optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., \texttt{axis = None}).

dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is \texttt{float64}; for floating point inputs, it is the same as the input dtype. New in version 0.18.0.
out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

Returns

m [np.matrix]

See also:

numpy.matrix.mean

NumPy’s implementation of ‘mean’ for matrices

scipy.sparse.dok_array.minimum
dok_array.minimum(other)
Element-wise minimum between this and another matrix.

scipy.sparse.dok_array.multiply
dok_array.multiply(other)
Point-wise multiplication by another matrix

scipy.sparse.dok_array.nonzero
dok_array.nonzero()
nonzero indices
Returns a tuple of arrays (row, col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix(([1,2,0],[0,0,3],[4,0,5]))
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.dok_array.pop
dok_array.pop(key, default=<unrepresentable>, /)
If the key is not found, return the default if given; otherwise, raise a KeyError.
scipy.sparse.dok_array.popitem

dok_array.popitem()  
Remove and return a (key, value) pair as a 2-tuple.  
Pairs are returned in LIFO (last-in, first-out) order. Raises KeyError if the dict is empty.

scipy.sparse.dok_array.power

dok_array.power(n, dtype=None)  
Element-wise power.

scipy.sparse.dok_array.reshape

dok_array.reshape(self, shape, order='C', copy=False)  
Gives a new shape to a sparse matrix without changing its data.

Parameters

- **shape** [length-2 tuple of ints] The new shape should be compatible with the original shape.
- **order** [{‘C’, ‘F’}, optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- **copy** [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

- **reshaped_matrix** [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

numpy.matrix.reshape  
NumPy’s implementation of ‘reshape’ for matrices

scipy.sparse.dok_array.resize

dok_array.resize(*shape)  
Resize the matrix in-place to dimensions given by shape.

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

- **shape** [(int, int)] number of rows and columns in the new matrix
Notes

The semantics are not identical to numpy.ndarray.resize or numpy.resize. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

**scipy.sparse.dok_array.set_shape**

dok_array.set_shape(shape)

See reshape.

**scipy.sparse.dok_array.setdefault**

dok_array.setdefault(key, default=None, /)

Insert key with a value of default if key is not in the dictionary.

Return the value for key if key is in the dictionary, else default.

**scipy.sparse.dok_array.setdiag**

dok_array.setdiag(values, k=0)

Set diagonal or off-diagonal elements of the array.

Parameters

values [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.
If a scalar value is given, all of the diagonal is set to it.

k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

**scipy.sparse.dok_array.sum**

dok_array.sum(axis=None, dtype=None, out=None)

Sum the matrix elements over a given axis.

Parameters

axis [-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., axis = None).
dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used.
New in version 0.18.0.
out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

Returns

sum_along_axis [np.matrix] A matrix with the same shape as self, with the specified axis removed.

See also:

numpy.matrix.sum

NumPy's implementation of 'sum' for matrices

scipy.sparse.dok_array.toarray
dok_array.toarray(order=None, out=None)

Return a dense ndarray representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', which provides no ordering guarantees. Cannot be specified in conjunction with the out argument.

out [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, out is required to be memory contiguous (either C or Fortran ordered).

Returns

arr [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed, the same object is returned after being modified in-place to contain the appropriate values.

scipy.sparse.dok_array.tobsr
dok_array.tobsr(blocksize=None, copy=False)

Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

scipy.sparse.dok_array.tocoo
dok_array.tocoo(copy=False)

Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.
scipy.sparse.dok_array.tocsc

dok_array.tocsc(copy=False)
    Convert this matrix to Compressed Sparse Column format.
    With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.dok_array.tocsr

dok_array.tocsr(copy=False)
    Convert this matrix to Compressed Sparse Row format.
    With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.dok_array.todense

dok_array.todense(order=None, out=None)
    Return a dense matrix representation of this matrix.

    Parameters
    ----------
    order : {'C', 'F'}, optional
        Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', which provides no ordering guarantees. Cannot be specified in conjunction with the out argument.
    out : ndarray, 2-D, optional
        If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

    Returns
    -------
    arr : numpy.matrix, 2-D
        A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

scipy.sparse.dok_array.todia

dok_array.todia(copy=False)
    Convert this matrix to sparse DIAgonal format.
    With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.dok_array.todok

dok_array.todok(copy=False)
    Convert this matrix to Dictionary Of Keys format.
    With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.
scipy.sparse.dok_array.tolil

dok_array.tolil(copy=False)
Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.dok_array.trace

dok_array.trace(offset=0)
Returns the sum along diagonals of the sparse matrix.

Parameters
offset [int, optional] Which diagonal to get, corresponding to elements a[i, i+offset]. Default: 0 (the main diagonal).

scipy.sparse.dok_array.transpose

dok_array.transpose(axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters
axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns
p [self with the dimensions reversed.]

See also:
numpy.matrix.transpose
NumPy’s implementation of ‘transpose’ for matrices

scipy.sparse.dok_array.update

dok_array.update([E], **F) → None. Update D from dict/iterable E and F.
If E is present and has a .keys() method, then does: for k in E: D[k] = E[k] If E is present and lacks a .keys() method, then does: for k, v in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]
scipy.sparse.dok_array.values

dok_array.values() → an object providing a view on D’s values

scipy.sparse.lil_array

class scipy.sparse.lil_array(arg1, shape=None, dtype=None, copy=False)
Row-based list of lists sparse array
This is a structure for constructing sparse arrays incrementally. Note that inserting a single item can take linear
time in the worst case; to construct a array efficiently, make sure the items are pre-sorted by index, per row.

This can be instantiated in several ways:

lil_array(D)
with a dense array or rank-2 ndarray D

lil_array(S)
with another sparse array S (equivalent to S.tolil())

lil_array((M, N), [dtype])
to construct an empty array with shape (M, N) dtype is optional, defaulting to dtype='d'.

Notes
Sparse arrays can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and
array power.

Advantages of the LIL format
• supports flexible slicing
• changes to the array sparsity structure are efficient

Disadvantages of the LIL format
• arithmetic operations LIL + LIL are slow (consider CSR or CSC)
• slow column slicing (consider CSC)
• slow array vector products (consider CSR or CSC)

Intended Usage
• LIL is a convenient format for constructing sparse arrays
• once a array has been constructed, convert to CSR or CSC format for fast arithmetic and array vector
  operations
• consider using the COO format when constructing large arrays

Data Structure
• An array (self.rows) of rows, each of which is a sorted list of column indices of non-zero elements.
• The corresponding nonzero values are stored in similar fashion in self.data.

Attributes

- **dtype** [dtype] Data type of the array
- **ndim** [int] Number of dimensions (this is always 2)
- **nnz** Number of stored values, including explicit zeros.
- **data** LIL format data array of the array
- **rows** LIL format row index array of the array

Methods

- **__len__()**
- **__mul__(**args, **kwargs**)**

  ```python
  asformat(format[, copy])
  asfptype()
  astype(dtype[, casting, copy])
  conj([copy])
  conjugate([copy])
  copy()
  count_nonzero()
  diagonal([k])
  dot(other)
  getH()
  get_shape()
  getcol(j)
  getformat()
  getmaxprint()
  getnnz([axis])
  getrow(i)
  getrowview(i)
  maximum(other)
  mean([axis, dtype, out])
  minimum(other)
  multiply(other)
  nonzero()
  power(n[, dtype])
  reshape(self, shape[, order, copy])
  resize(*shape)
  set_shape(shape)
  ```

**scipy.sparse.lil_array.__len__**

lil_array.__len__()

**scipy.sparse.lil_array.__mul__**

lil_array.__mul__(*args, **kwargs)*

**scipy.sparse.lil_array.asformat**

lil_array.asformat(format, copy=False)

Return this matrix in the passed format.

*Parameters*

- **format** [{str, None}] The desired matrix format (“csr”, “csc”, “lil”, “dok”, “array”, …) or None for no conversion.
- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

*Returns*

A [This matrix in the passed format.]

**scipy.sparse.lil_array.asfptype**

lil_array.asfptype()

Upcast matrix to a floating point format (if necessary)
**scipy.sparse.lil_array.astype**

lil_array.astype(*dtype*, *casting=unsafe*, *copy=True*)

Cast the matrix elements to a specified type.

**Parameters**

- **dtype** [string or numpy dtype] Typecode or data-type to which to cast the data.
- **casting** [{‘no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’}, optional] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
- **copy** [bool, optional] If *copy* is False, the result might share some memory with this matrix. If *copy* is True, it is guaranteed that the result and this matrix do not share any memory.

**scipy.sparse.lil_array.conj**

lil_array.conj(*copy=True*)

Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

**Parameters**

- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- **A** [The element-wise complex conjugate.]

**scipy.sparse.lil_array.conjugate**

lil_array.conjugate(*copy=True*)

Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

**Parameters**

- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- **A** [The element-wise complex conjugate.]
scipy.sparse.lil_array.copy

lil_array.copy()
   Returns a copy of this matrix.
   No data/indices will be shared between the returned value and current matrix.

scipy.sparse.lil_array.count_nonzero

lil_array.count_nonzero()
   Number of non-zero entries, equivalent to
   np.count_nonzero(a.toarray())
   Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data
   attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.lil_array.diagonal

lil_array.diagonal(k=0)
   Returns the kth diagonal of the matrix.
   
   Parameters
   
   k [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0
   (the main diagonal).
   New in version 1.0.
   
   See also:

   numpy.diagonal
   Equivalent numpy function.

Examples

>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])

scipy.sparse.lil_array.dot

lil_array.dot(other)
   Ordinary dot product
Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

**scipy.sparse.lil_array.getH**

`lil_array.getH()`
Return the Hermitian transpose of this matrix.

See also:

`numpy.matrix.getH`
NumPy's implementation of `getH` for matrices

**scipy.sparse.lil_array.get_shape**

`lil_array.get_shape()`
Get shape of a matrix.

**scipy.sparse.lil_array.getcol**

`lil_array.getcol(j)`
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

**scipy.sparse.lil_array.getformat**

`lil_array.getformat()`
Format of a matrix representation as a string.

**scipy.sparse.lil_array.getmaxprint**

`lil_array.getmaxprint()`
Maximum number of elements to display when printed.
scipy.sparse.lil_array.getnnz

lil_array.getnnz(axis=None)
Number of stored values, including explicit zeros.

Parameters
axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:
count_nonzero
Number of non-zero entries

scipy.sparse.lil_array.getrow

lil_array.getrow(i)
Returns a copy of the ‘i’th row.

scipy.sparse.lil_array.getrowview

lil_array.getrowview(i)
Returns a view of the ‘i’th row (without copying).

scipy.sparse.lil_array.maximum

lil_array.maximum(other)
Element-wise maximum between this and another matrix.

scipy.sparse.lil_array.mean

lil_array.mean(axis=None, dtype=None, out=None)
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters
axis [{-2, -1, 0, 1, None} optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., axis = None).
dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype.
New in version 0.18.0.
out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns
m [np.matrix]
See also:

```
numpy.matrix.mean
```

NumPy's implementation of ‘mean’ for matrices

```
scipy.sparse.lil_array.minimum
```

```
lil_array.minimum(other)
```

Element-wise minimum between this and another matrix.

```
scipy.sparse.lil_array.multiply
```

```
lil_array.multiply(other)
```

Point-wise multiplication by another matrix

```
scipy.sparse.lil_array.nonzero
```

```
lil_array.nonzero()
```

Nonzero indices

Returns a tuple of arrays (row, col) containing the indices of the non-zero elements of the matrix.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

```
scipy.sparse.lil_array.power
```

```
lil_array.power(n, dtype=None)
```

Element-wise power.

```
scipy.sparse.lil_array.reshape
```

```
lil_array.reshape(self, shape, order='C', copy=False)
```

Gives a new shape to a sparse matrix without changing its data.

**Parameters**

- **shape**
  - [length-2 tuple of ints] The new shape should be compatible with the original shape.
- **order**
  - [‘C’, ‘F’], optional) Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

reshaped_matrix

[sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

**See also:**

`numpy.matrix.reshape`

NumPy’s implementation of ‘reshape’ for matrices

**scipy.sparse.lil_array.resize**

`lil_array.resize(*shape)`

Resizes the matrix in-place to dimensions given by shape

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

**Parameters**

- **shape** 
  
  [(int, int)] number of rows and columns in the new matrix

**Notes**

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

**scipy.sparse.lil_array.set_shape**

`lil_array.set_shape(shape)`

See `reshape`.

**scipy.sparse.lil_array.setdiag**

`lil_array.setdiag(values, k=0)`

Set diagonal or off-diagonal elements of the array.

**Parameters**

- **values** 
  
  [array_like] New values of the diagonal elements.

  Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.

  If a scalar value is given, all of the diagonal is set to it.
k [int, optional] Which off-diagonal to set, corresponding to elements $a[i,i+k]$. Default: 0 (the main diagonal).

scipy.sparse.lil_array.sum

`lil_array.sum(axis=None, dtype=None, out=None)`

Sum the matrix elements over a given axis.

**Parameters**

- **axis** [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., $axis = None$).
- **dtype** [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of $a$ is used by default unless $a$ has an integer dtype of less precision than the default platform integer. In that case, if $a$ is signed then the platform integer is used while if $a$ is unsigned then an unsigned integer of the same precision as the platform integer is used. New in version 0.18.0.
- **out** [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

**Returns**

- **sum_along_axis** [np.matrix] A matrix with the same shape as $self$, with the specified axis removed.

See also:

numpy.matrix.sum

NumPy's implementation of 'sum' for matrices

scipy.sparse.lil_array.toarray

`lil_array.toarray(order=None, out=None)`

Return a dense ndarray representation of this matrix.

**Parameters**

- **order** [‘C’, ‘F’], optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', which provides no ordering guarantees. Cannot be specified in conjunction with the `out` argument.
- **out** [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, `out` is required to be memory contiguous (either C or Fortran ordered).

**Returns**

- **arr** [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed, the same object is returned after being modified in-place to contain the appropriate values.
**scipy.sparse.lil_array.tobsr**

```python
lil_array.tobsr(blocksize=None, copy=False)
```

Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

**scipy.sparse.lil_array.tocoo**

```python
lil_array.tocoo(copy=False)
```

Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

**scipy.sparse.lil_array.tocsc**

```python
lil_array.tocsc(copy=False)
```

Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

**scipy.sparse.lil_array.tocsr**

```python
lil_array.tocsr(copy=False)
```

Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

**scipy.sparse.lil_array.todense**

```python
lil_array.todense(order=None, out=None)
```

Return a dense matrix representation of this matrix.

**Parameters**

- `order` ([`‘C’, ‘F’`], optional) Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, which provides no ordering guarantees. Cannot be specified in conjunction with the `out` argument.

- `out` ([ndarray, 2-D, optional]) If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**

- `arr` ([`numpy.matrix`, 2-D]) A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.
scipy.sparse.lil_array.todia

lil_array.todia(copy=False)
Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.lil_array.todok

lil_array.todok(copy=False)
Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.lil_array.tolil

lil_array.tolil(copy=False)
Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.lil_array.trace

lil_array.trace(offset=0)
Returns the sum along diagonals of the sparse matrix.

Parameters

offset [int, optional] Which diagonal to get, corresponding to elements a[i, i+offset]. Default: 0 (the main diagonal).

scipy.sparse.lil_array.transpose

lil_array.transpose(axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [self with the dimensions reversed.]

### scipy.sparse.bsr_matrix

**class scipy.sparse.bsr_matrix** *(arg1, shape=None, dtype=None, copy=False, blocksize=None)*  
Block Sparse Row matrix

This can be instantiated in several ways:

- `bsr_matrix(D, [blocksize=(R,C)])`  
  where D is a dense matrix or 2-D ndarray.

- `bsr_matrix(S, [blocksize=(R,C)])`  
  with another sparse matrix S (equivalent to S.tobsr())

- `bsr_matrix((M, N), [blocksize=(R,C), dtype])`  
  to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

- `bsr_matrix((data, ij), [blocksize=(R,C), shape=(M, N)])`  
  where data and ij satisfy `a[ij[0, k], ij[1, k]] = data[k]`

- `bsr_matrix((data, indices, indptr), [shape=(M, N)])`  
  is the standard BSR representation where the block column indices for row i are stored in `indices[indptr[i]:indptr[i+1]]` and their corresponding block values are stored in `data[indptr[i]: indptr[i+1]]`. If the shape parameter is not supplied, the matrix dimensions are inferred from the index arrays.

### Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

### Summary of BSR format

The Block Compressed Row (BSR) format is very similar to the Compressed Sparse Row (CSR) format. BSR is appropriate for sparse matrices with dense sub matrices like the last example below. Block matrices often arise in vector-valued finite element discretizations. In such cases, BSR is considerably more efficient than CSR and CSC for many sparse arithmetic operations.

**Blocksize**
The blocksize \((R,C)\) must evenly divide the shape of the matrix \((M,N)\). That is, \(R\) and \(C\) must satisfy the relationship \(M \% R = 0\) and \(N \% C = 0\).

If no blocksize is specified, a simple heuristic is applied to determine an appropriate blocksize.

**Examples**

```python
>>> from scipy.sparse import bsr_matrix
>>> bsr_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```python
>>> row = np.array([0, 0, 1, 2, 2])
>>> col = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> bsr_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])
```

```python
>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6]).repeat(4).reshape(6, 2)
>>> bsr_matrix((data,indices,indptr), shape=(6, 6)).toarray()
array([[1, 1, 0, 0, 2, 2],
       [1, 1, 0, 0, 2, 2],
       [0, 0, 0, 0, 3, 3],
       [0, 0, 0, 0, 3, 3],
       [4, 4, 5, 5, 6, 6],
       [4, 4, 5, 5, 6, 6]])
```

**Attributes**

- `dtype` [dtype] Data type of the matrix
- `ndim` [int] Number of dimensions (this is always 2)
- `nnz` Number of stored values, including explicit zeros.
- `data` Data array of the matrix
- `indices` BSR format index array
- `indptr` BSR format index pointer array
- `blocksize` Block size of the matrix
- `has_sorted_indices` Determine whether the matrix has sorted indices

</tbody>
</table>

```python
scipy.sparse.bsr_matrix.__len__
```

```python
bsr_matrix.__len__()
```
scipy.sparse.bsr_matrix.arcsin

bsr_matrix.arcsin()

Element-wise arcsin.

See numpy.arcsin for more information.

scipy.sparse.bsr_matrix.arcsinh

bsr_matrix.arcsinh()

Element-wise arcsinh.

See numpy.arcsinh for more information.

scipy.sparse.bsr_matrix.arctan

bsr_matrix.arctan()

Element-wise arctan.

See numpy.arctan for more information.

scipy.sparse.bsr_matrix.arctanh

bsr_matrix.arctanh()

Element-wise arctanh.

See numpy.arctanh for more information.

scipy.sparse.bsr_matrix.argmax

bsr_matrix.argmax(axis=None, out=None)

Return indices of maximum elements along an axis.

Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

Parameters

- **axis**([-2, -1, 0, 1, None], optional) Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.
- **out**([None, optional]) This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

- **ind**([numpy.matrix or int]) Indices of maximum elements. If matrix, its size along axis is 1.
scipy.sparse.bsr_matrix.argmin

bsr_matrix.argmin(axis=None, out=None)

Return indices of minimum elements along an axis.
Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

Parameters

axis [{-2, -1, 0, 1, None}, optional] Axis along which the argmin is computed. If None (default), index of the minimum element in the flattened data is returned.
out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

ind [numpy.matrix or int] Indices of minimum elements. If matrix, its size along axis is 1.

scipy.sparse.bsr_matrix.asformat

bsr_matrix.asformat(format, copy=False)

Return this matrix in the passed format.

Parameters

format [[str, None]] The desired matrix format ("csr", "csc", "lil", "dok", "array", …) or None for no conversion.
copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [This matrix in the passed format.]

scipy.sparse.bsr_matrix.asfptype

bsr_matrix.asfptype()

Upcast matrix to a floating point format (if necessary)

scipy.sparse.bsr_matrix.astype

bsr_matrix.astype(dtype, casting='unsafe', copy=True)

Cast the matrix elements to a specified type.

Parameters

dtype [string or numy dtype] Typecode or data-type to which to cast the data.
casting [{‘no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’}, optional] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
copy [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.
**scipy.sparse.bsr_matrix.ceil**

`bsr_matrix.ceil()`  
Element-wise ceiling.  
See `numpy.ceil` for more information.

**scipy.sparse.bsr_matrix.check_format**

`bsr_matrix.check_format(full_check=True)`  
Check whether the matrix format is valid.  
**Parameters:**

- `full_check`:  
  True - rigorous check, O(N) operations; default False - basic check, O(1) operations

**scipy.sparse.bsr_matrix.conj**

`bsr_matrix.conj(copy=True)`  
Element-wise complex conjugation.  
If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.  
**Parameters**

- `copy` [bool, optional] If True, the result is guaranteed to not share data with self.  

**Returns**

- `A` [The element-wise complex conjugate.]

**scipy.sparse.bsr_matrix.conjugate**

`bsr_matrix.conjugate(copy=True)`  
Element-wise complex conjugation.  
If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.  
**Parameters**

- `copy` [bool, optional] If True, the result is guaranteed to not share data with self.  

**Returns**

- `A` [The element-wise complex conjugate.]
scipy.sparse.bsr_matrix.copy

bsr_matrix.copy()
Returns a copy of this matrix.
No data/indices will be shared between the returned value and current matrix.

scipy.sparse.bsr_matrix.count_nonzero

bsr_matrix.count_nonzero()
Number of non-zero entries, equivalent to
np.count_nonzero(a.toarray())
Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.bsr_matrix.deg2rad

bsr_matrix.deg2rad()
Element-wise deg2rad.
See numpy.deg2rad for more information.

scipy.sparse.bsr_matrix.diagonal

bsr_matrix.diagonal(k=0)
Returns the kth diagonal of the matrix.

Parameters
k [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
New in version 1.0.

See also:
numpy.diagonal
Equivalent numpy function.

Examples

>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
scipy.sparse.bsr_matrix.dot

bsr_matrix.dot(other)
Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.bsr_matrix.eliminate_zeros

bsr_matrix.eliminate_zeros()
Remove zero elements in-place.

scipy.sparse.bsr_matrix.expm1

bsr_matrix.expm1()
Element-wise expm1.
See numpy.expm1 for more information.

scipy.sparse.bsr_matrix.floor

bsr_matrix.floor()
Element-wise floor.
See numpy.floor for more information.

scipy.sparse.bsr_matrix.getH

bsr_matrix.getH()
Return the Hermitian transpose of this matrix.
See also:
	numpy.matrix.getH

NumPy's implementation of getH for matrices
scipy.sparse.bsr_matrix.get_shape

bsr_matrix.get_shape()
Get shape of a matrix.

scipy.sparse.bsr_matrix.getcol

bsr_matrix.getcol(j)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.bsr_matrix.getformat

bsr_matrix.getformat()
Format of a matrix representation as a string.

scipy.sparse.bsr_matrix.getmaxprint

bsr_matrix.getmaxprint()
Maximum number of elements to display when printed.

scipy.sparse.bsr_matrix.getnnz

bsr_matrix.getnnz(axis=None)
Number of stored values, including explicit zeros.

Parameters

  axis  [None, 0, or 1] Select between the number of values across the whole matrix, in each
        column, or in each row.

See also:

count_nonzero
Number of non-zero entries

scipy.sparse.bsr_matrix.getrow

bsr_matrix.getrow(i)
Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
scipy.sparse.bsr_matrix.log1p

bsr_matrix.log1p()  
Element-wise log1p.  
See numpy.log1p for more information.

scipy.sparse.bsr_matrix.matmat

bsr_matrix.matmat(**kwds)  
matmat is deprecated! BSR matmat is deprecated in SciPy 0.19.0. Use * operator instead.  
Multiply this sparse matrix by other matrix.

scipy.sparse.bsr_matrix.matvec

bsr_matrix.matvec(**kwds)  
matvec is deprecated! BSR matvec is deprecated in SciPy 0.19.0. Use * operator instead.  
Multiply matrix by vector.

scipy.sparse.bsr_matrix.max

bsr_matrix.max(axis=None, out=None)  
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters
axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e., axis = None).
out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns
amax [coo_matrix or scalar] Maximum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

min
The minimum value of a sparse matrix along a given axis.

numpy.matrix.max
NumPy’s implementation of ‘max’ for matrices
### scipy.sparse.bsr_matrix.maximum

```python
bsr_matrix.maximum(other)
```

Element-wise maximum between this and another matrix.

### scipy.sparse.bsr_matrix.mean

```python
bsr_matrix.mean(axis=None, dtype=None, out=None)
```

Computes the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. `float64` intermediate and return values are used for integer inputs.

**Parameters**

- `axis` [-2, -1, 0, 1, None] optional
  - Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., `axis = None`).
- `dtype` [data-type, optional]
  - Type to use in computing the mean. For integer inputs, the default is `float64`; for floating point inputs, it is the same as the input dtype.
- `out` [np.matrix, optional]
  - Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns**

- `m` [np.matrix]

See also:

- **numpy.matrix.mean**
  - NumPy's implementation of ‘mean’ for matrices

### scipy.sparse.bsr_matrix.min

```python
bsr_matrix.min(axis=None, out=None)
```

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters**

- `axis` [-2, -1, 0, 1, None] optional
  - Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e., `axis = None`).
- `out` [None, optional]
  - This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- `amin` [coo_matrix or scalar]
  - Minimum of `a`. If `axis` is None, the result is a scalar value. If `axis` is given, the result is a sparse.coo_matrix of dimension `a.ndim - 1`.

See also:
max

The maximum value of a sparse matrix along a given axis.

numpy.matrix.min

NumPy's implementation of 'min' for matrices

scipy.sparse.bsr_matrix.minimum

bsr_matrix.minimum(other)
Element-wise minimum between this and another matrix.

scipy.sparse.bsr_matrix.multiply

bsr_matrix.multiply(other)
Point-wise multiplication by another matrix, vector, or scalar.

scipy.sparse.bsr_matrix.nonzero

bsr_matrix.nonzero()
nonzero indices
Returns a tuple of arrays (row, col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.bsr_matrix.power

bsr_matrix.power(n, dtype=None)
This function performs element-wise power.

Parameters

- **n**: [n is a scalar]
- **dtype**: [If dtype is not specified, the current dtype will be preserved.]
scipy.sparse.bsr_matrix.prune

bsr_matrix.prune()

Remove empty space after all non-zero elements.

scipy.sparse.bsr_matrix.rad2deg

bsr_matrix.rad2deg()

Element-wise rad2deg.

See numpy.rad2deg for more information.

scipy.sparse.bsr_matrix.reshape

bsr_matrix.reshape(self, shape, order='C', copy=False)

Gives a new shape to a sparse matrix without changing its data.

Parameters

- shape [length-2 tuple of ints] The new shape should be compatible with the original shape.
- order [{‘C’, ‘F’}, optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

- reshaped_matrix [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

numpy.matrix.reshape

NumPy’s implementation of ‘reshape’ for matrices

scipy.sparse.bsr_matrix.resize

bsr_matrix.resize(*shape)

Resize the matrix in-place to dimensions given by shape

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

- shape [(int, int)] number of rows and columns in the new matrix
Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

**scipy.sparse.bsr_matrix.rint**

```python
csr_matrix.rint()
```

Element-wise `rint`.

See `numpy.rint` for more information.

**scipy.sparse.bsr_matrix.set_shape**

```python
csr_matrix.set_shape(shape)
```

See `reshape`.

**scipy.sparse.bsr_matrix.setdiag**

```python
csr_matrix.setdiag(values, k=0)
```

Set diagonal or off-diagonal elements of the array.

**Parameters**

- `values`  
  [array_like] New values of the diagonal elements. Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored. If a scalar value is given, all of the diagonal is set to it.

- `k`  
  [int, optional] Which off-diagonal to set, corresponding to elements `a[i,i+k]`. Default: 0 (the main diagonal).

**scipy.sparse.bsr_matrix.sign**

```python
csr_matrix.sign()
```

Element-wise `sign`.

See `numpy.sign` for more information.
scipy.sparse.bsr_matrix.sin

bsr_matrix.sin()
Element-wise sin.

See numpy.sin for more information.

scipy.sparse.bsr_matrix.sinh

bsr_matrix.sinh()
Element-wise sinh.

See numpy.sinh for more information.

scipy.sparse.bsr_matrix.sort_indices

bsr_matrix.sort_indices()
Sort the indices of this matrix in place.

scipy.sparse.bsr_matrix.sorted_indices

bsr_matrix.sorted_indices()
Return a copy of this matrix with sorted indices.

scipy.sparse.bsr_matrix.sqrt

bsr_matrix.sqrt()
Element-wise sqrt.

See numpy.sqrt for more information.

scipy.sparse.bsr_matrix.sum

bsr_matrix.sum(axis=None, dtype=None, out=None)
Sum the matrix elements over a given axis.

Parameters
axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., axis = None).
dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used. New in version 0.18.0.
out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.
**Returns**

**sum_along_axis**

[np.matrix] A matrix with the same shape as `self`, with the specified axis removed.

**See also:**

- `numpy.matrix.sum`
  - NumPy’s implementation of ‘sum’ for matrices

- `scipy.sparse.bsr_matrix.sum_duplicates`
  - Eliminate duplicate matrix entries by adding them together
  - The is an *in place* operation

- `scipy.sparse.bsr_matrix.tan`
  - Element-wise tan.
  - See `numpy.tan` for more information.

- `scipy.sparse.bsr_matrix.tanh`
  - Element-wise tanh.
  - See `numpy.tanh` for more information.

- `scipy.sparse.bsr_matrix.toarray`
  - Return a dense ndarray representation of this matrix.

  **Parameters**

  - `order` [{‘C’, ‘F’}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, which provides no ordering guarantees. Cannot be specified in conjunction with the `out` argument.

  - `out` [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, `out` is required to be memory contiguous (either C or Fortran ordered).

  **Returns**

  - `arr` [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed, the same object is returned after being modified in-place to contain the appropriate values.
**scipy.sparse.bsr_matrix.tobsr**

**bsr_matrix.tobsr**(blocksize=None, copy=False)

- **Convert this matrix into Block Sparse Row Format.**
- With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.
- If blocksize=(R, C) is provided, it will be used for determining block size of the bsr_matrix.

**scipy.sparse.bsr_matrix.tocoo**

**bsr_matrix.tocoo**(copy=True)

- **Convert this matrix to COOrdinate format.**
- When copy=False the data array will be shared between this matrix and the resultant coo_matrix.

**scipy.sparse.bsr_matrix.tocsc**

**bsr_matrix.tocsc**(copy=False)

- **Convert this matrix to Compressed Sparse Column format.**
- With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

**scipy.sparse.bsr_matrix.tocsr**

**bsr_matrix.tocsr**(copy=False)

- **Convert this matrix to Compressed Sparse Row format.**
- With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

**scipy.sparse.bsr_matrix.todense**

**bsr_matrix.todense**(order=None, out=None)

- **Return a dense matrix representation of this matrix.**

**Parameters**

- **order**
  - [‘C’, ‘F’, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, which provides no ordering guarantees. Cannot be specified in conjunction with the *out* argument.

- **out**
  - [ndarray, 2-D, optional] If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**

- **arr**
  - [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.
**scipy.sparse.bsr_matrix.todia**

`bsr_matrix.todia(copy=False)`

Convert this matrix to sparse DIAGONAL format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

**scipy.sparse.bsr_matrix.todok**

`bsr_matrix.todok(copy=False)`

Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

**scipy.sparse.bsr_matrix.tolil**

`bsr_matrix.tolil(copy=False)`

Convert this matrix to List of Lists format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

**scipy.sparse.bsr_matrix.trace**

`bsr_matrix.trace(offset=0)`

Returns the sum along diagonals of the sparse matrix.

**Parameters**

- `offset` : [int, optional] Which diagonal to get, corresponding to elements `a[i, i+offset]`. Default: 0 (the main diagonal).

**scipy.sparse.bsr_matrix.transpose**

`bsr_matrix.transpose(axes=None, copy=False)`

Reverses the dimensions of the sparse matrix.

**Parameters**

- `axes` : [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
- `copy` : [bool, optional] Indicates whether or not attributes of `self` should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- `p` : [self with the dimensions reversed.]

**See also:**

- `numpy.matrix.transpose`
  NumPy's implementation of ‘transpose’ for matrices
**SciPy Reference Guide, Release 1.8.0**

### scipy.sparse.bsr_matrix.trunc

```python
bsr_matrix.trunc()
```

Element-wise trunc.

See `numpy.trunc` for more information.

### scipy.sparse.coo_matrix

```python
class scipy.sparse.coo_matrix(arg1, shape=None, dtype=None, copy=False)
```

A sparse matrix in COOrdinate format.

Also known as the ‘ijv’ or ‘triplet’ format.

*This can be instantiated in several ways:*

- `coo_matrix(D)`
  - with a dense matrix D
- `coo_matrix(S)`
  - with another sparse matrix S (equivalent to S.tocoo())
- `coo_matrix((M, N), [dtype])`
  - to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.
- `coo_matrix((data, (i, j)), [shape=(M, N)])`

  to construct from three arrays:

  1. data[:]: the entries of the matrix, in any order
  2. i[:]: the row indices of the matrix entries
  3. j[:]: the column indices of the matrix entries

Where \( A[i[k], j[k]] = data[k] \). When shape is not specified, it is inferred from the index arrays

### Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

*Advantages of the COO format*

- facilitates fast conversion among sparse formats
- permits duplicate entries (see example)
- very fast conversion to and from CSR/CSC formats

*Disadvantages of the COO format*
• does not directly support:
  – arithmetic operations
  – slicing

**Intended Usage**

• COO is a fast format for constructing sparse matrices

• Once a matrix has been constructed, convert to CSR or CSC format for fast arithmetic and matrix vector operations

• By default when converting to CSR or CSC format, duplicate (i,j) entries will be summed together. This facilitates efficient construction of finite element matrices and the like. (see example)

**Examples**

```python
>>> # Constructing an empty matrix
>>> from scipy.sparse import coo_matrix
>>> coo_matrix((3, 4), dtype=np.int8).toarray()
daarray([[0, 0, 0, 0],
          [0, 0, 0, 0],
          [0, 0, 0, 0]], dtype=int8)
```

```python
>>> # Constructing a matrix using ijv format
>>> row = np.array([0, 3, 1, 0])
>>> col = np.array([0, 3, 1, 2])
>>> data = np.array([4, 5, 7, 9])
>>> coo_matrix((data, (row, col)), shape=(4, 4)).toarray()
daarray([[4, 0, 9, 0],
          [0, 7, 0, 0],
          [0, 0, 0, 0],
          [0, 0, 0, 5]])
```

```python
>>> # Constructing a matrix with duplicate indices
>>> row = np.array([0, 0, 1, 3, 1, 0])
>>> col = np.array([0, 2, 1, 3, 1, 0])
>>> data = np.array([1, 1, 1, 1, 1, 1])
>>> coo = coo_matrix((data, (row, col)), shape=(4, 4))
>>> # Duplicate indices are maintained until implicitly or explicitly summed
>>> np.max(coo.data)
1
>>> coo.toarray()
daarray([[3, 0, 1, 0],
          [0, 2, 0, 0],
          [0, 0, 0, 0],
          [0, 0, 0, 1]])
```

**Attributes**

- `dtype` [dtype] Data type of the matrix
ndim  [int] Number of dimensions (this is always 2)
nnz  Number of stored values, including explicit zeros.
data  COO format data array of the matrix
row  COO format row index array of the matrix
col  COO format column index array of the matrix

Methods

__len__()

arcsin()  Element-wise arcsin.
arcsinh()  Element-wise arcsinh.
arctan()  Element-wise arctan.
arctanh()  Element-wise arctanh.
argmax([axis, out])  Return indices of maximum elements along an axis.
argmin([axis, out])  Return indices of minimum elements along an axis.
asformat(format[, copy])  Return this matrix in the passed format.
asfptype()  Upcast matrix to a floating point format (if necessary)
astype(dtype[, casting, copy])  Cast the matrix elements to a specified type.
ceil()  Element-wise ceil.
conj([copy])  Element-wise complex conjugation.
conjugate([copy])  Element-wise complex conjugation.
copy()  Returns a copy of this matrix.
count_nonzero()  Number of non-zero entries, equivalent to
deg2rad()  Element-wise deg2rad.
diagonal([k])  Returns the kth diagonal of the matrix.
dot(other)  Ordinary dot product
eliminate_zeros()  Remove zero entries from the matrix
expm1()  Element-wise expm1.
floor()  Element-wise floor.
getH()  Return the Hermitian transpose of this matrix.
get_shape()  Get shape of a matrix.
getcol(j)  Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
getformat()  Format of a matrix representation as a string.
getmaxprint()  Maximum number of elements to display when printed.
getnnz([axis])  Number of stored values, including explicit zeros.
getrow(i)  Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
log1p()  Element-wise log1p.
max([axis, out])  Return the maximum of the matrix or maximum along an axis.
maximum(other)  Element-wise maximum between this and another matrix.
mean([axis, dtype, out])  Compute the arithmetic mean along the specified axis.
min([axis, out])  Return the minimum of the matrix or maximum along an axis.
minimum(other)  Element-wise minimum between this and another matrix.

</table>

**scipy.sparse.coo_matrix.__len__**

`coo_matrix.__len__()`

**scipy.sparse.coo_matrix.arcsin**

`coo_matrix.arcsin()`

Element-wise arcsin.

See `numpy.arcsin` for more information.
scipy.sparse.coo_matrix.arcsinh

coo_matrix.arcsinh()
   Element-wise arcsinh.
   See numpy.arcsinh for more information.

scipy.sparse.coo_matrix.arctan

coo_matrix.arctan()
   Element-wise arctan.
   See numpy.arctan for more information.

scipy.sparse.coo_matrix.arctanh

coo_matrix.arctanh()
   Element-wise arctanh.
   See numpy.arctanh for more information.

scipy.sparse.coo_matrix.argmax

coo_matrix.argmax(axis=None, out=None)
   Return indices of maximum elements along an axis.
   Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

   Parameters
   axis  [{-2, -1, 0, 1, None}, optional] Axis along which the argmax is computed. If None (default), index of the maximum element in the flattened data is returned.
   out   [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

   Returns
   ind   [numpy.matrix or int] Indices of maximum elements. If matrix, its size along axis is 1.

scipy.sparse.coo_matrix.argmin

coo_matrix.argmin(axis=None, out=None)
   Return indices of minimum elements along an axis.
   Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

   Parameters
   axis  [{-2, -1, 0, 1, None}, optional] Axis along which the argmin is computed. If None (default), index of the minimum element in the flattened data is returned.
   out   [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.
Returns

ind [numpy.matrix or int] Indices of minimum elements. If matrix, its size along axis is 1.

scipy.sparse.coo_matrix.asformat

coo_matrix.asformat (format, copy=False)
Return this matrix in the passed format.

Parameters

format [{str, None}] The desired matrix format (“csr”, “csc”, “lil”, “dok”, “array”, …) or None for no conversion.
copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [This matrix in the passed format.]

scipy.sparse.coo_matrix.asfptype

coo_matrix.asfptype()
Upcast matrix to a floating point format (if necessary)

scipy.sparse.coo_matrix.astype

coo_matrix.astype (dtype, casting='unsafe', copy=True)
Cast the matrix elements to a specified type.

Parameters

dtype [string or numpy.dtype] Typecode or data-type to which to cast the data.
casting [{‘no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’}, optional] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
copy [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.

scipy.sparse.coo_matrix.ceil

coo_matrix.ceil()
Element-wise ceil.

See numpy.ceil for more information.
**scipy.sparse.coo_matrix.conj**

```python
coo_matrix.conj(copy=True)
```

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- `copy` [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- `A` [The element-wise complex conjugate.]

**scipy.sparse.coo_matrix.conjugate**

```python
coo_matrix.conjugate(copy=True)
```

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- `copy` [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- `A` [The element-wise complex conjugate.]

**scipy.sparse.coo_matrix.copy**

```python
coo_matrix.copy()
```

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

**scipy.sparse.coo_matrix.count_nonzero**

```python
coo_matrix.count_nonzero()
```

Number of non-zero entries, equivalent to `np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.
**scipy.sparse.coo_matrix.deg2rad**

coo_matrix.deg2rad()  
Element-wise deg2rad.  
See *numpy.deg2rad* for more information.

**scipy.sparse.coo_matrix.diagonal**

coo_matrix.diagonal(k=0)  
Returns the kth diagonal of the matrix.

**Parameters**

- **k** [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).  
  New in version 1.0.

See also:

- *numpy.diagonal*  
  Equivalent numpy function.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

**scipy.sparse.coo_matrix.dot**

coo_matrix.dot(other)  
Ordinary dot product

**Examples**

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```
**scipy.sparse.coo_matrix.eliminate_zeros**

```python
coo_matrix.eliminate_zeros()
```
Remove zero entries from the matrix
This is an in place operation

**scipy.sparse.coo_matrix.expm1**

```python
coo_matrix.expm1()
```
Element-wise expm1.
See `numpy.expm1` for more information.

**scipy.sparse.coo_matrix.floor**

```python
coo_matrix.floor()
```
Element-wise floor.
See `numpy.floor` for more information.

**scipy.sparse.coo_matrix.getH**

```python
coo_matrix.getH()
```
Return the Hermitian transpose of this matrix.
See also:

```python
numpy.matrix.getH
```
NumPy's implementation of `getH` for matrices

**scipy.sparse.coo_matrix.get_shape**

```python
coo_matrix.get_shape()
```
Get shape of a matrix.

**scipy.sparse.coo_matrix.getcol**

```python
coo_matrix.getcol(j)
```
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
scipy.sparse.coo_matrix.getformat

coo_matrix.getformat()
   Format of a matrix representation as a string.

scipy.sparse.coo_matrix.getmaxprint

coo_matrix.getmaxprint()
   Maximum number of elements to display when printed.

scipy.sparse.coo_matrix.getnnz

coo_matrix.getnnz(axis=None)
   Number of stored values, including explicit zeros.

   Parameters
   axis [None, 0, or 1] Select between the number of values across the whole matrix, in each
   column, or in each row.

   See also:
       count_nonzero
       Number of non-zero entries

scipy.sparse.coo_matrix.getrow

coo_matrix.getrow(i)
   Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

scipy.sparse.coo_matrix.log1p

coo_matrix.log1p()
   Element-wise log1p.

   See numpy.log1p for more information.

scipy.sparse.coo_matrix.max

coo_matrix.max(axis=None, out=None)
   Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just
   the non-zero ones.

   Parameters
   axis [-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e., axis = None).
   out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.
Returns

amax  [coo_matrix or scalar] Maximum of \( a \). If \( axis \) is None, the result is a scalar value. If \( axis \) is given, the result is a sparse.coo_matrix of dimension \( a.n\text{dim} - 1 \).

See also:

\textit{min}

The minimum value of a sparse matrix along a given axis.

\texttt{numpy.matrix.max}

NumPy’s implementation of ‘max’ for matrices

\texttt{scipy.sparse.coo_matrix.maximum}

\texttt{coo_matrix.maximum(other)}

Element-wise maximum between this and another matrix.

\texttt{scipy.sparse.coo_matrix.mean}

\texttt{coo_matrix.mean(axis=None, dtype=None, out=None)}

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. \texttt{float64} intermediate and return values are used for integer inputs.

Parameters

axis  \{[-2, -1, 0, 1, None] optional\} Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., \( axis = \text{None} \)).

dtype  [data-type, optional] Type to use in computing the mean. For integer inputs, the default is \texttt{float64}; for floating point inputs, it is the same as the input dtype.

New in version 0.18.0.

out  [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

New in version 0.18.0.

Returns

\( m \)  [np.matrix]

See also:

\texttt{numpy.matrix.mean}

NumPy’s implementation of ‘mean’ for matrices
**scipy.sparse.coo_matrix.min**

```python
coo_matrix.min(axis=None, out=None)
```

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters**

- `axis` [{-2, -1, 0, 1, None] optional} Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e., `axis = None`).
- `out` [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- `amin` [coo_matrix or scalar] Minimum of `a`. If `axis` is None, the result is a scalar value. If `axis` is given, the result is a sparse.coo_matrix of dimension `a.ndim - 1`.

See also:

- `max`
  The maximum value of a sparse matrix along a given axis.

- `numpy.matrix.min`
  NumPy's implementation of 'min' for matrices

**scipy.sparse.coo_matrix.minimum**

```python
coo_matrix.minimum(other)
```

Element-wise minimum between this and another matrix.

**scipy.sparse.coo_matrix.multiply**

```python
coo_matrix.multiply(other)
```

Point-wise multiplication by another matrix

**scipy.sparse.coo_matrix.nonzero**

```python
coo_matrix.nonzero()
```

nonzero indices

Returns a tuple of arrays (row, col) containing the indices of the non-zero elements of the matrix.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

**scipy.sparse.coo_matrix.power**

`coo_matrix.power(n, dtype=None)`

This function performs element-wise power.

**Parameters**

- `n` [n is a scalar]
- `dtype` [If dtype is not specified, the current dtype will be preserved.]

**scipy.sparse.coo_matrix.rad2deg**

`coo_matrix.rad2deg()`

Element-wise rad2deg.

See `numpy.rad2deg` for more information.

**scipy.sparse.coo_matrix.reshape**

`coo_matrix.reshape(self, shape, order='C', copy=False)`

Gives a new shape to a sparse matrix without changing its data.

**Parameters**

- `shape` [length-2 tuple of ints] The new shape should be compatible with the original shape.
- `order` [{'C', 'F'}, optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- `copy` [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- `reshaped_matrix` [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

- `numpy.matrix.reshape`

NumPy’s implementation of ‘reshape’ for matrices
**scipy.sparse.coo_matrix.resize**

```python
coo_matrix.resize(*shape)
```

Resize the matrix in-place to dimensions given by `shape`

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

**Parameters**

- `shape`
  - [(int, int)] number of rows and columns in the new matrix

**Notes**

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

**scipy.sparse.coo_matrix.rint**

```python
coo_matrix.rint()
```

Element-wise `rint`.

See `numpy.rint` for more information.

**scipy.sparse.coo_matrix.set_shape**

```python
coo_matrix.set_shape(shape)
```

See `reshape`.

**scipy.sparse.coo_matrix.setdiag**

```python
coo_matrix.setdiag(values, k=0)
```

Set diagonal or off-diagonal elements of the array.

**Parameters**

- `values`
  - [array_like] New values of the diagonal elements.
  - Values may have any length. If the diagonal is longer than `values`, then the remaining diagonal entries will not be set. If `values` are longer than the diagonal, then the remaining values are ignored.
  - If a scalar value is given, all of the diagonal is set to it.

- `k`
  - [int, optional] Which off-diagonal to set, corresponding to elements `a[i,i+k]`. Default: 0 (the main diagonal).
**scipy.sparse.coo_matrix.sign**

`coo_matrix.sign()`  
Element-wise sign.  
See `numpy.sign` for more information.

**scipy.sparse.coo_matrix.sin**

`coo_matrix.sin()`  
Element-wise sin.  
See `numpy.sin` for more information.

**scipy.sparse.coo_matrix.sinh**

`coo_matrix.sinh()`  
Element-wise sinh.  
See `numpy.sinh` for more information.

**scipy.sparse.coo_matrix.sqrt**

`coo_matrix.sqrt()`  
Element-wise sqrt.  
See `numpy.sqrt` for more information.

**scipy.sparse.coo_matrix.sum**

`coo_matrix.sum(axis=None, dtype=None, out=None)`  
Sum the matrix elements over a given axis.

**Parameters**

- `axis`  
  [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., `axis = None`).

- `dtype`  
  [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of `a` is used by default unless `a` has an integer dtype of less precision than the default platform integer. In that case, if `a` is signed then the platform integer is used while if `a` is unsigned then an unsigned integer of the same precision as the platform integer is used.  
  New in version 0.18.0.

- `out`  
  [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.  
  New in version 0.18.0.

**Returns**

- `sum_along_axis`  
  [np.matrix] A matrix with the same shape as `self`, with the specified axis removed.

See also:
### numpy.matrix.sum

NumPy's implementation of 'sum' for matrices

**scipy.sparse.coo_matrix.sum_duplicates**

```python
coo_matrix.sum_duplicates()
```

Eliminate duplicate matrix entries by adding them together

This is an *in place* operation

**scipy.sparse.coo_matrix.tan**

```python
coo_matrix.tan()
```

Element-wise tan.

See `numpy.tan` for more information.

**scipy.sparse.coo_matrix.tanh**

```python
coo_matrix.tanh()
```

Element-wise tanh.

See `numpy.tanh` for more information.

**scipy.sparse.coo_matrix.toarray**

```python
coo_matrix.toarray(order=None, out=None)
```

See the docstring for `spmatrix.toarray`.

**scipy.sparse.coo_matrix.tobsr**

```python
coo_matrix.tobsr(blocksize=None, copy=False)
```

Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

**scipy.sparse.coo_matrix.tocoo**

```python
coo_matrix.tocoo(copy=False)
```

Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.
**scipy.sparse.coo_matrix.tocsc**

`coo_matrix.tocsc(copy=False)`

Convert this matrix to Compressed Sparse Column format

Duplicate entries will be summed together.

**Examples**

```python
>>> from numpy import array
>>> from scipy.sparse import coo_matrix
>>> row = array([0, 0, 1, 3, 1, 0, 0])
>>> col = array([0, 2, 1, 3, 1, 0, 0])
>>> data = array([1, 1, 1, 1, 1, 1, 1])
>>> A = coo_matrix((data, (row, col)), shape=(4, 4)).tocsc()
>>> A.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

**scipy.sparse.coo_matrix.tocsr**

`coo_matrix.tocsr(copy=False)`

Convert this matrix to Compressed Sparse Row format

Duplicate entries will be summed together.

**Examples**

```python
>>> from numpy import array
>>> from scipy.sparse import coo_matrix
>>> row = array([0, 0, 1, 3, 1, 0, 0])
>>> col = array([0, 2, 1, 3, 1, 0, 0])
>>> data = array([1, 1, 1, 1, 1, 1, 1])
>>> A = coo_matrix((data, (row, col)), shape=(4, 4)).tocsr()
>>> A.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```
scipy.sparse.coo_matrix.todense

```
coo_matrix.todense(order=None, out=None)
```

Return a dense matrix representation of this matrix.

**Parameters**

- `order` [{‘C’, ‘F’}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, which provides no ordering guarantees. Cannot be specified in conjunction with the `out` argument.

- `out` [ndarray, 2-D, optional] If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**

- `arr` [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

scipy.sparse.coo_matrix.todia

```
coo_matrix.todia(copy=False)
```

Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.coo_matrix.todok

```
coo_matrix.todok(copy=False)
```

Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.coo_matrix.tolil

```
coo_matrix.tolil(copy=False)
```

Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.coo_matrix.trace

```
coo_matrix.trace(offset=0)
```

Returns the sum along diagonals of the sparse matrix.

**Parameters**

- `offset` [int, optional] Which diagonal to get, corresponding to elements a[i, i+offset]. Default: 0 (the main diagonal).
scipy.sparse.coo_matrix.transpose

```python
coo_matrix.transpose(axes=None, copy=False)
```

Reverses the dimensions of the sparse matrix.

**Parameters**

- **axes**
  
  [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.

- **copy**
  
  [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- **p**
  
  [self with the dimensions reversed.]

See also:

- **numpy.matrix.transpose**
  
  NumPy's implementation of 'transpose' for matrices

scipy.sparse.coo_matrix.trunc

```python
coo_matrix.trunc()
```

Element-wise trunc.

See `numpy.trunc` for more information.

__mul__

scipy.sparse.csc_matrix

```python
class scipy.sparse.csc_matrix(arg1, shape=None, dtype=None, copy=False)
```

Compressed Sparse Column matrix

This can be instantiated in several ways:

- **csc_matrix(D)**
  
  with a dense matrix or rank-2 ndarray D

- **csc_matrix(S)**
  
  with another sparse matrix S (equivalent to S.tocsc())

- **csc_matrix((M, N), [dtype])**
  
  to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

- **csc_matrix((data, (row_ind, col_ind)), [shape=(M, N)])**
  
  where data, row_ind and col_ind satisfy the relationship a[row_ind[k], col_ind[k]] = data[k].

- **csc_matrix((data, indices, indptr), [shape=(M, N)])**
  
  is the standard CSC representation where the row indices for column i are stored in indices[indptr[i]:indptr[i+1]] and their corresponding values are stored in data[indptr[i]:indptr[i+1]]. If the shape parameter is not supplied, the matrix dimensions are inferred from the index arrays.
Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Advantages of the CSC format

- efficient arithmetic operations CSC + CSC, CSC * CSC, etc.
- efficient column slicing
- fast matrix vector products (CSR, BSR may be faster)

Disadvantages of the CSC format

- slow row slicing operations (consider CSR)
- changes to the sparsity structure are expensive (consider LIL or DOK)

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csc_matrix
>>> csc_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)

>>> row = np.array([0, 2, 2, 0, 1, 2])
>>> col = np.array([0, 0, 1, 2, 2, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csc_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 4],
       [0, 0, 5],
       [2, 3, 6]])

>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csc_matrix((data, indices, indptr), shape=(3, 3)).toarray()
array([[1, 0, 4],
       [0, 0, 5],
       [2, 3, 6]])
```

Attributes

dtype    [dtype] Data type of the matrix
nndim    [int] Number of dimensions (this is always 2)
nnz      Number of stored values, including explicit zeros.
data     Data array of the matrix
indices  CSC format index array
indptr   CSC format index pointer array
### has_sorted_indices
Determine whether the matrix has sorted indices

```
scipy.sparse.csc_matrix.__len__
```

csc_matrix.__len__()
scipy.sparse.csc_matrix.arcsin

csc_matrix.arcsin()
Element-wise arcsin.
See numpy.arcsin for more information.

scipy.sparse.csc_matrix.arcsinh

csc_matrix.arcsinh()
Element-wise arcsinh.
See numpy.arcsinh for more information.

scipy.sparse.csc_matrix.arctan

csc_matrix.arctan()
Element-wise arctan.
See numpy.arctan for more information.

scipy.sparse.csc_matrix.arctanh

csc_matrix.arctanh()
Element-wise arctanh.
See numpy.arctanh for more information.

scipy.sparse.csc_matrix.argmax

csc_matrix.argmax(axis=None, out=None)
Return indices of maximum elements along an axis.
Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

Parameters
axis [[-2, -1, 0, 1, None], optional] Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.
out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns
ind [numpy.matrix or int] Indices of maximum elements. If matrix, its size along axis is 1.
**scipy.sparse.csc_matrix.argmin**

```python
csc_matrix.argmin(axis=None, out=None)
```

Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters**

- **axis** ([{-2, -1, 0, 1, None}, optional]) Axis along which the argmin is computed. If None (default), index of the minimum element in the flattened data is returned.
- **out** [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- **ind** [numpy.matrix or int] Indices of minimum elements. If matrix, its size along axis is 1.

**scipy.sparse.csc_matrix.asformat**

```python
csc_matrix.asformat(format, copy=False)
```

Return this matrix in the passed format.

**Parameters**

- **format** [{str, None}] The desired matrix format ("csr", "csc", "lil", "dok", "array", ...) or None for no conversion.
- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- **A** [This matrix in the passed format.]

**scipy.sparse.csc_matrix.asfptype**

```python
csc_matrix.asfptype()
```

Upcast matrix to a floating point format (if necessary)

**scipy.sparse.csc_matrix.astype**

```python
csc_matrix.astype(dtype, casting='unsafe', copy=True)
```

Cast the matrix elements to a specified type.

**Parameters**

- **dtype** [string or numpy dtype] Typecode or data-type to which to cast the data.
- **casting** [{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all, 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.
- **copy** [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.
scipy.sparse.csc_matrix.ceil

csc_matrix.ceil()
   Element-wise ceil.

   See numpy.ceil for more information.

scipy.sparse.csc_matrix.check_format

csc_matrix.check_format (full_check=True)
   check whether the matrix format is valid

   Parameters
   full_check  [bool, optional] If True, rigorous check, O(N) operations. Otherwise basic check, O(1) operations (default True).

scipy.sparse.csc_matrix.conj

csc_matrix.conj (copy=True)
   Element-wise complex conjugation.

   If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

   Parameters
   copy  [bool, optional] If True, the result is guaranteed to not share data with self.

   Returns
   A  [The element-wise complex conjugate.]

scipy.sparse.csc_matrix.conjugate

csc_matrix.conjugate (copy=True)
   Element-wise complex conjugation.

   If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

   Parameters
   copy  [bool, optional] If True, the result is guaranteed to not share data with self.

   Returns
   A  [The element-wise complex conjugate.]
**scipy.sparse.csc_matrix.copy**

`csc_matrix.copy()`

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

**scipy.sparse.csc_matrix.count_nonzero**

`csc_matrix.count_nonzero()`

Number of non-zero entries, equivalent to

```python
np.count_nonzero(a.toarray())
```

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

**scipy.sparse.csc_matrix.deg2rad**

`csc_matrix.deg2rad()`

Element-wise deg2rad.

See `numpy.deg2rad` for more information.

**scipy.sparse.csc_matrix.diagonal**

`csc_matrix.diagonal(k=0)`

Returns the kth diagonal of the matrix.

**Parameters**

- `k` [int, optional] Which diagonal to get, corresponding to elements `a[i, i+k]`. Default: 0 (the main diagonal).

New in version 1.0.

See also:

- `numpy.diagonal`

Equivalent numpy function.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```
scipy.sparse.csc_matrix.dot

csc_matrix.dot(other)
Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.csc_matrix.eliminate_zeros

csc_matrix.eliminate_zeros()
Remove zero entries from the matrix
This is an in place operation.

scipy.sparse.csc_matrix.expm1

csc_matrix.expm1()
Element-wise expm1.
See numpy.expm1 for more information.

scipy.sparse.csc_matrix.floor

csc_matrix.floor()
Element-wise floor.
See numpy.floor for more information.

scipy.sparse.csc_matrix.getH

csc_matrix.getH()
Return the Hermitian transpose of this matrix.
See also:

```
numpy.matrix.getH
```
NumPy's implementation of getH for matrices
**scipy.sparse.csc_matrix.get_shape**

csc_matrix.get_shape()

Get shape of a matrix.

**scipy.sparse.csc_matrix.getcol**

csc_matrix.getcol(i)

Returns a copy of column i of the matrix, as a (m x 1) CSC matrix (column vector).

**scipy.sparse.csc_matrix.getformat**

csc_matrix.getformat()

Format of a matrix representation as a string.

**scipy.sparse.csc_matrix.getmaxprint**

csc_matrix.getmaxprint()

Maximum number of elements to display when printed.

**scipy.sparse.csc_matrix.getnnz**

csc_matrix.getnnz(axis=None)

Number of stored values, including explicit zeros.

*Parameters*

axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

*See also:*

count_nonzero

Number of non-zero entries

**scipy.sparse.csc_matrix.getrow**

csc_matrix.getrow(i)

Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).
scipy.sparse.csc_matrix.log1p

csc_matrix.log1p()
Element-wise log1p.

See numpy.log1p for more information.

scipy.sparse.csc_matrix.max

csc_matrix.max(axis=None, out=None)
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters
axis [[-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e., axis = None).
out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns
amax [coo_matrix or scalar] Maximum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:
min

The minimum value of a sparse matrix along a given axis.

numpy.matrix.max
NumPy's implementation of 'max' for matrices

scipy.sparse.csc_matrix.maximum

csc_matrix.maximum(other)
Element-wise maximum between this and another matrix.

scipy.sparse.csc_matrix.mean

csc_matrix.mean(axis=None, dtype=None, out=None)
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters
axis [[-2, -1, 0, 1, None] optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., axis = None).
dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype. New in version 0.18.0.
### scipy.sparse.csc_matrix.min

**scipy.sparse.csc_matrix.min** *(axis=None, out=None)*

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters**

- **axis** *(optional)*
  - [-2, -1, 0, 1, None] Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e., axis = None).

- **out** *(optional)*
  - [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- **amin** *(coo_matrix or scalar)* Minimum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

**See also:**

- **max**
  - The maximum value of a sparse matrix along a given axis.

- **numpy.matrix.min**
  - NumPy's implementation of `min` for matrices

**scipy.sparse.csc_matrix.minimum**

**csc_matrix.minimum** *(other)*

Element-wise minimum between this and another matrix.
scipy.sparse.csc_matrix.multiply

csc_matrix.multiply(other)
    Point-wise multiplication by another matrix, vector, or scalar.

scipy.sparse.csc_matrix.nonzero

csc_matrix.nonzero()
    nonzero indices
    Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.csc_matrix.power

csc_matrix.power(n, dtype=None)
    This function performs element-wise power.

    Parameters
    ----------
    n : [n is a scalar]
    dtype : [If dtype is not specified, the current dtype will be preserved.]

scipy.sparse.csc_matrix.prune

csc_matrix.prune()
    Remove empty space after all non-zero elements.

scipy.sparse.csc_matrix.rad2deg

csc_matrix.rad2deg()
    Element-wise rad2deg.

    See numpy.rad2deg for more information.
scipy.sparse.csc_matrix.reshape

csc_matrix . reshape ( self, shape, order='C', copy=False )
    Gives a new shape to a sparse matrix without changing its data.

    Parameters
        shape [length-2 tuple of ints] The new shape should be compatible with the original shape.
        order [{’C’, ’F’}, optional] Read the elements using this index order. ’C’ means to read and
          write the elements using C-like index order; e.g., read entire first row, then second row,
          etc. ’F’ means to read and write the elements using Fortran-like index order; e.g., read
          entire first column, then second column, etc.
        copy [bool, optional] Indicates whether or not attributes of self should be copied whenever
          possible. The degree to which attributes are copied varies depending on the type of
          sparse matrix being used.

    Returns
        reshaped_matrix [sparse matrix] A sparse matrix with the given shape, not necessarily of the same
          format as the current object.

    See also:
      numpy.matrix.reshape
        NumPy’s implementation of ‘reshape’ for matrices

scipy.sparse.csc_matrix.resize

csc_matrix . resize ( *shape )
    Resize the matrix in-place to dimensions given by shape

    Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying
    outside the new shape are removed.

    Parameters
        shape [(int, int)] number of rows and columns in the new matrix

    Notes
    The semantics are not identical to numpy.ndarray.resize or numpy.resize. Here, the same data
    will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy,
    resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a
    flattened representation.

    We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or
    replaced with new objects.

3.3.  API definition  1871
scipy.sparse.csc_matrix.rint

csc_matrix.rint()
Element-wise rint.

See numpy.rint for more information.

scipy.sparse.csc_matrix.set_shape

csc_matrix.set_shape(shape)
See reshape.

scipy.sparse.csc_matrix.setdiag

csc_matrix.setdiag(values, k=0)
Set diagonal or off-diagonal elements of the array.

Parameters
values [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.
If a scalar value is given, all of the diagonal is set to it.
k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

scipy.sparse.csc_matrix.sign

csc_matrix.sign()
Element-wise sign.

See numpy.sign for more information.

scipy.sparse.csc_matrix.sin

csc_matrix.sin()
Element-wise sin.

See numpy.sin for more information.

scipy.sparse.csc_matrix.sinh

csc_matrix.sinh()
Element-wise sinh.

See numpy.sinh for more information.
**scipy.sparse.csc_matrix.sort_indices**

```python
csc_matrix.sort_indices()
```

Sort the indices of this matrix \textit{in place}.

**scipy.sparse.csc_matrix.sorted_indices**

```python
csc_matrix.sorted_indices()
```

Return a copy of this matrix with sorted indices.

**scipy.sparse.csc_matrix.sqrt**

```python
csc_matrix.sqrt()
```

Element-wise sqrt.

See \texttt{numpy.sqrt} for more information.

**scipy.sparse.csc_matrix.sum**

```python
csc_matrix.sum(axis=None, dtype=None, out=None)
```

Sum the matrix elements over a given axis.

**Parameters**

- **axis**  
  [-2, -1, 0, 1, None] optional. Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., \textit{axis = None}).

- **dtype**  
  [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dttype of \texttt{a} is used by default unless \texttt{a} has an integer dttype of less precision than the default platform integer. In that case, if \texttt{a} is signed then the platform integer is used while if \texttt{a} is unsigned then an unsigned integer of the same precision as the platform integer is used. New in version 0.18.0.

- **out**  
  [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

**Returns**

- **sum_along_axis**  
  [np.matrix] A matrix with the same shape as \texttt{self}, with the specified axis removed.

**See also:**

- \texttt{numpy.matrix.sum}
  
  NumPy's implementation of 'sum' for matrices
scipy.sparse.csc_matrix.sum_duplicates

csc_matrix.sum_duplicates()
   Eliminate duplicate matrix entries by adding them together
   This is an in place operation.

scipy.sparse.csc_matrix.tan

csc_matrix.tan()
   Element-wise tan.
   See numpy.tan for more information.

scipy.sparse.csc_matrix.tanh

csc_matrix.tanh()
   Element-wise tanh.
   See numpy.tanh for more information.

scipy.sparse.csc_matrix.toarray

csc_matrix.toarray(order=None, out=None)
   Return a dense ndarray representation of this matrix.

   **Parameters**

   - **order** [{‘C’, ‘F’}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, which provides no ordering guarantees. Cannot be specified in conjunction with the `out` argument.

   - **out** [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, `out` is required to be memory contiguous (either C or Fortran ordered).

   **Returns**

   - **arr** [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed, the same object is returned after being modified in-place to contain the appropriate values.

scipy.sparse.csc_matrix.tobsr

csc_matrix.tobsr(blocksize=None, copy=False)
   Convert this matrix to Block Sparse Row format.

   With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

   When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.
scipy.sparse.csc_matrix.tocoo

csc_matrix.tocoo(copy=True)
   Convert this matrix to COOrdinate format.
   With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

scipy.sparse.csc_matrix.tocsc

csc_matrix.tocsc(copy=False)
   Convert this matrix to Compressed Sparse Column format.
   With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.csc_matrix.tocsr

csc_matrix.tocsr(copy=False)
   Convert this matrix to Compressed Sparse Row format.
   With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.csc_matrix.todense

csc_matrix.todense(order=None, out=None)
   Return a dense matrix representation of this matrix.

   Parameters
   order [{'C', 'F'}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', which provides no ordering guarantees. Cannot be specified in conjunction with the out argument.
   out [ndarray, 2-D, optional] If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

   Returns
   arr [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

scipy.sparse.csc_matrix.todia

csc_matrix.todia(copy=False)
   Convert this matrix to sparse DIAgonal format.
   With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.
scipy.sparse.csc_matrix.todok

csc_matrix.todok(copy=False)
Convert this matrix to Dictionary Of Keys format.
With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.csc_matrix.tolil

csc_matrix.tolil(copy=False)
Convert this matrix to List of Lists format.
With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.csc_matrix.trace

csc_matrix.trace(offset=0)
Returns the sum along diagonals of the sparse matrix.

Parameters
offset [int, optional] Which diagonal to get, corresponding to elements a[i, i+offset]. Default: 0 (the main diagonal).

scipy.sparse.csc_matrix.transpose

csc_matrix.transpose(axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters
axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns
p [self with the dimensions reversed.]

See also:
numpy.matrix.transpose
NumPy’s implementation of ‘transpose’ for matrices
scipy.sparse.csc_matrix.trunc

```
csc_matrix.trunc()

Element-wise trunc.

See numpy.trunc for more information.
```

scipy.sparse.csr_matrix

```
class scipy.sparse.csr_matrix(arg1, shape=None, dtype=None, copy=False)

Compressed Sparse Row matrix

This can be instantiated in several ways:

- csr_matrix(D)
  with a dense matrix or rank-2 ndarray D

- csr_matrix(S)
  with another sparse matrix S (equivalent to S.tocsr())

- csr_matrix((M, N), [dtype])
  to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

- csr_matrix((data, (row_ind, col_ind)), [shape=(M, N)])
  where data, row_ind and col_ind satisfy the relationship a[row_ind[k], col_ind[k]] = data[k].

- csr_matrix((data, indices, indptr), [shape=(M, N)])
  is the standard CSR representation where the column indices for row i are stored in indices[indptr[i]:indptr[i+1]] and their corresponding values are stored in data[indptr[i]:indptr[i+1]]. If the shape parameter is not supplied, the matrix dimensions are inferred from the index arrays.

Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Advantages of the CSR format

- efficient arithmetic operations CSR + CSR, CSR * CSR, etc.
- efficient row slicing
- fast matrix vector products

Disadvantages of the CSR format

- slow column slicing operations (consider CSC)
- changes to the sparsity structure are expensive (consider LIL or DOK)
Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> csr_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)

>>> row = np.array([0, 0, 0, 0, 0, 0])
>>> col = np.array([0, 0, 0, 0, 0, 0])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csr_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])

>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csr_matrix((data, indices, indptr), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])

Duplicate entries are summed together:

```python
>>> row = np.array([0, 1, 2, 0])
>>> col = np.array([0, 1, 0, 0])
>>> data = np.array([1, 2, 4, 8])
>>> csr_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 0],
       [0, 1, 1],
       [0, 4, 0]])
```

As an example of how to construct a CSR matrix incrementally, the following snippet builds a term-document matrix from texts:

```python
>>> docs = [["hello", "world", "hello"], ["goodbye", "cruel", "world"]]
>>> indptr = [0]
>>> indices = []
>>> data = []
>>> vocabulary = {}
>>> for d in docs:
...     for term in d:
...         index = vocabulary.setdefault(term, len(vocabulary))
...         indices.append(index)
...         data.append(1)
...     indptr.append(len(indices))

>>> csr_matrix((data, indices, indptr), dtype=int).toarray()
array([[2, 1, 0, 0],
       [0, 1, 1, 1]])
```
Attributes

dtype [dtype] Data type of the matrix
ndim [int] Number of dimensions (this is always 2)
nnz Number of stored values, including explicit zeros.
data CSR format data array of the matrix
indices CSR format index array of the matrix
indptr CSR format index pointer array of the matrix
has_sorted_indices
  Determine whether the matrix has sorted indices

Methods

__len__() Element-wise arcsin.

arcsinh() Element-wise arcsinh.

arctan() Element-wise arctan.

arctanh() Element-wise arctanh.

argmax(axis, out) Return indices of maximum elements along an axis.

argmin(axis, out) Return indices of minimum elements along an axis.

asformat(format[, copy]) Return this matrix in the passed format.

asfptype() Upcast matrix to a floating point format (if necessary)

astype(dtype[, casting, copy]) Cast the matrix elements to a specified type.

call() Element-wise ceil.

call_check_format([full_check]) check whether the matrix format is valid

conj([copy]) Element-wise complex conjugation.

conjugate([copy]) Element-wise complex conjugation.

copy() Returns a copy of this matrix.

count_nonzero() Number of non-zero entries, equivalent to
deg2rad() Element-wise deg2rad.

diagonal([k]) Returns the kth diagonal of the matrix.

dot(other) Ordinary dot product

elementwise_zeros() Remove zero entries from the matrix

elemwise_exp() Element-wise exp.

floor() Element-wise floor.

getH() Return the Hermitian transpose of this matrix.

get_shape() Get shape of a matrix.

col(i) Returns a copy of column i of the matrix, as a (m x 1) CSR matrix (column vector).

getformat() Format of a matrix representation as a string.

get_shape() Maximum number of elements to display when printed.

getnnz([axis]) Number of stored values, including explicit zeros.

getrow(i) Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).

log1p() Element-wise log1p.

max(axis, out) Return the maximum of the matrix or maximum along an axis.

scipy.sparse.csr_matrix.__len__

csr_matrix.__len__()

scipy.sparse.csr_matrix.arcsin

csr_matrix.arcsin()
   Element-wise arcsin.
   See numpy.arcsin for more information.

scipy.sparse.csr_matrix.arcsinh

csr_matrix.arcsinh()
   Element-wise arcsinh.
   See numpy.arcsinh for more information.

scipy.sparse.csr_matrix.arctan

csr_matrix.arctan()
   Element-wise arctan.
   See numpy.arctan for more information.

scipy.sparse.csr_matrix.arctanh

csr_matrix.arctanh()
   Element-wise arctanh.
   See numpy.arctanh for more information.

scipy.sparse.csr_matrix.argmax

csr_matrix.argmax(axis=None, out=None)
   Return indices of maximum elements along an axis.
   Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

   Parameters
   axis  [[-2, -1, 0, 1, None], optional] Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.
   out   [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

   Returns
   ind   [numpy.matrix or int] Indices of maximum elements. If matrix, its size along axis is 1.
**scipy.sparse.csr_matrix.argmin**

csr_matrix.argmin(axis=None, out=None)

Return indices of minimum elements along an axis.
Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters**

axis [{-2, -1, 0, 1, None}, optional] Axis along which the argmin is computed. If None (default), index of the minimum element in the flattened data is returned.

out [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

ind [numpy.matrix or int] Indices of minimum elements. If matrix, its size along axis is 1.

**scipy.sparse.csr_matrix.asformat**

csr_matrix.asformat(format, copy=False)

Return this matrix in the passed format.

**Parameters**

format [{str, None}] The desired matrix format ("csr", "csc", "lil", "dok", "array", ...) or None for no conversion.

copy [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

A [This matrix in the passed format.]

**scipy.sparse.csr_matrix.asfptype**

csr_matrix.asfptype()

Upcast matrix to a floating point format (if necessary)

**scipy.sparse.csr_matrix.astype**

csr_matrix.astype(dtype, casting='unsafe', copy=True)

Cast the matrix elements to a specified type.

**Parameters**

dtype [string or numpy dtype] Typecode or data-type to which to cast the data.

casting [{‘no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’}, optional] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.

copy [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.
```python
scipy.sparse.csr_matrix.ceil

csr_matrix.ceil()

Element-wise ceil.

See numpy.ceil for more information.

scipy.sparse.csr_matrix.check_format

csr_matrix.check_format(full_check=True)

check whether the matrix format is valid

Parameters

full_check [bool, optional] If True, rigorous check, O(N) operations. Otherwise basic check, O(1) operations (default True).

scipy.sparse.csr_matrix.conj

csr_matrix.conj(copy=True)

Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.csr_matrix.conjugate

csr_matrix.conjugate(copy=True)

Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]
```
**scipy.sparse.csr_matrix.copy**

csr_matrix.copy()

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

**scipy.sparse.csr_matrix.count_nonzero**

csr_matrix.count_nonzero()

Number of non-zero entries, equivalent to

np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

**scipy.sparse.csr_matrix.deg2rad**

csr_matrix.deg2rad()

Element-wise deg2rad.

See :func:`numpy.deg2rad` for more information.

**scipy.sparse.csr_matrix.diagonal**

csr_matrix.diagonal(k=0)

Returns the kth diagonal of the matrix.

**Parameters**

k : int, optional
    Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).

New in version 1.0.

**See also:**

:func:`numpy.diagonal`

Equivalent numpy function.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```
scipy.sparse.csr_matrix.dot

csr_matrix.dot(other)
   Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.csr_matrix.eliminate_zeros

csr_matrix.eliminate_zeros()
   Remove zero entries from the matrix
   This is an in place operation.

scipy.sparse.csr_matrix.expm1

csr_matrix.expm1()
   Element-wise expm1.
   See numpy.expm1 for more information.

scipy.sparse.csr_matrix.floor

csr_matrix.floor()
   Element-wise floor.
   See numpy.floor for more information.

scipy.sparse.csr_matrix.getH

csr_matrix.getH()
   Return the Hermitian transpose of this matrix.
   See also:

   numpy.matrix.getH
      NumPy’s implementation of getH for matrices
scipy.sparse.csr_matrix.get_shape

csr_matrix.get_shape()
Get shape of a matrix.

scipy.sparse.csr_matrix.getcol

csr_matrix.getcol(i)
Returns a copy of column i of the matrix, as a (m x 1) CSR matrix (column vector).

scipy.sparse.csr_matrix.getformat

csr_matrix.getformat()
Format of a matrix representation as a string.

scipy.sparse.csr_matrix.getmaxprint

csr_matrix.getmaxprint()
Maximum number of elements to display when printed.

scipy.sparse.csr_matrix.getnnz

csr_matrix.getnnz(axis=None)
Number of stored values, including explicit zeros.

Parameters

axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:

count_nonzero
Number of non-zero entries

scipy.sparse.csr_matrix.getrow

csr_matrix.getrow(i)
Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).
**scipy.sparse.csr_matrix.log1p**

csr_matrix.log1p()

Element-wise log1p.

See `numpy.log1p` for more information.

**scipy.sparse.csr_matrix.max**

csr_matrix.max(axis=None, out=None)

Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just
the non-zero ones.

**Parameters**

axis

[-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is
to compute the maximum over all the matrix elements, returning a scalar (i.e., axis =
None).

out

[None, optional] This argument is in the signature solely for NumPy compatibility rea-
sons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

amax

[coo_matrix or scalar] Maximum of a. If axis is None, the result is a scalar value. If
axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

min

The minimum value of a sparse matrix along a given axis.

**scipy.sparse.csr_matrix.maximum**

csr_matrix.maximum(other)

Element-wise maximum between this and another matrix.

**scipy.sparse.csr_matrix.mean**

csr_matrix.mean(axis=None, dtype=None, out=None)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default,
otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

**Parameters**

axis

[-2, -1, 0, 1, None] optional] Axis along which the mean is computed. The default is
to compute the mean of all elements in the matrix (i.e., axis = None).

dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is
float64; for floating point inputs, it is the same as the input dtype.

New in version 0.18.0.
**out**  [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

New in version 0.18.0.

**Returns**

- **m**  [np.matrix]

**See also:**

- `numpy.matrix.mean`
  - NumPy’s implementation of ‘mean’ for matrices

### scipy.sparse.csr_matrix.min

**csr_matrix.min**(axis=None, out=None)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters**

- **axis**  [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e., axis = None).
- **out**  [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- **amin**  [coo_matrix or scalar] Minimum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

**See also:**

- `max`
  - The maximum value of a sparse matrix along a given axis.

- `numpy.matrix.min`
  - NumPy’s implementation of ‘min’ for matrices

### scipy.sparse.csr_matrix.minimum

**csr_matrix.minimum**(other)

Element-wise minimum between this and another matrix.
scipy.sparse.csr_matrix.multiply

csr_matrix.multiply(other)
Point-wise multiplication by another matrix, vector, or scalar.

scipy.sparse.csr_matrix.nonzero

csr_matrix.nonzero()
nonzero indices
Returns a tuple of arrays (row, col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.csr_matrix.power

csr_matrix.power(n, dtype=None)
This function performs element-wise power.

Parameters

- n [n is a scalar]
- dtype [If dtype is not specified, the current dtype will be preserved.]

scipy.sparse.csr_matrix.prune

csr_matrix.prune()
Remove empty space after all non-zero elements.

scipy.sparse.csr_matrix.rad2deg

csr_matrix.rad2deg()
Element-wise rad2deg.
See numpy.rad2deg for more information.
**scipy.sparse.csr_matrix.reshape**

**csr_matrix.reshape** *(self, shape, order='C', copy=False)*

Gives a new shape to a sparse matrix without changing its data.

**Parameters**

- **shape** *(length-2 tuple of ints)* The new shape should be compatible with the original shape.
- **order** *['C', 'F'], optional* Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- **copy** *[bool, optional]* Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- **reshaped_matrix** *[sparse matrix]* A sparse matrix with the given shape, not necessarily of the same format as the current object.

**See also:**

- **numpy.matrix.reshape**
  
  NumPy's implementation of 'reshape' for matrices

**scipy.sparse.csr_matrix.resize**

**csr_matrix.resize** *(shape)*

Resize the matrix in-place to dimensions given by shape.

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

**Parameters**

- **shape** *[(int, int)]* number of rows and columns in the new matrix

**Notes**

The semantics are not identical to **numpy.ndarray.resize** or **numpy.resize**. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.
**scipy.sparse.csr_matrix.rint**

```python
csr_matrix.rint()
```
Element-wise rint.

See `numpy.rint` for more information.

**scipy.sparse.csr_matrix.set_shape**

```python
csr_matrix.set_shape(shape)
```

See `reshape`.

**scipy.sparse.csr_matrix.setdiag**

```python
csr_matrix.setdiag(values, k=0)
```
Set diagonal or off-diagonal elements of the array.

**Parameters**

- `values` ([array_like]) New values of the diagonal elements.
  Values may have any length. If the diagonal is longer than values, then the remaining
diagonal entries will not be set. If values are longer than the diagonal, then the remaining
values are ignored.
  If a scalar value is given, all of the diagonal is set to it.
- `k` ([int, optional]) Which off-diagonal to set, corresponding to elements `a[i,i+k]`. Default: 0
  (the main diagonal).

**scipy.sparse.csr_matrix.sign**

```python
csr_matrix.sign()
```
Element-wise sign.

See `numpy.sign` for more information.

**scipy.sparse.csr_matrix.sin**

```python
csr_matrix.sin()
```
Element-wise sin.

See `numpy.sin` for more information.

**scipy.sparse.csr_matrix.sinh**

```python
csr_matrix.sinh()
```
Element-wise sinh.

See `numpy.sinh` for more information.
scipy.sparse.csr_matrix.sort_indices

csr_matrix.sort_indices()
Sort the indices of this matrix in place

scipy.sparse.csr_matrix.sorted_indices

csr_matrix.sorted_indices()
Return a copy of this matrix with sorted indices

scipy.sparse.csr_matrix.sqrt

csr_matrix.sqrt()
Element-wise sqrt.
See numpy.sqrt for more information.

scipy.sparse.csr_matrix.sum

csr_matrix.sum(axis=None, dtype=None, out=None)
Sum the matrix elements over a given axis.

Parameters
axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., axis = None).
dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used.
New in version 0.18.0.
out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns
sum_along_axis [np.matrix] A matrix with the same shape as self, with the specified axis removed.

See also:
numpy.matrix.sum
NumPy's implementation of 'sum' for matrices
scipy.sparse.csr_matrix.sum_duplicates

csr_matrix.sum_duplicates()
   Eliminate duplicate matrix entries by adding them together
   This is an in place operation.

scipy.sparse.csr_matrix.tan

csr_matrix.tan()
   Element-wise tan.
   See numpy.tan for more information.

scipy.sparse.csr_matrix.tanh

csr_matrix.tanh()
   Element-wise tanh.
   See numpy.tanh for more information.

scipy.sparse.csr_matrix.toarray

csr_matrix.toarray(order=None, out=None)
   Return a dense ndarray representation of this matrix.

   Parameters
   order [{‘C’, ‘F’}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, which provides no ordering guarantees. Cannot be specified in conjunction with the out argument.
   out [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, out is required to be memory contiguous (either C or Fortran ordered).

   Returns
   arr [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed, the same object is returned after being modified in-place to contain the appropriate values.

scipy.sparse.csr_matrix.tobsr

csr_matrix.tobsr(blocksize=None, copy=True)
   Convert this matrix to Block Sparse Row format.

   With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

   When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.
scipy.sparse.csr_matrix.tocoo

csr_matrix.tocoo(copy=True)
Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

scipy.sparse.csr_matrix.tocsc

csr_matrix.tocsc(copy=False)
Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.csr_matrix.tocsr

csr_matrix.tocsr(copy=False)
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.csr_matrix.todense

csr_matrix.todense(order=None, out=None)
Return a dense matrix representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', which provides no ordering guarantees. Cannot be specified in conjunction with the out argument.

out [ndarray, 2-D, optional] If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

arr [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

scipy.sparse.csr_matrix.todia

csr_matrix.todia(copy=False)
Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.
scipy.sparse.csr_matrix.todok

csr_matrix.todok(copy=False)
    Convert this matrix to Dictionary Of Keys format.
    With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.csr_matrix.tolil

csr_matrix.tolil(copy=False)
    Convert this matrix to List of Lists format.
    With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.csr_matrix.trace

csr_matrix.trace(offset=0)
    Returns the sum along diagonals of the sparse matrix.
    Parameters
    offset [int, optional] Which diagonal to get, corresponding to elements a[i, i+offset]. Default: 0 (the main diagonal).

scipy.sparse.csr_matrix.transpose

csr_matrix.transpose(axes=None, copy=False)
    Reverses the dimensions of the sparse matrix.
    Parameters
    axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
    copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.
    Returns
    p [self with the dimensions reversed.]
    See also:
    numpy.matrix.transpose
        NumPy's implementation of 'transpose' for matrices
**scipy.sparse.csr_matrix.trunc**

csr_matrix.trunc()
    Element-wise trunc.
    See numpy.trunc for more information.

**scipy.sparse.dia_matrix**

class scipy.sparse.dia_matrix(arg1, shape=None, dtype=None, copy=False)
    Sparse matrix with DIAGONal storage

    This can be instantiated in several ways:

    - dia_matrix(D)
      with a dense matrix
    - dia_matrix(S)
      with another sparse matrix S (equivalent to S.todia())
    - dia_matrix((M, N), [dtype])
      to construct an empty matrix with shape (M, N), dtype is optional, defaulting to dtype='d'.
    - dia_matrix((data, offsets), shape=(M, N))
      where the data[k,:] stores the diagonal entries for diagonal offsets[k] (See example below)

**Notes**

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

**Examples**

```python
>>> import numpy as np
>>> from scipy.sparse import dia_matrix
>>> dia_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)

>>> data = np.array([[1, 2, 3, 4]]).repeat(3, axis=0)
>>> offsets = np.array([0, -1, 2])
>>> dia_matrix((data, offsets), shape=(4, 4)).toarray()
array([[1, 0, 3, 0],
       [1, 2, 0, 4],
       [1, 2, 0, 4],
       [1, 2, 0, 4]], dtype=int8)
```

(continues on next page)
from scipy.sparse import dia_matrix

n = 10
ex = np.ones(n)
data = np.array([ex, 2 * ex, ex])
offsets = np.array([-1, 0, 1])
dia_matrix((data, offsets), shape=(n, n)).toarray()

array([[2., 1., 0., ..., 0., 0., 0.],
        [1., 2., 1., ..., 0., 0., 0.],
        [0., 1., 2., ..., 0., 0., 0.],
        ...,
        [0., 0., 0., ..., 2., 1., 0.],
        [0., 0., 0., ..., 1., 2., 1.],
        [0., 0., 0., ..., 0., 1., 2.]])

Attributes

dtype [dtype] Data type of the matrix
ndim [int] Number of dimensions (this is always 2)
nnz Number of stored values, including explicit zeros.
data DIA format data array of the matrix
offsets DIA format offset array of the matrix

Methods

__len__()

arcsin() Element-wise arcsin.
arcsinh() Element-wise arcsinh.
arctan() Element-wise arctan.
arctanh() Element-wise arctanh.
asformat(format[, copy]) Return this matrix in the passed format.
asfptype() Upcast matrix to a floating point format (if necessary)
astype(dtype[, casting, copy]) Cast the matrix elements to a specified type.
ceil() Element-wise ceil.
conj([copy]) Element-wise complex conjugation.
conjugate([copy]) Element-wise complex conjugation.
copy() Returns a copy of this matrix.
count_nonzero() Number of non-zero entries, equivalent to
deg2rad() Element-wise deg2rad.
diagonal([k]) Returns the kth diagonal of the matrix.
dot(other) Ordinary dot product
expm1() Element-wise expm1.
floor() Element-wise floor.
getH() Return the Hermitian transpose of this matrix.
get_shape() Get shape of a matrix.

</tbody>
</table>
scipy.sparse.dia_matrix.__len__

dia_matrix.__len__()

scipy.sparse.dia_matrix.arcsin

dia_matrix.arcsin()
Element-wise arcsin.
    See numpy.arcsin for more information.

scipy.sparse.dia_matrix.arcsinh

dia_matrix.arcsinh()
Element-wise arcsinh.
    See numpy.arcsinh for more information.

scipy.sparse.dia_matrix.arctan

dia_matrix.arctan()
Element-wise arctan.
    See numpy.arctan for more information.

scipy.sparse.dia_matrix.arctanh

dia_matrix.arctanh()
Element-wise arctanh.
    See numpy.arctanh for more information.

scipy.sparse.dia_matrix.asformat

dia_matrix.asformat(format, copy=False)
Return this matrix in the passed format.

Parameters

    format  [[str, None]] The desired matrix format (“csr”, “csc”, “lil”, “dok”, “array”, …) or None
             for no conversion.
    copy    [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

    A  [This matrix in the passed format.]
scipy.sparse.dia_matrix.asfptype

`dia_matrix.asfptype()`

Upcast matrix to a floating point format (if necessary)

scipy.sparse.dia_matrix.astype

`dia_matrix.astype(dtype, casting='unsafe', copy=True)`

Cast the matrix elements to a specified type.

**Parameters**

- **dtype** [string or numpy dtype] Typecode or data-type to which to cast the data.
- **casting** [{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
- **copy** [bool, optional] If `copy` is False, the result might share some memory with this matrix. If `copy` is True, it is guaranteed that the result and this matrix do not share any memory.

scipy.sparse.dia_matrix.ceil

`dia_matrix.ceil()`

Element-wise `cei`l.

See `numpy.ceil` for more information.

scipy.sparse.dia_matrix.conj

`dia_matrix.conj(copy=True)`

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- **copy** [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- **A** [The element-wise complex conjugate.]
scipy.sparse.dia_matrix.conjugate

dia_matrix.conjugate(copy=True)
Element-wise complex conjugation.
If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

Parameters
  copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns
  A [The element-wise complex conjugate.]

scipy.sparse.dia_matrix.copy

dia_matrix.copy()
Returns a copy of this matrix.
No data/indices will be shared between the returned value and current matrix.

scipy.sparse.dia_matrix.count_nonzero

dia_matrix.count_nonzero()
Number of non-zero entries, equivalent to
np.count_nonzero(a.toarray())
Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.dia_matrix.deg2rad

dia_matrix.deg2rad()
Element-wise deg2rad.
See numpy.deg2rad for more information.

scipy.sparse.dia_matrix.diagonal

dia_matrix.diagonal(k=0)
Returns the kth diagonal of the matrix.

Parameters
  k [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
  New in version 1.0.

See also:

numpy.diagonal
Equivalent numpy function.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

**scipy.sparse.dia_matrix.dot**

dia_matrix.dot(other)

Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

**scipy.sparse.dia_matrix.expm1**

dia_matrix.expm1()

Element-wise `expm1`.

See `numpy.expm1` for more information.

**scipy.sparse.dia_matrix.floor**

dia_matrix.floor()

Element-wise floor.

See `numpy.floor` for more information.

**scipy.sparse.dia_matrix.getH**

dia_matrix.getH()

Return the Hermitian transpose of this matrix.

See also:

`numpy.matrix.getH`

NumPy's implementation of `getH` for matrices
scipy.sparse.dia_matrix.get_shape

dia_matrix.get_shape()
Get shape of a matrix.

scipy.sparse.dia_matrix.getcol

dia_matrix.getcol(j)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.dia_matrix.getformat

dia_matrix.getformat()
Format of a matrix representation as a string.

scipy.sparse.dia_matrix.getmaxprint

dia_matrix.getmaxprint()
Maximum number of elements to display when printed.

scipy.sparse.dia_matrix.getnnz

dia_matrix.getnnz(axis=None)
Number of stored values, including explicit zeros.

Parameters
axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:
count_nonzero
Number of non-zero entries

scipy.sparse.dia_matrix.getrow

dia_matrix.getrow(i)
Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
**scipy.sparse.dia_matrix.log1p**

dia_matrix.log1p()

Element-wise log1p.

See numpy.log1p for more information.

**scipy.sparse.dia_matrix.maximum**

dia_matrix.maximum(other)

Element-wise maximum between this and another matrix.

**scipy.sparse.dia_matrix.mean**

dia_matrix.mean(axis=None, dtype=None, out=None)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

**Parameters**

axis

[-2, -1, 0, 1, None] optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., axis = None).

dtype

[data-type, optional] Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype.

New in version 0.18.0.

out

[np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

New in version 0.18.0.

**Returns**

m

[np.matrix]

See also:

numpy.matrix.mean

NumPy’s implementation of ‘mean’ for matrices

**scipy.sparse.dia_matrix.minimum**

dia_matrix.minimum(other)

Element-wise minimum between this and another matrix.

scipy.sparse.dia_matrix.multiply

dia_matrix.multiply(other)
Point-wise multiplication by another matrix

scipy.sparse.dia_matrix.nonzero

dia_matrix.nonzero()
nonzero indices
Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.dia_matrix.power

dia_matrix.power(n, dtype=None)
This function performs element-wise power.

Parameters

- `n` [n is a scalar]
- `dtype` [If dtype is not specified, the current dtype will be preserved.]

scipy.sparse.dia_matrix.rad2deg

dia_matrix.rad2deg()
Element-wise rad2deg.
See numpy.rad2deg for more information.

scipy.sparse.dia_matrix.reshape

dia_matrix.reshape(self, shape, order='C', copy=False)
Gives a new shape to a sparse matrix without changing its data.

Parameters

- `shape` [length-2 tuple of ints] The new shape should be compatible with the original shape. [[‘C’, ‘F’], optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- `copy` [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.
Returns

resized_matrix

[sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

dia_matrix.resize

NumPy's implementation of 'reshape' for matrices

scipy.sparse.dia_matrix.resize

dia_matrix.resize(*shape)

Resize the matrix in-place to dimensions given by shape

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

shape [(int, int)] number of rows and columns in the new matrix

Notes

The semantics are not identical to numpy.ndarray.resize or numpy.resize. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

scipy.sparse.dia_matrix.rint

dia_matrix.rint()

Element-wise rint.

See numpy.rint for more information.

scipy.sparse.dia_matrix.set_shape

dia_matrix.set_shape(shape)

See reshape.
**scipy.sparse.dia_matrix.setdiag**

```python
dia_matrix.setdiag(values, k=0)
```

Set diagonal or off-diagonal elements of the array.

**Parameters**

- `values` : [array_like] New values of the diagonal elements.
- `k` : [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

**scipy.sparse.dia_matrix.sign**

```python
dia_matrix.sign()
```

Element-wise sign.

See `numpy.sign` for more information.

**scipy.sparse.dia_matrix.sin**

```python
dia_matrix.sin()
```

Element-wise sin.

See `numpy.sin` for more information.

**scipy.sparse.dia_matrix.sinh**

```python
dia_matrix.sinh()
```

Element-wise sinh.

See `numpy.sinh` for more information.

**scipy.sparse.dia_matrix.sqrt**

```python
dia_matrix.sqrt()
```

Element-wise sqrt.

See `numpy.sqrt` for more information.
scipy.sparse.dia_matrix.sum

dia_matrix.sum(axis=None, dtype=None, out=None)
    Sum the matrix elements over a given axis.

Parameters

    axis    [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., axis = None).

    dtype    [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used.
        New in version 0.18.0.

    out    [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
        New in version 0.18.0.

Returns

    sum_along_axis    [np.matrix] A matrix with the same shape as self, with the specified axis removed.

See also:

    numpy.matrix.sum
    NumPy's implementation of 'sum' for matrices

scipy.sparse.dia_matrix.tan

dia_matrix.tan()
    Element-wise tan.

    See numpy.tan for more information.

scipy.sparse.dia_matrix.tanh

dia_matrix.tanh()
    Element-wise tanh.

    See numpy.tanh for more information.
**scipy.sparse.dia_matrix.toarray**

`dia_matrix.toarray(order=None, out=None)`  
Return a dense ndarray representation of this matrix.

**Parameters**

- `order`  
  {{{'C', 'F'}, optional}} Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, which provides no ordering guarantees. Cannot be specified in conjunction with the `out` argument.

- `out`  
  [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, `out` is required to be memory contiguous (either C or Fortran ordered).

**Returns**

- `arr`  
  [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed, the same object is returned after being modified in-place to contain the appropriate values.

**scipy.sparse.dia_matrix.tobsr**

`dia_matrix.tobsr(blocksize=None, copy=False)`  
Convert this matrix to Block Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `bsr_matrix`.

When `blocksize=(R, C)` is provided, it will be used for construction of the `bsr_matrix`.

**scipy.sparse.dia_matrix.tocoo**

`dia_matrix.tocoo(copy=False)`  
Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `coo_matrix`.

**scipy.sparse.dia_matrix.tocsc**

`dia_matrix.tocsc(copy=False)`  
Convert this matrix to Compressed Sparse Column format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csc_matrix`.

3.3. API definition 1909
scipy.sparse.dia_matrix.tocsr

dia_matrix.tocsr (copy=False)
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.dia_matrix.todense

dia_matrix.todense (order=None, out=None)
Return a dense matrix representation of this matrix.

Parameters

order [‘C’, ‘F’], optional Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, which provides no ordering guarantees. Cannot be specified in conjunction with the out argument.

out [ndarray, 2-D, optional] If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

arr [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

scipy.sparse.dia_matrix.todia

dia_matrix.todia (copy=False)
Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.dia_matrix.todok

dia_matrix.todok (copy=False)
Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.dia_matrix.tolil

dia_matrix.tolil (copy=False)
Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.
scipy.sparse.dia_matrix.trace

dia_matrix.trace(offset=0)
Returns the sum along diagonals of the sparse matrix.

Parameters
offset [int, optional] Which diagonal to get, corresponding to elements a[i, i+offset]. Default: 0 (the main diagonal).

scipy.sparse.dia_matrix.transpose

dia_matrix.transpose(axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters
axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns
p [self with the dimensions reversed.]

See also:
numpy.matrix.transpose
NumPy's implementation of 'transpose' for matrices

scipy.sparse.dia_matrix.trunc

dia_matrix.trunc()
Element-wise trunc.

See numpy.trunc for more information.

__mul__

scipy.sparse.dok_matrix

class scipy.sparse.dok_matrix(arg1, shape=None, dtype=None, copy=False)
Dictionary Of Keys based sparse matrix.

This is an efficient structure for constructing sparse matrices incrementally.

This can be instantiated in several ways:

dok_matrix(D)
with a dense matrix, D

3.3. API definition
**dok_matrix(S)**

with a sparse matrix, S

**dok_matrix((M,N), [dtype])**

create the matrix with initial shape (M,N) dtype is optional, defaulting to dtype='d'

**Notes**

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Allows for efficient O(1) access of individual elements. Duplicates are not allowed. Can be efficiently converted to a coo_matrix once constructed.

**Examples**

```python
>>> import numpy as np
>>> from scipy.sparse import dok_matrix
>>> S = dok_matrix((5, 5), dtype=np.float32)
>>> for i in range(5):
...     for j in range(5):
...         S[i, j] = i + j  # Update element
```

**Attributes**

- **dtype** [dtype] Data type of the matrix
- **ndim** [int] Number of dimensions (this is always 2)
- **nnz** Number of stored values, including explicit zeros.

**Methods**

- **__len__()** Return len(self).
- **asformat(format[, copy])** Return this matrix in the passed format.
- **asfptype()** Upcast matrix to a floating point format (if necessary)
- **astype(dtype[, casting, copy])** Cast the matrix elements to a specified type.
- **clear()**
- **conj([copy])** Element-wise complex conjugation.
- **conjtransp()** Return the conjugate transpose.
- **conjugate([copy])** Element-wise complex conjugation.
- **copy()** Returns a copy of this matrix.
- **count_nonzero()** Number of non-zero entries, equivalent to
- **diagonal([k])** Returns the kth diagonal of the matrix.
- **dot(other)** Ordinary dot product
- **fromkeys(iterable[, value])** Create a new dictionary with keys from iterable and values set to value.
- **get(key[, default])** This overrides the dict.get method, providing type checking but otherwise equivalent functionality.

**3.3. API definition**

---

1913
Table 188 – continued from previous page

values()

scipy.sparse.dok_matrix.__len__

dok_matrix.__len__()
  Return len(self).

scipy.sparse.dok_matrix.asformat

dok_matrix.asformat(format, copy=False)
  Return this matrix in the passed format.

  Parameters

  format  [{str, None}] The desired matrix format (“csr”, “csc”, “lil”, “dok”, “array”, …) or None for no conversion.
  copy    [bool, optional] If True, the result is guaranteed to not share data with self.

  Returns

  A       [This matrix in the passed format.]

scipy.sparse.dok_matrix.asfptype

dok_matrix.asfptype()
  Upcast matrix to a floating point format (if necessary)

scipy.sparse.dok_matrix.astype

dok_matrix.astype(dtype, casting='unsafe', copy=True)
  Cast the matrix elements to a specified type.

  Parameters

  dtype      [string or numpy dtype] Typecode or data-type to which to cast the data.
  casting    [{‘no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’}, optional] Controls what kind of data casting may occur. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
  copy       [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.
**scipy.sparse.dok_matrix.clear**

```python
dok_matrix.clear() → None. Remove all items from D.
```

**scipy.sparse.dok_matrix.conj**

```python
dok_matrix.conj(copy=True)
Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

Parameters

- `copy` [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

- `A` [The element-wise complex conjugate.]
```

**scipy.sparse.dok_matrix.conjtransp**

```python
dok_matrix.conjtransp()
Return the conjugate transpose.
```

**scipy.sparse.dok_matrix.conjugate**

```python
dok_matrix.conjugate(copy=True)
Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

Parameters

- `copy` [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

- `A` [The element-wise complex conjugate.]
```

**scipy.sparse.dok_matrix.copy**

```python
dok_matrix.copy()
Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.
```
**scipy.sparse.dok_matrix.count_nonzero**

dok_matrix.count_nonzero()

Number of non-zero entries, equivalent to

np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

**scipy.sparse.dok_matrix.diagonal**

dok_matrix.diagonal(k=0)

Returns the kth diagonal of the matrix.

Parameters

- **k** [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).

New in version 1.0.

See also:

- **numpy.diagonal**

  Equivalent numpy function.

**Examples**

```python
>>> import scipy.sparse as sp
>>> A = sp.csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

**scipy.sparse.dok_matrix.dot**

dok_matrix.dot(other)

Ordinary dot product

**Examples**

```python
>>> import numpy as np
>>> A = sp.csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```
scipy.sparse.dok_matrix.fromkeys

dok_matrix.fromkeys(iterable, value=None)
Create a new dictionary with keys from iterable and values set to value.

scipy.sparse.dok_matrix.get

dok_matrix.get(key, default=0.0)
This overrides the dict.get method, providing type checking but otherwise equivalent functionality.

scipy.sparse.dok_matrix.getH

dok_matrix.getH()
Return the Hermitian transpose of this matrix.

See also:

numpy.matrix.getH
NumPy's implementation of getH for matrices

scipy.sparse.dok_matrix.get_shape

dok_matrix.get_shape()
Get shape of a matrix.

scipy.sparse.dok_matrix.getcol

dok_matrix.getcol(j)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.dok_matrix.getformat

dok_matrix.getformat()
Format of a matrix representation as a string.

scipy.sparse.dok_matrix.getmaxprint

dok_matrix.getmaxprint()
Maximum number of elements to display when printed.
scipy.sparse.dok_matrix.getnnz

dok_matrix.getnnz(axis=None)
   Number of stored values, including explicit zeros.

   Parameters
   axis  [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

   See also:

count_nonzero
   Number of non-zero entries

scipy.sparse.dok_matrix.getrow

dok_matrix.getrow(i)
   Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

scipy.sparse.dok_matrix.items

dok_matrix.items() → a set-like object providing a view on D's items

scipy.sparse.dok_matrix.keys

dok_matrix.keys() → a set-like object providing a view on D's keys

scipy.sparse.dok_matrix.maximum

dok_matrix.maximum(other)
   Element-wise maximum between this and another matrix.

scipy.sparse.dok_matrix.mean

dok_matrix.mean(axis=None, dtype=None, out=None)
   Compute the arithmetic mean along the specified axis.
   Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

   Parameters
   axis  [-2, -1, 0, 1, None] optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., axis = None).
   dtype  [data-type, optional] Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype. New in version 0.18.0.
out  [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

Returns

m  [np.matrix]

See also:

numpy.matrix.mean

NumPy’s implementation of ‘mean’ for matrices

scipy.sparse.dok_matrix.minimum

dok_matrix.minimum(other)

Element-wise minimum between this and another matrix.

scipy.sparse.dok_matrix.multiply

dok_matrix.multiply(other)

Point-wise multiplication by another matrix

scipy.sparse.dok_matrix.nonzero

dok_matrix.nonzero()

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.dok_matrix.pop

dok_matrix.pop(key, default=unrepresentable, /)

If the key is not found, return the default if given; otherwise, raise a KeyError.
scipy.sparse.dok_matrix.popitem

dok_matrix.

popitem (/)

Remove and return a (key, value) pair as a 2-tuple.

Pairs are returned in LIFO (last-in, first-out) order. Raises KeyError if the dict is empty.

scipy.sparse.dok_matrix.power

dok_matrix.

power (n, dtype=None)

Element-wise power.

scipy.sparse.dok_matrix.reshape

dok_matrix.

reshape (self, shape, order=’C’, copy=False)

Gives a new shape to a sparse matrix without changing its data.

Parameters

shape [length-2 tuple of ints] The new shape should be compatible with the original shape.

order [{‘C’, ‘F’}, optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.

copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

reshaped_matrix [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

numpy.matrix.reshape

NumPy’s implementation of ‘reshape’ for matrices

scipy.sparse.dok_matrix.resize

dok_matrix.

resize (*shape)

Resize the matrix in-place to dimensions given by shape.

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

shape [(int, int)] number of rows and columns in the new matrix
Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

`scipy.sparse.dok_matrix.set_shape`

dok_matrix.set_shape(shape)

See reshape.

`scipy.sparse.dok_matrix.setdefault`

dok_matrix.setdefault(key, default=None, /)

Insert key with a value of default if key is not in the dictionary.

Return the value for key if key is in the dictionary, else default.

`scipy.sparse.dok_matrix.setdiag`

dok_matrix.setdiag(values, k=0)

Set diagonal or off-diagonal elements of the array.

Parameters

values [array_like] New values of the diagonal elements. Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored. If a scalar value is given, all of the diagonal is set to it.

k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

`scipy.sparse.dok_matrix.sum`

dok_matrix.sum(axis=None, dtype=None, out=None)

Sum the matrix elements over a given axis.

Parameters

axis [-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., axis = None).

dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used. New in version 0.18.0.
**out** [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

New in version 0.18.0.

**Returns**

**sum_along_axis**

[np.matrix] A matrix with the same shape as `self`, with the specified axis removed.

See also:

`numpy.matrix.sum`

NumPy’s implementation of ‘sum’ for matrices

**scipy.sparse.dok_matrix.toarray**

dok_matrix.toarray(order=None, out=None)

Return a dense ndarray representation of this matrix.

**Parameters**

*order* [{'C', 'F'}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, which provides no ordering guarantees. Cannot be specified in conjunction with the `out` argument.

*out* [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, `out` is required to be memory contiguous (either C or Fortran ordered).

**Returns**

*arr* [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed, the same object is returned after being modified in-place to contain the appropriate values.

**scipy.sparse.dok_matrix.tobsr**

dok_matrix.tobsr(blocksize=None, copy=False)

Convert this matrix to Block Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When `blocksize=(R, C)` is provided, it will be used for construction of the bsr_matrix.

**scipy.sparse.dok_matrix.tocoo**

dok_matrix.tocoo(copy=False)

Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant coo_matrix.
scipy.sparse.dok_matrix.tocsc

dok_matrix.tocsc(copy=False)
   Convert this matrix to Compressed Sparse Column format.
   With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.dok_matrix.tocsr

dok_matrix.tocsr(copy=False)
   Convert this matrix to Compressed Sparse Row format.
   With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.dok_matrix.todense

dok_matrix.todense(order=None, out=None)
   Return a dense matrix representation of this matrix.

   Parameters
   order [{‘C’, ‘F’}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, which provides no ordering guarantees. Cannot be specified in conjunction with the out argument.

   out [ndarray, 2-D, optional] If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

   Returns
   arr [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

scipy.sparse.dok_matrix.todia

dok_matrix.todia(copy=False)
   Convert this matrix to sparse DIAgonal format.
   With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.dok_matrix.todok

dok_matrix.todok(copy=False)
   Convert this matrix to Dictionary Of Keys format.
   With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.
scipy.sparse.dok_matrix.tolil

dok_matrix.tolil(copy=False)
Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.dok_matrix.trace

dok_matrix.trace(offset=0)
Returns the sum along diagonals of the sparse matrix.

Parameters
offset [int, optional] Which diagonal to get, corresponding to elements a[i, i+offset]. Default: 0 (the main diagonal).

scipy.sparse.dok_matrix.transpose

dok_matrix.transpose(axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters
axes [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns
p [self with the dimensions reversed.]

See also:

numpy.matrix.transpose
NumPy’s implementation of ‘transpose’ for matrices

scipy.sparse.dok_matrix.update

dok_matrix.update([E], **F) → None. Update D from dict/iterable E and F.
If E is present and has a .keys() method, then does: for k in E: D[k] = E[k] If E is present and lacks a .keys() method, then does: for k, v in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]
scipy.sparse.dok_matrix.values

dok_matrix.values() → an object providing a view on D's values

scipy.sparse.lil_matrix

class scipy.sparse.lil_matrix(arg1, shape=None, dtype=None, copy=False)
Row-based list of list sparse matrix

This is a structure for constructing sparse matrices incrementally. Note that inserting a single item can take linear
time in the worst case; to construct a matrix efficiently, make sure the items are pre-sorted by index, per row.

This can be instantiated in several ways:

lil_matrix(D)
    with a dense matrix or rank-2 ndarray D

lil_matrix(S)
    with another sparse matrix S (equivalent to S.tolil())

lil_matrix((M, N), [dtype])
    to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division,
and matrix power.

Advantages of the LIL format

• supports flexible slicing
• changes to the matrix sparsity structure are efficient

Disadvantages of the LIL format

• arithmetic operations LIL + LIL are slow (consider CSR or CSC)
• slow column slicing (consider CSC)
• slow matrix vector products (consider CSR or CSC)

Intended Usage

• LIL is a convenient format for constructing sparse matrices
• once a matrix has been constructed, convert to CSR or CSC format for fast arithmetic and matrix vector
  operations
• consider using the COO format when constructing large matrices

Data Structure
• An array (self.rows) of rows, each of which is a sorted list of column indices of non-zero elements.
• The corresponding nonzero values are stored in similar fashion in self.data.

Attributes

dtype        [dtype] Data type of the matrix
ndim         [int] Number of dimensions (this is always 2)
nnz          Number of stored values, including explicit zeros.
data          LIL format data array of the matrix
rows          LIL format row index array of the matrix

Methods

__len__()  

asformat(format[, copy])  Return this matrix in the passed format.
astype()  Upcast matrix to a floating point format (if necessary)
astype(dtype[, casting, copy])  Cast the matrix elements to a specified type.
conj([copy])  Element-wise complex conjugation.
conjugate([copy])  Element-wise complex conjugation.
copy()  Returns a copy of this matrix.
count_nonzero()  Number of non-zero entries, equivalent to
diagonal([k])  Returns the kth diagonal of the matrix.
dot(other)  Ordinary dot product
getH()  Return the Hermitian transpose of this matrix.
get_shape()  Get shape of a matrix.
getcol(j)  Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
getformat()  Format of a matrix representation as a string.
getmaxprint()  Maximum number of elements to display when printed.
getnnz([axis])  Number of stored values, including explicit zeros.
getrow(i)  Returns a copy of the i’th row.
getrowview(i)  Returns a view of the i’th row (without copying).
maximum(other)  Element-wise maximum between this and another matrix.
mean([axis, dtype, out])  Compute the arithmetic mean along the specified axis.
minimum(other)  Element-wise minimum between this and another matrix.
multiply(other)  Point-wise multiplication by another matrix
nonzero()  nonzero indices
power(n[, dtype])  Element-wise power.
reshape(self, shape[, order, copy])  Gives a new shape to a sparse matrix without changing its data.
resize(*shape)  Resize the matrix in-place to dimensions given by shape
set_shape(shape)  See reshape.
setdiag(values[, k])  Set diagonal or off-diagonal elements of the array.
sum([axis, dtype, out])  Sum the matrix elements over a given axis.

```python
scipy.sparse.lil_matrix.__len__

lil_matrix.__len__()
```

```python
scipy.sparse.lil_matrix.asformat

lil_matrix.asformat(format, copy=False)
```

Return this matrix in the passed format.

**Parameters**

- **format**: [{str, None}] The desired matrix format ("csr", "csc", "lil", "dok", "array", ...) or None for no conversion.
- **copy**: [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- **A**: [This matrix in the passed format.]

```python
scipy.sparse.lil_matrix.asfptype

lil_matrix.asfptype()
```

Upcast matrix to a floating point format (if necessary)

```python
scipy.sparse.lil_matrix.astype

lil_matrix.astype(dtype, casting='unsafe', copy=True)
```

Cast the matrix elements to a specified type.

**Parameters**

- **dtype**: [string or numpy dtype] Typecode or data-type to which to cast the data.
- **casting**: [{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same_kind' means only safe
casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.

**copy**

[bool, optional] If `copy` is False, the result might share some memory with this matrix. If `copy` is True, it is guaranteed that the result and this matrix do not share any memory.

### `scipy.sparse.lil_matrix.conj`

```python
lil_matrix.conj(copy=True)
```

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- **copy**
  
  [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- **A**
  
  [The element-wise complex conjugate.]

### `scipy.sparse.lil_matrix.conjugate`

```python
lil_matrix.conjugate(copy=True)
```

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

**Parameters**

- **copy**
  
  [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- **A**
  
  [The element-wise complex conjugate.]

### `scipy.sparse.lil_matrix.copy`

```python
lil_matrix.copy()
```

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

### `scipy.sparse.lil_matrix.count_nonzero`

```python
lil_matrix.count_nonzero()
```

Number of non-zero entries, equivalent to `np.count_nonzero(a.toarray())`

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.
scipy.sparse.lil_matrix.diagonal

lil_matrix.diagonal(k=0)

Returns the kth diagonal of the matrix.

Parameters

- **k**  
  [int, optional] Which diagonal to get, corresponding to elements $a[i, i+k]$. Default: 0 (the main diagonal).
  New in version 1.0.

See also:

numpy.diagonal

Equivalent numpy function.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

scipy.sparse.lil_matrix.dot

lil_matrix.dot(other)

Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.lil_matrix.getH

lil_matrix.getH()

Return the Hermitian transpose of this matrix.

See also:

numpy.matrix.getH

NumPy's implementation of getH for matrices
**scipy.sparse.lil_matrix.get_shape**

```python
lil_matrix.get_shape()
Get shape of a matrix.
```

**scipy.sparse.lil_matrix.getcol**

```python
lil_matrix.getcol(j)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
```

**scipy.sparse.lil_matrix.getformat**

```python
lil_matrix.getformat()
Format of a matrix representation as a string.
```

**scipy.sparse.lil_matrix.getmaxprint**

```python
lil_matrix.getmaxprint()
Maximum number of elements to display when printed.
```

**scipy.sparse.lil_matrix.getnnz**

```python
lil_matrix.getnnz(axis=None)
Number of stored values, including explicit zeros.
```

*Parameters*

- **axis** [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

*See also:*

- **count_nonzero**
  Number of non-zero entries

**scipy.sparse.lil_matrix.getrow**

```python
lil_matrix.getrow(i)
Returns a copy of the ‘i’th row.
```
scipy.sparse.lil_matrix.getrowview

lil_matrix.getrowview(i)

Returns a view of the ‘i’th row (without copying).

scipy.sparse.lil_matrix.maximum

lil_matrix.maximum(other)

Element-wise maximum between this and another matrix.

scipy.sparse.lil_matrix.mean

lil_matrix.mean(axis=None, dtype=None, out=None)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., axis = None).
dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype.
out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

Returns

m [np.matrix]

See also:

numpy.matrix.mean

NumPy’s implementation of ‘mean’ for matrices

scipy.sparse.lil_matrix.minimum

lil_matrix.minimum(other)

Element-wise minimum between this and another matrix.
scipy.sparse.lil_matrix.multiply

lil_matrix.multiply(other)
Point-wise multiplication by another matrix

scipy.sparse.lil_matrix.nonzero

lil_matrix.nonzero()
nonzero indices
Returns a tuple of arrays (row, col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.lil_matrix.power

lil_matrix.power(n, dtype=None)
Element-wise power.

scipy.sparse.lil_matrix.reshape

lil_matrix.reshape(self, shape, order='C', copy=False)
Gives a new shape to a sparse matrix without changing its data.

Parameters

- shape [length-2 tuple of ints] The new shape should be compatible with the original shape.
- order [{'C', 'F'}, optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

reshaped_matrix [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

- numpy.matrix.reshape
  NumPy's implementation of 'reshape' for matrices
```python
scipy.sparse.lil_matrix.resize

lil_matrix.resize(*shape)

Resize the matrix in-place to dimensions given by shape

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

shape [(int, int)] number of rows and columns in the new matrix

Notes

The semantics are not identical to numpy.ndarray.resize or numpy.resize. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

scipy.sparse.lil_matrix.set_shape

lil_matrix.set_shape(shape)

See reshape.

scipy.sparse.lil_matrix.setdiag

lil_matrix.setdiag(values, k=0)

Set diagonal or off-diagonal elements of the array.

Parameters

values [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.
If a scalar value is given, all of the diagonal is set to it.

k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

scipy.sparse.lil_matrix.sum

lil_matrix.sum(axis=None, dtype=None, out=None)

Sum the matrix elements over a given axis.

Parameters

axis [{-2, -1, 0, 1} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., axis = None).
```
```
**dtype**

[dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used.

New in version 0.18.0.

**out**

[np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

New in version 0.18.0.

**Returns**

`sum_along_axis`

[np.matrix] A matrix with the same shape as `self`, with the specified axis removed.

See also:

- `numpy.matrix.sum`
  - NumPy's implementation of 'sum' for matrices

**scipy.sparse.lil_matrix.toarray**

`lil_matrix.toarray(order=None, out=None)`

Return a dense ndarray representation of this matrix.

**Parameters**

- **order** ![comment]
  
  [\{'C', 'F'\}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', which provides no ordering guarantees. Cannot be specified in conjunction with the `out` argument.

- **out** ![comment]
  
  [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, `out` is required to be memory contiguous (either C or Fortran ordered).

**Returns**

- **arr** ![comment]
  
  [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed, the same object is returned after being modified in-place to contain the appropriate values.

**scipy.sparse.lil_matrix.tobsr**

`lil_matrix.tobsr(blocksize=None, copy=False)`

Convert this matrix to Block Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When `blocksize=(R, C)` is provided, it will be used for construction of the bsr_matrix.
scipy.sparse.lil_matrix.tocoo

lil_matrix.tocoo(copy=False)
Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

scipy.sparse.lil_matrix.tocsc

lil_matrix.tocsc(copy=False)
Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.lil_matrix.tocsr

lil_matrix.tocsr(copy=False)
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.lil_matrix.todense

lil_matrix.todense(order=None, out=None)
Return a dense matrix representation of this matrix.

Parameters

order [{‘C’, ‘F’}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, which provides no ordering guarantees. Cannot be specified in conjunction with the out argument.

out [ndarray, 2-D, optional] If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

arr [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

scipy.sparse.lil_matrix.todia

lil_matrix.todia(copy=False)
Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.
**scipy.sparse.lil_matrix.todok**

```python
lil_matrix.todok(copy=False)
```
Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

**scipy.sparse.lil_matrix.tolil**

```python
lil_matrix.tolil(copy=False)
```
Convert this matrix to List of Lists format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

**scipy.sparse.lil_matrix.trace**

```python
lil_matrix.trace(offset=0)
```
Returns the sum along diagonals of the sparse matrix.

**Parameters**

- `offset` [int, optional] Which diagonal to get, corresponding to elements `a[i, i+offset]`. Default: 0 (the main diagonal).

**scipy.sparse.lil_matrix.transpose**

```python
lil_matrix.transpose(axes=None, copy=False)
```
Reverses the dimensions of the sparse matrix.

**Parameters**

- `axes` [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
- `copy` [bool, optional] Indicates whether or not attributes of `self` should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- `p` [self with the dimensions reversed.]

**See also:**

- `numpy.matrix.transpose`

NumPy's implementation of 'transpose' for matrices

1936 Chapter 3. SciPy API
scipy.sparse.spmatrix

**class scipy.sparse.spmatrix**(maxprint=50)

This class provides a base class for all sparse matrices. It cannot be instantiated. Most of the work is provided by subclasses.

**Attributes**

- **nnz**: Number of stored values, including explicit zeros.
- **shape**: Get shape of a matrix.

**Methods**

- **__len__()**: 
- **asformat**(format[, copy]) : Return this matrix in the passed format.
- **asfptype()** : Upcast matrix to a floating point format (if necessary).
- **astype**(dtype[, casting, copy]) : Cast the matrix elements to a specified type.
- **conj([copy])** : Element-wise complex conjugation.
- **conjugate([copy])** : Element-wise complex conjugation.
- **copy()** : Returns a copy of this matrix.
- **count_nonzero()** : Number of non-zero entries, equivalent to
- **diagonal([k])** : Returns the kth diagonal of the matrix.
- **dot(other)** : Ordinary dot product
- **getH()** : Return the Hermitian transpose of this matrix.
- **get_shape()** : Get shape of a matrix.
- **getcol(j)** : Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
- **getformat()** : Format of a matrix representation as a string.
- **getmaxprint()** : Maximum number of elements to display when printed.
- **getnnz([axis])** : Number of stored values, including explicit zeros.
- **getrow(i)** : Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
- **maximum(other)** : Element-wise maximum between this and another matrix.
- **mean([axis, dtype, out])** : Compute the arithmetic mean along the specified axis.
- **minimum(other)** : Element-wise minimum between this and another matrix.
- **multiply(other)** : Point-wise multiplication by another matrix
- **nonzero()** : nonzero indices
- **power(n[, dtype])** : Element-wise power.
- **reshape(self, shape[, order, copy])** : Gives a new shape to a sparse matrix without changing its data.
- **resize(shape)** : Resize the matrix in-place to dimensions given by shape
- **set_shape(shape)** : See reshape.
- **setdiag(values[, k])** : Set diagonal or off-diagonal elements of the array.
- **sum([axis, dtype, out])** : Sum the matrix elements over a given axis.
- **toarray([order, out])** : Return a dense ndarray representation of this matrix.
- **tobsr([blocksize, copy])** : Convert this matrix to Block Sparse Row format.

#### scipy.sparse.spmatrix.__len__

```python
spmatrix.__len__()
```

#### scipy.sparse.spmatrix.asformat

```python
spmatrix.asformat(format, copy=False)
```

Return this matrix in the passed format.

**Parameters**

- `format` ([str, None]) The desired matrix format (“csr”, “csc”, “lil”, “dok”, “array”, …) or None for no conversion.
- `copy` [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

- `A` [This matrix in the passed format.]

#### scipy.sparse.spmatrix.asfptype

```python
spmatrix.asfptype()
```

Upcast matrix to a floating point format (if necessary)

#### scipy.sparse.spmatrix.astype

```python
spmatrix.astype(dtype, casting='unsafe', copy=True)
```

Cast the matrix elements to a specified type.

**Parameters**

- `dtype` [string or numpy dtype] Typecode or data-type to which to cast the data.
- `casting` ([‘no’, ‘equiv’, ‘safe’, ‘same_kind’, ‘unsafe’], optional] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
copy [bool, optional] If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.

\textbf{scipy.sparse.spmatrix.conj}

\texttt{spmatrix.conj(copy=True)}

Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

\textbf{Parameters}

- \textit{copy} [bool, optional] If True, the result is guaranteed to not share data with self.

\textbf{Returns}

- \texttt{A} [The element-wise complex conjugate.]

\textbf{scipy.sparse.spmatrix.conjugate}

\texttt{spmatrix.conjugate(copy=True)}

Element-wise complex conjugation.

If the matrix is of non-complex data type and copy is False, this method does nothing and the data is not copied.

\textbf{Parameters}

- \textit{copy} [bool, optional] If True, the result is guaranteed to not share data with self.

\textbf{Returns}

- \texttt{A} [The element-wise complex conjugate.]

\textbf{scipy.sparse.spmatrix.copy}

\texttt{spmatrix.copy()}

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

\textbf{scipy.sparse.spmatrix.count_nonzero}

\texttt{spmatrix.count_nonzero()}

Number of non-zero entries, equivalent to

\texttt{np.count_nonzero(a.toarray())}

Unlike \texttt{getnnz()} and the \texttt{nnz} property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.
scipy.sparse.spmatrix.diagonal

spmatrix \texttt{.diagonal}(k=0)

Returns the \(k\)th diagonal of the matrix.

**Parameters**

- \(k\) [int, optional] Which diagonal to get, corresponding to elements \(a[i, i+k]\). Default: 0 (the main diagonal). New in version 1.0.

**See also:**

- \texttt{numpy.diagonal}

Equivalent numpy function.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

scipy.sparse.spmatrix.dot

spmatrix \texttt{.dot}(other)

Ordinary dot product

**Examples**

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.spmatrix.getH

spmatrix \texttt{.getH}()

Return the Hermitian transpose of this matrix.

**See also:**

- \texttt{numpy.matrix.getH}

NumPy's implementation of \texttt{getH} for matrices
scipy.sparse.spmatrix.get_shape

spmatrix.get_shape()
Get shape of a matrix.

scipy.sparse.spmatrix.getcol

spmatrix.getcol(j)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.spmatrix.getformat

spmatrix.getformat()
Format of a matrix representation as a string.

scipy.sparse.spmatrix.getmaxprint

spmatrix.getmaxprint()
Maximum number of elements to display when printed.

scipy.sparse.spmatrix.getnnz

spmatrix.getnnz(axis=None)
Number of stored values, including explicit zeros.

Parameters

axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:

count_nonzero
Number of non-zero entries

scipy.sparse.spmatrix.getrow

spmatrix.getrow(i)
Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
**scipy.sparse.spmatrix.maximum**

`spmatrix.maximum(other)`  
Element-wise maximum between this and another matrix.

**scipy.sparse.spmatrix.mean**

`spmatrix.mean(axis=None, dtype=None, out=None)`  
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. `float64` intermediate and return values are used for integer inputs.

**Parameters**

- `axis`  
  [{-2, -1, 0, 1, None} optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., `axis = None`).

- `dtype`  
  [data-type, optional] Type to use in computing the mean. For integer inputs, the default is `float64`; for floating point inputs, it is the same as the input dtype. New in version 0.18.0.

- `out`  
  [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. New in version 0.18.0.

**Returns**

- `m`  
  [np.matrix]

See also:

- `numpy.matrix.mean`  
  NumPy's implementation of `mean` for matrices

**scipy.sparse.spmatrix.minimum**

`spmatrix.minimum(other)`  
Element-wise minimum between this and another matrix.

**scipy.sparse.spmatrix.multiply**

`spmatrix.multiply(other)`  
Point-wise multiplication by another matrix
scipy.sparse.spmatrix.nonzero

spmatrix.nonzero()
nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.spmatrix.power

spmatrix.power(n, dtype=None)
Element-wise power.

scipy.sparse.spmatrix.reshape

spmatrix.reshape(self, shape, order='C', copy=False)
Gives a new shape to a sparse matrix without changing its data.

Parameters

- **shape** [length-2 tuple of ints] The new shape should be compatible with the original shape.
- **order** [{'C', 'F'}, optional] Read the elements using this index order. ‘C’ means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. ‘F’ means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- **copy** [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

reshaped_matrix
[sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

- **numpy.matrix.reshape**

    NumPy's implementation of 'reshape' for matrices
scipy.sparse.spmatrix.resize

```
spmatrix.resize(shape)
```
Resize the matrix in-place to dimensions given by shape

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

**Parameters**

- **shape**
  [(int, int)] number of rows and columns in the new matrix

**Notes**

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

scipy.sparse.spmatrix.set_shape

```
spmatrix.set_shape(shape)
```
See resize.

scipy.sparse.spmatrix.setdiag

```
spmatrix.setdiag(values, k=0)
```
Set diagonal or off-diagonal elements of the array.

**Parameters**

- **values**
  [array_like] New values of the diagonal elements.
  Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.
  If a scalar value is given, all of the diagonal is set to it.
- **k**
  [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

scipy.sparse.spmatrix.sum

```
spmatrix.sum(axis=None, dtype=None, out=None)
```
Sum the matrix elements over a given axis.

**Parameters**

- **axis**
  [-2, -1, 0, 1, None] optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., `axis = None`).
**dtype**

[**dtype**, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of **a** is used by default unless **a** has an integer dtype of less precision than the default platform integer. In that case, if **a** is signed then the platform integer is used while if **a** is unsigned then an unsigned integer of the same precision as the platform integer is used.

New in version 0.18.0.

**out**

[np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

New in version 0.18.0.

**Returns**

**sum_along_axis**

[np.matrix] A matrix with the same shape as **self**, with the specified axis removed.

**See also:**

`numpy.matrix.sum`

NumPy’s implementation of ‘sum’ for matrices

### scipy.sparse.spmatrix.toarray

**spmatrix.toarray**(order=None, out=None)

Return a dense ndarray representation of this matrix.

**Parameters**

**order**

[{'C', 'F'}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', which provides no ordering guarantees. Cannot be specified in conjunction with the **out** argument.

**out**

[ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, **out** is required to be memory contiguous (either C or Fortran ordered).

**Returns**

**arr**

[ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If **out** was passed, the same object is returned after being modified in-place to contain the appropriate values.

### scipy.sparse.spmatrix.tobsr

**spmatrix.tobsr**(blocksize=None, copy=False)

Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.
\texttt{scipy.sparse.spmatrix.tocoo}

\texttt{spmatrix.tocoo(copy=False)}

Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

\texttt{scipy.sparse.spmatrix.tocsc}

\texttt{spmatrix.tocsc(copy=False)}

Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

\texttt{scipy.sparse.spmatrix.tocsr}

\texttt{spmatrix.tocsr(copy=False)}

Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

\texttt{scipy.sparse.spmatrix.todense}

\texttt{spmatrix.todense(order=None, out=None)}

Return a dense matrix representation of this matrix.

Parameters

\begin{itemize}
\item \texttt{order} \([\{\texttt{C}, \texttt{F}\}, \text{optional}]\) Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is \texttt{None}, which provides no ordering guarantees. Cannot be specified in conjunction with the \texttt{out} argument.
\item \texttt{out} \([\texttt{ndarray}, \texttt{2-D}, \text{optional}]\) If specified, uses this array (or \texttt{numpy.matrix}) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.
\end{itemize}

Returns

\begin{itemize}
\item \texttt{arr} \([\texttt{numpy.matrix}, \texttt{2-D}]\) A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If \texttt{out} was passed and was an array (rather than a \texttt{numpy.matrix}), it will be filled with the appropriate values and returned wrapped in a \texttt{numpy.matrix} object that shares the same memory.
\end{itemize}

\texttt{scipy.sparse.spmatrix.todia}

\texttt{spmatrix.todia(copy=False)}

Convert this matrix to sparse DIAGonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.
scipy.sparse.spmatrix.todok

spmatrix.todok(copy=False)
Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.spmatrix.tolil

spmatrix.tolil(copy=False)
Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.spmatrix.trace

spmatrix.trace(offset=0)
Returns the sum along diagonals of the sparse matrix.

Parameters

offset [int, optional] Which diagonal to get, corresponding to elements a[i, i+offset]. Default: 0 (the main diagonal).

scipy.sparse.spmatrix.transpose

spmatrix.transpose(axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [self with the dimensions reversed.]

**scipy.sparse.eye**

`scipy.sparse.eye(m, n=\text{None}, k=0, dtype=\text{<class 'float'>}, format=\text{None})`

Sparse matrix with ones on diagonal

Returns a sparse (m x n) matrix where the kth diagonal is all ones and everything else is zeros.

**Parameters**

- `m` [int] Number of rows in the matrix.
- `n` [int, optional] Number of columns. Default: `m`.
- `k` [int, optional] Diagonal to place ones on. Default: 0 (main diagonal).
- `dtype` [dtype, optional] Data type of the matrix.
- `format` [str, optional] Sparse format of the result, e.g., `format=\text{"csr"}`, etc.

**Examples**

```python
>>> from scipy import sparse
>>> sparse.eye(3).toarray()
array([[ 1.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.]])
>>> sparse.eye(3, dtype=np.int8)
<3x3 sparse matrix of type '\text{<class 'numpy.int8'>}'
with 3 stored elements (1 diagonals) in \text{DIAgonal format}>
```
scipy.sparse.identity

**scipy.sparse.identity** *(n, dtype='d', format=None)*

Identity matrix in sparse format

Returns an identity matrix with shape (n,n) using a given sparse format and dtype.

**Parameters**

- **n** [int] Shape of the identity matrix.
- **dtype** [dtype, optional] Data type of the matrix
- **format** [str, optional] Sparse format of the result, e.g., format="csr", etc.

**Examples**

```python
>>> from scipy.sparse import identity
d>>> identity(3).toarray()
array([[ 1.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.]])
```

```python
>>> identity(3, dtype='int8', format='dia')
<3x3 sparse matrix of type '<class 'numpy.int8'>'
    with 3 stored elements (1 diagonals) in DIAgonal format>
```

scipy.sparse.kron

**scipy.sparse.kron** *(A, B, format=None)*

Kronecker product of sparse matrices A and B

**Parameters**

- **A** [sparse or dense matrix] first matrix of the product
- **B** [sparse or dense matrix] second matrix of the product
- **format** [str, optional] format of the result (e.g. “csr”)

**Returns**

Kronecker product in a sparse matrix format

**Examples**

```python
>>> from scipy import sparse
d>>> A = sparse.csr_matrix(np.array([[0, 2], [5, 0]]))
>>> B = sparse.csr_matrix(np.array([[1, 2], [3, 4]]))
>>> sparse.kron(A, B).toarray()
array([[  0,  10,  20,  0],
       [  0,  15,  20,  0],
       [  0,  20,  24,  0],
       [  0,  24,  10,  0],
       [  0,  24,  10,  0],
       [  0,  24,  20,  0],
       [  0,  24,  10,  0],
       [  0,  24,  20,  0]])
```
>>> sparse.kron(A, [[1, 2], [3, 4]]).toarray()
array([[ 0,  0,  2,  4],
       [ 0,  0,  6,  8],
       [ 5, 10,  0,  0],
       [15, 20,  0,  0]])

scipy.sparse.kronsum

scipy.sparse.kronsum(A, B, format=None)
  kron sum of sparse matrices A and B

Kronecker sum of two sparse matrices is a sum of two Kronecker products
kron(I_n,A) + kron(B,I_m) where A has shape (m,m) and B has shape (n,n) and I_m and I_n are identity matrices of shape (m,m) and (n,n), respectively.

Parameters
- A : square matrix
- B : square matrix
- format : [str] format of the result (e.g. "csr")

Returns
  kronecker sum in a sparse matrix format

scipy.sparse.diags

scipy.sparse.diags(diagonals, offsets=0, shape=None, format=None, dtype=None)
  Construct a sparse matrix from diagonals.

Parameters
- diagonals : [sequence of array_like] Sequence of arrays containing the matrix diagonals, corresponding to offsets.
- offsets : [sequence of int or an int, optional] Diagonals to set:
  • k = 0 the main diagonal (default)
  • k > 0 the kth upper diagonal
  • k < 0 the kth lower diagonal
- shape : [tuple of int, optional] Shape of the result. If omitted, a square matrix large enough to contain the diagonals is returned.
- format : [{“dia”, “csr”, “csc”, “lil”, …}, optional] Matrix format of the result. By default (format=None) an appropriate sparse matrix format is returned. This choice is subject to change.
- dtype : [dtype, optional] Data type of the matrix.

See also:
- spdiags
  construct matrix from diagonals
Notes

This function differs from \texttt{spdiags} in the way it handles off-diagonals.

The result from \texttt{diags} is the sparse equivalent of:

\begin{verbatim}
np.diag(diagonals[0], offsets[0])
+ ...
+ np.diag(diagonals[k], offsets[k])
\end{verbatim}

Repeated diagonal offsets are disallowed.

New in version 0.11.

Examples

\begin{verbatim}
>>> from scipy.sparse import diags
>>> diagonals = [[1, 2, 3, 4], [1, 2, 3], [1, 2]]
>>> diags(diagonals, [0, -1, 2]).toarray()
array([[1, 0, 1, 0],
       [1, 2, 0, 2],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
\end{verbatim}

Broadcasting of scalars is supported (but shape needs to be specified):

\begin{verbatim}
>>> diags([1, -2, 1], [-1, 0, 1], shape=(4, 4)).toarray()
array([[ 1., -2., 1., 0.],
       [ 1., -2., 1., 0.],
       [ 0., 1., -2., 1.],
       [ 0., 0., 1., -2.]])
\end{verbatim}

If only one diagonal is wanted (as in \texttt{numpy.diag}), the following works as well:

\begin{verbatim}
>>> diags([1, 2, 3], 1).toarray()
array([[ 0., 1., 0., 0.],
       [ 0., 0., 2., 0.],
       [ 0., 0., 0., 3.],
       [ 0., 0., 0., 0.]])
\end{verbatim}

\texttt{scipy.sparse.spdiags}

\texttt{scipy.sparse.spdiags} \texttt{(data, diags, m, n, format=None)}

Return a sparse matrix from diagonals.

\textbf{Parameters}

- \texttt{data} [array_like] Matrix diagonals stored row-wise
- \texttt{diags} [sequence of int or an int] Diagonals to set:
  - \texttt{k = 0} the main diagonal
  - \texttt{k > 0} the \texttt{kth} upper diagonal
  - \texttt{k < 0} the \texttt{kth} lower diagonal
- \texttt{m, n} [int] Shape of the result

3.3. API definition
format [str, optional] Format of the result. By default (format=None) an appropriate sparse matrix format is returned. This choice is subject to change.

See also:

diags
  more convenient form of this function
dia_matrix
  the sparse DIAgonal format.

Examples

```python
>>> from scipy.sparse import spdiags
>>> data = np.array([[1, 2, 3, 4], [1, 2, 3, 4], [1, 2, 3, 4]])
>>> diags = np.array([0, -1, 2])
>>> spdiags(data, diags, 4, 4).toarray()
array([[1, 0, 3, 0],
       [1, 2, 0, 4],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
```

scipy.sparse.block_diag

scipy.sparse.block_diag(mats, format=None, dtype=None)

Build a block diagonal sparse matrix from provided matrices.

Parameters

- mats [sequence of matrices] Input matrices.
- format [str, optional] The sparse format of the result (e.g., “csr”). If not given, the matrix is returned in “coo” format.
- dtype [dtype specifier, optional] The data-type of the output matrix. If not given, the dtype is determined from that of blocks.

Returns

- res [sparse matrix]

See also:

bmat, diags

Notes

New in version 0.11.0.
Examples

```python
>>> from scipy.sparse import coo_matrix, block_diag
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> C = coo_matrix([[7]])
>>> block_diag((A, B, C)).toarray()
array([[1, 2, 0, 0],
       [3, 4, 0, 0],
       [0, 0, 5, 0],
       [0, 0, 6, 0],
       [0, 0, 0, 7]])
```

scipy.sparse.tril

scipy.sparse.tril(A, k=0, format=None)

Return the lower triangular portion of a matrix in sparse format

Returns the elements on or below the k-th diagonal of the matrix A.

- k = 0 corresponds to the main diagonal
- k > 0 is above the main diagonal
- k < 0 is below the main diagonal

Parameters

- A [dense or sparse matrix] Matrix whose lower triangular portion is desired.
- k [integer] The top-most diagonal of the lower triangle.
- format [string] Sparse format of the result, e.g. format=”csr”, etc.

Returns

- L [sparse matrix] Lower triangular portion of A in sparse format.

See also:

triu

upper triangle in sparse format

Examples

```python
>>> from scipy.sparse import csr_matrix, tril
>>> A = csr_matrix([[1, 2, 0, 0, 3], [4, 5, 0, 6, 7], [0, 0, 8, 9, 0]],
                 dtype='int32')
>>> A.toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> tril(A).toarray()
array([[1, 0, 0, 0, 0],
       [4, 5, 0, 0, 0],
       [0, 0, 8, 9, 0]])
```
```python
>>> tril(A).nnz
4
>>> tril(A, k=1).toarray()
array([[1, 2, 0, 0, 0],
       [4, 5, 0, 0, 0],
       [0, 0, 8, 9, 0]])
>>> tril(A, k=-1).toarray()
array([[0, 0, 0, 0, 0],
       [4, 0, 0, 0, 0],
       [0, 0, 0, 0, 0]])
>>> tril(A, format='csc')
<3x5 sparse matrix of type '<class 'numpy.int32'>'
    with 4 stored elements in Compressed Sparse Column format>
```

**scipy.sparse.triu**

scipy.sparse.triu(A, k=0, format=None)

Return the upper triangular portion of a matrix in sparse format

*Returns the elements on or above the k-th diagonal of the matrix A.*

- k = 0 corresponds to the main diagonal
- k > 0 is above the main diagonal
- k < 0 is below the main diagonal

**Parameters**

- A [dense or sparse matrix] Matrix whose upper triangular portion is desired.
- k [integer] The bottom-most diagonal of the upper triangle.
- format [string] Sparse format of the result, e.g. format="csr", etc.

**Returns**

- L [sparse matrix] Upper triangular portion of A in sparse format.

**See also:**

- tril lower triangle in sparse format
Examples

```python
>>> from scipy.sparse import csr_matrix, triu
>>> A = csr_matrix([[1, 2, 0, 0, 3], [4, 5, 0, 6, 7], [0, 0, 8, 9, 0]],
                  dtype='int32')
>>> A.toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A).toarray()
array([[1, 2, 0, 0, 3],
       [0, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A).nnz
8
>>> triu(A, k=1).toarray()
array([[0, 2, 0, 0, 3],
       [0, 0, 0, 6, 7],
       [0, 0, 0, 9, 0]])
>>> triu(A, k=-1).toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A, format='csc')
<3x5 sparse matrix of type '<class 'numpy.int32'>'
     with 8 stored elements in Compressed Sparse Column format>
```

scipy.sparse.bmat

**scipy.sparse.bmat** *(blocks, format=None, dtype=None)*  
Build a sparse matrix from sparse sub-blocks

**Parameters**
- **blocks** [array_like] Grid of sparse matrices with compatible shapes. An entry of None implies an all-zero matrix.
- **format** [{'bsr', 'coo', 'csc', 'csr', 'dia', 'dok', 'lil'}, optional] The sparse format of the result (e.g. “csr”).
  By default an appropriate sparse matrix format is returned. This choice is subject to change.
- **dtype** [dtype, optional] The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

**Returns**
- **bmat** [sparse matrix]

See also:
- block_diag, diags

3.3. API definition
Examples

```python
>>> from scipy.sparse import coo_matrix, bmat
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> C = coo_matrix([[7]])
>>> bmat([[A, B], [None, C]]).toarray()
array([[1, 2, 5],
       [3, 4, 6],
       [0, 0, 7]])
```

```python
>>> bmat([[A, None], [None, C]]).toarray()
array([[1, 2, 0],
       [3, 4, 0],
       [0, 0, 7]])
```

scipy.sparse.hstack

`scipy.sparse.hstack` (`blocks, format=None, dtype=None`)
Stack sparse matrices horizontally (column wise)

**Parameters**
- `blocks`: sequence of sparse matrices with compatible shapes
- `format`: [str] sparse format of the result (e.g., “csr”) by default an appropriate sparse matrix format is returned. This choice is subject to change.
- `dtype`: [dtype, optional] The data-type of the output matrix. If not given, the dtype is determined from that of `blocks`.

**See also:**

vstack

stack sparse matrices vertically (row wise)

Examples

```python
>>> from scipy.sparse import coo_matrix, hstack
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> hstack([A, B]).toarray()
array([[1, 2, 5],
       [3, 4, 6]])
```
scipy.sparse.vstack

scipy.sparse.vstack(blocks, format=None, dtype=None)
Stack sparse matrices vertically (row wise)

Parameters
blocks sequence of sparse matrices with compatible shapes
format [str, optional] sparse format of the result (e.g., “csr”) by default an appropriate sparse matrix format is returned. This choice is subject to change.
dtype [dtype, optional] The data-type of the output matrix. If not given, the dtype is determined from that of blocks.

See also:
hstack
stack sparse matrices horizontally (column wise)

Examples

```python
>>> from scipy.sparse import coo_matrix, vstack
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5, 6]])
>>> vstack([A, B]).toarray()
array([[1, 2],
       [3, 4],
       [5, 6]])
```

scipy.sparse.rand

scipy.sparse.rand(m, n, density=0.01, format='coo', dtype=None, random_state=None)
Generate a sparse matrix of the given shape and density with uniformly distributed values.

Parameters
m, n [int] shape of the matrix
density [real, optional] density of the generated matrix: density equal to one means a full matrix, density of 0 means a matrix with no non-zero items.
format [str, optional] sparse matrix format.
dtype [dtype, optional] type of the returned matrix values.
random_state [[None, int, numpy.random.Generator],
numpy.random.RandomState], optional
If seed is None (or np.random), the numpy.random.RandomState singleton is used. If seed is an int, a new RandomState instance is used, seeded with seed. If seed is already a Generator or RandomState instance then that instance is used.

Returns
res [sparse matrix]

See also:
scipy.sparse.random

Similar function that allows a user-specified random data source.

Notes

Only float types are supported for now.

Examples

```python
>>> from scipy.sparse import rand
>>> matrix = rand(3, 4, density=0.25, format="csr", random_state=42)
>>> matrix
<3x4 sparse matrix of type '<class 'numpy.float64'>'
    with 3 stored elements in Compressed Sparse Row format>
>>> matrix.toarray()
array([[0.05641158, 0. , 0. , 0.65088847],
    [0. , 0. , 0. , 0.14286682],
    [0. , 0. , 0. , 0. ]])
```

scipy.sparse.random

scipy.sparse.random(m, n, density=0.01, format='coo', dtype=None, random_state=None, data_rvs=None)

Generate a sparse matrix of the given shape and density with randomly distributed values.

Parameters

- **m, n** [int] shape of the matrix
- **density** [real, optional] density of the generated matrix: density equal to one means a full matrix, density of 0 means a matrix with no non-zero items.
- **format** [str, optional] sparse matrix format.
- **dtype** [dtype, optional] type of the returned matrix values.
- **random_state** [None, int, numpy.random.Generator, numpy.random.RandomState], optional
  - If `seed` is None (or `np.random`), the `numpy.random.RandomState` singleton is used.
  - If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already a `Generator` or `RandomState` instance then that instance is used. This random state will be used for sampling the sparsity structure, but not necessarily for sampling the values of the structurally nonzero entries of the matrix.
- **data_rvs** [callable, optional] Samples a requested number of random values. This function should take a single argument specifying the length of the ndarray that it will return. The structurally nonzero entries of the sparse random matrix will be taken from the array sampled by this function. By default, uniform [0, 1) random values will be sampled using the same random state as is used for sampling the sparsity structure.

Returns

- **res** [sparse matrix]
Notes

Only float types are supported for now.

Examples

```python
>>> from scipy.sparse import random
>>> from scipy import stats
>>> from numpy.random import default_rng
>>> rng = default_rng()
>>> rvs = stats.poisson(25, loc=10).rvs
>>> S = random(3, 4, density=0.25, random_state=rng, data_rvs=rvs)
>>> S.A
array([[ 36.,  0.,  33.,  0.],
       [  0.,  0.,  0.,  0.],
       [  0.,  0.,  36.,  0.]]

>>> from scipy.sparse import random
>>> from scipy.stats import rv_continuous
>>> class CustomDistribution(rv_continuous):
...    ...    def _rvs(self, size=None, random_state=None):
...        ...        return random_state.standard_normal(size)
>>> X = CustomDistribution(seed=rng)
>>> Y = X()  # get a frozen version of the distribution
>>> S = random(3, 4, density=0.25, random_state=rng, data_rvs=Y.rvs)
>>> S.A
array([[ 0. ,  0. ,  0. ,  0. ],
       [ 0.13569738, 1.9467163 , -0.81205367,  0. ],
       [  0. ,  0. ,  0. ,  0. ]])
```

Save and load sparse matrices:

```
save_npz(file, matrix[, compressed])

Save a sparse matrix to a file using .npz format.

load_npz(file)

Load a sparse matrix from a file using .npz format.
```

```
save_npz(file, matrix[, compressed])

Save a sparse matrix to a file using .npz format.

Parameters

file [str or file-like object] Either the file name (string) or an open file (file-like object) where the data will be saved. If file is a string, the .npz extension will be appended to the file name if it is not already there.

matrix: spmatrix (format: `csc`, `csr`, `bsr`, `dia` or `coo`)
The sparse matrix to save.

compressed [bool, optional] Allow compressing the file. Default: True

See also:

3.3. API definition 1959
scipy.sparse.load_npz

Load a sparse matrix from a file using .npz format.

numpy.savez

Save several arrays into a .npz archive.

numpy.savez_compressed

Save several arrays into a compressed .npz archive.

Examples

Store sparse matrix to disk, and load it again:

```python
>>> import scipy.sparse
>>> sparse_matrix = scipy.sparse.csc_matrix(np.array([[0, 0, 3], [4, 0, 0]]))
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.toarray()
array([[0, 0, 3],
       [4, 0, 0]], dtype=int64)
```

```python
>>> scipy.sparse.save_npz('/tmp/sparse_matrix.npz', sparse_matrix)
>>> sparse_matrix = scipy.sparse.load_npz('/tmp/sparse_matrix.npz')
```

```
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.toarray()
array([[0, 0, 3],
       [4, 0, 0]], dtype=int64)
```

scipy.sparse.load_npz

scipy.sparse.load_npz(file)

Load a sparse matrix from a file using .npz format.

Parameters

- **file** [str or file-like object] Either the file name (string) or an open file (file-like object) where the data will be loaded.

Returns

- **result** [csc_matrix, csr_matrix, bsr_matrix, dia_matrix or coo_matrix] A sparse matrix containing the loaded data.

Raises

- **OSError** If the input file does not exist or cannot be read.

See also:
**scipy.sparse.save_npz**

Save a sparse matrix to a file using .npz format.

**numpy.load**

Load several arrays from a .npz archive.

### Examples

Store sparse matrix to disk, and load it again:

```python
>>> import scipy.sparse

>>> sparse_matrix = scipy.sparse.csc_matrix(np.array([[0, 0, 3], [4, 0, 0]])
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
 with 2 stored elements in Compressed Sparse Column format>

>>> sparse_matrix.toarray()
array([[0, 0, 3],
       [4, 0, 0]], dtype=int64)

>>> scipy.sparse.save_npz('/tmp/sparse_matrix.npz', sparse_matrix)

>>> sparse_matrix = scipy.sparse.load_npz('/tmp/sparse_matrix.npz')

>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
 with 2 stored elements in Compressed Sparse Column format>

>>> sparse_matrix.toarray()
array([[0, 0, 3],
       [4, 0, 0]], dtype=int64)
```

Sparse matrix tools:

**find(A)**  
Return the indices and values of the nonzero elements of a matrix

**scipy.sparse.find**

scipy.sparse.find(A)

Return the indices and values of the nonzero elements of a matrix

**Parameters**

A [dense or sparse matrix] Matrix whose nonzero elements are desired.

**Returns**

(I, J, V) [tuple of arrays] I, J, and V contain the row indices, column indices, and values of the nonzero matrix entries.
Examples

```python
>>> from scipy.sparse import csr_matrix, find
>>> A = csr_matrix([[7.0, 8.0, 0], [0, 0, 9.0]])
>>> find(A)
(array([0, 0, 1], dtype=int32), array([0, 1, 2], dtype=int32), array([ 7., 8., 9.]))
```

Identifying sparse matrices:

<table>
<thead>
<tr>

`scipy.sparse.issparse`

`scipy.sparse.issparse(x)`

Is x of a sparse matrix type?

**Parameters**

- **x**
  object to check for being a sparse matrix

**Returns**

- **bool**
  True if x is a sparse matrix, False otherwise

**Notes**

issparse and isspmatrix are aliases for the same function.

**Examples**

```python
>>> from scipy.sparse import csr_matrix, isspmatrix
>>> isspmatrix(csr_matrix([[5]]))
True
```

```python
>>> from scipy.sparse import isspmatrix
>>> isspmatrix(5)
False
```
scipy.sparse.isspmatrix

scipy.sparse.isspmatrix(x)
Is x of a sparse matrix type?

Parameters

x object to check for being a sparse matrix

Returns

bool True if x is a sparse matrix, False otherwise

Notes

issparse and isspmatrix are aliases for the same function.

Examples

```python
>>> from scipy.sparse import csr_matrix, isspmatrix
>>> isspmatrix(csr_matrix([[5]]))
True

>>> from scipy.sparse import isspmatrix
>>> isspmatrix(5)
False
```

scipy.sparse.isspmatrix_csc

scipy.sparse.isspmatrix_csc(x)
Is x of csc_matrix type?

Parameters

x object to check for being a csc matrix

Returns

bool True if x is a csc matrix, False otherwise

Examples

```python
>>> from scipy.sparse import csc_matrix, isspmatrix_csc
>>> isspmatrix_csc(csc_matrix([[5]]))
True

>>> from scipy.sparse import csc_matrix, csr_matrix, isspmatrix_csc
>>> isspmatrix_csc(csr_matrix([[5]]))
False
```
scipy.sparse.isspmatrix_csr

scipy.sparse.isspmatrix_csr(x)
Is x of csr_matrix type?

Parameters
x object to check for being a csr matrix

Returns
bool True if x is a csr matrix, False otherwise

Examples

```python
>>> from scipy.sparse import csr_matrix, isspmatrix_csr
>>> isspmatrix_csr(csr_matrix([[5]]))
True
```

```python
>>> from scipy.sparse import csc_matrix, csr_matrix, isspmatrix_csc
>>> isspmatrix_csr(csc_matrix([[5]]))
False
```

scipy.sparse.isspmatrix_bsr

scipy.sparse.isspmatrix_bsr(x)
Is x of a bsr_matrix type?

Parameters
x object to check for being a bsr matrix

Returns
bool True if x is a bsr matrix, False otherwise

Examples

```python
>>> from scipy.sparse import bsr_matrix, isspmatrix_bsr
>>> isspmatrix_bsr(bsr_matrix([[5]]))
True
```

```python
>>> from scipy.sparse import bsr_matrix, csr_matrix, isspmatrix_bsr
>>> isspmatrix_bsr(csr_matrix([[5]]))
False
```
scipy.sparse.isspmatrix_lil

scipy.sparse.isspmatrix_lil(x)
Is x of lil_matrix type?

Parameters
x object to check for being a lil matrix

Returns
bool True if x is a lil matrix, False otherwise

Examples

```python
>>> from scipy.sparse import lil_matrix, isspmatrix_lil
>>> isspmatrix_lil(lil_matrix([[5]]))
True

>>> from scipy.sparse import lil_matrix, csr_matrix, isspmatrix_lil
>>> isspmatrix_lil(csr_matrix([[5]]))
False
```

scipy.sparse.isspmatrix_dok

scipy.sparse.isspmatrix_dok(x)
Is x of dok_matrix type?

Parameters
x object to check for being a dok matrix

Returns
bool True if x is a dok matrix, False otherwise

Examples

```python
>>> from scipy.sparse import dok_matrix, isspmatrix_dok
>>> isspmatrix_dok(dok_matrix([[5]]))
True

>>> from scipy.sparse import dok_matrix, csr_matrix, isspmatrix_dok
>>> isspmatrix_dok(csr_matrix([[5]]))
False
```
scipy.sparse.isspmatrix_coo

scipy.sparse.\texttt{isspmatrix\_coo}(x)

Is \(x\) of coo\_matrix type?

\textbf{Parameters}

\textbf{x} \quad \text{object to check for being a coo matrix}

\textbf{Returns}

\textbf{bool} \quad \text{True if \(x\) is a coo matrix, False otherwise}

\textbf{Examples}

```python
>>> from scipy.sparse import coo_matrix, isspmatrix_coo
>>> isspmatrix_coo(coo_matrix([[5]]))
True

>>> from scipy.sparse import coo_matrix, csr_matrix, isspmatrix_coo
>>> isspmatrix_coo(csr_matrix([[5]]))
False
```

scipy.sparse.isspmatrix_dia

scipy.sparse.\texttt{isspmatrix\_dia}(x)

Is \(x\) of dia\_matrix type?

\textbf{Parameters}

\textbf{x} \quad \text{object to check for being a dia matrix}

\textbf{Returns}

\textbf{bool} \quad \text{True if \(x\) is a dia matrix, False otherwise}

\textbf{Examples}

```python
>>> from scipy.sparse import dia_matrix, isspmatrix_dia
>>> isspmatrix_dia(dia_matrix([[5]]))
True

>>> from scipy.sparse import dia_matrix, csr_matrix, isspmatrix_dia
>>> isspmatrix_dia(csr_matrix([[5]]))
False
```

Exceptions

`SparseEfficiencyWarning`

`SparseWarning`

```python
scipy.sparse.SparseEfficiencyWarning
def exception scipy.sparse.SparseEfficiencyWarning
    with_traceback():
        Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

`scipy.sparse.SparseWarning`

```python
scipy.sparse.SparseWarning
def exception scipy.sparse.SparseWarning
    with_traceback():
        Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

**Usage information**

There are seven available sparse matrix types:

1. `csc_matrix`: Compressed Sparse Column format
2. `csr_matrix`: Compressed Sparse Row format
3. `bsr_matrix`: Block Sparse Row format
4. `lil_matrix`: List of Lists format
5. `dok_matrix`: Dictionary of Keys format
6. `coo_matrix`: COOrdinate format (aka IJV, triplet format)
7. `dia_matrix`: DIAgonal format

To construct a matrix efficiently, use either `dok_matrix` or `lil_matrix`. The `lil_matrix` class supports basic slicing and fancy indexing with a similar syntax to NumPy arrays. As illustrated below, the COO format may also be used to efficiently construct matrices. Despite their similarity to NumPy arrays, it is strongly discouraged to use NumPy functions directly on these matrices because NumPy may not properly convert them for computations, leading to unexpected (and incorrect) results. If you do want to apply a NumPy function to these matrices, first check if SciPy has its own implementation for the given sparse matrix class, or convert the sparse matrix to a NumPy array (e.g., using the `toarray()` method of the class) first before applying the method.

To perform manipulations such as multiplication or inversion, first convert the matrix to either CSC or CSR format. The `lil_matrix` format is row-based, so conversion to CSR is efficient, whereas conversion to CSC is less so.

All conversions among the CSR, CSC, and COO formats are efficient, linear-time operations.
Matrix vector product

To do a vector product between a sparse matrix and a vector simply use the matrix \texttt{dot} method, as described in its docstring:

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

**Warning:** As of NumPy 1.7, \texttt{np.dot} is not aware of sparse matrices, therefore using it will result on unexpected results or errors. The corresponding dense array should be obtained first instead:

```python
>>> np.dot(A.toarray(), v)
array([ 1, -3, -1], dtype=int64)
```

but then all the performance advantages would be lost.

The CSR format is specially suitable for fast matrix vector products.

**Example 1**

Construct a 1000x1000 \texttt{lil_matrix} and add some values to it:

```python
>>> from scipy.sparse import lil_matrix
>>> from scipy.sparse.linalg import spsolve
>>> from numpy.linalg import solve, norm
>>> from numpy.random import rand

>>> A = lil_matrix((1000, 1000))
>>> A[0, :100] = rand(100)
>>> A[1, 100:200] = A[0, :100]
>>> A.setdiag(rand(1000))
```

Now convert it to CSR format and solve \( A \times b = x \) for \( x \):

```python
>>> A = A.tocsr()
>>> b = rand(1000)
>>> x = spsolve(A, b)
```

Convert it to a dense matrix and solve, and check that the result is the same:

```python
>>> x_ = solve(A.toarray(), b)
```

Now we can compute norm of the error with:

```python
>>> err = norm(x-x_)
>>> err < 1e-10
True
```

It should be small :)
Example 2

Construct a matrix in COO format:

```python
>>> from scipy import sparse
>>> from numpy import array

>>> I = array([0,3,1,0])
>>> J = array([0,3,1,2])
>>> V = array([4,5,7,9])
>>> A = sparse.coo_matrix((V,(I,J)),shape=(4,4))
```

Notice that the indices do not need to be sorted.

Duplicate (i,j) entries are summed when converting to CSR or CSC.

```python
>>> I = array([0,0,1,3,1,0])
>>> J = array([0,2,1,3,1,0])
>>> V = array([1,1,1,1,1,1])
>>> B = sparse.coo_matrix((V,(I,J)),shape=(4,4)).tocsr()
```

This is useful for constructing finite-element stiffness and mass matrices.

Further details

CSR column indices are not necessarily sorted. Likewise for CSC row indices. Use the .sorted_indices() and .sort_indices() methods when sorted indices are required (e.g., when passing data to other libraries).

3.3.23 Sparse linear algebra (scipy.sparse.linalg)

Abstract linear operators

```python
LinearOperator(*args, **kwargs)  Common interface for performing matrix vector products
```

```python
aslinearoperator(A)  Return A as a LinearOperator.
```

Scipy.sparse.linalg.LinearOperator

```python
class scipy.sparse.linalg.LinearOperator(*args, **kwargs)

Common interface for performing matrix vector products
```

Many iterative methods (e.g. cg, gmres) do not need to know the individual entries of a matrix to solve a linear system A*x=b. Such solvers only require the computation of matrix vector products, A*v where v is a dense vector. This class serves as an abstract interface between iterative solvers and matrix-like objects.

To construct a concrete LinearOperator, either pass appropriate callable objects to the constructor of this class, or subclass it.

A subclass must implement either one of the methods _matvec and _matmat, and the attributes/properties shape (pair of integers) and dtype (may be None). It may call the __init__ on this class to have these attributes validated. Implementing _matvec automatically implements _matmat (using a naive algorithm) and vice-versa.

Optionally, a subclass may implement _rmatvec or _adjoint to implement the Hermitian adjoint (conjugate transpose). As with _matvec and _matmat, implementing either _rmatvec or _adjoint implements the other automatically. Implementing _adjoint is preferable; _rmatvec is mostly there for backwards compatibility.

Parameters
shape [tuple] Matrix dimensions (M, N).
matvec [callable f(v)] Returns returns A * v.
rmatvec [callable f(v)] Returns A^H * v, where A^H is the conjugate transpose of A.
matmat [callable f(V)] Returns A * V, where V is a dense matrix with dimensions (N, K).
dtype [dtype] Data type of the matrix.
rmatmat [callable f(V)] Returns A^H * V, where V is a dense matrix with dimensions (M, K).

See also:

aslinearoperator

Construct LinearOperators

Notes

The user-defined matvec() function must properly handle the case where v has shape (N,) as well as the (N,1) case. The shape of the return type is handled internally by LinearOperator.

LinearOperator instances can also be multiplied, added with each other and exponentiated, all lazily: the result of these operations is always a new, composite LinearOperator, that defers linear operations to the original operators and combines the results.

More details regarding how to subclass a LinearOperator and several examples of concrete LinearOperator instances can be found in the external project PyLops.

Examples

```python
>>> import numpy as np
>>> from scipy.sparse.linalg import LinearOperator
>>> def mv(v):
...     return np.array([2*v[0], 3*v[1]])
...
>>> A = LinearOperator((2,2), matvec=mv)
>>> A
<2x2 _CustomLinearOperator with dtype=float64>
>>> A.matvec(np.ones(2))
array([2., 3.])
>>> A * np.ones(2)
array([2., 3.])
```

Attributes

args [tuple] For linear operators describing products etc. of other linear operators, the operands of the binary operation.
ndim [int] Number of dimensions (this is always 2)
Methods

```python
__call__(x) Call self as a function.
adjoint() Hermitian adjoint.
dot(x) Matrix-matrix or matrix-vector multiplication.
matmat(X) Matrix-matrix multiplication.
matvec(x) Matrix-vector multiplication.
rmatmat(X) Adjoint matrix-matrix multiplication.
rmatvec(x) Adjoint matrix-vector multiplication.
transpose() Transpose this linear operator.
```

```python
scipy.sparse.linalg.LinearOperator.__call__

LinearOperator.__call__(x)
Call self as a function.
```

```python
scipy.sparse.linalg.LinearOperator.adjoint

LinearOperator.adjoint()
Hermitian adjoint.

Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex
matrix, the Hermitian adjoint is equal to the conjugate transpose.

Can be abbreviated self.H instead of self.adjoint().

Returns

```

```python
scipy.sparse.linalg.LinearOperator.dot

LinearOperator.dot(x)
Matrix-matrix or matrix-vector multiplication.

Parameters

x [array_like] 1-d or 2-d array, representing a vector or matrix.

Returns

Ax [array] 1-d or 2-d array (depending on the shape of x) that represents the result of applying
this linear operator on x.
```
**scipy.sparse.linalg.LinearOperator.matmat**

LinearOperator.matmat(X)
Matrix-matrix multiplication.

Performs the operation y = A * X where A is an MxN linear operator and X dense N*K matrix or ndarray.

**Parameters**

X  
[[matrix, ndarray]] An array with shape (N,K).

**Returns**

Y  
[[matrix, ndarray]] A matrix or ndarray with shape (M,K) depending on the type of the X argument.

**Notes**

This matmat wraps any user-specified matmat routine or overridden _matmat method to ensure that y has the correct type.

**scipy.sparse.linalg.LinearOperator.matvec**

LinearOperator.matvec(x)
Matrix-vector multiplication.

Performs the operation y = A * x where A is an MxN linear operator and x is a column vector or 1-d array.

**Parameters**

x  
[[matrix, ndarray]] An array with shape (N,) or (N,1).

**Returns**

y  
[[matrix, ndarray]] A matrix or ndarray with shape (M,) or (M,1) depending on the type and shape of the x argument.

**Notes**

This matvec wraps the user-specified matvec routine or overridden _matvec method to ensure that y has the correct shape and type.

**scipy.sparse.linalg.LinearOperator.rmatmat**

LinearOperator.rmatmat(X)
Adjoint matrix-matrix multiplication.

Performs the operation y = A^H * x where A is an MxN linear operator and x is a column vector or 1-d array, or 2-d array. The default implementation defers to the adjoint.

**Parameters**

X  
[[matrix, ndarray]] A matrix or 2D array.

**Returns**

Y  
[[matrix, ndarray]] A matrix or 2D array depending on the type of the input.
Notes

This rmatmat wraps the user-specified rmatmat routine.

**scipy.sparse.linalg.LinearOperator.rmatvec**

`LinearOperator.rmatvec(x)`

Adjoint matrix-vector multiplication.

Performs the operation $y = A^H \times x$ where $A$ is an $M \times N$ linear operator and $x$ is a column vector or 1-d array.

**Parameters**

- `x`  
  [array_like] An array with shape `(M,)` or `(M,1)`.

**Returns**

- `y`  
  [array_like] A matrix or ndarray with shape `(N,)` or `(N,1)` depending on the type and shape of the `x` argument.

Notes

This rmatvec wraps the user-specified rmatvec routine or overridden _rmatvec method to ensure that $y$ has the correct shape and type.

**scipy.sparse.linalg.LinearOperator.transpose**

`LinearOperator.transpose()`

Transpose this linear operator.

Returns a `LinearOperator` that represents the transpose of this one. Can be abbreviated `self.T` instead of `self.transpose()`.

**scipy.sparse.linalg.aslinearoperator**

`scipy.sparse.linalg.aslinearoperator(A)`

Return $A$ as a `LinearOperator`.

‘$A$ may be any of the following types:

- ndarray
- matrix
- sparse matrix (e.g. csr_matrix, lil_matrix, etc.)
- LinearOperator
- An object with .shape and .matvec attributes

See the `LinearOperator` documentation for additional information.
Notes

If `A` has no `.dtype` attribute, the data type is determined by calling `LinearOperator.matvec` - set the `.dtype` attribute to prevent this call upon the linear operator creation.

Examples

```python
>>> from scipy.sparse.linalg import aslinearoperator
>>> M = np.array([[1, 2], [4, 5]], dtype=np.int32)
>>> aslinearoperator(M)
<2x3 MatrixLinearOperator with dtype=int32>
```

Matrix Operations

<table>
<thead>
<tr>
<th>inv(A)</th>
<th>Compute the inverse of a sparse matrix</th>
</tr>
</thead>
<tbody>
<tr>
<td>expm(A)</td>
<td>Compute the matrix exponential using Pade approximation</td>
</tr>
<tr>
<td>expm_multiply(A, B[, start, stop, num, endpoint])</td>
<td>Compute the action of the matrix exponential of A on B</td>
</tr>
</tbody>
</table>

scipy.sparse.linalg.inv

`scipy.sparse.linalg.inv(A)`
Compute the inverse of a sparse matrix

Parameters

- `A` [(M, M) sparse matrix] square matrix to be inverted

Returns

- `Ainv` [(M, M) sparse matrix] inverse of `A`

Notes

This computes the sparse inverse of `A`. If the inverse of `A` is expected to be non-sparse, it will likely be faster to convert `A` to dense and use `scipy.linalg.inv`.

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import inv
>>> A = csc_matrix([[1., 0.], [1., 2.]])
>>> Ainv = inv(A)
>>> Ainv
<2x2 sparse matrix of type '<class 'numpy.float64'>'
    with 3 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv)
<2x2 sparse matrix of type '<class 'numpy.float64'>'
    with 2 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv).toarray()
```
(continues on next page)
array([[ 1.,  0.],
       [ 0.,  1.]])

New in version 0.12.0.

**scipy.sparse.linalg.expm**

`scipy.sparse.linalg.expm(A)`

Compute the matrix exponential using Pade approximation.

**Parameters**

- A  
  [(M,M) array_like or sparse matrix] 2D Array or Matrix (sparse or dense) to be exponentiated

**Returns**

- expA  
  [(M,M) ndarray] Matrix exponential of A

**Notes**

This is algorithm (6.1) which is a simplification of algorithm (5.1).

New in version 0.12.0.

**References**

[1]

**Examples**

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import expm
>>> A = csc_matrix([[1, 0, 0],
                 [0, 2, 0],
                 [0, 0, 3]])
>>> A.todense()
array([[ 1.,  0.,  0.],
       [ 0.,  2.,  0.],
       [ 0.,  0.,  3.]], dtype=int64)
>>> Aexpm = expm(A)
>>> Aexpm
<3x3 sparse matrix of type '<class 'numpy.float64'>'
 with 3 stored elements in Compressed Sparse Column format>
>>> Aexpm.todense()
array([[ 2.71828183,  0.,         ,  0.        ],
       [ 0.        ,  7.3890561 ,  0.        ],
       [ 0.        ,  0.        , 20.08553692]])
```
scipy.sparse.linalg.expm_multiply

scipy.sparse.linalg.expm_multiply(A, B, start=None, stop=None, num=None, endpoint=None)

Compute the action of the matrix exponential of A on B.

Parameters

- **A** [transposable linear operator] The operator whose exponential is of interest.
- **B** [ndarray] The matrix or vector to be multiplied by the matrix exponential of A.
- **start** [scalar, optional] The starting time point of the sequence.
- **stop** [scalar, optional] The end time point of the sequence, unless endpoint is set to False. In that case, the sequence consists of all but the last of num + 1 evenly spaced time points, so that stop is excluded. Note that the step size changes when endpoint is False.
- **num** [int, optional] Number of time points to use.
- **endpoint** [bool, optional] If True, stop is the last time point. Otherwise, it is not included.

Returns

- **expm_A_B** [ndarray] The result of the action \(e^{t_i} A B\).

Notes

The optional arguments defining the sequence of evenly spaced time points are compatible with the arguments of numpy.linspace.

The output ndarray shape is somewhat complicated so I explain it here. The ndim of the output could be either 1, 2, or 3. It would be 1 if you are computing the expm action on a single vector at a single time point. It would be 2 if you are computing the expm action on a vector at multiple time points, or if you are computing the expm action on a matrix at a single time point. It would be 3 if you want the action on a matrix with multiple columns at multiple time points. If multiple time points are requested, expm_A_B[0] will always be the action of the expm at the first time point, regardless of whether the action is on a vector or a matrix.

References

[1], [2]

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import expm, expm_multiply

>>> A = csc_matrix([[1, 0], [0, 1]])
>>> A.toarray()
array([[1, 0],
       [0, 1]], dtype=int64)

>>> B = np.array([np.exp(-1.), np.exp(-2.)])

>>> expm_multiply(A, B, start=1, stop=2, num=3, endpoint=True)
array([[ 1. , 0.36787944],
       [ 1.64872127, 0.60653066],
       [ 2.71828183, 1. ]])

>>> expm(A).dot(B)  # Verify 1st timestep
```

(continues on next page)
Matrix norms

$$\text{norm}(x[, \text{ord}, \text{axis}])$$  Norm of a sparse matrix

$$\text{onenormest}(A[, t, \text{itmax}, \text{compute}_v, \text{compute}_w])$$  Compute a lower bound of the 1-norm of a sparse matrix.

**scipy.sparse.linalg.norm**

```python
scipy.sparse.linalg.norm (x, ord=None, axis=None)
```
Norm of a sparse matrix

This function is able to return one of seven different matrix norms, depending on the value of the `ord` parameter.

**Parameters**

- `x`  
  [a sparse matrix] Input sparse matrix.

- `ord`  
  [{non-zero int, inf, -inf, 'fro'}, optional] Order of the norm (see table under Notes). `inf` means numpy's `inf` object.

- `axis`  
  [{int, 2-tuple of ints, None}, optional] If `axis` is an integer, it specifies the axis of `x` along which to compute the vector norms. If `axis` is a 2-tuple, it specifies the axes that hold 2-D matrices, and the matrix norms of these matrices are computed. If `axis` is None then either a vector norm (when `x` is 1-D) or a matrix norm (when `x` is 2-D) is returned.

**Returns**

- `n`  
  [float or ndarray]

**Notes**

Some of the `ord` are not implemented because some associated functions like, `_multi_svd_norm`, are not yet available for sparse matrix.

This docstring is modified based on numpy.linalg.norm.  https://github.com/numpy/numpy/blob/master/numpy/linalg/linalg.py

The following norms can be calculated:

<table>
<thead>
<tr>
<th>ord</th>
<th>norm for sparse matrices</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Frobenius norm</td>
</tr>
<tr>
<td>'fro'</td>
<td>Frobenius norm</td>
</tr>
<tr>
<td>inf</td>
<td>max(sum(abs(x), axis=1))</td>
</tr>
<tr>
<td>-inf</td>
<td>min(sum(abs(x), axis=1))</td>
</tr>
<tr>
<td>0</td>
<td>abs(x).sum(axis=axis)</td>
</tr>
<tr>
<td>1</td>
<td>max(sum(abs(x), axis=0))</td>
</tr>
<tr>
<td>-1</td>
<td>min(sum(abs(x), axis=0))</td>
</tr>
<tr>
<td>-2</td>
<td>Not implemented</td>
</tr>
<tr>
<td>other</td>
<td>Not implemented</td>
</tr>
</tbody>
</table>
The Frobenius norm is given by [1]:

$$\|A\|_F = \left(\sum_{i,j} |a_{i,j}|^2\right)^{1/2}$$

References

[1]

Examples

```python
>>> from scipy.sparse import *
>>> import numpy as np
>>> from scipy.sparse.linalg import norm
>>> a = np.arange(9) - 4
>>> a
array([-4, -3, -2, -1, 0, 1, 2, 3, 4])
>>> b = a.reshape((3, 3))
>>> b
array([[-4, -3, -2],
       [-1, 0, 1],
       [ 2, 3, 4]])
```

```python
>>> b = csr_matrix(b)
>>> norm(b)
7.745966692414834
>>> norm(b, 'fro')
7.745966692414834
>>> norm(b, np.inf)
9
>>> norm(b, -np.inf)
2
>>> norm(b, 1)
7
>>> norm(b, -1)
6
```

**scipy.sparse.linalg.onenormest**

*scipy.sparse.linalg.onenormest*(A, t=2, itmax=5, compute_v=False, compute_w=False)  
Compute a lower bound of the 1-norm of a sparse matrix.

**Parameters**

- A: [ndarray or other linear operator] A linear operator that can be transposed and that can produce matrix products.
- t: [int, optional] A positive parameter controlling the tradeoff between accuracy versus time and memory usage. Larger values take longer and use more memory but give more accurate output.
- itmax: [int, optional] Use at most this many iterations.
- compute_v: [bool, optional] Request a norm-maximizing linear operator input vector if True.
- compute_w: [bool, optional] Request a norm-maximizing linear operator output vector if True.
Returns

- **est** [float] An underestimate of the 1-norm of the sparse matrix.
- **v** [ndarray, optional] The vector such that \|Av\|_1 == est*\|v\|_1. It can be thought of as an input to the linear operator that gives an output with particularly large norm.
- **w** [ndarray, optional] The vector Av which has relatively large 1-norm. It can be thought of as an output of the linear operator that is relatively large in norm compared to the input.

Notes

This is algorithm 2.4 of [1].

In [2] it is described as follows. “This algorithm typically requires the evaluation of about 4t matrix-vector products and almost invariably produces a norm estimate (which is, in fact, a lower bound on the norm) correct to within a factor 3.”

New in version 0.13.0.

References

[1], [2]

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import onenormest
>>> A = csc_matrix([[1., 0., 0.], [5., 8., 2.], [0., -1., 0.]],
                   dtype=float)
>>> A.toarray()
array([[ 1., 0., 0.],
       [ 5., 8., 2.],
       [ 0., -1., 0.]])
>>> onenormest(A)
9.0
>>> np.linalg.norm(A.toarray(), ord=1)
9.0
```

Solving linear problems

Direct methods for linear equation systems:

- **spsolve(A, b[, permc_spec, use_umfpack])** Solve the sparse linear system Ax=b, where b may be a vector or a matrix.
- **spsolve_triangular(A, b[, lower,...])** Solve the equation \( A x = b \) for \( x \), assuming \( A \) is a triangular matrix.
- **factorized(A)** Return a function for solving a sparse linear system, with A pre-factorized.
- **MatrixRankWarning**
- **use_solver(**k**wargs)** Select default sparse direct solver to be used.
scipy.sparse.linalg.spsolve

scipy.sparse.linalg.spsolve(A, b, permc_spec=None, use_umfpack=True)

Solve the sparse linear system $Ax=b$, where $b$ may be a vector or a matrix.

**Parameters**

- **A** [ndarray or sparse matrix] The square matrix $A$ will be converted into CSC or CSR form
- **b** [ndarray or sparse matrix] The matrix or vector representing the right hand side of the equation. If a vector, $b$.shape must be (n,) or (n, 1).
- **permc_spec** [str, optional] How to permute the columns of the matrix for sparsity preservation. (default: 'COLAMD')
  - NATURAL: natural ordering.
  - MMD_ATA: minimum degree ordering on the structure of $A^T A$.
  - MMD_AT_PLUS_A: minimum degree ordering on the structure of $A^T+A$.
  - COLAMD: approximate minimum degree column ordering
- **use_umfpack** [bool, optional] if True (default) then use umfpack for the solution. This is only referenced if $b$ is a vector and scikit-umfpack is installed.

**Returns**

- **x** [ndarray or sparse matrix] the solution of the sparse linear equation. If $b$ is a vector, then $x$ is a vector of size $A$.shape[1] If $b$ is a matrix, then $x$ is a matrix of size $(A$.shape[1], $b$.shape[1])

**Notes**

For solving the matrix expression $AX = B$, this solver assumes the resulting matrix $X$ is sparse, as is often the case for very sparse inputs. If the resulting $X$ is dense, the construction of this sparse result will be relatively expensive. In that case, consider converting $A$ to a dense matrix and using scipy.linalg.solve or its variants.

**Examples**

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spsolve
>>> A = csc_matrix(([3, 2, 0], [1, -1, 0], [0, 5, 1]), dtype=float)
>>> B = csc_matrix(([2, 0], [-1, 0], [2, 0]), dtype=float)
>>> x = spsolve(A, B)
>>> np.allclose(A.dot(x).toarray(), B.toarray())
True
```

scipy.sparse.linalg.spsolve_triangular

scipy.sparse.linalg.spsolve_triangular(A, b, lower=True, overwrite_A=False, overwrite_b=False, unit_diagonal=False)

Solve the equation $A x = b$ for $x$, assuming $A$ is a triangular matrix.

**Parameters**

- **A** [(M, M) sparse matrix] A sparse square triangular matrix. Should be in CSR format.
- **b** [(M, ) or (M, N) array_like] Right-hand side matrix in $A x = b$
- **lower** [bool, optional] Whether $A$ is a lower or upper triangular matrix. Default is lower triangular matrix.
overwrite_A
[bool, optional] Allow changing A. The indices of A are going to be sorted and zero entries are going to be removed. Enabling gives a performance gain. Default is False.

overwrite_b
[bool, optional] Allow overwriting data in b. Enabling gives a performance gain. Default is False. If overwrite_b is True, it should be ensured that b has an appropriate dtype to be able to store the result.

unit_diagonal
[bool, optional] If True, diagonal elements of a are assumed to be 1 and will not be referenced. New in version 1.4.0.

Returns
x [(M,) or (M, N) ndarray] Solution to the system A x = b. Shape of return matches shape of b.

Raises
LinAlgError
If A is singular or not triangular.

ValueError
If shape of A or shape of b do not match the requirements.

Notes
New in version 0.19.0.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.linalg import spsolve_triangular
>>> A = csr_matrix([[3, 0, 0], [1, -1, 0], [2, 0, 1]], dtype=float)
>>> B = np.array([[2, 0], [-1, 0], [2, 0]], dtype=float)
>>> x = spsolve_triangular(A, B)
>>> np.allclose(A.dot(x), B)
True
```

scipy.sparse.linalg.factorized

scipy.sparse.linalg.factorized(A)
Return a function for solving a sparse linear system, with A pre-factorized.

Parameters
A [(N, N) array_like] Input.

Returns
solve [callable] To solve the linear system of equations given in A, the solve callable should be passed an ndarray of shape (N,).
Examples

```python
>>> from scipy.sparse.linalg import factorized
>>> A = np.array([[3., 2., -1.],
                ...                [2., -2., 4.],
                ...                [-1., 0.5, -1.]]
>>> solve = factorized(A)  # Makes LU decomposition.
>>> rhs1 = np.array([1, -2, 0])
>>> solve(rhs1)  # Uses the LU factors.
array([ 1., -2., -2.])
```

`scipy.sparse.linalg.MatrixRankWarning` exception

```python
scipy.sparse.linalg.MatrixRankWarning

with_traceback()
```

`scipy.sparse.linalg.use_solver` function

```python
scipy.sparse.linalg.use_solver(**kwargs)
```
Select default sparse direct solver to be used.

Parameters

- **useUmfpack**
  - [bool, optional] Use UMFPACK over SuperLU. Has effect only if scikits.umfpack is installed. Default: True
- **assumeSortedIndices**
  - [bool, optional] Allow UMFPACK to skip the step of sorting indices for a CSR/CSC matrix. Has effect only if useUmfpack is True and scikits.umfpack is installed. Default: False

Notes

The default sparse solver is umfpack when available (scikits.umfpack is installed). This can be changed by passing useUmfpack = False, which then causes the always present SuperLU based solver to be used.

Umfpack requires a CSR/CSC matrix to have sorted column/row indices. If sure that the matrix fulfills this, pass assumeSortedIndices=True to gain some speed.

### scipy.sparse.linalg.bicg

**scipy.sparse.linalg.bicg** *(A, b[, x0=None, tol=1e-05, maxiter=None, M=None, callback=None, atol=None])*

Use BiConjugate Gradient iteration to solve $Ax = b$.

#### Parameters

- **A**
  - [{sparse matrix, ndarray, LinearOperator}]
  - The real or complex N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce $Ax$ and $A^T x$ using, e.g., `scipy.sparse.linalg.LinearOperator`.

- **b**
  - [ndarray]
  - Right hand side of the linear system. Has shape (N,) or (N,1).

#### Returns

- **x**
  - [ndarray]
  - The converged solution.

- **info**
  - [integer]
  - Provides convergence information:
    - 0 : successful exit
    - >0 : convergence to tolerance not achieved, number of iterations
    - <0 : illegal input or breakdown

#### Other Parameters

- **x0**
  - [ndarray]
  - Starting guess for the solution.

- **tol, atol**
  - [float, optional]
  - Tolerances for convergence, $\text{norm(residual)} \leq \max(\text{tol*norm(b)}, \text{atol})$. The default for atol is 'legacy', which emulates a different legacy behavior.

#### Warning

The default value for atol will be changed in a future release. For future compatibility, specify atol explicitly.

- **maxiter**
  - [integer]
  - Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

- **M**
  - [{sparse matrix, ndarray, LinearOperator}]
  - Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

- **callback**
  - [function]
  - User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

#### Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import bicg
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = bicg(A, b)
>>> print(exitCode)  # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```
scipy.sparse.linalg.bicgstab

Use BiConjugate Gradient STABilized iteration to solve $Ax = b$.

**Parameters**

- **A**
  - [sparse matrix, ndarray, LinearOperator] The real or complex N-by-N matrix of the linear system. Alternatively, $A$ can be a linear operator which can produce $Ax$ using, e.g., `scipy.sparse.linalg.LinearOperator`.
- **b**
  - [ndarray] Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- **x**
  - [ndarray] The converged solution.
- **info**
  - [integer]

*Provides convergence information:*

0 : successful exit
>0 : convergence to tolerance not achieved, number of iterations
<0 : illegal input or breakdown

**Other Parameters**

- **x0**
  - [ndarray] Starting guess for the solution.
- **tol, atol**
  - [float, optional] Tolerances for convergence, $\text{norm(residual)} \leq \max(\text{tol} \times \text{norm}(b), \text{atol})$. The default for atol is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for atol will be changed in a future release. For future compatibility, specify atol explicitly.

- **maxiter**
  - [integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **M**
  - [sparse matrix, ndarray, LinearOperator] Preconditioner for $A$. The preconditioner should approximate the inverse of $A$. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- **callback**
  - [function] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

scipy.sparse.linalg.cg

Use Conjugate Gradient iteration to solve $Ax = b$.

**Parameters**

- **A**
  - [sparse matrix, ndarray, LinearOperator] The real or complex N-by-N matrix of the linear system. $A$ must represent a hermitian, positive definite matrix. Alternatively, $A$ can be a linear operator which can produce $Ax$ using, e.g., `scipy.sparse.linalg.LinearOperator`.
- **b**
  - [ndarray] Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- **x**
  - [ndarray] The converged solution.
- **info**
  - [integer]

*Provides convergence information:*

0 : successful exit
>0 : convergence to tolerance not achieved, number of iterations
<0 : illegal input or breakdown
**SciPy Reference Guide, Release 1.8.0**

### Other Parameters

- **x0** ([ndarray]) Starting guess for the solution.
- **tol, atol** ([float, optional]) Tolerances for convergence, \( \text{norm(residual)} \leq \max(\text{tol} \cdot \text{norm}(b), \text{atol}) \). The default for atol is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for atol will be changed in a future release. For future compatibility, specify atol explicitly.

- **maxiter** [integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **M** ([sparse matrix, ndarray, LinearOperator]) Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- **callback** [function] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

### scipy.sparse.linalg.cgs

**scipy.sparse.linalg.cgs**

**(A, b, x0=None, tol=1e-05, maxiter=None, M=None, callback=None, atol=None)**

Use Conjugate Gradient Squared iteration to solve \( Ax = b \).

**Parameters**

- **A** ([sparse matrix, ndarray, LinearOperator]) The real-valued N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce \( Ax \) using, e.g., scipy.sparse.linalg.LinearOperator.
- **b** [ndarray] Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- **x** [ndarray] The converged solution.
- **info** [integer]

**Provides convergence information:**

- 0 : successful exit
- >0 : convergence to tolerance not achieved, number of iterations
- <0 : illegal input or breakdown

### Other Parameters

- **x0** ([ndarray]) Starting guess for the solution.
- **tol, atol** ([float, optional]) Tolerances for convergence, \( \text{norm(residual)} \leq \max(\text{tol} \cdot \text{norm}(b), \text{atol}) \). The default for atol is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for atol will be changed in a future release. For future compatibility, specify atol explicitly.

- **maxiter** [integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **M** ([sparse matrix, ndarray, LinearOperator]) Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- **callback** [function] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

---

**3.3. API definition** 1985
**scipy.sparse.linalg.gmres**

Use Generalized Minimal RESidual iteration to solve $Ax = b$.

**Parameters**

- **A**
  - \{sparse matrix, ndarray, LinearOperator\}
  - The real or complex N-by-N matrix of the linear system. Alternatively, $A$ can be a linear operator which can produce $Ax$ using, e.g., `scipy.sparse.linalg.LinearOperator`.

- **b** 
  - [ndarray]
  - Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- **x** 
  - [ndarray]
  - The converged solution.

- **info** 
  - [int]
  - Provides convergence information:
    - 0: successful exit
    - >0: convergence to tolerance not achieved, number of iterations
    - <0: illegal input or breakdown

**Other Parameters**

- **x0** 
  - [ndarray] Starting guess for the solution (a vector of zeros by default).

- **tol, atol** 
  - [float, optional]
  - Tolerances for convergence, $\text{norm(residual)} \leq \max(\text{tol} \times \text{norm(b)}, \text{atol})$. The default for atol is 'legacy', which emulates a different legacy behavior.

  **Warning**: The default value for atol will be changed in a future release. For future compatibility, specify atol explicitly.

- **restart** 
  - [int, optional]
  - Number of iterations between restarts. Larger values increase iteration cost, but may be necessary for convergence. Default is 20.

- **maxiter** 
  - [int, optional]
  - Maximum number of iterations (restart cycles). Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

- **M** 
  - \{sparse matrix, ndarray, LinearOperator\]
  - Inverse of the preconditioner of $A$. $M$ should approximate the inverse of $A$ and be easy to solve for (see Notes). Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance. By default, no preconditioner is used.

- **callback** 
  - [function]
  - User-supplied function to call after each iteration. It is called as `callback(args)`, where `args` are selected by `callback_type`.

- **callback_type** 
  - [\{'x', 'pr_norm', 'legacy'\}, optional]
  - Callback function argument requested:
    - `x`: current iterate (ndarray), called on every restart
    - `pr_norm`: relative (preconditioned) residual norm (float), called on every inner iteration
    - `legacy` (default): same as `pr_norm`, but also changes the meaning of 'maxiter' to count inner iterations instead of restart cycles.

- **restr** 
  - [int, optional]
  - DEPRECATED - use restart instead.

**See also:**

- `LinearOperator`
Notes

A preconditioner, \(P\), is chosen such that \(P\) is close to \(A\) but easy to solve for. The preconditioner parameter required by this routine is \(M = P^{-1}\). The inverse should preferably not be calculated explicitly. Rather, use the following template to produce \(M\):

```python
# Construct a linear operator that computes \(P^{-1} @ x\).
import scipy.sparse.linalg as spla
M_x = lambda x: spla.spsolve(P, x)
M = spla.LinearOperator((n, n), M_x)
```

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import gmres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = gmres(A, b)
>>> print(exitCode)  # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

**scipy.sparse.linalg.lgmres**

The LGMRES algorithm \([1] [2]\) is designed to avoid some problems in the convergence in restarted GMRES, and often converges in fewer iterations.

**Parameters**

- **A** ([sparse matrix, ndarray, LinearOperator]) The real or complex N-by-N matrix of the linear system. Alternatively, \(A\) can be a linear operator which can produce \(Ax\) using, e.g., `scipy.sparse.linalg.LinearOperator`.
- **b** ([ndarray]) Right hand side of the linear system. Has shape \((N,)\) or \((N,1)\).
- **x0** ([ndarray]) Starting guess for the solution.
- **tol, atol** ([float, optional]) Tolerances for convergence, \(\|\text{residual}\| \leq \text{max}(\text{tol} \times \|b\|, \text{atol})\). The default for atol is tol.
- **maxiter** ([int, optional]) Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **M** ([sparse matrix, ndarray, LinearOperator], optional) Preconditioner for \(A\). The preconditioner should approximate the inverse of \(A\). Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- **callback** ([function, optional]) User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

**Warning:** The default value for atol will be changed in a future release. For future compatibility, specify atol explicitly.
inner_m  [int, optional] Number of inner GMRES iterations per each outer iteration.
outer_k  [int, optional] Number of vectors to carry between inner GMRES iterations. According to [1], good values are in the range of 1…3. However, note that if you want to use the additional vectors to accelerate solving multiple similar problems, larger values may be beneficial.
outer_v  [list of tuples, optional] List containing tuples (v, A*v) of vectors and corresponding matrix-vector products, used to augment the Krylov subspace, and carried between inner GMRES iterations. The element A*v can be None if the matrix-vector product should be re-evaluated. This parameter is modified in-place by lgmres, and can be used to pass “guess” vectors in and out of the algorithm when solving similar problems.
store_outer_Av  [bool, optional] Whether LGMRES should store also A*v in addition to vectors v in the outer_v list. Default is True.

Returns

- x  [ndarray] The converged solution.
- info  [int] Provides convergence information:
  - 0: successful exit
  - >0: convergence to tolerance not achieved, number of iterations
  - <0: illegal input or breakdown

Notes

The LGMRES algorithm [1] [2] is designed to avoid the slowing of convergence in restarted GMRES, due to alternating residual vectors. Typically, it often outperforms GMRES(m) of comparable memory requirements by some measure, or at least is not much worse.

Another advantage in this algorithm is that you can supply it with ‘guess’ vectors in the outer_v argument that augment the Krylov subspace. If the solution lies close to the span of these vectors, the algorithm converges faster. This can be useful if several very similar matrices need to be inverted one after another, such as in Newton-Krylov iteration where the Jacobian matrix often changes little in the nonlinear steps.

[1], [2]

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lgmres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = lgmres(A, b)
>>> print(exitCode)  # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```
**scipy.sparse.linalg.minres**

**scipy.sparse.linalg.minres** *(A, b, x0=None, shift=0.0, tol=1e-05, maxiter=None, M=None, callback=None, show=False, check=False)*

Use MINimum RESidual iteration to solve Ax=b

MINRES minimizes norm(Ax - b) for a real symmetric matrix A. Unlike the Conjugate Gradient method, A can be indefinite or singular.

If shift != 0 then the method solves (A - shift*I)x = b

**Parameters**

- **A** ([sparse matrix, ndarray, LinearOperator]) The real symmetric N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce Ax using, e.g., `scipy.sparse.linalg.LinearOperator`.
- **b** ([ndarray]) Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- **x** ([ndarray]) The converged solution.
- **info** ([integer]) Provides convergence information:
  - 0 : successful exit
  - >0 : convergence to tolerance not achieved, number of iterations
  - <0 : illegal input or breakdown

**Other Parameters**

- **x0** ([ndarray]) Starting guess for the solution.
- **shift** ([float]) Value to apply to the system (A - shift * I)x = b. Default is 0.
- **tol** ([float]) Tolerance to achieve. The algorithm terminates when the relative residual is below tol.
- **maxiter** ([integer]) Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **M** ([sparse matrix, ndarray, LinearOperator]) Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- **callback** ([function]) User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.
- **show** ([bool]) If True, print out a summary and metrics related to the solution during iterations. Default is False.
- **check** ([bool]) If True, run additional input validation to check that A and M (if specified) are symmetric. Default is False.

```

**scipy.sparse.linalg.qmr**

scipy.sparse.linalg.qmr(A, b, x0=None, tol=1e-05, maxiter=None, M1=None, M2=None, callback=None, atol=None)

Use Quasi-Minimal Residual iteration to solve $Ax = b$.

**Parameters**

- **A**  
  [{sparse matrix, ndarray, LinearOperator}] The real-valued N-by-N matrix of the linear system. Alternatively, $A$ can be a linear operator which can produce $Ax$ and $A^T x$ using, e.g. `scipy.sparse.linalg.LinearOperator`.

- **b**  
  [ndarray] Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- **x**  
  [ndarray] The converged solution.

- **info**  
  [integer] Provides convergence information:
  
  - 0: successful exit
  - >0: convergence to tolerance not achieved, number of iterations
  - <0: illegal input or breakdown

**Other Parameters**

- **x0**  
  [ndarray] Starting guess for the solution.

- **tol, atol**  
  [float, optional] Tolerances for convergence, $\text{norm(residual)} \leq \max(\text{tol} \cdot \text{norm(b)}, \text{atol})$. The default for atol is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for atol will be changed in a future release. For future compatibility, specify atol explicitly.

- **maxiter**  
  [integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

- **M1, M2**  
  [{sparse matrix, ndarray, LinearOperator}] Left preconditioner for $A$.

- **callback**  
  [function] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

**See also:**

LinearOperator
Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import qmr
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = qmr(A, b)
>>> print(exitCode)  # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

**scipy.sparse.linalg.gcrqtm**

Solve a matrix equation using flexible GCROT(m,k) algorithm.

Parameters

- **A** [{sparse matrix, ndarray, LinearOperator}] The real or complex N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce A x using, e.g., scipy.sparse.linalg.LinearOperator.
- **b** [ndarray] Right hand side of the linear system. Has shape (N,) or (N,1).
- **x0** [ndarray] Starting guess for the solution.
- **tol, atol** [float, optional] Tolerances for convergence, norm(residual) <= max(tol*norm(b), atol). The default for atol is tol.

**Warning:** The default value for atol will be changed in a future release. For future compatibility, specify atol explicitly.

- **maxiter** [int, optional] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **M** [{sparse matrix, ndarray, LinearOperator}, optional] Preconditioner for A. The preconditioner should approximate the inverse of A. gcrqtm is a ‘flexible’ algorithm and the preconditioner can vary from iteration to iteration. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- **callback** [function, optional] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.
- **m** [int, optional] Number of inner FGMRES iterations per each outer iteration. Default: 20
- **k** [int, optional] Number of vectors to carry between inner FGMRES iterations. According to [2], good values are around m. Default: m
- **CU** [list of tuples, optional] List of tuples (c, u) which contain the columns of the matrices C and U in the GCROT(m,k) algorithm. For details, see [2]. The list given and vectors contained in it are modified in-place. If not given, start from empty matrices. The c elements in the tuples can be None, in which case the vectors are recomputed via c = A u on start and orthogonalized as described in [3].
- **discard_C** [bool, optional] Discard the C-vectors at the end. Useful if recycling Krylov subspaces for different linear systems.

Returns
x       [ndarray] The solution found.
info    [int] Provides convergence information:
        • 0: successful exit
        • >0: convergence to tolerance not achieved, number of iterations

References

[1], [2], [3]

scipy.sparse.linalg.tfqmr

scipy.sparse.linalg.tfqmr(A, b, x0=None, tol=1e-05, maxiter=None, M=None, callback=None, atol=None, show=False)

Use Transpose-Free Quasi-Minimal Residual iteration to solve \( Ax = b \).

Parameters

A        [[sparse matrix, ndarray, LinearOperator]] The real or complex N-by-N matrix of the linear system. Alternatively, \( A \) can be a linear operator which can produce \( Ax \) using, e.g., scipy.sparse.linalg.LinearOperator.
b        [[ndarray]] Right hand side of the linear system. Has shape \((N,)\) or \((N,1)\).
x0       [[ndarray]] Starting guess for the solution.
tol, atol [float, optional] Tolerances for convergence, \( \| Ax - b \| \leq \max(\text{tol} \times \| b \|, \text{atol}) \). The default for \( \text{tol} \) is 1.0e-5. The default for \( \text{atol} \) is \( 10^{-6} \times \| b \| \). Warning: The default value for \( \text{atol} \) will be changed in a future release. For future compatibility, specify \( \text{atol} \) explicitly.
maxiter  [int, optional] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved. Default is \( \min(10000, \text{ndofs} \times 10) \), where \text{ndofs} = \( A \).shape[0].
M        [[sparse matrix, ndarray, LinearOperator]] Inverse of the preconditioner of \( A \). \( M \) should approximate the inverse of \( A \) and be easy to solve for (see Notes). Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance. By default, no preconditioner is used.
callback [function, optional] User-supplied function to call after each iteration. It is called as \( \text{callback}(xk) \), where \( xk \) is the current solution vector.
show     [bool, optional] Specify \( \text{show} = \text{True} \) to show the convergence, \( \text{show} = \text{False} \) to close the output of the convergence. Default is \( \text{False} \).

Returns

x        [ndarray] The converged solution.
info     [int] Provides convergence information:
        • 0 : successful exit
        • >0 : convergence to tolerance not achieved, number of iterations
        • <0 : illegal input or breakdown
Notes

The Transpose-Free QMR algorithm is derived from the CGS algorithm. However, unlike CGS, the convergence curves for the TFQMR method is smoothed by computing a quasi minimization of the residual norm. The implementation supports left preconditioner, and the “residual norm” to compute in convergence criterion is actually an upper bound on the actual residual norm $||b - Ax_k||$.

References

[1], [2], [3]

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import tfqmr
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = tfqmr(A, b)
>>> print(exitCode)  # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

Iterative methods for least-squares problems:

```python
scipy.sparse.linalg.lsmr
```

The functions solves $Ax = b$ or $\min ||Ax - b||^2$ or $\min ||Ax - b||^2 + d^2 ||x - x_0||^2$.

Parameters

- $A$ [{sparse matrix, ndarray, LinearOperator}] Representation of an m-by-n matrix. Alternatively, $A$ can be a linear operator which can produce $Ax$ and $A^T x$ using, e.g., `scipy.sparse.linalg.LinearOperator`. 

3.3. API definition 1993

b [array_like, shape (m,)] Right-hand side vector b.
damp [float] Damping coefficient. Default is 0.
atol, btol [float, optional] Stopping tolerances. \( \text{lsqr} \) continues iterations until a certain backward error estimate is smaller than some quantity depending on atol and btol. Let \( r = b - Ax \) be the residual vector for the current approximate solution \( x \). If \( Ax = b \) seems to be consistent, \( \text{lsqr} \) terminates when \( \text{norm}(r) <\) atol * norm(A) * norm(x) + btol * norm(b). Otherwise, \( \text{lsqr} \) terminates when \( \text{norm}(A^H r) <\) atol * norm(A) * norm(r). If both tolerances are 1.0e-6 (default), the final \( \text{norm}(r) \) should be accurate to about 6 digits. (The final \( x \) will usually have fewer correct digits, depending on \text{cond}(A) \) and the size of LAMBDA.) If \( \text{atol or btol} \) is None, a default value of 1.0e-6 will be used. Ideally, they should be estimates of the relative error in the entries of \( A \) and \( b \) respectively. For example, if the entries of \( A \) have 7 correct digits, set \( \text{atol} = 1e-7 \). This prevents the algorithm from doing unnecessary work beyond the uncertainty of the input data.

conlim [float, optional] Another stopping tolerance. \( \text{lsqr} \) terminates if an estimate of \( \text{cond}(A) \) exceeds conlim. For compatible systems \( Ax = b \), conlim could be as large as 1.0e+12 (say). For least-squares problems, conlim should be less than 1.0e+8. Maximum precision can be obtained by setting \( \text{atol = btol = conlim = zero} \). For least-squares problems, conlim should be less than 1.0e+8. Maximumprecision can be obtained by setting \( \text{atol = btol = conlim = zero} \), but the number of iterations may then be excessive. Default is 1e8.

iter_lim [int, optional] Explicit limitation on number of iterations (for safety).
show [bool, optional] Display an iteration log. Default is False.
calc_var [bool, optional] Whether to estimate diagonals of \((A'A + \text{damp}^2I)^{-1}\). x0 [array_like, shape (n,), optional] Initial guess of \( x \), if None zeros are used. Default is None. New in version 1.0.0.

Returns

- \( x \) [ndarray of float] The final solution.
- istop [int] Gives the reason for termination. 1 means \( x \) is an approximate solution to \( Ax = b \). 2 means \( x \) approximately solves the least-squares problem.
- itn [int] Iteration number upon termination.
- r1norm [float] \( \text{norm}(r) \), where \( r = b - Ax \).
- r2norm [float] \( \sqrt{\text{norm}(r)^2 + \text{damp}^2 \text{norm}(x - x0)^2} \). Equal to \( r1norm \) if damp == 0.
- anorm [float] Estimate of Frobenius norm of \( Abar = [ [A]; [\text{damp}^2I] ] \).
- acond [float] Estimate of \( \text{cond}(Abar) \).
- arnorm [float] Estimate of \( \text{norm}(A'^H r - \text{damp}^2(x - x0))^2 \).
- xnorm [float] \( \text{norm}(x) \).
- var [ndarray of float] If \( \text{calc_var} \) is True, estimates all diagonals of \((A'A)^{-1}\) (if damp == 0) or more generally \((A'A + \text{damp}^2I)^{-1}\). This is well defined if \( A \) has full column rank or damp > 0. (Not sure what var means if rank(A) < n and damp = 0.)

Notes

\( \text{LSQR} \) uses an iterative method to approximate the solution. The number of iterations required to reach a certain accuracy depends strongly on the scaling of the problem. Poor scaling of the rows or columns of \( A \) should therefore be avoided where possible.

For example, in problem 1 the solution is unaltered by row-scaling. If a row of \( A \) is very small or large compared to the other rows of \( A \), the corresponding row of \((A b)\) should be scaled up or down.

In problems 1 and 2, the solution \( x \) is easily recovered following column-scaling. Unless better information is known, the nonzero columns of \( A \) should be scaled so that they all have the same Euclidean norm (e.g., 1.0).
In problem 3, there is no freedom to re-scale if damp is nonzero. However, the value of damp should be assigned only after attention has been paid to the scaling of A.

The parameter damp is intended to help regularize ill-conditioned systems, by preventing the true solution from being very large. Another aid to regularization is provided by the parameter acond, which may be used to terminate iterations before the computed solution becomes very large.

If some initial estimate \( x_0 \) is known and if \( \text{damp} = 0 \), one could proceed as follows:

1. Compute a residual vector \( r_0 = b - A@x_0 \).
2. Use LSQR to solve the system \( A@dx = r_0 \).
3. Add the correction \( dx \) to obtain a final solution \( x = x_0 + dx \).

This requires that \( x_0 \) be available before and after the call to LSQR. To judge the benefits, suppose LSQR takes \( k_1 \) iterations to solve \( A@x = b \) and \( k_2 \) iterations to solve \( A@dx = r_0 \). If \( x_0 \) is “good”, \( \text{norm}(r_0) \) will be smaller than \( \text{norm}(b) \). If the same stopping tolerances atol and btol are used for each system, \( k_1 \) and \( k_2 \) will be similar, but the final solution \( x_0 + dx \) should be more accurate. The only way to reduce the total work is to use a larger stopping tolerance for the second system. If some value btol is suitable for \( A@x = b \), the larger value \( \text{btol} \times \text{norm}(b)/\text{norm}(r_0) \) should be suitable for \( A@dx = r_0 \).

Preconditioning is another way to reduce the number of iterations. If it is possible to solve a related system \( M@x = b \) efficiently, where \( M \) approximates \( A \) in some helpful way (e.g. \( M - A \) has low rank or its elements are small relative to those of \( A \)), LSQR may converge more rapidly on the system \( A@M(\text{inverse})@z = b \), after which \( x \) can be recovered by solving \( M@x = z \).

If \( A \) is symmetric, LSQR should not be used!

Alternatives are the symmetric conjugate-gradient method (cg) and/or SYMMLQ. SYMMLQ is an implementation of symmetric cg that applies to any symmetric \( A \) and will converge more rapidly than LSQR. If \( A \) is positive definite, there are other implementations of symmetric cg that require slightly less work per iteration than SYMMLQ (but will take the same number of iterations).

References

[1], [2], [3]

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsqr
>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)
```

The first example has the trivial solution \([0, 0] \)

```python
>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
>>> istop
0
>>> x
array([ 0.,  0.])
```

The stopping code \( \text{istop}=0 \) returned indicates that a vector of zeros was found as a solution. The returned solution \( x \) indeed contains \([0, 0] \). The next example has a non-trivial solution:
As indicated by \( istop=1 \), \( lsmr \) found a solution obeying the tolerance limits. The given solution \([1., -1.]\) obviously solves the equation. The remaining return values include information about the number of iterations (\( itn=1 \)) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```python
>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, r1norm = lsmr(A, b)[:4]
>>> istop
2
>>> x
array([ 1.00333333, -0.99666667])
>>> A.dot(x) - b
array([ 0.00333333, -0.00333333, 0.00333333])
>>> r1norm
0.005773502691896255
```

\( istop \) indicates that the system is inconsistent and thus \( x \) is rather an approximate solution to the corresponding least-squares problem. \( r1norm \) contains the norm of the minimal residual that was found.

### scipy.sparse.linalg.lsmr

scipy.sparse.linalg.lsmr (\( A, b, damp=0.0, atol=1e-06, btol=1e-06, conlim=100000000.0, maxiter=None, show=False, x0=None \))

Iterative solver for least-squares problems.

\( lsmr \) solves the system of linear equations \( Ax = b \). If the system is inconsistent, it solves the least-squares problem \[ \min ||b - Ax||_2 \] \( A \) is a rectangular matrix of dimension \( m \)-by-\( n \), where all cases are allowed: \( m=n \), \( m>n \), or \( m<n \). \( b \) is a vector of length \( m \). The matrix \( A \) may be dense or sparse (usually sparse).

#### Parameters

- \( A \) : [[sparse matrix, ndarray, LinearOperator]] Matrix \( A \) in the linear system. Alternatively, \( A \) can be a linear operator which can produce \( Ax \) and \( A^H x \) using, e.g., scipy.sparse.linalg.LinearOperator.
- \( b \) : [array_like, shape (m,)] Vector \( b \) in the linear system.
- \( damp \) : [float] Damping factor for regularized least-squares. \( lsmr \) solves the regularized least-squares problem:

\[
\min ||(b) - (A)x||_2
\]

\[ ||(0) - (damp*I)x||_2 \]

where \( damp \) is a scalar. If \( damp \) is None or 0, the system is solved without regularization. Default is 0.

- \( atol, btol \) : [float, optional] Stopping tolerances. \( lsmr \) continues iterations until a certain backward error estimate is smaller than some quantity depending on \( atol \) and \( btol \). Let \( r = b - Ax \) be the residual of the current approximate solution \( x \):
Ax be the residual vector for the current approximate solution x. If \( Ax = b \) seems to be consistent, \texttt{lsmr} terminates when
\[
\text{norm}(r) \leq \text{atol} \times \text{norm}(A) \times \text{norm}(x) + \text{btol} \times \text{norm}(b).
\]
Otherwise, \texttt{lsmr} terminates when
\[
\text{norm}(A^H r) \leq \text{atol} \times \text{norm}(A) \times \text{norm}(r).
\]
If both tolerances are 1.0e-6 (default), the final \( \text{norm}(r) \) should be accurate to about 6 digits. (The final x will usually have fewer correct digits, depending on \( \text{cond}(A) \) and the size of LAMBDA.) If \( \text{atol} \) or \( \text{btol} \) is None, a default value of 1.0e-6 will be used. Ideally, they should be estimates of the relative error in the entries of A and b respectively. For example, if the entries of A have 7 correct digits, set \( \text{atol} = 1 \times 10^{-7} \). This prevents the algorithm from doing unnecessary work beyond the uncertainty of the input data.

\begin{itemize}
  \item \texttt{conlim} \[ \text{float, optional} \] \texttt{lsmr} terminates if an estimate of \( \text{cond}(A) \) exceeds \texttt{conlim}. For compatible systems \( Ax = b \), \texttt{conlim} could be as large as 1.0e+12 (say). For least-squares problems, \texttt{conlim} should be less than 1.0e+8. If \texttt{conlim} is None, the default value is 1e+8. Maximum precision can be obtained by setting \( \text{atol} = \text{btol} = \text{conlim} = 0 \), but the number of iterations may then be excessive. Default is 1e8.
  \item \texttt{maxiter} \[ \text{int, optional} \] \texttt{lsmr} terminates if the number of iterations reaches \texttt{maxiter}. The default is \( \text{maxiter} = \min(m, n) \). For ill-conditioned systems, a larger value of \texttt{maxiter} may be needed. Default is False.
  \item \texttt{show} \[ \text{bool, optional} \] Print iterations logs if \texttt{show=\text{True}}. Default is False.
  \item \texttt{x0} \[ \text{array_like, shape (n,), optional} \] Initial guess of \( x \), if None zeros are used. Default is None. New in version 1.0.0.
\end{itemize}

\textbf{Returns}

\begin{itemize}
  \item \texttt{x} \[ \text{ndarray of float} \] Least-square solution returned.
  \item \texttt{istop} \[ \text{int} \] istop gives the reason for stopping:
    \begin{verbatim}
    istop = 0 means x=0 is a solution. If x0 was given, then x=x0 is a solution.  
    = 1 means x is an approximate solution to A@x = B, according to atol and btol. 
    = 2 means x approximately solves the least-squares problem according to atol. 
    = 3 means COND(A) seems to be greater than CONLIM. 
    = 4 is the same as 1 with atol = btol = eps_ (machine precision) 
    = 5 is the same as 2 with atol = eps. 
    = 6 is the same as 3 with CONLIM = 1/eps. 
    = 7 means ITN reached maxiter before the other stopping conditions were satisfied.
    \end{verbatim}
  \item \texttt{itn} \[ \text{int} \] Number of iterations used.
  \item \texttt{normr} \[ \text{float} \] \( \text{norm}(b-Ax) \)
  \item \texttt{normar} \[ \text{float} \] \( \text{norm}(A^H (b - Ax)) \)
  \item \texttt{norma} \[ \text{float} \] \( \text{norm}(A) \)
  \item \texttt{conda} \[ \text{float} \] Condition number of A.
  \item \texttt{normx} \[ \text{float} \] \( \text{norm}(x) \)
\end{itemize}

3.3. API definition 1997
Notes

New in version 0.11.0.

References

[1],[2]

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsmr
>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)
```

The first example has the trivial solution \([0, 0]\)

```python
>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsmr(A, b)[:4]
>>> istop
0
>>> x
array([0., 0.])
```

The stopping code \texttt{istop}=0 returned indicates that a vector of zeros was found as a solution. The returned solution \texttt{x} indeed contains \([0, 0]\). The next example has a non-trivial solution:

```python
>>> b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, normr = lsmr(A, b)[:4]
>>> istop
1
>>> x
array([ 1., -1.])
>>> itn
1
>>> normr
4.440892098500627e-16
```

As indicated by \texttt{istop}=1, \texttt{lsmr} found a solution obeying the tolerance limits. The given solution \([1., -1.]\) obviously solves the equation. The remaining return values include information about the number of iterations (\texttt{itn}=1) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```python
>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, normr = lsmr(A, b)[:4]
>>> istop
2
>>> x
array([ 1.00333333, -0.99666667])
>>> A.dot(x) - b
array([-0.00333333, -0.00333333, -0.00333333])
>>> normr
0.005773502691896255
```

**scipy.sparse.linalg.eigs**

```
scipy.sparse.linalg.eigs (A, k=6, M=None, sigma=None, which='LM', v0=None, ncv=None, maxiter=None, tol=0, return_eigenvectors=True, Minv=None, OPinv=None, OPpart=None)
```

Find `k` eigenvalues and eigenvectors of the square matrix `A`.

Solves `A @ x[i] = w[i] * x[i]`, the standard eigenvalue problem for `w[i]` eigenvalues with corresponding eigenvectors `x[i]`.

If `M` is specified, solves `A @ x[i] = w[i] * M @ x[i]`, the generalized eigenvalue problem for `w[i]` eigenvalues with corresponding eigenvectors `x[i]`.

**Parameters**

- `A` ([ndarray, sparse matrix or LinearOperator]) An array, sparse matrix, or LinearOperator representing the operation `A @ x`, where `A` is a real or complex square matrix.
- `k` ([int, optional]) The number of eigenvalues and eigenvectors desired. `k` must be smaller than `N-1`. It is not possible to compute all eigenvectors of a matrix.
- `M` ([ndarray, sparse matrix or LinearOperator, optional]) An array, sparse matrix, or LinearOperator representing the operation `M @ x` for the generalized eigenvalue problem `A @ x = w * M @ x`.

`M` must represent a real symmetric matrix if `A` is real, and must represent a complex Hermitian matrix if `A` is complex. For best results, the data type of `M` should be the same as that of `A`. Additionally:

- If `sigma` is None, `M` is positive definite
- If `sigma` is specified, `M` is positive semi-definite

If `sigma` is None, `eigs` requires an operator to compute the solution of the linear equation `M @ x = b`. This is done internally via a (sparse) LU decomposition for an explicit matrix `M`, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator `Minv`, which gives `x = Minv @ b = M^{-1} @ b`.

- `sigma` ([real or complex, optional]) Find eigenvalues near `sigma` using shift-invert mode. This requires an operator to compute the solution of the linear system `[A - sigma * M] @ x = b`, where `M` is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices `A` & `M`, or via an iterative solver if either `A` or `M` is a general linear operator. Alternatively, the user can supply the matrix or operator `OPinv`, which gives `x = OPinv @ b = [A - sigma * M]^{-1} @ b`. For a real matrix `A`, shift-invert can either be done in imaginary mode or real mode, specified by the parameter `OPpart` (`'r'` or `'i'`). Note that when `sigma` is specified, the keyword `'which'` (below) refers to the shifted eigenvalues `w' [i]` where:
If A is real and OPpart == 'r' (default),

\[ w'[i] = \frac{1}{2} \left( \frac{1}{w[i]-\sigma} + \frac{1}{w[i]-\overline{\sigma}} \right) \]

If A is real and OPpart == 'i',

\[ w'[i] = \frac{1}{2i} \left( \frac{1}{w[i]-\sigma} - \frac{1}{w[i]-\overline{\sigma}} \right) \]

If A is complex, \( w'[i] = \frac{1}{w[i]-\sigma} \).

v0 [ndarray, optional] Starting vector for iteration. Default: random
ncv [int, optional] The number of Lanczos vectors generated ncv must be greater than k; it is recommended that ncv > 2*k. Default: \min(n, \max(2k + 1, 20))
which [str, ['LM'|'SM'|'LR'|'SR'|'LI'|'SI'], optional] Which k eigenvectors and eigenvalues to find:
  ‘LM’: largest magnitude
  ‘SM’: smallest magnitude
  ‘LR’: largest real part
  ‘SR’: smallest real part
  ‘LI’: largest imaginary part
  ‘SI’: smallest imaginary part
When sigma != None, ‘which’ refers to the shifted eigenvalues w'[i] (see discussion in ‘sigma’, above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.
maxiter [int, optional] Maximum number of Arnoldi update iterations allowed. Default: n*10
tol [float, optional] Relative accuracy for eigenvalues (stopping criterion) The default value of 0 implies machine precision.
return_eigenvectors [bool, optional] Return eigenvectors (True) in addition to eigenvalues
Minv [ndarray, sparse matrix or LinearOperator, optional] See notes in M, above.
OPinv [ndarray, sparse matrix or LinearOperator, optional] See notes in sigma, above.
OPpart [{‘r’ or ‘i’}, optional] See notes in sigma, above

Returns

w [ndarray] Array of k eigenvalues.
v [ndarray] An array of k eigenvectors. v[:, i] is the eigenvector corresponding to the eigenvalue w[i].

Raises

ArpackNoConvergence
When the requested convergence is not obtained. The currently converged eigenvalues and eigenvectors can be found as eigenvalues and eigenvectors attributes of the exception object.

singular value decomposition for a matrix A
Notes

This function is a wrapper to the ARPACK [1] SNEUPD, DNEUPD, CNEUPD, ZNEUPD, functions which use the Implicitly Restarted Arnoldi Method to find the eigenvalues and eigenvectors [2].

References

[1], [2]

Examples

Find 6 eigenvectors of the identity matrix:

```python
>>> from scipy.sparse.linalg import eigs
>>> id = np.eye(13)
>>> vals, vecs = eigs(id, k=6)
>>> vals
array([ 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j])
>>> vecs.shape
(13, 6)
```

scipy.sparse.linalg.eigsh

`scipy.sparse.linalg.eigsh(A, k=6, M=None, sigma=None, which='LM', v0=None, ncv=None, maxiter=None, tol=0, return_eigenvectors=True, Minv=None, OPinv=None, mode='normal')`

Find k eigenvalues and eigenvectors of the real symmetric square matrix or complex Hermitian matrix A.

Solves $A @ x[i] = w[i] * x[i]$, the standard eigenvalue problem for $w[i]$ eigenvalues with corresponding eigenvectors $x[i]$.

If $M$ is specified, solves $A @ x[i] = w[i] * M @ x[i]$, the generalized eigenvalue problem for $w[i]$ eigenvalues with corresponding eigenvectors $x[i]$.

Note that there is no specialized routine for the case when $A$ is a complex Hermitian matrix. In this case, `eigsh()` will call `eigs()` and return the real parts of the eigenvalues thus obtained.

Parameters

- **A** [ndarray, sparse matrix or LinearOperator] A square operator representing the operation $A @ x$, where $A$ is real symmetric or complex Hermitian. For buckling mode (see below) $A$ must additionally be positive-definite.
- **k** [int, optional] The number of eigenvalues and eigenvectors desired. $k$ must be smaller than $N$. It is not possible to compute all eigenvectors of a matrix.
- **M** [An N x N matrix, array, sparse matrix, or linear operator representing] the operation $M @ x$ for the generalized eigenvalue problem $A @ x = w * M @ x$.

Returns

- **w** [array] Array of $k$ eigenvalues.
- **v** [array] An array representing the $k$ eigenvectors. The column $v[:, i]$ is the eigenvector corresponding to the eigenvalue $w[i]$.

Other Parameters

- **sigma** [Optional] Shift used to transform the problem to a generalized eigenvalue problem. For `which='LM'` this must be a complex number.
- **which** [str] How the selected eigenvalues are chosen from the spectrum. 'LM' means the eigenvalues with the largest magnitude (or, if complex, magnitude); 'SM' the eigenvalues with the smallest magnitude; 'LR' the eigenvalues with largest real part, 'SR' with smallest (
- **v0** [Optional, ndarray] Starting vector for the Arnoldi iteration.
- **ncv** [Optional, int] Dimension of the working space used. Must be greater than or equal to $2 * k$. Larger values can improve the speed of the computation.
- **maxiter** [Optional, int] Maximum number of Arnoldi update iterations allowed.
- **tol** [Optional, float] Relative accuracy for eigenvalues (stopping criterion). The default value is 0.
- **return_eigenvectors** [Optional, bool] Whether to return the set of eigenvectors corresponding to the eigenvalues (True or False).
- **Minv** [Optional, LinearOperator] Inverse of $M$.
- **OPinv** [Optional, LinearOperator] Inverse of $M @ x$.
M must represent a real symmetric matrix if A is real, and must represent a complex Hermitian matrix if A is complex. For best results, the data type of M should be the same as that of A. Additionally:

If sigma is None, M is symmetric positive definite.
If sigma is specified, M is symmetric positive semi-definite.

In buckling mode, M is symmetric indefinite.
If sigma is None, eigsh requires an operator to compute the solution of the linear equation \( M \mathbf{x} = \mathbf{b} \). This is done internally via a (sparse) LU decomposition for an explicit matrix M, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator Minv, which gives \( \mathbf{x} = \text{Minv} \mathbf{b} = M^{-1} \mathbf{b} \).

sigma: [real] Find eigenvalues near sigma using shift-invert mode. This requires an operator to compute the solution of the linear system \( [A - \sigma \times M] \mathbf{x} = \mathbf{b} \), where M is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices A & M, or via an iterative solver if either A or M is a general linear operator. Alternatively, the user can supply the matrix or operator OPinv, which gives \( \mathbf{x} = \text{OPinv} \mathbf{b} = [A - \sigma \times M]^{-1} \mathbf{b} \). Note that when sigma is specified, the keyword 'which' refers to the shifted eigenvalues \( w'[i] \) where:

- if mode == 'normal', \( w'[i] = 1 / (w[i] - \sigma) \).
- if mode == 'cayley', \( w'[i] = (w[i] + \sigma) / (w[i] - \sigma) \).
- if mode == 'buckling', \( w'[i] = w[i] / (w[i] - \sigma) \).

(see further discussion in 'mode' below)

v0: [ndarray, optional] Starting vector for iteration. Default: random
ncv: [int, optional] The number of Lanczos vectors generated ncv must be greater than k and smaller than n; it is recommended that \( ncv > 2k \). Default: \( \min(n, \max(2k + 1, 20)) \)
which: [str ['LM', 'SM', 'LA', 'SA', 'BE']] If A is a complex Hermitian matrix, 'BE' is invalid. Which k eigenvectors and eigenvalues to find:
- 'LM': Largest (in magnitude) eigenvalues.
- 'SM': Smallest (in magnitude) eigenvalues.
- 'LA': Largest (algebraic) eigenvalues.
- 'SA': Smallest (algebraic) eigenvalues.
- 'BE': Half \((k/2)\) from each end of the spectrum.
When k is odd, return one more \((k/2+1)\) from the high end. When sigma != None, 'which' refers to the shifted eigenvalues \( w'[i] \) (see discussion in 'sigma', above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

maxiter: [int, optional] Maximum number of Arnoldi update iterations allowed. Default: \( n \times 10 \)
tol: [float] Relative accuracy for eigenvalues (stopping criterion). The default value of 0 implies machine precision.

Minv: [N x N matrix, array, sparse matrix, or LinearOperator] See notes in M, above.
OPinv: [N x N matrix, array, sparse matrix, or LinearOperator] See notes in sigma, above.
return_eigenvectors: [bool] Return eigenvectors (True) in addition to eigenvalues. This value determines the order in which eigenvalues are sorted. The sort order is also dependent on the which variable.

For which = 'LM' or 'SA':
- If return_eigenvectors is True, eigenvalues are sorted by algebraic value.
- If return_eigenvectors is False, eigenvalues are sorted by absolute value.

For which = 'BE' or 'LA':
- eigenvalues are always sorted by algebraic value.

For which = 'SM':
- If return_eigenvectors is True, eigenvalues are sorted by algebraic value.
- If return_eigenvectors is False, eigenvalues are sorted by decreasing absolute value.
mode  [string ['normal' | 'buckling' | 'cayley']] Specify strategy to use for shift-invert mode. This argument applies only for real-valued A and sigma != None. For shift-invert mode, ARPACK internally solves the eigenvalue problem \( OP \circ x'[i] = w'[i] * B \circ x'[i] \) and transforms the resulting Ritz vectors \( x'[i] \) and Ritz values \( w'[i] \) into the desired eigenvectors and eigenvalues of the problem \( A \circ x[i] = w[i] * M \circ x[i] \). The modes are as follows:

- **'normal'**: \( OP = (A - \sigma M)^{-1} \circ M, B = M, w'[i] = 1 / (w[i] - \sigma) \)
- **'buckling'**: \( OP = (A - \sigma M)^{-1} \circ A, B = A, w'[i] = w[i] / (w[i] - \sigma) \)
- **'cayley'**: \( OP = (A - \sigma M)^{-1} \circ (A + \sigma M), B = M, w'[i] = (w[i] + \sigma) / (w[i] - \sigma) \)

The choice of mode will affect which eigenvalues are selected by the keyword 'which', and can also impact the stability of convergence (see [2] for a discussion).

### Raises

**ArpackNoConvergence**

When the requested convergence is not obtained. The currently converged eigenvalues and eigenvectors can be found as `eigenvalues` and `eigenvectors` attributes of the exception object.

### Examples

```python
>>> from scipy.sparse.linalg import eigsh
>>> identity = np.eye(13)
>>> eigenvalues, eigenvectors = eigsh(identity, k=6)
>>> eigenvalues
array([1., 1., 1., 1., 1., 1.])
>>> eigenvectors.shape
(13, 6)
```
Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

LOBPCG is a preconditioned eigensolver for large symmetric positive definite (SPD) generalized eigenproblems.

Parameters

- **A** ([sparse matrix, dense matrix, LinearOperator]) The symmetric linear operator of the problem, usually a sparse matrix. Often called the “stiffness matrix”.
- **X** ([ndarray, float32 or float64]) Initial approximation to the $k$ eigenvectors (non-sparse). If $A$ has shape=$(n,n)$ then $X$ should have shape shape=$(n,k)$.
- **B** ([dense matrix, sparse matrix, LinearOperator], optional) The right hand side operator in a generalized eigenproblem. By default, $B = Identity$. Often called the “mass matrix”.
- **M** ([dense matrix, sparse matrix, LinearOperator], optional) Preconditioner to $A$; by default $M = Identity$. $M$ should approximate the inverse of $A$.
- **Y** ([ndarray, float32 or float64, optional]) n-by-sizeY matrix of constraints (non-sparse), sizeY $< n$. The iterations will be performed in the B-orthogonal complement of the column-space of Y. $Y$ must be full rank.
- **tol** ([scalar, optional]) Solver tolerance (stopping criterion). The default is tol=n*sqrt(eps).
- **maxiter** ([int, optional]) Maximum number of iterations. The default is maxiter = 20.
- **largest** ([bool, optional]) When True, solve for the largest eigenvalues, otherwise the smallest.
- **verbosityLevel** ([int, optional]) Controls solver output. The default is verbosityLevel=0.
- **retLambdaHistory** ([bool, optional]) Whether to return eigenvalue history. Default is False.
- **retResidualNormsHistory** ([bool, optional]) Whether to return history of residual norms. Default is False.

Returns

- **w** ([ndarray]) Array of $k$ eigenvalues
- **v** ([ndarray]) An array of $k$ eigenvectors. $v$ has the same shape as $X$.
- **lambdas** ([list of ndarray, optional]) The eigenvalue history, if retLambdaHistory is True.
- **rnorms** ([list of ndarray, optional]) The history of residual norms, if retResidualNormsHistory is True.

Notes

If both retLambdaHistory and retResidualNormsHistory are True, the return tuple has the following format (lambda, V, lambda history, residual norms history).

In the following $n$ denotes the matrix size and $m$ the number of required eigenvalues (smallest or largest).

The LOBPCG code internally solves eigenproblems of the size $3m$ on every iteration by calling the “standard” dense eigensolver, so if $m$ is not small enough compared to $n$, it does not make sense to call the LOBPCG code, but rather one should use the “standard” eigensolver, e.g. numpy or scipy function in this case. If one calls the LOBPCG algorithm for $5m > n$, it will most likely break internally, so the code tries to call the standard function instead.

It is not that $n$ should be large for the LOBPCG to work, but rather the ratio $n / m$ should be large. It you call LOBPCG with $m=1$ and $n=10$, it works though $n$ is small. The method is intended for extremely large $n / m$.

The convergence speed depends basically on two factors:

1. How well relatively separated the seeking eigenvalues are from the rest of the eigenvalues. One can try to vary $m$ to make this better.
2. How well conditioned the problem is. This can be changed by using proper preconditioning. For example, a rod vibration test problem (under tests directory) is ill-conditioned for large n, so convergence will be slow, unless efficient preconditioning is used. For this specific problem, a good simple preconditioner function would be a linear solve for A, which is easy to code since A is tridiagonal.

References

[1], [2], [3]

Examples

Solve \( A \ x = \lambda \ x \) with constraints and preconditioning.

```python
>>> import numpy as np
>>> from scipy.sparse import spdiags, issparse
>>> from scipy.sparse.linalg import lobpcg, LinearOperator
>>> n = 100
>>> vals = np.arange(1, n + 1)
>>> A = spdiags(vals, 0, n, n)
>>> A.toarray()
array([[ 1., 0., 0., ..., 0., 0., 0.],
[ 0., 2., 0., ..., 0., 0., 0.],
[ 0., 0., 3., ..., 0., 0., 0.],
..., 
[ 0., 0., 0., ..., 98., 0., 0.],
[ 0., 0., 0., ..., 0., 99., 0.],
[ 0., 0., 0., ..., 0., 0., 100.]])
```

Constraints:

```python
>>> Y = np.eye(n, 3)
```

Initial guess for eigenvectors, should have linearly independent columns. Column dimension = number of requested eigenvalues.

```python
>>> rng = np.random.default_rng()
>>> X = rng.random((n, 3))
```

Preconditioner in the inverse of A in this example:

```python
>>> invA = spdiags([1./vals], 0, n, n)
```

The preconditioner must be defined by a function:

```python
>>> def precond( x ):
...    return invA @ x
```

The argument x of the preconditioner function is a matrix inside lobpcg, thus the use of matrix-matrix product @.

The preconditioner function is passed to lobpcg as a LinearOperator:

```python
>>> M = LinearOperator(matvec=precond, matmat=precond,
...    shape=(n, n), dtype=np.float64)
```
Let us now solve the eigenvalue problem for the matrix A:

```python
>>> eigenvalues, _ = lobpcg(A, X, Y=Y, M=M, largest=False)
>>> eigenvalues
array([4., 5., 6.])
```

Note that the vectors passed in Y are the eigenvectors of the 3 smallest eigenvalues. The results returned are orthogonal to those.

Singular values problems:

```python
scipy.sparse.linalg.svds(scipy.sparse.linalg.svds(A[, k, ncv, tol, which, v0, maxiter,...]))
```

Partial singular value decomposition of a sparse matrix.

### Parameters

- **A** [sparse matrix or LinearOperator] Matrix to decompose.
- **k** [int, default: 6] Number of singular values and singular vectors to compute. Must satisfy $1 \leq k \leq \text{min}(M, N)$ for solver='propack' and $k = \text{min}(M, N) - 1$ otherwise.
- **ncv** [int, optional] When solver='arpack', this is the number of Lanczos vectors generated. See 'arpack' for details. When solver='lobpcg' or solver='propack', this parameter is ignored.
- **which** ['LM', 'SM'] Which k singular values to find: either the largest magnitude ('LM') or smallest magnitude ('SM') singular values.
- **v0** [ndarray, optional] The starting vector for iteration; see method-specific documentation (’arpack’, ’lobpcg’), or ’propack’ for details.
- **maxiter** [int, optional] Maximum number of iterations; see method-specific documentation (’arpack’, ’lobpcg’), or ’propack’ for details.
- **return_singular_vectors** [{True, False, “u”, “vh”}] Singular values are always computed and returned; this parameter controls the computation and return of singular vectors.
  * True: return singular vectors.
  * False: do not return singular vectors.
  * "u": if $M \leq N$, compute only the left singular vectors and return None for the right singular vectors. Otherwise, compute all singular vectors.
  * "vh": if $M > N$, compute only the right singular vectors and return None for the left singular vectors. Otherwise, compute all singular vectors.
- **random_state** [{None, int, numpy.random.Generator, numpy.random.RandomState}, optional]
Pseudorandom number generator state used to generate resamples. If `random_state` is `None` (or `np.random`), the `numpy.random.RandomState` singleton is used. If `random_state` is an int, a new `RandomState` instance is used, seeded with `random_state`. If `random_state` is already a `Generator` or `RandomState` instance then that instance is used.

**options**  
[dict, optional] A dictionary of solver-specific options. No solver-specific options are currently supported; this parameter is reserved for future use.

**Returns**
- `u`  
  [ndarray, shape=(M, k)] Unitary matrix having left singular vectors as columns.
- `s`  
  [ndarray, shape=(k,)] The singular values.
- `vh`  
  [ndarray, shape=(k, N)] Unitary matrix having right singular vectors as rows.

**Notes**
This is a naive implementation using ARPACK or LOBPCG as an eigensolver on \( A^\top A \) or \( A A^\top \), depending on which one is more efficient.

**Examples**
Construct a matrix \( A \) from singular values and vectors.

```python
>>> from scipy.stats import ortho_group
>>> from scipy.sparse import csc_matrix, diags
>>> from scipy.sparse.linalg import svds
>>> rng = np.random.default_rng()
>>> orthogonal = csc_matrix(ortho_group.rvs(10, random_state=rng))
>>> s = [0.0001, 0.001, 3, 4, 5]  # singular values
>>> u = orthogonal[:, :5]  # left singular vectors
>>> vT = orthogonal[:, 5:].T  # right singular vectors
>>> A = u @ diags(s) @ vT
```

With only three singular values/vectors, the SVD approximates the original matrix.

```python
>>> u2, s2, vT2 = svds(A, k=3)
>>> A2 = u2 @ np.diag(s2) @ vT2
>>> np.allclose(A2, A.toarray(), atol=1e-3)
True
```

With all five singular values/vectors, we can reproduce the original matrix.

```python
>>> u3, s3, vT3 = svds(A, k=5)
>>> A3 = u3 @ np.diag(s3) @ vT3
>>> np.allclose(A3, A.toarray())
True
```

The singular values match the expected singular values, and the singular vectors are as expected up to a difference in sign.

```python
>>> (np.allclose(s3, s) and...
... np.allclose(np.abs(u3), np.abs(u.toarray())) and...
... np.allclose(np.abs(vT3), np.abs(vT.toarray())))
True
```
The singular vectors are also orthogonal. >>> (np.allclose(u3.T @ u3, np.eye(5)) and ... np.allclose(vT3 @ vT3.T, np.eye(5))) True

The \texttt{svds} function supports the following solvers:

\texttt{svds(solver=’arpack’)}

\begin{verbatim}
scipy.sparse.linalg.svds (A, k=6, ncv=None, tol=0, which='LM', v0=None, maxiter=None, return_singular_vectors=True, solver='arpack', random_state=None, options={})
\end{verbatim}

Partial singular value decomposition of a sparse matrix using ARPACK.

Compute the largest or smallest \( k \) singular values and corresponding singular vectors of a sparse matrix \( A \). The order in which the singular values are returned is not guaranteed.

In the descriptions below, let \( M, N = A.shape \).

**Parameters**

- **A** [sparse matrix or LinearOperator] Matrix to decompose.
- **k** [int, optional] Number of singular values and singular vectors to compute. Must satisfy \( 1 \leq k \leq \min(M, N) - 1 \). Default is 6.
- **ncv** [int, optional] The number of Lanczos vectors generated. The default is \( \min(n, \max(2*k + 1, 20)) \). If specified, must satisfy \( k + 1 < ncv < \min(M, N); ncv > 2*k \) is recommended.
- **which** [\{'LM', 'SM'\}] Which \( k \) singular values to find: either the largest magnitude ('LM') or smallest magnitude ('SM') singular values.
- **v0** [ndarray, optional] The starting vector for iteration: an (approximate) left singular vector if \( N > M \) and a right singular vector otherwise. Must be of length \( \min(M, N) \). Default: random
- **maxiter** [int, optional] Maximum number of Arnoldi update iterations allowed; default is \( \min(M, N) * 10 \).
- **return_singular_vectors** [\{True, False, “u”, “vh”\}] Singular values are always computed and returned; this parameter controls the computation and return of singular vectors.
  - True: return singular vectors.
  - False: do not return singular vectors.
  - "u": if \( M \leq N \), compute only the left singular vectors and return None for the right singular vectors. Otherwise, compute all singular vectors.
  - "vh": if \( M > N \), compute only the right singular vectors and return None for the left singular vectors. Otherwise, compute all singular vectors.
- **solver** [\{'arpack', 'propack', 'lobpcg'\}, optional] This is the solver-specific documentation for solver='arpack', 'lobpcg' and 'propack' are also supported.
- **random_state** [\{None, int, numpy.random.Generator,\]
  - numpy.random.RandomState\}], optional
  Pseudorandom number generator state used to generate resamples.
  If random_state is None (or np.random), the numpy.random.RandomState singleton is used. If random_state is an int, a new RandomState instance is used, seeded with random_state. If random_state is already a Generator or RandomState instance then that instance is used.
- **options** [dict, optional] A dictionary of solver-specific options. No solver-specific options are currently supported; this parameter is reserved for future use.

**Returns**

- **u** [ndarray, shape=\((M, k)\)] Unitary matrix having left singular vectors as columns.
- **s** [ndarray, shape=\((k, k)\)] The singular values.
vh  [ndarray, shape=(k, N)] Unitary matrix having right singular vectors as rows.

Notes

This is a naive implementation using ARPACK as an eigensolver on $A \cdot \text{conj}(.)^T \circ A$ or $A \circ A \cdot \text{conj}(.)^T$, depending on which one is more efficient.

Examples

Construct a matrix $A$ from singular values and vectors.

```python
>>> from scipy.stats import ortho_group
>>> from scipy.sparse import csc_matrix, diags
>>> from scipy.sparse.linalg import svds
>>> rng = np.random.default_rng()
>>> orthogonal = csc_matrix(ortho_group.rvs(10, random_state=rng))
>>> s = [0.0001, 0.001, 3, 4, 5]  # singular values
>>> u = orthogonal[:, :, 5]  # left singular vectors
>>> vT = orthogonal[:, 5:].T  # right singular vectors
>>> A = u @ np.diag(s) @ vT

With only three singular values/vectors, the SVD approximates the original matrix.

```python
>>> u2, s2, vT2 = svds(A, k=3, solver='arpack')
>>> A2 = u2 @ np.diag(s2) @ vT2
>>> np.allclose(A2, A.toarray(), atol=1e-3)
True
```)

With all five singular values/vectors, we can reproduce the original matrix.

```python
>>> u3, s3, vT3 = svds(A, k=5, solver='arpack')
>>> A3 = u3 @ np.diag(s3) @ vT3
>>> np.allclose(A3, A.toarray())
True
```)

The singular values match the expected singular values, and the singular vectors are as expected up to a difference in sign.

```python
>>> (np.allclose(s3, s) and ...
... np.allclose(np.abs(u3), np.abs(u.toarray())) and ...
... np.allclose(np.abs(vT3), np.abs(vT.toarray())))
True
```)

The singular vectors are also orthogonal.

```python
>>> (np.allclose(u3.T @ u3, np.eye(5)) and ...
... np.allclose(vT3 @ vT3.T, np.eye(5)))
True
```
svds(solver='lobpcg')

scipy.sparse.linalg.svds (A, k=6, ncv=None, tol=0, which='LM', v0=None, maxiter=None,
return_singular_vectors=True, solver='arpack', random_state=None, options={})

Partial singular value decomposition of a sparse matrix using LOBPCG.

Compute the largest or smallest $k$ singular values and corresponding singular vectors of a sparse matrix $A$. The order in which the singular values are returned is not guaranteed.

In the descriptions below, let $M, N = A.shape$.

**Parameters**

- **A** [sparse matrix or LinearOperator] Matrix to decompose.
- **k** [int, default: 6] Number of singular values and singular vectors to compute. Must satisfy $1 <= k <= \min(M, N) - 1$.
- **ncv** [int, optional] Ignored.
- **which** [‘LM’, ‘SM’] Which $k$ singular values to find: either the largest magnitude (‘LM’) or smallest magnitude (‘SM’) singular values.
- **v0** [ndarray, optional] If $k$ is 1, the starting vector for iteration: an (approximate) left singular vector if $N > M$ and a right singular vector otherwise. Must be of length $\min(M, N)$. Ignored otherwise. Default: random
- **maxiter** [int, default: 20] Maximum number of iterations.
- **return_singular_vectors** [True, False, “u”, “vh”] Singular values are always computed and returned; this parameter controls the computation and return of singular vectors.
  - True: return singular vectors.
  - False: do not return singular vectors.
  - “u”: if $M <= N$, compute only the left singular vectors and return None for the right singular vectors. Otherwise, compute all singular vectors.
  - “vh”: if $M > N$, compute only the right singular vectors and return None for the left singular vectors. Otherwise, compute all singular vectors.
- **solver** [‘arpack’, ‘propack’, ‘lobpcg’], optional This is the solver-specific documentation for solver='lobpcg’. ‘arpack’ and ‘propack’ are also supported.
- **random_state** [None, int, numpy.random.Generator, numpy.random.RandomState], optional Pseudorandom number generator state used to generate resamples. If random_state is None (or np.random), the numpy.random.RandomState singleton is used. If random_state is an int, a new RandomState instance is used, seeded with random_state. If random_state is already a Generator or RandomState instance then that instance is used.
- **options** [dict, optional] A dictionary of solver-specific options. No solver-specific options are currently supported; this parameter is reserved for future use.

**Returns**

- **u** [ndarray, shape=(M, k)] Unitary matrix having left singular vectors as columns.
- **s** [ndarray, shape=(k,)] The singular values.
- **vh** [ndarray, shape=(k, N)] Unitary matrix having right singular vectors as rows.
Notes

This is a naive implementation using LOBPCG as an eigensolver on $A \cdot \text{conj()} \cdot ^T \otimes A$ or $A \otimes A \cdot \text{conj()} \cdot ^T$, depending on which one is more efficient.

Examples

Construct a matrix $A$ from singular values and vectors.

```python
>>> from scipy.stats import ortho_group
>>> from scipy.sparse import csc_matrix, diags
>>> from scipy.sparse.linalg import svds
>>> rng = np.random.default_rng()
>>> orthogonal = csc_matrix(ortho_group.rvs(10, random_state=rng))
>>> s = [0.0001, 0.001, 3, 4, 5]  # singular values
>>> u = orthogonal[:, :5]  # left singular vectors
>>> vT = orthogonal[:, 5:].T  # right singular vectors
>>> A = u @ diags(s) @ vT
```

With only three singular values/vectors, the SVD approximates the original matrix.

```python
>>> u2, s2, vT2 = svds(A, k=3, solver='lobpcg')
>>> A2 = u2 @ np.diag(s2) @ vT2
>>> np.allclose(A2, A.toarray(), atol=1e-3)  
True
```

With all five singular values/vectors, we can reproduce the original matrix.

```python
>>> u3, s3, vT3 = svds(A, k=5, solver='lobpcg')
>>> A3 = u3 @ np.diag(s3) @ vT3
>>> np.allclose(A3, A.toarray())  
True
```

The singular values match the expected singular values, and the singular vectors are as expected up to a difference in sign.

```python
>>> (np.allclose(s3, s) and ...
... np.allclose(np.abs(u3), np.abs(u.todense())) and ...
... np.allclose(np.abs(vT3), np.abs(vT.todense()))))
True
```

The singular vectors are also orthogonal. >>> (np.allclose(u3.T @ u3, np.eye(5)) and ... np.allclose(vT3 @ vT3.T, np.eye(5))) True

svds(solver='propack')

scipy.sparse.linalg.svds(A, k=6, ncv=None, tol=0, which='LM', v0=None, maxiter=None, return_singular_vectors=True, solver='arpack', random_state=None, options={})

Partial singular value decomposition of a sparse matrix using PROPACK.

Compute the largest or smallest $k$ singular values and corresponding singular vectors of a sparse matrix $A$. The order in which the singular values are returned is not guaranteed.

In the descriptions below, let $M$, $N = A.shape.
A [sparse matrix or LinearOperator] Matrix to decompose. If A is a LinearOperator object, it must define both matvec and rmatvec methods.

k [int, default: 6] Number of singular values and singular vectors to compute. Must satisfy 1 <= k <= min(M, N).

ncv [int, optional] Ignored.

which [{‘LM’, ‘SM’}] Which k singular values to find: either the largest magnitude (‘LM’) or smallest magnitude (‘SM’) singular values. Note that choosing which='SM' will force the irl option to be set True.

v0 [ndarray, optional] Starting vector for iterations: must be of length A.shape[0]. If not specified, PROPACK will generate a starting vector.

maxiter [int, optional] Maximum number of iterations / maximal dimension of the Krylov subspace. Default is 10 * k.

return_singular_vectors [{True, False, “u”, “vh”}] Singular values are always computed and returned; this parameter controls the computation and return of singular vectors.

• True: return singular vectors.
• False: do not return singular vectors.
• "u": compute only the left singular vectors; return None for the right singular vectors.
• "vh": compute only the right singular vectors; return None for the left singular vectors.

solver [{‘arpack’, ‘propack’, ‘lobpcg’}, optional] This is the solver-specific documentation for solver='propack'. ‘arpack’ and ‘lobpcg’ are also supported.

random_state [{None, int, numpy.random.Generator.], numpy.random.RandomState}, optional] Pseudorandom number generator state used to generate resamples.

If random_state is None (or np.random), the numpy.random.RandomState singleton is used. If random_state is an int, a new RandomState instance is used, seeded with random_state. If random_state is already a Generator or RandomState instance then that instance is used.

options [dict, optional] A dictionary of solver-specific options. No solver-specific options are currently supported; this parameter is reserved for future use.

Returns

u [ndarray, shape=(M, k)] Unitary matrix having left singular vectors as columns.

s [ndarray, shape=(k,)] The singular values.

vh [ndarray, shape=(k, N)] Unitary matrix having right singular vectors as rows.

Notes

This is an interface to the Fortran library PROPACK [1]. The current default is to run with IRL mode disabled unless seeking the smallest singular values/vectors (which='SM').
Examples

Construct a matrix $A$ from singular values and vectors.

```python
>>> from scipy.stats import ortho_group
>>> from scipy.sparse import csc_matrix, diags
>>> from scipy.sparse.linalg import svds
>>> rng = np.random.default_rng()
>>> orthogonal = csc_matrix(ortho_group.rvs(10, random_state=rng))
>>> s = [0.0001, 0.001, 3, 4, 5]  # singular values
>>> u = orthogonal[:, :5]  # left singular vectors
>>> vT = orthogonal[:, 5:].T  # right singular vectors
>>> A = u @ diags(s) @ vT
```

With only three singular values/vectors, the SVD approximates the original matrix.

```python
>>> u2, s2, vT2 = svds(A, k=3, solver='propack')
>>> A2 = u2 @ np.diag(s2) @ vT2
>>> np.allclose(A2, A.todense(), atol=1e-3)
True
```

With all five singular values/vectors, we can reproduce the original matrix.

```python
>>> u3, s3, vT3 = svds(A, k=5, solver='propack')
>>> A3 = u3 @ np.diag(s3) @ vT3
>>> np.allclose(A3, A.todense())
True
```

The singular values match the expected singular values, and the singular vectors are as expected up to a difference in sign.

```python
>>> (np.allclose(s3, s) and ...
... np.allclose(np.abs(u3), np.abs(u.toarray())) and ...
... np.allclose(np.abs(vT3), np.abs(vT.toarray())))
True
```

The singular vectors are also orthogonal.

```python
>>> (np.allclose(u3.T @ u3, np.eye(5)) and ... np.allclose(vT3 @ vT3.T, np.eye(5)))
True
```

Complete or incomplete LU factorizations

- `splu(A[, permc_spec, diag_pivot_thresh, ...])` Compute the LU decomposition of a sparse, square matrix.
- `spilsu(A[, drop_tol, fill_factor, drop_rule, ...])` Compute an incomplete LU decomposition for a sparse, square matrix.
- `SuperLU()` LU factorization of a sparse matrix.
scipy.sparse.linalg.spilu

scipy.sparse.linalg.spilu(A, perm_spec=None, diag_pivot_thresh=None, relax=None, panel_size=None, options={} )

Compute the LU decomposition of a sparse, square matrix.

Parameters

- `A` [sparse matrix] Sparse matrix to factorize. Should be in CSR or CSC format.
- `perm_spec` [str, optional] How to permute the columns of the matrix for sparsity preservation. (default: 'COLAMD')
  - NATURAL: natural ordering.
  - MMD_ATA: minimum degree ordering on the structure of $A^T A$.
  - MMD_AT_PLUS_A: minimum degree ordering on the structure of $A^T + A$.
  - COLAMD: approximate minimum degree column ordering
- `diag_pivot_thresh` [float, optional] Threshold used for a diagonal entry to be an acceptable pivot. See SuperLU user's guide for details.
- `relax` [int, optional] Expert option for customizing the degree of relaxing supernodes. See SuperLU user's guide for details.
- `panel_size` [int, optional] Expert option for customizing the panel size. See SuperLU user's guide for details.
- `options` [dict, optional] Dictionary containing additional expert options to SuperLU. See SuperLU user guide (section 2.4 on the 'Options' argument) for more details. For example, you can specify `options=dict(Equil=False, IterRefine='SINGLE'))` to turn equilibration off and perform a single iterative refinement.

Returns

See also:

- `spilu`
  - incomplete LU decomposition

Notes

This function uses the SuperLU library.

References

[1]
Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spilu
>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]],
                dtype=float)
>>> B = spilu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([ 1., -3., -1.5])
>>> A.dot(B.solve(x))
array([ 1., 2., 3.])
>>> B.solve(A.dot(x))
array([ 1., 2., 3.])
```

```
scipy.sparse.linalg.spilu

scipy.sparse.linalg.spilu(A, drop_tol=None, fill_factor=None, drop_rule=None, permc_spec=None, diag_pivot_thresh=None, relax=None, panel_size=None, options=None)

Compute an incomplete LU decomposition for a sparse, square matrix.

The resulting object is an approximation to the inverse of A.

Parameters

- **A** [(N, N) array_like] Sparse matrix to factorize
- **drop_tol** [float, optional] Drop tolerance (0 <= tol <= 1) for an incomplete LU decomposition. (default: 1e-4)
- **fill_factor** [float, optional] Specifies the fill ratio upper bound (>= 1.0) for ILU. (default: 10)
- **drop_rule** [str, optional] Comma-separated string of drop rules to use. Available rules: basic, prows, column, area, secondary, dynamic, interp. (Default: basic, area)
  
  See SuperLU documentation for details.

Remaining other options

- Same as for `spilu`

Returns

- **invA_approx** [scipy.sparse.linalg.SuperLU] Object, which has a `solve` method.

See also:

- `spilu`
  
  complete LU decomposition

Notes

To improve the better approximation to the inverse, you may need to increase `fill_factor` AND decrease `drop_tol`.

This function uses the SuperLU library.
Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spilu

A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]],
               dtype=float)
>>> B = spilu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([ 1. , -3. , -1.5])
```

`scipy.sparse.linalg.SuperLU`

class `scipy.sparse.linalg.SuperLU`  
LU factorization of a sparse matrix.

Factorization is represented as:

\[ P @ A @ P_c = L @ U \]

To construct these `SuperLU` objects, call the `spilu` and `spilu` functions.

Notes

New in version 0.14.0.

Examples

The LU decomposition can be used to solve matrix equations. Consider:

```python
>>> import numpy as np
>>> from scipy.sparse import csc_matrix, linalg as sla
>>> A = csc_matrix([[1,2,0,4],[1,0,0,1],[1,0,2,1],[2,2,1,0]])
```

This can be solved for a given right-hand side:

```python
>>> lu = sla.spilu(A)
>>> b = np.array([1, 2, 3, 4])
>>> x = lu.solve(b)
>>> A.dot(x)
array([ 1.,  2.,  3.,  4.])
```

The `lu` object also contains an explicit representation of the decomposition. The permutations are represented as mappings of indices:

```python
>>> lu.perm_r
array([0, 2, 1, 3], dtype=int32)
>>> lu.perm_c
array([2, 0, 1, 3], dtype=int32)
```
The L and U factors are sparse matrices in CSC format:

```python
>>> lu.L.A
array([[ 1. , 0. , 0. , 0. ],
    [ 0. , 1. , 0. , 0. ],
    [ 0. , 0. , 1. , 0. ],
    [ 1. , 0.5, 0.5, 1. ]])
```
```
>>> lu.U.A
array([[ 2. , 0. , 1. , 4. ],
    [ 0. , 2. , 1. , 1. ],
    [ 0. , 0. , 1. , 1. ],
    [ 0. , 0. , 0., -5. ]])
```

The permutation matrices can be constructed:

```python
>>> Pr = csc_matrix((np.ones(4), (lu.perm_r, np.arange(4))))
>>> Pc = csc_matrix((np.ones(4), (np.arange(4), lu.perm_c)))
```

We can reassemble the original matrix:

```python
>>> (Pr.T @ (lu.L @ lu.U) @ Pc.T).A
array([[ 1., 2., 0., 4.],
    [ 1., 0., 0., 1.],
    [ 1., 0., 2., 1.],
    [ 2., 2., 1., 0.]])
```

**Attributes**

- **shape**  
  Shape of the original matrix as a tuple of ints.
- **nnz**  
  Number of nonzero elements in the matrix.
- **perm_c**  
  Permutation Pc represented as an array of indices.
- **perm_r**  
  Permutation Pr represented as an array of indices.
- **L**  
  Lower triangular factor with unit diagonal as a `scipy.sparse.csc_matrix`
- **U**  
  Upper triangular factor as a `scipy.sparse.csc_matrix`

**Methods**

- `solve(rhs[, trans])`  
  Solves linear system of equations with one or several right-hand sides.

---

**scipy.sparse.linalg.SuperLU.solve**

`SuperLU.solve(rhs[, trans])`

Solves linear system of equations with one or several right-hand sides.

**Parameters**

- **rhs**  
  [ndarray, shape (n,) or (n, k)] Right hand side(s) of equation
- **trans**  
  [{‘N’, ‘T’, ‘H’}, optional] Type of system to solve:
'N': A @ x == rhs (default)
'T': A^T @ x == rhs
'H': A^H @ x == rhs

i.e., normal, transposed, and hermitian conjugate.

Returns

x [ndarray, shape rhs.shape] Solution vector(s)

Exceptions

<table>
<thead>

3.3.24 Compressed sparse graph routines *(scipy.sparse.csgraph)*

Fast graph algorithms based on sparse matrix representations.

Contents

- `connected_components(csgraph[, directed,...])` Analyze the connected components of a sparse graph
- `laplacian(csgraph[, normed, return_diag,...])` Return the Laplacian matrix of a directed graph.
- `shortest_path(csgraph[, method, directed,...])` Perform a shortest-path graph search on a directed or undirected graph.
- `dijkstra(csgraph[, directed, indices,...])` Dijkstra algorithm using Fibonacci Heaps
- `floyd_warshall(csgraph[, directed,...])` Compute the shortest path lengths using the Floyd-Warshall algorithm
- `bellman_ford(csgraph[, directed, indices,...])` Compute the shortest path lengths using the Bellman-Ford algorithm.
- `johnson(csgraph[, directed, indices,...])` Compute the shortest path lengths using Johnson's algorithm.
- `breadth_first_order(csgraph,i_start[,,...])` Return a breadth-first ordering starting with specified node.
- `depth_first_order(csgraph,i_start[,,...])` Return a depth-first ordering starting with specified node.
- `breadth_first_tree(csgraph,i_start[, directed])` Return the tree generated by a breadth-first search
- `depth_first_tree(csgraph,i_start[, directed])` Return a tree generated by a depth-first search.
- `minimum_spanning_tree(csgraph[, overwrite])` Return a minimum spanning tree of an undirected graph
- `reverse_cuthill_mckee(graph[, symmetric_mode])` Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill-McKee ordering.
- `maximum_flow(csgraph,source,sink)` Maximize the flow between two vertices in a graph.
- `maximum_bipartite_matching(graph[, perm_type])` Returns a matching of a bipartite graph whose cardinality is as least that of any given matching of the graph.
- `min_weight_full_bipartite_matching(...[,...])` Returns the minimum weight full matching of a bipartite graph.
- `structural_rank(graph)` Compute the structural rank of a graph (matrix) with a given sparsity pattern.

```
with_traceback()  
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

**scipy.sparse.csgraph.connected_components**

scipy.sparse.csgraph.connected_components *(csgraph, directed=True, connection='weak', return_labels=True)*

Analyze the connected components of a sparse graph

New in version 0.11.0.

**Parameters**

- **csgraph** [array_like or sparse matrix] The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- **directed** [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].
connection

[str, optional] ['weak'|'strong']. For directed graphs, the type of connection to use. Nodes i and j are strongly connected if a path exists both from i to j and from j to i. A directed graph is weakly connected if replacing all of its directed edges with undirected edges produces a connected (undirected) graph. If directed == False, this keyword is not referenced.

return_labels

[bool, optional] If True (default), then return the labels for each of the connected components.

Returns

n_components: int
The number of connected components.

labels: ndarray
The length-N array of labels of the connected components.

References

[1]

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import connected_components

>>> graph = [
... [0, 1, 1, 0, 0],
... [0, 0, 1, 0, 0],
... [0, 0, 0, 0, 0],
... [0, 0, 0, 0, 1],
... [0, 0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 1
(1, 2) 1
(3, 4) 1

>>> n_components, labels = connected_components(csgraph=graph,
... directed=False, return_labels=True)
>>> n_components
2
>>> labels
array([0, 0, 0, 1, 1], dtype=int32)
```
scipy.sparse.csgraph.laplacian

scipy.sparse.csgraph.laplacian(csgraph, normed=False, return_diag=False, use_out_degree=False)

Return the Laplacian matrix of a directed graph.

Parameters

- **csgraph** [array_like or sparse matrix, 2 dimensions] compressed-sparse graph, with shape (N, N).
- **normed** [bool, optional] If True, then compute symmetric normalized Laplacian.
- **return_diag** [bool, optional] If True, then also return an array related to vertex degrees.
- **use_out_degree** [bool, optional] If True, then use out-degree instead of in-degree. This distinction matters only if the graph is asymmetric. Default: False.

Returns

- **lap** [ndarray or sparse matrix] The N x N laplacian matrix of csgraph. It will be a NumPy array (dense) if the input was dense, or a sparse matrix otherwise.
- **diag** [ndarray, optional] The length-N diagonal of the Laplacian matrix. For the normalized Laplacian, this is the array of square roots of vertex degrees or 1 if the degree is zero.

Notes

The Laplacian matrix of a graph is sometimes referred to as the “Kirchoff matrix” or the “admittance matrix”, and is useful in many parts of spectral graph theory. In particular, the eigen-decomposition of the laplacian matrix can give insight into many properties of the graph.

Examples

```python
>>> from scipy.sparse import csgraph
>>> G = np.arange(5) * np.arange(5)[np.newaxis]
>>> G
array([[ 0,  0,  0,  0,  0],
       [ 0,  1,  2,  3,  4],
       [ 0,  2,  4,  6,  8],
       [ 0,  3,  6,  9, 12],
       [ 0,  4,  8, 12, 16]])
>>> csgraph.laplacian(G, normed=False)
array([[ 0,  0,  0,  0,  0],
       [ 0,  9, -2, -3, -4],
       [ 0, -2, 16, -6, -8],
       [ 0, -3, -6, 21, -12],
       [ 0, -4, -8, -12, 24]])
```
scipy.sparse.csgraph.shortest_path

scipy.sparse.csgraph.shortest_path(csgraph, method='auto', directed=True, return_predecessors=False, unweighted=False, overwrite=False, indices=None)

Perform a shortest-path graph search on a positive directed or undirected graph.

New in version 0.11.0.

**Parameters**

- **csgraph** [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.
- **method** [string ['auto'|'FW'|'D'], optional] Algorithm to use for shortest paths. Options are:
  - **auto** – (default) select the best among ‘FW’, ‘D’, ‘BF’, or ‘J’ based on the input data.
  - **FW** – Floyd-Warshall algorithm. Computational cost is \(O[N^3]\). The input csgraph will be converted to a dense representation.
  - **D** – Dijkstra’s algorithm with Fibonacci heaps. Computational cost is approximately \(O[N(N*k + N*log(N))]\), where \(k\) is the average number of connected edges per node. The input csgraph will be converted to a csr representation.
  - **BF** – Bellman-Ford algorithm. This algorithm can be used when weights are negative. If a negative cycle is encountered, an error will be raised. Computational cost is approximately \(O[N(N^2 + N)*k]\), where \(k\) is the average number of connected edges per node. The input csgraph will be converted to a csr representation.
  - **J** – Johnson’s algorithm. Like the Bellman-Ford algorithm, Johnson’s algorithm is designed for use when the weights are negative. It combines the Bellman-Ford algorithm with Dijkstra’s algorithm for faster computation.
- **directed** [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
- **return_predecessors** [bool, optional] If True, return the size (N, N) predecessor matrix
- **unweighted** [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- **overwrite** [bool, optional] If True, overwrite csgraph with the result. This applies only if method == ‘FW’ and csgraph is a dense, c-ordered array with dtype=float64.
- **indices** [array_like or int, optional] If specified, only compute the paths from the points at the given indices. Incompatible with method == ‘FW’.

**Returns**

- **dist_matrix** [ndarray] The N x N matrix of distances between graph nodes. dist_matrix[i, j] gives the shortest distance from point i to point j along the graph.
- **predecessors** [ndarray] Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index
of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

**Raises**

NegativeCycleError:
if there are negative cycles in the graph

**Notes**

As currently implemented, Dijkstra’s algorithm and Johnson’s algorithm do not work for graphs with direction-dependent distances when directed == False. i.e., if csgraph[i,j] and csgraph[j,i] are non-equal edges, method='D' may yield an incorrect result.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import shortest_path

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> dist_matrix, predecessors = shortest_path(csgraph=graph, 
... directed=False, indices=0, return_predecessors=True)
>>> dist_matrix
array([0. , 1. , 2. , 2. ])
>>> predecessors
array([-9999, 0, 0, 1], dtype=int32)
```

**scipy.sparse.csgraph.dijkstra**

Dijkstra algorithm using Fibonacci Heaps

New in version 0.11.0.

**Parameters**

csgraph  [array, matrix, or sparse matrix, 2 dimensions] The N x N array of non-negative distances representing the input graph.
directed [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j] and from point j to i along paths csgraph[j, i]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j or j to i along either csgraph[i, j] or csgraph[j, i].

indices [array_like or int, optional] If specified, only compute the paths from the points at the given indices.

return_predecessors [bool, optional] If True, return the size (N, N) predecessor matrix

unweighted [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

limit [float, optional] The maximum distance to calculate, must be >= 0. Using a smaller limit will decrease computation time by aborting calculations between pairs that are separated by a distance > limit. For such pairs, the distance will be equal to np.inf (i.e., not connected). New in version 0.14.0.

min_only [bool, optional] If False (default), for every node in the graph, find the shortest path from every node in indices. If True, for every node in the graph, find the shortest path from any of the nodes in indices (which can be substantially faster). New in version 1.3.0.

Returns

dist_matrix [ndarray, shape ([n_indices, n_nodes,])] The matrix of distances between graph nodes. If min_only=False, dist_matrix has shape (n_indices, n_nodes) and dist_matrix[i, j] gives the shortest distance from point i to point j along the graph. If min_only=True, dist_matrix has shape (n_nodes, n_nodes) and contains for a given node the shortest path to that node from any of the nodes in indices.

predecessors [ndarray, shape ([n_indices, n_nodes,])] If min_only=False, this has shape (n_indices, n_nodes), otherwise it has shape (n_nodes, n_nodes). Returned only if return_predecessors == True. The matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

sources [ndarray, shape (n_nodes,)] Returned only if min_only=True and return_predecessors=True. Contains the index of the source which had the shortest path to each target. If no path exists within the limit, this will contain -9999. The value at the indices passed will be equal to that index (i.e. the fastest way to reach node i, is to start on node i).

Notes

As currently implemented, Dijkstra’s algorithm does not work for graphs with direction-dependent distances when directed == False. i.e., if csgraph[i,j] and csgraph[j,i] are not equal and both are nonzero, setting directed=False will not yield the correct result.

Also, this routine does not work for graphs with negative distances. Negative distances can lead to infinite cycles that must be handled by specialized algorithms such as Bellman-Ford’s algorithm or Johnson’s algorithm.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import dijkstra

>>> graph = [
    ... [0, 1, 2, 0],
    ... [0, 0, 0, 1],
    ... [0, 0, 3, 0],
    ... [0, 0, 0, 0]
    ...
]
>>> graph = csr_matrix(graph)
>>> print(graph)

type: (0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 3) 3

>>> dist_matrix, predecessors = dijkstra(csgraph=graph, directed=False,
                                        indices=0, return_predecessors=True)
>>> dist_matrix
array([0., 1., 2., 2.])
>>> predecessors
array([-9999, 0, 0, 1], dtype=int32)
```

`scipy.sparse.csgraph.floyd_warshall`

`scipy.sparse.csgraph.floyd_warshall` *(csgraph, directed=True, return_predecessors=False, unweighted=False, overwrite=False)*

Compute the shortest path lengths using the Floyd-Warshall algorithm

New in version 0.11.0.

**Parameters**

- `csgraph` ([array, matrix, or sparse matrix, 2 dimensions]) The N x N array of distances representing the input graph.
- `directed` ([bool, optional]) If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].
- `return_predecessors` ([bool, optional]) If True, return the size (N, N) predecessor matrix.
- `unweighted` ([bool, optional]) If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- `overwrite` ([bool, optional]) If True, overwrite csgraph with the result. This applies only if csgraph is a dense, c-ordered array with dtype=float64.

**Returns**

- `dist_matrix` ([ndarray]) The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.
predecessors

[ndarray] Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

Raises

NegativeCycleError:

if there are negative cycles in the graph

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import floyd_warshall

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> dist_matrix, predecessors = floyd_warshall(csgraph=graph,
... directed=False, return_predecessors=True)
```

```python
>>> dist_matrix
dtype=int32)
```

```python
array([[0., 1., 2., 2.],
[1., 0., 3., 1.],
[2., 3., 0., 3.],
[2., 1., 3., 1.]],
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3)
```

```python
array([[-9999, 0, 0, 1],
[1, -9999, 0, 1],
[2, 0, -9999, 2],
[1, 3, 3, -9999]],
```
scipy.sparse.csgraph.bellman_ford

scipy.sparse.csgraph.bellman_ford(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False)

Compute the shortest path lengths using the Bellman-Ford algorithm.

The Bellman-Ford algorithm can robustly deal with graphs with negative weights. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, Dijkstra's algorithm may be faster.

New in version 0.11.0.

Parameters

- **csgraph**: [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.
- **directed**: [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
- **indices**: [array_like or int, optional] if specified, only compute the paths from the points at the given indices.
- **return_predecessors**: [bool, optional] If True, return the size (N, N) predecessor matrix
- **unweighted**: [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

Returns

- **dist_matrix**: [ndarray] The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.
- **predecessors**: [ndarray] Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

Raises

- **NegativeCycleError**: if there are negative cycles in the graph

Notes

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra's algorithm is a better choice.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import bellman_ford

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
  (0, 1) 1
  (0, 2) 2
  (1, 3) 1
  (2, 0) 2
  (2, 3) 3

>>> dist_matrix, predecessors = bellman_ford(csgraph=graph,
... directed=False, indices=0, return_predecessors=True)
>>> dist_matrix
array([0., 1., 2., 2.])
>>> predecessors
array([-9999, 0, 0, 1], dtype=int32)
```

**scipy.sparse.csgraph.johnson**

`scipy.sparse.csgraph.johnson(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False)`

Compute the shortest path lengths using Johnson’s algorithm.

Johnson’s algorithm combines the Bellman-Ford algorithm and Dijkstra’s algorithm to quickly find shortest paths in a way that is robust to the presence of negative cycles. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, dijkstra may be faster.

New in version 0.11.0.

**Parameters**

- `csgraph` [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.
- `directed` [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
- `indices` [array_like or int, optional] If specified, only compute the paths from the points at the given indices.
- `return_predecessors` [bool, optional] If True, return the size (N, N) predecessor matrix
- `unweighted` [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

**Returns**
**dist_matrix**

[array] The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.

**predecessors**

[array] Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

**Raises**

NegativeCycleError:

if there are negative cycles in the graph

**Notes**

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra’s algorithm is a better choice.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import johnson

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> dist_matrix, predecessors = johnson(csgraph=graph, directed=False,
... indices=0, return_predecessors=True)
>>> dist_matrix
array([0., 1., 2., 2.])
>>> predecessors
array([-9999, 0, 0, 1], dtype=int32)
```
scipy.sparse.csgraph.breadth_first_order

scipy.sparse.csgraph.breadth_first_order(csgraph, i_start, directed=True, return_predecessors=True)

Return a breadth-first ordering starting with specified node.

Note that a breadth-first order is not unique, but the tree which it generates is unique.

New in version 0.11.0.

Parameters

- csgraph [array_like or sparse matrix] The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i_start [int] The index of starting node.
- directed [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].
- return_predecessors [bool, optional] If True (default), then return the predecessor array (see below).

Returns

- node_array [ndarray, one dimension] The breadth-first list of nodes, starting with specified node. The length of node_array is the number of nodes reachable from the specified node.
- predecessors [ndarray, one dimension] Returned only if return_predecessors is True. The length-N list of predecessors of each node in a breadth-first tree. If node i is in the tree, then its parent is given by predecessors[i]. If node i is not in the tree (and for the parent node) then predecessors[i] = -9999.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_order

>>> graph = [
...   [0, 1, 2, 0],
...   [0, 0, 0, 1],
...   [2, 0, 0, 3],
...   [0, 0, 0, 0]
... ]

>>> graph = csr_matrix(graph)

>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> breadth_first_order(graph, 0)
(array([0, 1, 2, 3], dtype=int32), array([-9999, 0, 0, 1], dtype=int32))
```
scipy.sparse.csgraph.depth_first_order

`scipy.sparse.csgraph.depth_first_order(csgraph, i_start, directed=True, return_predecessors=True)`

Return a depth-first ordering starting with specified node.

Note that a depth-first order is not unique. Furthermore, for graphs with cycles, the tree generated by a depth-first search is not unique either.

New in version 0.11.0.

**Parameters**

- `csgraph` [array_like or sparse matrix] The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- `i_start` [int] The index of starting node.
- `directed` [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].
- `return_predecessors` [bool, optional] If True (default), then return the predecessor array (see below).

**Returns**

- `node_array` [ndarray, one dimension] The depth-first list of nodes, starting with specified node. The length of node_array is the number of nodes reachable from the specified node.
- `predecessors` [ndarray, one dimension] Returned only if return_predecessors is True. The length-N list of predecessors of each node in a depth-first tree. If node i is in the tree, then its parent is given by predecessors[i]. If node i is not in the tree (and for the parent node) then predecessors[i] = -9999.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_order

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]

>>> graph = csr_matrix(graph)

>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> depth_first_order(graph, 0)
(array([0, 1, 3, 2], dtype=int32), array([-9999, 0, 0, 1],
   dtype=int32))
```
**scipy.sparse.csgraph.breadth_first_tree**

`scipy.sparse.csgraph.breadth_first_tree(csgraph, i_start, directed=True)`

Return the tree generated by a breadth-first search

Note that a breadth-first tree from a specified node is unique.

New in version 0.11.0.

**Parameters**

- `csgraph` [array_like or sparse matrix] The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- `i_start` [int] The index of starting node.
- `directed` [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

**Returns**

- `cstree` [csr matrix] The N x N directed compressed-sparse representation of the breadth-first tree drawn from csgraph, starting at the specified node.

**Examples**

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

```
input graph          breadth first tree  from (0)

(0)                 (0)
/ \                  / \ 
3  8                 3  8
/ \                  / \ 
(3)---5---(1)      (3)  (1)
 \ /                  / 
 6  2                 2
 \ /                  / 
(2)                  (2)
```

In compressed sparse representation, the solution looks like this:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                  [0, 0, 2, 5],
...                  [0, 0, 0, 6],
...                  [0, 0, 0, 0]])
>>> Tcsr = breadth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 3],
       [0, 0, 2, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])
```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. A breadth-first tree from a given node is unique.
scipy.sparse.csgraph.depth_first_tree

scipy.sparse.csgraph.depth_first_tree(csgraph, i_start, directed=True)

Return a tree generated by a depth-first search.

Note that a tree generated by a depth-first search is not unique: it depends on the order that the children of each
node are searched.

New in version 0.11.0.

Parameters

csgraph [array_like or sparse matrix] The N x N matrix representing the compressed sparse graph.
The input csgraph will be converted to csr format for the calculation.
i_start [int] The index of starting node.
directed [bool, optional] If True (default), then operate on a directed graph: only move from point
i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected
graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

Returns
cstree [csr matrix] The N x N directed compressed-sparse representation of the depth-first tree
drawn from csgraph, starting at the specified node.

Examples

The following example shows the computation of a depth-first tree over a simple four-component graph, starting
at node 0:

```
input graph   depth first tree from (0)
  (0)           (0)
  / \          / \  
  3  8         8
  / \                / \  
(3)---5---(1) (3) (1)  
  \ /          \ /    
  6  2         6  2
  \ /            \ /    
(2) (2)
```

In compressed sparse representation, the solution looks like this:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                  [0, 0, 5, 0],
...                  [0, 0, 6, 0],
...                  [0, 0, 0, 0]])
>>> Tcsr = depth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 0],
       [0, 0, 2, 0],
       [0, 0, 0, 6],
       [0, 0, 0, 0]])
```
Note that the resulting graph is a Directed Acyclic Graph which spans the graph. Unlike a breadth-first tree, a depth-first tree of a given graph is not unique if the graph contains cycles. If the above solution had begun with the edge connecting nodes 0 and 3, the result would have been different.

**scipy.sparse.csgraph.minimum_spanning_tree**

`scipy.sparse.csgraph.minimum_spanning_tree(csgraph, overwrite=False)`

Return a minimum spanning tree of an undirected graph

A minimum spanning tree is a graph consisting of the subset of edges which together connect all connected nodes, while minimizing the total sum of weights on the edges. This is computed using the Kruskal algorithm.

New in version 0.11.0.

**Parameters**

- `csgraph` [array_like or sparse matrix, 2 dimensions] The N x N matrix representing an undirected graph over N nodes (see notes below).
- `overwrite` [bool, optional] If true, then parts of the input graph will be overwritten for efficiency. Default is False.

**Returns**

- `span_tree` [csr matrix] The N x N compressed-sparse representation of the undirected minimum spanning tree over the input (see notes below).

**Notes**

This routine uses undirected graphs as input and output. That is, if graph[i, j] and graph[j, i] are both zero, then nodes i and j do not have an edge connecting them. If either is nonzero, then the two are connected by the minimum nonzero value of the two.

This routine loses precision when users input a dense matrix. Small elements < 1E-8 of the dense matrix are rounded to zero. All users should input sparse matrices if possible to avoid it.

**Examples**

The following example shows the computation of a minimum spanning tree over a simple four-component graph:

```
input graph               minimum spanning tree
  (0)                     (0)
    /                     /
  3  8                   3
    /                     /
(3)---5---(1)           (3)---5---(1)
   \                     /                     /
  6  2                   2                     /
    \                   /                      /
(2)                     (2)
```

It is easy to see from inspection that the minimum spanning tree involves removing the edges with weights 8 and 6. In compressed sparse representation, the solution looks like this:
```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import minimum_spanning_tree
>>> X = csr_matrix([[0, 8, 0, 3],
                  ...                 [0, 0, 2, 5],
                  ...                 [0, 0, 0, 6],
                  ...                 [0, 0, 0, 0]])
>>> Tcsr = minimum_spanning_tree(X)
>>> Tcsr.toarray().astype(int)
array([[0, 0, 0, 3],
       [0, 0, 2, 5],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])
```

**scipy.sparse.csgraph.reverse_cuthill_mckee**

`scipy.sparse.csgraph.reverse_cuthill_mckee(graph, symmetric_mode=False)`  
Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.

It is assumed by default, `symmetric_mode=False`, that the input matrix is not symmetric and works on the matrix `A + A.T`. If you are guaranteed that the matrix is symmetric in structure (values of matrix elements do not matter) then set `symmetric_mode=True`.

**Parameters**

- `graph` [sparse matrix] Input sparse in CSC or CSR sparse matrix format.
- `symmetric_mode` [bool, optional] Is input matrix guaranteed to be symmetric.

**Returns**

- `perm` [ndarray] Array of permuted row and column indices.

**Notes**

New in version 0.15.0.

**References**

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import reverse_cuthill_mckee

>>> graph = [
            ... [0, 1, 2, 0],
            ... [0, 0, 0, 1],
            ... [2, 0, 0, 3],
            ... [0, 0, 0, 0]]
```
```python
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> reverse_cuthill_mckee(graph)
array([3, 2, 1, 0], dtype=int32)
```

**scipy.sparse.csgraph.maximum_flow**

`scipy.sparse.csgraph.maximum_flow(csgraph, source, sink)`

Maximize the flow between two vertices in a graph.

New in version 1.4.0.

**Parameters**

- `csgraph` [csr_matrix] The square matrix representing a directed graph whose (i, j)’th entry is an integer representing the capacity of the edge between vertices i and j.
- `source` [int] The source vertex from which the flow flows.
- `sink` [int] The sink vertex to which the flow flows.
- `method`: {'edmonds_karp', 'dinic'}, optional

The method/algorith to be used for computing the maximum flow. Following methods are supported,
- ‘edmonds_karp’: Edmonds Karp algorithm in [1].
- ‘dinic’: Dinic’s algorithm in [4].

Default is ‘dinic’.

New in version 1.8.0.

**Returns**

- `res` [MaximumFlowResult] A maximum flow represented by a MaximumFlowResult which includes the value of the flow in `flow_value`, and the residual graph in `residual`.

**Raises**

- `TypeError`: if the input graph is not in CSR format.
- `ValueError`: if the capacity values are not integers, or the source or sink are out of bounds.

**Notes**

This solves the maximum flow problem on a given directed weighted graph: A flow associates to every edge a value, also called a flow, less than the capacity of the edge, so that for every vertex (apart from the source and the sink vertices), the total incoming flow is equal to the total outgoing flow. The value of a flow is the sum of the flow of all edges leaving the source vertex, and the maximum flow problem consists of finding a flow whose value is maximal.

By the max-flow min-cut theorem, the maximal value of the flow is also the total weight of the edges in a minimum cut.

To solve the problem, we provide Edmonds–Karp [1] and Dinic’s algorithm [4]. The implementation of both algorithms strive to exploit sparsity. The time complexity of the former $O(|V| |E|^2)$ and its space complexity is

---

3.3. API definition
\(O(|E|)\). The latter achieves its performance by building level graphs and finding blocking flows in them. Its time complexity is \(O(|V|^2 |E|)\) and its space complexity is \(O(|E|)\).

The maximum flow problem is usually defined with real valued capacities, but we require that all capacities are integral to ensure convergence. When dealing with rational capacities, or capacities belonging to \(\mathbb{Q}\) for some fixed \(x \in \mathbb{R}\), it is possible to reduce the problem to the integral case by scaling all capacities accordingly.

Solving a maximum-flow problem can be used for example for graph cuts optimization in computer vision [3].

**References**

[1], [2], [3], [4]

**Examples**

Perhaps the simplest flow problem is that of a graph of only two vertices with an edge from source (0) to sink (1):

\[
(0) \rightarrow 5 \rightarrow (1)
\]

Here, the maximum flow is simply the capacity of the edge:

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import maximum_flow
>>> graph = csr_matrix([[0, 5], [0, 0]])
>>> maximum_flow(graph, 0, 1).flow_value
5
>>> maximum_flow(graph, 0, 1, method='edmonds_karp').flow_value
5
```

If, on the other hand, there is a bottleneck between source and sink, that can reduce the maximum flow:

\[
(0) --5--> (1) --3--> (2)
\]

```python
>>> graph = csr_matrix([[0, 5, 0], [0, 0, 3], [0, 0, 0]])
>>> maximum_flow(graph, 0, 2).flow_value
3
```

A less trivial example is given in [2], Chapter 26.1:

```python
>>> graph = csr_matrix([[0, 16, 13, 0, 0, 0],
... [0, 0, 10, 12, 0, 0],
... [0, 4, 0, 0, 14, 0],
... [0, 0, 9, 0, 0, 20],
... [0, 0, 0, 7, 0, 4],
... [0, 0, 0, 0, 0, 0]])
>>> maximum_flow(graph, 0, 5).flow_value
23
```

It is possible to reduce the problem of finding a maximum matching in a bipartite graph to a maximum flow problem: Let \(G = ((U, V), E)\) be a bipartite graph. Then, add to the graph a source vertex with edges to every vertex in \(U\) and a sink vertex with edges from every vertex in \(V\). Finally, give every edge in the resulting graph a capacity of 1. Then, a maximum flow in the new graph gives a maximum matching in the original graph consisting of the edges in \(E\) whose flow is positive.
Assume that the edges are represented by a $|U| \times |V|$ matrix in CSR format whose $(i,j)$th entry is 1 if there is an edge from $i \in U$ to $j \in V$ and 0 otherwise; that is, the input is of the form required by \texttt{maximum_bipartite_matching}. Then the CSR representation of the graph constructed above contains this matrix as a block. Here’s an example:

```python
>>> graph = csr_matrix([[0, 1, 0, 1], [1, 0, 1, 0], [0, 1, 1, 0]])
>>> print(graph.toarray())
[[0 1 0 1]
 [1 0 1 0]
 [0 1 1 0]]
>>> i, j = graph.shape
>>> n = graph.nnz
>>> indptr = np.concatenate([0,
...                           graph.indptr + i,
...                           np.arange(n + i + 1, n + i + j + 1),
...                           [n + i + j]])
>>> indices = np.concatenate([np.arange(i, i + 1),
...                            graph.indices + i + 1,
...                            np.repeat(i + j + 1, j)])
>>> data = np.ones(n + i + j, dtype=int)
>>> graph_flow = csr_matrix((data, indices, indptr))
>>> print(graph_flow.toarray())
[[0 1 1 1 0 0 0 0 0]
 [0 0 0 0 1 0 1 0 0]
 [0 0 0 1 0 1 0 0 0]
 [0 0 0 0 1 1 0 0 0]
 [0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 0]]
```

At this point, we can find the maximum flow between the added sink and the added source and the desired matching can be obtained by restricting the residual graph to the block corresponding to the original graph:

```python
>>> flow = maximum_flow(graph_flow, 0, i+j+1, method='dinic')
>>> matching = flow.residual[1:i+1, i+1:i+j+1]
>>> print(matching.toarray())
[[0 1 0 0]
 [1 0 0 0]
 [0 0 1 0]]
```

This tells us that the first, second, and third vertex in $U$ are matched with the second, first, and third vertex in $V$ respectively.

While this solves the maximum bipartite matching problem in general, note that algorithms specialized to that problem, such as \texttt{maximum_bipartite_matching}, will generally perform better.

This approach can also be used to solve various common generalizations of the maximum bipartite matching problem. If, for instance, some vertices can be matched with more than one other vertex, this may be handled by modifying the capacities of the new graph appropriately.
scipy.sparse.csgraph.maximum_bipartite_matching

scipy.sparse.csgraph.maximum_bipartite_matching(graph, perm_type='row')

Returns a matching of a bipartite graph whose cardinality is as least that of any given matching of the graph.

Parameters

- **graph** [sparse matrix] Input sparse in CSR format whose rows represent one partition of the graph and whose columns represent the other partition. An edge between two vertices is indicated by the corresponding entry in the matrix existing in its sparse representation.

- **perm_type** [str, {'row', 'column'}] Which partition to return the matching in terms of: If 'row', the function produces an array whose length is the number of columns in the input, and whose \( j \)'th element is the row matched to the \( j \)'th column. Conversely, if \( \text{perm}_\text{type} \) is 'column', this returns the columns matched to each row.

Returns

- **perm** [ndarray] A matching of the vertices in one of the two partitions. Unmatched vertices are represented by a \(-1\) in the result.

Notes

This function implements the Hopcroft–Karp algorithm \[1\]. Its time complexity is \( O(|E|\sqrt{|V|}) \), and its space complexity is linear in the number of rows. In practice, this asymmetry between rows and columns means that it can be more efficient to transpose the input if it contains more columns than rows.

By Konig’s theorem, the cardinality of the matching is also the number of vertices appearing in a minimum vertex cover of the graph.

Note that if the sparse representation contains explicit zeros, these are still counted as edges.

The implementation was changed in SciPy 1.4.0 to allow matching of general bipartite graphs, where previous versions would assume that a perfect matching existed. As such, code written against 1.4.0 will not necessarily work on older versions.

References

[1]

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import maximum_bipartite_matching
```

As a simple example, consider a bipartite graph in which the partitions contain 2 and 3 elements respectively. Suppose that one partition contains vertices labelled 0 and 1, and that the other partition contains vertices labelled A, B, and C. Suppose that there are edges connecting 0 and C, 1 and A, and 1 and B. This graph would then be represented by the following sparse matrix:

```python
>>> graph = csr_matrix([[0, 0, 1], [1, 1, 0]])
```

Here, the 1s could be anything, as long as they end up being stored as elements in the sparse matrix. We can now calculate maximum matchings as follows:
```python
>>> print(maximum_bipartite_matching(graph, perm_type='column'))
[2 0]
>>> print(maximum_bipartite_matching(graph, perm_type='row'))
[ 1 -1 0]
```

The first output tells us that 1 and 2 are matched with C and A respectively, and the second output tells us that A, B, and C are matched with 1, nothing, and 0 respectively.

Note that explicit zeros are still converted to edges. This means that a different way to represent the above graph is by using the CSR structure directly as follows:

```python
>>> data = [0, 0, 0]
>>> indices = [2, 0, 1]
>>> indptr = [0, 1, 3]
>>> graph = csr_matrix((data, indices, indptr))
>>> print(maximum_bipartite_matching(graph, perm_type='column'))
[2 0]
>>> print(maximum_bipartite_matching(graph, perm_type='row'))
[ 1 -1 0]
```

When one or both of the partitions are empty, the matching is empty as well:

```python
>>> graph = csr_matrix((2, 0))
>>> print(maximum_bipartite_matching(graph, perm_type='column'))
[-1 -1]
>>> print(maximum_bipartite_matching(graph, perm_type='row'))
[]
```

When the input matrix is square, and the graph is known to admit a perfect matching, i.e. a matching with the property that every vertex in the graph belongs to some edge in the matching, then one can view the output as the permutation of rows (or columns) turning the input matrix into one with the property that all diagonal elements are non-empty:

```python
>>> a = [[0, 1, 2, 0], [1, 0, 0, 1], [2, 0, 0, 3], [0, 1, 3, 0]]
>>> graph = csr_matrix(a)
>>> perm = maximum_bipartite_matching(graph, perm_type='row')
>>> print(graph[perm].toarray())
[[1 0 0 1]
 [0 1 2 0]
 [0 1 3 0]
 [2 0 0 3]]
```

### scipy.sparse.csgraph.min_weight_full_bipartite_matching

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>scipy.sparse.csgraph.min_weight_full_bipartite_matching</code></td>
<td>Returns the minimum weight full matching of a bipartite graph.</td>
<td><code>biadjacency_matrix</code>, <code>maximize=False</code></td>
</tr>
</tbody>
</table>

New in version 1.6.0.

**Parameters**

- **biadjacency_matrix**
  - [sparse matrix] Biadjacency matrix of the bipartite graph: A sparse matrix in CSR, CSC, or COO format whose rows represent one partition of the graph and whose columns represent the other partition. An edge between two vertices is indicated by the corresponding entry in

---

**3.3. API definition**

2041
the matrix, and the weight of the edge is given by the value of that entry. This should not be confused with the full adjacency matrix of the graph, as we only need the submatrix defining the bipartite structure.

**maximize**  [bool (default: False)] Calculates a maximum weight matching if true.

**Returns**

**row_ind, col_ind**

[array] An array of row indices and one of corresponding column indices giving the optimal matching. The total weight of the matching can be computed as `graph[row_ind, col_ind].sum()`. The row indices will be sorted; in the case of a square matrix they will be equal to `numpy.arange(graph.shape[0])`.

**Notes**

Let $G = ((U, V), E)$ be a weighted bipartite graph with non-zero weights $w : E \to \mathbb{R} \setminus \{0\}$. This function then produces a matching $M \subseteq E$ with cardinality

$$|M| = \min(|U|, |V|),$$

which minimizes the sum of the weights of the edges included in the matching, $\sum_{e \in M} w(e)$, or raises an error if no such matching exists.

When $|U| = |V|$, this is commonly referred to as a perfect matching; here, since we allow $|U|$ and $|V|$ to differ, we follow Karp [1] and refer to the matching as full.

This function implements the LAPJVsp algorithm [2], short for “Linear assignment problem, Jonker–Volgenant, sparse”.

The problem it solves is equivalent to the rectangular linear assignment problem. [3] As such, this function can be used to solve the same problems as `scipy.optimize.linear_sum_assignment`. That function may perform better when the input is dense, or for certain particular types of inputs, such as those for which the $(i, j)$’th entry is the distance between two points in Euclidean space.

If no full matching exists, this function raises a `ValueError`. For determining the size of the largest matching in the graph, see `maximum_bipartite_matching`.

We require that weights are non-zero only to avoid issues with the handling of explicit zeros when converting between different sparse representations. Zero weights can be handled by adding a constant to all weights, so that the resulting matrix contains no zeros.

**References**

[1], [2], [3]

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import min_weight_full_bipartite_matching
```

Let us first consider an example in which all weights are equal:

```python
>>> biadjacency_matrix = csr_matrix([[1, 1, 1], [1, 0, 0], [0, 1, 0]])
```

Here, all we get is a perfect matching of the graph:
That is, the first, second, and third rows are matched with the third, first, and second column respectively. Note that in this example, the 0 in the input matrix does not correspond to an edge with weight 0, but rather a pair of vertices not paired by an edge.

Note also that in this case, the output matches the result of applying `maximum_bipartite_matching`:

```
>>> from scipy.sparse.csgraph import maximum_bipartite_matching
>>> biadjacency = csr_matrix([[1, 1, 1], [0, 0, 1], [0, 1, 0]])
>>> print(maximum_bipartite_matching(biadjacency, perm_type='column'))
[2 0 1]
```

When multiple edges are available, the ones with lowest weights are preferred:

```
>>> biadjacency = csr_matrix([[3, 3, 6], [4, 3, 5], [10, 1, 8]])
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(col_ind)
[0 2 1]
```

The total weight in this case is $3 + 5 + 1 = 9$:

```
>>> print(biadjacency[row_ind, col_ind].sum())
9
```

When the matrix is not square, i.e. when the two partitions have different cardinalities, the matching is as large as the smaller of the two partitions:

```
>>> biadjacency = csr_matrix([[0, 1, 1], [0, 2, 3]])
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(row_ind, col_ind)
[0 1] [2 1]
```

```
>>> biadjacency = csr_matrix([[0, 1], [3, 1], [1, 4]])
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(row_ind, col_ind)
[0 2] [1 0]
```

When one or both of the partitions are empty, the matching is empty as well:

```
>>> biadjacency = csr_matrix((2, 0))
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(row_ind, col_ind)
[] []
```

In general, we will always reach the same sum of weights as if we had used `scipy.optimize.linear_sum_assignment` but note that for that one, missing edges are represented by a matrix entry of `float('inf')`. Let us generate a random sparse matrix with integer entries between 1 and 10:

```
>>> import numpy as np
>>> from scipy.sparse import random
>>> from scipy.optimize import linear_sum_assignment
>>> sparse = random(10, 10, random_state=42, density=.5, format='coo') *...
    ~10
```
>>> sparse.data = np.ceil(sparse.data)
>>> dense = sparse.toarray()
>>> dense = np.full(sparse.shape, np.inf)
>>> dense[sparse.row, sparse.col] = sparse.data
>>> sparse = sparse.tocsr()
>>> row_ind, col_ind = linear_sum_assignment(dense)
>>> print(dense[row_ind, col_ind].sum())
28.0
>>> row_ind, col_ind = min_weight_full_bipartite_matching(sparse)
>>> print(sparse[row_ind, col_ind].sum())
28.0

scipy.sparse.csgraph.structural_rank

scipy.sparse.csgraph.structural_rank(graph)

Compute the structural rank of a graph (matrix) with a given sparsity pattern.

The structural rank of a matrix is the number of entries in the maximum transversal of the corresponding bipartite graph, and is an upper bound on the numerical rank of the matrix. A graph has full structural rank if it is possible to permute the elements to make the diagonal zero-free.

New in version 0.19.0.

Parameters

- graph [sparse matrix] Input sparse matrix.

Returns

- rank [int] The structural rank of the sparse graph.

References

[1],[2]

Examples

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import structural_rank

>>> graph = [
... [0, 1, 2, 0],
... [1, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 1, 3, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 0) 1
(1, 3) 1
(2, 0) 2
>>> structural_rank(graph)
4

scipy.sparse.csgraph.NegativeCycleError

`exception scipy.sparse.csgraph.NegativeCycleError (message='')
with_traceback(self)`

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

**scipy.sparse.csgraph.construct_dist_matrix**

`scipy.sparse.csgraph.construct_dist_matrix (graph, predecessors[, directed=True, null_value=np.inf])`

Construct distance matrix from a predecessor matrix

New in version 0.11.0.

**Parameters**

- **graph** `[array_like or sparse]` The N x N matrix representation of a directed or undirected graph. If dense, then non-edges are indicated by zeros or infinities.
- **predecessors** `[array_like]` The N x N matrix of predecessors of each node (see Notes below).
- **directed** `[bool, optional]` If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then operate on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].
- **null_value** `[bool, optional]` value to use for distances between unconnected nodes. Default is np.inf

**Returns**

- **dist_matrix** `[ndarray]` The N x N matrix of distances between nodes along the path specified by the predecessor matrix. If no path exists, the distance is zero.
Notes

The predecessor matrix is of the form returned by `shortest_path`. Row \( i \) of the predecessor matrix contains information on the shortest paths from point \( i \): each entry \( \text{predecessors}[i, j] \) gives the index of the previous node in the path from point \( i \) to point \( j \). If no path exists between point \( i \) and \( j \), then \( \text{predecessors}[i, j] = -9999 \).

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import construct_dist_matrix

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 1],
... [0, 0, 3],
... [0, 0, 0]
... ]

>>> graph = csr_matrix(graph)

>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 3) 3

>>> pred = np.array([[-9999, 0, 0, 2],
... [1, -9999, 0, 1],
... [2, 0, -9999, 2],
... [1, 3, 3, -9999]], dtype=np.int32)

>>> construct_dist_matrix(graph=graph, predecessors=pred, directed=False)
array([[0., 1., 2., 5.],
       [1., 0., 3., 1.],
       [2., 3., 0., 3.],
       [2., 1., 3., 0.]]))
```

`scipy.sparse.csgraph.csgraph_from_dense`

`scipy.sparse.csgraph.csgraph_from_dense(graph, null_value=0, nan_null=True, infinity_null=True)`

Construct a CSR-format sparse graph from a dense matrix.

New in version 0.11.0.

**Parameters**

- `graph` : [array_like] Input graph. Shape should be (n_nodes, n_nodes).
- `null_value` : [float or None (optional)] Value that denotes non-edges in the graph. Default is zero.
- `infinity_null` : [bool] If True (default), then infinite entries (both positive and negative) are treated as null edges.
- `nan_null` : [bool] If True (default), then NaN entries are treated as non-edges

**Returns**

- `csgraph` : [csr_matrix] Compressed sparse representation of graph,
Examples

```python
>>> from scipy.sparse.csgraph import csgraph_from_dense

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]

>>> csgraph_from_dense(graph)
<4x4 sparse matrix of type '<class 'numpy.float64'>'
with 4 stored elements in Compressed Sparse Row format>
```

\textbf{scipy.sparse.csgraph.csgraph\(_{\text{from\_masked}}\)}

\texttt{scipy.sparse.csgraph.csgraph\(_{\text{from\_masked}}\)(graph)}

Construct a CSR-format graph from a masked array.

New in version 0.11.0.

**Parameters**

- \texttt{graph}  
  [MaskedArray] Input graph. Shape should be (n\_nodes, n\_nodes).

**Returns**

- \texttt{csgraph}  
  [csr\_matrix] Compressed sparse representation of graph.

Examples

```python
>>> import numpy as np
>>> from scipy.sparse.csgraph import csgraph_from_masked

>>> graph_masked = np.ma.masked_array(data =[
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ],
... mask=[[ True, False, False, True],
... [ True, True, True, False],
... [ True, True, True, False],
... [ True, True, True, True]],
... fill_value = 0)

>>> csgraph_from_masked(graph_masked)
<4x4 sparse matrix of type '<class 'numpy.float64'>'
with 4 stored elements in Compressed Sparse Row format>
```
scipy.sparse.csgraph.csgraph_masked_from_dense

`scipy.sparse.csgraph.csgraph_masked_from_dense(graph, null_value=0, nan_null=True, infinity_null=True, copy=True)`

Construct a masked array graph representation from a dense matrix.

New in version 0.11.0.

**Parameters**

- **graph** *(array_like)* Input graph. Shape should be (n_nodes, n_nodes).
- **null_value** *(float or None (optional))* Value that denotes non-edges in the graph. Default is zero.
- **infinity_null** *(bool)* If True (default), then infinite entries (both positive and negative) are treated as null edges.
- **nan_null** *(bool)* If True (default), then NaN entries are treated as non-edges.

**Returns**

- **csgraph** *[MaskedArray]* masked array representation of graph

**Examples**

```python
>>> from scipy.sparse.csgraph import csgraph_masked_from_dense

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]

>>> csgraph_masked_from_dense(graph)
masked_array(
    data=[[--, 1, 2, --],
          [--, --, --, 1],
          [--, --, --, 3],
          [--, --, --, --]],
    mask=[[ True, False, False, True],
           [ True, True, True, False],
           [ True, True, True, False],
           [ True, True, True, True]],
    fill_value=0)
```

scipy.sparse.csgraph.csgraph_to_dense

`scipy.sparse.csgraph.csgraph_to_dense(csgraph, null_value=0)`

Convert a sparse graph representation to a dense representation.

New in version 0.11.0.

**Parameters**

- **csgraph** *[csr_matrix, csc_matrix, or lil_matrix]* Sparse representation of a graph.
- **null_value** *[float, optional]* The value used to indicate null edges in the dense representation. Default is 0.
Returns

**graph**  [ndarray] The dense representation of the sparse graph.

Notes

For normal sparse graph representations, calling `csgraph_to_dense` with `null_value=0` produces an equivalent result to using dense format conversions in the main sparse package. When the sparse representations have repeated values, however, the results will differ. The tools in `scipy.sparse` will add repeating values to obtain a final value. This function will select the minimum among repeating values to obtain a final value. For example, here we'll create a two-node directed sparse graph with multiple edges from node 0 to node 1, of weights 2 and 3. This illustrates the difference in behavior:

```python
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([2, 3])
>>> indices = np.array([1, 1])
>>> indptr = np.array([0, 2, 2])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 5],
       [0, 0]])
>>> csgraph.csgraph_to_dense(M)
array([[0., 2.],
       [0., 0.]])
```

The reason for this difference is to allow a compressed sparse graph to represent multiple edges between any two nodes. As most sparse graph algorithms are concerned with the single lowest-cost edge between any two nodes, the default `scipy.sparse` behavior of summing multiple weights does not make sense in this context.

The other reason for using this routine is to allow for graphs with zero-weight edges. Let's look at the example of a two-node directed graph, connected by an edge of weight zero:

```python
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([0.0])
>>> indices = np.array([1])
>>> indptr = np.array([0, 1, 1])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 0],
       [0, 0]])
>>> csgraph.csgraph_to_dense(M, np.inf)
array([[inf, 0.],
       [inf, inf]])
```

In the first case, the zero-weight edge gets lost in the dense representation. In the second case, we can choose a different null value and see the true form of the graph.
Examples

```python
>>> from scipy.sparse import csr_matrix
csr_matrix
```

```python
>>> from scipy.sparse.csgraph import csgraph_to_dense
csgraph_to_dense
```

```python
graph = csr_matrix( [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]
)
graph
<4x4 sparse matrix of type '<class 'numpy.int64'>'
    with 4 stored elements in Compressed Sparse Row format>
```

```python
csgraph_to_dense(graph)
array([[0., 1., 2., 0.],
   [0., 0., 0., 1.],
   [0., 0., 0., 3.],
   [0., 0., 0., 0.]]))
```

**scipy.sparse.csgraph.csgraph_to_masked**

Convert a sparse graph representation to a masked array representation

New in version 0.11.0.

**Parameters**

csgraph: [csr_matrix, csc_matrix, or lil_matrix] Sparse representation of a graph.

**Returns**

graph: [MaskedArray] The masked dense representation of the sparse graph.
data=[[ --, 1.0, 2.0, --],
      [ --, --, --, 1.0],
      [ --, --, --, 3.0],
      [ --, --, --, --]],
mask=[[ True, False, False, True],
      [ True, True, True, False],
      [ True, True, True, False],
      [ True, True, True, True]],
fill_value=1e+20)

scipy.sparse.csgraph.reconstruct_path

scipy.sparse.csgraph.reconstruct_path(csgraph, predecessors, directed=True)

Construct a tree from a graph and a predecessor list.
New in version 0.11.0.

Parameters

- csgraph [array_like or sparse matrix] The N x N matrix representing the directed or undirected graph from which the predecessors are drawn.
- predecessors [array_like, one dimension] The length-N array of indices of predecessors for the tree. The index of the parent of node i is given by predecessors[i].
- directed [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then operate on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

Returns
cstree [csr matrix] The N x N directed compressed-sparse representation of the tree drawn from csgraph which is encoded by the predecessor list.

Examples

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import reconstruct_path

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 3) 3

>>> pred = np.array([-9999, 0, 0, 1], dtype=np.int32)
```python
>>> cstree = reconstruct_path(csgraph=graph, predecessors=pred, _
directed=False)
>>> cstree.todense()
```

```matlab
matrix([[0., 1., 2., 0.],
        [0., 0., 0., 1.],
        [0., 0., 0., 0.],
        [0., 0., 0., 0.]])
```

### Graph Representations

This module uses graphs which are stored in a matrix format. A graph with \( N \) nodes can be represented by an \( (N \times N) \) adjacency matrix \( G \). If there is a connection from node \( i \) to node \( j \), then \( G[i, j] = w \), where \( w \) is the weight of the connection. For nodes \( i \) and \( j \) which are not connected, the value depends on the representation:

- for dense array representations, non-edges are represented by \( G[i, j] = 0 \), infinity, or NaN.
- for dense masked representations (of type np.ma.MaskedArray), non-edges are represented by masked values. This can be useful when graphs with zero-weight edges are desired.
- for sparse array representations, non-edges are represented by non-entries in the matrix. This sort of sparse representation also allows for edges with zero weights.

As a concrete example, imagine that you would like to represent the following undirected graph:

![Graph](image)

This graph has three nodes, where node 0 and 1 are connected by an edge of weight 2, and nodes 0 and 2 are connected by an edge of weight 1. We can construct the dense, masked, and sparse representations as follows, keeping in mind that an undirected graph is represented by a symmetric matrix:

```python
>>> G_dense = np.array([[0, 2, 1],
                      ...                     [2, 0, 0],
                      ...                     [1, 0, 0]])
>>> G_masked = np.ma.masked_values(G_dense, 0)
>>> from scipy.sparse import csr_matrix
>>> G_sparse = csr_matrix(G_dense)
```

This becomes more difficult when zero edges are significant. For example, consider the situation when we slightly modify the above graph:

![Graph](image)
This is identical to the previous graph, except nodes 0 and 2 are connected by an edge of zero weight. In this case, the dense representation above leads to ambiguities: how can non-edges be represented if zero is a meaningful value? In this case, either a masked or sparse representation must be used to eliminate the ambiguity:

```python
>>> G2_data = np.array([[np.inf, 2, 0],
                      [2, np.inf, np.inf],
                      [0, np.inf, np.inf]])
>>> G2_masked = np.ma.masked_invalid(G2_data)
>>> from scipy.sparse.csgraph import csgraph_from_dense
>>> # G2_sparse = csr_matrix(G2_data) would give the wrong result
>>> G2_sparse = csgraph_from_dense(G2_data, null_value=np.inf)
>>> G2_sparse.data
array([ 2., 0., 2., 0.])
```

Here we have used a utility routine from the csgraph submodule in order to convert the dense representation to a sparse representation which can be understood by the algorithms in submodule. By viewing the data array, we can see that the zero values are explicitly encoded in the graph.

### Directed vs. undirected

Matrices may represent either directed or undirected graphs. This is specified throughout the csgraph module by a boolean keyword. Graphs are assumed to be directed by default. In a directed graph, traversal from node i to node j can be accomplished over the edge G[i, j], but not the edge G[j, i]. Consider the following dense graph:

```python
>>> G_dense = np.array([[0, 1, 0],
                      [2, 0, 3],
                      [0, 4, 0]])
```

When `directed=True` we get the graph:

```
---1--> ---3-->  
(0)      (1)      (2)
<--2--- <--4---
```

In a non-directed graph, traversal from node i to node j can be accomplished over either G[i, j] or G[j, i]. If both edges are not null, and the two have unequal weights, then the smaller of the two is used.

So for the same graph, when `directed=False` we get the graph:

```
(0)--1--(1)--3--(2)
```

Note that a symmetric matrix will represent an undirected graph, regardless of whether the 'directed' keyword is set to True or False. In this case, using `directed=True` generally leads to more efficient computation.

The routines in this module accept as input either scipy.sparse representations (csr, csc, or lil format), masked representations, or dense representations with non-edges indicated by zeros, infinities, and NaN entries.
3.3.25 Spatial algorithms and data structures (*scipy.spatial*)

**Spatial transformations**

These are contained in the `scipy.spatial.transform` submodule.

**Nearest-neighbor queries**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>scipy.spatial.KDTree</code></td>
<td>kd-tree for quick nearest-neighbor lookup.</td>
</tr>

</tr>
</tbody>
</table>

**scipy.spatial.KDTree**

```python
class scipy.spatial.KDTree(data, leafsize=10, compact_nodes=True, copy_data=False, balanced_tree=True, boxsize=None)
```

kd-tree for quick nearest-neighbor lookup.

This class provides an index into a set of k-dimensional points which can be used to rapidly look up the nearest neighbors of any point.

**Parameters**

- **data** [array_like, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles, and so modifying this data will result in bogus results. The data are also copied if the kd-tree is built with copy_data=True.
- **leafsize** [positive int, optional] The number of points at which the algorithm switches over to brute-force. Default: 10.
- **compact_nodes** [bool, optional] If True, the kd-tree is built to shrink the hyperrectangles to the actual data range. This usually gives a more compact tree that is robust against degenerated input data and gives faster queries at the expense of longer build time. Default: True.
- **copy_data** [bool, optional] If True the data is always copied to protect the kd-tree against data corruption. Default: False.
- **balanced_tree** [bool, optional] If True, the median is used to split the hyperrectangles instead of the midpoint. This usually gives a more compact tree and faster queries at the expense of longer build time. Default: True.
- **boxsize** [array_like or scalar, optional] Apply a m-d toroidal topology to the KDTree. The topology is generated by \( x_i + n_i L_i \) where \( n_i \) are integers and \( L_i \) is the boxsize along i-th dimension. The input data shall be wrapped into \([0, L_i)\). A ValueError is raised if any of the data is outside of this bound.
Notes

The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary tree, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value. During construction, the axis and splitting point are chosen by the “sliding midpoint” rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the r closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the r approximate closest neighbors.

For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

Attributes

- **data**  
  [ndarray, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles. The data are also copied if the kd-tree is built with `copy_data=True`.

- **leafsize**  
  [positive int] The number of points at which the algorithm switches over to brute-force.

- **m**  
  [int] The dimension of a single data-point.

- **n**  
  [int] The number of data points.

- **maxes**  
  [ndarray, shape (m,)] The maximum value in each dimension of the n data points.

- **mins**  
  [ndarray, shape (m,)] The minimum value in each dimension of the n data points.

- **size**  
  [int] The number of nodes in the tree.

Methods

- **count_neighbors**(other, r[, p, weights,...])  
  Count how many nearby pairs can be formed.

- **query**(x[, k, eps, p, distance_upper_bound,...])  
  Query the kd-tree for nearest neighbors.

- **query_ball_point**(x, r[, p, eps, workers,...])  
  Find all points within distance r of point(s) x.

- **query_ball_tree**(other, r[, p, eps])  
  Find all pairs of points between self and other whose distance is at most r.

- **query_pairs**(r[, p, eps, output_type])  
  Find all pairs of points in self whose distance is at most r.

- **sparse_distance_matrix**(other, max_distance)  
  Compute a sparse distance matrix.

```
scipy.spatial.KDTree.count_neighbors

KDTree.count_neighbors (other, r=2.0, weights=None, cumulative=True)

Count how many nearby pairs can be formed.

Count the number of pairs (x1, x2) can be formed, with x1 drawn from self and x2 drawn from other, and where distance(x1, x2, p) <= r.

Data points on self and other are optionally weighted by the weights argument. (See below)

This is adapted from the “two-point correlation” algorithm described by Gray and Moore [1]. See notes for further discussion.

Parameters

- **other**  
  [KDTree] The other tree to draw points from, can be the same tree as self.
```

**r** [float or one-dimensional array of floats] The radius to produce a count for. Multiple radii are searched with a single tree traversal. If the count is non-cumulative (`cumulative=False`), `r` defines the edges of the bins, and must be non-decreasing.

**p** [float, optional] $1 \leq p \leq \infty$. Which Minkowski p-norm to use. Default 2.0. A finite large $p$ may cause a ValueError if overflow can occur.

**weights** [tuple, array_like, or None, optional] If None, the pair-counting is unweighted. If given as a tuple, `weights[0]` is the weights of points in `self`, and `weights[1]` is the weights of points in `other`; either can be `None` to indicate the points are unweighted. If given as an array_like, `weights` is the weights of points in `self` and `other`. For this to make sense, `self` and `other` must be the same tree. If `self` and `other` are two different trees, a ValueError is raised. Default: None

**cumulative** [bool, optional] Whether the returned counts are cumulative. When `cumulative` is set to `False` the algorithm is optimized to work with a large number of bins ($>10$) specified by `r`. When `cumulative` is set to `True`, the algorithm is optimized to work with a small number of `r`. Default: `True`

New in version 1.6.0.

**Returns**

**result** [scalar or 1-D array] The number of pairs. For unweighted counts, the result is integer. For weighted counts, the result is float. If `cumulative` is `False`, `result[i]` contains the counts with $(-\infty \text{ if } i == 0 \text{ else } r[i-1]) < R \leq r[i]$

**Notes**

Pair-counting is the basic operation used to calculate the two point correlation functions from a data set composed of position of objects.

Two point correlation function measures the clustering of objects and is widely used in cosmology to quantify the large scale structure in our Universe, but it may be useful for data analysis in other fields where self-similar assembly of objects also occur.

The Landy-Szalay estimator for the two point correlation function of $D$ measures the clustering signal in $D$. [2]

For example, given the position of two sets of objects,

- objects $D$ (data) contains the clustering signal, and
- objects $R$ (random) that contains no signal,

\[
\xi(r) = \frac{\langle D, D \rangle - 2f \langle D, R \rangle + f^2 \langle R, R \rangle}{f^2 \langle R, R \rangle},
\]

where the brackets represents counting pairs between two data sets in a finite bin around $r$ (distance), corresponding to setting `cumulative=False`, and $f = \frac{\text{float(len(D))}}{\text{float(len(R))}}$ is the ratio between number of objects from data and random.

The algorithm implemented here is loosely based on the dual-tree algorithm described in [1]. We switch between two different pair-accumulation scheme depending on the setting of `cumulative`. The computing time of the method we use when for `cumulative == False` does not scale with the total number of bins. The algorithm for `cumulative == True` scales linearly with the number of bins, though it is slightly faster when only 1 or 2 bins are used. [5].
As an extension to the naive pair-counting, weighted pair-counting counts the product of weights instead of number of pairs. Weighted pair-counting is used to estimate marked correlation functions ([3], section 2.2), or to properly calculate the average of data per distance bin (e.g. [4], section 2.1 on redshift).

Examples

You can count neighbors number between two kd-trees within a distance:

```python
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((5, 2))
>>> points2 = rng.random((5, 2))
>>> kd_tree1 = KDTree(points1)
>>> kd_tree2 = KDTree(points2)
>>> kd_tree1.count_neighbors(kd_tree2, 0.2)
1
```

This number is same as the total pair number calculated by `query_ball_tree`:

```python
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> sum([len(i) for i in indexes])
1
```

scipy.spatial.KDTree.query

KDTree.query(x, k=1, eps=0, p=2, distance_upper_bound=inf, workers=1)

Query the kd-tree for nearest neighbors.

**Parameters**

- `x` [array_like, last dimension self.m] An array of points to query.
- `k` [int or Sequence[int], optional] Either the number of nearest neighbors to return, or a list of the k-th nearest neighbors to return, starting from 1.
- `eps` [nonnegative float, optional] Return approximate nearest neighbors; the kth returned value is guaranteed to be no further than (1+eps) times the distance to the real kth nearest neighbor.
- `p` [float, 1<=p<=infinity, optional] Which Minkowski p-norm to use. 1 is the sum-of-absolute-values distance (“Manhattan” distance). 2 is the usual Euclidean distance. infinity is the maximum-coordinate-difference distance. A large, finite p may cause a ValueError if overflow can occur.
- `distance_upper_bound` [nonnegative float, optional] Return only neighbors within this distance. This is used to prune tree searches, so if you are doing a series of nearest-neighbor queries, it may help to supply the distance to the nearest neighbor of the most recent point.
- `workers` [int, optional] Number of workers to use for parallel processing. If -1 is given all CPU threads are used. Default: 1. New in version 1.6.0.

**Returns**

- `d` [float or array of floats] The distances to the nearest neighbors. If `x` has shape `tuple+(self.m,)`, then `d` has shape `tuple+(k,)`. When `k == 1`, the last dimen-
sion of the output is squeezed. Missing neighbors are indicated with infinite distances. Hits are sorted by distance (nearest first).

Deprecated since version 1.6.0: If k=None, then d is an object array of shape tuple, containing lists of distances. This behavior is deprecated and will be removed in SciPy 1.8.0, use query_ball_point instead.

Examples

```python
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> x, y = np.mgrid[0:5, 2:8]
>>> tree = KDTree(np.c_[x.ravel(), y.ravel()])

To query the nearest neighbours and return squeezed result, use

```python
>>> dd, ii = tree.query([[0, 0], [2.2, 2.9]], k=1)
>>> print(dd, ii, sep='\n')
[2.0 0.2236068]
[0 13]
```

To query the nearest neighbours and return unsqueezed result, use

```python
>>> dd, ii = tree.query([[0, 0], [2.2, 2.9]], k=[1])
>>> print(dd, ii, sep='\n')
[[2.0 0.2236068]]
[[0 13]]
```

To query the second nearest neighbours and return unsqueezed result, use

```python
>>> dd, ii = tree.query([[0, 0], [2.2, 2.9]], k=[2])
>>> print(dd, ii, sep='\n')
[[2.23606798 0.80622577]]
[[6 19]]
```

To query the first and second nearest neighbours, use

```python
>>> dd, ii = tree.query([[0, 0], [2.2, 2.9]], k=2)
>>> print(dd, ii, sep='\n')
[[2.23606798 0.80622577]]
[[0 6]
 [13 19]]
```

or, be more specific

```python
>>> dd, ii = tree.query([[0, 0], [2.2, 2.9]], k=[1, 2])
>>> print(dd, ii, sep='\n')
```

(continues on next page)

(continued from previous page)

[[2.0  2.32606798]
 [0.2236068 0.80622577]
 [[ 0  6]
 [ 13  19]]

scipy.spatial.KDTree.query_ball_point

KDTree.query_ball_point (x, r, p=2.0, eps=0, workers=1, return_sorted=None, return_length=False)

Find all points within distance r of point(s) x.

Parameters

x [array_like, shape tuple + (self.m,)] The point or points to search for neighbors of.
r [array_like, float] The radius of points to return, must broadcast to the length of x.
p [float, optional] Which Minkowski p-norm to use. Should be in the range [1, inf]. A finite large p may cause a ValueError if overflow can occur.
eps [nonnegative float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than r / (1 + eps), and branches are added in bulk if their furthest points are nearer than r * (1 + eps).
workers [int, optional] Number of jobs to schedule for parallel processing. If -1 is given all processors are used. Default: 1.
New in version 1.6.0.
return_sorted [bool, optional] Sorts returned indicies if True and does not sort them if False. If None, does not sort single point queries, but does sort multi-point queries which was the behavior before this option was added.
New in version 1.6.0.
return_length: bool, optional
Return the number of points inside the radius instead of a list of the indices.
New in version 1.6.0.

Returns

results [list or array of lists] If x is a single point, returns a list of the indices of the neighbors of x. If x is an array of points, returns an object array of shape tuple containing lists of neighbors.

Notes

If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a KDTree and using query_ball_tree.
Examples

```python
>>> from scipy import spatial
>>> x, y = np.mgrid[0:5, 0:5]
>>> points = np.c_[x.ravel(), y.ravel()]
>>> tree = spatial.KDTree(points)
>>> sorted(tree.query_ball_point(([2, 0], 1))
[5, 10, 11, 15]

Query multiple points and plot the results:

```python
>>> import matplotlib.pyplot as plt
>>> points = np.asarray(points)
>>> plt.plot(points[:,0], points[:,1], '.')
>>> for results in tree.query_ball_point(([2, 0], [3, 3]), 1):
...     nearby_points = points[results]
...     plt.plot(nearby_points[:,0], nearby_points[:,1], 'o')
>>> plt.margins(0.1, 0.1)
>>> plt.show()
```

scipy.spatial.KDTree.query_ball_tree

KDTree.query_ball_tree (other, r, p=2.0, eps=0)

Find all pairs of points between self and other whose distance is at most r.

Parameters

- **other**: [KDTree instance] The tree containing points to search against.
- **r**: [float] The maximum distance, has to be positive.
- **p**: [float, optional] Which Minkowski norm to use. p has to meet the condition 1 <= p <= infinity.
- **eps**: [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than r/(1+eps), and branches are added in bulk if their furthest points are nearer than r * (1+eps). eps has to be non-negative.
Returns

results  [list of lists] For each element self.data[i] of this tree, results[i] is a list of the indices of its neighbors in other.data.

Examples

You can search all pairs of points between two kd-trees within a distance:

```python
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((15, 2))
>>> points2 = rng.random((15, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points1[:, 0], points1[:, 1], "xk", markersize=14)
>>> plt.plot(points2[:, 0], points2[:, 1], "og", markersize=14)
>>> kd_tree1 = KDTree(points1)
>>> kd_tree2 = KDTree(points2)
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> for i in range(len(indexes)):
...     for j in indexes[i]:
...         plt.plot([points1[i, 0], points2[j, 0]],
...                  [points1[i, 1], points2[j, 1]], "-r")
>>> plt.show()
```

scipy.spatial.KDTree.query_pairs

KDTree.query_pairs(r, p=2.0, eps=0, output_type='set')

Find all pairs of points in self whose distance is at most r.

Parameters

- r  [positive float] The maximum distance.
- p  [float, optional] Which Minkowski norm to use. p has to meet the condition 1 <= p <= infinity.
- eps  [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than r/(1+eps), and branches are added in bulk if their furthest points are nearer than r * (1+eps). eps has to be non-negative.
- output_type  [string, optional] Choose the output container, ‘set’ or ‘ndarray’. Default: ‘set’

New in version 1.6.0.

Returns

results  [set or ndarray] Set of pairs (i, j), with i < j, for which the corresponding positions are close. If output_type is ‘ndarray’, an ndarry is returned instead of a set.
Examples

You can search all pairs of points in a kd-tree within a distance:

```python
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> rng = np.random.default_rng()
>>> points = rng.random((20, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points[:, 0], points[:, 1], "xk", markersize=14)
>>> kd_tree = KDTree(points)
>>> pairs = kd_tree.query_pairs(r=0.2)
>>> for (i, j) in pairs:
...     plt.plot([points[i, 0], points[j, 0]],
...              [points[i, 1], points[j, 1]], "-r")
>>> plt.show()
```

scipy.spatial.KDTree.sparse_distance_matrix

KDTree.sparse_distance_matrix(other, max_distance, p=2.0, output_type='dok_matrix')

Compute a sparse distance matrix.

Computes a distance matrix between two KDTrees, leaving as zero any distance greater than max_distance.

**Parameters**

- **other** [KDTree]
- **max_distance** [positive float]
- **p** [float, 1<=p<=infinity] Which Minkowski p-norm to use. A finite large p may cause a ValueError if overflow can occur.

**Returns**

- **result** [dok_matrix, coo_matrix, dict or ndarray] Sparse matrix representing the results in “dictionary of keys” format. If a dict is returned the keys are (i,j) tuples of indices. If output_type is ‘ndarray’ a record array with fields ‘i’, ‘j’, and ‘v’ is returned.

Examples

You can compute a sparse distance matrix between two kd-trees:

```python
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((5, 2))
>>> points2 = rng.random((5, 2))
>>> kd_tree1 = KDTree(points1)
>>> kd_tree2 = KDTree(points2)
```
You can check distances above the \textit{max distance} are zeros:

```python
>>> from scipy.spatial import distance_matrix
>>> distance_matrix(points1, points2)
array([[0.56906522, 0.39923701, 0.12295571, 0.8658745 , 0.79428925],
       [0.37327919, 0.7225693 , 0.87665969, 0.32580855, 0.75679479],
       [0.28942611, 0.30088013, 0.6395831 , 0.2333084 , 0.33630734],
       [0.31994999, 0.72658602, 0.71124834, 0.55396483, 0.90785663],
       [0.24617575, 0.29571802, 0.26836782, 0.57714465, 0.6473269 ]])
```

### scipy.spatial.cKDTree

```python
class scipy.spatial.cKDTree(data, leafsize=16, compact_nodes=True, copy_data=False, balanced_tree=True, boxsize=None)
```

kd-tree for quick nearest-neighbor lookup

This class provides an index into a set of k-dimensional points which can be used to rapidly look up the nearest neighbors of any point.

**Note:** `cKDTree` is functionally identical to `KDTree`. Prior to SciPy v1.6.0, `cKDTree` had better performance and slightly different functionality but now the two names exist only for backward-compatibility reasons. If compatibility with SciPy < 1.6 is not a concern, prefer `KDTree`.

**Parameters**

- **data** [array_like, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles, and so modifying this data will result in bogus results. The data are also copied if the kd-tree is built with `copy_data=True`.

- **leafsize** [positive int, optional] The number of points at which the algorithm switches over to brute-force. Default: 16.

- **compact_nodes** [bool, optional] If True, the kd-tree is built to shrink the hyperrectangles to the actual data range. This usually gives a more compact tree that is robust against degenerated input data and gives faster queries at the expense of longer build time. Default: True.

- **copy_data** [bool, optional] If True the data is always copied to protect the kd-tree against data corruption. Default: False.

- **balanced_tree**
[bool, optional] If True, the median is used to split the hyperrectangles instead of the midpoint. This usually gives a more compact tree and faster queries at the expense of longer build time. Default: True.

**boxsize**
[array_like or scalar, optional] Apply a m-d toroidal topology to the KDTree. The topology is generated by \(x_i + n_i L_i\) where \(n_i\) are integers and \(L_i\) is the boxsize along \(i\)-th dimension. The input data shall be wrapped into \([0, L_i)\). A ValueError is raised if any of the data is outside of this bound.

**Notes**

The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary tree, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value.

During construction, the axis and splitting point are chosen by the “sliding midpoint” rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the \(r\) closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the \(r\) approximate closest neighbors.

For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

**Attributes**

- **data** [ndarray, shape (n,m)] The \(n\) data points of dimension \(m\) to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles. The data are also copied if the kd-tree is built with \(copy\_data=True\).
- **leafsize** [positive int] The number of points at which the algorithm switches over to brute-force.
- **m** [int] The dimension of a single data-point.
- **n** [int] The number of data points.
- **maxes** [ndarray, shape (m,)] The maximum value in each dimension of the \(n\) data points.
- **mins** [ndarray, shape (m,)] The minimum value in each dimension of the \(n\) data points.
- **tree** [object, class cKDTreeNode] This attribute exposes a Python view of the root node in the cKDTree object. A full Python view of the kd-tree is created dynamically on the first access. This attribute allows you to create your own query functions in Python.
- **size** [int] The number of nodes in the tree.

**Methods**

- **count_neighbors**(self, other, r[, p,...]) Count how many nearby pairs can be formed.
- **query**(self, x[, k, eps, p, ...]) Query the kd-tree for nearest neighbors.
- **query_ball_point**(self, x, r[, p, eps, ...]) Find all points within distance \(r\) of point(s) \(x\).
- **query_ball_tree**(self, other, r[, p, eps]) Find all pairs of points between \(self\) and \(other\) whose distance is at most \(r\).
- **query_pairs**(self, r[, p, eps]) Find all pairs of points in \(self\) whose distance is at most \(r\).
- **sparse_distance_matrix**(self, other, max_distance) Compute a sparse distance matrix.
scipy.spatial.cKDTree.count_neighbors

**scipy.spatial.cKDTree.count_neighbors** *(self, other, r, p=2., weights=None, cumulative=True)*

Count how many nearby pairs can be formed.

Count the number of pairs \((x_1, x_2)\) can be formed, with \(x_1\) drawn from `self` and \(x_2\) drawn from `other`, and where \(\text{distance}(x_1, x_2, p) \leq r\).

Data points on `self` and `other` are optionally weighted by the `weights` argument. (See below)

This is adapted from the “two-point correlation” algorithm described by Gray and Moore [1]. See notes for further discussion.

**Parameters**

- `other` : [cKDTree instance] The other tree to draw points from, can be the same tree as `self`.  
- `r` : [float or one-dimensional array of floats] The radius to produce a count for. Multiple radii are searched with a single tree traversal. If the count is non-cumulative(`cumulative=False`), `r` defines the edges of the bins, and must be non-decreasing.
- `p` : [float, optional] \(1 \leq p \leq \infty\). Which Minkowski p-norm to use. Default 2.0. A finite large p may cause a ValueError if overflow can occur.
- `weights` : [tuple, array_like, or None, optional] If None, the pair-counting is unweighted. If given as a tuple, `weights[0]` is the weights of points in `self`, and `weights[1]` is the weights of points in `other`; either can be None to indicate the points are unweighted. If given as an array_like, weights is the weights of points in `self` and `other`. For this to make sense, `self` and `other` must be the same tree. If `self` and `other` are two different trees, a ValueError is raised. Default: None
- `cumulative` : [bool, optional] Whether the returned counts are cumulative. When cumulative is set to False the algorithm is optimized to work with a large number of bins (>10) specified by `r`. When cumulative is set to True, the algorithm is optimized to work with a small number of `r`. Default: True

**Returns**

- `result` : [scalar or 1-D array] The number of pairs. For unweighted counts, the result is integer. For weighted counts, the result is float. If cumulative is False, `result[i]` contains the counts with \((-\infty \text{ if } i == 0 \text{ else } r[i-1]) < R \leq r[i]\)

**Notes**

Pair-counting is the basic operation used to calculate the two point correlation functions from a data set composed of position of objects.

Two point correlation function measures the clustering of objects and is widely used in cosmology to quantify the large scale structure in our Universe, but it may be useful for data analysis in other fields where self-similar assembly of objects also occur.

The Landy-Szalay estimator for the two point correlation function of \(D\) measures the clustering signal in \(D\). [2]

For example, given the position of two sets of objects,

- objects \(D\) (data) contains the clustering signal, and
- objects \(R\) (random) that contains no signal,
\[ \xi(r) = \frac{<D, D> - 2f <D, R> + f^2 <R, R>}{f^2 <R, R>}, \]

where the brackets represents counting pairs between two data sets in a finite bin around \( r \) (distance), corresponding to setting \( cumulative=False \), and \( f = \frac{\text{float(len(D))}}{\text{float(len(R))}} \) is the ratio between number of objects from data and random.

The algorithm implemented here is loosely based on the dual-tree algorithm described in [1]. We switch between two different pair-cumulation scheme depending on the setting of \( cumulative \). The computing time of the method we use when for \( cumulative == False \) does not scale with the total number of bins. The algorithm for \( cumulative == True \) scales linearly with the number of bins, though it is slightly faster when only 1 or 2 bins are used. [5].

As an extension to the naive pair-counting, weighted pair-counting counts the product of weights instead of number of pairs. Weighted pair-counting is used to estimate marked correlation functions ([3], section 2.2), or to properly calculate the average of data per distance bin (e.g. [4], section 2.1 on redshift).

**Examples**

You can count neighbors number between two kd-trees within a distance:

```python
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((5, 2))
>>> points2 = rng.random((5, 2))
>>> kd_tree1 = cKDTree(points1)
>>> kd_tree2 = cKDTree(points2)
>>> kd_tree1.count_neighbors(kd_tree2, 0.2)
1
```

This number is same as the total pair number calculated by `query_ball_tree`:

```python
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> sum([len(i) for i in indexes])
1
```

**scipy.spatial.cKDTree.query**

`cKDTree.query`(*self*, *x*, *k=1*, *eps=0*, *p=2*, *distance_upper_bound=np.inf*, *workers=1*)

Query the kd-tree for nearest neighbors.

**Parameters**

- **x** ([array_like, last dimension self.m]) An array of points to query.
- **k** ([list of integer or integer]) The list of k-th nearest neighbors to return. If k is an integer it is treated as a list of \([1, \ldots k]\) (range(1, k+1)). Note that the counting starts from 1.
- **eps** ([non-negative float]) Return approximate nearest neighbors; the k-th returned value is guaranteed to be no further than \((1+\text{eps})\) times the distance to the real k-th nearest neighbor.
- **p** ([float, \(1\leq p\leq \infty\)]) Which Minkowski p-norm to use. 1 is the sum-of-absolute-values “Manhattan” distance 2 is the usual Euclidean distance infinity is the maximum-coordinate-difference distance A finite large p may cause a `ValueError` if overflow can occur.
**distance_upper_bound**

[nonnegative float] Return only neighbors within this distance. This is used to prune tree searches, so if you are doing a series of nearest-neighbor queries, it may help to supply the distance to the nearest neighbor of the most recent point.

**workers**

[int, optional] Number of workers to use for parallel processing. If -1 is given all CPU threads are used. Default: 1.

Changed in version 1.6.0: The “n_jobs” argument was renamed “workers”. The old name “n_jobs” is deprecated and will stop working in SciPy 1.8.0.

**Returns**

- **d** [array of floats] The distances to the nearest neighbors. If x has shape tuple+(self.m,), then d has shape tuple+(k,). When k == 1, the last dimension of the output is squeezed. Missing neighbors are indicated with infinite distances.

- **i** [ndarray of ints] The index of each neighbor in self.data. If x has shape tuple+(self.m,), then i has shape tuple+(k,). When k == 1, the last dimension of the output is squeezed. Missing neighbors are indicated with self.n.

**Notes**

If the KD-Tree is periodic, the position x is wrapped into the box.

When the input k is a list, a query for arange(max(k)) is performed, but only columns that store the requested values of k are preserved. This is implemented in a manner that reduces memory usage.

**Examples**

```python
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> x, y = np.mgrid[0:5, 2:8]
>>> tree = cKDTree(np.c_[x.ravel(), y.ravel()])

To query the nearest neighbours and return squeezed result, use

```python
>>> dd, ii = tree.query([[0, 0], [2.2, 2.9]], k=1)
>>> print(dd, ii, sep='\n')
[2. 0.2236068]  
[ 0 13]
```  

To query the nearest neighbours and return unsqueezed result, use

```python
>>> dd, ii = tree.query([[0, 0], [2.2, 2.9]], k=[1])
>>> print(dd, ii, sep='\n')
[[2. ]
 [0.2236068]]
[[ 0]
 [13]]
```  

To query the second nearest neighbours and return unsqueezed result, use

```python
>>> dd, ii = tree.query([[0, 0], [2.2, 2.9]], k=[2])
>>> print(dd, ii, sep='\n')
[[2.23606798]
 [0.223606798]]
(continues on next page)
To query the first and second nearest neighbours, use

```python
>>> dd, ii = tree.query([[0, 0], [2.2, 2.9]], k=2)
>>> print(dd, ii, sep='\n')
[[2. 2.23606798] [0.2236068 0.80622577]]
[[ 0 6] [13 19]]
```

or, be more specific

```python
>>> dd, ii = tree.query([[0, 0], [2.2, 2.9]], k=[1, 2])
>>> print(dd, ii, sep='\n')
[[2. 2.23606798] [0.2236068 0.80622577]]
[[ 0 6] [13 19]]
```

```
scipy.spatial.cKDTree.query_ball_point
```

cKDTree.query_ball_point (self, x, r=2., eps=0, workers=1, return_sorted=None, return_length=False)

Find all points within distance r of point(s) x.

**Parameters**

- **x** [array_like, shape tuple + (self.m,)] The point or points to search for neighbors of.
- **r** [array_like, float] The radius of points to return, shall broadcast to the length of x.
- **p** [float, optional] Which Minkowski p-norm to use. Should be in the range [1, inf]. A finite large p may cause a ValueError if overflow can occur.
- **eps** [nonnegative float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than \( r / (1 + \text{eps}) \), and branches are added in bulk if their furthest points are nearer than \( r * (1 + \text{eps}) \).
- **workers** [int, optional] Number of jobs to schedule for parallel processing. If -1 is given all processors are used. Default: 1. Changed in version 1.6.0: The “n_jobs” argument was renamed “workers”. The old name “n_jobs” is deprecated and will stop working in SciPy 1.8.0.
- **return_sorted** [bool, optional] Sorts returned indicies if True and does not sort them if False. If None, does not sort single point queries, but does sort multi-point queries which was the behavior before this option was added. New in version 1.2.0.
- **return_length**: bool, optional
  Return the number of points inside the radius instead of a list of the indices. .. version-added:: 1.3.0

**Returns**
results  [list or array of lists] If x is a single point, returns a list of the indices of the neighbors of x. If x is an array of points, returns an object array of shape tuple containing lists of neighbors.

Notes

If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a cKDTree and using query_ball_tree.

Examples

```python
>>> from scipy import spatial
>>> x, y = np.mgrid[0:4, 0:4]
>>> points = np.c_[x.ravel(), y.ravel()]
>>> tree = spatial.cKDTree(points)
>>> tree.query_ball_point([2, 0], 1)
[4, 8, 9, 12]
```

Query multiple points and plot the results:

```python
>>> import matplotlib.pyplot as plt
>>> points = np.asarray(points)
>>> plt.plot(points[:,0], points[:,1], '.')
>>> for results in tree.query_ball_point(([2, 0], [3, 3]), 1):
...     nearby_points = points[results]
...     plt.plot(nearby_points[:,0], nearby_points[:,1], 'o')
>>> plt.margins(0.1, 0.1)
>>> plt.show()
```
scipy.spatial.cKDTree.query_ball_tree

cKDTree.query_ball_tree(self, other, r, p=2., eps=0)

Find all pairs of points between self and other whose distance is at most r

Parameters

other [cKDTree instance] The tree containing points to search against.
r [float] The maximum distance, has to be positive.
p [float, optional] Which Minkowski norm to use. p has to meet the condition 1 <= p <= infinity. A finite large p may cause a ValueError if overflow can occur.
eps [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than r/(1+eps), and branches are added in bulk if their furthest points are nearer than r * (1+eps). eps has to be non-negative.

Returns

results [list of lists] For each element self.data[i] of this tree, results[i] is a list of the indices of its neighbors in other.data.

Examples

You can search all pairs of points between two kd-trees within a distance:

```python
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((15, 2))
>>> points2 = rng.random((15, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points1[:, 0], points1[:, 1], "xk", markersize=14)
>>> plt.plot(points2[:, 0], points2[:, 1], "og", markersize=14)
>>> kd_tree1 = cKDTree(points1)
>>> kd_tree2 = cKDTree(points2)
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> for i in range(len(indexes)):
...     for j in indexes[i]:
...         plt.plot([points1[i, 0], points2[j, 0]],
...                  [points1[i, 1], points2[j, 1]], "+r")
>>> plt.show()
```

scipy.spatial.cKDTree.query_pairs

cKDTree.query_pairs(self, r, p=2., eps=0)

Find all pairs of points in self whose distance is at most r.

Parameters

r [positive float] The maximum distance.
p [float, optional] Which Minkowski norm to use. p has to meet the condition 1 <= p <= infinity. A finite large p may cause a ValueError if overflow can occur.
eps [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than r/(1+eps), and branches are added in bulk if their furthest points are nearer than r * (1+eps). eps has to be non-negative.
3.3. API definition
output_type

[string, optional] Choose the output container, ‘set’ or ‘ndarray’. Default: ‘set’

Returns

results

[set or.ndarray] Set of pairs \((i, j)\), with \(i < j\), for which the corresponding positions
are close. If output_type is ‘ndarray’, an ndarray is returned instead of a set.

Examples

You can search all pairs of points in a kd-tree within a distance:

```python
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> rng = np.random.default_rng()
>>> points = rng.random((20, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points[:, 0], points[:, 1], "xk", markersize=14)
>>> kd_tree = cKDTree(points)
>>> pairs = kd_tree.query_pairs(r=0.2)
>>> for (i, j) in pairs:
...     plt.plot([points[i, 0], points[j, 0]],
...              [points[i, 1], points[j, 1]], "-r")
>>> plt.show()
```

`scipy.spatial.cKDTree.sparse_distance_matrix`

`cKDTree.sparse_distance_matrix`(self, other, max_distance, p=2.)
Computes a sparse distance matrix between two cKDTrees, leaving as zero any distance greater than max_distance.

Parameters

other [cKDTree]
max_distance [positive float] Which Minkowski p-norm to use. A finite large p may cause a
ValueError if overflow can occur.
p [float, 1<=p<=infinity] Which Minkowski p-norm to use. A finite large p may cause a
ValueError if overflow can occur.
output_type [string, optional] Which container to use for output data. Options: ‘dok_matrix’,

Returns

result [dok_matrix, coo_matrix, dict or ndarray] Sparse matrix representing the results in “diction-
ary of keys” format. If a dict is returned the keys are \((i, j)\) tuples of indices. If
output_type is ‘ndarray’ a record array with fields ‘i’, ‘j’, and ‘v’ is returned,
Examples

You can compute a sparse distance matrix between two kd-trees:

```python
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((5, 2))
>>> points2 = rng.random((5, 2))
>>> kd_tree1 = cKDTree(points1)
>>> kd_tree2 = cKDTree(points2)
>>> sdm = kd_tree1.sparse_distance_matrix(kd_tree2, 0.3)
>>> sdm.toarray()
array([[0. , 0. , 0.12295571, 0. , 0. ],
       [0. , 0. , 0. , 0. , 0. ],
       [0.28942611, 0. , 0. , 0.2333084 , 0. ],
       [0. , 0. , 0. , 0. , 0. ],
       [0.24617575, 0.29571802, 0.26836782, 0. , 0. ]])
```

You can check distances above the `max_distance` are zeros:

```python
>>> from scipy.spatial import distance_matrix
>>> distance_matrix(points1, points2)
array([[0.56906522, 0.39923701, 0.12295571, 0.8658745 , 0.79428925],
       [0.37327919, 0.7225693 , 0.87665969, 0.32580855, 0.75679479],
       [0.28942611, 0.30088013, 0.6395831 , 0.2333084 , 0.33630734],
       [0.31994999, 0.72658602, 0.71124834, 0.55396483, 0.90785663],
       [0.24617575, 0.29571802, 0.26836782, 0.57714465, 0.6473269 ]])
```

**scipy.spatial.Rectangle**

**class scipy.spatial.Rectangle (maxes, mins)**

Hyperrectangle class.

Represents a Cartesian product of intervals.

**Methods**

- `max_distance_point(x[, p])`  
  Return the maximum distance between input and points in the hyperrectangle.

- `max_distance_rectangle(other[, p])`  
  Compute the maximum distance between points in the two hyperrectangles.

- `min_distance_point(x[, p])`  
  Return the minimum distance between input and points in the hyperrectangle.

- `min_distance_rectangle(other[, p])`  
  Compute the minimum distance between points in the two hyperrectangles.

- `split(d, split)`  
  Produce two hyperrectangles by splitting.

- `volume()`  
  Total volume.
scipy.spatial.Rectangle.max_distance_point

Rectangle.max_distance_point(x, p=2.0)
Return the maximum distance between input and points in the hyperrectangle.

Parameters
x [array_like] Input array.
p [float, optional] Input.

scipy.spatial.Rectangle.max_distance_rectangle

Rectangle.max_distance_rectangle(other, p=2.0)
Compute the maximum distance between points in the two hyperrectangles.

Parameters
other [hyperrectangle] Input.
p [float, optional] Input.

scipy.spatial.Rectangle.min_distance_point

Rectangle.min_distance_point(x, p=2.0)
Return the minimum distance between input and points in the hyperrectangle.

Parameters
x [array_like] Input.
p [float, optional] Input.

scipy.spatial.Rectangle.min_distance_rectangle

Rectangle.min_distance_rectangle(other, p=2.0)
Compute the minimum distance between points in the two hyperrectangles.

Parameters
other [hyperrectangle] Input.
p [float] Input.

scipy.spatial.Rectangle.split

Rectangle.split(d, split)
Produce two hyperrectangles by splitting.

In general, if you need to compute maximum and minimum distances to the children, it can be done more efficiently by updating the maximum and minimum distances to the parent.

Parameters
d [int] Axis to split hyperrectangle along.
split [float] Position along axis d to split at.
scipy.spatial.Rectangle.volume

    Rectangle.volume()

    Total volume.

Distance metrics are contained in the `scipy.spatial.distance` submodule.

**Delaunay triangulation, convex hulls, and Voronoi diagrams**

<table>

</tbody>
</table>

**scipy.spatial.Delaunay**

class `scipy.spatial.Delaunay`(points, furthest_site=False, incremental=False, qhull_options=None)

    Delaunay tessellation in N dimensions.

    New in version 0.9.

    Parameters

    points  [ndarray of floats, shape (npoints, ndim)] Coordinates of points to triangulate
    incremental  [bool, optional] Allow adding new points incrementally. This takes up some additional resources.
    qhull_options  [str, optional] Additional options to pass to Qhull. See Qhull manual for details. Option “Qt” is always enabled. Default: “Qbb Qc Qz Qx Q12” for ndim > 4 and “Qbb Qc Qz Q12” otherwise. Incremental mode omits “Qz”. New in version 0.12.0.

    Raises

    QhullError  Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.
    ValueError  Raised if an incompatible array is given as input.
Notes

The tessellation is computed using the Qhull library.

Note: Unless you pass in the Qhull option “QJ”, Qhull does not guarantee that each input point appears as a vertex in the Delaunay triangulation. Omitted points are listed in the *coplanar* attribute.

Examples

Triangulation of a set of points:

```python
>>> points = np.array([[0, 0], [0, 1.1], [1, 0], [1, 1]])
>>> from scipy.spatial import Delaunay
>>> tri = Delaunay(points)
```

We can plot it:

```python
>>> import matplotlib.pyplot as plt
>>> plt.triplot(points[:,0], points[:,1], tri.simplices)
>>> plt.plot(points[:,0], points[:,1], 'o')
>>> plt.show()
```

Point indices and coordinates for the two triangles forming the triangulation:

```python
>>> tri.simplices
array([[2, 3, 0], # may vary
        [3, 1, 0]], dtype=int32)
```

Note that depending on how rounding errors go, the simplices may be in a different order than above.

```python
>>> points[tri.simplices]
array([[1., 0.], # may vary
        [1., 1.],
        [0., 1.]])
```
Triangle 0 is the only neighbor of triangle 1, and it’s opposite to vertex 1 of triangle 1:

```python
>>> tri.neighbors[1]
array([-1, 0, -1], dtype=int32)
>>> points[tri.simplices[1,1]]
array([0., 1.1])
```

We can find out which triangle points are in:

```python
>>> p = np.array([(0.1, 0.2), (1.5, 0.5), (0.5, 1.05)])
>>> tri.find_simplex(p)
array([1, -1, 1], dtype=int32)
```

The returned integers in the array are the indices of the simplex the corresponding point is in. If -1 is returned, the point is in no simplex. Be aware that the shortcut in the following example only works correctly for valid points as invalid points result in -1 which is itself a valid index for the last simplex in the list.

```python
>>> p_valids = np.array([(0.1, 0.2), (0.5, 1.05)])
>>> tri.simplices[tri.find_simplex(p_valids)]
array([[3, 1, 0], # may vary
       [3, 1, 0]], dtype=int32)
```

We can also compute barycentric coordinates in triangle 1 for these points:

```python
>>> b = tri.transform[1,:2].dot(np.transpose(p - tri.transform[1,2]))
>>> np.c_[np.transpose(b), 1 - b.sum(axis=0)]
array([[ 0.1, 0.09090909, 0.80909091],
       [ 1.5, -0.90909091, 0.40909091],
       [ 0.5, 0.5, 0. ]])
```

The coordinates for the first point are all positive, meaning it is indeed inside the triangle. The third point is on a vertex, hence its null third coordinate.

**Attributes**

- **points**  [ndarray of double, shape (npoints, ndim)] Coordinates of input points.
- **simplices**  [ndarray of ints, shape (nsimplex, ndim+1)] Indices of the points forming the simplices in the triangulation. For 2-D, the points are oriented counterclockwise.
- **neighbors**  [ndarray of ints, shape (nsimplex, ndim+1)] Indices of neighbor simplices for each simplex. The kth neighbor is opposite to the kth vertex. For simplices at the boundary, -1 denotes no neighbor.
- **equations**  [ndarray of double, shape (nsimplex, ndim+2)] [normal, offset] forming the hyperplane equation of the facet on the paraboloid (see Qhull documentation for more).
- **paraboloid_scale, paraboloid_shift**  [float] Scale and shift for the extra paraboloid dimension (see Qhull documentation for more).
- **transform**  [ndarray of double, shape (nsimplex, ndim+1, ndim)] Affine transform from \( x \) to the barycentric coordinates \( c \).
vertex_to_simplex
[ndarray of int, shape (npoints,)] Lookup array, from a vertex, to some simplex which it is a part of.

convex_hull
[ndarray of int, shape (nfaces, ndim)] Vertices of facets forming the convex hull of the point set.

coplanar
[ndarray of int, shape (ncoplanar, 3)] Indices of coplanar points and the corresponding indices of the nearest facet and the nearest vertex. Coplanar points are input points which were not included in the triangulation due to numerical precision issues. If option “Qc” is not specified, this list is not computed. New in version 0.12.0.

vertices
Same as simplices, but deprecated.

vertex_neighbor_vertices
[tuple of two ndarrays of int; (indptr, indices)] Neighboring vertices of vertices.

furthest_site
True if this was a furthest site triangulation and False if not. New in version 1.4.0.

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>add_points(points[, restart])</td>

</tbody>
</table>

scipy.spatial.Delaunay.add_points

Delaunay.add_points(points, restart=False)
Process a set of additional new points.

Parameters

- **points** [ndarray] New points to add. The dimensionality should match that of the initial points.
- **restart** [bool, optional] Whether to restart processing from scratch, rather than adding points incrementally.

Raises

- **QhullError** Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

See also:

close
Notes

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after `close` has been called.

scipy.spatial.Delaunay.close

Delaunay.close()

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

scipy.spatial.Delaunay.find_simplex

Delaunay.find_simplex(self, xi, bruteforce=False, tol=None)

Find the simplices containing the given points.

Parameters

- `tri` [DelaunayInfo] Delaunay triangulation
- `xi` [ndarray of double, shape (…, ndim)] Points to locate
- `bruteforce` [bool, optional] Whether to only perform a brute-force search
- `tol` [float, optional] Tolerance allowed in the inside-triangle check. Default is `100*eps`.

Returns

- `i` [ndarray of int, same shape as `xi`] Indices of simplices containing each point. Points outside the triangulation get the value -1.

Notes

This uses an algorithm adapted from Qhull's `qh_findbestfacet`, which makes use of the connection between a convex hull and a Delaunay triangulation. After finding the simplex closest to the point in N+1 dimensions, the algorithm falls back to directed search in N dimensions.

scipy.spatial.Delaunay.lift_points

Delaunay.lift_points(self, x)

Lift points to the Qhull paraboloid.

scipy.spatial.Delaunay.plane_distance

Delaunay.plane_distance(self, xi)

Compute hyperplane distances to the point `xi` from all simplices.
scipy.spatial.ConvexHull

class scipy.spatial.ConvexHull(points, incremental=False, qhull_options=None)
Convex hulls in N dimensions.
New in version 0.12.0.

Parameters
points [ndarray of floats, shape (npoints, ndim)] Coordinates of points to construct a convex hull from
incremental [bool, optional] Allow adding new points incrementally. This takes up some additional resources.
qhull_options [str, optional] Additional options to pass to Qhull. See Qhull manual for details. (Default: “Qx” for ndim > 4 and “” otherwise) Option “Qt” is always enabled.

Raises
QhullError Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.
ValueError Raised if an incompatible array is given as input.

Notes
The convex hull is computed using the Qhull library.

References
[Qhull]

Examples
Convex hull of a random set of points:

```python
>>> from scipy.spatial import ConvexHull, convex_hull_plot_2d
>>> rng = np.random.default_rng()
>>> points = rng.random((30, 2))  # 30 random points in 2-D
>>> hull = ConvexHull(points)
```

Plot it:

```python
>>> import matplotlib.pyplot as plt
>>> plt.plot(points[:, 0], points[:, 1], 'o')
>>> for simplex in hull.simplices:
...     plt.plot(points[simplex, 0], points[simplex, 1], 'k-')
```

We could also have directly used the vertices of the hull, which for 2-D are guaranteed to be in counterclockwise order:
Facets visible from a point:

Create a square and add a point above the square.

```python
>>> generators = np.array([[[0.2, 0.2],
                        ... [0.2, 0.4],
                        ... [0.4, 0.4],
                        ... [0.4, 0.2],
                        ... [0.3, 0.6]]])
```

Call ConvexHull with the QG option. QG4 means compute the portions of the hull not including point 4, indicating the facets that are visible from point 4.

```python
>>> hull = ConvexHull(points=generators,
                     ...qhull_options='QG4')
```

The “good” array indicates which facets are visible from point 4.

```python
>>> print(hull.simplices)
[[1 0]
 [1 2]
 [3 0]
 [3 2]]
>>> print(hull.good)
[False True False False]
```

Now plot it, highlighting the visible facets.

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1,1,1)
(continues on next page)```
```python
>>> for visible_facet in hull.simplices[hull.good]:
...     ax.plot(hull.points[visible_facet, 0],
...             hull.points[visible_facet, 1],
...             color='violet',
...             lw=6)
>>> convex_hull_plot_2d(hull, ax=ax)
<Figure size 640x480 with 1 Axes> # may vary
>>> plt.show()
```

**Attributes**

- **points**  
  [ndarray of double, shape (npoints, ndim)] Coordinates of input points.
- **vertices**  
  [ndarray of ints, shape (nvertices,)] Indices of points forming the vertices of the convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order.
- **simplices**  
  [ndarray of ints, shape (nfacet, ndim)] Indices of points forming the simplical facets of the convex hull.
- **neighbors**  
  [ndarray of ints, shape (nfacet, ndim)] Indices of neighbor facets for each facet. The kth neighbor is opposite to the kth vertex. -1 denotes no neighbor.
- **equations**  
  [ndarray of double, shape (nfacet, ndim+1)] [normal, offset] forming the hyperplane equation of the facet (see Qhull documentation for more).
- **coplanar**  
  [ndarray of int, shape (ncoplanar, 3)] Indices of coplanar points and the corresponding indices of the nearest facets and nearest vertex indices. Coplanar points are input points which were not included in the triangulation due to numerical precision issues. If option “Qc” is not specified, this list is not computed.
- **good**  
  [ndarray of bool or None] A one-dimensional Boolean array indicating which facets are good. Used with options that compute good facets, e.g. QGn and QG-n. Good facets are defined as those that are visible (n) or invisible (-n) from point n, where n is the nth point in 'points'. The 'good' attribute may be used as an index into 'simplices' to return the good (visible) facets: simplices[good]. A facet is visible from the outside of the hull only, and neither coplanarity nor degeneracy count as cases of visibility. If a “QGn” or “QG-n” option is not specified, None is returned. New in version 1.3.0.
area  [float] Surface area of the convex hull when input dimension > 2. When input points are 2-dimensional, this is the perimeter of the convex hull.
   New in version 0.17.0.
volume  [float] Volume of the convex hull when input dimension > 2. When input points are 2-dimensional, this is the area of the convex hull.
   New in version 0.17.0.

</tr>
</tbody>
</table>

scipy.spatial.ConvexHull.add_points

ConvexHull.add_points(points, restart=False)
   Process a set of additional new points.

Parameters

- points  [ndarray] New points to add. The dimensionality should match that of the initial points.
- restart  [bool, optional] Whether to restart processing from scratch, rather than adding points incrementally.

Raises

- QhullError
   Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

See also:

- close

Notes

You need to specify incremental=True when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after close has been called.

scipy.spatial.ConvexHull.close

ConvexHull.close()
   Finish incremental processing.

   Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.
scipy.spatial.Voronoi

**class** scipy.spatial.Voronoi *(points, furthest_site=False, incremental=False, qhull_options=None)*

Voronoi diagrams in N dimensions.

New in version 0.12.0.

**Parameters**

- **points** *(ndarray of floats, shape (npoints, ndim))* Coordinates of points to construct a Voronoi diagram from
- **furthest_site** *(bool, optional)* Whether to compute a furthest-site Voronoi diagram. Default: False
- **incremental** *(bool, optional)* Allow adding new points incrementally. This takes up some additional resources.
- **qhull_options** *(str, optional)* Additional options to pass to Qhull. See Qhull manual for details. (Default: “Qbb Qc Qz Qx” for ndim > 4 and “Qbb Qc Qz” otherwise. Incremental mode omits “Qz”.)

**Raises**

- **QhullError**
  Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.
- **ValueError**
  Raised if an incompatible array is given as input.

**Notes**

The Voronoi diagram is computed using the Qhull library.

**Examples**

Voronoi diagram for a set of points:

```python
>>> points = np.array([[0, 0], [0, 1], [0, 2], [1, 0], [1, 1], [1, 2], ...
                     [2, 0], [2, 1], [2, 2]])
>>> from scipy.spatial import Voronoi, voronoi_plot_2d
>>> vor = Voronoi(points)
```

Plot it:

```python
>>> import matplotlib.pyplot as plt
>>> fig = voronoi_plot_2d(vor)
>>> plt.show()
```

The Voronoi vertices:

```python
>>> vor.vertices
array([[0.5, 0.5],
       [0.5, 1.5],
       [1.5, 0.5],
       [1.5, 1.5]])
```

There is a single finite Voronoi region, and four finite Voronoi ridges:
The ridges are perpendicular between lines drawn between the following input points:

```python
>>> vor.ridge_points
array([[0, 3],
       [0, 1],
       [2, 5],
       [2, 1],
       [1, 4],
       [7, 8],
       [7, 6],
       [7, 4],
       [8, 5],
       [6, 3],
       [4, 5],
       [4, 3]], dtype=int32)
```

**Attributes**

- **points**  
  [ndarray of double, shape (npoints, ndim)] Coordinates of input points.
- **vertices**  
  [ndarray of double, shape (nvertices, ndim)] Coordinates of the Voronoï vertices.
- **ridge_points**  
  [ndarray of ints, shape (nridges, 2)] Indices of the points between which each Voronoï ridge lies.
- **ridge_vertices**  
  [list of list of ints, shape (nridges, *)] Indices of the Voronoï vertices forming each Voronoï ridge.
regions [list of list of ints, shape (nregions, *)] Indices of the Voronoi vertices forming each Voronoi region. -1 indicates vertex outside the Voronoi diagram.

point_region [list of ints, shape (npoints)] Index of the Voronoi region for each input point. If qhull option “Qc” was not specified, the list will contain -1 for points that are not associated with a Voronoi region.

furthest_site True if this was a furthest site triangulation and False if not. New in version 1.4.0.

**scipy.spatial.Voronoi.add_points**

Voronoi.add_points (points, restart=False)  
Process a set of additional new points.

**Parameters**

points [ndarray] New points to add. The dimensionality should match that of the initial points.

restart [bool, optional] Whether to restart processing from scratch, rather than adding points incrementally.

**Raises**

QhullError Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**See also:**

close

**Notes**

You need to specify incremental=True when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after close has been called.

**scipy.spatial.Voronoi.close**

Voronoi.close ()  
Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.
scipy.spatial.SphericalVoronoi

class scipy.spatial.SphericalVoronoi(points, radius=1, center=None, threshold=1e-06)

Voronoi diagrams on the surface of a sphere.

New in version 0.18.0.

Parameters

- **points**: [ndarray of floats, shape (npoints, ndim)] Coordinates of points from which to construct a spherical Voronoi diagram.
- **radius**: [float, optional] Radius of the sphere (Default: 1)
- **center**: [ndarray of floats, shape (ndim,)] Center of sphere (Default: origin)
- **threshold**: [float] Threshold for detecting duplicate points and mismatches between points and sphere parameters. (Default: 1e-06)

Raises

- **ValueError**

  If there are duplicates in points. If the provided radius is not consistent with points.

See also:

Voronoi

Conventional Voronoi diagrams in N dimensions.

Notes

The spherical Voronoi diagram algorithm proceeds as follows. The Convex Hull of the input points (generators) is calculated, and is equivalent to their Delaunay triangulation on the surface of the sphere [Caroli]. The Convex Hull neighbour information is then used to order the Voronoi region vertices around each generator. The latter approach is substantially less sensitive to floating point issues than angle-based methods of Voronoi region vertex sorting.

Empirical assessment of spherical Voronoi algorithm performance suggests quadratic time complexity (loglinear is optimal, but algorithms are more challenging to implement).

References

[Caroli], [VanOosterom]

Examples

Do some imports and take some points on a cube:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import SphericalVoronoi, geometric_slerp
>>> from mpl_toolkits.mplot3d import proj3d
>>> # set input data
>>> points = np.array([[0, 0, 1], [0, 0, -1], [1, 0, 0],
... [0, 1, 0], [0, -1, 0], [-1, 0, 0], ])
```

Calculate the spherical Voronoi diagram:
```python
>>> radius = 1
center = np.array([0, 0, 0])
sv = SphericalVoronoi(points, radius, center)
```

Generate plot:

```python
>>> # sort vertices (optional, helpful for plotting)
>>> sv.sort_vertices_of_regions()
>>> t_vals = np.linspace(0, 1, 2000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111, projection='3d')
>>> # plot the unit sphere for reference (optional)
>>> u = np.linspace(0, 2 * np.pi, 100)
>>> v = np.linspace(0, np.pi, 100)
>>> x = np.outer(np.cos(u), np.sin(v))
>>> y = np.outer(np.sin(u), np.sin(v))
>>> z = np.outer(np.ones(np.size(u)), np.cos(v))
>>> ax.plot_surface(x, y, z, color='y', alpha=0.1)
>>> # plot generator points
>>> ax.scatter(points[:, 0], points[:, 1], points[:, 2], c='b')
>>> # plot Voronoi vertices
>>> ax.scatter(sv.vertices[:, 0], sv.vertices[:, 1], sv.vertices[:, 2],
>>>     c='g')
>>> # indicate Voronoi regions (as Euclidean polygons)
>>> for region in sv.regions:
>>>     n = len(region)
>>>     for i in range(n):
>>>         start = sv.vertices[region][i]
>>>         end = sv.vertices[region][(i + 1) % n]
>>>         result = geometric_slerp(start, end, t_vals)
>>>         ax.plot(result[:, 0],
>>>                 result[:, 1],
>>>                 result[:, 2],
>>>                 c='k')
>>> ax.azim = 10
>>> ax.elev = 40
>>> _ = ax.set_xticks([])
>>> _ = ax.set_yticks([])
>>> _ = ax.set_zticks([])
>>> fig.set_size_inches(4, 4)
>>> plt.show()
```

Attributes

- **points**: [double array of shape (npoints, ndim)] the points in ndim dimensions to generate the Voronoi diagram from
- **radius**: [double] radius of the sphere
- **center**: [double array of shape (ndim,)] center of the sphere
- **vertices**: [double array of shape (nvertices, ndim)] Voronoi vertices corresponding to points
- **regions**: [list of list of integers of shape (npoints, _)] the n-th entry is a list consisting of the indices of the vertices belonging to the n-th point in points

3.3. API definition 2091
Methods

`calculate_areas()`  Calculates the areas of the Voronoi regions.

`scipy.spatial.SphericalVoronoi.calculate_areas`

SphericalVoronoi.calculate_areas()
Calculates the areas of the Voronoi regions.

For 2D point sets, the regions are circular arcs. The sum of the areas is \(2 \times \pi \times \text{radius}\).

For 3D point sets, the regions are spherical polygons. The sum of the areas is \(4 \times \pi \times \text{radius}^2\).

New in version 1.5.0.

**Returns**

`areas`  [double array of shape (npoints,)] The areas of the Voronoi regions.
**scipy.spatial.HalfspaceIntersection**

**class scipy.spatial.HalfspaceIntersection(halfspaces, interior_point, incremental=False, qhull_options=None)**

Halfspace intersections in N dimensions.
New in version 0.19.0.

**Parameters**

- **halfspaces** [ndarray of floats, shape (nineq, ndim+1)] Stacked Inequalities of the form $Ax + b \leq 0$ in format $[A; b]$
- **interior_point** [ndarray of floats, shape (ndim,)] Point clearly inside the region defined by halfspaces. Also called a feasible point, it can be obtained by linear programming.
- **incremental** [bool, optional] Allow adding new halfspaces incrementally. This takes up some additional resources.
- **qhull_options** [str, optional] Additional options to pass to Qhull. See Qhull manual for details. (Default: “Qx” for ndim > 4 and “” otherwise) Option “H” is always enabled.

**Raises**

- **QhullError** Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.
- **ValueError** Raised if an incompatible array is given as input.

**Notes**

The intersections are computed using the Qhull library. This reproduces the “qhalf” functionality of Qhull.

**References**

[Qhull], [1]

**Examples**

Halfspace intersection of planes forming some polygon

```python
>>> from scipy.spatial import HalfspaceIntersection
>>> halfspaces = np.array([[−1, 0., 0.],
...                         [0., −1., 0.],
...                         [2., 1., −4.],
...                         [−0.5, 1., −2.]])
>>> feasible_point = np.array([0.5, 0.5])
>>> hs = HalfspaceIntersection(halfspaces, feasible_point)
```

Plot halfspaces as filled regions and intersection points:
By default, qhull does not provide with a way to compute an interior point. This can easily be computed using linear programming. Considering halfspaces of the form $Ax + b \leq 0$, solving the linear program:

$$
\begin{align*}
  & \text{max } y \\
  & \text{s.t. } Ax + y||A_i|| \leq -b \\
\end{align*}
$$

With $A_i$ being the rows of $A$, i.e. the normals to each plane.

Will yield a point $x$ that is furthest inside the convex polyhedron. To be precise, it is the center of the largest hypersphere of radius $y$ inscribed in the polyhedron. This point is called the Chebyshev center of the polyhedron (see [1] 4.3.1, pp148-149). The equations outputted by Qhull are always normalized.

```python
>>> from scipy.optimize import linprog
>>> from matplotlib.patches import Circle
>>> norm_vector = np.reshape(np.linalg.norm(halfspaces[:, -1], axis=1), (halfspaces.shape[0], 1))
>>> c = np.zeros((halfspaces.shape[1],))
>>> c[-1] = -1
>>> A = np.hstack((halfspaces[:, -1], norm_vector))
>>> b = - halfspaces[:, -1]
>>> res = linprog(c, A_ub=A, b_ub=b, bounds=(None, None))
>>> x = res.x[:-1]
>>> y = res.x[-1]
>>> circle = Circle(x, radius=y, alpha=0.3)
>>> ax.add_patch(circle)
>>> plt.legend(bbox_to_anchor=(1.6, 1.0))
>>> plt.show()
```

**Attributes**

- `halfspaces` [ndarray of double, shape (nineq, ndim+1)] Input halfspaces.
**interior_point** : ndarray of floats, shape (ndim,)
   Input interior point.

**intersections**
   [ndarray of double, shape (ninter, ndim)] Intersections of all halfspaces.

**dual_points**
   [ndarray of double, shape (nineq, ndim)] Dual points of the input halfspaces.

**dual_facets**
   [list of lists of ints] Indices of points forming the (non necessarily simplicial) facets of the dual convex hull.

**dual_vertices**
   [ndarray of ints, shape (nvertices,)] Indices of halfspaces forming the vertices of the dual convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order.

**dual_equations**
   [ndarray of double, shape (nfacet, ndim+1)] [normal, offset] forming the hyperplane equation of the dual facet (see Qhull documentation for more).

**dual_area**
   [float] Area of the dual convex hull

**dual_volume**
   [float] Volume of the dual convex hull

---

**Methods**

- `add_halfspaces(halfspaces[, restart])` Process a set of additional new halfspaces.
- `close()` Finish incremental processing.
scipy.spatial.HalfspaceIntersection.add_halfspaces

HalfspaceIntersection.add_halfspaces(halfspaces, restart=False)
Process a set of additional new halfspaces.

**Parameters**

- **halfspaces** [ndarray] New halfspaces to add. The dimensionality should match that of the initial halfspaces.
- **restart** [bool, optional] Whether to restart processing from scratch, rather than adding halfspaces incrementally.

**Raises**

- QhullError
  Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**See also:**

- close

**Notes**

You need to specify incremental=True when constructing the object to be able to add halfspaces incrementally. Incremental addition of halfspaces is also not possible after close has been called.
**scipy.spatial.HalfspaceIntersection.close**

HalfspaceIntersection.close()

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

</tbody>
</table>

**scipy.spatial.delaunay_plot_2d**

`scipy.spatial.delaunay_plot_2d(tri, ax=None)`

Plot the given Delaunay triangulation in 2-D

**Parameters**

- `tri` [scipy.spatial.Delaunay instance] Triangulation to plot
- `ax` [matplotlib.axes.Axes instance, optional] Axes to plot on

**Returns**

- `fig` [matplotlib.figure.Figure instance] Figure for the plot

**See also:**

- `Delaunay`
- `matplotlib.pyplot.triplot`

**Notes**

Requires Matplotlib.

**Examples**

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import Delaunay, delaunay_plot_2d
```

The Delaunay triangulation of a set of random points:

```python
>>> rng = np.random.default_rng()
>>> points = rng.random((30, 2))
>>> tri = Delaunay(points)
```

Plot it:

```python
>>> _ = delaunay_plot_2d(tri)
>>> plt.show()
```
scipy.spatial.convex_hull_plot_2d

```
scipy.spatial.convex_hull_plot_2d(hull, ax=None)
```

Plot the given convex hull diagram in 2-D

**Parameters**

- `hull` [scipy.spatial.ConvexHull instance] Convex hull to plot
- `ax` [matplotlib.axes.Axes instance, optional] Axes to plot on

**Returns**

- `fig` [matplotlib.figure.Figure instance] Figure for the plot

**See also:**

ConvexHull

**Notes**

Requires Matplotlib.

**Examples**

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import ConvexHull, convex_hull_plot_2d
```

The convex hull of a random set of points:

```python
>>> rng = np.random.default_rng()
>>> points = rng.random((30, 2))
>>> hull = ConvexHull(points)
```

Plot it:
scipy.spatial.voronoi_plot_2d

scipy.spatial.voronoi_plot_2d(vor, ax=None, **kw)

Plot the given Voronoi diagram in 2-D

**Parameters**

- **vor** ([scipy.spatial.Voronoi instance]) Diagram to plot
- **ax** ([matplotlib.axes.Axes instance, optional]) Axes to plot on
- **show_points**: bool, optional
  Add the Voronoi points to the plot.
- **show_vertices**: bool, optional
  Add the Voronoi vertices to the plot.
- **line_colors**: string, optional
  Specifies the line color for polygon boundaries
- **line_width**: float, optional
  Specifies the line width for polygon boundaries
- **line_alpha**: float, optional
  Specifies the line alpha for polygon boundaries
- **point_size**: float, optional
  Specifies the size of points

**Returns**

- **fig** ([matplotlib.figure.Figure instance]) Figure for the plot

**See also:**

Voronoi
Notes

Requires Matplotlib.

Examples

Set of point:

```python
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
>>> points = rng.random((10, 2))
```

Voronoi diagram of the points:

```python
>>> from scipy.spatial import Voronoi, voronoi_plot_2d
>>> vor = Voronoi(points)
```

using `voronoi_plot_2d` for visualisation:

```python
>>> fig = voronoi_plot_2d(vor)
```

using `voronoi_plot_2d` for visualisation with enhancements:

```python
>>> fig = voronoi_plot_2d(vor, show_vertices=False, line_colors='orange',
...                        line_width=2, line_alpha=0.6, point_size=2)
>>> plt.show()
```

Tutorial
Simplex representation

The simplices (triangles, tetrahedra, etc.) appearing in the Delaunay tessellation (N-D simplices), convex hull facets, and Voronoi ridges (N-1-D simplices) are represented in the following scheme:

```python
# coordinates of the jth vertex of the ith simplex
tess.points[tess.simplices[i, j], :]  # tessellation element
hull.points[hull.simplices[i, j], :]  # convex hull facet
voro.vertices[voro.ridge_vertices[i, j], :] # ridge between Voronoi cells
```

For Delaunay triangulations and convex hulls, the neighborhood structure of the simplices satisfies the condition: `tess.neighbors[i, j]` is the neighboring simplex of the `i`th simplex, opposite to the `j`-vertex. It is -1 in case of no neighbor.

Convex hull facets also define a hyperplane equation:

```python
(hull.equations[i, :-1] * coord).sum() + hull.equations[i, -1] == 0
```

Similar hyperplane equations for the Delaunay triangulation correspond to the convex hull facets on the corresponding N+1-D paraboloid.

The Delaunay triangulation objects offer a method for locating the simplex containing a given point, and barycentric coordinate computations.

\texttt{scipy.spatial.tsearch}

\texttt{scipy.spatial.tsearch(tri, xi)}

Find simplices containing the given points. This function does the same thing as \texttt{Delaunay.find_simplex}.

New in version 0.9.

See also:

\texttt{Delaunay.find_simplex}

Examples

```
>>> import numpy as np
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import Delaunay, delaunay_plot_2d, tsearch
>>> rng = np.random.default_rng()
```

The Delaunay triangulation of a set of random points:

```
>>> pts = rng.random((20, 2))
>>> tri = Delaunay(pts)
>>> _ = delaunay_plot_2d(tri)
```

Find the simplices containing a given set of points:

```
>>> loc = rng.uniform(0.2, 0.8, (5, 2))
>>> s = tsearch(tri, loc)
>>> plt.triplot(pts[:, 0], pts[:, 1], tri.simplices[s], 'b-', mask=s==-1)
>>> plt.scatter(loc[:, 0], loc[:, 1], c='r', marker='x')
>>> plt.show()
```
**scipy.spatial.distance_matrix**

**scipy.spatial.distance_matrix** *(x, y, p=2, threshold=1000000)*

Compute the distance matrix.

Returns the matrix of all pair-wise distances.

**Parameters**

- **x** *(M, K) array_like* Matrix of M vectors in K dimensions.
- **y** *(N, K) array_like* Matrix of N vectors in K dimensions.
- **p** *[float, 1 <= p <= infinity]* Which Minkowski p-norm to use.
- **threshold** *[positive int]* If $M \times N \times K > threshold$, algorithm uses a Python loop instead of large temporary arrays.

**Returns**

- **result** *(M, N) ndarray* Matrix containing the distance from every vector in x to every vector in y.

**Examples**

```python
>>> from scipy.spatial import distance_matrix
>>> distance_matrix([[0, 0], [0, 1]], [[1, 0], [1, 1]])
array([[ 1., 1.41421356],
       [ 1.41421356, 1.]])
```
scipy.spatial.minkowski_distance

scipy.spatial.minkowski_distance(x, y, p=2)

Compute the L**p distance between two arrays.

Parameters

- **x** [(M, K) array_like] Input array.
- **y** [(N, K) array_like] Input array.
- **p** [float, 1 <= p <= infinity] Which Minkowski p-norm to use.

Examples

```python
>>> from scipy.spatial import minkowski_distance

>>> minkowski_distance([[0,0],[0,0]], [[1,1],[0,1]])
array([1.41421356, 1.])
```

scipy.spatial.minkowski_distance_p

scipy.spatial.minkowski_distance_p(x, y, p=2)

Compute the pth power of the L**p distance between two arrays.

For efficiency, this function computes the L**p distance but does not extract the pth root. If p is 1 or infinity, this is equal to the actual L**p distance.

Parameters

- **x** [(M, K) array_like] Input array.
- **y** [(N, K) array_like] Input array.
- **p** [float, 1 <= p <= infinity] Which Minkowski p-norm to use.

Examples

```python
>>> from scipy.spatial import minkowski_distance_p

>>> minkowski_distance_p([[0,0],[0,0]], [[1,1],[0,1]])
array([2, 1])
```

scipy.spatial.procrustes

scipy.spatial.procrustes(data1, data2)

Procrustes analysis, a similarity test for two data sets.

Each input matrix is a set of points or vectors (the rows of the matrix). The dimension of the space is the number of columns of each matrix. Given two identically sized matrices, procrustes standardizes both such that:

- \(tr(AA^T) = 1\).
- Both sets of points are centered around the origin.

Procrustes ([1], [2]) then applies the optimal transform to the second matrix (including scaling/dilation, rotations, and reflections) to minimize \(M^2 = \sum(data1 - data2)^2\), or the sum of the squares of the pointwise differences between the two input datasets.
This function was not designed to handle datasets with different numbers of datapoints (rows). If two data sets have different dimensionality (different number of columns), simply add columns of zeros to the smaller of the two.

**Parameters**

- **data1** [array_like] Matrix, n rows represent points in k (columns) space. data1 is the reference data, after it is standardised, the data from data2 will be transformed to fit the pattern in data1 (must have >1 unique points).

- **data2** [array_like] n rows of data in k space to be fit to data1. Must be the same shape (numrows, numcols) as data1 (must have >1 unique points).

**Returns**

- **mtx1** [array_like] A standardized version of data1.
- **mtx2** [array_like] The orientation of data2 that best fits data1. Centered, but not necessarily $tr(AA^T) = 1$.
- **disparity** [float] $M^2$ as defined above.

**Raises**

- **ValueError**
  
  If the input arrays are not two-dimensional. If the shape of the input arrays is different. If the input arrays have zero columns or zero rows.

**See also:**

- scipy.linalg.orthogonal_procrustes
- scipy.spatial.distance.directed_hausdorff

Another similarity test for two data sets

**Notes**

- The disparity should not depend on the order of the input matrices, but the output matrices will, as only the first output matrix is guaranteed to be scaled such that $tr(AA^T) = 1$.
- Duplicate data points are generally ok, duplicating a data point will increase its effect on the procrustes fit.
- The disparity scales as the number of points per input matrix.

**References**

[1], [2]

**Examples**

```python
>>> from scipy.spatial import procrustes
```

The matrix b is a rotated, shifted, scaled and mirrored version of a here:

```python
>>> a = np.array([[1, 3], [1, 2], [1, 1], [2, 1]], 'd')
>>> b = np.array([[4, -2], [4, -4], [4, -6], [2, -6]], 'd')
>>> mtx1, mtx2, disparity = procrustes(a, b)
>>> round(disparity)
0.0
```
scipy.spatial.geometric_slerp

**scipy.spatial.geometric_slerp**(start, end, t, tol=1e-07)

Geometric spherical linear interpolation.

The interpolation occurs along a unit-radius great circle arc in arbitrary dimensional space.

**Parameters**

- **start**: [(n_dimensions, ) array-like] Single n-dimensional input coordinate in a 1-D array-like object. n must be greater than 1.
- **end**: [(n_dimensions, ) array-like] Single n-dimensional input coordinate in a 1-D array-like object. n must be greater than 1.
- **t**: float or (n_points,) 1D array-like
  A float or 1D array-like of doubles representing interpolation parameters, with values required in the inclusive interval between 0 and 1. A common approach is to generate the array with `np.linspace(0, 1, n_pts)` for linearly spaced points. Ascending, descending, and scrambled orders are permitted.
- **tol**: float
  The absolute tolerance for determining if the start and end coordinates are antipodes.

**Returns**

- **result**: [(t.size, D)] An array of doubles containing the interpolated spherical path and including start and end when 0 and 1 t are used. The interpolated values should correspond to the same sort order provided in the t array. The result may be 1-dimensional if t is a float.

**Raises**

- **ValueError**
  If start and end are antipodes, not on the unit n-sphere, or for a variety of degenerate conditions.

**See also:**

- **scipy.spatial.transform.Slerp**
  3-D Slerp that works with quaternions

**Notes**

The implementation is based on the mathematical formula provided in [1], and the first known presentation of this algorithm, derived from study of 4-D geometry, is credited to Glenn Davis in a footnote of the original quaternion Slerp publication by Ken Shoemake [2].

New in version 1.5.0.

**References**

[1], [2]
Examples

Interpolate four linearly-spaced values on the circumference of a circle spanning 90 degrees:

```python
from scipy.spatial import geometric_slerp
import matplotlib.pyplot as plt
fig = plt.figure()
ax = fig.add_subplot(111)
start = np.array([1, 0])
end = np.array([0, 1])
t_vals = np.linspace(0, 1, 4)
result = geometric_slerp(start, end, t_vals)
ax.scatter(result[:,0], result[:,1], c='k')
circle = plt.Circle((0,0), 1, color='grey')
ax.add_artist(circle)
ax.set_aspect('equal')
plt.show()
```

The interpolated results should be at 30 degree intervals recognizable on the unit circle:

```python
>>> ax.scatter(result[...,0], result[...,1], c='k')
>>> circle = plt.Circle((0,0), 1, color='grey')
>>> ax.add_artist(circle)
>>> ax.set_aspect('equal')
>>> plt.show()
```

Attempting to interpolate between antipodes on a circle is ambiguous because there are two possible paths, and on a sphere there are infinite possible paths on the geodesic surface. Nonetheless, one of the ambiguous paths is returned along with a warning:

```python
opposite_pole = np.array([-1, 0])
with np.testing.suppress_warnings() as sup:
    sup.filter(UserWarning)
    geometric_slerp(start, opposite_pole, t_vals)
array([[ 1.00000000e+00, 0.00000000e+00],
        [ 1.00000000e+00, 0.00000000e+00],
        ...
```
Extend the original example to a sphere and plot interpolation points in 3D:

```python
>>> from mpl_toolkits.mplot3d import Axes3D
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111, projection='3d')

Plot the unit sphere for reference (optional):

```python
>>> u = np.linspace(0, 2 * np.pi, 100)
>>> v = np.linspace(0, np.pi, 100)
>>> x = np.outer(np.cos(u), np.sin(v))
>>> y = np.outer(np.sin(u), np.sin(v))
>>> z = np.outer(np.ones(np.size(u)), np.cos(v))
>>> ax.plot_surface(x, y, z, color='y', alpha=0.1)
```

Interpolating over a larger number of points may provide the appearance of a smooth curve on the surface of the sphere, which is also useful for discretized integration calculations on a sphere surface:

```python
>>> start = np.array([1, 0, 0])
>>> end = np.array([0, 0, 1])
>>> t_vals = np.linspace(0, 1, 200)
>>> result = geometric_slerp(start, ...
...           end, ...
...           t_vals)
>>> ax.plot(result[...,0], ...
...           result[...,1], ...
...           result[...,2], ...
...           c='k')
>>> plt.show()
```

scipy.spatial.distance.pdist

scipy.spatial.distance.pdist(X, metric='euclidean', *, out=None, **kwargs)

Pairwise distances between observations in n-dimensional space.

See Notes for common calling conventions.

Parameters

- **X** [array_like] An m by n array of m original observations in an n-dimensional space.
- **metric** [str or function, optional] The distance metric to use. The distance function can be 'braycurtis', 'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'euclidean', 'hamming', 'jaccard', 'jensenshannon', 'kulsinski', 'kulczynski1', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'.
- ****kwars [dict, optional] Extra arguments to metric: refer to each metric documentation for a list of all possible arguments.

Some possible arguments:
- p: scalar The p-norm to apply for Minkowski, weighted and unweighted. Default: 2.
- w: ndarray The weight vector for metrics that support weights (e.g., Minkowski).
- V: ndarray The variance vector for standardized Euclidean. Default: var(X, axis=0, ddof=1)
- VI: ndarray The inverse of the covariance matrix for Mahalanobis. Default: inv(cov(X.T)).T
- out: ndarray. The output array If not None, condensed distance matrix Y is stored in this array.

Returns
Y

[ndarray] Returns a condensed distance matrix Y. For each $i$ and $j$ (where $i < j < m$), where $m$ is the number of original observations. The metric $\text{dist}(u=X[i], v=X[j])$ is computed and stored in entry $m * i + j - ((i + 2) * (i + 1)) // 2$.

See also:

squareform

converts between condensed distance matrices and square distance matrices.

Notes

See squareform for information on how to calculate the index of this entry or to convert the condensed distance matrix to a redundant square matrix.

The following are common calling conventions.

1. Y = pdist(X, 'euclidean')

Computes the distance between m points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as m n-dimensional row vectors in the matrix X.

2. Y = pdist(X, 'minkowski', p=2.)

Computes the distances using the Minkowski distance $\|u - v\|_p$ ($p$-norm) where $p > 0$ (note that this is only a quasi-metric if $0 < p < 1$).

3. Y = pdist(X, 'cityblock')

Computes the city block or Manhattan distance between the points.

4. Y = pdist(X, 'seuclidean', V=None)

Computes the standardized Euclidean distance. The standardized Euclidean distance between two n-vectors $u$ and $v$ is

$$
\sqrt{\sum (u_i - v_i)^2 / V[x_i]}
$$

$V$ is the variance vector; $V[i]$ is the variance computed over all the i'th components of the points. If not passed, it is automatically computed.

5. Y = pdist(X, 'sqeuclidean')

Computes the squared Euclidean distance $\|u - v\|_2^2$ between the vectors.

6. Y = pdist(X, 'cosine')

Computes the cosine distance between vectors $u$ and $v$,

$$
1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}
$$

where $\|\cdot\|_2$ is the 2-norm of its argument *, and $u \cdot v$ is the dot product of $u$ and $v$.

7. Y = pdist(X, 'correlation')

Computes the correlation distance between vectors $u$ and $v$. This is

$$
1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\|(u - \bar{u})\|_2 \|(v - \bar{v})\|_2}
$$

where $\bar{v}$ is the mean of the elements of vector $v$, and $x \cdot y$ is the dot product of $x$ and $y$. 
8. \( Y = \text{pdist}(X, \text{'hamming'}) \)

Computes the normalized Hamming distance, or the proportion of those vector elements between two n-vectors \( u \) and \( v \) which disagree. To save memory, the matrix \( X \) can be of type boolean.

9. \( Y = \text{pdist}(X, \text{'jaccard'}) \)

Computes the Jaccard distance between the points. Given two vectors, \( u \) and \( v \), the Jaccard distance is the proportion of those elements \( u[i] \) and \( v[i] \) that disagree.

10. \( Y = \text{pdist}(X, \text{'jensenshannon'}) \)

Computes the Jensen-Shannon distance between two probability arrays. Given two probability vectors, \( p \) and \( q \), the Jensen-Shannon distance is

\[
\sqrt{\frac{D(p \parallel m) + D(q \parallel m)}{2}}
\]

where \( m \) is the pointwise mean of \( p \) and \( q \) and \( D \) is the Kullback-Leibler divergence.

11. \( Y = \text{pdist}(X, \text{'chebyshev'}) \)

Computes the Chebyshev distance between the points. The Chebyshev distance between two n-vectors \( u \) and \( v \) is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

\[
d(u, v) = \max_i |u_i - v_i|
\]

12. \( Y = \text{pdist}(X, \text{'canberra'}) \)

Computes the Canberra distance between the points. The Canberra distance between two points \( u \) and \( v \) is

\[
d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}
\]

13. \( Y = \text{pdist}(X, \text{'braycurtis'}) \)

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points \( u \) and \( v \) is

\[
d(u, v) = \frac{\sum_i |u_i - v_i|}{\sum_i |u_i + v_i|}
\]

14. \( Y = \text{pdist}(X, \text{'mahalanobis'}, \text{VI=\text{None}}) \)

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points \( u \) and \( v \) is \( \sqrt{(u - v)(1/\text{V})(u - v)^T} \) where \( (1/\text{V}) \) (the \( \text{VI} \) variable) is the inverse covariance. If \( \text{VI} \) is not None, \( \text{VI} \) will be used as the inverse covariance matrix.

15. \( Y = \text{pdist}(X, \text{'yule'}) \)

Computes the Yule distance between each pair of boolean vectors. (see yule function documentation)

16. \( Y = \text{pdist}(X, \text{'matching'}) \)

Synonym for 'hamming'.

17. \( Y = \text{pdist}(X, \text{'dice'}) \)

Computes the Dice distance between each pair of boolean vectors. (see dice function documentation)
18. $Y = \text{pdist}(X, \text{'kulsinski'})$

Computes the Kulsinski distance between each pair of boolean vectors. (see kulsinski function documentation)

19. $Y = \text{pdist}(X, \text{'rogerstanimoto'})$

Computes the Rogers-Tanimoto distance between each pair of boolean vectors. (see rogerstanimoto function documentation)

20. $Y = \text{pdist}(X, \text{'russellrao'})$

Computes the Russell-Rao distance between each pair of boolean vectors. (see russellrao function documentation)

21. $Y = \text{pdist}(X, \text{'sokalmichener'})$

Computes the Sokal-Michener distance between each pair of boolean vectors. (see sokalmichener function documentation)

22. $Y = \text{pdist}(X, \text{'sokalsneath'})$

Computes the Sokal-Sneath distance between each pair of boolean vectors. (see sokalsneath function documentation)

23. $Y = \text{pdist}(X, \text{'kulczynski1'})$

Computes the Kulczynski 1 distance between each pair of boolean vectors. (see kulczynski1 function documentation)

24. $Y = \text{pdist}(X, f)$

Computes the distance between all pairs of vectors in $X$ using the user supplied 2-arity function $f$. For example, Euclidean distance between the vectors could be computed as follows:

$$dm = \text{pdist}(X, \lambda u, v: \text{np.sqrt}((u-v)^2).\text{sum}())$$

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example,:

$$dm = \text{pdist}(X, \text{sokalsneath})$$

would calculate the pair-wise distances between the vectors in $X$ using the Python function sokalsneath. This would result in sokalsneath being called \(\binom{n}{2}\) times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax.:

$$dm = \text{pdist}(X, \text{'sokalsneath'})$$

**scipy.spatial.distance.cdist**

`scipy.spatial.distance.cdist`($XA, XB, metric='euclidean', *, out=None, **kwargs)`

Compute distance between each pair of the two collections of inputs.

See Notes for common calling conventions.

**Parameters**

- **XA**  
  [array_like] An $m_A$ by $n$ array of $m_A$ original observations in an $n$-dimensional space. Inputs are converted to float type.

- **XB**  
  [array_like] An $m_B$ by $n$ array of $m_B$ original observations in an $n$-dimensional space. Inputs are converted to float type.
**metric** [str or callable, optional] The distance metric to use. If a string, the distance function can be 'braycurtis', 'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'euclidean', 'hamming', 'jaccard', 'jensenshannon', 'kulsinski', 'kulczynski1', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'.

**kwargs** [dict, optional] Extra arguments to `metric`: refer to each metric documentation for a list of all possible arguments.

Some possible arguments:
- `p`: scalar The p-norm to apply for Minkowski, weighted and unweighted. Default: 2.
- `w`: array_like The weight vector for metrics that support weights (e.g., Minkowski).
- `V`: array_like The variance vector for standardized Euclidean. Default: `var(vstack([XA, XB]), axis=0, ddof=1)`.  
- `VI`: array_like The inverse of the covariance matrix for Mahalanobis. Default: `inv(cov(vstack([XA, XB]).T)).T`.
- `out`: ndarray The output array. If not None, the distance matrix Y is stored in this array.

**Returns**

Y [ndarray] A $m_A$ by $m_B$ distance matrix is returned. For each $i$ and $j$, the metric $\text{dist}(u=XA[i], v=XB[j])$ is computed and stored in the $ij$ th entry.

**Raises**

ValueError An exception is thrown if $XA$ and $XB$ do not have the same number of columns.

**Notes**

The following are common calling conventions:

1. $Y = \text{cdist}(XA, XB, 'euclidean')$
   
   Computes the distance between $m$ points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as $m$ $n$-dimensional row vectors in the matrix X.

2. $Y = \text{cdist}(XA, XB, 'minkowski', p=2.)$
   
   Computes the distances using the Minkowski distance $\|u - v\|_p$ ($p$-norm) where $p > 0$ (note that this is only a quasi-metric if $0 < p < 1$).

3. $Y = \text{cdist}(XA, XB, 'cityblock')$
   
   Computes the city block or Manhattan distance between the points.

4. $Y = \text{cdist}(XA, XB, 'sqeuclidean', V=None)$
   
   Computes the standardized Euclidean distance. The standardized Euclidean distance between two n-vectors $u$ and $v$ is

   \[ \sqrt{\sum (u_i - v_i)^2 / V[x_i]} \].

   V is the variance vector; V[i] is the variance computed over all the i'th components of the points. If not passed, it is automatically computed.

5. $Y = \text{cdist}(XA, XB, 'sqeuclidean')$
   
   Computes the squared Euclidean distance $\|u - v\|_2^2$ between the vectors.
6. \( Y = \text{cdist}(X_A, X_B, \texttt{'cosine'}) \)

Computes the cosine distance between vectors \( u \) and \( v \),

\[
1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}
\]

where \( \| \ast \|_2 \) is the 2-norm of its argument \( \ast \), and \( u \cdot v \) is the dot product of \( u \) and \( v \).

7. \( Y = \text{cdist}(X_A, X_B, \texttt{'correlation'}) \)

Computes the correlation distance between vectors \( u \) and \( v \). This is

\[
1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\|(u - \bar{u})\|_2 \|(v - \bar{v})\|_2}
\]

where \( \bar{v} \) is the mean of the elements of vector \( v \), and \( x \cdot y \) is the dot product of \( x \) and \( y \).

8. \( Y = \text{cdist}(X_A, X_B, \texttt{'hamming'}) \)

Computes the normalized Hamming distance, or the proportion of those vector elements between two n-vectors \( u \) and \( v \) which disagree. To save memory, the matrix \( X \) can be of type boolean.

9. \( Y = \text{cdist}(X_A, X_B, \texttt{'jaccard'}) \)

Computes the Jaccard distance between the points. Given two vectors, \( u \) and \( v \), the Jaccard distance is the proportion of those elements \( u[i] \) and \( v[i] \) that disagree where at least one of them is non-zero.

10. \( Y = \text{cdist}(X_A, X_B, \texttt{'jensenshannon'}) \)

Computes the Jensen-Shannon distance between two probability arrays. Given two probability vectors, \( p \) and \( q \), the Jensen-Shannon distance is

\[
\sqrt{\frac{D(p \parallel m) + D(q \parallel m)}{2}}
\]

where \( m \) is the pointwise mean of \( p \) and \( q \) and \( D \) is the Kullback-Leibler divergence.

11. \( Y = \text{cdist}(X_A, X_B, \texttt{'chebyshev'}) \)

Computes the Chebyshev distance between the points. The Chebyshev distance between two n-vectors \( u \) and \( v \) is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

\[
d(u, v) = \max_i |u_i - v_i|.
\]

12. \( Y = \text{cdist}(X_A, X_B, \texttt{'canberra'}) \)

Computes the Canberra distance between the points. The Canberra distance between two points \( u \) and \( v \) is

\[
d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}
\]

13. \( Y = \text{cdist}(X_A, X_B, \texttt{'braycurtis'}) \)

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points \( u \) and \( v \) is

\[
d(u, v) = \frac{\sum_i (|u_i - v_i|)}{\sum_i (|u_i + v_i|)}
\]
14. \( Y = \text{cdist}(XA, XB, 'mahalanobis', VI=\text{None}) \)

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points \( u \) and \( v \) is \( \sqrt{(u - v)^T (1/V)(u - v)} \) where \( (1/V) \) (the \( VI \) variable) is the inverse covariance. If \( VI \) is not None, \( VI \) will be used as the inverse covariance matrix.

15. \( Y = \text{cdist}(XA, XB, 'yule') \)

Computes the Yule distance between the boolean vectors. (see yule function documentation)

16. \( Y = \text{cdist}(XA, XB, 'matching') \)

Synonym for 'hamming'.

17. \( Y = \text{cdist}(XA, XB, 'dice') \)

Computes the Dice distance between the boolean vectors. (see dice function documentation)

18. \( Y = \text{cdist}(XA, XB, 'kulsinski') \)

Computes the Kulsinski distance between the boolean vectors. (see kulsinski function documentation)

19. \( Y = \text{cdist}(XA, XB, 'rogerstanimoto') \)

Computes the Rogers-Tanimoto distance between the boolean vectors. (see rogerstanimoto function documentation)

20. \( Y = \text{cdist}(XA, XB, 'russellrao') \)

Computes the Russell-Rao distance between the boolean vectors. (see russellrao function documentation)

21. \( Y = \text{cdist}(XA, XB, 'sokalmichener') \)

Computes the Sokal-Michener distance between the boolean vectors. (see sokalmichener function documentation)

22. \( Y = \text{cdist}(XA, XB, 'sokalsneath') \)

Computes the Sokal-Sneath distance between the vectors. (see sokalsneath function documentation)

23. \( Y = \text{cdist}(XA, XB, f) \)

Computes the distance between all pairs of vectors in \( X \) using the user supplied 2-arity function \( f \). For example, Euclidean distance between the vectors could be computed as follows:

\[
\text{dm} = \text{cdist}(XA, XB, \text{lambda} \ u, v: \ \text{np.sqrt}(((u-v)**2).\text{sum}()))
\]

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example:

\[
\text{dm} = \text{cdist}(XA, XB, \text{'sokalsneath'})
\]

would calculate the pair-wise distances between the vectors in \( X \) using the Python function \text{sokalsneath}. This would result in \text{sokalsneath} being called \( \binom{n}{2} \) times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax:

\[
\text{dm} = \text{cdist}(XA, XB, \text{'sokalsneath'})
\]
**Examples**

Find the Euclidean distances between four 2-D coordinates:

```python
>>> from scipy.spatial import distance
>>> coords = [(35.0456, -85.2672), ...
             (35.1174, -89.9711), ...
             (35.9728, -83.9422), ...
             (36.1667, -86.7833)]
>>> distance.cdist(coords, coords, 'euclidean')
array([[ 0. , 4.7044, 1.6172, 1.8856],
       [ 4.7044, 0. , 6.0893, 3.3561],
       [ 1.6172, 6.0893, 0. , 2.8477],
       [ 1.8856, 3.3561, 2.8477, 0. ]])
```

Find the Manhattan distance from a 3-D point to the corners of the unit cube:

```python
>>> a = np.array([[0, 0, 0],
                ... [0, 0, 1],
                ... [0, 1, 0],
                ... [0, 1, 1],
                ... [1, 0, 0],
                ... [1, 0, 1],
                ... [1, 1, 0],
                ... [1, 1, 1]])
>>> b = np.array([[0.1, 0.2, 0.4]])
>>> distance.cdist(a, b, 'cityblock')
array([[ 0.7],
       [ 0.9],
       [ 1.3],
       [ 1.5],
       [ 1.5],
       [ 1.7],
       [ 2.1],
       [ 2.3]])
```

**scipy.spatial.distance.squareform**

`scipy.spatial.distance.squareform(X, force='no', checks=True)`

Convert a vector-form distance vector to a square-form distance matrix, and vice-versa.

**Parameters**

- **X** [array_like] Either a condensed or redundant distance matrix.
- **force** [str, optional] As with MATLAB(TM), if force is equal to 'tovector' or 'tomatrix', the input will be treated as a distance matrix or distance vector respectively.
- **checks** [bool, optional] If set to False, no checks will be made for matrix symmetry nor zero diagonals. This is useful if it is known that \(X - X.T\) is small and \(\text{diag}(X)\) is close to zero. These values are ignored anyway so they do not disrupt the squareform transformation.

**Returns**

- **Y** [ndarray] If a condensed distance matrix is passed, a redundant one is returned, or if a redundant one is passed, a condensed distance matrix is returned.
Notes

1. v = squareform(X)
   Given a square n-by-n symmetric distance matrix X, v = squareform(X) returns a \( n * (n-1) / 2 \) (i.e. binomial coefficient \( n \choose 2 \)) sized vector v where \( v[i] = \frac{n!}{(n-i)!i!} + (j-i-1) \) is the distance between distinct points \( i \) and \( j \). If X is non-square or asymmetric, an error is raised.

2. X = squareform(v)
   Given a \( n * (n-1) / 2 \) sized vector v for some integer \( n \geq 1 \) encoding distances as described, X = squareform(v) returns a n-by-n distance matrix X. The X[i, j] and X[j, i] values are set to \( v[i] = \frac{n!}{(n-i)!i!} + (j-i-1) \) and all diagonal elements are zero.

In SciPy 0.19.0, squareform stopped casting all input types to float64, and started returning arrays of the same dtype as the input.

scipy.spatial.distance.directed_hausdorff

scipy.spatial.distance.directed_hausdorff (u, v, seed=0)
Compute the directed Hausdorff distance between two 2-D arrays.

Distances between pairs are calculated using a Euclidean metric.

Parameters
    u [(M,N) array_like] Input array.
    v [(O,N) array_like] Input array.
    seed [int or None] Local numpy.random.RandomState seed. Default is 0, a random shuffling of u and v that guarantees reproducibility.

Returns
    d [double] The directed Hausdorff distance between arrays u and v.
    index_1 [int] index of point contributing to Hausdorff pair in u
    index_2 [int] index of point contributing to Hausdorff pair in v

Raises
    ValueError
    An exception is thrown if u and v do not have the same number of columns.

See also:

scipy.spatial.procrustes
    Another similarity test for two data sets

Notes
Uses the early break technique and the random sampling approach described by [1]. Although worst-case performance is \( O(m * o) \) (as with the brute force algorithm), this is unlikely in practice as the input data would have to require the algorithm to explore every single point interaction, and after the algorithm shuffles the input points at that. The best case performance is \( O(m) \), which is satisfied by selecting an inner loop distance that is less than cmax and leads to an early break as often as possible. The authors have formally shown that the average runtime is closer to \( O(m) \).

New in version 0.19.0.
References

[1]

Examples

Find the directed Hausdorff distance between two 2-D arrays of coordinates:

```python
>>> from scipy.spatial.distance import directed_hausdorff
>>> u = np.array([(1.0, 0.0),
...                (0.0, 1.0),
...                (-1.0, 0.0),
...                (0.0, -1.0)])
>>> v = np.array([(2.0, 0.0),
...                (0.0, 2.0),
...                (-2.0, 0.0),
...                (0.0, -4.0)])

>>> directed_hausdorff(u, v)[0]
2.23606797749979
>>> directed_hausdorff(v, u)[0]
3.0
```

Find the general (symmetric) Hausdorff distance between two 2-D arrays of coordinates:

```python
>>> max(directed_hausdorff(u, v)[0], directed_hausdorff(v, u)[0])
3.0
```

Find the indices of the points that generate the Hausdorff distance (the Hausdorff pair):

```python
>>> directed_hausdorff(v, u)[1:]
(3, 3)
```

Predicates for checking the validity of distance matrices, both condensed and redundant. Also contained in this module are functions for computing the number of observations in a distance matrix.

- `is_valid_dm(D[, tol, throw, name, warning])` Return True if input array is a valid distance matrix.
- `is_valid_y(Y[, warning, throw, name])` Return True if the input array is a valid condensed distance matrix.
- `num_obs_dm(d)` Return the number of original observations that correspond to a square, redundant distance matrix.
- `num_obs_y(Y)` Return the number of original observations that correspond to a condensed distance matrix.
scipy.spatial.distance.is_valid_dm

scipy.spatial.distance.is_valid_dm(D, tol=0.0, throw=False, name='D', warning=False)

Return True if input array is a valid distance matrix.

Distance matrices must be 2-dimensional numpy arrays. They must have a zero-diagonal, and they must be symmetric.

Parameters

- D [array_like] The candidate object to test for validity.
- tol [float, optional] The distance matrix should be symmetric. $tol$ is the maximum difference between entries $ij$ and $ji$ for the distance metric to be considered symmetric.
- throw [bool, optional] An exception is thrown if the distance matrix passed is not valid.
- name [str, optional] The name of the variable to checked. This is useful if throw is set to True so the offending variable can be identified in the exception message when an exception is thrown.
- warning [bool, optional] Instead of throwing an exception, a warning message is raised.

Returns

- valid [bool] True if the variable $D$ passed is a valid distance matrix.

Notes

Small numerical differences in $D$ and $D.T$ and non-zeroness of the diagonal are ignored if they are within the tolerance specified by $tol$.

scipy.spatial.distance.is_valid_y

scipy.spatial.distance.is_valid_y(y, warning=False, throw=False, name=None)

Return True if the input array is a valid condensed distance matrix.

Condensed distance matrices must be 1-dimensional numpy arrays. Their length must be a binomial coefficient $\binom{n}{2}$ for some positive integer $n$.

Parameters

- y [array_like] The condensed distance matrix.
- warning [bool, optional] Invokes a warning if the variable passed is not a valid condensed distance matrix. The warning message explains why the distance matrix is not valid. $name$ is used when referencing the offending variable.
- throw [bool, optional] Throws an exception if the variable passed is not a valid condensed distance matrix.
- name [bool, optional] Used when referencing the offending variable in the warning or exception message.

scipy.spatial.distance.num_obs_dm

scipy.spatial.distance.num_obs_dm(d)

Return the number of original observations that correspond to a square, redundant distance matrix.

Parameters

- d [array_like] The target distance matrix.

Returns

- num_obs_dm [int] The number of observations in the redundant distance matrix.
scipy.spatial.distance.num_obs_y

Return the number of original observations that correspond to a condensed distance matrix.

Parameters

Y [array_like] Condensed distance matrix.

Returns

n [int] The number of observations in the condensed distance matrix Y.

Distance functions between two numeric vectors u and v. Computing distances over a large collection of vectors is inefficient for these functions. Use pdist for this purpose.

scipy.spatial.distance.braycurtis

Compute the Bray-Curtis distance between two 1-D arrays.

Bray-Curtis distance is defined as

\[ \frac{\sum |u_i - v_i|}{\sum |u_i + v_i|} \]

The Bray-Curtis distance is in the range [0, 1] if all coordinates are positive, and is undefined if the inputs are of length zero.

Parameters

u [(N,) array_like] Input array. 
v [(N,) array_like] Input array. 
w [(N,) array_like, optional] The weights for each value in u and v. Default is None, which gives each value a weight of 1.0.

Returns

braycurtis [double] The Bray-Curtis distance between 1-D arrays u and v.
Examples

```python
>>> from scipy.spatial import distance
>>> distance.braycurtis([1, 0, 0], [0, 1, 0])
1.0
>>> distance.braycurtis([1, 1, 0], [0, 1, 0])
0.33333333333333331
```

scipy.spatial.distance.canberra

```python
scipy.spatial.distance.canberra(u, v, w=None)
```

Compute the Canberra distance between two 1-D arrays.

The Canberra distance is defined as

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}.$$

Parameters

- **u** [(N,) array_like] Input array.
- **v** [(N,) array_like] Input array.
- **w** [(N,) array_like, optional] The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns

- **canberra** [double] The Canberra distance between vectors u and v.

Notes

When $u[i]$ and $v[i]$ are 0 for given i, then the fraction 0/0 = 0 is used in the calculation.

Examples

```python
>>> from scipy.spatial import distance
>>> distance.canberra([1, 0, 0], [0, 1, 0])
2.0
>>> distance.canberra([1, 1, 0], [0, 1, 0])
1.0
```

scipy.spatial.distance.chebyshev

```python
scipy.spatial.distance.chebyshev(u, v, w=None)
```

Computes the Chebyshev distance between two 1-D arrays $u$ and $v$, which is defined as

$$\max_i |u_i - v_i|.$$ 

Parameters

- **u** [(N,) array_like] Input vector.
- **v** [(N,) array_like] Input vector.
- **w** [(N,) array_like, optional] Unused, as ‘max’ is a weightless operation. Here for API consistency.
Returns

chebyshev  [double] The Chebyshev distance between vectors u and v.

Examples

```python
>>> from scipy.spatial import distance
>>> distance.chebyshev([1, 0, 0], [0, 1, 0])
1
>>> distance.chebyshev([1, 1, 0], [0, 1, 0])
```

scipy.spatial.distance.cityblock

scipy.spatial.distance.cityblock(u, v, w=None)
Compute the City Block (Manhattan) distance.
Computes the Manhattan distance between two 1-D arrays u and v, which is defined as

\[ \sum_i |u_i - v_i|. \]

Parameters

- u  [(N,) array_like] Input array.
- v  [(N,) array_like] Input array.
- w  [(N,) array_like, optional] The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns

cityblock  [double] The City Block (Manhattan) distance between vectors u and v.

Examples

```python
>>> from scipy.spatial import distance
>>> distance.cityblock([1, 0, 0], [0, 1, 0])
2
>>> distance.cityblock([1, 0, 0], [0, 2, 0])
3
>>> distance.cityblock([1, 0, 0], [1, 1, 0])
1
```

scipy.spatial.distance.correlation

scipy.spatial.distance.correlation(u, v, w=None, centered=True)
Compute the correlation distance between two 1-D arrays.
The correlation distance between u and v, is defined as

\[ 1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\|u - \bar{u}\|_2 \|v - \bar{v}\|_2} \]

where \( \bar{u} \) is the mean of the elements of u and \( x \cdot y \) is the dot product of x and y.

Parameters

**SciPy**

**API definition**

### scipy.spatial.distance.cosine

#### scipy.spatial.distance.cosine(u, v, w=None)

Compute the Cosine distance between 1-D arrays.

The Cosine distance between $u$ and $v$, is defined as

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}.$$

where $u \cdot v$ is the dot product of $u$ and $v$.

**Parameters**

- **u** [(N,) array_like] Input array.
- **v** [(N,) array_like] Input array.
- **w** [(N,) array_like, optional] The weights for each value in $u$ and $v$. Default is None, which gives each value a weight of 1.0

**Returns**

- **cosine** [double] The Cosine distance between vectors $u$ and $v$.

**Examples**

```python
def main():
    from scipy.spatial import distance
    print(distance.cosine([1, 0, 0], [0, 1, 0]))
    print(distance.cosine([100, 0, 0], [0, 1, 0]))
    print(distance.cosine([1, 1, 0], [0, 1, 0]))
```

```text
1.0
1.0
0.29289321881345254
```

### scipy.spatial.distance.euclidean

#### scipy.spatial.distance.euclidean(u, v, w=None)

Computes the Euclidean distance between two 1-D arrays.

The Euclidean distance between 1-D arrays $u$ and $v$, is defined as

$$\|u - v\|_2 \left(\sum \frac{w_i}{(u_i - v_i)^2}\right)^{1/2}.$$

**Parameters**

- **u** [(N,) array_like] Input array.
- **v** [(N,) array_like] Input array.

w  [(N,) array_like, optional] The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns

euclidean  [double] The Euclidean distance between vectors u and v.

Examples

```python
>>> from scipy.spatial import distance
>>> distance.euclidean([1, 0, 0], [0, 1, 0])
1.4142135623730951
>>> distance.euclidean([1, 1, 0], [0, 1, 0])
1.0
```

scipy.spatial.distance.jensenshannon

scipy.spatial.distance.jensenshannon(p, q, base=None, *, axis=0, keepdims=False)

Compute the Jensen-Shannon distance (metric) between two probability arrays. This is the square root of the Jensen-Shannon divergence.

The Jensen-Shannon distance between two probability vectors p and q is defined as,

$$\sqrt{\frac{D(p \parallel m) + D(q \parallel m)}{2}}$$

where m is the pointwise mean of p and q and D is the Kullback-Leibler divergence.

This routine will normalize p and q if they don’t sum to 1.0.

Parameters

- p  [(N,) array_like] left probability vector
- q  [(N,) array_like] right probability vector
- base  [double, optional] the base of the logarithm used to compute the output if not given, then the routine uses the default base of scipy.stats.entropy.
- axis  [int, optional] Axis along which the Jensen-Shannon distances are computed. The default is 0.
  New in version 1.7.0.
- keepdims  [bool, optional] If this is set to True, the reduced axes are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array. Default is False.
  New in version 1.7.0.

Returns

- js  [double or ndarray] The Jensen-Shannon distances between p and q along the axis.
Notes

New in version 1.2.0.

Examples

```python
>>> from scipy.spatial import distance
>>> distance.jensenshannon([1.0, 0.0, 0.0], [0.0, 1.0, 0.0], 2.0)
1.0
>>> distance.jensenshannon([1.0, 0.0], [0.5, 0.5])
0.46450140402245893
>>> distance.jensenshannon([1.0, 0.0, 0.0], [1.0, 0.0, 0.0])
0.0
>>> a = np.array([[1, 2, 3, 4],
... [5, 6, 7, 8],
... [9, 10, 11, 12]])
>>> b = np.array([[13, 14, 15, 16],
... [17, 18, 19, 20],
... [21, 22, 23, 24]])
>>> distance.jensenshannon(a, b, axis=0)
array([0.1954288, 0.1447697, 0.1138377, 0.0927636])
>>> distance.jensenshannon(a, b, axis=1)
array([0.1402339, 0.0399106, 0.0201815])
```

**scipy.spatial.distance.mahalanobis**

```
scipy.spatial.distance.mahalanobis(u, v, VI)
```

Compute the Mahalanobis distance between two 1-D arrays.

The Mahalanobis distance between 1-D arrays \( u \) and \( v \), is defined as

\[
\sqrt{(u - v)V^{-1}(u - v)^T}
\]

where \( V \) is the covariance matrix. Note that the argument \( VI \) is the inverse of \( V \).

**Parameters**

- \( u \) : [(N,) array_like] Input array.
- \( v \) : [(N,) array_like] Input array.
- \( VI \) : [array_like] The inverse of the covariance matrix.

**Returns**

- \( mahalanobis \) : [double] The Mahalanobis distance between vectors \( u \) and \( v \).
Examples

```python
from scipy.spatial import distance
distance.mahalanobis([1, 0, 0], [0, 1, 0], iv)
1.0
distance.mahalanobis([0, 2, 0], [0, 1, 0], iv)
1.0
distance.mahalanobis([2, 0, 0], [0, 1, 0], iv)
1.7320508075688772
```

**scipy.spatial.distance.minkowski**

`scipy.spatial.distance.minkowski(u, v, p=2, w=None)`  
Compute the Minkowski distance between two 1-D arrays.

The Minkowski distance between 1-D arrays `u` and `v`, is defined as

\[
\|u - v\|_p = \left( \sum_{i=0}^{N} |u_i - v_i|^p \right)^{1/p}.
\]

Parameters:

- `u` : [(N,) array_like] Input array.
- `v` : [(N,) array_like] Input array.
- `p` : [scalar] The order of the norm of the difference `\|u - v\|_p`. Note that for `0 < p < 1`, the triangle inequality only holds with an additional multiplicative factor, i.e. it is only a quasi-metric.
- `w` : [(N,) array_like, optional] The weights for each value in `u` and `v`. Default is None, which gives each value a weight of 1.0

Returns:

- `minkowski` : [double] The Minkowski distance between vectors `u` and `v`.

Examples

```python
from scipy.spatial import distance
distance.minkowski([1, 0, 0], [0, 1, 0], 1)
2.0
distance.minkowski([1, 0, 0], [0, 1, 0], 2)
1.4142135623730951
distance.minkowski([1, 0, 0], [0, 1, 0], 3)
1.2599210498948732
distance.minkowski([1, 1, 0], [0, 1, 0], 1)
1.0
distance.minkowski([1, 1, 0], [0, 1, 0], 2)
1.0
distance.minkowski([1, 1, 0], [0, 1, 0], 3)
1.0
```
scipy.spatial.distance.seuclidean

scipy.spatial.distance.seuclidean(u, v, V)

Return the standardized Euclidean distance between two 1-D arrays.

The standardized Euclidean distance between \(u\) and \(v\).

Parameters

- **u** [(N,) array_like] Input array.
- **v** [(N,) array_like] Input array.
- **V** [(N,) array_like] \(V\) is an 1-D array of component variances. It is usually computed among a larger collection vectors.

Returns

- **seuclidean** [double] The standardized Euclidean distance between vectors \(u\) and \(v\).

Examples

```python
>>> from scipy.spatial import distance
>>> distance.seuclidean([1, 0, 0], [0, 1, 0], [0.1, 0.1, 0.1])
4.4721359549995796
>>> distance.seuclidean([1, 0, 0], [0, 1, 0], [1, 0.1, 0.1])
3.3166247903553998
>>> distance.seuclidean([1, 0, 0], [0, 1, 0], [10, 0.1, 0.1])
3.1780497164141406
```

scipy.spatial.distance.sqeuclidean

scipy.spatial.distance.sqeuclidean(u, v, w=None)

Compute the squared Euclidean distance between two 1-D arrays.

The squared Euclidean distance between \(u\) and \(v\) is defined as

\[
\|
\begin{pmatrix}
u \\
v
\end{pmatrix}
\|^2 \\
\sum (w_i |(u_i - v_i)|^2)
\]

Parameters

- **u** [(N,) array_like] Input array.
- **v** [(N,) array_like] Input array.
- **w** [(N,) array_like, optional] The weights for each value in \(u\) and \(v\). Default is None, which gives each value a weight of 1.0

Returns

- **sqeuclidean** [double] The squared Euclidean distance between vectors \(u\) and \(v\).
## Examples

```python
>>> from scipy.spatial import distance
>>> distance.sqeuclidean([1, 0, 0], [0, 1, 0])
2.0
>>> distance.sqeuclidean([1, 1, 0], [0, 1, 0])
1.0
```

Distance functions between two boolean vectors (representing sets) \( u \) and \( v \). As in the case of numerical vectors, \texttt{pdist} is more efficient for computing the distances between all pairs.

### scipy.spatial.distance.dice

\texttt{scipy.spatial.distance.dice(u, v, w=None)}

Compute the Dice dissimilarity between two boolean 1-D arrays.

The Dice dissimilarity between \( u \) and \( v \) is

\[
\frac{c_{TF} + c_{FT}}{2c_{TT} + c_{FT} + c_{TF}}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \).

**Parameters**

- \( u \) [[(N,) array_like, bool]] Input 1-D array.
- \( v \) [[(N,) array_like, bool]] Input 1-D array.
- \( w \) [[(N,) array_like, optional]] The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

**Returns**

- \( \text{dice} \) [double] The Dice dissimilarity between 1-D arrays \( u \) and \( v \).
Examples

```python
>>> from scipy.spatial import distance
>>> distance.dice([1, 0, 0], [0, 1, 0])
1.0
>>> distance.dice([1, 0, 0], [1, 1, 0])
0.33333333333333333
>>> distance.dice([1, 0, 0], [2, 0, 0])
-0.33333333333333333
```

**scipy.spatial.distance.hamming**

`scipy.spatial.distance.hamming(u, v, w=None)`

Compute the Hamming distance between two 1-D arrays.

The Hamming distance between 1-D arrays `u` and `v`, is simply the proportion of disagreeing components in `u` and `v`. If `u` and `v` are boolean vectors, the Hamming distance is

\[
\frac{c_{01} + c_{10}}{n}
\]

where \(c_{ij}\) is the number of occurrences of \(u[k] = i\) and \(v[k] = j\) for \(k < n\).

**Parameters**

- `u` [(N,) array_like] Input array.
- `v` [(N,) array_like] Input array.
- `w` [(N,) array_like, optional] The weights for each value in `u` and `v`. Default is None, which gives each value a weight of 1.0

**Returns**

- `hamming` [double] The Hamming distance between vectors `u` and `v`.

Examples

```python
>>> from scipy.spatial import distance
>>> distance.hamming([1, 0, 0], [0, 1, 0])
0.66666666666666663
>>> distance.hamming([1, 0, 0], [1, 1, 0])
0.33333333333333331
>>> distance.hamming([1, 0, 0], [2, 0, 0])
0.33333333333333331
>>> distance.hamming([1, 0, 0], [3, 0, 0])
0.33333333333333331
```

**scipy.spatial.distance.jaccard**

`scipy.spatial.distance.jaccard(u, v, w=None)`

Compute the Jaccard-Needham dissimilarity between two boolean 1-D arrays.

The Jaccard-Needham dissimilarity between 1-D boolean arrays `u` and `v`, is defined as

\[
\frac{c_{TF} + c_{FT}}{c_{TT} + c_{FT} + c_{TF}}
\]

where \(c_{ij}\) is the number of occurrences of \(u[k] = i\) and \(v[k] = j\) for \(k < n\).
Parameters

- **u** [(N,) array_like, bool] Input array.
- **v** [(N,) array_like, bool] Input array.
- **w** [(N,) array_like, optional] The weights for each value in `u` and `v`. Default is None, which gives each value a weight of 1.0

Returns

- **jaccard** [double] The Jaccard distance between vectors `u` and `v`.

Notes

When both `u` and `v` lead to a 0/0 division i.e. there is no overlap between the items in the vectors the returned distance is 0. See the Wikipedia page on the Jaccard index [1], and this paper [2].

Changed in version 1.2.0: Previously, when `u` and `v` lead to a 0/0 division, the function would return NaN. This was changed to return 0 instead.

References

[1], [2]

Examples

```python
>>> from scipy.spatial import distance
>>> distance.jaccard([1, 0, 0], [0, 1, 0])
1.0
>>> distance.jaccard([1, 0, 0], [1, 1, 0])
0.5
>>> distance.jaccard([1, 0, 0], [1, 2, 0])
0.5
>>> distance.jaccard([1, 0, 0], [1, 1, 1])
0.6666666666666663
```

**scipy.spatial.distance.kulsinski**

`scipy.spatial.distance.kulsinski(u, v, w=None)`

Compute the Kulsinski dissimilarity between two boolean 1-D arrays.

The Kulsinski dissimilarity between two boolean 1-D arrays `u` and `v`, is defined as

\[
\frac{c_{TF} + c_{FT} - c_{TT} + n}{c_{FT} + c_{TF} + n}
\]

where \(c_{ij}\) is the number of occurrences of \(u[k] = i\) and \(v[k] = j\) for \(k < n\).

Parameters

- **u** [(N,) array_like, bool] Input array.
- **v** [(N,) array_like, bool] Input array.
- **w** [(N,) array_like, optional] The weights for each value in `u` and `v`. Default is None, which gives each value a weight of 1.0

Returns

- **kulsinski** [double] The Kulsinski distance between vectors `u` and `v`. 

Examples

```python
>>> from scipy.spatial import distance
>>> distance.kulsinski([1, 0, 0], [0, 1, 0])
1.0
>>> distance.kulsinski([1, 0, 0], [1, 1, 0])
0.75
>>> distance.kulsinski([1, 0, 0], [2, 1, 0])
0.33333333333333331
>>> distance.kulsinski([1, 0, 0], [3, 1, 0])
-0.5
```

`scipy.spatial.distance.kulczynski1`

`scipy.spatial.distance.kulczynski1(u, v, *, w=None)`

Compute the Kulczynski 1 dissimilarity between two boolean 1-D arrays.

The Kulczynski 1 dissimilarity between two boolean 1-D arrays \( u \) and \( v \) of length \( n \), is defined as

\[
\frac{c_{11}}{c_{01} + c_{10}}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k \in 0, 1, \ldots, n - 1 \).

**Parameters**

- \( u \) [(N,) array_like, bool] Input array.
- \( v \) [(N,) array_like, bool] Input array.
- \( w \) [(N,) array_like, optional] The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

**Returns**

- \( \text{kulczynski1} \) [float] The Kulczynski 1 distance between vectors \( u \) and \( v \).

**See also:**

- \( \text{kulsinski} \)

**Notes**

This measure has a minimum value of 0 and no upper limit. It is un-defined when there are no non-matches.

New in version 1.8.0.

**References**

[1]
Examples

```python
>>> from scipy.spatial import distance
>>> distance.kulczynski1([1, 0, 0], [0, 1, 0])
0.0
>>> distance.kulczynski1([True, False, False], [True, True, False])
1.0
>>> distance.kulczynski1([True, False, False], True)
0.5
>>> distance.kulczynski1([1, 0, 0], [3, 1, 0])
-3.0
```

`scipy.spatial.distance.rogerstanimoto`

`scipy.spatial.distance.rogerstanimoto(u, v, w=none)`

Compute the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.

The Rogers-Tanimoto dissimilarity between two boolean 1-D arrays, \( u \) and \( v \), is defined as

\[
R = \frac{c_{TF} + c_{FT}}{c_{TT} + c_{FF}}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \) and \( R = 2(c_{TF} + c_{FT}) \).

Parameters

- **u** [(N,) array_like, bool] Input array.
- **v** [(N,) array_like, bool] Input array.
- **w** [(N,) array_like, optional] The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

Returns

- **rogerstanimoto** [double] The Rogers-Tanimoto dissimilarity between vectors \( u \) and \( v \).

Examples

```python
>>> from scipy.spatial import distance
>>> distance.rogerstanimoto([1, 0, 0], [0, 1, 0])
0.8
>>> distance.rogerstanimoto([1, 0, 0], [1, 1, 0])
0.5
>>> distance.rogerstanimoto([1, 0, 0], [2, 0, 0])
-1.0
```

`scipy.spatial.distance.russellrao`

`scipy.spatial.distance.russellrao(u, v, w=none)`

Compute the Russell-Rao dissimilarity between two boolean 1-D arrays.

The Russell-Rao dissimilarity between two boolean 1-D arrays, \( u \) and \( v \), is defined as

\[
R = \frac{n - c_{TT}}{n}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \).
Parameters

- **u** [(N,) array_like, bool] Input array.
- **v** [(N,) array_like, bool] Input array.
- **w** [(N,) array_like, optional] The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns

- **russellrao** [double] The Russell-Rao dissimilarity between vectors u and v.

Examples

```python
>>> from scipy.spatial import distance
>>> distance.russellrao([1, 0, 0], [0, 1, 0])
1.0
>>> distance.russellrao([1, 0, 0], [1, 1, 0])
0.6666666666666666
>>> distance.russellrao([1, 0, 0], [2, 0, 0])
0.3333333333333333
```

**scipy.spatial.distance.sokalmichener**

**scipy.spatial.distance.sokalmichener** *(u, v, w=None)*

Compute the Sokal-Michener dissimilarity between two boolean 1-D arrays.

The Sokal-Michener dissimilarity between boolean 1-D arrays u and v, is defined as

\[
\frac{R}{S + R}
\]

where \(c_{ij}\) is the number of occurrences of \(u[k] = i\) and \(v[k] = j\) for \(k < n\), \(R = 2 \times (c_{TF} + c_{FT})\) and \(S = c_{FF} + c_{TT}\).

Parameters

- **u** [(N,) array_like, bool] Input array.
- **v** [(N,) array_like, bool] Input array.
- **w** [(N,) array_like, optional] The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns

- **sokalmichener** [double] The Sokal-Michener dissimilarity between vectors u and v.

Examples

```python
>>> from scipy.spatial import distance
>>> distance.sokalmichener([1, 0, 0], [0, 1, 0])
0.8
>>> distance.sokalmichener([1, 0, 0], [1, 1, 0])
0.5
>>> distance.sokalmichener([1, 0, 0], [2, 0, 0])
-1.0
```
scipy.spatial.distance.sokalsneath

`scipy.spatial.distance.sokalsneath(u, v, w=None)`

Compute the Sokal-Sneath dissimilarity between two boolean 1-D arrays.

The Sokal-Sneath dissimilarity between \( u \) and \( v \),

\[
\frac{R}{c_{TT} + R}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \) and \( R = 2(c_{TF} + c_{FT}) \).

**Parameters**

- **u** [(N,) array_like, bool] Input array.
- **v** [(N,) array_like, bool] Input array.
- **w** [(N,) array_like, optional] The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

**Returns**

- **sokalsneath** [double] The Sokal-Sneath dissimilarity between vectors \( u \) and \( v \).

**Examples**

```python
>>> from scipy.spatial import distance
>>> distance.sokalsneath([1, 0, 0], [0, 1, 0])
1.0
>>> distance.sokalsneath([1, 0, 0], [1, 1, 0])
0.6666666666666663
>>> distance.sokalsneath([1, 0, 0], [2, 1, 0])
0.0
>>> distance.sokalsneath([1, 0, 0], [3, 1, 0])
-2.0
```

scipy.spatial.distance.yule

`scipy.spatial.distance.yule(u, v, w=None)`

Compute the Yule dissimilarity between two boolean 1-D arrays.

The Yule dissimilarity is defined as

\[
\frac{R}{c_{TT} \ast c_{FF} + \frac{R}{2}}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \) and \( R = 2.0 \ast c_{TF} \ast c_{FT} \).

**Parameters**

- **u** [(N,) array_like, bool] Input array.
- **v** [(N,) array_like, bool] Input array.
- **w** [(N,) array_like, optional] The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

**Returns**

- **yule** [double] The Yule dissimilarity between vectors \( u \) and \( v \).
Examples

```python
>>> from scipy.spatial import distance
>>> distance.yule([1, 0, 0], [0, 1, 0])
2.0
>>> distance.yule([1, 1, 0], [0, 1, 0])
0.0
```

`hamming` also operates over discrete numerical vectors.

### 3.3.27 Special functions (scipy.special)

Nearly all of the functions below are universal functions and follow broadcasting and automatic array-looping rules.

See also:

- `scipy.special.cython_special` — Typed Cython versions of special functions

#### Error handling

Errors are handled by returning NaNs or other appropriate values. Some of the special function routines can emit warnings or raise exceptions when an error occurs. By default this is disabled; to query and control the current error handling state the following functions are provided.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>geterr</code></td>
<td>Get the current way of handling special-function errors.</td>
</tr>
<tr>
<td><code>seterr</code></td>
<td>Set how special-function errors are handled.</td>
</tr>
<tr>
<td><code>errstate(**kwargs)</code></td>
<td>Context manager for special-function error handling.</td>
</tr>
<tr>
<td><code>SpecialFunctionWarning</code></td>
<td>Warning that can be emitted by special functions.</td>
</tr>
<tr>
<td><code>SpecialFunctionError</code></td>
<td>Exception that can be raised by special functions.</td>
</tr>
</tbody>
</table>

**scipy.special.geterr**

- `scipy.special.geterr()`
  - Get the current way of handling special-function errors.

  **Returns**

  - `err [dict]` A dictionary with keys “singular”, “underflow”, “overflow”, “slow”, “loss”, “no_result”, “domain”, “arg”, and “other”, whose values are from the strings “ignore”, “warn”, and “raise”. The keys represent possible special-function errors, and the values define how these errors are handled.

  **See also:**

  - `seterr` set how special-function errors are handled
  - `errstate` context manager for special-function error handling
  - `numpy.geterr` similar numpy function for floating-point errors
Notes

For complete documentation of the types of special-function errors and treatment options, see `seterr`.

Examples

By default all errors are ignored.

```python
>>> import scipy.special as sc
>>> for key, value in sorted(sc.geterr().items()):
...     print("{}: {}\n".format(key, value))
... arg: ignore
domain: ignore
loss: ignore
no_result: ignore
other: ignore
overflow: ignore
singular: ignore
slow: ignore
underflow: ignore
```

`scipy.special.seterr`

`scipy.special.seterr()`

Set how special-function errors are handled.

Parameters

- **all** : [{‘ignore’, ‘warn’, ‘raise’}, optional] Set treatment for all type of special-function errors at once. The options are:
  - ‘ignore’ Take no action when the error occurs
  - ‘warn’ Print a `SpecialFunctionWarning` when the error occurs (via the Python `warnings` module)
  - ‘raise’ Raise a `SpecialFunctionError` when the error occurs.
  The default is to not change the current behavior. If behaviors for additional categories of special-function errors are specified, then all is applied first, followed by the additional categories.

- **no_result** : [{‘ignore’, ‘warn’, ‘raise’}, optional] Treatment for failing to find a result.

Returns

- **olderr** : [dict] Dictionary containing the old settings.

See also:

- `geterr`
get the current way of handling special-function errors

**errstate**

context manager for special-function error handling

**numpy.seterr**

similar numpy function for floating-point errors

### Examples

```python
>>> import scipy.special as sc
>>> from pytest import raises
>>> sc.gammaln(0)
inf
>>> olderr = sc.seterr(singular='raise')
>>> with raises(sc.SpecialFunctionError):
...     sc.gammaln(0)
...     sc.spence(-1)
..._ = sc.seterr(**olderr)
```

We can also raise for every category except one.

```python
>>> olderr = sc.seterr(all='raise', singular='ignore')
>>> sc.gammaln(0)
inf
>>> with raises(sc.SpecialFunctionError):
...     sc.spence(-1)
..._ = sc.seterr(**olderr)
```

**scipy.special.errstate**

```python
class scipy.special.errstate(**kwargs)
```

Context manager for special-function error handling.

Using an instance of `errstate` as a context manager allows statements in that context to execute with a known error handling behavior. Upon entering the context the error handling is set with `seterr`, and upon exiting it is restored to what it was before.

**Parameters**

- **kwargs**
  
  {[all, singular, underflow, overflow, slow, loss, no_result, domain, arg, other]} Keyword arguments. The valid keywords are possible special-function errors. Each keyword should have a string value that defines the treatment for the particular type of error. Values must be ‘ignore’, ‘warn’, or ‘other’. See `seterr` for details.

**See also:**

- **geterr**
  
  get the current way of handling special-function errors

- **seterr**
  
  set how special-function errors are handled
**numpy.errstate**

Similar numpy function for floating-point errors.

**Examples**

```python
>>> import scipy.special as sc
>>> from pytest import raises
>>> sc.gammaln(0)
inf
>>> with sc.errstate(singular='raise):
...     with raises(sc.SpecialFunctionError):
...         sc.gammaln(0)
...     with raises(sc.SpecialFunctionError):
...         sc.spence(-1)
inf
```

We can also raise on every category except one.

```python
>>> with sc.errstate(all='raise', singular='ignore'):
...     sc.gammaln(0)
...     with raises(sc.SpecialFunctionError):
...         sc.spence(-1)
inf
```

**scipy.special.SpecialFunctionWarning**

**exception scipy.special.SpecialFunctionWarning**

Warning that can be emitted by special functions.

```python
with_traceback()  
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

**scipy.special.SpecialFunctionError**

**exception scipy.special.SpecialFunctionError**

Exception that can be raised by special functions.

```python
with_traceback()  
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

scipy.special.airy

```
scipy.special.airy(z) = <ufunc 'airy'>
Airy functions and their derivatives.

Parameters
z         [array_like] Real or complex argument.

Returns
Ai, Aip, Bi, Bip
[ndarrays] Airy functions Ai and Bi, and their derivatives Aip and Bip.

See also:
airy
exponentially scaled Airy functions.

Notes
The Airy functions Ai and Bi are two independent solutions of

\[ y''(x) = xy(x) \]

For real \( z \) in \([-10, 10]\), the computation is carried out by calling the Cephes [1] airy routine, which uses power series summation for small \( z \) and rational minimax approximations for large \( z \).

Outside this range, the AMOS [2] zairy and zbiry routines are employed. They are computed using power series for \(|z| < 1\) and the following relations to modified Bessel functions for larger \( z \) (where \( t = 2z^{3/2}/3 \)):

\[
\begin{align*}
Ai(z) & = \frac{1}{\pi \sqrt{3}} K_{1/3}(t) \\
Ai'(z) & = -\frac{z}{\pi \sqrt{3}} K_{2/3}(t) \\
Bi(z) & = \sqrt{\frac{2}{3}} (I_{-1/3}(t) + I_{1/3}(t)) \\
Bi'(z) & = \frac{z}{\sqrt{3}} (I_{-2/3}(t) + I_{2/3}(t))
\end{align*}
\]

References
[1], [2]

Examples
Compute the Airy functions on the interval \([-15, 5]\).

```
>>> from scipy import special
>>> x = np.linspace(-15, 5, 201)
>>> ai, aip, bi, bip = special.airy(x)
```
Plot \( Ai(x) \) and \( Bi(x) \).
scipy.special.airye

scipy.special.airye(z) = <ufunc 'airye'>
ExpONENTIALLY SCALED AIRY FUNCTIONS AND THEIR DERIVATIVES.

SCALING:

eAi = Ai * exp(2.0/3.0*z*sqrt(z))
eAip = Aip * exp(2.0/3.0*z*sqrt(z))
eBi = Bi * exp(-abs(2.0/3.0*(z*sqrt(z)).real))
eBip = Bip * exp(-abs(2.0/3.0*(z*sqrt(z)).real))

Parameters
z [array_like] real or complex argument.

Returns
eAi, eAip, eBi, eBip [array_like] exponentially scaled airy functions eAi and eBi, and their derivates eAip and eBip

See also:
airy
Notes

Wrapper for the AMOS [1] routines `zairy` and `zbiry`.

References

[1]

Examples

We can compute exponentially scaled Airy functions and their derivatives:

```python
>>> from scipy.special import airye
>>> import matplotlib.pyplot as plt
>>> z = np.linspace(0, 50, 500)
>>> eAi, eAip, eBi, eBip = airye(z)
>>> f, ax = plt.subplots(2, 1, sharex=True)
>>> for ind, data in enumerate([eAi, eAip, "eAi", "eAip"], [eBi, eBip, "eBi", "eBip"]):
...     ax[ind].plot(z, data[0], "-r", z, data[1], "-b")
...     ax[ind].legend(data[2])
...     ax[ind].grid(True)
>>> plt.show()
```

![Graph showing exponentially scaled Airy functions and their derivatives.]

We can compute these using usual non-scaled Airy functions by:

```python
>>> from scipy.special import airy
>>> Ai, Aip, Bi, Bip = airy(z)
>>> np.allclose(eAi, Ai * np.exp(2.0 / 3.0 * z * np.sqrt(z)))
True
>>> np.allclose(eAip, Aip * np.exp(2.0 / 3.0 * z * np.sqrt(z)))
True
```
Comparing non-scaled and exponentially scaled ones, the usual non-scaled function quickly underflows for large values, whereas the exponentially scaled function does not.

```python
>>> np.allclose(eBi, Bi * np.exp(-abs(np.real(2.0 / 3.0 * z * np.sqrt(z)))))
True
>>> np.allclose(eBip, Bip * np.exp(-abs(np.real(2.0 / 3.0 * z * np.sqrt(z)))))
True
```

scipy.special.ai_zeros

**scipy.special.ai_zeros**(nt)

Compute nt zeros and values of the Airy function Ai and its derivative.

Computes the first nt zeros, a, of the Airy function Ai(x); first nt zeros, ap, of the derivative of the Airy function Ai'(x); the corresponding values Ai(a'); and the corresponding values Ai'(a).

**Parameters**

- nt [int] Number of zeros to compute

**Returns**

- a [ndarray] First nt zeros of Ai(x)
- ap [ndarray] First nt zeros of Ai'(x)
- ai [ndarray] Values of Ai(x) evaluated at first nt zeros of Ai'(x)
- aip [ndarray] Values of Ai'(x) evaluated at first nt zeros of Ai(x)

**References**

[1]

**Examples**

```python
>>> from scipy import special
>>> a, ap, ai, aip = special.ai_zeros(3)
>>> a
array([-2.33810741, -4.08794944, -5.52055983])
>>> ap
array([-1.01879297, -3.24819758, -4.82009921])
>>> ai
array([ 0.53565666, -0.41901548, 0.38040647])
>>> aip
array([ 0.70121082, -0.80311137, 0.86520403])
```
scipy.special.bi_zeros

scipy.special.bi_zeros(nt)
Compute nt zeros and values of the Airy function Bi and its derivative.

Computes the first nt zeros, b, of the Airy function Bi(x); first nt zeros, b', of the derivative of the Airy function Bi'(x); the corresponding values Bi(b'); and the corresponding values Bi'(b).

Parameters
- nt [int] Number of zeros to compute

Returns
- b [ndarray] First nt zeros of Bi(x)
- bp [ndarray] First nt zeros of Bi'(x)
- bi [ndarray] Values of Bi(x) evaluated at first nt zeros of Bi'(x)
- bip [ndarray] Values of Bi'(x) evaluated at first nt zeros of Bi(x)

References
[1]

Examples

```python
>>> from scipy import special
>>> b, bp, bi, bip = special.bi_zeros(3)
>>> b
array([-1.17371322, -3.2710933 , -4.83073784])
>>> bp
array([-2.29443968, -4.07315509, -5.51239573])
>>> bi
array([-0.45494438, 0.39652284, -0.36796916])
>>> bip
array([ 0.60195789, -0.76031014, 0.83699101])
```

scipy.special.itairy

scipy.special.itairy(x) = <ufunc 'itairy'>
Integrals of Airy functions
Calculates the integrals of Airy functions from 0 to x.

Parameters
- x: array_like
  Upper limit of integration (float).

Returns
- Apt Integral of Ai(t) from 0 to x.
- Bpt Integral of Bi(t) from 0 to x.
- Ant Integral of Ai(-t) from 0 to x.
- Bnt Integral of Bi(-t) from 0 to x.
Notes

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

scipy.special.ellipj

`scipy.special.ellipj(u, m) = <ufunc 'ellipj'>`

Jacobian elliptic functions

Calculates the Jacobian elliptic functions of parameter m between 0 and 1, and real argument u.

Parameters

- **m** [array_like] Parameter.
- **u** [array_like] Argument.

Returns

- **sn, cn, dn, ph** [ndarrays] The returned functions:

  - \( sn(u|m) \), \( cn(u|m) \), \( dn(u|m) \)

  The value \( ph \) is such that if \( u = ellipkinc(ph, m) \), then \( sn(u|m) = \sin(ph) \) and \( cn(u|m) = \cos(ph) \).

See also:

- `ellipk`
  Complete elliptic integral of the first kind
- `ellipkinc`
  Incomplete elliptic integral of the first kind
Notes

These functions are periodic, with quarter-period on the real axis equal to the complete elliptic integral $\text{ellip}(m)$. Relation to incomplete elliptic integral: If $u = \text{ellipinc}(\phi, m)$, then $\text{sn}(u|m) = \sin(\phi)$, and $\text{cn}(u|m) = \cos(\phi)$. The $\phi$ is called the amplitude of $u$.

Computation is by means of the arithmetic-geometric mean algorithm, except when $m$ is within $1e-9$ of 0 or 1. In the latter case with $m$ close to 1, the approximation applies only for $\phi < \pi/2$.

References

[1]

**scipy.special.ellipk**

```
scipy.special.ellipk(m) = <ufunc 'ellipk'>
```

Complete elliptic integral of the first kind.

This function is defined as

$$K(m) = \int_0^{\pi/2} \frac{1}{\sqrt{1 - m \sin(t)^2}} dt$$

**Parameters**

- $m$ [array_like] The parameter of the elliptic integral.

**Returns**

- $K$ [array_like] Value of the elliptic integral.

See also:

- **ellipkm1**
  Complete elliptic integral of the first kind around $m = 1$

- **ellipkinc**
  Incomplete elliptic integral of the first kind

- **ellipe**
  Complete elliptic integral of the second kind

- **ellipeinc**
  Incomplete elliptic integral of the second kind

- **elliprf**
  Completely-symmetric elliptic integral of the first kind.
**Notes**

For more precision around point \( m = 1 \), use \( \text{ellipkm1} \), which this function calls.

The parameterization in terms of \( m \) follows that of section 17.2 in [1]. Other parameterizations in terms of the complementary parameter \( 1 - m \), modular angle \( \sin^2(\alpha) = m \), or modulus \( k^2 = m \) are also used, so be careful that you choose the correct parameter.

The Legendre \( K \) integral is related to Carlson’s symmetric \( R_F \) function by [2]:

\[
K(m) = R_F(0, 1 - k^2, 1).
\]

**References**

[1], [2]

**scipy.special.ellipkm1**

\( \text{scipy.special.ellipkm1}(p) = \text{<ufunc 'ellipkm1'>} \)

Complete elliptic integral of the first kind around \( m = 1 \)

This function is defined as

\[
K(p) = \int_0^{\pi/2} [1 - m \sin(t)^2]^{-1/2} dt
\]

where \( m = 1 - p \).

**Parameters**

- \( p \) [array_like] Defines the parameter of the elliptic integral as \( m = 1 - p \).

**Returns**

- \( K \) [ndarray] Value of the elliptic integral.

**See also:**

- \( \text{ellipk} \)
  Complete elliptic integral of the first kind

- \( \text{ellipkinc} \)
  Incomplete elliptic integral of the first kind

- \( \text{ellipe} \)
  Complete elliptic integral of the second kind

- \( \text{ellipeinc} \)
  Incomplete elliptic integral of the second kind

- \( \text{elliprf} \)
  Completely-symmetric elliptic integral of the first kind.
Notes

Wrapper for the Cephes [1] routine $\text{ellpk}$.

For $p \leq 1$, computation uses the approximation,

$$K(p) \approx P(p) - \log(p)Q(p),$$

where $P$ and $Q$ are tenth-order polynomials. The argument $p$ is used internally rather than $m$ so that the logarithmic singularity at $m = 1$ will be shifted to the origin; this preserves maximum accuracy. For $p > 1$, the identity

$$K(p) = K(1/p) / \sqrt{p}$$

is used.

References

[1]

**scipy.special.ellipkinc**

```python
scipy.special.ellipkinc(phi, m) = <ufunc 'ellipkinc'>
```

Incomplete elliptic integral of the first kind

This function is defined as

$$K(\phi, m) = \int_0^{\phi} \frac{1}{1 - m \sin^2(t)} dt$$

This function is also called $F(\phi, m)$.

**Parameters**

- **phi** [array_like] amplitude of the elliptic integral
- **m** [array_like] parameter of the elliptic integral

**Returns**

- **K** [ndarray] Value of the elliptic integral

See also:

- **ellipkm1**
  Complete elliptic integral of the first kind, near $m = 1$
- **ellip**
  Complete elliptic integral of the first kind
- **ellipe**
  Complete elliptic integral of the second kind
- **ellipeinc**
  Incomplete elliptic integral of the second kind
- **elliprf**
  Completely-symmetric elliptic integral of the first kind.
Notes

Wrapper for the Cephes [1] routine ellik. The computation is carried out using the arithmetic-geometric mean algorithm.

The parameterization in terms of \( m \) follows that of section 17.2 in [2]. Other parameterizations in terms of the complementary parameter \( 1 - m \), modular angle \( \sin^2(\alpha) = m \), or modulus \( k^2 = m \) are also used, so be careful that you choose the correct parameter.

The Legendre K incomplete integral (or F integral) is related to Carlson’s symmetric R_F function [3]. Setting \( c = \csc^2 \phi \),

\[
F(\phi, m) = R_F(c - 1, c - k^2, c).
\]

References

[1], [2], [3]

\texttt{scipy.special.ellipe}

\texttt{scipy.special.ellipe}(m) = <ufunc 'ellipe'>

Complete elliptic integral of the second kind

This function is defined as

\[
E(m) = \int_0^{\pi/2} \frac{dt}{\sqrt{1 - m \sin^2(t)}}
\]

Parameters

\( m \) [array_like] Defines the parameter of the elliptic integral.

Returns

\( E \) [ndarray] Value of the elliptic integral.

See also:

\texttt{ellipkm1}

Complete elliptic integral of the first kind, near \( m = 1 \)

\texttt{ellipk}

Complete elliptic integral of the first kind

\texttt{ellipkinc}

Incomplete elliptic integral of the first kind

\texttt{ellipeinc}

Incomplete elliptic integral of the second kind

\texttt{elliprd}

Symmetric elliptic integral of the second kind

\texttt{elliprg}

Completely-symmetric elliptic integral of the second kind.
Notes

For $m > 0$ the computation uses the approximation,

$$ E(m) \approx P(1 - m) - (1 - m) \log(1 - m) Q(1 - m), $$

where $P$ and $Q$ are tenth-order polynomials. For $m < 0$, the relation

$$ E(m) = E(m/(m - 1)) \sqrt{(1 - m)} $$

is used.

The parameterization in terms of $m$ follows that of section 17.2 in [2]. Other parameterizations in terms of the complementary parameter $1 - m$, modular angle $\sin^2(\alpha) = m$, or modulus $k^2 = m$ are also used, so be careful that you choose the correct parameter.

The Legendre E integral is related to Carlson’s symmetric R_D or R_G functions in multiple ways [3]. For example,

$$ E(m) = 2R_G(0, 1 - k^2, 1). $$

References

[1], [2], [3]

Examples

This function is used in finding the circumference of an ellipse with semi-major axis $a$ and semi-minor axis $b$.

```python
>>> from scipy import special

>>> a = 3.5
>>> b = 2.1
>>> e_sq = 1.0 - b**2/a**2  # eccentricity squared

Then the circumference is found using the following:

```python
>>> C = 4*a*special.ellipe(e_sq)  # circumference formula
>>> C
17.868899204378693
```

When $a$ and $b$ are the same (meaning eccentricity is 0), this reduces to the circumference of a circle.

```python
>>> 4*a*special.ellipe(0.0)  # formula for ellipse with a = b
21.991148575128552
>>> 2*np.pi*a  # formula for circle of radius a
21.991148575128552
```
scipy.special.ellipeinc

scipy.special.ellipeinc(phi, m) = <ufunc 'ellipeinc'>

Incomplete elliptic integral of the second kind

This function is defined as

\[ E(\phi, m) = \int_0^\phi \frac{1}{\sqrt{1 - m \sin^2 t}} \, dt \]

**Parameters**

- **phi** [array_like] amplitude of the elliptic integral.
- **m** [array_like] parameter of the elliptic integral.

**Returns**

- **E** [ndarray] Value of the elliptic integral.

See also:

- **ellipkm1**
  Complete elliptic integral of the first kind, near \( m = 1 \)
- **ellipk**
  Complete elliptic integral of the first kind
- **ellipkinc**
  Incomplete elliptic integral of the first kind
- **ellipe**
  Complete elliptic integral of the second kind
- **elliprd**
  Symmetric elliptic integral of the second kind.
- **elliprf**
  Completely-symmetric elliptic integral of the first kind.
- **elliprg**
  Completely-symmetric elliptic integral of the second kind.

**Notes**

Computation uses arithmetic-geometric means algorithm.

The parameterization in terms of \( m \) follows that of section 17.2 in [2]. Other parameterizations in terms of the complementary parameter \( 1 - m \), modular angle \( \sin^2(\alpha) = m \), or modulus \( k^2 = m \) are also used, so be careful that you choose the correct parameter.

The Legendre E incomplete integral can be related to combinations of Carlson’s symmetric integrals \( R_D \), \( R_F \), and \( R_G \) in multiple ways [3]. For example, with \( c = \csc^2 \phi \),

\[ E(\phi, m) = R_F(c - 1, c - k^2, c) - \frac{1}{3} k^2 R_D(c - 1, c - k^2, c) \]
References

[1], [2], [3]

scipy.special.elliprc

scipy.special.elliprc(x, y) = <ufunc 'elliprc'>

Degenerate symmetric elliptic integral.

The function RC is defined as [1]

\[ R_C(x, y) = \frac{1}{2} \int_0^{+\infty} \frac{1}{(t + x)(t + y)} dt = R_F(x, y, y) \]

Parameters:

- x, y [array_like] Real or complex input parameters. x can be any number in the complex plane cut along the negative real axis. y must be non-zero.

Returns:

- R [ndarray] Value of the integral. If y is real and negative, the Cauchy principal value is returned. If both of x and y are real, the return value is real. Otherwise, the return value is complex.

See also:

- elliprf
  Completely-symmetric elliptic integral of the first kind.

- elliprd
  Symmetric elliptic integral of the second kind.

- elliprg
  Completely-symmetric elliptic integral of the second kind.

- elliprj
  Symmetric elliptic integral of the third kind.

Notes

RC is a degenerate case of the symmetric integral RF: elliprc(x, y) == elliprf(x, y, y). It is an elementary function rather than an elliptic integral.

The code implements Carlson’s algorithm based on the duplication theorems and series expansion up to the 7th order. [2]

New in version 1.8.0.
References

[1], [2]

scipy.special.elliprd

scipy.special.elliprd(x, y, z) = <ufunc 'elliprd'>
Symmetric elliptic integral of the second kind.

The function RD is defined as [1]

\[
R_D(x, y, z) = \frac{3}{2} \int_0^{+\infty} \left[ \frac{1}{(t + x)(t + y)} \right]^{-1/2} \left( \frac{1}{t + z} \right)^{-3/2} dt
\]

Parameters

x, y, z [array_like] Real or complex input parameters. x or y can be any number in the complex plane cut along the negative real axis, but at most one of them can be zero, while z must be non-zero.

Returns

R [ndarray] Value of the integral. If all of x, y, and z are real, the return value is real. Otherwise, the return value is complex.

See also:

elliprc
Degenerate symmetric elliptic integral.

elliprf
Completely-symmetric elliptic integral of the first kind.

elliprg
Completely-symmetric elliptic integral of the second kind.

elliprj
Symmetric elliptic integral of the third kind.

Notes

RD is a degenerate case of the elliptic integral RJ: elliprd(x, y, z) == elliprj(x, y, z, z).

The code implements Carlson’s algorithm based on the duplication theorems and series expansion up to the 7th order. [2]

New in version 1.8.0.
References

[1], [2]

scipy.special.elliprf

```python
scipy.special.elliprf(x, y, z) = <ufunc 'elliprf'>
```

Completely-symmetric elliptic integral of the first kind.

The function RF is defined as

\[
RF(x, y, z) = \frac{1}{2} \int_0^{+\infty} \left[ (t + x)(t + y)(t + z) \right]^{-1/2} dt
\]

**Parameters**

- `x`, `y`, `z` (array_like) Real or complex input parameters. `x`, `y`, or `z` can be any number in the complex plane cut along the negative real axis, but at most one of them can be zero.

**Returns**

- `R` (ndarray) Value of the integral. If all of `x`, `y`, and `z` are real, the return value is real. Otherwise, the return value is complex.

See also:

- `elliprc`
  
  Degenerate symmetric integral.

- `elliprd`
  
  Symmetric elliptic integral of the second kind.

- `elliprg`
  
  Completely-symmetric elliptic integral of the second kind.

- `elliprj`
  
  Symmetric elliptic integral of the third kind.

Notes

The code implements Carlson's algorithm based on the duplication theorems and series expansion up to the 7th order (cf.: https://dlmf.nist.gov/19.36.i) and the AGM algorithm for the complete integral. [2]

New in version 1.8.0.

References

[1], [2]
scipy.special.elliprg

```python
scipy.special.elliprg(x, y, z) = <ufunc 'elliprg'>
```

Completely-symmetric elliptic integral of the second kind.

The function \( R_G \) is defined as [1]

\[
R_G(x, y, z) = \frac{1}{4} \int_0^{+\infty} \left( \frac{x}{t+x} + \frac{y}{t+y} + \frac{z}{t+z} \right) tdt
\]

**Parameters**

- \( x, y, z \) [array_like] Real or complex input parameters. \( x, y, \) or \( z \) can be any number in the complex plane cut along the negative real axis.

**Returns**

- \( R \) [ndarray] Value of the integral. If all of \( x, y, \) and \( z \) are real, the return value is real. Otherwise, the return value is complex.

**See also:**

- `elliprc`
  - Degenerate symmetric integral.
- `elliprd`
  - Symmetric elliptic integral of the second kind.
- `elliprf`
  - Completely-symmetric elliptic integral of the first kind.
- `elliprj`
  - Symmetric elliptic integral of the third kind.

**Notes**

The implementation uses the relation [1]

\[
2R_G(x, y, z) = zR_F(x, y, z) - \frac{1}{3}(x - z)(y - z)R_D(x, y, z) + \sqrt{\frac{xy}{z}}
\]

and the symmetry of \( x, y, z \) when at least one non-zero parameter can be chosen as the pivot. When one of the arguments is close to zero, the AGM method is applied instead. Other special cases are computed following Ref. [2]

New in version 1.8.0.

**References**

[1], [2]
Examples

The surface area of a triaxial ellipsoid with semiaxes $a$, $b$, and $c$ is given by

$$S = 4\pi abc R_G(1/a^2, 1/b^2, 1/c^2).$$

```python
>>> from scipy.special import elliprg
>>> def ellipsoid_area(a, b, c):
...     r = 4.0 * np.pi * a * b * c
...     return r * elliprg(1.0 / (a * a), 1.0 / (b * b), 1.0 / (c * c))
>>> print(ellipsoid_area(1, 3, 5))
108.62688289491807
```

```python
scipy.special.elliprj
```

The function $R_J$ is defined as [1]

$$R_J(x, y, z, p) = \frac{3}{2} \int_0^{+\infty} \frac{(t+x)(t+y)(t+z)}{(t+p)^{1/2}(t+p)^{-1}} dt$$

**Warning:** This function should be considered experimental when the inputs are unbalanced. Check correctness with another independent implementation.

**Parameters**

$x, y, z, p$  [array_like] Real or complex input parameters. $x, y,$ or $z$ are numbers in the complex plane cut along the negative real axis (subject to further constraints, see Notes), and at most one of them can be zero. $p$ must be non-zero.

**Returns**

$R$  [ndarray] Value of the integral. If all of $x, y, z,$ and $p$ are real, the return value is real. Otherwise, the return value is complex. If $p$ is real and negative, while $x, y,$ and $z$ are real, non-negative, and at most one of them is zero, the Cauchy principal value is returned. [1] [2]

**See also:**

- `elliprc`
  Degenerate symmetric integral.
- `elliprd`
  Symmetric elliptic integral of the second kind.
- `elliprf`
  Completely-symmetric elliptic integral of the first kind.
- `elliprg`
  Completely-symmetric elliptic integral of the second kind.
Notes

The code implements Carlson’s algorithm based on the duplication theorems and series expansion up to the 7th order. [3] The algorithm is slightly different from its earlier incarnation as it appears in [1], in that the call to elliprc (or atan/atanh, see [4]) is no longer needed in the inner loop. Asymptotic approximations are used where arguments differ widely in the order of magnitude. [5]

The input values are subject to certain sufficient but not necessary constraints when input arguments are complex. Notably, x, y, and z must have non-negative real parts, unless two of them are non-negative and complex-conjugates to each other while the other is a real non-negative number. [1] If the inputs do not satisfy the sufficient condition described in Ref. [1] they are rejected outright with the output set to NaN.

In the case where one of x, y, and z is equal to p, the function elliprd should be preferred because of its less restrictive domain.

New in version 1.8.0.

scipy.special.jv

`scipy.special.jv(v, z) = <ufunc 'jv'>`

Bessel function of the first kind of real order and complex argument.

**Parameters**

- `v` [array_like] Order (float).
- `z` [array_like] Argument (float or complex).

**Returns**

- `J` [ndarray] Value of the Bessel function, $J_v(z)$.

See also:

- `jve` $J_v$ with leading exponential behavior stripped off.
- `spherical_jn` spherical Bessel functions.

**Notes**

For positive $v$ values, the computation is carried out using the AMOS [1] `zbesj` routine, which exploits the connection to the modified Bessel function $I_v$,

$$
J_v(z) = \exp(v\pi i/2)I_v(-iz) \quad (\Im z > 0)
$$

$$
J_v(z) = \exp(-v\pi i/2)I_v(iz) \quad (\Im z < 0)
$$

For negative $v$ values the formula,

$$
J_{-v}(z) = J_v(z) \cos(\pi v) - Y_v(z) \sin(\pi v)
$$

is used, where $Y_v(z)$ is the Bessel function of the second kind, computed using the AMOS routine `zbys`. Note that the second term is exactly zero for integer $v$; to improve accuracy the second term is explicitly omitted for $v$ values such that $v = \text{floor}(v)$.

Not to be confused with the spherical Bessel functions (see `spherical_jn`).

**References**

[1]
scipy.special.jve

scipy.special.jve(v, z) = <ufunc 'jve'>
Exponentially scaled Bessel function of order v.

Defined as:

\[
jve(v, z) = jv(v, z) * \exp(-\text{abs}(z.\text{imag}))
\]

**Parameters**

- *v* [array_like] Order (float).
- *z* [array_like] Argument (float or complex).

**Returns**

- *J* [ndarray] Value of the exponentially scaled Bessel function.

**Notes**

For positive *v* values, the computation is carried out using the AMOS [1] `zbessj` routine, which exploits the connection to the modified Bessel function *I*<sub>*v*</sub>:

\[
J_v(z) = \exp(v\pi i/2)I_v(-iz) \quad (\Im z > 0)
\]

\[
J_v(z) = \exp(-v\pi i/2)I_v(iz) \quad (\Im z < 0)
\]

For negative *v* values the formula,

\[
J_{-v}(z) = J_v(z) \cos(\pi v) - Y_v(z) \sin(\pi v)
\]

is used, where *Y*<sub>*v*</sub>(*z*) is the Bessel function of the second kind, computed using the AMOS routine `zbessy`. Note that the second term is exactly zero for integer *v*; to improve accuracy the second term is explicitly omitted for *v* values such that *v* = floor(*v*).

**References**

[1]

scipy.special.yn

scipy.special.yn(n, x) = <ufunc 'yn'>
Bessel function of the second kind of integer order and real argument.

**Parameters**

- *n* [array_like] Order (integer).
- *z* [array_like] Argument (float).

**Returns**

- *Y* [ndarray] Value of the Bessel function, *Y*<sub>*n*</sub>(*x*).

See also:

- *yv*

For real order and real or complex argument.
Notes

Wrapper for the Cephes [1] routine \( yn \).

The function is evaluated by forward recurrence on \( n \), starting with values computed by the Cephes routines \( y0 \) and \( y1 \). If \( n = 0 \) or 1, the routine for \( y0 \) or \( y1 \) is called directly.

References

[1]

\texttt{scipy.special.yv}

\texttt{scipy.special.yv(v, z) = <ufunc 'yv'>}

Bessel function of the second kind of real order and complex argument.

\textbf{Parameters}

- \( v \) [array_like] Order (float).
- \( z \) [array_like] Argument (float or complex).

\textbf{Returns}

- \( Y \) [ndarray] Value of the Bessel function of the second kind, \( Y_v(x) \).

\textbf{See also:}

\texttt{yve}

\( Y_v \) with leading exponential behavior stripped off.

Notes

For positive \( v \) values, the computation is carried out using the AMOS [1] \texttt{zbesy} routine, which exploits the connection to the Hankel Bessel functions \( H_v^{(1)} \) and \( H_v^{(2)} \),

\[ Y_v(z) = \frac{1}{2i} (H_v^{(1)} - H_v^{(2)}). \]

For negative \( v \) values the formula,

\[ Y_{-v}(z) = Y_v(z) \cos(\pi v) + J_v(z) \sin(\pi v) \]

is used, where \( J_v(z) \) is the Bessel function of the first kind, computed using the AMOS routine \texttt{zbesj}. Note that the second term is exactly zero for integer \( v \); to improve accuracy the second term is explicitly omitted for \( v \) values such that \( v = \text{floor}(v) \).
References

[1]

scipy.special.yve

scipy.special.yve(v, z) = <ufunc 'yve'>

Exponentially scaled Bessel function of the second kind of real order.

Returns the exponentially scaled Bessel function of the second kind of real order \( v \) at complex \( z \):

\[
yve(v, z) = yv(v, z) \times \exp(-\text{abs}(z.im))
\]

Parameters

\( v \) [array_like] Order (float).
\( z \) [array_like] Argument (float or complex).

Returns

\( Y \) [ndarray] Value of the exponentially scaled Bessel function.

Notes

For positive \( v \) values, the computation is carried out using the AMOS [1] \( zbesy \) routine, which exploits the connection to the Hankel Bessel functions \( H_v^{(1)} \) and \( H_v^{(2)} \),

\[
Y_v(z) = \frac{1}{2i} \left( H_v^{(1)} - H_v^{(2)} \right).
\]

For negative \( v \) values the formula,

\[
Y_{-v}(z) = Y_v(z) \cos(\pi v) + J_v(z) \sin(\pi v)
\]

is used, where \( J_v(z) \) is the Bessel function of the first kind, computed using the AMOS routine \( zbesj \). Note that the second term is exactly zero for integer \( v \); to improve accuracy the second term is explicitly omitted for \( v \) values such that \( v = \text{floor}(v) \).

References

[1]

scipy.special.kn

scipy.special.kn(n, x) = <ufunc 'kn'>

Modified Bessel function of the second kind of integer order \( n \)

Returns the modified Bessel function of the second kind for integer order \( n \) at real \( z \).

These are also sometimes called functions of the third kind, Basset functions, or Macdonald functions.

Parameters

\( n \) [array_like of int] Order of Bessel functions (floats will truncate with a warning)
\( z \) [array_like of float] Argument at which to evaluate the Bessel functions
Returns

out [ndarray] The results

See also:

kv

Same function, but accepts real order and complex argument

kvp

Derivative of this function

Notes

References

[1],[2]

Examples

Plot the function of several orders for real input:

```python
>>> from scipy.special import kn
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 5, 1000)
>>> for N in range(6):
...     plt.plot(x, kn(N, x), label=r'$K_\{\}$\(x\)'.format(N))
>>> plt.ylim(0, 10)
>>> plt.legend()
>>> plt.title(r'Modified Bessel function of the second kind $K_n(x)$')
>>> plt.show()
```

![Modified Bessel function of the second kind $K_n(x)$](image-url)
Calculate for a single value at multiple orders:

```python
>>> kn([4, 5, 6], 1)
array([ 44.23241585, 360.9605896 , 3653.83831186])
```

### scipy.special.kv

scipy.special.kv(v, z) = <ufunc 'kv'>

Modified Bessel function of the second kind of real order \( v \)

Returns the modified Bessel function of the second kind for real order \( v \) at complex \( z \).

These are also sometimes called functions of the third kind, Basset functions, or Macdonald functions. They are defined as those solutions of the modified Bessel equation for which,

\[
K_v(x) \sim \sqrt{\pi/(2x)} \exp(-x)
\]

as \( x \to \infty \).[3]

**Parameters**

- \( v \) [array_like of float] Order of Bessel functions
- \( z \) [array_like of complex] Argument at which to evaluate the Bessel functions

**Returns**

- \( out \) [ndarray] The results. Note that input must be of complex type to get complex output, e.g. \( kv(3, -2+0j) \) instead of \( kv(3, -2) \).

**See also:**

- kve
  - This function with leading exponential behavior stripped off.
- kvp
  - Derivative of this function

**Notes**

**References**

[1], [2], [3]
# Examples

Plot the function of several orders for real input:

```python
>>> from scipy.special import kv
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 5, 1000)
>>> for N in np.linspace(0, 6, 5):
...     plt.plot(x, kv(N, x), label='$K_{{}}(x)$'.format(N))
>>> plt.ylim(0, 10)
>>> plt.legend()
>>> plt.title(r'Modified Bessel function of the second kind $K_{{\nu}}(x)$')
>>> plt.show()
```

![Modified Bessel function of the second kind $K_{{\nu}}(x)$](#)

Calculate for a single value at multiple orders:

```python
>>> kv([4, 4.5, 5], 1+2j)
array([0.1992+2.3892j, 2.3493+3.6j , 7.2827+3.8104j])
```

**scipy.special.kve**

`scipy.special.kve(v, z) = <ufunc 'kve'>`

Exponentially scaled modified Bessel function of the second kind.

Returns the exponentially scaled, modified Bessel function of the second kind (sometimes called the third kind) for real order $v$ at complex $z$:

$kve(v, z) = kv(v, z) * \exp(z)$

Parameters

- $v$ [array_like of float]: Order of Bessel functions
- $z$ [array_like of complex]: Argument at which to evaluate the Bessel functions

Returns
out [ndarray] The exponentially scaled modified Bessel function of the second kind.

Notes

References

[1], [2]

\texttt{scipy.special.iv}

\texttt{scipy.special.iv(v,z) = \texttt{ufunc 'iv'}

Modified Bessel function of the first kind of real order.

Parameters

\begin{itemize}
  \item \texttt{v} [array_like] Order. If \( z \) is of real type and negative, \( v \) must be integer valued.
  \item \texttt{z} [array_like of float or complex] Argument.
\end{itemize}

Returns

\begin{itemize}
  \item \texttt{out} [ndarray] Values of the modified Bessel function.
\end{itemize}

See also:

\texttt{kve}

This function with leading exponential behavior stripped off.

Notes

For real \( z \) and \( v \in [-50, 50] \), the evaluation is carried out using Temme’s method [1]. For larger orders, uniform asymptotic expansions are applied.

For complex \( z \) and positive \( v \), the AMOS [2] \texttt{zbesi} routine is called. It uses a power series for small \( z \), the asymptotic expansion for large \( \text{abs}(z) \), the Miller algorithm normalized by the Wronskian and a Neumann series for intermediate magnitudes, and the uniform asymptotic expansions for \( I_v(z) \) and \( J_v(z) \) for large orders. Backward recurrence is used to generate sequences or reduce orders when necessary.

The calculations above are done in the right half plane and continued into the left half plane by the formula,

\[ I_v(z \exp(\pm i\pi)) = \exp(\pm \pi v)I_v(z) \]

(valid when the real part of \( z \) is positive). For negative \( v \), the formula

\[ I_{-v}(z) = I_v(z) + \frac{2}{\pi} \sin(\pi v)K_v(z) \]

is used, where \( K_v(z) \) is the modified Bessel function of the second kind, evaluated using the AMOS routine \texttt{zbesk}.
References

[1], [2]

scipy.special.ive

scipy.special.ive(v, z) = <ufunc 'ive'>
Exponentially scaled modified Bessel function of the first kind

Defined as:

\[ \text{ive}(v, z) = iv(v, z) * \exp(-\text{abs}(z.\text{real})) \]

Parameters

- **v**: [array_like of float] Order.
- **z**: [array_like of float or complex] Argument.

Returns

- **out**: [ndarray] Values of the exponentially scaled modified Bessel function.

Notes

For positive \( v \), the AMOS [1] \( zbesi \) routine is called. It uses a power series for small \( z \), the asymptotic expansion for large \( \text{abs}(z) \), the Miller algorithm normalized by the Wronskian and a Neumann series for intermediate magnitudes, and the uniform asymptotic expansions for \( I_v(z) \) and \( J_v(z) \) for large orders. Backward recurrence is used to generate sequences or reduce orders when necessary.

The calculations above are done in the right half plane and continued into the left half plane by the formula,

\[ I_v(z \exp(\pm i\pi)) = \exp(\pm \pi v) I_v(z) \]

(valid when the real part of \( z \) is positive). For negative \( v \), the formula

\[ I_{-v}(z) = I_v(z) + \frac{2}{\pi} \sin(\pi v) K_v(z) \]

is used, where \( K_v(z) \) is the modified Bessel function of the second kind, evaluated using the AMOS routine \( zbesk \).

References

[1]

scipy.special.hankel1

scipy.special.hankel1(v, z) = <ufunc 'hankell'>
Hankel function of the first kind

Parameters

- **v**: [array_like] Order (float).
- **z**: [array_like] Argument (float or complex).

Returns
out [Values of the Hankel function of the first kind.]

See also:

hankel1e

this function with leading exponential behavior stripped off.

Notes

A wrapper for the AMOS [1] routine zbesh, which carries out the computation using the relation,

$$H_v^{(1)}(z) = \frac{2}{i\pi} \exp(-i\pi v/2)K_v(z \exp(-i\pi/2))$$

where $K_v$ is the modified Bessel function of the second kind. For negative orders, the relation

$$H_{-v}^{(1)}(z) = H_v^{(1)}(z) \exp(i\pi v)$$

is used.

References

[1]

scipy.special.hankel1e

scipy.special.hankel1e(v, z) = <ufunc 'hankel1e'>

Exponentially scaled Hankel function of the first kind

Defined as:

\[
\text{hankel1e}(v, z) = \text{hankel1}(v, z) \times \exp(-i \times z)
\]

Parameters

v [array_like] Order (float).
z [array_like] Argument (float or complex).

Returns

out [Values of the exponentially scaled Hankel function.]
References

[1]

scipy.special.hankel2

```python
cal.atan2(v, z) = <ufunc 'hankel2'>
```

Hankel function of the second kind

Parameters

- `v`: [array_like] Order (float).
- `z`: [array_like] Argument (float or complex).

Returns

- `out`: [Values of the Hankel function of the second kind.]

See also:

hankel2e

this function with leading exponential behavior stripped off.

Notes

A wrapper for the AMOS [1] routine zbesh, which carries out the computation using the relation,

\[ H_v^{(2)}(z) = -\frac{2}{i\pi} \exp(i\pi v/2) K_v(z \exp(i\pi/2)) \]

where \( K_v \) is the modified Bessel function of the second kind. For negative orders, the relation

\[ H_{-v}^{(2)}(z) = H_v^{(2)}(z) \exp(-i\pi v) \]

is used.

References

[1]

scipy.special.hankel2e

```python
cal.atan2(v, z) = <ufunc 'hankel2e'>
```

Exponentially scaled Hankel function of the second kind

Defined as:

```python
hankel2e(v, z) = hankel2(v, z) * \exp(1j * z)
```

Parameters

- `v`: [array_like] Order (float).
- `z`: [array_like] Argument (float or complex).

Returns

- `out`: [Values of the exponentially scaled Hankel function of the second kind.]
Notes

A wrapper for the AMOS [1] routine \textit{zbesh}, which carries out the computation using the relation,

\[ H_v^{(2)}(z) = -\frac{2}{i\pi} \exp\left(\frac{i\pi v}{2}\right) K_v\left(z\exp\left(\frac{i\pi}{2}\right)\right) \]

where \(K_v\) is the modified Bessel function of the second kind. For negative orders, the relation

\[ H_{-v}^{(2)}(z) = H_v^{(2)}(z) \exp(-i\pi v) \]

is used.

References

[1]

\texttt{scipy.special.wright\_bessel}

\begin{verbatim}
scipy.special.wright_bessel(a, b, x) = <ufunc 'wright_bessel'>
Wright’s generalized Besselfunction.

Wright’s generalized Besselfunction is an entire function and defined as

\[ \Phi(a, b; x) = \sum_{k=0}^{\infty} \frac{x^k}{k! \Gamma(ak + b)} \]

See also [1].

Parameters

- \(a\) [array_like of float] \(a \geq 0\)
- \(b\) [array_like of float] \(b \geq 0\)
- \(x\) [array_like of float] \(x \geq 0\)

Notes

Due to the complexity of the function with its three parameters, only non-negative arguments are implemented.

References

[1]

Examples

```python
>>> from scipy.special import wright_bessel
>>> a, b, x = 1.5, 1.1, 2.5
>>> wright_bessel(a, b-1, x)
4.531446593943025
```
Now, let us verify the relation

$$\Phi(a, b - 1; x) = ax\Phi(a, b + a; x) + (b - 1)\Phi(a, b; x)$$

```
>>> a * x * wright_bessel(a, b+a, x) + (b-1) * wright_bessel(a, b, x)
4.5314465939443025
```

The following is not a universal function:

```python
jmbda(v, x)
```

Jahnke-Emden Lambda function, \( \Lambda_v(x) \).

**scipy.special.lmbda**

```python
scipy.special.lmbda(v, x)
```

Jahnke-Emden Lambda function, \( \Lambda_v(x) \).

This function is defined as \([2]\),

$$\Lambda_v(x) = \Gamma(v + 1) \frac{J_v(x)}{(x/2)^v},$$

where \( \Gamma \) is the gamma function and \( J_v \) is the Bessel function of the first kind.

**Parameters**

- \( v \) [float] Order of the Lambda function
- \( x \) [float] Value at which to evaluate the function and derivatives

**Returns**

- \( vl \) [ndarray] Values of \( \Lambda_v(x) \) for \( vi=v\text{-int}(v), vi=1+v\text{-int}(v), \ldots, vi=v \).
- \( dl \) [ndarray] Derivatives \( \Lambda_v'(x) \) for \( vi=v\text{-int}(v), vi=1+v\text{-int}(v), \ldots, vi=v \).

**References**

[1], [2]

### scipy.special.jnjnp_zeros

\texttt{scipy.special.jnjnp_zeros(nt)}

Compute nt zeros of integer-order Bessel functions Jn and Jn'.

Results are arranged in order of the magnitudes of the zeros.

**Parameters**

- \texttt{nt} [int] Number (\(\leq 1200\)) of zeros to compute

**Returns**

- \texttt{zo[l-1]} [ndarray] Value of the \(l\)th zero of Jn(x) and Jn'(x). Of length \(nt\).
- \texttt{n[l-1]} [ndarray] Order of the Jn(x) or Jn'(x) associated with \(l\)th zero. Of length \(nt\).
- \texttt{m[l-1]} [ndarray] Serial number of the zeros of Jn(x) or Jn'(x) associated with \(l\)th zero. Of length \(nt\).
- \texttt{t[l-1]} [ndarray] 0 if \(l\)th zero in \(zo\) is zero of Jn(x), 1 if it is a zero of Jn'(x). Of length \(nt\).

See also:

- \texttt{jn_zeros}, \texttt{jnp_zeros}
  - to get separated arrays of zeros.

### References

[1]

### scipy.special.jnyn_zeros

\texttt{scipy.special.jnyn_zeros(n, nt)}

Compute nt zeros of Bessel functions Jn(x), Jn'(x), Yn(x), and Yn'(x).

Returns 4 arrays of length nt, corresponding to the first nt zeros of Jn(x), Jn'(x), Yn(x), and Yn'(x), respectively. The zeros are returned in ascending order.

**Parameters**

- \texttt{n} [int] Order of the Bessel functions
- \texttt{nt} [int] Number (\(\leq 1200\)) of zeros to compute

**Returns**

- \texttt{Jn} [ndarray] First nt zeros of Jn
- \texttt{Jnp} [ndarray] First nt zeros of Jn'
- \texttt{Yn} [ndarray] First nt zeros of Yn
- \texttt{Ynp} [ndarray] First nt zeros of Yn'

See also:
jn_zeros, jnp_zeros, yn_zeros, ynp_zeros

References

[1]

scipy.special.jn_zeros

scipy.special.jn_zeros(n, nt)

Compute zeros of integer-order Bessel functions \( J_n \).

Compute \( nt \) zeros of the Bessel functions \( J_n(x) \) on the interval \((0, \infty)\). The zeros are returned in ascending order. Note that this interval excludes the zero at \( x = 0 \) that exists for \( n > 0 \).

Parameters

- \( n \) [int] Order of Bessel function
- \( nt \) [int] Number of zeros to return

Returns

- ndarray First \( nt \) zeros of the Bessel function.

See also:

- \( jv \)

References

[1]

Examples

```python
>>> import scipy.special as sc

We can check that we are getting approximations of the zeros by evaluating them with \( jv \).

```n = 1
````
>>> x = sc.jn_zeros(n, 3)
````
```x
array([ 3.83170597, 7.01558667, 10.17346814])
```
```sc.jv(n, x)
array([-0.00000000e+00, 1.72975330e-16, 2.89157291e-16])
```

Note that the zero at \( x = 0 \) for \( n > 0 \) is not included.

```sc.jv(1, 0)
0.0
```
scipy.special.jnp_zeros

scipy.special.jnp_zeros(n, nt)

Compute zeros of integer-order Bessel function derivatives $J'_n$.

Compute $nt$ zeros of the functions $J'_n(x)$ on the interval $(0, \infty)$. The zeros are returned in ascending order. Note that this interval excludes the zero at $x = 0$ that exists for $n > 1$.

Parameters

- $n$ [int] Order of Bessel function
- $nt$ [int] Number of zeros to return

Returns

- ndarray First $nt$ zeros of the Bessel function.

See also:

jvp, jv

References

[1]

Examples

```python
>>> import scipy.special as sc
```

We can check that we are getting approximations of the zeros by evaluating them with $jvp$.

```python
>>> n = 2
>>> x = sc.jnp_zeros(n, 3)
>>> x
array([3.05423693, 6.70613319, 9.96946782])
>>> sc.jvp(n, x)
array([ 2.77555756e-17, 2.08166817e-16, -3.01841885e-16])
```

Note that the zero at $x = 0$ for $n > 1$ is not included.

```python
>>> sc.jvp(n, 0)
0.0
```

scipy.special.yn_zeros

scipy.special.yn_zeros(n, nt)

Compute zeros of integer-order Bessel function $Y_n(x)$.

Compute $nt$ zeros of the functions $Y_n(x)$ on the interval $(0, \infty)$. The zeros are returned in ascending order.

Parameters

- $n$ [int] Order of Bessel function
- $nt$ [int] Number of zeros to return

Returns
**ndarray**  
First $nt$ zeros of the Bessel function.

See also:

*yn, yv*

**References**

[1]

**Examples**

```python
>>> import scipy.special as sc
```

We can check that we are getting approximations of the zeros by evaluating them with $yn$.

```python
>>> n = 2
>>> x = sc.yn_zeros(n, 3)
>>> x
array([ 3.38424177, 6.79380751, 10.02347798])
```

```python
>>> sc.yn(n, x)
array([-1.94289029e-16, 8.32667268e-17, -1.52655666e-16])
```

**scipy.special.ynp_zeros**

`scipy.special.ynp_zeros(n, nt)`  
Compute zeros of integer-order Bessel function derivatives $Y_n'(x)$.

Compute $nt$ zeros of the functions $Y_n'(x)$ on the interval $(0, \infty)$. The zeros are returned in ascending order.

**Parameters**

- $n$  
  [int] Order of Bessel function

- $nt$  
  [int] Number of zeros to return

**Returns**

- ndarray  
  First $nt$ zeros of the Bessel derivative function.

See also:

*yp*

**References**

[1]
Examples

```python
>>> import scipy.special as sc
```

We can check that we are getting approximations of the zeros by evaluating them with `yvp`.

```python
>>> n = 2
>>> x = sc.ynp_zeros(n, 3)
>>> x
array([ 5.00258293, 8.3507247 , 11.57419547])
>>> sc.yvp(n, x)
array([ 2.22044605e-16, -3.33066907e-16, 2.94902991e-16])
```

### scipy.special.y0_zeros

**scipy.special.y0_zeros**(nt, complex=False)

Compute nt zeros of Bessel function Y0(z), and derivative at each zero.

The derivatives are given by Y0(z0) = -Y1(z0) at each zero z0.

**Parameters**

- `nt` [int] Number of zeros to return
- `complex` [bool, default False] Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

**Returns**

- `z0n` [ndarray] Location of nth zero of Y0(z)
- `y0pz0n` [ndarray] Value of derivative Y0'(z0) for nth zero

**References**

[1]

### scipy.special.y1_zeros

**scipy.special.y1_zeros**(nt, complex=False)

Compute nt zeros of Bessel function Y1(z), and derivative at each zero.

The derivatives are given by Y1'(z1) = Y0(z1) at each zero z1.

**Parameters**

- `nt` [int] Number of zeros to return
- `complex` [bool, default False] Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

**Returns**

- `z1n` [ndarray] Location of nth zero of Y1(z)
- `y1pz1n` [ndarray] Value of derivative Y1'(z1) for nth zero
References

[1]

scipy.special.y1p_zeros

```python
scipy.special.y1p_zeros(nt, complex=False)
```

Compute nt zeros of Bessel derivative \( Y_1'(z) \), and value at each zero.

The values are given by \( Y_1(z_1) \) at each \( z_1 \) where \( Y_1'(z_1)=0 \).

**Parameters**

- `nt` [int] Number of zeros to return
- `complex` [bool, default False] Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

**Returns**

- `z1pn` [ndarray] Location of nth zero of \( Y_1'(z) \)
- `y1z1pn` [ndarray] Value of derivative \( Y_1(z_1) \) for nth zero

3.3. API definition
scipy.special.j0

scipy.special.j0(x) = <ufunc 'j0'>
Bessel function of the first kind of order 0.

Parameters

x [array_like] Argument (float).

Returns

J [ndarray] Value of the Bessel function of the first kind of order 0 at x.

See also:

jv
Bessel function of real order and complex argument.
spherical_jn
spherical Bessel functions.

Notes

The domain is divided into the intervals [0, 5] and (5, infinity). In the first interval the following rational approximation is used:

\[ J_0(x) \approx (w - r_1^2)(w - r_2^2) \frac{P_3(w)}{Q_8(w)}, \]

where \( w = x^2 \) and \( r_1, r_2 \) are the zeros of \( J_0 \), and \( P_3 \) and \( Q_8 \) are polynomials of degrees 3 and 8, respectively.

In the second interval, the Hankel asymptotic expansion is employed with two rational functions of degree 6/6 and 7/7.

This function is a wrapper for the Cephes [1] routine \( j0 \). It should not be confused with the spherical Bessel functions (see spherical_jn).

References

[1]

scipy.special.j1

scipy.special.j1(x) = <ufunc 'j1'>
Bessel function of the first kind of order 1.

Parameters

x [array_like] Argument (float).

Returns

J [ndarray] Value of the Bessel function of the first kind of order 1 at x.

See also:

jv
spherical_jn

spherical Bessel functions.

Notes

The domain is divided into the intervals [0, 8] and (8, infinity). In the first interval a 24 term Chebyshev expansion is used. In the second, the asymptotic trigonometric representation is employed using two rational functions of degree 5/5.

This function is a wrapper for the Cephes [1] routine \texttt{j1}. It should not be confused with the spherical Bessel functions (see \texttt{spherical_jn}).

References

[1]

\texttt{scipy.special.y0}

\texttt{scipy.special.y0(x) = <ufunc 'y0'>}

Bessel function of the second kind of order 0.

Parameters

\texttt{x} [array_like] Argument (float).

Returns

\texttt{Y} [ndarray] Value of the Bessel function of the second kind of order 0 at \texttt{x}.

See also:

\texttt{j0}
\texttt{yv}

Notes

The domain is divided into the intervals [0, 5] and (5, infinity). In the first interval a rational approximation $R(x)$ is employed to compute,

$$Y_0(x) = R(x) + \frac{2\log(x)J_0(x)}{\pi},$$

where $J_0$ is the Bessel function of the first kind of order 0.

In the second interval, the Hankel asymptotic expansion is employed with two rational functions of degree 6/6 and 7/7.

This function is a wrapper for the Cephes [1] routine $y0$. 

3.3. API definition 2177
References

[1]

scipy.special.y1

scipy.special.y1(x) = <ufunc 'y1'>
Bessel function of the second kind of order 1.

Parameters
x   [array_like] Argument (float).

Returns
Y   [ndarray] Value of the Bessel function of the second kind of order 1 at x.

See also:

j1
yn
yv

Notes

The domain is divided into the intervals [0, 8] and (8, infinity). In the first interval a 25 term Chebyshev expansion is used, and computing \( J_1 \) (the Bessel function of the first kind) is required. In the second, the asymptotic trigonometric representation is employed using two rational functions of degree 5/5.

This function is a wrapper for the Cephes [1] routine \( y1 \).

References

[1]

scipy.special.i0

scipy.special.i0(x) = <ufunc 'i0'>
Modified Bessel function of order 0.

Defined as,

\[
I_0(x) = \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{(k!)^2} = J_0(ix),
\]

where \( J_0 \) is the Bessel function of the first kind of order 0.

Parameters
x   [array_like] Argument (float)

Returns
I   [ndarray] Value of the modified Bessel function of order 0 at x.
See also:

iv
i0

Notes

The range is partitioned into the two intervals \([0, 8]\) and \((8, \infty)\). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine \(i0\).

References

[1]

`scipy.special.i0e`

`scipy.special.i0e(x) = <ufunc 'i0e'>`

Exponentially scaled modified Bessel function of order 0.

Defined as:

\[
i0e(x) = \exp(-\text{abs}(x)) \times i0(x).
\]

Parameters

- **x** [array_like] Argument (float)

Returns

- **I** [ndarray] Value of the exponentially scaled modified Bessel function of order 0 at \(x\).

See also:

iv
i0

Notes

The range is partitioned into the two intervals \([0, 8]\) and \((8, \infty)\). Chebyshev polynomial expansions are employed in each interval. The polynomial expansions used are the same as those in \(i0\), but they are not multiplied by the dominant exponential factor.

This function is a wrapper for the Cephes [1] routine \(i0e\).
References

[1]

scipy.special.i1

\texttt{scipy.special.i1(x) = <ufunc }'i1'\texttt{>}

Modified Bessel function of order 1.

Defined as,

\[ I_1(x) = \frac{1}{2} x \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{k!(k + 1)!} = -i J_1(ix), \]

where \( J_1 \) is the Bessel function of the first kind of order 1.

Parameters

\( x \) [array_like] Argument (float)

Returns

\( I \) [ndarray] Value of the modified Bessel function of order 1 at \( x \).

See also:

iv
i1e

Notes

The range is partitioned into the two intervals \([0, 8]\) and \((8, \infty)\). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine \texttt{i1}.

References

[1]

scipy.special.i1e

\texttt{scipy.special.i1e(x) = <ufunc }'i1e'\texttt{>}

Exponentially scaled modified Bessel function of order 1.

Defined as:

\[ i1e(x) = \exp(-\text{abs}(x)) \times i1(x) \]

Parameters

\( x \) [array_like] Argument (float)

Returns
See also:
iv
i1

Notes
The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval. The polynomial expansions used are the same as those in i1, but they are not multiplied by the dominant exponential factor.
This function is a wrapper for the Cephes [1] routine i1e.

References
[1]

scipy.special.k0

scipy.special.k0(x) = <ufunc 'k0'>
Modified Bessel function of the second kind of order 0, \( K_0 \).
This function is also sometimes referred to as the modified Bessel function of the third kind of order 0.

Parameters
x 
[array_like] Argument (float).

Returns
K 
[ndarray] Value of the modified Bessel function \( K_0 \) at \( x \).

See also:
kv
k0e

Notes
The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.
This function is a wrapper for the Cephes [1] routine k0.
scipy.special.k0e

scipy.special.k0e(x) = <ufunc 'k0e'>

Exponentially scaled modified Bessel function K of order 0

Defined as:

\[ k0e(x) = \exp(x) \times k0(x). \]

**Parameters**

- x : [array_like] Argument (float)

**Returns**

- K : [ndarray] Value of the exponentially scaled modified Bessel function K of order 0 at x.

**See also:**

- kv
- k0

**Notes**

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine \( k0e \).

**References**

[1]

scipy.special.k1

scipy.special.k1(x) = <ufunc 'k1'>

Modified Bessel function of the second kind of order 1, \( K_1(x) \).

**Parameters**

- x : [array_like] Argument (float)

**Returns**

- K : [ndarray] Value of the modified Bessel function K of order 1 at x.

**See also:**

- kv
- k1e
Notes

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine \texttt{k1}.

References

[1]

scipy.special.k1e

scipy.special.\texttt{k1e}(x) = <ufunc 'k1e'>

Exponentially scaled modified Bessel function \textit{K} of order 1

Defined as:

\[
\text{k1e}(x) = \exp(x) * k1(x)
\]

Parameters

\texttt{x} [array_like] Argument (float)

Returns

\texttt{K} [ndarray] Value of the exponentially scaled modified Bessel function \textit{K} of order 1 at \texttt{x}.

See also:

\texttt{kv}

\texttt{k1}

Notes

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine \texttt{k1e}.

\[ \int_0^x K_0(t)dt. \]

For more on \( I_0 \) and \( K_0 \) see \( i0 \) and \( k0 \).

Parameters
- x : array_like
  Values at which to evaluate the integrals.
- out : tuple of ndarrays, optional
  Optional output arrays for the function results.

Returns
- ii0 : scalar or ndarray
  The integral for \( i0 \)
- ik0 : scalar or ndarray
  The integral for \( k0 \)

scipy.special.it2i0k0

scipy.special.it2i0k0(x, out=None) = <ufunc 'it2i0k0'>
Integrals related to modified Bessel functions of order 0.
Computes the integrals

\[ \int_0^x \frac{I_0(t) - 1}{t}dt \]
\[ \int_x^\infty \frac{K_0(t)}{t}dt. \]

Parameters
- x : array_like
  Values at which to evaluate the integrals.
- out : tuple of ndarrays, optional
  Optional output arrays for the function results.

Returns
- ii0 : scalar or ndarray
  The integral for \( i0 \)
- ik0 : scalar or ndarray
  The integral for \( k0 \)

scipy.special.besselpoly

scipy.special.besselpoly(a, lmb, nu, out=None) = <ufunc 'besselpoly'>
Weighted integral of the Bessel function of the first kind.
Computes

\[ \int_0^1 x^\lambda J_\nu(2ax) dx \]

where \( J_\nu \) is a Bessel function and \( \lambda = lmb, \nu = nu \).
**Parameters**

- **a** [array_like] Scale factor inside the Bessel function.
- **lmb** [array_like] Power of $x$.
- **nu** [array_like] Order of the Bessel function.
- **out** [ndarray, optional] Optional output array for the function results.

**Returns**

- **scalar or ndarray** Value of the integral.

#### `scipy.special.jvp`

**`scipy.special.jvp(v, z[, n])`**

Compute derivatives of Bessel functions of the first kind.

Compute the nth derivative of the Bessel function $J_v$ with respect to $z$.

**Parameters**

- **v** [float] Order of Bessel function.
- **z** [complex] Argument at which to evaluate the derivative; can be real or complex.
- **n** [int, default 1] Order of derivative.

**Returns**

- **scalar or ndarray** Values of the derivative of the Bessel function.

**Notes**

The derivative is computed using the relation DLFM 10.6.7 [2].
scipy.special.yvp

\texttt{scipy.special.yvp}(v, z, n=1)

Compute derivatives of Bessel functions of the second kind.

Compute the \(n\)th derivative of the Bessel function \(Y_v\) with respect to \(z\).

\textit{Parameters}

\begin{itemize}
  \item \texttt{v} [float] Order of Bessel function
  \item \texttt{z} [complex] Argument at which to evaluate the derivative
  \item \texttt{n} [int, default 1] Order of derivative
\end{itemize}

\textit{Returns}

\texttt{scalar or ndarray}

\(n\)th derivative of the Bessel function.

\textbf{Notes}

The derivative is computed using the relation DLMF 10.6.7 [2].

\textbf{References}

[1], [2]

scipy.special.kvp

\texttt{scipy.special.kvp}(v, z, n=1)

Compute \(n\)th derivative of real-order modified Bessel function \(K_v(z)\)

\(K_v(z)\) is the modified Bessel function of the second kind. Derivative is calculated with respect to \(z\).

\textit{Parameters}

\begin{itemize}
  \item \texttt{v} [array_like of float] Order of Bessel function
  \item \texttt{z} [array_like of complex] Argument at which to evaluate the derivative
  \item \texttt{n} [int] Order of derivative. Default is first derivative.
\end{itemize}

\textit{Returns}

\texttt{out} [ndarray] The results
Notes

The derivative is computed using the relation DLFM 10.29.5 [2].

References

[1], [2]

Examples

Calculate multiple values at order 5:

```python
>>> from scipy.special import kvp
>>> kvp(5, (1, 2, 3+5j))
array([[-1.84903536e+03+0.j , -2.57735387e+01+0.j ,
       -3.06627741e-02+0.08750845j]])
```

Calculate for a single value at multiple orders:

```python
>>> kvp((4, 4.5, 5), 1)
array([-184.0309, -568.9585, -1849.0354])
```

scipy.special.ivp

scipy.special.\texttt{ivp}(\texttt{v}, \texttt{z}, \texttt{n}=\texttt{1})

Compute derivatives of modified Bessel functions of the first kind.

Compute the $n$th derivative of the modified Bessel function $I_v$ with respect to $z$.

**Parameters**

- $v$ [array_like] Order of Bessel function
- $z$ [array_like] Argument at which to evaluate the derivative; can be real or complex.
- $n$ [int, default 1] Order of derivative

**Returns**

- scalar or ndarray
  
nth derivative of the modified Bessel function.

**See also:**

$iv$
Notes
The derivative is computed using the relation DLFM 10.29.5 [2].

References
[1], [2]

**scipy.special.h1vp**

`scipy.special.h1vp(v, z, n=1)`  
Compute nth derivative of Hankel function $H_1^v(z)$ with respect to $z$.

**Parameters**
- `v` : array_like  
  Order of Hankel function
- `z` : array_like  
  Argument at which to evaluate the derivative. Can be real or complex.
- `n` : int, default 1  
  Order of derivative

**Returns**
- scalar or ndarray  
  Values of the derivative of the Hankel function.

Notes
The derivative is computed using the relation DLFM 10.6.7 [2].

References
[1], [2]

**scipy.special.h2vp**

`scipy.special.h2vp(v, z, n=1)`  
Compute nth derivative of Hankel function $H_2^v(z)$ with respect to $z$.

**Parameters**
- `v` : array_like  
  Order of Hankel function
- `z` : array_like  
  Argument at which to evaluate the derivative. Can be real or complex.
- `n` : int, default 1  
  Order of derivative

**Returns**
- scalar or ndarray  
  Values of the derivative of the Hankel function.
Notes

The derivative is computed using the relation DLMF 10.6.7 [2].

</tr>
</tbody>
</table>

`scipy.special.spherical_jn`

`scipy.special.spherical_jn(n, z[, derivative=False])`  
Spherical Bessel function of the first kind or its derivative.

Defined as [1],

\[ j_n(z) = \sqrt{\frac{\pi}{2z}} J_{n+1/2}(z), \]

where \( J_n \) is the Bessel function of the first kind.

Parameters

- **n** [int, array_like] Order of the Bessel function (n >= 0).
- **z** [complex or float, array_like] Argument of the Bessel function.
- **derivative** [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

Returns

- **jn** [ndarray]

Notes

For real arguments greater than the order, the function is computed using the ascending recurrence [2]. For small real or complex arguments, the definitional relation to the cylindrical Bessel function of the first kind is used.

The derivative is computed using the relations [3],

\[
\begin{align*}
    j'_n(z) &= j_{n-1}(z) - \frac{n + 1}{z} j_n(z). \\
    j'_0(z) &= -j_1(z)
\end{align*}
\]

New in version 0.18.0.
References

[1], [2], [3], [AS]

Examples

The spherical Bessel functions of the first kind $j_n$ accept both real and complex second argument. They can return a complex type:

```python
>>> from scipy.special import spherical_jn
>>> spherical_jn(0, 3+5j)
(-9.878987731663194-8.021894345786002j)
>>> type(spherical_jn(0, 3+5j))
<class 'numpy.complex128'>
```

We can verify the relation for the derivative from the Notes for $n = 3$ in the interval $[1, 2]$:

```python
>>> from scipy.special import spherical_jn
>>> x = np.arange(1.0, 2.0, 0.01)
>>> np.allclose(spherical_jn(3, x, True), ...
... spherical_jn(2, x) - 4/x * spherical_jn(3, x))
True
```

The first few $j_n$ with real argument:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.special import spherical_jn
>>> x = np.arange(0.0, 10.0, 0.01)
>>> fig, ax = plt.subplots()
>>> ax.set_ylim(-0.5, 1.5)
>>> ax.set_title(r'$Spherical Bessel functions$ $j_n$')
>>> for n in np.arange(0, 4):
...     ax.plot(x, spherical_jn(n, x), label=rf'$j_{n}$')
>>> plt.legend(loc='best')
>>> plt.show()
```

`scipy.special.spherical_y`n

`scipy.special.spherical_y`n $(n, z, derivative=False)$

Spherical Bessel function of the second kind or its derivative.

Defined as [1],

$$y_n(z) = \sqrt{\frac{\pi}{2z}} Y_{n+1/2}(z),$$

where $Y_n$ is the Bessel function of the second kind.

**Parameters**

- $n$ : [int, array_like] Order of the Bessel function ($n >= 0$).
- $z$ : [complex or float, array_like] Argument of the Bessel function.
- $derivative$ : [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

3.3. API definition 2191
Spherical Bessel functions $j_n$

```

<table>
<thead>
<tr>
<th>j0</th>
<th>j1</th>
<th>j2</th>
<th>j3</th>
</tr>
</thead>
</table>
```

**Notes**

For real arguments, the function is computed using the ascending recurrence [2]. For complex arguments, the definitional relation to the cylindrical Bessel function of the second kind is used.

The derivative is computed using the relations [3],

\[ y'_n = y_{n-1} - \frac{n + 1}{z} y_n, \]
\[ y'_0 = -y_1 \]

New in version 0.18.0.

**References**

[1], [2], [3], [AS]

**Examples**

The spherical Bessel functions of the second kind $y_n$ accept both real and complex second argument. They can return a complex type:

```python
>>> from scipy.special import spherical_yn
>>> spherical_yn(0, 3+5j)
(8.022343088587197-9.880052589376795j)
>>> type(spherical_yn(0, 3+5j))
<class 'numpy.complex128'>
```

We can verify the relation for the derivative from the Notes for $n = 3$ in the interval [1, 2]:

\[ y'_3 = y_2 - \frac{3 + 1}{z} y_3 = -y_2 \]
The first few $y_n$ with real argument:

```python
>>> from scipy.special import spherical_yn
>>> x = np.arange(1.0, 2.0, 0.01)
>>> np.allclose(spherical_yn(3, x, True),
              spherical_yn(2, x) - 4/x * spherical_yn(3, x))
True
```

```
>>> import matplotlib.pyplot as plt
>>> from scipy.special import spherical_yn
>>> x = np.arange(0.0, 10.0, 0.01)
>>> fig, ax = plt.subplots()
>>> ax.set_ylim(-2.0, 1.0)
>>> ax.set_title(r'Spherical Bessel functions $y_n$')
>>> for n in np.arange(0, 4):
...    ax.plot(x, spherical_yn(n, x), label=rf'$y_{n}$')
>>> plt.legend(loc='best')
>>> plt.show()
```

![Spherical Bessel functions $y_n$](image)

**scipy.special.spherical_in**

`scipy.special.spherical_in(n, z, derivative=False)`  
Modified spherical Bessel function of the first kind or its derivative.  
Defined as [1],

$$i_n(z) = \sqrt{\frac{\pi}{2z}} I_{n+\frac{1}{2}}(z),$$

where $I_n$ is the modified Bessel function of the first kind.  

**Parameters**

- **n**  
  [int, array_like] Order of the Bessel function ($n \geq 0$).  
- **z**  
  [complex or float, array_like] Argument of the Bessel function.
derivative  [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

Returns
in     [ndarray]

Notes
The function is computed using its definitional relation to the modified cylindrical Bessel function of the first kind. The derivative is computed using the relations

\[ i'_n = i_{n-1} - \frac{n+1}{z} i_n. \]

\[ i'_1 = i_0 \]

New in version 0.18.0.

References
[1], [2], [AS]

Examples
The modified spherical Bessel functions of the first kind \( i_n \) accept both real and complex second argument. They can return a complex type:

```python
>>> from scipy.special import spherical_in
>>> spherical_in(0, 3+5j)
(-1.1689867793369182-1.2697305267234222j)
>>> type(spherical_in(0, 3+5j))
<class 'numpy.complex128'>
```

We can verify the relation for the derivative from the Notes for \( n = 3 \) in the interval \([1, 2]\):

```python
>>> from scipy.special import spherical_in
>>> x = np.arange(1.0, 2.0, 0.01)
>>> np.allclose(spherical_in(3, x, True),
... spherical_in(2, x) - 4/x * spherical_in(3, x))
True
```

The first few \( i_n \) with real argument:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.special import spherical_in
>>> x = np.arange(0.0, 6.0, 0.01)
>>> fig, ax = plt.subplots()
>>> ax.set_xlim(-0.5, 5.0)
>>> ax.set_title(r'Modified spherical Bessel functions $i_n$')
>>> for n in np.arange(0, 4):
...     ax.plot(x, spherical_in(n, x), label=rf'$i_\{n\}$')
>>> plt.legend(loc='best')
>>> plt.show()
```
scipy.special.spherical_kn

scipy.special.spherical_kn(n, z, derivative=False)
Modified spherical Bessel function of the second kind or its derivative.

Defined as [1],

\[ k_n(z) = \sqrt{\frac{z}{2}} K_{n+1/2}(z), \]

where \( K_n \) is the modified Bessel function of the second kind.

**Parameters**

- **n** [int, array_like] Order of the Bessel function (\( n \geq 0 \)).
- **z** [complex or float, array_like] Argument of the Bessel function.
- **derivative** [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

- **kn** [ndarray]

**Notes**

The function is computed using its definitional relation to the modified cylindrical Bessel function of the second kind.

The derivative is computed using the relations [2],

\[ k'_n = -k_{n-1} - \frac{n+1}{z} k_n. \]

\[ k'_0 = -k_1 \]

New in version 0.18.0.
References

[1], [2], [AS]

Examples

The modified spherical Bessel functions of the second kind $k_n$ accept both real and complex second argument. They can return a complex type:

```python
>>> from scipy.special import spherical_kn
>>> spherical_kn(0, 3+5j)
(0.012985785614001561+0.003354691603137546j)
>>> type(spherical_kn(0, 3+5j))
<class 'numpy.complex128'>
```

We can verify the relation for the derivative from the Notes for $n = 3$ in the interval [1, 2]:

```python
>>> from scipy.special import spherical_kn
>>> x = np.arange(1.0, 2.0, 0.01)
>>> np.allclose(spherical_kn(3, x, True),
...              -4/x * spherical_kn(3, x) - spherical_kn(2, x))
True
```

The first few $k_n$ with real argument:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.special import spherical_kn
>>> x = np.arange(0.0, 4.0, 0.01)
>>> fig, ax = plt.subplots()
>>> ax.set_ylim(0.0, 5.0)
>>> ax.set_title(r'Modified spherical Bessel functions $k_n$')
>>> for n in np.arange(0, 4):
...     ax.plot(x, spherical_kn(n, x), label=rf'$k_{n}$')
>>> plt.legend(loc='best')
>>> plt.show()
```

Riccati-Bessel functions

These are not universal functions:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
scipy.special.riccati_jn

scipy.special.riccati_jn(n, x)

Compute Ricatti-Bessel function of the first kind and its derivative.

The Ricatti-Bessel function of the first kind is defined as \( x j_n(x) \), where \( j_n \) is the spherical Bessel function of the first kind of order \( n \).

This function computes the value and first derivative of the Ricatti-Bessel function for all orders up to and including \( n \).

**Parameters**

- \( n \) [int] Maximum order of function to compute
- \( x \) [float] Argument at which to evaluate

**Returns**

- \( jn \) [ndarray] Value of \( j0(x) \), ..., \( jn(x) \)
- \( jnp \) [ndarray] First derivative \( j0'(x) \), ..., \( jn'(x) \)

**Notes**

The computation is carried out via backward recurrence, using the relation DLMF 10.51.1 [2].

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

**References**

[1], [2]

scipy.special.riccati_yn

scipy.special.riccati_yn(n, x)

Compute Ricatti-Bessel function of the second kind and its derivative.

The Ricatti-Bessel function of the second kind is defined as \( xy_n(x) \), where \( y_n \) is the spherical Bessel function of the second kind of order \( n \).

This function computes the value and first derivative of the function for all orders up to and including \( n \).
Notes

The computation is carried out via ascending recurrence, using the relation DLMF 10.51.1 [2]. Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

Struve functions

- `struve(v, x)` Struve function.
- `modstruve(v, x)` Modified Struve function.
- `itstruve0(x)` Integral of the Struve function of order 0.
- `it2struve0(x)` Integral related to the Struve function of order 0.
- `itmodstruve0(x)` Integral of the modified Struve function of order 0.

### scipy.special.struve

`scipy.special.struve(v, x) = <ufunc 'struve'>`

Struve function.

Return the value of the Struve function of order \( v \) at \( x \). The Struve function is defined as,

\[
H_v(x) = \frac{z}{2}^{v+1} \sum_{n=0}^{\infty} \frac{(-1)^n (z/2)^{2n}}{\Gamma(n + \frac{3}{2}) \Gamma(n + v + \frac{3}{2})},
\]

where \( \Gamma \) is the gamma function.

**Parameters**

- `v` [array_like] Order of the Struve function (float).
- `x` [array_like] Argument of the Struve function (float; must be positive unless \( v \) is an integer).

**Returns**

- `H` [ndarray] Value of the Struve function of order \( v \) at \( x \).

See also:

- `modstruve`

Notes

Three methods discussed in [1] are used to evaluate the Struve function:

- power series
- expansion in Bessel functions (if \( |z| < |v| + 20 \))
- asymptotic large-\( z \) expansion (if \( z \geq 0.7v + 12 \))

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.
References

[1]

scipy.special.modstruve

scipy.special.modstruve \((v, x) = \langle\text{ufunc 'modstruve'}\rangle\)

Modified Struve function.

Return the value of the modified Struve function of order \(v\) at \(x\). The modified Struve function is defined as,

\[
L_v(x) = -i \exp(-\pi i v/2) H_v(ix),
\]

where \(H_v\) is the Struve function.

Parameters

- \(v\) [array_like] Order of the modified Struve function (float).
- \(x\) [array_like] Argument of the Struve function (float; must be positive unless \(v\) is an integer).

Returns

- \(L\) [ndarray] Value of the modified Struve function of order \(v\) at \(x\).

See also:

struve

Notes

Three methods discussed in [1] are used to evaluate the function:

- power series
- expansion in Bessel functions (if \(|x| < |v| + 20\)
- asymptotic large-x expansion (if \(x \geq 0.7v + 12\))

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.

References

[1]

scipy.special.itstruve0

scipy.special.itstruve0 \((x) = \langle\text{ufunc 'itstruve0'}\rangle\)

Integral of the Struve function of order 0.

\[
I = \int_0^x H_0(t) \, dt
\]

Parameters

- \(x\) [array_like] Upper limit of integration (float).
Returns

I [ndarray] The integral of $H_0$ from 0 to $x$.

See also:

struve

Notes

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

References

[1]

scipy.special.it2struve0

c scipy.special.it2struve0 ($x$) = <ufunc 'it2struve0'>

Integral related to the Struve function of order 0.

Returns the integral,

$$
\int_{x}^{\infty} \frac{H_0(t)}{t} \, dt
$$

where $H_0$ is the Struve function of order 0.

Parameters

x [array_like] Lower limit of integration.

Returns

I [ndarray] The value of the integral.

See also:

struve

Notes

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

**scipy.special.bdtr**

*scipy.special.bdtr(k, n, p) = <ufunc 'bdtr'>*

Binomial distribution cumulative distribution function.

Sum of the terms 0 through $\lfloor k \rfloor$ of the Binomial probability density.

$$bdtr(k, n, p) = \sum_{j=0}^{\lfloor k \rfloor} \binom{n}{j} p^j (1 - p)^{n-j}$$

**Parameters**

- **k** [array_like] Number of successes (double), rounded down to the nearest integer.
- **n** [array_like] Number of events (int).
- **p** [array_like] Probability of success in a single event (float).

**Returns**

- **y** [ndarray] Probability of $\lfloor k \rfloor$ or fewer successes in $n$ independent events with success probabilities of $p$.

**Notes**

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$bdtr(k, n, p) = I_{1-p}(n - \lfloor k \rfloor, \lfloor k \rfloor + 1).$$

**References**

[1]

**scipy.special.bdtrc**

*scipy.special.bdtrc(k, n, p) = <ufunc 'bdtrc'>*

Binomial distribution survival function.

Sum of the terms $\lfloor k \rfloor + 1$ through $n$ of the binomial probability density,

$$bdtrc(k, n, p) = \sum_{j=\lfloor k \rfloor + 1}^{n} \binom{n}{j} p^j (1 - p)^{n-j}$$

**Parameters**

**k**
[array_like] Number of successes (double), rounded down to nearest integer.

**n**
[array_like] Number of events (int)

**p**
[array_like] Probability of success in a single event.

**Returns**

**y**
[ndarray] Probability of \( \lfloor k \rfloor + 1 \) or more successes in \( n \) independent events with success probabilities of \( p \).

**See also:**

bdtr
betainc

**Notes**

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

\[
bdtrc(k, n, p) = I_p([k] + 1, n - [k]).
\]

Wrapper for the Cephes \([1]\) routine \(bdtrc\).

**References**

[1]

```python
scipy.special.bdtri
```

\[
\text{scipy.special.bdtri}(k, n, y) = \text{ufunc } \text{"bdtri"}
\]

Inverse function to \(bdtr\) with respect to \(p\).

Finds the event probability \(p\) such that the sum of the terms 0 through \(k\) of the binomial probability density is equal to the given cumulative probability \(y\).

**Parameters**

**k**
[array_like] Number of successes (float), rounded down to the nearest integer.

**n**
[array_like] Number of events (float)

**y**
[array_like] Cumulative probability (probability of \(k\) or fewer successes in \(n\) events).

**Returns**

**p**
[ndarray] The event probability such that \(bdtr(\lfloor k \rfloor, n, p) = y\).

**See also:**

bdtr
betaincinv
Notes

The computation is carried out using the inverse beta integral function and the relation:

\[ 1 - p = \text{betaincinv}(n - k, k + 1, y). \]

Wrapper for the Cephes [1] routine \textit{bdtri}.

References

[1]

\texttt{scipy.special.bdtrik}

\texttt{scipy.special.bdtrik(y, n, p) = \texttt{<ufunc 'bdtrik'>}}

Inverse function to \textit{bdtr} with respect to \( k \).

Finds the number of successes \( k \) such that the sum of the terms 0 through \( k \) of the Binomial probability density for \( n \) events with probability \( p \) is equal to the given cumulative probability \( y \).

\begin{itemize}
  \item \textbf{Parameters}
    \begin{itemize}
      \item \texttt{y} [array_like] Cumulative probability (probability of \( k \) or fewer successes in \( n \) events).
      \item \texttt{n} [array_like] Number of events (float).
      \item \texttt{p} [array_like] Success probability (float).
    \end{itemize}
  \item \textbf{Returns}
    \begin{itemize}
      \item \texttt{k} [ndarray] The number of successes \( k \) such that \( \text{bdtr}(k, n, p) = y \).
    \end{itemize}
\end{itemize}

See also:

\texttt{bdtr}

Notes

Formula 26.5.24 of [1] is used to reduce the binomial distribution to the cumulative incomplete beta distribution. Computation of \( k \) involves a search for a value that produces the desired value of \( y \). The search relies on the monotonicity of \( y \) with \( k \).

References

[1], [2]
scipy.special.bdtrin

\[ \text{scipy.special.bdtrin}(k, y, p) = \texttt{<ufunc 'bdtrin'>} \]
Inverse function to \texttt{bdtr} with respect to \( n \).

Finds the number of events \( n \) such that the sum of the terms 0 through \( k \) of the Binomial probability density for events with probability \( p \) is equal to the given cumulative probability \( y \).

**Parameters**
- \( k \) [array_like] Number of successes (float).
- \( y \) [array_like] Cumulative probability (probability of \( k \) or fewer successes in \( n \) events).
- \( p \) [array_like] Success probability (float).

**Returns**
- \( n \) [ndarray] The number of events \( n \) such that \( \text{bdtr}(k, n, p) = y \).

See also:
\texttt{bdtr}

**Notes**
Formula 26.5.24 of [1] is used to reduce the binomial distribution to the cumulative incomplete beta distribution.

Computation of \( n \) involves a search for a value that produces the desired value of \( y \). The search relies on the monotonicity of \( y \) with \( n \).

Wrapper for the CDFLIB [2] Fortran routine \texttt{cdfbin}.

**References**
[1], [2]

scipy.special.btdtr

\[ \text{scipy.special.btdtr}(a, b, x) = \texttt{<ufunc 'btdtr'>} \]
Cumulative distribution function of the beta distribution.

Returns the integral from zero to \( x \) of the beta probability density function,
\[
I = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1}(1-t)^{b-1} \, dt
\]
where \( \Gamma \) is the gamma function.

**Parameters**
- \( a \) [array_like] Shape parameter (\( a > 0 \)).
- \( b \) [array_like] Shape parameter (\( b > 0 \)).
- \( x \) [array_like] Upper limit of integration, in [0, 1].

**Returns**
- \( I \) [ndarray] Cumulative distribution function of the beta distribution with parameters \( a \) and \( b \) at \( x \).

See also:
betainc

Notes

This function is identical to the incomplete beta integral function \texttt{betainc}.
Wrapper for the Cephes [1] routine \texttt{btdtr}.

References

[1]

\texttt{scipy.special.btdtri}

\texttt{scipy.special.btdtri}(a, b, p) = <ufunc 'btdtri'>
The \(p\)-th quantile of the beta distribution.

This function is the inverse of the beta cumulative distribution function, \texttt{btdtr}, returning the value of \(x\) for which \(btdtr(a, b, x) = p\), or

\[
p = \int_0^x \frac{\Gamma(a + b)}{\Gamma(a)\Gamma(b)} t^{a-1}(1-t)^{b-1} \, dt
\]

Parameters

- \(a\) [array_like] Shape parameter \((a > 0)\).
- \(b\) [array_like] Shape parameter \((b > 0)\).
- \(p\) [array_like] Cumulative probability, in \([0, 1]\).

Returns

- \(x\) [ndarray] The quantile corresponding to \(p\).

See also:

betaincinv
btdtr

Notes

The value of \(x\) is found by interval halving or Newton iterations.
Wrapper for the Cephes [1] routine \texttt{incbi}, which solves the equivalent problem of finding the inverse of the incomplete beta integral.
References

[1]

scipy.special.btdtria

\texttt{scipy.special.btdtria}(p, b, x) = <ufunc 'btdtria'>

Inverse of \texttt{btdtr} with respect to \(a\).

This is the inverse of the beta cumulative distribution function, \texttt{btdtr}, considered as a function of \(a\), returning the value of \(a\) for which \(\texttt{btdtr}(a, b, x) = p\), or

\[
p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1 - t)^{b-1} dt
\]

Parameters

\(p\) [array_like] Cumulative probability, in [0, 1].

\(b\) [array_like] Shape parameter \((b > 0)\).

\(x\) [array_like] The quantile, in [0, 1].

Returns

\(a\) [ndarray] The value of the shape parameter \(a\) such that \(\texttt{btdtr}(a, b, x) = p\).

See also:

\texttt{btdtr}

Cumulative distribution function of the beta distribution.

\texttt{btdtri}

Inverse with respect to \(x\).

\texttt{btdtrib}

Inverse with respect to \(b\).

Notes

Wrapper for the CDFLIB [1] Fortran routine \texttt{cdfbet}.

The cumulative distribution function \(p\) is computed using a routine by DiDinato and Morris [2]. Computation of \(a\) involves a search for a value that produces the desired value of \(p\). The search relies on the monotonicity of \(p\) with \(a\).

References

[1], [2]
scipy.special.btdtrib

```python
scipy.special.btdtrib(a, p, x) = <ufunc 'btdtrib'>
```

Inverse of `btdtr` with respect to $b$.

This is the inverse of the beta cumulative distribution function, `btdtr`, considered as a function of $b$, returning the value of $b$ for which $btdtr(a, b, x) = p$, or

$$
p = \int_0^x \frac{\Gamma(a + b)}{\Gamma(a)\Gamma(b)} t^{a-1}(1 - t)^{b-1} dt
$$

**Parameters**

- `a` [array_like] Shape parameter ($a > 0$).
- `p` [array_like] Cumulative probability, in [0, 1].
- `x` [array_like] The quantile, in [0, 1].

**Returns**

- `b` [ndarray] The value of the shape parameter $b$ such that $btdtr(a, b, x) = p$.

**See also:**

- `btdtr` Cumulative distribution function of the beta distribution.
- `btdtri` Inverse with respect to $x$.
- `btdtria` Inverse with respect to $a$.

**Notes**

The cumulative distribution function $p$ is computed using a routine by DiDinato and Morris [2]. Computation of $b$ involves a search for a value that produces the desired value of $p$. The search relies on the monotonicity of $p$ with $b$.

**References**

[1], [2]

scipy.special.fdtr

```python
scipy.special.fdtr(dfn, dfd, x) = <ufunc 'fdtr'>
```

F cumulative distribution function.

Returns the value of the cumulative distribution function of the F-distribution, also known as Snedecor's F-distribution or the Fisher-Snedecor distribution.

The F-distribution with parameters $d_n$ and $d_d$ is the distribution of the random variable,

$$
X = \frac{U_n/d_n}{U_d/d_d}
$$
where \( U_n \) and \( U_d \) are random variables distributed \( \chi^2 \), with \( d_n \) and \( d_d \) degrees of freedom, respectively.

### Parameters
- **dfn**: [array_like] First parameter (positive float).
- **dfd**: [array_like] Second parameter (positive float).
- **x**: [array_like] Argument (nonnegative float).

### Returns
- **y**: [ndarray] The CDF of the F-distribution with parameters \( dfn \) and \( dfd \) at \( x \).

### Notes
The regularized incomplete beta function is used, according to the formula,

\[
F(d_n, d_d; x) = I_{xd_n/(d_d+xd_n)}(d_n/2, d_d/2).
\]

Wrapper for the Cephes \([1]\) routine `fdtr`.

### References
1. scipy.special.fdtrc

```python
scipy.special.fdtrc(dfn, dfd, x) = <ufunc 'fdtrc'>
```

F survival function.

Returns the complemented F-distribution function (the integral of the density from \( x \) to infinity).

### Parameters
- **dfn**: [array_like] First parameter (positive float).
- **dfd**: [array_like] Second parameter (positive float).
- **x**: [array_like] Argument (nonnegative float).

### Returns
- **y**: [ndarray] The complemented F-distribution function with parameters \( dfn \) and \( dfd \) at \( x \).

See also:
- `fdtr`

### Notes
The regularized incomplete beta function is used, according to the formula,

\[
F(d_n, d_d; x) = I_{d_d/(d_n+xd_n)}(d_d/2, d_n/2).
\]

Wrapper for the Cephes \([1]\) routine `fdtrc`. 
References

[1]

**scipy.special.fdtri**

\[
\text{scipy.special.fdtri}(dfn, dfd, p) = \text{<ufunc 'fdtri'>}
\]

The  \(p\)-th quantile of the F-distribution.

This function is the inverse of the F-distribution CDF, \(\text{fdtr}\), returning the \(x\) such that \(\text{fdtr}(dfn, dfd, x) = p\).

**Parameters**
- **dfn** : [array_like] First parameter (positive float).
- **dfd** : [array_like] Second parameter (positive float).
- **p** : [array_like] Cumulative probability, in [0, 1].

**Returns**
- **x** : [ndarray] The quantile corresponding to \(p\).

**Notes**

The computation is carried out using the relation to the inverse regularized beta function, \(\text{I}^{-1}_x(a, b)\). Let \(z = \text{I}^{-1}_p(d_d/2, d_n/2)\). Then,

\[
x = \frac{d_d(1 - z)}{d_n z}.
\]

If \(p\) is such that \(x < 0.5\), the following relation is used instead for improved stability: let \(z' = \text{I}^{-1}_{1-p}(d_n/2, d_d/2)\). Then,

\[
x = \frac{d_d z'}{d_n(1 - z')}.
\]

Wrapper for the Cephes [1] routine \(\text{fdtri}\).

**References**

[1]

**scipy.special.fdtridfd**

\[
\text{scipy.special.fdtridfd}(dfn, p, x) = \text{<ufunc 'fdtridfd'>}
\]

Inverse to \(\text{fdtr}\) vs \(\text{dfd}\)

Finds the F density argument \(\text{dfd}\) such that \(\text{fdtr}(dfn, dfd, x) = p\).
scipy.special.gdtr

\[ \text{scipy.special.gdtr}(a, b, x) = \text{ufunc 'gdtr'} \]

Gamma distribution cumulative distribution function.

Returns the integral from zero to \( x \) of the gamma probability density function,

\[
F = \int_0^x \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at} dt,
\]

where \( \Gamma \) is the gamma function.

Parameters

- \( a \) [array_like] The rate parameter of the gamma distribution, sometimes denoted \( \beta \) (float). It is also the reciprocal of the scale parameter \( \theta \).
- \( b \) [array_like] The shape parameter of the gamma distribution, sometimes denoted \( \alpha \) (float).
- \( x \) [array_like] The quantile (upper limit of integration; float).

Returns

- \( F \) [ndarray] The CDF of the gamma distribution with parameters \( a \) and \( b \) evaluated at \( x \).

See also:

gdtrc

1 - CDF of the gamma distribution.

Notes

The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function). Wrapper for the Cephes [1] routine \( \text{gdtr} \).

References

[1]

scipy.special.gdtrc

\[ \text{scipy.special.gdtrc}(a, b, x) = \text{ufunc 'gdtrc'} \]

Gamma distribution survival function.

Integral from \( x \) to infinity of the gamma probability density function,

\[
F = \int_x^\infty \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at} dt,
\]

where \( \Gamma \) is the gamma function.

Parameters

- \( a \) [array_like] The rate parameter of the gamma distribution, sometimes denoted \( \beta \) (float). It is also the reciprocal of the scale parameter \( \theta \).
- \( b \) [array_like] The shape parameter of the gamma distribution, sometimes denoted \( \alpha \) (float).
- \( x \) [array_like] The quantile (lower limit of integration; float).
Returns

\[ F \] [ndarray] The survival function of the gamma distribution with parameters \( a \) and \( b \) evaluated at \( x \).

See also:

\texttt{gdtr, gdtrix}

Notes

The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function).

Wrapper for the Cephes [1] routine \texttt{gdtrc}.

References

[1]

\texttt{scipy.special.gdtria}

\texttt{scipy.special.gdtria}(p, b, x, out=None) = <ufunc 'gdtria'>

Inverse of \texttt{gdtr} vs \( a \).

Returns the inverse with respect to the parameter \( a \) of \( p = \text{gdtr}(a, b, x) \), the cumulative distribution function of the gamma distribution.

Parameters

\( p \) [array_like] Probability values.
\( b \) [array_like] \( b \) parameter values of \( \text{gdtr}(a, b, x) \). \( b \) is the “shape” parameter of the gamma distribution.
\( x \) [array_like] Nonnegative real values, from the domain of the gamma distribution.
\( \text{out} \) [ndarray, optional] If a fourth argument is given, it must be a numpy.ndarray whose size matches the broadcast result of \( a, b \) and \( x \). \( \text{out} \) is then the array returned by the function.

Returns

\( a \) [ndarray] Values of the \( a \) parameter such that \( p = \text{gdtr}(a, b, x) \). \( 1/a \) is the “scale” parameter of the gamma distribution.

See also:

\texttt{gdtr}

CDF of the gamma distribution.

\texttt{gdtrib}

Inverse with respect to \( b \) of \( \text{gdtr}(a, b, x) \).

\texttt{gdtrix}

Inverse with respect to \( x \) of \( \text{gdtr}(a, b, x) \).
Notes

The cumulative distribution function $p$ is computed using a routine by DiDinato and Morris [2]. Computation of $a$ involves a search for a value that produces the desired value of $p$. The search relies on the monotonicity of $p$ with $a$.

References

[1], [2]

Examples

First evaluate $gdtr$.

```python
>>> from scipy.special import gdtr, gdtrib
>>> p = gdtr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```python
>>> gdtrib(p, 3.4, 5.6)
1.2
```

`scipy.special.gdtrib`

`scipy.special.gdtrib`($a, p, x$, `out=None`) = `<ufunc 'gdtrib'>`

Inverse of $gdtr$ vs $b$.

Returns the inverse with respect to the parameter $b$ of $p = gdtr(a, b, x)$, the cumulative distribution function of the gamma distribution.

**Parameters**

- $a$ [array_like] $a$ parameter values of $gdtr(a, b, x)$. $1/a$ is the “scale” parameter of the gamma distribution.
- $p$ [array_like] Probability values.
- $x$ [array_like] Nonnegative real values, from the domain of the gamma distribution.
- `out` [ndarray, optional] If a fourth argument is given, it must be a numpy.ndarray whose size matches the broadcast result of $a$, $b$ and $x$. `out` is then the array returned by the function.

**Returns**

- $b$ [ndarray] Values of the $b$ parameter such that $p = gdtr(a, b, x)$. $b$ is the “shape” parameter of the gamma distribution.

**See also:**

- $gdtr$

CDF of the gamma distribution.
**gdtria**

Inverse with respect to $a$ of $\text{gdtr}(a, b, x)$.

**gdtrix**

Inverse with respect to $x$ of $\text{gdtr}(a, b, x)$.

### Notes

Wrapper for the CDFLIB [1] Fortran routine $\text{cdfgam}$.

The cumulative distribution function $p$ is computed using a routine by DiDinato and Morris [2]. Computation of $b$ involves a search for a value that produces the desired value of $p$. The search relies on the monotonicity of $p$ with $b$.

### References

[1], [2]

### Examples

First evaluate $\text{gdtr}$.

```python
>>> from scipy.special import gdtr, gdtrib
>>> p = gdtr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```python
>>> gdtrib(1.2, p, 5.6)
3.3999999997238882
```

**scipy.special.gdtrix**

`scipy.special.gdtrix(a, b, p, out=None) = <ufunc 'gdtrix'>`

Inverse of $\text{gdtr}$ vs $x$.

Returns the inverse with respect to the parameter $x$ of $p = \text{gdtr}(a, b, x)$, the cumulative distribution function of the gamma distribution. This is also known as the $p$th quantile of the distribution.

#### Parameters

- **a**
  - [array_like] $a$ parameter values of $\text{gdtr}(a, b, x)$. $1/a$ is the “scale” parameter of the gamma distribution.
- **b**
  - [array_like] $b$ parameter values of $\text{gdtr}(a, b, x)$. $b$ is the “shape” parameter of the gamma distribution.
- **p**
  - [array_like] Probability values.
- **out**
  - [ndarray, optional] If a fourth argument is given, it must be a numpy.ndarray whose size matches the broadcast result of $a$, $b$ and $x$. $\text{out}$ is then the array returned by the function.

#### Returns

- **x**
  - [ndarray] Values of the $x$ parameter such that $p = \text{gdtr}(a, b, x)$.
See also:

\texttt{gdtr}

CDF of the gamma distribution.

\texttt{gdtria}

Inverse with respect to \( a \) of \( \text{gdtr}(a, b, x) \).

\texttt{gdtrib}

Inverse with respect to \( b \) of \( \text{gdtr}(a, b, x) \).

Notes

Wrapper for the CDFLIB [1] Fortran routine \texttt{cdfgam}.

The cumulative distribution function \( p \) is computed using a routine by DiDinato and Morris [2]. Computation of \( x \) involves a search for a value that produces the desired value of \( p \). The search relies on the monotonicity of \( p \) with \( x \).

References

[1], [2]

Examples

First evaluate \texttt{gdtr}.

```python
>>> from scipy.special import gdtr, gdtrix
>>> p = gdtr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```python
>>> gdtrix(1.2, 3.4, p)
5.5999999999999996
```

\texttt{scipy.special.nbdtr}

\texttt{scipy.special.nbdtr}(k, n, p) = \texttt{ufunc 'nbdtr'}

Negative binomial cumulative distribution function.

Returns the sum of the terms 0 through \( k \) of the negative binomial distribution probability mass function,

\[
F = \sum_{j=0}^{k} \binom{n+j-1}{j} p^n (1-p)^j.
\]

In a sequence of Bernoulli trials with individual success probabilities \( p \), this is the probability that \( k \) or fewer failures precede the \( n \)th success.

Parameters

\( k \) [array_like] The maximum number of allowed failures (nonnegative int).
\( n \) [array_like] The target number of successes (positive int).
\( p \) [array_like] Probability of success in a single event (float).

**Returns**

\( F \) [ndarray] The probability of \( k \) or fewer failures before \( n \) successes in a sequence of events with individual success probability \( p \).

**See also:**

*nbdtrc*

**Notes**

If floating point values are passed for \( k \) or \( n \), they will be truncated to integers.

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

\[
nbdtr(k, n, p) = I_p(n, k + 1).
\]

Wrapper for the Cephes [1] routine *nbdtr*.

**References**

[1]

*scipy.special.nbdtrc*

*scipy.special.nbdtrc*(\( k, n, p \)) = <ufunc 'nbdtrc'>

Negative binomial survival function.

Returns the sum of the terms \( k + 1 \) to infinity of the negative binomial distribution probability mass function,

\[
F = \sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j.
\]

In a sequence of Bernoulli trials with individual success probabilities \( p \), this is the probability that more than \( k \) failures precede the \( nth \) success.

**Parameters**

\( k \) [array_like] The maximum number of allowed failures (nonnegative int).
\( n \) [array_like] The target number of successes (positive int).
\( p \) [array_like] Probability of success in a single event (float).

**Returns**

\( F \) [ndarray] The probability of \( k + 1 \) or more failures before \( n \) successes in a sequence of events with individual success probability \( p \).
Notes

If floating point values are passed for \( k \) or \( n \), they will be truncated to integers.

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

\[
\text{nbdtrc}(k, n, p) = I_{1-p}(k + 1, n).
\]

Wrapper for the Cephes [1] routine \text{nbdtrc}.

References

[1]

\texttt{scipy.special.nbdtri}

\texttt{scipy.special.nbdtri}(k, n, y) = <ufunc 'nbdtri'>

Inverse of \text{nbdtr} vs \( p \).

Returns the inverse with respect to the parameter \( p \) of \( y = nbdtr(k, n, p) \), the negative binomial cumulative distribution function.

\textbf{Parameters}

\begin{itemize}
  \item \( k \) [array_like] The maximum number of allowed failures (nonnegative int).
  \item \( n \) [array_like] The target number of successes (positive int).
  \item \( y \) [array_like] The probability of \( k \) or fewer failures before \( n \) successes (float).
\end{itemize}

\textbf{Returns}

\( p \) [ndarray] Probability of success in a single event (float) such that \( nbdtr(k, n, p) = y \).

See also:

\texttt{nbdtr}

Cumulative distribution function of the negative binomial.

\texttt{nbdtrik}

Inverse with respect to \( k \) of \( nbdtr(k, n, p) \).

\texttt{nbdtrin}

Inverse with respect to \( n \) of \( nbdtr(k, n, p) \).

Notes

Wrapper for the Cephes [1] routine \text{nbdtri}.
References

[1]

scipy.special.nbdtrik

\texttt{scipy.special.nbdtrik}(y, n, p) = \texttt{ufunc 'nbdtrik'}

Inverse of \texttt{nbdtr} vs \( k \).

Returns the inverse with respect to the parameter \( k \) of \( y = \text{nbdtr}(k, n, p) \), the negative binomial cumulative distribution function.

\textit{Parameters}

- \( y \) [array_like] The probability of \( k \) or fewer failures before \( n \) successes (float).
- \( n \) [array_like] The target number of successes (positive int).
- \( p \) [array_like] Probability of success in a single event (float).

\textit{Returns}

- \( k \) [ndarray] The maximum number of allowed failures such that \( \text{nbdtr}(k, n, p) = y \).

\textit{See also:}

- \texttt{nbdtr}
  Cumulative distribution function of the negative binomial.
- \texttt{nbdtri}
  Inverse with respect to \( p \) of \( \text{nbdtr}(k, n, p) \).
- \texttt{nbdtrin}
  Inverse with respect to \( n \) of \( \text{nbdtr}(k, n, p) \).

\textit{Notes}

Wrapper for the CDFLIB [1] Fortran routine \texttt{cdfnbn}.

Formula 26.5.26 of [2],

\[
\sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j = I_{1-p}(k+1, n),
\]

is used to reduce calculation of the cumulative distribution function to that of a regularized incomplete beta \( I \).

Computation of \( k \) involves a search for a value that produces the desired value of \( y \). The search relies on the monotonicity of \( y \) with \( k \).
scipy.special.nbdtrin

scipy.special.nbdtrin(k, y, p) = <ufunc 'nbdtrin'>
Inverse of nbdtr vs n.
Returns the inverse with respect to the parameter $n$ of $y = nbdtr(k, n, p)$, the negative binomial cumulative distribution function.

**Parameters**
- **k** [array_like] The maximum number of allowed failures (nonnegative int).
- **y** [array_like] The probability of $k$ or fewer failures before $n$ successes (float).
- **p** [array_like] Probability of success in a single event (float).

**Returns**
- **n** [ndarray] The number of successes $n$ such that $nbdtr(k, n, p) = y$.

**See also:**
- **nbdtr** Cumulative distribution function of the negative binomial.
- **nbdtri** Inverse with respect to $p$ of $nbdtr(k, n, p)$.
- **nbdtrik** Inverse with respect to $k$ of $nbdtr(k, n, p)$.

**Notes**
Wrapper for the CDFLIB [1] Fortran routine *cdfnb*.  
Formula 26.5.26 of [2],
\[
\sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j = I_{1-p}(k+1, n),
\]
is used to reduce calculation of the cumulative distribution function to that of a regularized incomplete beta $I$.

Computation of $n$ involves a search for a value that produces the desired value of $y$. The search relies on the monotonicity of $y$ with $n$.

References
[1], [2]
References

[1], [2]

scipy.special.ncfdtr

`scipy.special.ncfdtr(dfn, dfd, nc, f) = <ufunc 'ncfdtr'>`

Cumulative distribution function of the non-central F distribution.

The non-central F describes the distribution of,

\[ Z = \frac{X/d_n}{Y/d_d} \]

where \( X \) and \( Y \) are independently distributed, with \( X \) distributed non-central \( \chi^2 \) with noncentrality parameter \( nc \) and \( d_n \) degrees of freedom, and \( Y \) distributed \( \chi^2 \) with \( d_d \) degrees of freedom.

**Parameters**

- `dfn` [array_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).
- `dfd` [array_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).
- `nc` [array_like] Noncentrality parameter. Should be in range (0, 1e4).
- `f` [array_like] Quantiles, i.e. the upper limit of integration.

**Returns**

- `cdf` [float or ndarray] The calculated CDF. If all inputs are scalar, the return will be a float. Otherwise it will be an array.

See also:

- `ncfdtri` Quantile function; inverse of `ncfdtr` with respect to \( f \).
- `ncfdtridfd` Inverse of `ncfdtr` with respect to \( dfd \).
- `ncfdtridfn` Inverse of `ncfdtr` with respect to \( dfn \).
- `ncfdtrinc` Inverse of `ncfdtr` with respect to \( nc \).

**Notes**

The cumulative distribution function is computed using Formula 26.6.20 of [2]:

\[ F(d_n, d_d, n_c, f) = \sum_{j=0}^{\infty} e^{-n_c/2} \frac{(n_c/2)^j}{j!} I_x \left( \frac{d_n}{2} + j, \frac{d_d}{2} \right), \]

where \( I \) is the regularized incomplete beta function, and \( x = fd_n/(fd_n + d_d) \).

The computation time required for this routine is proportional to the noncentrality parameter \( nc \). Very large values of this parameter can consume immense computer resources. This is why the search range is bounded by 10,000.
References

[1],[2]

Examples

```python
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt

Plot the CDF of the non-central F distribution, for nc=0. Compare with the F-distribution from scipy.stats:

```python
>>> x = np.linspace(-1, 8, num=500)
>>> dfn = 3
>>> dfd = 2
>>> ncf_stats = stats.f.cdf(x, dfn, dfd)
>>> ncf_special = special.ncfdtr(dfn, dfd, 0, x)
```  
```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, ncf_stats, 'b-', lw=3)
>>> ax.plot(x, ncf_special, 'r-')
>>> plt.show()
```
scipy.special.ncfdtridfd

scipy.special.ncfdtridfd(dfn, p, nc, f) = <ufunc 'ncfdtridfd'>

Calculate degrees of freedom (denominator) for the noncentral F-distribution.

This is the inverse with respect to dfd of ncfdtr. See ncfdtr for more details.

Parameters

- dfn [array_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).
- p [array_like] Value of the cumulative distribution function. Must be in the range [0, 1].
- nc [array_like] Noncentrality parameter. Should be in range (0, 1e4).
- f [array_like] Quantiles, i.e., the upper limit of integration.

Returns

- dfd [float] Degrees of freedom of the denominator sum of squares.

See also:

ncfdtr

CDF of the non-central F distribution.

ncfdtri

Quantile function; inverse of ncfdtr with respect to f.

ncfdtridfn

Inverse of ncfdtr with respect to dfn.

ncfdtrinc

Inverse of ncfdtr with respect to nc.

Notes

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom.

There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an
arbitrary one of the two values.

Examples

```python
>>> from scipy.special import ncfdtr, ncfdtridfd

Compute the CDF for several values of dfd:

>>> dfd = [1, 2, 3]
>>> p = ncfdtr(2, dfd, 0.25, 15)
>>> p
array([ 0.8097138 , 0.93020416, 0.96787852])

Compute the inverse. We recover the values of dfd, as expected:

>>> ncfdtridfd(2, p, 0.25, 15)
array([ 1., 2., 3.])
```
scipy.special.ncfdtridfn

scipy.special.ncfdtridfn(p, dfd, nc, f) = <ufunc 'ncfdtridfn'>
Calculate degrees of freedom (numerator) for the noncentral F-distribution.
This is the inverse with respect to dfn of ncftr. See ncftr for more details.

Parameters

- p [array_like] Value of the cumulative distribution function. Must be in the range [0, 1].
- dfd [array_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).
- nc [array_like] Noncentrality parameter. Should be in range (0, 1e4).
- f [float] Quantiles, i.e., the upper limit of integration.

Returns

- dfn [float] Degrees of freedom of the numerator sum of squares.

See also:

- ncftr
  CDF of the non-central F distribution.
- ncftridf
  Quantile function; inverse of ncftr with respect to f.
- ncftridfd
  Inverse of ncftr with respect to dfd.
- ncftrinc
  Inverse of ncftr with respect to nc.

Notes

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom.
There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an
arbitrary one of the two values.

Examples

```python
>>> from scipy.special import ncftr, ncftridfn
```

Compute the CDF for several values of dfn:

```python
>>> dfn = [1, 2, 3]
>>> p = ncftr(dfn, 2, 0.25, 15)
>>> p
array([ 0.92562363, 0.93020416, 0.93188394])
```

Compute the inverse. We recover the values of dfn, as expected:

```python
>>> ncftridfn(p, 2, 0.25, 15)
array([[ 1., 2., 3.]])
```
scipy.special.ncfdtri

scipy.special.ncfdtri(dfn, dfd, nc, p) = <ufunc 'ncfdtri'>
Inverse with respect to \( f \) of the CDF of the non-central F distribution.

See ncfctr for more details.

Parameters

- dfn [array_like] Degrees of freedom of the numerator sum of squares. Range (0, \( \infty \)).
- dfd [array_like] Degrees of freedom of the denominator sum of squares. Range (0, \( \infty \)).
- nc [array_like] Noncentrality parameter. Should be in range (0, \( 1e4 \)).
- p [array_like] Value of the cumulative distribution function. Must be in the range [0, 1].

Returns

- f [float] Quantiles, i.e., the upper limit of integration.

See also:
ncfctr
CDF of the non-central F distribution.
ncfdtridfd
Inverse of ncfctr with respect to dfd.
ncfdtridfn
Inverse of ncfctr with respect to dfn.
ncfdtrinc
Inverse of ncfctr with respect to nc.

Examples

```python
>>> from scipy.special import ncfctr, ncfdtri

Compute the CDF for several values of \( f \):

```python
def f = [0.5, 1, 1.5]
>>> p = ncfctr(2, 3, 1.5, f)
>>> p
array([0.20782291, 0.36107392, 0.47345752])
```

Compute the inverse. We recover the values of \( f \), as expected:

```python
>>> ncfdtri(2, 3, 1.5, p)
array([0.5, 1. , 1.5])
```
scipy.special.ncftrinc

scipy.special.ncftrinc(dfn, dfd, p, f) = <ufunc 'ncftrinc'>
Calculate non-centrality parameter for non-central F distribution.

This is the inverse with respect to nc of ncftr. See ncftr for more details.

Parameters

- dfn [array_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).
- dfd [array_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).
- p [array_like] Value of the cumulative distribution function. Must be in the range [0, 1].
- f [array_like] Quantiles, i.e., the upper limit of integration.

Returns

- nc [float] Noncentrality parameter.

See also:

- ncftr
  CDF of the non-central F distribution.
- ncftri
  Quantile function; inverse of ncftr with respect to f.
- ncftridfd
  Inverse of ncftr with respect to dfd.
- ncftridfn
  Inverse of ncftr with respect to dfn.

Examples

```python
>>> from scipy.special import ncftr, ncftrinc

Compute the CDF for several values of nc:

```python
>>> nc = [0.5, 1.5, 2.0]
>>> p = ncftr(2, 3, nc, 15)
>>> p
array([ 0.96309246, 0.94327955, 0.93304098])
```  

Compute the inverse. We recover the values of nc, as expected:

```python
>>> ncftrinc(2, 3, p, 15)
array([ 0.5, 1.5, 2.])
```
**scipy.special.nctdtr**

```
scipy.special.nctdtr(df, nc, t) = <ufunc 'nctdtr'>
```

Cumulative distribution function of the non-central t distribution.

**Parameters**

- `df` [array_like] Degrees of freedom of the distribution. Should be in range `(0, inf)`.  
- `nc` [array_like] Noncentrality parameter. Should be in range `(-1e6, 1e6)`.  
- `t` [array_like] Quantiles, i.e., the upper limit of integration.

**Returns**

- `cdf` [float or ndarray] The calculated CDF. If all inputs are scalar, the return will be a float. Otherwise, it will be an array.

**See also:**

- `nctdtrit`  
  Inverse CDF (iCDF) of the non-central t distribution.

- `nctdtridf`  
  Calculate degrees of freedom, given CDF and iCDF values.

- `nctdtrinc`  
  Calculate non-centrality parameter, given CDF iCDF values.

**Examples**

```python
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Plot the CDF of the non-central t distribution, for `nc=0`. Compare with the t-distribution from scipy.stats:

```python
>>> x = np.linspace(-5, 5, num=500)
>>> df = 3
>>> nct_stats = stats.t.cdf(x, df)
>>> nct_special = special.nctdtr(df, 0, x)
```

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, nct_stats, 'b-', lw=3)
>>> ax.plot(x, nct_special, 'r-')
>>> plt.show()
```
scipy.special.nctdtridf

scipy.special.nctdtridf(p, nc, t) = <ufunc 'nctdtridf'>
Calculate degrees of freedom for non-central t distribution.

See nctdtr for more details.

Parameters

p [array_like] CDF values, in range (0, 1).
nc [array_like] Noncentrality parameter. Should be in range (-1e6, 1e6).
t [array_like] Quantiles, i.e., the upper limit of integration.

scipy.special.nctdtrit

scipy.special.nctdtrit(df, nc, p) = <ufunc 'nctdtrit'>
Inverse cumulative distribution function of the non-central t distribution.

See nctdtr for more details.

Parameters

df [array_like] Degrees of freedom of the distribution. Should be in range (0, inf).
nc [array_like] Noncentrality parameter. Should be in range (-1e6, 1e6).
p [array_like] CDF values, in range (0, 1).
scipy.special.nctdtrinc

scipy.special.nctdtrinc(df, p, t) = <ufunc 'nctdtrinc'>

Calculate non-centrality parameter for non-central t distribution.

See nctdtr for more details.

Parameters

df [array_like] Degrees of freedom of the distribution. Should be in range (0, inf).
p [array_like] CDF values, in range (0, 1].
t [array_like] Quantiles, i.e., the upper limit of integration.

scipy.special.nrdtrimn

scipy.special.nrdtrimn(p, x, std) = <ufunc 'nrdtrimn'>

Calculate mean of normal distribution given other params.

Parameters

p [array_like] CDF values, in range (0, 1].
x [array_like] Quantiles, i.e. the upper limit of integration.
std [array_like] Standard deviation.

Returns

mn [float or ndarray] The mean of the normal distribution.

See also:

nrdtrimn, ndtr

scipy.special.nrdtrisd

scipy.special.nrdtrisd(p, x, mn) = <ufunc 'nrdtrisd'>

Calculate standard deviation of normal distribution given other params.

Parameters

p [array_like] CDF values, in range (0, 1].
x [array_like] Quantiles, i.e. the upper limit of integration.
mn [float or ndarray] The mean of the normal distribution.

Returns

std [array_like] Standard deviation.

See also:

ndtr
scipy.special.pdtr

`scipy.special.pdtr(k, m, out=None)` = `<ufunc 'pdtr'>`

Poisson cumulative distribution function.

Defined as the probability that a Poisson-distributed random variable with event rate \( m \) is less than or equal to \( k \). More concretely, this works out to be [1]

\[
\exp(-m) \sum_{j=0}^{[k]} \frac{m^j}{j!}.
\]

**Parameters**

- `k` [array_like] Nonnegative real argument
- `m` [array_like] Nonnegative real shape parameter
- `out` [ndarray] Optional output array for the function results

**Returns**

- scalar or ndarray
  Values of the Poisson cumulative distribution function

**See also:**

- `pdtrc`
  Poisson survival function

- `pdtrik`
  inverse of `pdtr` with respect to \( k \)

- `pdtri`
  inverse of `pdtr` with respect to \( m \)

**References**

[1]

**Examples**

```python
>>> import scipy.special as sc
```

It is a cumulative distribution function, so it converges to 1 monotonically as \( k \) goes to infinity.

```python
>>> sc.pdtr([1, 10, 100, np.inf], 1)
array([0.73575888, 0.99999999, 1., 1.])
```

It is discontinuous at integers and constant between integers.

```python
>>> sc.pdtr([1, 1.5, 1.9, 2], 1)
array([0.73575888, 0.73575888, 0.73575888, 0.9196986])
```
scipy.special.pdtrc

`scipy.special.pdtrc(k, m) = <ufunc 'pdtrc'>`

Poisson survival function

Returns the sum of the terms from k+1 to infinity of the Poisson distribution: 
\[ \text{sum} \left( \exp(-m) \cdot m^j / j!, \quad j=k+1..\infty \right) \]
\[ = \text{gammainc}(k+1, m) \]
Arguments must both be non-negative doubles.

scipy.special.pdtri

`scipy.special.pdtri(k, y) = <ufunc 'pdtri'>`

Inverse to pdtr vs m

Returns the Poisson variable m such that the sum from 0 to k of the Poisson density is equal to the given probability y: calculated by gammaincinv(k+1, y). k must be a nonnegative integer and y between 0 and 1.

scipy.special.pdtrik

`scipy.special.pdtrik(p, m) = <ufunc 'pdtrik'>`

Inverse to pdtr vs k

Returns the quantile k such that pdtr(k, m) = p

scipy.special.stdtr

`scipy.special.stdtr(df, t) = <ufunc 'stdtr'>`

Student t distribution cumulative distribution function

Returns the integral from minus infinity to t of the Student t distribution with df > 0 degrees of freedom:

\[
\frac{\Gamma((df+1)/2)}{\sqrt{df\pi}\Gamma(df/2)} \quad \int_{-\infty}^{t} (1+x**2/df)**(-df/2-1/2), \quad x=-\infty..t
\]

scipy.special.stdtridf

`scipy.special.stdtridf(p, t) = <ufunc 'stdtridf'>`

Inverse of stdtr vs df

Returns the argument df such that stdtr(df, t) is equal to p.

scipy.special.stdtrit

`scipy.special.stdtrit(df, p) = <ufunc 'stdtrit'>`

Inverse of stdtr vs t

Returns the argument t such that stdtr(df, t) is equal to p.
scipy.special.chdtr

scipy.special.chdtr(v, x, out=None) = <ufunc 'chdtr'>

Chi square cumulative distribution function.

Returns the area under the left tail (from 0 to x) of the Chi square probability density function with v degrees of freedom:

\[
\frac{1}{2^{v/2}\Gamma(v/2)} \int_0^x t^{v/2-1}e^{-t/2}dt
\]

Here \(\Gamma\) is the Gamma function; see gamma. This integral can be expressed in terms of the regularized lower incomplete gamma function gammainc as gammainc(v / 2, x / 2).[1]

Parameters

- v [array_like] Degrees of freedom.
- x [array_like] Upper bound of the integral.
- out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Values of the cumulative distribution function.

See also:

chdtrc, chdtri, chdtriv, gammainc

References

[1]

Examples

```python
>>> import scipy.special as sc
```

It can be expressed in terms of the regularized lower incomplete gamma function.

```python
>>> v = 1
>>> x = np.arange(4)
>>> sc.chdtr(v, x)
array([0.       , 0.68268949, 0.84270079, 0.91673548])
>>> sc.gammainc(v / 2, x / 2)
array([0.       , 0.68268949, 0.84270079, 0.91673548])
```
scipy.special.chdtrc

scipy.special.chdtrc(v, x, out=None) = <ufunc 'chdtrc'>

Chi square survival function.

Returns the area under the right hand tail (from x to infinity) of the Chi square probability density function with v degrees of freedom:

\[
\frac{1}{2^{v/2} \Gamma(v/2)} \int_x^{\infty} t^{v/2-1} e^{-t/2} dt
\]

Here \( \Gamma \) is the Gamma function; see \texttt{gamma}. This integral can be expressed in terms of the regularized upper incomplete gamma function \texttt{gammaincc} as \texttt{gammaincc(v/2, x/2)}. [1]

**Parameters**

- \( v \)  [array_like] Degrees of freedom.
- \( x \)  [array_like] Lower bound of the integral.
- \( \text{out} \)  [ndarray, optional] Optional output array for the function results.

**Returns**

- scalar or ndarray
  Values of the survival function.

**See also:**

\texttt{chdtr}, \texttt{chdtri}, \texttt{chdtriv}, \texttt{gammaincc}

**References**

[1]

**Examples**

```python
>>> import scipy.special as sc

It can be expressed in terms of the regularized upper incomplete gamma function.

```
scipy.special.chdtri

scipy.special.chdtri\(v, p, \text{out=None}\) = <ufunc 'chdtri'>

Inverse to \(chdtrc\) with respect to \(x\).

Returns \(x\) such that \(chdtrc(v, x) == p\).

**Parameters**

\(v\)  
[array_like] Degrees of freedom.

\(p\)  
[array_like] Probability.

\(\text{out}\)  
[ndarray, optional] Optional output array for the function results.

**Returns**

\(x\)  
[scalar or ndarray] Value so that the probability a Chi square random variable with \(v\) degrees of freedom is greater than \(x\) equals \(p\).

See also:

chdtrc, chdtr, chdtriv

**References**

[1]

**Examples**

```python
>>> import scipy.special as sc

It inverts \(chdtrc\).

>>> v, p = 1, 0.3
>>> sc.chdtrc(v, sc.chdtri(v, p))
0.3
>>> x = 1
>>> sc.chdtri(v, sc.chdtrc(v, x))
1.0
```

scipy.special.chdtriv

scipy.special.chdtriv\(p, x, \text{out=None}\) = <ufunc 'chdtriv'>

Inverse to \(chdtr\) with respect to \(v\).

Returns \(v\) such that \(chdtr(v, x) == p\).

**Parameters**

\(p\)  
[array_like] Probability that the Chi square random variable is less than or equal to \(x\).

\(x\)  
[array_like] Nonnegative input.

\(\text{out}\)  
[ndarray, optional] Optional output array for the function results.

**Returns**

**scalar or ndarray**

Degrees of freedom.
See also:

chdtr, chdtrc, chdtri

References

[1]

Examples

```python
>>> import scipy.special as sc

It inverts chdtr.

>>> p, x = 0.5, 1
>>> sc.chdtr(sc.chdtriv(p, x), x)
0.5000000000202172
>>> v = 1
>>> sc.chdtriv(sc.chdtr(v, x), v)
1.0000000000000013
```

**scipy.special.ndtr**

c scipy.special.ndtr(x) = <ufunc 'ndtr'>

Gaussian cumulative distribution function.

Returns the area under the standard Gaussian probability density function, integrated from minus infinity to \( x \)

\[
\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} \exp(-t^2/2) dt
\]

**Parameters**

- x : array_like, real or complex Argument

**Returns**

- ndarray The value of the normal CDF evaluated at \( x \)

See also:

- erf
- erfc
- scipy.stats.norm
- log_ndtr
scipy.special.log_ndtr

\texttt{scipy.special.log\textunderscore ndtr}(x) = \texttt{ufunc 'log\textunderscore ndtr'}

Logarithm of Gaussian cumulative distribution function.

Returns the log of the area under the standard Gaussian probability density function, integrated from minus infinity to \(x\):

\[
\log\left(\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} \exp\left(-t^2 / 2\right) dt\right)
\]

\textit{Parameters}

\(x\) [array_like, real or complex] Argument

\textit{Returns}

\(\text{ndarray}\) The value of the log of the normal CDF evaluated at \(x\)

See also:

\texttt{erf}
\texttt{erfc}
\texttt{scipy.stats.norm}
\texttt{ndtr}

scipy.special.ndtri

\texttt{scipy.special.ndtri}(y) = \texttt{ufunc 'ndtri'}

Inverse of \texttt{ndtr} vs \(x\)

Returns the argument \(x\) for which the area under the Gaussian probability density function (integrated from minus infinity to \(x\)) is equal to \(y\).

scipy.special.ndtri_exp

\texttt{scipy.special.ndtri\textunderscore exp}(y) = \texttt{ufunc 'ndtri\textunderscore exp'}

Inverse of \texttt{log\textunderscore ndtr} vs \(x\). Allows for greater precision than \texttt{ndtri} composed with \texttt{numpy.exp} for very small values of \(y\) and for \(y\) close to 0.

\textit{Parameters}

\(y\) [array_like of float]

\textit{Returns}

\texttt{scalar or ndarray}\n
Inverse of the log CDF of the standard normal distribution, evaluated at \(y\).

See also:

\texttt{log\textunderscore ndtr, ndtri, ndtr}
Examples

```python
>>> import scipy.special as sc

dndiexpagreesthennaitiveimplementationwhenthelatterdoesnotsufferfromunderflow.

```n```python
>>> sc.ndtri_exp(-1)
-0.33747496376420244
```n```python
>>> sc.ndtri(np.exp(-1))
-0.33747496376420244

For extreme values of y, the naive approach fails

```python
>>> sc.ndtri(np.exp(-800))
-inf
```n```python
```n```python
>>> sc.ndtri(np.exp(-1e-20))
inf

whereas `ndtri_exp` is still able to compute the result to high precision.

```python
>>> sc.ndtri_exp(-800)
-39.88469483825668
```n```python
```n```python
>>> sc.ndtri_exp(-1e-20)
9.262340089798409
```

`scipy.special.chndtr`

`scipy.special.chndtr(x, df, nc) = <ufunc 'chndtr'>`

Non-central chi square cumulative distribution function

`scipy.special.chndtridf`

`scipy.special.chndtridf(x, p, nc) = <ufunc 'chndtridf'>`

Inverse to `chndtr` vs `df`

`scipy.special.chndtrinc`

`scipy.special.chndtrinc(x, df, p) = <ufunc 'chndtrinc'>`

Inverse to `chndtr` vs `nc`

`scipy.special.chndtrix`

`scipy.special.chndtrix(p, df, nc) = <ufunc 'chndtrix'>`

Inverse to `chndtr` vs `x`
scipy.special.smirnov

scipy.special.smirnov(n, d) = <ufunc 'smirnov'>

Kolmogorov-Smirnov complementary cumulative distribution function

Returns the exact Kolmogorov-Smirnov complementary cumulative distribution function (aka the Survival Function) of Dn+ (or Dn-) for a one-sided test of equality between an empirical and a theoretical distribution. It is equal to the probability that the maximum difference between a theoretical distribution and an empirical one based on n samples is greater than d.

Parameters

- n [int] Number of samples
- d [float array_like] Deviation between the Empirical CDF (ECDF) and the target CDF.

Returns

- float The value(s) of smirnov(n, d), Prob(Dn+ >= d) (Also Prob(Dn- >= d))

See also:

- smirnovi The Inverse Survival Function for the distribution
- scipy.stats.ksone Provides the functionality as a continuous distribution
- kolmogorov, kolmogi Functions for the two-sided distribution

Notes

smirnov is used by stats.kstest in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in scipy.special, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the stats.ksone distribution.

Examples

```python
>>> from scipy.special import smirnov

Show the probability of a gap at least as big as 0, 0.5 and 1.0 for a sample of size 5

```python
>>> smirnov(5, [0, 0.5, 1.0])
array([ 1. , 0.056, 0. ])
```  

Compare a sample of size 5 drawn from a source N(0.5, 1) distribution against a target N(0, 1) CDF.

```python
>>> from scipy.stats import norm
>>> rng = np.random.default_rng()
>>> n = 5
>>> gendist = norm(0.5, 1)  # Normal distribution, mean 0.5, stddev 1
>>> x = np.sort(gendist.rvs(size=n, random_state=rng))
>>> x
array([-1.3922078 , -0.13526532, 0.1371477 , 0.18981686, 1.81948167])
```
>>> target = norm(0, 1)
>>> cdfs = target.cdf(x)
>>> cdfs
array([0.08192974, 0.44620105, 0.55427368, 0.96558101])

# Construct the Empirical CDF and the K-S statistics (Dn+, Dn-, Dn)
>>> ecdfs = np.arange(n+1, dtype=float)/n
>>> cols = np.column_stack([x, ecdfs[1:], cdfs, cdfs - ecdfs[:n],
               -ecdfs[1:] - cdfs])
>>> np.set_printoptions(precision=3)
>>> cols
array([[-1.392, 0.2 , 0.082, 0.082, 0.118],
        [-0.135, 0.4 , 0.446, 0.246, -0.046],
        [ 0.137, 0.6 , 0.555, 0.155, 0.045],
        [ 0.19 , 0.8 , 0.575, -0.025, 0.225],
        [ 1.819, 1. , 0.966, 0.166, 0.034]])

>>> gaps = cols[:, -2:]
>>> Dnpm = np.max(gaps, axis=0)
>>> print('Dn-=%f, Dn+=%f' % (Dnpm[0], Dnpm[1]))
Dn-=0.246201, Dn+=0.224726
>>> probs = smirnov(n, Dnpm)
>>> print(chr(10).join(['For a sample of size %d drawn from a N(0, 1)
                distribution:
                ' % n,
                ...    ' Smirnov n=%d: Prob(Dn- >= %f) = %.4f' % (n, Dnpm[0],
                ...              -probs[0]),
                ...    ' Smirnov n=%d: Prob(Dn+ >= %f) = %.4f' % (n, Dnpm[1],
                ...              -probs[1]))
        ]))
For a sample of size 5 drawn from a N(0, 1) distribution:
Smirnov n=5: Prob(Dn- >= 0.246201) = 0.4713
Smirnov n=5: Prob(Dn+ >= 0.224726) = 0.5243

Plot the Empirical CDF against the target N(0, 1) CDF

>>> import matplotlib.pyplot as plt
>>> plt.step(np.concatenate([[-3], x]), ecdfs, where='post', label=
              'Empirical CDF')
>>> x3 = np.linspace(-3, 3, 100)
>>> plt.plot(x3, target.cdf(x3), label='CDF for N(0, 1)')
>>> plt.ylim([0, 1]); plt.grid(True); plt.legend();
# Add vertical lines marking Dn+ and Dn-
>>> iminus, iplus = np.argmax(gaps, axis=0)
>>> plt.vlines([x[iminus]], ecdfs[iminus], cdfs[iminus], color='r',
              linestyle='dashed', lw=4)
>>> plt.vlines([x[iplus]], cdfs[iplus], ecdfs[iplus+1], color='m',
              linestyle='dashed', lw=4)
>>> plt.show()
scipy.special.smirnovi

`scipy.special.smirnovi(n, p) = <ufunc 'smirnovi'>`

Inverse to `smirnov`

Returns $d$ such that $\text{smirnov}(n, d) == p$, the critical value corresponding to $p$.

**Parameters**

- **n** [int] Number of samples
- **p** [float array_like] Probability

**Returns**

- **float** The value(s) of `smirnovi(n, p)`, the critical values.

**See also:**

- `smirnov`
  - The Survival Function (SF) for the distribution
- `scipy.stats.ksone`
  - Provides the functionality as a continuous distribution
- `kolmogorov, kolmogi, scipy.stats.kstwobign`
  - Functions for the two-sided distribution
Notes

`smirnov` is used by `stats.kstest` in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in `scipy.special`, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the `stats.ksone` distribution.

`scipy.special.kolmogorov`

`scipy.special.kolmogorov(y) = <ufunc 'kolmogorov'>`

Complementary cumulative distribution (Survival Function) function of Kolmogorov distribution.

Returns the complementary cumulative distribution function of Kolmogorov’s limiting distribution \((\sqrt{n} \cdot D_n)\) as \(n\) goes to infinity) of a two-sided test for equality between an empirical and a theoretical distribution. It is equal to the (limit as \(n\to\infty\) of the) probability that \(\sqrt{n} \cdot \max \text{ absolute deviation} > y\).

Parameters

- `y` : [float array_like] Absolute deviation between the Empirical CDF (ECDF) and the target CDF, multiplied by \(\sqrt{n}\).

Returns

- `float` : The value(s) of `kolmogorov(y)`

See also:

- `kolmogi` : The Inverse Survival Function for the distribution
- `scipy.stats.kstwobign` : Provides the functionality as a continuous distribution
- `smirnov, smirnovi` : Functions for the one-sided distribution

Notes

`kolmogorov` is used by `stats.kstest` in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in `scipy.special`, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the `stats.kstwobign` distribution.

Examples

Show the probability of a gap at least as big as 0, 0.5 and 1.0.

```python
>>> from scipy.special import kolmogorov
>>> from scipy.stats import kstwobign
>>> kolmogorov([0, 0.5, 1.0])
array([ 1.        , 0.96394524, 0.26999967])
```

Compare a sample of size 1000 drawn from a Laplace(0, 1) distribution against the target distribution, a Normal(0, 1) distribution.
>>> from scipy.stats import norm, laplace
>>> rng = np.random.default_rng()
>>> n = 1000
>>> lap01 = laplace(0, 1)
>>> x = np.sort(lap01.rvs(n, random_state=rng))
>>> np.mean(x), np.std(x)
(-0.05841730131499543, 1.3968109101997568)

Construct the Empirical CDF and the K-S statistic $D_n$.

```python
>>> target = norm(0,1)  # Normal mean 0, stddev 1
>>> cdfs = target.cdf(x)
>>> ecdfs = np.arange(n+1, dtype=float)/n
>>> gaps = np.column_stack([cdfs - ecdfs[:n], ecdfs[1:] - cdfs])
>>> Dn = np.max(gaps)
>>> Kn = np.sqrt(n) * Dn
>>> print('Dn=%f, sqrt(n)*Dn=%f' % (Dn, Kn))
Dn=0.043363, sqrt(n)*Dn=1.371265
```

For a sample of size $n$ drawn from a $N(0, 1)$ distribution:
the approximate Kolmogorov probability that $\sqrt{n}\times D_n \geq \sqrt{n}\times D_n$ is $0.046533$
the approximate Kolmogorov probability that $\sqrt{n}\times D_n \leq \sqrt{n}\times D_n$ is $0.953467$

Plot the Empirical CDF against the target $N(0, 1)$ CDF.

```python
>>> import matplotlib.pyplot as plt
>>> x3 = np.linspace(-3, 3, 100)
>>> plt.plot(x3, target.cdf(x3), label='CDF for N(0, 1)')
>>> plt.ylim([0, 1]); plt.grid(True); plt.legend();
>>> # Add vertical lines marking $D_n+$ and $D_n-$
>>> iminus, iplus = np.argmax(gaps, axis=0)
>>> plt.vlines([x[iminus]], ecdfs[iminus], cdfs[iminus], color='r',
             linestyle='dashed', lw=4)
>>> plt.vlines([x[plus]], cdfs[plus], ecdfs[plus+1], color='r',
             linestyle='dashed', lw=4)
>>> plt.show()
```
scipy.special.kolmogi

scipy.special.kolmogi(p) = <ufunc 'kolmogi'>
Inverse Survival Function of Kolmogorov distribution

It is the inverse function to kolmogorov. Returns y such that kolmogorov(y) == p.

Parameters

p [float array_like] Probability

Returns

float The value(s) of kolmogi(p)

See also:

kolmogorov
The Survival Function for the distribution

scipy.stats.kstwobign
Provides the functionality as a continuous distribution

smirnov, smirnovi
Functions for the one-sided distribution

3.3. API definition
**Notes**

`kolmogorov` is used by `stats.kstest` in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in `scipy.special`, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the `stats.kstwobign` distribution.

**Examples**

```python
>>> from scipy.special import kolmogi
>>> kolmogi([0, 0.1, 0.25, 0.5, 0.75, 0.9, 1.0])
array([ inf, 1.22384787, 1.01918472, 0.82757356, 0.67644769,
         0.57117327, 0.])
```

**scipy.special.tklmbda**

`scipy.special.tklmbda(x, lmbda) = <ufunc 'tklmbda'>`

Tukey-Lambda cumulative distribution function.

**scipy.special.logit**

`scipy.special.logit(x) = <ufunc 'logit'>`

Logit ufunc for ndarrays.

The logit function is defined as logit(p) = log(p/(1-p)). Note that logit(0) = -inf, logit(1) = inf, and logit(p) for p<0 or p>1 yields nan.

**Parameters**

- `x` [ndarray] The ndarray to apply logit to element-wise.

**Returns**

- `out` [ndarray] An ndarray of the same shape as x. Its entries are logit of the corresponding entry of x.

**See also:**

- `expit`

**Notes**

As a ufunc logit takes a number of optional keyword arguments. For more information see `ufuncs`

New in version 0.10.0.
Examples

```python
>>> from scipy.special import logit, expit

>>> logit([0, 0.25, 0.5, 0.75, 1])
array([-inf, -1.09861229, 0., 1.09861229, inf])

expit is the inverse of logit:

>>> expit(logit([0.1, 0.75, 0.999]))
array([ 0.1 , 0.75 , 0.999])
```

Plot logit(x) for x in [0, 1]:

```python
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 1, 501)
>>> y = logit(x)
>>> plt.plot(x, y)
>>> plt.grid()
>>> plt.ylim(-6, 6)
>>> plt.xlabel('x')
>>> plt.title('logit(x)')
>>> plt.show()
```

![Plot of logit(x) for x in [0, 1]](image-url)
**scipy.special.expit**

```python
scipy.special.expit(x) = <ufunc 'expit'>
```

Exipt (a.k.a. logistic sigmoid) ufunc for ndarrays.

The expit function, also known as the logistic sigmoid function, is defined as $\expit(x) = 1/(1+\exp(-x))$. It is the inverse of the logit function.

**Parameters**

- **x** ([ndarray]) The ndarray to apply expit to element-wise.

**Returns**

- **out** ([ndarray]) An ndarray of the same shape as x. Its entries are expit of the corresponding entry of x.

**See also:**

logit

**Notes**

As a ufunc expit takes a number of optional keyword arguments. For more information see ufuncs

New in version 0.10.0.

**Examples**

```python
>>> from scipy.special import expit, logit

>>> expit([-np.inf, -1.5, 0, 1.5, np.inf])
array([ 0. , 0.18242552, 0.5 , 0.81757448, 1. ])

logit is the inverse of expit:

>>> logit(expit([-2.5, 0, 3.1, 5.0]))
array([-2.5, 0. , 3.1, 5. ])
```

Plot expit(x) for x in [-6, 6]:

```python
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-6, 6, 121)
>>> y = expit(x)
>>> plt.plot(x, y)
>>> plt.grid()
>>> plt.xlim(-6, 6)
>>> plt.xlabel('x')
>>> plt.title('expit(x)')
>>> plt.show()
```
scipy.special.log_expit

scipy.special.log_expit(x) = <ufunc 'log_expit'>
Logarithm of the logistic sigmoid function.

The SciPy implementation of the logistic sigmoid function is scipy.special.expit, so this function is called log_expit.

The function is mathematically equivalent to \( \log(\text{expit}(x)) \), but is formulated to avoid loss of precision for inputs with large (positive or negative) magnitude.

Parameters
- x [array_like] The values to apply log_expit to element-wise.

Returns
- out [ndarray] The computed values, an ndarray of the same shape as x.

See also:
- expit

Notes

As a ufunc, log_expit takes a number of optional keyword arguments. For more information see ufuncs
New in version 1.8.0.
Examples

```python
>>> from scipy.special import log_expit, expit

>>> log_expit([-3.0, 0.25, 2.5, 5.0])
array([-3.04858735, -0.57593942, -0.07888973, -0.00671535])

Large negative values:

```python
>>> log_expit([-100, -500, -1000])
array([-100., -500., -1000.])

Note that expit(-1000) returns 0, so the naive implementation \( \log(\text{expit}(-1000)) \) return -inf.

Large positive values:

```python
>>> log_expit([29, 120, 400])
array([-2.54366565e-013, -7.66764807e-053, -1.91516960e-174])

Compare that to the naive implementation:

```python
>>> np.log(expit([29, 120, 400]))
array([-2.54463117e-13, 0.00000000e+00, 0.00000000e+00])

The first value is accurate to only 3 digits, and the larger inputs lose all precision and return 0.

scipy.special.boxcox

```python
scipy.special.boxcox(x, lmbda) = <ufunc 'boxcox'>
```

Compute the Box-Cox transformation.

The Box-Cox transformation is:

```latex
y = (x**lmbda - 1) / lmbda \quad \text{if } lmbda \neq 0
\log(x) \quad \text{if } lmbda == 0
```

Returns \( \text{nan} \) if \( x < 0 \). Returns \( -\infty \) if \( x == 0 \) and \( lmbda < 0 \).

Parameters

- \( x \) [array_like] Data to be transformed.
- \( lmbda \) [array_like] Power parameter of the Box-Cox transform.

Returns

- \( y \) [array] Transformed data.
Notes

New in version 0.14.0.

Examples

```python
>>> from scipy.special import boxcox
>>> boxcox([1, 4, 10], 2.5)
array([ 0. , 12.4 , 126.09110641])
>>> boxcox(2, [0, 1, 2])
array([ 0.69314718, 1. , 1.5 ])```

```
scipy.special.boxcox1p

scipy.special.boxcox1p(x, lmbda) = <ufunc 'boxcox1p'>

Compute the Box-Cox transformation of 1 + x.

The Box-Cox transformation computed by `boxcox1p` is:

\[
y = \frac{(1+x)^*lmbda - 1}{lmbda} \quad \text{if } lmbda \neq 0
\]
\[
\log(1+x) \quad \text{if } lmbda = 0
\]

Returns `nan` if \( x < -1 \). Returns `-inf` if \( x = -1 \) and \( lmbda < 0 \).

Parameters

- **x** [array_like] Data to be transformed.
- **lmbda** [array_like] Power parameter of the Box-Cox transform.

Returns

- **y** [array] Transformed data.

Notes

New in version 0.14.0.

Examples

```python
>>> from scipy.special import boxcox1p
>>> boxcox1p(1e-4, [0, 0.5, 1])
array([ 9.99950003e-05, 9.99975001e-05, 1.00000000e-04])
>>> boxcox1p([0.01, 0.1], 0.25)
array([ 0.00996272, 0.09645476])
```
scipy.special.inv_boxcox

scipy.special.inv_boxcox(y, lmbda) = <ufunc 'inv_boxcox'>
Compute the inverse of the Box-Cox transformation.

Find x such that:

\[
y = \begin{cases} 
(x^{lmbda} - 1) / lmbda & \text{if } lmbda \neq 0 \\
\log(x) & \text{if } lmbda = 0 
\end{cases}
\]

Parameters

    y [array_like] Data to be transformed.
    lmbda [array_like] Power parameter of the Box-Cox transform.

Returns

    x [array] Transformed data.

Notes

New in version 0.16.0.

Examples

>>> from scipy.special import boxcox, inv_boxcox
>>> y = boxcox([1, 4, 10], 2.5)
>>> inv_boxcox(y, 2.5)
array([1., 4., 10.])

scipy.special.inv_boxcox1p

scipy.special.inv_boxcox1p(y, lmbda) = <ufunc 'inv_boxcox1p'>
Compute the inverse of the Box-Cox transformation.

Find x such that:

\[
y = \begin{cases} 
((1+x)^{lmbda} - 1) / lmbda & \text{if } lmbda \neq 0 \\
\log(1+x) & \text{if } lmbda = 0 
\end{cases}
\]

Parameters

    y [array_like] Data to be transformed.
    lmbda [array_like] Power parameter of the Box-Cox transform.

Returns

    x [array] Transformed data.
Notes

New in version 0.16.0.

Examples

```python
>>> from scipy.special import boxcox1p, inv_boxcox1p
>>> y = boxcox1p([1, 4, 10], 2.5)
>>> inv_boxcox1p(y, 2.5)
array([1., 4., 10.])
```

**scipy.special.owens_t**

`scipy.special.owens_t(h, a) = <ufunc 'owens_t'>`

Owen's T Function.

The function $T(h, a)$ gives the probability of the event $(X > h$ and $0 < Y < a \cdot X)$ where $X$ and $Y$ are independent standard normal random variables.

**Parameters**

- **h**: array_like
  - Input value.
- **a**: array_like
  - Input value.

**Returns**

- **t**: scalar or ndarray
  - Probability of the event $(X > h$ and $0 < Y < a \cdot X)$, where $X$ and $Y$ are independent standard normal random variables.

References

[1]

Examples

```python
>>> from scipy import special
>>> a = 3.5
>>> h = 0.78
>>> special.owens_t(h, a)
0.10877216734852274
```

#### scipy.special.entr

```python
scipy.special.entr(x) = <ufunc 'entr'>
```

Elementwise function for computing entropy.

\[
\text{entr}(x) = \begin{cases} 
-x \log(x) & x > 0 \\
0 & x = 0 \\
-\infty & \text{otherwise}
\end{cases}
\]

**Parameters**
- `x` [ndarray] Input array.

**Returns**
- `res` [ndarray] The value of the elementwise entropy function at the given points `x`.

**See also:**
- `kl_div`, `rel_entr`

**Notes**
This function is concave.
New in version 0.15.0.

#### scipy.special.rel_entr

```python
scipy.special.rel_entr(x, y, out=None) = <ufunc 'rel_entr'>
```

Elementwise function for computing relative entropy.

\[
\text{rel_entr}(x, y) = \begin{cases} 
x \log(x/y) & x > 0, y > 0 \\
0 & x = 0, y \geq 0 \\
\infty & \text{otherwise}
\end{cases}
\]

**Parameters**
- `x, y` [array_like] Input arrays
- `out` [ndarray, optional] Optional output array for the function results

**Returns**
- `scalar or ndarray` Relative entropy of the inputs

See also:

entr, kl_div

Notes

New in version 0.15.0.

This function is jointly convex in x and y.

The origin of this function is in convex programming; see [1]. Given two discrete probability distributions $p_1, \ldots, p_n$ and $q_1, \ldots, q_n$, to get the relative entropy of statistics compute the sum

$$
\sum_{i=1}^n \text{rel}_\text{entr}(p_i, q_i).
$$

References

[1], [2]

scipy.special.kl_div

scipy.special.kl_div(x, y, out=None) = <ufunc 'kl_div'>

Elementwise function for computing Kullback-Leibler divergence.

$$
\text{kl}_\text{div}(x, y) = \begin{cases} 
  x \log(x/y) - x + y & x > 0, y > 0 \\
  y & x = 0, y \geq 0 \\
  \infty & \text{otherwise}
\end{cases}
$$

Parameters

x, y [array_like] Real arguments

out [ndarray, optional] Optional output array for the function results

Returns

scalar or ndarray

Values of the Kullback-Liebler divergence.

See also:

entr, rel_entr

Notes

New in version 0.15.0.

This function is non-negative and is jointly convex in x and y.

The origin of this function is in convex programming; see [1] for details. This is why the the function contains the extra $-x+y$ terms over what might be expected from the Kullback-Leibler divergence. For a version of the function without the extra terms, see rel_entr.
References

[1]

scipy.special.huber

`scipy.special.huber(delta, r) = <ufunc 'huber'>`

Huber loss function.

\[
\text{huber}(\delta, r) = \begin{cases} 
\infty & \delta < 0 \\
\frac{1}{2} r^2 & 0 \leq \delta, |r| \leq \delta \\
\delta(|r| - \frac{1}{2} \delta) & \text{otherwise}
\end{cases}
\]

Parameters

- `delta` [ndarray] Input array, indicating the quadratic vs. linear loss changepoint.
- `r` [ndarray] Input array, possibly representing residuals.

Returns

- `res` [ndarray] The computed Huber loss function values.

Notes

This function is convex in \( r \).
New in version 0.15.0.

scipy.special.pseudo_huber

`scipy.special.pseudo_huber(delta, r) = <ufunc 'pseudo_huber'>`

Pseudo-Huber loss function.

\[
\text{pseudo}_\text{huber}(\delta, r) = \delta^2 \left( \sqrt{1 + \left( \frac{r}{\delta} \right)^2} - 1 \right)
\]

Parameters

- `delta` [ndarray] Input array, indicating the soft quadratic vs. linear loss changepoint.
- `r` [ndarray] Input array, possibly representing residuals.

Returns

Notes

This function is convex in \( r \).
New in version 0.15.0.

scipy.special.gamma

scipy.special.gamma(z) = <ufunc 'gamma'>

gamma function.

The gamma function is defined as

\[ \Gamma(z) = \int_0^{\infty} t^{z-1} e^{-t} dt \]

for \( \Re(z) > 0 \) and is extended to the rest of the complex plane by analytic continuation. See [dlmf] for more details.

Parameters

- z : [array_like] Real or complex valued argument

Returns

- scalar or ndarray Values of the gamma function
Notes

The gamma function is often referred to as the generalized factorial since \( \Gamma(n + 1) = n! \) for natural numbers \( n \). More generally it satisfies the recurrence relation \( \Gamma(z + 1) = z \cdot \Gamma(z) \) for complex \( z \), which, combined with the fact that \( \Gamma(1) = 1 \), implies the above identity for \( z = n \).

References

[dlmf]

Examples

```python
>>> from scipy.special import gamma, factorial

>>> gamma([0, 0.5, 1, 5])
array([ inf, 1.77245385, 1. , 24. ])

>>> z = 2.5 + 1j
>>> gamma(z)
(0.77476210455108352+0.70763120437959293j)
>>> gamma(z+1), z*gamma(z)  # Recurrence property
((1.2292740569981158+2.5438401155000658j),
 (1.2292740569981158+2.5438401155000658j))

>>> gamma(0.5)**2  # gamma(0.5) = sqrt(pi)
3.1415926535897927

Plot gamma(x) for real x

>>> x = np.linspace(-3.5, 5.5, 2251)
>>> y = gamma(x)

>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'b', alpha=0.6, label='gamma(x)')
>>> k = np.arange(1, 7)
>>> plt.plot(k, factorial(k-1), 'k*', alpha=0.6,
... label='(x-1)!, x = 1, 2, ...')
>>> plt.xlim(-3.5, 5.5)
>>> plt.ylim(-10, 25)
>>> plt.grid()
>>> plt.xlabel('x')
>>> plt.ylabel('gamma(x)')
>>> plt.legend(loc='lower right')
>>> plt.show()
```
**scipy.special.gammaln**

*scipy.special.gammaln(x, out=None) = <ufunc 'gammaln'>*

Logarithm of the absolute value of the gamma function.

Defined as

\[ \ln(|\Gamma(x)|) \]

where \( \Gamma \) is the gamma function. For more details on the gamma function, see [dlmf].

**Parameters**

- **x** [array_like] Real argument
- **out** [ndarray, optional] Optional output array for the function results

**Returns**

- **scalar or ndarray**
  Values of the log of the absolute value of gamma

See also:

- **gammasgn**
  sign of the gamma function
- **loggamma**
  principal branch of the logarithm of the gamma function
Notes

It is the same function as the Python standard library function \texttt{math.lgamma}.

When used in conjunction with \texttt{gammasgn}, this function is useful for working in logspace on the real axis without having to deal with complex numbers via the relation \( \exp(\text{gammaln}(x)) = \text{gammasgn}(x) \times \text{gamma}(x) \).

For complex-valued log-gamma, use \texttt{loggamma} instead of \texttt{gammaln}.

References

[dlmf]

Examples

```python
>>> import scipy.special as sc
```

It has two positive zeros.

```python
>>> sc.gammaln([1, 2])
array([0., 0.])
```

It has poles at nonpositive integers.

```python
>>> sc.gammaln([0, -1, -2, -3, -4])
array([inf, inf, inf, inf, inf])
```

It asymptotically approaches \( x \times \log(x) \) (Stirling’s formula).

```python
>>> x = np.array([1e10, 1e20, 1e40, 1e80])
>>> sc.gammaln(x)
array([2.20258509e+11, 4.50517019e+21, 9.11034037e+41, 1.83206807e+82])
>>> x * np.log(x)
array([2.30258509e+11, 4.60517019e+21, 9.21034037e+41, 1.84206807e+82])
```

\texttt{scipy.special.loggamma}

\texttt{scipy.special.loggamma}(z, out=None) = <ufunc 'loggamma'>

Principal branch of the logarithm of the gamma function.

Defined to be \( \log(\Gamma(x)) \) for \( x > 0 \) and extended to the complex plane by analytic continuation. The function has a single branch cut on the negative real axis.

New in version 0.18.0.

Parameters

- **z** [array-like] Values in the complex plain at which to compute \texttt{loggamma}
- **out** [ndarray, optional] Output array for computed values of \texttt{loggamma}

Returns

- **loggamma** [ndarray] Values of \texttt{loggamma} at z.

See also:
**gammaln**

logarithm of the absolute value of the gamma function

**gammagammasgn**

sign of the gamma function

### Notes

It is not generally true that \( \log \Gamma(z) = \log(\Gamma(z)) \), though the real parts of the functions do agree. The benefit of not defining \( \loggamma \) as \( \log(\Gamma(z)) \) is that the latter function has a complicated branch cut structure whereas \( \loggamma \) is analytic except for on the negative real axis.

The identities

\[
\exp(\log \Gamma(z)) = \Gamma(z) \\
\log \Gamma(z + 1) = \log(z) + \log \Gamma(z)
\]

make \( \loggamma \) useful for working in complex logspace.

On the real line \( \loggamma \) is related to \( \gammaln \) via \( \exp(\loggamma(x + 0j)) = \gammagammasgn(x) \times \exp(\gammaln(x)) \), up to rounding error.

The implementation here is based on [hare1997].

### References

[hare1997]

**scipy.special.gammasgn**

\[ \text{scipy.special.gammasgn}(x) = \text{<ufunc 'gammasgn'}}> \]

Sign of the gamma function.

It is defined as

\[
\text{gammagammasgn}(x) = \begin{cases} 
  +1 & \Gamma(x) > 0 \\
  -1 & \Gamma(x) < 0 
\end{cases}
\]

where \( \Gamma \) is the gamma function; see \( \text{gamma} \). This definition is complete since the gamma function is never zero; see the discussion after [dlmf].

**Parameters**

- \( x \) [array_like] Real argument

**Returns**

- scalar or ndarray

  Sign of the gamma function

**See also:**

- \( \text{gamma} \)

  the gamma function

3.3. API definition 2259
**gammaln**

log of the absolute value of the gamma function

**loggamma**

analytic continuation of the log of the gamma function

**Notes**

The gamma function can be computed as \( \text{gammag}
\text{sn}(x) \times \exp(\text{gammaln}(x)) \).

**References**

[dlmf]

**Examples**

```python
>>> import scipy.special as sc
```

It is 1 for \( x > 0 \).

```python
>>> sc.gammag
\text{sn}([1, 2, 3, 4])
array([1., 1., 1., 1.])
```

It alternates between -1 and 1 for negative integers.

```python
>>> sc.gammag
\text{sn}([-0.5, -1.5, -2.5, -3.5])
array([-1., 1., -1., 1.])
```

It can be used to compute the gamma function.

```python
>>> x = [1.5, 0.5, -0.5, -1.5]
>>> sc.gammag
\text{sn}(x) \times \exp(sc.gammaln(x))
array([0.88622693, 1.77245385, -3.5449077, 2.3632718])
>>> sc.gammainc(x)
array([0.88622693, 1.77245385, -3.5449077, 2.3632718])
```

**scipy.special.gammainc**

\texttt{scipy.special.gammainc}(a, x) = <ufunc 'gammainc'>

Regularized lower incomplete gamma function.

It is defined as

\[
P(a,x) = \frac{1}{\Gamma(a)} \int_0^x t^{a-1} e^{-t} dt
\]

for \( a > 0 \) and \( x \geq 0 \). See [dlmf] for details.

**Parameters**

- **a** [array_like] Positive parameter
- **x** [array_like] Nonnegative argument
**Returns**

`scalar or ndarray`

Values of the lower incomplete gamma function

**See also:**

`gammaincc`

regularized upper incomplete gamma function

`gammaincinv`

inverse of the regularized lower incomplete gamma function

`gammainccinv`

inverse of the regularized upper incomplete gamma function

**Notes**

The function satisfies the relation $\text{gammainc}(a, x) + \text{gammaincc}(a, x) = 1$ where $\text{gammaincc}$ is the regularized upper incomplete gamma function.

The implementation largely follows that of [boost].

**References**

[dlmf], [boost]

**Examples**

```python
>>> import scipy.special as sc
```

It is the CDF of the gamma distribution, so it starts at 0 and monotonically increases to 1.

```python
>>> sc.gammainc(0.5, [0, 1, 10, 100])
array([0. , 0.84270079, 0.99999226, 1.])
```

It is equal to one minus the upper incomplete gamma function.

```python
>>> a, x = 0.5, 0.4
>>> sc.gammainc(a, x)
0.6289066304773024
>>> 1 - sc.gammaincc(a, x)
0.6289066304773024
```
scipy.special.gammaincinv

```python
gammaincinv \(a, y\) = \text{<ufunc 'gammaincinv'>}
```

Inverse to the regularized lower incomplete gamma function.

Given an input \(y\) between 0 and 1, returns \(x\) such that \(y = P(a,x)\). Here \(P\) is the regularized lower incomplete gamma function; see \texttt{gammainc}. This is well-defined because the lower incomplete gamma function is monotonic as can be seen from its definition in \[\text{dlmf}\].

**Parameters**

- \(a\) [array_like] Positive parameter
- \(y\) [array_like] Parameter between 0 and 1, inclusive

**Returns**

- scalar or ndarray Values of the inverse of the lower incomplete gamma function

See also:

- \texttt{gammainc} regularized lower incomplete gamma function
- \texttt{gammaincc} regularized upper incomplete gamma function
- \texttt{gammainccinv} inverse of the regularized upper incomplete gamma function

**References**

- \[\text{dlmf}\]

**Examples**

```python
>>> import scipy.special as sc
```

It starts at 0 and monotonically increases to infinity.

```python
>>> sc.gammaincinv(0.5, [0, 0.1, 0.5, 1])
array([0. , 0.00789539, 0.22746821, inf])
```

It inverts the lower incomplete gamma function.

```python
>>> a, x = 0.5, [0, 0.1, 0.5, 1]
>>> sc.gammainc(a, sc.gammaincinv(a, x))
array([0. , 0.1, 0.5, 1.1])
```

```python
>>> a, x = 0.5, [0, 10, 25]
>>> sc.gammaincinv(a, sc.gammainc(a, x))
array([ 0. , 10. , 25.00001465])
```
scipy.special.gammaincc

scipy.special.gammaincc(a, x) = <ufunc 'gammaincc'>

Regularized upper incomplete gamma function.

It is defined as

\[ Q(a, x) = \frac{1}{\Gamma(a)} \int_x^\infty t^{a-1}e^{-t} dt \]

for \( a > 0 \) and \( x \geq 0 \). See [dlmf] for details.

Parameters

- a [array_like] Positive parameter
- x [array_like] Nonnegative argument

Returns

scalar or ndarray

Values of the upper incomplete gamma function

See also:

gammainc

regularized lower incomplete gamma function

gammaincinv

inverse of the regularized lower incomplete gamma function

gammainccinv

inverse of the regularized upper incomplete gamma function

Notes

The function satisfies the relation \( \text{gammainc}(a, x) + \text{gammaincc}(a, x) = 1 \) where \( \text{gammainc} \) is the regularized lower incomplete gamma function.

The implementation largely follows that of [boost].

References

[dlmf], [boost]

Examples

```python
>>> import scipy.special as sc
```

It is the survival function of the gamma distribution, so it starts at 1 and monotonically decreases to 0.

```python
>>> sc.gammaincc(0.5, [0, 1, 10, 100, 1000])
array([1.00000000e+00, 1.57299207e-01, 7.74421643e-06, 2.08848758e-45,
       0.00000000e+00])
```

It is equal to one minus the lower incomplete gamma function.
scipy.special.gammainccinv

scipy.special.gammainccinv(a, y) = <ufunc 'gammainccinv'>

Inverse of the regularized upper incomplete gamma function.

Given an input \( y \) between 0 and 1, returns \( x \) such that \( y = Q(a, x) \). Here \( Q \) is the regularized upper incomplete gamma function; see gammaincc. This is well-defined because the upper incomplete gamma function is monotonic as can be seen from its definition in [dlmf].

**Parameters**

- **a** [array_like] Positive parameter
- **y** [array_like] Argument between 0 and 1, inclusive

**Returns**

- **scalar or ndarray**
  Values of the inverse of the upper incomplete gamma function

**See also:**

- gammaincc
  regularized upper incomplete gamma function
- gammainc
  regularized lower incomplete gamma function
- gammaincinv
  inverse of the regularized lower incomplete gamma function

**References**

[dlmf]

**Examples**

```python
>>> import scipy.special as sc
```

It starts at infinity and monotonically decreases to 0.

```python
>>> sc.gammainccinv(0.5, [0., 0.1, 0.5, 1.])
array([inf, 1.35277173, 0.22746821, 0.])
```

It inverts the upper incomplete gamma function.
```python
>>> a, x = 0.5, [0, 0.1, 0.5, 1]
>>> sc.gammaincc(a, sc.gammainccinv(a, x))
array([0., 0.1, 0.5, 1.])
```

```python
>>> a, x = 0.5, [0, 10, 50]
>>> sc.gammainccinv(a, sc.gammaincc(a, x))
array([ 0., 10., 50.])
```

### scipy.special.beta

The function `scipy.special.beta(a, b, out=None)` is defined in [1] as

\[
B(a, b) = \int_0^1 t^{a-1} (1-t)^{b-1} \, dt = \frac{\Gamma(a) \Gamma(b)}{\Gamma(a + b)},
\]

where \( \Gamma \) is the gamma function.

**Parameters**

- `a`, `b` ([array-like]) Real-valued arguments
- `out` [ndarray, optional] Optional output array for the function result

**Returns**

- `scalar` or `ndarray` Value of the beta function

**See also:**

- `gamma` the gamma function
- `betainc` the incomplete beta function
- `betaincinv` the incomplete beta function
- `betainv` the natural logarithm of the absolute value of the beta function

**References**

[1]
Examples

```python
>>> import scipy.special as sc
```

The beta function relates to the gamma function by the definition given above:

```python
>>> sc.beta(2, 3)
0.08333333333333333
>>> sc.gamma(2)*sc.gamma(3)/sc.gamma(2 + 3)
0.08333333333333333
```

As this relationship demonstrates, the beta function is symmetric:

```python
>>> sc.beta(1.7, 2.4)
0.16567527689031739
>>> sc.beta(2.4, 1.7)
0.16567527689031739
```

This function satisfies $B(1, b) = 1/b$:

```python
>>> sc.beta(1, 4)
0.25
```

**scipy.special.betaln**

`scipy.special.betaln(a, b) = <ufunc 'betaln'>`

Natural logarithm of absolute value of beta function.

Computes $\ln(\text{abs}(\text{beta}(a, b)))$.

**scipy.special.betainc**

`scipy.special.betainc(a, b, x, out=None) = <ufunc 'betainc'>`

Incomplete beta function.

Computes the incomplete beta function, defined as [1]:

$$I_x(a,b) = \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} \int_0^x t^{a-1}(1-t)^{b-1}dt,$$

for $0 \leq x \leq 1$.

**Parameters**
- `a, b` [array-like] Positive, real-valued parameters
- `x` [array-like] Real-valued such that $0 \leq x \leq 1$, the upper limit of integration
- `out` [ndarray, optional] Optional output array for the function values

**Returns**
- `array-like` Value of the incomplete beta function

See also:
- `beta`

betaincinv

inverse of the incomplete beta function

Notes

The incomplete beta function is also sometimes defined without the \texttt{gamma} terms, in which case the above definition is the so-called regularized incomplete beta function. Under this definition, you can get the incomplete beta function by multiplying the result of the SciPy function by \texttt{beta}.

References

[1]

Examples

Let $B(a, b)$ be the \texttt{beta} function.

```python
>>> import scipy.special as sc
```

The coefficient in terms of \texttt{gamma} is equal to $1/B(a, b)$. Also, when $x = 1$ the integral is equal to $B(a, b)$. Therefore, $I_{x=1}(a, b) = 1$ for any $a, b$.

```python
>>> sc.betainc(0.2, 3.5, 1.0)
1.0
```

It satisfies $I_x(a, b) = x^a F(a, 1 - b, a + 1, x)/(aB(a, b))$, where $F$ is the hypergeometric function \texttt{hyp2f1}:

```python
>>> a, b, x = 1.4, 3.1, 0.5
>>> x**a * sc.hyp2f1(a, 1 - b, a + 1, x) / (a * sc.beta(a, b))
0.8148904036225295
>>> sc.betainc(a, b, x)
0.8148904036225296
```

This functions satisfies the relationship $I_x(a, b) = 1 - I_{1-x}(b, a)$:

```python
>>> sc.betainc(2.2, 3.1, 0.4)
0.49339638807619446
>>> 1 - sc.betainc(3.1, 2.2, 1 - 0.4)
0.49339638807619446
```

\texttt{scipy.special.betaincinv}

\texttt{scipy.special.betaincinv}(a, b, y, out=None) = <ufunc 'betaincinv'>

Inverse of the incomplete beta function.

Computes $x$ such that:

$$y = I_x(a, b) = \frac{\Gamma(a + b)}{\Gamma(a)\Gamma(b)} \int_0^x t^{a-1}(1 - t)^{b-1}dt,$$

where $I_x$ is the normalized incomplete beta function \texttt{betainc} and $\Gamma$ is the \texttt{gamma} function [1].

3.3. API definition 2267
Parameters

- \(a, b\) [array-like] Positive, real-valued parameters
- \(y\) [array-like] Real-valued input
- \(\text{out}\) [ndarray, optional] Optional output array for function values

Returns

- array-like Value of the inverse of the incomplete beta function

See also:

- `betainc`
  - incomplete beta function
- `gamma`
  - gamma function

References

[1]

Examples

```python
>>> import scipy.special as sc
```

This function is the inverse of `betainc` for fixed values of \(a\) and \(b\).

```python
>>> a, b = 1.2, 3.1
>>> y = sc.betainc(a, b, 0.2)
>>> sc.betaincinv(a, b, y)
0.2
>>> a, b = 7.5, 0.4
>>> x = sc.betaincinv(a, b, 0.5)
>>> sc.betainc(a, b, x)
0.5
```

`scipy.special.psi`

`scipy.special.psi(z, out=None) = <ufunc 'psi'>`

The digamma function.

The logarithmic derivative of the gamma function evaluated at \(z\).

Parameters

- \(z\) [array_like] Real or complex argument.
- \(\text{out}\) [ndarray, optional] Array for the computed values of \(\psi\).

Returns

- \(\psi\) [ndarray] Computed values of \(\psi\).
Notes

For large values not close to the negative real axis, $\psi$ is computed using the asymptotic series (5.11.2) from [1]. For small arguments not close to the negative real axis, the recurrence relation (5.5.2) from [1] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis, the reflection formula (5.5.4) from [1] is used first. Note that $\psi$ has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [2], so the function should maintain full accuracy around the origin.

References

[1],[2]

Examples

```python
>>> from scipy.special import psi
>>> z = 3 + 4j
>>> psi(z)
(1.55035981733341+1.0105022091860445j)
```

Verify $\psi(z) = \psi(z + 1) - 1/z$:

```python
>>> psi(z + 1) - 1/z
(1.55035981733341+1.0105022091860445j)
```

**scipy.special.rgamma**

scipy.special.\texttt{rgamma}(z, \texttt{out}=\texttt{None}) = <ufunc 'rgamma'>

Reciprocal of the gamma function.

Defined as $1/\Gamma(z)$, where $\Gamma$ is the gamma function. For more on the gamma function see \texttt{gamma}.

**Parameters**

- **z** [array_like] Real or complex valued input
- **out** [ndarray, optional] Optional output array for the function results

**Returns**

- scalar or ndarray
  Function results

See also:

\texttt{gamma}, \texttt{gammaln}, \texttt{loggamma}
Notes

The gamma function has no zeros and has simple poles at nonpositive integers, so \( \text{rgamma} \) is an entire function with zeros at the nonpositive integers. See the discussion in [dlmf] for more details.

References

[dlmf]

Examples

```python
>>> import scipy.special as sc
```

It is the reciprocal of the gamma function.

```python
>>> sc.rgamma([1, 2, 3, 4])
array([1. , 1. , 0.5 , 0.16666667])
>>> 1 / sc.gamma([1, 2, 3, 4])
array([1. , 1. , 0.5 , 0.16666667])
```

It is zero at nonpositive integers.

```python
>>> sc.rgamma([0, -1, -2, -3])
array([0., 0., 0., 0.])
```

It rapidly underflows to zero along the positive real axis.

```python
>>> sc.rgamma([10, 100, 179])
array([2.75573192e-006, 1.07151029e-156, 0.00000000e+000])
```

`scipy.special.polygamma`

`scipy.special.polygamma(n, x)`

Polygamma functions.

Defined as \( \psi^{(n)}(x) \) where \( \psi \) is the \text{digamma} function. See [dlmf] for details.

**Parameters**

- `n` [array_like] The order of the derivative of the digamma function; must be integral
- `x` [array_like] Real valued input

**Returns**

- `ndarray` Function results

See also:

- `digamma`
References

[dlmf]

Examples

```python
>>> from scipy import special
>>> x = [2, 3, 25.5]
>>> special.polygamma(1, x)
array([ 0.64493407, 0.39493407, 0.03999467])
>>> special.polygamma(0, x) == special.psi(x)
array([ True, True, True], dtype=bool)
```

**scipy.special.multigammaln**

`scipy.special.multigammaln(a, d)`

Returns the log of multivariate gamma, also sometimes called the generalized gamma.

- **Parameters**
  - `a` [ndarray] The multivariate gamma is computed for each item of `a`.
  - `d` [int] The dimension of the space of integration.

- **Returns**
  - `res` [ndarray] The values of the log multivariate gamma at the given points `a`.

**Notes**

The formal definition of the multivariate gamma of dimension `d` for a real `a` is

\[
\Gamma_d(a) = \int_{A>0} e^{-\text{tr}(A)} |A|^{a-(d+1)/2} dA
\]

with the condition `a > (d - 1)/2`, and `A > 0` being the set of all the positive definite matrices of dimension `d`. Note that `a` is a scalar: the integrand only is multivariate, the argument is not (the function is defined over a subset of the real set).

This can be proven to be equal to the much friendlier equation

\[
\Gamma_d(a) = \pi^{d(d-1)/4} \prod_{i=1}^{d} \Gamma(a - (i - 1)/2).
\]

**References**

Examples

```python
>>> from scipy.special import multigammaln, gammaln
>>> a = 23.5
>>> d = 10
>>> multigammaln(a, d)
454.1488605074416
```

Verify that the result agrees with the logarithm of the equation shown above:

```python
>>> d*(d-1)/4*np.log(np.pi) + gammaln(a - 0.5*np.arange(0, d)).sum()
454.1488605074416
```

**scipy.special.digamma**

`scipy.special.digamma(z, out=None) = <ufunc 'psi'>`

The digamma function.

The logarithmic derivative of the gamma function evaluated at `z`.

**Parameters**

- `z` : array_like
  Real or complex argument.
- `out` : ndarray, optional
  Array for the computed values of `psi`.

**Returns**

- `digamma` : ndarray
  Computed values of `psi`.

**Notes**

For large values not close to the negative real axis, `psi` is computed using the asymptotic series (5.11.2) from [1]. For small arguments not close to the negative real axis, the recurrence relation (5.5.2) from [1] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis, the reflection formula (5.5.4) from [1] is used first. Note that `psi` has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [2], so the function should maintain full accuracy around the origin.

**References**

[1], [2]
Examples

```python
>>> from scipy.special import psi
>>> z = 3 + 4j
>>> psi(z)
(1.55035981733341+1.0105022091860445j)
```

Verify $\psi(z) = \psi(z+1) - 1/z$:

```python
>>> psi(z + 1) - 1/z
(1.55035981733341+1.0105022091860445j)
```

**scipy.special.poch**

scipy.special.poch(z, m) = <ufunc 'poch'>

Pochhammer symbol.

The Pochhammer symbol (rising factorial) is defined as

\[
(z)_m = \frac{\Gamma(z + m)}{\Gamma(z)}
\]

For positive integer $m$ it reads

\[
(z)_m = z(z+1)...(z+m-1)
\]

See [dlmf] for more details.

**Parameters**

- **z, m**  
  [array_like] Real-valued arguments.

**Returns**

- **scalar or ndarray**  
  The value of the function.

**References**

[dlmf]

**Examples**

```python
>>> import scipy.special as sc
```

It is 1 when $m$ is 0.

```python
>>> sc.poch([1, 2, 3, 4], 0)
array([1., 1., 1., 1.])
```

For $z$ equal to 1 it reduces to the factorial function.
>>> sc.poch(1, 5)
120.0
>>> 1 * 2 * 3 * 4 * 5
120

It can be expressed in terms of the gamma function.

>>> z, m = 3.7, 2.1
>>> sc.poch(z, m)
20.52958193377693
>>> sc.gamma(z + m) / sc.gamma(z)
20.52958193377696

scipy.special.erf

scipy.special.erf(z) = <ufunc 'erf'>

Returns the error function of complex argument.

It is defined as \( \frac{2}{\sqrt{\pi}} \int \exp(-t^2) \, dt \) at \( t=0..z \).  

Parameters

- x [ndarray] Input array.

Returns

- res [ndarray] The values of the error function at the given points x.

See also:

erfc, erfinv, erfcinv, wofz, erfcx, erfi
Notes

The cumulative of the unit normal distribution is given by $\Phi(z) = \frac{1}{2}[1 + \text{erf}(z/\sqrt{2})]$.

References

[1], [2], [3]

Examples

```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erf(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$\text{erf}(x)$')
>>> plt.show()
```

![Graph of erf(x)](image)

**scipy.special.erfc**

`scipy.special.erfc(x, out=None) = <ufunc 'erfc'>`  
Complementary error function, $1 - \text{erf}(x)$.

**Parameters**

- `x` : array_like  
  Real or complex valued argument
- `out` : ndarray, optional  
  Optional output array for the function results

**Returns**

- `scalar or ndarray`  
  Values of the complementary error function
See also:

- **erf**, **erfi**, **erfcx**, **dawsn**, **wofz**

References

[1]

Examples

```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erfc(x))
>>> plt.xlabel(r'$x$')
>>> plt.ylabel(r'$erfc(x)$')
>>> plt.show()
```

![Graph of erfc(x)](image)

**scipy.special.erfcx**

`scipy.special.erfcx(x, out=None) = <ufunc 'erfcx'>`

Scaled complementary error function, \( \exp(x^2) \cdot \text{erfc}(x) \).

**Parameters**

- **x** [array_like] Real or complex valued argument
- **out** [ndarray, optional] Optional output array for the function results

**Returns**

- **scalar or ndarray** Values of the scaled complementary error function

See also:
erf, erfc, erfi, dawsn, wofz

Notes

New in version 0.12.0.

scipy.special.erfi

scipy.special.erfi(z, out=None) = <ufunc 'erfi'>

Imaginary error function, \(-i \text{erf}(i \, z)\).

Parameters

- **z** [array_like] Real or complex valued argument
- **out** [ndarray, optional] Optional output array for the function results

Returns
scalar or ndarray
Values of the imaginary error function

See also:

erf, erfc, erfcx, dawsn, wofz

Notes

New in version 0.12.0.

References

[1]

Examples

```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erfi(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$\text{erfi}(x)$')
>>> plt.show()
```
scipy.special.erfinv

scipy.special.erfinv(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True) = <ufunc 'erfinv'>

Inverse of the error function.

Computes the inverse of the error function.
In the complex domain, there is no unique complex number w satisfying erf(w)=z. This indicates a true inverse function would have multi-value. When the domain restricts to the real, -1 < x < 1, there is a unique real number satisfying erf(erfinv(x)) = x.

Parameters

- y [ndarray] Argument at which to evaluate. Domain: [-1, 1]

Returns

- erfinv [ndarray] The inverse of erf of y, element-wise)

See also:

- erf
  Error function of a complex argument

- erfc
  Complementary error function, 1 - erf(x)

- erfcinv
  Inverse of the complementary error function

Examples

1) evaluating a float number

```python
>>> from scipy import special
>>> special.erfinv(0.5)
0.4769362762044698
```

2) evaluating an ndarray

```python
>>> from scipy import special
>>> y = np.linspace(-1.0, 1.0, num=10)
>>> special.erfinv(y)
array([-inf, -0.86312307, -0.5407314 , -0.30457019, -0.0987901 ,
       0.0987901 , 0.30457019, 0.5407314 , 0.86312307, inf])
```
scipy.special.erfcinv

```python
scipy.special.erfcinv(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True, signature=None, extobj=None)
```

Inverse of the complementary error function.

Computes the inverse of the complementary error function.
In the complex domain, there is no unique complex number \( w \) satisfying \( \text{erfc}(w)=z \). This indicates a true inverse function would have multi-value. When the domain restricts to the real, \( 0 < x < 2 \), there is a unique real number satisfying \( \text{erfc}(\text{erfcinv}(x))=\text{erfcinv}(\text{erfc}(x)) \).

It is related to inverse of the error function by \( \text{erfcinv}(1-x)=\text{erfinv}(x) \)

**Parameters**

- \( y \) [ndarray] Argument at which to evaluate. Domain: \([0, 2]\)

**Returns**

- \( \text{erfcinv} \) [ndarray] The inverse of \( \text{erfc} \) of \( y \), element-wise

**See also:**

- \( \text{erf} \)
  Error function of a complex argument

- \( \text{erfc} \)
  Complementary error function, \( 1 - \text{erf}(x) \)

- \( \text{erfinv} \)
  Inverse of the error function

**Examples**

1) evaluating a float number

```python
>>> from scipy import special
>>> special.erfcinv(0.5)
0.4769362762044698
```

2) evaluating an ndarray

```python
>>> from scipy import special
>>> y = np.linspace(0.0, 2.0, num=11)
>>> special.erfcinv(y)
array([        inf,    0.9061938 ,    0.59511608,    0.37080716,    0.17914345,
       -0. ,    -0.17914345,    -0.37080716,    -0.59511608,    -0.9061938 ,
       -inf])
```
scipy.special.wofz

scipy.special.wofz(z) = <ufunc 'wofz'>

Faddeeva function

Returns the value of the Faddeeva function for complex argument:

\[ \exp(-z^2) \times \text{erfc}(-i\cdot z) \]

See also:
dawsn, erf, erfc, erfcx, erfi

References

[1]

Examples

```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt

>>> x = np.linspace(-3, 3)
>>> z = special.wofz(x)

>>> plt.plot(x, z.real, label='wofz(x).real')
>>> plt.plot(x, z.imag, label='wofz(x).imag')
>>> plt.xlabel('$x$')
>>> plt.legend(framealpha=1, shadow=True)
>>> plt.grid(alpha=0.25)
>>> plt.show()
```
scipy.special.dawsn

scipy.special.dawsn(x) = <ufunc 'dawsn'>
Dawson’s integral.

Computes:
\[ \exp(-x^2) \times \text{integral}(\exp(t^2), t=0..x). \]

See also:

wofz, erf, erfc, erfcx, erfi

References

[1]

Examples

```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-15, 15, num=1000)
>>> plt.plot(x, special.dawsn(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$dawsn(x)$')
>>> plt.show()
```
scipy.special.fresnel

scipy.special.fresnel(z, out=None) = <ufunc 'fresnel'>

Fresnel integrals.

The Fresnel integrals are defined as

\[
S(z) = \int_0^z \sin(\pi t^2 / 2) dt \\
C(z) = \int_0^z \cos(\pi t^2 / 2) dt.
\]

See [dlmf] for details.

Parameters

- **z** [array_like] Real or complex valued argument
- **out** [2-tuple of ndarrays, optional] Optional output arrays for the function results

Returns

- **S, C** [2-tuple of scalar or ndarray] Values of the Fresnel integrals

See also:

- fresnel_zeros
  - zeros of the Fresnel integrals

References

- [dlmf]

Examples

```python
given:

As z goes to infinity along the real axis, S and C converge to 0.5.

```python
>>> S, C = sc.fresnel([0.1, 1, 10, 100, np.inf])
>>> S
array([0.00052359, 0.43825915, 0.46816998, 0.4968169 , 0.5 ])
>>> C
array([0.09999753, 0.7798934 , 0.49989869, 0.4999999 , 0.5 ])
```

They are related to the error function `erf`.

```python
>>> z = np.array([1, 2, 3, 4])
>>> zeta = 0.5 * np.sqrt(np.pi) * (1 + 1j) * z
>>> S, C = sc.fresnel(zeta)
>>> C + 1j*S
array([0.7798934 +0.43825915j, 0.48825341+0.34341568j, 
       0.60572079+0.496313j , 0.49842603+0.42051575j])
```
scipy.special.fresnel_zeros

scipy.special.fresnel_zeros(nt)
Compute nt complex zeros of sine and cosine Fresnel integrals S(z) and C(z).

References
[1]

scipy.special.modfresnelp

scipy.special.modfresnelp(x) = <ufunc 'modfresnelp'>
Modified Fresnel positive integrals

Returns
fp       Integral F_+(x): integral(exp(1j*t*t), t=x..inf)
kp       Integral K_+(x): 1/sqrt(pi)*exp(-1j*(x*x+pi/4))*fp

scipy.special.modfresnelm

scipy.special.modfresnelm(x) = <ufunc 'modfresnelm'>
Modified Fresnel negative integrals

Returns
fm       Integral F_-(x): integral(exp(-1j*t*t), t=x..inf)
km       Integral K_-(x): 1/sqrt(pi)*exp(1j*(x*x+pi/4))*fp

scipy.special.voigt_profile

scipy.special.voigt_profile(x, sigma, gamma, out=None) = <ufunc 'voigt_profile'>
Voigt profile.
The Voigt profile is a convolution of a 1-D Normal distribution with standard deviation sigma and a 1-D Cauchy
distribution with half-width at half-maximum gamma.

If sigma = 0, PDF of Cauchy distribution is returned. Conversely, if gamma = 0, PDF of Normal distribution
is returned. If sigma = gamma = 0, the return value is Inf for x = 0, and 0 for all other x.

Parameters
x        [array_like] Real argument
sigma    [array_like] The standard deviation of the Normal distribution part
gamma    [array_like] The half-width at half-maximum of the Cauchy distribution part
out      [ndarray, optional] Optional output array for the function values

Returns
scalar or ndarray
The Voigt profile at the given arguments

See also:
wofz

Faddeeva function

Notes

It can be expressed in terms of Faddeeva function

\[ V(x; \sigma, \gamma) = \frac{\text{Re}[w(z)]}{\sigma \sqrt{2\pi}}, \]

\[ z = \frac{x + i\gamma}{\sqrt{2\sigma}} \]

where \( w(z) \) is the Faddeeva function.

scipy.special.erf_zeros

\[ \text{scipy.special.erf_zeros}(nt) \]

Compute the first nt zero in the first quadrant, ordered by absolute value.

Zeros in the other quadrants can be obtained by using the symmetries \( \text{erf}(-z) = \text{erf}(z) \) and \( \text{erf}(\text{conj}(z)) = \text{conj}(\text{erf}(z)) \).

Parameters

- \( nt \) [int] The number of zeros to compute

Returns

- The locations of the zeros of \( \text{erf} \) [ndarray (complex)] Complex values at which zeros of \( \text{erf}(z) \)

References

[1]
Examples

```python
>>> from scipy import special
>>> special.erf_zeros(1)
array([1.45061616+1.880943j])
```

Check that erf is (close to) zero for the value returned by erf_zeros

**Legendre functions**

<table>
<thead>
<tr>
<th>( lpmv(m, v, x) )</th>
<th>Associated Legendre function of integer order and real degree.</th>
</tr>
</thead>
<tbody>
<tr>
<td>( sph_harm(m, n, theta, phi) )</td>
<td>Compute spherical harmonics.</td>
</tr>
</tbody>
</table>

**scipy.special.lpmv**

`scipy.special.lpmv(m, v, x) = <ufunc 'lpmv'>`

Associated Legendre function of integer order and real degree.

Defined as

\[
P_v^m = (-1)^m (1 - x^2)^{m/2} \frac{d^m}{dx^m} P_v(x)
\]

where

\[
P_v = \sum_{k=0}^{\infty} \frac{(-v)_k (v + 1)_k}{(k!)^2} \left( \frac{1 - x}{2} \right)^k
\]

is the Legendre function of the first kind. Here \((\cdot)_k\) is the Pochhammer symbol; see `poch`.  

Parameters

- \( m \) [array_like] Order (int or float). If passed a float not equal to an integer the function returns NaN.
- \( v \) [array_like] Degree (float).
- \( x \) [array_like] Argument (float). Must have \(|x| \leq 1\).

Returns

- \( pmv \) [ndarray] Value of the associated Legendre function.

See also:

- \( lpmn \)
  Compute the associated Legendre function for all orders 0, ..., \( m \) and degrees 0, ..., \( n \).
- \( clpmn \)
  Compute the associated Legendre function at complex arguments.

Notes

Note that this implementation includes the Condon-Shortley phase.

References

[1]

`scipy.special.sph_harm`

`scipy.special.sph_harm(m, n, theta, phi) = <ufunc 'sph_harm'>`

Compute spherical harmonics.

The spherical harmonics are defined as

\[
Y_n^m(\theta, \phi) = \frac{2n+1}{4\pi} \frac{(n-m)!}{(n+m)!} e^{im\theta} P_n^m(\cos(\phi))
\]

where \( P_n^m \) are the associated Legendre functions; see \( lpmv \).

Parameters

- \( m \) [array_like] Order of the harmonic (int); must have \(|m| \leq n\).
- \( n \) [array_like] Degree of the harmonic (int); must have \( n \geq 0 \). This is often denoted by \( l \) (lower case L) in descriptions of spherical harmonics.
- \( \theta \) [array_like] Azimuthal (longitudinal) coordinate; must be in \([0, 2\pi]\].
- \( \phi \) [array_like] Polar (colatitudinal) coordinate; must be in \([0, \pi]\).

Returns

- \( y_{mn} \) [complex float] The harmonic \( Y_n^m \) sampled at \( \theta \) and \( \phi \).
Notes

There are different conventions for the meanings of the input arguments theta and phi. In SciPy theta is the azimuthal angle and phi is the polar angle. It is common to see the opposite convention, that is, theta as the polar angle and phi as the azimuthal angle.

Note that SciPy’s spherical harmonics include the Condon-Shortley phase because it is part of lpmv.

With SciPy’s conventions, the first several spherical harmonics are

\[
Y_0^0(\theta, \phi) = \frac{1}{2} \sqrt{\frac{1}{\pi}} \\
Y_1^{-1}(\theta, \phi) = \frac{1}{2} \sqrt{\frac{3}{2\pi}} e^{-i\phi} \sin(\phi) \\
Y_1^0(\theta, \phi) = \frac{1}{2} \sqrt{\frac{3}{\pi}} \cos(\phi) \\
Y_1^1(\theta, \phi) = \frac{1}{2} \sqrt{\frac{3}{2\pi}} e^{i\phi} \sin(\phi).
\]

scipy.special.clpmn

scipy.special.clpmn(m, n, z[, type=3])

Associated Legendre function of the first kind for complex arguments.

Computes the associated Legendre function of the first kind of order m and degree n, \( P_{mn}(z) = \frac{P^m_n(z)}{P^m_n(1)} \), and its derivative, \( P_{mn}'(z) \). Returns two arrays of size (m+1, n+1) containing \( P_{mn}(z) \) and \( P_{mn}'(z) \) for all orders from 0..m and degrees from 0..n.

Parameters

- m : [int] \(|m| \leq n\); the order of the Legendre function.
- n : [int] where \( n \geq 0 \); the degree of the Legendre function. Often called \( l \) (lower case L) in descriptions of the associated Legendre function.
- z : [float or complex] Input value.
- type : [int, optional] takes values 2 or 3 2: cut on the real axis \(|x| > 1\); 3: cut on the real axis \(-1 < x < 1\) (default)

Returns

\[ P_{m,n} \] \[(m+1, n+1)\text{array}\] Values for all orders \(0 \ldots m\) and degrees \(0 \ldots n\)

\[ P_{m,n}^{d} \] \[(m+1, n+1)\text{array}\] Derivatives for all orders \(0 \ldots m\) and degrees \(0 \ldots n\)

See also:

\lpmn\n
associated Legendre functions of the first kind for real \(z\)

Notes

By default, i.e. for \texttt{type=3}, phase conventions are chosen according to \cite{1} such that the function is analytic. The cut lies on the interval (-1, 1). Approaching the cut from above or below in general yields a phase factor with respect to Ferrer's function of the first kind (cf. \lpmn).

For \texttt{type=2} a cut at \(|x| > 1\) is chosen. Approaching the real values on the interval (-1, 1) in the complex plane yields Ferrer's function of the first kind.

References

\cite{1}, \cite{2}

\texttt{scipy.special.lpn}

\texttt{scipy.special.lpn(n,z)}

Legendre function of the first kind.

Compute sequence of Legendre functions of the first kind (polynomials), \(P_n(z)\) and derivatives for all degrees from 0 to \(n\) (inclusive).

See also \texttt{special.legendre} for polynomial class.

References

\cite{1}

\texttt{scipy.special.lqn}

\texttt{scipy.special.lqn(n,z)}

Legendre function of the second kind.

Compute sequence of Legendre functions of the second kind, \(Q_n(z)\) and derivatives for all degrees from 0 to \(n\) (inclusive).
**scipy.special.lpmn**

Sequence of associated Legendre functions of the first kind.

Computes the associated Legendre function of the first kind of order \( m \) and degree \( n \), \( P_{mn}(z) = P^n_m(z) \), and its derivative, \( P_{mn}'(z) \). Returns two arrays of size \((m+1, n+1)\) containing \( P_{mn}(z) \) and \( P_{mn}'(z) \) for all orders from \( 0..m \) and degrees from \( 0..n \).

This function takes a real argument \( z \). For complex arguments \( z \) use clpmn instead.

**Parameters**

- \( m \) : [int] \(|m| \leq n\); the order of the Legendre function.
- \( n \) : [int] where \( n \geq 0 \); the degree of the Legendre function. Often called \( l \) (lower case L) in descriptions of the associated Legendre function
- \( z \) : [float] Input value.

**Returns**

- \( P_{mn\_z} \) : [(m+1, n+1) array] Values for all orders \( 0..m \) and degrees \( 0..n \)
- \( P_{mn\_d\_z} \) : [(m+1, n+1) array] Derivatives for all orders \( 0..m \) and degrees \( 0..n \)

See also:

- **clpmn**

  associated Legendre functions of the first kind for complex \( z \)

**Notes**

In the interval \((-1, 1)\), Ferrer’s function of the first kind is returned. The phase convention used for the intervals \((1, \infty)\) and \((-\infty, -1)\) is such that the result is always real.

**References**

[1], [2]

**scipy.special.lqmn**

Sequence of associated Legendre functions of the second kind.

Computes the associated Legendre function of the second kind of order \( m \) and degree \( n \), \( Q_{mn}(z) = Q^n_m(z) \), and its derivative, \( Q_{mn}'(z) \). Returns two arrays of size \((m+1, n+1)\) containing \( Q_{mn}(z) \) and \( Q_{mn}'(z) \) for all orders from \( 0..m \) and degrees from \( 0..n \).

**Parameters**

- \( m \) : [int] \(|m| \leq n\); the order of the Legendre function.
- \( n \) : [int] where \( n \geq 0 \); the degree of the Legendre function. Often called \( l \) (lower case L) in descriptions of the associated Legendre function
z [complex] Input value.

Returns

Qmn_z [(m+1, n+1) array] Values for all orders 0..m and degrees 0..n
Qmn_d_z [(m+1, n+1) array] Derivatives for all orders 0..m and degrees 0..n

Ellipsoidal harmonics

scipy.special.ellip_harm

scipy.special.ellip_harm(h2, k2, n, p, s[, signm, signn]) Ellipsoidal harmonic functions E^p_n(l)

These are also known as Lame functions of the first kind, and are solutions to the Lame equation:

\[(s^2 - h^2)(s^2 - k^2)E''(s) + s(2s^2 - h^2 - k^2)E'(s) + (a - qs^2)E(s) = 0\]

where \(q = (n + 1)n\) and \(a\) is the eigenvalue (not returned) corresponding to the solutions.

Parameters

h2 [float] \(h^2\)

k2 [float] \(k^2\); should be larger than \(h^2\)

n [int] Degree

s [float] Coordinate

p [int] Order, can range between [1,2n+1]

signm [[1, -1], optional] Sign of prefactor of functions. Can be +/-1. See Notes.

signn [[1, -1], optional] Sign of prefactor of functions. Can be +/-1. See Notes.

Returns

E [float] the harmonic \(E_p^n(s)\)

See also:

ellip_harm_2, ellip_normal
Notes

The geometric interpretation of the ellipsoidal functions is explained in [2], [3], [4]. The `signm` and `signn` arguments control the sign of prefactors for functions according to their type:

<p>| | |</p>

Examples

```python
>>> from scipy.special import ellip_harm
>>> w = ellip_harm(5, 8, 1, 1, 2.5)
>>> w
2.5
```

Check that the functions indeed are solutions to the Lame equation:

```python
>>> from scipy.interpolate import UnivariateSpline
>>> def eigenvalue(f, df, ddf):
...     r = ((s**2 - h**2)*(s**2 - k**2)*ddf + s*(2*s**2 - h**2 -
...         k**2)*df - n*(n+1)*s**2*f)/f
...     return -r.mean(), r.std()
... >>> s = np.linspace(0.1, 10, 200)
... >>> k, h, n, p = 8.0, 2.2, 3, 2
... >>> E = ellip_harm(h**2, k**2, n, p, s)
... >>> E_spl = UnivariateSpline(s, E)
... >>> a, a_err = eigenvalue(E_spl(s), E_spl(s, 1), E_spl(s, 2))
... >>> a, a_err
(583.44366156701483, 6.4580890640310646e-11)
```

`scipy.special.ellip_harm_2`

`scipy.special.ellip_harm_2(h2, k2, n, p, s)`

Ellipsoidal harmonic functions $F^p_n(l)$

These are also known as Lame functions of the second kind, and are solutions to the Lame equation:

$$(s^2 - h^2)(s^2 - k^2)F''(s) + s(2s^2 - h^2 - k^2)F'(s) + (a - qs^2)F(s) = 0$$

where $q = (n+1)n$ and $a$ is the eigenvalue (not returned) corresponding to the solutions.

**Parameters**

- **h2** [float] $h^2$
- **k2** [float] $k^2$; should be larger than $h^2$

Parameters

- \(n\) [int] Degree.
- \(p\) [int] Order, can range between \([1, 2n+1]\).
- \(s\) [float] Coordinate

Returns

- \(F\) [float] The harmonic \(F^p_n(s)\)

See also:

- `ellip_harm`, `ellip_normal`

Notes

Lame functions of the second kind are related to the functions of the first kind:

\[
F^p_n(s) = (2n + 1)E^p_n(s) \int_0^{1/s} \frac{du}{(E^p_n(1/u))^2 \sqrt{(1-u^2k^2)(1-u^2h^2)}}
\]

New in version 0.15.0.

Examples

```python
>>> from scipy.special import ellip_harm_2
>>> w = ellip_harm_2(5, 8, 2, 1, 10)
>>> w
0.00108056853382
```

scipy.special.ellip_normal

`scipy.special.ellip_normal(h2, k2, n, p)`

Ellipsoidal harmonic normalization constants \(\gamma^p_n\)

The normalization constant is defined as

\[
\gamma^p_n = 8 \int_0^{h} dx \int_h^{k} dy \frac{(y^2 - x^2)(E^p_n(y)E^p_n(x))^2}{\sqrt{(k^2 - y^2)(y^2 - h^2)(h^2 - x^2)(k^2 - x^2)}}
\]

Parameters

- \(h2\) [float] \(h^2\)
- \(k2\) [float] \(k^2\); should be larger than \(h^2\)
- \(n\) [int] Degree.
- \(p\) [int] Order, can range between \([1, 2n+1]\).

Returns

- \(gamma\) [float] The normalization constant \(\gamma^p_n\)

See also:

- `ellip_harm`, `ellip_harm_2`
Notes

New in version 0.15.0.

Examples

```python
>>> from scipy.special import ellip_normal
>>> w = ellip_normal(5, 8, 3, 7)
>>> w
1723.38796997
```

Orthogonal polynomials

The following functions evaluate values of orthogonal polynomials:

```python
assoc_laguerre(x, n[, k])  # Compute the generalized (associated) Laguerre polynomial of degree n and order k.
eval_legendre(n, x[, out])  # Evaluate Legendre polynomial at a point.
eval_chebyt(n, x[, out])  # Evaluate Chebyshev polynomial of the first kind at a point.
eval_chebyu(n, x[, out])  # Evaluate Chebyshev polynomial of the second kind at a point.
eval_chebyc(n, x[, out])  # Evaluate Chebyshev polynomial of the first kind on [-2, 2] at a point.
eval_chebys(n, x[, out])  # Evaluate Chebyshev polynomial of the second kind on [-2, 2] at a point.
eval_jacobi(n, alpha, beta, x[, out])  # Evaluate Jacobi polynomial at a point.
eval_laguerre(n, x[, out])  # Evaluate Laguerre polynomial at a point.
eval_genlaguerre(n, alpha, x[, out])  # Evaluate generalized Laguerre polynomial at a point.
eval_hermite(n, x[, out])  # Evaluate physicist's Hermite polynomial at a point.
eval_hermitenorm(n, x[, out])  # Evaluate probabilist's (normalized) Hermite polynomial at a point.
eval_gegenbauer(n, alpha, x[, out])  # Evaluate Gegenbauer polynomial at a point.
eval_sh_legendre(n, x[, out])  # Evaluate shifted Legendre polynomial at a point.
eval_sh_chebyt(n, x[, out])  # Evaluate shifted Chebyshev polynomial of the first kind at a point.
eval_sh_chebyu(n, x[, out])  # Evaluate shifted Chebyshev polynomial of the second kind at a point.
eval_sh_jacobi(n, p, q, x[, out])  # Evaluate shifted Jacobi polynomial at a point.
```

scipy.special.assoc_laguerre

Computes the generalized (associated) Laguerre polynomial of degree n and order k.

The polynomial \( L_n^{(k)}(x) \) is orthogonal over \([0, \infty)\), with weighting function \( \exp(-x) \times x^k \) with \( k > -1 \).
Notes

`assoc_laguerre` is a simple wrapper around `eval_genlaguerre`, with reversed argument order 
\((x, \ n, \ k=0.0) \rightarrow (n, \ k, \ x)\).

**scipy.special.eval_legendre**

`scipy.special.eval_legendre(n, x, out=None) = <ufunc 'eval_legendre'>`

Evaluate Legendre polynomial at a point.

The Legendre polynomials can be defined via the Gauss hypergeometric function \(2F_1\) as
\[
P_n(x) = \frac{\pi}{2} \frac{\Gamma(n+1)}{\Gamma(1/2)} \frac{\Gamma(n+1/2)}{\Gamma(n+1)} \frac{\Gamma(1-n)}{\Gamma(-n)} \, _2\!F_1\left(-n, n + 1; 1; \frac{1-x}{2}\right) .
\]

When \(n\) is an integer the result is a polynomial of degree \(n\). See 22.5.49 in \[AS\] for details.

**Parameters**

- **n** [array_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
- **x** [array_like] Points at which to evaluate the Legendre polynomial

**Returns**

- **P** [ndarray] Values of the Legendre polynomial

See also:

- `roots_legendre`
  roots and quadrature weights of Legendre polynomials
- `legendre`
  Legendre polynomial object
- `hyp2f1`
  Gauss hypergeometric function
- `numpy.polynomial.legendre.Legendre`
  Legendre series

**References**

\[AS\]

**Examples**

```python
>>> from scipy.special import eval_legendre
```

Evaluate the zero-order Legendre polynomial at \(x = 0\)

```python
>>> eval_legendre(0, 0)
1.0
```

Evaluate the first-order Legendre polynomial between -1 and 1

```python
>>> eval_legendre(1, 0)
1.0
```
Evaluate Legendre polynomials of order 0 through 4 at $x = 0$

```python
>>> X = np.linspace(-1, 1, 5)  # Domain of Legendre polynomials
>>> eval_legendre(1, X)
array([-1. , -0.5, 0. , 0.5, 1. ])
```

Plot Legendre polynomials of order 0 through 4

```python
>>> N = range(0, 5)
>>> eval_legendre(N, 0)
array([ 1. , 0. , -0.5 , 0. , 0.375])
```

```python
>>> X = np.linspace(-1, 1)

>>> import matplotlib.pyplot as plt
>>> for n in range(0, 5):
...     y = eval_legendre(n, X)
...     plt.plot(X, y, label=r'$P_{}(x)$'.format(n))

>>> plt.title("Legendre Polynomials")
>>> plt.xlabel("x")
>>> plt.ylabel(r'$P_n(x)$')
>>> plt.legend(loc='lower right')
>>> plt.show()
```
scipy.special.eval_chebyt

scipy.special.eval_chebyt(n, x, out=None) = <ufunc 'eval_chebyt'>

Evaluate Chebyshev polynomial of the first kind at a point.

The Chebyshev polynomials of the first kind can be defined via the Gauss hypergeometric function $2F_1$ as

$$T_n(x) = 2F_1(n, -n; 1/2; (1 - x)/2).$$

When $n$ is an integer the result is a polynomial of degree $n$. See 22.5.47 in [AS] for details.

Parameters

- **n** [array_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
- **x** [array_like] Points at which to evaluate the Chebyshev polynomial

Returns

- **T** [ndarray] Values of the Chebyshev polynomial

See also:

- roots_chebyt

where \( T_n \) is a Chebyshev polynomial of the first kind. See 22.5.14 in [AS] for details.

\textbf{Parameters}

\[ n \in \text{array_like} \] Degree of the polynomial. If not an integer, the result is determined via the relation to `eval_chebyt`.

\[ x \in \text{array_like} \] Points at which to evaluate the shifted Chebyshev polynomial

**Returns**

\[ T \in \text{ndarray} \] Values of the shifted Chebyshev polynomial

**scipy.special.eval_sh_chebyu**

`scipy.special.eval_sh_chebyu(n, x, out=None) = <ufunc 'eval_sh_chebyu'>`

Evaluate shifted Chebyshev polynomial of the second kind at a point.

These polynomials are defined as

\[ U_n^*(x) = U_n(2x - 1) \]

where \( U_n \) is a Chebyshev polynomial of the first kind. See 22.5.15 in [AS] for details.

**Parameters**

- \( n \in \text{array_like} \) Degree of the polynomial. If not an integer, the result is determined via the relation to `eval_chebyu`.

- \( x \in \text{array_like} \) Points at which to evaluate the shifted Chebyshev polynomial

**Returns**

- \( U \in \text{ndarray} \) Values of the shifted Chebyshev polynomial

**See also:**

scipy.special.eval_sh_jacobi

scipy.special.eval_sh_jacobi(n, p, q, x, out=None) = <ufunc 'eval_sh_jacobi'>

Evaluate shifted Jacobi polynomial at a point.

Defined by

\[ G_n^{(p,q)}(x) = \binom{2n + p - 1}{n}^{-1} P_n^{(p-q,q-1)}(2x - 1), \]

where \( P_n^{(r,s)} \) is the n-th Jacobi polynomial. See 22.5.2 in [AS] for details.

Parameters

- n [int] Degree of the polynomial. If not an integer, the result is determined via the relation to binom and eval_jacobi.
- p [float] Parameter
- q [float] Parameter

Returns

- G [ndarray] Values of the shifted Jacobi polynomial.

See also:

- roots_sh_jacobi
  - roots and quadrature weights of shifted Jacobi polynomials

scipy.special.roots_legendre

**scipy.special.roots_legendre**(n, mu=False)

Gauss-Legendre quadrature.

Compute the sample points and weights for Gauss-Legendre quadrature [GL]. The sample points are the roots of the nth degree Legendre polynomial \( P_n(x) \). These sample points and weights correctly integrate polynomials of degree \( 2n - 1 \) or less over the interval \([-1, 1]\) with weight function \( w(x) = 1 \). See 2.2.10 in [AS] for more details.

**Parameters**

- **n** [int] quadrature order
- **mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

- **x** [ndarray] Sample points
- **w** [ndarray] Weights
- **mu** [float] Sum of the weights

See also:

- `scipy.integrate.quadrature`
- `scipy.integrate.fixed_quad`
- `numpy.polynomial.legendre.leggauss`

**References**

[AS], [GL]

**Examples**

```python
>>> from scipy.special import roots_legendre, eval_legendre

>>> roots, weights = roots_legendre(9)

roots holds the roots, and weights holds the weights for Gauss-Legendre quadrature.
```

```python
>>> roots
array([-0.96816024, -0.83603111, -0.61337143, -0.32425342, 0.,
       0.32425342, 0.61337143, 0.83603111, 0.96816024])

>>> weights
array([0.08127439, 0.18064816, 0.2606107 , 0.31234708, 0.33023936,
       0.31234708, 0.2606107 , 0.18064816, 0.08127439])
```
Verify that we have the roots by evaluating the degree 9 Legendre polynomial at \texttt{roots}. All the values are approximately zero:

\begin{verbatim}
>>> eval_legendre(9, roots)
array([-8.88178420e-16, -2.22044605e-16, 1.11022302e-16, 1.11022302e-16,
    0.00000000e+00, -5.55111512e-17, -1.94289029e-16, 1.38777878e-16,
   -8.32667268e-17])
\end{verbatim}

Here we’ll show how the above values can be used to estimate the integral from 1 to 2 of \( f(t) = t + 1/t \) with Gauss-Legendre quadrature \([GL]\). First define the function and the integration limits.

\begin{verbatim}
>>> def f(t):
...     return t + 1/t
...
>>> a = 1
>>> b = 2
\end{verbatim}

We’ll use \texttt{integral(f(t), t=a, t=b)} to denote the definite integral of \( f \) from \( t=a \) to \( t=b \). The sample points in \texttt{roots} are from the interval \([-1, 1]\), so we’ll rewrite the integral with the simple change of variable:

\[
x = \frac{2}{b - a} \cdot t - \frac{a + b}{b - a}
\]

with inverse:

\[
t = \frac{(b - a)/2 \cdot x + (a + 2)/2}{x = -1, x = 1}
\]

Then:

\[
\text{integral}(f(t), a, b) = \frac{(b - a)/2 \cdot \text{integral}(f((b-a)/2 \cdot x + (a+b)/2), x=-1, x=1)}{x = -1, x = 1}
\]

We can approximate the latter integral with the values returned by \texttt{roots_legendre}.

Map the roots computed above from \([-1, 1]\) to \([a, b]\).

\begin{verbatim}
>>> t = (b - a)/2 * roots + (a + b)/2
\end{verbatim}

Approximate the integral as the weighted sum of the function values.

\begin{verbatim}
>>> (b - a)/2 * f(t).dot(weights)
2.1931471805599276
\end{verbatim}

Compare that to the exact result, which is \( 3/2 + \log(2) \):

\begin{verbatim}
>>> 1.5 + np.log(2)
2.1931471805599454
\end{verbatim}
scipy.special.roots_chebyt

scipy.special.roots_chebyt(n, mu=False)

Gauss-Chebyshev (first kind) quadrature.
Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the nth degree Chebyshev polynomial of the first kind, \( T_n(x) \). These sample points and weights correctly integrate polynomials of degree \( 2n - 1 \) or less over the interval \([-1, 1]\) with weight function \( w(x) = \frac{1}{\sqrt{1 - x^2}} \). See 22.2.4 in [AS] for more details.

Parameters

- \( n \) [int] quadrature order
- \( mu \) [bool, optional] If True, return the sum of the weights, optional.

Returns

- \( x \) [ndarray] Sample points
- \( w \) [ndarray] Weights
- \( mu \) [float] Sum of the weights

[AS]

scipy.special.roots_chebyu

scipy.special.roots_chebyu(n, mu=False)

Gauss-Chebyshev (second kind) quadrature.
Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the nth degree Chebyshev polynomial of the second kind, \( U_n(x) \). These sample points and weights correctly integrate polynomials of degree \( 2n - 1 \) or less over the interval \([-1, 1]\) with weight function \( w(x) = \sqrt{1 - x^2} \). See 22.2.5 in [AS] for details.

Parameters

- \( n \) [int] quadrature order
- \( mu \) [bool, optional] If True, return the sum of the weights, optional.

Returns

- \( x \) [ndarray] Sample points
- \( w \) [ndarray] Weights
- \( mu \) [float] Sum of the weights

See also:

scipy.integrate.quadrature
scipy.integrate.fixed_quad
scipy.special.roots_chebyc

Compute the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the
nth degree Chebyshev polynomial of the first kind, \( C_n(x) \). These sample points and weights correctly integrate
degree 2n – 1 or less over the interval \([-2, 2]\) with weight function \( w(x) = 1/\sqrt{1 - (x/2)^2} \). See
22.2.6 in [AS] for more details.

Parameters

\( n \) : [int] quadrature order
\( mu \) : [bool, optional] If True, return the sum of the weights, optional.

Returns

\( x \) : [ndarray] Sample points
\( w \) : [ndarray] Weights
\( mu \) : [float] Sum of the weights

See also:

scipy.integrate.quadrature
scipy.integrate.fixed_quad

scipy.special.roots_chebys

Compute the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the
nth degree Chebyshev polynomial of the second kind, \( S_n(x) \). These sample points and weights correctly integrate
degree 2n – 1 or less over the interval \([-2, 2]\) with weight function \( w(x) = \sqrt{1 - (x/2)^2} \). See
22.2.7 in [AS] for more details.

Parameters

\( n \) : [int] quadrature order
\( mu \) : [bool, optional] If True, return the sum of the weights, optional.

Returns

\( x \) : [ndarray] Sample points
\( w \) : [ndarray] Weights
\( mu \) : [float] Sum of the weights

```

scipy.special.roots_genlaguerre

```python
scipy.special.roots_genlaguerre(n, alpha, mu=False)
```

Gauss-generalized Laguerre quadrature.

Compute the sample points and weights for Gauss-generalized Laguerre quadrature. The sample points are the roots of the nth degree generalized Laguerre polynomial, \( L_α^n(x) \). These sample points and weights correctly integrate polynomials of degree \( 2n - 1 \) or less over the interval \([0, \infty]\) with weight function \( w(x) = x^α e^{-x} \). See 22.3.9 in [AS] for details.

Parameters

- n [int] quadrature order
- alpha [float] alpha must be > -1
- mu [bool, optional] If True, return the sum of the weights, optional.

Returns

- x [ndarray] Sample points
- w [ndarray] Weights
- mu [float] Sum of the weights

See also:

scipy.integrate.quadrature
scipy.integrate.fixed_quad

References

[AS]
**scipy.special.roots_hermite**

**scipy.special.roots_hermite(n, mu=False)**

Gauss-Hermite (physicist’s) quadrature.

Compute the sample points and weights for Gauss-Hermite quadrature. The sample points are the roots of the nth degree Hermite polynomial, \( H_n(x) \). These sample points and weights correctly integrate polynomials of degree \( 2n - 1 \) or less over the interval \([-\infty, \infty]\) with weight function \( w(x) = e^{-x^2} \). See 22.2.14 in [AS] for details.

**Parameters**

- **n** [int] quadrature order
- **mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

- **x** [ndarray] Sample points
- **w** [ndarray] Weights
- **mu** [float] Sum of the weights

**See also:**

- `scipy.integrate.quadrature`
- `scipy.integrate.fixed_quad`
- `numpy.polynomial.hermite.hermgauss`
- `roots_hermitenorm`

**Notes**

For small n up to 150 a modified version of the Golub-Welsch algorithm is used. Nodes are computed from the eigenvalue problem and improved by one step of a Newton iteration. The weights are computed from the well-known analytical formula.

For n larger than 150 an optimal asymptotic algorithm is applied which computes nodes and weights in a numerically stable manner. The algorithm has linear runtime making computation for very large n (several thousand or more) feasible.

[AS]

The functions below, in turn, return the polynomial coefficients in orthopoly1d objects, which function similarly as numpy.poly1d. The orthopoly1d class also has an attribute weights, which returns the roots, weights, and total weights for the appropriate form of Gaussian quadrature. These are returned in an \( n \times 3 \) array with roots in the first column, weights in the second column, and total weights in the final column. Note that orthopoly1d objects are converted to poly1d when doing arithmetic, and lose information of the original orthogonal polynomial.

scipy.special.legendre

scipy.special.legendre(n, monic=False)

Legends polynomial.

Defined to be the solution of

\[
\frac{d}{dx} \left( (1 - x^2) \frac{d}{dx} P_n(x) \right) + n(n + 1) P_n(x) = 0;
\]

\( P_n(x) \) is a polynomial of degree \( n \).

Parameters

- \( n \) [int] Degree of the polynomial.
- \( \text{monic} \) [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

Returns

\[ P \] [orthopoly1d] Legendre polynomial.

**Notes**

The polynomials \( P_n \) are orthogonal over \([-1, 1]\) with weight function 1.

**Examples**

Generate the 3rd-order Legendre polynomial \( \frac{1}{2} (5x^3 + 0x^2 - 3x + 0) \):

```python
>>> from scipy.special import legendre
>>> legendre(3)
poly1d([2.5, 0., -1.5, 0.])
```

**scipy.special.chebyt**

scipy.special.chebyt \((n, \text{monic}=False)\)

Chebyshev polynomial of the first kind.

Defined to be the solution of

\[
(1 - x^2) \frac{d^2}{dx^2} T_n - x \frac{d}{dx} T_n + n^2 T_n = 0;
\]

\( T_n \) is a polynomial of degree \( n \).

**Parameters**

- \( n \) [int] Degree of the polynomial.
- \( \text{monic} \) [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

**Returns**

- \( T \) [orthopoly1d] Chebyshev polynomial of the first kind.

**See also:**

chebyu

Chebyshev polynomial of the second kind.

**Notes**

The polynomials \( T_n \) are orthogonal over \([-1, 1]\) with weight function \((1 - x^2)^{-1/2}\).
References

[AS]

Examples

Chebyshev polynomials of the first kind of order \( n \) can be obtained as the determinant of specific \( n \times n \) matrices. As an example we can check how the points obtained from the determinant of the following \( 3 \times 3 \) matrix lay exactly on \( T_3 \):

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.linalg import det
>>> from scipy.special import chebyt
>>> x = np.arange(-1.0, 1.0, 0.01)
>>> fig, ax = plt.subplots()
>>> ax.set_ylim(-2.0, 2.0)
>>> ax.set_title(r'Chebyshev polynomial $T_3$')
>>> ax.plot(x, chebyt(3)(x), label=rf'$T_3$')
>>> for p in np.arange(-1.0, 1.0, 0.1):
...     ax.plot(p,
...     det(np.array([[p, 1, 0], [1, 2*p, 1], [0, 1, 2*p]])),
...     'rx')
>>> plt.legend(loc='best')
>>> plt.show()
```

They are also related to the Jacobi Polynomials \( P_n^{(-0.5,-0.5)} \) through the relation:

\[
P_n^{(-0.5,-0.5)}(x) = \frac{1}{4^n} \binom{2n}{n} T_n(x)
\]

Let's verify it for \( n = 3 \):

```python
>>> from scipy.special import binom
>>> from scipy.special import chebyt
```
We can plot the Chebyshev polynomials $T_n$ for some values of $n$:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.special import chebyt
>>> x = np.arange(-1.5, 1.5, 0.01)
>>> fig, ax = plt.subplots()
>>> ax.set_ylim(-4.0, 4.0)
>>> ax.set_title(r'Chebyshev polynomials $T_n$')
>>> for n in np.arange(2, 5):
...    ax.plot(x, chebyt(n)(x), label=rf'$T_n={n}$')
>>> plt.legend(loc='best')
>>> plt.show()
```

### scipy.special.chebyu

`scipy.special.chebyu(n, monic=False)`

Chebyshev polynomial of the second kind.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} U_n - 3x \frac{d}{dx} U_n + n(n+2)U_n = 0;$$

$U_n$ is a polynomial of degree $n$.

**Parameters**

- `n` [int] Degree of the polynomial.
monic [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

Returns

U[orthopoly1d] Chebyshev polynomial of the second kind.

See also:

chebyt

Chebyshev polynomial of the first kind.

Notes

The polynomials $U_n$ are orthogonal over $[-1, 1]$ with weight function $(1 - x^2)^{1/2}$.

References

[AS]

Examples

Chebyshev polynomials of the second kind of order $n$ can be obtained as the determinant of specific $n \times n$ matrices. As an example we can check how the points obtained from the determinant of the following $3 \times 3$ matrix lay exactly on $U_3$:

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.linalg import det
>>> from scipy.special import chebyu
>>> x = np.arange(-1.0, 1.0, 0.01)
>>> fig, ax = plt.subplots()
>>> ax.set_ylim(-2.0, 2.0)
>>> ax.set_title(r'Chebyshev polynomial $U_3$')
>>> ax.plot(x, chebyu(3)(x), label='U_3')
>>> for p in np.arange(-1.0, 1.0, 0.1):
...     det(np.array([[2*p, 1, 0], [1, 2*p, 1], [0, 1, 2*p]])),
...     'rx')
>>> plt.legend(loc='best')
>>> plt.show()
```

They satisfy the recurrence relation:

$$U_{2n-1}(x) = 2T_n(x)U_{n-1}(x)$$

where the $T_n$ are the Chebyshev polynomial of the first kind. Let’s verify it for $n = 2$:

```python
>>> from scipy.special import chebyt
>>> from scipy.special import chebyu
>>> x = np.arange(-1.0, 1.0, 0.01)
>>> np.allclose(chebyu(3)(x), 2 * chebyt(2)(x) * chebyu(1)(x))
True
```

We can plot the Chebyshev polynomials $U_n$ for some values of $n$:  

```python
>>> for n in range(5):
...     x = np.arange(-1.0, 1.0, 0.01)
...     plt.plot(x, chebyu(n)(x), label=f'$U_{n}$')
>>> plt.legend()
>>> plt.show()
```
>>> import matplotlib.pyplot as plt
>>> from scipy.special import chebyu
>>> x = np.arange(-1.0, 1.0, 0.01)
>>> fig, ax = plt.subplots()
>>> ax.set_ylim(-1.5, 1.5)
>>> ax.set_title(r'Chebyshev polynomials $U_n$')
>>> for n in np.arange(1, 5):
...     ax.plot(x, chebyu(n)(x), label=rf'$U_n={n}$')
>>> plt.legend(loc='best')
>>> plt.show()
scipy.special.chebyc

`scipy.special.chebyc(n, monic=False)`

Chebyshev polynomial of the first kind on $[-2, 2]$.

Defined as $C_n(x) = 2T_n(x/2)$, where $T_n$ is the nth Chebychev polynomial of the first kind.

**Parameters**

- `n` [int] Degree of the polynomial.
- `monic` [bool, optional] If `True`, scale the leading coefficient to be 1. Default is `False`.

**Returns**

- `C` [orthopoly1d] Chebyshev polynomial of the first kind on $[-2, 2]$.

**See also:**

- `chebyt`
  Chebyshev polynomial of the first kind.

**Notes**

The polynomials $C_n(x)$ are orthogonal over $[-2, 2]$ with weight function $1/\sqrt{1-(x/2)^2}$.

**References**

[1]

scipy.special.chebys

`scipy.special.chebys(n, monic=False)`

Chebyshev polynomial of the second kind on $[-2, 2]$.

Defined as $S_n(x) = U_n(x/2)$ where $U_n$ is the nth Chebychev polynomial of the second kind.

**Parameters**

- `n` [int] Degree of the polynomial.
- `monic` [bool, optional] If `True`, scale the leading coefficient to be 1. Default is `False`.

**Returns**

- `S` [orthopoly1d] Chebyshev polynomial of the second kind on $[-2, 2]$.

**See also:**

- `chebyu`
  Chebyshev polynomial of the second kind
Notes

The polynomials $S_n(x)$ are orthogonal over $[-2, 2]$ with weight function $\sqrt{1 - (x/2)^2}$.

References

[1]

scipy.special.jacobi

scipy.special.jacobi($n$, $alpha$, $beta$, monic=False)

Jacobi polynomial.

defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} P_n^{(\alpha,\beta)} + (\beta - \alpha - (\alpha + \beta + 2)x) \frac{d}{dx} P_n^{(\alpha,\beta)} + n(n + \alpha + \beta + 1)P_n^{(\alpha,\beta)} = 0$$

for $\alpha, \beta > -1$; $P_n^{(\alpha,\beta)}$ is a polynomial of degree $n$.

Parameters

$n$ [int] Degree of the polynomial.
$alpha$ [float] Parameter, must be greater than -1.
$beta$ [float] Parameter, must be greater than -1.
monic [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

Returns

$P$ [orthopoly1d] Jacobi polynomial.

Notes

For fixed $\alpha, \beta$, the polynomials $P_n^{(\alpha,\beta)}$ are orthogonal over $[-1, 1]$ with weight function $(1 - x)^{\alpha}(1 + x)^{\beta}$.

References

[AS]

Examples

The Jacobi polynomials satisfy the recurrence relation:

$P_n^{(\alpha,\beta-1)}(x) - P_n^{(\alpha-1,\beta)}(x) = P_{n-1}^{(\alpha,\beta)}(x)$

This can be verified, for example, for $\alpha = \beta = 2$ and $n = 1$ over the interval $[-1, 1]$:

```python
>>> import numpy as np
d >>> from scipy.special import jacobi
d >>> x = np.arange(-1.0, 1.0, 0.01)
d >>> np.allclose(jacobi(0, 2, 2)(x),
... jacobi(0, 2, 2)(x) - jacobi(1, 2, 1)(x) - jacobi(1, 1, 2)(x))
True
```
Plot of the Jacobi polynomial $P_5^{(\alpha,-0.5)}$ for different values of $\alpha$:

```python
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.special import jacobi
>>> x = np.arange(-1.0, 1.0, 0.01)
>>> fig, ax = plt.subplots()
>>> ax.set_ylim(-2.0, 2.0)
>>> ax.set_title(r'$Jacobi polynomials P_5^{(\alpha, -0.5)}$')
>>> for alpha in np.arange(0, 4, 1):
...    ax.plot(x, jacobi(5, alpha, -0.5)(x), label=rf'$\alpha={alpha}$')
>>> plt.legend(loc='best')
>>> plt.show()
```

Scipy.special.laguerre

**Scipy.special.laguerre** ($n$, monic=False)

Laguerre polynomial.

Defined to be the solution of

$$x \frac{d^2}{dx^2} L_n + (1-x) \frac{d}{dx} L_n + n L_n = 0;$$

$L_n$ is a polynomial of degree $n$.

**Parameters**

- **n** [int] Degree of the polynomial.
- **monic** [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

**Returns**

- **L** [orthopoly1d] Laguerre Polynomial.

See also:
genlaguerre

Generalized (associated) Laguerre polynomial.

Notes

The polynomials \( L_n \) are orthogonal over \([0, \infty)\) with weight function \( e^{-x} \).

References

[AS]

Examples

The Laguerre polynomials \( L_n \) are the special case \( \alpha = 0 \) of the generalized Laguerre polynomials \( L_n^{(\alpha)} \). Let’s verify it on the interval \([-1, 1]\):

```python
>>> from scipy.special import genlaguerre
>>> from scipy.special import laguerre
>>> x = np.arange(-1.0, 1.0, 0.01)
>>> np.allclose(genlaguerre(3, 0)(x), laguerre(3)(x))
True
```

The polynomials \( L_n \) also satisfy the recurrence relation:

\[
(n + 1)L_{n+1}(x) = (2n + 1 - x)L_n(x) - nL_{n-1}(x)
\]

This can be easily checked on \([0, 1]\) for \( n = 3 \):

```python
>>> from scipy.special import laguerre
>>> x = np.arange(0.0, 1.0, 0.01)
>>> np.allclose(4 * laguerre(4)(x),
...             (7 - x) * laguerre(3)(x) - 3 * laguerre(2)(x))
True
```

This is the plot of the first few Laguerre polynomials \( L_n \):

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.special import laguerre
>>> x = np.arange(-1.0, 5.0, 0.01)
>>> fig, ax = plt.subplots()
>>> ax.set_xlim(-5.0, 5.0)
>>> ax.set_title(r'Laguerre polynomials $L_n$')
>>> for n in np.arange(0, 5):
...     ax.plot(x, laguerre(n)(x), label=rf'$L_{n}$')
>>> plt.legend(loc='best')
>>> plt.show()
```
scipy.special.genlaguerre

scipy.special.genlaguerre(n, alpha, monic=False)

Generalized (associated) Laguerre polynomial.

Defined to be the solution of

\[ x \frac{d^2}{dx^2} L_n^{(\alpha)} + (\alpha + 1 - x) \frac{d}{dx} L_n^{(\alpha)} + n L_n^{(\alpha)} = 0, \]

where \( \alpha > -1; L_n^{(\alpha)} \) is a polynomial of degree \( n \).

Parameters

- **n** [int] Degree of the polynomial.
- **alpha** [float] Parameter, must be greater than -1.
- **monic** [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

Returns

- **L** [orthopoly1d] Generalized Laguerre polynomial.

See also:

- **laguerre**
  
  Laguerre polynomial.

- **hyp1f1**

  confluent hypergeometric function
Notes

For fixed \( \alpha \), the polynomials \( L_n^{(\alpha)} \) are orthogonal over \([0, \infty)\) with weight function \( e^{-x}x^{\alpha} \).
The Laguerre polynomials are the special case where \( \alpha = 0 \).

References

[AS]

Examples

The generalized Laguerre polynomials are closely related to the confluent hypergeometric function \( \, _1F_1 \):

\[
L_n^{(\alpha)} = \binom{n + \alpha}{n} \, _1F_1(-n, \alpha + 1, x)
\]

This can be verified, for example, for \( n = \alpha = 3 \) over the interval \([-1, 1]\):

```
>>> from scipy.special import binom
>>> from scipy.special import genlaguerre
>>> from scipy.special import hyp1f1
>>> x = np.arange(-1.0, 1.0, 0.01)
>>> np.allclose(genlaguerre(3, 3)(x), binom(6, 3) * hyp1f1(-3, 4, x))
True
```

This is the plot of the generalized Laguerre polynomials \( L_3^{(\alpha)} \) for some values of \( \alpha \):

```
>>> from matplotlib import pyplot as plt
>>> from scipy.special import genlaguerre
>>> x = np.arange(-4.0, 12.0, 0.01)
>>> fig, ax = plt.subplots()
>>> ax.set_ylim(-5.0, 10.0)
>>> ax.set_title(r'Generalized Laguerre polynomials $L_3^{(\alpha)}$')
>>> for alpha in np.arange(0, 5):
...     ax.plot(x, genlaguerre(3, alpha)(x), label=r'$L_3^{(' + str(alpha) + r')}$$')
>>> plt.legend(loc='best')
>>> plt.show()
```

\texttt{scipy.special.hermite}

\texttt{scipy.special.hermite(n, monic=False)}

Physicist's Hermite polynomial.

Defined by

\[
H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2};
\]

\( H_n \) is a polynomial of degree \( n \).
Generalized Laguerre polynomials \( L^g \)

### Parameters
- **n** [int] Degree of the polynomial.
- **monic** [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

### Returns
- **H** [orthopoly1d] Hermite polynomial.

### Notes
The polynomials \( H_n \) are orthogonal over \((-\infty, \infty)\) with weight function \( e^{-x^2} \).

### Examples
```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> import numpy as np

>>> p_monic = special.hermite(3, monic=True)
>>> p_monic.poly1d([ 1. , 0. , -1.5, 0. ])
>>> p_monic(1)
-0.4999999999999983
>>> x = np.linspace(-3, 3, 400)
>>> y = p_monic(x)
>>> plt.plot(x, y)
>>> plt.title("Monic Hermite polynomial of degree 3")
>>> plt.xlabel("x")
>>> plt.ylabel("H_3(x)")
>>> plt.show()
```
**scipy.special.hermitenorm**

*scipy.special.hermitenorm*(n, monic=False)

Normalized (probabilist’s) Hermite polynomial.

Defined by

\[ H_n(x) = (-1)^n e^{x^2/2} \frac{d^n}{dx^n} e^{-x^2/2}; \]

\( H_n \) is a polynomial of degree \( n \).

**Parameters**

- **n** [int] Degree of the polynomial.
- **monic** [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

**Returns**

- **He** [orthopoly1d] Hermite polynomial.

**Notes**

The polynomials \( H_n \) are orthogonal over \((−∞, ∞)\) with weight function \( e^{-x^2/2} \).

**scipy.special.gegenbauer**

*scipy.special.gegenbauer*(n, alpha, monic=False)

Gegenbauer (ultraspherical) polynomial.

Defined to be the solution of

\[ (1 - x^2) \frac{d^2}{dx^2} C_n^{(α)} - (2α + 1)x \frac{d}{dx} C_n^{(α)} + n(n + 2α)C_n^{(α)} = 0 \]

for \( α > -1/2 \); \( C_n^{(α)} \) is a polynomial of degree \( n \).
Parameters

- **n** [int] Degree of the polynomial.
- **alpha** [float] Parameter, must be greater than -0.5.
- **monic** [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

Returns

- **C** [orthopoly1d] Gegenbauer polynomial.

Notes

The polynomials $C_n^{(\alpha)}$ are orthogonal over $[-1, 1]$ with weight function $(1 - x^2)^{(\alpha-1)/2}$.

Examples

```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt

We can initialize a variable \( p \) as a Gegenbauer polynomial using the `gegenbauer` function and evaluate at a point \( x = 1 \).

```python
>>> p = special.gegenbauer(3, 0.5, monic=False)
>>> p
poly1d([ 2.5, 0. , -1.5, 0. ])
>>> p(1)
1.0
```

To evaluate \( p \) at various points \( x \) in the interval \((-3, 3)\), simply pass an array \( x \) to \( p \) as follows:

```python
>>> x = np.linspace(-3, 3, 400)
>>> y = p(x)
```

We can then visualize \( x, y \) using `matplotlib.pyplot`.

```python
>>> fig, ax = plt.subplots()
>>> ax.plot(x, y)
>>> ax.set_title("Gegenbauer (ultraspherical) polynomial of degree 3")
>>> ax.set_xlabel("x")
>>> ax.set_ylabel("G_3(x)")
>>> plt.show()
```

`scipy.special.sh_legendre`

`scipy.special.sh_legendre(n, monic=False)`

Shifted Legendre polynomial.

Defined as $P_n^*(x) = P_n(2x - 1)$ for $P_n$ the \( n \)th Legendre polynomial.

Parameters

- **n** [int] Degree of the polynomial.
- **monic** [bool, optional] If True, scale the leading coefficient to be 1. Default is False.
Gegenbauer (ultraspherical) polynomial of degree 3

Returns
P [orthopoly1d] Shifted Legendre polynomial.

Notes
The polynomials $P_n^*$ are orthogonal over $[0, 1]$ with weight function $1$.

scipy.special.sh_chebyt

scipy.special.sh_chebyt$(n, monic=False)$
Shifted Chebyshev polynomial of the first kind.
Defined as $T_n^*(x) = T_n(2x - 1)$ for $T_n$ the nth Chebyshev polynomial of the first kind.

Parameters
- n [int] Degree of the polynomial.
- monic [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

Returns
T [orthopoly1d] Shifted Chebyshev polynomial of the first kind.

Notes
The polynomials $T_n^*$ are orthogonal over $[0, 1]$ with weight function $(x - x^2)^{-1/2}$.
scipy.special.sh_chebyu

\[ \text{scipy.special.sh_chebyu}(n, \text{monic}=False) \]
Shifted Chebyshev polynomial of the second kind.

Defined as \[ U_n^*(x) = U_n(2x - 1) \] for \( U_n \) the nth Chebyshev polynomial of the second kind.

**Parameters**

- `n` [int] Degree of the polynomial.
- `monic` [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

**Returns**

- `U` [orthopoly1d] Shifted Chebyshev polynomial of the second kind.

**Notes**

The polynomials \( U_n^* \) are orthogonal over \([0, 1]\) with weight function \( (x - x^2)^{1/2} \).

scipy.special.sh_jacobi

\[ \text{scipy.special.sh_jacobi}(n, p, q, \text{monic}=False) \]
Shifted Jacobi polynomial.

Defined by

\[ G_n^{(p,q)}(x) = \binom{2n + p - 1}{n}^{-1} P_n^{(p-q,q-1)}(2x - 1), \]

where \( P_n^{(\cdot,\cdot)} \) is the nth Jacobi polynomial.

**Parameters**

- `n` [int] Degree of the polynomial.
- `p` [float] Parameter, must have \( p > q - 1 \).
- `q` [float] Parameter, must be greater than 0.
- `monic` [bool, optional] If True, scale the leading coefficient to be 1. Default is False.

**Returns**

- `G` [orthopoly1d] Shifted Jacobi polynomial.

**Notes**

For fixed \( p, q \), the polynomials \( G_n^{(p,q)} \) are orthogonal over \([0, 1]\) with weight function \( (1 - x)^{p-q} x^{q-1} \).

**Warning:** Computing values of high-order polynomials (around order > 20) using polynomial coefficients is numerically unstable. To evaluate polynomial values, the eval_* functions should be used instead.
Hypergeometric functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>

</tbody>
</table>

scipy.special.hyp2f1

scipy.special.hyp2f1(a, b, c, z) = <ufunc 'hyp2f1'>
Gauss hypergeometric function 2F1(a, b; c; z)

Parameters

a, b, c  array_like  Arguments, should be real-valued.
z  array_like  Argument, real or complex.

Returns

hyp2f1  [scalar or ndarray]  The values of the gaussian hypergeometric function.

See also:

hyp0f1  confluent hypergeometric limit function.

hyp1f1  Kummer’s (confluent hypergeometric) function.

Notes

This function is defined for |z| < 1 as

\[ \text{hyp2f1}(a, b, c, z) = \sum_{n=0}^{\infty} \frac{(a)_n (b)_n}{(c)_n n!} z^n, \]

and defined on the rest of the complex z-plane by analytic continuation [1]. Here \((\cdot)_n\) is the Pochhammer symbol; see poch. When \(n\) is an integer the result is a polynomial of degree \(n\).

The implementation for complex values of \(z\) is described in [2], except for \(z\) in the region defined by

\[ 0.9 \leq |z| < 1.1, |1 - z| > 0.9, \text{real}(z) \geq 0 \]

in which the implementation follows [4].

References

[1], [2], [3], [4]
Examples

```python
>>> import scipy.special as sc
```

It has poles when \( c \) is a negative integer.

```python
>>> sc.hyp2f1(1, 1, -2, 1)
inf
```

It is a polynomial when \( a \) or \( b \) is a negative integer.

```python
da, b, c = -1, 1, 1.5
z = np.linspace(0, 1, 5)
>>> sc.hyp2f1(a, b, c, z)
array([1. , 0.83333333, 0.66666667, 0.5 , 0.33333333])
```

```python
>>> 1 + a * b * z / c
array([1. , 0.83333333, 0.66666667, 0.5 , 0.33333333])
```

It is symmetric in \( a \) and \( b \).

```python
>>> a = np.linspace(0, 1, 5)
>>> b = np.linspace(0, 1, 5)
>>> sc.hyp2f1(a, b, 1, 0.5)
array([1. , 1.03997334, 1.1803406 , 1.47074441, 2. ])
```

```python
>>> sc.hyp2f1(b, a, 1, 0.5)
array([1. , 1.03997334, 1.1803406 , 1.47074441, 2. ])
```

It contains many other functions as special cases.

```python
>>> z = 0.5
>>> sc.hyp2f1(1, 1, 2, z)
1.3862943611198901
>>> -np.log(1 - z) / z
1.3862943611198906
```

```python
>>> sc.hyp2f1(0.5, 1, 1.5, z**2)
1.098612288868109
>>> np.log((1 + z) / (1 - z)) / (2 * z)
1.0986122888681098
```

```python
>>> sc.hyp2f1(0.5, 1, 1.5, -z**2)
0.9272952180016117
>>> np.arctan(z) / z
0.9272952180016123
```
scipy.special.hyp1f1

scipy.special.hyp1f1(a, b, x, out=None) = <ufunc 'hyp1f1'>

Confluent hypergeometric function 1F1.

The confluent hypergeometric function is defined by the series

\[ \text{I}_1 F_1(a; b; x) = \sum_{k=0}^{\infty} \frac{(a)_k}{(b)_k k!} x^k. \]

See [dlmf] for more details. Here \( (\cdot)_k \) is the Pochhammer symbol; see `poch`.

Parameters

- **a**, **b** [array_like] Real parameters
- **x** [array_like] Real or complex argument
- **out** [ndarray, optional] Optional output array for the function results

Returns

- scalar or ndarray
  Values of the confluent hypergeometric function

See also:

`hyperu`

another confluent hypergeometric function

`hyp0f1`

confluent hypergeometric limit function

`hyp2f1`

Gaussian hypergeometric function

References

[dlmf]

Examples

```python
>>> import scipy.special as sc
```

It is one when \( x \) is zero:

```python
>>> sc.hyp1f1(0.5, 0.5, 0)
1.0
```

It is singular when \( b \) is a nonpositive integer.

```python
>>> sc.hyp1f1(0.5, -1, 0)
inf
```

It is a polynomial when \( a \) is a nonpositive integer.
```python
>>> a, b, x = -1, 0.5, np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.hyp1f1(a, b, x)
array([-1., -3., -5., -7.])
>>> 1 + (a / b) * x
array([-1., -3., -5., -7.])
```

It reduces to the exponential function when \( a = b \).

```python
>>> sc.hyp1f1(2, 2, [1, 2, 3, 4])
array([ 2.71828183, 7.3890561, 20.08553692, 54.59815003])
>>> np.exp([1, 2, 3, 4])
array([ 2.71828183, 7.3890561, 20.08553692, 54.59815003])
```

### scipy.special.hyperu

`scipy.special.hyperu(a, b, x, out=None) = <ufunc 'hyperu'>`

Confluent hypergeometric function \( U \)

It is defined as the solution to the equation

\[
x \frac{d^2w}{dx^2} + (b - x) \frac{dw}{dx} - aw = 0
\]

which satisfies the property

\[
U(a, b, x) \sim x^{-a}
\]

as \( x \to \infty \). See [dlmf] for more details.

**Parameters**

- **a** [array_like]: Real-valued parameters
- **b** [array_like]: Real-valued argument
- **x** [array_like]: Real-valued argument
- **out** [ndarray]: Optional output array for the function values

**Returns**

- **scalar** or **ndarray**: Values of \( U \)

**References**

[dlmf]

**Examples**

```python
>>> import scipy.special as sc
```

It has a branch cut along the negative \( x \) axis.

```python
>>> x = np.linspace(-0.1, -10, 5)
>>> sc.hyperu(1, 1, x)
array([nan, nan, nan, nan, nan])
```
It approaches zero as $x$ goes to infinity.

```python
>>> x = np.array([1, 10, 100])
>>> sc.hyperu(1, 1, x)
array([0.59634736, 0.09156333, 0.00990194])
```

It satisfies Kummer's transformation.

```python
>>> a, b, x = 2, 1, 1
>>> sc.hyperu(a, b, x)
0.1926947246463881
>>> x**(1 - b) * sc.hyperu(a - b + 1, 2 - b, x)
0.1926947246463881
```

**scipy.special.hyp0f1**

*scipy.special.hyp0f1(v, z, out=None) = <ufunc 'hyp0f1'>*

Confluent hypergeometric limit function 0F1.

**Parameters**

- `v`  
  [array_like] Real-valued parameter

- `z`  
  [array_like] Real- or complex-valued argument

- `out`  
  [ndarray, optional] Optional output array for the function results

**Returns**

- `scalar or ndarray`
  The confluent hypergeometric limit function

**Notes**

This function is defined as:

$$0F_1(v, z) = \sum_{k=0}^{\infty} \frac{z^k}{(v)_k k!}.$$  

It's also the limit as $q \to \infty$ of $1F_1(q; v; z/q)$, and satisfies the differential equation $f''(z) + vf'(z) = f(z)$. See [1] for more information.

**References**

[1]
Examples

```python
>>> import scipy.special as sc
```

It is one when \( z \) is zero.

```python
>>> sc.hyp0f1(1, 0)
1.0
```

It is the limit of the confluent hypergeometric function as \( q \) goes to infinity.

```python
>>> q = np.array([1, 10, 100, 1000])
>>> v = 1
>>> z = 1
>>> sc.hyp1f1(q, v, z / q)
array([2.71828183, 2.31481985, 2.28303778, 2.27992985])
```

It is related to Bessel functions.

```python
>>> n = 1
>>> x = np.linspace(0, 1, 5)
>>> sc.jv(n, x)
array([0. , 0.12402598, 0.24226846, 0.3492436 , 0.44005059])
```

Parabolic cylinder functions

- `pbdv(v, x)` Parabolic cylinder function D
- `pbvv(v, x)` Parabolic cylinder function V
- `pbwa(a, x)` Parabolic cylinder function W.

**scipy.special.pbdv**

```
scipy.special.pbdv(v, x) = <ufunc 'pbdv'>
```

Parabolic cylinder function D

Returns \( (d, dp) \) the parabolic cylinder function \( D(v)(x) \) in \( d \) and the derivative, \( D(v)(x) \) in \( dp \).

**Returns**

- **d** Value of the function
- **dp** Value of the derivative vs \( x \)
scipy.special.pbvv

scipy.special.pbvv(v, x) = <ufunc 'pbvv'>
Parabolic cylinder function $V$

Returns the parabolic cylinder function $V_v(x)$ in $v$ and the derivative, $V'_v(x)$ in $vp$.

Returns

$v$  Value of the function
$vp$  Value of the derivative vs $x$

scipy.special.pbwa

scipy.special.pbwa(a, x) = <ufunc 'pbwa'>
Parabolic cylinder function $W$.

The function is a particular solution to the differential equation

$$y'' + \left( \frac{1}{4} x^2 - a \right) y = 0,$$

for a full definition see section 12.14 in [1].

Parameters

$a$  [array_like] Real parameter
$x$  [array_like] Real argument

Returns

$w$  [scalar or ndarray] Value of the function
$wp$  [scalar or ndarray] Value of the derivative in $x$

Notes

The function is a wrapper for a Fortran routine by Zhang and Jin [2]. The implementation is accurate only for $|a|, |x| < 5$ and returns NaN outside that range.

scipy.special.pbdv_seq

scipy.special.pbdv_seq(v, x)
Parabolic cylinder functions Dv(x) and derivatives.

Parameters

v [float] Order of the parabolic cylinder function
x [float] Value at which to evaluate the function and derivatives

Returns

dv [ndarray] Values of D_vi(x), for vi=v-int(v), vi=1+v-int(v), ..., vi=v.
dp [ndarray] Derivatives D_vi'(x), for vi=v-int(v), vi=1+v-int(v), ..., vi=v.

scipy.special.pbdn_seq

scipy.special.pbdn_seq(n, z)
Parabolic cylinder functions Dn(z) and derivatives.

Parameters

n [int] Order of the parabolic cylinder function
z [complex] Value at which to evaluate the function and derivatives

Returns

dv [ndarray] Values of D_i(z), for i=0, ..., i=n.
dp [ndarray] Derivatives D_i'(z), for i=0, ..., i=n.

### Mathieu and related functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mathieu_a(m, q)</code></td>
<td>Characteristic value of even Mathieu functions</td>
</tr>
<tr>
<td><code>mathieu_b(m, q)</code></td>
<td>Characteristic value of odd Mathieu functions</td>
</tr>
</tbody>
</table>

### scipy.special.mathieu_a

```python
scipy.special.mathieu_a(m, q) = <ufunc 'mathieu_a'>
```

Characteristic value of even Mathieu functions

Returns the characteristic value for the even solution, \(ce_m(z, q)\), of Mathieu’s equation.

### scipy.special.mathieu_b

```python
scipy.special.mathieu_b(m, q) = <ufunc 'mathieu_b'>
```

Characteristic value of odd Mathieu functions

Returns the characteristic value for the odd solution, \(se_m(z, q)\), of Mathieu’s equation.

These are not universal functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mathieu_even_coef(m, q)</code></td>
<td>Fourier coefficients for even Mathieu and modified Mathieu functions.</td>
</tr>
<tr>
<td><code>mathieu_odd_coef(m, q)</code></td>
<td>Fourier coefficients for even Mathieu and modified Mathieu functions.</td>
</tr>
</tbody>
</table>

### scipy.special.mathieu_even_coef

```python
scipy.special.mathieu_even_coef(m, q)
```

Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the even solutions of the Mathieu differential equation are of the form

\[
ce_{2n}(z, q) = \sum_{k=0}^{\infty} A_{(2n)}^{(2k)} \cos 2kz
\]

\[
ce_{2n+1}(z, q) = \sum_{k=0}^{\infty} A_{(2n+1)}^{(2k+1)} \cos(2k + 1)z
\]

This function returns the coefficients \(A_{(2n)}^{(2k)}\) for even input \(m=2n\), and the coefficients \(A_{(2n+1)}^{(2k+1)}\) for odd input \(m=2n+1\).

**Parameters**

- \(m\) [int] Order of Mathieu functions. Must be non-negative.
- \(q\) [float (>=0)] Parameter of Mathieu functions. Must be non-negative.

**Returns**

- \(Ak\) [ndarray] Even or odd Fourier coefficients, corresponding to even or odd \(m\).
scipy.special.mathieu_odd_coef

scipy.special.mathieu_odd_coef(m, q)

Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the odd solutions of the Mathieu differential equation are of the form

\[ se_{2n+1}(z, q) = \sum_{k=0}^{\infty} B^{(2k+1)}_{(2n+1)} \sin(2k + 1)z \]

\[ se_{2n+2}(z, q) = \sum_{k=0}^{\infty} B^{(2k+2)}_{(2n+2)} \sin(2k + 2)z \]

This function returns the coefficients \( B^{(2k+2)}_{(2n+2)} \) for even input \( m=2n+2 \), and the coefficients \( B^{(2k+1)}_{(2n+1)} \) for odd input \( m=2n+1 \).

Parameters

- **m** [int] Order of Mathieu functions. Must be non-negative.
- **q** [float (>=0)] Parameter of Mathieu functions. Must be non-negative.

Returns

- **Bk** [ndarray] Even or odd Fourier coefficients, corresponding to even or odd m.

</tr>
</tbody>
</table>
scipy.special.mathieu_cem

```python
scipy.special.mathieu_cem(m, q, x) = <ufunc 'mathieu_cem'>
```

Even Mathieu function and its derivative

Returns the even Mathieu function, $ce_m(x, q)$, of order $m$ and parameter $q$ evaluated at $x$ (given in degrees). Also returns the derivative with respect to $x$ of $ce_m(x, q)$

Parameters

- **m**: Order of the function
- **q**: Parameter of the function
- **x**: Argument of the function, *given in degrees, not radians*

Returns

- **y**: Value of the function
- **yp**: Value of the derivative vs $x$

scipy.special.mathieu_sem

```python
scipy.special.mathieu_sem(m, q, x) = <ufunc 'mathieu_sem'>
```

Odd Mathieu function and its derivative

Returns the odd Mathieu function, $se_m(x, q)$, of order $m$ and parameter $q$ evaluated at $x$ (given in degrees). Also returns the derivative with respect to $x$ of $se_m(x, q)$.

Parameters

- **m**: Order of the function
- **q**: Parameter of the function
- **x**: Argument of the function, *given in degrees, not radians*

Returns

- **y**: Value of the function
- **yp**: Value of the derivative vs $x$

scipy.special.mathieu_modcem1

```python
scipy.special.mathieu_modcem1(m, q, x) = <ufunc 'mathieu_modcem1'>
```

Even modified Mathieu function of the first kind and its derivative

Evaluates the even modified Mathieu function of the first kind, $Mc1m(x, q)$, and its derivative at $x$ for order $m$ and parameter $q$.

Returns

- **y**: Value of the function
- **yp**: Value of the derivative vs $x$
scipy.special.mathieu_modcem2

scipy.special.mathieu_modcem2(m, q, x) = <ufunc 'mathieu_modcem2'>

Even modified Mathieu function of the second kind and its derivative

Evaluates the even modified Mathieu function of the second kind, Mc2m(x, q), and its derivative at x (given in degrees) for order m and parameter q.

Returns

y Value of the function
yp Value of the derivative vs x

scipy.special.mathieu_modsem1

scipy.special.mathieu_modsem1(m, q, x) = <ufunc 'mathieu_modsem1'>

Odd modified Mathieu function of the first kind and its derivative

Evaluates the odd modified Mathieu function of the first kind, Ms1m(x, q), and its derivative at x (given in degrees) for order m and parameter q.

Returns

y Value of the function
yp Value of the derivative vs x

scipy.special.mathieu_modsem2

scipy.special.mathieu_modsem2(m, q, x) = <ufunc 'mathieu_modsem2'>

Odd modified Mathieu function of the second kind and its derivative

Evaluates the odd modified Mathieu function of the second kind, Ms2m(x, q), and its derivative at x (given in degrees) for order m and parameter q.

Returns

y Value of the function
yp Value of the derivative vs x

**scipy.special.pro_ang1**

```python
scipy.special.pro_ang1(m, n, c, x) = <ufunc 'pro_ang1'>
```

Prolate spheroidal angular function of the first kind and its derivative

Computes the prolate spheroidal angular function of the first kind and its derivative (with respect to \(x\)) for mode parameters \(m \geq 0\) and \(n \geq m\), spheroidal parameter \(c\) and \(|x| < 1.0\).

**Returns**

- **s**: Value of the function
- **sp**: Value of the derivative vs \(x\)

**scipy.special.pro_rad1**

```python
scipy.special.pro_rad1(m, n, c, x) = <ufunc 'pro_rad1'>
```

Prolate spheroidal radial function of the first kind and its derivative

Computes the prolate spheroidal radial function of the first kind and its derivative (with respect to \(x\)) for mode parameters \(m \geq 0\) and \(n \geq m\), spheroidal parameter \(c\) and \(|x| < 1.0\).

**Returns**

- **s**: Value of the function
- **sp**: Value of the derivative vs \(x\)

**scipy.special.pro_rad2**

```python
scipy.special.pro_rad2(m, n, c, x) = <ufunc 'pro_rad2'>
```

Prolate spheroidal radial function of the second kind and its derivative

Computes the prolate spheroidal radial function of the second kind and its derivative (with respect to \(x\)) for mode parameters \(m \geq 0\) and \(n \geq m\), spheroidal parameter \(c\) and \(|x| < 1.0\).

**Returns**

- **s**: Value of the function
- **sp**: Value of the derivative vs \(x\)

**scipy.special.obl_ang1**

```python
scipy.special.obl_ang1(m, n, c, x) = <ufunc 'obl_ang1'>
```

Oblate spheroidal angular function of the first kind and its derivative

Computes the oblate spheroidal angular function of the first kind and its derivative (with respect to \(x\)) for mode parameters \(m \geq 0\) and \(n \geq m\), spheroidal parameter \(c\) and \(|x| < 1.0\).

**Returns**

- **s**: Value of the function
- **sp**: Value of the derivative vs \(x\)
scipy.special.obl_rad1

```python
def scipy.special.obl_rad1(m, n, c, x):
    # Oblate spheroidal radial function of the first kind and its derivative
    Computes the oblate spheroidal radial function of the first kind and its derivative (with respect to x) for mode parameters m>=0 and n>=m, spheroidal parameter c and |x|<1.0.
    Returns
    s : Value of the function
    sp : Value of the derivative vs x
```
**References**

[1]

**scipy.special.obl_cv_seq**

`scipy.special.obl_cv_seq(m, n, c)`  
Characteristic values for oblate spheroidal wave functions.  
Compute a sequence of characteristic values for the oblate spheroidal wave functions for mode \( m \) and \( n'=m..n \) and spheroidal parameter \( c \).

**scipy.special.pro_ang1_cv**

`scipy.special.pro_ang1_cv(m, n, c, cv, x) = <ufunc 'pro_ang1_cv'>`  
Prolate spheroidal angular function \( \text{pro}_{\text{ang1}} \) for precomputed characteristic value  
Computes the prolate spheroidal angular function of the first kind and its derivative (with respect to \( x \)) for mode parameters \( m\geq 0 \) and \( n\geq m \), spheroidal parameter \( c \) and \( |x| < 1.0 \). Requires pre-computed characteristic value.

**Returns**

- \( s \) Value of the function
- \( sp \) Value of the derivative vs \( x \)
scipy.special.pro_rad1_cv

```python
scipy.special.pro_rad1_cv(m, n, c, cv, x) = <ufunc 'pro_rad1_cv'>
```

Prolate spheroidal radial function pro_rad1 for precomputed characteristic value

Computes the prolate spheroidal radial function of the first kind and its derivative (with respect to \(x\)) for mode parameters \(m \geq 0\) and \(n \geq m\), spheroidal parameter \(c\) and \(|x| < 1.0\). Requires pre-computed characteristic value.

**Returns**

- **s**: Value of the function
- **sp**: Value of the derivative vs \(x\)

scipy.special.pro_rad2_cv

```python
scipy.special.pro_rad2_cv(m, n, c, cv, x) = <ufunc 'pro_rad2_cv'>
```

Prolate spheroidal radial function pro_rad2 for precomputed characteristic value

Computes the prolate spheroidal radial function of the second kind and its derivative (with respect to \(x\)) for mode parameters \(m \geq 0\) and \(n \geq m\), spheroidal parameter \(c\) and \(|x| < 1.0\). Requires pre-computed characteristic value.

**Returns**

- **s**: Value of the function
- **sp**: Value of the derivative vs \(x\)

scipy.special.obl_ang1_cv

```python
scipy.special.obl_ang1_cv(m, n, c, cv, x) = <ufunc 'obl_ang1_cv'>
```

Oblate spheroidal angular function obl_ang1 for precomputed characteristic value

Computes the oblate spheroidal angular function of the first kind and its derivative (with respect to \(x\)) for mode parameters \(m \geq 0\) and \(n \geq m\), spheroidal parameter \(c\) and \(|x| < 1.0\). Requires pre-computed characteristic value.

**Returns**

- **s**: Value of the function
- **sp**: Value of the derivative vs \(x\)

scipy.special.obl_rad1_cv

```python
scipy.special.obl_rad1_cv(m, n, c, cv, x) = <ufunc 'obl_rad1_cv'>
```

Oblate spheroidal radial function obl_rad1 for precomputed characteristic value

Computes the oblate spheroidal radial function of the first kind and its derivative (with respect to \(x\)) for mode parameters \(m \geq 0\) and \(n \geq m\), spheroidal parameter \(c\) and \(|x| < 1.0\). Requires pre-computed characteristic value.

**Returns**

scipy.special.kelvin

scipy.special.kelvin(x) = <ufunc 'kelvin'>

Kelvin functions as complex numbers

**Returns**

- \(Be, Ke, Bep, Kep\)

  The tuple \((Be, Ke, Bep, Kep)\) contains complex numbers representing the real and imaginary Kelvin functions and their derivatives evaluated at \(x\). For example, \(kelvin(x)[0].real = ber x\) and \(kelvin(x)[0].imag = bei x\) with similar relationships for \(ker\) and \(kei\).

scipy.special.kelvin_zeros

scipy.special.kelvin_zeros(nt)

Compute nt zeros of all Kelvin functions.

Returned in a length-8 tuple of arrays of length nt. The tuple contains the arrays of zeros of (ber, bei, ker, kei, ber', bei', ker', kei').

3.3. API definition 2351
References

[1]

scipy.special.ber

scipy.special.ber(x, out=None) = <ufunc 'ber'>
Kelvin function ber.
Defined as
\[
ber(x) = \Re[J_0(xe^{3\pi i/4})]
\]
where \(J_0\) is the Bessel function of the first kind of order zero (see jv). See [dlmf] for more details.

Parameters

- **x** [array_like] Real argument.
- **out** [ndarray, optional] Optional output array for the function results.

Returns

- scalar or ndarray
  Values of the Kelvin function.

See also:

- **bei**
  the corresponding real part
- **berp**
  the derivative of bei
- **jv**
  Bessel function of the first kind

References

[dlmf]

Examples

It can be expressed using Bessel functions.

```python
>>> import scipy.special as sc
>>> x = np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.jv(0, x * np.exp(3 * np.pi * 1j / 4)).real
array([ 0.98438178, 0.75173418, -0.22138025, -2.56341656])
>>> sc.ber(x)
array([ 0.98438178, 0.75173418, -0.22138025, -2.56341656])
```
scipy.special.bei

`scipy.special.bei(x, out=None) = <ufunc 'bei'>`

Kelvin function bei.

Defined as

\[ bei(x) = \Im\left[J_0(xe^{3\pi i/4})\right] \]

where \( J_0 \) is the Bessel function of the first kind of order zero (see \( jv \)). See [dlmf] for more details.

**Parameters**

- `x` : [array_like] Real argument.
- `out` : [ndarray, optional] Optional output array for the function results.

**Returns**

- scalar or ndarray
  Values of the Kelvin function.

**See also:**

- `ber`
  the corresponding real part
- `beip`
  the derivative of bei
- `jv`
  Bessel function of the first kind

**References**

[dlmf]

**Examples**

It can be expressed using Bessel functions.

```python
>>> import scipy.special as sc
>>> x = np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.jv(0, x * np.exp(3 * np.pi * 1j / 4)).imag
array([0.24956604, 0.97229163, 1.93758679, 2.29269032])
>>> sc.bei(x)
array([0.24956604, 0.97229163, 1.93758679, 2.29269032])
```
scipy.special.berp

scipy.special.berp(x, out=None) = <ufunc 'berp'>
Derivative of the Kelvin function ber.

Parameters

x [array_like] Real argument.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
The values of the derivative of ber.

See also:
ber

References

[dlmf]

scipy.special.beip

scipy.special.beip(x, out=None) = <ufunc 'beip'>
Derivative of the Kelvin function bei.

Parameters

x [array_like] Real argument.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
The values of the derivative of bei.

See also:
bei

References

[dlmf]
scipy.special.ker

scipy.special.ker(x, out=None) = <ufunc 'ker'>
Kelvin function ker.

Defined as

\[ \ker(x) = \Re[K_0(xe^{\pi i/4})] \]

Where \( K_0 \) is the modified Bessel function of the second kind (see \( kv \)). See [dlmf] for more details.

**Parameters**

- **x** [array_like] Real argument.
- **out** [ndarray, optional] Optional output array for the function results.

**Returns**

- scalar or ndarray
  Values of the Kelvin function.

**See also:**

- **kei**
  the corresponding imaginary part
- **kerp**
  the derivative of ker
- **kv**
  modified Bessel function of the second kind

**References**

[dlmf]

**Examples**

It can be expressed using the modified Bessel function of the second kind.

```python
>>> import scipy.special as sc
>>> x = np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.kv(0, x * np.exp(np.pi * 1j / 4)).real
array([ 0.28670621, -0.04166451, -0.06702923, -0.03617885])
>>> sc.ker(x)
array([ 0.28670621, -0.04166451, -0.06702923, -0.03617885])
```
scipy.special.kei

scipy.special.kei(x, out=None) = <ufunc 'kei'>
Kelvin function kei.
Defined as

\[ \text{kei}(x) = \Im[K_0(xe^{\pi i/4})] \]

where \( K_0 \) is the modified Bessel function of the second kind (see \( kv \)). See [dlmf] for more details.

**Parameters**

- \( x \) : [array_like] Real argument.
- \( \text{out} \) : [ndarray, optional] Optional output array for the function results.

**Returns**

- scalar or ndarray: Values of the Kelvin function.

**See also:**

- \( ker \): the corresponding real part
- \( keip \): the derivative of \( kei \)
- \( kv \): modified Bessel function of the second kind

**References**

[dlmf]

**Examples**

It can be expressed using the modified Bessel function of the second kind.

```python
>>> import scipy.special as sc
>>> x = np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.kv(0, x * np.exp(np.pi * 1j / 4)).imag
array([-0.49499464, -0.20240007, -0.05112188, 0.0021984 ])
>>> sc.kei(x)
array([-0.49499464, -0.20240007, -0.05112188, 0.0021984 ])
```
scipy.special.kerp

\texttt{scipy.special.kerp(x, out=\texttt{None}) = \texttt{ufunc \ 'kerp'}}

Derivative of the Kelvin function \texttt{ker}.

\textbf{Parameters}

- \texttt{x} \ [\texttt{array_like}] Real argument.
- \texttt{out} \ [\texttt{ndarray, optional}] Optional output array for the function results.

\textbf{Returns}

- \texttt{scalar or ndarray}
  
  Values of the derivative of \texttt{ker}.

\textbf{See also:}

- \texttt{ker}

\textbf{References}

[dlmf]

scipy.special.keip

\texttt{scipy.special.keip(x, out=\texttt{None}) = \texttt{ufunc \ 'keip'}}

Derivative of the Kelvin function \texttt{kei}.

\textbf{Parameters}

- \texttt{x} \ [\texttt{array_like}] Real argument.
- \texttt{out} \ [\texttt{ndarray, optional}] Optional output array for the function results.

\textbf{Returns}

- \texttt{scalar or ndarray}
  
  The values of the derivative of \texttt{kei}.

\textbf{See also:}

- \texttt{kei}

### scipy.special.ber_zeros

**scipy.special.ber_zeros**

`scipy.special.ber_zeros(nt)`

Compute nt zeros of the Kelvin function ber.

**Parameters**

- `nt` [int] Number of zeros to compute. Must be positive.

**Returns**

- `ndarray` First nt zeros of the Kelvin function.

**See also:**

- `ber`

**References**

[1]

### scipy.special.bei_zeros

**scipy.special.bei_zeros**

`scipy.special.bei_zeros(nt)`

Compute nt zeros of the Kelvin function bei.

**Parameters**

- `nt` [int] Number of zeros to compute. Must be positive.

**Returns**

- `ndarray` First nt zeros of the Kelvin function.

**See also:**

- `bei`

### Combinatorics

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>comb</strong>(<em>N, k[, exact, repetition]</em>)</td>
<td>The number of combinations of <em>N</em> things taken <em>k</em> at a time.</td>
</tr>
<tr>
<td><strong>perm</strong>(<em>N, k[, exact]</em>)</td>
<td>Permutations of <em>N</em> things taken <em>k</em> at a time, i.e., <em>k</em>-permutations of <em>N</em>.</td>
</tr>
</tbody>
</table>

**scipy.special.comb**

**scipy.special.comb**(*N, k, exact=False, repetition=False*)

The number of combinations of *N* things taken *k* at a time.

This is often expressed as “*N* choose *k*”.

**Parameters**

*N*  
[int, ndarray] Number of things.

*k*  
[int, ndarray] Number of elements taken.

*exact*  
[bool, optional] If *exact* is False, then floating point precision is used, otherwise exact long integer is computed.

*repetition*  
[bool, optional] If *repetition* is True, then the number of combinations with repetition is computed.

**Returns**

*val*  
[int, float, ndarray] The total number of combinations.

**See also:**

*binom*

Binomial coefficient ufunc
Notes

- Array arguments accepted only for exact=False case.
- If N < 0, or k < 0, then 0 is returned.
- If k > N and repetition=False, then 0 is returned.

Examples

```python
>>> from scipy.special import comb
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> comb(n, k, exact=False)
array([ 120.,  210.])
>>> comb(10, 3, exact=True)
120
>>> comb(10, 3, exact=True, repetition=True)
220
```

```
scipy.special.perm
```

`scipy.special.perm(N, k, exact=False)`

Permutations of N things taken k at a time, i.e., k-permutations of N.

It’s also known as “partial permutations”.

**Parameters**

- **N** [int, ndarray] Number of things.
- **k** [int, ndarray] Number of elements taken.
- **exact** [bool, optional] If exact is False, then floating point precision is used, otherwise exact long integer is computed.

**Returns**

- **val** [int, ndarray] The number of k-permutations of N.

Notes

- Array arguments accepted only for exact=False case.
- If k > N, N < 0, or k < 0, then a 0 is returned.

Examples

```python
>>> from scipy.special import perm
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> perm(n, k)
array([ 720., 5040.])
>>> perm(10, 3, exact=True)
720
```
Lambert W and related functions

\[ \text{lambertw}(z, k, \text{tol}) \] Lambert W function.

\[ \text{wrightomega}(z, \text{out}) \] Wright Omega function.

**scipy.special.lambertw**

```
scipy.special.lambertw(z, k=0, tol=1e-8)
```
Lambert W function.

The Lambert W function \( W(z) \) is defined as the inverse function of \( w \times \exp(w) \). In other words, the value of \( W(z) \) is such that \( z = W(z) \times \exp(W(z)) \) for any complex number \( z \).

The Lambert W function is a multivalued function with infinitely many branches. Each branch gives a separate solution of the equation \( z = w \exp(w) \). Here, the branches are indexed by the integer \( k \).

**Parameters**

- \( z \) [array_like] Input argument.
- \( k \) [int, optional] Branch index.
- \( \text{tol} \) [float, optional] Evaluation tolerance.

**Returns**

- \( w \) [array] \( w \) will have the same shape as \( z \).

**See also:**

- \[ \text{wrightomega} \]
  - the Wright Omega function

**Notes**

All branches are supported by \( \text{lambertw} \):

- \( \text{lambertw}(z) \) gives the principal solution (branch 0)
- \( \text{lambertw}(z, k) \) gives the solution on branch \( k \)

The Lambert W function has two partially real branches: the principal branch \( k = 0 \) is real for real \( z > -1/e \), and the \( k = -1 \) branch is real for \( -1/e < z < 0 \). All branches except \( k = 0 \) have a logarithmic singularity at \( z = 0 \).

**Possible issues**

The evaluation can become inaccurate very close to the branch point at \( -1/e \). In some corner cases, \( \text{lambertw} \) might currently fail to converge, or can end up on the wrong branch.

**Algorithm**

Halley’s iteration is used to invert \( w \times \exp(w) \), using a first-order asymptotic approximation \( O(\log(w)) \) or \( O(w) \) as the initial estimate.

The definition, implementation and choice of branches is based on [2].

3.3. API definition 2363
References
[1],[2]

Examples
The Lambert W function is the inverse of $w \exp(w)$:

```python
>>> from scipy.special import lambertw
>>> w = lambertw(1)
>>> w
(0.56714329040978384+0j)
>>> w * np.exp(w)
(1.0+0j)
```

Any branch gives a valid inverse:

```python
>>> w = lambertw(1, k=3)
>>> w
(-2.8535817554090377+17.113535539412148j)
>>> w * np.exp(w)
(1.0000000000000002+1.609823385706477e-15j)
```

Applications to equation-solving
The Lambert W function may be used to solve various kinds of equations, such as finding the value of the infinite power tower $z^{z^{\ldots}}$:

```python
>>> def tower(z, n):
...     if n == 0:
...         return z
...     return z ** tower(z, n-1)
...
>>> tower(0.5, 100)
0.641185744504986
>>> -lambertw(-np.log(0.5)) / np.log(0.5)
(0.64118574450498589+0j)
```

`scipy.special.wrightomega`

`scipy.special.wrightomega(z, out=None) = <ufunc 'wrightomega'>`
Wright Omega function.
Defined as the solution to

$$\omega + \log(\omega) = z$$

where log is the principal branch of the complex logarithm.

Parameters

- `z` [array_like] Points at which to evaluate the Wright Omega function

Returns
omega  [ndarray] Values of the Wright Omega function

See also:

lambertw

The Lambert W function

Notes

New in version 0.19.0.

The function can also be defined as

\[ \omega(z) = W_{K(z)}(e^z) \]

where \( K(z) = \lceil (3(z - \pi)/(2\pi) \rceil \) is the unwinding number and \( W \) is the Lambert W function.

The implementation here is taken from [1].
