scipy.stats.invgamma

scipy.stats.invgamma = <scipy.stats._continuous_distns.invgamma_gen object>

An inverted gamma continuous random variable.

As an instance of the rv_continuous class, invgamma object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for invgamma is:

$$f(x, a) = x^{-a-1} \frac{1}{\Gamma(a)} \exp\left(-\frac{1}{x}\right)$$

for $x \geq 0$, $a > 0$. $\Gamma$ is the gamma function (scipy.special.gamma).

invgamma takes $a$ as a shape parameter for $a$.

invgamma is a special case of gengamma with $c=-1$, and it is a different parameterization of the scaled inverse chi-squared distribution. Specifically, if the scaled inverse chi-squared distribution is parameterized with degrees of freedom $\nu$ and scaling parameter $\tau^2$, then it can be modeled using invgamma with $a=\nu/2$ and scale=$\nu \tau^2/2$. 
The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{invgamma.pdf(x, a, loc, scale)} is identically equivalent to \texttt{invgamma.pdf(y, a) / scale} with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```python
>>> from scipy.stats import invgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> a = 4.07
>>> mean, var, skew, kurt = invgamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(invgamma.ppf(0.01, a),
...                  invgamma.ppf(0.99, a), 100)
>>> ax.plot(x, invgamma.pdf(x, a),
...          'r-', lw=5, alpha=0.6, label='invgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = invgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = invgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], invgamma.cdf(vals, a))
True
```

Generate random numbers:

```python
>>> r = invgamma.rvs(a, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.invgauss

scipy.stats.invgauss = <scipy.stats._continuous_distns.invgauss_gen object>
An inverse Gaussian continuous random variable.

As an instance of the rv_continuous class, invgauss object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for invgauss is:

\[
f(x, \mu) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{(x - \mu)^2}{2x\mu^2}\right)
\]

for \(x \geq 0\) and \(\mu > 0\).

invgauss takes \(mu\) as a shape parameter for \(\mu\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, invgauss.pdf(\(x\), \(mu\), loc, scale) is identically equivalent to invgauss.pdf(\(y\), \(mu\)) / scale with \(y = (x - loc) / scale\). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```python
>>> from scipy.stats import invgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> mu = 0.145
>>> mean, var, skew, kurt = invgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(invgauss.ppf(0.01, mu),
...                 invgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, invgauss.pdf(x, mu),
...         'r-', lw=5, alpha=0.6, label='invgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = invgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:
>>> vals = invgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], invgauss.cdf(vals, mu))
True

Generate random numbers:

>>> r = invgauss.rvs(mu, size=1000)

And compare the histogram:

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

scipy.stats.invweibull

`scipy.stats.invweibull = <scipy.stats._continuous_distns.invweibull_gen object>`
An inverted Weibull continuous random variable.

This distribution is also known as the Fréchet distribution or the type II extreme value distribution.

As an instance of the `rv_continuous` class, `invweibull` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `invweibull` is:

\[ f(x, c) = cx^{-c-1} \exp(-x^{-c}) \]

for \( x > 0, \ c > 0 \).

`invweibull` takes \( c \) as a shape parameter for \( c \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invweibull.pdf(x, c, loc, scale)` is identically equivalent to `invweibull.pdf(y, c) / scale` with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location
of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

Examples

```python
>>> from scipy.stats import invweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> c = 10.6
>>> mean, var, skew, kurt = invweibull.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(invweibull.ppf(0.01, c), ...
... invweibull.ppf(0.99, c), 100)
>>> ax.plot(x, invweibull.pdf(x, c), ...
... 'r-', lw=5, alpha=0.6, label='invweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = invweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = invweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], invweibull.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = invweibull.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.johnsonsb

A Johnson SB continuous random variable.

As an instance of the rv_continuous class, johnsonsb object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

johnsonsu

Notes

The probability density function for johnsonsb is:

\[ f(x, a, b) = \frac{b}{x(1-x)} \phi(a + b \log \frac{x}{1-x}) \]

where \( x, a, \) and \( b \) are real scalars; \( b > 0 \) and \( x \in [0, 1] \). \( \phi \) is the pdf of the normal distribution.

johnsonsb takes \( a \) and \( b \) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, johnsonsb.pdf(x, a, b, loc, scale) is identically equivalent to johnsonsb.pdf(y, a, b) / scale with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```python
>>> from scipy.stats import johnsonsb
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> a, b = 4.32, 3.18
>>> mean, var, skew, kurt = johnsonsb.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(johnsonsb.ppf(0.01, a, b),
...                  johnsonsb.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsb.pdf(x, a, b),
...          'r-', lw=5, alpha=0.6, label='johnsonsb pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = johnsonsb(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:
>>> vals = johnsonsb.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsb.cdf(vals, a, b))
True

Generate random numbers:

>>> r = johnsonsb.rvs(a, b, size=1000)

And compare the histogram:

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

**scipy.stats.johnsonsu**

A Johnson SU continuous random variable.

As an instance of the rv_continuous class, johnsonsu object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

johnsonsb

**Notes**

The probability density function for johnsonsu is:

\[
f(x, a, b) = \frac{b}{\sqrt{x^2 + 1}} \phi(a + b \log(x + \sqrt{x^2 + 1}))
\]

where \(x, a,\) and \(b\) are real scalars; \(b > 0.\ \phi\) is the pdf of the normal distribution.

johnsonsu takes \(a\) and \(b\) as shape parameters.
The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{johnsonsu.pdf(x, a, b, loc, scale)} is identically equivalent to \texttt{johnsonsu.pdf(y, a, b) / scale} with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```python
>>> from scipy.stats import johnsonsu
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> a, b = 2.55, 2.25
>>> mean, var, skew, kurt = johnsonsu.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(johnsonsu.ppf(0.01, a, b), ...
... johnsonsu.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsu.pdf(x, a, b), ...
... 'r-', lw=5, alpha=0.6, label='johnsonsu pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = johnsonsu(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of \texttt{cdf} and \texttt{ppf}:

```python
>>> vals = johnsonsu.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsu.cdf(vals, a, b))
True
```

Generate random numbers:

```python
>>> r = johnsonsu.rvs(a, b, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.kappa4

scipy.stats.kappa4 = <scipy.stats._continuous_distns.kappa4_gen object>

Kappa 4 parameter distribution.

As an instance of the \texttt{rv_continuous} class, \texttt{kappa4} object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for kappa4 is:

\[
f(x, h, k) = \frac{(1 - kx)^{1/k-1}(1 - h(1 - kx)^{1/k})^{1/h-1}}{1 - kx - h(1 - kx)^{1/k}}
\]

if \(h\) and \(k\) are not equal to 0.

If \(h\) or \(k\) are zero then the pdf can be simplified:

- \(h = 0\) and \(k \neq 0\):
  \[
  \text{kappa4.pdf}(x, h, k) = (1 - kx)^{1/k} - 1 \left(1 - h(1 - kx)^{1/k}\right)^{1/h} - 1
  \]

- \(h \neq 0\) and \(k = 0\):
  \[
  \text{kappa4.pdf}(x, h, k) = \exp(-x) \left(1.0 - (1.0 - h \exp(-x))^{1.0/h} - 1.0\right)
  \]

- \(h = 0\) and \(k = 0\):
  \[
  \text{kappa4.pdf}(x, h, k) = \exp(-x) \exp(-\exp(-x))
  \]

kappa4 takes \(h\) and \(k\) as shape parameters.

The kappa4 distribution returns other distributions when certain \(h\) and \(k\) values are used.

(1) There are at least five generalized logistic distributions. Four are described here: https://en.wikipedia.org/wiki/Generalized_logistic_distribution The “fifth” one is the one kappa4 should match which currently isn’t implemented in scipy: https://en.wikipedia.org/wiki/Talk:Generalized_logistic_distribution https://www.mathwave.com/help/easyfit/html/analyses/distributions/gen_logistic.html

(2) This distribution is currently not in scipy.
References

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \( \text{loc} \) and \( \text{scale} \) parameters. Specifically, \( \text{kappa4.pdf}(x, h, k, \text{loc}, \text{scale}) \) is identically equivalent to \( \text{kappa4.pdf}(y, h, k) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```python
>>> from scipy.stats import kappa4
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> h, k = 0.1, 0
>>> mean, var, skew, kurt = kappa4.stats(h, k, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(kappa4.ppf(0.01, h, k),
                      kappa4.ppf(0.99, h, k), 100)
>>> ax.plot(x, kappa4.pdf(x, h, k),
              'r-', lw=5, alpha=0.6, label='kappa4 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = kappa4(h, k)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = kappa4.ppf([0.001, 0.5, 0.999], h, k)
>>> np.allclose([0.001, 0.5, 0.999], kappa4.cdf(vals, h, k))
True
```

Generate random numbers:

```python
>>> r = kappa4.rvs(h, k, size=1000)
```
And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.kappa3**

```python
scipy.stats.kappa3 = <scipy.stats._continuous_distns.kappa3_gen object>
```

Kappa 3 parameter distribution.

As an instance of the `rv_continuous` class, kappa3 object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `kappa3` is:

\[
f(x, a) = a(a + x^a)^{-(a+1)/a}
\]

for \(x > 0\) and \(a > 0\).

`kappa3` takes \(a\) as a shape parameter for \(a\).
References

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, kappa3.pdf(x, a, loc, scale) is identically equivalent to kappa3.pdf(y, a) / scale with y = (x - loc) / scale. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```python
>>> from scipy.stats import kappa3
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> a = 1
>>> mean, var, skew, kurt = kappa3.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(kappa3.ppf(0.01, a), ...
... kappa3.ppf(0.99, a), 100)
>>> ax.plot(x, kappa3.pdf(x, a), ...
... 'r-', lw=5, alpha=0.6, label='kappa3 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = kappa3(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = kappa3.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], kappa3.cdf(vals, a))
True
```

Generate random numbers:

```python
>>> r = kappa3.rvs(a, size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.ksone

*scipy.stats.ksone = <scipy.stats._continuous_distns.ksone_gen object>*

Kolmogorov-Smirnov one-sided test statistic distribution.

This is the distribution of the one-sided Kolmogorov-Smirnov (KS) statistics \( D^+_n \) and \( D^-_n \) for a finite sample size \( n \) (the shape parameter).

As an instance of the `rv_continuous` class, `ksone` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

kstwobign, kstwo, kstest

Notes

\( D^+_n \) and \( D^-_n \) are given by

\[
D^+_n = \sup_x (F_n(x) - F(x)), \\
D^-_n = \sup_x (F(x) - F_n(x)),
\]

where \( F \) is a continuous CDF and \( F_n \) is an empirical CDF. `ksone` describes the distribution under the null hypothesis of the KS test that the empirical CDF corresponds to \( n \) i.i.d. random variates with CDF \( F \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ksone.pdf(x, n, loc, scale)` is identically equivalent to `ksone.pdf(y, n) / scale` with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1]

Examples

```python
>>> from scipy.stats import ksone
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> n = 1e+03
>>> mean, var, skew, kurt = ksone.stats(n, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(ksone.ppf(0.01, n),
...                 ksone.ppf(0.99, n), 100)
>>> ax.plot(x, ksone.pdf(x, n),
...         'r-', lw=5, alpha=0.6, label='ksone pdf')
```
Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = ksonedist(n)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = ksonedist.ppf([0.001, 0.5, 0.999], n)
>>> np.allclose([0.001, 0.5, 0.999], ksonedist.cdf(vals, n))
True
```

Generate random numbers:

```python
>>> r = ksonedist.rvs(n, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.kstwo**

`scipy.stats.kstwo = <scipy.stats._continuous_distns.kstwo_gen object>`  
Kolmogorov-Smirnov two-sided test statistic distribution.

This is the distribution of the two-sided Kolmogorov-Smirnov (KS) statistic $D_n$ for a finite sample size $n$ (the shape parameter).

As an instance of the rv_continuous class, kstwo object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

- kstwobign, ksone, kstest
Notes

$D_n$ is given by

\[ D_n = \sup_x |F_n(x) - F(x)| \]

where $F$ is a (continuous) CDF and $F_n$ is an empirical CDF. `kstwo` describes the distribution under the null hypothesis of the KS test that the empirical CDF corresponds to $n$ i.i.d. random variates with CDF $F$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, $kstwo.pdf(x, n, loc, scale)$ is identically equivalent to $kstwo.pdf(y, n) / scale$ with $y = (x - loc) / scale$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1]

Examples

```python
>>> from scipy.stats import kstwo
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> n = 10
>>> mean, var, skew, kurt = kstwo.stats(n, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(kstwo.ppf(0.01, n), ...
...                   kstwo.ppf(0.99, n), 100)
>>> ax.plot(x, kstwo.pdf(x, n), ...
...         'r-', lw=5, alpha=0.6, label='kstwo pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = kstwo(n)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = kstwo.ppf([0.001, 0.5, 0.999], n)
>>> np.allclose([0.001, 0.5, 0.999], kstwo.cdf(vals, n))
```

Generate random numbers:
>>> r = kstwo.rvs(n, size=1000)

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.kstwobign**

`scipy.stats.kstwobign = <scipy.stats._continuous_distns.kstwobign_gen object>`

Limiting distribution of scaled Kolmogorov-Smirnov two-sided test statistic.

This is the asymptotic distribution of the two-sided Kolmogorov-Smirnov statistic \( \sqrt{n}D_n \) that measures the maximum absolute distance of the theoretical (continuous) CDF from the empirical CDF. (see `kstest`).

As an instance of the `rv_continuous` class, `kstwobign` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

```
ksone, kstwo, kstest
```
Notes

\( \sqrt{n}D_n \) is given by

\[
D_n = \sup_x |F_n(x) - F(x)|
\]

where \( F \) is a continuous CDF and \( F_n \) is an empirical CDF. \texttt{kstwobign} describes the asymptotic distribution (i.e. the limit of \( \sqrt{n}D_n \)) under the null hypothesis of the KS test that the empirical CDF corresponds to i.i.d. random variates with CDF \( F \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{kstwobign.pdf(x, loc, scale)} is identically equivalent to \texttt{kstwobign.pdf(y) / scale} with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

```python
scipy.stats.laplace
```

`scipy.stats.laplace = <scipy.stats._continuous_distns.laplace_gen object>`

A Laplace continuous random variable.

As an instance of the `rv_continuous` class, `laplace` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `laplace` is

\[
f(x) = \frac{1}{2} \exp(-|x|)
\]

for a real number \(x\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `laplace.pdf(x, loc, scale)` is identically equivalent to `laplace.pdf(y) / scale` with \(y = (x - \text{loc}) / \text{scale}\). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.
Examples

```python
>>> from scipy.stats import laplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> mean, var, skew, kurt = laplace.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(laplace.ppf(0.01), laplace.ppf(0.99), 100)
>>> ax.plot(x, laplace.pdf(x), 'r-', lw=5, alpha=0.6, label='laplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = laplace()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = laplace.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], laplace.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = laplace.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.laplace_asymmetric

scipy.stats.laplace_asymmetric = <scipy.stats._continuous_distns.laplace_asymmetric_gen object>
An asymmetric Laplace continuous random variable.

As an instance of the rv_continuous class, laplace_asymmetric object inherits from it a collection of
generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

laplace
Laplace distribution

Notes
The probability density function for laplace_asymmetric is

\[
f(x, \kappa) = \frac{1}{\kappa + \kappa^{-1}} \exp(-x\kappa), \quad x \geq 0
\]

\[
= \frac{1}{\kappa + \kappa^{-1}} \exp(x/\kappa), \quad x < 0
\]

for \(-\infty < x < \infty, \kappa > 0\).

laplace_asymmetric takes kappa as a shape parameter for \(\kappa\). For \(\kappa = 1\), it is identical to a Laplace
distribution.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the
loc and scale parameters. Specifically, laplace_asymmetric.pdf(x, kappa, loc, scale) is
identically equivalent to laplace_asymmetric.pdf(y, kappa) / scale with y = (x - loc) / scale. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral
generalizations of some distributions are available in separate classes.

[1], [2]

Examples

```python
>>> from scipy.stats import laplace_asymmetric
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> kappa = 2
>>> mean, var, skew, kurt = laplace_asymmetric.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):
Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = laplace_asymmetric(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = laplace_asymmetric.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], laplace_asymmetric.cdf(vals, kappa))
True
```

Generate random numbers:

```python
>>> r = laplace_asymmetric.rvs(kappa, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### scipy.stats.levy

`scipy.stats.levy = <scipy.stats._continuous_distns.levy_gen object>`

A Levy continuous random variable.

As an instance of the `rv_continuous` class, `levy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

- `levy_stable`, `levy_l`

### Notes

The probability density function for `levy` is:

$$f(x) = \frac{1}{\sqrt{2\pi x^3}} \exp \left( -\frac{1}{2x} \right)$$

for $x \geq 0$.

This is the same as the Levy-stable distribution with $\alpha = 1/2$ and $b = 1$. 

2386 Chapter 3. SciPy API
The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \( \text{loc} \) and \( \text{scale} \) parameters. Specifically, \( \text{levy.pdf}(x, \text{loc}, \text{scale}) \) is identically equivalent to \( \text{levy.pdf}(y) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```python
>>> from scipy.stats import levy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> mean, var, skew, kurt = levy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(levy.ppf(0.01),
...                  levy.ppf(0.99), 100)
>>> ax.plot(x, levy.pdf(x),
...          'r-', lw=5, alpha=0.6, label='levy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = levy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = levy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy.cdf(vals))
```

Generate random numbers:

```python
>>> r = levy.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.levy_l

scipy.stats.levy_l = <scipy.stats._continuous_distns.levy_l_gen object>

A left-skewed Levy continuous random variable.

As an instance of the rv_continuous class, levy_l object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

levy, levy_stable

Notes

The probability density function for levy_l is:

\[ f(x) = \frac{1}{|x|\sqrt{2\pi}|x|} \exp\left(-\frac{1}{2|x|}\right) \]

for \( x \leq 0 \).

This is the same as the Levy-stable distribution with \( \alpha = 1/2 \) and \( \beta = -1 \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, \( \text{levy}_l.pdf(x, \text{loc}, \text{scale}) \) is identically equivalent to \( \text{levy}_l.pdf(y) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```python
>>> from scipy.stats import levy_l
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> mean, var, skew, kurt = levy_l.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(levy_l.ppf(0.01),
...                 levy_l.ppf(0.99), 100)
>>> ax.plot(x, levy_l.pdf(x),
...         'r-', lw=5, alpha=0.6, label='levy_l pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = levy_l()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:
>>> vals = levy_l.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy_l.cdf(vals))
True

Generate random numbers:

>>> r = levy_l.rvs(size=1000)

And compare the histogram:

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

scipy.stats.levy_stable

scipy.stats.levy_stable = <scipy.stats._continuous_distns.levy_stable_gen object>

A Levy-stable continuous random variable.

As an instance of the rv_continuous class, levy_stable object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

levy, levy_1

Notes

The distribution for levy_stable has characteristic function:

\[ \varphi(t, \alpha, \beta, c, \mu) = e^{it\mu - |ct|^\alpha(1-i\beta\text{sign}(t)\Phi(\alpha, t))} \]

where:

\[ \Phi = \begin{cases} \tan \left( \frac{\alpha\pi}{2} \right) & \alpha \neq 1 \\ -\frac{2}{\pi} \log |t| & \alpha = 1 \end{cases} \]
The probability density function for `levy_stable` is:

\[ f(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \varphi(t)e^{-ixt} dt \]

where \(-\infty < t < \infty\). This integral does not have a known closed form.

For evaluation of pdf we use either Zolotarev S_0 parameterization with integration, direct integration of standard parameterization of characteristic function or FFT of characteristic function. If set to other than None and if number of points is greater than `levy_stable.pdf_fft_min_points_threshold` (defaults to None) we use FFT otherwise we use one of the other methods.

The default method is ‘best’ which uses Zolotarev’s method if alpha = 1 and integration of characteristic function otherwise. The default method can be changed by setting `levy_stable.pdf_default_method` to either ‘zolotarev’, ‘quadrature’ or ‘best’.

To increase accuracy of FFT calculation one can specify `levy_stable.pdf_fft_grid_spacing` (defaults to 0.001) and `pdf_fft_n_points_two_power` (defaults to a value that covers the input range * 4). Setting `pdf_fft_n_points_two_power` to 16 should be sufficiently accurate in most cases at the expense of CPU time.

For evaluation of cdf we use Zolotarev S_0 parameterization with integration or integral of the pdf FFT interpolated spline. The settings affecting FFT calculation are the same as for pdf calculation. Setting the threshold to `None` (default) will disable FFT. For cdf calculations the Zolotarev method is superior in accuracy, so FFT is disabled by default.

Fitting estimate uses quantile estimation method in [MC]. MLE estimation of parameters in fit method uses this quantile estimate initially. Note that MLE doesn’t always converge if using FFT for pdf calculations; so it’s best that `pdf_fft_min_points_threshold` is left unset.

**Warning:** For pdf calculations implementation of Zolotarev is unstable for values where alpha = 1 and beta != 0. In this case the quadrature method is recommended. FFT calculation is also considered experimental.

For cdf calculations FFT calculation is considered experimental. Use Zolotarev’s method instead (default).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy_stable.pdf(x, alpha, beta, loc, scale)` is identically equivalent to `levy_stable.pdf(y, alpha, beta) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**References**

[MC], [MS], [BS]

**Examples**

```python
>>> from scipy.stats import levy_stable
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:
>>> alpha, beta = 1.8, -0.5
>>> mean, var, skew, kurt = levy_stable.stats(alpha, beta, moments='mvsk')

Display the probability density function (pdf):

```python
>>> x = np.linspace(levy_stable.ppf(0.01, alpha, beta),
...                  levy_stable.ppf(0.99, alpha, beta), 100)
>>> ax.plot(x, levy_stable.pdf(x, alpha, beta),
...          'r-', lw=5, alpha=0.6, label='levy_stable pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = levy_stable(alpha, beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = levy_stable.ppf([0.001, 0.5, 0.999], alpha, beta)
>>> np.allclose([0.001, 0.5, 0.999], levy_stable.cdf(vals, alpha, beta))
True
```

Generate random numbers:

```python
>>> r = levy_stable.rvs(alpha, beta, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.logistic

A logistic (or Sech-squared) continuous random variable.

As an instance of the rv_continuous class, logistic object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for logistic is:

\[ f(x) = \frac{\exp(-x)}{(1 + \exp(-x))^2} \]

logistic is a special case of genlogistic with c=1.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, logistic.pdf(x, loc, scale) is identically equivalent to logistic.pdf(y) / scale with y = (x - loc) / scale. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.
Examples

```python
>>> from scipy.stats import logistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> mean, var, skew, kurt = logistic.stats(moments='mvsk')
```  
Display the probability density function (pdf):

```python
>>> x = np.linspace(logistic.ppf(0.01),
...                  logistic.ppf(0.99), 100)
>>> ax.plot(x, logistic.pdf(x),
...          'r-', lw=5, alpha=0.6, label='logistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = logistic()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = logistic.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], logistic.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = logistic.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

2396 Chapter 3. SciPy API
scipy.stats.loggamma

scipy.stats.loggamma = <scipy.stats._continuous_distns.loggamma_gen object>

A log gamma continuous random variable.

As an instance of the rv_continuous class, loggamma object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for loggamma is:

\[ f(x, c) = \frac{\exp(cx - \exp(x))}{\Gamma(c)} \]

for all \( x, c > 0 \). Here, \( \Gamma \) is the gamma function (scipy.special.gamma).

loggamma takes \( c \) as a shape parameter for \( c \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, loggamma.pdf(x, c, loc, scale) is identically equivalent to loggamma.pdf(y, c) / scale with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```python
>>> from scipy.stats import loggamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> c = 0.414
>>> mean, var, skew, kurt = loggamma.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(loggamma.ppf(0.01, c),
...                loggamma.ppf(0.99, c), 100)
>>> ax.plot(x, loggamma.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='loggamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = loggamma(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:
```python
>>> vals = loggamma.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loggamma.cdf(vals, c))
True

Generate random numbers:

```python
>>> r = loggamma.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.loglaplace

`scipy.stats.loglaplace = <scipy.stats._continuous_distns.loglaplace_gen object>`

A log-Laplace continuous random variable.

As an instance of the `rv_continuous` class, `loglaplace` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `loglaplace` is:

\[
f(x, c) = \begin{cases} 
\frac{c}{x} x^{c-1} & \text{for } 0 < x < 1 \\
\frac{c}{x^c} - 1 & \text{for } x \geq 1 
\end{cases}
\]

for \(c > 0\).

`loglaplace` takes \(c\) as a shape parameter for \(c\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `loglaplace.pdf(x, c, loc, scale)` is identically equivalent to `loglaplace.pdf(y, c) / scale` with \(y = (x - \text{loc}) / \text{scale}\). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.
References

Examples

```python
>>> from scipy.stats import loglaplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> c = 3.25
>>> mean, var, skew, kurt = loglaplace.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(loglaplace.ppf(0.01, c),
...                  loglaplace.ppf(0.99, c), 100)
>>> ax.plot(x, loglaplace.pdf(x, c),
...          'r-', lw=5, alpha=0.6, label='loglaplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = loglaplace(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = loglaplace.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loglaplace.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = loglaplace.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.lognorm

scipy.stats.lognorm = <scipy.stats._continuous_distns.lognorm_gen object>
A lognormal continuous random variable.

As an instance of the rv_continuous class, lognorm object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for lognorm is:

\[
    f(x, s) = \frac{1}{sx\sqrt{2\pi}} \exp\left(-\frac{\log^2(x)}{2s^2}\right)
\]

for \(x > 0, s > 0\).

lognorm takes \(s\) as a shape parameter for \(s\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, lognorm.pdf(x, s, loc, scale) is identically equivalent to lognorm.pdf(y, s) / scale with y = (x - loc) / scale. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

A common parametrization for a lognormal random variable \(Y\) is in terms of the mean, \(\mu\), and standard deviation, \(\sigma\), of the unique normally distributed random variable \(X\) such that \(\exp(X) = Y\). This parametrization corresponds to setting \(s = \sigma\) and \(\text{scale} = \exp(\mu)\).

Examples

```python
>>> from scipy.stats import lognorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> s = 0.954
>>> mean, var, skew, kurt = lognorm.stats(s, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(lognorm.ppf(0.01, s),
...                 lognorm.ppf(0.99, s), 100)
>>> ax.plot(x, lognorm.pdf(x, s),
...         'r-', lw=5, alpha=0.6, label='lognorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = lognorm(s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```
Check accuracy of cdf and ppf:

```python
>>> vals = lognorm.ppf([0.001, 0.5, 0.999], s)
>>> np.allclose([0.001, 0.5, 0.999], lognorm.cdf(vals, s))
True
```

Generate random numbers:

```python
>>> r = lognorm.rvs(s, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.loguniform**

`scipy.stats.loguniform = <scipy.stats._continuous_distns.reciprocal_gen object>`

A loguniform or reciprocal continuous random variable.

As an instance of the `rv_continuous` class, `loguniform` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for this class is:

\[
f(x, a, b) = \frac{1}{x \log(b/a)}
\]

for \(a \leq x \leq b, b > a > 0\). This class takes \(a\) and \(b\) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `loguniform.pdf(x, a, b, loc, scale)` is identically equivalent to `loguniform.pdf(y, a, b) / scale` with \(y = (x - \text{loc}) / \text{scale}\). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.
Examples

```python
>>> from scipy.stats import loguniform
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> a, b = 0.01, 1.25
>>> mean, var, skew, kurt = loguniform.stats(a, b, moments='mvsk')
```  
Display the probability density function (pdf):

```python
>>> x = np.linspace(loguniform.ppf(0.01, a, b),
...                  loguniform.ppf(0.99, a, b), 100)
>>> ax.plot(x, loguniform.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='loguniform pdf')
```  
Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = loguniform(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```  
Check accuracy of cdf and ppf:

```python
>>> vals = loguniform.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], loguniform.cdf(vals, a, b))
True
```  
Generate random numbers:

```python
>>> r = loguniform.rvs(a, b, size=1000)
```  
And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```  
This doesn’t show the equal probability of 0.01, 0.1 and 1. This is best when the x-axis is log-scaled:

```python
>>> import numpy as np
>>> fig, ax = plt.subplots(1, 1)
>>> ax.hist(np.log10(r))
>>> ax.set_yscale("Frequency")
>>> ax.set_xlabel("Value of random variable")
>>> ax.xaxis.set_major_locator(plt.FixedLocator([-2, -1, 0]))
>>> ticks = ['$10^{{{}}}$'.format(i) for i in [-2, -1, 0]]
>>> ax.set_xticklabels(ticks)
>>> plt.show()
```  
This random variable will be log-uniform regardless of the base chosen for a and b. Let’s specify with base 2 instead:

3.3. API definition
Values of 1/4, 1/2 and 1 are equally likely with this random variable. Here’s the histogram:

```python
>>> rvs = loguniform(2**-2, 2**0).rvs(size=1000)
```

```python
>>> fig, ax = plt.subplots(1, 1)
>>> ax.hist(np.log2(rvs))
>>> ax.set_ylabel("Frequency")
>>> ax.set_xlabel("Value of random variable")
>>> ax.xaxis.set_major_locator(plt.FixedLocator([-2, -1, 0]))
>>> ticks = ['$2^\{\}\$'.format(i) for i in [-2, -1, 0]]
>>> ax.set_xticklabels(ticks)
>>> plt.show()
```

**scipy.stats.lomax**

`scipy.stats.lomax = <scipy.stats._continuous_distns.lomax_gen object>`

A Lomax (Pareto of the second kind) continuous random variable.

As an instance of the `rv_continuous` class, `lomax` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `lomax` is:

\[
f(x, c) = \frac{c}{(1 + x)^{c+1}}
\]

for \( x \geq 0, c > 0 \).

`lomax` takes `c` as a shape parameter for `c`.

`lomax` is a special case of `pareto` with `loc=-1.0`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `lomax.pdf(x, c, loc, scale)` is identically equivalent to `lomax.pdf(y, c) / scale` with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of
a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```python
>>> from scipy.stats import lomax
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> c = 1.88
>>> mean, var, skew, kurt = lomax.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(lomax.ppf(0.01, c),
...                 lomax.ppf(0.99, c), 100)
>>> ax.plot(x, lomax.pdf(x, c),
...          'r-', lw=5, alpha=0.6, label='lomax pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = lomax(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = lomax.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], lomax.cdf(vals, c))
```

Generate random numbers:

```python
>>> r = lomax.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

</table>
**scipy.stats.maxwell**

`scipy.stats.maxwell = <scipy.stats._continuous_distns.maxwell_gen object>`

A Maxwell continuous random variable.

As an instance of the `rv_continuous` class, `maxwell` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

A special case of a **chi** distribution, with df=3, loc=0.0, and given scale = a, where a is the parameter used in the Mathworld description [1].

The probability density function for `maxwell` is:

\[
f(x) = \frac{2}{\pi x^2} \exp(-x^2/2)
\]

for \(x \geq 0\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `maxwell.pdf(x, loc, scale)` is identically equivalent to `maxwell.pdf(y) / scale` with \(y = (x - loc) / scale\). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**References**

[1]

**Examples**

```python
>>> from scipy.stats import maxwell
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> mean, var, skew, kurt = maxwell.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(maxwell.ppf(0.01),
                     maxwell.ppf(0.99), 100)
>>> ax.plot(x, maxwell.pdf(x),
              'r-', lw=5, alpha=0.6, label='maxwell pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = maxwell()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=5, alpha=0.6, label='frozen pdf')
```
Check accuracy of \texttt{cdf} and \texttt{ppf}:

\begin{verbatim}
>>> vals = maxwell.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], maxwell.cdf(vals))
True
\end{verbatim}

Generate random numbers:

\begin{verbatim}
>>> r = maxwell.rvs(size=1000)
\end{verbatim}

And compare the histogram:

\begin{verbatim}
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
\end{verbatim}

**scipy.stats.mielke**

`scipy.stats.mielke = <scipy.stats._continuous_distns.mielke_gen object>`

A Mielke Beta-Kappa / Dagum continuous random variable.

As an instance of the `rv_continuous` class, `mielke` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `mielke` is:

\[
f(x, k, s) = \frac{kx^{k-1}}{(1 + x^s)^{1+k/s}}
\]

for \( x > 0 \) and \( k, s > 0 \). The distribution is sometimes called Dagum distribution ([2]). It was already defined in [3], called a Burr Type III distribution (`burr` with parameters \( c=s \) and \( d=k/s \)).

`mielke` takes \( k \) and \( s \) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `mielke.pdf(x, k, s, loc, scale)` is identically equivalent to `mielke.pdf(y, k, s) / scale` with \( y = (x - loc) / scale \). Note that shifting the location
of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References
[1], [2], [3]

Examples

```python
from scipy.stats import mielke
import matplotlib.pyplot as plt
fig, ax = plt.subplots(1, 1)

Calculate the first four moments:
```n
ek, s = 10.4, 4.6
mean, var, skew, kurt = mielke.stats(k, s, moments='mvsk')
```

Display the probability density function (pdf):
```python
x = np.linspace(mielke.ppf(0.01, k, s), ...
    ...  mielke.ppf(0.99, k, s), 100)
ax.plot(x, mielke.pdf(x, k, s), ...
    ...  'r-', lw=5, alpha=0.6, label='mielke pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
```python
rv = mielke(k, s)
ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:
```python
vals = mielke.ppf([0.001, 0.5, 0.999], k, s)
np.allclose([0.001, 0.5, 0.999], mielke.cdf(vals, k, s))
True
```

Generate random numbers:
```python
r = mielke.rvs(k, s, size=1000)
```

And compare the histogram:
```python
ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
ax.legend(loc='best', frameon=False)
plt.show()
```

</table>
scipy.stats.moyal

scipy.stats.moyal = <scipy.stats._continuous_distns.moyal_gen object>

A Moyal continuous random variable.

As an instance of the rv_continuous class, moyal object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for moyal is:

\[ f(x) = \exp\left(-\frac{x + \exp(-x)}{2}\right)/\sqrt{2\pi} \]

for a real number \( x \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, moyal.pdf(x, loc, scale) is identically equivalent to moyal.pdf(y) / scale with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

This distribution has utility in high-energy physics and radiation detection. It describes the energy loss of a charged relativistic particle due to ionization of the medium [1]. It also provides an approximation for the Landau distribution. For an in-depth description see [2]. For additional description, see [3].

References

New in version 1.1.0.

[1],[2],[3]

Examples

```python
>>> from scipy.stats import moyal
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> mean, var, skew, kurt = moyal.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(moyal.ppf(0.01),
...                 moyal.ppf(0.99), 100)
>>> ax.plot(x, moyal.pdf(x),
...         'r-', lw=5, alpha=0.6, label='moyal pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
```python
>>> rv = moyal()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

Check accuracy of cdf and ppf:

```python
>>> vals = moyal.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], moyal.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = moyal.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.nakagami**

`scipy.stats.nakagami = <scipy.stats._continuous_distns.nakagami_gen object>`

A Nakagami continuous random variable.

As an instance of the `rv_continuous` class, `nakagami` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `nakagami` is:

$$f(x, \nu) = \frac{2^{\nu} \nu^{\nu} x^{2\nu - 1}}{\Gamma(\nu)} \exp(-\nu x^2)$$

for $x \geq 0, \nu > 0$.

`nakagami` takes `nu` as a shape parameter for $\nu$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `nakagami.pdf(x, nu, loc, scale)` is identically equivalent to `nakagami.pdf(y, nu) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.
Examples

```python
>>> from scipy.stats import nakagami
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> nu = 4.97
>>> mean, var, skew, kurt = nakagami.stats(nu, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(nakagami.ppf(0.01, nu), ...
...                 nakagami.ppf(0.99, nu), 100)
>>> ax.plot(x, nakagami.pdf(x, nu), ...
...          'r-', lw=5, alpha=0.6, label='nakagami pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = nakagami(nu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = nakagami.ppf([0.001, 0.5, 0.999], nu)
>>> np.allclose([0.001, 0.5, 0.999], nakagami.cdf(vals, nu))
True
```

Generate random numbers:

```python
>>> r = nakagami.rvs(nu, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.ncx2

scipy.stats.ncx2 = <scipy.stats._continuous_distns.ncx2_gen object>
A non-central chi-squared continuous random variable.
As an instance of the rv_continuous class, ncx2 object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for ncx2 is:

\[ f(x, k, \lambda) = \frac{1}{2} \exp\left(-\frac{(\lambda + x)}{2}(k-2)/4 \right) \frac{1}{\sqrt{\lambda x}} I_{\frac{k-2}{2}}(\sqrt{\lambda x}) \]

for \( x \geq 0 \) and \( k, \lambda > 0 \). \( k \) specifies the degrees of freedom (denoted \( df \) in the implementation) and \( \lambda \) is the non-centrality parameter (denoted \( nc \) in the implementation). \( I_\nu \) denotes the modified Bessel function of first order of degree \( \nu \) (scipy.special.iv).

ncx2 takes \( df \) and \( nc \) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, ncx2.pdf(x, df, nc, loc, scale) is identically equivalent to ncx2.pdf(y, df, nc) / scale with \( y = (x - loc) / scale \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```python
>>> from scipy.stats import ncx2
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> df, nc = 21, 1.06
>>> mean, var, skew, kurt = ncx2.stats(df, nc, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(ncx2.ppf(0.01, df, nc), ...
...     ncx2.ppf(0.99, df, nc), 100)
>>> ax.plot(x, ncx2.pdf(x, df, nc), ...
...     'r-', lw=5, alpha=0.6, label='ncx2 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = ncx2(df, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

3.3. API definition 2421
Generate random numbers:

```python
>>> r = ncx2.rvs(df, nc, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.ncf**

`scipy.stats.ncf = <scipy.stats._continuous_distns.ncf_gen object>`

A non-central F distribution continuous random variable.

As an instance of the `rv_continuous` class, `ncf` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

**scipy.stats.f**

Fisher distribution
Notes

The probability density function for \( \text{ncf} \) is:

\[
f(x, n_1, n_2, \lambda) = \exp \left( \frac{\lambda}{2} + \lambda n_1 \frac{x}{2(n_1 x + n_2)} \right) n_1^{n_1/2} n_2^{n_2/2} x^{n_1/2 - 1} \left( n_2 + n_1 x \right)^{-\frac{n_1 + n_2}{2}} \gamma\left(\frac{n_1}{2}\right) \gamma\left(1 + \frac{n_2}{2}\right) \frac{L_{n_1/2}^{-1} \left(-\lambda n_1 \frac{x}{2(n_1 x + n_2)}\right) }{B\left(n_1/2, n_2/2\right) \gamma\left(\frac{n_1 + n_2}{2}\right)}
\]

for \( n_1, n_2 > 0, \lambda \geq 0 \). Here \( n_1 \) is the degrees of freedom in the numerator, \( n_2 \) the degrees of freedom in the denominator, \( \lambda \) the non-centrality parameter, \( \gamma \) is the logarithm of the Gamma function, \( L_n^k \) is a generalized Laguerre polynomial and \( B \) is the beta function.

\( \text{ncf} \) takes \( df1, df2 \) and \( nc \) as shape parameters. If \( nc=0 \), the distribution becomes equivalent to the Fisher distribution.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \( \text{loc} \) and \( \text{scale} \) parameters. Specifically, \( \text{ncf.pdf}(x, df_n, df_d, nc) \) is identically equivalent to \( \text{ncf.pdf}(y, df_n, df_d, nc) \) with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```python
>>> from scipy.stats import ncf
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> dfn, dfd, nc = 27, 27, 0.416
>>> mean, var, skew, kurt = ncf.stats(dfn, dfd, nc, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(ncf.ppf(0.01, dfn, dfd, nc), ... ncf.ppf(0.99, dfn, dfd, nc), 100)
>>> ax.plot(x, ncf.pdf(x, dfn, dfd, nc), ... 'r-', lw=5, alpha=0.6, label='ncf pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = ncf(dfn, dfd, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = ncf.ppf([0.001, 0.5, 0.999], dfn, dfd, nc)
>>> np.allclose([0.001, 0.5, 0.999], ncf.cdf(vals, dfn, dfd, nc))
True
```
Generate random numbers:

```python
>>> r = ncf.rvs(dfn, dfd, nc, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

</tbody>
</table>

**scipy.stats.nct**

`scipy.stats.nct = <scipy.stats._continuous_distns.nct_gen object>`

A non-central Student's t continuous random variable.

As an instance of the `rv_continuous` class, `nct` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

If \(Y\) is a standard normal random variable and \(V\) is an independent chi-square random variable (\(\text{chi2}\)) with \(k\) degrees of freedom, then

\[
X = \frac{Y + c}{\sqrt{V/k}}
\]

has a non-central Student's t distribution on the real line. The degrees of freedom parameter \(k\) (denoted \(df\) in the implementation) satisfies \(k > 0\) and the noncentrality parameter \(c\) (denoted \(nc\) in the implementation) is a real number.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `nct.pdf(x, df, nc, loc, scale)` is identically equivalent...
to \texttt{nct.pdf(y, df, nc)} / scale with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```python
>>> from scipy.stats import nct
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
def, nc = 14, 0.24
mean, var, skew, kurt = nct.stats(df, nc, moments='mvsk')
```  
Display the probability density function (pdf):

```python
x = np.linspace(nct.ppf(0.01, df, nc), ...
    nct.ppf(0.99, df, nc), 100)
ax.plot(x, nct.pdf(x, df, nc), ...
    'r-', lw=5, alpha=0.6, label='nct pdf')
```  
Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
rv = nct(df, nc)
ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```  
Check accuracy of cdf and ppf:

```python
vals = nct.ppf([0.001, 0.5, 0.999], df, nc)
np.allclose([0.001, 0.5, 0.999], nct.cdf(vals, df, nc))
```

Generate random numbers:

```python
r = nct.rvs(df, nc, size=1000)
```  
And compare the histogram:

```python
ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
ax.legend(loc='best', frameon=False)
plt.show()
```

</tbody>
</table>
scipy.stats.norm

scipy.stats.norm = <scipy.stats._continuous_distns.norm_gen object>
A normal continuous random variable.

The location (loc) keyword specifies the mean. The scale (scale) keyword specifies the standard deviation.

As an instance of the rv_continuous class, norm object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for norm is:

\[ f(x) = \frac{\exp(-x^2/2)}{\sqrt{2\pi}} \]

for a real number \( x \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, norm.pdf(x, loc, scale) is identically equivalent to norm.pdf(y) / scale with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```python
>>> from scipy.stats import norm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:
```n
```python
>>> mean, var, skew, kurt = norm.stats(moments='mvsk')
```

Display the probability density function (pdf):
```python
>>> x = np.linspace(norm.ppf(0.01),
...                 norm.ppf(0.99), 100)
>>> ax.plot(x, norm.pdf(x),
...         'r-', lw=5, alpha=0.6, label='norm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
```python
>>> rv = norm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:
```python
>>> vals = norm.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], norm.cdf(vals))
```

True
Generate random numbers:

```python
>>> r = norm.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.norminvgauss**

`scipy.stats.norminvgauss = <scipy.stats._continuous_distns.norminvgauss_gen object>`

A Normal Inverse Gaussian continuous random variable.

As an instance of the `rv_continuous` class, `norminvgauss` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `norminvgauss` is:

$$f(x, a, b) = \frac{a K_1(a \sqrt{1 + x^2})}{\pi \sqrt{1 + x^2}} \exp(\sqrt{a^2 - b^2 + bx})$$

where $x$ is a real number, the parameter $a$ is the tail heaviness and $b$ is the asymmetry parameter satisfying $a > 0$ and $|b| <= a$. $K_1$ is the modified Bessel function of second kind (`scipy.special.k1`).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `norminvgauss.pdf(x, a, b, loc, scale)` is identically equivalent to `norminvgauss.pdf(y, a, b) / scale` with $y = (x - loc) / scale$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.
A normal inverse Gaussian random variable $Y$ with parameters $a$ and $b$ can be expressed as a normal mean-variance mixture: $Y = b \ast V + \sqrt{V} \ast X$ where $X$ is $\text{norm}(0,1)$ and $V$ is $\text{invgauss}(\mu=1/\sqrt{a^2 - b^2})$. This representation is used to generate random variates.

**References**

**Examples**

```python
>>> from scipy.stats import norminvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> a, b = 1.25, 0.5
>>> mean, var, skew, kurt = norminvgauss.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(norminvgauss.ppf(0.01, a, b),
                      norminvgauss.ppf(0.99, a, b), 100)
>>> ax.plot(x, norminvgauss.pdf(x, a, b),
                      'r-', lw=5, alpha=0.6, label='norminvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = norminvgauss(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = norminvgauss.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], norminvgauss.cdf(vals, a, b))
```

Generate random numbers:

```python
>>> r = norminvgauss.rvs(a, b, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.pareto

scipy.stats.pareto = <scipy.stats._continuous_distns.pareto_gen object>
A Pareto continuous random variable.

As an instance of the rv_continuous class, pareto object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for pareto is:

\[ f(x, b) = \frac{b}{x^{b+1}} \]

for \( x \geq 1, b > 0 \).

pareto takes \( b \) as a shape parameter for \( b \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, pareto.pdf(x, b, loc, scale) is identically equivalent to pareto.pdf(y, b) / scale with y = (x - loc) / scale. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```python
>>> from scipy.stats import pareto
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> b = 2.62
>>> mean, var, skew, kurt = pareto.stats(b, moments='mvsk')
```  
Display the probability density function (pdf):

```python
>>> x = np.linspace(pareto.ppf(0.01, b),
...                   pareto.ppf(0.99, b), 100)
>>> ax.plot(x, pareto.pdf(x, b),
...         'r-', lw=5, alpha=0.6, label='pareto pdf')
```  
Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = pareto(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```  
Check accuracy of cdf and ppf:

```python
>>> vals = pareto.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], pareto.cdf(vals, b))
```

Generate random numbers:

```python
>>> r = pareto.rvs(b, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.pearson3**

`scipy.stats.pearson3 = <scipy.stats._continuous_distns.pearson3_gen object>`

A Pearson type III continuous random variable.

As an instance of the `rv_continuous` class, `pearson3` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `pearson3` is:

\[
f(x, \kappa) = \frac{|\beta|}{\Gamma(\alpha)} (\beta(x - \zeta))^\alpha - 1 \exp(-\beta(x - \zeta))
\]

where:

\[
\beta = \frac{2}{\kappa} \\
\alpha = \beta^2 = \frac{4}{\kappa^2} \\
\zeta = \frac{\alpha}{\beta} = -\beta
\]
Γ is the gamma function (scipy.special.gamma). Pass the skew $\kappa$ into pearson3 as the shape parameter skew.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, pearson3.pdf(x, skew, loc, scale) is identically equivalent to pearson3.pdf(y, skew) / scale with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

Examples

```python
>>> from scipy.stats import pearson3
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
def skew = 0.1
def mean, var, skew, kurt = pearson3.stats(skew, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(pearson3.ppf(0.01, skew),
...                  pearson3.ppf(0.99, skew), 100)
>>> ax.plot(x, pearson3.pdf(x, skew),
...          'r-', lw=5, alpha=0.6, label='pearson3 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = pearson3(skew)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = pearson3.ppf([0.001, 0.5, 0.999], skew)
>>> np.allclose([0.001, 0.5, 0.999], pearson3.cdf(vals, skew))
True
```

Generate random numbers:

```python
>>> r = pearson3.rvs(skew, size=1000)
```
And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.powerlaw

scipy.stats.powerlaw = <scipy.stats._continuous_distns.powerlaw_gen object>

A power-function continuous random variable.

As an instance of the rv_continuous class, powerlaw object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for powerlaw is:

\[ f(x, a) = ax^{a-1} \]

for \( 0 \leq x \leq 1, \ a > 0 \).

powerlaw takes \( a \) as a shape parameter for \( a \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, powerlaw.pdf(x, a, loc, scale) is identically equivalent to powerlaw.pdf(y, a) / scale with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.
powerlaw is a special case of beta with $b=1$.

**Examples**

```python
>>> from scipy.stats import powerlaw
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> a = 1.66
>>> mean, var, skew, kurt = powerlaw.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(powerlaw.ppf(0.01, a),
...                  powerlaw.ppf(0.99, a), 100)
>>> ax.plot(x, powerlaw.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='powerlaw pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = powerlaw(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = powerlaw.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], powerlaw.cdf(vals, a))
True
```

Generate random numbers:

```python
>>> r = powerlaw.rvs(a, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

3.3. API definition
scipy.stats.powerlognorm

scipy.stats.powerlognorm = <scipy.stats._continuous_distns.powerlognorm_gen object>
A power log-normal continuous random variable.

As an instance of the rv_continuous class, powerlognorm object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for powerlognorm is:

\[
 f(x, c, s) = \frac{c}{xs} \phi(\log(x)/s)(\Phi(-\log(x)/s))^{c-1}
\]

where \( \phi \) is the normal pdf, and \( \Phi \) is the normal cdf, and \( x > 0, s, c > 0 \).

powerlognorm takes \( c \) and \( s \) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, powerlognorm.pdf(\( x, c, s, \) loc, scale) is identically equivalent to powerlognorm.pdf(\( y, c, s \)) / scale with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```python
>>> from scipy.stats import powerlognorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> c, s = 2.14, 0.446
>>> mean, var, skew, kurt = powerlognorm.stats(c, s, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(powerlognorm.ppf(0.01, c, s),
.. powerlognorm.ppf(0.99, c, s), 100)
>>> ax.plot(x, powerlognorm.pdf(x, c, s),
... 'r-', lw=5, alpha=0.6, label='powerlognorm pdf')

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = powerlognorm(c, s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = powerlognorm.ppf([0.001, 0.5, 0.999], c, s)
>>> np.allclose([0.001, 0.5, 0.999], powerlognorm.cdf(vals, c, s))
True
```
Generate random numbers:

```python
>>> r = powerlognorm.rvs(c, s, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.powernorm`

`scipy.stats.powernorm = <scipy.stats._continuous_distns.powernorm_gen object>`

A power normal continuous random variable.

As an instance of the `rv_continuous` class, `powernorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `powernorm` is:

$$ f(x, c) = c\phi(x)(\Phi(-x))^{c-1} $$

where $\phi$ is the normal pdf, and $\Phi$ is the normal cdf, and $x \geq 0$, $c > 0$.

`powernorm` takes $c$ as a shape parameter for $c$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `powernorm.pdf(x, c, loc, scale)` is identically equivalent to `powernorm.pdf(y, c) / scale` with $y = (x - loc) / scale$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.
Examples

```python
>>> from scipy.stats import powernorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> c = 4.45
>>> mean, var, skew, kurt = powernorm.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(powernorm.ppf(0.01, c), ...
...                 powernorm.ppf(0.99, c), 100)
>>> ax.plot(x, powernorm.pdf(x, c), ...
...         'r-', lw=5, alpha=0.6, label='powernorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = powernorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = powernorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], powernorm.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = powernorm.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

</table>
scipy.stats.rdist

scipy.stats.rdist = <scipy.stats._continuous_distns.rdist_gen object>

An R-distributed (symmetric beta) continuous random variable.

As an instance of the rv_continuous class, rdist object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for rdist is:

\[ f(x, c) = \frac{(1 - x^2)^{c/2 - 1}}{B(1/2, c/2)} \]

for \(-1 \leq x \leq 1, c > 0\). rdist is also called the symmetric beta distribution: if B has a beta distribution with parameters (c/2, c/2), then \(X = 2B - 1\) follows a R-distribution with parameter c.

rdist takes c as a shape parameter for c.

This distribution includes the following distribution kernels as special cases:

- c = 2: uniform
- c = 3: `semicircular`
- c = 4: Epanechnikov (parabolic)
- c = 6: quartic (biweight)
- c = 8: triweight

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, rdist.pdf(x, c, loc, scale) is identically equivalent to rdist.pdf(y, c) / scale with y = (x - loc) / scale. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```python
>>> from scipy.stats import rdist
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> c = 1.6
>>> mean, var, skew, kurt = rdist.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(rdist.ppf(0.01, c),
... rdist.ppf(0.99, c), 100)
>>> ax.plot(x, rdist.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='rdist pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
```python
>>> rv = rdist(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

Check accuracy of cdf and ppf:

```python
>>> vals = rdist.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], rdist.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = rdist.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.rayleigh

scipy.stats.rayleigh = <scipy.stats._continuous_dists.rayleigh_gen object>

A Rayleigh continuous random variable.

As an instance of the rv_continuous class, rayleigh object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for rayleigh is:

$$f(x) = x \exp(-x^2/2)$$

for $x \geq 0$.

Rayleigh is a special case of chi with df=2.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, rayleigh.pdf(x, loc, scale) is identically equivalent to rayleigh.pdf(y) / scale with y = (x - loc) / scale. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.
Examples

```python
>>> from scipy.stats import rayleigh
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:
```n
```python
>>> mean, var, skew, kurt = rayleigh.stats(moments='mvsk')

Display the probability density function (pdf):
```n
```python
>>> x = np.linspace(rayleigh.ppf(0.01),
                  rayleigh.ppf(0.99), 100)
>>> ax.plot(x, rayleigh.pdf(x),
          'r-', lw=5, alpha=0.6, label='rayleigh pdf')

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
```n
```python
>>> rv = rayleigh()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

Check accuracy of cdf and ppf:
```n
```python
>>> vals = rayleigh.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], rayleigh.cdf(vals))
True

Generate random numbers:
```n
```python
>>> r = rayleigh.rvs(size=1000)

And compare the histogram:
```n
```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

</table>
scipy.stats.rice

scipy.stats.rice = <scipy.stats._continuous_distns.rice_gen object>

A Rice continuous random variable.

As an instance of the rv_continuous class, rice object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for rice is:

\[ f(x, b) = x \exp\left(-\frac{x^2 + b^2}{2}\right) I_0(xb) \]

for \( x \geq 0, b > 0 \). \( I_0 \) is the modified Bessel function of order zero (scipy.special.i0).

rice takes \( b \) as a shape parameter for \( b \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, rice.pdf(\( x, b \), loc, scale) is identically equivalent to rice.pdf(\( y, b \)) / scale with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

The Rice distribution describes the length, \( r \), of a 2-D vector with components \((U + u, V + v)\), where \( U, V \) are constant, \( u, v \) are independent Gaussian random variables with standard deviation \( s \). Let \( R = \sqrt{U^2 + V^2} \). Then the pdf of \( r \) is rice.pdf(\( x, R/s \), scale=s).

Examples

```python
>>> from scipy.stats import rice
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> b = 0.775
>>> mean, var, skew, kurt = rice.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(rice.ppf(0.01, b), ...      rice.ppf(0.99, b), 100)
>>> ax.plot(x, rice.pdf(x, b), ...      'r-', lw=5, alpha=0.6, label='rice pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = rice(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:
```python
>>> vals = rice.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], rice.cdf(vals, b))
True

Generate random numbers:
```n
```python
>>> r = rice.rvs(b, size=1000)

And compare the histogram:
```n
```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.recipinvgauss**

`scipy.stats.recipinvgauss = <scipy.stats._continuous_distns.recipinvgauss_gen object>`

A reciprocal inverse Gaussian continuous random variable.

As an instance of the `rv_continuous` class, `recipinvgauss` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `recipinvgauss` is:

\[ f(x, \mu) = \frac{1}{\sqrt{2\pi x}} \exp \left( -\frac{(1 - \mu x)^2}{2\mu^2 x} \right) \]

for \( x \geq 0 \).

`recipinvgauss` takes \( \mu \) as a shape parameter for \( \mu \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \( \text{loc} \) and \( \text{scale} \) parameters. Specifically, `recipinvgauss.pdf(x, \mu, \text{loc}, \text{scale})` is identically equivalent to `recipinvgauss.pdf(y, \mu) / \text{scale with } y = (x - \text{loc}) / \text{scale}`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.
Examples

```python
>>> from scipy.stats import recipinvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> mu = 0.63
>>> mean, var, skew, kurt = recipinvgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(recipinvgauss.ppf(0.01, mu),...
... recipinvgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, recipinvgauss.pdf(x, mu),...
... 'r-', lw=5, alpha=0.6, label='recipinvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = recipinvgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = recipinvgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], recipinvgauss.cdf(vals, mu))
True
```

Generate random numbers:

```python
>>> r = recipinvgauss.rvs(mu, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.semicircular**

```python
scipy.stats.semicircular = <scipy.stats._continuous_distns.semicircular_gen object>
```

A semicircular continuous random variable.

As an instance of the `rv_continuous` class, `semicircular` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`rdist`

**Notes**

The probability density function for `semicircular` is:

\[
f(x) = \frac{2}{\pi} \sqrt{1 - x^2}
\]

for \(-1 \leq x \leq 1\).

The distribution is a special case of `rdist` with \(c = 3\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `semicircular.pdf(x, loc, scale)` is identically equivalent to `semicircular.pdf(y) / scale` with \(y = (x - loc) / scale\). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**References**

[1]

**Examples**

```python
>>> from scipy.stats import semicircular
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> mean, var, skew, kurt = semicircular.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(semicircular.ppf(0.01),
...                 semicircular.ppf(0.99), 100)
>>> ax.plot(x, semicircular.pdf(x),
...         'r-', lw=5, alpha=0.6, label='semicircular pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
>>> rv = semicircular()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

Check accuracy of cdf and ppf:

```python
>>> vals = semicircular.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], semicircular.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = semicircular.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### scipy.stats.skewcauchy

`scipy.stats.skewcauchy = <scipy.stats._continuous_distns.skewcauchy_gen object>`

A skewed Cauchy random variable.

As an instance of the `rv_continuous` class, `skewcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

**cauchy**

Cauchy distribution
Notes

The probability density function for `skewcauchy` is:

\[ f(x) = \frac{1}{\pi \left(a \text{sign}(x) + 1\right)^2 + 1} \]

for a real number \( x \) and skewness parameter \(-1 < a < 1\).

When \( a = 0 \), the distribution reduces to the usual Cauchy distribution.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `skewcauchy.pdf(x, a, loc, scale)` is identically equivalent to `skewcauchy.pdf(y, a) / scale` with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1]

Examples

```python
>>> from scipy.stats import skewcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> a = 0.5
>>> mean, var, skew, kurt = skewcauchy.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(skewcauchy.ppf(0.01, a),
...                 skewcauchy.ppf(0.99, a), 100)
>>> ax.plot(x, skewcauchy.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='skewcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = skewcauchy(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = skewcauchy.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], skewcauchy.cdf(vals, a))
```

Generate random numbers:
```python
>>> r = skewcauchy.rvs(a, size=1000)

And compare the histogram:
```

**scipy.stats.skewnorm**

```python
scipy.stats.skewnorm = <scipy.stats._continuous_distns.skew_norm_gen object>
```

A skew-normal random variable.

As an instance of the `rv_continuous` class, `skewnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The pdf is:

```python
skewnorm.pdf(x, a) = 2 * norm.pdf(x) * norm.cdf(a*x)
```

`skewnorm` takes a real number `a` as a skewness parameter. When `a = 0` the distribution is identical to a normal distribution (`norm`). `rvs` implements the method of [1].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `skewnorm.pdf(x, a, loc, scale)` is identically equivalent to `skewnorm.pdf(y, a) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.
Examples

```python
>>> from scipy.stats import skewnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> a = 4
>>> mean, var, skew, kurt = skewnorm.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(skewnorm.ppf(0.01, a),
...                   skewnorm.ppf(0.99, a), 100)
>>> ax.plot(x, skewnorm.pdf(x, a),
...          'r-', lw=5, alpha=0.6, label='skewnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = skewnorm(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = skewnorm.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], skewnorm.cdf(vals, a))
True
```

Generate random numbers:

```python
>>> r = skewnorm.rvs(a, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.studentized_range

scipy.stats.studentized_range = <scipy.stats._continuous_distns.studentized_range_gen object>
A studentized range continuous random variable.

As an instance of the rv_continuous class, studentized_range object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

t  Student’s t distribution

Notes

The probability density function for studentized_range is:

\[
f(x; k, \nu) = \frac{k(k-1)\nu^{\nu/2}}{\Gamma(\nu/2)2^{\nu/2-1}} \int_0^\infty \int_{-\infty}^{\infty} s^{\nu-1} e^{-\nu s^2/2} \phi(s) \phi(sx + z) \left[ \Phi(sx + z) - \Phi(z) \right] k \, ds \, dz
\]

for \( x \geq 0 \), \( k > 1 \), and \( \nu > 0 \).

studentized_range takes \( k \) for \( k \) and \( \nu \) for \( \nu \) as shape parameters.

When \( \nu \) exceeds 100,000, an asymptotic approximation (infinite degrees of freedom) is used to compute the cumulative distribution function [4].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, studentized_range.pdf \((x, k, df, loc, scale)\) is identically equivalent to studentized_range.pdf \((y, k, df) / scale\) with \( y = (x - loc) / scale\). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1], [2], [3], [4]

Examples

```python
>>> from scipy.stats import studentized_range
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> k, df = 3, 10
>>> mean, var, skew, kurt = studentized_range.stats(k, df, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(studentized_range.ppf(0.01, k, df), ...
... studentized_range.ppf(0.99, k, df), 100)
>>> ax.plot(x, studentized_range.pdf(x, k, df), ...
... 'r-', lw=5, alpha=0.6, label='studentized_range pdf')
```
Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = studentized_range(k, df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = studentized_range.ppf([0.001, 0.5, 0.999], k, df)
>>> np.allclose([0.001, 0.5, 0.999], studentized_range.cdf(vals, k, df))
True
```

Rather than using (studentized_range.rvs) to generate random variates, which is very slow for this distribution, we can approximate the inverse CDF using an interpolator, and then perform inverse transform sampling with this approximate inverse CDF.

This distribution has an infinite but thin right tail, so we focus our attention on the leftmost 99.9 percent.

```python
>>> a, b = studentized_range.ppf([0, .999], k, df)
>>> a, b
0, 7.41058083802274
```

```python
>>> from scipy.interpolate import interp1d
>>> rng = np.random.default_rng()
>>> xs = np.linspace(a, b, 50)
>>> cdf = studentized_range.cdf(xs, k, df)
# Create an interpolant of the inverse CDF
>>> ppf = interp1d(cdf, xs, fill_value='extrapolate')
# Perform inverse transform sampling using the interpolant
>>> r = ppf(rng.uniform(size=1000))
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

</tbody>
</table>
scipy.stats.t

scipy.stats.t = <scipy.stats._continuous_distns.t_gen object>

A Student’s t continuous random variable.

For the noncentral t distribution, see nct.

As an instance of the rv_continuous class, t object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

nct

Notes

The probability density function for $t$ is:

$$f(x, \nu) = \frac{\Gamma((\nu + 1)/2)}{\sqrt{\pi\nu}\Gamma(\nu/2)} (1 + x^2/\nu)^{-(\nu+1)/2}$$

where $x$ is a real number and the degrees of freedom parameter $\nu$ (denoted df in the implementation) satisfies $\nu > 0$. $\Gamma$ is the gamma function (scipy.special.gamma).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, $t$.pdf($x$, df, loc, scale) is identically equivalent to $t$.pdf($y$, df) / scale with $y = (x - loc) / scale$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```python
>>> from scipy.stats import t
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> df = 2.74
>>> mean, var, skew, kurt = t.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(t.ppf(0.01, df),
                   ...                 t.ppf(0.99, df), 100)
>>> ax.plot(x, t.pdf(x, df),
          ...         'r-', lw=5, alpha=0.6, label='t pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = t(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=5, alpha=0.6, label='frozen pdf')
```
Check accuracy of \texttt{cdf} and \texttt{ppf}:

```python
>>> vals = t.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], t.cdf(vals, df))
True
```

Generate random numbers:

```python
>>> r = t.rvs(df, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`sans.stats.trapezoid`

`sans.stats.trapezoid = <scans.stats._continuous_distns.trapezoid_gen object>`

A trapezoidal continuous random variable.

As an instance of the `rv_continuous` class, `trapezoid` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The trapezoidal distribution can be represented with an up-sloping line from $loc$ to $(loc + c*scale)$, then constant to $(loc + d*scale)$ and then downsloping from $(loc + d*scale)$ to $(loc+scale)$. This defines the trapezoid base from $loc$ to $(loc+scale)$ and the flat top from $c$ to $d$ proportional to the position along the base with $0 \leq c \leq d \leq 1$. When $c=d$, this is equivalent to `triang` with the same values for $loc$, $scale$ and $c$. The method of [1] is used for computing moments.

`trapezoid` takes $c$ and $d$ as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `trapezoid.pdf(x, c, d, loc, scale)` is identically equivalent to `trapezoid.pdf(y, c, d) / scale` with $y = (x - loc) / scale$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.
The standard form is in the range [0, 1] with c the mode. The location parameter shifts the start to loc. The scale parameter changes the width from 1 to scale.

References

[1]

Examples

```python
>>> from scipy.stats import trapezoid
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
>>> c, d = 0.2, 0.8
>>> mean, var, skew, kurt = trapezoid.stats(c, d, moments='mvsk')

Display the probability density function (pdf):

```python
>>> x = np.linspace(trapezoid.ppf(0.01, c, d), ...
... trapezoid.ppf(0.99, c, d), 100)
>>> ax.plot(x, trapezoid.pdf(x, c, d), ...
... 'r-', lw=5, alpha=0.6, label='trapezoid pdf')
``` Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = trapezoid(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

Check accuracy of cdf and ppf:

```python
>>> vals = trapezoid.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], trapezoid.cdf(vals, c, d))
True
``` Generate random numbers:

```python
>>> r = trapezoid.rvs(c, d, size=1000)
``` And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.triang

**scipy.stats.triang** = `<scipy.stats._continuous_distns.triang_gen object>

A triangular continuous random variable.

As an instance of the *rv_continuous* class, *triang* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The triangular distribution can be represented with an up-sloping line from *loc* to (loc + c*scale) and then downsloping for (loc + c*scale) to (loc + scale).

*triang* takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, *triang.pdf(x, c, loc, scale)* is identically equivalent to *triang.pdf(y, c) / scale* with *y = (x - loc) / scale*. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

The standard form is in the range [0, 1] with *c* the mode. The location parameter shifts the start to *loc*. The scale parameter changes the width from 1 to *scale*.

**Examples**

```python
>>> from scipy.stats import triang
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> c = 0.158
>>> mean, var, skew, kurt = triang.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(triang.ppf(0.01, c),
...                 triang.ppf(0.99, c), 100)
>>> ax.plot(x, triang.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='triang pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = triang(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=5, alpha=0.6, label='frozen pdf')
```

Check accuracy of *cdf* and *ppf*:

```python
>>> vals = triang.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], triang.cdf(vals, c))
True
```
Generate random numbers:

```python
>>> r = triang.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### scipy.stats.truncexpon

**scipy.stats.truncexpon = <scipy.stats._continuous_distns.truncexpon_gen object>**

A truncated exponential continuous random variable.

As an instance of the `rv_continuous` class, `truncexpon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `truncexpon` is:

\[ f(x; b) = \frac{\exp(-x)}{1 - \exp(-b)} \]

for $0 \leq x \leq b$.

`truncexpon` takes $b$ as a shape parameter for $b$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `truncexpon.pdf(x, b, loc, scale)` is identically equivalent to `truncexpon.pdf(y, b) / scale` with $y = (x - loc) / scale$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.
Examples

```python
>>> from scipy.stats import truncexpon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
cdf = 4.69
mean, var, skew, kurt = truncexpon.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(truncexpon.ppf(0.01, b),
...                 truncexpon.ppf(0.99, b), 100)
>>> ax.plot(x, truncexpon.pdf(x, b),
...          'r-', lw=5, alpha=0.6, label='truncexpon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

```
Freeze the distribution and display the frozen pdf:

```python
>>> rv = truncexpon(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = truncexpon.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], truncexpon.cdf(vals, b))
True
```

Generate random numbers:

```python
>>> r = truncexpon.rvs(b, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.truncnorm

The standard form of this distribution is a standard normal truncated to the range [a, b] — notice that a and b are defined over the domain of the standard normal. To convert clip values for a specific mean and standard deviation, use:

\[
a, b = (\text{myclip}_a - \text{my}_\text{mean}) / \text{my}_\text{std}, (\text{myclip}_b - \text{my}_\text{mean}) / \text{my}_\text{std}
\]

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, \( \text{truncnorm.pdf}(x, a, b, \text{loc}, \text{scale}) \) is identically equivalent to \( \text{truncnorm.pdf}(y, a, b) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```python
>>> from scipy.stats import truncnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> a, b = 0.1, 2
>>> mean, var, skew, kurt = truncnorm.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(truncnorm.ppf(0.01, a, b),
...                 truncnorm.ppf(0.99, a, b), 100)
>>> ax.plot(x, truncnorm.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='truncnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = truncnorm(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:
>>> vals = truncnorm.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], truncnorm.cdf(vals, a, b))
True

Generate random numbers:

>>> r = truncnorm.rvs(a, b, size=1000)

And compare the histogram:

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

\texttt{scipy.stats.tukeylambda}

\texttt{scipy.stats.tukeylambda} = <\texttt{scipy.stats._continuous_distns.tukeylambda_gen object}>

A Tukey-Lambda continuous random variable.

As an instance of the \texttt{rv_continuous} class, \texttt{tukeylambda} object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

A flexible distribution, able to represent and interpolate between the following distributions:

- Cauchy (\(\lambda = -1\))
- logistic (\(\lambda = 0\))
- approx Normal (\(\lambda = 0.14\))
- uniform from -1 to 1 (\(\lambda = 1\))

\texttt{tukeylambda} takes a real number \(\lambda\) (denoted \texttt{lam} in the implementation) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{tukeylambda.pdf(x, lam, loc, scale)} is identically equivalent to \texttt{tukeylambda.pdf(y, lam) / scale} with \(y = (x - \text{loc}) / \text{scale}\). Note that
shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```python
>>> from scipy.stats import tukeylambda
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> lam = 3.13
>>> mean, var, skew, kurt = tukeylambda.stats(lam, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(tukeylambda.ppf(0.01, lam),
...                 tukeylambda.ppf(0.99, lam), 100)
>>> ax.plot(x, tukeylambda.pdf(x, lam),
...         'r-', lw=5, alpha=0.6, label='tukeylambda pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = tukeylambda(lam)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = tukeylambda.ppf([0.001, 0.5, 0.999], lam)
>>> np.allclose([0.001, 0.5, 0.999], tukeylambda.cdf(vals, lam))
```

Generate random numbers:

```python
>>> r = tukeylambda.rvs(lam, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

2482 Chapter 3. SciPy API
**scipy.stats.uniform**

`scipy.stats.uniform = <scipy.stats._continuous_distns.uniform_gen object>`

A uniform continuous random variable.

In the standard form, the distribution is uniform on [0, 1]. Using the parameters `loc` and `scale`, one obtains the uniform distribution on `[loc, loc + scale]`.

As an instance of the `rv_continuous` class, `uniform` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Examples

```python
>>> from scipy.stats import uniform
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> mean, var, skew, kurt = uniform.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(uniform.ppf(0.01), uniform.ppf(0.99), 100)
>>> ax.plot(x, uniform.pdf(x), 'r-', lw=5, alpha=0.6, label='uniform pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = uniform()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = uniform.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], uniform.cdf(vals))
```

Generate random numbers:

```python
>>> r = uniform.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.vonmises

scipy.stats.vonmises = <scipy.stats._continuous_distns.vonmises_gen object>
A Von Mises continuous random variable.

As an instance of the rv_continuous class, vonmises object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for vonmises and vonmises_line is:

\[ f(x, \kappa) = \frac{\exp(\kappa \cos(x))}{2\pi I_0(\kappa)} \]

for \(-\pi \leq x \leq \pi, \kappa > 0\). \(I_0\) is the modified Bessel function of order zero (scipy.special.i0).

vonmises is a circular distribution which does not restrict the distribution to a fixed interval. Currently, there is no circular distribution framework in scipy. The cdf is implemented such that cdf(x + 2*np.pi) == cdf(x) + 1.

donmises_line is the same distribution, defined on \([-\pi, \pi]\) on the real line. This is a regular (i.e. non-circular) distribution.

donmises and vonmises_line take kappa as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, vonmises.pdf(x, kappa, loc, scale) is identically equivalent to vonmises.pdf(y, kappa) / scale with y = (x - loc) / scale. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```python
>>> from scipy.stats import vonmises
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> kappa = 3.99
>>> mean, var, skew, kurt = vonmises.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(vonmises.ppf(0.01, kappa), ...
...                 vonmises.ppf(0.99, kappa), 100)
>>> ax.plot(x, vonmises.pdf(x, kappa), ...
...         'r-', lw=5, alpha=0.6, label='vonmises pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
>>> rv = vonmises(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

Check accuracy of cdf and ppf:

>>> vals = vonmises.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], vonmises.cdf(vals, kappa))
True

Generate random numbers:

>>> r = vonmises.rvs(kappa, size=1000)

And compare the histogram:

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

scipy.stats.vonmises_line

scipy.stats.vonmises_line = <scipy.stats._continuous_distns.vonmises_gen object>

A Von Mises continuous random variable.

As an instance of the rv_continuous class, vonmises_line object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for vonmises and vonmises_line is:

\[
f(x, \kappa) = \frac{\exp(\kappa \cos(x))}{2\pi I_0(\kappa)}
\]

for \(-\pi \leq x \leq \pi, \kappa > 0\). \(I_0(\kappa)\) is the modified Bessel function of order zero (scipy.special.i0).

vonmises is a circular distribution which does not restrict the distribution to a fixed interval. Currently, there is no circular distribution framework in scipy. The cdf is implemented such that cdf(x + 2*np.pi) == cdf(x) + 1.

vonmises_line is the same distribution, defined on \([-\pi, \pi]\) on the real line. This is a regular (i.e. non-circular) distribution.
\texttt{vonmises} and \texttt{vonmises\_line} take kappa as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{vonmises\_line.pdf(x, kappa, loc, scale)} is identically equivalent to \texttt{vonmises\_line.pdf(y, kappa) / scale} with \( y = (x - \text{loc}) / \text{scale} \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

\section*{Examples}

\begin{verbatim}
>>> from scipy.stats import vonmises_line
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

>>> kappa = 3.99
>>> mean, var, skew, kurt = vonmises_line.stats(kappa, moments='mvsk')

Display the probability density function (pdf):

>>> x = np.linspace(vonmises_line.ppf(0.01, kappa), ...
...                 vonmises_line.ppf(0.99, kappa), 100)
>>> ax.plot(x, vonmises_line.pdf(x, kappa), ...
...          'r-', lw=5, alpha=0.6, label='vonmises\_line pdf')

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

>>> rv = vonmises_line(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

Check accuracy of cdf and ppf:

>>> vals = vonmises_line.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], vonmises_line.cdf(vals, kappa))

Generate random numbers:

>>> r = vonmises_line.rvs(kappa, size=1000)

And compare the histogram:

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
\end{verbatim}

SciPy Reference Guide, Release 1.7.0

scipy.stats.wald

**scipy.stats.wald = <scipy.stats._continuous_distns.wald_gen object>**

A Wald continuous random variable.

As an instance of the `rv_continuous` class, `wald` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `wald` is:

\[
    f(x) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{(x-1)^2}{2x}\right)
\]

for \( x \geq 0 \).

`wald` is a special case of `invgauss` with \( \mu=1 \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `wald.pdf(x, loc, scale)` is identically equivalent to `wald.pdf(y) / scale` with \( y = (x - loc) / scale \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```python
>>> from scipy.stats import wald
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> mean, var, skew, kurt = wald.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(wald.ppf(0.01),
...                 wald.ppf(0.99), 100)
>>> ax.plot(x, wald.pdf(x),
...         'r-', lw=5, alpha=0.6, label='wald pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = wald()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = wald.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], wald.cdf(vals))
```

True
Generate random numbers:

```python
>>> r = wald.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.weibull_min`

`scipy.stats.weibull_min = <scipy.stats._continuous_distns.weibull_min_gen object>`

Weibull minimum continuous random variable.

The Weibull Minimum Extreme Value distribution, from extreme value theory (Fisher-Gnedenko theorem), is also often simply called the Weibull distribution. It arises as the limiting distribution of the rescaled minimum of iid random variables.

As an instance of the `rv_continuous` class, `weibull_min` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`weibull_max, numpy.random.Generator.weibull, exponweib`
Notes

The probability density function for `weibull_min` is:

\[ f(x, c) = cx^{c-1} \exp(-x^c) \]

for \( x > 0, c > 0 \).

`weibull_min` takes \( c \) as a shape parameter for \( c \). (named \( k \) in Wikipedia article and \( a \) in `numpy.random.weibull`). Special shape values are \( c = 1 \) and \( c = 2 \) where Weibull distribution reduces to the `expon` and `rayleigh` distributions respectively.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `weibull_min.pdf(x, c, loc, scale)` is identically equivalent to `weibull_min.pdf(y, c) / scale` with \( y = (x - loc) / scale \). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

https://en.wikipedia.org/wiki/Weibull_distribution

Examples

```python
>>> from scipy.stats import weibull_min
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> c = 1.79
>>> mean, var, skew, kurt = weibull_min.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(weibull_min.ppf(0.01, c),
...                 weibull_min.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_min.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='weibull_min pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = weibull_min(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = weibull_min.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_min.cdf(vals, c))
```

True
Generate random numbers:

```python
>>> r = weibull_min.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### scipy.stats.weibull_max

`scipy.stats.weibull_max = <scipy.stats._continuous_distns.weibull_max_gen object>`

Weibull maximum continuous random variable.

The Weibull Maximum Extreme Value distribution, from extreme value theory (Fisher-Gnedenko theorem), is the limiting distribution of rescaled maximum of iid random variables. This is the distribution of -X if X is from the `weibull_min` function.

As an instance of the `rv_continuous` class, `weibull_max` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`weibull_min`
Notes

The probability density function for `weibull_max` is:

\[
    f(x, c) = c(-x)^{c-1} \exp(-(-x)^c)
\]

for \(x < 0, c > 0\).

`weibull_max` takes \(c\) as a shape parameter for \(c\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `weibull_max.pdf(x, c, loc, scale)` is identically equivalent to `weibull_max.pdf(y, c) / scale` with \(y = (x - loc) / scale\). Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

https://en.wikipedia.org/wiki/Weibull_distribution

Examples

```python
>>> from scipy.stats import weibull_max
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> c = 2.87
>>> mean, var, skew, kurt = weibull_max.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(weibull_max.ppf(0.01, c),
...                  weibull_max.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_max.pdf(x, c),
...          'r-', lw=5, alpha=0.6, label='weibull_max pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = weibull_max(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = weibull_max.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_max.cdf(vals, c))
```

Generate random numbers:
```python
>>> r = weibull_max.rvs(c, size=1000)

And compare the histogram:
```

`scipy.stats.wrapcauchy`

`scipy.stats.wrapcauchy = <scipy.stats._continuous_distns.wrapcauchy_gen object>`

A wrapped Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `wrapcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `wrapcauchy` is:

$$ f(x, c) = \frac{1 - c^2}{2\pi(1 + c^2 - 2c\cos(x))} $$

for $0 \leq x \leq 2\pi$, $0 < c < 1$.

`wrapcauchy` takes $c$ as a shape parameter for $c$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `wrapcauchy.pdf(x, c, loc, scale)` is identically equivalent to `wrapcauchy.pdf(y, c) / scale` with $y = (x - loc) / scale$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.
Examples

```python
>>> from scipy.stats import wrapcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> c = 0.0311
>>> mean, var, skew, kurt = wrapcauchy.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(wrapcauchy.ppf(0.01, c), ...
... wrapcauchy.ppf(0.99, c), 100)
>>> ax.plot(x, wrapcauchy.pdf(x, c), ...
... 'r-', lw=5, alpha=0.6, label='wrapcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = wrapcauchy(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = wrapcauchy.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], wrapcauchy.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = wrapcauchy.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### scipy.stats.multivariate_normal

```python
scipy.stats.multivariate_normal = <scipy.stats._multivariate.multivariate_normal_gen object>
```

A multivariate normal random variable.

The `mean` keyword specifies the mean. The `cov` keyword specifies the covariance matrix.

**Parameters**

- `x` [array_like] Quantiles, with the last axis of `x` denoting the components.
- `mean` [array_like, optional] Mean of the distribution (default zero)
- `cov` [array_like, optional] Covariance matrix of the distribution (default one)
- `allow_singular` [bool, optional] Whether to allow a singular covariance matrix. (Default: False)
- `random_state` [[None, int, numpy.random.Generator.]
  numpy.random.RandomState], optional
  If `seed` is None (or `np.random`), the `numpy.random.RandomState` singleton is used.
  If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already
  a `Generator` or `RandomState` instance then that instance is used.

Alternatively, the object may be called (as a function) to fix the mean
and covariance parameters, returning a “frozen” multivariate normal
random variable:

```python
rv = multivariate_normal(mean=None, cov=1, allow_singular=False)
```

- Frozen object with the same methods but holding the given mean and covariance fixed.

### Notes

**Setting the parameter mean to None is equivalent to having mean**

be the zero-vector. The parameter `cov` can be a scalar, in which case the covariance matrix is the identity times
that value, a vector of diagonal entries for the covariance matrix, or a two-dimensional array_like.

The covariance matrix `cov` must be a (symmetric) positive semi-definite matrix. The determinant and inverse of
`cov` are computed as the pseudo-determinant and pseudo-inverse, respectively, so that `cov` does not need to have
full rank.
The probability density function for \texttt{multivariate_normal} is
\[
f(x) = \frac{1}{\sqrt{(2\pi)^k \det \Sigma}} \exp\left(-\frac{1}{2} (x - \mu)^T \Sigma^{-1} (x - \mu)\right),
\]
where \(\mu\) is the mean, \(\Sigma\) the covariance matrix, and \(k\) is the dimension of the space where \(x\) takes values.

New in version 0.14.0.

**Examples**

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import multivariate_normal

>>> x = np.linspace(0, 5, 10, endpoint=False)
>>> y = multivariate_normal.pdf(x, mean=2.5, cov=0.5); y
array([ 0.00108914, 0.01033349, 0.05946514, 0.20755375, 0.43939129,
        0.56418958, 0.43939129, 0.20755375, 0.05946514, 0.01033349])

>>> fig1 = plt.figure()
>>> ax = fig1.add_subplot(111)
>>> ax.plot(x, y)
```

The input quantiles can be any shape of array, as long as the last axis labels the components. This allows us for instance to display the frozen pdf for a non-isotropic random variable in 2D as follows:

```python
>>> x, y = np.mgrid[-1:1:.01, -1:1:.01]
>>> pos = np.dstack((x, y))
>>> rv = multivariate_normal([0.5, -0.2], [[2.0, 0.3], [0.3, 0.5]])
>>> fig2 = plt.figure()
>>> ax2 = fig2.add_subplot(111)
>>> ax2.contourf(x, y, rv.pdf(pos))
```

![Contour plot](image_url)

**scipy.stats.matrix_normal**

`scipy.stats.matrix_normal` = `<scipy.stats._multivariate.matrix_normal_gen object>`

A matrix normal random variable.

The `mean` keyword specifies the mean. The `rowcov` keyword specifies the among-row covariance matrix. The `colcov` keyword specifies the among-column covariance matrix.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>[array_like] Quantiles, with the last two axes of X denoting the components.</td>
</tr>
<tr>
<td>mean</td>
<td>[array_like, optional] Mean of the distribution (default: None)</td>
</tr>
<tr>
<td>rowcov</td>
<td>[array_like, optional] Among-row covariance matrix of the distribution (default: I)</td>
</tr>
<tr>
<td>colcov</td>
<td>[array_like, optional] Among-column covariance matrix of the distribution (default: I)</td>
</tr>
</tbody>
</table>
| random_state | [{None, int, numpy.random.Generator},
          numpy.random.RandomState], optional |

If `seed` is None (or `np.random`), the `numpy.random.RandomState` singleton is used. If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already
A Generator or RandomState instance then that instance is used.
Alternatively, the object may be called (as a function) to fix the mean
and covariance parameters, returning a “frozen” matrix normal
random variable:
\[
\text{rv} = \text{matrix\_normal}(<\text{mean}=\text{None}, \text{rowcov}=1, \text{colcov}=1>)
\]
- Frozen object with the same methods but holding the given mean and covariance fixed.

Notes

If **mean** is set to **None** then a matrix of zeros is used for the mean.

The dimensions of this matrix are inferred from the shape of **rowcov** and **colcov**, if these are provided, or set
to 1 if ambiguous.
**rowcov** and **colcov** can be two-dimensional array_likes specifying the covariance matrices directly. Alter-
natively, a one-dimensional array will be be interpreted as the entries of a diagonal matrix, and a scalar or
zero-dimensional array will be interpreted as this value times the identity matrix.

The covariance matrices specified by **rowcov** and **colcov** must be (symmetric) positive definite. If the samples in \(X\)
are \(m \times n\), then **rowcov** must be \(m \times m\) and **colcov** must be \(n \times n\). **mean** must be the same shape as \(X\).

The probability density function for **matrix\_normal** is
\[
f(X) = (2\pi)^{-\frac{mn}{2}}|U|^{-\frac{m}{2}}|V|^{-\frac{n}{2}} \exp\left(-\frac{1}{2} \text{Tr} \left[U^{-1}(X - M)V^{-1}(X - M)^T\right]\right),
\]
where **M** is the mean, **U** the among-row covariance matrix, **V** the among-column covariance matrix.

The allow_singular behaviour of the **multivariate\_normal** distribution is not currently supported. Covari-
ance matrices must be full rank.

The **matrix\_normal** distribution is closely related to the **multivariate\_normal** distribution. Specifi-
cally, \(\text{Vec}(X)\) (the vector formed by concatenating the columns of \(X\)) has a multivariate normal distribution with
mean \(\text{Vec}(M)\) and covariance \(V \otimes U\) (where \(\otimes\) is the Kronecker product). Sampling and pdf evaluation are
\(O(m^3 + n^3 + m^2 n + mn^2)\) for the matrix normal, but \(O(m^3 n^3)\) for the equivalent multivariate normal, making
this equivalent form algorithmically inefficient.

New in version 0.17.0.

Examples

```python
>>> from scipy.stats import matrix_normal

>>> M = np.arange(6).reshape(3,2); M
array([[0, 1],
       [2, 3],
       [4, 5]])
>>> U = np.diag([1,2,3]); U
array([[1, 0, 0],
       [0, 2, 0],
       [0, 0, 3]])
>>> V = 0.3*np.identity(2); V
array([[ 0.3, 0.],
       [ 0., 0.3]])
```
```python
>>> X = M + 0.1; X
array([[ 0.1,  1.1],
       [ 2.1,  3.1],
       [ 4.1,  5.1]])
>>> matrix_normal.pdf(X, mean=M, rowcov=U, colcov=V)
0.023410202050005054
```

```python
>>> # Equivalent multivariate normal
>>> from scipy.stats import multivariate_normal
>>> vectorised_X = X.T.flatten()
>>> equiv_mean = M.T.flatten()
>>> equiv_cov = np.kron(V,U)
>>> multivariate_normal.pdf(vectorised_X, mean=equiv_mean, cov=equiv_cov)
```

### Methods

```
pdf(X, mean=None, rowcov=1, colcov=1)``
Probability density function.

```
logpdf(X, mean=None, rowcov=1, colcov=1)``
Log of the probability density function.

```
rvs(mean=None, rowcov=1, colcov=1, size=1, random_state=None)``
Draw random samples.
```

`scipy.stats.dirichlet`

`scipy.stats.dirichlet = <scipy.stats._multivariate.dirichlet_gen object>`
A Dirichlet random variable.

The `alpha` keyword specifies the concentration parameters of the distribution.

New in version 0.15.0.

**Parameters**

`x` [array_like] Quantiles, with the last axis of `x` denoting the components.

`alpha` [array_like] The concentration parameters. The number of entries determines the dimensionality of the distribution.

`random_state` ([None, int, numpy.random.Generator.] numpy.random.RandomState], optional)
If `seed` is None (or `np.random`), the `numpy.random.RandomState` singleton is used. If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already a `Generator` or `RandomState` instance then that instance is used.

Alternatively, the object may be called (as a function) to fix concentration parameters, returning a “frozen” Dirichlet random variable:

```python
r = dirichlet(alpha)
```

- Frozen object with the same methods but holding the given concentration parameters fixed.

3.3. API definition
Notes

Each $\alpha$ entry must be positive. The distribution has only support on the simplex defined by

$$\sum_{i=1}^{K} x_i = 1$$

where $0 < x_i < 1$.

If the quantiles don’t lie within the simplex, a ValueError is raised.

The probability density function for `dirichlet` is

$$f(x) = \frac{1}{B(\alpha)} \prod_{i=1}^{K} x_i^{\alpha_i-1}$$

where

$$B(\alpha) = \frac{\prod_{i=1}^{K} \Gamma(\alpha_i)}{\Gamma(\sum_{i=1}^{K} \alpha_i)}$$

and $\alpha = (\alpha_1, \ldots, \alpha_K)$, the concentration parameters and $K$ is the dimension of the space where $x$ takes values.

Note that the dirichlet interface is somewhat inconsistent. The array returned by the rvs function is transposed with respect to the format expected by the pdf and logpdf.

Examples

```python
>>> from scipy.stats import dirichlet

Generate a dirichlet random variable

```quantiles = np.array([0.2, 0.2, 0.6]) # specify quantiles
```alpha = np.array([0.4, 5, 15]) # specify concentration parameters
```dirichlet.pdf(quantiles, alpha)
0.2843831684937255

The same PDF but following a log scale

```dirichlet.logpdf(quantiles, alpha)
-1.2574327653159187

Once we specify the dirichlet distribution we can then calculate quantities of interest

```dirichlet.mean(alpha) # get the mean of the distribution
array([0.01960784, 0.24509804, 0.73529412])
```dirichlet.var(alpha) # get variance
array([0.00089829, 0.00864603, 0.00909517])
```dirichlet.entropy(alpha) # calculate the differential entropy
-4.3280162474082715

We can also return random samples from the distribution

```
```python
>>> dirichlet.rvs(alpha, size=1, random_state=1)
array([[0.00766178, 0.24670518, 0.74563305]])
>>> dirichlet.rvs(alpha, size=2, random_state=2)
array([[0.01639427, 0.1292273 , 0.85437844],
       [0.00156917, 0.19033695, 0.80809388]])
```

### Methods

- `pdf(x, alpha)`
  - Probability density function.
- `logpdf(x, alpha)`
  - Log of the probability density function.
- `rvs(alpha, size=1, random_state=1)`
  - Draw random samples from a Dirichlet distribution.
- `mean(alpha)`
  - The mean of the Dirichlet distribution
- `var(alpha)`
  - The variance of the Dirichlet distribution
- `entropy(alpha)`
  - Compute the differential entropy of the Dirichlet distribution.

### scipy.stats.wishart

```python
scipy.stats.wishart = <scipy.stats._multivariate.wishart_gen object>
```

A Wishart random variable.

The `df` keyword specifies the degrees of freedom. The `scale` keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal precision matrix (the inverse of the covariance matrix). These arguments must satisfy the relationship \( df > scale.ndim - 1 \), but see notes on using the `rvs` method with \( df < scale.ndim \).

**Parameters**

- `x` [array_like] Quantiles, with the last axis of `x` denoting the components.
- `df` [int] Degrees of freedom, must be greater than or equal to dimension of the scale matrix.
- `scale` [array_like] Symmetric positive definite scale matrix of the distribution.
- `random_state` [{None, int, numpy.random.Generator, numpy.random.RandomState}, optional]
  - If `seed` is None (or `np.random`), the `numpy.random.RandomState` singleton is used.
  - If `seed` is an int, a new RandomState instance is used, seeded with `seed`. If `seed` is already a Generator or RandomState instance then that instance is used.

Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” Wishart random variable:

```python
rv = wishart(df=1, scale=1)
```

- Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

See also:

- `invwishart`, `chi2`
Notes

The scale matrix \( scale \) must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The Wishart distribution is often denoted

\[
W_p(\nu, \Sigma)
\]

where \( \nu \) is the degrees of freedom and \( \Sigma \) is the \( p \times p \) scale matrix.

The probability density function for \( \text{wishart} \) has support over positive definite matrices \( S \); if \( S \sim W_p(\nu, \Sigma) \), then its PDF is given by:

\[
f(S) = \frac{|S|^{\nu-p-1/2}}{2^{\nu/2} \Gamma_p (\frac{\nu}{2})} \exp\left(\frac{-\text{tr}(\Sigma^{-1} S)}{2}\right)
\]

If \( S \sim W_p(\nu, \Sigma) \) (Wishart) then \( S^{-1} \sim \text{W}^{-1}_p(\nu, \Sigma^{-1}) \) (inverse Wishart).

If the scale matrix is 1-dimensional and equal to one, then the Wishart distribution \( W_1(\nu, 1) \) collapses to the \( \chi^2(\nu) \) distribution.

The algorithm [2] implemented by the \texttt{rvs} method may produce numerically singular matrices with \( p - 1 < \nu < p \); the user may wish to check for this condition and generate replacement samples as necessary.

New in version 0.16.0.

References

[1], [2]

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import wishart, chi2
>>> x = np.linspace(1e-5, 8, 100)
>>> w = wishart.pdf(x, df=3, scale=1); w[:5]
aarray([0.00126156, 0.10892176, 0.14793434, 0.17400548, 0.1929669])
>>> c = chi2.pdf(x, 3); c[:5]
aarray([0.00126156, 0.10892176, 0.14793434, 0.17400548, 0.1929669])
>>> plt.plot(x, w)
```

The input quantiles can be any shape of array, as long as the last axis labels the components.

Methods

```
"pdf(x, df, scale)"
Probability density function.

"logpdf(x, df, scale)"
Log of the probability density function.

"rvs(df, scale, size=1, random_state= None)"
Draw random samples from a Wishart distribution.

"entropy()"
Compute the differential entropy of the Wishart distribution.
```
**scipy.stats.invwishart**

```python
class scipy.stats.invwishart = <scipy.stats._multivariate.invwishart_gen object>

An inverse Wishart random variable.

The `df` keyword specifies the degrees of freedom. The `scale` keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal covariance matrix.

**Parameters**

- `x` : [array_like] Quantiles, with the last axis of `x` denoting the components.
- `df` : [int] Degrees of freedom, must be greater than or equal to dimension of the scale matrix
- `scale` : [array_like] Symmetric positive definite scale matrix of the distribution
- `random_state` : [[None, int, numpy.random.Generator],
                      numpy.random.RandomState], optional
  If `seed` is None (or `np.random`), the `numpy.random.RandomState` singleton is used.
  If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already a `Generator` or `RandomState` instance then that instance is used.

Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” inverse Wishart random variable:

```python
rv = invwishart(df=1, scale=1)
```

- Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

**See also:**

- `wishart`
Notes

The scale matrix \( scale \) must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The inverse Wishart distribution is often denoted

\[
W_p^{-1}(\nu, \Psi)
\]

where \( \nu \) is the degrees of freedom and \( \Psi \) is the \( p \times p \) scale matrix.

The probability density function for \( \text{invwishart} \) has support over positive definite matrices \( S \); if \( S \sim W_p^{-1}(\nu, \Sigma) \), then its PDF is given by:

\[
f(S) = \frac{|\Sigma|^{\frac{\nu}{2}}}{2^{\frac{p(p+1)}{4}} |S|^{\frac{\nu+p+1}{2}} \Gamma_p \left( \frac{\nu}{2} \right)} \exp \left( -tr(\Sigma S^{-1})/2 \right)
\]

If \( S \sim W_p^{-1}(\nu, \Psi) \) (inverse Wishart) then \( S^{-1} \sim W_p(\nu, \Psi^{-1}) \) (Wishart).

If the scale matrix is 1-dimensional and equal to one, then the inverse Wishart distribution \( W_1(\nu, 1) \) collapses to the inverse Gamma distribution with parameters \( \text{shape}=\frac{\nu}{2} \) and \( \text{scale}=\frac{1}{2} \).

New in version 0.16.0.

References

[1], [2]

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import invwishart, invgamma
>>> x = np.linspace(0.01, 1, 100)
>>> iw = invwishart.pdf(x, df=6, scale=1)
>>> iw[:3]
array([ 1.20546865e-15, 5.42497807e-06, 4.45813929e-03])
>>> ig = invgamma.pdf(x, 6/2., scale=1./2)
>>> ig[:3]
array([ 1.20546865e-15, 5.42497807e-06, 4.45813929e-03])
>>> plt.plot(x, iw)
```

The input quantiles can be any shape of array, as long as the last axis labels the components.

Methods

```
``pdf(x, df, scale)`
Probability density function.
``logpdf(x, df, scale)`
Log of the probability density function.
``rvs(df, scale, size=1, random_state=None)`
Draw random samples from an inverse Wishart distribution.
```
scipy.stats.multinomial

scipy.stats.multinomial = <scipy.stats._multivariate.multinomial_gen object>
A multinomial random variable.

Parameters

x  [array_like] Quantiles, with the last axis of x denoting the components.
n  [int] Number of trials
p  [array_like] Probability of a trial falling into each category; should sum to 1
random_state

[(None, int, numpy.random.Generator,]
numpy.random.RandomState], optional
If seed is None (or np.random), the numpy.random.RandomState singleton is used.
If seed is an int, a new RandomState instance is used, seeded with seed. If seed is already
a Generator or RandomState instance then that instance is used.

See also:

scipy.stats.binom
The binomial distribution.
numpy.random.Generator.multinomial
Sampling from the multinomial distribution.
scipy.stats.multivariate_hypergeom
The multivariate hypergeometric distribution.
Notes

\( n \) should be a positive integer. Each element of \( p \) should be in the interval \([0, 1]\) and the elements should sum to 1. If they do not sum to 1, the last element of the \( p \) array is not used and is replaced with the remaining probability left over from the earlier elements.

Alternatively, the object may be called (as a function) to fix the \( n \) and \( p \) parameters, returning a “frozen” multinomial random variable:

The probability mass function for \texttt{multinomial} is

\[
f(x) = \frac{n!}{x_1! \cdots x_k!} p_1^{x_1} \cdots p_k^{x_k},
\]

supported on \( x = (x_1, \ldots, x_k) \) where each \( x_i \) is a nonnegative integer and their sum is \( n \).

New in version 0.19.0.

Examples

```python
>>> from scipy.stats import multinomial
>>> rv = multinomial(8, [0.3, 0.2, 0.5])
>>> rv.pmf([1, 3, 4])
0.042000000000000072
```

The multinomial distribution for \( k = 2 \) is identical to the corresponding binomial distribution (tiny numerical differences notwithstanding):

```python
>>> from scipy.stats import binom
>>> multinomial.pmf([3, 4], n=7, p=[0.4, 0.6])
0.29030399999999973
```

The functions \texttt{pmf}, \texttt{logpmf}, \texttt{entropy}, and \texttt{cov} support broadcasting, under the convention that the vector parameters (\( x \) and \( p \)) are interpreted as if each row along the last axis is a single object. For instance:

```python
>>> multinomial.pmf([[3, 4], [3, 5]], n=[7, 8], p=[.3, .7])
array([0.2268945, 0.25412184])
```

Here, \( x \).shape == (2, 2), \( n \).shape == (2,), and \( p \).shape == (2,), but following the rules mentioned above they behave as if the rows \([3, 4]\) and \([3, 5]\) in \( x \) and \([.3, .7]\) in \( p \) were a single object, and as if we had \( x \).shape == (2,), \( n \).shape == (2,), and \( p \).shape == (1,). To obtain the individual elements without broadcasting, we would do this:

```python
>>> multinomial.pmf([[3, 4], [3, 5]], n=7, p=[.3, .7])
0.2268945
```

This broadcasting also works for \texttt{cov}, where the output objects are square matrices of size \( p \).shape[-1]. For example:

```python
>>> multinomial.cov([[4, 5], [.3, .7], [.4, .6]])
array([[ 0.84, -0.84],
       [-0.84,  0.84]])
```
In this example, `n.shape == (2,)` and `p.shape == (2, 2)`, and following the rules above, these broadcast as if `p.shape == (2,)`. Thus the result should also be of shape `(2,)`, but since each output is a $2 \times 2$ matrix, the result in fact has shape `(2, 2, 2)`, where `result[0]` is equal to `multinomial.cov(n=4, p=[.3, .7])` and `result[1]` is equal to `multinomial.cov(n=5, p=[.4, .6])`.

### scipy.stats.special_ortho_group

`scipy.stats.special_ortho_group = <scipy.stats._multivariate.special_ortho_group_gen object>`

A matrix-valued SO(N) random variable.

Return a random rotation matrix, drawn from the Haar distribution (the only uniform distribution on SO(n)).

The `dim` keyword specifies the dimension N.

**Parameters**

- `dim` [scalar] Dimension of matrices

**See also:**

- `ortho_group`, `scipy.spatial.transform.Rotation.random`

### Notes

This class is wrapping the random_rot code from the MDP Toolkit, [https://github.com/mdp-toolkit/mdp-toolkit](https://github.com/mdp-toolkit/mdp-toolkit)

Return a random rotation matrix, drawn from the Haar distribution (the only uniform distribution on SO(n)). The algorithm is described in the paper Stewart, G.W., “The efficient generation of random orthogonal matrices with an application to condition estimators”, SIAM Journal on Numerical Analysis, 17(3), pp. 403-409, 1980. For more information see [https://en.wikipedia.org/wiki/Orthogonal_matrix#Randomization](https://en.wikipedia.org/wiki/Orthogonal_matrix#Randomization)

See also the similar `ortho_group`. For a random rotation in three dimensions, see `scipy.spatial.transform.Rotation.random`. 

---

3.3. API definition 2513
Examples

```python
>>> from scipy.stats import special_ortho_group
>>> x = special_ortho_group.rvs(3)
```

```python
>>> np.dot(x, x.T)
array([[ 1.00000000e+00,  1.13231364e-17, -2.86852790e-16],
       [ 1.13231364e-17,  1.00000000e+00, -1.46845020e-16],
       [ -2.86852790e-16, -1.46845020e-16,  1.00000000e+00]])
```

```python
>>> import scipy.linalg
>>> scipy.linalg.det(x)
1.0
```

This generates one random matrix from SO(3). It is orthogonal and has a determinant of 1.

Methods

```python
\texttt{``rvs(dim=None, size=1, random_state=None)``}
```

\textit{Draw random samples from SO(N).}

\texttt{scipy.stats.ortho_group}

\texttt{scipy.stats.ortho_group = \textless scipy.stats._multivariate.ortho_group_gen \textgreater \texttt{object}}

A matrix-valued O(N) random variable.

Return a random orthogonal matrix, drawn from the O(N) Haar distribution (the only uniform distribution on O(N)).

The \textit{dim} keyword specifies the dimension N.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{dim} \quad [\text{scalar}] \quad \text{Dimension of matrices}
\end{itemize}

\textbf{Notes}

This class is closely related to \texttt{special_ortho_group}.

Some care is taken to avoid numerical error, as per the paper by Mezzadri.

\textbf{References}

[1]
Examples

```python
>>> from scipy.stats import ortho_group
>>> x = ortho_group.rvs(3)

>>> np.dot(x, x.T)
array([[ 1.00000000e+00,  1.13231364e-17,  2.86852790e-16],
       [ 1.13231364e-17,  1.00000000e+00,  1.46845020e-16],
       [ 2.86852790e-16,  1.46845020e-16,  1.00000000e+00]])

>>> import scipy.linalg
>>> np.fabs(scipy.linalg.det(x))
1.0
```

This generates one random matrix from O(3). It is orthogonal and has a determinant of +1 or -1.

Methods

```
``rvs(dim=None, size=1, random_state=None)`
Draw random samples from O(N).
```

scipy.stats.unitary_group

```
scipy.stats.unitary_group = <scipy.stats._multivariate.unitary_group_gen object>
A matrix-valued U(N) random variable.
Return a random unitary matrix.
The dim keyword specifies the dimension N.

Parameters

dim [scalar] Dimension of matrices
```

Notes

This class is similar to ortho_group.

References

[1]
Examples

```python
>>> from scipy.stats import unitary_group
>>> x = unitary_group.rvs(3)
```

```python
>>> np.dot(x, x.conj().T)
array([[ 1.00000000e+00, 1.13231364e-17, -2.86852790e-16],
       [ 1.13231364e-17, 1.00000000e+00, -1.46845020e-16],
       [-2.86852790e-16, -1.46845020e-16, 1.00000000e+00]])
```

This generates one random matrix from U(3). The dot product confirms that it is unitary up to machine precision.

Methods

```
rvs(dim=None, size=1, random_state=None)`'
```

Draw random samples from U(N).

scipy.stats.random_correlation

```python
scipy.stats.random_correlation = <scipy.stats._multivariate.random_correlation_gen object>
```

A random correlation matrix.

Return a random correlation matrix, given a vector of eigenvalues.

The `eigs` keyword specifies the eigenvalues of the correlation matrix, and implies the dimension.

Parameters

- `eigs` [1d ndarray] Eigenvalues of correlation matrix.

Notes

Generates a random correlation matrix following a numerically stable algorithm spelled out by Davies & Higham. This algorithm uses a single O(N) similarity transformation to construct a symmetric positive semi-definite matrix, and applies a series of Givens rotations to scale it to have ones on the diagonal.

References

[1]

Examples

```python
>>> from scipy.stats import random_correlation
>>> rng = np.random.default_rng()
>>> x = random_correlation.rvs((.5, .8, 1.2, 1.5), random_state=rng)
>>> x
array([[ 1.        , -0.07198934, -0.20411041, -0.24385796],
       [-0.07198934,  1.        ,  0.12968613, -0.29471382],
       [-0.20411041,  0.12968613,  1.        ,  0.2828693 ],
       [-0.24385796, -0.29471382,  0.2828693 ,  1.        ]])
```
```python
>>> import scipy.linalg
>>> e, v = scipy.linalg.eigh(x)
>>> e
array([ 0.5,  0.8,  1.2,  1.5])
```

Methods

```python
```
rvs(eigs=None, random_state=None)``
Draw random correlation matrices, all with eigenvalues eigs.

scipy.stats.multivariate_t

```python
scipy.stats.multivariate_t = <scipy.stats._multivariate.multivariate_t_gen object>
```
A multivariate t-distributed random variable.

The loc parameter specifies the location. The shape parameter specifies the positive semidefinite shape matrix. The df parameter specifies the degrees of freedom.

In addition to calling the methods below, the object itself may be called as a function to fix the location, shape matrix, and degrees of freedom parameters, returning a “frozen” multivariate t-distribution random.

Parameters

- x [array_like] Quantiles, with the last axis of $x$ denoting the components.
- loc [array_like, optional] Location of the distribution. (default 0)
- shape [array_like, optional] Positive semidefinite matrix of the distribution. (default 1)
- df [float, optional] Degrees of freedom of the distribution; must be greater than zero. If np.inf then results are multivariate normal. The default is 1.
- allow_singular [bool, optional] Whether to allow a singular matrix. (default False)
- random_state [{None, int, numpy.random.Generator, numpy.random.RandomState}, optional]
  If seed is None (or np.random), the numpy.random.RandomState singleton is used. If seed is an int, a new RandomState instance is used, seeded with seed. If seed is already a Generator or RandomState instance then that instance is used.

Notes

Setting the parameter loc to None is equivalent to having loc be the zero-vector. The parameter shape can be a scalar, in which case the shape matrix is the identity times that value, a vector of diagonal entries for the shape matrix, or a two-dimensional array_like. The matrix shape must be a (symmetric) positive semidefinite matrix. The determinant and inverse of shape are computed as the pseudo-determinant and pseudo-inverse, respectively, so that shape does not need to have full rank.

The probability density function for multivariate_t is

\[
f(x) = \frac{\Gamma((\nu + p)/2)}{\Gamma(\nu/2)p^{p/2}\pi^{p(p+1)/4}\Sigma^{1/2}} \exp \left[ 1 + \frac{1}{\nu} (x - \mu)\Sigma^{-1}(x - \mu) \right]^{-(\nu+p)/2},
\]

where $p$ is the dimension of $x$, $\mu$ is the $p$-dimensional location, $\Sigma$ the $p \times p$-dimensional shape matrix, and $\nu$ is the degrees of freedom.

New in version 1.6.0.
Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import multivariate_t
>>> x, y = np.mgrid[-1:3:0.01, -2:1.5:0.01]
>>> pos = np.dstack((x, y))
>>> rv = multivariate_t([1.0, -0.5], [[2.1, 0.3], [0.3, 1.5]], df=2)
>>> fig, ax = plt.subplots(1, 1)
>>> ax.set_aspect('equal')
>>> plt.contourf(x, y, rv.pdf(pos))
```

![Contour plot of multivariate t-distribution](image)

Methods

```
``pdf(x, loc=None, shape=1, df=1, allow_singular=False)`
 Probability density function.
``logpdf(x, loc=None, shape=1, df=1, allow_singular=False)`
 Log of the probability density function.
``rvs(loc=None, shape=1, df=1, size=1, random_state=None)`
 Draw random samples from a multivariate t-distribution.
```

scipy.stats.multivariate_hypergeom

```python
scipy.stats.multivariate_hypergeom = <scipy.stats._multivariate.multivariate_hypergeom_gen object>
```

A multivariate hypergeometric random variable.

**Parameters**

- **m** [array_like] The number of each type of object in the population. That is, \(m[i]\) is the number of objects of type \(i\).
- **n** [array_like] The number of samples taken from the population.
- **random_state** [{None, int, numpy.random.Generator}]

```
If `seed` is None (or `np.random`), the `numpy.random.RandomState` singleton is used. If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already a `Generator` or `RandomState` instance then that instance is used.

See also:

`scipy.stats.hypergeom`

The hypergeometric distribution.

`scipy.stats.multinomial`

The multinomial distribution.

Notes

`m` must be an array of positive integers. If the quantile `i` contains values out of the range `[0, m_i]` where `m_i` is the number of objects of type `i` in the population or if the parameters are inconsistent with one another (e.g. `x . sum ()` != `n`), methods return the appropriate value (e.g. 0 for `pmf`). If `m` or `n` contain negative values, the result will contain `nan` there.

The probability mass function for `multivariate_hypergeom` is

\[
P(X_1 = x_1, X_2 = x_2, \ldots, X_k = x_k) = \frac{\binom{m_1}{x_1} \binom{m_2}{x_2} \cdots \binom{m_k}{x_k}}{\binom{M}{n}},
\]

\[(x_1, x_2, \ldots, x_k) \in \mathbb{N}^k \text{ with } \sum_{i=1}^{k} x_i = n\]

where `m_i` are the number of objects of type `i`, `M` is the total number of objects in the population (sum of all the `m_i`), and `n` is the size of the sample to be taken from the population.

New in version 1.6.0.

References

[1], [2]

Examples

To evaluate the probability mass function of the multivariate hypergeometric distribution, with a dichotomous population of size 10 and 20, at a sample of size 12 with 8 objects of the first type and 4 objects of the second type, use:

```python
>>> from scipy.stats import multivariate_hypergeom
>>> multivariate_hypergeom.pmf(x=[8, 4], m=[10, 20], n=12)
0.0025207176631464523
```

The `multivariate_hypergeom` distribution is identical to the corresponding `hypergeom` distribution (tiny numerical differences notwithstanding) when only two types (good and bad) of objects are present in the population as in the example above. Consider another example for a comparison with the hypergeometric distribution:
```
>>> from scipy.stats import hypergeom
>>> multivariate_hypergeom.pmf(x=[3, 1], m=[10, 5], n=4)
0.4395604395604395
>>> hypergeom.pmf(k=3, M=15, n=4, N=10)
0.43956043956044005
```

The functions `pmf`, `logpmf`, `mean`, `var`, `cov`, and `rvs` support broadcasting, under the convention that the vector parameters \((x, m, \text{and } n)\) are interpreted as if each row along the last axis is a single object. For instance, we can combine the previous two calls to `multivariate_hypergeom` as

```
>>> multivariate_hypergeom.pmf(x=[[8, 4], [3, 1]], m=[[10, 20], [10, 5]],
   n=[12, 4])
array([0.00252072, 0.43956044])
```

This broadcasting also works for `cov`, where the output objects are square matrices of size \(m.\text{shape}[1]\). For example:

```
>>> multivariate_hypergeom.cov(m=[[7, 9], [10, 15]], n=[8, 12])
array([[ 1.05, -1.05],
       [-1.05,  1.05],
       [ 1.56, -1.56],
       [-1.56,  1.56]])
```

That is, `result[0]` is equal to `multivariate_hypergeom.cov(m=[7, 9], n=8)` and `result[1]` is equal to `multivariate_hypergeom.cov(m=[10, 15], n=12)`.

Alternatively, the object may be called (as a function) to fix the \(m\) and \(n\) parameters, returning a “frozen” multivariate hypergeometric random variable.

```
>>> rv = multivariate_hypergeom(m=[10, 20], n=12)
>>> rv.pmf(x=[8, 4])
0.0025207176631464523
```

**Methods**

```
``pmf(x, m, n)``
``logpmf(x, m, n)``
``rvs(m, n, size=1,
 random_state=None)``
``mean(m, n)``
``var(m, n)``
``cov(m, n)``
```
Probability mass function.
Log of the probability mass function.
Draw random samples from a multivariate hypergeometric distribution.
Mean of the multivariate hypergeometric distribution.
Variance of the multivariate hypergeometric distribution.
Compute the covariance matrix of the multivariate hypergeometric distribution.
```
Discrete distributions

- `bernoulli`  
  A Bernoulli discrete random variable.

- `betabinom`  
  A beta-binomial discrete random variable.

- `binom`  
  A binomial discrete random variable.

- `geom`  
  A geometric discrete random variable.

- `hypergeom`  
  A hypergeometric discrete random variable.

- `logser`  
  A Logarithmic (Log-Series, Series) discrete random variable.

- `nbinom`  
  A negative binomial discrete random variable.

- `nchypergeom_fisher`  
  A Fisher’s noncentral hypergeometric discrete random variable.

- `nchypergeom_wallenius`  
  A Wallenius’ noncentral hypergeometric discrete random variable.

- `nhypergeom`  
  A negative hypergeometric discrete random variable.

- `planck`  
  A Planck discrete exponential random variable.

- `poisson`  
  A Poisson discrete random variable.

- `randint`  
  A uniform discrete random variable.

- `skellam`  
  A Skellam discrete random variable.

- `yulesimon`  
  A Yule-Simon discrete random variable.

- `zipf`  
  A Zipf (Zeta) discrete random variable.

- `zipfian`  
  A Zipfian discrete random variable.

**scipy.stats.bernoulli**

`scipy.stats.bernoulli = <scipy.stats._discrete_distns.bernoulli_gen object>`  
A Bernoulli discrete random variable.

As an instance of the `rv_discrete` class, `bernoulli` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for `bernoulli` is:

\[
 f(k) = \begin{cases} 
 1 - p & \text{if } k = 0 \\ 
  p & \text{if } k = 1 
\end{cases}
\]

for \( k \in \{0, 1\}, 0 \leq p \leq 1 \)

`bernoulli` takes \( p \) as shape parameter, where \( p \) is the probability of a single success and \( 1 - p \) is the probability of a single failure.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `bernoulli.pmf(k, p, loc)` is identically equivalent to `bernoulli.pmf(k - loc, p)`.
Examples

```python
>>> from scipy.stats import bernoulli
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> p = 0.3
>>> mean, var, skew, kurt = bernoulli.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(bernoulli.ppf(0.01, p), bernoulli.ppf(0.99, p))
>>> ax.plot(x, bernoulli.pmf(x, p), 'bo', ms=8, label='bernoulli pmf')
>>> ax.vlines(x, 0, bernoulli.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = bernoulli(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1, label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```python
>>> prob = bernoulli.cdf(x, p)
>>> np.allclose(x, bernoulli.ppf(prob, p))
True
```

Generate random numbers:
```python
>>> r = bernoulli.rvs(p, size=1000)
```

**scipy.stats.betabinom**

`scipy.stats.betabinom = <scipy.stats._discrete_distns.betabinom_gen object>`

A beta-binomial discrete random variable.

As an instance of the `rv_discrete` class, `betabinom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`beta`, `binom`

### Notes

The beta-binomial distribution is a binomial distribution with a probability of success $p$ that follows a beta distribution.

The probability mass function for `betabinom` is:

$$ f(k) = \binom{n}{k} \frac{B(k + a, n - k + b)}{B(a, b)} $$

for $k \in \{0, 1, \ldots, n\}$, $n \geq 0$, $a > 0$, $b > 0$, where $B(a, b)$ is the beta function.

`betabinom` takes $n$, $a$, and $b$ as shape parameters.
References

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, `betabinom.pmf(k, n, a, b, loc)` is identically equivalent to `betabinom.pmf(k - loc, n, a, b)`.

New in version 1.4.0.

[1]

Examples

```python
>>> from scipy.stats import betabinom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> n, a, b = 5, 2.3, 0.63
>>> mean, var, skew, kurt = betabinom.stats(n, a, b, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(betabinom.ppf(0.01, n, a, b),
...                betabinom.ppf(0.99, n, a, b))
>>> ax.plot(x, betabinom.pmf(x, n, a, b), 'bo', ms=8, label='betabinom pmf')
>>> ax.vlines(x, 0, betabinom.pmf(x, n, a, b), colors='b', lw=5, alpha=0.35)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = betabinom(n, a, b)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```python
>>> prob = betabinom.cdf(x, n, a, b)
>>> np.allclose(x, betabinom.ppf(prob, n, a, b))
True
```

Generate random numbers:

```python
>>> r = betabinom.rvs(n, a, b, size=1000)
```

scipy.stats.binom

scipy.stats.binom = <scipy.stats._discrete_distns.binom_gen object>
A binomial discrete random variable.

As an instance of the rv_discrete class, binom object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:
hypergeom, nbinom, nhypergeom

Notes
The probability mass function for binom is:

\[ f(k) = \binom{n}{k} p^k (1 - p)^{n-k} \]

for \( k \in \{0, 1, \ldots, n\} \), \( 0 \leq p \leq 1 \)

binom takes \( n \) and \( p \) as shape parameters, where \( p \) is the probability of a single success and \( 1 - p \) is the probability of a single failure.

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, \( \text{binom.pmf}(k, n, p, \text{loc}) \) is identically equivalent to \( \text{binom.pmf}(k - \text{loc}, n, p) \).

Examples

```python
>>> from scipy.stats import binom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> n, p = 5, 0.4
>>> mean, var, skew, kurt = binom.stats(n, p, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(binom.ppf(0.01, n, p),
...                binom.ppf(0.99, n, p))
>>> ax.plot(x, binom.pmf(x, n, p), 'bo', ms=8, label='binom pmf')
>>> ax.vlines(x, 0, binom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = binom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=5, alpha=0.5)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Check accuracy of `cdf` and `ppf`:

```python
>>> prob = binom.cdf(x, n, p)
>>> np.allclose(x, binom.ppf(prob, n, p))
True
```

Generate random numbers:

```python
>>> r = binom.rvs(n, p, size=1000)
```

**scipy.stats.boltzmann**

`scipy.stats.boltzmann = <scipy.stats._discrete_distns.boltzmann_gen object>`

A Boltzmann (Truncated Discrete Exponential) random variable.

As an instance of the `rv_discrete` class, `boltzmann` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for `boltzmann` is:

\[
    f(k) = \frac{(1 - \exp(-\lambda)) \exp(-\lambda k)/(1 - \exp(-\lambda N))}
\]

for \( k = 0, \ldots, N - 1 \).

`boltzmann` takes \( \lambda > 0 \) and \( N > 0 \) as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `boltzmann.pmf(k, lambda_, N, loc)` is identically equivalent to `boltzmann.pmf(k - loc, lambda_, N)`.

**Examples**

```python
>>> from scipy.stats import boltzmann
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> lambda_, N = 1.4, 19
>>> mean, var, skew, kurt = boltzmann.stats(lambda_, N, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(boltzmann.ppf(0.01, lambda_, N),
...                boltzmann.ppf(0.99, lambda_, N))
>>> ax.plot(x, boltzmann.pmf(x, lambda_, N), 'bo', ms=8, label='boltzmann pmf')
>>> ax.vlines(x, 0, boltzmann.pmf(x, lambda_, N), colors='b', lw=5, ... alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = boltzmann(lambda_, N)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1, ... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of `cdf` and `ppf`:

### scipy.stats.dlaplace

`scipy.stats.dlaplace = <scipy.stats._discrete_distns.dlaplace_gen object>`

A Laplacian discrete random variable.

As an instance of the `rv_discrete` class, `dlaplace` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `dlaplace` is:

\[
f(k) = \tanh(a/2) \exp(-a|k|)
\]

for integers \(k\) and \(a > 0\).

`dlaplace` takes \(a\) as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `dlaplace.pmf(k, a, loc)` is identically equivalent to `dlaplace.pmf(k - loc, a).`
Examples

```python
>>> from scipy.stats import dlaplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> a = 0.8
>>> mean, var, skew, kurt = dlaplace.stats(a, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(dlaplace.ppf(0.01, a), dlaplace.ppf(0.99, a))
>>> ax.plot(x, dlaplace.pmf(x, a), 'bo', ms=8, label='dlaplace pmf')
>>> ax.vlines(x, 0, dlaplace.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = dlaplace(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```python
>>> prob = dlaplace.cdf(x, a)
>>> np.allclose(x, dlaplace.ppf(prob, a))
True
```

Generate random numbers:
```python
>>> r = dlaplace.rvs(a, size=1000)
```

`scipy.stats.geom`

`scipy.stats.geom = <scipy.stats._discrete_distns.geom_gen object>`

A geometric discrete random variable.

As an instance of the `rv_discrete` class, `geom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`planck`

**Notes**

The probability mass function for `geom` is:

\[ f(k) = (1 - p)^{k-1} p \]

for \( k \geq 1, 0 < p \leq 1 \)

`geom` takes \( p \) as shape parameter, where \( p \) is the probability of a single success and \( 1 - p \) is the probability of a single failure.

The probability mass function above is defined in the “standardized” form. To shift distribution use the \( \text{loc} \) parameter. Specifically, `geom.pmf(k, p, loc)` is identically equivalent to `geom.pmf(k - loc, p).`
Examples

```python
>>> from scipy.stats import geom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> p = 0.5
>>> mean, var, skew, kurt = geom.stats(p, moments='mvsk')
``` 

Display the probability mass function (pmf):

```python
>>> x = np.arange(geom.ppf(0.01, p), ...
... geom.ppf(0.99, p))
>>> ax.plot(x, geom.pmf(x, p), 'bo', ms=8, label='geom pmf')
>>> ax.vlines(x, 0, geom.pmf(x, p), colors='b', lw=5, alpha=0.5)
``` 

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = geom(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1, ...
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```python
>>> prob = geom.cdf(x, p)
>>> np.allclose(x, geom.ppf(prob, p))
```

Generate random numbers:
```python
>>> r = geom.rvs(p, size=1000)
```

**scipy.stats.hypergeom**

`scipy.stats.hypergeom = <scipy.stats._discrete_distns.hypergeom_gen object>`

A hypergeometric discrete random variable.

The hypergeometric distribution models drawing objects from a bin. \( M \) is the total number of objects, \( n \) is total number of Type I objects. The random variate represents the number of Type I objects in \( N \) drawn without replacement from the total population.

As an instance of the `rv_discrete` class, `hypergeom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`nhypergeom`, `binom`, `nbinom`
Notes

The symbols used to denote the shape parameters \((M, n, \text{and } N)\) are not universally accepted. See the Examples for a clarification of the definitions used here.

The probability mass function is defined as,

\[
p(k, M, n, N) = \frac{n^k (M-n)^{N-k}}{M^N}
\]

for \(k \in \left[\max(0, N - M + n), \min(n, N)\right]\), where the binomial coefficients are defined as,

\[
\binom{n}{k} = \frac{n!}{k!(n-k)!}
\]

The probability mass function above is defined in the “standardized” form. To shift distribution use the \text{loc} parameter. Specifically, \text{hypergeom.pmf}(k, M, n, N, \text{loc}) is identically equivalent to \text{hypergeom.pmf}(k - \text{loc}, M, n, N).

Examples

```python
>>> from scipy.stats import hypergeom
>>> import matplotlib.pyplot as plt
```

Suppose we have a collection of 20 animals, of which 7 are dogs. Then if we want to know the probability of finding a given number of dogs if we choose at random 12 of the 20 animals, we can initialize a frozen distribution and plot the probability mass function:

```python
>>> [M, n, N] = [20, 7, 12]
>>> rv = hypergeom(M, n, N)
>>> x = np.arange(0, n+1)
>>> pmf_dogs = rv.pmf(x)
```

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, pmf_dogs, 'bo')
>>> ax.vlines(x, 0, pmf_dogs, lw=2)
>>> ax.set_xlabel('# of dogs in our group of chosen animals')
>>> ax.set_ylabel('hypergeom PMF')
>>> plt.show()
```

Instead of using a frozen distribution we can also use \text{hypergeom} methods directly. To for example obtain the cumulative distribution function, use:

```python
>>> prb = hypergeom.cdf(x, M, n, N)
```

And to generate random numbers:

```python
>>> R = hypergeom.rvs(M, n, N, size=10)
```

scipy.stats.logser

`scipy.stats.logser = <scipy.stats._discrete_distns.logser_gen object>`

A Logarithmic (Log-Series, Series) discrete random variable.

As an instance of the `rv_discrete` class, `logser` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for `logser` is:

\[
f(k) = -\frac{p^k}{k \log(1 - p)}
\]

for \(k \geq 1, 0 < p < 1\)

`logser` takes `p` as shape parameter, where `p` is the probability of a single success and \(1 - p\) is the probability of a single failure.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `logser.pmf(k, p, loc)` is identically equivalent to `logser.pmf(k - loc, p)`.

**Examples**

```python
>>> from scipy.stats import logser
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> p = 0.6
>>> mean, var, skew, kurt = logser.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(logser.ppf(0.01, p), ...
...    logser.ppf(0.99, p))
>>> ax.plot(x, logser.pmf(x, p), 'bo', ms=8, label='logser pmf')
>>> ax.vlines(x, 0, logser.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = logser(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1, ...
...    label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:
```python
>>> prob = logser.cdf(x, p)
>>> np.allclose(x, logser.ppf(prob, p))
True
```

Generate random numbers:

```python
>>> r = logser.rvs(p, size=1000)
```

scipy.stats.nbinom

scipy.stats.nbinom = <scipy.stats._discrete_distns.nbinom_gen object>
A negative binomial discrete random variable.

As an instance of the rv_discrete class, nbinom object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:
hypergeom, binom, nhypergeom

Notes

Negative binomial distribution describes a sequence of i.i.d. Bernoulli trials, repeated until a predefined, non-random number of successes occurs.

The probability mass function of the number of failures for nbinom is:

\[ f(k) = \binom{k + n - 1}{n - 1} p^n (1 - p)^k \]

for \( k \geq 0 \), \( 0 < p \leq 1 \)

nbinom takes \( n \) and \( p \) as shape parameters where \( n \) is the number of successes, \( p \) is the probability of a single success, and \( 1 - p \) is the probability of a single failure.

Another common parameterization of the negative binomial distribution is in terms of the mean number of failures \( \mu \) to achieve \( n \) successes. The mean \( \mu \) is related to the probability of success as

\[ p = \frac{n}{n + \mu} \]

The number of successes \( n \) may also be specified in terms of a “dispersion”, “heterogeneity”, or “aggregation” parameter \( \alpha \), which relates the mean \( \mu \) to the variance \( \sigma^2 \), e.g. \( \sigma^2 = \mu + \alpha \mu^2 \). Regardless of the convention used for \( \alpha \),

\[ p = \frac{\mu}{\sigma^2} \]

\[ n = \frac{\mu^2}{\sigma^2 - \mu} \]

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, nbinom.pmf(k, n, p, loc) is identically equivalent to nbinom.pmf(k - loc, n, p).

Examples

```python
>>> from scipy.stats import nbinom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> n, p = 5, 0.5
>>> mean, var, skew, kurt = nbinom.stats(n, p, moments='mvsk')
```
Display the probability mass function (pmf):

```python
>>> x = np.arange(nbinom.ppf(0.01, n, p),
...                nbinom.ppf(0.99, n, p))
>>> ax.plot(x, nbinom.pmf(x, n, p), 'bo', ms=8, label='nbinom pmf')
>>> ax.vlines(x, 0, nbinom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = nbinom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```python
>>> prob = nbinom.cdf(x, n, p)
>>> np.allclose(x, nbinom.ppf(prob, n, p))
True
```

Generate random numbers:

```python
>>> r = nbinom.rvs(n, p, size=1000)
```

</table>

`scipy.stats.nchypergeom_fisher`

A Fisher's noncentral hypergeometric discrete random variable.

Fisher’s noncentral hypergeometric distribution models drawing objects of two types from a bin. $M$ is the total number of objects, $n$ is the number of Type I objects, and $\text{odds}$ is the odds ratio: the odds of selecting a Type I object rather than a Type II object when there is only one object of each type. The random variate represents the number of Type I objects drawn if we take a handful of objects from the bin at once and find out afterwards that we took $N$ objects.

As an instance of the `rv_discrete` class, `nchypergeom_fisher` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`nchypergeom_wallenius`, `hypergeom`, `nhypergeom`

Notes

Let mathematical symbols $N$, $n$, and $M$ correspond with parameters $N$, $n$, and $M$ (respectively) as defined above. The probability mass function is defined as

$$p(x; M, n, N, \omega) = \binom{n}{x} \binom{M-n}{N-x} \omega^x \left(1-\omega\right)^{N-x},$$

for $x \in [x_l, x_u]$, $M \in \mathbb{N}$, $n \in [0, M]$, $N \in [0, M]$, $\omega > 0$, where $x_l = \max(0, N - (M - n))$, $x_u = \min(N, n)$,

$$P_0 = \sum_{y=x_l}^{x_u} \binom{n}{y} \binom{M-n}{N-y} \omega^y,$$
and the binomial coefficients are defined as
\[ \binom{n}{k} \equiv \frac{n!}{k!(n-k)!}. \]

nchypergeom_fisher uses the BiasedUrn package by Agner Fog with permission for it to be distributed under SciPy's license.

The symbols used to denote the shape parameters \((N, n, \text{and} M)\) are not universally accepted; they are chosen for consistency with hypergeom.

Note that Fisher's noncentral hypergeometric distribution is distinct from Wallenius' noncentral hypergeometric distribution, which models drawing a pre-determined \(N\) objects from a bin one by one. When the odds ratio is unity, however, both distributions reduce to the ordinary hypergeometric distribution.

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, nchypergeom_fisher.pmf\((k, M, n, N, \text{odds, loc})\) is identically equivalent to nchypergeom_fisher.pmf\((k - \text{loc, M, n, N, odds})\).

Examples

```python
>>> from scipy.stats import nchypergeom_fisher
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> M, n, N, odds = 140, 80, 60, 0.5
>>> mean, var, skew, kurt = nchypergeom_fisher.stats(M, n, N, odds, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(nchypergeom_fisher.ppf(0.01, M, n, N, odds), ...
...     nchypergeom_fisher.ppf(0.99, M, n, N, odds))
>>> ax.plot(x, nchypergeom_fisher.pmf(x, M, n, N, odds), 'bo', ms=8, ...
...     label='nchypergeom_fisher pmf')
>>> ax.vlines(x, 0, nchypergeom_fisher.pmf(x, M, n, N, odds), colors='b', ...
...     lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = nchypergeom_fisher(M, n, N, odds)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1, ...
...     label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:
```python
>>> prob = nchypergeom_fisher.cdf(x, M, n, N, odds)
>>> np.allclose(x, nchypergeom_fisher.ppf(prob, M, n, N, odds))
True

Generate random numbers:

```python

**scipy.stats.nchypergeom_wallenius**

`scipy.stats.nchypergeom_wallenius = <scipy.stats._discrete_distns.nchypergeom_wallenius_gen object>`

A Wallenius’ noncentral hypergeometric discrete random variable.

Wallenius' noncentral hypergeometric distribution models drawing objects of two types from a bin. $M$ is the total number of objects, $n$ is the number of Type I objects, and $odds$ is the odds ratio: the odds of selecting a Type I object rather than a Type II object when there is only one object of each type. The random variate represents the number of Type I objects drawn if we draw a pre-determined $N$ objects from a bin one by one.

As an instance of the `rv_discrete` class, `nchypergeom_wallenius` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

- `nchypergeom_fisher`, `hypergeom`, `nhypergeom`
Notes

Let mathematical symbols $N$, $n$, and $M$ correspond with parameters $N$, $n$, and $M$ (respectively) as defined above.

The probability mass function is defined as

\[
p(x; N, n, M) = \binom{n}{x} \binom{M - n}{N - x} \int_0^1 \left( 1 - \frac{t\omega}{D} \right)^x \left( 1 - \frac{t^{1/D}}{D} \right)^{N-x} dt
\]

for $x \in [x_l, x_u]$, $M \in \mathbb{N}$, $n \in [0, M]$, $N \in [0, M]$, $\omega > 0$, where $x_l = \max(0, N - (M - n))$, $x_u = \min(N, n)$,

\[
D = \omega(n - x) + ((M - n) - (N - x)),
\]

and the binomial coefficients are defined as

\[
\binom{n}{k} \equiv \frac{n!}{k!(n-k)!}.
\]

\nchypergeom_wallenius\ uses the BiasedUrn package by Agner Fog with permission for it to be distributed under SciPy’s license.

The symbols used to denote the shape parameters ($N$, $n$, and $M$) are not universally accepted; they are chosen for consistency with hypergeom.

Note that Wallenius’ noncentral hypergeometric distribution is distinct from Fisher’s noncentral hypergeometric distribution, which models take a handful of objects from the bin at once, finding out afterwards that $N$ objects were taken. When the odds ratio is unity, however, both distributions reduce to the ordinary hypergeometric distribution.

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, \nchypergeom_wallenius\ .pmf($k$, $M$, $n$, $N$, odds, loc) is identically equivalent to \nchypergeom_wallenius\ .pmf($k - loc$, $M$, $n$, $N$, odds).

Examples

```python
>>> from scipy.stats import nchypergeom_wallenius
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> M, n, N, odds = 140, 80, 60, 0.5
>>> mean, var, skew, kurt = nchypergeom_wallenius.stats(M, n, N, odds, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(nchypergeom_wallenius.ppf(0.01, M, n, N, odds),
... nchypergeom_wallenius.ppf(0.99, M, n, N, odds))
>>> ax.plot(x, nchypergeom_wallenius.pmf(x, M, n, N, odds), 'bo', ms=8, label='nchypergeom_wallenius pmf')
>>> ax.vlines(x, 0, nchypergeom_wallenius.pmf(x, M, n, N, odds), colors='b', lw=5, alpha=0.5)
```
Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = nchypergeom_wallenius(M, n, N, odds)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
...    label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

![nchypergeom_wallenius pmf vs frozen pmf](image)

Check accuracy of `cdf` and `ppf`:

```python
>>> prob = nchypergeom_wallenius.cdf(x, M, n, N, odds)
>>> np.allclose(x, nchypergeom_wallenius.ppf(prob, M, n, N, odds))
True
```

Generate random numbers:

```python
>>> r = nchypergeom_wallenius.rvs(M, n, N, odds, size=1000)
```

**scipy.stats.nhypergeom**

`scipy.stats.nhypergeom = <scipy.stats._discrete_distns.nhypergeom_gen object>`

A negative hypergeometric discrete random variable.

Consider a box containing $M$ balls; $n$ red and $M - n$ blue. We randomly sample balls from the box, one at a time and without replacement, until we have picked $r$ blue balls. **nhypergeom** is the distribution of the number of red balls $k$ we have picked.

As an instance of the **rv_discrete** class, **nhypergeom** object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

**hypergeom, binom, nbinom**

**Notes**

The symbols used to denote the shape parameters ($M$, $n$, and $r$) are not universally accepted. See the Examples for a clarification of the definitions used here.

The probability mass function is defined as,

$$f(k; M, n, r) = \binom{k+r-1}{k} \frac{M-r-k}{n} \frac{n-k}{M-n}$$
for \( k \in [0, n], n \in [0, M], r \in [0, M - n], \) and the binomial coefficient is:

\[
\binom{n}{k} = \frac{n!}{k!(n-k)!}.
\]

It is equivalent to observing \( k \) successes in \( k + r - 1 \) samples with \( k + r \)th sample being a failure. The former can be modelled as a hypergeometric distribution. The probability of the latter is simply the number of failures remaining \( M - n - (r - 1) \) divided by the size of the remaining population \( M - (k + r - 1) \). This relationship can be shown as:

\[
NHG(k; M, n, r) = HG(k; M, n, k + r - 1) \frac{(M - n - (r - 1))}{(M - (k + r - 1))}
\]

where \( NHG \) is probability mass function (PMF) of the negative hypergeometric distribution and \( HG \) is the PMF of the hypergeometric distribution.

The probability mass function above is defined in the “standardized” form. To shift distribution use the \( \text{loc} \) parameter. Specifically, \( \text{nhypergeom}.pmf(k, M, n, r, \text{loc}) \) is identically equivalent to \( \text{nhypergeom}.pmf(k - \text{loc}, M, n, r) \).

**References**

[1], [2]

**Examples**

```python
>>> from scipy.stats import nhypergeom
>>> import matplotlib.pyplot as plt
```

Suppose we have a collection of 20 animals, of which 7 are dogs. Then if we want to know the probability of finding a given number of dogs (successes) in a sample with exactly 12 animals that aren’t dogs (failures), we can initialize a frozen distribution and plot the probability mass function:

```python
>>> M, n, r = [20, 7, 12]
>>> rv = nhypergeom(M, n, r)
>>> x = np.arange(0, n+2)
>>> pmf_dogs = rv.pmf(x)
```

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, pmf_dogs, 'bo')
>>> ax.vlines(x, 0, pmf_dogs, lw=2)
>>> ax.set_xlabel('# of dogs in our group with given 12 failures')
>>> ax.set_ylabel('nhypergeom PMF')
>>> plt.show()
```

Instead of using a frozen distribution we can also use \( nhypergeom \) methods directly. To for example obtain the probability mass function, use:

```python
>>> prb = nhypergeom.pmf(x, M, n, r)
```

And to generate random numbers:
To verify the relationship between `hypergeom` and `nhypergeom`, use:

```python
>>> from scipy.stats import hypergeom, nhypergeom
>>> M, n, r = 45, 13, 8
>>> k = 6
>>> nhypergeom.pmf(k, M, n, r)
0.06180776620271643
>>> hypergeom.pmf(k, M, n, k+r-1) * (M - n - (r-1)) / (M - (k+r-1))
0.06180776620271644
```
Methods

- `rvs(M, n, r, loc=0, size=1, random_state=None)` Random variates.
- `pmf(k, M, n, r, loc=0)` Probability mass function.
- `logpmf(k, M, n, r, loc=0)` Log of the probability mass function.
- `cdf(k, M, n, r, loc=0)` Cumulative distribution function.
- `logcdf(k, M, n, r, loc=0)` Log of the cumulative distribution function.
- `sf(k, M, n, r, loc=0)` Survival function (also defined as $1 - cdf$, but $sf$ is sometimes more accurate).
- `logsf(k, M, n, r, loc=0)` Log of the survival function.
- `ppf(q, M, n, r, loc=0)` Percent point function (inverse of $cdf$ — percentiles).
- `isf(q, M, n, r, loc=0)` Inverse survival function (inverse of $sf$).
- `stats(M, n, r, loc=0, moments='mv')` Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
- `entropy(M, n, r, loc=0)` (Differential) entropy of the RV.
- `expect(func, args=(M, n, r), loc=0, lb=None, ub=None, conditional=False)` Expected value of a function (of one argument) with respect to the distribution.
- `median(M, n, r, loc=0)` Median of the distribution.
- `mean(M, n, r, loc=0)` Mean of the distribution.
- `var(M, n, r, loc=0)` Variance of the distribution.
- `std(M, n, r, loc=0)` Standard deviation of the distribution.
- `interval(alpha, M, n, r, loc=0)` Endpoints of the range that contains fraction alpha [0, 1] of the distribution.

**scipy.stats.planck**

A Planck discrete exponential random variable.

As an instance of the `rv_discrete` class, `planck` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:** `geom`

**Notes**

The probability mass function for `planck` is:

$$f(k) = (1 - \exp(-\lambda)) \exp(-\lambda k)$$

for $k \geq 0$ and $\lambda > 0$.

`planck` takes $\lambda$ as shape parameter. The Planck distribution can be written as a geometric distribution (`geom`) with $p = 1 - \exp(-\lambda)$ shifted by $\text{loc} = -1$.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `planck.pmf(k, lambda_, loc)` is identically equivalent to `planck.pmf(k - loc, lambda_)`.  

---

2550 Chapter 3. SciPy API
Examples

```python
>>> from scipy.stats import planck
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> lambda_ = 0.51
>>> mean, var, skew, kurt = planck.stats(lambda_, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(planck.ppf(0.01, lambda_), ...
... planck.ppf(0.99, lambda_))
>>> ax.plot(x, planck.pmf(x, lambda_), 'bo', ms=8, label='planck pmf')
>>> ax.vlines(x, 0, planck.pmf(x, lambda_), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = planck(lambda_)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1, ...
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```python
>>> prob = planck.cdf(x, lambda_)
>>> np.allclose(x, planck.ppf(prob, lambda_))
True
```

Generate random numbers:
>>> r = planck.rvs(lambda_, size=1000)

**scipy.stats.poisson**

`scipy.stats.poisson = <scipy.stats._discrete_distns.poisson_gen object>`

A Poisson discrete random variable.

As an instance of the `rv_discrete` class, poisson object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for poisson is:

\[
f(k) = \exp(-\mu) \frac{\mu^k}{k!}
\]

for \(k \geq 0\).

poisson takes \(\mu \geq 0\) as shape parameter. When \(\mu = 0\), the pmf method returns 1.0 at quantile \(k = 0\).

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, poisson.pmf(k, mu, loc) is identically equivalent to poisson.pmf(k - loc, mu).
Examples

```python
>>> from scipy.stats import poisson
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> mu = 0.6
>>> mean, var, skew, kurt = poisson.stats(mu, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(poisson.ppf(0.01, mu),
...               poisson.ppf(0.99, mu))
>>> ax.plot(x, poisson.pmf(x, mu), 'bo', ms=8, label='poisson pmf')
>>> ax.vlines(x, 0, poisson.pmf(x, mu), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = poisson(mu)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```python
>>> prob = poisson.cdf(x, mu)
>>> np.allclose(x, poisson.ppf(prob, mu))
True
```

Generate random numbers:
```python
>>> r = poisson.rvs(mu, size=1000)
```

**scipy.stats.randint**

`scipy.stats.randint` = `<scipy.stats._discrete_distns.randint_gen object>`

A uniform discrete random variable.

As an instance of the rv_discrete class, randint object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for randint is:

$$f(k) = \frac{1}{\text{high} - \text{low}}$$

for \(k \in \{\text{low}, \ldots, \text{high} - 1\}\).

randint takes low and high as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, randint.pmf(k, low, high, loc) is identically equivalent to randint.pmf(k - loc, low, high).
Examples

```python
>>> from scipy.stats import randint
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> low, high = 7, 31
>>> mean, var, skew, kurt = randint.stats(low, high, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(randint.ppf(0.01, low, high),
...                randint.ppf(0.99, low, high))
>>> ax.plot(x, randint.pmf(x, low, high), 'bo', ms=8, label='randint pmf')
>>> ax.vlines(x, 0, randint.pmf(x, low, high), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = randint(low, high)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```python
>>> prob = randint.cdf(x, low, high)
>>> np.allclose(x, randint.ppf(prob, low, high))
True
```
Generate random numbers:

```python
>>> r = randint.rvs(low, high, size=1000)
```

### scipy.stats.skellam

`scipy.stats.skellam = <scipy.stats._discrete_distns.skellam_gen object>`

A Skellam discrete random variable.

As an instance of the `rv_discrete` class, `skellam` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

Probability distribution of the difference of two correlated or uncorrelated Poisson random variables.

Let $k_1$ and $k_2$ be two Poisson-distributed r.v. with expected values $\lambda_1$ and $\lambda_2$. Then, $k_1 - k_2$ follows a Skellam distribution with parameters $\mu_1 = \lambda_1 - \rho \sqrt{\lambda_1 \lambda_2}$ and $\mu_2 = \lambda_2 - \rho \sqrt{\lambda_1 \lambda_2}$, where $\rho$ is the correlation coefficient between $k_1$ and $k_2$. If the two Poisson-distributed r.v. are independent then $\rho = 0$.

Parameters $\mu_1$ and $\mu_2$ must be strictly positive.

For details see: [https://en.wikipedia.org/wiki/Skellam_distribution](https://en.wikipedia.org/wiki/Skellam_distribution)

`skellam` takes $\mu_1$ and $\mu_2$ as shape parameters.
The probability mass function above is defined in the “standardized” form. To shift distribution use the \texttt{loc} parameter. Specifically, \texttt{skellam.pmf(k, \mu1, \mu2, \texttt{loc})} is identically equivalent to \texttt{skellam.pmf(k - \texttt{loc}, \mu1, \mu2)}.

**Examples**

```python
>>> from scipy.stats import skellam
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> mu1, mu2 = 15, 8
>>> mean, var, skew, kurt = skellam.stats(mu1, mu2, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(skellam.ppf(0.01, mu1, mu2),
...                skellam.ppf(0.99, mu1, mu2))
>>> ax.plot(x, skellam.pmf(x, mu1, mu2), 'bo', ms=8, label='skellam pmf')
>>> ax.vlines(x, 0, skellam.pmf(x, mu1, mu2), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = skellam(mu1, mu2)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=4, 
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of \texttt{cdf} and \texttt{ppf}:
```python
>>> prob = skellam.cdf(x, mu1, mu2)
>>> np.allclose(x, skellam.ppf(prob, mu1, mu2))
True
```

Generate random numbers:

```python
>>> r = skellam.rvs(mu1, mu2, size=1000)
```

</tbody>
</table>
scipy.stats.yulesimon

scipy.stats.yulesimon = <scipy.stats._discrete_distns.yulesimon_gen object>
A Yule-Simon discrete random variable.

As an instance of the rv_discrete class, yulesimon object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability mass function for the yulesimon is:

\[ f(k) = \alpha B(k, \alpha + 1) \]

for \( k = 1, 2, 3, \ldots \), where \( \alpha > 0 \). Here \( B \) refers to the scipy.special.beta function.

The sampling of random variates is based on pg 553, Section 6.3 of [1]. Our notation maps to the referenced logic via \( \alpha = a - 1 \).

For details see the wikipedia entry [2].

References

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, yulesimon.pmf(k, alpha, loc) is identically equivalent to yulesimon.pmf(k - loc, alpha).

[1], [2]

Examples

```python
>>> from scipy.stats import yulesimon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> alpha = 11
>>> mean, var, skew, kurt = yulesimon.stats(alpha, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(yulesimon.ppf(0.01, alpha),
...               yulesimon.ppf(0.99, alpha))
>>> ax.plot(x, yulesimon.pmf(x, alpha), 'bo', ms=8, label='yulesimon pmf')
>>> ax.vlines(x, 0, yulesimon.pmf(x, alpha), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:
```python
>>> rv = yulesimon(alpha)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of `cdf` and `ppf`:

```python
>>> prob = yulesimon.cdf(x, alpha)
>>> np.allclose(x, yulesimon.ppf(prob, alpha))
True
```

Generate random numbers:

```python
>>> r = yulesimon.rvs(alpha, size=1000)
```

**scipy.stats.zipf**

`scipy.stats.zipf = <scipy.stats._discrete_distns.zipf_gen object>`

A Zipf (Zeta) discrete random variable.

As an instance of the `rv_discrete` class, `zipf` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

zipfian

**Notes**

The probability mass function for `zipf` is:

\[ f(k, a) = \frac{1}{\zeta(a)k^a} \]

for \( k \geq 1, a > 1 \).

`zipf` takes \( a > 1 \) as shape parameter. \( \zeta \) is the Riemann zeta function (`scipy.special.zeta`).

The Zipf distribution is also known as the zeta distribution, which is a special case of the Zipfian distribution (`zipfian`).

The probability mass function above is defined in the "standardized" form. To shift distribution use the `loc` parameter. Specifically, `zipf.pmf(k, a, loc)` is identically equivalent to `zipf.pmf(k - loc, a).`
References

[1]

Examples

```python
>>> from scipy.stats import zipf
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```python
>>> a = 6.5
>>> mean, var, skew, kurt = zipf.stats(a, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(zipf.ppf(0.01, a), ...
...              zipf.ppf(0.99, a))
>>> ax.plot(x, zipf.pmf(x, a), 'bo', ms=8, label='zipf pmf')
>>> ax.vlines(x, 0, zipf.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = zipf(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='--', lw=1, ...
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:
Generate random numbers:

```python
>>> r = zipf.rvs(a, size=1000)
```

Confirm that `zipf` is the large $n$ limit of `zipfian`.

```python
>>> from scipy.stats import zipfian
>>> k = np.arange(11)
>>> np.allclose(zipf.pmf(k, a), zipfian.pmf(k, a, n=1000000))
True
```

### Methods

- `rvs(a, loc=0, size=1, random_state=None)`: Random variates.
- `pmf(k, a, loc=0)`: Probability mass function.
- `logpmf(k, a, loc=0)`: Log of the probability mass function.
- `cdf(k, a, loc=0)`: Cumulative distribution function.
- `logcdf(k, a, loc=0)`: Log of the cumulative distribution function.
- `sf(k, a, loc=0)`: Survival function (also defined as $1 - cdf$, but $sf$ is sometimes more accurate).
- `logsf(k, a, loc=0)`: Log of the survival function.
- `ppf(q, a, loc=0)`: Percent point function (inverse of cdf — percentiles).
- `isf(q, a, loc=0)`: Inverse survival function (inverse of $sf$).
- `stats(a, loc=0, moments='mv')`: Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
- `entropy(a, loc=0)`: (Differential) entropy of the RV.
- `expect(func, args=(a,), loc=0, lb=None, ub=None, conditional=False)`: Expected value of a function (of one argument) with respect to the distribution.
- `median(a, loc=0)`: Median of the distribution.
- `mean(a, loc=0)`: Mean of the distribution.
- `var(a, loc=0)`: Variance of the distribution.
- `std(a, loc=0)`: Standard deviation of the distribution.
- `interval(alpha, a, loc=0)`: Endpoints of the range that contains fraction alpha $[0, 1]$ of the distribution.

### scipy.stats.zipfian

`scipy.stats.zipfian = <scipy.stats._discrete_distns.zipfian_gen object>`

A Zipfian discrete random variable.

As an instance of the `rv_discrete` class, `zipfian` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`zipf`
Notes

The probability mass function for zipfian is:

\[ f(k, a, n) = \frac{1}{H_{n,a} k^a} \]

for \( k \in \{1, 2, \ldots, n-1, n\}, a \geq 0, n \in \{1, 2, 3, \ldots\} \).

zipfian takes \( a \) and \( n \) as shape parameters. \( H_{n,a} \) is the \( n^{th} \) generalized harmonic number of order \( a \).

The Zipfian distribution reduces to the Zipf (zeta) distribution as \( n \to \infty \).

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, \( \text{zipfian.pmf}(k, a, n, \text{loc}) \) is identically equivalent to \( \text{zipfian.pmf}(k - \text{loc}, a, n) \).

References

[1], [2]

Examples

```python
>>> from scipy.stats import zipfian
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate the first four moments:

```python
>>> a, n = 1.25, 10
>>> mean, var, skew, kurt = zipfian.stats(a, n, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(zipfian.ppf(0.01, a, n), ...
...     zipfian.ppf(0.99, a, n))
>>> ax.plot(x, zipfian.pmf(x, a, n), 'bo', ms=8, label='zipfian pmf')
>>> ax.vlines(x, 0, zipfian.pmf(x, a, n), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = zipfian(a, n)
>>> ax.vlines(x, 0, rv.pdf(x), colors='k', linestyles='--', lw=1, ...
...     label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```python
>>> prob = zipfian.cdf(x, a, n)
>>> np.allclose(prob, zipfian.pdf(prob, a, n))
True
```
Generate random numbers:

```python
>>> r = zipfian.rvs(a, n, size=1000)
```

Confirm that `zipfian` reduces to `zipf` for large $n, a > 1$.

```python
>>> from scipy.stats import zipf
>>> k = np.arange(11)
>>> np.allclose(zipfian.pmf(k, a=3.5, n=1000000), zipf.pmf(k, a=3.5))
True
```

**scipy.stats.describe**

`scipy.stats.describe(a, axis=0, ddof=1, bias=True, nan_policy='propagate')`

Compute several descriptive statistics of the passed array.

**Parameters**

- a: array_like [Input data.]
- axis: [int or None, optional] Axis along which statistics are calculated. Default is 0. If None, compute over the whole array a.
- ddof: [int, optional] Delta degrees of freedom (only for variance). Default is 1.
- bias: [bool, optional] If False, then the skewness and kurtosis calculations are corrected for statistical bias.
- nan_policy: [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
  - ‘propagate’: returns nan
  - ‘raise’: throws an error
  - ‘omit’: performs the calculations ignoring nan values

**Returns**

- nobs: [int or ndarray of ints] Number of observations (length of data along axis). When ‘omit’ is chosen as nan_policy, the length along each axis slice is counted separately.
- minmax: tuple of ndarrays or floats Minimum and maximum value of a along the given axis.
- mean: [ndarray or float] Arithmetic mean of a along the given axis.
- variance: [ndarray or float] Unbiased variance of a along the given axis; denominator is number of observations minus one.
- skewness: [ndarray or float] Skewness of a along the given axis, based on moment calculations with denominator equal to the number of observations, i.e. no degrees of freedom correction.
- kurtosis: [ndarray or float] Kurtosis (Fisher) of a along the given axis. The kurtosis is normalized so that it is zero for the normal distribution. No degrees of freedom are used.

**See also:**

- skew, kurtosis
Examples

```python
>>> from scipy import stats
>>> a = np.arange(10)
>>> stats.describe(a)
DescribeResult(nobs=10, minmax=(0, 9), mean=4.5,
                 variance=9.166666666666666, skewness=0.0,
                 kurtosis=-1.2242424242424244)
>>> b = [[1, 2], [3, 4]]
>>> stats.describe(b)
DescribeResult(nobs=2, minmax=(array([1, 2]), array([3, 4])),
                 mean=array([2., 3.]), variance=array([2., 2.]),
                 skewness=array([0., 0.]), kurtosis=array([-2., -2.]))
```

**scipy.stats.gmean**

`scipy.stats.gmean(a, axis=0, dtype=None, weights=None)`

Compute the geometric mean along the specified axis.

Return the geometric average of the array elements. That is: n-th root of (x1 * x2 * ... * xn)

**Parameters**

- `a` [array_like] Input array or object that can be converted to an array.
- `axis` [int or None, optional] Axis along which the geometric mean is computed. Default is 0. If None, compute over the whole array `a`.
- `dtype` [dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If `dtype` is not specified, it defaults to the dtype of `a`, unless `a` has an integer `dtype` with a precision less than that of the default platform integer. In that case, the default platform integer is used.
- `weights` [array_like, optional] The weights array can either be 1-D (in which case its length must be the size of `a` along the given `axis`) or of the same shape as `a`. Default is None, which gives each value a weight of 1.0.

**Returns**

- `gmean` [ndarray] See `dtype` parameter above.

See also:

- `numpy.mean`
  Arithmetic average
- `numpy.average`
  Weighted average
- `hmean`
  Harmonic mean
Notes

The geometric average is computed over a single dimension of the input array, axis=0 by default, or all values in the array if axis=None. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.

References

[1]

Examples

```python
>>> from scipy.stats import gmean
>>> gmean([1, 4])
2.0
>>> gmean([1, 2, 3, 4, 5, 6, 7])
3.3800151591412964
```
Notes

The harmonic mean is computed over a single dimension of the input array, axis=0 by default, or all values in the array if axis=None. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

Examples

```python
>>> from scipy.stats import hmean
>>> hmean([1, 4])
1.6000000000000001
>>> hmean([1, 2, 3, 4, 5, 6, 7])
2.6997245179063363
```

scipy.stats.kurtosis

`scipy.stats.kurtosis(a, axis=0, fisher=True, bias=True, nan_policy='propagate')`

Compute the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher’s definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If bias is False then the kurtosis is calculated using k statistics to eliminate bias coming from biased moment estimators

Use `kurtosistest` to see if result is close enough to normal.

Parameters

- `a` [array] Data for which the kurtosis is calculated.
- `axis` [int or None, optional] Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array `a`.
- `fisher` [bool, optional] If True, Fisher’s definition is used (normal ==> 0.0). If False, Pearson’s definition is used (normal ==> 3.0).
- `bias` [bool, optional] If False, then the calculations are corrected for statistical bias.
- `nan_policy` [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

Returns

- `kurtosis` [array] The kurtosis of values along an axis. If all values are equal, return -3 for Fisher’s definition and 0 for Pearson’s definition.
References

[1]

Examples

In Fisher’s definition, the kurtosis of the normal distribution is zero. In the following example, the kurtosis is close to zero, because it was calculated from the dataset, not from the continuous distribution.

```
>>> from scipy.stats import norm, kurtosis
>>> data = norm.rvs(size=1000, random_state=3)
>>> kurtosis(data)
-0.06928694200380558
```

The distribution with a higher kurtosis has a heavier tail. The zero valued kurtosis of the normal distribution in Fisher’s definition can serve as a reference point.

```
>>> import matplotlib.pyplot as plt
>>> import scipy.stats as stats
>>> x = np.linspace(-5, 5, 100)
>>> ax = plt.subplot()
>>> distnames = ['laplace', 'norm', 'uniform']

>>> for distname in distnames:
...    if distname == 'uniform':
...        dist = getattr(stats, distname)(loc=-2, scale=4)
...    else:
...        dist = getattr(stats, distname)
...        data = dist.rvs(size=1000)
...        kur = kurtosis(data, fisher=True)
...        y = dist.pdf(x)
...        ax.plot(x, y, label="{}, {:.3f}".format(distname, round(kur, 3)))
... ax.legend()
```

The Laplace distribution has a heavier tail than the normal distribution. The uniform distribution (which has negative kurtosis) has the thinnest tail.

```
scipy.stats.mode

scipy.stats.mode(a, axis=0, nan_policy='propagate')
Return an array of the modal (most common) value in the passed array.

If there is more than one such value, only the smallest is returned. The bin-count for the modal bins is also returned.

Parameters

a          [array_like] n-dimensional array of which to find mode(s).
axis       [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array a.
nan_policy [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
• ‘propagate’: returns nan
```

3.3. API definition 2571
• ‘raise’: throws an error
• ‘omit’: performs the calculations ignoring nan values

Returns

mode [ndarray] Array of modal values.
count [ndarray] Array of counts for each mode.

Examples

```python
>>> a = np.array([[6, 8, 3, 0],
... [3, 2, 1, 7],
... [8, 1, 8, 4],
... [5, 3, 0, 5],
... [4, 7, 5, 9]])
>>> from scipy import stats
>>> stats.mode(a)
ModeResult(mode=array([[3, 1, 0, 0]]), count=array([[1, 1, 1, 1]]))
```

To get mode of whole array, specify axis=None:

```python
>>> stats.mode(a, axis=None)
ModeResult(mode=array([3]), count=array([3]))
```

scipy.stats.moment

scipy.stats.moment(a, moment=1, axis=0, nan_policy='propagate')

Calculate the nth moment about the mean for a sample.

A moment is a specific quantitative measure of the shape of a set of points. It is often used to calculate coefficients of skewness and kurtosis due to its close relationship with them.

Parameters

- **a** [array_like] Input array.
- **moment** [int or array_like of ints, optional] Order of central moment that is returned. Default is 1.
axis [int or None, optional] Axis along which the central moment is computed. Default is 0. If None, compute over the whole array a.

nan_policy [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
• 'propagate': returns nan
• 'raise': throws an error
• 'omit': performs the calculations ignoring nan values

Returns
n-th central moment [ndarray or float] The appropriate moment along the given axis or over all values if axis is None. The denominator for the moment calculation is the number of observations, no degrees of freedom correction is done.

See also:
kurtosis, skew, describe

Notes

The k-th central moment of a data sample is:

\[ m_k = \frac{1}{n} \sum_{i=1}^{n} (x_i - \bar{x})^k \]

Where n is the number of samples and x-bar is the mean. This function uses exponentiation by squares [1] for efficiency.

References

[1]

Examples

```python
>>> from scipy.stats import moment
>>> moment([1, 2, 3, 4, 5], moment=1)
0.0
>>> moment([1, 2, 3, 4, 5], moment=2)
2.0
```

scipy.stats.skew

scipy.stats.skew(a, axis=0, bias=True, nan_policy='propagate')

Compute the sample skewness of a data set.

For normally distributed data, the skewness should be about zero. For unimodal continuous distributions, a skewness value greater than zero means that there is more weight in the right tail of the distribution. The function skewtest can be used to determine if the skewness value is close enough to zero, statistically speaking.

Parameters

a [ndarray] Input array.
axis [int or None, optional] Axis along which skewness is calculated. Default is 0. If None, compute over the whole array a.

bias [bool, optional] If False, then the calculations are corrected for statistical bias.

nan_policy [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
• ‘propagate’: returns nan
• ‘raise’: throws an error
• ‘omit’: performs the calculations ignoring nan values

Returns

skewness [ndarray] The skewness of values along an axis, returning 0 where all values are equal.

Notes

The sample skewness is computed as the Fisher-Pearson coefficient of skewness, i.e.

\[ g_1 = \frac{m_3}{m_2^{3/2}} \]

where

\[ m_i = \frac{1}{N} \sum_{n=1}^{N} (x[n] - \bar{x})^i \]

is the biased sample \( i \)th central moment, and \( \bar{x} \) is the sample mean. If \( \text{bias} \) is False, the calculations are corrected for bias and the value computed is the adjusted Fisher-Pearson standardized moment coefficient, i.e.

\[ G_1 = \frac{k_3}{k_2^{3/2}} = \frac{\sqrt{N(N-1)}}{N-2} \frac{m_3}{m_2^{3/2}}. \]

References

[1]

Examples

```python
>>> from scipy.stats import skew
>>> skew([1, 2, 3, 4, 5])
0.0
>>> skew([2, 8, 0, 4, 1, 9, 9, 0])
0.2650554122698573
```

scipy.stats.kstat

scipy.stats.kstat(data, n=2)
Return the nth k-statistic (1<=n<=4 so far).

The nth k-statistic \( k_n \) is the unique symmetric unbiased estimator of the nth cumulant kappa_n.

Parameters

data [array_like] Input array. Note that n-D input gets flattened.
n [int, {1, 2, 3, 4}, optional] Default is equal to 2.
Returns

\( k_{stat} \) [float] The nth k-statistic.

See also:

\( kstatvar \)

Returns an unbiased estimator of the variance of the k-statistic.

\( \text{moment} \)

Returns the n-th central moment about the mean for a sample.

Notes

For a sample size \( n \), the first few k-statistics are given by:

\[
\begin{align*}
  k_1 &= \mu_k = \frac{n}{n-1} m_2 \\
  k_2 &= \frac{n^2}{(n-1)(n-2)} m_3 \\
  k_3 &= \frac{n^2[(n+1)m_4 - 3(n-1)m_2^2]}{(n-1)(n-2)(n-3)} \\
\end{align*}
\]

where \( \mu \) is the sample mean, \( m_2 \) is the sample variance, and \( m_i \) is the i-th sample central moment.

References

http://mathworld.wolfram.com/k-Statistic.html
http://mathworld.wolfram.com/Cumulant.html

Examples

```python
>>> from scipy import stats
>>> from numpy.random import default_rng
>>> rng = default_rng()

As sample size increases, n-th moment and n-th k-statistic converge to the same number (although they aren’t identical). In the case of the normal distribution, they converge to zero.

>>> for n in [2, 3, 4, 5, 6, 7]:
...     x = rng.normal(size=10**n)
...     m, k = stats.moment(x, 3), stats.kstat(x, 3)
...     print("%.3g %.3g %.3g" % (m, k, m-k))
-0.631 -0.651 0.0194  # random
0.0282 0.0283 -8.49e-05
-0.0454 -0.0454 1.36e-05
7.53e-05 7.53e-05 -2.26e-09
0.00166 0.00166 -4.99e-09
-2.88e-06 -2.88e-06 8.63e-13
```
**scipy.stats.kstatvar**

**scipy.stats.kstatvar**(data, n=2)

Return an unbiased estimator of the variance of the k-statistic.

See kstat for more details of the k-statistic.

**Parameters**

- **data** [array_like] Input array. Note that n-D input gets flattened.
- **n** [int, {1, 2}, optional] Default is equal to 2.

**Returns**

- **kstatvar** [float] The nth k-statistic variance.

See also:

- **kstat** Returns the n-th k-statistic.
- **moment** Returns the n-th central moment about the mean for a sample.

Notes

The variances of the first few k-statistics are given by:

\[
var(k_1) = \frac{\kappa^2}{n}
\]

\[
var(k_2) = \frac{\kappa^4}{n} + \frac{2\kappa_2^2}{n-1}
\]

\[
var(k_3) = \frac{\kappa^6}{n} + \frac{9\kappa_2\kappa_4}{n-1} + \frac{9\kappa_3^2}{n-1} + \frac{6n\kappa_2^3}{(n-1)(n-2)}
\]

\[
var(k_4) = \frac{\kappa^8}{n} + \frac{16\kappa_2\kappa_6}{n-1} + \frac{48\kappa_3\kappa_5}{n-1}
\]

**scipy.stats.tmean**

**scipy.stats.tmean**(a, limits=None, inclusive=(True, True), axis=None)

Compute the trimmed mean.

This function finds the arithmetic mean of given values, ignoring values outside the given limits.

**Parameters**

- **a** [array_like] Array of values.
- **limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.
- **inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- **axis** [int or None, optional] Axis along which to compute test. Default is None.

**Returns**

- **tmean** [float] Trimmed mean.

See also:

- **trim_mean** Returns mean after trimming a proportion from both tails.
Examples

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmean(x)
9.5
>>> stats.tmean(x, (3,17))
10.0
```

**scipy.stats.tvar**

`scipy.stats.tvar(a, limits=None, inclusive=(True, True), axis=0, ddof=1)`

Compute the trimmed variance.

This function computes the sample variance of an array of values, while ignoring values which are outside of given `limits`.

**Parameters**

- `a` : array_like
  Array of values.
- `limits` : None or (lower limit, upper limit), optional
  Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.
- `inclusive` : (bool, bool), optional
  A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- `axis` : int or None, optional
  Axis along which to operate. Default is 0. If None, compute over the whole array `a`.
- `ddof` : int, optional
  Delta degrees of freedom. Default is 1.

**Returns**

- `tvar` : float
  Trimmed variance.

**Notes**

`tvar` computes the unbiased sample variance, i.e. it uses a correction factor \( n / (n - 1) \).

**Examples**

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tvar(x)
35.0
>>> stats.tvar(x, (3,17))
20.0
```
**scipy.stats.tmin**

`scipy.stats.tmin(a, lowerlimit=None, axis=0, inclusive=True, nan_policy='propagate')`

Compute the trimmed minimum.

This function finds the minimum value of an array `a` along the specified axis, but only considering values greater than a specified lower limit.

**Parameters**

- `a` : [array_like] Array of values.
- `lowerlimit` : [None or float, optional] Values in the input array less than the given limit will be ignored. When `lowerlimit` is None, then all values are used. The default value is None.
- `axis` : [int or None, optional] Axis along which to operate. Default is 0. If `axis` is None, compute over the whole array `a`.
- `inclusive` : [{True, False}, optional] This flag determines whether values exactly equal to the lower limit are included. The default value is True.
- `nan_policy` : [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains `nan`. The following options are available (default is 'propagate'):
  - 'propagate': returns `nan`
  - 'raise': throws an error
  - 'omit': performs the calculations ignoring `nan` values

**Returns**

- `tmin` : [float, int or ndarray] Trimmed minimum.

**Examples**

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmin(x)
0
```

```python
>>> stats.tmin(x, 13)
13
```

```python
>>> stats.tmin(x, 13, inclusive=False)
14
```

**scipy.stats.tmax**

`scipy.stats.tmax(a, upperlimit=None, axis=0, inclusive=True, nan_policy='propagate')`

Compute the trimmed maximum.

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

**Parameters**

- `a` : [array_like] Array of values.
- `upperlimit` : [None or float, optional] Values in the input array greater than the given limit will be ignored. When `upperlimit` is None, then all values are used. The default value is None.
- `axis` : [int or None, optional] Axis along which to operate. Default is 0. If `axis` is None, compute over the whole array `a`. 
inclusive  [{'True', False}, optional] This flag determines whether values exactly equal to the upper limit are included. The default value is True.

nan_policy
[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
• 'propagate': returns nan
• 'raise': throws an error
• 'omit': performs the calculations ignoring nan values

Returns
tmax  [float, int or ndarray] Trimmed maximum.

Examples

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmax(x)
19
```

```python
>>> stats.tmax(x, 13)
13
```

```python
>>> stats.tmax(x, 13, inclusive=False)
12
```

scipy.stats.tstd

scipy.stats.tstd(a, limits=None, inclusive=(True, True), axis=0, ddof=1)
Computes the trimmed sample standard deviation.

This function finds the sample standard deviation of given values, ignoring values outside the given limits.

Parameters

a  [array_like] Array of values.
limits  [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.
inclusive  [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
axis  [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array a.
ddof  [int, optional] Delta degrees of freedom. Default is 1.

Returns
tstd  [float] Trimmed sample standard deviation.
Notes

`tstd` computes the unbiased sample standard deviation, i.e. it uses a correction factor $n / (n - 1)$.

Examples

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tstd(x)
5.9160797830996161
>>> stats.tstd(x, (3,17))
4.472135954995796
```

`s scipy.stats.tsem`

`s scipy.stats.tsem(a, limits=None, inclusive=(True, True), axis=0, ddof=1)`

Compute the trimmed standard error of the mean.

This function finds the standard error of the mean for given values, ignoring values outside the given `limits`.

**Parameters**

- `a` [array_like] Array of values.
- `limits` [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.
- `inclusive` [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- `axis` [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array `a`.

**Returns**

- `tsem` [float] Trimmed standard error of the mean.

Notes

`tsem` uses unbiased sample standard deviation, i.e. it uses a correction factor $n / (n - 1)$.

Examples

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tsem(x)
1.3228756555322954
>>> stats.tsem(x, (3,17))
1.1547005383792515
```
scipy.stats.variation

scipy.stats.variation(a, axis=0, nan_policy='propagate', ddof=0)

Compute the coefficient of variation.

The coefficient of variation is the standard deviation divided by the mean. This function is equivalent to:

np.std(x, axis=axis, ddof=ddof) / np.mean(x)

The default for ddof is 0, but many definitions of the coefficient of variation use the square root of the unbiased sample variance for the sample standard deviation, which corresponds to ddof=1.

Parameters

- a [array_like] Input array.
- axis [int or None, optional] Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array a.
- nan_policy [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
  - 'propagate': returns nan  
  - 'raise': throws an error  
  - 'omit': performs the calculations ignoring nan values
- ddof [int, optional] Delta degrees of freedom. Default is 0.

Returns

- variation [ndarray] The calculated variation along the requested axis.

References

[1]

Examples

```python
>>> from scipy.stats import variation
>>> variation([1, 2, 3, 4, 5])
0.47140452079103173
```

scipy.stats.find_repeats

scipy.stats.find_repeats(arr)

Find repeats and repeat counts.

Parameters

- arr [array_like] Input array. This is cast to float64.

Returns

- values [ndarray] The unique values from the (flattened) input that are repeated.
- counts [ndarray] Number of times the corresponding ‘value’ is repeated.
Notes

In numpy >= 1.9 numpy.unique provides similar functionality. The main difference is that find_repeats only returns repeated values.

Examples

```python
>>> from scipy import stats
>>> stats.find_repeats([2, 1, 2, 3, 2, 5])
RepeatedResults(values=array([2.]), counts=array([4]))

>>> stats.find_repeats([[10, 20, 1, 2], [5, 4]])
RepeatedResults(values=array([4., 5.]), counts=array([2, 2]))
```

scipy.stats.trim_mean

scipy.stats.trim_mean(a, proportiontocut, axis=0)

Return mean of array after trimming distribution from both tails.

If proportiontocut = 0.1, slices off ‘leftmost’ and ‘rightmost’ 10% of scores. The input is sorted before slicing. Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off proportiontocut).

Parameters

- a [array_like] Input array.
- proportiontocut [float] Fraction to cut off of both tails of the distribution.
- axis [int or None, optional] Axis along which the trimmed means are computed. Default is 0. If None, compute over the whole array a.

Returns

- trim_mean [ndarray] Mean of trimmed array.

See also:

- trimboth
- tmean

Examples

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.trim_mean(x, 0.1)
9.5
>>> x2 = x.reshape(5, 4)
>>> x2
array([[ 0, 1, 2, 3],
        [ 4, 5, 6, 7],
        [ 8, 9, 10, 11],
        [12, 13, 14, 15],
        [16, 17, 18, 19]])
```
```python
>>> stats.trim_mean(x2, 0.25)
array([ 8., 9., 10., 11.])
>>> stats.trim_mean(x2, 0.25, axis=1)
array([ 1.5, 5.5, 9.5, 13.5, 17.5])
```

Calculates the geometric standard deviation of an array.

The geometric standard deviation describes the spread of a set of numbers where the geometric mean is preferred. It is a multiplicative factor, and so a dimensionless quantity.

It is defined as the exponent of the standard deviation of \( \log(a) \). Mathematically the population geometric standard deviation can be evaluated as:

\[
gstd = \exp(\text{std}(\log(a)))
\]

New in version 1.3.0.

**Parameters**

- **a** [array_like] An array like object containing the sample data.
- **axis** [int, tuple or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array \( a \).
- **ddof** [int, optional] Degree of freedom correction in the calculation of the geometric standard deviation. Default is 1.

**Returns**

- **ndarray or float**
  An array of the geometric standard deviation. If \( \text{axis} \) is None or \( a \) is a 1d array a float is returned.

**Notes**

As the calculation requires the use of logarithms the geometric standard deviation only supports strictly positive values. Any non-positive or infinite values will raise a \( \text{ValueError} \). The geometric standard deviation is sometimes confused with the exponent of the standard deviation, \( \exp(\text{std}(a)) \). Instead the geometric standard deviation is \( \exp(\text{std}(\log(a))) \). The default value for \( \text{ddof} \) is different to the default value (0) used by other \( \text{ddof} \) containing functions, such as \( \text{np.std} \) and \( \text{np.nanstd} \).

**Examples**

Find the geometric standard deviation of a log-normally distributed sample. Note that the standard deviation of the distribution is one, on a log scale this evaluates to approximately \( \exp(1) \).

```python
>>> from scipy.stats import gstd
>>> rng = np.random.default_rng()
>>> sample = rng.lognormal(mean=0, sigma=1, size=1000)
>>> gstd(sample)
2.810010162475324
```

Compute the geometric standard deviation of a multidimensional array and of a given axis.
The geometric standard deviation further handles masked arrays.

```python
>>> a = np.arange(1, 25).reshape(2, 3, 4)
>>> ma = np.ma.masked_where(a > 16, a)
>>> ma
masked_array(data=[[[[1, 2, 3, 4],
                      [5, 6, 7, 8],
                      [9, 10, 11, 12]],
                     [[13, 14, 15, 16],
                      [--, --, --, --],
                      [--, --, --, --]]],
                mask=[[[False, False, False, False],
                        [False, False, False, False],
                        [False, False, False, False]],
                       [[False, False, False, False],
                        [True, True, True, True],
                        [True, True, True, True]],
                fill_value=999999])
>>> gstd(ma, axis=2)
masked_array(data=[[1.8242475707663655, 1.2243686572447428, 1.1318311657788478],
                   [1.0934830582350938, --, --]],
               mask=[[False, False, False],
                      [True, True, True],
                fill_value=999999])
```

**scipy.stats.iqr**

*scipy.stats.iqr(x, axis=None, rng=(25, 75), scale=1.0, nan_policy='propagate', interpolation='linear', keepdims=False)*

Compute the interquartile range of the data along the specified axis.

The interquartile range (IQR) is the difference between the 75th and 25th percentile of the data. It is a measure of the dispersion similar to standard deviation or variance, but is much more robust against outliers [2].

The `rng` parameter allows this function to compute other percentile ranges than the actual IQR. For example, setting `rng=(0, 100)` is equivalent to `numpy.ptp`.

The IQR of an empty array is `np.nan`.

New in version 0.18.0.

**Parameters**

- `x` : [array_like] Input array or object that can be converted to an array.
- `axis` : [int or sequence of int, optional] Axis along which the range is computed. The default is to compute the IQR for the entire array.
rng [Two-element sequence containing floats in range of [0, 100] optional] Percentiles over which to compute the range. Each must be between 0 and 100, inclusive. The default is the true IQR: (25, 75). The order of the elements is not important.

scale [scalar or str, optional] The numerical value of scale will be divided out of the final result. The following string values are recognized:
- ‘raw’: No scaling, just return the raw IQR. Deprecated! Use scale=1 instead.
- ‘normal’: Scale by \(2\sqrt{2}\text{erf}^{-1}(\frac{1}{2}) \approx 1.349\).

The default is 1.0. The use of scale=’raw’ is deprecated. Array-like scale is also allowed, as long as it broadcasts correctly to the output such that \(\text{out} / \text{scale}\) is a valid operation. The output dimensions depend on the input array, \(x\), the \(axis\) argument, and the \(keepdims\) flag.

nan_policy [{'propagate','raise','omit'},optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
- ‘propagate’: returns nan
- ‘raise’: throws an error
- ‘omit’: performs the calculations ignoring nan values

interpolation [{'linear','lower','higher','midpoint','nearest'},optional]
Specifies the interpolation method to use when the percentile boundaries lie between two data points \(i\) and \(j\). The following options are available (default is ‘linear’):
- ‘linear’: \(i + (j - i) * \text{fraction}\), where \(\text{fraction}\) is the fractional part of the index surrounded by \(i\) and \(j\).
- ‘lower’: \(i\).
- ‘higher’: \(j\).
- ‘nearest’: \(i\) or \(j\) whichever is nearest.
- ‘midpoint’: \((i + j) / 2\).

keepdims [bool, optional] If this is set to True, the reduced axes are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array \(x\).

Returns

\(iqr\) [scalar or ndarray] If \(axis=None\), a scalar is returned. If the input contains integers or floats of smaller precision than np.float64, then the output data-type is np.float64. Otherwise, the output data-type is the same as that of the input.

See also:

numpy.std, numpy.var

Notes

This function is heavily dependent on the version of numpy that is installed. Versions greater than 1.11.0b3 are highly recommended, as they include a number of enhancements and fixes to numpy.percentile and numpy.nanpercentile that affect the operation of this function. The following modifications apply:

Below 1.10.0

[nan_policy is poorly defined.] The default behavior of numpy.percentile is used for ‘propagate’. This is a hybrid of ‘omit’ and ‘propagate’ that mostly yields a skewed version of ‘omit’ since NaNs are sorted to the end of the data. A warning is raised if there are NaNs in the data.

Below 1.9.0: numpy.nanpercentile does not exist.

This means that numpy.percentile is used regardless of nan_policy and a warning is issued. See previous item for a description of the behavior.
Below 1.9.0: keepdims and interpolation are not supported.

The keywords get ignored with a warning if supplied with non-default values. However, multiple axes are still supported.

References

[1], [2], [3]

Examples

```python
>>> from scipy.stats import iqr
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10,  7,  4],
       [ 3,  2,  1]])
>>> iqr(x)
4.0
>>> iqr(x, axis=0)
array([ 3.5,  2.5,  1.5])
>>> iqr(x, axis=1)
array([ 3.,  1.])
>>> iqr(x, axis=1, keepdims=True)
array([[ 3.],
       [ 1.]])
```

`scipy.stats.sem`

`scipy.stats.sem(a, axis=0, ddof=1, nan_policy='propagate')`

Compute standard error of the mean.

Calculate the standard error of the mean (or standard error of measurement) of the values in the input array.

**Parameters**

- `a`: [array_like] An array containing the values for which the standard error is returned.
- `axis`: [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array `a`.
- `ddof`: [int, optional] Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.
- `nan_policy`: [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
  - 'propagate': returns nan
  - 'raise': throws an error
  - 'omit': performs the calculations ignoring nan values

**Returns**

- `s`: [ndarray or float] The standard error of the mean in the sample(s), along the input axis.
Notes

The default value for ddof is different to the default (0) used by other ddof containing routines, such as np.std and np.nanstd.

Examples

Find standard error along the first axis:

```python
>>> from scipy import stats
>>> a = np.arange(20).reshape(5, 4)
>>> stats.sem(a)
array([ 2.8284,  2.8284,  2.8284,  2.8284])
```

Find standard error across the whole array, using n degrees of freedom:

```python
>>> stats.sem(a, axis=None, ddof=0)
1.2893796958227628
```

scipy.stats.bayes_mvs

```python
scipy.stats.bayes_mvs(data, alpha=0.9)
```

Bayesian confidence intervals for the mean, var, and std.

Parameters

- **data**: [array_like] Input data, if multi-dimensional it is flattened to 1-D by `bayes_mvs`. Requires 2 or more data points.
- **alpha**: [float, optional] Probability that the returned confidence interval contains the true parameter.

Returns

- **mean_cntr, var_cntr, std_cntr**: [tuple] The three results are for the mean, variance and standard deviation, respectively. Each result is a tuple of the form:

```python
(center, (lower, upper))
```

Notes

Each tuple of mean, variance, and standard deviation estimates represent the (center, (lower, upper)) with center the mean of the conditional pdf of the value given the data and (lower, upper) a confidence interval centered on the median, containing the estimate to a probability `alpha`.

Converting data to 1-D and assumes all data has the same mean and variance. Uses Jeffrey’s prior for variance and std.

Equivalent to `tuple((x.mean(), x.interval(alpha)) for x in mvsdist(dat))`
Examples

First a basic example to demonstrate the outputs:

```python
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.bayes_mvs(data)
>>> mean
Mean(statistic=9.0, minmax=(7.103650222612533, 10.896349777387467))
>>> var
Variance(statistic=10.0, minmax=(3.176724206..., 24.45910382...))
>>> std
Std_dev(statistic=2.9724954732045084, minmax=(1.782367265645143, 4.945614605014631))
```

Now we generate some normally distributed random data, and get estimates of mean and standard deviation with 95% confidence intervals for those estimates:

```python
>>> n_samples = 100000
>>> data = stats.norm.rvs(size=n_samples)
>>> res_mean, res_var, res_std = stats.bayes_mvs(data, alpha=0.95)

>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.hist(data, bins=100, density=True, label='Histogram of data')
>>> ax.vlines(res_mean.statistic, 0, 0.5, colors='r', label='Estimated mean')
>>> ax.axvspan(res_mean.minmax[0], res_mean.minmax[1], facecolor='r', alpha=0.2, label='Estimated mean (95% limits)')
>>> ax.vlines(res_std.statistic, 0, 0.5, colors='g', label='Estimated scale')
>>> ax.axvspan(res_std.minmax[0], res_std.minmax[1], facecolor='g', alpha=0.2, label='Estimated scale (95% limits)')
>>> ax.legend(fontsize=10)
>>> ax.set_xlim([-4, 4])
>>> ax.set_ylim([0, 0.5])
>>> plt.show()
```
scipy.stats.mvsdist

`scipy.stats.mvsdist(data)`

‘Frozen’ distributions for mean, variance, and standard deviation of data.

**Parameters**

- `data` [array_like] Input array. Converted to 1-D using ravel. Requires 2 or more data-points.

**Returns**

- `mdist` ['frozen' distribution object] Distribution object representing the mean of the data.
- `vdist` ['frozen' distribution object] Distribution object representing the variance of the data.
- `sdist` ['frozen' distribution object] Distribution object representing the standard deviation of the data.

**See also:**

`bayes_mvs`

**Notes**

The return values from `bayes_mvs(data)` is equivalent to `tuple((x.mean(), x.interval(0.90))` for x in `mvsdist(data)`).

In other words, calling `<dist>.mean()` and `<dist>.interval(0.90)` on the three distribution objects returned from this function will give the same results that are returned from `bayes_mvs`. 
References

Examples

```python
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.mvsdist(data)
```

We now have frozen distribution objects “mean”, “var” and “std” that we can examine:

```python
>>> mean.mean()
9.0
>>> mean.interval(0.95)
(6.6120585482655692, 11.387941451734431)
>>> mean.std()
1.1952286093343936
```

**scipy.stats.entropy**

`scipy.stats.entropy(pk=None, qk=None, base=None, axis=0)`

Calculate the entropy of a distribution for given probability values.

If only probabilities `pk` are given, the entropy is calculated as $S = -\sum pk \times \log(pk), \text{axis}=axis$.

If `qk` is not None, then compute the Kullback-Leibler divergence $S = \sum pk \times \log(pk / qk), \text{axis}=axis$.

This routine will normalize `pk` and `qk` if they don’t sum to 1.

**Parameters**

- `pk` [sequence] Defines the (discrete) distribution. `pk[i]` is the (possibly unnormalized) probability of event `i`.
- `qk` [sequence, optional] Sequence against which the relative entropy is computed. Should be in the same format as `pk`.
- `base` [float, optional] The logarithmic base to use, defaults to `e` (natural logarithm).
- `axis` [int, optional] The axis along which the entropy is calculated. Default is 0.

**Returns**

- `S` [float] The calculated entropy.

**Examples**

```python
>>> from scipy.stats import entropy

Bernoulli trial with different `p`. The outcome of a fair coin is the most uncertain:

```python
>>> entropy([1/2, 1/2], base=2)
1.0
```

The outcome of a biased coin is less uncertain:
```python
>>> entropy([9/10, 1/10], base=2)
0.4689959358928117
```

Relative entropy:

```python
>>> entropy([1/2, 1/2], qk=[9/10, 1/10])
0.5108256237659907
```

### scipy.stats.differential_entropy

`scipy.stats.differential_entropy` *(values, *, window_length=None, base=None, axis=0, method='auto')*

Given a sample of a distribution, estimate the differential entropy.

Several estimation methods are available using the `method` parameter. By default, a method is selected based on the size of the sample.

**Parameters**

- `values` [sequence] Sample from a continuous distribution.
- `window_length` [int, optional] Window length for computing Vasicek estimate. Must be an integer between 1 and half of the sample size. If `None` (the default), it uses the heuristic value \( \sqrt{n} + 0.5 \)

where \( n \) is the sample size. This heuristic was originally proposed in \([2]\) and has become common in the literature.
- `base` [float, optional] The logarithmic base to use, defaults to \( e \) (natural logarithm).
- `axis` [int, optional] The axis along which the differential entropy is calculated. Default is 0.

**Returns**

- `entropy` [float] The calculated differential entropy.

**Notes**

This function will converge to the true differential entropy in the limit

\[
n \to \infty, \quad m \to \infty, \quad \frac{m}{n} \to 0
\]

The optimal choice of `window_length` for a given sample size depends on the (unknown) distribution. Typically, the smoother the density of the distribution, the larger the optimal value of `window_length` \([1]\).

The following options are available for the `method` parameter.

- 'vasicek' uses the estimator presented in \([1]\). This is one of the first and most influential estimators of differential entropy.
- 'van es' uses the bias-corrected estimator presented in \([3]\), which is not only consistent but, under some conditions, asymptotically normal.
- 'ebrahimi' uses an estimator presented in \([4]\), which was shown in simulation to have smaller bias and mean squared error than the Vasicek estimator.
- 'correa' uses the estimator presented in \([5]\) based on local linear regression. In a simulation study, it had consistently smaller mean square error than the Vasicek estimator, but it is more expensive to compute.

3.3. API definition 2591
• 'auto' selects the method automatically (default). Currently, this selects 'van es' for very small samples (<10), 'ebrahimi' for moderate sample sizes (11-1000), and 'vasicek' for larger samples, but this behavior is subject to change in future versions.

All estimators are implemented as described in [6].

References

[1], [2], [3], [4], [5], [6]

Examples

```python
>>> from scipy.stats import differential_entropy, norm
```

Entropy of a standard normal distribution:

```python
>>> rng = np.random.default_rng()
>>> values = rng.standard_normal(100)
>>> differential_entropy(values)
1.3407817436640392
```

Compare with the true entropy:

```python
>>> float(norm.entropy())
1.4189385332046727
```

For several sample sizes between 5 and 1000, compare the accuracy of the 'vasicek', 'van es', and 'ebrahimi' methods. Specifically, compare the root mean squared error (over 1000 trials) between the estimate and the true differential entropy of the distribution.

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt

>>> def rmse(res, expected):
...     '''Root mean squared error'''
...     return np.sqrt(np.mean((res - expected)**2))

>>> a, b = np.log10(5), np.log10(1000)
>>> ns = np.round(np.logspace(a, b, 10)).astype(int)
>>> reps = 1000 # number of repetitions for each sample size
>>> expected = stats.expon.entropy()

>>> method_errors = {'vasicek': [], 'van es': [], 'ebrahimi': []}

>>> for method in method_errors:
...     for n in ns:
...         rvs = stats.expon.rvs(size=(reps, n), random_state=rng)
...         res = stats.differential_entropy(rvs, method=method, axis=-1)
...         error = rmse(res, expected)
...         method_errors[method].append(error)
```
>>> for method, errors in method_errors.items():
...     plt.loglog(ns, errors, label=method)
>>> plt.legend()
>>> plt.xlabel('sample size')
>>> plt.ylabel('RMSE (1000 trials)')
>>> plt.title('Entropy Estimator Error (Exponential Distribution)')

```python
Entropy Estimator Error (Exponential Distribution)

RMSE (1000 trials)

sample size
```

**scipy.stats.median_absolute_deviation**

[`scipy.stats.median_absolute_deviation(*args, **kwds)`](scipy/stats.py)

`median_absolute_deviation` is deprecated, use `median_abs_deviation` instead!

To preserve the existing default behavior, use `scipy.stats.median_abs_deviation(..., scale=1/1.4826)`. The value 1.4826 is not numerically precise for scaling with a normal distribution. For a numerically precise value, use `scipy.stats.median_abs_deviation(..., scale='normal')`

Compute the median absolute deviation of the data along the given axis.

The median absolute deviation (MAD, [1]) computes the median over the absolute deviations from the median. It is a measure of dispersion similar to the standard deviation but more robust to outliers [2].

The MAD of an empty array is `np.nan`.

New in version 1.3.0.

**Parameters**

- `x` [array_like] Input array or object that can be converted to an array.
- `axis` [int or None, optional] Axis along which the range is computed. Default is 0. If None, compute the MAD over the entire array.
- `center` [callable, optional] A function that will return the central value. The default is to use `np.median`. Any user defined function used will need to have the function signature `func(arr, axis)`.
- `scale` [int, optional] The scaling factor applied to the MAD. The default scale (1.4826) ensures consistency with the standard deviation for normally distributed data.
nan_policy

[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

• 'propagate': returns nan
• 'raise': throws an error
• 'omit': performs the calculations ignoring nan values

Returns

mad [scalar or ndarray] If axis=None, a scalar is returned. If the input contains integers or floats of smaller precision than np.float64, then the output data-type is np.float64. Otherwise, the output data-type is the same as that of the input.

See also:

numpy.std, numpy.var, numpy.median, scipy.stats.iqr, scipy.stats.tmean
scipy.stats.tstd, scipy.stats.tvar

Notes

The center argument only affects the calculation of the central value around which the MAD is calculated. That is, passing in center=np.mean will calculate the MAD around the mean - it will not calculate the mean absolute deviation.

References

[1], [2]

Examples

When comparing the behavior of median_absolute_deviation with np.std, the latter is affected when we change a single value of an array to have an outlier value while the MAD hardly changes:

```python
>>> from scipy import stats
>>> x = stats.norm.rvs(size=100, scale=1, random_state=123456)
>>> x.std()
0.9973906394005013
>>> stats.median_absolute_deviation(x)
1.2280762773108278
>>> x[0] = 345.6
>>> x.std()
34.42304872314415
>>> stats.median_absolute_deviation(x)
1.2340335571164334
```

Axis handling example:

```python
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10, 7, 4],
       [3, 2, 1]])
>>> stats.median_absolute_deviation(x)
```

(continues on next page)
array([5.1891, 3.7065, 2.2239])
>>> stats.median_absolute_deviation(x, axis=None)
2.9652

scipy.stats.median_abs_deviation

scipy.stats.median_abs_deviation(x, axis=0, center=<function median>, scale=1.0, nan_policy='propagate')

Compute the median absolute deviation of the data along the given axis.

The median absolute deviation (MAD, [1]) computes the median over the absolute deviations from the median. It is a measure of dispersion similar to the standard deviation but more robust to outliers [2].

The MAD of an empty array is np.nan.

New in version 1.5.0.

Parameters

x
[array_like] Input array or object that can be converted to an array.

axis
[int or None, optional] Axis along which the range is computed. Default is 0. If None, compute the MAD over the entire array.

center
[callable, optional] A function that will return the central value. The default is to use np.median. Any user defined function used will need to have the function signature func(arr, axis).

scale
[scalar or str, optional] The numerical value of scale will be divided out of the final result. The default is 1.0. The string “normal” is also accepted, and results in scale being the inverse of the standard normal quantile function at 0.75, which is approximately 0.67449. Array-like scale is also allowed, as long as it broadcasts correctly to the output such that out / scale is a valid operation. The output dimensions depend on the input array, x, and the axis argument.

nan_policy
[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
• 'propagate': returns nan
• 'raise': throws an error
• 'omit': performs the calculations ignoring nan values

Returns

mad
[scalar or ndarray] If axis=None, a scalar is returned. If the input contains integers or floats of smaller precision than np.float64, then the output data-type is np.float64. Otherwise, the output data-type is the same as that of the input.

See also:

numpy.std, numpy.var, numpy.median, scipy.stats.iqr, scipy.stats.tmean
scipy.stats.tstd, scipy.stats.tvar
Notes

The center argument only affects the calculation of the central value around which the MAD is calculated. That is, passing in center=np.mean will calculate the MAD around the mean - it will not calculate the mean absolute deviation.

The input array may contain inf, but if center returns inf, the corresponding MAD for that data will be nan.

References

[1], [2]

Examples

When comparing the behavior of median_abs_deviation with np.std, the latter is affected when we change a single value of an array to have an outlier value while the MAD hardly changes:

```python
>>> from scipy import stats
>>> x = stats.norm.rvs(size=100, scale=1, random_state=123456)
>>> x.std()
0.9973906394005013
>>> stats.median_abs_deviation(x)
0.82832610097857
>>> x[0] = 345.6
>>> x.std()
34.4204872314415
>>> stats.median_abs_deviation(x)
0.8323442311590675
```

Axis handling example:

```python
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10,  7,  4],
       [ 3,  2,  1]])
>>> stats.median_abs_deviation(x)
array([3.5, 2.5, 1.5])
>>> stats.median_abs_deviation(x, axis=None)
2.0
```

Scale normal example:

```python
>>> x = stats.norm.rvs(size=1000000, scale=2, random_state=123456)
>>> stats.median_abs_deviation(x)
1.3487398527041636
>>> stats.median_abs_deviation(x, scale='normal')
1.9996446978061115
```
scipy.stats.bootstrap

**scipy.stats.bootstrap** *(data, statistic, *, vectorized=True, paired=False, axis=0, confidence_level=0.95, n_resamples=9999, batch=None, method='BCa', random_state=None)*

Compute a two-sided bootstrap confidence interval of a statistic.

When *method* is 'percentile', a bootstrap confidence interval is computed according to the following procedure.

1. Resample the data: for each sample in *data* and for each of *n_resamples*, take a random sample of the original sample (with replacement) of the same size as the original sample.
2. Compute the bootstrap distribution of the statistic: for each set of resamples, compute the test statistic.
3. Determine the confidence interval: find the interval of the bootstrap distribution that is
   - symmetric about the median and
   - contains *confidence_level* of the resampled statistic values.

While the 'percentile' method is the most intuitive, it is rarely used in practice. Two more common methods are available, 'basic' (‘reverse percentile’) and 'BCa' (‘bias-corrected and accelerated’); they differ in how step 3 is performed.

If the samples in *data* are taken at random from their respective distributions *n* times, the confidence interval returned by *bootstrap* will contain the true value of the statistic for those distributions approximately *confidence_level* × *n* times.

**Parameters**

- **data** [sequence of array-like] Each element of data is a sample from an underlying distribution.
- **statistic** [callable] Statistic for which the confidence interval is to be calculated. *statistic* must be a callable that accepts `len(data)` samples as separate arguments and returns the resulting statistic. If *vectorized* is set *True*, *statistic* must also accept a keyword argument *axis* and be vectorized to compute the statistic along the provided *axis*.
- **vectorized** [bool, default: True] If *vectorized* is set *False*, *statistic* will not be passed keyword argument *axis* and is assumed to calculate the statistic only for 1D samples.
- **paired** [bool, default: False] Whether the statistic treats corresponding elements of the samples in *data* as paired.
- **axis** [int, default: 0] The axis of the samples in *data* along which the *statistic* is calculated.
- **confidence_level** [float, default: 0.95] The confidence level of the confidence interval.
- **n_resamples** [int, default: 9999] The number of resamples performed to form the bootstrap distribution of the statistic.
- **batch** [int, optional] The number of resamples to process in each vectorized call to *statistic*. Memory usage is O(*batch* × *n*), where *n* is the sample size. Default is *None*, in which case *batch* = *n_resamples* (or *batch* = max(*n_resamples*, *n*)) for *method*='BCa'.
- **method** [{'percentile', 'basic', 'bca'}, default: 'BCa'] Whether to return the 'percentile' bootstrap confidence interval ('percentile'), the 'reverse' or the bias-corrected and accelerated bootstrap confidence interval ('BCa'). Note that only 'percentile' and 'basic' support multi-sample statistics at this time.
- **random_state** [{None, int, numpy.random.Generator}] `numpy.random.RandomState`, optional
  If *seed* is *None* (or np.random), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new RandomState instance is used, seeded with *seed*. If *seed* is already a Generator or RandomState instance then that instance is used. Pseudorandom number generator state used to generate resamples.
Returns

res

[BootstrapResult] An object with attributes:

confidence_interval

[ConfidenceInterval] The bootstrap confidence interval as an instance of collections.namedtuple with attributes low and high.

standard_error

[float or ndarray] The bootstrap standard error, that is, the sample standard deviation of the bootstrap distribution

References

[1], [2], [3]

Examples

Suppose we have sampled data from an unknown distribution.

```python
>>> import numpy as np
>>> rng = np.random.default_rng()
>>> from scipy.stats import norm
>>> dist = norm(loc=2, scale=4)  # our "unknown" distribution
>>> data = dist.rvs(size=100, random_state=rng)
```

We are interested in the standard deviation of the distribution.

```python
>>> std_true = dist.std()  # the true value of the statistic
>>> print(std_true)
4.0
>>> std_sample = np.std(data)  # the sample statistic
>>> print(std_sample)
3.9460644295563863
```

We can calculate a 90% confidence interval of the statistic using bootstrap.

```python
>>> from scipy.stats import bootstrap
>>> data = (data,)  # samples must be in a sequence
>>> res = bootstrap(data, np.std, confidence_level=0.9,
...                   random_state=rng)
>>> print(res.confidence_interval)
ConfidenceInterval(low=3.57655333533867, high=4.382043696342881)
```

If we sample from the distribution 1000 times and form a bootstrap confidence interval for each sample, the confidence interval contains the true value of the statistic approximately 900 times.

```python
>>> n_trials = 1000
>>> ci_contains_true_std = 0
>>> for i in range(n_trials):
...     data = (dist.rvs(size=100, random_state=rng),)
...     ci = bootstrap(data, np.std, confidence_level=0.9, n_resamples=1000,
...                    random_state=rng).confidence_interval
...     if ci[0] < std_true < ci[1]:
...         ci_contains_true_std += 1
```

(continues on next page)
Rather than writing a loop, we can also determine the confidence intervals for all 1000 samples at once.

```python
>>> data = (dist.rvs(size=(n_trials, 100), random_state=rng),)
>>> res = bootstrap(data, np.std, axis=-1, confidence_level=0.9,
...                 n_resamples=1000, random_state=rng)
>>> ci_l, ci_u = res.confidence_interval
```

Here, `ci_l` and `ci_u` contain the confidence interval for each of the `n_trials = 1000` samples.

```python
>>> print(ci_l[995:])
[3.77729695 3.75090233 3.45829131 3.34078217 3.48072829]
>>> print(ci_u[995:])
```

And again, approximately 90% contain the true value, `std_true = 4`.

```python
>>> print(np.sum((ci_l < std_true) & (std_true < ci_u)))
900
```

`bootstrap` can also be used to estimate confidence intervals of multi-sample statistics, including those calculated by hypothesis tests. `scipy.stats.mood` perform's Mood's test for equal scale parameters, and it returns two outputs: a statistic, and a p-value. To get a confidence interval for the test statistic, we first wrap `scipy.stats.mood` in a function that accepts two sample arguments, accepts an `axis` keyword argument, and returns only the statistic.

```python
>>> from scipy.stats import mood
>>> def my_statistic(sample1, sample2, axis):
...    statistic, _ = mood(sample1, sample2, axis=-1)
...    return statistic
```

Here, we use the 'percentile' method with the default 95% confidence level.

```python
>>> sample1 = norm.rvs(scale=1, size=100, random_state=rng)
>>> sample2 = norm.rvs(scale=2, size=100, random_state=rng)
>>> data = (sample1, sample2)
>>> res = bootstrap(data, my_statistic, method='basic', random_state=rng)
>>> print(mood(sample1, sample2)[0])  # element 0 is the statistic
-5.521109549096542
>>> print(res.confidence_interval)
ConfidenceInterval(low=-7.255994487314675, high=-4.016202624747605)
```

The bootstrap estimate of the standard error is also available.

```python
>>> print(res.standard_error)
0.8344963846318795
```

Paired-sample statistics work, too. For example, consider the Pearson correlation coefficient.
from scipy.stats import pearsonr

n = 100
x = np.linspace(0, 10, n)
y = x + rng.uniform(size=n)
print(pearsonr(x, y)[0])  # element 0 is the statistic
0.9962357936065914

We wrap `pearsonr` so that it returns only the statistic.

def my_statistic(x, y):
    ...
    return pearsonr(x, y)[0]

We call `bootstrap` using `paired=True`. Also, since `my_statistic` isn’t vectorized to calculate the statistic along a given axis, we pass in `vectorized=False`.

res = bootstrap((x, y), my_statistic, vectorized=False, paired=True, ...
    random_state=rng)
print(res.confidence_interval)
ConfidenceInterval(low=0.9950085825848624, high=0.9971212407917498)

**scipy.stats.cumfreq**

`scipy.stats.cumfreq(a, numbins=10, defaultreallimits=None, weights=None)`

Return a cumulative frequency histogram, using the histogram function.

A cumulative histogram is a mapping that counts the cumulative number of observations in all of the bins up to the specified bin.

**Parameters**

- `a` [array_like] Input array.
- `numbins` [int, optional] The number of bins to use for the histogram. Default is 10.
- `defaultreallimits` [tuple (lower, upper), optional] The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than the range of the values in `a` is used. Specifically `(a.min() - s, a.max() + s), where s = (1/2)(a.max() - a.min()) / (numbins - 1).`
- `weights` [array_like, optional] The weights for each value in `a`. Default is None, which gives each value a weight of 1.0

**Returns**
cumcount  [ndarray] Binned values of cumulative frequency.
lowerlimit  [float] Lower real limit
binsize    [float] Width of each bin.
extrapoints [int] Extra points.

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from numpy.random import default_rng
>>> from scipy import stats
>>> rng = default_rng()
>>> x = [1, 4, 2, 1, 3, 1]
>>> res = stats.cumfreq(x, numbins=4, defaultreallimits=(1.5, 5))
>>> res.cumcount
array([ 1.,  2.,  3.,  3.])
>>> res.extrapoints
3

Create a normal distribution with 1000 random values

```python
>>> samples = stats.norm.rvs(size=1000, random_state=rng)
```

Calculate cumulative frequencies

```python
>>> res = stats.cumfreq(samples, numbins=25)
``` Calculate space of values for x

```python
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.cumcount.size,
...                                res.cumcount.size)
``` Plot histogram and cumulative histogram

```python
>>> fig = plt.figure(figsize=(10, 4))
>>> ax1 = fig.add_subplot(1, 2, 1)
>>> ax2 = fig.add_subplot(1, 2, 2)
>>> ax1.hist(samples, bins=25)
>>> ax1.set_title('Histogram')
>>> ax2.bar(x, res.cumcount, width=res.binsize)
>>> ax2.set_title('Cumulative histogram')
>>> ax2.set_xlim([x.min(), x.max()])
```
scipy.stats.itemfreq

scipy.stats.itemfreq(*args, **kwds)

`itemfreq` is deprecated! `itemfreq` is deprecated and will be removed in a future version. Use instead `np.unique(..., return_counts=True)`

Return a 2-D array of item frequencies.

**Parameters**

- `a` *(N,) array_like* Input array.

**Returns**

- `itemfreq` *[K, 2] ndarray* A 2-D frequency table. Column 1 contains sorted, unique values from `a`, column 2 contains their respective counts.

**Examples**

```python
>>> from scipy import stats
>>> a = np.array([1, 1, 5, 0, 1, 2, 2, 0, 1, 4])
>>> stats.itemfreq(a)
array([[ 0.,  2.],
       [ 1.,  4.],
       [ 2.,  2.],
       [ 4.,  1.],
       [ 5.,  1.])
>>> np.bincount(a)
array([2, 4, 2, 0, 1, 1])

>>> stats.itemfreq(a/10.)
array([[ 0.,  2.],
       [ 0.1,  4.],
       [ 0.2,  2.],
       [ 0.4,  1.],
       [ 0.5,  1.]])
```
scipy.stats.percentileofscore

`scipy.stats.percentileofscore(a, score, kind='rank')`

Compute the percentile rank of a score relative to a list of scores.

A `percentileofscore` of, for example, 80% means that 80% of the scores in `a` are below the given score. In the case of gaps or ties, the exact definition depends on the optional keyword, `kind`.

**Parameters**

- **a** ([array_like]) Array of scores to which `score` is compared.
- **score** ([int or float]) Score that is compared to the elements in `a`.
- **kind** ([{'rank', 'weak', 'strict', 'mean'}, optional]) Specifies the interpretation of the resulting score. The following options are available (default is 'rank'):
  - 'rank': Average percentage ranking of score. In case of multiple matches, average the percentage rankings of all matching scores.
  - 'weak': This kind corresponds to the definition of a cumulative distribution function. A percentileofscore of 80% means that 80% of values are less than or equal to the provided score.
  - 'strict': Similar to “weak”, except that only values that are strictly less than the given score are counted.
  - 'mean': The average of the “weak” and “strict” scores, often used in testing. See https://en.wikipedia.org/wiki/Percentile_rank

**Returns**

- **pcos** ([float]) Percentile-position of score (0-100) relative to `a`.

See also:

- `numpy.percentile`

**Examples**

Three-quarters of the given values lie below a given score:

```python
>>> from scipy import stats
>>> stats.percentileofscore([1, 2, 3, 4], 3)
75.0
```

With multiple matches, note how the scores of the two matches, 0.6 and 0.8 respectively, are averaged:

```python
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3)
70.0
```

Only 2/5 values are strictly less than 3:

```python
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='strict')
40.0
```

But 4/5 values are less than or equal to 3:

```python
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='weak')
80.0
```

The average between the weak and the strict scores is:
scipy.stats.scoreatpercentile

scipy.stats.scoreatpercentile(a, per, limit=(), interpolation_method='fraction', axis=None)

Calculate the score at a given percentile of the input sequence.

For example, the score at per=50 is the median. If the desired quantile lies between two data points, we interpolate between them, according to the value of interpolation. If the parameter limit is provided, it should be a tuple (lower, upper) of two values.

Parameters

- **a** [array_like] A 1-D array of values from which to extract score.
- **per** [array_like] Percentile(s) at which to extract score. Values should be in range [0,100].
- **limit** [tuple, optional] Tuple of two scalars, the lower and upper limits within which to compute the percentile. Values of a outside this (closed) interval will be ignored.
- **interpolation_method** ['fraction', 'lower', 'higher'], optional] Specifies the interpolation method to use, when the desired quantile lies between two data points i and j. The following options are available (default is ‘fraction’):
  - ‘fraction’: i + (j − i) * fraction where fraction is the fractional part of the index surrounded by i and j
  - ‘lower’: i
  - ‘higher’: j
- **axis** [int, optional] Axis along which the percentiles are computed. Default is None. If None, compute over the whole array a.

Returns

- **score** [float or ndarray] Score at percentile(s).

See also:

percentileofscore, numpy.percentile

Notes

This function will become obsolete in the future. For NumPy 1.9 and higher, numpy.percentile provides all the functionality that scoreatpercentile provides. And it’s significantly faster. Therefore it’s recommended to use numpy.percentile for users that have numpy >= 1.9.

Examples

```python
>>> from scipy import stats
>>> a = np.arange(100)
>>> stats.scoreatpercentile(a, 50)
49.5
```
**scipy.stats.relfreq**

```python
scipy.stats.relfreq(a, numbins=10, defaultreallimits=None, weights=None)
```

Return a relative frequency histogram, using the histogram function.

A relative frequency histogram is a mapping of the number of observations in each of the bins relative to the total of observations.

**Parameters**

- `a` [array_like] Input array.
- `numbins` [int, optional] The number of bins to use for the histogram. Default is 10.
- `defaultreallimits` [tuple (lower, upper), optional] The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than the range of the values in `a` is used. Specifically `a.min() - s, a.max() + s`, where `s = (1/2)(a.max() - a.min()) / (numbins - 1)`.
- `weights` [array_like, optional] The weights for each value in `a`. Default is None, which gives each value a weight of 1.0

**Returns**

- `frequency` [ndarray] Binned values of relative frequency.
- `lowerlimit` [float] Lower real limit.
- `binsize` [float] Width of each bin.
- `extrapoints` [int] Extra points.

**Examples**

```python
>>> import matplotlib.pyplot as plt
>>> from numpy.random import default_rng
>>> from scipy import stats
>>> rng = default_rng()
>>> a = np.array([2, 4, 1, 2, 3, 2])
>>> res = stats.relfreq(a, numbins=4)
>>> res.frequency
array([0.16666667, 0.5 , 0.16666667, 0.16666667])
>>> np.sum(res.frequency) # relative frequencies should add up to 1
1.0
```

Create a normal distribution with 1000 random values

```python
>>> samples = stats.norm.rvs(size=1000, random_state=rng)
```

Calculate relative frequencies

```python
>>> res = stats.relfreq(samples, numbins=25)
```

Calculate space of values for x

```python
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.frequency.size, res.frequency.size)
```

Plot relative frequency histogram
>>> fig = plt.figure(figsize=(5, 4))
>>> ax = fig.add_subplot(1, 1, 1)
>>> ax.bar(x, res.frequency, width=res.bin_size)
>>> ax.set_title('Relative frequency histogram')
>>> ax.set_xlim([x.min(), x.max()])

>>> plt.show()

Relative frequency histogram

```
import scipy.stats

scipy.stats.binned_statistic

scipy.stats.binned_statistic(x, values, statistic='mean', bins=10, range=None)

Compute a binned statistic for one or more sets of data.

This is a generalization of a histogram function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values (or set of values) within each bin.

Parameters

- **x**: [(N,) array_like] A sequence of values to be binned.
- **values**: [(N,) array_like or list of (N,) array_like] The data on which the statistic will be computed. This must be the same shape as x, or a set of sequences - each the same shape as x. If values
```
is a set of sequences, the statistic will be computed on each independently.

**statistic** [string or callable, optional] The statistic to compute (default is 'mean'). The following statistics are available:
- 'mean': compute the mean of values for points within each bin. Empty bins will be represented by NaN.
- 'std': compute the standard deviation within each bin. This is implicitly calculated with ddof=0.
- 'median': compute the median of values for points within each bin. Empty bins will be represented by NaN.
- 'count': compute the count of points within each bin. This is identical to an unweighted histogram. values array is not referenced.
- 'sum': compute the sum of values for points within each bin. This is identical to a weighted histogram.
- 'min': compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
- 'max': compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
- function: a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by function([]), or NaN if this returns an error.

**bins** [int or sequence of scalars, optional] If bins is an int, it defines the number of equal-width bins in the given range (10 by default). If bins is a sequence, it defines the bin edges, including the rightmost edge, allowing for non-uniform bin widths. Values in x that are smaller than lowest bin edge are assigned to bin number 0, values beyond the highest bin are assigned to bins[-1]. If the bin edges are specified, the number of bins will be, (nx = len(bins)-1).

**range** [(float, float) or [(float, float)], optional] The lower and upper range of the bins. If not provided, range is simply (x.min(), x.max()). Values outside the range are ignored.

**Returns**
- statistic [array] The values of the selected statistic in each bin.
- bin_edges [array of dtype float] Return the bin edges (length(statistic)+1).
- binnumber: 1-D ndarray of ints
  Indices of the bins (corresponding to bin_edges) in which each value of x belongs. Same length as values. A binnumber of i means the corresponding value is between (bin_edges[i-1], bin_edges[i]).

See also:
- *numpy-digitize*, *numpy.histogram*, *binned_statistic_2d*, *binned_statistic_dd*

**Notes**

All but the last (righthand-most) bin is half-open. In other words, if bins is [1, 2, 3, 4], then the first bin is [1, 2) (including 1, but excluding 2) and the second [2, 3). The last bin, however, is [3, 4], which includes 4.

New in version 0.11.0.
Examples

```python
from scipy import stats
import matplotlib.pyplot as plt
```

First some basic examples:
Create two evenly spaced bins in the range of the given sample, and sum the corresponding values in each of those bins:

```python
values = [1.0, 1.0, 2.0, 1.5, 3.0]
stats.binned_statistic([1, 1, 2, 5, 7], values, 'sum', bins=2)
```

Multiple arrays of values can also be passed. The statistic is calculated on each set independently:

```python
values = [[1.0, 1.0, 2.0, 1.5, 3.0], [2.0, 2.0, 4.0, 3.0, 6.0]]
stats.binned_statistic([1, 1, 2, 5, 7], values, 'sum', bins=2)
```

As a second example, we now generate some random data of sailing boat speed as a function of wind speed, and then determine how fast our boat is for certain wind speeds:

```python
rng = np.random.default_rng()
windspeed = 8 * rng.random(500)
boatspeed = .3 * windspeed**.5 + .2 * rng.random(500)
bin_means, bin_edges, binnumber = stats.binned_statistic(windspeed, boatspeed, statistic='median', bins=[1, 2, 3, 4, 5, 6, 7])
```

Now we can use `binnumber` to select all datapoints with a windspeed below 1:

```python
low_boatspeed = boatspeed[binnumber == 0]
```

As a final example, we will use `bin_edges` and `binnumber` to make a plot of a distribution that shows the mean and distribution around that mean per bin, on top of a regular histogram and the probability distribution function:

```python
x = np.linspace(0, 5, num=500)
x_pdf = stats.maxwell.pdf(x)
samples = stats.maxwell.rvs(size=10000)
```
```python
>>> bin_means, bin_edges, binnumber = stats.binned_statistic(x, x_pdf,
... statistic='mean', bins=25)
>>> bin_width = (bin_edges[1] - bin_edges[0])
>>> bin_centers = bin_edges[1:] - bin_width/2

>>> plt.figure()
>>> plt.hist(samples, bins=50, density=True, histtype='stepfilled',
... alpha=0.2, label='histogram of data')
>>> plt.plot(x, x_pdf, 'r-', label='analytical pdf')
>>> plt.hlines(bin_means, bin_edges[:-1], bin_edges[1:], colors='g', lw=2,
... label='binned statistic of data')
>>> plt.plot((binnumber - 0.5) * bin_width, x_pdf, 'g.', alpha=0.5)
>>> plt.legend(fontsize=10)
>>> plt.show()
```
scipy.stats.binned_statistic_2d

`scipy.stats.binned_statistic_2d(x, y, values, statistic='mean', bins=10, range=None, expand_binnumbers=False)`

Compute a bidimensional binned statistic for one or more sets of data.

This is a generalization of a histogram2d function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values (or set of values) within each bin.

**Parameters**

- `x` [(N,) array_like] A sequence of values to be binned along the first dimension.
- `y` [(N,) array_like] A sequence of values to be binned along the second dimension.
- `values` [(N,) array_like or list of (N,) array_like] The data on which the statistic will be computed. This must be the same shape as `x`, or a list of sequences - each with the same shape as `x`. If `values` is such a list, the statistic will be computed on each independently.
- `statistic` [string or callable, optional] The statistic to compute (default is 'mean'). The following statistics are available:
  - 'mean': compute the mean of values for points within each bin. Empty bins will be represented by NaN.
  - 'std': compute the standard deviation within each bin. This is implicitly calculated with `ddof=0`.
  - 'median': compute the median of values for points within each bin. Empty bins will be represented by NaN.
  - 'count': compute the count of points within each bin. This is identical to an unweighted histogram. `values` array is not referenced.
  - 'sum': compute the sum of values for points within each bin. This is identical to a weighted histogram.
  - 'min': compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
  - 'max': compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
  - `function`: a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by `function([])`, or NaN if this returns an error.
- `bins` [int or [int, int] or array_like or [array, array], optional] The bin specification:
  - the number of bins for the two dimensions `(nx = ny = bins)`,
  - the number of bins in each dimension `(nx, ny = bins)`,
  - the bin edges for the two dimensions `(x_edge = y_edge = bins)`,
  - the bin edges in each dimension `(x_edge, y_edge = bins)`.
If the bin edges are specified, the number of bins will be, `(nx = len(x_edge)-1, ny = len(y_edge)-1)`.
- `range` [(2,2) array_like, optional] The leftmost and rightmost edges of the bins along each dimension (if not specified explicitly in the `bins` parameters): `[xmin, xmax], [ymin, ymax]`. All values outside of this range will be considered outliers and not tallied in the histogram.
- `expand_binnumbers` [bool, optional] 'False' (default): the returned `binnumber` is a shape (N,) array of linearized bin indices. 'True': the returned `binnumber` is 'unraveled' into a shape (2,N) ndarray, where each row gives the bin numbers in the corresponding dimension. See the `binnumber` returned value, and the Examples section.

**Returns**

- `statistic` [(nx, ny) ndarray] The values of the selected statistic in each two-dimensional bin.
- `x_edge` [(nx + 1) ndarray] The bin edges along the first dimension.
**y_edge**

[(ny + 1) ndarray] The bin edges along the second dimension.

**binnumber**

[(N,) array of ints or (2,N) ndarray of ints] This assigns to each element of *sample* an integer that represents the bin in which this observation falls. The representation depends on the *expand_binnumbers* argument. See *Notes* for details.

See also:

*numpy.digitize, numpy.histogram2d, binned_statistic, binned_statistic_dd*

**Notes**

Binedges: All but the last (righthand-most) bin is half-open. In other words, if *bins* is [1, 2, 3, 4], then the first bin is [1, 2) (including 1, but excluding 2) and the second [2, 3). The last bin, however, is [3, 4], which includes 4.

*binnumber*: This returned argument assigns to each element of *sample* an integer that represents the bin in which it belongs. The representation depends on the *expand_binnumbers* argument. If ‘False’ (default): The returned *binnumber* is a shape (N,) array of linearized indices mapping each element of *sample* to its corresponding bin (using row-major ordering). If ‘True’: The returned *binnumber* is a shape (2,N) ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a binnumber of *i* means the corresponding value is between (*D_edge*[i-1], *D_edge*[i]), where ‘D’ is either ‘x’ or ‘y’.

New in version 0.11.0.

**Examples**

```python
>>> from scipy import stats

Calculate the counts with explicit bin-edges:
```

```python
defualt)
>>> x = [0.1, 0.1, 0.1, 0.6]
>>> y = [2.1, 2.6, 2.1, 2.1]
>>> binx = [0.0, 0.5, 1.0]
>>> biny = [2.0, 2.5, 3.0]
>>> ret = stats.binned_statistic_2d(x, y, 'count', bins=[binx, biny])
>>> ret.statistic
array([[2., 1.],
       [1., 0.]])
```

The bin in which each sample is placed is given by the *binnumber* returned parameter. By default, these are the linearized bin indices:

```python
>>> ret.binnumber
array([5, 6, 5, 9])
```

The bin indices can also be expanded into separate entries for each dimension using the *expand_binnumbers* parameter:

```python
>>> ret = stats.binned_statistic_2d(x, y, 'count', bins=[binx, biny],
... expand_binnumbers=True)
```

(continues on next page)
Which shows that the first three elements belong in the xbin 1, and the fourth into xbin 2; and so on for y.

**scipy.stats.binned_statistic_dd**

The function `scipy.stats.binned_statistic_dd` computes a multidimensional binned statistic for a set of data.

This is a generalization of a histogram `dd` function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values within each bin.

**Parameters**

- **sample** [array_like] Data to histogram passed as a sequence of N arrays of length D, or as an (N,D) array.
- **values** [(N,) array_like or list of (N,) array_like] The data on which the statistic will be computed. This must be the same shape as `sample`, or a list of sequences - each with the same shape as `sample`. If `values` is such a list, the statistic will be computed on each independently.
- **statistic** [string or callable, optional] The statistic to compute (default is ‘mean’). The following statistics are available:
  - ‘mean’: compute the mean of values for points within each bin. Empty bins will be represented by NaN.
  - ‘median’: compute the median of values for points within each bin. Empty bins will be represented by NaN.
  - ‘count’: compute the count of points within each bin. This is identical to an unweighted histogram. `values` array is not referenced.
  - ‘sum’: compute the sum of values for points within each bin. This is identical to a weighted histogram.
  - ‘std’: compute the standard deviation within each bin. This is implicitly calculated with `ddof=0`. If the number of values within a given bin is 0 or 1, the computed standard deviation value will be 0 for the bin.
  - ‘min’: compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
  - ‘max’: compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
  - `function`: a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by `function([])`, or NaN if this returns an error.
- **bins** [sequence or positive int, optional] The bin specification must be in one of the following forms:
  - A sequence of arrays describing the bin edges along each dimension.
  - The number of bins for each dimension (nx, ny, ... = bins).
  - The number of bins for all dimensions (nx = ny = ... = bins).
- **range** [sequence, optional] A sequence of lower and upper bin edges to be used if the edges are not given explicitly in `bins`. Defaults to the minimum and maximum values along each dimension.
- **expand_binnumbers** [bool, optional] ‘False’ (default): the returned `binnumber` is a shape (N,) array of linearized bin indices. ‘True’: the returned `binnumber` is ‘unraveled’ into a shape (D,N) ndarray, where each row gives the bin numbers in the corresponding dimension. See the `binnumber` returned value, and the `Examples` section of `binned_statistic_2d`.

2612 Chapter 3. SciPy API
binned_statistic_result
[binnedStatisticddResult] Result of a previous call to the function in order to reuse bin edges and bin numbers with new values and/or a different statistic. To reuse bin numbers, expand_binnumbers must have been set to False (the default)
New in version 0.17.0.

Returns

statistic [ndarray, shape(nx1, nx2, nx3,...)] The values of the selected statistic in each two-dimensional bin.
bin_edges [list of ndarrays] A list of D arrays describing the (nxi + 1) bin edges for each dimension.
binnumber [(N,) array of ints or (D,N) ndarray of ints] This assigns to each element of sample an integer that represents the bin in which this observation falls. The representation depends on the expand_binnumbers argument. See Notes for details.

numpy.digitize, numpy.histogramdd, binned_statistic, binned_statistic_2d

Notes

Binedges: All but the last (righthand-most) bin is half-open in each dimension. In other words, if bins is [1, 2, 3, 4], then the first bin is [1, 2) (including 1, but excluding 2) and the second [2, 3). The last bin, however, is [3, 4], which includes 4.

binnumber: This returned argument assigns to each element of sample an integer that represents the bin in which it belongs. The representation depends on the expand_binnumbers argument. If ‘False’ (default): The returned binnumber is a shape (N,) array of linearized indices mapping each element of sample to its corresponding bin (using row-major ordering). If ‘True’: The returned binnumber is a shape (D,N) ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a binnumber of i means the corresponding value is between (bin_edges[D][i-1], bin_edges[D][i]), for each dimension ‘D’.
New in version 0.11.0.

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.mplot3d import Axes3D

Take an array of 600 (x, y) coordinates as an example. binned_statistic_dd can handle arrays of higher dimension D. But a plot of dimension D+1 is required.

```python
>>> mu = np.array([0., 1.])
>>> sigma = np.array([[1., -0.5], [-0.5, 1.5]])
>>> multinormal = stats.multivariate_normal(mu, sigma)
>>> data = multinormal.rvs(size=600, random_state=235412)
>>> data.shape
(600, 2)
```

Create bins and count how many arrays fall in each bin:

```python
```
```python
>>> N = 60
>>> x = np.linspace(-3, 3, N)
>>> y = np.linspace(-3, 4, N)
>>> ret = stats.binned_statistic_dd(data, np.arange(600), bins=[x, y],
... statistic='count')
>>> bincounts = ret.statistic

Set the volume and the location of bars:

```python
>>> dx = x[1] - x[0]
>>> dy = y[1] - y[0]
>>> x, y = np.meshgrid(x[:-1]+dx/2, y[:-1]+dy/2)
>>> z = 0

```python
>>> bincounts = bincounts.ravel()
>>> x = x.ravel()
>>> y = y.ravel()

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111, projection='3d')
>>> with np.errstate(divide='ignore'):  # silence random axes3d warning
...     ax.bar3d(x, y, z, dx, dy, bincounts)

Reuse bin numbers and bin edges with new values:

```python
>>> ret2 = stats.binned_statistic_dd(data, -np.arange(600),
... binned_statistic_result=ret,
... statistic='mean')
```
Correlation functions

- **f_oneway(**args[, axis])** Perform one-way ANOVA.
- **alexandergovern(**args[, nan_policy])** Performs the Alexander Govern test.
- **pearsonr**(x, y) Pearson correlation coefficient and p-value for testing non-correlation.
- **spearmanr**(a[, b, axis, nan_policy, alternative]) Calculate a Spearman correlation coefficient with associated p-value.
- **pointbiserialr**(x, y) Calculate a point biserial correlation coefficient and its p-value.
- **kendalltau**(x, y[, initial_lexsort, ...]) Calculate Kendall’s tau, a correlation measure for ordinal data.
- **weightedtau**(x, y[, rank, weigher, additive]) Compute a weighted version of Kendall’s $\tau$.
- **somersd**(x[, y]) Calculates Somers’ D, an asymmetric measure of ordinal association.
- **linregress**(x[, y, alternative]) Calculate a linear least-squares regression for two sets of measurements.
- **siegelslopes**(y[, x, method]) Computes the Siegel estimator for a set of points (x, y).
- **theilslopes**(y[, x, alpha]) Computes the Theil-Sen estimator for a set of points (x, y).
- **multiscale_graphcorr**(x, y[, ...]) Computes the Multiscale Graph Correlation (MGC) test statistic.

**scipy.stats.f_oneway**

**scipy.stats.f_oneway (**args, axis=0**)**
Perform one-way ANOVA.

The one-way ANOVA tests the null hypothesis that two or more groups have the same population mean. The test is applied to samples from two or more groups, possibly with differing sizes.

**Parameters**
- **sample1, sample2, ...**
  [array_like] The sample measurements for each group. There must be at least two arguments. If the arrays are multidimensional, then all the dimensions of the array must be the same except for `axis`.
- **axis**
  [int, optional] Axis of the input arrays along which the test is applied. Default is 0.

**Returns**
- **statistic**
  [float] The computed F statistic of the test.
- **pvalue**
  [float] The associated p-value from the F distribution.

**Warns**
- **F_onewayConstantInputWarning**
  Raised if each of the input arrays is constant array. In this case the F statistic is either infinite or isn't defined, so `np.inf` or `np.nan` is returned.
- **F_onewayBadInputSizesWarning**
  Raised if the length of any input array is 0, or if all the input arrays have length 1. `np.nan` is returned for the F statistic and the p-value in these cases.
Notes

The ANOVA test has important assumptions that must be satisfied in order for the associated p-value to be valid.

1. The samples are independent.
2. Each sample is from a normally distributed population.
3. The population standard deviations of the groups are all equal. This property is known as homoscedasticity.

If these assumptions are not true for a given set of data, it may still be possible to use the Kruskal-Wallis H-test (`scipy.stats.kruskal`) or the Alexander-Govern test (`scipy.stats.alexandergovern`) although with some loss of power.

The length of each group must be at least one, and there must be at least one group with length greater than one. If these conditions are not satisfied, a warning is generated and `(np.nan, np.nan)` is returned.

If each group contains constant values, and there exist at least two groups with different values, the function generates a warning and returns `(np.inf, 0)`.

If all values in all groups are the same, function generates a warning and returns `(np.nan, np.nan)`.

The algorithm is from Heiman [2], pp.394-7.

[1], [2], [3]

Examples

```python
>>> from scipy.stats import f_oneway
```

Here are some data [3] on a shell measurement (the length of the anterior adductor muscle scar, standardized by dividing by length) in the mussel Mytilus trossulus from five locations: Tillamook, Oregon; Newport, Oregon; Petersburg, Alaska; Magadan, Russia; and Tvarminne, Finland, taken from a much larger data set used in McDonald et al. (1991).

```python
>>> tillamook = [0.0571, 0.0813, 0.0831, 0.0976, 0.0817, 0.0859, 0.0735,
               ... 0.0659, 0.0923, 0.0836]
>>> newport = [0.0873, 0.0662, 0.0672, 0.0819, 0.0749, 0.0649, 0.0835,
               ... 0.0725]
>>> petersburg = [0.0974, 0.1352, 0.0819, 0.1016, 0.0968, 0.1064, 0.105]
>>> magadan = [0.1033, 0.0915, 0.0781, 0.0685, 0.0677, 0.0697, 0.0764,
               ... 0.0689]
>>> tvarminne = [0.0703, 0.1026, 0.0956, 0.0973, 0.1039, 0.1045]
>>> f_oneway(tillamook, newport, petersburg, magadan, tvarminne)
F_onewayResult(statistic=7.121019471642447, pvalue=0.0002812242314534544)
```

`f_oneway` accepts multidimensional input arrays. When the inputs are multidimensional and `axis` is not given, the test is performed along the first axis of the input arrays. For the following data, the test is performed three times, once for each column.

```python
>>> a = np.array([[9.87, 9.03, 6.81],
                ... [7.18, 8.35, 7.00],
                ... [8.39, 7.58, 7.68],
                ... [7.45, 6.33, 9.35],
                ... (continues on next page)
```

(continues on next page)
scipy.stats.alexandergovern

**scipy.stats.alexandergovern(***args, nan_policy='propagate')**

Performs the Alexander-Govern test.

The Alexander-Govern approximation tests the equality of \( k \) independent means in the face of heterogeneity of variance. The test is applied to samples from two or more groups, possibly with differing sizes.

**Parameters**

- **sample1, sample2, ...**
  - [array_like] The sample measurements for each group. There must be at least two samples.

- **nan_policy**
  - [dict] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
    - 'propagate': returns nan
    - 'raise': throws an error
    - 'omit': performs the calculations ignoring nan values

**Returns**

- **statistic** [float] The computed A statistic of the test.
- **pvalue** [float] The associated p-value from the chi-squared distribution.

**Warns**

**AlexanderGovernConstantInputWarning**

Raised if an input is a constant array. The statistic is not defined in this case, so `np.nan` is returned.

**See also:**

- **f_oneway**
  - one-way ANOVA
Notes

The use of this test relies on several assumptions.

1. The samples are independent.
2. Each sample is from a normally distributed population.
3. Unlike `f_oneway`, this test does not assume on homoscedasticity, instead relaxing the assumption of equal variances.

Input samples must be finite, one dimensional, and with size greater than one.

[1]

Examples

```python
>>> from scipy.stats import alexandergovern
```

Here are some data on annual percentage rate of interest charged on new car loans at nine of the largest banks in four American cities taken from the National Institute of Standards and Technology's ANOVA dataset.

We use `alexandergovern` to test the null hypothesis that all cities have the same mean APR against the alternative that the cities do not all have the same mean APR. We decide that a significance level of 5% is required to reject the null hypothesis in favor of the alternative.

```python
>>> atlanta = [13.75, 13.75, 13.5, 13.5, 13.0, 13.0, 12.75, 12.5]
>>> chicago = [14.25, 13.0, 12.75, 12.5, 12.4, 12.3, 11.9, 11.9]
>>> houston = [14.0, 14.0, 13.51, 13.5, 13.5, 13.25, 13.0, 12.5, 12.5]
>>> memphis = [15.0, 14.0, 13.75, 13.59, 13.25, 12.97, 12.5, 12.25, ...
            11.89]
>>> alexandergovern(atlanta, chicago, houston, memphis)
AlexanderGovernResult(statistic=4.65087071883494,
pvalue=0.19922132490385214)
```

The p-value is 0.1992, indicating a nearly 20% chance of observing such an extreme value of the test statistic under the null hypothesis. This exceeds 5%, so we do not reject the null hypothesis in favor of the alternative.

**scipy.stats.pearsonr**

`scipy.stats.pearsonr(x, y)`

Pearson correlation coefficient and p-value for testing non-correlation.

The Pearson correlation coefficient [1] measures the linear relationship between two datasets. The calculation of the p-value relies on the assumption that each dataset is normally distributed. (See Kowalski [3] for a discussion of the effects of non-normality of the input on the distribution of the correlation coefficient.) Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship. Positive correlations imply that as x increases, so does y. Negative correlations imply that as x increases, y decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Pearson correlation at least as extreme as the one computed from these datasets.

Parameters
**SciPy Reference Guide, Release 1.7.0**

**x**  
[(N,) array_like] Input array.

**y**  
[(N,) array_like] Input array.

**Returns**

**r**  
[float] Pearson’s correlation coefficient.

**p-value**  
[float] Two-tailed p-value.

**Warns**

**PearsonRConstantInputWarning**

Raised if an input is a constant array. The correlation coefficient is not defined in this case, so `np.nan` is returned.

**PearsonRNearConstantInputWarning**

Raised if an input is “nearly” constant. The array $x$ is considered nearly constant if $\text{norm}(x - \text{mean}(x)) < 1e-13 \times \text{abs}(\text{mean}(x))$. Numerical errors in the calculation $x - \text{mean}(x)$ in this case might result in an inaccurate calculation of $r$.

**See also:**

**spearmanr**

Spearman rank-order correlation coefficient.

**kendalltau**

Kendall’s tau, a correlation measure for ordinal data.

**Notes**

The correlation coefficient is calculated as follows:

$$r = \frac{\sum (x - m_x)(y - m_y)}{\sqrt{\sum (x - m_x)^2 \sum (y - m_y)^2}}$$

where $m_x$ is the mean of the vector $x$ and $m_y$ is the mean of the vector $y$.

Under the assumption that $x$ and $m_y$ are drawn from independent normal distributions (so the population correlation coefficient is 0), the probability density function of the sample correlation coefficient $r$ is ([1], [2]):

$$f(r) = \frac{(1 - r^2)^{n/2-2}}{B(\frac{1}{2}, \frac{n}{2} - 1)}$$

where $n$ is the number of samples, and $B$ is the beta function. This is sometimes referred to as the exact distribution of $r$. This is the distribution that is used in `pearsonr` to compute the p-value. The distribution is a beta distribution on the interval $[-1, 1]$, with equal shape parameters $a = b = n/2 - 1$. In terms of SciPy’s implementation of the beta distribution, the distribution of $r$ is:

```python
dist = scipy.stats.beta(n/2 - 1, n/2 - 1, loc=-1, scale=2)
```

The p-value returned by `pearsonr` is a two-sided p-value. For a given sample with correlation coefficient $r$, the p-value is the probability that $\text{abs}(r')$ of a random sample $x'$ and $y'$ drawn from the population with zero correlation would be greater than or equal to $\text{abs}(r)$. In terms of the object `dist` shown above, the p-value for a given $r$ and length $n$ can be computed as:

```python
p = 2*dist.cdf(-abs(r))
```
When $n$ is 2, the above continuous distribution is not well-defined. One can interpret the limit of the beta distribution as the shape parameters $a$ and $b$ approach $a = b = 0$ as a discrete distribution with equal probability masses at $r = 1$ and $r = -1$. More directly, one can observe that, given the data $x = [x_1, x_2]$ and $y = [y_1, y_2]$, and assuming $x_1 \neq x_2$ and $y_1 \neq y_2$, the only possible values for $r$ are 1 and -1. Because $\text{abs}(r')$ for any sample $x'$ and $y'$ with length 2 will be 1, the two-sided p-value for a sample of length 2 is always 1.

[1], [2], [3]

Examples

```python
>>> from scipy import stats
>>> a = np.array([0, 0, 0, 1, 1, 1])
>>> b = np.arange(7)
>>> stats.pearsonr(a, b)
(0.8660254037844386, 0.011724811003954649)

>>> stats.pearsonr([1, 2, 3, 4, 5], [10, 9, 2.5, 6, 4])
(-0.7426106572325057, 0.1505558088534455)
```

**scipy.stats.spearmanr**

`scipy.stats.spearmanr(a, b=None, axis=0, nan_policy='propagate', alternative='two-sided')`

Calculate a Spearman correlation coefficient with associated p-value.

The Spearman rank-order correlation coefficient is a nonparametric measure of the monotonicity of the relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact monotonic relationship. Positive correlations imply that as $x$ increases, so does $y$. Negative correlations imply that as $x$ increases, $y$ decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters**

- **a, b** [1D or 2D array_like, b is optional] One or two 1-D or 2-D arrays containing multiple variables and observations. When these are 1-D, each represents a vector of observations of a single variable. For the behavior in the 2-D case, see under axis, below. Both arrays need to have the same length in the axis dimension.
- **axis** [int or None, optional] If axis=0 (default), then each column represents a variable, with observations in the rows. If axis=1, the relationship is transposed: each row represents a variable, while the columns contain observations. If axis=None, then both arrays will be raveled.
- **nan_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
  - 'propagate': returns nan
  - 'raise': throws an error
  - 'omit': performs the calculations ignoring nan values
alternative

[[‘two-sided’, ‘less’, ‘greater’], optional] Defines the alternative hypothesis. Default is ‘two-sided’. The following options are available:

• ‘two-sided’: the correlation is nonzero
• ‘less’: the correlation is negative (less than zero)
• ‘greater’: the correlation is positive (greater than zero)

New in version 1.7.0.

Returns

correlation

[float or ndarray (2-D square)] Spearman correlation matrix or correlation coefficient (if only 2 variables are given as parameters). Correlation matrix is square with length equal to total number of variables (columns or rows) in a and b combined.

pvalue

[float] The p-value for a hypothesis test whose null hypothesis is that two sets of data are uncorrelated. See alternative above for alternative hypotheses. pvalue has the same shape as correlation.

scipy.stats.kendalltau

`scipy.stats.kendalltau(x, y, initial_lexsort=None, nan_policy='propagate', method='auto', variant='b')`

Calculate Kendall's tau, a correlation measure for ordinal data.

Kendall's tau is a measure of the correspondence between two rankings. Values close to 1 indicate strong agreement, and values close to -1 indicate strong disagreement. This implements two variants of Kendall's tau: tau-b (the default) and tau-c (also known as Stuart's tau-c). These differ only in how they are normalized to lie within the range -1 to 1; the hypothesis tests (their p-values) are identical. Kendall's original tau-a is not implemented separately because both tau-b and tau-c reduce to tau-a in the absence of ties.

**Parameters**

- `x, y` [array_like] Arrays of rankings, of the same shape. If arrays are not 1-D, they will be flattened to 1-D.
- `initial_lexsort` [bool, optional] Unused (deprecated).
- `nan_policy` [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
  - 'propagate': returns nan
  - 'raise': throws an error
  - 'omit': performs the calculations ignoring nan values
- `method` [{'auto', 'asymptotic', 'exact'}, optional] Defines which method is used to calculate the p-value [5]. The following options are available (default is 'auto'):
  - 'auto': selects the appropriate method based on a trade-off between speed and accuracy
  - 'asymptotic': uses a normal approximation valid for large samples
  - 'exact': computes the exact p-value, but can only be used if no ties are present. As the sample size increases, the 'exact' computation time may grow and the result may lose some precision.
- `variant`: {'b', 'c'}, optional
  Defines which variant of Kendall's tau is returned. Default is 'b'.

**Returns**

- `correlation` [float] The tau statistic.
**pvalue**  [float] The two-sided p-value for a hypothesis test whose null hypothesis is an absence of association, $\tau = 0$.

See also:

**spearmanr**
Calculates a Spearman rank-order correlation coefficient.

**theilslopes**
Computes the Theil-Sen estimator for a set of points $(x, y)$.

**weightedtau**
Computes a weighted version of Kendall’s $\tau$.

Notes

The definition of Kendall’s $\tau$ that is used is [2]:

$$
\tau_b = \frac{P - Q}{\sqrt{(P + Q + T) \cdot (P + Q + U)}}
$$
$$
\tau_c = 2 \frac{(P - Q)}{(n^2 \cdot (m - 1) / m)}
$$

where $P$ is the number of concordant pairs, $Q$ the number of discordant pairs, $T$ the number of ties only in $x$, and $U$ the number of ties only in $y$. If a tie occurs for the same pair in both $x$ and $y$, it is not added to either $T$ or $U$. $n$ is the total number of samples, and $m$ is the number of unique values in either $x$ or $y$, whichever is smaller.

[1], [2], [3], [4], [5]

Examples

```python
>>> from scipy import stats
>>> x1 = [12, 2, 1, 12, 2]
>>> x2 = [1, 4, 7, 1, 0]
>>> tau, p_value = stats.kendalltau(x1, x2)
>>> tau
-0.47140452079103173
>>> p_value
0.2827454599327748
```

**scipy.stats.weightedtau**

`scipy.stats.weightedtau(x, y, rank=True, weigher=None, additive=True)`

Compute a weighted version of Kendall’s $\tau$.

The weighted $\tau$ is a weighted version of Kendall’s $\tau$ in which exchanges of high weight are more influential than exchanges of low weight. The default parameters compute the additive hyperbolic version of the index, $\tau_h$, which has been shown to provide the best balance between important and unimportant elements [1].

The weighting is defined by means of a rank array, which assigns a nonnegative rank to each element (higher importance ranks being associated with smaller values, e.g., 0 is the highest possible rank), and a weigher function, which assigns a weight based on the rank to each element. The weight of an exchange is then the sum or the product
of the weights of the ranks of the exchanged elements. The default parameters compute \( \tau_h \): an exchange between elements with rank \( r \) and \( s \) (starting from zero) has weight \( 1/(r + 1) + 1/(s + 1) \).

Specifying a rank array is meaningful only if you have in mind an external criterion of importance. If, as it usually happens, you do not have in mind a specific rank, the weighted \( \tau \) is defined by averaging the values obtained using the decreasing lexicographical rank by \((x, y)\) and by \((y, x)\). This is the behavior with default parameters. Note that the convention used here for ranking (lower values imply higher importance) is opposite to that used by other SciPy statistical functions.

**Parameters**

- \( x, y \) [array_like] Arrays of scores, of the same shape. If arrays are not 1-D, they will be flattened to 1-D.
- \( \text{rank} \) [array_like of ints or bool, optional] A nonnegative rank assigned to each element. If it is None, the decreasing lexicographical rank by \((x, y)\) will be used: elements of higher rank will be those with larger \( x \)-values, using \( y \)-values to break ties (in particular, swapping \( x \) and \( y \) will give a different result). If it is False, the element indices will be used directly as ranks. The default is True, in which case this function returns the average of the values obtained using the decreasing lexicographical rank by \((x, y)\) and by \((y, x)\).
- \( \text{weigher} \) [callable, optional] The weigher function. Must map nonnegative integers (zero representing the most important element) to a nonnegative weight. The default, None, provides hyperbolic weighing, that is, rank \( r \) is mapped to weight \( 1/(r + 1) \).
- \( \text{additive} \) [bool, optional] If True, the weight of an exchange is computed by adding the weights of the ranks of the exchanged elements; otherwise, the weights are multiplied. The default is True.

**Returns**

- \( \text{correlation} \) [float] The weighted \( \tau \) correlation index.
- \( \text{pvalue} \) [float] Presently \( \text{np.nan} \), as the null statistics is unknown (even in the additive hyperbolic case).

**See also:**

- \texttt{kendalltau} Calculates Kendall's tau.
- \texttt{spearmanr} Calculates a Spearman rank-order correlation coefficient.
- \texttt{theilslopes} Computes the Theil-Sen estimator for a set of points \( (x, y) \).

**Notes**

This function uses an \( O(n \log n) \), mergesort-based algorithm [1] that is a weighted extension of Knight's algorithm for Kendall's \( \tau \) [2]. It can compute Shieh's weighted \( \tau \) [3] between rankings without ties (i.e., permutations) by setting \texttt{additive} and \texttt{rank} to False, as the definition given in [1] is a generalization of Shieh's.

NaNs are considered the smallest possible score.

New in version 0.19.0.
References

[1], [2], [3]

Examples

```python
>>> from scipy import stats
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> tau, p_value = stats.weightedtau(x, y)
>>> tau
-0.56694968153682723
>>> p_value
nan
>>> tau, p_value = stats.weightedtau(x, y, additive=False)
>>> tau
-0.62205716951801038

NaNs are considered the smallest possible score:

```python
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, np.nan]
>>> tau, _ = stats.weightedtau(x, y)
>>> tau
-0.56694968153682723
```

This is exactly Kendall's tau:

```python
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> tau, _ = stats.weightedtau(x, y, weigher=lambda x: 1)
>>> tau
-0.47140452079103173

scipy.stats.somersd

scipy.stats.somersd(x, y=None)
Calculates Somers' D, an asymmetric measure of ordinal association.
Like Kendall's \( \tau \), Somers' \( D \) is a measure of the correspondence between two rankings. Both statistics consider the difference between the number of concordant and discordant pairs in two rankings \( X \) and \( Y \), and both are normalized such that values close to 1 indicate strong agreement and values close to -1 indicate strong disagreement. They differ in how they are normalized. To show the relationship, Somers' \( D \) can be defined in terms of Kendall's \( \tau_a \):

\[
D(Y|X) = \frac{\tau_a(Y,X)}{\tau_a(X,X)}
\]
Suppose the first ranking $X$ has $r$ distinct ranks and the second ranking $Y$ has $s$ distinct ranks. These two lists of $n$ rankings can also be viewed as an $r \times s$ contingency table in which element $i, j$ is the number of rank pairs with rank $i$ in ranking $X$ and rank $j$ in ranking $Y$. Accordingly, \texttt{somersd} also allows the input data to be supplied as a single, 2D contingency table instead of as two separate, 1D rankings.

Note that the definition of Somers’ $D$ is asymmetric: in general, $D(Y|X) \neq D(X|Y)$. \texttt{somersd(x, y)} calculates Somers’ $D(Y|X)$: the “row” variable $X$ is treated as an independent variable, and the “column” variable $Y$ is dependent. For Somers’ $D(X|Y)$, swap the input lists or transpose the input table.

**Parameters**

- **x**: array_like
  1D array of rankings, treated as the (row) independent variable. Alternatively, a 2D contingency table.

- **y**: array_like
  If $x$ is a 1D array of rankings, $y$ is a 1D array of rankings of the same length, treated as the (column) dependent variable. If $x$ is 2D, $y$ is ignored.

**Returns**

- **res** [SomersDResult] A SomersDResult object with the following fields:
  - **correlation** [float] The Somers’ $D$ statistic.
  - **pvalue** [float] The two-sided p-value for a hypothesis test whose null hypothesis is an absence of association, $D = 0$. See notes for more information.
  - **table** [2D array] The contingency table formed from rankings $x$ and $y$ (or the provided contingency table, if $x$ is a 2D array)

**See also:**

- **kendalltau**
  Calculates Kendall’s tau, another correlation measure.

- **weightedtau**
  Computes a weighted version of Kendall’s tau.

- **spearmanr**
  Calculates a Spearman rank-order correlation coefficient.

- **pearsonr**
  Calculates a Pearson correlation coefficient.

**Notes**

This function follows the contingency table approach of [2] and [3]. $p$-values are computed based on an asymptotic approximation of the test statistic distribution under the null hypothesis $D = 0$.

Theoretically, hypothesis tests based on Kendall's tau and Somers’ $D$ should be identical. However, the $p$-values returned by \texttt{kendalltau} are based on the null hypothesis of independence between $X$ and $Y$ (i.e. the population from which pairs in $X$ and $Y$ are sampled contains equal numbers of all possible pairs), which is more specific than the null hypothesis $D = 0$ used here. If the null hypothesis of independence is desired, it is acceptable to use the $p$-value returned by \texttt{kendalltau} with the statistic returned by \texttt{somersd} and vice versa. For more information, see [2].

Contingency tables are formatted according to the convention used by SAS and R: the first ranking supplied ($x$) is the “row” variable, and the second ranking supplied ($y$) is the “column” variable. This is opposite the convention of Somers’ original paper [1].
References

[1], [2], [3], [4]

Examples

We calculate Somers’ D for the example given in [4], in which a hotel chain owner seeks to determine the association between hotel room cleanliness and customer satisfaction. The independent variable, hotel room cleanliness, is ranked on an ordinal scale: “below average (1)”, “average (2)”, or “above average (3)”. The dependent variable, customer satisfaction, is ranked on a second scale: “very dissatisfied (1)”, “moderately dissatisfied (2)”, “neither dissatisfied nor satisfied (3)”, “moderately satisfied (4)”, or “very satisfied (5)”. 189 customers respond to the survey, and the results are cast into a contingency table with the hotel room cleanliness as the “row” variable and customer satisfaction as the “column” variable.

<table>
<thead>
<tr>
<th></th>
<th>(1)</th>
<th>(2)</th>
<th>(3)</th>
<th>(4)</th>
<th>(5)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1)</td>
<td>27</td>
<td>25</td>
<td>14</td>
<td>7</td>
<td>0</td>
</tr>
<tr>
<td>(2)</td>
<td>7</td>
<td>14</td>
<td>18</td>
<td>35</td>
<td>12</td>
</tr>
<tr>
<td>(3)</td>
<td>1</td>
<td>3</td>
<td>2</td>
<td>7</td>
<td>17</td>
</tr>
</tbody>
</table>

For example, 27 customers assigned their room a cleanliness ranking of “below average (1)” and a corresponding satisfaction of “very dissatisfied (1)”. We perform the analysis as follows.

```python
>>> from scipy.stats import somersd
>>> table = [[27, 25, 14, 7, 0], [7, 14, 18, 35, 12], [1, 3, 2, 7, 17]]
>>> res = somersd(table)
>>> res.statistic
0.6032766111513396
>>> res.pvalue
1.0007091191074533e-27
```

The value of the Somers’ D statistic is approximately 0.6, indicating a positive correlation between room cleanliness and customer satisfaction in the sample. The p-value is very small, indicating a very small probability of observing such an extreme value of the statistic under the null hypothesis that the statistic of the entire population (from which our sample of 189 customers is drawn) is zero. This supports the alternative hypothesis that the true value of Somers’ D for the population is nonzero.
scipy.stats.linregress

**scipy.stats.linregress** (x, y=None, alternative='two-sided')

Calculate a linear least-squares regression for two sets of measurements.

**Parameters**

- **x, y**  
  [array_like] Two sets of measurements. Both arrays should have the same length. If only x is given (and y=None), then it must be a two-dimensional array where one dimension has length 2. The two sets of measurements are then found by splitting the array along the length-2 dimension. In the case where y=None and x is a 2x2 array, linregress(x) is equivalent to linregress(x[0], x[1]).

- **alternative**  
  [{‘two-sided’, ‘less’, ‘greater’}, optional] Defines the alternative hypothesis. Default is ‘two-sided’. The following options are available:
  - ‘two-sided’: the slope of the regression line is nonzero
  - ‘less’: the slope of the regression line is less than zero
  - ‘greater’: the slope of the regression line is greater than zero

New in version 1.7.0.

**Returns**

- **result**  
  [LinregressResult instance] The return value is an object with the following attributes:

  - **slope**  
    [float] Slope of the regression line.

  - **intercept**  
    [float] Intercept of the regression line.

  - **rvalue**  
    [float] Correlation coefficient.

  - **pvalue**  
    [float] The p-value for a hypothesis test whose null hypothesis is that the slope is zero, using Wald Test with t-distribution of the test statistic. See alternative above for alternative hypotheses.

  - **stderr**  
    [float] Standard error of the estimated slope (gradient), under the assumption of residual normality.

  - **intercept_stderr**  
    [float] Standard error of the estimated intercept, under the assumption of residual normality.

**See also:**

- **scipy.optimize.curve_fit**
  Use non-linear least squares to fit a function to data.

- **scipy.optimize.leastsq**
  Minimize the sum of squares of a set of equations.

**Notes**

Missing values are considered pair-wise: if a value is missing in x, the corresponding value in y is masked.

For compatibility with older versions of SciPy, the return value acts like a namedtuple of length 5, with fields slope, intercept, rvalue, pvalue and stderr, so one can continue to write:

```python
slope, intercept, r, p, se = linregress(x, y)
```

With that style, however, the standard error of the intercept is not available. To have access to all the computed values, including the standard error of the intercept, use the return value as an object with attributes, e.g.:
result = linregress(x, y)
print(result.intercept, result.intercept_stderr)

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> rng = np.random.default_rng()

Generate some data:

```python
>>> x = rng.random(10)
>>> y = 1.6*x + rng.random(10)
``` 

Perform the linear regression:

```python
>>> res = stats.linregress(x, y)
``` 

Coefficient of determination (R-squared):

```python
>>> print(f"R-squared: {res.rvalue**2:.6f}")
R-squared: 0.717533
``` 

Plot the data along with the fitted line:

```python
>>> plt.plot(x, y, 'o', label='original data')
>>> plt.plot(x, res.intercept + res.slope*x, 'r', label='fitted line')
>>> plt.legend()
>>> plt.show()
```

Calculate 95% confidence interval on slope and intercept:
```python
>>> # Two-sided inverse Students t-distribution
>>> # p - probability, df - degrees of freedom
>>> from scipy.stats import t
>>> tinv = lambda p, df: abs(t.ppf(p/2, df))

```}

scipy.stats.siegelslopes

**scipy.stats.siegelslopes**(y, x=None, method='hierarchical')

Computes the Siegel estimator for a set of points (x, y).

*siegelslopes* implements a method for robust linear regression using repeated medians (see [1]) to fit a line to the points (x, y). The method is robust to outliers with an asymptotic breakdown point of 50%.

**Parameters**

- **y** : [array_like] Dependent variable.
- **x** : [array_like or None, optional] Independent variable. If None, use `arange(len(y))` instead.
- **method** : [({'hierarchical', 'separate'})] If 'hierarchical', estimate the intercept using the estimated slope `medslope` (default option). If 'separate', estimate the intercept independent of the estimated slope. See Notes for details.

**Returns**

- **medslope** : [float] Estimate of the slope of the regression line.
- **medintercept** : [float] Estimate of the intercept of the regression line.

**See also:**

-theilslopes

... a similar technique without repeated medians

**Notes**

With n = len(y), compute m_j as the median of the slopes from the point (x[j], y[j]) to all other n-1 points. medslope is then the median of all slopes m_j. Two ways are given to estimate the intercept in [1] which can be chosen via the parameter method. The hierarchical approach uses the estimated slope medslope and computes medintercept as the median of y - medslope*x. The other approach estimates the intercept separately as follows: for each point (x[j], y[j]), compute the intercepts of all the n-1 lines through the remaining points and take the median i_j.medintercept is the median of the i_j.

The implementation computes n times the median of a vector of size n which can be slow for large vectors. There are more efficient algorithms (see [2]) which are not implemented here.
References

[1],[2]

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt

>>> x = np.linspace(-5, 5, num=150)
>>> y = x + np.random.normal(size=x.size)
>>> y[11:15] += 10  # add outliers
>>> y[-5:] -= 7

Compute the slope and intercept. For comparison, also compute the least-squares fit with `linregress`:

```python
>>> res = stats.siegelslopes(y, x)
>>> lsq_res = stats.linregress(x, y)
```  
Plot the results. The Siegel regression line is shown in red. The green line shows the least-squares fit for comparison.

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, y, 'b. ')
>>> ax.plot(x, res[1] + res[0] * x, 'r- ')
>>> ax.plot(x, lsq_res[1] + lsq_res[0] * x, 'g- ')
>>> plt.show()
```
scipy.stats.theilslopes

scipy.stats.theilslopes(y, x=None, alpha=0.95)

Computes the Theil-Sen estimator for a set of points (x, y).

theilslopes implements a method for robust linear regression. It computes the slope as the median of all slopes between paired values.

Parameters

- `y` [array_like] Dependent variable.
- `x` [array_like or None, optional] Independent variable. If None, use `arange(len(y))` instead.
- `alpha` [float, optional] Confidence degree between 0 and 1. Default is 95% confidence. Note that `alpha` is symmetric around 0.5, i.e. both 0.1 and 0.9 are interpreted as “find the 90% confidence interval”.

Returns

- `medslope` [float] Theil slope.
- `medintercept` [float] Intercept of the Theil line, as `median(y) - medslope*median(x)`.
- `lo_slope` [float] Lower bound of the confidence interval on `medslope`.
- `up_slope` [float] Upper bound of the confidence interval on `medslope`.

See also:

- siegelslopes
  a similar technique using repeated medians

Notes

The implementation of theilslopes follows [1]. The intercept is not defined in [1], and here it is defined as `median(y) - medslope*median(x)`, which is given in [3]. Other definitions of the intercept exist in the literature. A confidence interval for the intercept is not given as this question is not addressed in [1].

References

[1], [2], [3]

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt

>>> x = np.linspace(-5, 5, num=150)
>>> y = x + np.random.normal(size=x.size)
>>> y[11:15] += 10  # add outliers
>>> y[-5:] -= 7

Compute the slope, intercept and 90% confidence interval. For comparison, also compute the least-squares fit with linregress:
```
```python
>>> res = stats.theilslopes(y, x, 0.90)
>>> lsq_res = stats.linregress(x, y)
```

Plot the results. The Theil-Sen regression line is shown in red, with the dashed red lines illustrating the confidence interval of the slope (note that the dashed red lines are not the confidence interval of the regression as the confidence interval of the intercept is not included). The green line shows the least-squares fit for comparison.

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, y, 'b.'
>>> ax.plot(x, res[1] + res[0] * x, 'r-')
>>> ax.plot(x, lsq_res[1] + lsq_res[0] * x, 'g-')
>>> plt.show()
```

![Graph showing regression results](image)

**scipy.stats.multiscale_graphcorr**

`scipy.stats.multiscale_graphcorr(x, y, compute_distance=<function _euclidean_dist>, reps=1000, workers=1, is_twosamp=False, random_state=None)`

Computes the Multiscale Graph Correlation (MGC) test statistic.

Specifically, for each point, MGC finds the $k$-nearest neighbors for one property (e.g. cloud density), and the $l$-nearest neighbors for the other property (e.g. grass wetness) \[1\]. This pair $(k, l)$ is called the “scale”. A priori, however, it is not know which scales will be most informative. So, MGC computes all distance pairs, and then efficiently computes the distance correlations for all scales. The local correlations illustrate which scales are relatively informative about the relationship. The key, therefore, to successfully discover and decipher relationships between disparate data modalities is to adaptively determine which scales are the most informative, and the geometric implication for the most informative scales. Doing so not only provides an estimate of whether the modalities are related, but also provides insight into how the determination was made. This is especially important in high-dimensional data, where simple visualizations do not reveal relationships to the unaided human eye. Characterizations of this implementation in particular have been derived from and benchmarked within in \[2\].

**Parameters**
If \( x \) and \( y \) have shapes \((n, p)\) and \((n, q)\) where \( n \) is the number of samples and \( p \) and \( q \) are the number of dimensions, then the MGC independence test will be run. Alternatively, \( x \) and \( y \) can have shapes \((n, n)\) if they are distance or similarity matrices, and `compute_distance` must be sent to `None`. If \( x \) and \( y \) have shapes \((n, p)\) and \((m, p)\), an unpaired two-sample MGC test will be run.

`compute_distance`

Callable, \( \text{optional} \). A function that computes the distance or similarity among the samples within each data matrix. Set to `None` if \( x \) and \( y \) are already distance matrices. The default uses the euclidean norm metric. If you are calling a custom function, either create the distance matrix beforehand or create a function of the form `compute_distance(x)` where \( x \) is the data matrix for which pairwise distances are calculated.

`reps`

\[ \text{int, optional} \] The number of replications used to estimate the null when using the permutation test. The default is 1000.

`workers`

\[ \text{int or map-like callable, optional} \] If `workers` is an int the population is subdivided into `workers` sections and evaluated in parallel (uses `multiprocessing.Pool <multiprocessing>`). Supply `-1` to use all cores available to the Process. Alternatively supply a map-like callable, such as `multiprocessing.Pool.map` for evaluating the p-value in parallel. This evaluation is carried out as `workers(func, iterable)`. Requires that `func` be pickleable. The default is 1.

`is_twosamp`

\[ \text{bool, optional} \] If `True`, a two sample test will be run. If \( x \) and \( y \) have shapes \((n, p)\) and \((m, p)\), this optional will be overridden and set to `True`. Set to `True` if \( x \) and \( y \) both have shapes \((n, p)\) and a two sample test is desired. The default is `False`. Note that this will not run if inputs are distance matrices.

`random_state`

\[ \{ \text{None, int, numpy.random.Generator,} \text{ numpy.random.RandomState} \}, \text{optional} \] If `seed` is `None` (or `np.random`), the `numpy.random.RandomState` singleton is used. If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already a `Generator` or `RandomState` instance then that instance is used.

**Returns**

- `stat` \[ float \] The sample MGC test statistic within \([-1, 1]\).
- `pvalue` \[ float \] The p-value obtained via permutation.
- `mgc_dict` \[ dict \] Contains additional useful additional returns containing the following keys:
  - `mgc_map` \[ ndarray \] A 2D representation of the latent geometry of the relationship.
  - `opt_scale` \[ (int, int) \] The estimated optimal scale as a \((x, y)\) pair.
  - `null_dist` \[ list \] The null distribution derived from the permuted matrices

See also:

- `pearsonr`
  - Pearson correlation coefficient and p-value for testing non-correlation.
- `kendalltau`
  - Calculates Kendall's tau.
- `spearmanr`
  - Calculates a Spearman rank-order correlation coefficient.
A description of the process of MGC and applications on neuroscience data can be found in [1]. It is performed using the following steps:

1. Two distance matrices \( D^X \) and \( D^Y \) are computed and modified to be mean zero columnwise. This results in two \( n \times n \) distance matrices \( A \) and \( B \) (the centering and unbiased modification) [3].

2. For all values \( k \) and \( l \) from \( 1, ..., n \),
   - The \( k \)-nearest neighbor and \( l \)-nearest neighbor graphs are calculated for each property. Here, \( G_k(i, j) \) indicates the \( k \)-smallest values of the \( i \)-th row of \( A \) and \( H_l(i, j) \) indicates the \( l \) smallested values of the \( i \)-th row of \( B \)
   - Let \( \circ \) denotes the entry-wise matrix product, then local correlations are summed and normalized using the following statistic:

\[
e_{kl} = \frac{\sum_{ij} A G_k B H_l}{\sqrt{\sum_{ij} A^2 G_k \times \sum_{ij} B^2 H_l}}
\]

1. The MGC test statistic is the smoothed optimal local correlation of \( \{e_{kl}\} \). Denote the smoothing operation as \( R(\cdot) \) (which essentially set all isolated large correlations) as 0 and connected large correlations the same as before, see [3].) MGC is,

\[
MGC_n(x, y) = \max_{(k,l)} R(e_{kl}(x_n, y_n))
\]

The test statistic returns a value between \((-1, 1)\) since it is normalized.

The p-value returned is calculated using a permutation test. This process is completed by first randomly permuting \( y \) to estimate the null distribution and then calculating the probability of observing a test statistic, under the null, at least as extreme as the observed test statistic.

MGC requires at least 5 samples to run with reliable results. It can also handle high-dimensional data sets. In addition, by manipulating the input data matrices, the two-sample testing problem can be reduced to the independence testing problem [4]. Given sample data \( U \) and \( V \) of sizes \( p \times n \) \( p \times m \), data matrix \( X \) and \( Y \) can be created as follows:

\[
X = [U|V] \in \mathcal{R}^{p \times (n+m)} Y = [0_{1 \times n}|1_{1 \times m}] \in \mathcal{R}^{(n+m)}
\]

Then, the MGC statistic can be calculated as normal. This methodology can be extended to similar tests such as distance correlation [4].

New in version 1.4.0.

Examples

```python
>>> from scipy.stats import multiscale_graphcorr
>>> x = np.arange(100)
>>> y = x
>>> stat, pvalue, _ = multiscale_graphcorr(x, y, workers=-1)
>>> '%.1f, %.3f' % (stat, pvalue)
'1.0, 0.001'
```
Alternatively,

```python
>>> x = np.arange(100)
>>> y = x
>>> mgc = multiscale_graphcorr(x, y)
>>> '%.1f, %.3f' % (mgc.stat, mgc.pvalue)
'1.0, 0.001'
```

To run an unpaired two-sample test,

```python
>>> x = np.arange(100)
>>> y = np.arange(79)
>>> mgc = multiscale_graphcorr(x, y)
>>> '%.3f, %.2f' % (mgc.stat, mgc.pvalue)
'0.033, 0.02'
```

or, if shape of the inputs are the same,

```python
>>> x = np.arange(100)
>>> y = x
>>> mgc = multiscale_graphcorr(x, y, is_twosamp=True)
>>> '%.3f, %.1f' % (mgc.stat, mgc.pvalue)
'-0.008, 1.0'
```

**scipy.stats.ttest_1samp**

`scipy.stats.ttest_1samp(a, popmean, axis=0, nan_policy='propagate', alternative='two-sided')`

Calculate the T-test for the mean of ONE group of scores.

This is a two-sided test for the null hypothesis that the expected value (mean) of a sample of independent observations is equal to the given population mean, `popmean`.

**Parameters**

- `a` [array_like] Sample observation.
- `popmean` [float or array_like] Expected value in null hypothesis. If array_like, then it must have the same shape as `a` excluding the axis dimension.
- `axis` [int or None, optional] Axis along which to compute test; default is 0. If None, compute over the whole array `a`.
- `nan_policy` [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
  - ‘propagate’: returns nan
  - ‘raise’: throws an error
  - ‘omit’: performs the calculations ignoring nan values
- `alternative` [{‘two-sided’, ‘less’, ‘greater’}, optional] Defines the alternative hypothesis. The following options are available (default is ‘two-sided’):
  - ‘two-sided’
  - ‘less’: one-sided
  - ‘greater’: one-sided
  New in version 1.6.0.

**Returns**

- `statistic` [float or array] t-statistic.
- `pvalue` [float or array] Two-sided p-value.
Examples

```python
>>> from scipy import stats
>>> rng = np.random.default_rng()
>>> rvs = stats.norm.rvs(loc=5, scale=10, size=(50, 2), random_state=rng)
```

Test if mean of random sample is equal to true mean, and different mean. We reject the null hypothesis in the second case and don't reject it in the first case.

```python
>>> stats.ttest_1samp(rvs, 5.0)
Ttest_1sampResult(statistic=array([-2.09794637, -1.75977004]),
                        pvalue=array([0.04108952, 0.08468867]))
>>> stats.ttest_1samp(rvs, 0.0)
Ttest_1sampResult(statistic=array([1.64495065, 1.62095307]),
                        pvalue=array([0.10638103, 0.11144602]))
```

Examples using axis and non-scalar dimension for population mean.

```python
>>> result = stats.ttest_1samp(rvs, [5.0, 0.0])
>>> result.statistic
array([-2.09794637, 1.62095307])
>>> result.pvalue
array([0.04108952, 0.11144602])
```

```python
>>> result = stats.ttest_1samp(rvs.T, [5.0, 0.0], axis=1)
>>> result.statistic
array([-2.09794637, 1.62095307])
>>> result.pvalue
array([0.04108952, 0.11144602])
```

```python
>>> result = stats.ttest_1samp(rvs, [[5.0], [0.0]])
>>> result.statistic
array([[-2.09794637, -1.75977004],
                [1.64495065, 1.62095307]])
>>> result.pvalue
array([[0.04108952, 0.08468867],
                [0.10638103, 0.11144602]])
```

**scipy.stats.ttest_ind**

```
scipy.stats.ttest_ind(a, b, axis=0, equal_var=True, nan_policy='propagate', permutations=None, random_state=None, alternative='two-sided', trim=0)
```

Calculate the T-test for the means of two independent samples of scores.

This is a two-sided test for the null hypothesis that 2 independent samples have identical average (expected) values. This test assumes that the populations have identical variances by default.

**Parameters**

- **a, b**  [array_like] The arrays must have the same shape, except in the dimension corresponding to **axis** (the first, by default).
- **axis**  [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, a, and b.
- **equal_var**  [bool, optional] If True (default), perform a standard independent 2 sample test that assumes equal population variances [1]. If False, perform Welch’s t-test, which does not assume equal
population variance [2].
New in version 0.11.0.

nan_policy

[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
• 'propagate': returns nan
• 'raise': throws an error
• 'omit': performs the calculations ignoring nan values
The ‘omit’ option is not currently available for permutation tests or one-sided asymptotic tests.

permutations

[non-negative int, np.inf, or None (default), optional] If 0 or None (default), use the t-
distribution to calculate p-values. Otherwise, permutations is the number of random permutations that will be used to estimate p-values using a permutation test. If permutations equals or exceeds the number of distinct partitions of the pooled data, an exact test is performed instead (i.e. each distinct partition is used exactly once). See Notes for details.
New in version 1.7.0.

random_state

[None, int, numpy.random.Generator, numpy.random.RandomState], optional
If seed is None (or np.random), the numpy.random.RandomState singleton is used. If seed is an int, a new RandomState instance is used, seeded with seed. If seed is already a Generator or RandomState instance then that instance is used.
Pseudorandom number generator state used to generate permutations (used only when permutations is not None).
New in version 1.7.0.

alternative

[{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. The following options are available (default is 'two-sided'):
• 'two-sided'
• 'less': one-sided
• 'greater': one-sided
New in version 1.6.0.

trim

[float, optional] If nonzero, performs a trimmed (Yuen’s) t-test. Defines the fraction of elements to be trimmed from each end of the input samples. If 0 (default), no elements will be trimmed from either side. The number of trimmed elements from each tail is the floor of the trim times the number of elements. Valid range is [0, .5).
New in version 1.7.

Returns

statistic [float or array] The calculated t-statistic.
pvalue [float or array] The two-tailed p-value.

Notes

Suppose we observe two independent samples, e.g. flower petal lengths, and we are considering whether the two samples were drawn from the same population (e.g. the same species of flower or two species with similar petal characteristics) or two different populations.

The t-test quantifies the difference between the arithmetic means of the two samples. The p-value quantifies the probability of observing as or more extreme values assuming the null hypothesis, that the samples are drawn from populations with the same population means, is true. A p-value larger than a chosen threshold (e.g. 5% or 1%) indicates that our observation is not so unlikely to have occurred by chance. Therefore, we do not reject the null
hypothesis of equal population means. If the p-value is smaller than our threshold, then we have evidence against the null hypothesis of equal population means.

By default, the p-value is determined by comparing the t-statistic of the observed data against a theoretical t-distribution. When $1 < \text{permutations} < \binom{n}{k}$, where

- $k$ is the number of observations in $a$,
- $n$ is the total number of observations in $a$ and $b$, and
- $\binom{n}{k}$ is the binomial coefficient $(n \text{ choose } k)$,

the data are pooled (concatenated), randomly assigned to either group $a$ or $b$, and the t-statistic is calculated. This process is performed repeatedly ($\text{permutation}$ times), generating a distribution of the t-statistic under the null hypothesis, and the t-statistic of the observed data is compared to this distribution to determine the p-value. When $\text{permutations} \geq \binom{n}{k}$, an exact test is performed: the data are partitioned between the groups in each distinct way exactly once.

The permutation test can be computationally expensive and not necessarily more accurate than the analytical test, but it does not make strong assumptions about the shape of the underlying distribution.

Use of trimming is commonly referred to as the trimmed t-test. At times called Yuen's t-test, this is an extension of Welch's t-test, with the difference being the use of winsorized means in calculation of the variance and the trimmed sample size in calculation of the statistic. Trimming is recommended if the underlying distribution is long-tailed or contaminated with outliers [4].

References

[1], [2], [3], [4], [5]

Examples

```python
>>> from scipy import stats
>>> rng = np.random.default_rng()
```

Test with sample with identical means:

```python
>>> rvs1 = stats.norm.rvs(loc=5, scale=10, size=500, random_state=rng)
>>> rvs2 = stats.norm.rvs(loc=5, scale=10, size=500, random_state=rng)
>>> stats.ttest_ind(rvs1, rvs2)
Ttest_indResult(statistic=-0.4390847099199348, pvalue=0.6606952038870015)
```

`ttest_ind` underestimates p for unequal variances:

```python
>>> rvs3 = stats.norm.rvs(loc=5, scale=20, size=500, random_state=rng)
>>> stats.ttest_ind(rvs1, rvs3)
Ttest_indResult(statistic=-1.6370984482905417, pvalue=0.1019251574705033)
>>> stats.ttest_ind(rvs1, rvs3, equal_var=False)
Ttest_indResult(statistic=-1.637098448290542, pvalue=0.10202110497954867)
```

When $n_1 \neq n_2$, the equal variance t-statistic is no longer equal to the unequal variance t-statistic:
```python
>>> rvs4 = stats.norm.rvs(loc=5, scale=20, size=100, random_state=rng)
>>> stats.ttest_ind(rvs1, rvs4)
Ttest_indResult(statistic=-1.9481646859513422, pvalue=0.05186270935842703)
>>> stats.ttest_ind(rvs1, rvs4, equal_var=False)
Ttest_indResult(statistic=-1.3146566100751664, pvalue=0.1913495266513811)
```

T-test with different means, variance, and n:

```python
>>> rvs5 = stats.norm.rvs(loc=8, scale=20, size=100, random_state=rng)
>>> stats.ttest_ind(rvs1, rvs5)
Ttest_indResult(statistic=-2.8415950600298774, pvalue=0.0046418707568707885)
>>> stats.ttest_ind(rvs1, rvs5, equal_var=False)
Ttest_indResult(statistic=-1.8686598649188084, pvalue=0.06434714193919686)
```

When performing a permutation test, more permutations typically yields more accurate results. Use a np.random.Generator to ensure reproducibility:

```python
>>> stats.ttest_ind(rvs1, rvs5, permutations=10000, random_state=rng)
Ttest_indResult(statistic=-2.8415950600298774, pvalue=0.0052)
```

Take these two samples, one of which has an extreme tail.

```python
>>> a = (56, 128.6, 12, 123.8, 64.34, 78, 763.3)
>>> b = (1.1, 2.9, 4.2)
```

Use the `trim` keyword to perform a trimmed (Yuen) t-test. For example, using 20% trimming, `trim=.2`, the test will reduce the impact of one `(np.floor(trim*len(a))` element from each tail of sample `a`. It will have no effect on sample `b` because `np.floor(trim*len(b))` is 0.

```python
>>> stats.ttest_ind(a, b, trim=.2)
Ttest_indResult(statistic=3.4463884028073513, pvalue=0.01369338726499547)
```

**scipy.stats.ttest_ind_from_stats**

```python
scipy.stats.ttest_ind_from_stats(mean1, std1, nobs1, mean2, std2, nobs2, equal_var=True, alternative='two-sided')
```

T-test for means of two independent samples from descriptive statistics.

This is a two-sided test for the null hypothesis that two independent samples have identical average (expected) values.

**Parameters**

- `mean1` [array_like] The mean(s) of sample 1.
- `std1` [array_like] The standard deviation(s) of sample 1.
- `nobs1` [array_like] The number(s) of observations of sample 1.
- `mean2` [array_like] The mean(s) of sample 2.
- `std2` [array_like] The standard deviations(s) of sample 2.
- `nobs2` [array_like] The number(s) of observations of sample 2.
- `equal_var` [bool, optional] If True (default), perform a standard independent 2 sample test that assumes equal population variances [1]. If False, perform Welch's t-test, which does not assume equal population variance [2].
alternative

[‘two-sided’, ‘less’, ‘greater’], optional] Defines the alternative hypothesis. The following options are available (default is ‘two-sided’):

• ‘two-sided’
• ‘less’: one-sided
• ‘greater’: one-sided

New in version 1.6.0.

Returns

statistic [float or array] The calculated t-statistics.
pvalue [float or array] The two-tailed p-value.

See also:

scipy.stats.ttest_ind

Notes

New in version 0.16.0.

References

[1], [2]

Examples

Suppose we have the summary data for two samples, as follows:

<table>
<thead>
<tr>
<th>Sample</th>
<th>Sample</th>
</tr>
</thead>
<tbody>
<tr>
<td>Size</td>
<td>Mean</td>
</tr>
<tr>
<td>Sample 1</td>
<td>13</td>
</tr>
<tr>
<td>Sample 2</td>
<td>11</td>
</tr>
</tbody>
</table>

Apply the t-test to this data (with the assumption that the population variances are equal):

```python
>>> from scipy.stats import ttest_ind_from_stats
>>> ttest_ind_from_stats(mean1=15.0, std1=np.sqrt(87.5), nobs1=13,
... mean2=12.0, std2=np.sqrt(39.0), nobs2=11)
Ttest_indResult(statistic=0.9051358093310269, pvalue=0.3751996797581487)
```

For comparison, here is the data from which those summary statistics were taken. With this data, we can compute the same result using scipy.stats.ttest_ind:

```python
>>> a = np.array([1, 3, 4, 6, 11, 13, 15, 19, 22, 24, 25, 26, 26])
>>> b = np.array([2, 4, 6, 9, 11, 13, 14, 15, 18, 19, 21])
>>> from scipy.stats import ttest_ind
>>> ttest_ind(a, b)
Ttest_indResult(statistic=0.905135809331027, pvalue=0.3751996797581486)
```

Suppose we instead have binary data and would like to apply a t-test to compare the proportion of 1s in two independent groups:
The sample mean $\hat{p}$ is the proportion of ones in the sample and the variance for a binary observation is estimated by $\hat{p}(1 - \hat{p})$.

```
>>> ttest_ind_from_stats(mean1=0.2, std1=np.sqrt(0.16), nobs1=150,
...                      mean2=0.225, std2=np.sqrt(0.17437), nobs2=200)
Ttest_indResult(statistic=-0.564327545549774, pvalue=0.5728947691244874)
```

For comparison, we could compute the t statistic and p-value using arrays of 0s and 1s and `scipy.stats.ttest_ind`, as above.

```
>>> group1 = np.array([1]*30 + [0]*(150-30))
>>> group2 = np.array([1]*45 + [0]*(200-45))
>>> ttest_ind(group1, group2)
Ttest_indResult(statistic=-0.5627179589855622, pvalue=0.573989277115258)
```

`scipy.stats.ttest_rel`

`scipy.stats.ttest_rel(a, b, axis=0, nan_policy='propagate', alternative='two-sided')`

Calculate the t-test on TWO RELATED samples of scores, a and b.

This is a two-sided test for the null hypothesis that 2 related or repeated samples have identical average (expected) values.

**Parameters**

- `a, b`  
  [array_like] The arrays must have the same shape.
- `axis`  
  [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, a and b.
- `nan_policy`  
  [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
  - 'propagate': returns nan
  - 'raise': throws an error
  - 'omit': performs the calculations ignoring nan values
- `alternative`  
  [{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. The following options are available (default is 'two-sided'):
  - 'two-sided'
  - 'less': one-sided
  - 'greater': one-sided
  New in version 1.6.0.

**Returns**

- `statistic`  
  [float or array] t-statistic.
- `pvalue`  
  [float or array] Two-sided p-value.
Notes

Examples for use are scores of the same set of student in different exams, or repeated sampling from the same units. The test measures whether the average score differs significantly across samples (e.g. exams). If we observe a large p-value, for example greater than 0.05 or 0.1 then we cannot reject the null hypothesis of identical average scores. If the p-value is smaller than the threshold, e.g. 1%, 5% or 10%, then we reject the null hypothesis of equal averages. Small p-values are associated with large t-statistics.

https://en.wikipedia.org/wiki/T-test#Dependent_t-test_for_paired_samples

Examples

```python
>>> from scipy import stats
>>> rng = np.random.default_rng()

>>> rvs1 = stats.norm.rvs(loc=5, scale=10, size=500, random_state=rng)
>>> rvs2 = (stats.norm.rvs(loc=5, scale=10, size=500, random_state=rng)
...        + stats.norm.rvs(scale=0.2, size=500, random_state=rng))
>>> stats.ttest_rel(rvs1, rvs2)
Ttest_relResult(statistic=-0.4549717054410304, pvalue=0.6493274702088672)

>>> rvs3 = (stats.norm.rvs(loc=8, scale=10, size=500, random_state=rng)
...        + stats.norm.rvs(scale=0.2, size=500, random_state=rng))
>>> stats.ttest_rel(rvs1, rvs3)
Ttest_relResult(statistic=-5.879467544540889, pvalue=7.540777129099917e-09)
```

`scipy.stats.chisquare`

`scipy.stats.chisquare`(f_obs, f_exp=None, ddof=0, axis=0)

Calculate a one-way chi-square test.

The chi-square test tests the null hypothesis that the categorical data has the given frequencies.

Parameters

- **f_obs** [array_like] Observed frequencies in each category.
- **f_exp** [array_like, optional] Expected frequencies in each category. By default the categories are assumed to be equally likely.
- **ddof** [int, optional] “Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with \( k - 1 - ddof \) degrees of freedom, where \( k \) is the number of observed frequencies. The default value of \( ddof \) is 0.
- **axis** [int or None, optional] The axis of the broadcast result of \( f_obs \) and \( f_exp \) along which to apply the test. If axis is None, all values in \( f_obs \) are treated as a single data set. Default is 0.

Returns

- **chisq** [float or ndarray] The chi-squared test statistic. The value is a float if axis is None or \( f_obs \) and \( f_exp \) are 1-D.
- **p** [float or ndarray] The p-value of the test. The value is a float if \( ddof \) and the return value \( chisq \) are scalars.
See also:

```
scipy.stats.power_divergence
scipy.stats.fisher_exact
```

Fisher exact test on a 2x2 contingency table.

```
scipy.stats.barnard_exact
```

An unconditional exact test. An alternative to chi-squared test for small sample sizes.

**Notes**

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5. According to [3], the total number of samples is recommended to be greater than 13, otherwise exact tests (such as Barnard’s Exact test) should be used because they do not overreject.

Also, the sum of the observed and expected frequencies must be the same for the test to be valid; `chisquare` raises an error if the sums do not agree within a relative tolerance of $1e^{-8}$.

The default degrees of freedom, $k-1$, are for the case when no parameters of the distribution are estimated. If $p$ parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are $k-1-p$. If the parameters are estimated in a different way, then the dof can be between $k-1-p$ and $k-1$. However, it is also possible that the asymptotic distribution is not chi-square, in which case this test is not appropriate.

**References**

[1], [2], [3]

**Examples**

When just `f_obs` is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies.

```python
>>> from scipy.stats import chisquare
>>> chisquare([16, 18, 16, 14, 12, 12])
(2.0, 0.84914503608460956)
```

With `f_exp` the expected frequencies can be given.

```python
>>> chisquare([16, 18, 16, 14, 12, 12], f_exp=[16, 16, 16, 16, 16, 8])
(3.5, 0.62338762774958223)
```

When `f_obs` is 2-D, by default the test is applied to each column.

```python
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]]).T
>>> obs.shape
(6, 2)
>>> chisquare(obs)
(array([ 2. , 6.66666667]), array([ 0.84914504, 0.24663415]))
```

By setting `axis=None`, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.
>>> chisquare(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> chisquare(obs.ravel())
(23.31034482758621, 0.015975692534127565)

\textit{ddof} is the change to make to the default degrees of freedom.

>>> chisquare([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.7357588234288467)

The calculation of the p-values is done by broadcasting the chi-squared statistic with \textit{ddof}.

>>> chisquare([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504, 0.73575882, 0.5724067 ]))

\textit{f\_obs} and \textit{f\_exp} are also broadcast. In the following, \textit{f\_obs} has shape (6,) and \textit{f\_exp} has shape (2, 6), so the result of broadcasting \textit{f\_obs} and \textit{f\_exp} has shape (2, 6). To compute the desired chi-squared statistics, we use \textit{axis}=1:

>>> chisquare([16, 18, 16, 14, 12, 12],
... f\_exp=[[16, 16, 16, 16, 16, 8],
... [8, 20, 20, 16, 12, 12]],
... axis=1)
(array([ 3.5 , 9.25]), array([ 0.62338763, 0.09949846]))

\textbf{scipy.stats.cramervonmises}

\texttt{scipy.stats.cramervonmises(rvs, cdf, args=())}

Perform the one-sample Cramér-von Mises test for goodness of fit.

This performs a test of the goodness of fit of a cumulative distribution function (cdf) \textit{F} compared to the empirical distribution function \textit{F} \textsubscript{n} of observed random variates \(X_1, \ldots, X_n\) that are assumed to be independent and identically distributed ([1]). The null hypothesis is that the \(X_i\) have cumulative distribution \textit{F}.

\textbf{Parameters}

- \textit{rvs} [array_like] A 1-D array of observed values of the random variables \(X_i\).
- \textit{cdf} [str or callable] The cumulative distribution function \textit{F} to test the observations against. If a string, it should be the name of a distribution in \texttt{scipy.stats}. If a callable, that callable is used to calculate the cdf: \texttt{cdf(x, *args) \rightarrow float}.
- \textit{args} [tuple, optional] Distribution parameters. These are assumed to be known; see Notes.

\textbf{Returns}

- \textit{res} [object with attributes]
  - \texttt{statistic} [float] Cramér-von Mises statistic.
  - \texttt{pvalue} [float] The p-value.

\textbf{See also:}

\texttt{kstest}, \texttt{cramervonmises_2samp}
Notes

New in version 1.6.0.

The p-value relies on the approximation given by equation 1.8 in [2]. It is important to keep in mind that the p-value is only accurate if one tests a simple hypothesis, i.e. the parameters of the reference distribution are known. If the parameters are estimated from the data (composite hypothesis), the computed p-value is not reliable.

References

[1], [2]

Examples

Suppose we wish to test whether data generated by scipy.stats.norm.rvs were, in fact, drawn from the standard normal distribution. We choose a significance level of alpha=0.05.

```python
>>> from scipy import stats
>>> rng = np.random.default_rng()
>>> x = stats.norm.rvs(size=500, random_state=rng)
>>> res = stats.cramervonmises(x, 'norm')
>>> res.statistic, res.pvalue
(0.49121480855028343, 0.04189256516661377)
```

The p-value 0.79 exceeds our chosen significance level, so we do not reject the null hypothesis that the observed sample is drawn from the standard normal distribution.

Now suppose we wish to check whether the same samples shifted by 2.1 is consistent with being drawn from a normal distribution with a mean of 2.

```python
>>> y = x + 2.1
>>> res = stats.cramervonmises(y, 'norm', args=(2,))
>>> res.statistic, res.pvalue
(0.07400330012187435, 0.7274595666160468)
```

Here we have used the `args` keyword to specify the mean (loc) of the normal distribution to test the data against. This is equivalent to the following, in which we create a frozen normal distribution with mean 2.1, then pass its cdf method as an argument.

```python
>>> frozen_dist = stats.norm(loc=2)
>>> res = stats.cramervonmises(y, frozen_dist.cdf)
>>> res.statistic, res.pvalue
(0.07400330012187435, 0.7274595666160468)
```

In either case, we would reject the null hypothesis that the observed sample is drawn from a normal distribution with a mean of 2 (and default variance of 1) because the p-value 0.04 is less than our chosen significance level.
scipy.stats.cramervonmises_2samp

scipy.stats.cramervonmises_2samp(x, y, method='auto')

Perform the two-sample Cramér-von Mises test for goodness of fit.

This is the two-sample version of the Cramér-von Mises test ([1]): for two independent samples \( X_1, \ldots, X_n \) and \( Y_1, \ldots, Y_m \), the null hypothesis is that the samples come from the same (unspecified) continuous distribution.

**Parameters**

- **x**  
  [array_like] A 1-D array of observed values of the random variables \( X_i \).
- **y**  
  [array_like] A 1-D array of observed values of the random variables \( Y_i \).
- **method**  
  [‘auto’, ‘asymptotic’, ‘exact’], optional] The method used to compute the p-value, see Notes for details. The default is ‘auto’.

**Returns**

- **res**  
  [object with attributes]
  - **statistic** [float] Cramér-von Mises statistic.
  - **pvalue** [float] The p-value.

**See also:**

cramervonmises, anderson_ksamp, epps_singleton_2samp, ks_2samp

**Notes**

New in version 1.7.0.

The statistic is computed according to equation 9 in [2]. The calculation of the p-value depends on the keyword method:

- **asymptotic**: The p-value is approximated by using the limiting distribution of the test statistic.
- **exact**: The exact p-value is computed by enumerating all possible combinations of the test statistic, see [2].

The exact calculation will be very slow even for moderate sample sizes as the number of combinations increases rapidly with the size of the samples. If method='auto', the exact approach is used if both samples contain less than 10 observations, otherwise the asymptotic distribution is used.

If the underlying distribution is not continuous, the p-value is likely to be conservative (Section 6.2 in [3]). When ranking the data to compute the test statistic, midranks are used if there are ties.

**References**

[1], [2], [3]

**Examples**

Suppose we wish to test whether two samples generated by scipy.stats.norm.rvs have the same distribution. We choose a significance level of alpha=0.05.

```python
>>> from scipy import stats  
>>> rng = np.random.default_rng()  
>>> x = stats.norm.rvs(size=100, random_state=rng)  
>>> y = stats.norm.rvs(size=70, random_state=rng)  
>>> res = stats.cramervonmises_2samp(x, y)
```

(continues on next page)
The p-value exceeds our chosen significance level, so we do not reject the null hypothesis that the observed samples are drawn from the same distribution.

For small sample sizes, one can compute the exact p-values:

```python
>>> x = stats.norm.rvs(size=7, random_state=rng)
>>> y = stats.t.rvs(df=2, size=6, random_state=rng)
>>> res = stats.cramervonmises_2samp(x, y, method='exact')
>>> res.statistic, res.pvalue
(0.197802197802198, 0.31643356643356646)
```

The p-value based on the asymptotic distribution is a good approximation even though the sample size is small.

```python
>>> res = stats.cramervonmises_2samp(x, y, method='asymptotic')
>>> res.statistic, res.pvalue
(0.197802197802198, 0.2966041181527128)
```

Independent of the method, one would not reject the null hypothesis at the chosen significance level in this example.

### scipy.stats.power_divergence

The function tests the null hypothesis that the categorical data has the given frequencies, using the Cressie-Read power divergence statistic.

**Parameters**

- `f_obs` [array_like] Observed frequencies in each category.
- `f_exp` [array_like, optional] Expected frequencies in each category. By default the categories are assumed to be equally likely.
- `ddof` [int, optional] “Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with \( k - 1 - ddof \) degrees of freedom, where \( k \) is the number of observed frequencies. The default value of `ddof` is 0.
- `axis` [int or None, optional] The axis of the broadcast result of `f_obs` and `f_exp` along which to apply the test. If `axis` is None, all values in `f_obs` are treated as a single data set. Default is 0.
- `lambda_` [float or str, optional] The power in the Cressie-Read power divergence statistic. The default is 1. For convenience, `lambda_` may be assigned one of the following strings, in which case the corresponding numerical value is used:

<table>
<thead>
<tr>
<th>String</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;pearson&quot;</td>
<td>1</td>
<td>Pearson's chi-squared statistic.</td>
</tr>
<tr>
<td>&quot;statistic&quot;.</td>
<td></td>
<td>In this case, the function is equivalent to <code>stats.chisquare</code>.</td>
</tr>
<tr>
<td>&quot;chisquare&quot;.</td>
<td></td>
<td>Log-likelihood ratio. Also known as the G-test [Rf6c2a1ea428c-3].</td>
</tr>
</tbody>
</table>
Returns

statistic [float or ndarray] The Cressie-Read power divergence test statistic. The value is a float if `axis` is None or if `f_obs` and `f_exp` are 1-D.

pvalue [float or ndarray] The p-value of the test. The value is a float if `ddof` and the return value `stat` are scalars.

See also:

chisquare

Notes

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

Also, the sum of the observed and expected frequencies must be the same for the test to be valid; `power_divergence` raises an error if the sums do not agree within a relative tolerance of 1e-8.

When `lambda_` is less than zero, the formula for the statistic involves dividing by `f_obs`, so a warning or error may be generated if any value in `f_obs` is 0.

Similarly, a warning or error may be generated if any value in `f_exp` is zero when `lambda_` >= 0.

The default degrees of freedom, k-1, are for the case when no parameters of the distribution are estimated. If `p` parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are k-1-p. If the parameters are estimated in a different way, then the dof can be between k-1-p and k-1. However, it is also possible that the asymptotic distribution is not a chi-square, in which case this test is not appropriate.

This function handles masked arrays. If an element of `f_obs` or `f_exp` is masked, then data at that position is ignored, and does not count towards the size of the data set.

New in version 0.13.0.

References

[1], [2], [3], [4], [5]

Examples

(See `chisquare` for more examples.)

When just `f_obs` is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies. Here we perform a G-test (i.e. use the log-likelihood ratio statistic):

```python
>>> from scipy.stats import power_divergence
>>> power_divergence([16, 18, 16, 14, 12, 12], lambda_='log-likelihood')
(2.006573162632538, 0.84823476779463769)
```
The expected frequencies can be given with the `f_exp` argument:

```python
>>> power_divergence([16, 18, 16, 14, 12, 12],
...                  f_exp=[16, 16, 16, 16, 16, 8],
...                  lambda_='log-likelihood')
(3.3281031458963746, 0.6495419288047497)
```

When `f_obs` is 2-D, by default the test is applied to each column.

```python
>>> obs = np.array([[16, 18, 16, 14, 12, 12],
...                  [32, 24, 16, 28, 20, 24]]).T
>>> obs.shape
(6, 2)
>>> power_divergence(obs, lambda_="log-likelihood")
(array([ 2.00657316, 6.77634498]), array([ 0.84823477, 0.23781225]))
```

By setting `axis=None`, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```python
>>> power_divergence(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> power_divergence(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

`ddof` is the change to make to the default degrees of freedom.

```python
>>> power_divergence([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.7357588234288467)
```

The calculation of the p-values is done by broadcasting the test statistic with `ddof`.

```python
>>> power_divergence([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504, 0.73575888, 0.5724067 ]))
```

`f_obs` and `f_exp` are also broadcast. In the following, `f_obs` has shape (6,) and `f_exp` has shape (2, 6), so the result of broadcasting `f_obs` and `f_exp` has shape (2, 6). To compute the desired chi-squared statistics, we must use `axis=1`:

```python
>>> power_divergence([16, 18, 16, 14, 12, 12],
...                  f_exp=[[16, 16, 16, 16, 16, 8],
...                        [8, 20, 20, 16, 12, 12]],
...                  axis=1)
(array([ 3.5 , 9.25]), array([ 0.62338763, 0.09949846]))
```

`scipy.stats.kstest`

`scipy.stats.kstest` *(rvs, cdf, args=(), N=20, alternative='two-sided', mode='auto')*

Performs the (one-sample or two-sample) Kolmogorov-Smirnov test for goodness of fit.

The one-sample test compares the underlying distribution \( F(x) \) of a sample against a given distribution \( G(x) \). The two-sample test compares the underlying distributions of two independent samples. Both tests are valid only for continuous distributions.

**Parameters**

- `rvs` *[str, array_like, or callable]* If an array, it should be a 1-D array of observations of random variables. If a callable, it should be a function to generate random variables; it is required to
have a keyword argument `size`. If a string, it should be the name of a distribution in `scipy.stats`, which will be used to generate random variables.

**cdf**

[str, array_like or callable] If array_like, it should be a 1-D array of observations of random variables, and the two-sample test is performed (and `rvs` must be array_like). If a callable, that callable is used to calculate the cdf. If a string, it should be the name of a distribution in `scipy.stats`, which will be used as the cdf function.

**args**

[tuple, sequence, optional] Distribution parameters, used if `rvs` or `cdf` are strings or callables.

**N**

[int, optional] Sample size if `rvs` is string or callable. Default is 20.

**alternative**

[{'two-sided', 'less', 'greater'}, optional] Defines the null and alternative hypotheses. Default is 'two-sided'. Please see explanations in the Notes below.

**mode**

[{'auto', 'exact', 'approx', 'asymp'}, optional] Defines the distribution used for calculating the p-value. The following options are available (default is 'auto'):

- 'auto': selects one of the other options.
- 'exact': uses the exact distribution of test statistic.
- 'approx': approximates the two-sided probability with twice the one-sided probability
- 'asymp': uses asymptotic distribution of test statistic

**Returns**

- `statistic` [float] KS test statistic, either D, D+ or D-.
- `pvalue` [float] One-tailed or two-tailed p-value.

**See also:**

`ks_2samp`

**Notes**

There are three options for the null and corresponding alternative hypothesis that can be selected using the `alternative` parameter.

- **two-sided**: The null hypothesis is that the two distributions are identical, \( F(x) = G(x) \) for all \( x \); the alternative is that they are not identical.
- **less**: The null hypothesis is that \( F(x) \geq G(x) \) for all \( x \); the alternative is that \( F(x) < G(x) \) for at least one \( x \).
- **greater**: The null hypothesis is that \( F(x) \leq G(x) \) for all \( x \); the alternative is that \( F(x) > G(x) \) for at least one \( x \).

Note that the alternative hypotheses describe the CDFs of the underlying distributions, not the observed values. For example, suppose \( x1 \sim F \) and \( x2 \sim G \). If \( F(x) > G(x) \) for all \( x \), the values in \( x1 \) tend to be less than those in \( x2 \).

**Examples**

```python
>>> from scipy import stats
>>> rng = np.random.default_rng()

>>> x = np.linspace(-15, 15, 9)
>>> stats.kstest(x, 'norm')
KstestResult(statistic=0.444356027159..., pvalue=0.038850140086...)

>>> stats.kstest(stats.norm.rvs(size=100, random_state=rng), stats.norm.←cdf)
KstestResult(statistic=0.165471391799..., pvalue=0.007331283245...)
```
The above lines are equivalent to:

```python
>>> stats.kstest(stats.norm.rvs, 'norm', N=100)
KstestResult(statistic=0.113810164200..., pvalue=0.138690052319...)  #← may vary
```

**Test against one-sided alternative hypothesis**

Shift distribution to larger values, so that $\text{CDF}(x) < \text{norm.cdf}(x)$:

```python
>>> x = stats.norm.rvs(loc=0.2, size=100, random_state=rng)
>>> stats.kstest(x, 'norm', alternative='less')
KstestResult(statistic=0.1002033514..., pvalue=0.1255446444...)
```

Reject null hypothesis in favor of alternative hypothesis: less

```python
>>> stats.kstest(x, 'norm', alternative='greater')
KstestResult(statistic=0.018749806388..., pvalue=0.920581859791...)
```

Don’t reject null hypothesis in favor of alternative hypothesis: greater

```python
>>> stats.kstest(x, 'norm')
KstestResult(statistic=0.100203351482..., pvalue=0.250616879765...)
```

**Testing t distributed random variables against normal distribution**

With 100 degrees of freedom the t distribution looks close to the normal distribution, and the K-S test does not reject the hypothesis that the sample came from the normal distribution:

```python
>>> stats.kstest(stats.t.rvs(100, size=100, random_state=rng), 'norm')
KstestResult(statistic=0.064273776544..., pvalue=0.778737758305...)
```

With 3 degrees of freedom the t distribution looks sufficiently different from the normal distribution, that we can reject the hypothesis that the sample came from the normal distribution at the 10% level:

```python
>>> stats.kstest(stats.t.rvs(3, size=100, random_state=rng), 'norm')
KstestResult(statistic=0.128678487493..., pvalue=0.066569081515...)
```

### scipy.stats.ks_1samp

**scipy.stats.ks_1samp** $(x, cdf, args=(), alternative='two-sided', mode='auto')$

Performs the one-sample Kolmogorov-Smirnov test for goodness of fit.

This test compares the underlying distribution F(x) of a sample against a given continuous distribution G(x). See Notes for a description of the available null and alternative hypotheses.

**Parameters**

- **x** [array_like] a 1-D array of observations of iid random variables.
- **cdf** [callable] callable used to calculate the cdf.
- **args** [tuple, sequence, optional] Distribution parameters, used with cdf.
- **alternative** [{’two-sided’, ‘less’, ‘greater’}, optional] Defines the null and alternative hypotheses. Default is ‘two-sided’. Please see explanations in the Notes below.
- **mode** [{’auto’, ‘exact’, ‘approx’, ‘asymp’}, optional] Defines the distribution used for calculating the p-value. The following options are available (default is ‘auto’):
  - ‘auto’: selects one of the other options.
  - ‘exact’: uses the exact distribution of test statistic.
• ‘approx’: approximates the two-sided probability with twice the one-sided probability
• ‘asymp’: uses asymptotic distribution of test statistic

Returns

**statistic**  [float]  KS test statistic, either D, D+ or D- (depending on the value of ‘alternative’)

**pvalue**  [float]  One-tailed or two-tailed p-value.

See also:

**ks_2samp, kstest**

Notes

There are three options for the null and corresponding alternative hypothesis that can be selected using the *alternative* parameter.

- **two-sided**: The null hypothesis is that the two distributions are identical, F(x)=G(x) for all x; the alternative is that they are not identical.
- **less**: The null hypothesis is that F(x) >= G(x) for all x; the alternative is that F(x) < G(x) for at least one x.
- **greater**: The null hypothesis is that F(x) <= G(x) for all x; the alternative is that F(x) > G(x) for at least one x.

Note that the alternative hypotheses describe the CDFs of the underlying distributions, not the observed values. For example, suppose x1 ~ F and x2 ~ G. If F(x) > G(x) for all x, the values in x1 tend to be less than those in x2.

Examples

```python
>>> from scipy import stats
>>> rng = np.random.default_rng()

>>> x = np.linspace(-15, 15, 9)
>>> stats.ks_1samp(x, stats.norm.cdf)
(0.44435602715924361, 0.038850142705171065)

>>> stats.ks_1samp(stats.norm.rvs(size=100, random_state=rng), stats.norm.cdf)
KstestResult(statistic=0.165471391799..., pvalue=0.007331283245...)

Test against one-sided alternative hypothesis

Shift distribution to larger values, so that "CDF(x) < norm.cdf(x)"

```python
>>> x = stats.norm.rvs(loc=0.2, size=100, random_state=rng)
>>> stats.ks_1samp(x, stats.norm.cdf, alternative='less')
KstestResult(statistic=0.100203351482..., pvalue=0.12554464447...)

Reject null hypothesis in favor of alternative hypothesis: less

```python
>>> stats.ks_1samp(x, stats.norm.cdf, alternative='greater')
KstestResult(statistic=0.018749806388..., pvalue=0.920581859791...)

Reject null hypothesis in favor of alternative hypothesis: greater
```
Don’t reject null hypothesis in favor of alternative hypothesis: two-sided

*Testing t distributed random variables against normal distribution*

With 100 degrees of freedom the t distribution looks close to the normal distribution, and the K-S test does not reject the hypothesis that the sample came from the normal distribution:

```python
>>> stats.ks_1samp(stats.t.rvs(100, size=100, random_state=rng),
                  stats.norm.cdf)
KstestResult(statistic=0.064273776544..., pvalue=0.778737758305...)
```

With 3 degrees of freedom the t distribution looks sufficiently different from the normal distribution, that we can reject the hypothesis that the sample came from the normal distribution at the 10% level:

```python
>>> stats.ks_1samp(stats.t.rvs(3, size=100, random_state=rng),
                  stats.norm.cdf)
KstestResult(statistic=0.128678487493..., pvalue=0.066569081515...)
```

**scipy.stats.ks_2samp**

`scipy.stats.ks_2samp(data1, data2, alternative='two-sided', mode='auto')`

Performs the two-sample Kolmogorov-Smirnov test for goodness of fit.

This test compares the underlying continuous distributions F(x) and G(x) of two independent samples. See Notes for a description of the available null and alternative hypotheses.

*Parameters*

- **data1, data2**
  [array_like, 1-Dimensional] Two arrays of sample observations assumed to be drawn from a continuous distribution, sample sizes can be different.

- **alternative**

- **mode**
  [{‘auto’, ‘exact’, ‘asymp’}, optional] Defines the method used for calculating the p-value. The following options are available (default is ‘auto’):
  - ‘auto’: use ‘exact’ for small size arrays, ‘asymp’ for large
  - ‘exact’: use exact distribution of test statistic
  - ‘asymp’: use asymptotic distribution of test statistic

*Returns*

- **statistic** [float] KS statistic.
- **pvalue** [float] One-tailed or two-tailed p-value.

See also:

- `kstest`, `ks_1samp`, `epps_singleton_2samp`, `anderson_ksamp`
Notes

There are three options for the null and corresponding alternative hypothesis that can be selected using the `alternative` parameter.

- **two-sided**: The null hypothesis is that the two distributions are identical, \( F(x) = G(x) \) for all \( x \); the alternative is that they are not identical.
- **less**: The null hypothesis is that \( F(x) \geq G(x) \) for all \( x \); the alternative is that \( F(x) < G(x) \) for at least one \( x \).
- **greater**: The null hypothesis is that \( F(x) \leq G(x) \) for all \( x \); the alternative is that \( F(x) > G(x) \) for at least one \( x \).

Note that the alternative hypotheses describe the CDFs of the underlying distributions, not the observed values. For example, suppose \( x_1 \sim F \) and \( x_2 \sim G \). If \( F(x) > G(x) \) for all \( x \), the values in \( x_1 \) tend to be less than those in \( x_2 \).

If the KS statistic is small or the p-value is high, then we cannot reject the null hypothesis in favor of the alternative.

If the mode is ‘auto’, the computation is exact if the sample sizes are less than 10000. For larger sizes, the computation uses the Kolmogorov-Smirnov distributions to compute an approximate value.

The ‘two-sided’ ‘exact’ computation computes the complementary probability and then subtracts from 1. As such, the minimum probability it can return is about 1e-16. While the algorithm itself is exact, numerical errors may accumulate for large sample sizes. It is most suited to situations in which one of the sample sizes is only a few thousand.

We generally follow Hodges’ treatment of Drion/Gnedenko/Korolyuk [1].

References

[1]

Examples

```python
>>> from scipy import stats
>>> rng = np.random.default_rng()

>>> n1 = 200  # size of first sample
>>> n2 = 300  # size of second sample
```

For a different distribution, we can reject the null hypothesis since the p-value is below 1%:

```python
>>> rvs1 = stats.norm.rvs(size=n1, loc=0., scale=1, random_state=rng)
>>> rvs2 = stats.norm.rvs(size=n2, loc=0.5, scale=1.5, random_state=rng)
>>> stats.ks_2samp(rvs1, rvs2)
KstestResult(statistic=0.24833333333333332, pvalue=5.846586728086578e-07)
```

For a slightly different distribution, we cannot reject the null hypothesis at a 10% or lower alpha since the p-value at 0.144 is higher than 10%:

```python
>>> rvs3 = stats.norm.rvs(size=n2, loc=0.01, scale=1.0, random_state=rng)
>>> stats.ks_2samp(rvs1, rvs3)
KstestResult(statistic=0.07833333333333334, pvalue=0.437965845642945)
```

For an identical distribution, we cannot reject the null hypothesis since the p-value is high, 41%:
```python
>>> rvs4 = stats.norm.rvs(size=n2, loc=0.0, scale=1.0, random_state=rng)
>>> stats.ks_2samp(rvs1, rvs4)
KstestResult(statistic=0.12166666666666667, pvalue=0.05401863039081145)
```

**scipy.stats.epps_singleton_2samp**

*scipy.stats.epps_singleton_2samp*(x, y, t=(0.4, 0.8))

Compute the Epps-Singleton (ES) test statistic.

Test the null hypothesis that two samples have the same underlying probability distribution.

**Parameters**

- **x, y**  
  [array-like] The two samples of observations to be tested. Input must not have more than one dimension. Samples can have different lengths.

- **t**  
  [array-like, optional] The points (t1, ..., tn) where the empirical characteristic function is to be evaluated. It should be positive distinct numbers. The default value (0.4, 0.8) is proposed in [1]. Input must not have more than one dimension.

**Returns**

- **statistic**  
  [float] The test statistic.

- **pvalue**  
  [float] The associated p-value based on the asymptotic chi2-distribution.

**See also:**

- **ks_2samp**, **anderson_ksamp**

**Notes**

Testing whether two samples are generated by the same underlying distribution is a classical question in statistics. A widely used test is the Kolmogorov-Smirnov (KS) test which relies on the empirical distribution function. Epps and Singleton introduce a test based on the empirical characteristic function in [1].

One advantage of the ES test compared to the KS test is that it does not assume a continuous distribution. In [1], the authors conclude that the test also has a higher power than the KS test in many examples. They recommend the use of the ES test for discrete samples as well as continuous samples with at least 25 observations each, whereas **anderson_ksamp** is recommended for smaller sample sizes in the continuous case.

The p-value is computed from the asymptotic distribution of the test statistic which follows a chi2 distribution. If the sample size of both x and y is below 25, the small sample correction proposed in [1] is applied to the test statistic.

The default values of t are determined in [1] by considering various distributions and finding good values that lead to a high power of the test in general. Table III in [1] gives the optimal values for the distributions tested in that study. The values of t are scaled by the semi-interquartile range in the implementation, see [1].

scipy.stats.mannwhitneyu

scipy.stats.mannwhitneyu(x, y, use_continuity=True, alternative='two-sided', axis=0, method='auto')

Perform the Mann-Whitney U rank test on two independent samples.

The Mann-Whitney U test is a nonparametric test of the null hypothesis that the distribution underlying sample \( x \) is the same as the distribution underlying sample \( y \). It is often used as a test of of difference in location between distributions.

Parameters

- **x, y** [array-like] N-d arrays of samples. The arrays must be broadcastable except along the dimension given by **axis**.
- **use_continuity** [bool, optional] Whether a continuity correction (1/2) should be applied. Default is True when **method** is 'asymptotic'; has no effect otherwise.
- **alternative** [{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. Default is 'two-sided'. Let \( F(u) \) and \( G(u) \) be the cumulative distribution functions of the distributions underlying \( x \) and \( y \), respectively. Then the following alternative hypotheses are available:
  - 'two-sided': the distributions are not equal, i.e. \( F(u) \neq G(u) \) for at least one \( u \).
  - 'less': the distribution underlying \( x \) is stochastically less than the distribution underlying \( y \), i.e. \( F(u) > G(u) \) for all \( u \).
  - 'greater': the distribution underlying \( x \) is stochastically greater than the distribution underlying \( y \), i.e. \( F(u) < G(u) \) for all \( u \).

Under a more restrictive set of assumptions, the alternative hypotheses can be expressed in terms of the locations of the distributions; see [5] section 5.1.

- **axis** [int, optional] Axis along which to perform the test. Default is 0.
- **method** [{'auto', 'asymptotic', 'exact'}, optional] Selects the method used to calculate the \( p \)-value. Default is 'auto'. The following options are available.
  - 'asymptotic': compares the standardized test statistic against the normal distribution, correcting for ties.
  - 'exact': computes the exact \( p \)-value by comparing the observed \( U \) statistic against the exact distribution of the \( U \) statistic under the null hypothesis. No correction is made for ties.
  - 'auto': chooses 'exact' when the size of one of the samples is less than 8 and there are no ties; chooses 'asymptotic' otherwise.

Returns

- **res** [MannwhitneyuResult] An object containing attributes:
  - **statistic** [float] The Mann-Whitney U statistic corresponding with sample \( x \). See Notes for the test statistic corresponding with sample \( y \).
  - **pvalue** [float] The associated \( p \)-value for the chosen alternative.

See also:

- `scipy.stats.wilcoxon`
- `scipy.stats.ranksums`
- `scipy.stats.ttest_ind`
Notes

If $U_1$ is the statistic corresponding with sample $x$, then the statistic corresponding with sample $y$ is $U_2 = x.shape[\text{axis}] \times y.shape[\text{axis}] - U_1$.

`mannwhitneyu` is for independent samples. For related / paired samples, consider `scipy.stats.wilcoxon`.

`method` `'exact'` is recommended when there are no ties and when either sample size is less than 8 [1]. The implementation follows the recurrence relation originally proposed in [1] as it is described in [3]. Note that the exact method is *not* corrected for ties, but `mannwhitneyu` will not raise errors or warnings if there are ties in the data.

The Mann-Whitney U test is a non-parametric version of the t-test for independent samples. When the the means of samples from the populations are normally distributed, consider `scipy.stats.ttest_ind`.

References

[1], [2], [3], [4], [5]

Examples

We follow the example from [4]: nine randomly sampled young adults were diagnosed with type II diabetes at the ages below.

```python
>>> males = [19, 22, 16, 29, 24]
>>> females = [20, 11, 17, 12]
```

We use the Mann-Whitney U test to assess whether there is a statistically significant difference in the diagnosis age of males and females. The null hypothesis is that the distribution of male diagnosis ages is the same as the distribution of female diagnosis ages. We decide that a confidence level of 95% is required to reject the null hypothesis in favor of the alternative that that the distributions are different. Since the number of samples is very small and there are no ties in the data, we can compare the observed test statistic against the exact distribution of the test statistic under the null hypothesis.

```python
>>> from scipy.stats import mannwhitneyu
>>> U1, p = mannwhitneyu(males, females, method="exact")
>>> print(U1)
17.0
```

`mannwhitneyu` always reports the statistic associated with the first sample, which, in this case, is males. This agrees with $U_M = 17$ reported in [4]. The statistic associated with the second statistic can be calculated:

```python
>>> nx, ny = len(males), len(females)
>>> U2 = nx*ny - U1
>>> print(U2)
3.0
```

This agrees with $U_F = 3$ reported in [4]. The two-sided $p$-value can be calculated from either statistic, and the value produced by `mannwhitneyu` agrees with $p = 0.11$ reported in [4].

```python
>>> print(p)
0.1111111111111111
```
The exact distribution of the test statistic is asymptotically normal, so the example continues by comparing the exact \( p \)-value against the \( p \)-value produced using the normal approximation.

```python
>>> _, pnorm = mannwhitneyu(males, females, method="asymptotic")
>>> print(pnorm)
0.11134688653314041
```

Here \texttt{mannwhitneyu}'s reported \( p \)-value appears to conflict with the value \( p = 0.09 \) given in [4]. The reason is that [4] does not apply the continuity correction performed by \texttt{mannwhitneyu}; \texttt{mannwhitneyu} reduces the distance between the test statistic and the mean \( \mu = n_x n_y / 2 \) by 0.5 to correct for the fact that the discrete statistic is being compared against a continuous distribution. Here, the \( U \) statistic used is less than the mean, so we reduce the distance by adding 0.5 in the numerator.

```python
>>> import numpy as np
>>> from scipy.stats import norm
>>> U = min(U1, U2)
>>> N = nx + ny
>>> z = (U - nx*ny/2 + 0.5) / np.sqrt(nx*ny * (N + 1)/12)
>>> p = 2 * norm.cdf(z) # use CDF to get p-value from smaller statistic
>>> print(p)
0.11134688653314041
```

If desired, we can disable the continuity correction to get a result that agrees with that reported in [4].

```python
>>> _, pnorm = mannwhitneyu(males, females, use_continuity=False, ... method="asymptotic")
>>> print(pnorm)
0.0864107329737
```

Regardless of whether we perform an exact or asymptotic test, the probability of the test statistic being as extreme or more extreme by chance exceeds 5\%, so we do not consider the results statistically significant.

Suppose that, before seeing the data, we had hypothesized that females would tend to be diagnosed at a younger age than males. In that case, it would be natural to provide the female ages as the first input, and we would have performed a one-sided test using \texttt{alternative = 'less'}: females are diagnosed at an age that is stochastically less than that of males.

```python
>>> res = mannwhitneyu(females, males, alternative="less", method="exact")
>>> print(res)
MannwhitneyuResult(statistic=3.0, pvalue=0.05555555555555555)
```

Again, the probability of getting a sufficiently low value of the test statistic by chance under the null hypothesis is greater than 5\%, so we do not reject the null hypothesis in favor of our alternative.

If it is reasonable to assume that the means of samples from the populations are normally distributed, we could have used a \( t \)-test to perform the analysis.

```python
>>> from scipy.stats import ttest_ind
>>> res = ttest_ind(females, males, alternative="less")
>>> print(res)
Ttest_indResult(statistic=-2.239334696520584, pvalue=0.030068441095757924)
```

Under this assumption, the \( p \)-value would be low enough to reject the null hypothesis in favor of the alternative.
scipy.stats.tiecorrect

```python
scipy.stats.tiecorrect(rankvals)
```

Tie correction factor for Mann-Whitney U and Kruskal-Wallis H tests.

**Parameters**

- **rankvals** [array_like] A 1-D sequence of ranks. Typically this will be the array returned by `rankdata`.

**Returns**

- **factor** [float] Correction factor for U or H.

**See also:**

- `rankdata`
  Assign ranks to the data

- `mannwhitneyu`
  Mann-Whitney rank test

- `kruskal`
  Kruskal-Wallis H test

**References**

[1]

**Examples**

```python
>>> from scipy.stats import tiecorrect, rankdata
>>> tiecorrect([1, 2.5, 2.5, 4])
0.9
>>> ranks = rankdata([1, 3, 2, 4, 5, 7, 2, 8, 4])
>>> ranks
array([1., 4., 2.5, 5.5, 7., 8., 2.5, 9., 5.5])
>>> tiecorrect(ranks)
0.9833333333333333
```

scipy.stats.rankdata

```python
scipy.stats.rankdata(a, method='average', *, axis=None)
```

Assign ranks to data, dealing with ties appropriately.

By default (axis=None), the data array is first flattened, and a flat array of ranks is returned. Separately reshape the rank array to the shape of the data array if desired (see Examples).

Ranks begin at 1. The method argument controls how ranks are assigned to equal values. See [1] for further discussion of ranking methods.

**Parameters**

- **a** [array_like] The array of values to be ranked.
- **method** [‘average’, ‘min’, ‘max’, ‘dense’, ‘ordinal’], optional The method used to assign ranks to tied elements. The following methods are available (default is ‘average’):
• ‘average’: The average of the ranks that would have been assigned to all the tied values is assigned to each value.
• ‘min’: The minimum of the ranks that would have been assigned to all the tied values is assigned to each value. (This is also referred to as “competition” ranking.)
• ‘max’: The maximum of the ranks that would have been assigned to all the tied values is assigned to each value.
• ‘dense’: Like ‘min’, but the rank of the next highest element is assigned the rank immediately after those assigned to the tied elements.
• ‘ordinal’: All values are given a distinct rank, corresponding to the order that the values occur in a.

axis \[\{None, \text{int}\}, \text{optional}\] Axis along which to perform the ranking. If None, the data array is first flattened.

Returns

ranks [ndarray] An array of size equal to the size of \(a\), containing rank scores.

References

[1]

Examples

```python
>>> from scipy.stats import rankdata
>>> rankdata([0, 2, 3, 2])
array([ 1., 2.5, 4., 2.5])
>>> rankdata([0, 2, 3, 2], method='min')
array([ 1, 2, 4, 2])
>>> rankdata([0, 2, 3, 2], method='max')
array([ 1, 3, 4, 3])
>>> rankdata([0, 2, 3, 2], method='dense')
array([ 1, 2, 3, 2])
>>> rankdata([0, 2, 3, 2], method='ordinal')
array([ 1, 2, 3, 4])
>>> rankdata([[0, 2], [3, 2]]).reshape(2,2)
array([[1., 2.5],
       [4., 2.5]])
>>> rankdata([[0, 2, 2], [3, 2, 5]], axis=1)
array([[ 1., 2.5, 2.5],
       [ 2., 1., 3.5]])
```

scipy.stats.ranksums

scipy.stats.ranksums(x, y, alternative='two-sided')

Compute the Wilcoxon rank-sum statistic for two samples.

The Wilcoxon rank-sum test tests the null hypothesis that two sets of measurements are drawn from the same distribution. The alternative hypothesis is that values in one sample are more likely to be larger than the values in the other sample.

This test should be used to compare two samples from continuous distributions. It does not handle ties between measurements in x and y. For tie-handling and an optional continuity correction see scipy.stats.mannwhitneyu.

Parameters
SciPy Reference Guide, Release 1.7.0

\[x, y\] [array_like] The data from the two samples.

**alternative**

[{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. Default is 'two-sided'. The following options are available:

- 'two-sided': one of the distributions (underlying \(x\) or \(y\)) is stochastically greater than the other.
- 'less': the distribution underlying \(x\) is stochastically less than the distribution underlying \(y\).
- 'greater': the distribution underlying \(x\) is stochastically greater than the distribution underlying \(y\).

New in version 1.7.0.

**Returns**

- **statistic** [float] The test statistic under the large-sample approximation that the rank sum statistic is normally distributed.
- **pvalue** [float] The p-value of the test.

**References**

[1]

**Examples**

We can test the hypothesis that two independent unequal-sized samples are drawn from the same distribution with computing the Wilcoxon rank-sum statistic.

```python
>>> from scipy.stats import ranksums
>>> rng = np.random.default_rng()
>>> sample1 = rng.uniform(-1, 1, 200)  # a shifted distribution
>>> sample2 = rng.uniform(-0.5, 1.5, 300)
>>> ranksums(sample1, sample2)
RanksumsResult(statistic=-7.887059, pvalue=3.09390448e-15)  # may vary
>>> ranksums(sample1, sample2, alternative='less')
RanksumsResult(statistic=-7.750585297581713, pvalue=4.573497606342543e-15)  # may vary
>>> ranksums(sample1, sample2, alternative='greater')
RanksumsResult(statistic=-7.750585297581713, pvalue=0.9999999999999954)  # may vary
```

The p-value of less than 0.05 indicates that this test rejects the hypothesis at the 5% significance level.

**scipy.stats.wilcoxon**

\[
\text{scipy.stats.wilcoxon}(x, y=None, zero_method='wilcox', correction=False, alternative='two-sided', mode='auto')
\]

Calculate the Wilcoxon signed-rank test.

The Wilcoxon signed-rank test tests the null hypothesis that two related paired samples come from the same distribution. In particular, it tests whether the distribution of the differences \(x - y\) is symmetric about zero. It is a non-parametric version of the paired T-test.

**Parameters**

- **x** [array_like] Either the first set of measurements (in which case \(y\) is the second set of measurements), or the differences between two sets of measurements (in which case \(y\) is not to be specified.) Must be one-dimensional.
y [array_like, optional] Either the second set of measurements (if $x$ is the first set of measurements), or not specified (if $x$ is the differences between two sets of measurements.) Must be one-dimensional.

zero_method ["pratt", "wilcox", "zsplit", optional] The following options are available (default is "wilcox"): • "pratt": Includes zero-differences in the ranking process, but drops the ranks of the zeros, see [4], (more conservative). • "wilcox": Discards all zero-differences, the default. • "zsplit": Includes zero-differences in the ranking process and split the zero rank between positive and negative ones.

correction [bool, optional] If True, apply continuity correction by adjusting the Wilcoxon rank statistic by 0.5 towards the mean value when computing the z-statistic if a normal approximation is used. Default is False.

alternative [{"two-sided", "greater", "less"}, optional] The alternative hypothesis to be tested, see Notes. Default is "two-sided".

mode [{"auto", "exact", "approx"}] Method to calculate the p-value, see Notes. Default is "auto".

Returns

statistic [float] If alternative is "two-sided", the sum of the ranks of the differences above or below zero, whichever is smaller. Otherwise the sum of the ranks of the differences above zero.

pvalue [float] The p-value for the test depending on alternative and mode.

See also:

kruskal, mannwhitneyu

Notes

The test has been introduced in [4]. Given $n$ independent samples $(x_i, y_i)$ from a bivariate distribution (i.e. paired samples), it computes the differences $d_i = x_i - y_i$. One assumption of the test is that the differences are symmetric, see [2]. The two-sided test has the null hypothesis that the median of the differences is zero against the alternative that it is different from zero. The one-sided test has the null hypothesis that the median is positive against the alternative that it is negative (alternative == 'less'), or vice versa (alternative == 'greater').

To derive the p-value, the exact distribution (mode == 'exact') can be used for sample sizes of up to 25. The default mode == 'auto' uses the exact distribution if there are at most 25 observations and no ties, otherwise a normal approximation is used (mode == 'approx').

The treatment of ties can be controlled by the parameter zero_method. If zero_method == 'pratt', the normal approximation is adjusted as in [5]. A typical rule is to require that $n > 20$ ([2], p. 383).
References

[1], [2], [3], [4], [5]

Examples

In [4], the differences in height between cross- and self-fertilized corn plants is given as follows:

```python
>>> d = [6, 8, 14, 16, 23, 24, 28, 29, 41, -48, 49, 56, 60, -67, 75]
```

Cross-fertilized plants appear to be higher. To test the null hypothesis that there is no height difference, we can apply the two-sided test:

```python
>>> from scipy.stats import wilcoxon
>>> w, p = wilcoxon(d)
>>> w, p
(24.0, 0.041259765625)
```

Hence, we would reject the null hypothesis at a confidence level of 5%, concluding that there is a difference in height between the groups. To confirm that the median of the differences can be assumed to be positive, we use:

```python
>>> w, p = wilcoxon(d, alternative='greater')
>>> w, p
(96.0, 0.0206298828125)
```

This shows that the null hypothesis that the median is negative can be rejected at a confidence level of 5% in favor of the alternative that the median is greater than zero. The p-values above are exact. Using the normal approximation gives very similar values:

```python
>>> w, p = wilcoxon(d, mode='approx')
>>> w, p
(24.0, 0.04088813291185591)
```

Note that the statistic changed to 96 in the one-sided case (the sum of ranks of positive differences) whereas it is 24 in the two-sided case (the minimum of sum of ranks above and below zero).

**scipy.stats.kruskal**

`scipy.stats.kruskal(*args, nan_policy='propagate')`

Compute the Kruskal-Wallis H-test for independent samples.

The Kruskal-Wallis H-test tests the null hypothesis that the population median of all of the groups are equal. It is a non-parametric version of ANOVA. The test works on 2 or more independent samples, which may have different sizes. Note that rejecting the null hypothesis does not indicate which of the groups differs. Post hoc comparisons between groups are required to determine which groups are different.

**Parameters**

- **sample1, sample2, ...** [array_like] Two or more arrays with the sample measurements can be given as arguments. Samples must be one-dimensional.

- **nan_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
  - 'propagate': returns nan
  - 'raise': throws an error
• ‘omit’: performs the calculations ignoring nan values

Returns

statistic  [float] The Kruskal-Wallis H statistic, corrected for ties.
pvalue  [float] The p-value for the test using the assumption that H has a chi square distribution. The p-value returned is the survival function of the chi square distribution evaluated at H.

See also:

f_oneway

1-way ANOVA.
mannwhitneyu

Mann-Whitney rank test on two samples.
friedmanchisquare

Friedman test for repeated measurements.

Notes

Due to the assumption that H has a chi square distribution, the number of samples in each group must not be too small. A typical rule is that each sample must have at least 5 measurements.

References

[1], [2]

Examples

```python
>>> from scipy import stats
>>> x = [1, 3, 5, 7, 9]
>>> y = [2, 4, 6, 8, 10]
>>> stats.kruskal(x, y)
KruskalResult(statistic=0.2727272727272734, pvalue=0.6015081344405895)

>>> x = [1, 1, 1]
>>> y = [2, 2, 2]
>>> z = [2, 2]
>>> stats.kruskal(x, y, z)
KruskalResult(statistic=7.0, pvalue=0.0301973834223185)
```

scipy.stats.friedmanchisquare

Compute the Friedman test for repeated measurements.

The Friedman test tests the null hypothesis that repeated measurements of the same individuals have the same distribution. It is often used to test for consistency among measurements obtained in different ways. For example, if two measurement techniques are used on the same set of individuals, the Friedman test can be used to determine if the two measurement techniques are consistent.

Parameters
measurements1, measurements2, measurements3…

[array_like] Arrays of measurements. All of the arrays must have the same number of elements. At least 3 sets of measurements must be given.

Returns

statistic [float] The test statistic, correcting for ties.
pvalue [float] The associated p-value assuming that the test statistic has a chi squared distribution.

Notes

Due to the assumption that the test statistic has a chi squared distribution, the p-value is only reliable for $n > 10$ and more than 6 repeated measurements.

References

[1]

scipy.stats.brunnermunzel

scipy.stats.brunnermunzel(x, y, alternative='two-sided', distribution='t', nan_policy='propagate')

Compute the Brunner-Munzel test on samples x and y.

The Brunner-Munzel test is a nonparametric test of the null hypothesis that when values are taken one by one from each group, the probabilities of getting large values in both groups are equal. Unlike the Wilcoxon-Mann-Whitney’s U test, this does not require the assumption of equivariance of two groups. Note that this does not assume the distributions are same. This test works on two independent samples, which may have different sizes.

Parameters

x, y [array_like] Array of samples, should be one-dimensional.

alternative [{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. The following options are available (default is 'two-sided'):

• 'two-sided'
• 'less': one-sided
• 'greater': one-sided

distribution [{'t', 'normal'}, optional] Defines how to get the p-value. The following options are available (default is 't'):

• 't': get the p-value by t-distribution
• 'normal': get the p-value by standard normal distribution.

nan_policy [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

• 'propagate': returns nan
• 'raise': throws an error
• 'omit': performs the calculations ignoring nan values

Returns

pvalue [float] p-value assuming an t distribution. One-sided or two-sided, depending on the choice of alternative and distribution.

See also:
mannwhitneyu

Mann-Whitney rank test on two samples.

Notes

Brunner and Munzel recommended to estimate the p-value by t-distribution when the size of data is 50 or less. If
the size is lower than 10, it would be better to use permuted Brunner Munzel test (see [2]).

References

[1], [2]

Examples

```python
>>> from scipy import stats
>>> x1 = [1, 2, 1, 1, 1, 1, 1, 1, 2, 4, 1]
>>> x2 = [3, 3, 4, 3, 1, 2, 3, 1, 1, 5, 4]
>>> w, p_value = stats.brunnermunzel(x1, x2)
>>> w
3.1374674823029505
>>> p_value
0.0057862086661515377
```

scipy.stats.combine_pvalues

`scipy.stats.combine_pvalues (pvalues, method='fisher', weights=None)`

Combine p-values from independent tests bearing upon the same hypothesis.

Parameters

- `pvalues` [array_like, 1-D] Array of p-values assumed to come from independent tests.
- `method` ['fisher', 'pearson', 'tippett', 'stouffer', 'mudholkar_george'], optional
  - Name of method to use to combine p-values. The following methods are available (default is 'fisher'):
    - 'fisher': Fisher's method (Fisher's combined probability test), the sum of the logarithm of the p-values
    - 'pearson': Pearson's method (similar to Fisher's but uses sum of the complement of the p-values inside the logarithms)
    - 'tippett': Tippett's method (minimum of p-values)
    - 'stouffer': Stouffer's Z-score method
    - 'mudholkar_george': the difference of Fisher's and Pearson's methods divided by 2
- `weights` [array_like, 1-D, optional] Optional array of weights used only for Stouffer's Z-score method.

Returns

- `statistic`: float
  - The statistic calculated by the specified method.
- `pval`: float
  - The combined p-value.
Notes

Fisher’s method (also known as Fisher’s combined probability test) [1] uses a chi-squared statistic to compute a combined p-value. The closely related Stouffer’s Z-score method [2] uses Z-scores rather than p-values. The advantage of Stouffer’s method is that it is straightforward to introduce weights, which can make Stouffer’s method more powerful than Fisher’s method when the p-values are from studies of different size [6] [7]. The Pearson’s method uses \( \log(1 - p_i) \) inside the sum whereas Fisher’s method uses \( \log(p_i) \) [4]. For Fisher’s and Pearson’s method, the sum of the logarithms is multiplied by -2 in the implementation. This quantity has a chi-square distribution that determines the p-value. The mudholkar_george method is the difference of the Fisher’s and Pearson’s test statistics, each of which include the -2 factor [4]. However, the mudholkar_george method does not include these -2 factors. The test statistic of mudholkar_george is the sum of logistic random variables and equation 3.6 in [3] is used to approximate the p-value based on Student’s t-distribution.

Fisher’s method may be extended to combine p-values from dependent tests [5]. Extensions such as Brown’s method and Kost’s method are not currently implemented.

New in version 0.15.0.

`scipy.stats.jarque_bera`

`scipy.stats.jarque_bera(x)`

Perform the Jarque-Bera goodness of fit test on sample data.

The Jarque-Bera test tests whether the sample data has the skewness and kurtosis matching a normal distribution.

Note that this test only works for a large enough number of data samples (>2000) as the test statistic asymptotically has a Chi-squared distribution with 2 degrees of freedom.

**Parameters**

- x: [array_like] Observations of a random variable.

**Returns**

- jb_value: [float] The test statistic.
- p: [float] The p-value for the hypothesis test.

References

[1]

Examples

```python
>>> from scipy import stats
>>> rng = np.random.default_rng()
>>> x = rng.normal(0, 1, 10000)
>>> jarque_bera_test = stats.jarque_bera(x)
>>> jarque_bera_test
Jarque_BeraResult(statistic=3.3415184718131554, pvalue=0.18810419594996775)
>>> jarque_bera_test.statistic
(continues on next page)```
>>> jarque_bera_test
0.18810419594996775

c scipy.stats.page_trend_test
scipy.stats.page_trend_test (data, ranked=False, predicted_ranks=None, method='auto')

Perform Page's Test, a measure of trend in observations between treatments.

Page's Test (also known as Page's $L$ test) is useful when:

- there are $n \geq 3$ treatments,
- $m \geq 2$ subjects are observed for each treatment, and
- the observations are hypothesized to have a particular order.

Specifically, the test considers the null hypothesis that

$$m_1 = m_2 = m_3 \cdots = m_n,$$

where $m_j$ is the mean of the observed quantity under treatment $j$, against the alternative hypothesis that

$$m_1 \leq m_2 \leq m_3 \leq \cdots \leq m_n,$$

where at least one inequality is strict.

As noted by [4], Page's $L$ test has greater statistical power than the Friedman test against the alternative that there is a difference in trend, as Friedman's test only considers a difference in the means of the observations without considering their order. Whereas Spearman $\rho$ considers the correlation between the ranked observations of two variables (e.g. the airspeed velocity of a swallow vs. the weight of the coconut it carries), Page's $L$ is concerned with a trend in an observation (e.g. the airspeed velocity of a swallow) across several distinct treatments (e.g. carrying each of five coconuts of different weight) even as the observation is repeated with multiple subjects (e.g. one European swallow and one African swallow).

**Parameters**

- **data** [array-like] A $m \times n$ array; the element in row $i$ and column $j$ is the observation corresponding with subject $i$ and treatment $j$. By default, the columns are assumed to be arranged in order of increasing predicted mean.

- **ranked** [boolean, optional] By default, data is assumed to be observations rather than ranks; it will be ranked with scipy.stats.rankdata along axis=1. If data is provided in the form of ranks, pass argument True.

- **predicted_ranks** [array-like, optional] The predicted ranks of the column means. If not specified, the columns are assumed to be arranged in order of increasing predicted mean, so the default predicted_ranks are $[1, 2, \ldots, n - 1, n]$.

- **method** [[‘auto’, ‘asymptotic’, ‘exact’], optional] Selects the method used to calculate the $p$-value. The following options are available.
  - ‘auto’: selects between ‘exact’ and ‘asymptotic’ to achieve reasonably accurate results in reasonable time (default)
  - ‘asymptotic’: compares the standardized test statistic against the normal distribution
  - ‘exact’: computes the exact $p$-value by comparing the observed $L$ statistic against those realized by all possible permutations of ranks (under the null hypothesis that each permutation is equally likely)

**Returns**
res [PageTrendTestResult] An object containing attributes:

statistic [float] Page’s $L$ test statistic.
pvalue [float] The associated $p$-value
method [{'asymptotic', 'exact'}] The method used to compute the $p$-value

rankdata, friedmanchisquare, spearman

Notes

As noted in [1], “the $n$ ‘treatments’ could just as well represent $n$ objects or events or performances or persons or trials ranked.” Similarly, the $m$ ‘subjects’ could equally stand for $m$ “groupings by ability or some other control variable, or judges doing the ranking, or random replications of some other sort.”

The procedure for calculating the $L$ statistic, adapted from [1], is:

1. “Predetermine with careful logic the appropriate hypotheses concerning the predicted ordering of the experimental results. If no reasonable basis for ordering any treatments is known, the $L$ test is not appropriate.”

2. “As in other experiments, determine at what level of confidence you will reject the null hypothesis that there is no agreement of experimental results with the monotonic hypothesis.”

3. “Cast the experimental material into a two-way table of $n$ columns (treatments, objects ranked, conditions) and $m$ rows (subjects, replication groups, levels of control variables).”

4. “When experimental observations are recorded, rank them across each row”, e.g. $\text{ranks} = \text{scipy.stats.rankdata(data, axis=1)}$.

5. “Add the ranks in each column”, e.g. $\text{colsums} = \text{np.sum(ranks, axis=0)}$.

6. “Multiply each sum of ranks by the predicted rank for that same column”, e.g. $\text{products} = \text{predicted_ranks} \times \text{colsums}$.

7. “Sum all such products”, e.g. $L = \text{products}.\text{sum}()$.

[1] continues by suggesting use of the standardized statistic

$$\chi^2_L = \frac{[12L - 3mn(n+1)^2]^2}{mn^2(n^2-1)(n+1)^2}$$

“which is distributed approximately as chi-square with 1 degree of freedom. The ordinary use of $\chi^2$ tables would be equivalent to a two-sided test of agreement. If a one-sided test is desired, as will almost always be the case, the probability discovered in the chi-square table should be halved.”

However, this standardized statistic does not distinguish between the observed values being well correlated with the predicted ranks and being _anti_-correlated with the predicted ranks. Instead, we follow [2] and calculate the standardized statistic

$$\Lambda = \frac{L - E_0}{\sqrt{V_0}},$$

where $E_0 = \frac{1}{4}mn(n+1)^2$ and $V_0 = \frac{1}{144}mn^2(n+1)(n^2-1)$, “which is asymptotically normal under the null hypothesis”.

The $p$-value for method='exact' is generated by comparing the observed value of $L$ against the $L$ values generated for all $(n!)^m$ possible permutations of ranks. The calculation is performed using the recursive method of [5].

The $p$-values are not adjusted for the possibility of ties. When ties are present, the reported 'exact' $p$-values may be somewhat larger (i.e. more conservative) than the true $p$-value [2]. The 'asymptotic' $p$-values, however, tend to be smaller (i.e. less conservative) than the 'exact' $p$-values.

[1], [2], [3], [4], [5]

Examples

We use the example from [3]: 10 students are asked to rate three teaching methods - tutorial, lecture, and seminar - on a scale of 1-5, with 1 being the lowest and 5 being the highest. We have decided that a confidence level of 99% is required to reject the null hypothesis in favor of our alternative: that the seminar will have the highest ratings and the tutorial will have the lowest. Initially, the data have been tabulated with each row representing an individual student’s ratings of the three methods in the following order: tutorial, lecture, seminar.

```python
>>> table = [[3, 4, 3],
          ...  [2, 2, 4],
          ...  [3, 3, 5],
          ...  [1, 3, 2],
          ...  [2, 3, 2],
          ...  [2, 4, 5],
          ...  [1, 2, 4],
          ...  [3, 4, 4],
          ...  [2, 4, 5],
          ...  [1, 3, 4]]
```

Because the tutorial is hypothesized to have the lowest ratings, the column corresponding with tutorial rankings should be first; the seminar is hypothesized to have the highest ratings, so its column should be last. Since the columns are already arranged in this order of increasing predicted mean, we can pass the table directly into `page_trend_test`.

```python
>>> from scipy.stats import page_trend_test
>>> res = page_trend_test(table)
>>> res
PageTrendTestResult(statistic=133.5, pvalue=0.0018191161948127822,
method='exact')
```

This p-value indicates that there is a 0.1819% chance that the L statistic would reach such an extreme value under the null hypothesis. Because 0.1819% is less than 1%, we have evidence to reject the null hypothesis in favor of our alternative at a 99% confidence level.

The value of the L statistic is 133.5. To check this manually, we rank the data such that high scores correspond with high ranks, settling ties with an average rank:

```python
>>> from scipy.stats import rankdata
>>> ranks = rankdata(table, axis=1)
>>> ranks
array([[ 1.5,  3. ,  1.5],
       [ 1.5,  1.5,  3. ],
       [ 1.5,  1.5,  3. ],
       [ 1. ,  3. ,  2. ],
       [ 1.5,  3. ,  1.5],
       [ 1. ,  2. ,  3. ],
       [ 1. ,  2. ,  3. ],
       [ 1. ,  2.5,  2.5],
       [ 1. ,  2. ,  3. ],
       [ 1. ,  2. ,  3. ]])
```
We add the ranks within each column, multiply the sums by the predicted ranks, and sum the products.

```python
>>> import numpy as np
>>> m, n = ranks.shape
>>> predicted_ranks = np.arange(1, n+1)
>>> L = (predicted_ranks * np.sum(ranks, axis=0)).sum()
>>> res.statistic == L
True
```

As presented in [3], the asymptotic approximation of the $p$-value is the survival function of the normal distribution evaluated at the standardized test statistic:

```python
>>> from scipy.stats import norm
>>> E0 = (m*n*(n+1)**2)/4
>>> V0 = (m*n**2*(n+1)*(n**2-1))/144
>>> Lambda = (L-E0)/np.sqrt(V0)
>>> p = norm.sf(Lambda)
>>> p
0.0012693433690751756
```

This does not precisely match the $p$-value reported by `page_trend_test` above. The asymptotic distribution is not very accurate, nor conservative, for $m \leq 12$ and $n \leq 8$, so `page_trend_test` chose to use `method='exact'` based on the dimensions of the table and the recommendations in Page’s original paper [1]. To override `page_trend_test`'s choice, provide the `method` argument.

```python
>>> res = page_trend_test(table, method="asymptotic")
>>> res
PageTrendTestResult(statistic=133.5, pvalue=0.0012693433690751756, method='asymptotic')
```

If the data are already ranked, we can pass in the `ranks` instead of the `table` to save computation time.

```python
>>> res = page_trend_test(ranks,                      # ranks of data
...                        ranked=True,                  # data is already ranked
...                        )
>>> res
PageTrendTestResult(statistic=133.5, pvalue=0.0018191161948127822, method='exact')
```

Suppose the raw data had been tabulated in an order different from the order of predicted means, say lecture, seminar, tutorial.

```python
>>> table = np.asarray(table)[:, [1, 2, 0]]
```

Since the arrangement of this table is not consistent with the assumed ordering, we can either rearrange the table or provide the `predicted_ranks`. Remembering that the lecture is predicted to have the middle rank, the seminar the highest, and tutorial the lowest, we pass:

```python
>>> res = page_trend_test(table,                        # data as originally tabulated
...                        predicted_ranks=[2, 3, 1],     # our predicted order
...                        )
>>> res
```

**scipy.stats.ansari**

Perform the Ansari-Bradley test for equal scale parameters.

The Ansari-Bradley test ([1], [2]) is a non-parametric test for the equality of the scale parameter of the distributions from which two samples were drawn. The null hypothesis states that the ratio of the scale of the distribution underlying x to the scale of the distribution underlying y is 1.

**Parameters**

- `x, y` [array_like] Arrays of sample data.
- `alternative` [{‘two-sided’, ‘less’, ‘greater’}, optional] Defines the alternative hypothesis. Default is ‘two-sided’. The following options are available:
  - ‘two-sided’: the ratio of scales is not equal to 1.
  - ‘less’: the ratio of scales is less than 1.
  - ‘greater’: the ratio of scales is greater than 1.

**Returns**

- `pvalue` [float] The p-value of the hypothesis test.

**See also:**

- `fligner` A non-parametric test for the equality of k variances
- `mood` A non-parametric test for the equality of two scale parameters

---

3.3. API definition
Notes

The p-value given is exact when the sample sizes are both less than 55 and there are no ties, otherwise a normal approximation for the p-value is used.

References

[1], [2], [3]

Examples

```python
>>> from scipy.stats import ansari
>>> rng = np.random.default_rng()
```

For these examples, we’ll create three random data sets. The first two, with sizes 35 and 25, are drawn from a normal distribution with mean 0 and standard deviation 2. The third data set has size 25 and is drawn from a normal distribution with standard deviation 1.25.

```python
>>> x1 = rng.normal(loc=0, scale=2, size=35)
>>> x2 = rng.normal(loc=0, scale=2, size=25)
>>> x3 = rng.normal(loc=0, scale=1.25, size=25)
```

First we apply `ansari` to `x1` and `x2`. These samples are drawn from the same distribution, so we expect the Ansari-Bradley test should not lead us to conclude that the scales of the distributions are different.

```python
>>> ansari(x1, x2)
AnsariResult(statistic=541.0, pvalue=0.9762532927399098)
```

With a p-value close to 1, we cannot conclude that there is a significant difference in the scales (as expected).

Now apply the test to `x1` and `x3`:

```python
>>> ansari(x1, x3)
AnsariResult(statistic=425.0, pvalue=0.0003087020407974518)
```

The probability of observing such an extreme value of the statistic under the null hypothesis of equal scales is only 0.03087%. We take this as evidence against the null hypothesis in favor of the alternative: the scales of the distributions from which the samples were drawn are not equal.

We can use the alternative parameter to perform a one-tailed test. In the above example, the scale of `x1` is greater than `x3` and so the ratio of scales of `x1` and `x3` is greater than 1. This means that the p-value when alternative='greater' should be near 0 and hence we should be able to reject the null hypothesis:

```python
>>> ansari(x1, x3, alternative='greater')
AnsariResult(statistic=425.0, pvalue=0.0001543510203987259)
```

As we can see, the p-value is indeed quite low. Use of alternative='less' should thus yield a large p-value:

```python
>>> ansari(x1, x3, alternative='less')
AnsariResult(statistic=425.0, pvalue=0.9998643258449039)
```
scipy.stats.bartlett

scipy.stats.bartlett(*args)

Perform Bartlett’s test for equal variances.

Bartlett’s test tests the null hypothesis that all input samples are from populations with equal variances. For samples from significantly non-normal populations, Levene’s test `levene` is more robust.

Parameters

sample1, sample2,...

[array_like] arrays of sample data. Only 1d arrays are accepted, they may have different lengths.

Returns

statistic [float] The test statistic.
pvalue [float] The p-value of the test.

See also:

fligner

A non-parametric test for the equality of k variances

levene

A robust parametric test for equality of k variances

Notes

Conover et al. (1981) examine many of the existing parametric and nonparametric tests by extensive simulations and they conclude that the tests proposed by Fligner and Killeen (1976) and Levene (1960) appear to be superior in terms of robustness of departures from normality and power ([3]).

References

[1], [2], [3], [4]

Examples

Test whether or not the lists $a$, $b$ and $c$ come from populations with equal variances.

```python
>>> from scipy.stats import bartlett
>>> a = [8.88, 9.12, 9.04, 8.98, 9.00, 9.08, 8.85, 9.06, 8.99]
>>> b = [8.88, 8.95, 9.29, 9.44, 9.15, 9.58, 8.36, 9.18, 8.67, 9.05]
>>> c = [8.95, 9.12, 8.95, 8.85, 9.03, 8.84, 9.07, 8.98, 8.86, 8.98]
>>> stat, p = bartlett(a, b, c)
```

The very small p-value suggests that the populations do not have equal variances.

This is not surprising, given that the sample variance of $b$ is much larger than that of $a$ and $c$:

```python
>>> [np.var(x, ddof=1) for x in [a, b, c]]
[0.007054444444444413, 0.13073888888888888, 0.00889000000000002]
```
**scipy.stats.levene**

`scipy.stats.levene(*args, center='median', proportiontocut=0.05)`

Perform Levene test for equal variances.

The Levene test tests the null hypothesis that all input samples are from populations with equal variances. Levene's test is an alternative to Bartlett's test `bartlett` in the case where there are significant deviations from normality.

**Parameters**

- `sample1, sample2, ...`  
  [array_like] The sample data, possibly with different lengths. Only one-dimensional samples are accepted.
- `center`  
  [{'mean', 'median', 'trimmed'}, optional] Which function of the data to use in the test. The default is 'median'.
- `proportiontocut`  
  [float, optional] When `center` is 'trimmed', this gives the proportion of data points to cut from each end. (See `scipy.stats.trim_mean`.) Default is 0.05.

**Returns**

- `statistic`  
  [float] The test statistic.
- `pvalue`  
  [float] The p-value for the test.

**Notes**

Three variations of Levene's test are possible. The possibilities and their recommended usages are:

- 'median': Recommended for skewed (non-normal) distributions
- 'mean': Recommended for symmetric, moderate-tailed distributions.
- 'trimmed': Recommended for heavy-tailed distributions.

The test version using the mean was proposed in the original article of Levene ([2]) while the median and trimmed mean have been studied by Brown and Forsythe ([3]), sometimes also referred to as Brown-Forsythe test.

**References**

[1], [2], [3]

**Examples**

Test whether or not the lists `a`, `b` and `c` come from populations with equal variances.

```python
>>> from scipy.stats import levene
>>> a = [8.88, 9.12, 9.04, 8.98, 9.00, 9.08, 8.85, 9.06, 8.99]
>>> b = [8.88, 8.95, 9.29, 9.44, 9.15, 9.58, 8.36, 9.18, 8.67, 9.05]
>>> c = [8.95, 9.12, 8.95, 8.85, 9.03, 8.84, 9.07, 8.98, 8.86, 8.98]
>>> stat, p = levene(a, b, c)
>>> p
0.002431505967249681
```

The small p-value suggests that the populations do not have equal variances.

This is not surprising, given that the sample variance of `b` is much larger than that of `a` and `c`:
```python
>>> [np.var(x, ddof=1) for x in [a, b, c]]
[0.007054444444444413, 0.13073888888888888, 0.008890000000000002]
```

**scipy.stats.shapiro**

`scipy.stats.shapiro(x)`

Perform the Shapiro-Wilk test for normality.

The Shapiro-Wilk test tests the null hypothesis that the data was drawn from a normal distribution.

**Parameters**

- `x` : [array_like] Array of sample data.

**Returns**

- `statistic` : [float] The test statistic.
- `p-value` : [float] The p-value for the hypothesis test.

**See also:**

- `anderson` : The Anderson-Darling test for normality
- `kstest` : The Kolmogorov-Smirnov test for goodness of fit.

**Notes**

The algorithm used is described in [4] but censoring parameters as described are not implemented. For N > 5000 the W test statistic is accurate but the p-value may not be.

The chance of rejecting the null hypothesis when it is true is close to 5% regardless of sample size.

**References**

[1], [2], [3], [4]

**Examples**

```python
>>> from scipy import stats
>>> rng = np.random.default_rng()
>>> x = stats.norm.rvs(loc=5, scale=3, size=100, random_state=rng)
>>> shapiro_test = stats.shapiro(x)
>>> shapiro_test
ShapiroResult(statistic=0.9813305735588074, pvalue=0.16855233907699585)
>>> shapiro_test.statistic
0.9813305735588074
>>> shapiro_test.pvalue
0.16855233907699585
```
Anderson-Darling test for data coming from a particular distribution.

The Anderson-Darling test tests the null hypothesis that a sample is drawn from a population that follows a particular distribution. For the Anderson-Darling test, the critical values depend on which distribution is being tested against. This function works for normal, exponential, logistic, or Gumbel (Extreme Value Type I) distributions.

Parameters

- `x` (array_like) Array of sample data.
- `dist` ([{'norm', 'expon', 'logistic', 'gumbel', 'gumbel_l', 'gumbel_r', 'extreme1'}, optional]) The type of distribution to test against. The default is 'norm'. The names 'extreme1', 'gumbel_l' and 'gumbel' are synonyms for the same distribution.

Returns

- `statistic` (float) The Anderson-Darling test statistic.
- `critical_values` (list) The critical values for this distribution.
- `significance_level` (list) The significance levels for the corresponding critical values in percents. The function returns critical values for a differing set of significance levels depending on the distribution that is being tested against.

See also:

- `kstest` The Kolmogorov-Smirnov test for goodness-of-fit.

Notes

Critical values provided are for the following significance levels:

- **normal/exponential**
  - 15%, 10%, 5%, 2.5%, 1%

- **logistic**
  - 25%, 10%, 5%, 2.5%, 1%, 0.5%

- **Gumbel**
  - 25%, 10%, 5%, 2.5%, 1%

If the returned statistic is larger than these critical values then for the corresponding significance level, the null hypothesis that the data come from the chosen distribution can be rejected. The returned statistic is referred to as ‘A2’ in the references.
scipy.stats.anderson_ksamp

scipy.stats.anderson_ksamp(samples, midrank=True)

The k-sample Anderson-Darling test for k-samples.

The k-sample Anderson-Darling test is a modification of the one-sample Anderson-Darling test. It tests the null hypothesis that k-samples are drawn from the same population without having to specify the distribution function of that population. The critical values depend on the number of samples.

Parameters

- samples [sequence of 1-D array_like] Array of sample data in arrays.
- midrank [bool, optional] Type of Anderson-Darling test which is computed. Default (True) is the midrank test applicable to continuous and discrete populations. If False, the right side empirical distribution is used.

Returns

- statistic [float] Normalized k-sample Anderson-Darling test statistic.
- critical_values [array] The critical values for significance levels 25%, 10%, 5%, 2.5%, 1%, 0.5%, 0.1%.
- significance_level [float] An approximate significance level at which the null hypothesis for the provided samples can be rejected. The value is floored / capped at 0.1% / 25%.

Raises

- ValueError
  If less than 2 samples are provided, a sample is empty, or no distinct observations are in the samples.

See also:

- ks_2samp
  2 sample Kolmogorov-Smirnov test

  1 sample Anderson-Darling test

Notes

[1] defines three versions of the k-sample Anderson-Darling test: one for continuous distributions and two for discrete distributions, in which ties between samples may occur. The default of this routine is to compute the version based on the midrank empirical distribution function. This test is applicable to continuous and discrete data. If midrank is set to False, the right side empirical distribution is used for a test for discrete data. According to [1], the two discrete test statistics differ only slightly if a few collisions due to round-off errors occur in the test not adjusted for ties between samples.

The critical values corresponding to the significance levels from 0.01 to 0.25 are taken from [1]. p-values are floored / capped at 0.1% / 25%. Since the range of critical values might be extended in future releases, it is recommended not to test p == 0.25, but rather p >= 0.25 (analogously for the lower bound).

New in version 0.14.0.
Examples

```python
>>> from scipy import stats
>>> rng = np.random.default_rng()

The null hypothesis that the two random samples come from the same distribution can be rejected at the 5% level because the returned test value is greater than the critical value for 5% (1.961) but not at the 2.5% level. The interpolation gives an approximate significance level of 3.2%:

```python
>>> stats.anderson_ksamp([rng.normal(size=50),
...                         rng.normal(loc=0.5, size=30)])
(1.974403288713695,
 array([0.325, 1.226, 1.961, 2.718, 3.752, 4.592, 6.546]),
 0.04991293614572478)
```

The null hypothesis cannot be rejected for three samples from an identical distribution. The reported p-value (25%) has been capped and may not be very accurate (since it corresponds to the value 0.449 whereas the statistic is -0.731):

```python
>>> stats.anderson_ksamp([rng.normal(size=50),
...                         rng.normal(size=30), rng.normal(size=20)])
(-0.29103725200789504,
 array([ 0.44925884, 1.3052767 , 1.9434184 , 2.57696569, 3.41634856,
          4.07210043, 5.56419101]),
 0.25)
```

`scipy.stats.binom_test`

`scipy.stats.binom_test(x, n=None, p=0.5, alternative='two-sided')`

Perform a test that the probability of success is p.

Note: `binom_test` is deprecated; it is recommended that `binomtest` be used instead.

This is an exact, two-sided test of the null hypothesis that the probability of success in a Bernoulli experiment is p.

**Parameters**

- **x**
  [int or array_like] The number of successes, or if x has length 2, it is the number of successes and the number of failures.

- **n**
  [int] The number of trials. This is ignored if x gives both the number of successes and failures.

- **p**
  [float, optional] The hypothesized probability of success. 0 <= p <= 1. The default value is p = 0.5.

- **alternative**
  [{'two-sided', 'greater', 'less'}, optional] Indicates the alternative hypothesis. The default value is 'two-sided'.

**Returns**

- **p-value**
  [float] The p-value of the hypothesis test.
References

[1]

Examples

```python
>>> from scipy import stats

A car manufacturer claims that no more than 10% of their cars are unsafe. 15 cars are inspected for safety, 3 were found to be unsafe. Test the manufacturer’s claim:

```python
>>> stats.binom_test(3, n=15, p=0.1, alternative='greater')
0.18406106910639114
``` 

The null hypothesis cannot be rejected at the 5% level of significance because the returned p-value is greater than the critical value of 5%.

`scipy.stats.binomtest`

`scipy.stats.binomtest(k, n, p=0.5, alternative='two-sided')`

Perform a test that the probability of success is $p$.

The binomial test [1] is a test of the null hypothesis that the probability of success in a Bernoulli experiment is $p$.

Details of the test can be found in many texts on statistics, such as section 24.5 of [2].

**Parameters**

- **k** [int] The number of successes.
- **n** [int] The number of trials.
- **p** [float, optional] The hypothesized probability of success, i.e. the expected proportion of successes. The value must be in the interval $0 \leq p \leq 1$. The default value is $p = 0.5$.
- **alternative** [{’two-sided’, ‘greater’, ‘less’}, optional] Indicates the alternative hypothesis. The default value is ‘two-sided’.

**Returns**

- **result** [BinomTestResult instance] The return value is an object with the following attributes:
  - **k** [int] The number of successes (copied from `binomtest` input).
  - **n** [int] The number of trials (copied from `binomtest` input).
  - **alternative** [str] Indicates the alternative hypothesis specified in the input to `binomtest`. It will be one of ‘two-sided’, ‘greater’, or ‘less’.
  - **pvalue** [float] The p-value of the hypothesis test.
  - **proportion_estimate** [float] The estimate of the proportion of successes.

The object has the following methods:

- **proportion_ci** *confidenced_level=0.95, method=’exact’*:
  Compute the confidence interval for `proportion_estimate`.
Notes

New in version 1.7.0.

References

[1], [2]

Examples

```python
>>> from scipy.stats import binomtest

A car manufacturer claims that no more than 10% of their cars are unsafe. 15 cars are inspected for safety, 3 were found to be unsafe. Test the manufacturer’s claim:

```python
classified result = binomtest(3, n=15, p=0.1, alternative='greater')
classified result.pvalue
0.18406106910639114
```  
The null hypothesis cannot be rejected at the 5% level of significance because the returned p-value is greater than the critical value of 5%.

The estimated proportion is simply 3/15:

```python
classified result.proportion_estimate
0.2
```  
We can use the `proportion_ci()` method of the result to compute the confidence interval of the estimate:

```python
classified result.proportion_ci(confidence_level=0.95)
ConfidenceInterval(low=0.05684686759024681, high=0.4032248191719589)
```  

`scipy.stats.fligner`

`scipy.stats.fligner(*args, center='median', proportiontocut=0.05)`

Perform Fligner-Killeen test for equality of variance.

Fligner’s test tests the null hypothesis that all input samples are from populations with equal variances. Fligner-Killeen’s test is distribution free when populations are identical [2].

**Parameters**

- `sample1, sample2, ...` [array_like] Arrays of sample data. Need not be the same length.
- `center` ['mean', 'median', 'trimmed'], optional] Keyword argument controlling which function of the data is used in computing the test statistic. The default is ‘median’.
- `proportiontocut` [float, optional] When `center` is ‘trimmed’, this gives the proportion of data points to cut from each end. (See `scipy.stats.trim_mean`) Default is 0.05.

**Returns**

- `statistic` [float] The test statistic.
- `pvalue` [float] The p-value for the hypothesis test.

See also:
**Bartlett**

A parametric test for equality of k variances in normal samples

**Levene**

A robust parametric test for equality of k variances

**Notes**

As with Levene's test there are three variants of Fligner's test that differ by the measure of central tendency used in the test. See `levene` for more information.

Conover et al. (1981) examine many of the existing parametric and nonparametric tests by extensive simulations and they conclude that the tests proposed by Fligner and Killeen (1976) and Levene (1960) appear to be superior in terms of robustness of departures from normality and power [3].

**References**

[1], [2], [3], [4]

**Examples**

Test whether or not the lists `a`, `b` and `c` come from populations with equal variances.

```python
>>> from scipy.stats import fligner
>>> a = [8.88, 9.12, 9.04, 8.98, 9.00, 9.01, 8.85, 9.06, 8.99]
>>> b = [8.88, 8.95, 9.29, 9.44, 9.15, 9.58, 8.36, 9.18, 8.67, 9.05]
>>> c = [8.95, 9.12, 8.95, 8.85, 9.03, 8.84, 9.07, 8.98, 8.86, 8.98]
>>> stat, p = fligner(a, b, c)
>>> p
0.00450826080004775
```

The small p-value suggests that the populations do not have equal variances.

This is not surprising, given that the sample variance of `b` is much larger than that of `a` and `c`:

```python
>>> [np.var(x, ddof=1) for x in a, b, c]
[0.007054444444444413, 0.13073888888888888, 0.008890000000000002]
```

**scipy.stats.median_test**

*scipy.stats.median_test*(args, ties='below', correction=True, lambda_=1, nan_policy='propagate')

Perform a Mood's median test.

Test that two or more samples come from populations with the same median.

Let `n` = `len(args)` be the number of samples. The “grand median” of all the data is computed, and a contingency table is formed by classifying the values in each sample as being above or below the grand median. The contingency table, along with `correction` and `lambda_`, are passed to `scipy.stats.chi2_contingency` to compute the test statistic and p-value.

**Parameters**
sample1, sample2, …
[array_like] The set of samples. There must be at least two samples. Each sample must be a one-dimensional sequence containing at least one value. The samples are not required to have the same length.

ties
[str, optional] Determines how values equal to the grand median are classified in the contingency table. The string must be one of:

- "below": Values equal to the grand median are counted as "below"
- "above": Values equal to the grand median are counted as "above"
- "ignore": Values equal to the grand median are not counted.

The default is "below".

correction [bool, optional] If True, and there are just two samples, apply Yates’ correction for continuity when computing the test statistic associated with the contingency table. Default is True.

lambda_ [float or str, optional] By default, the statistic computed in this test is Pearson’s chi-squared statistic. lambda_ allows a statistic from the Cressie-Read power divergence family to be used instead. See power_divergence for details. Default is 1 (Pearson’s chi-squared statistic).

Returns

- [float] The test statistic. The statistic that is returned is determined by lambda_. The default is Pearson’s chi-squared statistic.
- [float] The p-value of the test.
- [float] The grand median.
- [ndarray] The contingency table. The shape of the table is (2, n), where n is the number of samples. The first row holds the counts of the values above the grand median, and the second row holds the counts of the values below the grand median. The table allows further analysis with, for example, scipy.stats.chi2_contingency, or with scipy.stats.fisher_exact if there are two samples, without having to recompute the table. If nan_policy is "propagate" and there are nans in the input, the return value for table is None.

[1], [2]

Examples

A biologist runs an experiment in which there are three groups of plants. Group 1 has 16 plants, group 2 has 15 plants, and group 3 has 17 plants. Each plant produces a number of seeds. The seed counts for each group are:

| Group 1: 10 14 14 18 20 22 24 25 31 31 32 39 43 43 48 49 |
| Group 2: 28 30 31 33 34 35 36 40 44 55 57 61 91 92 99 |
| Group 3:  0  3  9 22 23 25 33 34 40 45 46 48 62 67 84 |

The following code applies Mood's median test to these samples.

```python
>>> g1 = [10, 14, 14, 18, 20, 22, 24, 25, 31, 31, 32, 39, 43, 43, 48, 49]
>>> g2 = [28, 30, 31, 33, 34, 35, 36, 40, 44, 55, 57, 61, 91, 92, 99]
>>> g3 = [0, 3, 9, 22, 23, 25, 33, 34, 40, 45, 46, 48, 62, 67, 84]
>>> from scipy.stats import median_test
>>> stat, p, med, tbl = median_test(g1, g2, g3)
```

The median is

```python
>>> med
34.0
```

and the contingency table is

```python
>>> tbl
array([[ 5,  8,  7],
       [11,  5, 10]])
```

$p$ is too large to conclude that the medians are not the same:

```python
>>> p
0.12609082774093244
```

The “G-test” can be performed by passing `lambda_="log-likelihood"` to `median_test`.

```python
>>> g, p, med, tbl = median_test(g1, g2, g3, lambda_="log-likelihood")
>>> p
0.12224779737117837
```

The median occurs several times in the data, so we'll get a different result if, for example, `ties="above"` is used:

```python
>>> stat, p, med, tbl = median_test(g1, g2, g3, ties="above")
>>> p
0.06387327606955327
```
This example demonstrates that if the data set is not large and there are values equal to the median, the p-value can be sensitive to the choice of ties.

```python
>>> tbl
array([[ 5, 11,  9],
       [11,  4,  8]])
```

Mood’s two-sample test for scale parameters is a non-parametric test for the null hypothesis that two samples are drawn from the same distribution with the same scale parameter.

**Parameters**

- `x, y` [array_like] Arrays of sample data.
- `axis` [int, optional] The axis along which the samples are tested. `x` and `y` can be of different length along `axis`. If `axis` is None, `x` and `y` are flattened and the test is done on all values in the flattened arrays.
- `alternative` [{‘two-sided’, ‘less’, ‘greater’}, optional] Defines the alternative hypothesis. Default is ‘two-sided’. The following options are available:
  - ‘two-sided’: the scales of the distributions underlying `x` and `y` are different.
  - ‘less’: the scale of the distribution underlying `x` is less than the scale of the distribution underlying `y`.
  - ‘greater’: the scale of the distribution underlying `x` is greater than the scale of the distribution underlying `y`.

New in version 1.7.0.

**Returns**

- `z` [scalar or ndarray] The z-score for the hypothesis test. For 1-D inputs a scalar is returned.
- `p-value` [scalar or ndarray] The p-value for the hypothesis test.

See also:

- `fligner` A non-parametric test for the equality of k variances
- `ansari` A non-parametric test for the equality of 2 variances
- `bartlett` A parametric test for equality of k variances in normal samples
- `levene` A parametric test for equality of k variances
Notes

The data are assumed to be drawn from probability distributions \( f(x) \) and \( f(x/s) / s \) respectively, for some probability density function \( f \). The null hypothesis is that \( s == 1 \).

For multi-dimensional arrays, if the inputs are of shapes \((n_0, n_1, n_2, n_3)\) and \((n_0, m_1, n_2, n_3)\), then if \(axis=1\), the resulting \(z\) and \(p\) values will have shape \((n_0, n_2, n_3)\). Note that \(n_1\) and \(m_1\) don't have to be equal, but the other dimensions do.

Examples

```python
>>> from scipy import stats
>>> rng = np.random.default_rng()
>>> x2 = rng.standard_normal((2, 45, 6, 7))
>>> x1 = rng.standard_normal((2, 30, 6, 7))
>>> z, p = stats.mood(x1, x2, axis=1)
>>> p.shape
(2, 6, 7)

Find the number of points where the difference in scale is not significant:
```n
```python
>>> (p > 0.1).sum()
78
```n

Perform the test with different scales:
```python
>>> x1 = rng.standard_normal((2, 30))
>>> x2 = rng.standard_normal((2, 35)) * 10.0
>>> stats.mood(x1, x2, axis=1)
(array([-5.76174136, -6.12650783]), array([8.32505043e-09, 8.98287869e-10]))
```

`scipy.stats.skewtest`

`scipy.stats.skewtest(a, axis=0, nan_policy='propagate', alternative='two-sided')`

Test whether the skew is different from the normal distribution.

This function tests the null hypothesis that the skewness of the population that the sample was drawn from is the same as that of a corresponding normal distribution.

Parameters

- \(a\) [array] The data to be tested.
- \(axis\) [int or None, optional] Axis along which statistics are calculated. Default is 0. If None, compute over the whole array \(a\).
- \(nan\_policy\) [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
  - ‘propagate’: returns nan
  - ‘raise’: throws an error
  - ‘omit’: performs the calculations ignoring nan values
- \(alternative\) [{‘two-sided’, ‘less’, ‘greater’}, optional] Defines the alternative hypothesis. Default is ‘two-sided’. The following options are available:
• ‘two-sided’: the skewness of the distribution underlying the sample is different from that of the normal distribution (i.e. 0)
• ‘less’: the skewness of the distribution underlying the sample is less than that of the normal distribution
• ‘greater’: the skewness of the distribution underlying the sample is greater than that of the normal distribution
New in version 1.7.0.

Returns

- statistic [float] The computed z-score for this test.
- pvalue [float] The p-value for the hypothesis test.

Notes
The sample size must be at least 8.

Examples

```python
>>> from scipy.stats import skewtest
>>> skewtest([1, 2, 3, 4, 5, 6, 7, 8])
SkewtestResult(statistic=1.0108048609177787, pvalue=0.3121098361421897)
>>> skewtest([2, 8, 0, 4, 1, 9, 9, 0])
SkewtestResult(statistic=0.44626385374196975, pvalue=0.6554066631275459)
>>> skewtest([1, 2, 3, 5, 6, 7, 8000])
SkewtestResult(statistic=3.571773510360407, pvalue=0.00354571990582313)
>>> skewtest([100, 100, 100, 100, 100, 100, 101])
SkewtestResult(statistic=3.571776638478072, pvalue=0.00354567720281634)
>>> skewtest([1, 2, 3, 4, 5, 6, 7, 8], alternative='less')
SkewtestResult(statistic=1.0108048609177787, pvalue=0.15605491807109484)
>>> skewtest([1, 2, 3, 4, 5, 6, 7, 8], alternative='greater')
SkewtestResult(statistic=1.0108048609177787, pvalue=0.8439450819289052)
```

scipy.stats.kurtosistest

scipy.stats.kurtosistest(a, axis=0, nan_policy='propagate', alternative='two-sided')

Test whether a dataset has normal kurtosis.

This function tests the null hypothesis that the kurtosis of the population from which the sample was drawn is that of the normal distribution.

Parameters

- a [array] Array of the sample data.
- axis [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array a.
- nan_policy [{`propagate`, `raise`, `omit`}, optional] Defines how to handle when input contains nan. The following options are available (default is `propagate`):
  - `propagate`: returns nan
• `raise`: throws an error
• `omit`: performs the calculations ignoring nan values

**alternative**

[{‘two-sided’, ‘less’, ‘greater’}, optional] Defines the alternative hypothesis. The following options are available (default is ‘two-sided’):
• ‘two-sided’: the kurtosis of the distribution underlying the sample is different from that of the normal distribution
• ‘less’: the kurtosis of the distribution underlying the sample is less than that of the normal distribution
• ‘greater’: the kurtosis of the distribution underlying the sample is greater than that of the normal distribution
New in version 1.7.0.

**Returns**

- **statistic** [float] The computed z-score for this test.
- **pvalue** [float] The p-value for the hypothesis test.

**Notes**

Valid only for n>20. This function uses the method described in [1].

**References**

[1]

**Examples**

```python
>>> from scipy.stats import kurtosistest
>>> kurtosistest(list(range(20)))
KurtosistestResult(statistic=-1.7058104152122062, pvalue=0.98088338332528348)
>>> kurtosistest(list(range(20)), alternative='less')
KurtosistestResult(statistic=-1.7058104152122062, pvalue=0.04402169166264174)
>>> kurtosistest(list(range(20)), alternative='greater')
KurtosistestResult(statistic=-1.7058104152122062, pvalue=0.9559783083373583)
```

```python
>>> rng = np.random.default_rng()
>>> s = rng.normal(0, 1, 1000)
>>> kurtosistest(s)
KurtosistestResult(statistic=-1.475047944490622, pvalue=0.14019965402996987)
```
**scipy.stats.normaltest**

`scipy.stats.normaltest(a, axis=0, nan_policy='propagate')`

Test whether a sample differs from a normal distribution.

This function tests the null hypothesis that a sample comes from a normal distribution. It is based on D'Agostino and Pearson's [1], [2] test that combines skew and kurtosis to produce an omnibus test of normality.

**Parameters**

- `a` : array_like
  The array containing the sample to be tested.
- `axis` : int or None, optional
  Axis along which to compute test. Default is 0. If None, compute over the whole array `a`.
- `nan_policy` : {'propagate', 'raise', 'omit'}, optional
  Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
  - 'propagate': returns nan
  - 'raise': throws an error
  - 'omit': performs the calculations ignoring nan values

**Returns**

- `statistic` : float or array
  \[s^2 + k^2\], where \(s\) is the z-score returned by `skewtest` and \(k\) is the z-score returned by `kurtosistest`.
- `pvalue` : float or array
  A 2-sided chi squared probability for the hypothesis test.

**References**

[1], [2]

**Examples**

```python
>>> from scipy import stats
cd1 = np.random.default_rng()
cd1 = 1000
cd2 = cd1.normal(0, 1, size=cd1)
cd3 = cd1.normal(2, 1, size=cd1)
cd = np.concatenate((cd1, cd2))
cd, p = stats.normaltest(cd)
cd = 1e-3
>>> print("p = {:.g}".format(p))
p = 8.4713e-19
>>> if p < alpha: # null hypothesis: x comes from a normal distribution
...   print("The null hypothesis can be rejected")
... else:
...   print("The null hypothesis cannot be rejected")
The null hypothesis can be rejected
```
Quasi-Monte Carlo

Quasi-Monte Carlo submodule (**scipy.stats.qmc**)  
This module provides Quasi-Monte Carlo generators and associated helper functions.

**Engines**

**scipy.stats.qmc.QMCEngine**

**class scipy.stats.qmc.QMCEngine** (d, *, seed=None)  
A generic Quasi-Monte Carlo sampler class meant for subclassing.

QMCEngine is a base class to construct a specific Quasi-Monte Carlo sampler. It cannot be used directly as a sampler.

**Parameters**

- **d** [int] Dimension of the parameter space.
- **seed** [{None, int, numpy.random.Generator}, optional] If seed is None the numpy.random.Generator singleton is used. If seed is an int, a new Generator instance is used, seeded with seed. If seed is already a Generator instance then that instance is used.

**Notes**

By convention samples are distributed over the half-open interval $[0, 1)$. Instances of the class can access the attributes: d for the dimension; and rng for the random number generator (used for the seed).

**Subclassing**

When subclassing **QMCEngine** to create a new sampler, **__init__** and random must be redefined.

- **__init__(d, seed=None)**: at least fix the dimension. If the sampler does not take advantage of a seed (deterministic methods like Halton), this parameter can be omitted.
- **random(n)**: draw $n$ from the engine and increase the counter num_generated by $n$.

Optionally, two other methods can be overwritten by subclasses:

- **reset**: Reset the engine to its original state.
- **fast_forward**: If the sequence is deterministic (like Halton sequence), then fast_forward($n$) is skipping the $n$ first draw.
Examples

To create a random sampler based on `np.random.random`, we would do the following:

```python
>>> from scipy.stats import qmc
>>> class RandomEngine(qmc.QMCEngine):
...     def __init__(self, d, seed=None):
...         super().__init__(d=d, seed=seed)
...     def random(self, n=1):
...         self.num_generated += n
...         return self.rng.random((n, self.d))
...     def reset(self):
...         super().__init__(d=self.d, seed=self.rng_seed)
...         return self
...     def fast_forward(self, n):
...         self.random(n)
...         return self
```

After subclassing `QMCEngine` to define the sampling strategy we want to use, we can create an instance to sample from.

```python
>>> engine = RandomEngine(2)
>>> engine.random(5)
array([[0.22733602, 0.31675834],  # random
       [0.79736546, 0.67625467],
       [0.39110955, 0.33281393],
       [0.59830875, 0.18673419],
       [0.67275604, 0.94180287]])
```

We can also reset the state of the generator and resample again.

```python
>>> _ = engine.reset()
>>> engine.random(5)
array([[0.22733602, 0.31675834],  # random
       [0.79736546, 0.67625467],
       [0.39110955, 0.33281393],
       [0.59830875, 0.18673419],
       [0.67275604, 0.94180287]])
```

scipy.stats.qmc.QMCEngine.fast_forward

QMEngine.fast_forward \((n)\)

Fast-forward the sequence by \( n \) positions.

Parameters

- \( n \) [int] Number of points to skip in the sequence.

Returns

- engine [QMCEngine] Engine reset to its base state.

scipy.stats.qmc.QMCEngine.random

abstract QMEngine.random \((n=1)\)

Draw \( n \) in the half-open interval \([0, 1)\).

Parameters

- \( n \) [int, optional] Number of samples to generate in the parameter space. Default is 1.

Returns

- sample [array_like (n, d)] QMC sample.

scipy.stats.qmc.QMCEngine.reset

QMEngine.reset()

Reset the engine to base state.

Returns

- engine [QMCEngine] Engine reset to its base state.

scipy.stats.qmc.Sobol

class scipy.stats.qmc.Sobol \((d, *, scramble=True, seed=None)\)

Engine for generating (scrambled) Sobol’ sequences.

Sobol’ sequences are low-discrepancy, quasi-random numbers. Points can be drawn using two methods:

- \( \text{random}_{\text{base}2} \): safely draw \( n = 2^m \) points. This method guarantees the balance properties of the sequence.
- \( \text{random} \): draw an arbitrary number of points from the sequence. See warning below.

Parameters
SciPy Reference Guide, Release 1.7.0

d [int] Dimensionality of the sequence. Max dimensionality is 21201.
scramble [bool, optional] If True, use Owen scrambling. Otherwise no scrambling is done. Default is True.
seed [{None, int, numpy.random.Generator}, optional] If seed is None the numpy.random.Generator singleton is used. If seed is an int, a new Generator instance is used, seeded with seed. If seed is already a Generator instance then that instance is used.

Notes

Sobol’ sequences [1] provide \( n = 2^m \) low discrepancy points in \([0, 1)^d\). Scrambling them [2] makes them suitable for singular integrands, provides a means of error estimation, and can improve their rate of convergence.

There are many versions of Sobol’ sequences depending on their ‘direction numbers’. This code uses direction numbers from [3]. Hence, the maximum number of dimension is 21201. The direction numbers have been pre-computed with search criterion 6 and can be retrieved at https://web.maths.unsw.edu.au/~fkuo/sobol/.

**Warning:** Sobol’ sequences are a quadrature rule and they lose their balance properties if one uses a sample size that is not a power of 2, or skips the first point, or thins the sequence [4].

If \( n = 2^m \) points are not enough then one should take \( 2^M \) points for \( M > m \). When scrambling, the number R of independent replicates does not have to be a power of 2.

Sobol’ sequences are generated to some number \( B \) of bits. After \( 2^B \) points have been generated, the sequence will repeat. Currently \( B = 30 \).

References

[1], [2], [3], [4]

Examples

Generate samples from a low discrepancy sequence of Sobol’.

```python
>>> from scipy.stats import qmc
>>> sampler = qmc.Sobol(d=2, scramble=False)
>>> sample = sampler.random_base2(m=3)
>>> sample
array([[0. , 0. ],
       [0.5 , 0.5 ],
       [0.75, 0.25 ],
       [0.25 , 0.75 ],
       [0.375, 0.375],
       [0.875, 0.875],
       [0.625, 0.125],
       [0.125, 0.625]])
```

Compute the quality of the sample using the discrepancy criterion.

```python
>>> qmc.discrepancy(sample)
0.013882107204860938
```
To continue an existing design, extra points can be obtained by calling again `random_base2`. Alternatively, you can skip some points like:

```python
>>> _ = sampler.reset()
>>> _ = sampler.fast_forward(4)
>>> sample_continued = sampler.random_base2(m=2)
>>> sample_continued
array([[0.375, 0.375],
       [0.875, 0.875],
       [0.625, 0.125],
       [0.125, 0.625]])
```

Finally, samples can be scaled to bounds.

```python
>>> l_bounds = [0, 2]
>>> u_bounds = [10, 5]
>>> qmc.scale(sample_continued, l_bounds, u_bounds)
array([[3.75 , 3.125],
       [8.75 , 4.625],
       [6.25 , 2.375],
       [1.25 , 3.875]])
```

#### scipy.stats.qmc.Sobol.fast_forward

`Sobol.fast_forward(n)`

Fast-forward the sequence by n positions.

**Parameters**

- **n** (int): Number of points to skip in the sequence.

**Returns**

- **engine**: `Sobol`
  The fast-forwarded engine.
scipy.stats.qmc.Sobol.random

Sobol.random(n=1)
Draw next point(s) in the Sobol' sequence.

Parameters
n [int, optional] Number of samples to generate in the parameter space. Default is 1.

Returns
sample [array_like (n, d)] Sobol' sample.

scipy.stats.qmc.Sobol.random_base2

Sobol.random_base2(m)
Draw point(s) from the Sobol' sequence.

This function draws \( n = 2^m \) points in the parameter space ensuring the balance properties of the sequence.

Parameters
m [int] Logarithm in base 2 of the number of samples; i.e., \( n = 2^m \).

Returns
sample [array_like (n, d)] Sobol' sample.

scipy.stats.qmc.Sobol.reset

Sobol.reset()
Reset the engine to base state.

Returns
engine [Sobol] Engine reset to its base state.

scipy.stats.qmc.Halton

class scipy.stats.qmc.Halton(d, *, scramble=True, seed=None)
Halton sequence.

Pseudo-random number generator that generalize the Van der Corput sequence for multiple dimensions. The Halton sequence uses the base-two Van der Corput sequence for the first dimension, base-three for its second and base-\( n \) for its \( n \)-dimension.

Parameters
d [int] Dimension of the parameter space.
scramble [bool, optional] If True, use Owen scrambling. Otherwise no scrambling is done. Default is True.
seed [[None, int, numpy.random.Generator], optional] If seed is None the numpy.random.Generator singleton is used. If seed is an int, a new Generator instance is used, seeded with seed. If seed is already a Generator instance then that instance is used.
Notes

The Halton sequence has severe striping artifacts for even modestly large dimensions. These can be ameliorated by scrambling. Scrambling also supports replication-based error estimates and extends applicability to unbounded integrands.

References

[1], [2]

Examples

Generate samples from a low discrepancy sequence of Halton.

```python
>>> from scipy.stats import qmc
>>> sampler = qmc.Halton(d=2, scramble=False)
>>> sample = sampler.random(n=5)
>>> sample
array([[0.    , 0.    ],
       [0.5   , 0.33333333],
       [0.25  , 0.66666667],
       [0.75  , 0.11111111],
       [0.125 , 0.44444444]])
```

Compute the quality of the sample using the discrepancy criterion.

```python
>>> qmc.discrepancy(sample)
0.088893711419753
```

If some wants to continue an existing design, extra points can be obtained by calling again `random`. Alternatively, you can skip some points like:

```python
>>> _ = sampler.fast_forward(5)
>>> sample_continued = sampler.random(n=5)
>>> sample_continued
array([[0.3125 , 0.37037037],
       [0.8125 , 0.7037037 ],
       [0.1875 , 0.14814815],
       [0.6875 , 0.48148148],
       [0.4375 , 0.81481481]])
```

Finally, samples can be scaled to bounds.

```python
>>> l_bounds = [0, 2]
>>> u_bounds = [10, 5]
>>> qmc.scale(sample_continued, l_bounds, u_bounds)
array([[3.125  , 3.11111111],
       [8.125   , 4.11111111],
       [1.875   , 2.44444444],
       [6.875   , 3.44444444],
       [4.375   , 4.44444444]])
```

### scipy.stats.qmc.Halton.fast_forward

Halton.fast_forward(n)
Fast-forward the sequence by n positions.

**Parameters**
- **n** [int] Number of points to skip in the sequence.

**Returns**
- **engine** [QMCEngine] Engine reset to its base state.

### scipy.stats.qmc.Halton.random

Halton.random(n=1)
Draw n in the half-open interval [0, 1).

**Parameters**
- **n** [int, optional] Number of samples to generate in the parameter space. Default is 1.

**Returns**
- **sample** [array_like (n, d)] QMC sample.

### scipy.stats.qmc.Halton.reset

Halton.reset()
Reset the engine to base state.

**Returns**
- **engine** [QMCEngine] Engine reset to its base state.

### scipy.stats.qmc.LatinHypercube

class scipy.stats.qmc.LatinHypercube(d, *, centered=False, seed=None)
Latin hypercube sampling (LHS).

A Latin hypercube sample [1] generates n points in [0, 1)^d. Each univariate marginal distribution is stratified, placing exactly one point in [j/n, (j + 1)/n) for j = 0, 1, ..., n − 1. They are still applicable when n << d. LHS is extremely effective on integrands that are nearly additive [2]. LHS on n points never has more variance than plain MC on n − 1 points [3]. There is a central limit theorem for LHS [4], but not necessarily for optimized LHS.

**Parameters**
- **d** [int] Dimension of the parameter space.
- **centered** [bool, optional] Center the point within the multi-dimensional grid. Default is False.
seed  [[None, int, numpy.random.Generator], optional] If `seed` is None the `numpy.random.Generator` singleton is used. If `seed` is an int, a new Generator instance is used, seeded with `seed`. If `seed` is already a Generator instance then that instance is used.

References

[1], [2], [3], [4]

Examples

Generate samples from a Latin hypercube generator.

```python
>>> from scipy.stats import qmc
>>> sampler = qmc.LatinHypercube(d=2)
>>> sample = sampler.random(n=5)
>>> sample
array([[0.1545328 , 0.53664833],
       [0.84052691, 0.06474907],
       [0.52177809, 0.93343721],
       [0.68033825, 0.36265316],
       [0.26544879, 0.61163943]])
```

Compute the quality of the sample using the discrepancy criterion.

```python
>>> qmc.discrepancy(sample)
0.019558034794794565  # random
```

Finally, samples can be scaled to bounds.

```python
>>> l_bounds = [0, 2]
>>> u_bounds = [10, 5]
>>> qmc.scale(sample, l_bounds, u_bounds)
array([[1.54532796, 3.609945],
       [8.40526909, 2.1942472],
       [5.2177809, 4.80031164],
       [6.80338249, 3.08795949],
       [2.65448791, 3.83491828]])
```

scipy.stats.qmc.LatinHypercube.fast_forward

LatinHypercube.fast_forward(n)
Fast-forward the sequence by n positions.

Parameters
n [int] Number of points to skip in the sequence.

Returns
generate [QMCEngine] Engine reset to its base state.

scipy.stats.qmc.LatinHypercube.random

LatinHypercube.random(n=1)
Draw n in the half-open interval [0, 1).

Parameters
n [int, optional] Number of samples to generate in the parameter space. Default is 1.

Returns
sample [array_like (n, d)] LHS sample.

scipy.stats.qmc.LatinHypercube.reset

LatinHypercube.reset()
Reset the engine to base state.

Returns
generate [QMCEngine] Engine reset to its base state.

class scipy.stats.qmc.MultinomialQMC

MultinomialQMC(pvals, *, engine=None, seed=None)
QMC sampling from a multinomial distribution.

Parameters
pvals [array_like (k,)] Vector of probabilities of size k, where k is the number of categories. Elements must be non-negative and sum to 1.
engine [QMCEngine, optional] Quasi-Monte Carlo engine sampler. If None, Sobol is used.
seed [None, int, numpy.random.Generator, optional] If seed is None the numpy.random.Generator singleton is used. If seed is an int, a new Generator instance is used, seeded with seed. If seed is already a Generator instance then that instance is used.
Examples

```python
>>> from scipy.stats import qmc
>>> engine = qmc.MultinomialQMC(pvals=[0.2, 0.4, 0.4])
>>> sample = engine.random(10)
```

**scipy.stats.qmc.MultinomialQMC.fast_forward**

MultinomialQMC.fast_forward(n)
Fast-forward the sequence by `n` positions.

**Parameters**

- **n** (int) Number of points to skip in the sequence.

**Returns**

- engine (QMCEngine) Engine reset to its base state.

**scipy.stats.qmc.MultinomialQMC.random**

MultinomialQMC.random(n=1)
Draw `n` QMC samples from the multinomial distribution.

**Parameters**

- **n** (int, optional) Number of samples to generate in the parameter space. Default is 1.

**Returns**

- samples (array_like) Vector of size `p` summing to `n`.

**scipy.stats.qmc.MultinomialQMC.reset**

MultinomialQMC.reset()
Reset the engine to base state.

**Returns**

- engine (MultinomialQMC) Engine reset to its base state.
scipy.stats.qmc.MultivariateNormalQMC

class scipy.stats.qmc.MultivariateNormalQMC (mean, cov=None, *, cov_root=None, inv_transform=True, engine=None, seed=None)

QMC sampling from a multivariate Normal $N(\mu, \Sigma)$.

Parameters

- mean [array_like(d,)] The mean vector. Where $d$ is the dimension.
- cov [array_like(d, d), optional] The covariance matrix. If omitted, use cov_root instead. If both cov and cov_root are omitted, use the identity matrix.
- cov_root [array_like(d, d'), optional] A root decomposition of the covariance matrix, where $d'$ may be less than $d$ if the covariance is not full rank. If omitted, use cov.
- inv_transform [bool, optional] If True, use inverse transform instead of Box-Muller. Default is True.
- engine [QMCEngine, optional] Quasi-Monte Carlo engine sampler. If None, Sobol is used.
- seed [{None, int, numpy.random.Generator}, optional] If seed is None the numpy.random.Generator singleton is used. If seed is an int, a new Generator instance is used, seeded with seed. If seed is already a Generator instance then that instance is used.

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import qmc
>>> engine = qmc.MultivariateNormalQMC(mean=[0, 5], cov=[[1, 0], [0, 1]]
>>> sample = engine.random(512)
>>> _ = plt.scatter(sample[:, 0], sample[:, 1])
>>> plt.show()
```

scipy.stats.qmc.MultivariateNormalQMC.fast_forward

MultivariateNormalQMC.fast_forward($n$)
Fast-forward the sequence by $n$ positions.

Parameters
n [int] Number of points to skip in the sequence.

Returns
engine [QMCEngine] Engine reset to its base state.

scipy.stats.qmc.MultivariateNormalQMC.random

MultivariateNormalQMC.random($n=1$)
Draw $n$ QMC samples from the multivariate Normal.

Parameters
n [int, optional] Number of samples to generate in the parameter space. Default is 1.

Returns
sample [array_like (n, d)] Sample.

scipy.stats.qmc.MultivariateNormalQMC.reset

MultivariateNormalQMC.reset()
Reset the engine to base state.

Returns
engine [MultivariateNormalQMC] Engine reset to its base state.

Helpers

<table>
<thead>

</tr>
<tr>
<td>scale(sample, l_bounds, u_bounds, *[, reverse])</td>
<td>Sample scaling from unit hypercube to different bounds.</td>
</tr>
</tbody>
</table>
scipy.stats.qmc.discrepancy

Parameters

- `sample` [array_like (n, d)] The sample to compute the discrepancy from.
- `iterative` [bool, optional] Must be False if not using it for updating the discrepancy. Default is False. Refer to the notes for more details.
- `method` [str, optional] Type of discrepancy, can be CD, WD, MD or L2-star. Refer to the notes for more details. Default is CD.
- `workers` [int, optional] Number of workers to use for parallel processing. If -1 is given all CPU threads are used. Default is 1.

Returns

- `discrepancy` [float] Discrepancy.

Notes

The discrepancy is a uniformity criterion used to assess the space filling of a number of samples in a hypercube. A discrepancy quantifies the distance between the continuous uniform distribution on a hypercube and the discrete uniform distribution on n distinct sample points.

The lower the value is, the better the coverage of the parameter space is.

For a collection of subsets of the hypercube, the discrepancy is the difference between the fraction of sample points in one of those subsets and the volume of that subset. There are different definitions of discrepancy corresponding to different collections of subsets. Some versions take a root mean square difference over subsets instead of a maximum.

A measure of uniformity is reasonable if it satisfies the following criteria [1]:

1. It is invariant under permuting factors and/or runs.
2. It is invariant under rotation of the coordinates.
3. It can measure not only uniformity of the sample over the hypercube, but also the projection uniformity of the sample over non-empty subset of lower dimension hypercubes.
4. There is some reasonable geometric meaning.
5. It is easy to compute.
6. It satisfies the Koksma-Hlawka-like inequality.
7. It is consistent with other criteria in experimental design.

Four methods are available:

- **CD**: Centered Discrepancy - subspace involves a corner of the hypercube
- **WD**: Wrap-around Discrepancy - subspace can wrap around bounds
- **MD**: Mixture Discrepancy - mix between CD/WD covering more criteria
- **L2-star**: L2-star discrepancy - like CD BUT variant to rotation
See [2] for precise definitions of each method.

Lastly, using `iterative=True`, it is possible to compute the discrepancy as if we had $n + 1$ samples. This is useful if we want to add a point to a sampling and check the candidate which would give the lowest discrepancy. Then you could just update the discrepancy with each candidate using `update_discrepancy`. This method is faster than computing the discrepancy for a large number of candidates.

**References**

[1], [2], [3]

**Examples**

Calculate the quality of the sample using the discrepancy:

```python
>>> from scipy.stats import qmc
>>> space = np.array([[1, 3], [2, 6], [3, 2], [4, 5], [5, 1], [6, 4]])
>>> l_bounds = [0.5, 0.5]
>>> u_bounds = [6.5, 6.5]
>>> space = qmc.scale(space, l_bounds, u_bounds, reverse=True)
>>> space
array([[0.08333333, 0.41666667],
       [0.25    , 0.91666667],
       [0.41666667, 0.25    ],
       [0.58333333, 0.75    ],
       [0.75    , 0.08333333],
       [0.91666667, 0.58333333]])
>>> qmc.discrepancy(space)
0.008142039609053464
```

We can also compute iteratively the CD discrepancy by using `iterative=True`.

```python
>>> disc_init = qmc.discrepancy(space[:-1], iterative=True)
>>> disc_init
0.04769081147119336
>>> qmc.update_discrepancy(space[:-1], space[:-1], disc_init)
0.008142039609053513
```

**scipy.stats.qmc.update_discrepancy**

The `scipy.stats.qmc.update_discrepancy` function updates the centered discrepancy with a new sample.

**Parameters**

- `x_new`: array_like (1, d) The new sample to add in `sample`.
- `sample`: array_like (n, d) The initial sample.
- `initial_disc`: float Centered discrepancy of the `sample`.

**Returns**

- `discrepancy`: float Centered discrepancy of the sample composed of `x_new` and `sample`.
Examples

We can also compute iteratively the discrepancy by using `iterative=True`.

```python
from scipy.stats import qmc

space = np.array([[1, 3], [2, 6], [3, 2], [4, 5], [5, 1], [6, 4]])
l_bounds = [0.5, 0.5]
u_bounds = [6.5, 6.5]
space = qmc.scale(space, l_bounds, u_bounds, reverse=True)
disc_init = qmc.discrepancy(space[:-1], iterative=True)
disc_init
0.04769081147119336
qmc.update_discrepancy(space[-1], space[:-1], disc_init)
0.008142039609053513
```

`scipy.stats.qmc.scale`

`scipy.stats.qmc.scale`(sample, l_bounds, u_bounds, *, reverse=False)

Sample scaling from unit hypercube to different bounds.

To convert a sample from \([0, 1)\) to \([a, b)\), \(b > a\), with \(a\) the lower bounds and \(b\) the upper bounds. The following transformation is used:

\[(b - a) \cdot \text{sample} + a\]

**Parameters**

- `sample` [array_like(n, d)] Sample to scale.
- `l_bounds, u_bounds` [array_like(d,)] Lower and upper bounds (resp. \(a, b\)) of transformed data. If `reverse` is True, range of the original data to transform to the unit hypercube.
- `reverse` [bool, optional] Reverse the transformation from different bounds to the unit hypercube. Default is False.

**Returns**

- `sample` [array_like(n, d)] Scaled sample.

**Examples**

Transform 3 samples in the unit hypercube to bounds:

```python
from scipy.stats import qmc

l_bounds = [-2, 0]
u_bounds = [6, 5]
sample = [[0.5, 0.75],
          ...
          [0.5, 0.5],
          ...
          [0.75, 0.25]]
sample_scaled = qmc.scale(sample, l_bounds, u_bounds)
sample_scaled
array([[2. , 3.75],
       [2. , 2.5 ],
       [4. , 1.25]])
```
And convert back to the unit hypercube:

```python
>>> sample_ = qmc.scale(sample_scaled, l_bounds, u_bounds, reverse=True)
>>> sample_
array([[[0.5 , 0.75],
        [0.5 , 0.5 ],
        [0.75, 0.25]]])
```

### Introduction to Quasi-Monte Carlo

Quasi-Monte Carlo (QMC) methods\(^1\),\(^2\),\(^3\) provide an \(n \times d\) array of numbers in \([0, 1]^d\). They can be used in place of \(n\) points from the \(U[0, 1]^d\) distribution. Compared to random points, QMC points are designed to have fewer gaps and clumps. This is quantified by discrepancy measures\(^4\). From the Koksma-Hlawka inequality\(^5\) we know that low discrepancy reduces a bound on integration error. Averaging a function \(f\) over \(n\) QMC points can achieve an integration error close to \(O(n^{-1})\) for well behaved functions\(^2\).

Most QMC constructions are designed for special values of \(n\) such as powers of 2 or large primes. Changing the sample size by even one can degrade their performance, even their rate of convergence\(^6\). For instance \(n = 100\) points may give less accuracy than \(n = 64\) if the method was designed for \(n = 2^m\).

Some QMC constructions are extensible in \(n\): we can find another special sample size \(n' > n\) and often an infinite sequence of increasing special sample sizes. Some QMC constructions are extensible in \(d\): we can increase the dimension, possibly to some upper bound, and typically without requiring special values of \(d\). Some QMC methods are extensible in both \(n\) and \(d\).

QMC points are deterministic. That makes it hard to estimate the accuracy of integrals estimated by averages over QMC points. Randomized QMC (RQMC)\(^7\) points are constructed so that each point is individually \(U[0, 1]^d\) while collectively the \(n\) points retain their low discrepancy. One can make \(R\) independent replications of RQMC points to see how stable a computation is. From \(R\) independent values, a t-test (or bootstrap t-test\(^8\)) then gives approximate confidence intervals on the mean value. Some RQMC methods produce a root mean squared error that is actually \(O(1/n)\) and smaller than the rate seen in unrandomized QMC. An intuitive explanation is that the error is a sum of many small ones and random errors cancel in a way that deterministic ones do not. RQMC also has advantages on integrands that are singular or, for other reasons, fail to be Riemann integrable.

(R)QMC cannot beat Bahvalov’s curse of dimension (see\(^9\)). For any random or deterministic method, there are worst case functions that will give it poor performance in high dimensions. A worst case function for QMC might be 0 at all \(n\) points but very large elsewhere. Worst case analyses get very pessimistic in high dimensions. (R)QMC can bring a great improvement over MC when the functions on which it is used are not worst case. For instance (R)QMC can be especially effective on integrands that are well approximated by sums of functions of some small number of their input variables at a time\(^10\),\(^11\). That property is often a surprising finding about those functions.

Also, to see an improvement over IID MC, (R)QMC requires a bit of smoothness of the integrand, roughly the mixed first order derivative in each direction, \(\partial^d f / \partial x_1 \cdots \partial x_d\), must be integral. For instance, a function that is 1 inside the hypersphere and 0 outside of it has infinite variation in the sense of Hardy and Krause for any dimension \(d = 2\).

Scrambled nets are a kind of RQMC that have some valuable robustness properties\(^12\). If the integrand is square integrable, they give variance \(\text{var}_{\text{SNET}} = o(1/n)\). There is a finite upper bound on \(\text{var}_{\text{SNET}}/\text{var}_{\text{MC}}\) that holds simultaneously for every square integrable integrand. Scrambled nets satisfy a strong law of large numbers for \(f\) in \(L^p\) when \(p > 1\). In some special cases there is a central limit theorem\(^13\). For smooth enough integrands they can achieve RMSE nearly \(O(n^{-3/2})\). See\(^12\) for references about these properties.

The main kinds of QMC methods are lattice rules\(^14\) and digital nets and sequences\(^2\),\(^15\). The theories meet up in polynomial lattice rules\(^16\) which can produce digital nets. Lattice rules require some form of search for good constructions. For digital nets there are widely used default constructions.

The most widely used QMC methods are Sobol’ sequences\(^17\). These are digital nets. They are extensible in both \(n\) and \(d\). They can be scrambled. The special sample sizes are powers of 2. Another popular method are Halton sequences\(^18\).
The constructions resemble those of digital nets. The earlier dimensions have much better equidistribution properties than later ones. There are essentially no special sample sizes. They are not thought to be as accurate as Sobol’ sequences. They can be scrambled. The nets of Faure [19] are also widely used. All dimensions are equally good, but the special sample sizes grow rapidly with dimension \( d \). They can be scrambled. The nets of Niederreiter and Xing [20] have the best asymptotic properties but have not shown good empirical performance [21].

Higher order digital nets are formed by a digit interleaving process in the digits of the constructed points. They can achieve higher levels of asymptotic accuracy given higher smoothness conditions on \( f \) and they can be scrambled [22]. There is little or no empirical work showing the improved rate to be attained.

Using QMC is like using the entire period of a small random number generator. The constructions are similar and so therefore are the computational costs [23].

(R)QMC is sometimes improved by passing the points through a baker’s transformation (tent function) prior to using them. That function has the form \( 1 - 2|x - 1/2| \). As \( x \) goes from 0 to 1, this function goes from 0 to 1 and then back. It is very useful to produce a periodic function for lattice rules [14], and sometimes it improves the convergence rate [24].

It is not straightforward to apply QMC methods to Markov chain Monte Carlo (MCMC). We can think of MCMC as using \( n = 1 \) point in \([0, 1]^d\) for very large \( d \), with ergodic results corresponding to \( d \to \infty \). One proposal is in [25] and under strong conditions an improved rate of convergence has been shown [26].

Returning to Sobol’ points: there are many versions depending on what are called direction numbers. Those are the result of searches and are tabulated. A very widely used set of direction numbers come from [27]. It is extensible in dimension up to \( d = 21201 \).

Masked statistics functions

Statistical functions for masked arrays (scipy.stats.mstats)

This module contains a large number of statistical functions that can be used with masked arrays.

Most of these functions are similar to those in scipy.stats but might have small differences in the API or in the algorithm used. Since this is a relatively new package, some API changes are still possible.

Summary statistics

### scipy.stats.mstats.describe

`scipy.stats.mstats.describe (a, axis=0, ddof=0, bias=True)`

Computes several descriptive statistics of the passed array.

**Parameters**

- `a` [array_like] Data array
- `axis` [int or None, optional] Axis along which to calculate statistics. Default 0. If None, compute over the whole array `a`.
- `ddof` [int, optional] degree of freedom (default 0); note that default ddof is different from the same routine in stats.describe
- `bias` [bool, optional] If False, then the skewness and kurtosis calculations are corrected for statistical bias.

**Returns**

- `nobs` [int] (size of the data (discarding missing values)
- `minmax` [int, int] min, max
- `mean` [float] arithmetic mean
- `variance` [float] unbiased variance
- `skewness` [float] biased skewness
- `kurtosis` [float] biased kurtosis

3.3. API definition
Examples

```python
>>> from scipy.stats.mstats import describe
>>> ma = np.ma.array(range(6), mask=[0, 0, 0, 1, 1, 1])
>>> describe(ma)
DescribeResult(nobs=3, minmax=(masked_array(data=0,
    mask=False,
    fill_value=999999), masked_array(data=2,
    mask=False,
    fill_value=999999)), mean=1.0, variance=0.6666666666666666,
skewness=masked_array(data=0., mask=False, fill_value=1e+20),
kurtosis=-1.5)
```

`scipy.stats.mstats.gmean`

`scipy.stats.mstats.gmean(a, axis=0, dtype=None, weights=None)`

Compute the geometric mean along the specified axis.

Return the geometric average of the array elements. That is: n-th root of (x1 * x2 * ... * xn)

**Parameters**

- `a` : array_like Input array or object that can be converted to an array.
- `axis` : int or None, optional Axis along which the geometric mean is computed. Default is 0. If None, compute over the whole array `a`.
- `dtype` : dtype, optional Type of the returned array and of the accumulator in which the elements are summed. If `dtype` is not specified, it defaults to the dtype of `a`, unless `a` has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.
- `weights` : array_like, optional The weights array can either be 1-D (in which case its length must be the size of `a` along the given `axis`) or of the same shape as `a`. Default is None, which gives each value a weight of 1.0.

**Returns**

- `gmean` : ndarray See `dtype` parameter above.

See also:

- `numpy.mean`
  Arithmetic average
- `numpy.average`
  Weighted average
- `hmean`
  Harmonic mean
Notes
The geometric average is computed over a single dimension of the input array, axis=0 by default, or all values in the array if axis=None. float64 intermediate and return values are used for integer inputs.
Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.

References
[1]

Examples
```python
>>> from scipy.stats import gmean
>>> gmean([1, 4])
2.0
>>> gmean([1, 2, 3, 4, 5, 6, 7])
3.3800151591412964
```

scipy.stats.mstats.hmean

scipy.stats.mstats.hmean(a, axis=0, dtype=None)
Calculate the harmonic mean along the specified axis.
That is: n / (1/x1 + 1/x2 + ... + 1/xn)

Parameters
---
a : [array_like] Input array, masked array or object that can be converted to an array.
axis : [int or None, optional] Axis along which the harmonic mean is computed. Default is 0. If None, compute over the whole array a.
dtype : [dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of a, unless a has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

Returns
---
hmean : [ndarray] See dtype parameter above.

See also:
---
numpy.mean
Arithmetic average

numpy.average
Weighted average
gmean
Geometric mean
Notes

The harmonic mean is computed over a single dimension of the input array, axis=0 by default, or all values in the array if axis=None. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

Examples

```python
>>> from scipy.stats import hmean
>>> hmean([1, 4])
1.6000000000000001
>>> hmean([1, 2, 3, 4, 5, 6, 7])
2.6997245179063363
```

`scipy.stats.mstats.kurtosis`

`scipy.stats.mstats.kurtosis(a, axis=0, fisher=True, bias=True)`

Computes the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher's definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If bias is False then the kurtosis is calculated using k statistics to eliminate bias coming from biased moment estimators

Use `kurtosistest` to see if result is close enough to normal.

Parameters

- `a` : array data for which the kurtosis is calculated
- `axis` : [int or None, optional] Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array `a`.
- `fisher` : [bool, optional] If True, Fisher’s definition is used (normal ==> 0.0). If False, Pearson’s definition is used (normal ==> 3.0).
- `bias` : [bool, optional] If False, then the calculations are corrected for statistical bias.

Returns

- `kurtosis` : [array] The kurtosis of values along an axis. If all values are equal, return -3 for Fisher’s definition and 0 for Pearson’s definition.

Notes

For more details about `kurtosis`, see `stats.kurtosis`. 
scipy.stats.mstats.mode

{scipy.stats.mstats}.mode(a, axis=0)

Returns an array of the modal (most common) value in the passed array.

Parameters

- a: [array_like] n-dimensional array of which to find mode(s).
- axis: [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array a.

Returns

- mode: [ndarray] Array of modal values.
- count: [ndarray] Array of counts for each mode.

Notes

For more details, see stats.mode.

Examples

```python
>>> from scipy import stats
>>> from scipy.stats import mstats
>>> m_arr = np.ma.array([1, 1, 0, 0, 0, 0], mask=[0, 0, 1, 1, 1, 0])
>>> stats.mode(m_arr)
ModeResult(mode=array([0]), count=array([4]))
>>> mstats.mode(m_arr)
ModeResult(mode=array([1.]), count=array([2.]))
```

scipy.stats.mstats.mquantiles

{scipy.stats.mstats}.mquantiles(a, prob=[0.25, 0.5, 0.75], alphap=0.4, betap=0.4, axis=None, limit=())

Computes empirical quantiles for a data array.

Samples quantile are defined by Q(p) = (1-gamma)*x[j] + gamma*x[j+1], where x[j] is the j-th order statistic, and gamma is a function of j = floor(n*p + m), m = alphap + p*(1 - alphap - betap) and g = n*p + m - j.

Reinterpreting the above equations to compare to R lead to the equation: p(k) = (k - alphap)/(n + 1 - alphap - betap)

Typical values of (alphap,betap) are:

- (0,1): p(k) = k/n: linear interpolation of cdf (R type 4)
- (.5,.5): p(k) = (k - 1/2.)/n: piecewise linear function (R type 5)
- (0,0): p(k) = k/(n+1): (R type 6)
- (1,1): p(k) = (k-1)/(n-1): p(k) = mode[F(x[k])]. (R type 7, R default)
- (1/3,1/3): p(k) = (k-1/3)/(n+1/3): Then p(k) ~ median[F(x[k])]. The resulting quantile estimates are approximately median-unbiased regardless of the distribution of x. (R type 8)
SciPy Reference Guide, Release 1.7.0

• (3/8, 3/8): \( p(k) = (k - 3/8) / (n + 1/4) \): Blom. The resulting quantile estimates are approximately unbiased if \( x \) is normally distributed (R type 9)

• (.4, .4): approximately quantile unbiased (Cunnane)

• (.35, .35): APL, used with PWM

Parameters

- \( a \) [array_like] Input data, as a sequence or array of dimension at most 2.
- prob [array_like, optional] List of quantiles to compute.
- alphap [float, optional] Plotting positions parameter, default is 0.4.
- betap [float, optional] Plotting positions parameter, default is 0.4.
- axis [int, optional] Axis along which to perform the trimming. If None (default), the input array is first flattened.
- limit [tuple, optional] Tuple of (lower, upper) values. Values of \( a \) outside this open interval are ignored.

Returns

- mquantiles [MaskedArray] An array containing the calculated quantiles.

Notes

This formulation is very similar to R except the calculation of \( m \) from \( \text{alphap} \) and \( \text{betap} \), where in R \( m \) is defined with each type.

References

[1], [2]

Examples

```python
>>> from scipy.stats import mquantiles
>>> a = np.array([6., 47., 49., 15., 42., 41., 7., 39., 43., 40., 36.])
>>> mquantiles(a)
array([ 19.2, 40. , 42.8])
```

Using a 2D array, specifying axis and limit.

```python
>>> data = np.array([[[ 6.,  7.,  1.],
...                    [47., 15.,  2.],
...                    [49., 36.,  3.],
...                    [15., 39.,  4.],
...                    [42., 40., -999.],
...                    [41., 41., -999.],
...                    [ 7., -999., -999.],
...                    [39., -999., -999.],
...                    [43., -999., -999.],
...                    [40., -999., -999.],
...                    [36., -999., -999.]]])
>>> print(mquantiles(data, axis=0, limit=(0, 50)))
```

(continues on next page)

```python
>>> data[:, 2] = -999.
>>> print(mquantiles(data, axis=0, limit=(0, 50)))
[[19.200000000000003 14.6 --]
 [40.0 37.5 --]
 [42.800000000000004 40.05 --]]
```

### scipy.stats.mstats.hdmedian

**scipy.stats.mstats.hdmedian** *(data, axis=-1, var=False)*

Returns the Harrell-Davis estimate of the median along the given axis.

**Parameters**
- **data** : [ndarray] Data array.
- **axis** : [int, optional] Axis along which to compute the quantiles. If None, use a flattened array.
- **var** : [bool, optional] Whether to return the variance of the estimate.

**Returns**
- **hdmedian** : [MaskedArray] The median values. If var=True, the variance is returned inside the masked array. E.g. for a 1-D array the shape change from (1,) to (2,).

### scipy.stats.mstats.hdquantiles

**scipy.stats.mstats.hdquantiles** *(data, prob=[0.25, 0.5, 0.75], axis=None, var=False)*

Computes quantile estimates with the Harrell-Davis method.

The quantile estimates are calculated as a weighted linear combination of order statistics.

**Parameters**
- **data** : [array_like] Data array.
- **prob** : [sequence, optional] Sequence of quantiles to compute.
- **axis** : [int or None, optional] Axis along which to compute the quantiles. If None, use a flattened array.
- **var** : [bool, optional] Whether to return the variance of the estimate.

**Returns**
- **hdquantiles** : [MaskedArray] A (p,) array of quantiles (if var is False), or a (2,p) array of quantiles and variances (if var is True), where p is the number of quantiles.

**See also:**
- **hdquantiles_sd**
scipy.stats.mstats.hdquantiles_sd

`scipy.stats.mstats.hdquantiles_sd(data, prob=[0.25, 0.5, 0.75], axis=None)`
The standard error of the Harrell-Davis quantile estimates by jackknife.

**Parameters**
- `data` : [array_like] Data array.
- `prob` : [sequence, optional] Sequence of quantiles to compute.
- `axis` : [int, optional] Axis along which to compute the quantiles. If None, use a flattened array.

**Returns**

**See also:**
- `hdquantiles`

scipy.stats.mstats.idealfourths

`scipy.stats.mstats.idealfourths(data, axis=None)`
Returns an estimate of the lower and upper quartiles.

Uses the ideal fourths algorithm.

**Parameters**
- `data` : [array_like] Input array.
- `axis` : [int, optional] Axis along which the quartiles are estimated. If None, the arrays are flattened.

**Returns**
- `idealfourths` : [list of floats, masked array] Returns the two internal values that divide `data` into four parts using the ideal fourths algorithm either along the flattened array (if `axis` is None) or along `axis` of `data`.

scipy.stats.mstats.plotting_positions

`scipy.stats.mstats.plotting_positions(data, alpha=0.4, beta=0.4)`

Returns plotting positions (or empirical percentile points) for the data.

**Plotting positions are defined as** \((i - \alpha) / (n + 1 - \alpha - \beta)\), **where:**

- \(i\) is the rank order statistics
- \(n\) is the number of unmasked values along the given axis
- \(\alpha\) and \(\beta\) are two parameters.

**Typical values for \(\alpha\) and \(\beta\) are:**

- \((0,1)\) : \(p(k) = k/n\), linear interpolation of cdf (R, type 4)
- \((.5,.5)\) : \(p(k) = (k-1/2.) / n\), piecewise linear function (R, type 5)
- \((0,0)\) : \(p(k) = k/ (n+1)\), Weibull (R type 6)
• (1,1): \( p(k) = (k-1)/(n-1) \), in this case, \( p(k) = \text{mode}[F(x[k])] \). That’s R default (R type 7)

• (1/3,1/3): \( p(k) = (k-1/3)/(n+1/3) \), then \( p(k) \sim \text{median}[F(x[k])] \). The resulting quantile estimates are approximately median-unbiased regardless of the distribution of \( x \). (R type 8)

• (3/8,3/8): \( p(k) = (k-3/8)/(n+1/4) \), Blom. The resulting quantile estimates are approximately unbiased if \( x \) is normally distributed (R type 9)

• (.4,.4): approximately quantile unbiased (Cunnane)

• (.35,.35): APL, used with PWM

• (.3175,.3175): used in scipy.stats.probplot

**Parameters**

- **data** [array_like] Input data, as a sequence or array of dimension at most 2.
- **alpha** [float, optional] Plotting positions parameter. Default is 0.4.
- **beta** [float, optional] Plotting positions parameter. Default is 0.4.

**Returns**

- **positions** [MaskedArray] The calculated plotting positions.

**scipy.stats.mstats.meppf**

**scipy.stats.mstats.meppf**(data, alpha=0.4, beta=0.4)

Returns plotting positions (or empirical percentile points) for the data.

*Plotting positions are defined as \((i - \alpha)/(n + 1 - \alpha - \beta)\), where:*

- \( i \) is the rank order statistics
- \( n \) is the number of unmasked values along the given axis
- \( \alpha \) and \( \beta \) are two parameters.

**Typical values for alpha and beta are:**

- (0,1): \( p(k) = k/n \), linear interpolation of cdf (R, type 4)
- (.5,.5): \( p(k) = (k-1/2.)/n \), piecewise linear function (R, type 5)
- (0,0): \( p(k) = k/(n+1) \), Weibull (R type 6)
- (1,1): \( p(k) = (k-1)/(n-1) \), in this case, \( p(k) = \text{mode}[F(x[k])] \). That’s R default (R type 7)
- (1/3,1/3): \( p(k) = (k-1/3)/(n+1/3) \), then \( p(k) \sim \text{median}[F(x[k])] \). The resulting quantile estimates are approximately median-unbiased regardless of the distribution of \( x \). (R type 8)
- (3/8,3/8): \( p(k) = (k-3/8)/(n+1/4) \), Blom. The resulting quantile estimates are approximately unbiased if \( x \) is normally distributed (R type 9)
- (.4,.4): approximately quantile unbiased (Cunnane)

• (.35,.35): APL, used with PWM

• (.3175,.3175): used in scipy.stats.probplot

**Parameters**
data    [array_like] Input data, as a sequence or array of dimension at most 2.
alpha  [float, optional] Plotting positions parameter. Default is 0.4.
beta   [float, optional] Plotting positions parameter. Default is 0.4.

Returns
positions  [MaskedArray] The calculated plotting positions.

scipy.stats.mstats.moment

scipy.stats.mstats.moment(a, moment=1, axis=0)
Calculates the nth moment about the mean for a sample.

Parameters
a   [array_like] data
moment  [int, optional] order of central moment that is returned
axis   [int or None, optional] Axis along which the central moment is computed. Default is 0. If
        None, compute over the whole array a.

Returns
n-th central moment
[ndarray or float] The appropriate moment along the given axis or over all values if axis
is None. The denominator for the moment calculation is the number of observations, no
degrees of freedom correction is done.

Notes
For more details about moment, see stats.moment.

scipy.stats.mstats.skew

scipy.stats.mstats.skew(a, axis=0, bias=True)
Computes the skewness of a data set.

Parameters
a   [ndarray] data
axis   [int or None, optional] Axis along which skewness is calculated. Default is 0. If None,
        compute over the whole array a.
bias   [bool, optional] If False, then the calculations are corrected for statistical bias.

Returns
skewness  [ndarray] The skewness of values along an axis, returning 0 where all values are equal.
Notes

For more details about `skew`, see `stats.skew`.

**scipy.stats.mstats.tmean**

`scipy.stats.mstats.tmean(a, limits=None, inclusive=(True, True), axis=None)`

Compute the trimmed mean.

**Parameters**

- `a` [array_like] Array of values.
- `limits` [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.
- `inclusive` [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- `axis` [int or None, optional] Axis along which to operate. If None, compute over the whole array. Default is None.

**Returns**

- `tmean` [float]

Notes

For more details on `tmean`, see `stats.tmean`.

**Examples**

```python
c>> from scipy.stats import mstats
c>> a = np.array([[6, 8, 3, 0],
... [3, 9, 1, 2],
... [8, 7, 8, 2],
... [5, 6, 0, 2],
... [4, 5, 5, 2]])
... mstats.tmean(a, (2,5))
c3.3
>> mstats.tmean(a, (2,5), axis=0)
m masked_array(data=[4.0, 5.0, 4.0, 2.0],
  mask=[False, False, False, False],
fill_value=1e+20)
```
**scipy.stats.mstats.tvar**

`scipy.stats.mstats.tvar(a, limits=None, inclusive=(True, True), axis=0, ddof=1)`

Compute the trimmed variance

This function computes the sample variance of an array of values, while ignoring values which are outside of given limits.

**Parameters**

- `a` : array_like
  Array of values.
- `limits` : [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.
- `inclusive` : [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- `axis` : [int or None, optional] Axis along which to operate. If None, compute over the whole array. Default is zero.
- `ddof` : [int, optional] Delta degrees of freedom. Default is 1.

**Returns**

- `tvar` : [float] Trimmed variance.

**Notes**

For more details on `tvar`, see `stats.tvar`.

**scipy.stats.mstats.tmin**

`scipy.stats.mstats.tmin(a, lowerlimit=None, axis=0, inclusive=True)`

Compute the trimmed minimum

**Parameters**

- `a` : array_like
  Array of values.
- `lowerlimit` : [None or float, optional] Values in the input array less than the given limit will be ignored. When lowerlimit is None, then all values are used. The default value is None.
- `axis` : [int or None, optional] Axis along which to operate. If None, compute over the whole array. Default is 0. If None, compute over the whole array `a`.
- `inclusive` : [True, False], optional] This flag determines whether values exactly equal to the lower limit are included. The default value is True.

**Returns**

- `tmin` : [float, int or ndarray]
Notes

For more details on \texttt{tmin}, see \texttt{stats.tmin}.

Examples

```python
>>> from scipy.stats import mstats
>>> a = np.array([[6, 8, 3, 0],
...                [3, 2, 1, 2],
...                [8, 1, 8, 2],
...                [5, 3, 0, 2],
...                [4, 7, 5, 2]])
>>> mstats.tmin(a, 5)
masked_array(data=[5, 7, 5, --],
             mask=[False, False, False, True],
             fill_value=999999)
```

\texttt{scipy.stats.mstats.tmax}

\texttt{scipy.stats.mstats.tmax}(\texttt{a, upperlimit=None, axis=0, inclusive=True})

Compute the trimmed maximum

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

\textbf{Parameters}

- \texttt{a} [array_like] array of values
- \texttt{upperlimit} [None or float, optional] Values in the input array greater than the given limit will be ignored. When \texttt{upperlimit} is None, then all values are used. The default value is None.
- \texttt{axis} [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array \texttt{a}.
- \texttt{inclusive} [[True, False], optional] This flag determines whether values exactly equal to the upper limit are included. The default value is True.

\textbf{Returns}

- \texttt{tmax} [float, int or ndarray]

\textbf{Notes}

For more details on \texttt{tmax}, see \texttt{stats.tmax}.
scipy.stats.mstats.tsem

This function finds the standard error of the mean for given values, ignoring values outside the given limits.

Parameters

- `a` : array_like array of values
- `limits` : [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.
- `inclusive` : [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- `axis` : [int or None, optional] Axis along which to operate. If None, compute over the whole array. Default is zero.
- `ddof` : [int, optional] Delta degrees of freedom. Default is 1.

Returns

- `tsem` : [float]

Notes

For more details on `tsem`, see `stats.tsem`. 
**scipy.stats.mstats.variation**

`scipy.stats.mstats.variation(a, axis=0, ddof=0)`

Compute the coefficient of variation.

The coefficient of variation is the standard deviation divided by the mean. This function is equivalent to:

```python
np.std(x, axis=axis, ddof=ddof) / np.mean(x)
```

The default for `ddof` is 0, but many definitions of the coefficient of variation use the square root of the unbiased sample variance for the sample standard deviation, which corresponds to `ddof=1`.

**Parameters**
- `a` : array_like Input array.
- `axis` : int or None, optional Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array `a`.
- `ddof` : int, optional Delta degrees of freedom. Default is 0.

**Returns**
- `variation` : ndarray The calculated variation along the requested axis.

**Notes**
For more details about `variation`, see `stats.variation`.

**Examples**

```python
>>> from scipy.stats.mstats import variation
>>> a = np.array([2, 8, 4])
>>> variation(a)
0.5345224838248487
>>> b = np.array([2, 8, 3, 4])
>>> c = np.ma.masked_array(b, mask=[0, 0, 1, 0])
>>> variation(c)
0.5345224838248487
```

In the example above, it can be seen that this works the same as `stats.variation` except ‘stats.mstats.variation’ ignores masked array elements.

**scipy.stats.mstats.find_repeats**

`scipy.stats.mstats.find_repeats(arr)`

Find repeats in `arr` and return a tuple (repeats, repeat_count).

The input is cast to float64. Masked values are discarded.

**Parameters**
- `arr` : sequence Input array. The array is flattened if it is not 1D.

**Returns**
- `repeats` : ndarray Array of repeated values.
- `counts` : ndarray Array of counts.
scipy.stats.mstats.sem

scipy.stats.mstats.sem(a, axis=0, ddof=1)
Calculates the standard error of the mean of the input array.
Also sometimes called standard error of measurement.

Parameters

- a : [array_like] An array containing the values for which the standard error is returned.
- axis : [int or None, optional] If axis is None, ravel a first. If axis is an integer, this will be the axis over which to operate. Defaults to 0.
- ddof : [int, optional] Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.

Returns

- s : [ndarray or float] The standard error of the mean in the sample(s), along the input axis.

Notes

The default value for ddof changed in scipy 0.15.0 to be consistent with stats sem as well as with the most common definition used (like in the R documentation).

Examples

Find standard error along the first axis:

```python
>>> from scipy import stats
>>> a = np.arange(20).reshape(5, 4)
>>> print(stats.mstats.sem(a))
[2.8284271247461903 2.8284271247461903 2.8284271247461903 2.8284271247461903]
```

Find standard error across the whole array, using n degrees of freedom:

```python
>>> print(stats.mstats.sem(a, axis=None, ddof=0))
1.2893796958227628
```

scipy.stats.mstats.trimmed_mean

scipy.stats.mstats.trimmed_mean(a, limits=(0.1, 0.1), inclusive=(1, 1), relative=True, axis=None)

Returns the trimmed mean of the data along the given axis.

Parameters

- a : [sequence] Input array
- limits : [[None, tuple], optional] If relative is False, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked. If relative is True, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data.
- inclusive : (1, 1) Noting n the number of unmasked data before trimming, the (n*limits[0])th smallest data and the (n*limits[1])th largest data are masked, and the total number of unmasked data after
trimming is \( n^*(1. - \text{sum}(\text{limits})) \). In each case, the value of one limit can be set to None to indicate an open interval.

If limits is None, no trimming is performed.

**inclusive**  
[(bool, bool) tuple, optional] If relative is False, tuple indicating whether values exactly equal to the absolute limits are allowed. If relative is True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).

**relative**  
[bool, optional] Whether to consider the limits as absolute values (False) or proportions to cut (True).

**axis**  
[int, optional] Axis along which to trim.

### scipy.stats.mstats.trimmed_mean_ci

**scipy.stats.mstats.trimmed_mean_ci**  
\( \text{scipy.stats.mstats.trimmed_mean_ci}(\text{data}, \text{limits}=(0.2, 0.2), \text{inclusive}=(\text{True, True}), \text{alpha}=0.05, \text{axis}=\text{None}) \)

Selected confidence interval of the trimmed mean along the given axis.

**Parameters**

- **data**  
[array_like] Input data.

- **limits**  
[(None, tuple), optional] None or a two item tuple. Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. If \( n \) is the number of unmasked data before trimming, then \((n * \text{limits[0]})\)th smallest data and \((n * \text{limits[1]})\)th largest data are masked. The total number of unmasked data after trimming is \( n * (1. - \text{sum}(\text{limits})) \). The value of one limit can be set to None to indicate an open interval.

- **inclusive**  
[(2,) tuple of boolean, optional] If relative==False, tuple indicating whether values exactly equal to the absolute limits are allowed. If relative==True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).

- **alpha**  
[float, optional] Confidence level of the intervals.

- **axis**  
[int, optional] Axis along which to cut. If None, uses a flattened version of data.

**Returns**

- **trimmed_mean_ci**  
[(2,) ndarray] The lower and upper confidence intervals of the trimmed data.

### scipy.stats.mstats.trimmed_std

**scipy.stats.mstats.trimmed_std**  
\( \text{scipy.stats.mstats.trimmed_std}(\text{a}, \text{limits}=(0.1, 0.1), \text{inclusive}=(1, 1), \text{relative}=\text{True}, \text{axis}=	ext{None}, \text{ddof}=0) \)

Returns the trimmed standard deviation of the data along the given axis.

**Parameters**

- **a**  
[sequence] Input array.

- **limits**  
[(None, tuple), optional] If relative is False, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked. If relative is True, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data.

Noting \( n \) the number of unmasked data before trimming, the \((n*\text{limits[0]})\)th smallest data and the \((n*\text{limits[1]})\)th largest data are masked, and the total number of unmasked data after trimming is \( n * (1. - \text{sum}(\text{limits})) \). The value of one limit can be set to None to indicate an open interval.
trimming is n*(1.-sum(limits)) In each case, the value of one limit can be set to None to indicate an open interval.
If limits is None, no trimming is performed

inclusive [{(bool, bool) tuple}, optional] If relative is False, tuple indicating whether values exactly equal to the absolute limits are allowed. If relative is True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).

relative [bool, optional] Whether to consider the limits as absolute values (False) or proportions to cut (True).

axis [int, optional] Axis along which to trim.

ddof [{0, integer}, optional] Means Delta Degrees of Freedom. The denominator used during computations is (n-ddof). DDOF=0 corresponds to a biased estimate, DDOF=1 to an unbiased estimate of the variance.

scipy.stats.mstats.trimmed_var

scipy.stats.mstats.trimmed_var (a, limits=(0.1, 0.1), inclusive=(1, 1), relative=True, axis=None, ddof=0)

Returns the trimmed variance of the data along the given axis.

Parameters

- a [sequence] Input array
- limits [{None, tuple}, optional] If relative is False, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked. If relative is True, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data.
  Noting n the number of unmasked data before trimming, the (n*limits[0])th smallest data and the (n*limits[1])th largest data are masked, and the total number of unmasked data after trimming is n*(1.-sum(limits)) In each case, the value of one limit can be set to None to indicate an open interval.
  If limits is None, no trimming is performed
- inclusive [{(bool, bool) tuple}, optional] If relative is False, tuple indicating whether values exactly equal to the absolute limits are allowed. If relative is True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
- relative [bool, optional] Whether to consider the limits as absolute values (False) or proportions to cut (True).
- axis [int, optional] Axis along which to trim.
- ddof [{0, integer}, optional] Means Delta Degrees of Freedom. The denominator used during computations is (n-ddof). DDOF=0 corresponds to a biased estimate, DDOF=1 to an unbiased estimate of the variance.

Frequency statistics

scoreatpercentile(data, per[, limit, ...]) Calculate the score at the given ‘per’ percentile of the sequence a.
scipy.stats.mstats.scoreatpercentile

`scipy.stats.mstats.scoreatpercentile(data, per, limit=(), alphap=0.4, betap=0.4)`

Calculate the score at the given 'per' percentile of the sequence `a`. For example, the score at per=50 is the median.

This function is a shortcut to `mquantile`

**scipy.stats.mstats.f_oneway**

`scipy.stats.mstats.f_oneway(*args)`

Performs a 1-way ANOVA, returning an F-value and probability given any number of groups. From Heiman, pp.394-7.

**Usage:** `f_oneway(*args)`, where *args is 2 or more arrays, one per treatment group.

**Returns**

- statistic [float] The computed F-value of the test.
- pvalue [float] The associated p-value from the F-distribution.

**scipy.stats.mstats.pearsonr**

`scipy.stats.mstats.pearsonr(x, y)`

Calculates a Pearson correlation coefficient and the p-value for testing non-correlation.

The Pearson correlation coefficient measures the linear relationship between two datasets. Strictly speaking, Pearson’s correlation requires that each dataset be normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship. Positive correlations imply that as `x` increases, so does `y`. Negative correlations imply that as `x` increases, `y` decreases.
The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Pearson correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters**

- **x** [1-D array_like] Input
- **y** [1-D array_like] Input

**Returns**

- **pearsonr** [float] Pearson’s correlation coefficient, 2-tailed p-value.

**References**

http://www.statsoft.com/textbook/glosp.html#Pearson%20Correlation

**scipy.stats.mstats.spearmanr**

Calculates a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.

The Spearman correlation is a nonparametric measure of the linear relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply a monotonic relationship. Positive correlations imply that as \( x \) increases, so does \( y \). Negative correlations imply that as \( x \) increases, \( y \) decreases.

Missing values are discarded pair-wise: if a value is missing in \( x \), the corresponding value in \( y \) is masked.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters**

- **x, y** [1D or 2D array_like, y is optional] One or two 1-D or 2-D arrays containing multiple variables and observations. When these are 1-D, each represents a vector of observations of a single variable. For the behavior in the 2-D case, see under \( \text{axis} \), below.
- **use_ties** [bool, optional] DO NOT USE. Does not do anything, keyword is only left in place for backwards compatibility reasons.
- **axis** [int or None, optional] If axis=0 (default), then each column represents a variable, with observations in the rows. If axis=1, the relationship is transposed: each row represents a variable, while the columns contain observations. If axis=None, then both arrays will be raveled.
- **nan_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.
- **alternative** [{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. Default is 'two-sided'. The following options are available:
  - 'two-sided': the correlation is nonzero
  - 'less': the correlation is negative (less than zero)
  - 'greater': the correlation is positive (greater than zero)

New in version 1.7.0.
### Returns

- **correlation**  
  [float] Spearman correlation coefficient  
- **pvalue**  
  [float] 2-tailed p-value.

### References

**scipy.stats.mstats.pointbiserialr**

Calculates a point biserial correlation coefficient and its p-value.

### Parameters

- **x**  
  [array_like of bools] Input array.  
- **y**  
  [array_like] Input array.

### Returns

- **correlation**  
  [float] R value  
- **pvalue**  
  [float] 2-tailed p-value

### Notes

Missing values are considered pair-wise: if a value is missing in x, the corresponding value in y is masked.

For more details on `pointbiserialr`, see `stats.pointbiserialr`.

**scipy.stats.mstats.kendalltau**

Computes Kendall's rank correlation tau on two variables x and y.

### Parameters

- **x**  
  [sequence] First data list (for example, time).  
- **y**  
  [sequence] Second data list.  
- **use_ties**  
  [{True, False}, optional] Whether ties correction should be performed.  
- **use_missing**  
  [{False, True}, optional] Whether missing data should be allocated a rank of 0 (False) or the average rank (True)  
- **method**  
  {'auto', 'asymptotic', 'exact'}, optional  
  Defines which method is used to calculate the p-value [1]. 'asymptotic' uses a normal approximation valid for large samples. 'exact' computes the exact p-value, but can only be used if no ties are present. As the sample size increases, the 'exact' computation time may grow and the result may lose some precision. 'auto' is the default and selects the appropriate method based on a trade-off between speed and accuracy.

### Returns
correlation

    [float] Kendall tau

pvalue

References

[1]

scipy.stats.mstats.kendalltau_seasonal

**scipy.stats.mstats.kendalltau_seasonal** (*x*)

Computes a multivariate Kendall’s rank correlation tau, for seasonal data.

Parameters

- **x** ([2-D ndarray]) Array of seasonal data, with seasons in columns.

scipy.stats.mstats.linregress

**scipy.stats.mstats.linregress** (*x*, *y*=`None`)

Linear regression calculation

Note that the non-masked version is used, and that this docstring is replaced by the non-masked docstring + some info on missing data.

scipy.stats.mstats.siegelslopes

**scipy.stats.mstats.siegelslopes** (*y*, *x*=`None`, *method*=`'hierarchical'`)

Computes the Siegel estimator for a set of points (*x*, *y*).

**siegelslopes** implements a method for robust linear regression using repeated medians to fit a line to the points (*x*, *y*). The method is robust to outliers with an asymptotic breakdown point of 50%.

Parameters

- **y** ([array_like]) Dependent variable.
- **x** ([array_like or None, optional]) Independent variable. If None, use `arange(len(y))` instead.
- **method** ([‘hierarchical’, ‘separate’]) If ‘hierarchical’, estimate the intercept using the estimated slope `medslope` (default option). If ‘separate’, estimate the intercept independent of the estimated slope. See Notes for details.

Returns

- **medslope** [float] Estimate of the slope of the regression line.
- **medintercept** [float] Estimate of the intercept of the regression line.

See also:

**theilslopes**

a similar technique without repeated medians
Notes

For more details on siegelslopes, see scipy.stats.siegelslopes.

scipy.stats.mstats.theilslopes

scipy.stats.mstats.theilslopes(y, x=None, alpha=0.95)
Computes the Theil-Sen estimator for a set of points (x, y).

theilslopes implements a method for robust linear regression. It computes the slope as the median of all slopes between paired values.

Parameters

- `y` [array_like] Dependent variable.
- `x` [array_like or None, optional] Independent variable. If None, use arange(len(y)) instead.
- `alpha` [float, optional] Confidence degree between 0 and 1. Default is 95% confidence. Note that alpha is symmetric around 0.5, i.e. both 0.1 and 0.9 are interpreted as “find the 90% confidence interval”.

Returns

- `medslope` [float] Theil slope.
- `medintercept` [float] Intercept of the Theil line, as median(y) - medslope*median(x).
- `lo_slope` [float] Lower bound of the confidence interval on medslope.
- `up_slope` [float] Upper bound of the confidence interval on medslope.

Notes

For more details on `ttest_1samp`, see `stats.ttest_1samp`.

```python
scipy.stats.mstats.ttest_onesamp
```

Calculates the T-test for the mean of ONE group of scores.

**Parameters**

- `a` [array_like] sample observation
- `popmean` [float or array_like] expected value in null hypothesis, if array_like than it must have the same shape as `a` excluding the axis dimension
- `axis` [int or None, optional] Axis along which to compute test. If None, compute over the whole array `a`.

**Returns**

- `statistic` [float or array] t-statistic
- `pvalue` [float or array] two-tailed p-value

Notes

For more details on `ttest_1samp`, see `stats.ttest_1samp`.

```python
scipy.stats.mstats.ttest_ind
```

Calculates the T-test for the means of TWO INDEPENDENT samples of scores.

**Parameters**

- `a, b` [array_like] The arrays must have the same shape, except in the dimension corresponding to `axis` (the first, by default).
- `axis` [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, `a`, and `b`.
- `equal_var` [bool, optional] If True, perform a standard independent 2 sample test that assumes equal population variances. If False, perform Welch’s t-test, which does not assume equal population variance.

New in version 0.17.0.

**Returns**

- `statistic` [float or array] The calculated t-statistic.
- `pvalue` [float or array] The two-tailed p-value.
Notes

For more details on `ttest_ind`, see `stats.ttest_ind`.

`scipy.stats.mstats.ttest_rel`

`scipy.stats.mstats.ttest_rel(a, b, axis=0)`
Calculates the T-test on TWO RELATED samples of scores, a and b.

Parameters

- `a`, `b` [array_like] The arrays must have the same shape.
- `axis` [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, `a`, and `b`.

Returns

- `statistic` [float or array] t-statistic
- `pvalue` [float or array] two-tailed p-value

Notes

For more details on `ttest_rel`, see `stats.ttest_rel`.

`scipy.stats.mstats.chisquare`

`scipy.stats.mstats.chisquare(f_obs, f_exp=None, ddof=0, axis=0)`
Calculate a one-way chi-square test.

The chi-square test tests the null hypothesis that the categorical data has the given frequencies.

Parameters

- `f_obs` [array_like] Observed frequencies in each category.
- `f_exp` [array_like, optional] Expected frequencies in each category. By default the categories are assumed to be equally likely.
- `ddof` [int, optional] “Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with $k - 1 - ddof$ degrees of freedom, where $k$ is the number of observed frequencies. The default value of `ddof` is 0.
- `axis` [int or None, optional] The axis of the broadcast result of `f_obs` and `f_exp` along which to apply the test. If axis is None, all values in `f_obs` are treated as a single data set. Default is 0.

Returns

- `chisq` [float or ndarray] The chi-squared test statistic. The value is a float if `axis` is None or `f_obs` and `f_exp` are 1-D.
- `p` [float or ndarray] The p-value of the test. The value is a float if `ddof` and the return value `chisq` are scalars.

See also:

`scipy.stats.power_divergence`
scipy.stats.fisher_exact

Fisher exact test on a 2x2 contingency table.

scipy.stats.barnard_exact

An unconditional exact test. An alternative to chi-squared test for small sample sizes.

Notes

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5. According to [3], the total number of samples is recommended to be greater than 13, otherwise exact tests (such as Barnard’s Exact test) should be used because they do not overreject.

Also, the sum of the observed and expected frequencies must be the same for the test to be valid; chisquare raises an error if the sums do not agree within a relative tolerance of 1e-8.

The default degrees of freedom, k-1, are for the case when no parameters of the distribution are estimated. If p parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are k-1-p. If the parameters are estimated in a different way, then the dof can be between k-1-p and k-1. However, it is also possible that the asymptotic distribution is not chi-square, in which case this test is not appropriate.

References

[1], [2], [3]

Examples

When just f_obs is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies.

```python
>>> from scipy.stats import chisquare
>>> chisquare([16, 18, 16, 14, 12, 12])
(2.0, 0.84914503608460956)
```

With f_exp the expected frequencies can be given.

```python
>>> chisquare([16, 18, 16, 14, 12, 12], f_exp=[16, 16, 16, 16, 16, 8])
(3.5, 0.62338762774958223)
```

When f_obs is 2-D, by default the test is applied to each column.

```python
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]]).T
>>> obs.shape
(6, 2)
>>> chisquare(obs)
(array([ 2. , 6.66666667]), array([ 0.84914504, 0.24663415]))
```

By setting axis=None, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.
```python
>>> chisquare(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> chisquare(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```
d dof is the change to make to the default degrees of freedom.

```python
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the chi-squared statistic with ddof.

```python
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=[0, 1, 2])
(2.0, array([ 0.84914504, 0.73575888, 0.5724067 ]))
```

\( f_{\text{obs}} \) and \( f_{\text{exp}} \) are also broadcast. In the following, \( f_{\text{obs}} \) has shape (6,) and \( f_{\text{exp}} \) has shape (2, 6), so the result of broadcasting \( f_{\text{obs}} \) and \( f_{\text{exp}} \) has shape (2, 6). To compute the desired chi-squared statistics, we use axis=1:

```python
>>> chisquare([16, 18, 16, 14, 12, 12], ...
...    f_exp=[[16, 16, 16, 16, 16, 8], ...
...    [8, 20, 20, 16, 12, 12]], ...
...    axis=1)
(array([ 3.5 , 9.25]), array([ 0.62338763, 0.09949846]))
```

**scipy.stats.mstats.kstest**

`scipy.stats.mstats.kstest(data1, data2, args=(), alternative='two-sided', mode='auto')`

**Parameters**

- **data1** [array_like]
- **data2** [str, callable or array_like]
- **args** [tuple, sequence, optional] Distribution parameters, used if data1 or data2 are strings.
- **alternative** [str, as documented in stats.kstest]
- **mode** [str, as documented in stats.kstest]

**Returns**

tuple of (K-S statistic, probability)

**scipy.stats.mstats.ks_2samp**

`scipy.stats.mstats.ks_2samp(data1, data2, alternative='two-sided', mode='auto')`

Computes the Kolmogorov-Smirnov test on two samples.

Missing values in \( x \) and/or \( y \) are discarded.

**Parameters**

- **data1** [array_like] First data set
- **data2** [array_like] Second data set
- **alternative** [{'two-sided', 'less', 'greater'}, optional] Indicates the alternative hypothesis. Default is 'two-sided'.
mode  
[['auto', 'exact', 'asymp'], optional] Defines the method used for calculating the p-value. The following options are available (default is 'auto'):
• 'auto': use 'exact' for small size arrays, 'asymp' for large
• 'exact': use approximation to exact distribution of test statistic
• 'asymp': use asymptotic distribution of test statistic

Returns

d  [float] Value of the Kolmogorov Smirnov test
p  [float] Corresponding p-value.

scipy.stats.mstats.ks_1samp

scipy.stats.mstats.ks_1samp(x, cdf, args=(), alternative='two-sided', mode='auto')
Computes the Kolmogorov-Smirnov test on one sample of masked values.
Missing values in x are discarded.

Parameters

x  [array_like] a 1-D array of observations of random variables.
cdf  [str or callable] If a string, it should be the name of a distribution in scipy.stats. If a callable, that callable is used to calculate the cdf.
args  [tuple, sequence, optional] Distribution parameters, used if cdf is a string.
alternative  [['two-sided', 'less', 'greater'], optional] Indicates the alternative hypothesis. Default is 'two-sided'.
mode  [['auto', 'exact', 'asymp'], optional] Defines the method used for calculating the p-value. The following options are available (default is 'auto'):
• 'auto': use 'exact' for small size arrays, 'asymp' for large
• 'exact': use approximation to exact distribution of test statistic
• 'asymp': use asymptotic distribution of test statistic

Returns

d  [float] Value of the Kolmogorov Smirnov test
p  [float] Corresponding p-value.

scipy.stats.mstats.ks_twosamp

scipy.stats.mstats.ks_twosamp(data1, data2, alternative='two-sided', mode='auto')
Computes the Kolmogorov-Smirnov test on two samples.
Missing values in x and/or y are discarded.

Parameters

data1  [array_like] First data set
data2  [array_like] Second data set
alternative  [['two-sided', 'less', 'greater'], optional] Indicates the alternative hypothesis. Default is 'two-sided'.
mode  [['auto', 'exact', 'asymp'], optional] Defines the method used for calculating the p-value. The following options are available (default is 'auto'):
• 'auto': use 'exact' for small size arrays, 'asymp' for large
• 'exact': use approximation to exact distribution of test statistic
• 'asymp': use asymptotic distribution of test statistic
Returns

d  [float] Value of the Kolmogorov Smirnov test
p  [float] Corresponding p-value.

**scipy.stats.mstats.mannwhitneyu**

**scipy.stats.mstats.mannwhitneyu** \((x, y, use\_continuity=True)\)

Computes the Mann-Whitney statistic

Missing values in \(x\) and/or \(y\) are discarded.

**Parameters**

- \(x\)  [sequence] Input
- \(y\)  [sequence] Input
- \(use\_continuity\)  [[True, False], optional] Whether a continuity correction \((1/2.)\) should be taken into account.

**Returns**

- \(statistic\)  [float] The minimum of the Mann-Whitney statistics
- \(pvalue\)  [float] Approximate two-sided p-value assuming a normal distribution.

**scipy.stats.mstats.rankdata**

**scipy.stats.mstats.rankdata** \((data, axis=None, use\_missing=False)\)

Returns the rank (also known as order statistics) of each data point along the given axis.

If some values are tied, their rank is averaged. If some values are masked, their rank is set to 0 if use\_missing is False, or set to the average rank of the unmasked values if use\_missing is True.

**Parameters**

- \(data\)  [sequence] Input data. The data is transformed to a masked array
- \(axis\)  [[None,int], optional] Axis along which to perform the ranking. If None, the array is first flattened. An exception is raised if the axis is specified for arrays with a dimension larger than 2
- \(use\_missing\)  [bool, optional] Whether the masked values have a rank of 0 (False) or equal to the average rank of the unmasked values (True).

**scipy.stats.mstats.kruskal**

**scipy.stats.mstats.kruskal** \(*args\)

Compute the Kruskal-Wallis H-test for independent samples

**Parameters**

- \(sample1, sample2, \ldots\)  [array_like] Two or more arrays with the sample measurements can be given as arguments.

**Returns**

- \(statistic\)  [float] The Kruskal-Wallis H statistic, corrected for ties
- \(pvalue\)  [float] The p-value for the test using the assumption that H has a chi square distribution
Notes

For more details on `kruskal`, see `stats.kruskal`.

Examples

```python
>>> from scipy.stats.mstats import kruskal
```

Random samples from three different brands of batteries were tested to see how long the charge lasted. Results were as follows:

```python
>>> a = [6.3, 5.4, 5.7, 5.2, 5.0]
>>> b = [6.9, 7.0, 6.1, 7.9]
>>> c = [7.2, 6.9, 6.1, 6.5]
```

Test the hypothesis that the distribution functions for all of the brands’ durations are identical. Use 5% level of significance.

```python
>>> kruskal(a, b, c)
KruskalResult(statistic=7.113812154696133, pvalue=0.028526948491942164)
```

The null hypothesis is rejected at the 5% level of significance because the returned p-value is less than the critical value of 5%.

`scipy.stats.mstats.kruskalwallis`

`scipy.stats.mstats.kruskalwallis(*args)`

Compute the Kruskal-Wallis H-test for independent samples

Parameters

- `sample1, sample2, ...` [array_like] Two or more arrays with the sample measurements can be given as arguments.

Returns

- `statistic` [float] The Kruskal-Wallis H statistic, corrected for ties
- `pvalue` [float] The p-value for the test using the assumption that H has a chi square distribution

Notes

For more details on `kruskal`, see `stats.kruskal`.

Examples

```python
>>> from scipy.stats.mstats import kruskal
```

Random samples from three different brands of batteries were tested to see how long the charge lasted. Results were as follows:
Test the hypothesis that the distribution functions for all of the brands' durations are identical. Use 5% level of significance.

```python
>>> kruskal(a, b, c)
KruskalResult(statistic=7.113812154696133, pvalue=0.028526948491942164)
```

The null hypothesis is rejected at the 5% level of significance because the returned p-value is less than the critical value of 5%.

**scipy.stats.mstats.friedmanchisquare**

```python
scipy.stats.mstats.friedmanchisquare(*args)
```

Friedman Chi-Square is a non-parametric, one-way within-subjects ANOVA. This function calculates the Friedman Chi-square test for repeated measures and returns the result, along with the associated probability value.

Each input is considered a given group. Ideally, the number of treatments among each group should be equal. If this is not the case, only the first n treatments are taken into account, where n is the number of treatments of the smallest group. If a group has some missing values, the corresponding treatments are masked in the other groups. The test statistic is corrected for ties.

Masked values in one group are propagated to the other groups.

**Returns**

- **statistic** [float] the test statistic.
- **pvalue** [float] the associated p-value.

**scipy.stats.mstats.brunnermunzel**

```python
scipy.stats.mstats.brunnermunzel(x, y, alternative='two-sided', distribution='t')
```

Computes the Brunner-Munzel test on samples x and y

Missing values in x and/or y are discarded.

**Parameters**

- **x, y** [array_like] Array of samples, should be one-dimensional.
- **alternative** ['less', 'two-sided', or 'greater', optional] Whether to get the p-value for the one-sided hypothesis ('less' or 'greater') or for the two-sided hypothesis ('two-sided'). Defaults value is 'two-sided'.
- **distribution**: 't' or 'normal', optional
  Whether to get the p-value by t-distribution or by standard normal distribution. Defaults value is 't'.

**Returns**

- **statistic** [float] The Brunner-Munzer W statistic.
- **pvalue** [float] p-value assuming an t distribution. One-sided or two-sided, depending on the choice of alternative and distribution.

See also:
**mannwhitneyu**

Mann-Whitney rank test on two samples.

**Notes**

For more details on `brunnermunzel`, see `stats.brunnermunzel`.

**scipy.stats.mstats.skewtest**

`scipy.stats.mstats.skewtest(a, axis=0)`

Tests whether the skew is different from the normal distribution.

**Parameters**

- `a` [array] The data to be tested
- `axis` [int or None, optional] Axis along which statistics are calculated. Default is 0. If None, compute over the whole array `a`.

**Returns**

- `statistic` [float] The computed z-score for this test.
- `pvalue` [float] a 2-sided p-value for the hypothesis test

**Notes**

For more details about `skewtest`, see `stats.skewtest`.

**scipy.stats.mstats.kurtosistest**

`scipy.stats.mstats.kurtosistest(a, axis=0)`

Tests whether a dataset has normal kurtosis

**Parameters**

- `a` [array] array of the sample data
- `axis` [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array `a`.

**Returns**

- `statistic` [float] The computed z-score for this test.
- `pvalue` [float] The 2-sided p-value for the hypothesis test

**Notes**

For more details about `kurtosistest`, see `stats.kurtosistest`. 

---

3.3. API definition 2743
Tests whether a sample differs from a normal distribution.

**Parameters**

- **a** [array_like] The array containing the data to be tested.
- **axis** [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array a.

**Returns**

- **statistic** [float or array] $s^2 + k^2$, where $s$ is the $z$-score returned by *skewtest* and $k$ is the $z$-score returned by *kurtosistest*.
- **pvalue** [float or array] A 2-sided chi squared probability for the hypothesis test.

**Notes**

For more details about *normaltest*, see *stats.normaltest*.

</tbody>
</table>

**scipy.stats.mstats.obrientransform**

Computes a transform on input data (any number of columns). Used to test for homogeneity of variance prior to running one-way stats. Each array in *args* is one level of a factor. If an *f_oneway()* run on the transformed data and found significant, variances are unequal. From Maxwell and Delaney, p.112.

Returns: transformed data for use in an ANOVA
scipy.stats.mstats.trim

scipy.stats.mstats.trim(a, limits=None, inclusive=(True, True), relative=False, axis=None)

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

**Parameters**

- **a** [sequence] Input array.
- **limits** [{None, tuple}, optional] If relative is False, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked. If relative is True, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data. Noting n the number of unmasked data before trimming, the (n*limits[0])th smallest data and the (n*limits[1])th largest data are masked, and the total number of unmasked data after trimming is n*(1.-sum(limits)) In each case, the value of one limit can be set to None to indicate an open interval. If limits is None, no trimming is performed
- **inclusive** [{(bool, bool) tuple}, optional] If relative is False, tuple indicating whether values exactly equal to the absolute limits are allowed. If relative is True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
- **relative** [bool, optional] Whether to consider the limits as absolute values (False) or proportions to cut (True).
- **axis** [int, optional] Axis along which to trim.

**Examples**

```python
>>> from scipy.stats.mstats import trim
>>> z = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
>>> print(trim(z, (3, 8)))
[-- -- 3 4 5 6 7 8 -- --]
>>> print(trim(z, (0.1, 0.2), relative=True))
[-- 2 3 4 5 6 7 8 -- --]
```

scipy.stats.mstats.trimmed

scipy.stats.mstats.trimmed(a, limits=None, inclusive=(True, True))

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

**Parameters**

- **a** [array_like] Input array.
- **limits** [{None, tuple}, optional] Tuple of (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit will be masked. A limit is None indicates an open interval.
- **inclusive** [{(bool, bool) tuple}, optional] Tuple of (lower flag, upper flag), indicating whether values exactly equal to the lower (upper) limit are allowed.
Examples

```python
>>> from scipy.stats.mstats import trim

```a = np.arange(10)```

The interval is left-closed and right-open, i.e., \([2, 8)\). Trim the array by keeping only values in the interval.

```python
>>> trim(a, limits=(2, 8), inclusive=(True, False))
masked_array(data=[--, --, 2, 3, 4, 5, 6, 7, --, --],
             mask=[True, True, False, False, False, False, False, False, True, True],
             fill_value=999999)
```

### scipy.stats.mstats.trimmed_stde

scipy.stats.mstats.trimmed_stde\(a, \text{limits}=(0.1, 0.1), \text{inclusive}=(1, 1), \text{axis}=\text{None}\)

Returns the standard error of the trimmed mean along the given axis.

**Parameters**

- `a`: [sequence] Input array.
- `limits`: [{(0.1, 0.1), tuple of float}, optional] Tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data.
  
  If \(n\) is the number of unmasked data before trimming, the values smaller than \(n \times \text{limits}[0]\) and the values larger than \(n \times \text{limits}[1]\) are masked, and the total number of unmasked data after trimming is \(n \times (1. - \text{sum(limits)})\). In each case, the value of one limit can be set to None to indicate an open interval. If limits is None, no trimming is performed.
- `inclusive`: [{(bool, bool) tuple}, optional] Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
- `axis`: [int, optional] Axis along which to trim.

**Returns**

- `trimmed_stde`: [scalar or ndarray]

### scipy.stats.mstats.trimr

scipy.stats.mstats.trimr\(a, \text{limits}=\text{None}, \text{inclusive}=(True, True), \text{axis}=\text{None}\)

Trims an array by masking some proportion of the data on each end. Returns a masked version of the input array.

**Parameters**

- `a`: [sequence] Input array.
- `limits`: [{None, tuple}, optional] Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting \(n\) the number of unmasked data before trimming, the \((n \times \text{limits}[0])\)th smallest data and the \((n \times \text{limits}[1])\)th largest data are masked, and the total number of unmasked data after trimming is \(n \times (1. - \text{sum(limits)})\). The value of one limit can be set to None to indicate an open interval.
- `inclusive`: [{(True, True) tuple}, optional] Tuple of flags indicating whether the number of data being masked on the left (right) end should be truncated (True) or rounded (False) to integers.
axis  
[[None,int], optional] Axis along which to trim. If None, the whole array is trimmed, but its shape is maintained.

**scipy.stats.mstats.trimtail**

`scipy.stats.mstats.trimtail(data, proportiontocut=0.2, tail='left', inclusive=(True, True), axis=None)`

Trims the data by masking values from one tail.

**Parameters**

- **data**  
  [array_like] Data to trim.

- **proportiontocut**  
  [float, optional] Percentage of trimming. If n is the number of unmasked values before trimming, the number of values after trimming is \((1 - \text{proportiontocut}) \times n\). Default is 0.2.

- **tail**  
  [{'left','right'}, optional] If 'left' the `proportiontocut` lowest values will be masked. If 'right' the `proportiontocut` highest values will be masked. Default is 'left'.

- **inclusive**  
  [((bool, bool) tuple], optional] Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False). Default is (True, True).

- **axis**  
  [int, optional] Axis along which to perform the trimming. If None, the input array is first flattened. Default is None.

**Returns**

- **trimtail**  
  [ndarray] Returned array of same shape as `data` with masked tail values.

**scipy.stats.mstats.trimboth**

`scipy.stats.mstats.trimboth(data, proportiontocut=0.2, inclusive=(True, True), axis=None)`

Trims the smallest and largest data values.

Trims the `data` by masking the \(\text{int}(\text{proportiontocut} \times n)\) smallest and \(\text{int}(\text{proportiontocut} \times n)\) largest values of data along the given axis, where n is the number of unmasked values before trimming.

**Parameters**

- **data**  
  [ndarray] Data to trim.

- **proportiontocut**  
  [float, optional] Percentage of trimming (as a float between 0 and 1). If n is the number of unmasked values before trimming, the number of values after trimming is \((1 - 2*\text{proportiontocut}) \times n\). Default is 0.2.

- **inclusive**  
  [((bool, bool) tuple], optional] Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).

- **axis**  
  [int, optional] Axis along which to perform the trimming. If None, the input array is first flattened.
**scipy.stats.mstats.winsorize**

```python
scipy.stats.mstats.winsorize(a, limits=None, inclusive=(True, True), inplace=False, axis=None, nan_policy='propagate')
```

Returns a Winsorized version of the input array.

The (limits[0])th lowest values are set to the (limits[0])th percentile, and the (limits[1])th highest values are set to the (1 - limits[1])th percentile. Masked values are skipped.

**Parameters**

- `a` [sequence] Input array.
- `limits` [{None, tuple of float}, optional] Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting n the number of unmasked data before trimming, the (n*limits[0])th smallest data and the (n*limits[1])th largest data are masked, and the total number of unmasked data after trimming is n*(1.-sum(limits)). The value of one limit can be set to None to indicate an open interval.
- `inclusive` [{(True, True) tuple}, optional] Tuple indicating whether the number of data being masked on each side should be truncated (True) or rounded (False).
- `inplace` [{False, True}, optional] Whether to winsorize in place (True) or to use a copy (False).
- `axis` [{None, int}, optional] Axis along which to trim. If None, the whole array is trimmed, but its shape is maintained.
- `nan_policy` [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
  - 'propagate': allows nan values and may overwrite or propagate them
  - 'raise': throws an error
  - 'omit': performs the calculations ignoring nan values

**Notes**

This function is applied to reduce the effect of possibly spurious outliers by limiting the extreme values.

**Examples**

```python
>>> from scipy.stats.mstats import winsorize
```

A shuffled array contains integers from 1 to 10.

```python
>>> a = np.array([10, 4, 9, 8, 5, 3, 7, 2, 1, 6])
```

The 10% of the lowest value (i.e., 1) and the 20% of the highest values (i.e., 9 and 10) are replaced.

```python
>>> winsorize(a, limits=[0.1, 0.2])
masked_array(data=[8, 4, 8, 8, 5, 3, 7, 2, 2, 6],
             mask=False,
             fill_value=999999)
```
scipy.stats.mstats.zmap

scipy.stats.mstats.zmap(scores, compare, axis=0, ddof=0, nan_policy='propagate')

Calculate the relative z-scores.

Return an array of z-scores, i.e., scores that are standardized to zero mean and unit variance, where mean and variance are calculated from the comparison array.

Parameters

- **scores**: [array_like] The input for which z-scores are calculated.
- **compare**: [array_like] The input from which the mean and standard deviation of the normalization are taken; assumed to have the same dimension as `scores`.
- **axis**: [int or None, optional] Axis over which mean and variance of `compare` are calculated. Default is 0. If None, compute over the whole array `scores`.
- **ddof**: [int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.
- **nan_policy**: [{'propagate', 'raise', 'omit'}, optional] Defines how to handle the occurrence of nans in `compare`. 'propagate' returns nan, 'raise' raises an exception, 'omit' performs the calculations ignoring nan values. Default is 'propagate'. Note that when the value is 'omit', nans in `scores` also propagate to the output, but they do not affect the z-scores computed for the non-nan values.

Returns

- **zscore**: [array_like] Z-scores, in the same shape as `scores`.

Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses `asanyarray` instead of `asarray` for parameters).

Examples

```python
>>> from scipy.stats import zmap
>>> a = [0.5, 2.0, 2.5, 3]
>>> b = [0, 1, 2, 3, 4]
>>> zmap(a, b)
array([-1.06066017, 0. , 0.35355339, 0.70710678])
```

scipy.stats.mstats.zscore

scipy.stats.mstats.zscore(a, axis=0, ddof=0, nan_policy='propagate')

Compute the z score.

Compute the z score of each value in the sample, relative to the sample mean and standard deviation.

Parameters

- **a**: [array_like] An array like object containing the sample data.
- **axis**: [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array `a`.
ddof          [int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

nan_policy   [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'. Note that when the value is 'omit', nans in the input also propagate to the output, but they do not affect the z-scores computed for the non-nan values.

Returns

zscore       [array_like] The z-scores, standardized by mean and standard deviation of input array a.

Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses asanyarray instead of asarray for parameters).

Examples

```python
def main():
    a = np.array([ 0.7972, 0.0767, 0.4383, 0.7866, 0.8091, 0.1954, 0.6307, 0.6599, 0.1065, 0.0508])

    from scipy import stats
    stats.zscore(a)
    array([ 1.1273, -1.247 , -0.0552, 1.0923, 1.1664, -0.8559, 0.5786, 0.6748, -1.1488, -1.3324])

    b = np.array([[[ 0.3148, 0.0478, 0.6243, 0.4608],
                   [ 0.7149, 0.0775, 0.6072, 0.9656],
                   [ 0.6341, 0.1403, 0.9759, 0.4064],
                   [ 0.5918, 0.6948, 0.904 , 0.3721],
                   [ 0.0921, 0.2481, 0.1188, 0.1366]]])

    stats.zscore(b, axis=1, ddof=1)
    array([[-0.19264823, -1.28415119, 1.07259584, 0.40420358],
           [-0.91611681, -0.89090508, 1.49830362, 0.88731639, -0.5785977]])

    x = np.array([25.11, 30.10, np.nan, 32.02, 43.15],
                  [14.95, 16.06, 121.25, 94.35, 29.81])

    stats.zscore(x, axis=1, nan_policy='omit')
    array([-1.13490897, -0.37830299, nan, -0.08718406, 1.60039602],
           [-0.91611681, -0.89090508, 1.49830362, 0.88731639, -0.5785977]])
```

Computing along a specified axis, using n-1 degrees of freedom (ddof=1) to calculate the standard deviation:

```python
>>> a = np.array([ 0.7972, 0.0767, 0.4383, 0.7866, 0.8091, 0.1954, 0.6307, 0.6599, 0.1065, 0.0508])
>>> from scipy import stats
>>> stats.zscore(a)
array([ 1.1273, -1.247 , -0.0552, 1.0923, 1.1664, -0.8559, 0.5786, 0.6748, -1.1488, -1.3324])
```

Computing along a specified axis, using n-1 degrees of freedom (ddof=1) to calculate the standard deviation:

```python
>>> b = np.array([[[ 0.3148, 0.0478, 0.6243, 0.4608],
                   [ 0.7149, 0.0775, 0.6072, 0.9656],
                   [ 0.6341, 0.1403, 0.9759, 0.4064],
                   [ 0.5918, 0.6948, 0.904 , 0.3721],
                   [ 0.0921, 0.2481, 0.1188, 0.1366]]])
>>> stats.zscore(b, axis=1, ddof=1)
array([[-0.19264823, -1.28415119, 1.07259584, 0.40420358],
           [-0.91611681, -0.89090508, 1.49830362, 0.88731639, -0.5785977]])
```

An example with `nan_policy='omit'`:

```python
>>> x = np.array([25.11, 30.10, np.nan, 32.02, 43.15],
                  [14.95, 16.06, 121.25, 94.35, 29.81])
>>> stats.zscore(x, axis=1, nan_policy='omit')
array([-1.13490897, -0.37830299, nan, -0.08718406, 1.60039602],
           [-0.91611681, -0.89090508, 1.49830362, 0.88731639, -0.5785977]])
```

### scipy.stats.mstats.argstoarray

```python
c scipy.stats.mstats.argstoarray(*args)
```

Constructs a 2D array from a group of sequences. Sequences are filled with missing values to match the length of the longest sequence.

**Parameters**

**Returns**

- `argstoarray` [MaskedArray] A (m x n) masked array, where m is the number of arguments and n the length of the longest argument.

**Notes**

`numpy.ma.row_stack` has identical behavior, but is called with a sequence of sequences.

**Examples**

A 2D masked array constructed from a group of sequences is returned.

```python
>>> from scipy.stats.mstats import argstoarray
>>> argstoarray([[1, 2, 3], [4, 5, 6]])
masked_array(data=[[1.0, 2.0, 3.0],
                   [4.0, 5.0, 6.0]],
               mask=[[False, False, False],
                      [False, False, False]],
               fill_value=1e+20)
```

The returned masked array filled with missing values when the lengths of sequences are different.
>>> argstoarray([1, 3], [4, 5, 6])
masked_array(
data=[[1.0, 3.0, --],
     [4.0, 5.0, 6.0]],
mask=[[False, False, True],
     [False, False, False]],
fill_value=1e+20)

scipy.stats.mstats.count_tied_groups

scipy.stats.mstats.count_tied_groups(x, use_missing=False)
Counts the number of tied values.

Parameters

x [sequence] Sequence of data on which to count the ties
use_missing [bool, optional] Whether to consider missing values as tied.

Returns

count_tied_groups [dict] Returns a dictionary (nb of ties: nb of groups).

Examples

>>> from scipy.stats import mstats
>>> z = [0, 0, 0, 2, 2, 2, 3, 3, 4, 5, 6]
>>> mstats.count_tied_groups(z)
{2: 1, 3: 2}

In the above example, the ties were 0 (3x), 2 (3x) and 3 (2x).

>>> z = np.ma.array([0, 0, 1, 2, 2, 2, 3, 3, 4, 5, 6])
>>> mstats.count_tied_groups(z)
{2: 2, 3: 1}
>>> z[[1,-1]] = np.ma.masked
>>> mstats.count_tied_groups(z, use_missing=True)
{2: 2, 3: 1}

scipy.stats.mstats.msign

scipy.stats.mstats.msign(x)
Returns the sign of x, or 0 if x is masked.
scipy.stats.mstats.compare_medians_ms

scipy.stats.mstats.compare_medians_ms (group_1, group_2, axis=None)

Compares the medians from two independent groups along the given axis.

The comparison is performed using the McKean-Schrader estimate of the standard error of the medians.

Parameters

- **group_1** [array_like] First dataset. Has to be of size >=7.
- **group_2** [array_like] Second dataset. Has to be of size >=7.
- **axis** [int, optional] Axis along which the medians are estimated. If None, the arrays are flattened. If axis is not None, then group_1 and group_2 should have the same shape.

Returns

- **compare_medians_ms** [{float, ndarray}] If axis is None, then returns a float, otherwise returns a 1-D ndarray of floats with a length equal to the length of group_1 along axis.

scipy.stats.mstats.median_cihs

scipy.stats.mstats.median_cihs (data, alpha=0.05, axis=None)

Computes the alpha-level confidence interval for the median of the data.

Uses the Hettmasperger-Sheather method.

Parameters

- **data** [array_like] Input data. Masked values are discarded. The input should be 1D only, or axis should be set to None.
- **alpha** [float, optional] Confidence level of the intervals.
- **axis** [int or None, optional] Axis along which to compute the quantiles. If None, use a flattened array.

Returns

- **median_cihs** Alpha level confidence interval.

scipy.stats.mstats.mjci

scipy.stats.mstats.mjci (data, prob=[0.25, 0.5, 0.75], axis=None)

Returns the Maritz-Jarrett estimators of the standard error of selected experimental quantiles of the data.

Parameters

- **data** [ndarray] Data array.
- **prob** [sequence, optional] Sequence of quantiles to compute.
- **axis** [int or None, optional] Axis along which to compute the quantiles. If None, use a flattened array.
scipy.stats.mstats.mquantiles_cimj

Computes the alpha confidence interval for the selected quantiles of the data, with Maritz-Jarrett estimators.

Parameters

- **data**: [ndarray] Data array.
- **prob**: [sequence, optional] Sequence of quantiles to compute.
- **alpha**: [float, optional] Confidence level of the intervals.
- **axis**: [int or None, optional] Axis along which to compute the quantiles. If None, use a flattened array.

Returns

- **ci_lower**: [ndarray] The lower boundaries of the confidence interval. Of the same length as prob.
- **ci_upper**: [ndarray] The upper boundaries of the confidence interval. Of the same length as prob.

scipy.stats.mstats.rsh

Evaluates Rosenblatt's shifted histogram estimators for each data point.

Rosenblatt's estimator is a centered finite-difference approximation to the derivative of the empirical cumulative distribution function.

Parameters

- **data**: [sequence] Input data, should be 1-D. Masked values are ignored.
- **points**: [sequence or None, optional] Sequence of points where to evaluate Rosenblatt shifted histogram. If None, use the data.

scipy.stats.boxcox

```python
scipy.stats.boxcox(x, lmbda=None, alpha=None, optimizer=None)
```

Return a dataset transformed by a Box-Cox power transformation.

**Parameters**

- `x` : [ndarray] Input array. Must be positive 1-dimensional. Must not be constant.
- `lmbda` : [{None, scalar}, optional] If `lmbda` is not None, do the transformation for that value. If `lmbda` is None, find the lambda that maximizes the log-likelihood function and return it as the second output argument.
- `alpha` : [{None, float}, optional] If `alpha` is not None, return the \(100 \times (1-\alpha)\) % confidence interval for `lmbda` as the third output argument. Must be between 0.0 and 1.0.
- `optimizer` : [callable, optional] If `lmbda` is None, `optimizer` is the scalar optimizer used to find the value of `lmbda` that minimizes the negative log-likelihood function. `optimizer` is a callable that accepts one argument:
  - `fun` : [callable] The objective function, which evaluates the negative log-likelihood function at a provided value of `lmbda` and returns an object, such as an instance of `scipy.optimize.OptimizeResult`, which holds the optimal value of `lmbda` in an attribute `x`. See the example in `boxcox_normmax` or the documentation of `scipy.optimize.minimize_scalar` for more information.
  - If `lmbda` is not None, `optimizer` is ignored.

**Returns**

- `boxcox` : [ndarray] Box-Cox power transformed array.
- `maxlog` : [float, optional] If the `lmbda` parameter is None, the second returned argument is the lambda that maximizes the log-likelihood function.
- `(min_ci, max_ci)` : [tuple of float, optional] If `lmbda` parameter is None and `alpha` is not None, this returned tuple of floats represents the minimum and maximum confidence limits given `alpha`.

See also:

- `probplot`, `boxcox_normplot`, `boxcox_normmax`, `boxcox_llf`

**Notes**

The Box-Cox transform is given by:

\[
y = \begin{cases} 
(x^{*lmbda} - 1) / lmbda, & \text{for } lmbda \neq 0 \\
\log(x), & \text{for } lmbda = 0
\end{cases}
\]

`boxcox` requires the input data to be positive. Sometimes a Box-Cox transformation provides a shift parameter to achieve this; `boxcox` does not. Such a shift parameter is equivalent to adding a positive constant to `x` before calling `boxcox`.

The confidence limits returned when `alpha` is provided give the interval where:

\[
llf(\hat{\lambda}) - llf(\lambda) < \frac{1}{2} \chi^2(1 - \alpha, 1),
\]

with `llf` the log-likelihood function and `\chi^2` the chi-squared function.
References

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

We generate some random variates from a non-normal distribution and make a probability plot for it, to show it is non-normal in the tails:

```python
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(211)
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> prob = stats.probplot(x, dist=stats.norm, plot=ax1)
>>> ax1.set_xlabel('')
>>> ax1.set_title('Probplot against normal distribution')
```

We now use `boxcox` to transform the data so it’s closest to normal:

```python
>>> ax2 = fig.add_subplot(212)
>>> xt, _ = stats.boxcox(x)
>>> prob = stats.probplot(xt, dist=stats.norm, plot=ax2)
>>> ax2.set_title('Probplot after Box-Cox transformation')
```
scipy.stats.boxcox_normmax

`scipy.stats.boxcox_normmax(x, brack=None, method='pearsonr', optimizer=None)`

Compute optimal Box-Cox transform parameter for input data.

**Parameters**

- **x** (array_like) Input array.
- **brack** (2-tuple, optional, default (-2.0, 2.0)) The starting interval for a downhill bracket search for the default `optimize.brent` solver. Note that this is in most cases not critical; the final result is allowed to be outside this bracket. If `optimizer` is passed, `brack` must be None.
- **method** (str, optional) The method to determine the optimal transform parameter (boxcox lambda parameter). Options are:
  - `'pearsonr'` (default) Maximizes the Pearson correlation coefficient between $y = \text{boxcox}(x)$ and the expected values for $y$ if $x$ would be normally-distributed.
  - `'mle'` Minimizes the log-likelihood `boxcox_llf`. This is the method used in `boxcox`.
  - `'all'` Use all optimization methods available, and return all results. Useful to compare different methods.
- **optimizer** (callable, optional) `optimizer` is a callable that accepts one argument:
  - **fun** (callable) The objective function to be optimized. `fun` accepts one argument, the Box-Cox transform parameter `lmbda`, and returns the negative log-likelihood function at the provided value. The job of `optimizer` is to find the value of `lmbda` that minimizes `fun` and returns an object, such as an instance of `scipy.optimize.OptimizeResult`, which holds the optimal value of `lmbda` in an attribute `x`.

See the example below or the documentation of `scipy.optimize.minimize_scalar` for more information.

**Returns**

- **maxlog** (float or ndarray) The optimal transform parameter found. An array instead of a scalar for method='all'.

See also:

`boxcox, boxcox_llf, boxcox_normplot, scipy.optimize.minimize_scalar`

**Examples**

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

We can generate some data and determine the optimal `lmbda` in various ways:

```python
>>> rng = np.random.default_rng()
>>> x = stats.loggamma.rvs(5, size=30, random_state=rng) + 5
>>> y, lmax_mle = stats.boxcox(x)
>>> lmax_pearsonr = stats.boxcox_normmax(x)
```

```python
>>> lmax_mle
1.4613865614008015
>>> lmax_pearsonr
```

(continues on next page)
Alternatively, we can define our own optimizer function. Suppose we are only interested in values of \( \lambda \) on the interval \([6, 7]\), we want to use `scipy.optimize.minimize_scalar` with method='bounded', and we want to use tighter tolerances when optimizing the log-likelihood function. To do this, we define a function that accepts positional argument `fun` and uses `scipy.optimize.minimize_scalar` to minimize `fun` subject to the provided bounds and tolerances:

```python
>>> from scipy import optimize
>>> options = {'xatol': 1e-12}  # absolute tolerance on `x`
>>> def optimizer(fun):
...     return optimize.minimize_scalar(fun, bounds=(6, 7),
...                                      method="bounded", options=options)
>>> stats.boxcox_normmax(x, optimizer=optimizer)
6.000...
```
scipy.stats.boxcox_llf

scipy.stats.boxcox_llf(lmb, data)
The boxcox log-likelihood function.

Parameters

lmb [scalar] Parameter for Box-Cox transformation. See boxcox for details.
data [array_like] Data to calculate Box-Cox log-likelihood for. If data is multi-dimensional, the log-likelihood is calculated along the first axis.

Returns

llf [float or ndarray] Box-Cox log-likelihood of data given lmb. A float for 1-D data, an array otherwise.

See also:

boxcox, probplot, boxcox_normplot, boxcox_normmax

Notes

The Box-Cox log-likelihood function is defined here as

\[ llf = (\lambda - 1) \sum_i (\log(x_i) - \bar{y})^2 / N, \]

where \( y \) is the Box-Cox transformed input data \( x \).

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.axes_grid1.inset_locator import inset_axes

Generate some random variates and calculate Box-Cox log-likelihood values for them for a range of \( \lambda \) values:

```python
>>> rng = np.random.default_rng()
>>> x = stats.loggamma.rvs(5, loc=10, size=1000, random_state=rng)
>>> lmbdas = np.linspace(-2, 10)
>>> llf = np.zeros(lmbdas.shape, dtype=float)
>>> for ii, lmbda in enumerate(lmbdas):
...     llf[ii] = stats.boxcox_llf(lmbda, x)
```

Also find the optimal \( \lambda \) value with boxcox:

```python
>>> x_most_normal, lmbda_optimal = stats.boxcox(x)
```

Plot the log-likelihood as function of \( \lambda \). Add the optimal \( \lambda \) as a horizontal line to check that that’s really the optimum:

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(lmbdas, llf, 'b-')
>>> ax.axhline(stats.boxcox_llf(lmbda_optimal, x), color='r')
```

(continues on next page)
Now add some probability plots to show that where the log-likelihood is maximized the data transformed with `boxcox` looks closest to normal:

```python
>>> locs = [3, 10, 4]  # 'lower left', 'center', 'lower right'
>>> for lmbda, loc in zip([-1, lmbda_optimal, 9], locs):
...     xt = stats.boxcox(x, lmbda=lmbda)
...     (osm, osr), (slope, intercept, r_sq) = stats.probplot(xt)
...     ax_inset = inset_axes(ax, width="20%", height="20%", loc=loc)
...     ax_inset.plot(osm, osr, 'c.', osm, slope*osm + intercept, 'k-')
...     ax_inset.set_xticklabels([])
...     ax_inset.set_yticklabels([])
...     ax_inset.set_title(r'$\lambda=%.2f$' % lmbda)
```

```python
>>> plt.show()
```

![Graph showing probability plots for different lambda values](image)

### scipy.stats.yeojohnson

`scipy.stats.yeojohnson(x, lmbda=None)`

Return a dataset transformed by a Yeo-Johnson power transformation.

**Parameters**

- `x` ([ndarray]) Input array. Should be 1-dimensional.
- `lmbda` ([float, optional]) If `lmbda` is None, find the lambda that maximizes the log-likelihood function and return it as the second output argument. Otherwise the transformation is done for the given value.

**Returns**

- `yeojohnson`: [ndarray]
  Yeo-Johnson power transformed array.
The Yeo-Johnson transform is given by:

\[
\begin{align*}
  y &= \frac{(x + 1)^{\lambda} - 1}{\lambda}, \quad \text{for } x \geq 0, \lambda \neq 0 \\
  \log(x + 1), \quad &\text{for } x > 0, \lambda = 0 \\
  -\frac{(-x + 1)^{2 - \lambda} - 1}{2 - \lambda}, \quad &\text{for } x < 0, \lambda \neq 2 \\
  -\log(-x + 1), \quad &\text{for } x < 0, \lambda = 2
\end{align*}
\]

Unlike `boxcox`, `yeojohnson` does not require the input data to be positive.

New in version 1.2.0.

References

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt

We generate some random variates from a non-normal distribution and make a probability plot for it, to show it is non-normal in the tails:

```python
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(211)
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> prob = stats.probplot(x, dist=stats.norm, plot=ax1)
>>> ax1.set_xlabel('')
>>> ax1.set_title('Probplot against normal distribution')
```

We now use `yeojohnson` to transform the data so it's closest to normal:

```python
>>> ax2 = fig.add_subplot(212)
>>> xt, lambda_ = stats.yeojohnson(x)
>>> prob = stats.probplot(xt, dist=stats.norm, plot=ax2)
>>> ax2.set_title('Probplot after Yeo-Johnson transformation')
```

```python
>>> plt.show()
```
scipy.stats.yeojohnson_normmax

scipy.stats.yeojohnson_normmax(x, brack=(-2, 2))

Compute optimal Yeo-Johnson transform parameter.

Compute optimal Yeo-Johnson transform parameter for input data, using maximum likelihood estimation.

Parameters

   x       [array_like] Input array.

Note that this is in most cases not critical; the final result is allowed to be outside this bracket.

Returns

   maxlog  [float] The optimal transform parameter found.

See also:

yeojohnson, yeojohnson_llf, yeojohnson_normplot

Notes

New in version 1.2.0.

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt

Generate some data and determine optimal lambda

>>> rng = np.random.default_rng()
>>> x = stats.loggamma.rvs(5, size=30, random_state=rng) + 5
>>> lmax = stats.yeojohnson_normmax(x)
```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.yeojohnson_normplot(x, -10, 10, plot=ax)
>>> ax.axvline(lmax, color='r')

>>> plt.show()

![Yeo-Johnson Normality Plot](image)

**scipy.stats.yeojohnson_llf**

The yeojohnson log-likelihood function.

**Parameters**

- **lmb** [scalar] Parameter for Yeo-Johnson transformation. See `yeojohnson` for details.
- **data** [array_like] Data to calculate Yeo-Johnson log-likelihood for. If `data` is multi-dimensional, the log-likelihood is calculated along the first axis.

**Returns**

- **llf** [float] Yeo-Johnson log-likelihood of `data` given `lmb`.

**See also:**

- `yeojohnson`, `probplot`, `yeojohnson_normplot`, `yeojohnson_normmax`
Notes

The Yeo-Johnson log-likelihood function is defined here as

$$llf = -N/2 \log(\hat{\sigma}^2) + (\lambda - 1) \sum_i \text{sign}(x_i) \log(|x_i| + 1)$$

where $\hat{\sigma}^2$ is estimated variance of the the Yeo-Johnson transformed input data $x$.

New in version 1.2.0.

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> import mpl_toolkits.axes_grid1.inset_locator as inset_axes

Generate some random variates and calculate Yeo-Johnson log-likelihood values for them for a range of $\lambda$ values:

```py
>>> x = stats.loggamma.rvs(5, loc=10, size=1000)
>>> lmbdas = np.linspace(-2, 10)
>>> llf = np.zeros(lmbdas.shape, dtype=float)
>>> for ii, lmbda in enumerate(lmbdas):
...     llf[ii] = stats.yeojohnson_llf(lmbda, x)
```

Also find the optimal $\lambda$ value with `yeojohnson`:

```py
>>> x_most_normal, lmbda_optimal = stats.yeojohnson(x)
```

Plot the log-likelihood as function of $\lambda$. Add the optimal $\lambda$ as a horizontal line to check that that's really the optimum:

```py
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(lmbdas, llf, 'b.-')
>>> ax.axhline(stats.yeojohnson_llf(lmbda_optimal, x), color='r')
>>> ax.set_xlabel('lmbda parameter')
>>> ax.set_ylabel('Yeo-Johnson log-likelihood')
```

Now add some probability plots to show that where the log-likelihood is maximized the data transformed with `yeojohnson` looks closest to normal:

```py
>>> locs = [3, 10, 4]  # 'lower left', 'center', 'lower right'
>>> for lmbda, loc in zip([-1, lmbda_optimal, 9], locs):
...     xt = stats.yeojohnson(x, lmbda=lmbda)
...     (osm, osr), (slope, intercept, r_sq) = stats.probplot(xt)
...     ax_inset = inset_axes(ax, width="20\%", height="20\%", loc=loc)
...     ax_inset.plot(osm, osr, 'c.', osm, slope*osm + intercept, 'k-')
...     ax_inset.set_xticklabels([])
...     ax_inset.set_yticklabels([])
...     ax_inset.set_title(r'\$\lambda=\$1.2f\$' % lmbda)
```
scipy.stats.obrientransform

`scipy.stats.obrientransform(*args)`

Compute the O’Brien transform on input data (any number of arrays).

Used to test for homogeneity of variance prior to running one-way stats. Each array in *args is one level of a factor. If `f_oneway` is run on the transformed data and found significant, the variances are unequal. From Maxwell and Delaney [1], p.112.

**Parameters**

*args  
[tuple of array_like] Any number of arrays.

**Returns**

`obrientransform`  
[ndarray] Transformed data for use in an ANOVA. The first dimension of the result corresponds to the sequence of transformed arrays. If the arrays given are all 1-D of the same length, the return value is a 2-D array; otherwise it is a 1-D array of type object, with each element being an ndarray.

**References**

[1]
Examples

We’ll test the following data sets for differences in their variance.

```python
>>> x = [10, 11, 13, 9, 7, 12, 12, 9, 10]
>>> y = [13, 21, 5, 10, 8, 14, 10, 12, 7, 15]
```

Apply the O’Brien transform to the data.

```python
>>> from scipy.stats import obrientransform
>>> tx, ty = obrientransform(x, y)
```

Use `scipy.stats.f_oneway` to apply a one-way ANOVA test to the transformed data.

```python
>>> from scipy.stats import f_oneway
>>> F, p = f_oneway(tx, ty)
>>> p
0.1314139477040335
```

If we require that \( p < 0.05 \) for significance, we cannot conclude that the variances are different.

**scipy.stats.sigmaclip**

`scipy.stats.sigmaclip(a, low=4.0, high=4.0)`

Perform iterative sigma-clipping of array elements.

Starting from the full sample, all elements outside the critical range are removed, i.e. all elements of the input array \( c \) that satisfy either of the following conditions:

\[
c < \text{mean}(c) - \text{std}(c) \times \text{low}
\]
\[
c > \text{mean}(c) + \text{std}(c) \times \text{high}
\]

The iteration continues with the updated sample until no elements are outside the (updated) range.

**Parameters**

- **a** [array_like] Data array, will be raveled if not 1-D.
- **low** [float, optional] Lower bound factor of sigma clipping. Default is 4.
- **high** [float, optional] Upper bound factor of sigma clipping. Default is 4.

**Returns**

- **clipped** [ndarray] Input array with clipped elements removed.
- **lower** [float] Lower threshold value use for clipping.
- **upper** [float] Upper threshold value use for clipping.
Examples

```python
>>> from scipy.stats import sigmaclip
>>> a = np.concatenate((np.linspace(9.5, 10.5, 31),
...                       np.linspace(0, 20, 5)))
>>> fact = 1.5
>>> c, low, upp = sigmaclip(a, fact, fact)
>>> c
array([ 9.96666667, 10.0, 10.03333333, 10.0])
>>> c.var(), c.std()
(0.00005555555555555165, 0.023570226039551501)
>>> low, c.mean() - fact*c.std(), c.min()
(9.966446609406727, 9.966446609406727, 9.9666666666666668)
>>> upp, c.mean() + fact*c.std(), c.max()
(10.035355339059327, 10.035355339059327, 10.033333333333333)

>>> a = np.concatenate((np.linspace(9.5, 10.5, 11),
...                       np.linspace(-100, -50, 3)))
>>> c, low, upp = sigmaclip(a, 1.8, 1.8)
>>> (c == np.linspace(9.5, 10.5, 11)).all()
True
```

**scipy.stats.trimboth**

scipy.stats.<b>trimboth</b>(<i>a</i>, <i>proportiontocut</i>, <i>axis=0</i>)

Slice off a proportion of items from both ends of an array.

Slice off the passed proportion of items from both ends of the passed array (i.e., with <i>proportiontocut</i> = 0.1, slices leftmost 10% and rightmost 10% of scores). The trimmed values are the lowest and highest ones. Slice off less if proportion results in a non-integer slice index (i.e. conservatively slices off <i>proportiontocut</i>).

**Parameters**

- <i>a</i> [array_like] Data to trim.
- <i>proportiontocut</i> [float] Proportion (in range 0-1) of total dataset to trim of each end.
- <i>axis</i> [int or None, optional] Axis along which to trim data. Default is 0. If None, compute over the whole array <i>a</i>.

**Returns**

- <i>out</i> [ndarray] Trimmed version of array <i>a</i>. The order of the trimmed content is undefined.

**See also:**

- trim_mean
Examples

```python
>>> from scipy import stats
>>> a = np.arange(20)
>>> b = stats.trimboth(a, 0.1)
>>> b.shape
(16,)
```

**scipy.stats.trim1**

`scipy.stats.trim1(a, proportiontocut, tail='right', axis=0)`

Slice off a proportion from ONE end of the passed array distribution.

If `proportiontocut = 0.1`, slices off 'leftmost' or 'rightmost' 10% of scores. The lowest or highest values are trimmed (depending on the tail). Slice off less if proportion results in a non-integer slice index (i.e. conservatively slices off `proportiontocut`).

**Parameters**

- `a` [array_like] Input array.
- `proportiontocut` [float] Fraction to cut off of ‘left’ or ‘right’ of distribution.
- `tail` [‘left’, ‘right’], optional] Defaults to ‘right’.
- `axis` [int or None, optional] Axis along which to trim data. Default is 0. If None, compute over the whole array `a`.

**Returns**

- `trim1` [ndarray] Trimmed version of array `a`. The order of the trimmed content is undefined.

Examples

```python
>>> from scipy import stats
>>> a = np.arange(20)
>>> b = stats.trim1(a, 0.5, 'left')
>>> b
array([10, 11, 12, 13, 14, 16, 15, 17, 18, 19])
```

**scipy.stats.zmap**

`scipy.stats.zmap(scores, compare, axis=0, ddof=0, nan_policy='propagate')`

Calculate the relative z-scores.

Return an array of z-scores, i.e., scores that are standardized to zero mean and unit variance, where mean and variance are calculated from the comparison array.

**Parameters**

- `scores` [array_like] The input for which z-scores are calculated.
- `compare` [array_like] The input from which the mean and standard deviation of the normalization are taken; assumed to have the same dimension as `scores`.
- `axis` [int or None, optional] Axis over which mean and variance of `compare` are calculated. Default is 0. If None, compute over the whole array `scores`.

2768 Chapter 3. SciPy API
**ddof**
[int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

**nan_policy**
[{'propagate', 'raise', 'omit'}, optional] Defines how to handle the occurrence of nans in `compare`. 'propagate' returns nan, 'raise' raises an exception, 'omit' performs the calculations ignoring nan values. Default is 'propagate'. Note that when the value is 'omit', nans in `scores` also propagate to the output, but they do not affect the z-scores computed for the non-nan values.

**Returns**

**zscore**
[array_like] Z-scores, in the same shape as `scores`.

**Notes**

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses `asanyarray` instead of `asarray` for parameters).

**Examples**

```python
def zmap(a, b):
    return scipy.stats.zscore(a, axis=0, ddof=0, nan_policy='propagate')
```
Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses `asanyarray` instead of `asarray` for parameters).

Examples

```python
>>> a = np.array([0.7972, 0.0767, 0.4383, 0.7866, 0.8091,
... 0.1954, 0.6307, 0.6599, 0.1065, 0.0508])
>>> from scipy import stats
>>> stats.zscore(a)
array([ 1.1273, -1.247 , -0.0552, 1.0923, 1.1664, -0.8559, 0.5786,
    0.6748, -1.1488, -1.3324])
```

Computing along a specified axis, using n-1 degrees of freedom (ddof=1) to calculate the standard deviation:

```python
>>> b = np.array([[[0.3148, 0.0478, 0.6243, 0.4608],
... [0.7149, 0.0775, 0.6072, 0.9656],
... [0.6341, 0.1403, 0.9759, 0.4064],
... [0.5918, 0.6948, 0.904 , 0.3721],
... [0.0921, 0.2481, 0.1188, 0.1366]]])
>>> stats.zscore(b, axis=1, ddof=1)
array([[-0.19264823, -1.28415119, 1.07259584, 0.40420358],
    [ 0.33048416, -1.37380874, 0.04251374, 1.00081084],
    [ 0.26796377, -1.12598418, 1.23283094, -0.37481053],
    [-0.22095197, 0.24468594, 1.19042819, -1.21416216],
    [-0.82780366, 1.4457416 , -0.43867764, -0.1792603 ]])
```

An example with `nan_policy='omit'`:

```python
>>> x = np.array([[25.11, 30.10, np.nan, 32.02, 43.15],
... [14.95, 16.06, 121.25, 94.35, 29.81]])
>>> stats.zscore(x, axis=1, nan_policy='omit')
array([[-1.13490897, -0.37830299, nan, -0.08718406, 1.60039602],
    [-0.91611681, -0.89090508, 1.4983032 , 0.88731639, -0.5785977 ]])
```

Statistical distances

- `wasserstein_distance(u_values, v_values[, …])`: Compute the first Wasserstein distance between two 1D distributions.
- `energy_distance(u_values, v_values[, …])`: Compute the energy distance between two 1D distributions.
scipy.stats.wasserstein_distance

Compute the first Wasserstein distance between two 1D distributions.

This distance is also known as the earth mover's distance, since it can be seen as the minimum amount of “work” required to transform $u$ into $v$, where “work” is measured as the amount of distribution weight that must be moved, multiplied by the distance it has to be moved.

New in version 1.0.0.

Parameters

- **u_values, v_values**
  [array_like] Values observed in the (empirical) distribution.

- **u_weights, v_weights**
  [array_like, optional] Weight for each value. If unspecified, each value is assigned the same weight. $u_weights$ (resp. $v_weights$) must have the same length as $u_values$ (resp. $v_values$). If the weight sum differs from 1, it must still be positive and finite so that the weights can be normalized to sum to 1.

Returns

- **distance** [float] The computed distance between the distributions.

Notes

The first Wasserstein distance between the distributions $u$ and $v$ is:

$$l_1(u, v) = \inf_{\pi \in \Gamma(u, v)} \int_{\mathbb{R} \times \mathbb{R}} |x - y| \, d\pi(x, y)$$

where $\Gamma(u, v)$ is the set of (probability) distributions on $\mathbb{R} \times \mathbb{R}$ whose marginals are $u$ and $v$ on the first and second factors respectively.

If $U$ and $V$ are the respective CDFs of $u$ and $v$, this distance also equals to:

$$l_1(u, v) = \int_{-\infty}^{+\infty} |U - V|$$

See [2] for a proof of the equivalence of both definitions.

The input distributions can be empirical, therefore coming from samples whose values are effectively inputs of the function, or they can be seen as generalized functions, in which case they are weighted sums of Dirac delta functions located at the specified values.

```

`scipy.stats.energy_distance`

`scipy.stats.energy_distance(u_values, v_values, u_weights=None, v_weights=None)`

Compute the energy distance between two 1D distributions.

New in version 1.0.0.

Parameters

- `u_values, v_values` ([array_like]) Values observed in the (empirical) distribution.
- `u_weights, v_weights` ([array_like, optional]) Weight for each value. If unspecified, each value is assigned the same weight. `u_weights` (resp. `v_weights`) must have the same length as `u_values` (resp. `v_values`). If the weight sum differs from 1, it must still be positive and finite so that the weights can be normalized to sum to 1.

Returns

- `distance` [float] The computed distance between the distributions.

Notes

The energy distance between two distributions $u$ and $v$, whose respective CDFs are $U$ and $V$, equals to:

$$D(u, v) = (2E|X - Y| - E|X - X'| - E|Y - Y'|)^{1/2}$$

where $X$ and $X'$ (resp. $Y$ and $Y'$) are independent random variables whose probability distribution is $u$ (resp. $v$).

As shown in [2], for one-dimensional real-valued variables, the energy distance is linked to the non-distribution-free version of the Cramér-von Mises distance:

$$D(u, v) = \sqrt{2} l_2(u, v) = \left(2 \int_{-\infty}^{+\infty} (U - V)^2 \right)^{1/2}$$

Note that the common Cramér-von Mises criterion uses the distribution-free version of the distance. See [2] (section 2), for more details about both versions of the distance.

The input distributions can be empirical, therefore coming from samples whose values are effectively inputs of the function, or they can be seen as generalized functions, in which case they are weighted sums of Dirac delta functions located at the specified values.

</tr>
<tr>
<td><code>NumericalInverseHermite</code></td>
<td>A Hermite spline fast numerical inverse of a probability distribution.</td>
</tr>
</tbody>
</table>

**scipy.stats.rvs_ratio_uniforms**

Generate random samples from a probability density function using the ratio-of-uniforms method.

**Parameters**

- **pdf** [callable] A function with signature \( pdf(x) \) that is proportional to the probability density function of the distribution.
- **umax** [float] The upper bound of the bounding rectangle in the u-direction.
- **vmin** [float] The lower bound of the bounding rectangle in the v-direction.
- **vmax** [float] The upper bound of the bounding rectangle in the v-direction.
- **size** [int or tuple of ints, optional] Defining number of random variates (default is 1).
- **c** [float, optional.] Shift parameter of ratio-of-uniforms method, see Notes. Default is 0.
- **random_state** [None, int, numpy.random.Generator, numpy.random.RandomState], optional
  
  If `seed` is None (or `np.random`), the `numpy.random.RandomState` singleton is used.
  If `seed` is an int, a new RandomState instance is used, seeded with `seed`. If `seed` is already a
  Generator or RandomState instance then that instance is used.

**Returns**

- **rvs** [ndarray] The random variates distributed according to the probability distribution defined by the pdf.
Notes

Given a univariate probability density function $pdf$ and a constant $c$, define the set $A = \{(u, v) : 0 < u \leq \sqrt{pdf(v/u + c)}\}$. If $(U, V)$ is a random vector uniformly distributed over $A$, then $V/U + c$ follows a distribution according to $pdf$.

The above result (see [1], [2]) can be used to sample random variables using only the pdf, i.e. no inversion of the cdf is required. Typical choices of $c$ are zero or the mode of $pdf$. The set $A$ is a subset of the rectangle $R = [0, umax] \times [vmin, vmax]$ where

\begin{itemize}
  \item $umax = \sup \sqrt{pdf(x)}$
  \item $vmin = \inf (x - c) \sqrt{pdf(x)}$
  \item $vmax = \sup (x - c) \sqrt{pdf(x)}$
\end{itemize}

In particular, these values are finite if $pdf$ is bounded and $x^{**2} \ast pdf(x)$ is bounded (i.e. subquadratic tails). One can generate $(U, V)$ uniformly on $R$ and return $V/U + c$ if $(U, V)$ are also in $A$ which can be directly verified.

The algorithm is not changed if one replaces $pdf$ by $k \ast pdf$ for any constant $k > 0$. Thus, it is often convenient to work with a function that is proportional to the probability density function by dropping unnecessary normalization factors.

Intuitively, the method works well if $A$ fills up most of the enclosing rectangle such that the probability is high that $(U, V)$ lies in $A$ whenever it lies in $R$ as the number of required iterations becomes too large otherwise. To be more precise, note that the expected number of iterations to draw $(U, V)$ uniformly distributed on $R$ such that $(U, V)$ is also in $A$ is given by the ratio $\text{area}(R) / \text{area}(A) = 2 \ast umax \ast (vmax - vmin) / \text{area}(pdf)$, where $\text{area(pdf)}$ is the integral of $pdf$ (which is equal to one if the probability density function is used but can take on other values if a function proportional to the density is used). The equality holds since the area of $A$ is equal to $0.5 \ast \text{area(pdf)}$ (Theorem 7.1 in [1]). If the sampling fails to generate a single random variate after 50000 iterations (i.e. not a single draw is in $A$), an exception is raised.

If the bounding rectangle is not correctly specified (i.e. if it does not contain $A$), the algorithm samples from a distribution different from the one given by $pdf$. It is therefore recommended to perform a test such as $kstest$ as a check.

References

[1], [2], [3]

Examples

```python
>>> from scipy import stats
>>> rng = np.random.default_rng()
Simulate normally distributed random variables. It is easy to compute the bounding rectangle explicitly in that case.
For simplicity, we drop the normalization factor of the density.

```python
>>> f = lambda x: np.exp(-x**2 / 2)
>>> v_bound = np.sqrt(f(np.sqrt(2))) * np.sqrt(2)
>>> umax, vmin, vmax = np.sqrt(f(0)), -v_bound, v_bound
>>> rvs = stats.rvs_ratio_uniforms(f, umax, vmin, vmax, size=2500,
... random_state=rng)
```

The K-S test confirms that the random variates are indeed normally distributed (normality is not rejected at 5% significance level):
The exponential distribution provides another example where the bounding rectangle can be determined explicitly.

```python
>>> rvs = stats.rvs_ratio_uniforms(lambda x: np.exp(-x), umax=1,
... vmin=0, vmax=2*np.exp(-1), size=1000,
... random_state=rng)
>>> stats.kstest(rvs, 'expon')[1]
0.21121052054580314
```

### scipy.stats.NumericalInverseHermite

A Hermite spline fast numerical inverse of a probability distribution.

The initializer of `NumericalInverseHermite` accepts `dist`, an object representing a continuous distribution, and provides an object with methods that approximate `dist.ppf` and `dist.rvs`. For most distributions, these methods are faster than those of `dist` itself.

**Parameters**

- **dist** [object] Object representing the distribution for which a fast numerical inverse is desired; for instance, a frozen instance of a `scipy.stats` continuous distribution. See Notes and Examples for details.
- **tol** [float, optional] u-error tolerance (see Notes). The default is 1e-12.
- **max_intervals** [int, optional] Maximum number of intervals in the cubic Hermite spline used to approximate the percent point function. The default is 100000.

**Notes**

`NumericalInverseHermite` approximates the inverse of a continuous statistical distribution’s CDF with a cubic Hermite spline.

As described in [1], it begins by evaluating the distribution’s PDF and CDF at a mesh of quantiles \( x \) within the distribution’s support. It uses the results to fit a cubic Hermite spline \( H \) such that \( H(p) = x \), where \( p \) is the array of percentiles corresponding with the quantiles \( x \). Therefore, the spline approximates the inverse of the distribution’s CDF to machine precision at the percentiles \( p \), but typically, the spline will not be as accurate at the midpoints between the percentile points:

\[
p_{\text{mid}} = \frac{(p[:-1] + p[1:])/2}{p_{\text{mid}}}
\]

so the mesh of quantiles is refined as needed to reduce the maximum “u-error”:

\[
u_{\text{error}} = \text{np.max} \left( \text{np.abs}(\text{dist.cdf}(H(p_{\text{mid}})) - p_{\text{mid}}) \right)
\]

below the specified tolerance `tol`. Refinement stops when the required tolerance is achieved or when the number of mesh intervals after the next refinement could exceed the maximum allowed number `max_intervals`.

The object `dist` must have methods `pdf`, `cdf`, and `ppf` that behave like those of a `frozen` instance of `scipy.stats.rv_continuous`. Specifically, it must have methods `pdf` and `cdf` that accept exactly one ndarray argument \( x \) and return the probability density function and cumulative density function (respectively) at \( x \). The object must also have a method `ppf` that accepts a float \( p \) and returns the percentile point function at \( p \). The object may also have a method `isf` that accepts a float \( p \) and returns the inverse survival function at \( p \); if it does not, it will be assigned an attribute `isf` that calculates the inverse survival function using `ppf`. The `ppf` and `isf`
methods will each be evaluated at a small positive float \( p \) (e.g. \( p = \frac{\text{utol}}{10} \)), and the domain over which the approximate numerical inverse is defined will be \( \text{ppf}(p) \) to \( \text{isf}(p) \). The approximation will not be accurate in the extreme tails beyond this domain.

**References**

[1]

**Examples**

For some distributions, \( \text{dist.ppf} \) and \( \text{dist.rvs} \) are quite slow. For instance, consider \( \text{scipy.stats.genexpon} \). We freeze the distribution by passing all shape parameters into its initializer and time the resulting object's \( \text{ppf} \) and \( \text{rvs} \) functions.

```python
>>> import numpy as np
>>> from scipy import stats
>>> from timeit import timeit

>>> time_once = lambda f: f"({timeit(f, number=1)}*1000:.6) ms"

>>> dist = stats.genexpon(9, 16, 3) # freeze the distribution
>>> p = np.linspace(0.01, 0.99, 99) # percentiles from 1% to 99%

>>> time_once(lambda: dist.ppf(p))
'154.565 ms' # may vary

>>> time_once(lambda: dist.rvs(size=100))
'148.979 ms' # may vary
```

The \( \text{NumericalInverseHermite} \) has a method that approximates \( \text{dist.ppf} \).

```python
>>> from scipy.stats import NumericalInverseHermite

>>> fni = NumericalInverseHermite(dist)

>>> np.allclose(fni.ppf(p), dist.ppf(p))
True
```

In some cases, it is faster to both generate the fast numerical inverse and use it than to call \( \text{dist.ppf} \).

```python
>>> def time_me():
...     fni = NumericalInverseHermite(dist)
...     fni.ppf(p)

>>> time_once(time_me)
'11.9222 ms' # may vary
```

After generating the fast numerical inverse, subsequent calls to its methods are much faster.

```python
>>> time_once(lambda: fni.ppf(p))
'0.0819 ms' # may vary
```

The fast numerical inverse can also be used to generate random variates using inverse transform sampling.

```python
>>> time_once(lambda: fni.rvs(size=100))
'0.0911 ms' # may vary
```

Depending on the implementation of the distribution's random sampling method, the random variates generated may be nearly identical, given the same random state.
To use `NumericalInverseHermite` with a custom distribution, users may subclass `scipy.stats.rv_continuous` and initialize a frozen instance or create an object with equivalent pdf, cdf, and ppf methods. For instance, the following object represents the standard normal distribution. For simplicity, we use `scipy.special.ndtr` and `scipy.special.ndtri` to compute the cdf and ppf, respectively.

```python
>>> from scipy.special import ndtr, ndtri
>>> class MyNormal:
...     def pdf(self, x):
...         return 1/np.sqrt(2*np.pi) * np.exp(-x**2 / 2)
...     def cdf(self, x):
...         return ndtr(x)
...     def ppf(self, x):
...         return ndtri(x)
>>> dist1 = MyNormal()
>>> fni1 = NumericalInverseHermite(dist1)
>>> dist2 = stats.norm()
>>> fni2 = NumericalInverseHermite(dist2)
>>> print(fni1.rvs(random_state=seed), fni2.rvs(random_state=seed))
-1.9603810921759424 -1.9603810921747074
```

**Attributes**
- `intervals` [int] The number of intervals of the interpolant.
- `midpoint_error` [float] The maximum u-error at an interpolant interval midpoint.

**Methods**

- `ppf(q)` Approximate percent point function (inverse cdf) of the given RV.
- `qrvs([size, d, qmc_engine])` Quasi-random variates of the given RV.
- `rvs([size, random_state])` Random variates of the given RV.
**scipy.stats.NumericalInverseHermite.ppf**

NumericalInverseHermite.ppf(q)

Approximate percent point function (inverse cdf) of the given RV.

**Parameters**

q

[array_like] lower tail probability.

**Returns**

x

[array_like] quantile corresponding to the lower tail probability q.

**scipy.stats.NumericalInverseHermite.rvs**

NumericalInverseHermite.rvs(size=None, d=None, qmc_engine=None)

Quasi-random variates of the given RV.

The qmc_engine is used to draw uniform quasi-random variates, and these are converted to quasi-random variates of the given RV using inverse transform sampling.

**Parameters**

size

[int, tuple of ints, or None; optional] Defines shape of random variates array. Default is None.

d

[int or None, optional] Defines dimension of uniform quasi-random variates to be transformed. Default is None.

qmc_engine

[scipy.stats.qmc.QMCEngine(d=1), optional] Defines the object to use for drawing quasi-random variates. Default is None, which uses scipy.stats.qmc.Halton(1).

**Returns**

rvs

[ndarray or scalar] Quasi-random variates. See Notes for shape information.

**Notes**

The shape of the output array depends on size, d, and qmc_engine. The intent is for the interface to be natural, but the detailed rules to achieve this are complicated.

- If qmc_engine is None, a scipy.stats.qmc.Halton instance is created with dimension d. If d is not provided, d=1.
- If qmc_engine is not None and d is None, d is determined from the dimension of the qmc_engine.
- If qmc_engine is not None and d is not None but the dimensions are inconsistent, a ValueError is raised.
- After d is determined according to the rules above, the output shape is tuple_shape + d_shape, where:
  - tuple_shape = tuple() if size is None,
  - tuple_shape = (size,) if size is an int,
  - tuple_shape = size if size is a sequence,
  - d_shape = tuple() if d is None or d is 1, and
  - d_shape = (d,) if d is greater than 1.
The elements of the returned array are part of a low-discrepancy sequence. If \( d \) is 1, this means that none of the samples are truly independent. If \( d > 1 \), each slice \( \text{rvs}[..., i] \) will be of a quasi-independent sequence; see \texttt{scipy.stats.qmc.QMCEngine} for details. Note that when \( d > 1 \), the samples returned are still those of the provided univariate distribution, not a multivariate generalization of that distribution.

\texttt{scipy.stats.NumericalInverseHermite.rvs}

\texttt{NumericalInverseHermite.rvs}(\texttt{size=None, random_state=None})

Random variates of the given RV.

The \texttt{random_state} is used to draw uniform pseudo-random variates, and these are converted to pseudo-random variates of the given RV using inverse transform sampling.

**Parameters**

- \texttt{size} \[\text{int, tuple of ints, or None; optional}\] Defines shape of array of random variates. Default is \texttt{None}.
- \texttt{random_state} \[\text{[\text{None, int, numpy.random.Generator,} \text{numpy.random.RandomState}, \text{optional}]\}

Defines the object to use for drawing pseudorandom variates. If \texttt{random_state} is \texttt{None} the \texttt{np.random.RandomState} singleton is used. If \texttt{random_state} is an \texttt{int}, a new \texttt{RandomState} instance is used, seeded with \texttt{random_state}. If \texttt{random_state} is already a \texttt{RandomState} or \texttt{Generator} instance, then that object is used. Default is \texttt{None}.

**Returns**

- \texttt{rvs} \[\text{ndarray or scalar}\] Random variates of given \texttt{size}. If \texttt{size} is \texttt{None}, a scalar is returned.

**Circular statistical functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{circmean}</td>
<td>Compute the circular mean for samples in a range.</td>
</tr>
<tr>
<td>\texttt{circvar}</td>
<td>Compute the circular variance for samples assumed to be in a range.</td>
</tr>
<tr>
<td>\texttt{circstd}</td>
<td>Compute the circular standard deviation for samples assumed to be in the range [low to high].</td>
</tr>
</tbody>
</table>

\texttt{scipy.stats.circmean}

\texttt{scipy.stats.circmean}(\texttt{samples, high=6.283185307179586, low=0, axis=None, nan_policy='propagate')}  

Compute the circular mean for samples in a range.

**Parameters**

- \texttt{samples} \[\text{array_like}\] Input array.
- \texttt{high} \[\text{float or int, optional}\] High boundary for circular mean range. Default is \( 2 \times \pi \).
- \texttt{low} \[\text{float or int, optional}\] Low boundary for circular mean range. Default is \( 0 \).
- \texttt{axis} \[\text{int, optional}\] Axis along which means are computed. The default is to compute the mean of the flattened array.
- \texttt{nan_policy} \[\text{[\text{‘propagate’, ‘raise’, ‘omit’}, optional]}\] Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

3.3. API definition 2779
**Returns**

- `circmean` [float] Circular mean.

**Examples**

```python
>>> from scipy.stats import circmean
>>> circmean([0.1, 2*np.pi+0.2, 6*np.pi+0.3])
0.2
```

```python
>>> from scipy.stats import circmean
>>> circmean([0.2, 1.4, 2.6], high=1, low=0)
0.4
```

**scipy.stats.circvar**

`scipy.stats.circvar(samples, high=6.283185307179586, low=0, axis=None, nan_policy='propagate')`

Compute the circular variance for samples assumed to be in a range.

**Parameters**

- `samples` [array_like] Input array.
- `high` [float or int, optional] High boundary for circular variance range. Default is $2\pi$.
- `low` [float or int, optional] Low boundary for circular variance range. Default is 0.
- `axis` [int, optional] Axis along which variances are computed. The default is to compute the variance of the flattened array.
- `nan_policy` [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- `circvar` [float] Circular variance.

**Notes**

This uses a definition of circular variance that in the limit of small angles returns a number close to the 'linear' variance.

**Examples**

```python
>>> from scipy.stats import circvar
>>> circvar([0, 2*np.pi/3, 5*np.pi/3])
2.19722457734
```
scipy.stats.circstd

scipy.stats.circstd(samples, high=6.283185307179586, low=0, axis=None, nan_policy='propagate')

Compute the circular standard deviation for samples assumed to be in the range [low to high].

Parameters

- samples [array_like] Input array.
- high [float or int, optional] High boundary for circular standard deviation range. Default is 2*pi.
- low [float or int, optional] Low boundary for circular standard deviation range. Default is 0.
- axis [int, optional] Axis along which standard deviations are computed. The default is to compute the standard deviation of the flattened array.
- nan_policy [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

Returns

- circstd [float] Circular standard deviation.

Notes

This uses a definition of circular standard deviation that in the limit of small angles returns a number close to the 'linear' standard deviation.

Examples

```python
>>> from scipy.stats import circstd
>>> circstd([0, 0.1*np.pi/2, 0.001*np.pi, 0.03*np.pi/2])
0.063564063306
```

scipy.stats.chi2_contingency

**scipy.stats.chi2_contingency**(observed, correction=True, lambda_=None)

Chi-square test of independence of variables in a contingency table.

This function computes the chi-square statistic and p-value for the hypothesis test of independence of the observed frequencies in the contingency table \[1\] observed. The expected frequencies are computed based on the marginal sums under the assumption of independence; see scipy.stats.contingency.expected_freq. The number of degrees of freedom is (expressed using numpy functions and attributes):

\[
dof = \text{observed.size} - \sum(\text{observed.shape}) + \text{observed.ndim} - 1
\]

**Parameters**

- **observed** [array_like] The contingency table. The table contains the observed frequencies (i.e. number of occurrences) in each category. In the two-dimensional case, the table is often described as an “R x C table”.
- **correction** [bool, optional] If True, and the degrees of freedom is 1, apply Yates’ correction for continuity. The effect of the correction is to adjust each observed value by 0.5 towards the corresponding expected value.
- **lambda_** [float or str, optional] By default, the statistic computed in this test is Pearson’s chi-squared statistic \[2\]. \(\text{lambda}_\) allows a statistic from the Cressie-Read power divergence family \[3\] to be used instead. See power_divergence for details.

**Returns**

- **chi2** [float] The test statistic.
- **p** [float] The p-value of the test
- **dof** [int] Degrees of freedom
- **expected** [ndarray, same shape as observed] The expected frequencies, based on the marginal sums of the table.

See also:

- scipy.stats.contingency.expected_freq
- fisher_exact
- chisquare
- power_divergence
- barnard_exact
- boschloo_exact

**Notes**

An often quoted guideline for the validity of this calculation is that the test should be used only if the observed and expected frequencies in each cell are at least 5.

This is a test for the independence of different categories of a population. The test is only meaningful when the dimension of observed is two or more. Applying the test to a one-dimensional table will always result in expected equal to observed and a chi-square statistic equal to 0.

This function does not handle masked arrays, because the calculation does not make sense with missing values.
Like stats.chisquare, this function computes a chi-square statistic; the convenience this function provides is to figure out the expected frequencies and degrees of freedom from the given contingency table. If these were already known, and if the Yates’ correction was not required, one could use stats.chisquare. That is, if one calls:

```python
chi2, p, dof, ex = chi2_contingency(obs, correction=False)
```

then the following is true:

```python
(chi2, p) == stats.chisquare(obs.ravel(), f_exp=ex.ravel(), ddof=obs.size - 1 - dof)
```

The `lambda_` argument was added in version 0.13.0 of scipy.

**References**

[1], [2], [3]

**Examples**

A two-way example (2 x 3):

```python
>>> from scipy.stats import chi2_contingency
>>> obs = np.array([[10, 10, 20], [20, 20, 20]])
>>> chi2_contingency(obs)
(2.7777777777777777, 0.24935220877729619, 2,
 array([[ 12.,  12.,  16.],
        [ 18.,  18.,  24.]]))
```

Perform the test using the log-likelihood ratio (i.e. the “G-test”) instead of Pearson’s chi-squared statistic.

```python
>>> g, p, dof, expctd = chi2_contingency(obs, lambda_="log-likelihood")
>>> g, p
(2.7688587616781319, 0.25046668010954165)
```

A four-way example (2 x 2 x 2 x 2):

```python
>>> obs = np.array([... [[[12, 17], [... [11, 16]], [... [11, 12], [... [15, 16]]], [... [23, 15], [... [30, 22]], [... [14, 17], [... [15, 16]]]]])
>>> chi2_contingency(obs)
(8.7584514426741897, 0.64417725029295503, 11,
 array([[[ 14.15462386, 14.15462386],
         [ 16.49423111, 16.49423111]],
```
scipy.stats.contingency.crosstab

scipy.stats.contingency.crosstab(*args, levels=None, sparse=False)

Return table of counts for each possible unique combination in *args.

When len(args) > 1, the array computed by this function is often referred to as a contingency table [1].

The arguments must be sequences with the same length. The second return value, count, is an integer array with len(args) dimensions. If levels is None, the shape of count is (n0, n1, ...), where nk is the number of unique elements in args[k].

Parameters

args [sequences] A sequence of sequences whose unique aligned elements are to be counted. The sequences in args must all be the same length.

levels [sequence, optional] If levels is given, it must be a sequence that is the same length as args. Each element in levels is either a sequence or None. If it is a sequence, it gives the values in the corresponding sequence in args that are to be counted. If any value in the sequences in args does not occur in the corresponding sequence in levels, that value is ignored and not counted in the returned array count. The default value of levels for args[i] is np.unique(args[i])

sparse [bool, optional] If True, return a sparse matrix. The matrix will be an instance of the scipy.sparse.coo_matrix class. Because SciPy's sparse matrices must be 2-d, only two input sequences are allowed when sparse is True. Default is False.

Returns

elements [tuple of numpy.ndarrays.] Tuple of length len(args) containing the arrays of elements that are counted in count. These can be interpreted as the labels of the corresponding dimensions of count. If levels was given, then if levels[i] is not None, elements[i] will hold the values given in levels[i].

count [numpy.ndarray or scipy.sparse.coo_matrix] Counts of the unique elements in zip(*args), stored in an array. Also known as a contingency table when len(args) > 1.

numpy.unique
Notes

New in version 1.7.0.

References

[1]

Examples

```python
>>> from scipy.stats.contingency import crosstab
```

Given the lists `a` and `x`, create a contingency table that counts the frequencies of the corresponding pairs.

```python
>>> a = ['A', 'B', 'A', 'A', 'B', 'A', 'B', 'B']
>>> x = ['X', 'X', 'X', 'Y', 'Z', 'Y', 'Z', 'Z']
>>> (avals, xvals), count = crosstab(a, x)
>>> avals
array(['A', 'B'], dtype='<U1')
>>> xvals
array(['X', 'Y', 'Z'], dtype='<U1')
>>> count
array([[2, 3, 0],
       [1, 0, 4]])
```

So ('A', 'X') occurs twice, ('A', 'Y') occurs three times, etc.

Higher dimensional contingency tables can be created.

```python
>>> p = [0, 0, 0, 0, 1, 1, 1, 0, 0, 1]
>>> (avals, xvals, pvals), count = crosstab(a, x, p)
>>> count
array([[ [2, 3, 0],
          [2, 1],
          [0, 0]],
       [[1, 0],
          [0, 0],
          [1, 3]]])
>>> count.shape
(2, 3, 2)
```

The values to be counted can be set by using the `levels` argument. It allows the elements of interest in each input sequence to be given explicitly instead finding the unique elements of the sequence.

For example, suppose one of the arguments is an array containing the answers to a survey question, with integer values 1 to 4. Even if the value 1 does not occur in the data, we want an entry for it in the table.

```python
>>> q1 = [2, 3, 3, 2, 4, 4, 2, 3, 4, 4, 3, 3, 4]  # 1 does not occur.
>>> q2 = [4, 4, 2, 2, 2, 4, 1, 1, 2, 2, 4, 2, 2, 4]  # 3 does not occur.
>>> options = [1, 2, 3, 4]
>>> vals, count = crosstab(q1, q2, levels=(options, options))
```

(continues on next page)
>>> count
array([[0, 0, 0, 0],
       [1, 1, 0, 1],
       [1, 4, 0, 1],
       [0, 3, 0, 3]])

If `levels` is given, but an element of `levels` is None, the unique values of the corresponding argument are used. For example:

>>> vals, count = crosstab(q1, q2, levels=(None, options))
>>> vals
[array([[2, 3, 4],
       [1, 2, 3, 4]])
>>> count
array([[1, 1, 0, 1],
       [1, 4, 0, 1],
       [0, 3, 0, 3]])

If we want to ignore the pairs where 4 occurs in `q2`, we can give just the values [1, 2] to `levels`, and the 4 will be ignored:

>>> vals, count = crosstab(q1, q2, levels=(None, [1, 2]))
>>> vals
[array([[2, 3, 4],
       [1, 2]])
>>> count
array([[1, 1],
       [1, 4],
       [0, 3]])

Finally, let’s repeat the first example, but return a sparse matrix:

>>> (avals, xvals), count = crosstab(a, x, sparse=True)
>>> count
<2x3 sparse matrix of type '<class 'numpy.int64'>'
with 4 stored elements in COOrdinate format>
>>> count.A
array([[2, 3, 0],
       [1, 0, 4]])

scipy.stats.contingency.expected_freq

scipy.stats.contingency.expected_freq(removed)

Compute the expected frequencies from a contingency table.

Given an n-dimensional contingency table of observed frequencies, compute the expected frequencies for the table based on the marginal sums under the assumption that the groups associated with each dimension are independent.

Parameters

  observed [array_like] The table of observed frequencies. (While this function can handle a 1-D array, that case is trivial. Generally `observed` is at least 2-D.)

Returns
expected  [ndarray of float64] The expected frequencies, based on the marginal sums of the table. Same shape as observed.

Examples

```python
>>> from scipy.stats.contingency import expected_freq
>>> observed = np.array([[10, 10, 20], [20, 20, 20]])
>>> expected_freq(observed)
array([[ 12.,  12.,  16.],
       [ 18.,  18.,  24.]])
```

scipy.stats.contingency.margins

scipy.stats.contingency.margins(a)
Return a list of the marginal sums of the array a.

Parameters

- a  [ndarray] The array for which to compute the marginal sums.

Returns

- margsums  [list of ndarrays] A list of length `a.ndim`. `margsums[k]` is the result of summing `a` over all axes except `k`; it has the same number of dimensions as `a`, but the length of each axis except axis `k` will be 1.

Examples

```python
>>> a = np.arange(12).reshape(2, 6)
>>> a
array([[ 0,  1,  2,  3,  4,  5],
       [ 6,  7,  8,  9, 10, 11]])
>>> from scipy.stats.contingency import margins
>>> m0, m1 = margins(a)
>>> m0
array([[15],
       [51]])
>>> m1
array([[ 6,  8, 10, 12, 14, 16]])

>>> b = np.arange(24).reshape(2, 3, 4)
>>> m0, m1, m2 = margins(b)
>>> m0
array([[[ 66],
        [210]]])
>>> m1
array([[[ 60],
        [ 92],
        [124]]])
>>> m2
array([[[60, 66, 72, 78]]])
```
scipy.stats.contingency.relative_risk

scipy.stats.contingency.relative_risk(exposed_cases, exposed_total, control_cases, control_total)

Compute the relative risk (also known as the risk ratio).

This function computes the relative risk associated with a 2x2 contingency table ([1], section 2.2.3; [2], section 3.1.2). Instead of accepting a table as an argument, the individual numbers that are used to compute the relative risk are given as separate parameters. This is to avoid the ambiguity of which row or column of the contingency table corresponds to the “exposed” cases and which corresponds to the “control” cases. Unlike, say, the odds ratio, the relative risk is not invariant under an interchange of the rows or columns.

Parameters

exposed_cases
[nonnegative int] The number of “cases” (i.e. occurrence of disease or other event of interest) among the sample of “exposed” individuals.

exposed_total
[positive int] The total number of “exposed” individuals in the sample.

control_cases
[nonnegative int] The number of “cases” among the sample of “control” or non-exposed individuals.

control_total
[positive int] The total number of “control” individuals in the sample.

Returns

result
[instance of RelativeRiskResult] The object has the float attribute relative_risk, which is:

\[ \text{rr} = \frac{\text{exposed_cases}}{\text{exposed_total}} \div \frac{\text{control_cases}}{\text{control_total}} \]

The object also has the method confidence_interval to compute the confidence interval of the relative risk for a given confidence level.

Notes

The R package epitools has the function riskratio, which accepts a table with the following layout:

<table>
<thead>
<tr>
<th></th>
<th>disease=0</th>
<th>disease=1</th>
</tr>
</thead>
<tbody>
<tr>
<td>exposed=0 (ref)</td>
<td>n00</td>
<td>n01</td>
</tr>
<tr>
<td>exposed=1</td>
<td>n10</td>
<td>n11</td>
</tr>
</tbody>
</table>

With a 2x2 table in the above format, the estimate of the CI is computed by riskratio when the argument method=”wald” is given, or with the function riskratio.wald.

For example, in a test of the incidence of lung cancer among a sample of smokers and nonsmokers, the “exposed” category would correspond to “is a smoker” and the “disease” category would correspond to “has or had lung cancer”.

To pass the same data to relative_risk, use:

relative_risk(n11, n10 + n11, n01, n00 + n01)

New in version 1.7.0.
References

[1],[2]

Examples

```python
>>> from scipy.stats.contingency import relative_risk
```

This example is from Example 3.1 of [2]. The results of a heart disease study are summarized in the following table:

<table>
<thead>
<tr>
<th></th>
<th>High CAT</th>
<th>Low CAT</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHD</td>
<td>27</td>
<td>44</td>
<td>71</td>
</tr>
<tr>
<td>No CHD</td>
<td>95</td>
<td>443</td>
<td>538</td>
</tr>
<tr>
<td>Total</td>
<td>122</td>
<td>487</td>
<td>609</td>
</tr>
</tbody>
</table>

CHD is coronary heart disease, and CAT refers to the level of circulating catecholamine. CAT is the “exposure” variable, and high CAT is the “exposed” category. So the data from the table to be passed to `relative_risk` is:

```python
exposed_cases = 27
exposed_total = 122
control_cases = 44
control_total = 487
```

```python
>>> result = relative_risk(27, 122, 44, 487)
>>> result.relative_risk
2.4495156482861398
```

Find the confidence interval for the relative risk.

```python
>>> result.confidence_interval(confidence_level=0.95)
ConfidenceInterval(low=1.5836990926700116, high=3.7886786315466354)
```

The interval does not contain 1, so the data supports the statement that high CAT is associated with greater risk of CHD.

`scipy.stats.contingency.association`

`scipy.stats.contingency.association` (observed, method='cramer', correction=False, lambda_=None)

Calculates degree of association between two nominal variables.

The function provides the option for computing one of three measures of association between two nominal variables from the data given in a 2d contingency table: Tschuprow’s T, Pearson’s Contingency Coefficient and Cramer’s V.

Parameters

- `observed` [array-like] The array of observed values
- `method` [“(cramer”, “tschuprow”, “pearson”) (default = “cramer”)] The association test statistic.
- `correction` [bool, optional] Inherited from `scipy.stats.contingency.chi2_contingency`
- `lambda_` [float or str, optional] Inherited from `scipy.stats.contingency.chi2_contingency`
Returns

statistic  [float] Value of the test statistic

Notes

Cramer’s V, Tschuprow’s T and Pearson’s Contingency Coefficient, all measure the degree to which two nominal or ordinal variables are related, or the level of their association. This differs from correlation, although many often mistakenly consider them equivalent. Correlation measures in what way two variables are related, whereas, association measures how related the variables are. As such, association does not subsume independent variables, and is rather a test of independence. A value of 1.0 indicates perfect association, and 0.0 means the variables have no association.

Both the Cramer’s V and Tschuprow’s T are extensions of the phi coefficient. Moreover, due to the close relationship between the Cramer’s V and Tschuprow’s T the returned values can often be similar or even equivalent. They are likely to diverge more as the array shape diverges from a 2x2.

[1], [2], [3], [4], [5]

Examples

An example with a 4x2 contingency table:

```python
>>> from scipy.stats.contingency import association
>>> obs4x2 = np.array([[100, 150], [203, 322], [420, 700], [320, 210]])
```

Pearson’s contingency coefficient

```python
>>> association(obs4x2, method="pearson") 0.18303298140595667
```

Cramer’s V

```python
>>> association(obs4x2, method="cramer")
0.18617813077483678
```

Tschuprow’s T

```python
>>> association(obs4x2, method="tschuprow")
0.14146478765062995
```

**scipy.stats.fisher_exact**

`scipy.stats.fisher_exact(table, alternative='two-sided')`

Perform a Fisher exact test on a 2x2 contingency table.

**Parameters**

- `table`  [array_like of ints] A 2x2 contingency table. Elements must be non-negative integers.
- `alternative`  ['two-sided', 'less', 'greater'], optional Defines the alternative hypothesis. The following options are available (default is 'two-sided'):
  - 'two-sided'
  - 'less': one-sided
• ‘greater’: one-sided
  See the Notes for more details.

Returns

oddsratio [float] This is prior odds ratio and not a posterior estimate.
p_value [float] P-value, the probability of obtaining a distribution at least as extreme as the one that was actually observed, assuming that the null hypothesis is true.

See also:

chi2_contingency
  Chi-square test of independence of variables in a contingency table. This can be used as an alternative to fisher_exact when the numbers in the table are large.

barnard_exact
  Barnard’s exact test, which is a more powerful alternative than Fisher’s exact test for 2x2 contingency tables.

boschloo_exact
  Boschloo’s exact test, which is a more powerful alternative than Fisher’s exact test for 2x2 contingency tables.

Notes

Null hypothesis and p-values

The null hypothesis is that the input table is from the hypergeometric distribution with parameters (as used in hypergeom) M = a + b + c + d, n = a + b and N = a + c, where the input table is [[a, b], [c, d]]. This distribution has support max(0, N + n - M) <= x <= min(N, n). or, in terms of the values in the input table, min(0, a - d) <= x <= a + min(b, c). x can be interpreted as the upper-left element of a 2x2 table, so the tables in the distribution have form:

\[
\begin{bmatrix}
x & n-x \\
N-x & M-(n+N)+x
\end{bmatrix}
\]

For example, if:

```
>>> table = np.array([[6, 2], [1, 4]])
```

then the support is 2 <= x <= 7, and the tables in the distribution are:

```
[[2 6] [3 5] [4 4] [5 3] [6 2] [7 1]
[5 0] [4 1] [3 2] [2 3] [1 4] [0 5]]
```

The probability of each table is given by the hypergeometric distribution hypergeom.pmf(x, M, n, N). For this example, these are (rounded to three significant digits):

<table>
<thead>
<tr>
<th>x</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>p</td>
<td>0.0163</td>
<td>0.163</td>
<td>0.408</td>
<td>0.326</td>
<td>0.0816</td>
<td>0.00466</td>
</tr>
</tbody>
</table>

These can be computed with:

```python
>>> from scipy.stats import hypergeom
>>> table = np.array([[6, 2], [1, 4]])
>>> M = table.sum()
```
The two-sided p-value is the probability that, under the null hypothesis, a random table would have a probability equal to or less than the probability of the input table. For our example, the probability of the input table (where $x = 6$) is 0.0816. The $x$ values where the probability does not exceed this are 2, 6 and 7, so the two-sided p-value is $0.0163 + 0.0816 + 0.00466 \approx 0.10256$:

```python
from scipy.stats import fisher_exact

oddsr, p = fisher_exact(table, alternative='two-sided')
p
```

The one-sided p-value for alternative='greater' is the probability that a random table has $x \geq a$, which in our example is $x \geq 6$, or $0.0816 + 0.00466 \approx 0.08626$:

```python
oddsr, p = fisher_exact(table, alternative='greater')
p
```

This is equivalent to computing the survival function of the distribution at $x = 5$ (one less than $x$ from the input table, because we want to include the probability of $x = 6$ in the sum):

```python
hypergeom.sf(5, M, n, N)
```

For alternative='less', the one-sided p-value is the probability that a random table has $x \leq a$, (i.e. $x \leq 6$ in our example), or $0.0163 + 0.163 + 0.408 + 0.326 + 0.0816 \approx 0.9949$:

```python
oddsr, p = fisher_exact(table, alternative='less')
p
```

This is equivalent to computing the cumulative distribution function of the distribution at $x = 6$:

```python
hypergeom.cdf(6, M, n, N)
```

**Odds ratio**

The calculated odds ratio is different from the one R uses. This SciPy implementation returns the (more common) “unconditional Maximum Likelihood Estimate”, while R uses the “conditional Maximum Likelihood Estimate”.
Examples

Say we spend a few days counting whales and sharks in the Atlantic and Indian oceans. In the Atlantic ocean we find 8 whales and 1 shark, in the Indian ocean 2 whales and 5 sharks. Then our contingency table is:

<table>
<thead>
<tr>
<th></th>
<th>Atlantic</th>
<th>Indian</th>
</tr>
</thead>
<tbody>
<tr>
<td>whales</td>
<td>8</td>
<td>2</td>
</tr>
<tr>
<td>sharks</td>
<td>1</td>
<td>5</td>
</tr>
</tbody>
</table>

We use this table to find the p-value:

```python
>>> from scipy.stats import fisher_exact
>>> oddsratio, pvalue = fisher_exact([[8, 2], [1, 5]])
>>> pvalue
0.0349...
```

The probability that we would observe this or an even more imbalanced ratio by chance is about 3.5%. A commonly used significance level is 5%—if we adopt that, we can therefore conclude that our observed imbalance is statistically significant; whales prefer the Atlantic while sharks prefer the Indian ocean.

`scipy.stats.barnard_exact`

`scipy.stats.barnard_exact (table, alternative='two-sided', pooled=True, n=32)`

Perform a Barnard exact test on a 2x2 contingency table.

Parameters

- `table` [array_like of ints] A 2x2 contingency table. Elements should be non-negative integers.
- `alternative` [{'two-sided', 'less', 'greater'}, optional] Defines the null and alternative hypotheses. Default is 'two-sided'. Please see explanations in the Notes section below.
- `pooled` [bool, optional] Whether to compute score statistic with pooled variance (as in Student's t-test, for example) or unpoled variance (as in Welch's t-test). Default is True.
- `n` [int, optional] Number of sampling points used in the construction of the sampling method. Note that this argument will automatically be converted to the next higher power of 2 since `scipy.stats.qmc.Sobol` is used to select sample points. Default is 32. Must be positive. In most cases, 32 points is enough to reach good precision. More points comes at performance cost.

Returns

- `ber` [BarnardExactResult] A result object with the following attributes.
- `statistic` [float] The Wald statistic with pooled or unpoled variance, depending on the user choice of `pooled`.
- `pvalue` [float] P-value, the probability of obtaining a distribution at least as extreme as the one that was actually observed, assuming that the null hypothesis is true.

See also:

- `chi2_contingency`  
  Chi-square test of independence of variables in a contingency table.
- `fisher_exact`  
  Fisher exact test on a 2x2 contingency table.
**benschloo_exact**

Boschloo’s exact test on a 2x2 contingency table, which is an uniformly more powerful alternative to Fisher’s exact test.

**Notes**

Barnard’s test is an exact test used in the analysis of contingency tables. It examines the association of two categorical variables, and is a more powerful alternative than Fisher’s exact test for 2x2 contingency tables.

Let’s define $X_0$ a 2x2 matrix representing the observed sample, where each column stores the binomial experiment, as in the example below. Let’s also define $p_1, p_2$ the theoretical binomial probabilities for $x_{11}$ and $x_{12}$. When using Barnard exact test, we can assert three different null hypotheses:

- $H_0 : p_1 \geq p_2$ versus $H_1 : p_1 < p_2$, with alternative = “less”
- $H_0 : p_1 \leq p_2$ versus $H_1 : p_1 > p_2$, with alternative = “greater”
- $H_0 : p_1 = p_2$ versus $H_1 : p_1 \neq p_2$, with alternative = “two-sided” (default one)

In order to compute Barnard’s exact test, we are using the Wald statistic [3] with pooled or unpooled variance. Under the default assumption that both variances are equal (pooled = True), the statistic is computed as:

$$ T(X) = \frac{\hat{p}_1 - \hat{p}_2}{\sqrt{\hat{\pi}(1 - \hat{\pi})\left(\frac{1}{c_1} + \frac{1}{c_2}\right)}} $$

with $\hat{p}_1, \hat{p}_2$ and $\hat{\pi}$ the estimator of $p_1, p_2$ and $\pi$, the latter being the combined probability, given the assumption that $p_1 = p_2$.

If this assumption is invalid (pooled = False), the statistic is:

$$ T(X) = \frac{\hat{p}_1 - \hat{p}_2}{\sqrt{\frac{p_1(1-p_1)}{c_1} + \frac{p_2(1-p_2)}{c_2}}} $$

The p-value is then computed as:

$$ \sum \binom{c_1}{x_{11}} \binom{c_2}{x_{12}} \pi^{x_{11} + x_{12}} (1 - \pi)^{t - x_{11} - x_{12}} $$

where the sum is over all 2x2 contingency tables $X$ such that: * $T(X) \leq T(X_0)$ when alternative = “less”, * $T(X) \geq T(X_0)$ when alternative = “greater”, or * $T(X) \geq |T(X_0)|$ when alternative = “two-sided”. Above, $c_1, c_2$ are the sum of the columns 1 and 2, and $t$ the total (sum of the 4 sample’s element).

The returned p-value is the maximum p-value taken over the nuisance parameter $\pi$, where $0 \leq \pi \leq 1$.

This function’s complexity is $O(nc_1c_2)$, where $n$ is the number of sample points.

**References**

[1], [2], [3]
Examples

An example use of Barnard’s test is presented in [2].

Consider the following example of a vaccine efficacy study (Chan, 1998). In a randomized clinical trial of 30 subjects, 15 were inoculated with a recombinant DNA influenza vaccine and the 15 were inoculated with a placebo. Twelve of the 15 subjects in the placebo group (80%) eventually became infected with influenza whereas for the vaccine group, only 7 of the 15 subjects (47%) became infected. The data are tabulated as a 2 x 2 table:

<table>
<thead>
<tr>
<th>Vaccine</th>
<th>Placebo</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yes</td>
<td>7</td>
</tr>
<tr>
<td>No</td>
<td>8</td>
</tr>
</tbody>
</table>

When working with statistical hypothesis testing, we usually use a threshold probability or significance level upon which we decide to reject the null hypothesis $H_0$. Suppose we choose the common significance level of 5%.

Our alternative hypothesis is that the vaccine will lower the chance of becoming infected with the virus; that is, the probability $p_1$ of catching the virus with the vaccine will be less than the probability $p_2$ of catching the virus without the vaccine. Therefore, we call `barnard_exact` with the `alternative="less"` option:

```python
>>> import scipy.stats as stats
>>> res = stats.barnard_exact([[7, 12], [8, 3]], alternative="less")
>>> res.statistic
-1.894...
>>> res.pvalue
0.03407...
```

Under the null hypothesis that the vaccine will not lower the chance of becoming infected, the probability of obtaining test results at least as extreme as the observed data is approximately 3.4%. Since this p-value is less than our chosen significance level, we have evidence to reject $H_0$ in favor of the alternative.

Suppose we had used Fisher’s exact test instead:

```python
>>> _, pvalue = stats.fisher_exact([[7, 12], [8, 3]], alternative="less")
>>> pvalue
0.0640...
```

With the same threshold significance of 5%, we would not have been able to reject the null hypothesis in favor of the alternative. As stated in [2], Barnard’s test is uniformly more powerful than Fisher’s exact test because Barnard’s test does not condition on any margin. Fisher’s test should only be used when both sets of marginals are fixed.

`scipy.stats.boschloo_exact`

`scipy.stats.boschloo_exact` (table, alternative=’two-sided’, n=32)
Perform Boschloo’s exact test on a 2x2 contingency table.

Parameters

- table [array_like of ints] A 2x2 contingency table. Elements should be non-negative integers.
- n [int, optional] Number of sampling points used in the construction of the sampling method. Note that this argument will automatically be converted to the next higher power of 2 since `scipy.stats.qmc.Sobol` is used to select sample points. Default is 32. Must be
positive. In most cases, 32 points is enough to reach good precision. More points comes at performance cost.

**Returns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ber</td>
<td>[BoschlooExactResult] A result object with the following attributes.</td>
</tr>
<tr>
<td>statistic</td>
<td>[float] The statistic used in Boschloo’s test; that is, the p-value from Fisher’s exact test.</td>
</tr>
<tr>
<td>pvalue</td>
<td>[float] P-value, the probability of obtaining a distribution at least as extreme as the one that was actually observed, assuming that the null hypothesis is true.</td>
</tr>
</tbody>
</table>

**See also:**

- **chi2_contingency**
  
  Chi-square test of independence of variables in a contingency table.

- **fisher_exact**
  
  Fisher exact test on a 2x2 contingency table.

- **barnard_exact**
  
  Barnard’s exact test, which is a more powerful alternative than Fisher’s exact test for 2x2 contingency tables.

**Notes**

Boschloo’s test is an exact test used in the analysis of contingency tables. It examines the association of two categorical variables, and is a uniformly more powerful alternative to Fisher’s exact test for 2x2 contingency tables.

Let’s define $X_{0}$ a 2x2 matrix representing the observed sample, where each column stores the binomial experiment, as in the example below. Let’s also define $p_1, p_2$ the theoretical binomial probabilities for $x_{11}$ and $x_{12}$. When using Boschloo exact test, we can assert three different null hypotheses:

- $H_0 : p_1 \geq p_2$ versus $H_1 : p_1 < p_2$, with alternative = “less”
- $H_0 : p_1 \leq p_2$ versus $H_1 : p_1 > p_2$, with alternative = “greater”
- $H_0 : p_1 = p_2$ versus $H_1 : p_1 \neq p_2$, with alternative = “two-sided” (default one)

Boschloo’s exact test uses the p-value of Fisher’s exact test as a statistic, and Boschloo’s p-value is the probability under the null hypothesis of observing such an extreme value of this statistic.

Boschloo’s and Barnard’s are both more powerful than Fisher’s exact test.

New in version 1.7.0.

Examples

In the following example, we consider the article “Employee attitudes and job satisfaction” [3] which reports the results of a survey from 63 scientists and 117 college professors. Of the 63 scientists, 31 said they were very satisfied with their jobs, whereas 74 of the college professors were very satisfied with their work. Is this significant evidence that college professors are happier with their work than scientists? The following table summarizes the data mentioned above:

<table>
<thead>
<tr>
<th></th>
<th>College Professors</th>
<th>Scientists</th>
</tr>
</thead>
<tbody>
<tr>
<td>Very Satisfied</td>
<td>74</td>
<td>31</td>
</tr>
<tr>
<td>Dissatisfied</td>
<td>43</td>
<td>32</td>
</tr>
</tbody>
</table>

When working with statistical hypothesis testing, we usually use a threshold probability or significance level upon which we decide to reject the null hypothesis $H_0$. Suppose we choose the common significance level of 5%.

Our alternative hypothesis is that college professors are truly more satisfied with their work than scientists. Therefore, we expect $p_1$ the proportion of very satisfied college professors to be greater than $p_2$, the proportion of very satisfied scientists. We thus call `boschloo_exact` with the `alternative = "greater"` option:

```python
>>> import scipy.stats as stats
>>> res = stats.boschloo_exact([[74, 31], [43, 32]], alternative="greater")
>>> res.statistic
0.0483...
>>> res.pvalue
0.0355...
```

Under the null hypothesis that scientists are happier in their work than college professors, the probability of obtaining test results at least as extreme as the observed data is approximately 3.55%. Since this p-value is less than our chosen significance level, we have evidence to reject $H_0$ in favor of the alternative hypothesis.

Plot-tests

- `ppcc_max(x[, brack, dist])`: Calculate the shape parameter that maximizes the PPCC.
- `ppcc_plot(x, a, b[, dist, plot, N])`: Calculate and optionally plot probability plot correlation coefficient.
- `probplot(x[, params, dist, fit, plot, rvalue])`: Calculate quantiles for a probability plot, and optionally show the plot.
- `boxcox_normplot(x, la, lb[, plot, N])`: Compute parameters for a Box-Cox normality plot, optionally show it.
- `yeojohnson_normplot(x, la, lb[, plot, N])`: Compute parameters for a Yeo-Johnson normality plot, optionally show it.

**scipy.stats.ppcc_max**

`scipy.stats.ppcc_max(x, brack=(0.0, 1.0), dist='tukeylambda')`

Calculate the shape parameter that maximizes the PPCC.

The probability plot correlation coefficient (PPCC) plot can be used to determine the optimal shape parameter for a one-parameter family of distributions. `ppcc_max` returns the shape parameter that would maximize the probability plot correlation coefficient for the given data to a one-parameter family of distributions.

**Parameters**
SciPy Reference Guide, Release 1.7.0

x  [array_like] Input array.

brack  [tuple, optional] Triple (a,b,c) where (a<b<c). If bracket consists of two numbers (a, c) then they are assumed to be a starting interval for a downhill bracket search (see scipy.optimize.brent).

dist  [str or stats.distributions instance, optional] Distribution or distribution function name. Objects that look enough like a stats.distributions instance (i.e. they have a ppf method) are also accepted. The default is 'tukeylambda'.

Returns

shape_value  [float] The shape parameter at which the probability plot correlation coefficient reaches its max value.

See also:

ppcc_plot, probplot, boxcox

Notes

The brack keyword serves as a starting point which is useful in corner cases. One can use a plot to obtain a rough visual estimate of the location for the maximum to start the search near it.

References

[1], [2]

Examples

First we generate some random data from a Weibull distribution with shape parameter 2.5:

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
>>> c = 2.5
>>> x = stats.weibull_min.rvs(c, scale=4, size=2000, random_state=rng)
```

Generate the PPCC plot for this data with the Weibull distribution.

```python
>>> fig, ax = plt.subplots(figsize=(8, 6))
>>> res = stats.ppcc_plot(x, c/2, 2*c, dist='weibull_min', plot=ax)
```

We calculate the value where the shape should reach its maximum and a red line is drawn there. The line should coincide with the highest point in the PPCC graph.

```python
>>> cmax = stats.ppcc_max(x, brack=(c/2, 2*c), dist='weibull_min')
>>> ax.axvline(cmax, color='r')
>>> plt.show()
```
scipy.stats.ppcc_plot

`scipy.stats.ppcc_plot(x, a, b, dist='tukeylambda', plot=None, N=80)`

Calculate and optionally plot probability plot correlation coefficient.

The probability plot correlation coefficient (PPCC) plot can be used to determine the optimal shape parameter for a one-parameter family of distributions. It cannot be used for distributions without shape parameters (like the normal distribution) or with multiple shape parameters.

By default a Tukey-Lambda distribution (`stats.tukeylambda`) is used. A Tukey-Lambda PPCC plot interpolates from long-tailed to short-tailed distributions via an approximately normal one, and is therefore particularly useful in practice.

**Parameters**

- `x` [array_like] Input array.
- `a, b` [scalar] Lower and upper bounds of the shape parameter to use.
- `dist` [str or stats.distributions instance, optional] Distribution or distribution function name. Objects that look enough like a stats.distributions instance (i.e. they have a `ppf` method) are also accepted. The default is 'tukeylambda'.
- `plot` [object, optional] If given, plots PPCC against the shape parameter. `plot` is an object that has to have methods “plot” and “text”. The `matplotlib.pyplot` module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is None, which means that no plot is created.
- `N` [int, optional] Number of points on the horizontal axis (equally distributed from `a` to `b`).

**Returns**

- `svals` [ndarray] The shape values for which `ppcc` was calculated.
- `ppcc` [ndarray] The calculated probability plot correlation coefficient values.

See also:

- `ppcc_max`, `probplot`, `boxcox_normplot`, `tukeylambda`

**References**

**Examples**

First we generate some random data from a Weibull distribution with shape parameter 2.5, and plot the histogram of the data:

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
>>> c = 2.5
>>> x = stats.weibull_min.rvs(c, scale=4, size=2000, random_state=rng)
```

Take a look at the histogram of the data.
$$\text{fig1, ax} = \text{plt.subplots(figsize=(9, 4))}$$
$$\text{ax.hist(x, bins=50)}$$
$$\text{ax.set_title('Histogram of x')}$$
$$\text{plt.show()}$$

Now we explore this data with a PPCC plot as well as the related probability plot and Box-Cox normplot. A red line is drawn where we expect the PPCC value to be maximal (at the shape parameter $c$ used above):

$$\text{fig2 = plt.figure(figsize=(12, 4))}$$
$$\text{ax1 = fig2.add_subplot(1, 3, 1)}$$
$$\text{ax2 = fig2.add_subplot(1, 3, 2)}$$
$$\text{ax3 = fig2.add_subplot(1, 3, 3)}$$
$$\text{res = stats.probplot(x, plot=ax1)}$$
$$\text{res = stats.boxcox_normplot(x, -4, 4, plot=ax2)}$$
$$\text{res = stats.ppcc_plot(x, c/2, 2*c, dist='weibull_min', plot=ax3)}$$
$$\text{ax3.axvline(c, color='r')}$$
$$\text{plt.show()}$$
scipy.stats.probplot

**scipy.stats.probplot** \((x, sparams=(), \text{dist}='\text{norm}', \text{fit}=True, \text{plot}=\text{None}, rvalue=\text{False})\)

Calculate quantiles for a probability plot, and optionally show the plot.

Generates a probability plot of sample data against the quantiles of a specified theoretical distribution (the normal distribution by default). \textit{probplot} optionally calculates a best-fit line for the data and plots the results using Matplotlib or a given plot function.

**Parameters**

- **x** [array_like] Sample/response data from which \textit{probplot} creates the plot.
- **sparams** [tuple, optional] Distribution-specific shape parameters (shape parameters plus location and scale).
- **dist** [str or stats.distributions instance, optional] Distribution or distribution function name. The default is ‘\text{norm}’ for a normal probability plot. Objects that look enough like a stats.distributions instance (i.e. they have a \text{ppf} method) are also accepted.
- **fit** [bool, optional] Fit a least-squares regression (best-fit) line to the sample data if True (default).
- **plot** [object, optional] If given, plots the quantiles. If given and \text{fit} is True, also plots the least squares fit. \text{plot} is an object that has to have methods “plot” and “text”. The \text{matplotlib.pyplot} module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is None, which means that no plot is created.

**Returns**

- **(osm, osr)** [tuple of ndarrays] Tuple of theoretical quantiles (osm, or order statistic medians) and ordered responses (osr). \text{osr} is simply sorted input \text{x}. For details on how \text{osm} is calculated see the Notes section.
- **(slope, intercept, r)** [tuple of floats, optional] Tuple containing the result of the least-squares fit, if that is performed by \textit{probplot}. \text{r} is the square root of the coefficient of determination. If \text{fit}=False and \text{plot}=\text{None}, this tuple is not returned.

**Notes**

Even if \text{plot} is given, the figure is not shown or saved by \textit{probplot}; \text{plt.show()} or \text{plt.savefig('figname.png')} should be used after calling \textit{probplot}.

\textit{probplot} generates a probability plot, which should not be confused with a Q-Q or a P-P plot. Statsmodels has more extensive functionality of this type, see \text{statsmodels.api.ProbPlot}.

The formula used for the theoretical quantiles (horizontal axis of the probability plot) is Filliben’s estimate:

\[
\text{quantiles} = \text{dist.ppf}(\text{val}), \quad \text{for} \\

\begin{align*}
0.5**(1/n), & \quad \text{for} \quad i = n \\
(\text{i} - 0.3175) / (n + 0.365), & \quad \text{for} \quad i = 2, \ldots, n-1 \\
1 - 0.5**(1/n), & \quad \text{for} \quad i = 1
\end{align*}
\]

where \(i\) indicates the \(i\)-th ordered value and \(n\) is the total number of values.
Examples

```python
from scipy import stats
import matplotlib.pyplot as plt

nsample = 100
rng = np.random.default_rng()

A t distribution with small degrees of freedom:
```n
```python
ax1 = plt.subplot(221)
>> x = stats.t.rvs(3, size=nsample, random_state=rng)
>> res = stats.probplot(x, plot=plt)
```

A t distribution with larger degrees of freedom:
```python
ax2 = plt.subplot(222)
>> x = stats.t.rvs(25, size=nsample, random_state=rng)
>> res = stats.probplot(x, plot=plt)
```

A mixture of two normal distributions with broadcasting:
```python
ax3 = plt.subplot(223)
>> x = stats.norm.rvs(loc=[0, 5], scale=[1.5],
... size=(nsample//2, 2), random_state=rng).ravel()
>> res = stats.probplot(x, plot=plt)
```

A standard normal distribution:
```python
ax4 = plt.subplot(224)
>> x = stats.norm.rvs(loc=0, scale=1, size=nsample, random_state=rng)
>> res = stats.probplot(x, plot=plt)
```

Produce a new figure with a loggamma distribution, using the `dist` and `params` keywords:
```python
fig = plt.figure()
ax = fig.add_subplot(111)
>> x = stats.loggamma.rvs(c=2.5, size=500, random_state=rng)
>> res = stats.probplot(x, dist=stats.loggamma, params=(2.5,), plot=ax)
>> ax.set_title("Probplot for loggamma dist with shape parameter 2.5")
```

Show the results with Matplotlib:
```python
>>> plt.show()
```

`scipy.stats.boxcox_normplot`

`scipy.stats.boxcox_normplot(x, la, lb, plot=None, N=80)`  
Compute parameters for a Box-Cox normality plot, optionally show it.

A Box-Cox normality plot shows graphically what the best transformation parameter is to use in `boxcox` to obtain a distribution that is close to normal.

**Parameters**

- `x`  
  [array_like] Input array.
Theoretical quantiles
Ordered Values
Probability Plot

Probplot for loggamma dist with shape parameter 2.5

Theoretical quantiles
Ordered Values

Theoretical quantiles
Ordered Values
SciPy Reference Guide, Release 1.7.0

**la, lb**
[scalar] The lower and upper bounds for the \( \lambda \) values to pass to \textit{boxcox} for Box-Cox transformations. These are also the limits of the horizontal axis of the plot if that is generated.

**plot**
[object, optional] If given, plots the quantiles and least squares fit. \textit{plot} is an object that has to have methods “plot” and “text”. The \texttt{matplotlib.pyplot} module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is None, which means that no plot is created.

**N**
[int, optional] Number of points on the horizontal axis (equally distributed from \( la \) to \( lb \)).

**Returns**

- **lmbdas** [ndarray] The \( \lambda \) values for which a Box-Cox transform was done.
- **ppcc** [ndarray] Probability Plot Correlation Coefficient, as obtained from \textit{probplot} when fitting the Box-Cox transformed input \( x \) against a normal distribution.

**See also:**

\textit{probplot, boxcox, boxcox_normmax, boxcox_llf, ppcc_max}

**Notes**

Even if \textit{plot} is given, the figure is not shown or saved by \textit{boxcox_normplot}; \texttt{plt.show()} or \texttt{plt.savefig('figname.png')} should be used after calling \textit{probplot}.

**Examples**

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt

Generate some non-normally distributed data, and create a Box-Cox plot:

```python
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.boxcox_normplot(x, -20, 20, plot=ax)
```  
Determine and plot the optimal \( \lambda \) to transform \( x \) and plot it in the same plot:

```python
>>> l, maxlog = stats.boxcox(x)
>>> ax.axvline(maxlog, color='r')
>>> plt.show()
```  

**scipy.stats.yeojohnson_normplot**

\texttt{scipy.stats.yeojohnson_normplot} \((x, la, lb, plot=None, N=80)\)

Compute parameters for a Yeo-Johnson normality plot, optionally show it.

A Yeo-Johnson normality plot shows graphically what the best transformation parameter is to use in \textit{yeojohnson} to obtain a distribution that is close to normal.

**Parameters**

- **x** [array_like] Input array.
**la, lb**  
[scalar] The lower and upper bounds for the \( \lambda \) values to pass to `yeojohnson` for Yeo-Johnson transformations. These are also the limits of the horizontal axis of the plot if that is generated.

**plot**  
[object, optional] If given, plots the quantiles and least squares fit. `plot` is an object that has to have methods “plot” and “text”. The `matplotlib.pyplot` module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is None, which means that no plot is created.

**N**  
[int, optional] Number of points on the horizontal axis (equally distributed from \( la \) to \( lb \)).

**Returns**

- **lmbdas**  
[ndarray] The \( \lambda \) values for which a Yeo-Johnson transform was done.

- **ppcc**  
[ndarray] Probability Plot Correlation Coefficient, as obtained from `probplot` when fitting the Box-Cox transformed input \( x \) against a normal distribution.

**See also:**

- `probplot`, `yeojohnson`, `yeojohnson_normmax`, `yeojohnson_llf`, `ppcc_max`
Notes

Even if plot is given, the figure is not shown or saved by \texttt{boxcox\_normplot}; \texttt{plt.show()} or \texttt{plt.savefig('figname.png')} should be used after calling \texttt{probplot}.

New in version 1.2.0.

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt

Generate some non-normally distributed data, and create a Yeo-Johnson plot:

```python
>>> x = stats.loggamma.rvs(5, size=500) + 5
```  >>> fig = plt.figure()
```python
>>> ax = fig.add_subplot(111)
```  >>> prob = stats.yeojohnson_normplot(x, -20, 20, plot=ax)

Determine and plot the optimal \( \lambda \) to transform \( x \) and plot it in the same plot:

```python
>>> _, maxlog = stats.yeojohnson(x)
```  >>> ax.axvline(maxlog, color='r')

```python
>>> plt.show()
```
Univariate and multivariate kernel density estimation

**gaussian_kde**

`gaussian_kde(dataset[, bw_method, weights])`

Representation of a kernel-density estimate using Gaussian kernels.

**scipy.stats.gaussian_kde**

```python
class scipy.stats.gaussian_kde (dataset, bw_method=None, weights=None)
```

Representation of a kernel-density estimate using Gaussian kernels.

Kernel density estimation is a way to estimate the probability density function (PDF) of a random variable in a non-parametric way. `gaussian_kde` works for both uni-variate and multi-variate data. It includes automatic bandwidth determination. The estimation works best for a unimodal distribution; bimodal or multi-modal distributions tend to be oversmoothed.

**Parameters**

- `dataset` [array_like] Datapoints to estimate from. In case of univariate data this is a 1-D array, otherwise a 2-D array with shape (# of dims, # of data).
- `bw_method` [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be `scott`, `silverman`, a scalar constant or a callable. If a scalar, this will be used directly as `kde.factor`. If a callable, it should take a `gaussian_kde` instance as only parameter and return a scalar. If None (default), `scott` is used. See Notes for more details.
- `weights` [array_like, optional] weights of datapoints. This must be the same shape as dataset. If None (default), the samples are assumed to be equally weighted.

**Notes**

Bandwidth selection strongly influences the estimate obtained from the KDE (much more so than the actual shape of the kernel). Bandwidth selection can be done by a “rule of thumb”, by cross-validation, by “plug-in methods” or by other means; see [3], [4] for reviews. `gaussian_kde` uses a rule of thumb, the default is Scott’s Rule.

Scott’s Rule [1], implemented as `scotts_factor`, is:

```
n**(1./(d+4)),
```

with \( n \) the number of data points and \( d \) the number of dimensions. In the case of unequally weighted points, `scotts_factor` becomes:

```
neff**(1./(d+4)),
```

with \( neff \) the effective number of datapoints. Silverman’s Rule [2], implemented as `silverman_factor`, is:

```
(n * (d + 2) / 4.)**(1./(d + 4)).
```

or in the case of unequally weighted points:

```
(neff * (d + 2) / 4.)**(1./(d + 4)).
```

Good general descriptions of kernel density estimation can be found in [1] and [2], the mathematics for this multi-dimensional implementation can be found in [1].

With a set of weighted samples, the effective number of datapoints \( neff \) is defined by:
\[ \text{neff} = \frac{\text{sum}((\text{weights})^2)}{\text{sum}(\text{weights}^2)} \]

as detailed in [5].

References

[1], [2], [3], [4], [5]

Examples

Generate some random two-dimensional data:

```python
>>> from scipy import stats
>>> def measure(n):
...     "Measurement model, return two coupled measurements."
...     m1 = np.random.normal(size=n)
...     m2 = np.random.normal(scale=0.5, size=n)
...     return m1+m2, m1-m2

>>> m1, m2 = measure(2000)
>>> xmin = m1.min()
>>> xmax = m1.max()
>>> ymin = m2.min()
>>> ymax = m2.max()
```

Perform a kernel density estimate on the data:

```python
>>> X, Y = np.mgrid[xmin:xmax:100j, ymin:ymax:100j]
>>> positions = np.vstack([X.ravel(), Y.ravel()])
>>> values = np.vstack([m1, m2])
>>> kernel = stats.gaussian_kde(values)
>>> Z = np.reshape(kernel(positions).T, X.shape)
```

Plot the results:

```python
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> ax.imshow(np.rot90(Z), cmap=plt.cm.gist_earth_r,
...     extent=[xmin, xmax, ymin, ymax])
>>> ax.plot(m1, m2, 'k.', markersize=2)
>>> ax.set_xlim([xmin, xmax])
>>> ax.set_ylim([ymin, ymax])
>>> plt.show()
```

Attributes

- dataset [ndarray] The dataset with which `gaussian_kde` was initialized.
- d [int] Number of dimensions.
- n [int] Number of datapoints.
- neff [int] Effective number of datapoints.
  New in version 1.2.0.
factor  [float] The bandwidth factor, obtained from \texttt{kde.covariance\_factor}, with which the covariance matrix is multiplied.

covariance  [ndarray] The covariance matrix of \texttt{dataset}, scaled by the calculated bandwidth (\texttt{kde.factor}).

inv\_cov  [ndarray] The inverse of covariance.

Methods

\texttt{evaluate(points)}

Evaluate the estimated pdf on a set of points.

\texttt{__call__}(points)

Evaluate the estimated pdf on a set of points.

\texttt{integrate\_gaussian}(mean, cov)

Multiply estimated density by a multivariate Gaussian and integrate over the whole space.

\texttt{integrate\_box\_1d}(low, high)

Computes the integral of a 1D pdf between two bounds.

\texttt{integrate\_box}(low\_bounds, high\_bounds[, maxpts])

Computes the integral of a pdf over a rectangular interval.

\texttt{integrate\_kde}(other)

Computes the integral of the product of this kernel density estimate with another.

\texttt{pdf}(x)

Evaluate the estimated pdf on a provided set of points.

\texttt{logpdf}(x)

Evaluate the log of the estimated pdf on a provided set of points.

\texttt{resample}([size, seed])

Randomly sample a dataset from the estimated pdf.

\texttt{set\_bandwidth}([bw\_method])

Compute the estimator bandwidth with given method.

\texttt{covariance\_factor}()

Computes the coefficient (\texttt{kde.factor}) that multiplies the data covariance matrix to obtain the kernel covariance matrix.

\texttt{scipy.stats.gaussian\_kde.evaluate}

gaussian\_kde.\texttt{evaluate}(points)

Evaluate the estimated pdf on a set of points.

Parameters

points  [(\# of dimensions, \# of points)-array] Alternatively, a (\# of dimensions,) vector can be passed in and treated as a single point.

Returns

values  [\# of points,)-array] The values at each point.
scipy.stats.gaussian_kde.__call__

```python
gaussian_kde.__call__(points)
```
Evaluate the estimated pdf on a set of points.

**Parameters**
- `points` [(# of dimensions, # of points)-array] Alternatively, a ( # of dimensions,) vector can be passed in and treated as a single point.

**Returns**
- `values` [ (# of points,)-array] The values at each point.

**Raises**
- `ValueError` [if the dimensionality of the input points is different than] the dimensionality of the KDE.

scipy.stats.gaussian_kde.integrate_gaussian

```python
gaussian_kde.integrate_gaussian(mean, cov)
```
Multiply estimated density by a multivariate Gaussian and integrate over the whole space.

**Parameters**
- `cov` [array_like] A 2-D array, specifying the covariance matrix of the Gaussian.

**Returns**
- `result` [scalar] The value of the integral.

**Raises**
- `ValueError` If the mean or covariance of the input Gaussian differs from the KDE’s dimensionality.

scipy.stats.gaussian_kde.integrate_box_1d

```python
gaussian_kde.integrate_box_1d(low, high)
```
Computes the integral of a 1D pdf between two bounds.

**Parameters**
- `low` [scalar] Lower bound of integration.
- `high` [scalar] Upper bound of integration.

**Returns**
- `value` [scalar] The result of the integral.

**Raises**
- `ValueError` If the KDE is over more than one dimension.
scipy.stats.gaussian_kde.integrate_box

**gaussian_kde.integrate_box**(low_bounds, high_bounds, maxpts=None)

Computes the integral of a pdf over a rectangular interval.

**Parameters**

- **low_bounds**
- **high_bounds**
- **maxpts**
  [int, optional] The maximum number of points to use for integration.

**Returns**

- **value**
  [scalar] The result of the integral.

scipy.stats.gaussian_kde.integrate_kde

**gaussian_kde.integrate_kde**(other)

Computes the integral of the product of this kernel density estimate with another.

**Parameters**

- **other**
  [gaussian_kde instance] The other kde.

**Returns**

- **value**
  [scalar] The result of the integral.

**Raises**

- **ValueError**
  If the KDEs have different dimensionality.

scipy.stats.gaussian_kde.pdf

**gaussian_kde.pdf**(x)

Evaluate the estimated pdf on a provided set of points.

**Notes**

This is an alias for **gaussian_kde.evaluate**. See the **evaluate** docstring for more details.

scipy.stats.gaussian_kde.logpdf

**gaussian_kde.logpdf**(x)

Evaluate the log of the estimated pdf on a provided set of points.
**scipy.stats.gaussian_kde.resample**

`gaussian_kde.resample(size=None, seed=None)`

Randomly sample a dataset from the estimated pdf.

**Parameters**

- `size` [int, optional] The number of samples to draw. If not provided, then the size is the same as the effective number of samples in the underlying dataset.
- `seed` [None, int, `numpy.random.Generator`]
  - `numpy.random.RandomState`, optional

If `seed` is None (or `np.random`), the `numpy.random.RandomState` singleton is used. If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already a `Generator` or `RandomState` instance then that instance is used.

**Returns**

**scipy.stats.gaussian_kde.set_bandwidth**

`gaussian_kde.set_bandwidth(bw_method=None)`

Compute the estimator bandwidth with given method.

The new bandwidth calculated after a call to `set_bandwidth` is used for subsequent evaluations of the estimated density.

**Parameters**

- `bw_method` [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If a scalar, this will be used directly as `kde.factor`. If a callable, it should take a `gaussian_kde` instance as only parameter and return a scalar. If None (default), nothing happens; the current `kde.covariance_factor` method is kept.

**Notes**

New in version 0.11.

**Examples**

```python
>>> import scipy.stats as stats
>>> x1 = np.array([-7, -5, 1, 4, 5])
>>> kde = stats.gaussian_kde(x1)
>>> xs = np.linspace(-10, 10, num=50)
>>> y1 = kde(xs)
>>> kde.set_bandwidth(bw_method='silverman')
>>> y2 = kde(xs)
>>> kde.set_bandwidth(bw_method=kde.factor / 3.)
>>> y3 = kde(xs)
```
import matplotlib.pyplot as plt
fig, ax = plt.subplots()
ax.plot(x1, np.full(x1.shape, 1 / (4. * x1.size)), 'bo',
    label='Data points (rescaled)')
ax.plot(xs, y1, label='Scott (default)')
ax.plot(xs, y2, label='Silverman')
ax.plot(xs, y3, label='Const (1/3 * Silverman)')
ax.legend()
plt.show()

scipy.stats.gaussian_kde.covariance_factor

gaussian_kde.covariance_factor() computes the coefficient \( kde.factor \) that multiplies the data covariance matrix to obtain the kernel covariance matrix. The default is scotts_factor. A subclass can overwrite this method to provide a different method, or set it through a call to kde.set_bandwidth.

Warnings used in scipy.stats

<table>
<thead>
<tr>
<th>Warning name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F_onewayConstantInputWarning[[msg]]</td>
<td>Warning generated by f_oneway when an input is constant, e.g.</td>
</tr>
<tr>
<td>F_onewayBadInputSizesWarning</td>
<td>Warning generated by f_oneway when an input has length 0, or if all the inputs have length 1.</td>
</tr>

</tr>
<tr>
<td>SpearmanRConstantInputWarning[[msg]]</td>
<td>Warning generated by spearmanr when an input is constant.</td>
</tr>
</tbody>
</table>
scipy.stats.F_onewayConstantInputWarning

```
exception scipy.stats.F_onewayConstantInputWarning (msg=None)
    Warning generated by f_oneway when an input is constant, e.g. each of the samples provided is a constant array.

    with_traceback()
    Exception.with_traceback(tb) - set self.__traceback__ to tb and return self.
```

scipy.stats.F_onewayBadInputSizesWarning

```
exception scipy.stats.F_onewayBadInputSizesWarning
    Warning generated by f_oneway when an input has length 0, or if all the inputs have length 1.

    with_traceback()
    Exception.with_traceback(tb) - set self.__traceback__ to tb and return self.
```

scipy.stats.PearsonRConstantInputWarning

```
exception scipy.stats.PearsonRConstantInputWarning (msg=None)
    Warning generated by pearsonr when an input is constant.

    with_traceback()
    Exception.with_traceback(tb) - set self.__traceback__ to tb and return self.
```

scipy.stats.PearsonRNearConstantInputWarning

```
exception scipy.stats.PearsonRNearConstantInputWarning (msg=None)
    Warning generated by pearsonr when an input is nearly constant.

    with_traceback()
    Exception.with_traceback(tb) - set self.__traceback__ to tb and return self.
```

scipy.stats.SpearmanRConstantInputWarning

```
exception scipy.stats.SpearmanRConstantInputWarning (msg=None)
    Warning generated by spearmanr when an input is constant.

    with_traceback()
    Exception.with_traceback(tb) - set self.__traceback__ to tb and return self.
```

### 3.3.30 Result classes

<table>
<thead>
<tr>
<th>Class</th>
<th>Result of</th>
</tr>
</thead>
<tbody>
<tr>
<td>RelativeRiskResult</td>
<td>scipy.stats.contingency.relative_risk.</td>
</tr>
<tr>
<td>BinomTestResult</td>
<td>scipy.stats.binomtest.</td>
</tr>
</tbody>
</table>
**scipy.stats._result_classes.RelativeRiskResult**

**class** `scipy.stats._result_classes.RelativeRiskResult` *(relative_risk, exposed_cases, exposed_total, control_cases, control_total)*

Result of `scipy.stats.contingency.relative_risk`.

**Attributes**

relative_risk

[float] This is:

\[
\frac{\text{exposed_cases}}{\text{exposed_total}} / \frac{\text{control_cases}}{\text{control_total}}
\]

exposed_cases

[int] The number of “cases” (i.e. occurrence of disease or other event of interest) among the sample of “exposed” individuals.

exposed_total

[int] The total number of “exposed” individuals in the sample.

control_cases

[int] The number of “cases” among the sample of “control” or non-exposed individuals.

control_total

[int] The total number of “control” individuals in the sample.

**Methods**

`confidence_interval` : Compute the confidence interval for the relative risk estimate.

**scipy.stats._result_classes.BinomTestResult**

**class** `scipy.stats._result_classes.BinomTestResult` *(k, n, alternative, pvalue, proportion_estimate)*

Result of `scipy.stats.binomtest`.

**Attributes**

k

[int] The number of successes (copied from `binomtest` input).

n

[int] The number of trials (copied from `binomtest` input).

alternative

[str] Indicates the alternative hypothesis specified in the input to `binomtest`. It will be one of 'two-sided', 'greater', or 'less'.

pvalue

[float] The p-value of the hypothesis test.

proportion_estimate

[float] The estimate of the proportion of successes.
Methods

```
proportion_ci: Compute the confidence interval for the estimate of the proportion.
```

3.3.31 Low-level callback functions

Some functions in SciPy take as arguments callback functions, which can either be python callables or low-level compiled functions. Using compiled callback functions can improve performance somewhat by avoiding wrapping data in Python objects.

Such low-level functions in SciPy are wrapped in `LowLevelCallable` objects, which can be constructed from function pointers obtained from ctypes, cffi, Cython, or contained in Python `PyCapsule` objects.

```
LowLevelCallable(function[, user_data, …])  Low-level callback function.
```

**scipy.LowLevelCallable**

class `scipy.LowLevelCallable` (function, user_data=None, signature=None)

Low-level callback function.

**Parameters**

- `function` ([{'PyCapsule', 'ctypes function pointer', 'cffi function pointer}]) Low-level callback function.
- `user_data` ([{'PyCapsule', 'ctypes void pointer', 'cffi void pointer}]) User data to pass on to the callback function.
- `signature` [str, optional] Signature of the function. If omitted, determined from `function`, if possible.

**Notes**

The argument `function` can be one of:

- PyCapsule, whose name contains the C function signature
- ctypes function pointer
- cffi function pointer

The signature of the low-level callback must match one of those expected by the routine it is passed to.

If constructing low-level functions from a PyCapsule, the name of the capsule must be the corresponding signature, in the format:

```
return_type (arg1_type, arg2_type, …)
```

For example:

```
"void (double)"
"double (double, int *, void *)"
```

The context of a PyCapsule passed in as `function` is used as `user_data`, if an explicit value for `user_data` was not given.

**Attributes**

- `function` Callback function given.
user_data  User data given.
signature   Signature of the function.

Methods

```python
from_cython(module, name[, user_data, signature])
```
Create a low-level callback function from an exported Cython function.

```python
scipy.LowLevelCallable.from_cython
```

Class method `scipy.LowLevelCallable.from_cython(module, name, user_data=None, signature=None)`
Create a low-level callback function from an exported Cython function.

**Parameters**

- **module**  [module] Cython module where the exported function resides
- **name**   [str] Name of the exported function
- **user_data**   [[PyCapsule, ctypes void pointer, cffi void pointer], optional] User data to pass on to the callback function.
- **signature**   [str, optional] Signature of the function. If omitted, determined from `function`.

See also:

Functions accepting low-level callables:

```python
scipy.integrate.quad, scipy.ndimage.generic_filter, scipy.ndimage.generic_filter1d, scipy.ndimage.geometric_transform
```

Usage examples:

*Extending scipy.ndimage in C, Faster integration using low-level callback functions*

## 3.4 SciPy structure

All SciPy modules should follow the following conventions. In the following, a *SciPy module* is defined as a Python package, say `yyy`, that is located in the `scipy/` directory.

- Ideally, each SciPy module should be as self-contained as possible. That is, it should have minimal dependencies on other packages or modules. Even dependencies on other SciPy modules should be kept to a minimum. A dependency on NumPy is of course assumed.
- Directory `yyy/` contains:
  - A file `setup.py` that defines `configuration(parent_package='', top_path=None)` function for `numpy.distutils`.
  - A directory `tests/` that contains files `test_<name>.py` corresponding to modules `yyy/<name>{.py,.so,}/`
- Private modules should be prefixed with an underscore `_`, for instance `yyy/_somemodule.py`.
- User-visible functions should have good documentation following the NumPy documentation style.
- The `__init__.py` of the module should contain the main reference documentation in its docstring. This is connected to the Sphinx documentation under `doc/` via Sphinx’s automodule directive.
The reference documentation should first give a categorized list of the contents of the module using autosummary directives, and after that explain points essential for understanding the use of the module.

Tutorial-style documentation with extensive examples should be separate and put under doc/source/tutorial/.

See the existing SciPy submodules for guidance.

For further details on NumPy distutils, see NumPy Distutils - User's Guide.
Bellow you will find general information about contributing. For an overview of where help or new features are desired or planned, see the roadmap. And for a more detailed look at how the SciPy project works, see the organization section.

4.1 SciPy Code of Conduct

4.1.1 Introduction

This code of conduct applies to all spaces managed by the SciPy project, including all public and private mailing lists, issue trackers, wikis, blogs, Twitter, and any other communication channel used by our community. The SciPy project does not organize in-person events, however, events related to our community should have a code of conduct similar in spirit to this one.

This code of conduct should be honored by everyone who participates in the SciPy community formally or informally, or claims any affiliation with the project, in any project-related activities, and, especially, when representing the project, in any role.

This code is neither exhaustive nor complete. It serves to distill our common understanding of a collaborative, shared environment and goals. Please try to follow this code in spirit as much as in letter, to create a friendly and productive environment that enriches the surrounding community.

4.1.2 Specific guidelines

We strive to:

1. Be open. We invite anyone to participate in our community. We prefer to use public methods of communication for project-related messages, unless discussing something sensitive. This applies to messages for help or project-related support, too; not only is a public-support request much more likely to result in an answer to a question, it also ensures that any inadvertent mistakes in answering are more easily detected and corrected.

2. Be empathetic, welcoming, friendly, and patient. We work together to resolve conflict, and assume good intentions. We may all experience some frustration from time to time, but we do not allow frustration to turn into a personal attack. A community where people feel uncomfortable or threatened is not a productive one.

3. Be collaborative. Our work will be used by other people, and in turn we will depend on the work of others. When we make something for the benefit of the project, we are willing to explain to others how it works, so that they can build on the work to make it even better. Any decision we make will affect users and colleagues, and we take those consequences seriously when making decisions.

4. Be inquisitive. Nobody knows everything! Asking questions early avoids many problems later, so we encourage questions, although we may direct them to the appropriate forum. We will try hard to be responsive and helpful.
5. Be careful in the words that we choose. We are careful and respectful in our communication and we take responsibility for our own speech. Be kind to others. Do not insult or put down other participants. We will not accept harassment or other exclusionary behavior, such as:

- Violent threats or language directed against another person.
- Sexist, racist, or otherwise discriminatory jokes and language.
- Posting sexually explicit or violent material.
- Posting (or threatening to post) other people’s personally identifying information (“doxing”).
- Sharing private content, such as emails sent privately or non-publicly, or unlogged forums, such as IRC channel history, without the sender’s consent.
- Personal insults, especially those using racist or sexist terms.
- Unwelcome sexual attention.
- Excessive profanity. Please avoid swearwords; people differ greatly in their sensitivity to swearing.
- Repeated harassment of others. In general, if someone asks you to stop, then stop.
- Advocating for, or encouraging, any of the above behavior.

4.1.3 Diversity statement

The SciPy project welcomes and encourages participation by everyone. We are committed to being a community that everyone enjoys being part of. Although we may not always be able to accommodate each individual’s preferences, we try our best to treat everyone kindly.

No matter how you identify yourself or how others perceive you: we welcome you. Though no list can hope to be comprehensive, we explicitly honor diversity in: age, culture, ethnicity, genotype, gender identity or expression, language, national origin, neurotype, phenotype, political beliefs, profession, race, religion, sexual orientation, socioeconomic status, subculture and technical ability, to the extent that these do not conflict with this code of conduct.

Though we welcome people fluent in all languages, SciPy development is conducted in English.

Standards for behavior in the SciPy community are detailed in the Code of Conduct above. Participants in our community should uphold these standards in all their interactions and help others to do so as well (see next section).

4.1.4 Reporting guidelines

We know that it is painfully common for internet communication to start at or devolve into obvious and flagrant abuse. We also recognize that sometimes people may have a bad day, or be unaware of some of the guidelines in this Code of Conduct. Please keep this in mind when deciding on how to respond to a breach of this Code.

For clearly intentional breaches, report those to the Code of Conduct committee (see below). For possibly unintentional breaches, you may reply to the person and point out this Code of Conduct (either in public or in private, whatever is most appropriate). If you would prefer not to do that, please feel free to report to the Code of Conduct committee directly, or ask the committee for advice, in confidence.

You can report issues to the SciPy Code of Conduct Committee, at scipy-conduct@googlegroups.com. Currently, the committee consists of:

- Stefan van der Walt
- Nathaniel J. Smith
- Ralf Gommers
If your report involves any members of the committee, or if they feel they have a conflict of interest in handling it, then they will recuse themselves from considering your report. Alternatively, if, for any reason, you feel uncomfortable making a report to the committee, then you can also contact:

- Chair of the SciPy Steering Committee: Ralf Gommers, or
- Senior NumFOCUS staff: conduct@numfocus.org

4.1.5 Incident reporting resolution & Code of Conduct enforcement

This section summarizes the most important points, more details can be found in CoC_reporting_manual.

We will investigate and respond to all complaints. The SciPy Code of Conduct Committee and the SciPy Steering Committee (if involved) will protect the identity of the reporter, and treat the content of complaints as confidential (unless the reporter agrees otherwise).

In case of severe and obvious breaches, e.g., personal threat or violent, sexist or racist language, we will immediately disconnect the originator from SciPy communication channels; please see the manual for details.

In cases not involving clear severe and obvious breaches of this code of conduct, the process for acting on any received code of conduct violation report will be:

1. acknowledgement that the report has been received
2. reasonable discussion/feedback
3. mediation (if feedback didn't help, and only if both reporter and reportee agree to this)
4. enforcement via transparent decision (see CoC_resolutions) by the Code of Conduct Committee

The committee will respond to any report as soon as possible, and at most within 72 hours.

4.1.6 Endnotes

We are thankful to the groups behind the following documents, from which we drew content and inspiration:

- The Apache Foundation Code of Conduct
- The Contributor Covenant
- Jupyter Code of Conduct
- Open Source Guides - Code of Conduct

4.2 Ways to Contribute

This document aims to give an overview of the ways to contribute to SciPy. It tries to answer commonly asked questions and provide some insight into how the community process works in practice. Readers who are familiar with the SciPy community and are experienced Python coders may want to jump straight to the SciPy contributor guide.

There are a lot of ways you can contribute:

- Contributing new code
- Fixing bugs, improving documentation, and other maintenance work
- Reviewing open pull requests
- Triaging issues
4.2.1 Contributing new code

If you have been working with the scientific Python toolstack for a while, you probably have some code lying around of which you think “this could be useful for others too”. Perhaps it’s a good idea then to contribute it to SciPy or another open source project. The first question to ask is then, where does this code belong? That question is hard to answer here, so we start with a more specific one: what code is suitable for putting into SciPy? Almost all of the new code added to SciPy has in common that it’s potentially useful in multiple scientific domains and it fits in the scope of existing SciPy subpackages (see Deciding on new features). In principle new subpackages can be added too, but this is far less common. For code that is specific to a single application, there may be an existing project that can use the code. Some SciKits (scikit-learn, scikit-image, statsmodels, etc.) are good examples here; they have a narrower focus and because of that more domain-specific code than SciPy.

Now if you have code that you would like to see included in SciPy, how do you go about it? After checking that your code can be distributed in SciPy under a compatible license (see License Considerations), the first step is to discuss on the scipy-dev mailing list. All new features, as well as changes to existing code, are discussed and decided on there. You can, and probably should, already start this discussion before your code is finished. Remember that in order to be added to SciPy your code will need to be reviewed by someone else, so try to find someone willing to review your work while you’re at it.

Assuming the outcome of the discussion on the mailing list is positive and you have a function or piece of code that does what you need it to do, what next? Before code is added to SciPy, it at least has to have good documentation, unit tests, benchmarks, and correct code style.

1. **Unit tests**

   In principle you should aim to create unit tests that exercise all the code that you are adding. This gives some degree of confidence that your code runs correctly, also on Python versions and hardware or OSes that you don’t have available yourself. An extensive description of how to write unit tests is given in Testing Guidelines, and Running SciPy Tests Locally documents how to run them.

2. **Benchmarks**

   Unit tests check for correct functionality; benchmarks measure code performance. Not all existing SciPy code has benchmarks, but it should: as SciPy grows it is increasingly important to monitor execution times in order to catch unexpected regressions. More information about writing and running benchmarks is available in Benchmarking SciPy with airspeed velocity.

3. **Documentation**

   Clear and complete documentation is essential in order for users to be able to find and understand the code. Documentation for individual functions and classes – which includes at least a basic description, type and meaning of all parameters and returns values, and usage examples in doctest format – is put in docstrings. Those docstrings can be read within the interpreter, and are compiled into a reference guide in html and pdf format. Higher-level documentation for key (areas of) functionality is provided in tutorial format and/or in module docstrings. A guide on how to write documentation is given in A Guide to NumPy Documentation, and Rendering Documentation with Sphinx explains how to preview the documentation as it will appear online.

4. **Code style**

   Uniformity of style in which code is written is important to others trying to understand the code. SciPy follows the standard Python guidelines for code style, PEP8. In order to check that your code conforms to PEP8, you can use the pep8 package style checker. Most IDEs and text editors have settings that can help you follow PEP8, for example by translating tabs by four spaces. Using pyflakes to check your code is also a good idea. More information is available in PEP8 and SciPy.
A checklist, including these and other requirements, is available at the end of the example Development workflow.

Another question you may have is: where exactly do I put my code? To answer this, it is useful to understand how the SciPy public API (application programming interface) is defined. For most modules the API is two levels deep, which means your new function should appear as `scipy.subpackage.my_new_func`. `my_new_func` can be put in an existing or new file under `/scipy/<subpackage>/`, its name is added to the `__all__` list in that file (which lists all public functions in the file), and those public functions are then imported in `/scipy/<subpackage>/__init__.py`. Any private functions/classes should have a leading underscore (_) in their name. A more detailed description of what the public API of SciPy is, is given in SciPy API.

Once you think your code is ready for inclusion in SciPy, you can send a pull request (PR) on Github. We won’t go into the details of how to work with git here, this is described well in git-development and on the Github help pages. When you send the PR for a new feature, be sure to also mention this on the scipy-dev mailing list. This can prompt interested people to help review your PR. Assuming that you already got positive feedback before on the general idea of your code/feature, the purpose of the code review is to ensure that the code is correct, efficient and meets the requirements outlined above. In many cases the code review happens relatively quickly, but it’s possible that it stalls. If you have addressed all feedback already given, it's perfectly fine to ask on the mailing list again for review (after a reasonable amount of time, say a couple of weeks, has passed). Once the review is completed, the PR is merged into the “master” branch of SciPy.

The above describes the requirements and process for adding code to SciPy. It doesn’t yet answer the question though how decisions are made exactly. The basic answer is: decisions are made by consensus, by everyone who chooses to participate in the discussion on the mailing list. This includes developers, other users and yourself. Aiming for consensus in the discussion is important – SciPy is a project by and for the scientific Python community. In those rare cases that agreement cannot be reached, the maintainers of the module in question can decide the issue.

License Considerations

I based my code on existing Matlab/R/... code I found online, is this OK?

It depends. SciPy is distributed under a BSD license, so if the code that you based your code on is also BSD licensed or has a BSD-compatible license (e.g. MIT, PSF) then it’s OK. Code which is GPL or Apache licensed, has no clear license, requires citation or is free for academic use only can’t be included in SciPy. Therefore if you copied existing code with such a license or made a direct translation to Python of it, your code can’t be included. If you're unsure, please ask on the scipy-dev mailing list.

Why is SciPy under the BSD license and not, say, the GPL?

Like Python, SciPy uses a “permissive” open source license, which allows proprietary re-use. While this allows companies to use and modify the software without giving anything back, it is felt that the larger user base results in more contributions overall, and companies often publish their modifications anyway, without being required to. See John Hunter’s BSD pitch.

For more information about SciPy’s license, see Licensing.

4.2.2 Maintaining existing code

The previous section talked specifically about adding new functionality to SciPy. A large part of that discussion also applies to maintenance of existing code. Maintenance means fixing bugs, improving code quality, documenting existing functionality better, adding missing unit tests, adding performance benchmarks, keeping build scripts up-to-date, etc. The SciPy issue list contains all reported bugs, build/documentation issues, etc. Fixing issues helps improve the overall quality of SciPy, and is also a good way of getting familiar with the project. You may also want to fix a bug because you ran into it and need the function to work correctly.

The discussion on code style and unit testing above applies equally to bug fixes. It is usually best to start by writing a unit test that shows the problem, i.e. it should pass but doesn’t. Once you have that, you can fix the code so that the test does pass. That should be enough to send a PR for this issue. Unlike when adding new code, discussing this on the mailing list may not be necessary - if the old behavior of the code is clearly incorrect, no one will object to having it fixed. It may
be necessary to add some warning or deprecation message for the changed behavior. This should be part of the review process.

**Note:** Pull requests that only change code style, e.g. fixing some PEP8 issues in a file, are discouraged. Such PRs are often not worth cluttering the git annotate history, and take reviewer time that may be better spent in other ways. Code style cleanups of code that is touched as part of a functional change are fine however.

### 4.2.3 Reviewing pull requests

Reviewing open pull requests (PRs) is very welcome, and a valuable way to help increase the speed at which the project moves forward. If you have specific knowledge/experience in a particular area (say “optimization algorithms” or “special functions”) then reviewing PRs in that area is especially valuable - sometimes PRs with technical code have to wait for a long time to get merged due to a shortage of appropriate reviewers.

We encourage everyone to get involved in the review process; it’s also a great way to get familiar with the code base. Reviewers should ask themselves some or all of the following questions:

- Was this change adequately discussed (relevant for new features and changes in existing behavior)?
- Is the feature scientifically sound? Algorithms may be known to work based on literature; otherwise, closer look at correctness is valuable.
- Is the intended behavior clear under all conditions (e.g. unexpected inputs like empty arrays or nan/inf values)?
- Does the code meet the quality, test and documentation expectation outline under *Contributing new code*?

If we do not know you yet, consider introducing yourself.

### 4.2.4 Other ways to contribute

There are many ways to contribute other than writing code.

Triaging issues (investigating bug reports for validity and possible actions to take) is also a useful activity. SciPy has many hundreds of open issues; closing invalid ones and correctly labeling valid ones (ideally with some first thoughts in a comment) allows prioritizing maintenance work and finding related issues easily when working on an existing function or subpackage.

Participating in discussions on the scipy-user and scipy-dev mailing lists is a contribution in itself. Everyone who writes to those lists with a problem or an idea would like to get responses, and writing such responses makes the project and community function better and appear more welcoming.

The scipy.org website contains a lot of information on both SciPy the project and SciPy the community, and it can always use a new pair of hands. The sources for the website live in their own separate repo: https://github.com/scipy/scipy.org

### 4.2.5 Getting started

Thanks for your interest in contributing to SciPy! If you're interested in contributing code, we hope you'll continue on to the SciPy contributor guide for details on how to set up your development environment, implement your improvements, and submit your first PR!
4.3 Development environment quickerstart guide (Linux and Mac)

With conda installed (through Miniforge or Mambaforge, Miniconda or Anaconda), execute the following commands at the terminal from the base directory of your SciPy clone:

```bash
# Create an environment with all development dependencies
conda env create -f environment.yml  # works with `mamba` too
conda activate scipy-dev

# Initialize git submodules
git submodule update --init

# Build SciPy for development work plus run tests
python runtests.py  # Alternatively, it's fine to use `python setup.py develop`

# Install SciPy in develop mode in conda
conda develop
```

For more detailed instructions, see the other Development environment guides.

4.4 SciPy contributor guide

This guide is designed to help you quickly find the information you need about SciPy development after you’ve reviewed the introductory material in Ways to Contribute. If you’re new to this and want to start coding ASAP, you’ve found the right place.

- **Development environment** - how to set up and maintain a development environment, including installing compilers and SciPy dependencies, creating a personal fork of the SciPy repository on GitHub, using git to manage a local repository with development branches, performing an in-place build of SciPy, and creating a virtual environment that adds this development version of SciPy to the Python path

- **Editing SciPy** - how to edit SciPy Python code, with tips on finding which module contains SciPy functionality to be edited, adding new modules to SciPy, and complying with PEP8 style standards

- **Unit tests** - how to write and run unit tests for SciPy with the pytest framework

- **Documentation** - how to write reStructuredText documentation that complies with docstring standards, build documentation locally with Sphinx, and view documentation built during continuous integration checks

- **Benchmarks** - how to benchmark code with airspeed velocity

- **Compiled code** - how to add fast, compiled code to SciPy

- **Continuous Integration** - how does our continuous integration system works and how to debug your PR
4.4.1 Development environment

- Development environment quickerstart guide (Linux and Mac) contains just the commands you need to get started on Mac and Linux
- quickstart-pip presents an overview of setting up the development environment using pip on Linux
- Development environment quickstart guide (macOS) presents a step-by-step process for setting up a convenient SciPy development environment in macOS
- Development environment quickstart guide (Ubuntu) presents a step-by-step process for setting up a convenient SciPy development environment in Ubuntu
- build-windows presents a step-by-step process for building SciPy on Windows
- quickstart-docker presents a step-by-step process for building SciPy using Docker; if you have trouble with the instructions above, this may be your best option
- quickstart-gitpod presents a step-by-step process for using Gitpod for SciPy development; this process requires minimal setup and is newcomer friendly
- building may have some helpful hints if you need to deviate from the guides above
- recommended-development-setup includes additional notes about the development setup; all of this information is contained elsewhere, but it is retained as a legacy document

4.4.2 Editing SciPy

- Development workflow lays out what to do after your development environment is set up
- SciPy Development Workflow is a five-minute video example of fixing a bug and submitting a pull request
- PEP8 and SciPy gives some tips for ensuring that your code is PEP8 compliant
- git-development is a guide to using git, the distributed version-control system used to manage the changes made to SciPy code from around the world
- SciPy API contains some important notes about how SciPy code is organized and documents the structure of the SciPy API; if you are going to import other SciPy code, read this first
- reviewing-prs explains how to review another author’s SciPy code locally
- NumPy Distutils - Users Guide - check this out before adding any new files to SciPy
- Adding New Methods, Functions, and Classes has information on how to add new methods, functions and classes
- SciPy Core Developer Guide has background information including how decisions are made and how a release is prepared; it’s geared toward Core Developers, but contains useful information for all contributors

4.4.3 Unit tests

- Testing Guidelines is the definitive guide to writing unit tests of SciPy code
- Running SciPy Tests Locally documents runtests.py, a convenient script for building SciPy and running tests locally
4.4.4 Documentation

- A Guide to NumPy Documentation contains everything you need to know about writing docstrings, which are rendered to produce HTML documentation using Sphinx
- Rendering Documentation with Sphinx it’s important to check how changes to the documentation render before merging a PR; this document explains how you can do that

4.4.5 Benchmarks

- Benchmarking SciPy with airspeed velocity explains how to add benchmarks to SciPy using airspeed velocity

4.4.6 Compiled code

- Adding Cython to SciPy extending and compiling Python code with Cython can significantly improve its performance; this document helps you get started
- other-languages discusses the use of C, C++, and Fortran code in SciPy
- Public Cython APIs on guidelines on exposing public Cython APIs

4.5 SciPy Roadmap

This roadmap page contains only the most important ideas and needs for SciPy going forward. For a more detailed roadmap, including per-subpackage status, many more ideas, API stability and more, see Detailed SciPy Roadmap.

4.5.1 Support for distributed arrays and GPU arrays

NumPy has split its API from its execution engine with __array_function__ and __array_ufunc__. This will enable parts of SciPy to accept distributed arrays (e.g. dask.array.Array) and GPU arrays (e.g. cupy.ndarray) that implement the ndarray interface. At the moment it is not yet clear which algorithms will work out of the box, and if there are significant performance gains when they do. We want to create a map of which parts of the SciPy API work, and improve support over time.

In addition to making use of NumPy protocols like __array_function__, we can make use of these protocols in SciPy as well. That will make it possible to (re)implement SciPy functions like, e.g., those in scipy.signal for Dask or GPU arrays (see NEP 18 - use outside of NumPy). NumPy's features in this areas are still evolving, see e.g. NEP 37 - A dispatch protocol for NumPy-like modules, and SciPy is an important “client” for those features.

4.5.2 Performance improvements

Speed improvements, lower memory usage and the ability to parallelize algorithms are beneficial to most science domains and use cases. We have established an API design pattern for multiprocessing - using the workers keyword - that can be adopted in many more functions.

Enabling the use of an accelerator like Pythran, possibly via Transonic, and making it easier for users to use Numba’s @njit in their code that relies on SciPy functionality would unlock a lot of performance gain. That needs a strategy though, all solutions are still maturing (see for example this overview).

Finally, many individual functions can be optimized for performance. scipy.optimize and scipy.interpolate functions are particularly often requested in this respect.
4.5.3 Statistics enhancements

The `scipy.stats` enhancements listed in the Detailed SciPy Roadmap are of particularly high importance to the project.

- Improve the options for fitting a probability distribution to data.
- Expand the set of hypothesis tests. In particular, include all the basic variations of analysis of variance.
- Add confidence intervals for all statistical tests.

4.5.4 Support for more hardware platforms

SciPy now has continuous integration for ARM64 (or `aarch64`) and POWER8/9 (or `ppc64le`), and binaries are available via Miniforge. Wheels on PyPI for these platforms are now also possible (with the `manylinux2014` standard), and requests for those are becoming more frequent.

Additionally, having IBM Z (or `s390x`) in CI is now possible with TravisCI but not yet done - and `manylinux2014` wheels for that platform are also possible then. Finally, resolving open AIX build issues would help users.

4.5.5 Implement sparse arrays in addition to sparse matrices

The sparse matrix formats are mostly feature-complete, however the main issue is that they act like `numpy.matrix` (which will be deprecated in NumPy at some point). What we want is sparse arrays that act like `numpy.ndarray`.

This is being worked on in https://github.com/pydata/sparse, which is quite far along. The tentative plan is:

- Start depending on `pydata/sparse` once it's feature-complete enough (it still needs a CSC/CSR equivalent) and okay performance-wise.
- Indicate in the documentation that for new code users should prefer `pydata/sparse` over sparse matrices.
- When NumPy deprecates `numpy.matrix`, vendor that or maintain it as a stand-alone package.

4.6 Detailed SciPy Roadmap

Most of this roadmap is intended to provide a high-level view on what is most needed per SciPy submodule in terms of new functionality, bug fixes, etc. Besides important “business as usual” changes, it contains ideas for major new features - those are marked as such, and are expected to take significant dedicated effort. Things not mentioned in this roadmap are not necessarily unimportant or out of scope, however we (the SciPy developers) want to provide to our users and contributors a clear picture of where SciPy is going and where help is needed most.

**Note:** This is the detailed roadmap. A very high-level overview with only the most important ideas is *SciPy Roadmap.*
4.6.1 General

This roadmap will be evolving together with SciPy. Updates can be submitted as pull requests. For large or disruptive changes you may want to discuss those first on the scipy-dev mailing list.

API changes

In general, we want to evolve the API to remove known warts as much as possible, however as much as possible without breaking backwards compatibility.

Also, it should be made (even) more clear what is public and what is private in SciPy. Everything private should be named starting with an underscore as much as possible.

Test coverage

Test coverage of code added in the last few years is quite good, and we aim for a high coverage for all new code that is added. However, there is still a significant amount of old code for which coverage is poor. Bringing that up to the current standard is probably not realistic, but we should plug the biggest holes.

Besides coverage there is also the issue of correctness - older code may have a few tests that provide decent statement coverage, but that doesn't necessarily say much about whether the code does what it says on the box. Therefore code review of some parts of the code (stats, signal and ndimage in particular) is necessary.

Documentation

The main website, scipy.org, needs to be rewritten. As discussed in the mail list, the SciPy stack is not relevant anymore and this website should be made about SciPy only following the example of numpy.org. There is a lot of new content to write.

Otherwise, the documentation is in good shape. Expanding of current docstrings and putting them in the standard NumPy format should continue, so the number of reST errors and glitches in the html docs decreases. Most modules also have a tutorial in the reference guide that is a good introduction, however there are a few missing or incomplete tutorials - this should be fixed.

Benchmarks

The asv-based benchmark system is in reasonable shape. It is quite easy to add new benchmarks, however running the benchmarks is not very intuitive. Making this easier is a priority. In addition, we should run them in our CI (gh-8779 is an ongoing attempt at this).

Use of Cython

Regarding Cython code:

- It’s not clear how much functionality can be Cythonized without making the .so files too large. This needs measuring.
- Cython’s old syntax for using NumPy arrays should be removed and replaced with Cython memoryviews.
Windows build issues

SciPy critically relies on Fortran code. This is still problematic on Windows. There are currently only two options: using Intel Fortran, or using MSVC + gfortran. The former is expensive, while the latter works (it’s what we use for releases) but is quite hard to do correctly. For allowing contributors and end users to reliably build SciPy on Windows, using the Flang compiler looks like the best way forward long-term.

Continuous integration

Continuous integration is in good shape, it currently covers the Windows, macOS and Linux, ARM64 and ppc64le platforms, as well as a range of versions of our dependencies and building release quality wheels.

Size of binaries

SciPy binaries are quite large (e.g. an unzipped manylinux wheel for 1.4.1 is 91 MB), and this can be problematic - for example for use in AWS Lambda, which has a 250 MB size limit. We aim to keep binary size as low as possible; when adding new compiled extensions, this needs checking. Stripping of debug symbols in multibuild can likely be improved (see this issue).

4.6.2 Modules

cluster

This module is in good shape.

constants

This module is basically done, low-maintenance and without open issues.

fft

This module is in good shape.

integrate

Needed for ODE solvers:

- Documentation is pretty bad, needs fixing
- A new ODE solver interface (solve_ivp) was added in SciPy 1.0.0. In the future we can consider (soft-)deprecating the older API.

The numerical integration functions are in good shape. Support for integrating complex-valued functions and integrating multiple intervals (see gh-3325) could be added.
interpolate

Ideas for new features:

- Spline fitting routines with better user control.
- Transparent tensor-product splines.
- NURBS support.
- Mesh refinement and coarsening of B-splines and corresponding tensor products.

io

wavfile:

- PCM float will be supported, for anything else use audiolab or other specialized libraries.
- Raise errors instead of warnings if data not understood.

Other sub-modules (matlab, netcdf, idl, harwell-boeing, arff, matrix market) are in good shape.

linalg

scipy.linalg is in good shape.

Needed:

- Reduce duplication of functions with numpy.linalg, make APIs consistent.
- get_lapack_funcs should always use flapack
- Wrap more LAPACK functions
- One too many funcs for LU decomposition, remove one

Ideas for new features:

- Add type-generic wrappers in the Cython BLAS and LAPACK
- Make many of the linear algebra routines into gufuncs

BLAS and LAPACK

The Python and Cython interfaces to BLAS and LAPACK in scipy.linalg are one of the most important things that SciPy provides. In general scipy.linalg is in good shape, however we can make a number of improvements:

1. Library support. Our released wheels now ship with OpenBLAS, which is currently the only feasible performant option (ATLAS is too slow, MKL cannot be the default due to licensing issues, Accelerate support is dropped because Apple doesn’t update Accelerate anymore). OpenBLAS isn’t very stable though, sometimes its releases break things and it has issues with threading (currently the only issue for using SciPy with PyPy3). We need at the very least better support for debugging OpenBLAS issues, and better documentation on how to build SciPy with it. An option is to use BLIS for a BLAS interface (see numpy gh-7372).

2. Support for newer LAPACK features. In SciPy 1.2.0 we increased the minimum supported version of LAPACK to 3.4.0. Now that we dropped Python 2.7, we can increase that version further (MKL + Python 2.7 was the blocker for >3.4.0 previously) and start adding support for new features in LAPACK.
misc

`scipy.misc` will be removed as a public module. Most functions in it have been moved to another submodule or deprecated. The few that are left:

- `info, who`: these are NumPy functions
- `derivative, central_diff_weight`: remove, possibly replacing them with more extensive functionality for numerical differentiation.

ndimage

Underlying `ndimage` is a powerful interpolation engine. Users come with an expectation of one of two models: a pixel model with $(1, 1)$ elements having centers $(0.5, 0.5)$, or a data point model, where values are defined at points on a grid. Over time, we’ve become convinced that the data point model is better defined and easier to implement, but this should be clearly communicated in the documentation.

More importantly, still, SciPy implements one variant of this data point model, where datapoints at any two extremes of an axis share a spatial location under periodic wrapping mode. E.g., in a 1D array, you would have $x[0]$ and $x[-1]$ co-located. A very common use-case, however, is for signals to be periodic, with equal spacing between the first and last element along an axis (instead of zero spacing). Wrapping modes for this use-case were added in gh-8537, next the interpolation routines should be updated to use those modes. This should address several issues, including gh-1323, gh-1903, gh-2045 and gh-2640.

The morphology interface needs to be standardized:

- binary dilation/erosion/opening/closing take a “structure” argument, whereas their grey equivalent take size (has to be a tuple, not a scalar), footprint, or structure.
- a scalar should be acceptable for size, equivalent to providing that same value for each axis.
- for binary dilation/erosion/opening/closing, the structuring element is optional, whereas it’s mandatory for grey. Grey morphology operations should get the same default.
- other filters should also take that default value where possible.

odr

This module is in reasonable shape, although it could use a bit more maintenance. No major plans or wishes here.

optimize

Overall this module is in good shape. Two good global optimizers were added in 1.2.0; large-scale optimizers is still a gap that could be filled. Other things that are needed:

- Many ideas for additional functionality (e.g. integer constraints, sparse matrix support, performance improvements) in linprog, see gh-9269.
- Add functionality to the benchmark suite to compare results more easily (e.g. with summary plots).
- deprecate the `fmin_*` functions in the documentation, `minimize` is preferred.
- `scipy.optimize` has an extensive set of benchmarks for accuracy and speed of the global optimizers. That has allowed adding new optimizers (`shgo` and `dual_annealing`) with significantly better performance than the existing ones. The `optimize` benchmark system itself is slow and hard to use however; we need to make it faster and make it easier to compare performance of optimizers via plotting performance profiles.
signal

*Convolution and correlation:* (Relevant functions are convolve, correlate, fftconvolve, convolve2d, correlate2d, and sep-fir2d.) Eliminate the overlap with *ndimage* (and elsewhere). From *numpy, scipy.signal* and *scipy.ndimage* (and anywhere else we find them), pick the “best of class” for 1-D, 2-D and n-d convolution and correlation, put the implementation somewhere, and use that consistently throughout SciPy.

*B-splines:* (Relevant functions are bspline, cubic, quadratic, gauss_spline, cspline1d, qspline1d, cspline2d, qspline2d, cspline1d_eval, and spline_filter.) Move the good stuff to *interpolate* (with appropriate API changes to match how things are done in *interpolate*), and eliminate any duplication.

*Filter design:* merge *firwin* and *firwin2* so *firwin2* can be removed.

*Continuous-Time Linear Systems:* remove *lsim2, impulse2, step2.* The *lsim, impulse* and *step* functions now “just work” for any input system. Further improve the performance of *ltisys* (fewer internal transformations between different representations). Fill gaps in *lti* system conversion functions.

*Second Order Sections:* Make SOS filtering equally capable as existing methods. This includes *ltisys* objects, an *lfiltic* equivalent, and numerically stable conversions to and from other filter representations. SOS filters could be considered as the default filtering method for *ltisys* objects, for their numerical stability.

*Wavelets:* what’s there now doesn’t make much sense. Continuous wavelets only at the moment - decide whether to completely rewrite or remove them. Discrete wavelet transforms are out of scope (PyWavelets does a good job for those).

sparse

The sparse matrix formats are mostly feature-complete, however the main issue is that they act like *numpy.matrix* (which will be deprecated in NumPy at some point). What we want is sparse arrays, that act like *numpy.ndarray*. This is being worked on in *https://github.com/pydata/sparse*, which is quite far along. The tentative plan is:

- Start depending on *pydata/sparse* once it’s feature-complete enough (it still needs a CSC/CSR equivalent) and okay performance-wise.

- Add support for *pydata/sparse* to *scipy.sparse.linalg* (and perhaps to *scipy.sparse.csgraph* after that).

- Indicate in the documentation that for new code users should prefer *pydata/sparse* over sparse matrices.

- When NumPy deprecates *numpy.matrix*, vendor that or maintain it as a stand-alone package.

Regarding the different sparse matrix formats: there are a lot of them. These should be kept, but improvements/optimizations should go into CSR/CSC, which are the preferred formats. LIL may be the exception, it’s inherently inefficient. It could be dropped if DOK is extended to support all the operations LIL currently provides.

sparse.csgraph

This module is in good shape.
**sparse.linalg**

Arpack is in good shape.

isolve:

- callback keyword is inconsistent
- tol keyword is broken, should be relative tol
- Fortran code not re-entrant (but we don’t solve, maybe re-use from PyKrilov)

dsolve:

- add sparse Cholesky or incomplete Cholesky
- add sparse QR
- improve interface to SuiteSparse UMFPACK
- add interfaces to SuiteSparse CHOLMOD and SPQR

Ideas for new features:

- Wrappers for PROPACK for faster sparse SVD computation.

**spatial**

QHull wrappers are in good shape, as is cKDTree.

Needed:

- KDTree will be removed, and cKDTree will be renamed to KDTree in a backwards-compatible way.
- distance_wrap.c needs to be cleaned up (maybe rewrite in Cython).

**special**

Though there are still a lot of functions that need improvements in precision, probably the only show-stoppers are hypergeometric functions, parabolic cylinder functions, and spheroidal wave functions. Three possible ways to handle this:

1. Get good double-precision implementations. This is doable for parabolic cylinder functions (in progress). I think it’s possible for hypergeometric functions, though maybe not in time. For spheroidal wavefunctions this is not possible with current theory.

2. Port Boost’s arbitrary precision library and use it under the hood to get double precision accuracy. This might be necessary as a stopgap measure for hypergeometric functions; the idea of using arbitrary precision has been suggested before by @nmayorov and in gh-5349. Likely necessary for spheroidal wave functions, this could be reused: https://github.com/radelman/scattering.

3. Add clear warnings to the documentation about the limits of the existing implementations.
stats

The scipy.stats subpackage aims to provide fundamental statistical methods as might be covered in standard statistics texts such as Johnson’s “Miller & Freund’s Probability and Statistics for Engineers”, Sokal & Rohlf’s “Biometry”, or Zar’s “Biostatistical Analysis”. It does not seek to duplicate the advanced functionality of downstream packages (e.g. StatsModels, LinearModels, PyMC3); instead, it can provide a solid foundation on which they can build. (Note that these are rough guidelines, not strict rules. “Advanced” is an ill-defined and subjective term, and “advanced” methods may also be included in SciPy, especially if no other widely used and well-supported package covers the topic. Also note that some duplication with downstream projects is inevitable and not necessarily a bad thing.)

The following improvements will help SciPy better serve this role.

• Add fundamental and widely used hypothesis tests:
  – Tukey-Kramer test
  – Dunnett’s test
  – the various types of analysis of variance (ANOVA):
    ∗ two-way ANOVA (single replicate, uniform number of replicates, variable number of replicates)
    ∗ multiway ANOVA (i.e. generalize two-way ANOVA)
    ∗ nested ANOVA
    ∗ analysis of covariance (ANCOVA)
• Add additional tools for meta-analysis; currently we have just combine_pvalues.
• Enhance the fit method of the continuous probability distributions:
  – Expand the options for fitting to include:
    ∗ maximal product spacings
    ∗ method of L-moments / probability weighted moments
  – Include measures of goodness-of-fit in the results
  – Handle censored data (e.g. merge gh-13699)
• Implement additional widely used continuous and discrete probability distributions:
  – multivariate t distribution
  – mixture distributions
• Improve the core calculations provided by SciPy’s probability distributions so they can robustly handle wide ranges of parameter values. Specifically, replace many of the PDF and CDF methods from the Fortran library CDFLIB used in scipy.special with Boost implementations as in gh-13328.

In addition, we should:

• Continue work on making the function signatures of stats and stats.mstats more consistent, and add tests to ensure that that remains the case.
• Improve statistical tests: consistently provide options for one- and two-sided alternative hypotheses where applicable, return confidence intervals for the test statistic, and implement exact p-value calculations - considering the possibility of ties - where computationally feasible.
4.7 Toolchain Roadmap

The use of the SciPy library requires (or optionally depends upon) several other libraries in order to operate, the main dependencies being Python and NumPy. It requires a larger collection of libraries and tools in order to build the library or to build the documentation.

Of course, the tooling and libraries are themselves not static. This document aims to provide a guide as to how SciPy's use of these dynamic dependencies will proceed over time.

SciPy aims to be compatible with a number of releases of its dependent libraries and tools. Forcing the user base to other components for upgrade for every release would greatly diminish the value of SciPy. However, maintaining backwards compatibility with very old tooling/libraries imposes limitations on which newer functionalities and capabilities can be incorporated. SciPy takes a somewhat conservative approach, maintaining compatibility with several major releases of Python and NumPy on the major platforms. (That may in and of itself impose further restrictions. See the C Compilers section for an example.)

- First and foremost, SciPy is a Python project, hence it requires a Python environment.
- BLAS and LAPACK numerical libraries need to be installed.
- Compilers for C, C++, Fortran code are needed, as well as for Cython & Pythran (the latter is opt-out currently)
- The Python environment needs the NumPy package to be installed.
- Testing requires the pytest Python package.
- Building the documentation requires the matplotlib, Sphinx packages along with PyData theme, as well as a LaTeX installation.

The tooling used to build CPython has some implications for the tooling used in building SciPy. It also has implications for the examples used in the documentation (e.g., docstrings for functions), as these examples can only use functionality present in all supported configurations.

4.7.1 Building SciPy

Python Versions

SciPy is compatible with several versions of Python. When dropping support for older Python versions, SciPy takes guidance from NEP 29\(^\text{10}\). Python 2.7 support was dropped for SciPy releases numbered 1.3 and above but is still available in release 1.2.x, which is a long-term support release\(^\text{1,2}\).

<table>
<thead>
<tr>
<th>Date</th>
<th>Pythons supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>2018</td>
<td>Py2.7, Py3.4+ (SciPy 1.2.x is the last release to support Python 2.7)</td>
</tr>
<tr>
<td>2019</td>
<td>Py3.5+ (but Py2.7-specific code not removed)</td>
</tr>
<tr>
<td>2020</td>
<td>Py3.6+ (removal of Py2.7-specific code permitted)</td>
</tr>
<tr>
<td>2021</td>
<td>Py3.7+</td>
</tr>
</tbody>
</table>

\(^{10}\) https://numpy.org/neps/nep-0029-deprecation_policy.html
\(^1\) https://docs.scipy.org/doc/scipy/reference/release.1.2.0.html
\(^2\) https://python3statement.org
NumPy

SciPy depends on NumPy but releases of SciPy are not tied to releases of NumPy. SciPy attempts to be compatible with at least the 4 previous releases of NumPy. In particular, SciPy cannot rely on features of just the latest NumPy, but needs to be written using what is common in all of those 4 releases.\(^3\)

The table shows the NumPy versions suitable for each major Python version (for SciPy 1.3.x unless otherwise stated).

<table>
<thead>
<tr>
<th>Python</th>
<th>Minimum NumPy version</th>
<th>Maximum NumPy version</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.7 (SciPy 1.2)</td>
<td>1.8.2</td>
<td>1.16.x</td>
</tr>
<tr>
<td>3.5 (SciPy 1.4)</td>
<td>1.13.3</td>
<td>1.18.x</td>
</tr>
<tr>
<td>3.6 (SciPy 1.5)</td>
<td>1.14.5</td>
<td>1.19.x</td>
</tr>
<tr>
<td>3.7</td>
<td>1.16.5</td>
<td>&gt;= 1.20.x</td>
</tr>
<tr>
<td>3.8</td>
<td>1.17.3</td>
<td>&gt;= 1.20.x</td>
</tr>
<tr>
<td>3.9</td>
<td>1.19.3</td>
<td>&gt;= 1.20.x</td>
</tr>
</tbody>
</table>

Compilers

Building SciPy requires compilers for C, C++, Fortran, as well as the python transpilers Cython and Pythran (the latter is an opt-out dependency as of version 1.7.0).

To maintain compatibility with a large number of platforms & setups, especially where using the official wheels (or other distribution channels like Anaconda or conda-forge) is not possible, SciPy keeps compatibility with old compilers.

Official Builds

Currently, SciPy wheels are being built as follows:

<table>
<thead>
<tr>
<th>Platform</th>
<th>Azure Base Image(^14)</th>
<th>Compilers</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux (nightly)</td>
<td>ubuntu-18.04</td>
<td>GCC 4.8</td>
<td>See azure-pipelines.yml</td>
</tr>
<tr>
<td>Linux (release)</td>
<td>ubuntu-18.04</td>
<td>GCC 7.5</td>
<td></td>
</tr>
<tr>
<td>OSX</td>
<td>macOS-10.14</td>
<td>LLVM 11.0</td>
<td>Built in separate repo(^15)</td>
</tr>
<tr>
<td>Windows</td>
<td>VS2017-Win2016</td>
<td>Visual Studio 2017 (15.9)</td>
<td>See azure-pipelines.yml</td>
</tr>
</tbody>
</table>

Note that the OSX wheels additionally vendor gfortran 4.8, see\(^15\).

C Compilers

SciPy is compatible with most modern C compilers (in particular clang). In addition to concerns about compatibility with non-standard platforms, there was a long-standing restriction that Windows builds of SciPy had to use the same version of the Microsoft Visual C++ compiler as were used for CPython itself, for reasons of ABI-compatibility\(^6\),\(^7\),\(^8\),\(^9\).

With the introduction of the “Universal C Runtime”\(^16\) since the release of Visual Studio 2015, this restriction has been lifted. For more context, see the explanations by Steve Dower (member of the CPython-on-Windows core developers) on this topic\(^17\).

---

3 https://docs.scipy.org/doc/numpy/release.html
14 https://docs.microsoft.com/en-us/azure/devops/pipelines/agents/hosted
15 https://github.com/MacPython/scipy-wheels
7 https://pythondev.readthedocs.io/windows.html#python-and-visual-studio-version-matrix
9 https://wiki.python.org/moin/WindowsCCompilers
17 https://discuss.python.org/t/toolchain-upgrade-on-windows/6377/4
The use of MS Visual Studio 9.0 (which doesn’t have support C99) to build Python 2.7 has meant that C code in SciPy has had to conform to the earlier C90 standard for the language and standard library. With the dropping of Python 2.7 for SciPy 1.3.x, the C90 restriction is no longer imposed by compilers. For GCC version < 5, an explicit `-std=c99` may have to be added by the user if C99 features are used in SciPy code.

In terms of C language standards, it’s relevant to note that C11 has optional features\(^\text{12}\) (e.g. atomics, threading), some of which (VLAs & complex types) were mandatory in the C99 standard. C17 (occasionally called C18) can be considered a bug fix for C11, so generally, C11 may be skipped entirely.

SciPy has been restricted in the use of more advanced language features by the available compiler support, and Microsoft in particular has taken very long to achieve conformance to C99/C11/C17, however starting from MS Visual Studio 16.8, C11/C17 is supported\(^\text{11}\) (though without the C11 optional features).

Therefore, using C features beyond C90 is contingent upon updating the windows toolchain for SciPy, as well as checking compiler support for the desired feature across all minimally supported compiler versions. In short:

<table>
<thead>
<tr>
<th>CPython</th>
<th>MS Visual C++</th>
<th>C Standard</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.7, 3.0, 3.1, 3.2</td>
<td>9.0</td>
<td>C90</td>
</tr>
<tr>
<td>3.3, 3.4</td>
<td>10.0</td>
<td>C90 &amp; some of C99</td>
</tr>
<tr>
<td>3.5, 3.6</td>
<td>14.0</td>
<td>C90 &amp; most of C99</td>
</tr>
<tr>
<td>3.7, 3.8, 3.9</td>
<td>15.7</td>
<td>Dependent on MSVC version used to build SciPy</td>
</tr>
</tbody>
</table>

### C and C++ Language Standards

C and C++ language standards for SciPy are generally guidelines rather than official decisions. This is particularly true of attempting to predict adoption timelines for newer standards.

<table>
<thead>
<tr>
<th>Date</th>
<th>C/C++ Standard</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;= 2018</td>
<td>C90</td>
</tr>
<tr>
<td>2019</td>
<td>C90 for old code, may consider C99 for new</td>
</tr>
<tr>
<td>2020</td>
<td>C99</td>
</tr>
<tr>
<td>2020</td>
<td>C++11</td>
</tr>
<tr>
<td>2021</td>
<td>C++14</td>
</tr>
<tr>
<td>?</td>
<td>C11, C17, C++17, C++20</td>
</tr>
</tbody>
</table>

For C, C11/C17 support will be available as soon as the vmImage for building SciPy is upgraded to windows-2019 (which is compatible with currently supported CPython versions and “just” needs to be executed). This is because GCC & LLVM support all relevant C11 features with the oldest currently used versions, and C17 is just a bugfix for C11, as mentioned above.

On the C++ side, since dropping support for Python 2.7, C++11 can be used universally. For C++14, Windows is not a restriction anymore since Visual Studio 15.9 (<= _MSC_VER 19.16, see\(^\text{3}\)), has full support (same for C++17), see\(^\text{4}\). However, using C++14 still requires bumping the GCC minimal requirement to 5.6 and C++17 will require GCC >= 7\(^\text{5}\). Compiler support for C++20 is still under heavy development.

#### Note:
Developer Note: Some C99 features would be useful for scientific programming, in particular better support of IEEE 754\(^\text{5}\). SciPy has a small include file `scipy/_lib/_c99compat.h` which provides access to a few functions. Use in conjunction with `<numpy/npy_math.h>`.

\(^\text{12}\) https://en.wikipedia.org/wiki/C11_%28C_standard_revision%29#Optional_features
\(^\text{3}\) https://en.cppreference.com/w/cpp/compiler_support
\(^\text{4}\) https://en.cppreference.com/w/cpp/compiler_support
### Fortran Compilers

Generally, any well-maintained compiler is likely suitable and can be used to build SciPy.

<table>
<thead>
<tr>
<th>Tool</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>gfortran</td>
<td>&gt;= 4.8.0</td>
</tr>
<tr>
<td>ifort</td>
<td>A recent version</td>
</tr>
<tr>
<td>flang</td>
<td>A recent version</td>
</tr>
</tbody>
</table>

### Cython Compiler

SciPy always requires a recent Cython compiler.

<table>
<thead>
<tr>
<th>Tool</th>
<th>Tool Version</th>
<th>SciPy version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cython</td>
<td>&gt;= 0.29.13</td>
<td>1.4.1</td>
</tr>
<tr>
<td>Cython</td>
<td>&gt;= 0.29.18</td>
<td>1.5.0</td>
</tr>
</tbody>
</table>

### OpenMP support

For various reasons\(^{13}\), SciPy cannot be distributed with built-in OpenMP support. When using the optional Pythran support, OpenMP-enabled parallel code can be generated when building from source.

### Other Libraries

Any library conforming to the BLAS/LAPACK interface may be used. OpenBLAS, ATLAS, MKL, BLIS, and reference Netlib libraries are known to work.

<table>
<thead>
<tr>
<th>Library</th>
<th>Minimum version</th>
</tr>
</thead>
<tbody>
<tr>
<td>LAPACK</td>
<td>3.4.1</td>
</tr>
<tr>
<td>BLAS</td>
<td>A recent version of OpenBLAS, MKL or ATLAS. The Accelerate BLAS is no longer supported.</td>
</tr>
</tbody>
</table>

There are some additional optional dependencies.

<table>
<thead>
<tr>
<th>Library</th>
<th>Version</th>
<th>URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpmath</td>
<td>Recent</td>
<td><a href="http://mpmath.org/">http://mpmath.org/</a></td>
</tr>
<tr>
<td>scikit-umfpack</td>
<td>Recent</td>
<td><a href="https://pypi.org/project/scikit-umfpack/">https://pypi.org/project/scikit-umfpack/</a></td>
</tr>
</tbody>
</table>

Moreover, Scipy supports interaction with other libraries. The test suite has additional compatibility tests that are run when these are installed:

\(^{13}\) https://github.com/scipy/scipy/issues/10239
### 4.7.2 Testing and Benchmarking

Testing and benchmarking require recent versions of:

<table>
<thead>
<tr>
<th>Tool</th>
<th>Version</th>
<th>URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>pytest</td>
<td>Recent</td>
<td><a href="https://docs.pytest.org/en/latest/">https://docs.pytest.org/en/latest/</a></td>
</tr>
<tr>
<td>asv (airspeed velocity)</td>
<td>Recent</td>
<td><a href="https://asv.readthedocs.io/">https://asv.readthedocs.io/</a></td>
</tr>
</tbody>
</table>

### 4.7.3 Building the Documentation

<table>
<thead>
<tr>
<th>Tool</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sphinx</td>
<td>Whatever recent versions work. &gt;= 2.0.</td>
</tr>
<tr>
<td>PyData Sphinx theme</td>
<td>Whatever recent versions work. &gt;= 0.6.1.</td>
</tr>
<tr>
<td>Sphinx-Panels</td>
<td>Whatever recent versions work. &gt;= 0.5.2.</td>
</tr>
<tr>
<td>numpydoc</td>
<td>Whatever recent versions work. &gt;= 0.8.0.</td>
</tr>
<tr>
<td>matplotlib</td>
<td>Generally suggest &gt;= 2.0.</td>
</tr>
<tr>
<td>LaTeX</td>
<td>A recent distribution, such as TeX Live 2016.</td>
</tr>
</tbody>
</table>

[The \texttt{numpydoc} package is also used, but that is currently packaged in \texttt{doc/sphinxext}.]

**Note:** Developer Note: The versions of \texttt{numpy} and \texttt{matplotlib} required have implications for the examples in Python docstrings. Examples must be able to be executed both in the environment used to build the documentation, as well as with any supported versions of \texttt{numpy/matplotlib} that a user may use with this release of SciPy.

### 4.7.4 Packaging

A Recent version of:

<table>
<thead>
<tr>
<th>Tool</th>
<th>Version</th>
<th>URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>setuptools</td>
<td>Recent</td>
<td><a href="https://pypi.org/project/setuptools/">https://pypi.org/project/setuptools/</a></td>
</tr>
<tr>
<td>wheel</td>
<td>Recent</td>
<td><a href="https://pythonwheels.com">https://pythonwheels.com</a></td>
</tr>
<tr>
<td>multibuild</td>
<td>Recent</td>
<td><a href="https://github.com/matthew-brett/multibuild">https://github.com/matthew-brett/multibuild</a></td>
</tr>
</tbody>
</table>

*Making a SciPy release* and *Distributing* contain information on making and distributing a SciPy release.

4.8 SciPy Core Developer Guide

4.8.1 Decision making process

SciPy has a formal governance model, documented in SciPy Project Governance. The section below documents in an informal way what happens in practice for decision making about code and commit rights. The formal governance model is leading, the below is only provided for context.

Code

Any significant decisions on adding (or not adding) new features, breaking backwards compatibility or making other significant changes to the codebase should be made on the scipy-dev mailing list after a discussion (preferably with full consensus).

Any non-trivial change (where trivial means a typo, or a one-liner maintenance commit) has to go in through a pull request (PR). It has to be reviewed by another developer. In case review doesn't happen quickly enough and it is important that the PR is merged quickly, the submitter of the PR should send a message to mailing list saying he/she intends to merge that PR without review at time X for reason Y unless someone reviews it before then.

Changes and new additions should be tested. Untested code is broken code.

Commit rights

Who gets commit rights is decided by the SciPy Steering Council; changes in commit rights will then be announced on the scipy-dev mailing list.

4.9 Deciding on new features

The general decision rule to accept a proposed new feature has so far been conditional on:

1. The method is applicable in many fields and “generally agreed” to be useful,
2. It fits the topic of the submodule, and does not require extensive support frameworks to operate,
3. The implementation looks sound and unlikely to need much tweaking in the future (e.g., limited expected maintenance burden),
4. Someone wants to contribute it, and
5. Someone wants to review it.

The last criterion is often a sticking point for proposed features. Code cannot be merged until it has been thoroughly reviewed, and there is always a backlog of maintenance tasks that compete for reviewers’ time. Ideally, contributors should line up a reviewer with suitable domain expertise before beginning work.

Although it's difficult to give hard rules on what “generally useful and generally agreed to work” means, it may help to weigh the following against each other:

- Is the method used/useful in different domains in practice? How much domain-specific background knowledge is needed to use it properly?
- Consider the code already in the module. Is what you are adding an omission? Does it solve a problem that you’d expect the module be able to solve? Does it supplement an existing feature in a significant way?
• Consider the equivalence class of similar methods / features usually expected. Among them, what would in principle be the minimal set so that there’s not a glaring omission in the offered features remaining? How much stuff would that be? Does including a representative one of them cover most use cases? Would it in principle sound reasonable to include everything from the minimal set in the module?

• Is what you are adding something that is well understood in the literature? If not, how sure are you that it will turn out well? Does the method perform well compared to other similar ones?

• Note that the twice-a-year release cycle and backward-compatibility policy makes correcting things later on more difficult.

The scopes of the submodules also vary, so it’s probably best to consider each as if it’s a separate project - “numerical evaluation of special functions” is relatively well-defined, but “commonly needed optimization algorithms” less so.

### 4.9.1 Development on GitHub

SciPy development largely takes place on GitHub; this section describes the expected way of working for issues, pull requests and managing the main scipy repository.

#### Labels and Milestones

Each issue and pull request normally gets at least two labels: one for the topic or component (scipy.stats, Documentation, etc.), and one for the nature of the issue or pull request (enhancement, maintenance, defect, etc.). Other labels that may be added depending on the situation:

- **easy-fix**: for issues suitable to be tackled by new contributors.
- **needs-work**: for pull requests that have review comments that haven’t been addressed.
- **needs-decision**: for issues or pull requests that need a decision.
- **needs-champion**: for pull requests that were not finished by the original author, but are worth resurrecting.
- **backport-candidate**: bug fixes that should be considered for backporting by the release manager.

A milestone is created for each version number for which a release is planned. Issues that need to be addressed and pull requests that need to be merged for a particular release should be set to the corresponding milestone. After a pull request is merged, its milestone (and that of the issue it closes) should be set to the next upcoming release - this makes it easy to get an overview of changes and to add a complete list of those to the release notes.

#### Pull request review workflow

When reviewing pull requests, please make use of pull request workflow features, see pull-request-workflow-features.

#### Dealing with pull requests

- When merging contributions, a committer is responsible for ensuring that those meet the requirements outlined in Contributing to SciPy. Also check that new features and backwards compatibility breaks were discussed on the scipy-dev mailing list.
- New code goes in via a pull request (PR).
- Merge new code with the green button. In case of merge conflicts, ask the PR submitter to rebase (this may require providing some git instructions).
- Backports and trivial additions to finish a PR (really trivial, like a typo or PEP8 fix) can be pushed directly.
• For PRs that add new features or are in some way complex, wait at least a day or two before merging it. That way, others get a chance to comment before the code goes in.

• Squashing commits or cleaning up commit messages of a PR that you consider too messy is OK. Make sure though to retain the original author name when doing this.

• Make sure that the labels and milestone on a merged PR are set correctly.

• When you want to reject a PR: if it’s very obvious you can just close it and explain why, if not obvious then it’s a good idea to first explain why you think the PR is not suitable for inclusion in SciPy and then let a second committer comment or close.

**Backporting**

All pull requests (whether they contain enhancements, bug fixes or something else), should be made against master. Only bug fixes are candidates for backporting to a maintenance branch. The backport strategy for SciPy is to (a) only backport fixes that are important, and (b) to only backport when it’s reasonably sure that a new bugfix release on the relevant maintenance branch will be made. Typically, the developer who merges an important bugfix adds the `backport-candidate` label and pings the release manager, who decides on whether and when the backport is done. After the backport is completed, the `backport-candidate` label has to be removed again.

A good strategy for a backport pull request is to combine several master branch pull requests, to reduce the burden on continuous integration tests and to reduce the merge commit cluttering of maintenance branch history. It is generally best to have a single commit for each of the master branch pull requests represented in the backport pull request. This way, history is clear and can be reverted in a straightforward manner if needed.

**Release notes**

When a PR gets merged, consider if the changes need to be mentioned in the release notes. What needs mentioning: new features, backwards incompatible changes, deprecations, and “other changes” (anything else noteworthy enough, see older release notes for the kinds of things worth mentioning).

Release note entries are maintained on the wiki, (e.g. https://github.com/scipy/scipy/wiki/Release-note-entries-for-SciPy-1.2.0). The release manager will gather content from there and integrate it into the html docs. We use this mechanism to avoid merge conflicts that would happen if every PR touched the same file under `doc/release/` directly.

Changes can be monitored (Atom feed) and pulled (the wiki is a git repo: https://github.com/scipy/scipy/wiki.git).

**Other**

**PR status page:** When new commits get added to a pull request, GitHub doesn’t send out any notifications. The `needs-work` label may not be justified anymore though. This page gives an overview of PRs that were updated, need review, need a decision, etc.

**Cross-referencing:** Cross-referencing issues and pull requests on GitHub is often useful. GitHub allows doing that by using `gh-xxxx` or `#xxxx` with `xxxx` the issue/PR number. The `gh-xxxx` format is strongly preferred, because it’s clear that that is a GitHub link. Older issues contain `#xxxx` which is about Trac (what we used pre-GitHub) tickets.

**PR naming convention:** Pull requests, issues and commit messages usually start with a three-letter abbreviation like `ENH:` or `BUG:`. This is useful to quickly see what the nature of the commit/PR/issue is. For the full list of abbreviations, see writing the commit message.
4.9.2 Licensing

SciPy is distributed under the modified (3-clause) BSD license. All code, documentation and other files added to SciPy by contributors is licensed under this license, unless another license is explicitly specified in the source code. Contributors keep the copyright for code they wrote and submit for inclusion to SciPy.

Other licenses that are compatible with the modified BSD license that SciPy uses are 2-clause BSD, MIT and PSF. Incompatible licenses are GPL, Apache and custom licenses that require attribution/citation or prohibit use for commercial purposes.

PRs are often submitted with content copied or derived from unlicensed code or code from a default license that is not compatible with SciPy’s license. For instance, code published on StackOverflow is covered by a CC-BY-SA license, which is not compatible due to the share-alike clause. These contributions cannot be accepted for inclusion in SciPy unless the original code author is willing to (re)license his/her code under the modified BSD (or compatible) license. If the original author agrees, add a comment saying so to the source files and forward the relevant communication to the scipy-dev mailing list.

Another common occurrence is for code to be translated or derived from code in R, Octave (both GPL-licensed) or a commercial application. Such code also cannot be included in SciPy. Simply implementing functionality with the same API as found in R/Octave/… is fine though, as long as the author doesn’t look at the original incompatibly-licensed source code.

4.9.3 Version numbering

SciPy version numbering complies to PEP 440. Released final versions, which are the only versions appearing on PyPI, are numbered MAJOR.MINOR.MICRO where:

- **MAJOR** is an integer indicating the major version. It changes very rarely; a change in **MAJOR** indicates large (possibly backwards-incompatible) changes.
- **MINOR** is an integer indicating the minor version. Minor versions are typically released twice a year and can contain new features, deprecations and bug-fixes.
- **MICRO** is an integer indicating a bug-fix version. Bug-fix versions are released when needed, typically one or two per minor version. They cannot contain new features or deprecations.

Released alpha, beta and rc (release candidate) versions are numbered like final versions but with postfixes a#, b# and rc# respectively, with # an integer. Development versions are postfixed with .dev0+<git-commit-hash>.

Examples of valid SciPy version strings are:

```
0.16.0
0.15.1
0.14.0a1
0.14.0b2
0.14.0rc1
0.17.0.dev0+ac53f09
```

An installed SciPy version contains these version identifiers:

```
scipy.__version__ # complete version string, including git commit-
# hash for dev versions
scipy.version.short_version # string, only major.minor.micro
scipy.version.version # string, same as scipy.__version__
scipy.version.full_version # string, same as scipy.__version__
```

(continues on next page)
4.9.4 Deprecations

There are various reasons for wanting to remove existing functionality: it's buggy, the API isn't understandable, it's superseded by functionality with better performance, it needs to be moved to another SciPy submodule, etc.

In general it's not a good idea to remove something without warning users about that removal first. Therefore this is what should be done before removing something from the public API:

1. Propose to deprecate the functionality on the scipy-dev mailing list and get agreement that that's OK.
2. Add a `DeprecationWarning` for it, which states that the functionality was deprecated, and in which release. For Cython APIs, see Deprecating public Cython APIs for the practical steps.
3. Mention the deprecation in the release notes for that release.
4. Wait till at least 6 months after the release date of the release that introduced the `DeprecationWarning` before removing the functionality.
5. Mention the removal of the functionality in the release notes.

The 6 months waiting period in practice usually means waiting two releases. When introducing the warning, also ensure that those warnings are filtered out when running the test suite so they don't pollute the output.

It's possible that there is reason to want to ignore this deprecation policy for a particular deprecation; this can always be discussed on the scipy-dev mailing list.

4.9.5 Distributing

Distributing Python packages is nontrivial - especially for a package with complex build requirements like SciPy - and subject to change. For an up-to-date overview of recommended tools and techniques, see the Python Packaging User Guide. This document discusses some of the main issues and considerations for SciPy.

Dependencies

Dependencies are things that a user has to install in order to use (or build/test) a package. They usually cause trouble, especially if they're not optional. SciPy tries to keep its dependencies to a minimum; currently they are:

*Unconditional run-time dependencies:*
  - Numpy

*Conditional run-time dependencies:*
  - pytest (to run the test suite)
  - asv (to run the benchmarks)
  - matplotlib (for some functions that can produce plots)
  - Pillow (for image loading/saving)
  - scikits.umfpack (optionally used in `sparse.linalg`)

4.9. Deciding on new features
• mpmath (for more extended tests in special)
• pydata/sparse (compatibility support in scipy.sparse)

Unconditional build-time dependencies:

• Numpy
• A BLAS and LAPACK implementation (reference BLAS/LAPACK, ATLAS, OpenBLAS, MKL are all known to work)
• Cython
• setuptools
• pybind11

Conditional build-time dependencies:

• wheel (python setup.py bdist_wheel)
• Sphinx (docs)
• PyData Sphinx theme (docs)
• Sphinx-Panels (docs)
• matplotlib (docs)
• LaTeX (pdf docs)
• Pillow (docs)

Furthermore of course one needs C, C++ and Fortran compilers to build SciPy, but those we don’t consider to be dependencies and are therefore not discussed here. For details, see https://scipy.github.io/devdocs/building/.

When a package provides useful functionality and it’s proposed as a new dependency, consider also if it makes sense to vendor (i.e. ship a copy of it with scipy) the package instead. For example, decorator is vendored in scipy._lib.

The only dependency that is reported to pip is Numpy, see install_requires in SciPy’s main setup.py. The other dependencies aren’t needed for SciPy to function correctly.

Issues with dependency handling

There are some issues with how Python packaging tools handle dependencies reported by projects. Because SciPy gets regular bug reports about this, we go in a bit of detail here.

SciPy only reports its dependency on NumPy via install_requires if NumPy isn’t installed at all on a system, or when building wheels with bdist_wheel. SciPy no longer uses setup_requires (which in the past invoked easy_install); build dependencies are now handled only via pyproject.toml. pyproject.toml relies on PEP 517: pip has --no-use-egg2 and --no-build-isolation flags that may ignore pyproject.toml or treat it differently - if users use those flags, they are responsible for installing the correct build dependencies themselves.

Version ranges for NumPy and other dependencies

For dependencies it’s important to set lower and upper bounds on their versions. For build-time dependencies, they are specified in pyproject.toml and the versions will only apply to the SciPy build itself. It's fine to specify either a range or a specific version for a dependency like wheel or setuptools. For NumPy we have to worry about ABI compatibility too, hence we specify the version with == to the lowest supported version (because NumPy's ABI is backward but not forward compatible).

For run-time dependencies (currently only numpy), we specify the range of versions in pyproject.toml and in install_requires in setup.py. Getting the upper bound right is slightly tricky. If we don't set any bound, a too-new version will be pulled in a few years down the line, and NumPy may have deprecated and removed some API that SciPy depended on by then. On the other hand if we set the upper bound to the newest already-released version,
then as soon as a new NumPy version is released there will be no matching SciPy version that works with it. Given that NumPy and SciPy both release in a 6-monthly cadence and that features that get deprecated in NumPy should stay around for another two releases, we specify the upper bound as <1.xx+3.0 (where xx is the minor version of the latest already-released NumPy.

Supported Python and NumPy versions

The Python versions that SciPy supports are listed in the list of PyPI classifiers in setup.py, and mentioned in the release notes for each release. All newly released Python versions will be supported as soon as possible. For the general policy on dropping support for a Python or NumPy version, see NEP 29. The final decision on dropping support is always taken on the scipy-dev mailing list.

The lowest supported NumPy version for a SciPy version is mentioned in the release notes and is encoded in pyproject.toml, scipy/__init__.py and the install_requires field of setup.py. Typically the latest SciPy release supports ~5-7 minor versions of NumPy: up to 2.5 years' old NumPy versions, (given that the frequency of NumPy releases is about 2x/year at the time of writing) plus two versions into the future.

Supported versions of optional dependencies and compilers is documented in Toolchain Roadmap. Note that not all versions of optional dependencies that are supported are tested well or at all by SciPy’s Continuous Integration setup. Issues regarding this are dealt with as they come up in the issue tracker or mailing list.

Building binary installers

Note: This section is only about building SciPy binary installers to distribute. For info on building SciPy on the same machine as where it will be used, see this scipy.org page.

There are a number of things to take into consideration when building binaries and distributing them on PyPI or elsewhere.

General

• A binary is specific for a single Python version (because different Python versions aren’t ABI-compatible, at least up to Python 3.4).

• Build against the lowest NumPy version that you need to support, then it will work for all NumPy versions with the same major version number (NumPy does maintain backwards ABI compatibility).

Windows

• The currently most easily available toolchain for building Python.org compatible binaries for SciPy is installing MSVC (see https://wiki.python.org/moin/WindowsCompilers) and mingw64-gfortran. Support for this configuration requires numpy.distutils from NumPy >= 1.14.dev and a gcc/gfortran-compiled static openblas.a. This configuration is currently used in the Appveyor configuration for https://github.com/MacPython/scipy-wheels

• For 64-bit Windows installers built with a free toolchain, use the method documented at https://github.com/numpy/numpy/wiki/Mingw-static-toolchain. That method will likely be used for SciPy itself once it’s clear that the maintenance of that toolchain is sustainable long-term. See the MingwPy project and this thread for details.

• The other way to produce 64-bit Windows installers is with icc,ifort plus MKL (or MSVC instead of icc). For Intel toolchain instructions see this article and for (partial) MSVC instructions see this wiki page.

• Older SciPy releases contained a .exe “superpack” installer. Those contain 3 complete builds (no SSE, SSE2, SSE3), and were built with https://github.com/numpy/numpy-vendor. That build setup is known to not work well anymore and is no longer supported. It used g77 instead of gfortran, due to complex DLL distribution issues (see gh-2829). Because the toolchain is no longer supported, g77 support isn’t needed anymore and SciPy can now include Fortran 90/95 code.

4.9. Deciding on new features 2849
OS X

- To produce OS X wheels that work with various Python versions (from python.org, Homebrew, MacPython), use the build method provided by https://github.com/MacPython/scipy-wheels.

- DMG installers for the Python from python.org on OS X can still be produced by tools/scipy-macosx-installer/. SciPy doesn’t distribute those installers anymore though, now that there are binary wheels on PyPi.

Linux

- PyPi-compatible Linux wheels can be produced via the manylinux project. The corresponding build setup for TravisCI for SciPy is set up in https://github.com/MacPython/scipy-wheels.

Other Linux build-setups result to PyPi incompatible wheels, which would need to be distributed via custom channels, e.g. in a Wheelhouse, see at the wheel and Wheelhouse docs.

### 4.9.6 Making a SciPy release

At the highest level, this is what the release manager does to release a new SciPy version:

1. Propose a release schedule on the scipy-dev mailing list.
2. Create the maintenance branch for the release.
3. Tag the release.
4. Build all release artifacts (sources, installers, docs).
5. Upload the release artifacts.
6. Announce the release.
7. Port relevant changes to release notes and build scripts to master.

In this guide we attempt to describe in detail how to perform each of the above steps. In addition to those steps, which have to be performed by the release manager, here are descriptions of release-related activities and conventions of interest:

- **Backporting**
- **Labels and Milestones**
- **Version numbering**
- **Supported Python and NumPy versions**
- **Deprecations**

#### Proposing a release schedule

A typical release cycle looks like:

- Create the maintenance branch
- Release a beta version
- Release a “release candidate” (RC)
- If needed, release one or more new RCs
- Release the final version once there are no issues with the last release candidate
There’s usually at least one week between each of the above steps. Experience shows that a cycle takes between 4 and 8 weeks for a new minor version. Bug-fix versions don’t need a beta or RC, and can be done much quicker.

Ideally the final release is identical to the last RC, however there may be minor difference - it’s up to the release manager to judge the risk of that. Typically, if compiled code or complex pure Python code changes then a new RC is needed, while a simple bug-fix that’s backported from master doesn’t require a new RC.

To propose a schedule, send a list with estimated dates for branching and beta/rc/final releases to scipy-dev. In the same email, ask everyone to check if there are important issues/PRs that need to be included and aren’t tagged with the Milestone for the release or the “backport-candidate” label.

Creating the maintenance branch

Before branching, ensure that the release notes are updated as far as possible. Include the output of tools/gh_lists.py and tools/authors.py in the release notes.

Maintenance branches are named maintenance/<major>.<minor>.x (e.g. 0.19.x). To create one, simply push a branch with the correct name to the scipy repo. Immediately after, push a commit where you increment the version number on the master branch and add release notes for that new version. Send an email to scipy-dev to let people know that you’ve done this.

Updating upper bounds of dependencies

In master we do not set upper bounds, because we want to test new releases or development versions of dependencies there. In a maintenance branch however, the goal is to be able to create releases that stay working for years. Hence correct upper bounds must be set. The following places must be updated after creating a maintenance branch:

- **pyproject.toml**: all build-time dependencies, as well as supported Python and NumPy versions
- **setup.py**: supported Python and NumPy versions
- **scipy/__init__.py**: for NumPy version check

Each file has comments describing how to set the correct upper bounds.

Tagging a release

First ensure that you have set up GPG correctly. See https://github.com/scipy/scipy/issues/4919 for a discussion of signing release tags, and https://keyring.debian.org/creating-key.html for instructions on creating a GPG key if you do not have one. Note that on some platforms it may be more suitable to use gpg2 instead of gpg so that passwords may be stored by gpg-agent as discussed in https://github.com/scipy/scipy/issues/10189. When preparing a release remotely, it may be necessary to set pinentry-mode loopback in ~/.gnupg/gpg-agent.conf because use of gpg2 will otherwise proceed via an inaccessible graphical password prompt.

To make your key more readily identifiable as you, consider sending your key to public keyservers, with a command such as:

```
gpg --send-keys <yourkeyid>
```

Check that all relevant commits are in the branch. In particular, check issues and PRs under the Milestone for the release (https://github.com/scipy/scipy/milestones), PRs labeled “backport-candidate”, and that the release notes are up-to-date and included in the html docs.

Then edit setup.py to get the correct version number (set ISRELEASED = True) and commit it with a message like REL: set version to <version-number>. Don’t push this commit to the SciPy repo yet.

4.9. Deciding on new features
Finally tag the release locally with `git tag -s <v1.x.y>` (the `-s` ensures the tag is signed). If `gpg2` is preferred, then `git config --global gpg.program gpg2` may be appropriate. Continue with building release artifacts (next section). Only push the release commit to the scipy repo once you have built the sdists and docs successfully. Then continue with building wheels. Only push the release tag to the repo once all wheels have been built successfully on TravisCI and Appveyor (if it fails, you have to move the tag otherwise - which is bad practice). Finally, after pushing the tag, also push a second commit which increments the version number and sets `ISRELEASED` to False again. This also applies with new release candidates, and for removing the `rc` affix when switching from release candidate to release proper.

### Building release artifacts

Here is a complete list of artifacts created for a release:

- source archives (.tar.gz, .zip and .tar.xz for GitHub Releases, only .tar.gz is uploaded to PyPI)
- Binary wheels for Windows, Linx and OS X
- Documentation (html, pdf)
- A README file
- A Changelog file

Source archives, Changelog and README are built by running `paver release` in the repo root, and end up in `REPO_ROOT/release/`. Do this after you’ve created the signed tag locally. `paver release` will be sensitive to the version of Cython available in your build environment, so make sure your version matches the minimum requirements for the release. If this completes without issues, push the release commit (not the tag, see section above) to the scipy repo. If `pavement.py` is causing issues, it is also possible to simply use `python setup.py sdist` and perform the release notes task from `pavement.py` by hand.

To build wheels, push a commit to a branch used for the current release at `https://github.com/MacPython/scipy-wheels`. This triggers builds for all needed Python versions on TravisCI. Update and check the `travis.yml` and `appveyor.yml` config files what commit to build, and what Python and NumPy are used for the builds (it needs to be the lowest supported NumPy version for each Python version). See the README file in the scipy-wheels repo for more details. Note that because several months may pass between SciPy releases, it is sometimes necessary to update the versions of the `gfortran-install` and `multibuild` submodules used for wheel builds. If the wheels builds reveal issues that need to be fixed with backports on the maintenance branch, you may remove the local tags (for example `git tag -d v1.2.0rc1`) and restart with tagging above on the new candidate commit.

The TravisCI and Appveyor builds run the tests from the built wheels and if they pass, upload the wheels to a container pointed to at `https://github.com/MacPython/scipy-wheels`. Once there are successful wheel builds, it is recommended to create a versioned branch in the `scipy-wheels` repo, which will for example be adjusted to point to different maintenance branch commits if there are multiple release candidates.

From there you can download them for uploading to PyPI. This can be done in an automated fashion using `tools/download-wheels.py`:

```bash
$ python tools/download-wheels.py 1.5.0rc1 -w REPO_ROOT/release/installers
```

The correct URL to use is shown in `https://github.com/MacPython/scipy-wheels` and should agree with the above one. After this, we want to regenerate the README file, in order to have the MD5 and SHA256 checksums of the just downloaded wheels in it. Run:

```bash
$ paver write_release_and_log
```
Uploading release artifacts

For a release there are currently five places on the web to upload things to:

- PyPI (tarballs, wheels)
- Github releases (tarballs, release notes, Changelog)
- scipy.org (an announcement of the release)
- docs.scipy.org (html/pdf docs)

PyPI:

Upload first the wheels and then the sdist:

```
twine upload -s REPO_ROOT/release/installers/* .whl
twine upload -s REPO_ROOT/release/installers/scipy-1.x.y.tar.gz
```

If gpg2 is preferred, then the above commands may also include `--sign-with gpg2`

Github Releases:

Use GUI on [https://github.com/scipy/scipy/releases](https://github.com/scipy/scipy/releases) to create release and upload all release artifacts. At this stage, it is appropriate to push the tag and associate the new release (candidate) with this tag in the GUI. For example, `git push upstream v1.2.0rc1`, where `upstream` represents `scipy/scipy`. It is useful to check a previous release to determine exactly which artifacts should be included in the GUI upload process. Also, note that the release notes are not automatically populated into the release description on GitHub, and some manual reformatting to markdown can be quite helpful to match the formatting of previous releases on the site. We generally do not include Issue and Pull Request lists in these GUI descriptions.

scipy.org:

Sources for the site are in [https://github.com/scipy/scipy.org](https://github.com/scipy/scipy.org). Update the News section in `www/index.rst` and then do `make upload USERNAME=yourusername`. This is only for proper releases, not release candidates.

docs.scipy.org:

First build the scipy docs, by running `make dist` in `scipy/doc/`. Verify that they look OK, then upload them to the doc server with `make upload USERNAME=rgommers RELEASE=0.19.0`. Note that SSH access to the doc server is needed; ask @pv (server admin) or @rgommers (can upload) if you don’t have that.

The sources for the website itself are maintained in [https://github.com/scipy/docs.scipy.org/](https://github.com/scipy/docs.scipy.org/). Add the new SciPy version in the table of releases in `index.rst`. Push that commit, then do `make upload USERNAME=yourusername`. This is only for proper releases, not release candidates.

Wrapping up

Send an email announcing the release to the following mailing lists:

- scipy-dev
- numpy-discussion
- python-announce (not for beta/rc releases)

For beta and rc versions, ask people in the email to test (run the scipy tests and test against their own code) and report issues on Github or scipy-dev.

After the final release is done, port relevant changes to release notes, build scripts, author name mapping in `tools/authors.py` and any other changes that were only made on the maintenance branch to master.
4.10 SciPy API Development Guide

4.10.1 A Design Specification for nan_policy

Many functions in `scipy.stats` have a parameter called `nan_policy` that determines how the function handles data that contains `nan`. In this section, we provide SciPy developer guidelines for how `nan_policy` is intended to be used, to ensure that as this parameter is added to new functions, we maintain a consistent API.

The basic API

The parameter `nan_policy` accepts three possible strings: 'omit', 'raise' and 'propagate'. The meanings are:

- `nan_policy='omit'`: Ignore occurrences of `nan` in the input. Do not generate a warning if the input contains `nan` (unless the equivalent input with the `nan` values removed would generate a warning). For example, for the simple case of a function that accepts a single array and returns a scalar (and ignoring the possible use of `axis` for the moment):

  ```python
  func([1.0, 3.0, np.nan, 5.0], nan_policy='omit')
  ```

  should behave the same as:

  ```python
  func([1.0, 3.0, 5.0])
  ```

  More generally, for functions that return a scalar, `func(a, nan_policy='omit')` should behave the same as `func(a[~np.isnan(a)])`.

  For functions that transform a vector to a new vector of the same size and for which each entry in the output array depends on more than just the corresponding value in the input array\(^1\) (e.g. `scipy.stats.zscore`, `scipy.stats.boxcox` when `lmbda` is `None`):

  ```python
  y = func(a, nan_policy='omit')
  ```

  should behave the same as:

  ```python
  nan_mask = np.isnan(a)
  y = np.empty(a.shape, dtype=np.float64)
  y[~nan_mask] = func(a[~nan_mask])
  y[nan_mask] = np.nan
  ```

  (In general, the dtype of `y` might depend on `a` and on the expected behavior of `func`). In other words, a `nan` in the input gives a corresponding `nan` in the output, but the presence of that `nan` does not affect the calculation of the non-`nan` values.

  Unit tests for this property should be used to test functions that handle `nan_policy`.

  For functions that return a scalar and that accept two or more arguments but whose values are not related (e.g. `scipy.stats.ansari`, `scipy.stats.f_oneway`), the same idea applies to each input array. So:

  ```python
  func(a, b, nan_policy='omit')
  ```

  should behave the same as:

\(^1\) If an element of the output depends only on the corresponding element of the input (e.g. `numpy.sin`, `scipy.special.gamma`), then there is no need for a `nan_policy` parameter.
For inputs with related or paired values (e.g. `scipy.stats.pearsonr`, `scipy.stats.ttest_rel`) the recommended behavior is to omit all the values for which any of the related values are `nan`. For a function with two related array inputs, this means:

\[
y = \text{func}(a, b, \text{nan}_\text{policy}='\text{omit}')
\]

should behave the same as:

\[
\text{hasnan} = \text{np.isnan}(a) | \text{np.isnan}(b) \quad \# \text{Union of the isnan masks.}\\
y = \text{func}(a[\neg \text{hasnan}], b[\neg \text{hasnan}])
\]

The docstring for such a function should clearly state this behavior.

- `nan_policy='raise'`: Raise a `ValueError`.
- `nan_policy='propagate'`: Propagate the `nan` value to the output. Typically, this means just execute the function without checking for `nan`, but see
  
  https://github.com/scipy/scipy/issues/7818

for an example where that might lead to unexpected output.

**`nan_policy` combined with an `axis` parameter**

There is nothing surprising here—the principle mentioned above still applies when the function has an `axis` parameter. Suppose, for example, `func` reduces a 1-d array to a scalar, and handles n-d arrays as a collection of 1-d arrays, with the `axis` parameter specifying the axis along which the reduction is to be applied. If, say:

\[
\begin{align*}
\text{func}([1, 3, 4]) & \rightarrow 10.0 \\
\text{func}([2, -3, 8, 2]) & \rightarrow 4.2 \\
\text{func}([7, 8]) & \rightarrow 9.5 \\
\text{func}([]) & \rightarrow -\infty
\end{align*}
\]

then:

\[
\begin{align*}
\text{func}([[1, \text{nan}, 3, 4], \\
\quad [2, -3, 8, 2], \\
\quad [\text{nan}, \text{nan}, 7, \text{nan}], \\
\quad [\text{nan}, \text{nan}, \text{nan}, \text{nan}]], \text{nan}_\text{policy}='\text{omit}', \text{axis}=-1)
\end{align*}
\]

must give the result:

\[
\text{np.array}([10.0, 4.2, 9.5, -\infty])
\]
**Edge cases**

A function that implements the `nan_policy` parameter should gracefully handle the case where all the values in the input array(s) are `nan`. The basic principle described above still applies:

```python
func([nan, nan, nan], nan_policy='omit')
```

should behave the same as:

```python
func([])
```

In practice, when adding `nan_policy` to an existing function, it is not unusual to find that the function doesn’t already handle this case in a well-defined manner, and some thought and design may have to be applied to ensure that it works. The correct behavior (whether that be to return `nan`, return some other value, raise an exception, or something else) will be determined on a case-by-case basis.

**Why doesn’t `nan_policy` also apply to `inf`?**

Although we learn in grade school that “infinity is not a number”, the floating point values `nan` and `inf` are qualitatively different. The values `inf` and `-inf` act much more like regular floating point values than `nan`.

- One can compare `inf` to other floating point values and it behaves as expected, e.g. `3 < inf` is `True`.
- For the most part, arithmetic works “as expected” with `inf`, e.g. `inf + inf = inf`, `-2*inf = -inf`, `1/inf = 0`, etc.
- Many existing functions work “as expected” with `inf`: `np.log(inf) = inf`, `np.exp(-inf) = 0`, `np.array([1.0, -1.0, np.inf]).min() = -1.0`, etc.

So while `nan` almost always means “something went wrong” or “something is missing”, `inf` can in many cases be treated as a useful floating point value.

It is also consistent with the NumPy `nan` functions to not ignore `inf`:

```python
>>> np.nanmax([1, 2, 3, np.inf, np.nan])
nan
>>> np.nansum([1, 2, 3, np.inf, np.nan])
nan
>>> np.nanmean([8, -np.inf, 9, 1, np.nan])
-inf
```

**How not to implement `nan_policy`**

In the past (and possibly currently), some `stats` functions handled `nan_policy` by using a masked array to mask the `nan` values, and then computing the result using the functions in the `mstats` subpackage. The problem with this approach is that the masked array code might convert `inf` to a masked value, which we don’t want to do (see above). It also means that, if care is not taken, the return value will be a masked array, which will likely be a surprise to the user if they passed in regular arrays.
4.10.2 Adding vectorized ufuncs in `scipy.special`

Many of the functions in `special` are vectorized versions of scalar functions. The scalar functions are written by hand and the necessary loops for vectorization are generated automatically. This section discusses the steps necessary to add a new vectorized special function.

The first step in adding a new vectorized function is writing the corresponding scalar function. This can be done in Cython, C, C++, or Fortran. If starting from scratch then Cython should be preferred because the code is easier to maintain for developers only familiar with Python. If the primary code is in Fortran then it is necessary to write a C wrapper around the code; for examples of such wrappers see `specfun_wrappers.c`.

After implementing the scalar function, register the new function by adding an entry to `functions.json`. The doc-string in `generate_ufuncs.py` explains the format. Also add documentation for the new function by adding an entry to `add_newdocs.py`; look in the file for examples.

When writing the parameters section of the documentation for ufuncs, the type of an argument should be `array_like`. Discussion of whether an argument can be e.g. real or complex-valued should be saved for the description. So for example, if we were to document the parameters for the Gamma function then it should look like this:

```
Parameters
----------
z : array_like
   Real or complex valued argument
```

When documenting the returns section, the type of the returned value should be `scalar` or `ndarray` since ufuncs return scalars when given scalars as arguments. Also keep in mind that providing a name for the return value is optional, and indeed is often not helpful for special functions. So for the Gamma function we might have something like this:

```
Returns
-------
scalar or ndarray
   Values of the Gamma function
```

4.11 SciPy Project Governance

The purpose of this document is to formalize the governance process used by the SciPy project in both ordinary and extraordinary situations, and to clarify how decisions are made and how the various elements of our community interact, including the relationship between open source collaborative development and work that may be funded by for-profit or non-profit entities.

4.11.1 The Project

The SciPy Project (The Project) is an open source software project. The goal of The Project is to develop open source software for scientific computing in Python, and, in particular, the `scipy` package. The Software developed by The Project is released under the BSD (or similar) open source license, developed openly and hosted on public GitHub repositories under the `scipy` GitHub organization.

The Project is developed by a team of distributed developers, called Contributors. Contributors are individuals who have contributed code, documentation, designs, or other work to the Project. Anyone can be a Contributor. Contributors can be affiliated with any legal entity or none. Contributors participate in the project by submitting, reviewing, and discussing GitHub Pull Requests and Issues and participating in open and public Project discussions on GitHub, mailing lists, and other channels. The foundation of Project participation is openness and transparency.
The Project Community consists of all Contributors and Users of the Project. Contributors work on behalf of and are responsible to the larger Project Community and we strive to keep the barrier between Contributors and Users as low as possible.

The Project is not a legal entity, nor does it currently have any formal relationships with legal entities.

### 4.11.2 Governance

This section describes the governance and leadership model of The Project.

The foundations of Project governance are:

- openness and transparency
- active contribution
- institutional neutrality

Traditionally, Project leadership was provided by a subset of Contributors, called Core Developers, whose active and consistent contributions have been recognized by their receiving “commit rights” to the Project GitHub repositories. In general, all Project decisions are made through consensus among the Core Developers with input from the Community.

While this approach has served us well, as the Project grows, we see a need for a more formal governance model. The SciPy Core Developers expressed a preference for a leadership model which includes a BDFL (Benevolent Dictator for Life). Therefore, moving forward The Project leadership will consist of a BDFL and Steering Council.

#### BDFL

The Project will have a BDFL (Benevolent Dictator for Life), who is currently Pauli Virtanen. As Dictator, the BDFL has the authority to make all final decisions for The Project. As Benevolent, the BDFL, in practice, chooses to defer that authority to the consensus of the community discussion channels and the Steering Council (see below). It is expected, and in the past has been the case, that the BDFL will only rarely assert his/her final authority. Because rarely used, we refer to BDFL’s final authority as a “special” or “overriding” vote. When it does occur, the BDFL override typically happens in situations where there is a deadlock in the Steering Council or if the Steering Council asks the BDFL to make a decision on a specific matter. To ensure the benevolence of the BDFL, The Project encourages others to fork the project if they disagree with the overall direction the BDFL is taking. The BDFL may delegate his/her authority on a particular decision or set of decisions to any other Council member at his/her discretion.

The BDFL can appoint his/her successor, but it is expected that the Steering Council would be consulted on this decision. If the BDFL is unable to appoint a successor, the Steering Council will make this decision - preferably by consensus, but if needed, by a majority vote.

Note that the BDFL can step down at any time, and acting in good faith, will also listen to serious calls to do so. Also note that the BDFL is more a role for fallback decision making rather than that of a director/CEO.

#### Steering Council

The Project will have a Steering Council that consists of Project Contributors who have produced contributions that are substantial in quality and quantity, and sustained over at least one year. The overall role of the Council is to ensure, through working with the BDFL and taking input from the Community, the long-term well-being of the project, both technically and as a community.

The Council will have a Chair, who is tasked with keeping the organizational aspects of the functioning of the Council and the Project on track. The Council will also appoint a Release Manager for the Project, who has final responsibility for one or more releases.
During the everyday project activities, Council Members participate in all discussions, code review, and other project activities as peers with all other Contributors and the Community. In these everyday activities, Council Members do not have any special power or privilege through their membership on the Council. However, it is expected that because of the quality and quantity of their contributions and their expert knowledge of the Project Software and Services, Council Members will provide useful guidance, both technical and in terms of project direction, to potentially less experienced contributors.

The Steering Council and its Members play a special role in certain situations. In particular, the Council may:

- Make decisions about the overall scope, vision, and direction of the project.
- Make decisions about strategic collaborations with other organizations or individuals.
- Make decisions about specific technical issues, features, bugs, and pull requests. They are the primary mechanism of guiding the code review process and merging pull requests.
- Make decisions about the Services that are run by The Project and manage those Services for the benefit of the Project and Community.
- Make decisions when regular community discussion does not produce consensus on an issue in a reasonable time frame.
- Update policy documents, such as this one.

**Council membership**

To become eligible for being a Steering Council Member, an individual must be a Project Contributor who has produced contributions that are substantial in quality and quantity, and sustained over at least one year. Potential Council Members are nominated by existing Council members and voted upon by the existing Council after asking if the potential Member is interested and willing to serve in that capacity. The Council will be initially formed from the set of existing Core Developers who, as of January 2017, have been significantly active over the last two years.

When considering potential Members, the Council will look at candidates with a comprehensive view of their contributions. This will include, but is not limited to, code, code review, infrastructure work, mailing list and chat participation, community help/building, education and outreach, design work, etc. We are deliberately not setting arbitrary quantitative metrics (like “100 commits in this repo”) to avoid encouraging behavior that plays to the metrics rather than the project’s overall well-being. We want to encourage a diverse array of backgrounds, viewpoints, and talents in our team, which is why we explicitly do not define code as the sole metric on which council membership will be evaluated.

If a Council Member becomes inactive in the project for a period of one year, they will be considered for removal from the Council. Before removal, inactive Member will be approached to see if they plan on returning to active participation. If not, they will be removed immediately upon a Council vote. If they plan on returning to active participation soon, they will be given a grace period of one year. If they don't return to active participation within that time period they will be removed by vote of the Council without further grace period. All former Council Members can be considered for membership again at any time in the future, like any other Project Contributor. Retired Council Members will be listed on the project website, acknowledging the period during which they were active in the Council.

The Council reserves the right to eject current Members, other than the BDFL, if they are deemed to be actively harmful to the project’s well-being, and attempts at communication and conflict resolution have failed.

A list of current Steering Council Members is maintained at the page governance-people.
Council Chair
The Chair will be appointed by the Steering Council. The Chair can stay on as long as he/she wants, but may step down at any time and will listen to serious calls to do so (similar to the BDFL role). The Chair will be responsible for:

- Starting a review of the technical direction of the project (as captured by the SciPy Roadmap) bi-yearly, around mid-April and mid-October.
- At the same times of the year, summarizing any relevant organizational updates and issues in the preceding period, and asking for feedback/suggestions on the mailing list.
- Ensuring the composition of the Steering Council stays current.
- Ensuring matters discussed in private by the Steering Council get summarized on the mailing list to keep the Community informed.
- Ensuring other important organizational documents (e.g., Code of Conduct, Fiscal Sponsorship Agreement) stay current after they are added.

Release Manager
The Release Manager has final responsibility for making a release. This includes:

- Proposing of and deciding on the timing of a release.
- Determining the content of a release in case there is no consensus on a particular change or feature.
- Creating the release and announcing it on the relevant public channels.

For more details on what those responsibilities look like in practice, see Making a SciPy release.

Conflict of interest
It is expected that the BDFL and Council Members will be employed at a wide range of companies, universities, and non-profit organizations. Because of this, it is possible that Members will have a conflict of interest. Such conflicts of interest include, but are not limited to:

- Financial interest, such as investments, employment or contracting work, outside of The Project that may influence their work on The Project.
- Access to proprietary information of their employer that could potentially leak into their work with the Project.

All members of the Council, BDFL included, shall disclose to the rest of the Council any conflict of interest they may have. Members with a conflict of interest in a particular issue may participate in Council discussions on that issue, but must recuse themselves from voting on the issue. If the BDFL has recused his/herself for a particular decision, the Council will appoint a substitute BDFL for that decision.

Private communications of the Council
Unless specifically required, all Council discussions and activities will be public and done in collaboration and discussion with the Project Contributors and Community. The Council will have a private mailing list that will be used sparingly and only when a specific matter requires privacy. When private communications and decisions are needed, the Council will do its best to summarize those to the Community after removing personal/private/sensitive information that should not be posted to the public internet.
Council decision making

If it becomes necessary for the Steering Council to produce a formal decision, then they will use a form of the Apache Foundation voting process. This is a formalized version of consensus, in which +1 votes indicate agreement, -1 votes are vetoes (and must be accompanied with a rationale, as above), and one can also vote fractionally (e.g. -0.5, +0.5) if one wishes to express an opinion without registering a full veto. These numeric votes are also often used informally as a way of getting a general sense of people’s feelings on some issue, and should not normally be taken as formal votes. A formal vote only occurs if explicitly declared, and if this does occur, then the vote should be held open for long enough to give all interested Council Members a chance to respond – at least one week.

In practice, we anticipate that for most Steering Council decisions (e.g., voting in new members) a more informal process will suffice.

4.11.3 Institutional Partners and funding

The Steering Council is the primary leadership for the project. No outside institution, individual, or legal entity has the ability to own, control, usurp, or influence the project other than by participating in the Project as Contributors and Council Members. However, because institutions can be an important funding mechanism for the project, it is important to formally acknowledge institutional participation in the project. These are Institutional Partners.

An Institutional Contributor is any individual Project Contributor who contributes to the project as part of their official duties at an Institutional Partner. Likewise, an Institutional Council Member is any Project Steering Council Member who contributes to the project as part of their official duties at an Institutional Partner.

With these definitions, an Institutional Partner is any recognized legal entity in any country that employs at least 1 Institutional Contributor or Institutional Council Member. Institutional Partners can be for-profit or non-profit entities.

Institutions become eligible to become an Institutional Partner by employing individuals who actively contribute to The Project as part of their official duties. To state this another way, the only way for a Partner to influence the project is by actively contributing to the open development of the project, in equal terms to any other member of the community of Contributors and Council Members. Merely using Project Software in institutional context does not allow an entity to become an Institutional Partner. Financial gifts do not enable an entity to become an Institutional Partner. Once an institution becomes eligible for Institutional Partnership, the Steering Council must nominate and approve the Partnership.

If, at some point, an existing Institutional Partner stops having any contributing employees, then a one year grace period commences. If, at the end of this one-year period, they continue not to have any contributing employees, then their Institutional Partnership will lapse, and resuming it will require going through the normal process for new Partnerships.

An Institutional Partner is free to pursue funding for their work on The Project through any legal means. This could involve a non-profit organization raising money from private foundations and donors or a for-profit company building proprietary products and services that leverage Project Software and Services. Funding acquired by Institutional Partners to work on The Project is called Institutional Funding. However, no funding obtained by an Institutional Partner can override the Steering Council. If a Partner has funding to do SciPy work and the Council decides not to pursue that work as a project, the Partner is free to pursue it on their own. However, in this situation, that part of the Partner’s work will not be under the SciPy umbrella and cannot use the Project trademarks in any way that suggests a formal relationship.

Institutional Partner benefits are:

- acknowledgement on the SciPy website and in talks
- ability to acknowledge their own funding sources on the SciPy website and in talks
- ability to influence the project through the participation of their Council Member
- invitation of the Council Members to SciPy Developer Meetings

A list of current Institutional Partners is maintained at the page governance-people.
4.11.4 Document history

https://github.com/scipy/scipy/commits/master/doc/source/dev/governance/governance.rst

4.11.5 Acknowledgements

Substantial portions of this document were adapted from the Jupyter/IPython project’s governance document and NumPy’s governance document.

4.11.6 License

To the extent possible under law, the authors have waived all copyright and related or neighboring rights to the SciPy project governance document, as per the CC-0 public domain dedication / license.

4.12 Development environment quickstart guide (macOS)

This quickstart guide will cover:

• setting up and maintaining a development environment, including installing compilers and SciPy build dependencies;
• creating a personal fork of the SciPy repository on GitHub;
• using git to manage a local repository with development branches;
• performing an in-place build of SciPy; and
• creating a virtual environment that adds this development version of SciPy to the Python path in macOS (Tested on 11.1).

Note: This guide does not present the only way to set up a development environment; there are many valid choices of Python distribution, C/Fortran compiler, and installation options. The steps here can often be adapted for other choices, but we cannot provide documentation tailored for them.

This guide assumes that you are starting without an existing Python 3 installation. If you already have Python 3, you might want to uninstall it first to avoid ambiguity over which Python version is being used at the command line.

4.12.1 Building SciPy

1. Install Apple Developer Tools. An easy way to do this is to open a terminal window, enter the command `xcode-select --install`, and follow the prompts. Apple Developer Tools includes git, the software we need to download and manage the SciPy source code.

2. Download, install, and test the latest release of the Anaconda Distribution of Python. In addition to the latest version of Python 3, the Anaconda Distribution includes dozens of the most popular Python packages for scientific computing, the conda package manager, and tools for managing virtual environments.

   If you’re installing using the terminal, be sure to follow the “Next Steps” listed after the installer finishes. You might also need to restart your terminal window or enter `source ~/.bash_profile` for all the changes to take effect.
3. (Optional) In a terminal window, enter `conda list`. This shows a list of all the Python packages that came with the Anaconda Distribution of Python. Note the latest released version of SciPy is among them; this is not the development version you are going to build and will be able to modify.

Ideally, we’d like to have both versions, and we’d like to be able to switch between the two as needed. Virtual environments can do just that. With a few keystrokes in the terminal or even the click of an icon, we can enable or disable our development version. Let’s set that up.

**Note:** If `conda` is not a recognized command, try restarting your terminal. If it is still not recognized, please see “Should I add Anaconda to the macOS or Linux PATH?” in the Anaconda FAQ.

4. Enter `conda create --name scipydev` to create an empty virtual environment named `scipydev` (or another name that you prefer). This tells `conda` to create a new, empty environment for our packages. Activate the environment with `conda activate scipydev`. Note that you’ll need to have this virtual environment active whenever you want to work with the development version of SciPy.

5. Enter `conda config --env --add channels conda-forge` to tell Anaconda the source we want for our packages. Then enter `conda install python=3.8 numpy pybind11 cython pythran pytest compilers sphinx pydata-sphinx-theme sphinx-panels matplotlib mypy` to install the following packages:

- `numpy pybind11 cython pythran` are four packages that SciPy depends on.
- `compilers` holds compilers used to build SciPy’s Fortran, C, and C++ source code.
- `pytest` is needed for running the test suite.
- `sphinx, pydata-sphinx-theme, sphinx-panels and matplotlib` are required to render the SciPy documentation.
- `mypy` is a static type checker for Python. Consider using it.

Note that we’re installing SciPy’s build dependencies and some other software, but not SciPy itself.

6. Browse to the SciPy repository on GitHub and create your own fork. You’ll need to create a GitHub account if you don’t already have one.

7. Browse to your fork. Your fork will have a URL like `https://github.com/mdhaber/scipy`, except with your GitHub username in place of “mdhaber”.

8. Click the big, green “Clone or download” button, and copy the “.git” URL to the clipboard. The URL will be the same as your fork’s URL, except it will end in “.git”.

9. Create a folder for the SciPy source code in a convenient place on your computer. Navigate to it in the terminal.

10. Enter the command `git clone` followed by your fork’s .git URL. Note that this creates in the terminal’s working directory a `scipy` folder containing the SciPy source code.

11. In the terminal, navigate into the `scipy` root directory (e.g. `cd scipy`).

12. Initialize git submodules: `git submodule update --init`.

13. Do an in-place build: `enter python3 setup.py build_ext --inplace`. This will compile the C, C++, and Fortran code that comes with SciPy. We installed python3 with Anaconda. `setup.py` is a script in the root directory of SciPy, which is why you have to be in the SciPy root directory to call it. `build_ext` is a command defined in `setup.py`, and `--inplace` is an option we’ll use to ensure that the compiling happens in the SciPy directory you already have rather than the default location for Python packages. By building in-place, you avoid having to re-build SciPy before you can test changes to the Python code.

14. Test the build: `enter python3 runtests.py -v`. `runtests.py` is another script in the SciPy root directory. It runs a suite of tests that make sure SciPy is working as it should, and `-v` activates the `--verbose` option.
to show all the test output. If the tests are successful, you now have a working development build of SciPy! You could stop here, but you would only be able to use this development build when the Python working directory is the SciPy root directory.

15. Enter `conda develop .`, where . refers to the present directory. This will allow us to import the development version of SciPy in Python regardless of Python’s working directory.

16. In a new terminal window, test your setup. If you activate your virtual environment (e.g. `conda activate scipydev`) and run Python code that imports from SciPy, any changes you make to the SciPy code should be reflected when the code runs. After deactivating the virtual environment (conda deactivate), Python imports from the version of SciPy installed by Anaconda. You can also check which version of SciPy you’re using by executing in Python:

```python
import scipy
print(scipy.__version__)
```

If you have successfully imported a development version of SciPy, the word `dev` will appear in the output, e.g.:

```
1.6.0.dev0+be97f1a
```

### 4.13 Development environment quickstart guide (Ubuntu)

This quickstart guide will cover:

- setting up and maintaining a development environment, including installing compilers and SciPy build dependencies;
- creating a personal fork of the SciPy repository on GitHub;
- using git to manage a local repository with development branches;
- performing an in-place build of SciPy; and
- creating a virtual environment that adds this development version of SciPy to the Python path in Ubuntu. (Tested on 16.04, 18.04, and 20.04). Users running Windows can follow these instructions after setting up Windows Subsystem for Linux or an Amazon EC2 instance with Ubuntu 20.04. However, the instructions for setting up a development environment with Docker may be more reliable.

**Note:** This guide does not present the only way to set up a development environment; there are many valid choices of Python distribution, C/Fortran compiler, and installation options. The steps here can often be adapted for other choices, but we cannot provide documentation tailored for them.

This guide assumes that you are starting without an existing Python 3 installation. If you already have Python 3, you might want to uninstall it first to avoid ambiguity over which Python version is being used at the command line.
4.13.1 Building SciPy

1. Download, install, and test the latest release of the Anaconda Distribution of Python. In addition to the latest version of Python 3, the Anaconda Distribution includes dozens of the most popular Python packages for scientific computing, the conda package manager, and tools for managing virtual environments.

   If you’re installing using the terminal, be sure to follow the “Next Steps” listed after the installer finishes. You might also need to restart your terminal window or enter source ~/.bashrc for all the changes to take effect.

2. (Optional) In a terminal window, enter conda list. This shows a list of all the Python packages that came with the Anaconda Distribution of Python. Note the latest released version of SciPy is among them; this is not the development version you are going to build and will be able to modify.

   Ideally, we’d like to have both versions, and we’d like to be able to switch between the two as needed. Virtual environments can do just that. With a few keystrokes in the terminal or even the click of an icon, we can enable or disable our development version. Let’s set that up.

   **Note:** If conda is not a recognized command, try restarting your terminal. If it is still not recognized, please see “Should I add Anaconda to the macOS or Linux PATH?” in the Anaconda FAQ.

3. Enter conda create --name scipydev python=3.8 numpy pybind11 cython pythran pytest gfortran_linux-64 gxx_linux-64 sphinx pydata-sphinx-theme sphinx-panels matplotlib mypy git. This tells conda to create a virtual environment named scipydev (or another name that you prefer) with several packages.

   - numpy pybind11 cython pythran are four packages that SciPy depends on.
   - gfortran_linux-64 gxx_linux-64 are compilers used to build SciPy’s Fortran, C, and C++ source code.
   - pytest is needed for running the test suite.
   - sphinx, pydata-sphinx-theme, sphinx-panels and matplotlib are required to render the SciPy documentation.
   - mypy is a static type checker for Python. Consider using it.
   - git is a version control system used to download and manage the SciPy source code.

   Note that we’re installing SciPy’s build dependencies and some other software, but not SciPy itself.

   **Note:** You could conda create an empty virtual environment first, then conda install the packages, but creating the virtual environment with all the packages you need is preferable to installing packages individually because it makes it easier for conda to solve the package dependencies optimally.

4. You’re still in the base environment. Activate your new virtual environment by entering conda activate scipydev. If you’re working with an old version of conda, you might need to type source activate scipydev instead (see here). Note that you’ll need to have this virtual environment active whenever you want to work with the development version of SciPy.

5. Browse to the SciPy repository on GitHub and create your own fork. You’ll need to create a GitHub account if you don’t already have one.

6. Browse to your fork. Your fork will have a URL like https://github.com/mdhaber/scipy, except with your GitHub username in place of “mdhaber”.

7. Click the big, green “Clone or download” button, and copy the “.git” URL to the clipboard. The URL will be the same as your fork’s URL, except it will end in “.git”.

---

4.13. Development environment quickstart guide (Ubuntu) 2865
8. Create a folder for the SciPy source code in a convenient place on your computer. Navigate to it in the terminal.

9. Enter the command `git clone` followed by your fork's .git URL. Note that this creates in the terminal's working directory a `scipy` folder containing the SciPy source code.

10. In the terminal, navigate into the `scipy` root directory (e.g. `cd scipy`).

11. Initialize git submodules: `git submodule update --init`.

12. Do an in-place build: enter `python3 setup.py build_ext --inplace`. This will compile the C, C++, and Fortran code that comes with SciPy. We installed `python3` with Anaconda. `setup.py` is a script in the root directory of SciPy, which is why you have to be in the SciPy root directory to call it. `build_ext` is a command defined in `setup.py`, and `--inplace` is an option we'll use to ensure that the compiling happens in the SciPy directory you already have rather than the default location for Python packages. By building in-place, you avoid having to re-build SciPy before you can test changes to the Python code.

13. Test the build: enter `python3 runtests.py -v`. `runtests.py` is another script in the SciPy root directory. It runs a suite of tests that make sure SciPy is working as it should, and `-v` activates the `--verbose` option to show all the test output. If the tests are successful, you now have a working development build of SciPy! You could stop here, but you would only be able to use this development build when the Python working directory is the SciPy root directory.

14. Enter `conda develop ..`, where .. refers to the present directory. This will allow us to import the development version of SciPy in Python regardless of Python's working directory.

15. In a new terminal window, test your setup. If you activate your virtual environment (e.g. `conda activate scipydev`) and run Python code that imports from SciPy, any changes you make to the SciPy code should be reflected when the code runs. After deactivating the virtual environment (`conda deactivate`), Python imports from the version of SciPy installed by Anaconda. You can also check which version of SciPy you're using by executing in Python:

   ```python
   import scipy
   print(scipy.__version__)
   ```

   If you have successfully imported a development version of SciPy, the word `dev` will appear in the output, e.g.:

   ```
   1.6.0.dev0+be97f1a
   ```

### 4.14 Development workflow

*Note: consider watching SciPy Development Workflow before or after reading to see an example of fixing a bug and submitting a pull request.*

In *Development environment quickstart guide (macOS)* or *Development environment quickstart guide (Ubuntu)*, you created your own fork (copy) of the SciPy repository, cloned the repository on your own machine, and built SciPy from this source code. Before getting started here, there are two other things you need to do just once before you start modifying SciPy.

1. In a terminal, introduce yourself to Git:

   ```bash
   git config --global user.email you@yourdomain.com
   git config --global user.name "Your Name"
   ```

   This information credits you for your work, but note that it will become publicly available if you “push” your work to GitHub. See *Setting your commit email address in Git* for more information.

2. Navigate to the root directory of your local SciPy repository and enter:
This associates the name `upstream` with the official SciPy repository located at `https://github.com/scipy/scipy.git`. Note that when you cloned your fork of the SciPy repository, Git already associated the name `origin` with your fork. The reason you need both of these “remotes” is that you will typically start with the latest version of SciPy from the official repository `upstream`, make changes, “push” your changes to your fork of the repository `origin`, and then submit a “pull request” asking SciPy to “pull” your changes from your fork into the official repository.

3. Initialize git submodules:

```bash
git submodule update --init
```

This fetches and updates any submodules that SciPy needs (such as Boost).

### 4.14.1 Basic workflow

In short:

1. Start a new feature branch for each set of edits that you do. See below.
2. Hack away! See below.
3. When finished:
   - **Contributors**: push your feature branch to your own Github repo, and create a pull request.
   - **Core developers**: If you want to push changes without further review, see the notes below.

This way of working helps to keep work well organized and the history as clear as possible.

See also:

There are many online tutorials to help you learn git. For discussions of specific git workflows, see these discussions on [linux git workflow](https://www.example.com/linux-git-workflow) and [ipython git workflow](https://www.example.com/ipython-git-workflow).

### Making a new feature branch

First, navigate to the SciPy root directory in your terminal and fetch new commits from the upstream repository:

```bash
git fetch upstream
```

Then, create a new branch based on the master branch of the upstream repository:

```bash
git checkout -b my-new-feature upstream/master
```

Equivalently, you might want to keep the master branch of your own repository up to date and create a new branch based on that:

```bash
git checkout master
git rebase upstream/master
git checkout -b my-new-feature
```

In order, these commands

1. ensure that the master branch of your local repository is checked out,
2. apply all the latest changes from the upstream/master (main SciPy repository master branch) to your local master branch, and

3. create and check out a new branch (-b) based on your local master branch.

In any case, it's important that your feature branch include the latest changes from the upstream master to help avoid merge conflicts when it's time to submit a pull request.

It's also a good idea to build this branch and run tests before continuing. Assuming you've followed Development environment quickstart guide (macOS) or Development environment quickstart guide (Ubuntu) to set up your development environment, you'll need to activate your development virtual environment, perform an in-place build, and run tests:

```
conda activate name-of-your-virtual-environment
python setup.py build_ext --inplace
python runtests.py -v
```

Otherwise, see building, Running SciPy Tests Locally for more information.

### The editing workflow

#### Overview

```
# hack hack
git status # Optional
git diff # Optional
git add modified_file
git commit
# push the branch to your own Github repo
git push origin my-new-feature
```

#### In more detail

1. Make some changes. When you feel that you've made a complete, working set of related changes, move on to the next steps.

2. Optional: Check which files have changed with `git status` (see `git status`). You'll see a listing like this one:

```
# On branch my-new-feature
# Changed but not updated:
#   (use "git add <file>..." to update what will be committed)
#   (use "git checkout -- <file>..." to discard changes in working_
#       directory)
#
# modified:   README
#
# Untracked files:
#   (use "git add <file>..." to include in what will be committed)
#   INSTALL
# no changes added to commit (use "git add" and/or "git commit -a")
```

3. Optional: Compare the changes with the previous version using with `git diff` (git diff). This brings up a simple text browser interface that highlights the difference between your files and the previous version.

4. Add any relevant modified or new files using `git add modified_file` (see `git add`). This puts the files into a staging area, which is a queue of files that will be added to your next commit. Only add files that have related, complete changes. Leave files with unfinished changes for later commits.
5. To commit the staged files into the local copy of your repo, do `git commit`. At this point, a text editor will open up to allow you to write a commit message. Read the commit message section to be sure that you are writing a properly formatted and sufficiently detailed commit message. After saving your message and closing the editor, your commit will be saved. For trivial commits, a short commit message can be passed in through the command line using the `-m` flag. For example, `git commit -am "ENH: Some message"`. In some cases, you will see this form of the commit command: `git commit -a`. The extra `-a` flag automatically commits all modified files and removes all deleted files. This can save you some typing of numerous `git add` commands; however, it can add unwanted changes to a commit if you're not careful. For more information, see why the `-a` flag? - and the helpful use-case description in the tangled working copy problem.

6. Push the changes to your forked repo on `github`:

```bash
git push origin my-new-feature
```

For more information, see `git push`.

**Note:** Assuming you have followed the instructions in these pages, `git` will create a default link to your `github` repo called `origin`. In `git` >= 1.7, you can ensure that the link to `origin` is permanently set by using the `--set-upstream` option:

```bash
git push --set-upstream origin my-new-feature
```

From now on, `git` will know that `my-new-feature` is related to the `my-new-feature` branch in your own `github` repo. Subsequent push calls are then simplified to the following:

```bash
git push
```

You have to use `--set-upstream` for each new branch that you create.

It may be the case that while you were working on your edits, new commits have been added to `upstream` that affect your work. In this case, follow the rebasing-on-master instructions to apply those changes to your branch.

**Writing the commit message**

Commit messages should be clear and follow a few basic rules. Example:

```
ENH: add functionality X to SciPy.<submodule>.
```

The first line of the commit message starts with a capitalized acronym (options listed below) indicating what type of commit this is. Then a blank line, then more text if needed. Lines shouldn't be longer than 72 characters. If the commit is related to a ticket, indicate that with "See #3456", "See ticket 3456", "Closes #3456", or similar.

Describing the motivation for a change, the nature of a bug for bug fixes or some details on what an enhancement does are also good to include in a commit message. Messages should be understandable without looking at the code changes. A commit message like MAINT: fixed another one is an example of what not to do; the reader has to go look for context elsewhere.

Standard acronyms to start the commit message with are:

```
API: an (incompatible) API change
BENCH: changes to the benchmark suite
BLD: change related to building SciPy
BUG: bug fix
```

(continues on next page)
Note: You can add some markers to skip part of the continuous integration. See Continuous Integration.

**Asking for your changes to be merged with the main repo**

When you feel your work is finished, you can create a pull request (PR). Github has a nice help page that outlines the process for filing pull requests.

If your changes involve modifications to the API or addition/modification of a function, you should initiate a code review. This involves sending an email to the SciPy mailing list with a link to your PR along with a description of and a motivation for your changes.

**Checklist before submitting a PR**

- Did you check that the code can be distributed under a BSD license? See License Considerations.
- Are there unit tests with good code coverage? See NumPy/SciPy Testing Guidelines.
- Do all unit tests pass locally? See Running SciPy Tests Locally.
- Do all public function have docstrings including examples? See the numpydoc docstring guide.
- Does the documentation render correctly? See Rendering Documentation with Sphinx.
- Is the code style correct? See PEP8 and SciPy.
- Are there benchmarks? See Benchmarking SciPy with airspeed velocity.
- Is the commit message formatted correctly?
- Is the docstring of the new functionality tagged with .. versionadded:: X.Y.Z (where X.Y.Z is the version number of the next release? See the updating, workers, and constraints documentation of differential_evolution, for example. You can get the next version number from the most recent release notes on the wiki or from the MAJOR and MINOR version number variables in setup.py.
- In case of larger additions, is there a tutorial or more extensive module-level description? Tutorial files are in doc/source/tutorial.
- If compiled code is added, is it integrated correctly via setup.py? See Compiled code for more information.
4.15 PEP8 and SciPy

All SciPy Python code should adhere to PEP8 style guidelines. It's so important that some continuous integration tests on GitHub will fail due to certain PEP8 violations. Here are a few tips for ensuring PEP8 compliance before pushing your code:

- Many integrated development environments (IDEs) have options that automatically check for PEP8 compliance. In Spyder, for example, enable Real-time code style analysis in Tools → Preferences → Editor → Code Introspection/Analysis and “Automatically remove trailing spaces when saving files” in in Tools → Preferences → Editor → Advanced Settings. This can help you fix PEP8 issues as you write your code.

- You can also perform checks using the flake8 tool. After installing flake8, navigate to the SciPy root directory in a console window and try:

  ```bash
  flake8 scipy/optimize/linprog.py
  ```

  The absence of output indicates that there are no PEP8 issues with the file. Unfortunately, there is also no output if you get the file path wrong:

  ```bash
  flake8 scipy/optimize/linprog2.py
  ```

  (linprog2.py doesn’t exist.) To make sure you have the path right, consider introducing (and then removing) a small PEP8 issue in the target file, such as a line that is over 79 characters long.

- If you have existing code with a lot of PEP8 issues, consider using autopep8 to automatically fix most of them.

4.16 Rendering Documentation with Sphinx

SciPy docstrings are rendered to HTML using Sphinx and the PyData Sphinx theme. Writing docstrings is covered in the A Guide to NumPy Documentation; this document explains how to check that docstrings render properly.

*For a video walkthrough, please see Rendering SciPy Documentation with Sphinx.*

4.16.1 Rendering Documentation Locally

To render the documentation on your own machine:

0. Ensure that you have a working SciPy Development environment active. You need to be able to import scipy regardless of Python’s working directory; the python setup.py develop and conda develop commands from the quickstart guides make this possible.

1. Install Sphinx, PyData Sphinx theme, Sphinx-Panels and matplotlib. For example, if you’re using the Anaconda distribution of Python, enter in a terminal window conda install sphinx pydata-sphinx-theme sphinx-panels matplotlib --channel conda-forge. The list of requirements is in scipy/doc_requirements.txt.

2. In a terminal window, browse to the scipy/doc directory. Note the presence of the file Makefile.

3. Execute `git submodule update --init`. Some of the documentation theme files are not distributed with the main scipy repository; this keeps them up to date using `git submodules`.

4. Enter `make html-scipyorg`. If you have multiple version of Python on your path, you can choose which version to use by appending `PYTHON=python3.7` to this command, where `python3.7` is to be replaced with the name of the Python you use for SciPy development. This uses the Make build automation tool to execute the documentation build instructions from the Makefile. This can take a while the first time, but subsequent documentation builds are typically much faster.
5. View the documentation in `scipy/doc/build/html-scipyorg`. You can start with `index.html` and browse, or you can jump straight to the file you're interested in.

**Note:** Changes to certain documents do not take effect when Sphinx documentation is rebuilt. In this case, you can build from scratch by deleting the `scipy/doc/build` directory, then building again.

### 4.16.2 Checking Documentation on the Cloud

Once a PR is opened, you can check that documentation renders correctly on the cloud.

1. Log in to GitHub.
2. Log in CircleCI using your GitHub account.
3. Back in GitHub, at the bottom of the PR, select “Show all Checks”.
4. Next to “ci/circleci: build_docs artifact”, select “Details”.

### 4.17 Running SciPy Tests Locally

Basic test writing and execution from within the Python interpreter is documented in the NumPy/SciPy Testing Guidelines. This page includes information about running tests from the command line using SciPy's `runtests.py`, which permits greater control. **Note: Before beginning, ensure that pytest is installed.**

To run all tests, navigate to the root SciPy directory at the command line and execute:

```
python runtests.py -v
```

where `-v` activates the `--verbose` option. This builds SciPy (or updates an existing build) and runs the tests.

To run tests on a particular submodule, such as `optimize`, use the `--submodule` option:

```
python runtests.py -v -s optimize
```

To run a particular test module, use the `--test` option:

```
python runtests.py -v -t scipy.<module>.tests.<test_file>
```

Example for `scipy/optimize/tests/test_linprog.py` file tests, run:

```
python runtests.py -v -t scipy.optimize.tests.test_linprog
```

To run a test class:

```
python runtests.py -v -t scipy.<module>.tests.<test_file>::<TestClass>
```

Example for `TestLinprogRSCommon` class from `test_linprog.py`:

```
python runtests.py -v -t scipy.optimize.tests.test_<linprog>::TestLinprogRSCommon
```

To run a particular test:
Example for `test_unknown_solvers_and_options` from `test_linprog.py`:

```
python runtests.py -v -t scipy.optimize.tests.test_linprog::test_unknown_solvers_and_options
```

For tests within a class, you need to specify the class name and the test name:

```
python runtests.py -v -t scipy.<module>.tests.<test_file>::<TestClass>::<test_name>
```

Example:

```
python runtests.py -v -t scipy.optimize.tests.test_linprog::TestLinprogRSCommon::test_nontrivial_problem_with_guess
```

Other useful options include:

- `--coverage` to generate a test coverage report in `scipy/build/coverage/index.html`. *Note:* `pytest-cov` must be installed.
- `--doc` to build the docs in `scipy/doc/build`. By default, docs are built only in the html-scipyorg format, but you can change this by appending the name of the desired format (e.g. `--doc latex`).
- `--bench` to run all benchmarks. See *Benchmarking SciPy with airspeed velocity*.
- `--pep8` to perform pep8 check.
- `--mypy` to run mypy on the codebase.
- `--n` or `--no-build` to prevent SciPy from updating the build before testing
- `--j` or `--parallel n` to engage `n` cores when building SciPy; e.g. `python runtests.py --j 4` engages four cores. As of #10172 this also runs the tests on four cores if `pytest-xdist` is installed.
- `--m` or `--mode full` to run the full test suite, including slow tests. For example, `python runtests.py --m full`.
- `--` to send remaining command line arguments to `pytest` instead of `runtest.py`. For instance, while `--n` sent to `pytest.py` activates the `--no-build` option, `--n` sent to `pytest` runs the tests on multiple cores; e.g. `python runtests.py -- --n 4` runs tests using four cores. *Note:* `pytest-xdist` must be installed for testing on multiple cores.

Other options not documented here are listed in the main function of the source code for `runtests.py`. For much more information about `pytest`, see the `pytest` documentation.

### 4.17.1 Tips:

If you built SciPy from source but are having trouble running tests after a change to the codebase, try deleting the `scipy/build` directory. This forces `runtest.py` to completely rebuild SciPy before performing tests.

There is an additional level of very slow tests (several minutes), which are disabled even when calling `python runtests.py --m full`. They can be enabled by setting the environment variable `SCIPY_XSLOW=1` before running the test suite.
4.18 Benchmarking SciPy with airspeed velocity

This document introduces benchmarking, including reviewing SciPy benchmark test results online, writing a benchmark test, and running it locally. For a video run-through of writing a test and running it locally, see Benchmarking SciPy.

As written in the airspeed velocity (asv) documentation:

Airspeed velocity (asv) is a tool for benchmarking Python packages over their lifetime. Runtime, memory consumption, and even custom-computed values may be tracked. The results are displayed in an interactive web frontend that requires only a basic static webserver to host.

To see what this means, take a look at airspeed velocity of an unladen scipy. Each plot summarizes the execution time of a particular test over the commit history of the project; that is, as each commit is merged, the benchmark test is run, its execution time is measured, and the elapsed time is plotted. In addition to tracking the performance of the code, a commit is intended to affect, running all benchmarks for each commit is helpful for identifying unintentional regressions: significant increases in the execution time of one or more benchmark tests. As SciPy is a web of interconnected code, the repercussions of a small change may not be immediately obvious to a contributor, so this benchmark suite makes it easier to detect regressions and identify the commit that caused them. When you contribute a substantial new feature - or notice a feature that doesn’t already have a benchmark test - please consider writing benchmarks.

4.18.1 Writing benchmarks

The Writing benchmarks section of the airspeed velocity documentation is the definitive guide to writing benchmarks. Please see also the SciPy benchmarks readme.

To see how benchmarks are written, take a look at scipy/benchmarks/benchmarks/optimize_linprog.py. Each subclass of Benchmark defines a benchmark test. For example, the KleeMinty class defines a benchmark test based on the Klee-Minty hypercube problem, a diabolical test of the simplex algorithm for linear programming. The class has four parts:

- **setup** prepares the benchmark to run. The execution time of this function is not counted in the benchmark results, so this is a good place to set up all variables that define the problem. In the KleeMinty example, this involves generating arrays c, A_ub, and b_ub corresponding with a Klee-Minty hypercube in dims dimensions and storing them as instance variables.

- **time_klee_minty** actually runs the benchmark test. This function executes after a KleeMinty object has been instantiated and setup has run, so it gets the arrays defining the problem from self. Note that the prefix time in the function name indicates to asv that the execution time of this function is to be counted in the benchmark results.

- **params** is a list of lists defining parameters of the test. Benchmarks are run for all possible combinations of these parameters. For example, the first time the benchmark is run, the first element of methods (simplex) is passed into setup and time_klee_minty as the first argument, meth, and the first element of [3, 6, 9] (3) is passed into setup and time_klee_minty as the second argument, dims. The next time the benchmark is run, setup and time_klee_minty are passed revised simplex and 6 as arguments, and so this continues until all combinations of parameters have been used.

- **param_names** is a list of human-readable names for each element of the params list. These are used for presenting results.

Results of this benchmark over the past few years are available by clicking on the KleeMinty.time_klee_minty link at airspeed velocity of an unladen scipy. Note that each trace of the plot corresponds with a combination of benchmark parameters and environment settings (e.g., the Cython version), and that the visibility of the traces can be toggled using the control panel on the left.
4.18.2 Running benchmarks locally

Before beginning, ensure that airspeed velocity is installed.

After contributing new benchmarks, you should test them locally before submitting a pull request.

To run all benchmarks, navigate to the root SciPy directory at the command line and execute:

```
python runtests.py --bench
```

where `--bench` activates the benchmark suite instead of the test suite. This builds SciPy and runs the benchmarks. *(Note: this could take a while. Benchmarks often take longer to run than unit tests, and each benchmark is run multiple times to measure the distribution in execution times.)*

To run benchmarks from a particular benchmark module, such as `optimize_linprog.py`, simply append the file-name without the extension:

```
python runtests.py --bench optimize_linprog
```

To run a benchmark defined in a class, such as `KleeMinty` from `optimize_linprog.py`:

```
python runtests.py --bench optimize_linprog.KleeMinty
```

To compare benchmark results between the active branch and another, such as `master`:

```
python runtests.py --bench-compare master optimize_linprog.KleeMinty
```

All of the commands above display the results in plain text in the console, and the results are not saved for comparison with future commits. For greater control, a graphical view, and to have results saved for future comparison, you can use use the `asv` terminal command directly.

To use it, navigate to `scipy/benchmarks` in the console and then execute:

```
asv run
```

This command runs the whole benchmark suite and saves the results for comparison against future commits.

To run only a single benchmark, such as `KleeMinty` from `optimize_linprog.py`:

```
asv run --bench optimize_linprog.KleeMinty
```

One great feature of `asv` is that it can automatically run a benchmark not just for the current commit, but for every commit in a range. `linprog method='interior-point'` was merged into SciPy with commit `7fa17f2369e0e5ad055b23cc1a5ee079f9e8ca32`, so let’s run the `KleeMinty` benchmark for 10 commits between then and now to track its performance over time:

```
asv run --bench optimize_linprog.KleeMinty --steps 10 7fa17f..
```

*Note:* This will take a while, because SciPy has to be rebuilt for each commit! For more information about specifying ranges of commits, see the `git revisions` documentation.

To “publish” the results (prepare them to be viewed) and “preview” them in an interactive console:

```
asv publish
asv preview
```

4.18. Benchmarking SciPy with airspeed velocity 2875
ASV will report that it is running a server. Using any browser, you can review the results by navigating to http://127.0.0.1:8080 (local machine, port 8080).

For much more information about the asv commands, see the airspeed velocity Commands documentation. (Tip: check out the asv find command and the --quick, --skip-existing-commits, and --profile options for asv run.)

4.19 Adding Cython to SciPy

As written on the Cython website:

Cython is an optimising static compiler for both the Python programming language and the extended Cython programming language (based on Pyrex). It makes writing C extensions for Python as easy as Python itself.

If your code currently performs a lot of loops in Python, it might benefit from compilation with Cython. This document is intended to be a very brief introduction: just enough to see how to use Cython with SciPy. Once you have your code compiling, you can learn more about how to optimize it by reviewing the Cython documentation.

There are only two things you need to do in order for SciPy compile your code with Cython:

1. Include your code in a file with a .pyx extension rather than a .py extension. All files with a .pyx extension are automatically converted by Cython to .c files when SciPy is built.
2. Add an extension from this .c file to the configuration of the subpackage in which your code lives. Typically, this is very easy: add a single, formulaic line to the subpackage's setup.py file. Once added as an extension, the .c code will be compiled by your C compiler to machine code when SciPy is built.

4.19.1 Example

scipy.optimize._linprog_rs.py contains the implementation of the revised simplex method for scipy.optimize.linprog. The revised simplex method performs many elementary row operations on matrices, and so it was a natural candidate to be Cythonized.

Note that scipy/optimize/_linprog_rs.py imports the BGLU and LU classes from _bglu_dense exactly as if they were regular Python classes. But they're not. BGLU and LU are Cython classes defined in /scipy/optimize/_bglu_dense.pyx. There is nothing about the way they are imported or used that suggests that they are written in Cython; the only way so far that we can tell they are Cython classes is that they are defined in a file with a .pyx extension.

Even in /scipy/optimize/_bglu_dense.pyx, most of the code resembles Python. The most notable differences are the presence of cimport, cdef, and Cython decorators. None of these are strictly necessary. Without them, the pure Python code can still be compiled by Cython. The Cython language extensions are *just* tweaks to improve performance. This .py file is automatically converted to a .c file by Cython when SciPy is built.

The only thing left is to add an extension from this .c file using numpy.distutils. This takes just a single line in scipy/optimize/setup.py: config.add_extension('_bglu_dense', sources=['_bglu_dense.c']), _bglu_dense.c is the source and _bglu_dense is the name of the extension (for consistency). When SciPy is built, _bglu_dense.c will be compiled to machine code, and we will be able to import the LU and BGLU classes from the extension _bglu_dense.
4.19.2 Exercise

See a video run-through of this exercise: Cythonizing SciPy Code

1. Update Cython and create a new branch (e.g., `git checkout -b cython_test`) in which to make some experimental changes to SciPy.

2. Add some simple Python code in a `.py` file in the `/scipy/optimize` directory, say `/scipy/optimize/mypython.py`. For example:

   ```python
def myfun():
    i = 1
    while i < 1000000:
        i += 1
    return i
```

3. Let’s see how long this pure-Python loop takes so we can compare the performance of Cython. For example, in an IPython console in Spyder:

   ```python
   from scipy.optimize.mypython import myfun
   %timeit myfun()
   ```

   I get something like:

   715 ms ± 10.7 ms per loop

4. Save your `.py` file to a `.pyx` file, e.g., `mycython.pyx`.

5. Build SciPy. Note that a `.c` file has been added to the `/scipy/optimize` directory.

6. Somewhere near similar lines, add an extension from your `.c` file to `/scipy/optimize/setup.py`. e.g.:

   ```python
   config.add_extension('_group_columns', sources=['_group_columns.c'],)  # this was already here
   config.add_extension('mycython', sources=['mycython.c'])  # this was new
   config.add_extension('_bglu_dense', sources=['_bglu_dense.c'])  # was _already there
   ```

7. Rebuild SciPy. Note that a `.so` file has been added to the `/scipy/optimize` directory.

8. Time it:

   ```python
   from scipy.optimize.mycython import myfun
   %timeit myfun()
   ```

   I get something like:

   359 ms ± 6.98 ms per loop

   Cython sped up the pure Python code by a factor of ~2.

9. That’s not much of an improvement in the scheme of things. To see why, it helps to have Cython create an “annotated” version of our code to show bottlenecks. In a terminal window, call Cython on your `.pyx` file with the `--a` flag:

   ```bash
cython --a scipy/optimize/mycython.pyx
   ```

   Note that this creates a new `.html` file in the `/scipy/optimize` directory. Open the `.html` file in any browser.
10. The yellow-highlighted lines in the file indicate potential interaction between the compiled code and Python, which slows things down considerably. The intensity of the highlighting indicates the estimated severity of the interaction. In this case, much of the interaction can be avoided if we define the variable `i` as an integer so that Cython doesn't have to consider the possibility of it being a general Python object:

```python
def myfun():
cdef int i = 1  # our first line of Cython code
while i < 10000000:
    i += 1
return i
```

Recreating the annotated .html file shows that most of the Python interaction has disappeared.

11. Rebuild SciPy, open a fresh IPython console, and `%timeit`:

```python
from scipy.optimize.mycython import myfun
%timeit myfun()
```

I get something like: 68.6 ns ± 1.95 ns per loop. The Cython code ran about 10 million times faster than the original Python code.

In this case, the compiler probably optimized away the loop, simply returning the final result. This sort of speedup is not typical for real code, but this exercise certainly illustrates the power of Cython when the alternative is many low-level operations in Python.

### 4.20 Public Cython APIs

As of Apr 2020, the following modules in SciPy expose functionality via a public `cdef` Cython API declarations:

- `scipy.linalg.cython_blas`
- `scipy.linalg.cython_lapack`
- `scipy.optimize.cython_optimize`
- `scipy.special.cython_special`

This uses Cython's declaration sharing features, where shared `cdef` items are declared in `.pxd` files that are distributed together with the corresponding DLL/SO files in binary SciPy installations.

#### 4.20.1 Application Binary Interface

Using these features in SciPy however requires SciPy contributors to take additional care with regard to maintaining Application Binary Interface (ABI) stability. This is similar to developing libraries in C, and different from how backward compatibility works in pure Python.

The main difference to Python originates from the fact that the declarations in the header `.pxd` files are used when code written by users is compiled, but they must also match with what is available in SciPy when the user code is imported.

User code may be compiled with one version of SciPy, and the compiled binary (which uses the binary interface declared in the `.pxd` files) can be used with a different SciPy version installed on the system. If the interfaces are not compatible, either an exception is raised or runtime memory corruption and crash ensue.

At import time, Cython checks that signatures of functions in the installed SciPy SO/DLL file match the one in the `.pxd` file used by the user during compilation, and raises a Python exception if there is a mismatch. If the SciPy code is structured correctly (see below), this check is performed only for functions that are actually imported in the user code.
We rely on this feature to provide a runtime safety check, which makes it easier for the users to detect incompatible SciPy versions via Python exceptions, instead of hard-to-trace runtime crashes.

4.20.2 ABI stability aim

SciPy aims to maintain ABI stability in Cython code, in the following sense:

- Binaries produced by compiling user source with one version of SciPy, are compatible with any other SciPy version with which the source code can be compiled.
- Trying to use an incompatible version of SciPy at runtime will result in a Python exception at user module import time.
- Trying to use an incompatible version of SciPy at compile time will result in a Cython error.

This means that users can use any compatible version of SciPy to compile binaries without having to pay attention to ABI, i.e.,

$$ABI \text{ compatibility} = API \text{ compatibility}$$

Cython API backward/forward compatibility will be handled with a similar deprecation/removal policy as for the Python API, see Deprecations.

4.20.3 Implementing ABI stability in SciPy

The following rules in development of Cython APIs in SciPy are necessary to maintain the ABI stability aim above:

- Adding new cdef declarations (functions, structs, types, etc.) is allowed.
- Removing cdef declarations is allowed, but should follow general deprecation/removal policy.
- cdef declarations of functions may be changed.
  However, changes result in a backward incompatible API change which breaks any code using the changed signature, and should follow general deprecation/removal policy.
- cdef declarations of anything else (e.g. struct, enum, and types) are final. Once a declaration is exposed in the public Cython API in a released SciPy version, it must not be changed.
  If changes are necessary, they need to be carried out by adding new declarations with different names, and removing old ones.
- cdef classes are not allowed in the public APIs (TBD: backward compatibility of cdef classes needs more research, but must not be allowed when we are not sure)
- For each public API module (as in scipy.linalg.cython_blas), use a single interface .pxd declaration file.
  The public interface declaration file should not contain cimport statements. If it does, Cython’s signature check will check all of the cimported functions, not only the ones that are used by user code, so that changing one of them breaks the whole API.
- If data structures are necessary, prefer opaque structs in the public API. The interface declarations should not contain any declarations of struct members. Allocation, freeing, and attribute access of data structures should be done with functions.
4.20.4 Deprecating public Cython APIs

To deprecate a public Cython API function, for example:

```python
# scipy/something/foo.pxd
cdef public int somefunc()

# scipy/something/foo.pyx
cdef public int somefunc():
    return 42
```

you can add use the `scipy._lib.deprecation.deprecate_cython_api` function to do the deprecations at the end of the corresponding .pyx file:

```python
# scipy/something/foo.pyx
cdef public int somefunc():
    return 42

from scipy._lib.deprecation import deprecate_cython_api
import scipy.something.foo as mod
deprecate_cython_api(mod, "somefunc", new_name="scipy.something.newfunc",
                     message="Deprecated in Scipy 1.5.0")
decl deprecate_cython_api, mod
```

After this, Cython modules that `cimport` `somefunc`, will emit a `DeprecationWarning` at import time.

There is no way to deprecate Cython data structures and types. They can be however removed after all functions using them in the API are removed, having gone through the deprecation cycle.

Whole Cython modules can be deprecated similarly as Python modules, by emitting a `DeprecationWarning` on the top-level.

4.21 Adding New Methods, Functions, and Classes

While adding code to SciPy is in most cases quite straight forward, there are a few places where that is not the case. This document contains detailed information on some specific situations where it may not be clear from the outset what is involved in the task.

4.21.1 Adding A New Statistics Distribution

For hundreds of years statisticians, mathematicians and scientists have needed to understand, analyze and model data. This has led to a plethora of statistics distributions, many of which are related to others. Modeling of new types of data continues to give rise to new distributions, as does theoretical considerations being applied to new disciplines. SciPy models about a dozen discrete distributions `Discrete Statistical Distributions` and 100 continuous distributions `Continuous Statistical Distributions`.

To add a new distribution, a good reference is needed. Scipy typically uses [JKB] as its gold standard, with Wikipedia articles often providing some extra details and/or graphical plots.
How to create a new continuous distribution

There are a few steps to be done to add a continuous distribution to SciPy. (Adding a discrete distribution is similar). We'll use the fictitious “Squirrel” distribution in the instructions below.

Before Implementation

1. See if Squirrel has already been implemented—that saves a lot of effort!
   - It may have been implemented with a different name.
   - It may have been implemented with a different parameterization (shape parameters).
   - It may be a specialization of a more general family of distributions.

   It is very common for multiple disciplines to discover/rediscover a distribution (or a specialization or different parameterization). There are a few existing SciPy distributions which are specializations of other distributions. E.g. The scipy.stats.arcsine distribution is a specialization of the scipy.stats.beta distribution. These duplications exist for (very!) historical and widespread usage reasons. At this time, adding new specializations/reparametrizations of existing distributions to SciPy is not supported, mainly due to the increase in user confusion resulting from such additions.

2. Create a SciPy Issue on github, listing the distribution, references and reasons for its inclusion.

Implementation

1. Find an already existing distribution similar to Squirrel. Use its code as a template for Squirrel.

2. Read the docstring for class rv_continuous in scipy/stats/_distn_infrastructure.py.

3. Write the new code for class squirrel_gen and insert it into scipy/stats/_continuous_distns.py, which is in (mostly) alphabetical order by distribution name.

4. Does the distribution have infinite support? If not, left and/or right endpoints a, b need to be specified in the call to squirrel_gen(name='squirrel', a=?, b=?).

5. If the support depends upon the shape parameters, squirrel_gen._get_support() needs to be implemented.

6. The default inherited _argcheck() implementation checks that the shape parameters are positive. Create a more appropriate implementation.

7. If squirrel_gen.ppf() is expensive to compute relative to squirrel_gen.pdf(), consider setting the momtype in the call to squirrel_gen().

8. If squirrel_gen.rvs() is expensive to compute, consider implementing a specific squirrel_gen._rvs().

9. Add the name to the listing in the docstring of scipy/stats/__init__.py.

10. Add the name and a good set of example shape parameters to the distcont list in scipy/stats/_distr_params.py. These shape parameters are used both for testing and automatic documentation generation.

11. Add the name and an _invalid_ set of example shape parameters to the list in invdistcont, also in _distr_params.py. These shape parameters are also used for testing.

12. Add a TestSquirrel class and any specific tests to scipy/stats/tests/test_distributions.py.

13. Run and pass(!) the tests.
After Implementation

1. Add a tutorial `doc/source/tutorial/stats/continuous_squirrel.rst`
2. Add it to the listing of continuous distributions in `doc/source/tutorial/stats/continuous.rst`
3. Update the number of continuous distributions in the example code in `doc/source/tutorial/stats.rst`
4. Build the documentation successfully
5. Submit a PR

References

4.22 Continuous Integration

Continuous integration is part of our development process and ensure that every piece of code or documentation which is contributed to SciPy is working and does not have unforeseen effects.

**Note:** Before submitting or updating your PR, please ensure that you tested your changes locally. See Checklist before submitting a PR and Running SciPy Tests Locally.

4.22.1 Workflows

We run more than 20 different workflows with different versions of the dependencies, different architectures, etc. A PR must pass all these checks before it can be merged as to ensure a sustainable state of the project.

Apart from the unit tests, the documentation and examples in the docstrings are also checked. These are common failing workflows as Sphinx and doctests have very strict rules. These aspects are very important as documentation and examples are user facing elements. Ensures that these elements are properly rendered.

The logs can be long, but you will always find out why your build/test did not pass a check. Simply click on Details to access the logs.

Following is a list of all the different workflows in use. They are grouped by CI resources providers.

**GitHub Actions**

- **Linux Tests:** test suite runs for Linux (x86_64)
- **macOS Tests:** test suite runs for macOS (x86_64)

Test suite runs on GitHub Actions and other platforms cover a range of test/environment conditions: Python and NumPy versions (lowest-supported to nightly builds), 32-bit vs. 64-bit, different compilers, and more - for details, see the `.yml` configuration files.
Azure

- **Lint**: PEP8 and code style
- Windows Python: test suite runs for Windows
- Linux_Python_37_32bit_full
- wheel_optimized_gcc48
- source_distribution: install via sdist, then run the test suite
- refguide_asv_check: doctests from examples and benchmarks

CircleCI

- build_docs: build the documentation
- build_docs artifact: live preview of the documentation
- build_scipy
- run_benchmarks: verify how the changes impact performance

Codecov

- **patch**: the impact on code coverage due to your changes
- **project**: the coverage of the whole project

4.22.2 Skipping

Being an open-source project, we have access to a quota of CI resources. Ultimately, resources are limited and we should use them with care. This is why we ask you to verify your changes locally before pushing them.

Depending on the proposed change, you might want to skip part of the checks. It will be at the discretion of a maintainer to re-run some tests before integration.

Skipping CI can be achieved by adding a special text in the commit message:

- [skip azp]: will skip Azure
- [skip actions]: will skip GitHub Actions
- [skip ci]: will skip **all** CI

Of course, you can combine these to skip multiple workflows.

This skip information should be placed on a new line. In this example, we just updated a .rst file in the documentation and ask to skip Azure and GitHub Actions’ workflows:

```
DOC: improve QMCEngine examples.
[skip azp] [skip actions]
```
This is the list of changes to SciPy between each release. For full details, see the commit logs.

5.1 SciPy 1.7.0 Release Notes

        - New scipy.stats.qmc module
  - Deprecated features
    - scipy.linalg deprecations
    - scipy.spatial deprecations
SciPy 1.7.0 is the culmination of 6 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Before upgrading, we recommend that users check that their own code does not use deprecated SciPy functionality (to do so, run your code with python -Wd and check for DeprecationWarnings). Our development attention will now shift to bug-fix releases on the 1.7.x branch, and on adding new features on the master branch.

This release requires Python 3.7+ and NumPy 1.16.5 or greater.

For running on PyPy, PyPy3 6.0+ is required.

5.1.1 Highlights of this release

• A new submodule for quasi-Monte Carlo, scipy.stats.qmc, was added
• The documentation design was updated to use the same PyData-Sphinx theme as NumPy and other ecosystem libraries.
• We now vendor and leverage the Boost C++ library to enable numerous improvements for long-standing weaknesses in scipy.stats
• scipy.stats has six new distributions, eight new (or overhauled) hypothesis tests, a new function for bootstrapping, a class that enables fast random variate sampling and percentile point function evaluation, and many other enhancements.
• cdist and pdist distance calculations are faster for several metrics, especially weighted cases, thanks to a rewrite to a new C++ backend framework
• A new class for radial basis function interpolation, RBFInterpolator, was added to address issues with the Rbf class.

We gratefully acknowledge the Chan-Zuckerberg Initiative Essential Open Source Software for Science program for supporting many of the improvements to scipy.stats.

5.1.2 New features

scipy.cluster improvements

An optional argument, seed, has been added to kmeans and kmeans2 to set the random generator and random state.
**scipy.interpolate improvements**

Improved input validation and error messages for `fitpack.bispev` and `fitpack.parder` for scenarios that previously caused substantial confusion for users.

The class `RBFInterpolator` was added to supersede the `Rbf` class. The new class has usage that more closely follows other interpolator classes, corrects sign errors that caused unexpected smoothing behavior, includes polynomial terms in the interpolant (which are necessary for some RBF choices), and supports interpolation using only the k-nearest neighbors for memory efficiency.

**scipy.linalg improvements**

An LAPACK wrapper was added for access to the `tgexc` subroutine.

**scipy.ndimage improvements**

`scipy.ndimage.affine_transform` is now able to infer the `output_shape` from the `out` array.

**scipy.optimize improvements**

The optional parameter `bounds` was added to `_minimize_neldermead` to support bounds constraints for the Nelder-Mead solver.

trustregion methods trust-krylov, dogleg and trust-ncg can now estimate `hess` by finite difference using one of ["2-point", "3-point", "cs"].

halton was added as a `sampling_method` in `scipy.optimize.shgo`. sobol was fixed and is now using `scipy.stats.qmc.Sobol`.

halton and sobol were added as init methods in `scipy.optimize.differential_evolution`.

differential_evolution now accepts an `x0` parameter to provide an initial guess for the minimization.

least_squares has a modest performance improvement when SciPy is built with Pythran transpiler enabled.

When linprog is used with method 'highs', 'highs-ipm', or 'highs-ds', the result object now reports the marginals (AKA shadow prices, dual values) and residuals associated with each constraint.

**scipy.signal improvements**

`get_window` supports general cosine and general hamming window functions.

`scipy.signal.medfilt2d` now releases the GIL where appropriate to enable performance gains via multithreaded calculations.
**scipy.sparse improvements**

Addition of `dia_matrix` sparse matrices is now faster.

**scipy.spatial improvements**

`distance.cdist` and `distance.pdist` performance has greatly improved for certain weighted metrics. Namely: minkowski, euclidean, chebyshev, canberra, and cityblock.

Modest performance improvements for many of the unweighted `cdist` and `pdist` metrics noted above.

The parameter `seed` was added to `scipy.spatial.vq.kmeans` and `scipy.spatial.vq.kmeans2`.

The parameters `axis` and `keepdims` were added to `scipy.spatial.distance.jensenshannon`.

The rotation methods `from_rotvec` and `as_rotvec` now accept a `degrees` argument to specify usage of degrees instead of radians.

**scipy.special improvements**

Wright’s generalized Bessel function for positive arguments was added as `scipy.special.wright_bessel`.

An implementation of the inverse of the Log CDF of the Normal Distribution is now available via `scipy.special.ndtri_exp`.

**scipy.stats improvements**

**Hypothesis Tests**

The Mann-Whitney-Wilcoxon test, `mannwhitneyu`, has been rewritten. It now supports n-dimensional input, an exact test method when there are no ties, and improved documentation. Please see “Other changes” for adjustments to default behavior.

The new function `scipy.stats.binomtest` replaces `scipy.stats.binom_test`. The new function returns an object that calculates a confidence intervals of the proportion parameter. Also, performance was improved from O(n) to O(log(n)) by using binary search.

The two-sample version of the Cramer-von Mises test is implemented in `scipy.stats.cramervonmises_2samp`.

The Alexander-Govern test is implemented in the new function `scipy.stats.alexandergovern`.

The new functions `scipy.stats.barnard_exact` and `scipy.stats.boschloo_exact` respectively perform Barnard’s exact test and Boschloo’s exact test for 2x2 contingency tables.

The new function `scipy.stats.page_trend_test` performs Page’s test for ordered alternatives.

The new function `scipy.stats.somersd` performs Somers’ D test for ordinal association between two variables.

An option, `permutations`, has been added in `scipy.stats.ttest_ind` to perform permutation t-tests. A `trim` option was also added to perform a trimmed (Yuen’s) t-test.

The alternative parameter was added to the `skewtest`, `kurtosistest`, `ranksums`, `mood`, `ansari`, `linregress`, and `spearmanr` functions to allow one-sided hypothesis testing.
Sample statistics

The new function `scipy.stats.differential_entropy` estimates the differential entropy of a continuous distribution from a sample.

The `boxcox` and `boxcox_normmax` now allow the user to control the optimizer used to minimize the negative log-likelihood function.

A new function `scipy.stats.contingency.relative_risk` calculates the relative risk, or risk ratio, of a 2x2 contingency table. The object returned has a method to compute the confidence interval of the relative risk.

Performance improvements in the `skew` and `kurtosis` functions achieved by removal of repeated/redundant calculations.

Substantial performance improvements in `scipy.stats.mstats.hdquantiles_sd`.

The new function `scipy.stats.contingency.association` computes several measures of association for a contingency table: Pearson's contingency coefficient, Cramer's V, and Tschuprow's T.

The parameter `nan_policy` was added to `scipy.stats.zmap` to provide options for handling the occurrence of `nan` in the input data.

The parameter `ddof` was added to `scipy.stats.variation` and `scipy.stats.mstats.variation`.

The parameter `weights` was added to `scipy.stats.gmean`.

Statistical Distributions

We now vendor and leverage the Boost C++ library to address a number of previously reported issues in `stats`. Notably, `beta`, `binom`, `nbinom` now have Boost backends, and it is straightforward to leverage the backend for additional functions.

The skew Cauchy probability distribution has been implemented as `scipy.stats.skewcauchy`.

The Zipfian probability distribution has been implemented as `scipy.stats.zipfian`.

The new distributions `nchypergeom_fisher` and `nchypergeom_wallenius` implement the Fisher and Wallenius versions of the noncentral hypergeometric distribution, respectively.

The generalized hyperbolic distribution was added in `scipy.stats.genhyperbolic`.

The studentized range distribution was added in `scipy.stats.studentized_range`.

`scipy.stats.argus` now has improved handling for small parameter values.

Better argument handling/preparation has resulted in performance improvements for many distributions.

The `cosine` distribution has added ufuncs for `ppf`, `cdf`, `sf`, and `isf` methods including numerical precision improvements at the edges of the support of the distribution.

An option to fit the distribution to data by the method of moments has been added to the `fit` method of the univariate continuous distributions.

Other

`scipy.stats.bootstrap` has been added to allow estimation of the confidence interval and standard error of a statistic.

The new function `scipy.stats.contingency.crosstab` computes a contingency table (i.e. a table of counts of unique entries) for the given data.

`scipy.stats.NumericalInverseHermite` enables fast random variate sampling and percentile point function evaluation of an arbitrary univariate statistical distribution.
New `scipy.stats.qmc` module

This new module provides Quasi-Monte Carlo (QMC) generators and associated helper functions.

It provides a generic class `scipy.stats.qmc.QMCEngine` which defines a QMC engine/sampler. An engine is state aware: it can be continued, advanced and reset. 3 base samplers are available:

- `scipy.stats.qmc.Sobol` the well known Sobol low discrepancy sequence. Several warnings have been added to guide the user into properly using this sampler. The sequence is scrambled by default.
- `scipy.stats.qmc.Halton` Halton low discrepancy sequence. The sequence is scrambled by default.
- `scipy.stats.qmc.LatinHypercube` plain LHS design.

And 2 special samplers are available:

- `scipy.stats.qmc.MultinomialQMC` sampling from a multinomial distribution using any of the base `scipy.stats.qmc.QMCEngine`.

The module also provide the following helpers:

- `scipy.stats.qmc.discrepancy` assess the quality of a set of points in terms of space coverage.
- `scipy.stats.qmc.update_discrepancy` can be used in an optimization loop to construct a good set of points.
- `scipy.stats.qmc.scale` easily scale a set of points from (to) the unit interval to (from) a given range.

5.1.3 Deprecated features

`scipy.linalg` deprecations

- `scipy.linalg.pinv2` is deprecated and its functionality is completely subsumed into `scipy.linalg.pinv`

  Both `rcond`, `cond` keywords of `scipy.linalg.pinv` and `scipy.linalg.pinvh` were not working and now are deprecated. They are now replaced with functioning `atol` and `rtol` keywords with clear usage.

`scipy.spatial` deprecations

- `scipy.spatial.distance` metrics expect 1d input vectors but will call `np.squeeze` on their inputs to accept any extra length-1 dimensions. That behaviour is now deprecated.

5.1.4 Backwards incompatible changes

5.1.5 Other changes

We now accept and leverage performance improvements from the ahead-of-time Python-to-C++ transpiler, Pythran, which can be optionally disabled (via `export SCIPY_USE_PYTHRAN=0`) but is enabled by default at build time.

There are two changes to the default behavior of `scipy.stats.mannwhitneyu`:

- For years, use of the default `alternative=None` was deprecated; explicit `alternative` specification was required. Use of the new default value of `alternative`, “two-sided”, is now permitted.
- Previously, all p-values were based on an asymptotic approximation. Now, for small samples without ties, the p-values returned are exact by default.

Support has been added for PEP 621 (project metadata in `pyproject.toml`)

We now support a Gitpod environment to reduce the barrier to entry for SciPy development; for more details see `quickstart-gitpod`.

5.1.7 Issues closed for 1.7.0

• #636: Statistics Review: mannwhitneyu (Trac #109)
• #1346: signal.medfilt2d should fall back on signal.medfilt for types…
• #2118: Mann-Whitney statistic returns incorrect results (Trac #1593)
• #2158: special.chndtrix (ncx2.ppf) gives wrong results (Trac #1633)
• #3284: build_sphinx weirdness
• #3352: beta distribution sf
• #4067: Mannwhitneyu with arrays full of nan still reports significance
5.1. SciPy 1.7.0 Release Notes

- #4080: entropy in Scipy
- #4641: mstats.mannwhitneyu and stats.mannwhitneyu return inconsistent…
- #5122: scipy.stats.binom.ppf Incorrect for p=0
- #5180: Rbf interpolation - use only K nearest neighbors
- #5258: affine_transform complains about output_shape when output array…
- #5562: Wishart degrees of freedom should be $v > p-1$ instead of $v…
- #5933: mstats_basic.py - mannwhitneyu [scipy/scipy/stats/mstats_basic.py]
- #6409: unequal_var_ttest_denom causes ZeroDivisionError in early samples
- #6682: negative binomial survival function is imprecise
- #6897: scipy.stats.mannwhitneyu of empty sets gives p=0.0 and does not…
- #7303: stats.describe with nan_policy=omit returns matrix-wide minmax…
- #7406: scipy.stats.binom.ppf returns nan for q between 0 and 1 if n…
- #7437: ENH: add skewed Cauchy distribution to stats
- #7542: DOC: stats tutorials: Questions on arcsine and Student t formulae
- #7593: Meaning of ‘tol’ argument in ‘scipy.optimize.minimize’ is…
- #8565: Error in SmoothSphereBivariateSpline(): “ValueError: Error code…
- #8665: ‘scipy.ncx2.sf’ should be monotone decreasing
- #8836: scipy.optimize.linprog(method='simplex') needs to return duals
- #9184: Mann-Whitney implementation wrong?
- #9450: allow seeding of init methods in vq.kmeans2
- #9704: RectSphereBivariateSpline fails for negative longitude
- #9836: scipy.stats.rice gives incorrect results when s is very low compared…
- #9904: Request/Proposal: Greatly improve scipy.interpolate.Rbf
- #9981: stats.kruskal : add a warning for an input with 2 or more columns
- #10358: DOC: linprog and linear_sum_assignment tutorials needed
- #10908: Nakami fitting doesn’t converge (scipy.stats)
- #10933: Add scaled inverse chi2 distribution
- #11014: Barnard’s Test for More Powerful Hypothesis Testing of 2x2 Contingency…
- #11050: Feature request: Nelder-Mead with bounds
- #11086: scipy.stats.skew doesn’t work correctly for float point numbers
- #11113: inconsistent result from ttest_ind and mannwhitneyu when used…
- #11134: Wrong confidence interval for binomial distribution with p=0
- #11325: Add axis parameter for scipy.spatial.distance.jensenshannon
- #11474: scipy.stats.skellam.cdf(0) returns 0 for large mu1 = mu2
- #11523: scipy.stats.zipf doesn’t implement zipf distribution
- #11848: How to get Lagrange / lambda multipliers out of ‘linprog’ optimize…
- #11909: Enable bounds for lambda in boxcox
- #12118: Docstring missing defaults
- #12132: Slow tests to be trimmed or moved to test('full')
- #12230: Dendrogram: enable leaves labelling with 'labels' when using...
- #12282: scipy.stats.chisquare test does not check that observed and expected...
- #12298: BUG: fmin_powell missing squeeze in 1.5.0rc
- #12403: Add nan_policy to stats.zmap
- #12518: Null hypothesis of Kolmogorov Smirnov test is not correctly described
- #12534: Feature request: scipy.linalg.norm to deal with 0-size array
- #12622: scipy.interpolate.interpn docstring example
- #12635: scipy.stats.beta.ppf gives unexpected results
- #12669: Median-averaging of complex CSDs
- #12731: stats.ncx2.cdf fails for nc >> x >> 1
- #12778: Confusing documentation of scipy.stats.weightedtau
- #12794: [Bug] The result of stats.beta.isf is inconsistent with stats.beta.sf
- #12837: stats.mannwhitneyu could support arrays
- #12868: Vector-valued interpolation in `interp2d`
- #12922: Minimize with trust-constr method leads to TypeError if option...
- #12929: The use of starred expressions to create data detracts from understanding...
- #12965: domain of argument of scipy.interpolate.RectSphereBivariateSpline(u,...
- #13025: Generalized Hyperbolic Distribution
- #13090: Broken link in doc for signal.max_len_seq
- #13101: MAINT: Upgrade python version in docker file
- #13158: `signal.get_window()` has a missing doc link and cannot get...
- #13173: Uninformative error message from bisplev function
- #13234: BUG: stats: Wrong shape of burr.moment() and fisk.moment() when...
- #13242: Does kmeans “drop” clusters?
- #13243: tgsen uses an output argument for computing a default argument
- #13245: Kurtosis returning 1 for array of same elements
- #13257: GitHub Actions test failures for MacOS
- #13272: scipy.stats.yeojohnson_llf doc mistake
- #13280: Wrong results with hypergeom cdf
- #13285: description correction in scipy.stats.t
- #13287: Generate binomial CDF with mu instead of prob
- #13294: BUG: stats: wrong bounds returned by ‘support’ method for distributions...
- #13299: Typing for scipy.spatial
• #13300: Add a single individual to a latinhypercube initial population…
• #13311: MAINT: pavement.py PYVER is outdated

5.1.8 Pull requests for 1.7.0

- #4824: Permutation Test (new PR)
- #4933: ENH: Update the Mann-Whitney-Wilcoxon test
- #7702: ENH: stats: Add Skewed Cauchy Distribution
- #8306: Optional Pythran support for scipy.signal.max_len_seq_inner
- #10170: MAINT: stats: Implement cdf and ppf as ufuncs for the cosine…
- #10454: ENH: Extend find_peaks_cwt to take numbers and iterables for…
- #10844: ENH: add stats.qmc module with quasi Monte Carlo functionality
- #11313: ENH: add Wright’s generalized Bessel function
- #11352: ENH: stats: Add crosstab function.
- #11477: FIX: bounded parameter in cdffcn.f gives bad results
- #11695: ENH: stats: add method of moments to ‘rv_continuous.fit’
- #11911: ENH: Added bounds to boxcox and boxcox_normmax
- #12438: BUG: use ellipkm1 in elliptical filter design to prevent numerical…
- #12531: ENH: stats: add Page’s L test
- #12603: ENH: stats: Add `binomtest` to replace `binom_test`.
- #12653: ENH: stats: add Somers’ D test
- #12676: BUG: update median averaging in signal.csd
- #12760: BUG: special: erfinv(x<<1) loses precision
- #12801: ENH: Add single-sided p-values to remaining spearmanr and linregress
- #12873: ENH: Stats: add Alexander Govern Test
- #13008: ENH: Add ‘alternative’ to functions using normal CDF for p-value
- #13040: BUG: Allow RectSphereBivariateSpline to accept negative longitude
- #13048: ENH: stats: Add a function that computes the relative risk.
- #13067: ENH: Add weights parameter to stats.gmean
- #13084: ENH: fast Hankel transform
- #13104: MAINT: upgrade python version (drop python 3.6) for docker dev…
- #13153: ENH: added association measurements Pearsons Contingency Coefficient,…
- #13166: ENH: stats: Add nan_policy to zmap.
- #13175: MAINT: tests for tall cost matrices in ‘linear_sum_assignment’
- #13177: BUG: raise NotImplementedError in fourier_ellipsoid when ndim…
- #13184: BUG: stats: Fix min and max calculation of mstats.describe with…
- #13188: DOC: stats: make null and alternative hypotheses of kstest more…
- #13193: MAINT: stats: chisquare check sum of observed/expected frequencies
- #13197: ENH/MAINT: HiGHs upstream enhancements and bug fixes
- #13198: ENH: allow inference of output_shape from out array in affine_transform
- #13204: ENH: stats: add Zipfian (different from Zipf/zeta) distribution
- #13208: REL: set version to 1.7.0.dev0
- #13216: TST: stats: break up and mark slow tests
- #13224: Update docs for the weighted τ
- #13230: ENH: linalg: Add LAPACK wrapper for tgeuc.
- #13232: MAINT: stats: raise error when input to kruskal has >1 dim
- #13233: DOC: stats: fix MGF of arcsine and entropy of t in tutorial
- #13236: MAINT: reorganize shared linear assignment tests
- #13237: BENCH: Refactor stats.Distribution to easily add new distributions
- #13238: BUG: stats: fix wrong shape output of burr and fisk distributions
- #13240: MAINT: add tests of trivial cost matrices for linear sum assignment
- #13254: BUG: Fix precision issues for constant input in skew and kurtosis
- #13262: BUG: scipy.medfilt and .medfilt2d fixes
- #13263: ENH: add Cramer-von Mises test for two samples
- #13264: fix a minor typo in `stats.anderson` doc
- #13268: ENH: stats: Add implementation of _entropy for the t distr.
- #13273: DOC: stats: fix typo in Yeo-Johnson LL function documentation
- #13275: MAINT: stats: Correct a comment in the _fitstart method of gamma.
- #13283: BUG: stats: fix the cdf method of rv_discrete class
- #13286: DOC: stats: clarify rv_continuous/discrete.stats example
- #13288: DOC: stats: discrete distribution shape parameter restrictions
- #13289: MAINT: fix a build warning in sigtoolsmodule.c
- #13290: DOC: Expand the discussion of the nan_policy API.
- #13291: MAINT: signal, stats: Use keepdims where appropriate.
- #13292: DOC: stats: note another common parameterization of nbinom
- #13293: DOC: Change broken link for default values to archived link
- #13295: BUG: stats: fix the support method to return correct bounds
- #13296: DOC: stats: Fix latex markup in the kstwo docstring.
- #13297: TST: mark kde.logpdf overflow test as xslow
- #13298: Generalized Hyperbolic Distribution
- #13301: DOC: cluster: Add cluster number note to the docstring of cluster.vq.kmeans
- #13302: BUG: Fix ndimage.morphology.distance_transform_* argument handling
- #13303: CI: prevent Codecov giving false CI failures and wrong PR annotations
- #13313: ENH: static typing for qhull
- #13316: Pythran implementation of scipy.signal._spectral
- #13317: DOC: forward port 1.6.0 relnotes
- #13319: ENH: stats: add fast numerical inversion of distribution CDF
- #13320: ENH: x0 for differential_evolution
- #13324: DOC correct linprog highs version added to 1.6
- #13326: MAINT: update numpydoc to v1.1.0
- #13327: DOC: interpolate: improved docstring examples of `interpolate.interpn()`
- #13328: ENH: Boost stats distributions
- #13330: ENH: stats: add noncentral hypergeometric distributions (Fisher’s…
- #13331: MAINT/ENH: resolve mypy warnings/errors
- #13332: DOC: interpolate: improved docstring of `interpolate.interp2d`…
- #13333: ENH: stats: Some more _sf and _isf implementations.
- #13334: MAINT: stats: Clean up a few defunct comments in _continuous_distns.py
- #13336: Pythran version of scipy.optimize._group_columns
- #13337: DOC/ENH: type hinting in scipy.integrate.simpson
- #13346: ENH: stats: add 'ddof' parameter to the 'variation' function
- #13360: ENH/DOC: fix docstring and input validation in interpolate.RectSphereBivariateSpline
- #13366: BUG: stats: Don't raise ZeroDivisionError in _unequal_var_ttest_denom
- #13370: ENH: fix ARGUS distribution for small parameters in stats
- #13371: ENH: stats: add 'bootstrap' for estimating confidence interval…
- #13373: BUG: io/matlab: preserve dimensions of empty >=2D arrays
- #13374: ENH: stats: add skewed Cauchy distribution
- #13379: BUG: sparse: fix verbosity in sparse lq
- #13383: TST: stats: mark many dimension permutation t-test slow
- #13384: MAINT: Make keywords array static
- #13388: PERF: Avoid duplicate mean calculations in skew and kurtosis
- #13389: DOC: Fix deprecated directive syntax
- #13390: DOC: Correct line length for Parameter Section underline
- #13393: MAINT: stats: allow wishart dim - 1 < df < dim
- #13395: DOC: fix typo in setup.py warning message
- #13396: BUG: Fix MLE for Nakagami ’nakagami_gen.fit’
- #13397: MAINT:linalg: Fix tgsen family wrapper and ordqz
- #13406: TST: add error handling tests for sparse BSR ctor
- #13413: DOC: ultra-quickstart guide
- #13418: BUG: Fix moment returning inconsistent types and shapes
- #13423: DOC: Update example for leaf_label_func/dendrogram
- #13431: ENH: stats: override _rvs for nhypergeom
- #13432: Add indicator in NDInterpolator docstring that N must be > 1
- #13434: DOC: stats: note relationship between scaled-inv-chi2 and invgamma
- #13436: ENH: interpolate: add input validation to check input x-y is...
- #13441: ENH: add functionality 'barnard_exact' test to scipy.stats.
- #13443: MAINT: stats: Updates for skewcauchy
- #13444: DOC: clarify range of 'a' parameter for johnsonsu/johnsons
- #13445: DOC: fix runtests guidelines.
- #13446: MAINT: stats: Add _fitstart method to wrapcauchy.
- #13447: DEV: Update development Docker image
- #13448: ENH: Add annotations for 'scipy.spatial.distance'
- #13451: DOC: minor formatting.
- #13458: DOC: indent see also.
- #13460: DOC: stats: Fix link to Cramer-von Mises wikipedia article.
- #13461: DOC: reorganize scipy.stats overview docs page
- #13463: DOC: misc formatting fixes
- #13466: DOC: Typo in see also s/SmoothUni/SmoothBi/g
- #13467: DOC: optimize: add description about 'tol' argument for 'minimize'.
- #13469: MAINT: Refactor optimization methods to use scipy.stats.qmc
- #13477: CI: pin numpy to 1.19.5 for the three macOS CI jobs
- #13478: DOC: fix typos where double :: for Sphinx directives were missing
- #13481: CI: pin numpy to 1.19.5 in the 4 parallel Windows builds on Azure
- #13482: CI: use numpy 1.20.0 again in macOS CI
- #13483: DOC: Multiple documentation syntax fixes.
- #13484: Move some pythran config from CI to setup
- #13487: DOC: add a tutorial about scipy.stats.qmc
- #13492: ENH: GH actions should not run on forks
- #13493: DEV: Enable gitpod for SciPy
- #13495: DOC One-word typo in the documentation of optimize.linprog_simplex
- #13499: DOC: describe LSAP implementation
- #13502: BUG: Bounds created with lists weren't working for Powell
- #13507: MAINT, TST: stats: centralize invalid parameters list for all...
- #13510: DOC: stats: fix small doc errors in 'multivariate_hypergeom'
- #13513: DOC: Added math notation in examples in litsys.py
- #13514: ENH: simplify low_0_bit function for Sobol
- #13515: ENH: optimize: add bound constraint support for nelder-mead solver
5.1. SciPy 1.7.0 Release Notes

- #13516: DOC: reduce LaTeX usage for johnsonb docstring
- #13519: BLD: remove build_sphinx support from setup.py
- #13527: TST: stats: xfail test_ind_randperm_alternative2 on 32 bit
- #13530: DOC: correct comparisons between median filter functions
- #13532: ENH: release the GIL inside medfilt2d
- #13538: DOC: optimize: fix minor doc error in ‘fmin_powell’ (#13511)
- #13546: DOC: fix list of “mode” options for ndimage
- #13549: ENH: stats: add ‘alternative’ keyword to some normality tests.
- #13551: MAINT: add git to docker env
- #13552: MAINT: stats: remove float_power shim
- #13553: DOC: use support rather than a/b in stats tutorial
- #13560: MAINT: optimize: improve linprog error message for sparse input…
- #13566: ENH: Speed up hdquantiles_sd()
- #13569: BENCH: optimize: benchmark only HiGHS methods; add bigger linprog…
- #13574: DOC: In description of cluster.hierarchy.dendrogram ‘level’ parameter,…
- #13576: ENH: improve discrepancy performance
- #13579: TST: Add pybind11 to tox environments
- #13583: BUG: Fix Dockerfile apt-get installs
- #13588: MAINT: forward port 1.6.1 relnotes.
- #13593: BUG: stats: preserve sample dtype for bin edges
- #13595: ENH: interpolate: add RBFInterpolator
- #13596: DOC: Fix indentation in new_stats_distribution.rst.inc
- #13601: Add dpss for get_window function
- #13604: DOC: Correct dual annealing visiting param range.
- #13605: Add Codecov badge to README
- #13607: MAINT: stats: fix crystalball entropy
- #13611: Better argument preparation for distributions in stats package.
- #13612: Add docker run command for Windows cmd
- #13613: MAINT, CI: mypy: fix typing errors + add mypy to CI
- #13616: FIX: Return correct output for invgauss.cdf when mu is very small
- #13617: MAINT: accept numbers and iterables for width in find_peaks_cwt
- #13620: CI: disable the mypy CI job (partial revert of gh-13613)
- #13621: DOC: signal: use array_like for input types
- #13622: MAINT: clean up some unused files, make ‘mypy scipy’ pass
- #13623: CI: enable Mypy CI job again
- #13624: TST: test more values for `visiting_param` input to `dual_annealing`
- #13625: Rename integrate.simps to integrate.simps in documentation…
- #13631: ENH: add a `stats.differential_entropy` function
- #13633: BUG: stats.binned_statistic_2d user function expecting arrays
- #13641: ENH: Added degrees parameter to rotvec
- #13645: MAINT: muppy: don’t install numpy-stubs
- #13649: BUG: sparse: csc_matrix.argmax() integer overflow
- #13650: ENH: stats: add ‘alternative’ parameter to ansari
- #13652: DOC: fix eigvalsh documentation (#13651)
- #13654: BUG: Fix LatinHypercubes
- #13656: DOC: Fix PCHIP references
- #13657: TST: remove IPython warning in debug session
- #13658: Remove spurious quotes in docstring
- #13661: ENH: stats: improve efficiency of / fix bug in exact permutation…
- #13667: MAINT: Make latest Docker image default
- #13668: MAINT: add .theia/ to .gitignore
- #13669: BLD: change SCIPY_USE_PYTHRAN default to `1`
- #13676: ENH Small improvements for LSQR with damp
- #13678: MAINT: add Pythran-generated files to .gitignore
- #13679: MAINT: move the `conda develop` in the Gitpod config
- #13680: DOC: Add cKDTree note comparing it with KDTree
- #13681: DOC: build doc updates on Pythran, compiled code, and cleanups
- #13683: BUG: mmwrite correctly serializes non skew-symmetric arrays
- #13684: FIX: fix numerical overflow in gamma.isf method
- #13685: BUG: fix cosine distance range to 0-2
- #13694: MAINT: fix warning emitted when NumPy version is incorrect
- #13696: ENH: support trimming in test_ind
- #13701: DEV: scipy.interpolate b-splines (periodic case)
- #13702: DEP: Clean up spent deprecations in spatial.distance
- #13703: MAINT: fix issues found by static code analysis
- #13706: ENH: stats: Implement sf and isf for the laplace distribution.
- #13711: MAINT: stats: fix broadcasting for scipy.stats.entropy
- #13712: BUG: stats: Override _fitstart for the invweibull distribution.
- #13713: DOC: update toolchain.rst to reflect windows universal C runtime
- #13714: MAINT: stats: Remove an unused list from test_continuous_basic.py.
0. #13715: MAINT: stats: No need to suppress frechet deprecation warnings.
1. #13716: MAINT: use super() as described by PEP 3135
2. #13718: MAINT: new-style class, removing inheritance to object
3. #13721: MAINT: add a type-ignore for mpmath (#13721)
4. #13723: MAINT: mypy: ignore mpmath imports in mypy.ini
5. #13724: DOC: pydata sphinx theme
6. #13725: BENCH: add benchmark for Kendalltau
7. #13727: CI: simplify Pythran configuration setup for Azure
8. #13731: MAINT: stats: Some flake8-driven clean up.
9. #13732: ENH: stats: Studentized Range Distribution
10. #13735: DOC: correct Voronoi docstring
11. #13738: DOC: add example to wright_bessel
13. #13741: MAINT: prevent overwriting of x in minimize
14. #13747: DOC: Add note for interp1d for non-unique x-values
15. #13749: MAINT: forward port 1.6.2 relnotes
16. #13759: MAINT: simpson small performance speedups
17. #13765: FIX: npymath missing causing npy_log1p to be unknown
18. #13768: BENCH: Add missing pythran dependency
19. #13770: ENH: stats.contingency: Add the sparse option to crosstab.
20. #13774: DEP: Deprecate squeezing input vectors in spatial.distance
21. #13775: Enable trust region methods to use a finite difference Hessian…
22. #13777: DOC: Fix Ubuntu/Debian installation instructions
23. #13778: DOC: remove references to RandomState
24. #13782: MAINT: LBFGSB err msg on MAXLS changed closes #11718
25. #13785: BENCH: Add benchmark for cdist/pdist with weights
26. #13786: MAINT: Prepare cdist/pdist for C++ rework
27. #13787: MAINT: stats: move entropy and differential_entropy functions…
28. #13790: DOC: Add some dependencies for Dockerfile doc of scipy development.
29. #13792: BUG: stats: Fix broadcasting in wrapcauchy.cdf
30. #13795: MAINT: stats: add hypotests to __all__ in init.py, not stats.py
31. #13797: MAINT: stats: probplot: don’t plot least-squares fit line unless…
32. #13798: MAINT: fix incorrect code comment in ‘hierarchy.to_tree’
33. #13802: DEV: add environment.yml file for development with conda/mamba
34. #13803: DOC: fix doc build warning about arxiv role already being registered
35. #13804: DOC+MAINT: optimize: lb and ub in the Bounds constructor are…

5.1. SciPy 1.7.0 Release Notes 2905
• #13807: MAINT: Dont use parallel Sphinx
• #13808: MAINT: cluster.to_tree: more idiomatic looping over rows of matrix…
• #13810: MAINT: add a CODEOWNERS file
• #13811: MAINT: Add ci skip to azp
• #13814: ENH/DOC: pydata sphinx theme polishing
• #13817: DOC: Misc parameter typo and casing in scipy/linalg/_decomp_ldl.py
• #13818: MAINT: stats: keep 'entropy' importable from 'scipy.stats.distributions'
• #13820: BUG: update _kendall_p_exact ValueError to f-string
• #13831: FIX:DEP: Allow better tolerance control for pinv and pinvh and…
• #13832: BUG: stats: Fix rvs for levy_stable when alpha=1
• #13833: MAINT: Add inline type hintings for stats.qmc
• #13836: MAINT: Fix a couple compiler warnings.
• #13838: TST: relax test tolerances for BinomTest
• #13841: BLD: add `-std=c99` flag to scipy.special extensions using…
• #13845: ENH: stats: add `method` parameter to `differential_entropy`…
• #13847: TST: skip on optimize failure on macOS, mark one as xfail
• #13848: DOC: optimize: move Nelder Mead from Unconstrained minimization…
• #13849: DOC: Roadmap update
• #13852: CI: fix temporary wrong brew doc version from GitHub
• #13854: ENH: Update Scipy Gitpod
• #13859: TST: fix ultra-slow test permutations test
• #13860: MAINT: clean up LSAP error checking
• #13863: DOC: remove seed in examples
• #13865: DOC: optimize: The bounds param of differential_evolution is…
• #13866: MAINT: special: Remove an unused variable from _poly_approx in…
• #13867: DOC: stats: Explain meaning of alternatives for fisher_exact.
• #13868: CI: fix the failing job on linux.
• #13870: MAINT: move LSAP rectangular matrix handling into solver code
• #13871: DOC: Add Gitpod documentation
• #13876: Workflow : Add nightly release of NumPy in linux workflows
• #13877: DOC: Conform to numpydoc + uniformity.
• #13879: BUG: signal: fix get_window argument handling and add tests.
• #13881: CI: remove .travis.yml, remove codecov from CircleCI
• #13882: BLD: ensure incrementing dev version strings
• #13886: TST: optimize: skip test_network_flow_limited_capacity w/ UMFPACK…
• #13888: MAINT: Fix issues involving elif conditions
• #13891: Rename InivariateSpline to UnivariateSpline
• #13893: ENH: linprog HiGHS marginal/sensitivity analysis
• #13894: DOC: Add blank line before `Return` section.
• #13897: DOC: BLD: fix doc build version check, and improve build time
• #13903: MAINT: Gitpod fixes
• #13907: ENH: Rewrite minkowski metric in C++ with pybind11
• #13909: Revert “Workflow: Add nightly release of NumPy in linux workflows”
• #13910: DOC: update Readme
• #13911: MAINT: use dict built-in rather than OrderedDict
• #13920: BUG: Reactivate conda environment in init
• #13925: BUG: stats: magnitude of Yates’ correction <= abs(observed-expected)…
• #13926: DOC: correct return type in disjoint_set.subsets docstring
• #13927: DOC/MAINT: Add copyright notice to qmc.primes_from_2_to
• #13928: BUG: DOC: signal: fix need argument config and add missing doc…
• #13929: REL: add PEP 621 (project metadata in pyproject.toml) support
• #13931: MAINT: special: get rid of _logit.c.src
• #13934: ENH: signal: make `get_window` supports `general_cosine`…
• #13940: MAINT: QMCEngine d input validation
• #13941: MAINT: forward port 1.6.3 renotes
• #13944: BUG: spatial: fix weight handling of `distance.sokalmichener`.
• #13947: MAINT: Remove duplicate calculations in sokalmichener
• #13949: DOC: minor grammar fixes in minimize and KDTree.query
• #13951: ENH: Add Boschloo exact test to stats
• #13956: ENH: spatial: add `axis` and `keepdims` optional argument…
• #13963: MAINT: stats: Fix unused imports and a few other issues related…
• #13971: DOC: Add Karl Pearson’s reference to chi-square test
• #13972: ENH: cluster: add an optional argument `seed` for `kmeans`…
• #13973: BLD: fix build warnings for causal/anticausal pointers in ndimage
• #13975: ENH: set empty array norm to zero.
• #13977: MAINT: signal: replace distutils templating with tempita
• #13978: MAINT: improve validations and keyword only arguments for some…
• #13979: ENH: Add Inverse of Log CDF of Normal Distribution
• #13983: Fixing `ndimage.watershed_ift` tutorial’s documentation

5.1. SciPy 1.7.0 Release Notes
5.2 SciPy 1.6.3 Release Notes

Scipy 1.6.3 is a bug-fix release with no new features compared to 1.6.2.

5.2.1 Authors

- Peter Bell
- Ralf Gommers
- Matt Haberland
- Peter Mahler Larsen
- Tirth Patel
- Tyler Reddy
- Pamphile ROY +
- Xingyu Liu +

A total of 8 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

Issues closed for 1.6.3

- #13772: Divide by zero in distance.yule
- #13796: CI: prerelease_deps failures
- #13890: TST: spatial rotation failure in (1.6.3) wheels repo (ARM64)

Pull requests for 1.6.3

- #13755: CI: fix the matplotlib warning emitted during building docs
- #13773: BUG: Divide by zero in yule dissimilarity of constant vectors
- #13799: CI/MAINT: deprecated np.typeDict
- #13819: substitute np.math.factorial with math.factorial
- #13895: TST: add random seeds in Rotation module
5.3 SciPy 1.6.2 Release Notes

SciPy 1.6.2 is a bug-fix release with no new features compared to 1.6.1. This is also the first SciPy release to place upper bounds on some dependencies to improve the long-term repeatability of source builds.

5.3.1 Authors

• Pradipta Ghosh +
• Tyler Reddy
• Ralf Gommers
• Martin K. Scherer +
• Robert Uhl
• Warren Weckesser

A total of 6 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

Issues closed for 1.6.2

• #13512: `stats.gaussian_kde.evaluate` broken on S390X
• #13584: rotation._compute_euler_from_matrix() creates an array with negative…
• #13585: Behavior change in coo_matrix when dtype=None
• #13686: delta0 argument of scipy.odr.ODR() ignored

Pull requests for 1.6.2

• #12862: REL: put upper bounds on versions of dependencies
• #13575: BUG: fix `gaussian_kernel_estimate` on S390X
• #13586: BUG: sparse: Create a utility function ‘getdata’
• #13598: MAINT, BUG: enforce contiguous layout for output array in Rotation.as_euler
• #13687: BUG: fix scipy.odr to consider given delta0 argument
5.4 SciPy 1.6.1 Release Notes

SciPy 1.6.1 Release Notes

Authors

- Peter Bell
- Evgeni Burovski
- CJ Carey
- Ralf Gommers
- Peter Mahler Larsen
- Cheng H. Lee +
- Cong Ma
- Nicholas McKibben
- Nikola Forró
- Tyler Reddy
- Warren Weckesser

A total of 11 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

Issues closed for 1.6.1

- #13072: BLD: Quadpack undefined references
- #13241: Not enough values to unpack when passing tuple to `blocksize`…

- #13356: LSQBivariateSpline segmentation fault when quitting the Python…
- #13358: scipy.spatial.transform.Rotation object can not be deepcopied…
- #13408: Type of `has_sorted_indices` property
- #13412: Sorting spherical Voronoi vertices leads to crash in area calculation
- #13421: linear_sum_assignment - support for matrices with more than 2^31…
Pull requests for 1.6.1

- #13318: REL: prepare for SciPy 1.6.1
- #13344: BUG: fftpack doesn’t work with ndarray shape argument
- #13345: MAINT: Replace scipy.take with numpy.take in FFT function docstrings.
- #13354: BUG: optimize: rename private functions to include leading underscore
- #13387: BUG: Support big-endian platforms and big-endian WAVs
- #13394: BUG: Fix Python crash by allocating larger array in LSQBivariateSpline
- #13400: BUG: sparse: Better validation for BSR ctor
- #13403: BUG: sparse: Propagate dtype through CSR/CSC constructors
- #13414: BUG: maintain dtype of SphericalVoronoi regions
- #13422: FIX: optimize: use npy_intp to store array dims for lsap
- #13425: BUG: spatial: make Rotation pickable
- #13426: BUG: `has_sorted_indices` and `has_canonical_format` should…
- #13430: BUG: stats: Fix exponnorm.cdf and exponnorm.sf for small K
- #13470: MAINT: silence warning generated by `spatial.directed_hausdorff`
- #13473: TST: fix failures due to new FutureWarnings in NumPy 1.21.dev0
- #13479: MAINT: update directed_hausdorff Cython code
- #13485: BUG: KDTree weighted count_neighbors doesn’t work between two…
- #13503: TST: fix `test_fortranfile_read_mixed_record` on big-endian…
- #13518: DOC: document that pip >= 20.3.3 is needed for macOS 11
- #13520: BLD: update reqs based on oldest-supported-numpy in pyproject.toml
- #13567: TST, BUG: adjust tol on test_equivalence

5.5 SciPy 1.6.0 Release Notes
SciPy 1.6.0 is the culmination of 6 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Before upgrading, we recommend that users check that their own code does not use deprecated SciPy functionality (to do so, run your code with `python -Wd` and check for `DeprecationWarning`s). Our development attention will now shift to bug-fix releases on the 1.6.x branch, and on adding new features on the master branch.

This release requires Python 3.7+ and NumPy 1.16.5 or greater.

For running on PyPy, PyPy3 6.0+ is required.
5.5.1 Highlights of this release

- **scipy.ndimage** improvements: Fixes and enhancements to boundary extension modes for interpolation functions. Support for complex-valued inputs in many filtering and interpolation functions. New `grid_mode` option for `scipy.ndimage.zoom` to enable results consistent with scikit-image’s `rescale`.

- **scipy.optimize.linprog** has fast, new methods for large, sparse problems from the HiGHS library.

- **scipy.stats** improvements including new distributions, a new test, and enhancements to existing distributions and tests

New features

5.5.2 **scipy.special** improvements

`scipy.special` now has improved support for 64-bit LAPACK backend

5.5.3 **scipy.odr** improvements

`scipy.odr` now has support for 64-bit integer BLAS

`scipy.odr.ODR` has gained an optional `overwrite` argument so that existing files may be overwritten.

5.5.4 **scipy.integrate** improvements

Some renames of functions with poor names were done, with the old names retained without being in the reference guide for backwards compatibility reasons:  
- `integrate.simps` was renamed to `integrate.simpson`
- `integrate.trapz` was renamed to `integrate.trapezoid`
- `integrate.cumtrapz` was renamed to `integrate.cumulative_trapezoid`

5.5.5 **scipy.cluster** improvements

`scipy.cluster.hierarchy.DisjointSet` has been added for incremental connectivity queries.

`scipy.cluster.hierarchy.dendrogram` return value now also includes leaf color information in `leaves_color_list`.

5.5.6 **scipy.interpolate** improvements

`scipy.interpolate.interp1d` has a new method `nearest-up`, similar to the existing method `nearest` but rounds half-integers up instead of down.
5.5.7 scipy.io improvements

Support has been added for reading arbitrary bit depth integer PCM WAV files from 1- to 32-bit, including the commonly-requested 24-bit depth.

5.5.8 scipy.linalg improvements

The new function `scipy.linalg.matmul_toeplitz` uses the FFT to compute the product of a Toeplitz matrix with another matrix.

`scipy.linalg.sqrtm` and `scipy.linalg.logm` have performance improvements thanks to additional Cython code.

Python LAPACK wrappers have been added for `pptrf`, `pptrs`, `ppsv`, `pptri`, and `ppcon`.

`scipy.linalg.norm` and the `svd` family of functions will now use 64-bit integer backends when available.

5.5.9 scipy.ndimage improvements

`scipy.ndimage.convolve`, `scipy.ndimage.correlate` and their 1d counterparts now accept both complex-valued images and/or complex-valued filter kernels. All convolution-based filters also now accept complex-valued inputs (e.g. `gaussian_filter`, `uniform_filter`, etc.).

Multiple fixes and enhancements to boundary handling were introduced to `scipy.ndimage` interpolation functions (i.e. `affine_transform`, `geometric_transform`, `map_coordinates`, `rotate`, `shift`, `zoom`).

A new boundary mode, `grid-wrap` was added which wraps images periodically, using a period equal to the shape of the input image grid. This is in contrast to the existing `wrap` mode which uses a period that is one sample smaller than the original signal extent along each dimension.

A long-standing bug in the `reflect` boundary condition has been fixed and the mode `grid-mirror` was introduced as a synonym for `reflect`.

A new boundary mode, `grid-constant` is now available. This is similar to the existing `ndimage` constant mode, but interpolation will still performed at coordinate values outside of the original image extent. This `grid-constant` mode is consistent with OpenCV's `BORDER_CONSTANT` mode and scikit-image's `constant` mode.

Spline pre-filtering (used internally by `ndimage` interpolation functions when `order >= 2`), now supports all boundary modes rather than always defaulting to mirror boundary conditions. The standalone functions `spline_filter` and `spline_filter1d` have analytical boundary conditions that match modes `mirror`, `grid-wrap` and `reflect`.

`scipy.ndimage` interpolation functions now accept complex-valued inputs. In this case, the interpolation is applied independently to the real and imaginary components.

The `ndimage` tutorials (https://docs.scipy.org/doc/scipy/reference/tutorial/ndimage.html) have been updated with new figures to better clarify the exact behavior of all of the interpolation boundary modes.

`scipy.ndimage.zoom` now has a `grid_mode` option that changes the coordinate of the center of the first pixel along an axis from 0 to 0.5. This allows resizing in a manner that is consistent with the behavior of scikit-image's `resize` and `rescale` functions (and OpenCV's `cv2.resize`).
5.5.10 scipy.optimize improvements

scipy.optimize.linprog has fast, new methods for large, sparse problems from the HiGHS C++ library. method='highs-ds' uses a high performance dual revised simplex implementation (HSOL), method='highs-ipm' uses an interior-point method with crossover, and method='highs' chooses between the two automatically. These methods are typically much faster and often exceed the accuracy of other linprog methods, so we recommend explicitly specifying one of these three method values when using linprog.

scipy.optimize.quadratic_assignment has been added for approximate solution of the quadratic assignment problem.

scipy.optimize.linear_sum_assignment now has a substantially reduced overhead for small cost matrix sizes.

scipy.optimize.least_squares has improved performance when the user provides the jacobian as a sparse jacobian already in csr_matrix format.

scipy.optimize.linprog now has an rr_method argument for specification of the method used for redundancy handling, and a new method for this purpose is available based on the interpolative decomposition approach.

5.5.11 scipy.signal improvements

scipy.signal.gammatone has been added to design FIR or IIR filters that model the human auditory system.

scipy.signal.iircomb has been added to design IIR peaking/notching comb filters that can boost/attenuate a frequency from a signal.

scipy.signal.sosfilt performance has been improved to avoid some previously-observed slowdowns.

scipy.signal.windows.taylor has been added—the Taylor window function is commonly used in radar digital signal processing.

scipy.signal.gauss_spline now supports list type input for consistency with other related SciPy functions.

scipy.signal.correlation_lags has been added to allow calculation of the lag/displacement indices array for 1D cross-correlation.

5.5.12 scipy.sparse improvements

A solver for the minimum weight full matching problem for bipartite graphs, also known as the linear assignment problem, has been added in scipy.sparse.csgraph.min_weight_full_bipartite_matching. In particular, this provides functionality analogous to that of scipy.optimize.linear_sum_assignment, but with improved performance for sparse inputs, and the ability to handle inputs whose dense representations would not fit in memory.

The time complexity of scipy.sparse.block_diag has been improved dramatically from quadratic to linear.

5.5.13 scipy.sparse.linalg improvements

The vendored version of SuperLU has been updated.
5.5.14 scipy.fft improvements

The vendored pocketfft library now supports compiling with ARM neon vector extensions and has improved thread pool behavior.

5.5.15 scipy.spatial improvements

The python implementation of KDTree has been dropped and KDTree is now implemented in terms of cKDTree. You can now expect cKDTree-like performance by default. This also means sys.setrecursionlimit no longer needs to be increased for querying large trees.

transform.Rotation has been updated with support for Modified Rodrigues Parameters alongside the existing rotation representations (PR gh-12667).

scipy.spatial.transform.Rotation has been partially cythonized, with some performance improvements observed

scipy.spatial.distance.cdist has improved performance with the minkowski metric, especially for p-norm values of 1 or 2.

5.5.16 scipy.stats improvements

New distributions have been added to scipy.stats:

- The asymmetric Laplace continuous distribution has been added as scipy.stats.laplace_asymmetric.
- The negative hypergeometric distribution has been added as scipy.stats.nhypergeom.
- The multivariate t distribution has been added as scipy.stats.multivariate_t.
- The multivariate hypergeometric distribution has been added as scipy.stats.multivariate_hypergeom.

The fit method has been overridden for several distributions (laplace, pareto, rayleigh, invgauss, logistic, gumbel_l, gumbel_r); they now use analytical, distribution-specific maximum likelihood estimation results for greater speed and accuracy than the generic (numerical optimization) implementation.

The one-sample Cramér-von Mises test has been added as scipy.stats.cramervonmises.

An option to compute one-sided p-values was added to scipy.stats.ttest_1samp, scipy.stats.ttest_ind_from_stats, scipy.stats.ttest_ind and scipy.stats.ttest_rel.

The function scipy.stats.kendalltau now has an option to compute Kendall's tau-c (also known as Stuart's tau-c), and support has been added for exact p-value calculations for sample sizes > 171.

stats.trapz was renamed to stats.trapezoid, with the former name retained as an alias for backwards compatibility reasons.

The function scipy.stats.linregress now includes the standard error of the intercept in its return value.

The _logpdf, _sf, and _isf methods have been added to scipy.stats.nakagami; _sf and _isf methods also added to scipy.stats.gumbel_r

The sf method has been added to scipy.stats.levy and scipy.stats.levy_l for improved precision.

scipy.stats.binned_statistic_dd performance improvements for the following computed statistics: max, min, median, and std.

We gratefully acknowledge the Chan-Zuckerberg Initiative Essential Open Source Software for Science program for supporting many of these improvements to scipy.stats.
Deprecation features

5.5.17 *scipy.spatial* changes

Calling `KDTree.query` with `k=None` to find all neighbours is deprecated. Use `KDTree.query_ball_point` instead.

`distance.wminkowski` was deprecated; use `distance.minkowski` and supply weights with the `w` keyword instead.

Backwards incompatible changes

5.5.18 *scipy* changes

Using `scipy.fft` as a function aliasing `numpy.fft.fft` was removed after being deprecated in SciPy 1.4.0. As a result, the `scipy.fft` submodule must be explicitly imported now, in line with other SciPy subpackages.

5.5.19 *scipy.interpolate* changes

5.5.20 *scipy.linalg* changes

5.5.21 *scipy.signal* changes

The output of `decimate`, `lfilter_zi`, `lfiltic`, `sos2tf`, and `sosfilt_zi` have been changed to match `numpy.result_type` of their inputs.

The window function `slepian` was removed. It had been deprecated since SciPy 1.1.

5.5.22 *scipy.spatial* changes

`cKDTree.query` now returns 64-bit rather than 32-bit integers on Windows, making behaviour consistent between platforms (PR gh-12673).

5.5.23 *scipy.stats* changes

The `frechet_l` and `frechet_r` distributions were removed. They were deprecated since SciPy 1.0.

Other changes

`setup_requires` was removed from `setup.py`. This means that users invoking `python setup.py install` without having `numpy` already installed will now get an error, rather than having `numpy` installed for them via `easy_install`. This install method was always fragile and problematic, users are encouraged to use `pip` when installing from source.

- Fixed a bug in `scipy.optimize.dual_annealing accept_reject` calculation that caused uphill jumps to be accepted less frequently.
- The time required for (un)pickling of `scipy.stats.rv_continuous, scipy.stats.rv_discrete,` and `scipy.stats.rv_frozen` has been significantly reduced (gh12550). Inheriting subclasses should note that `__set_state__` no longer calls `__init__` upon unpickling.

5.6 SciPy 1.5.4 Release Notes

SciPy 1.5.4 is a bug-fix release with no new features compared to 1.5.3. Importantly, wheels are now available for Python 3.9 and a more complete fix has been applied for issues building with XCode 12.

5.6.1 Authors

- Peter Bell
- CJ Carey
- Andrew McCluskey +
- Andrew Nelson
- Tyler Reddy
- Eli Rykoff +
- Ian Thomas +

A total of 7 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

Issues closed for 1.5.4

- #12763: ndimage.fourier_ellipsoid segmentation fault
- #12789: TestConvolve2d.test_large_array failing on Windows ILP64 CI job
- #12857: sparse A[0,:] = ndarray is ok, A[:,0] = ndarray ValueError from…
- #12860: BUG: Build failure with Xcode 12
- #12935: Failure to build with Python 3.9.0 on macOS
- #12966: MAINT: lint_diff.py on some backport PRs
- #12988: BUG: Highly multi-dimensional ‘gaussian_kde’ giving ‘-inf’…
Pull requests for 1.5.4

- #12790: TST: Skip TestConvolve2d.test_large_array if not enough memory
- #12851: BUG: sparse: fix inner indexed assignment of a 1d array
- #12875: BUG: segfault in ndimage.fourier_ellipsoid with length-1 dims
- #12937: CI: macOS3.9 testing
- #12957: MAINT: fixes XCode 12/ python 3.9.0 build for 1.5.x maint branch
- #12959: CI: add Windows Python 3.9 to CI
- #12974: MAINT: Run lint_diff.py against the merge target and only for…
- #12978: DOC: next_fast_len output doesn’t match docstring
- #12979: BUG: fft.next_fast_len should accept keyword arguments
- #12989: BUG: improved the stability of kde for highly (1000s) multi-dimension…
- #13017: BUG: Add explicit cast to _tmp sum.
- #13022: TST: xfail test_maxiter_worsening()

5.7 SciPy 1.5.3 Release Notes

SciPy 1.5.3 is a bug-fix release with no new features compared to 1.5.2. In particular, Linux ARM64 wheels are now available and a compatibility issue with XCode 12 has been fixed.

5.7.1 Authors

- Peter Bell
- CJ Carey
- Thomas Duvernay +
- Gregory Lee
- Eric Moore
- odidev
- Dima Pasechnik
- Tyler Reddy
- Simon Segerblom Rex +
Daniel B. Smith
Will Tirone +
Warren Weckesser

A total of 12 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

• #12913: MAINT: Ignore pytest’s PytestConfigWarning

5.8 SciPy 1.5.2 Release Notes

SciPy 1.5.2 is a bug-fix release with no new features compared to 1.5.1.

5.8.1 Authors

• Peter Bell
• Tobias Biester +
• Evgeni Burovski
• Thomas A Caswell
• Ralf Gommers
• Sturla Molden
• Andrew Nelson
• ofirr +
• Sambit Panda
• Ilhan Polat
• Tyler Reddy
• Atsushi Sakai
• Pauli Virtanen

A total of 13 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.
Issues closed for 1.5.2

- #3847: Crash of interpolate.splprep(task=-1)
- #7395: splprep segfaults if fixed knots are specified

5.9 SciPy 1.5.1 Release Notes

Contents

- SciPy 1.5.1 Release Notes
  - Authors
    - Issues closed for 1.5.1
    - Pull requests for 1.5.1

SciPy 1.5.1 is a bug-fix release with no new features compared to 1.5.0. In particular, an issue where DLL loading can fail for SciPy wheels on Windows with Python 3.6 has been fixed.

5.9.1 Authors

- Peter Bell
- Loïc Estève
- Philipp Thölke +
- Tyler Reddy
- Paul van Mulbregt
- Pauli Virtanen
- Warren Weckesser

A total of 7 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

      - scipy.interpolate changes
SciPy 1.5.0 is the culmination of 6 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Before upgrading, we recommend that users check that their own code does not use deprecated SciPy functionality (to do so, run your code with `python -Wd` and check for `DeprecationWarning`s). Our development attention will now shift to bug-fix releases on the 1.5.x branch, and on adding new features on the master branch.

This release requires Python 3.6+ and NumPy 1.14.5 or greater.

For running on PyPy, PyPy 6.0+ and NumPy 1.15.0 are required.

5.10.1 Highlights of this release

- wrappers for more than a dozen new LAPACK routines are now available in `scipy.linalg.lapack`
- Improved support for leveraging 64-bit integer size from linear algebra backends
- addition of the probability distribution for two-sided one-sample Kolmogorov-Smirnov tests

New features

5.10.2 scipy.cluster improvements

Initialization of `scipy.cluster.vq.kmeans2` using `minit="++"` had a quadratic complexity in the number of samples. It has been improved, resulting in a much faster initialization with quasi-linear complexity.

`scipy.cluster.hierarchy.dendrogram` now respects the `matplotlib` color palette

5.10.3 scipy.fft improvements

A new keyword-only argument `plan` is added to all FFT functions in this module. It is reserved for passing in a pre-computed plan from libraries providing a FFT backend (such as `PyFFTW` and `mkl_fft`), and it is currently not used in SciPy.
5.10.4 `scipy.integrate` improvements

5.10.5 `scipy.interpolate` improvements

5.10.6 `scipy.io` improvements

`scipy.io.wavfile` error messages are more explicit about what’s wrong, and extraneous bytes at the ends of files are ignored instead of raising an error when the data has successfully been read.

`scipy.io.loadmat` gained a `simplify_cells` parameter, which if set to `True` simplifies the structure of the return value if the `.mat` file contains cell arrays.

`pathlib.Path` objects are now supported in `scipy.io` Matrix Market I/O functions.

5.10.7 `scipy.linalg` improvements

`scipy.linalg.eigh` has been improved. Now various LAPACK drivers can be selected at will and also subsets of eigenvalues can be requested via `subset_by_value` keyword. Another keyword `subset_by_index` is introduced. Keywords `turbo` and `eigvals` are deprecated.

Similarly, standard and generalized Hermitian eigenvalue LAPACK routines `<sy/he>vx` are added and existing ones now have full `_lwork` counterparts.

Wrappers for the following LAPACK routines have been added to `scipy.linalg.lapack`:

- `?getc2`: computes the LU factorization of a general matrix with complete pivoting
- `?gesc2`: solves a linear system given an LU factorization from `?getc2`
- `?gejsv`: computes the singular value decomposition of a general matrix
  - with higher accuracy calculation of tiny singular values and their corresponding singular vectors
- `?geqrf`: computes the QR factorization of a general matrix with non-negative elements on the diagonal of R
- `?gtsvx`: solves a linear system with general tridiagonal matrix
- `?gttrf`: computes the LU factorization of a tridiagonal matrix
- `?gttrs`: solves a linear system given an LU factorization from `?gttrf`
- `?ptsvx`: solves a linear system with symmetric positive definite tridiagonal matrix
- `?pttrf`: computes the LU factorization of a symmetric positive definite tridiagonal matrix
- `?pttrs`: solves a linear system given an LU factorization from `?pttrf`
- `?pteqr`: computes the eigenvectors and eigenvalues of a positive definite tridiagonal matrix
- `?tbtrs`: solves a linear system with a triangular banded matrix
- `?csd`: computes the Cosine Sine decomposition of an orthogonal/unitary matrix
Generalized QR factorization routines (\texttt{geqrf}) now have full \texttt{_lwork} counterparts.

\texttt{scipy.linalg.cossin} Cosine Sine decomposition of unitary matrices has been added.

The function \texttt{scipy.linalg.khatri_rao}, which computes the Khatri-Rao product, was added.

The new function \texttt{scipy.linalg.convolution_matrix} constructs the Toeplitz matrix representing one-dimensional convolution.

### 5.10.8 \texttt{scipy.ndimage} improvements

### 5.10.9 \texttt{scipy.optimize} improvements

The finite difference numerical differentiation used in various \texttt{minimize} methods that use gradients has several new features:

- 2-point, 3-point, or complex step finite differences can be used. Previously only a 2-step finite difference was available.
- There is now the possibility to use a relative step size, previously only an absolute step size was available.
- If the \texttt{minimize} method uses bounds the numerical differentiation strictly obeys those limits.
- The numerical differentiation machinery now makes use of a simple cache, which in some cases can reduce the number of function evaluations.
- \texttt{minimize}'s method= 'powell' now supports simple bound constraints

There have been several improvements to \texttt{scipy.optimize.linprog}:

- The \texttt{linprog} benchmark suite has been expanded considerably.
- \texttt{linprog}'s dense pivot-based redundancy removal routine and sparse presolve are faster
- When \texttt{scikit-sparse} is available, solving sparse problems with \texttt{method='interior-point'} is faster

The caching of values when optimizing a function returning both value and gradient together has been improved, avoiding repeated function evaluations when using a HessianApproximation such as BFGS.

\texttt{differential_evolution} can now use the modern \texttt{np.random.Generator} as well as the legacy \texttt{np.random.RandomState} as a seed.

### 5.10.10 \texttt{scipy.signal} improvements

A new optional argument \texttt{include_nyquist} is added to \texttt{freqz} functions in this module. It is used for including the last frequency (Nyquist frequency).

\texttt{scipy.signal.find_peaks_cwt} now accepts a \texttt{window_size} parameter for the size of the window used to calculate the noise floor.
5.10.11 **scipy.sparse improvements**

Outer indexing is now faster when using a 2d column vector to select column indices.

`scipy.sparse.lil.tocsr` is faster.

Fixed/improved comparisons between pydata sparse arrays and sparse matrices.

BSR format sparse multiplication performance has been improved.

`scipy.sparse.linalg.LinearOperator` has gained the new `ndim` class attribute.

5.10.12 **scipy.spatial improvements**

`scipy.spatial.geometric_slerp` has been added to enable geometric spherical linear interpolation on an n-sphere.

`scipy.spatial.SphericalVoronoi` now supports calculation of region areas in 2D and 3D cases.

The tree building algorithm used by `cKDTree` has improved from quadratic worst case time complexity to loglinear. Benchmarks are also now available for building and querying of balanced/unbalanced kd-trees.

5.10.13 **scipy.special improvements**

The following functions now have Cython interfaces in `cython_special`:

- `scipy.special.erfinv`
- `scipy.special.erfcinv`
- `scipy.special.spherical_jn`
- `scipy.special.spherical_yn`
- `scipy.special.spherical_in`
- `scipy.special.spherical_kn`

`scipy.special.log_softmax` has been added to calculate the logarithm of softmax function. It provides better accuracy than `log(scipy.special.softmax(x))` for inputs that make softmax saturate.

5.10.14 **scipy.stats improvements**

The function for generating random samples in `scipy.stats.dlaplace` has been improved. The new function is approximately twice as fast with a memory footprint reduction between 25 % and 60 % (see gh-11069).

`scipy.stats` functions that accept a seed for reproducible calculations using random number generation (e.g. random variates from distributions) can now use the modern `np.random.Generator` as well as the legacy `np.random.RandomState` as a seed.

The `axis` parameter was added to `scipy.stats.rankdata`. This allows slices of an array along the given axis to be ranked independently.

The `axis` parameter was added to `scipy.stats.f_oneway`, allowing it to compute multiple one-way ANOVA tests for data stored in n-dimensional arrays. The performance of `f_oneway` was also improved for some cases.

The PDF and CDF methods for `stats.geninvgauss` are now significantly faster as the numerical integration to calculate the CDF uses a Cython based `LowLevelCallable`.

5.10. SciPy 1.5.0 Release Notes 2947
Moments of the normal distribution (scipy.stats.norm) are now calculated using analytical formulas instead of numerical integration for greater speed and accuracy.

Moments and entropy trapezoidal distribution (scipy.stats.trapz) are now calculated using analytical formulas instead of numerical integration for greater speed and accuracy.

Methods of the truncated normal distribution (scipy.stats.truncnorm), especially _rvs, are significantly faster after a complete rewrite.

The fit method of the Laplace distribution, scipy.stats.laplace, now uses the analytical formulas for the maximum likelihood estimates of the parameters.

Generation of random variates is now thread safe for all SciPy distributions. 3rd-party distributions may need to modify the signature of the _rvs() method to conform to _rvs(self, ..., size=None, random_state=None). (A one-time VisibleDeprecationWarning is emitted when using non-conformant distributions.)

The Kolmogorov-Smirnov two-sided test statistic distribution (scipy.stats.kstwo) was added. Calculates the distribution of the K-S two-sided statistic \( D_n \) for a sample of size \( n \), using a mixture of exact and asymptotic algorithms.

The new function median_abs_deviation replaces the deprecated median_absolute_deviation.

The wilcoxon function now computes the p-value for Wilcoxon's signed rank test using the exact distribution for inputs up to length 25. The function has a new mode parameter to specify how the p-value is to be computed. The default is "auto", which uses the exact distribution for inputs up to length 25 and the normal approximation for larger inputs.

Added a new Cython-based implementation to evaluate gaussian kernel estimates, which should improve the performance of gaussian_kde.

The winsorize function now has a nan_policy argument for refined handling of nan input values.

The binned_statistic_dd function with statistic="std" performance was improved by ~4x.

scipy.stats.kstest(rvs, cdf,...) now handles both one-sample and two-sample testing. The one-sample variation uses scipy.stats.ksone (or scipy.stats.kstwo with back off to scipy.stats.kstwobign) to calculate the p-value. The two-sample variation, invoked if cdf is array_like, uses an algorithm described by Hodges to compute the probability directly, only backing off to scipy.stats.kstwo in case of overflow. The result in both cases is more accurate p-values, especially for two-sample testing with smaller (or quite different) sizes.

scipy.stats.maxwell performance improvements include a 20 % speed up for fit() and 5 % for pdf() for scipy.stats.shapiro and scipy.stats.jarque_bera now return a named tuple for greater consistency with other stats functions

**Deprecated features**

**5.10.15 scipy deprecations**

**5.10.16 scipy.special changes**

The bdtr, bdtrc, and bdtri functions are deprecating non-negative non-integral \( n \) arguments.
5.10.17 scipy.stats changes

The function `median_absolute_deviation` is deprecated. Use `median_abs_deviation` instead.
The use of the string "raw" with the `scale` parameter of `iqr` is deprecated. Use `scale=1` instead.

Backwards incompatible changes

5.10.18 scipy.interpolate changes

5.10.19 scipy.linalg changes

The output signatures of `?syevr`, `?heevr` have been changed from `w, v, info` to `w, v, m, isuppz, info`.
The order of output arguments `w, v` of `<sy/he>{gv, gvd, gvx}` is swapped.

5.10.20 scipy.signal changes

The output length of `scipy.signal.upfirdn` has been corrected, resulting outputs may now be shorter for some combinations of up/down ratios and input signal and filter lengths.
`scipy.signal.resample` now supports a `domain` keyword argument for specification of time or frequency domain input.

5.10.21 scipy.stats changes

Other changes

Improved support for leveraging 64-bit integer size from linear algebra backends in several parts of the SciPy codebase.
Shims designed to ensure the compatibility of SciPy with Python 2.7 have now been removed.
Many warnings due to unused imports and unused assignments have been addressed.
Many usage examples were added to function docstrings, and many input validations and intuitive exception messages have been added throughout the codebase.
Early stage adoption of type annotations in a few parts of the codebase

• #11296: DOC: special: add to docstrings of Bessel zeros and derivatives
• #11297: DOC: special: add parameters/returns sections for Bessel integrals
• #11300: MAINT: Update vendored uarray version
• #11301: CI: azure conditions should require succeeded()
• #11302: ENH: build infrastructure for ILP64 BLAS + ARPACK conversion
• #11303: DOC: special: fix typo in `besselpoly` docstring
• #11304: ENH: MAINT: Rewrite of eigh() and relevant wrappers
• #11306: TST: skip test_aligned_mem linalg test that is crashing on ppcle64
• #11307: MAINT: Fix typo 'solutuion' -> 'solution'
• #11308: ENH: do not create 1d array out of a scalar
• #11310: MAINT: clean up object array creation, scalar/1d confusion
• #11311: DOC: Specify custom callable option for metric in cluster.hierarchy.fclusterdata
• #11316: BUG: special: fix behavior for `rgamma` zeros
• #11317: BUG: fix floating-point literal comparisons under C99
• #11318: TST: optimize: mark two linprog tests for skipping
• #11320: BUG: Include `int64_t` declaration to `rectangular_lsap.cpp`
• #11330: MAINT: Update vendored pyfft version
• #11333: BUG: directed_hausdorff subset fix
• #11335: [ENH] sparse: Loosen check for sparse outer indexing fast path
• #11337: Undefined name ‘e’ in pavement.py
• #11338: scipyoptdoc.py: Remove unused variable ‘sixu’
• #11340: xrange() was removed in Python 3 in favor of range()
• #11342: range() was removed in Py3 in _binned_statistic.py
• #11343: BUG: constants: fix ‘exact’ values table
• #11347: ENH: add input validation function and apply it to needed functions
• #11348: MAINT: remove six.string_types usages
• #11349: MAINT: minor doc fix _minimize_trustregion_constr
• #11353: MAINT: py3 remove various six usages
• #11358: ENH: optimize: Use CSR format instead of LIL for speed
• #11362: MAINT: sys.version_info >= 3.5
• #11364: ENH: cache square of sums for f_oneway
• #11368: ENH: add optional argument, “include_nyquist”, for freqz()
• #11372: BENCH: optimize: added linprog presolve benchmarks
• #11376: ENH: Add wrapper for ?gttrf/?gttrs
• #11377: MAINT: Remove Python 2 code from tools/authors.py
• #11378: ENH (WIP): Python wrapper for ?tbtr
• #11379: MAINT: Remove six.with_metaclass from benchmarks/cython_special.py
• #11380: BUG: sparse/isolve: bicg and qmr don’t treat x0 correctly
• #11382: MAINT: remove error throw in binned_statistic_dd() on non-finite…
• #11383: MAINT: _lib: remove py2 compat shims in getargspec
• #11384: MAINT: Use numpy scalar types directly
• #11385: ENH: special: add spherical Bessel functions to `cython_special`
• #11389: MAINT: line.startswith shouldn’t be bytes
• #11393: ENH: Speed up truncnorm’s ppf()and rvs() methods
• #11394: MAINT: Remove self._size (and self._random_state) from stats…
• #11395: correction in error message (%d->%g format)
• #11396: DOC: revert gh10540, removing mtrand
• #11397: MAINT: differential_evolution accepts np.random.Generator
• #11402: ENH: stats can use np.random.Generator
• #11404: ENH: add docstring of butter() for transfer function syntax problem
• #11405: DOC: Fix “see also” for SmoothBivariateSpline
• #11408: ENH: Add a ‘plan’ argument to FFT functions in `scipy.fft`
• #11411: MAINT: check minimize duplicate evaluations
• #11418: ENH: Linalg: Python wrapper for ?geqrfp
• #11419: TST: Python 3.7 mac OS gcc multibuild fix
• #11423: ENH: Add tool to lint diffs
• #11425: FIX: _array_newton should preserve complex inputs
• #11426: MAINT: licence for global optimization benchmarks
• #11431: Make median_absolute_deviation scale argument aligned w/iqr
• #11432: Fix error message typo
• #11433: DOC: Remove L from longs
• #11434: MAINT: Python3 improvements to refguide_check.py
• #11435: DOC: Update runtest –parallel help
• #11436: MAINT: Remove checks for sys.version < 3.5
• #11437: DOC: Fix documentation issue
• #11439: Support path objects (PEP 519) in mmio functions
• #11440: correct bounds pass in run_dualannealing for benchmarks/optimize.py
• #11443: BENCH: optimize_linprog remove ImportError exception
• #11453: BUG: sparse: convert csc/csr indices to int64 as needed
• #11454: DOC: Remove caveat on 'maximum_bipartite_matching'
• #11455: BUG: Fix _lib._util.getargspec_no_self lack of KEYWORD ONLY support.
• #11456: Implementation of khatri_rao product
• #11459: BUG: fix augmentation being broken in maximum_bipartite_matching
• #11461: MAINT: minor spelling corrections in comments in SciPy.sparse.linalg.arpack
• #11467: [MRG] Make result data type of KDE evaluation like in the input…
• #11469: Update integrate.quad documentation
• #11472: Fixed result typo
• #11476: DOC: stats: Copy-edit the anderson docstring.
• #11478: ENH: avoid unnecessary array copies in matrix product
• #11481: BUG: Make special.hyperu return nan if any argument is nan
• #11483: BUG: Fixed ‘_kpp’ initialization on ‘scipy.cluster.vq’, closing…
• #11485: ENH: Update docstring of class KrylovJacobian to fix #2744
• #11486: BUG: make special.eval_hermite return nan if second argument…
• #11487: ENH: improve docstring of correlate and correlate2d to fix #1968
• #11488: FIX: change “func -> fun” of scipy.optimize _root.py to solve…
• #11489: BUG: fixes typo introduced in PR #11253 in stats.mstats.kendalltau()
• #11490: DOC: fix typo in scipy/io/matlab/mio4.py
• #11495: MAINT: refactor slsqp to fix issue in callback function
• #11498: [DOC] mention graph cuts in maximum flow docstring
• #11499: DOC: Improve documentation of scipy.signal.signaltools.wiener
• #11506: DOC: Fix typo in documentation of scipy.stats.morestats
• #11508: ENH: avoid copy on sparse __init__ when dtype is given
• #11509: ENH: avoid unnecessary array copies in matrix product (again)
• #11510: [DOC] An ex. for creating arbitrary size tri-diagonal
• #11511: TST: pin numba for Travis/sparse
• #11513: TST: disable NumPy cache dir ppc64le
• #11514: BUG: make special.eval_genlaguerre return nan if passed nan
• #11517: ENH: improve sparse.lil.tocsr performance
• #11519: Fix fresnel documentation
• #11520: BUG: make special.eval_gegenbauer return nan if passed nan
• #11524: ENH: Cosine Sine Decomposition
• #11526: BUG: fix SLSQP max iteration setting to fix #4921
• #11527: ENH: improve docstring of weibull_min_gen and weibull_max_gen…
• #11530: MAINT: Removed 3 unused imports, 3 unused assignments from ndimage.
• #11531: DOC: fix typos in bdt and bdtc from gh PR 11045
• #11532: MAINT: Fixed several unused imports and unused assignments from…
• #11533: MAINT: Fixed about 100 unused imports, unused assignment warnings…
• #11534: FIX: Allow non-native byte order inputs to scipy.fft
• #11535: MAINT: Fixed several unused imports in _lib.
• #11536: MAINT: Fixed several unused imports and unused assignments in…
• #11537: MAINT: Removed an unused import in scipy/constants.
• #11538: MAINT: Fixed several unused imports in scipy/fft.

• #11687: MAINT: sparse.linalg: avoid importing from `np.core`
• #11688: ENH: mypy: get specific about ignoring missing imports
• #11690: MAINT: mypy: fix errors about incompatible types in lists
• #11692: MAINT: mypy: fix remaining type errors
• #11694: TST, MAINT: bump to OpenBLAS 0.3.9 stable, raise tol for Win…
• #11697: DOC: fix pdf of norminvgauss in scipy.stats
• #11701: MAINT: special: add rudimentary types for `_ufuncs` extension…
• #11702: BUG: Fixed a post-merge bug for eight()
• #11703: Improves docstring with consistent L2-norm
• #11705: DOC: Slerp the SphericalVoronoi docstring
• #11706: ENH: mypy: add `--mypy` option to `runtests.py`
• #11710: ENH: Modified stats.kstest() to use the exact stats.kstwo.sf()
• #11715: DOC: add .. versionadded:: to as_matrix/from_matrix in spatial/transf…
• #11716: BENCH: fix benchmark imports for `optimize_linprog.py`
• #11721: MAINT: io: Remove now-unnecessary `# type: ignore`
• #11722: MAINT: mypy: remove mpmath from the ratchet
• #11726: Handle constant input for scipy.stats.f_oneway
• #11729: BENCH: optimize: added infeasible benchmarks for linprog
• #11731: fix inaccurate information about Mac OS compiler (#11696)
• #11733: Fix inaccurate docstring example of HalfspaceIntersection
• #11734: Doc: fix inaccurate docstring of SmoothBivariateSpline.
• #11735: Bug: stats: fix wrong shape from median_absolute_deviation for…
• #11736: ENH: add input validations and its tests for FITPACK in fitpack2.py
• #11737: BUG: Prevent crashes due to MKL bug in `?heevr`
• #11739: MAINT: special: add type stubs for `/_test_round.pyx`
• #11740: MAINT: special: remove unused specfun f2py wrappers
• #11741: BUG: fix small tolerances handling for minpack and add a test.
• #11743: Doc: fix docstring of rfft, rfft2, rfftn, irfft, irfft2, irfftn…
• #11744: MAINT: Remove unused py3k.h code
• #11745: DOC: stats: Clean up ncf documentation.
• #11748: MAINT: special: type `cython_special` as `Any`
- #11750: MAINT: type hints for `spherical_voronoi`
- #11752: DOC: fix docstring of scipy.optimize.least_squares
- #11753: ENH: add input validation for dendrogram and a test.
- #11755: MAINT: Replace uses of tostring with tobytes
- #11759: ENH: optimize: add HiGHS methods to linprog
- #11760: MAINT: Remove FileStream replaced by GenericStream
- #11761: MAINT: Replace npy_3kcompat.h shims
- #11765: TST: Speedup test_pascal which is VERY slow on Azure
- #11766: TST: speed up differential_evolution L8 test
- #11767: Change comment in continuous rv gamma fit function
- #11776: Add domain option for resample.
- #11784: BUG: Fixed calculation of nonzero elements in scipy.sparse.random
- #11786: ENH: stats: add axis keyword argument to scipy.stats.rankdata
- #11789: Doc: fix docstring of scipy.spatial.chebyshev
- #11792: DOC: dev: add guidelines for developing public Cython APIs
- #11794: MAINT: add comments explaining a problem in cython_optimize organization
- #11796: DOC: add a note about precision losing in csgraph.minimum_spanning_tree…
- #11797: ENH: Allow negative 'axis' in 'interpolate.BSpline'. Also…
- #11798: Add simplify_cells parameter to scipy.io.loadmat
- #11801: MAINT, DOC: minor changes of ratio-of-uniforms in scipy.stats
- #11802: BUG: fix scipy.odr to handle multidimensional independent and…
- #11803: scipy.stats.trapz: Use analytic formulas for stats and entropy.
- #11808: DOC: add Examples in the scipy.interpolate.interpn docstring.
- #11809: Duplicate entries are added together in csr_matrix constructor
- #11813: MAINT: bump pyflakes to version 2.1.1
- #11814: BUG: scipy.sparse.csr doctest failing with incorrect output value
- #11817: DOC: add Examples in the scipy.optimize.leastsq docstring
- #11820: ENH: Raise an error on incorrect bounds format in optimize.fmin_l_bfgs_b
- #11822: CI: add github actions for macOS
- #11824: DOC: add Examples in scipy.optimize.line_search docstring (line_search_wolfe2)
- #11830: TST: Always use fork for multiprocessing in fft tests
- #11831: DOC: add Examples and Returns in scipy.misc.central_diff_weights…
- #11832: DOC: stats: Some small corrections to a couple docstrings.
- #11833: BUG: Fix compiler_name when there are paths used in flags
- #11836: MAINT: re-introduce multiprocessing tests on Python3.8
• #11837: Doc: add Examples in scipy.optimize.fsolve docstring
• #11838: Doc: add Examples in scipy.sparse.linalg.minres docstring
• #11840: BUG: sparse.linalg: fix overflow in expm intermediate computation
• #11842: BLD: fix build with gfortran 10
• #11843: MAINT: Simplify floats in constants.py
• #11847: DOC: add a tutorial of scipy.optimize.linprog
• #11849: ENH: speed up geninvgauss by using cython
• #11852: CI: remove osx from travisCI
• #11857: BUG: Change parameter fc of gausspulse to float.
• #11861: order = degree + 1 for splines
• #11863: Make g77 ABI wrapper work with gfortran ABI lapack
• #11866: MAINT: add type ignores to symy and matplotlib imports
• #11867: CI: Add arm64 in travis-ci
• #11869: DOC: signal: Add an example to the lsim2 docstring.
• #11870: DOC: signal: Use impulse instead of impulse2 in the impulse example…
• #11871: ENH: type ufuncs in special as ufuncs instead of Any
• #11872: BUG: avoid recomputing in scipy.optimize.optimize.MemoizeJac

• #12095: MAINT: ndimage: change `shares_memory` to `may_share_memory`
• #12098: Doc: change 4 model instances of odr to be instances of `Model`…
• #12101: Removed more unused imports and assignments.
• #12107: ENH: Area calculation for 2D inputs in SphericalVoronoi
• #12108: MAINT: ensure attributes have correct data type in `SphericalVoronoi`
• #12109: degree is not order in splines
• #12110: ENH: More helpful/forgiving io.wavfile errors
• #12117: BUG: fix newline
• #12123: [MAINT] Fix error on PyData/Sparse import.
• #12124: TST: Always test matmul now that Python3.5+ is required
• #12126: TST: Cleanup unused matplotlib code.
• #12127: DOC: update docstrings of signal.cspline2d, qspline2d, sepfir2d
• #12130: MAINT: Fixing broken links with linkchecker
• #12135: ENH: linalg: Add the function convolution_matrix.
• #12136: MAINT: Cleanup np.poly1d hack
• #12137: TST, CI: reproduce wheels 32-bit setup
• #12140: TST: stats: add kstwo, ksone to slow tests.
• #12141: Support 64-bit integer size in Fitpack
• #12151: DOC: Correct Rosenbrock function sum
• #12159: BUG: Fix length calculation in upfirdn
• #12160: BUG: Fix M_PI
• #12168: DOC: add an obsolete version checking javascript to doc release…
• #12171: CI, MAINT: Azure OpenBLAS drive flip
• #12172: ENH: Bounds for the Powell minimization method
• #12175: BLD: support more Fortran compilers for ilp64 and macro expansion…
• #12179: BUG: stats: A few distributions didn’t accept lists as arguments.
• #12180: MAINT: removed redundant import in SphericalVoronoi tests
• #12181: DOC: for version warning don’t use $.getScript
• #12182: MAINT: random sampling on the hypersphere in SphericalVoronoi…
• #12194: MAINT: Module and example cleanups for doc build
• #12202: ENH: tool to DL release wheels from Anaconda
• #12210: Remove py.typed marker (at least for the release)
• #12217: BUG: stats: Fix handling of edge cases in median_abs_deviation.
• #12223: BUG: stats: wilcoxon returned p > 1 for certain inputs.
• #12227: BLD: Set macOS min version when building rectangular_lsap
• #12229: MAINT: tools/gh_lists.py: fix http header case sensitivity issue
• #12236: DOC: Fix a couple grammatical mistakes in 1.5.0-notes.rst.
• #12276: TST: skip test_heequb, it fails intermittently.
• #12285: CI: split travis arm64 run into two
• #12317: BUG: prevent error accumulation in Rotation multiplication
• #12318: BUG: sparse: avoid np.prod overflow in check_shape
• #12319: BUG: Make cobyla threadsafe
• #12335: MAINT: Work around Sphinx bug

5.11 SciPy 1.4.1 Release Notes

SciPy 1.4.1 is a bug-fix release with no new features compared to 1.4.0. Importantly, it aims to fix a problem where an older version of pybind11 may cause a segmentation fault when imported alongside incompatible libraries.

5.11.1 Authors

• Ralf Gommers
• Tyler Reddy
Issues closed for 1.4.1

- #11237: Seg fault when importing torch

Pull requests for 1.4.1

- #11238: BLD: update minimum pybind11 version to 2.4.0.

  - scipy.sparse changes
  - scipy.signal changes
  - scipy.stats changes
SciPy 1.4.0 is the culmination of 6 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Before upgrading, we recommend that users check that their own code does not use deprecated SciPy functionality (to do so, run your code with `python -Wd` and check for `DeprecationWarning`s). Our development attention will now shift to bug-fix releases on the 1.4.x branch, and on adding new features on the master branch.

This release requires Python 3.5+ and NumPy >=1.13.3 (for Python 3.5, 3.6), >=1.14.5 (for Python 3.7), >= 1.17.3 (for Python 3.8)

For running on PyPy, PyPy3 6.0+ and NumPy 1.15.0 are required.

### 5.12.1 Highlights of this release

- a new submodule, `scipy.fft`, now supersedes `scipy.fftpack`; this means support for `long double` transforms, faster multi-dimensional transforms, improved algorithm time complexity, release of the global interpreter lock, and control over threading behavior
- support for `pydata/sparse` arrays in `scipy.sparse.linalg`
- substantial improvement to the documentation and functionality of several `scipy.special` functions, and some new additions
- the generalized inverse Gaussian distribution has been added to `scipy.stats`
- an implementation of the Edmonds-Karp algorithm in `scipy.sparse.csgraph.maximum_flow`
- `scipy.spatial.SphericalVoronoi` now supports n-dimensional input,

### New features

### 5.12.2 Infrastructure

Documentation can now be built with `runtests.py --doc`

A `Dockerfile` is now available in the `scipy/scipy-dev` repository to facilitate getting started with SciPy development.
5.12.3 scipy.constants improvements

`scipy.constants` has been updated with the CODATA 2018 constants.

5.12.4 scipy.fft added

`scipy.fft` is a new submodule that supersedes the `scipy.fftpack` submodule. For the most part, this is a drop-in replacement for `numpy.fft` and `scipy.fftpack` alike. With some important differences, `scipy.fft`:

- uses NumPy’s conventions for real transforms (rfft). This means the return value is a complex array, half the size of the full fft output. This is different from the output of fftpack which returned a real array representing complex components packed together. - the inverse real to real transforms (idct and idst) are normalized for norm=None in the same way as ifft. This means the identity idct(dct(x)) == x is now True for all norm modes. - does not include the convolutions or pseudo-differential operators from fftpack.

This submodule is based on the pypocketfft library, developed by the author of pocketfft which was recently adopted by NumPy as well. pypocketfft offers a number of advantages over fortran FFTPACK: - support for long double (`np.longfloat`) precision transforms. - faster multi-dimensional transforms using vectorisation - Bluestein’s algorithm removes the worst-case $O(n^2)$ complexity of FFTPACK - the global interpreter lock (GIL) is released during transforms - optional multithreading of multi-dimensional transforms via the workers argument

Note that `scipy.fftpack` has not been deprecated and will continue to be maintained but is now considered legacy. New code is recommended to use `scipy.fft` instead, where possible.

5.12.5 scipy.fftpack improvements

`scipy.fftpack` now uses pypocketfft to perform its FFTs, offering the same speed and accuracy benefits listed for scipy.fft above but without the improved API.

5.12.6 scipy.integrate improvements

The function `scipy.integrate.solve_ivp` now has an `args` argument. This allows the user-defined functions passed to the function to have additional parameters without having to create wrapper functions or lambda expressions for them.

`scipy.integrate.solve_ivp` can now return a `y_events` attribute representing the solution of the ODE at event times

New OdeSolver is implemented — DOP853. This is a high-order explicit Runge-Kutta method originally implemented in Fortran. Now we provide a pure Python implementation usable through `solve_ivp` with all its features.

`scipy.integrate.quad` provides better user feedback when break points are specified with a weighted integrand.

`scipy.integrate.quad_vec` is now available for general purpose integration of vector-valued functions
5.12.7 `scipy.interpolate` improvements

`scipy.interpolate.pade` now handles complex input data gracefully

`scipy.interpolate.Rbf` can now interpolate multi-dimensional functions

5.12.8 `scipy.io` improvements

`scipy.io.wavfile.read` can now read data from a WAV file that has a malformed header, similar to other modern WAV file parsers

`scipy.io.FortranFile` now has an expanded set of available Exception classes for handling poorly-formatted files

5.12.9 `scipy.linalg` improvements

The function `scipy.linalg.subspace_angles(A, B)` now gives correct results for complex-valued matrices. Before this, the function only returned correct values for real-valued matrices.

New boolean keyword argument check_finite for `scipy.linalg.norm`; whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

`scipy.linalg.solve_triangular` has improved performance for a C-ordered triangular matrix

LAPACK wrappers have been added for ?geequ, ?geequb, ?syequb, and ?heequb

Some performance improvements may be observed due to an internal optimization in operations involving LAPACK routines via `_compute_lwork`. This is particularly true for operations on small arrays.

Block QR wrappers are now available in `scipy.linalg.lapack`

5.12.10 `scipy.ndimage` improvements

5.12.11 `scipy.optimize` improvements

It is now possible to use linear and non-linear constraints with `scipy.optimize.differential_evolution`

`scipy.optimize.linear_sum_assignment` has been re-written in C++ to improve performance, and now allows input costs to be infinite.

A `ScalarFunction.fun_and_grad` method was added for convenient simultaneous retrieval of a function and gradient evaluation

`scipy.optimize.minimize` BFGS method has improved performance by avoiding duplicate evaluations in some cases

Better user feedback is provided when an objective function returns an array instead of a scalar.
5.12.12 scipy.signal improvements

Added a new function to calculate convolution using the overlap-add method, named `scipy.signal.oaconvolve`. Like `scipy.signal.fftconvolve`, this function supports specifying dimensions along which to do the convolution.

`scipy.signal.cwt` now supports complex wavelets.

The implementation of `choose_conv_method` has been updated to reflect the new FFT implementation. In addition, the performance has been significantly improved (with rather drastic improvements in edge cases).

The function `upfirdn` now has a `mode` keyword argument that can be used to select the signal extension mode used at the signal boundaries. These modes are also available for use in `resample_poly` via a newly added `padtype` argument.

`scipy.signal.sosfilt` now benefits from Cython code for improved performance.

`scipy.signal.resample` should be more efficient by leveraging `rfft` when possible.

5.12.13 scipy.sparse improvements

It is now possible to use the LOBPCG method in `scipy.sparse.linalg.svds`.

`scipy.sparse.linalg.LinearOperator` now supports the operation `rmatmat` for adjoint matrix-matrix multiplication, in addition to `rmatvec`.

Multiple stability updates enable float32 support in the LOBPCG eigenvalue solver for symmetric and Hermitian eigenvalues problems in `scipy.sparse.linalg.lobpcg`.

A solver for the maximum flow problem has been added as `scipy.sparse.csgraph.maximum_flow`.

`scipy.sparse.csgraph.maximum_bipartite_matching` now allows non-square inputs, no longer requires a perfect matching to exist, and has improved performance.

`scipy.sparse.lil_matrix` conversions now perform better in some scenarios.

Basic support is available for `pydata/sparse` arrays in `scipy.sparse.linalg`.

`scipy.sparse.linalg.spsolve_triangular` now supports the `unit_diagonal` argument to improve call signature similarity with its dense counterpart, `scipy.linalg.solve_triangular`.

`assertAlmostEqual` may now be used with sparse matrices, which have added support for `__round__`.

5.12.14 scipy.spatial improvements

The bundled Qhull library was upgraded to version 2019.1, fixing several issues. Scipy-specific patches are no longer applied to it.

`scipy.spatial.SphericalVoronoi` now has linear memory complexity, improved performance, and supports single-hemisphere generators. Support has also been added for handling generators that lie on a great circle arc (geodesic input) and for generators in n-dimensions.

`scipy.spatial.transform.Rotation` now includes functions for calculation of a mean rotation, generation of the 3D rotation groups, and reduction of rotations with rotational symmetries.

`scipy.spatial.transform.Slerp` is now callable with a scalar argument.

`scipy.spatial.voronoi_plot_2d` now supports furthest site Voronoi diagrams.

`scipy.spatial.Delaunay` and `scipy.spatial.Voronoi` now have attributes for tracking whether they are furthest site diagrams.
5.12.15 scipy.special improvements

The Voigt profile has been added as scipy.special.voigt_profile.

A real dispatch has been added for the Wright Omega function (scipy.special.wrightomega).

The analytic continuation of the Riemann zeta function has been added. (The Riemann zeta function is the one-argument variant of scipy.special.zeta.)

The complete elliptic integral of the first kind (scipy.special.ellipk) is now available in scipy.special.

cython_special.

The accuracy of scipy.special.hyp1f1 for real arguments has been improved.

The documentation of many functions has been improved.

5.12.16 scipy.stats improvements

scipy.stats.multiscale_graphcorr added as an independence test that operates on high dimensional and nonlinear data sets. It has higher statistical power than other scipy.stats tests while being the only one that operates on multivariate data.

The generalized inverse Gaussian distribution (scipy.stats.geninvgauss) has been added.

It is now possible to efficiently reuse scipy.stats.binned_statistic_dd with new values by providing the result of a previous call to the function.

scipy.stats.hmean now handles input with zeros more gracefully.

The beta-binomial distribution is now available in scipy.stats.betabinom.

scipy.stats.zscore, scipy.stats.circmean, scipy.stats.circstd, and scipy.stats.circvar now support the nan_policy argument for enhanced handling of NaN values

scipy.stats.entropy now accepts an axis argument

scipy.stats.gaussian_kde.resample now accepts a seed argument to empower reproducibility

scipy.stats.kendalltau performance has improved, especially for large inputs, due to improved cache usage

scipy.stats.truncnorm distribution has been rewritten to support much wider tails

Deprecated features

5.12.17 scipy deprecations

Support for NumPy functions exposed via the root SciPy namespace is deprecated and will be removed in 2.0.0. For example, if you use scipy.rand or scipy.diag, you should change your code to directly use numpy.random.default_rng or numpy.diag, respectively. They remain available in the currently continuing Scipy 1.x release series.

The exception to this rule is using scipy.fft as a function – scipy.fft is now meant to be used only as a module, so the ability to call scipy.fft(...) will be removed in SciPy 1.5.0.

In scipy.spatial.Rotation methods from_dcm, as_dcm were renamed to from_matrix, as_matrix respectively. The old names will be removed in SciPy 1.6.0.

Method Rotation.match_vectors was deprecated in favor of Rotation.align_vectors, which provides a more logical and general API to the same functionality. The old method will be removed in SciPy 1.6.0.
Backwards incompatible changes

5.12.18 scipy.special changes

The deprecated functions hyp2f0, hyp1f2, and hyp3f0 have been removed.
The deprecated function bessel_diff_formula has been removed.
The function i0 is no longer registered with numpy.dual, so that numpy.dual.i0 will unconditionally refer to the NumPy version regardless of whether scipy.special is imported.
The function expn has been changed to return nan outside of its domain of definition \((x, n < 0)\) instead of inf.

5.12.19 scipy.sparse changes

Sparse matrix reshape now raises an error if shape is not two-dimensional, rather than guessing what was meant. The behavior is now the same as before SciPy 1.1.0.
CSR and CSC sparse matrix classes should now return empty matrices of the same type when indexed out of bounds. Previously, for some versions of SciPy, this would raise an IndexError. The change is largely motivated by greater consistency with ndarray and numpy.matrix semantics.

5.12.20 scipy.signal changes

scipy.signal.resample behavior for length-1 signal inputs has been fixed to output a constant (DC) value rather than an impulse, consistent with the assumption of signal periodicity in the FFT method.
scipy.signal.cwt now performs complex conjugation and time-reversal of wavelet data, which is a backwards-incompatible bugfix for time-asymmetric wavelets.

5.12.21 scipy.stats changes

scipy.stats.loguniform added with better documentation as (an alias for scipy.stats.reciprocal). loguniform generates random variables that are equally likely in the log space; e.g., 1, 10 and 100 are all equally likely if loguniform(10 ** 0, 10 ** 2).rvs() is used.

Other changes

The LSODA method of scipy.integrate.solve_ivp now correctly detects stiff problems.
scipy.spatial.cKDTree now accepts and correctly handles empty input data
scipy.stats.binned_statistic_dd now calculates the standard deviation statistic in a numerically stable way.
scipy.stats.binned_statistic_dd now throws an error if the input data contains either np.nan or np.inf. Similarly, in scipy.stats now all continuous distributions’ .fit() methods throw an error if the input data contain any instance of either np.nan or np.inf.

A total of 142 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

5.12.22 Issues closed for 1.4.0

- #1255: maxiter broken for Scipy.sparse.linalg gmres, in addition to…
- #1301: consolidate multipack.h from interpolate and integrate packages…
- #1739: Single precision FFT insufficiently accurate. (Trac #1212)
- #1795: stats test_distributions.py: replace old fuzz tests (Trac #1269)
- #2233: fftpack segfault with big arrays (Trac #1714)
- #2434: rmatmat and the sophistication of linear operator objects
- #2477: stats.truncnorm.rvs() does not give symmetric results for negative…
- #2629: FFTpack is unacceptably slow on non power of 2
- #2883: UnboundLocalError in scipy.interpolate.splrep
- #2956: Feature Request: axis argument for stats.entropy function
- #3528: Segfault on test_djbfft (possibly MKL-related?)
- #3793: cwt should also return complex array
- #4464: TST: residue/residuez/invres/invrez don’t have any tests
- #4561: BUG: tf filter trailing and leading zeros in residuez
- #4669: Rewrite sosfilt to make a single loop over the input?
- #5040: BUG: Empty data handling of (c)KDTrees
- #5112: boxcox transform edge cases could use more care
- #5441: scipy.stats.ncx2 fails for nc=0
- #5502: args keyword not handled in optimize.curve_fit
- #6484: Qhull segmentation fault
- #6900: linear_sum_assignment with infinite weights
- #6966: Hypergeometric Functions documentation is lacking
- #6999: possible false positive corruption check in compressed loadmat()
- #7018: ydata that needs broadcasting renders curve_fit unable to compute…
- #7140: trouble with documentation for windows
- #7327: interpolate.ndgriddata.griddata causes Python to crash rather…
- #7396: MatrixLinearOperator implements _adjoint(), but not _transpose()
- #7400: BUG(?): special: factorial and factorial2 return a 0-dimensional…
- #7434: Testing of scipy.stats continuous distributions misses 25 distributions
- #7491: Several scipy.stats distributions (fisk, burr, burr12, f) return…
- #7759: Overflow in stats.kruskal for large samples
- #7906: Wrong result from scipy.interpolate.UnivariateSpline.integral…
• #8165: ENH: match functionality of R for hmean
• #8417: optimize.minimize(method='L-BFGS-B', options={'disp': True})…
• #8535: Strictly increasing requirement in UnivariateSpline
• #8815: [BUG] GMRES: number of iteration is only increased if callback…
• #9207: scipy.linalg.solve_triangular speed after scipy.linalg.lu_factor
• #9275: new feature: adding LOBPCG solver in svds in addition to ARPACK
• #9403: range of truncnorm.logpdf could be extended
• #9429: gaussian_kde not working with numpy matrix
• #9515: ndimage implementation relies on undefined behavior
• #9643: arpack returns singular values in ascending order
• #9669: DOC: matthew-brett/build-openblas has been retired
• #9852: scipy.spatial.ConvexHull exit with code 134, free(): invalid…
• #9902: scipy.stats.truncnorm second moment may be wrong
• #9943: Custom sampling methods in shgo do not work
• #9947: DOC: Incorrect documentation for `nan_policy='propagate` in…
• #9994: BUG: sparse: reshape method allows a shape containing an arbitrary…
• #10036: Official Nelder mead tutorial uses xtol instead of xatol, which…
• #10078: possible to get a better error message when objective function…
• #10092: overflow in truncnorm.rvs
• #10121: A little spelling mistake
• #10126: inaccurate std implementation in binned_statistic
• #10161: Error in documentation scipy.special.modstruve
• #10195: Derivative of spline with ‘const’ extrapolation is also extrapoloted…
• #10206: sparse matrices indexing with scipy 1.3
• #10236: Non-descriptive error on type mismatch for functions of scipy.optimize…
• #10258: LOBPCG convergence failure if guess provided
• #10262: distance matrix lacks dtype checks / warnings
• #10271: BUG: optimize failure on wheels
• #10277: scipy.special.zeta(0) = NAN
• #10292: DOC/REL: Some sections of the release notes are not nested correctly.
• #10300: scipy.stats.rv_continuous.fit throws empty Runtime.Error when…
• #10319: events in scipy.integrate.solve_ivp: How do I setup an events…
• #10323: Adding more low-level LAPACK wrappers
• #10360: firwin2 inadvertently modifies input and may result in undefined…
• #10388: BLD: TestHerd::test_hetrd core dumps with Python-dbgl
• #10395: Remove warning about output shape of zoom
- #10403: DOC: scipy.signal.resample ignores t parameter
- #10421: Yeo-Johnson power transformation fails with integer input data
- #10422: BUG: scipy.fft does not support multiprocessing
- #10427: ENH: convolve numbers should be updated
- #10444: BUG: scipy.spatial.transform.Rotation.match_vectors returns improper…
- #10488: ENH: DCTs/DSTs for scipy.fft
- #10501: BUG: scipy.spatial.HalfspaceIntersection works incorrectly
- #10514: BUG: cKDTree GIL handling is incorrect
- #10535: TST: master branch CI failures
- #10588: scipy.fft and numpy.fft inconsistency when axes=None and shape…
- #10628: Scipy python>3.6 Windows wheels don’t ship msvcp*.dll
- #10733: DOC/BUG: min_only result does not match documentation
- #10775: UnboundLocalError in Radau when given a NaN
- #10835: io.wavfile.read unnecessarily raises an error for a bad wav header
- #10838: Error in documentation for scipy.linalg.lu_factor
- #10875: DOC: Graphical guides (using TikZ)
- #10880: setting verbose > 2 in minimize with trust-constr method leads…
- #10887: scipy.signal.signaltools._fftconv_faster has incorrect estimates
- #10948: gammainc(0, x) = nan but should be 1, gammaincc(0, x) = nan but…
- #10952: TestQRdelete_F.test_delete_last_p_col test failure
- #10968: API: Change normalized=False to normalize=True in Rotation
- #10987: Memory leak in shgo triangulation
- #10991: Error running openBlas probably missing a step
- #11033: deadlock on osx for python 3.8
- #11041: Test failure in wheel builds for TestTf2zpk.test_simple
- #11089: Regression in scipy.stats where distribution will not accept loc and scale parameters
- #11100: BUG: multiscale_graphcorr random state seeding and parallel use
- #11121: Calls to scipy.interpolate.splprep increase RAM usage.
- #11125: BUG: segfault when slicing a CSR or CSC sparse matrix with slice start index > stop index
- #11198: BUG: sparse eigs (arpack) shift-invert drops the smallest eigenvalue for some k
5.12.23 Pull requests for 1.4.0

- #4591: BUG, TST: Several issues with scipy.signal.residue
- #6629: ENH: sparse: canonicalize on initialization
- #7076: ENH: add complex wavelet support to scipy.signal.cwt.
- #8681: ENH: add generalized inverse Gaussian distribution to scipy.stats
- #9064: BUG/ENH: Added default _transpose into LinearOperator. Fixes…
- #9215: ENH: Rbf interpolation of large multi-dimensional data
- #9311: ENH: Added voigt in scipy.special.
- #9642: ENH: integrate: quad() for vector-valued functions
- #9679: DOC: expand docstring of exponweib distribution
- #9684: TST: add ppc64le ci testing
- #9800: WIP : ENH: Refactored _hungarian.py for speed and added a minimize/maximize…
- #9847: DOC: Change integrate tutorial to use solve_ivp instead of odeint
- #9876: ENH: Use rfft when possible in resampling
- #9998: BUG: Do not remove 1s when calling sparse: reshape method #9994
- #10002: ENH: adds constraints for differential evolution
- #10098: ENH: integrate: add args argument to solve_ivp.
- #10099: DOC: Add missing docs for linprog unknown_options
- #10104: BUG: Rewrite of stats.truncnorm distribution.
- #10105: MAINT improve efficiency of rvs_ratio_uniforms in scipy.stats
- #10107: TST: dual_annealing set seed
- #10108: ENH: stats: improve kendall_tau cache usage
- #10110: MAINT: _lib: Fix a build warning.
- #10114: FIX: only print bounds when supported by minimizer (shgo)
- #10115: TST: Add a test with an almost singular design matrix for lsq_linear
- #10118: MAINT: fix rdist methods in scipy.stats
- #10119: MAINT: improve rvs of randint in scipy.stats
- #10127: Fix typo in record array field name (spatial-ckdtree-sparse_distance…
- #10130: MAINT: ndimage: Fix some compiler warnings.
- #10131: DOC: Note the solve_ivp args enhancement in the 1.4.0 release…
- #10133: MAINT: add rvs for semicircular in scipy.stats
- #10138: BUG: special: Invalid arguments to ellip_harm can crash Python.
- #10139: MAINT: spatial: Fix some compiler warnings in the file distance_wrap.c.
- #10140: ENH: add handling of NaN in RuntimeWarning except clause
- #10142: DOC: return value of scipy.special.comb
- #10143: MAINT: Loosen linprog tol
• #10152: BUG: Fix custom sampling input for shgo, add unittest
• #10154: MAINT: add moments and improve doc of mielke in scipy.stats
• #10158: Issue #6999: read zlib checksum before checking bytes read.
• #10166: BUG: Correctly handle broadcasted ydata in curve_fit pcov computation.
• #10167: DOC: special: Add missing factor of \( i \) to `modstruve` docstring
• #10168: MAINT: stats: Fix an incorrect comment.
• #10169: ENH: optimize: Clarify error when objective function returns…
• #10172: DEV: Run tests in parallel when –parallel flag is passed to…
• #10173: ENH: Implement DOP853 ODE integrator
• #10176: Fixed typo
• #10182: TST: fix test issue for stats.pearsonr
• #10184: MAINT: stats: Simplify zmap and zscore (we can use keepdims now).
• #10191: DOC: fix a formatting issue in the scipy.spatial module docstring.
• #10193: DOC: Updated docstring for optimize.nnls
• #10198: DOC, ENH: special: Make ‘hyp2f1’ references more specific
• #10202: DOC: Format DST and DCT definitions as latex equations
• #10207: BUG: Compressed matrix indexing should return a scalar
• #10210: DOC: Update docs for connection=’weak’ in connected_components
• #10225: DOC: Clarify new interfaces for legacy functions in ‘optimize’
• #10231: DOC, MAINT: gpg2 updates to release docs / pavement
• #10235: LICENSE: split license file in standard BSD 3-clause and bundled.
• #10238: ENH: Add new scipy.fft module using pocketfft
• #10243: BUG: fix ARFF reader regression with quoted values.
• #10248: DOC: update README file
• #10255: CI: bump OpenBLAS to match wheels
• #10264: TST: add tests for stats.tvar with unflattened arrays
• #10280: MAINT: stats: Use a constant value for sqrt(2/PI).
• #10286: Development Documentation Overhaul
• #10290: MAINT: Deprecate NumPy functions in SciPy root
• #10291: FIX: Avoid importing xdist when checking for availability
• #10295: Disable deprecated Numpy API in __odrpack.c
• #10296: ENH: C++ extension for linear assignment problem
• #10298: ENH: Made pade function work with complex inputs
• #10301: DOC: Fix critical value significance levels in stats.anderson_ksamp
• #10307: Minkowski Distance Type Fix (issue #10262)
• #10309: BUG: Pass jac=None directly to lsoda
• #10310: BUG: interpolate: UnivariateSpline.derivative.ext is ‘zeros’…
• #10312: FIX: Fixing a typo in a comment
• #10314: scipy.spatial enhancement request
• #10315: DOC: Update integration tutorial to solve_ivp
• #10318: DOC: update the example for PPolysolve
• #10333: TST: add tests for stats.tvar with unflattened arrays
• #10334: MAINT: special: Remove deprecated ‘hyp2f0’, ‘hyp1f2’, and…
• #10336: BUG: linalg/interpolative: fix interp_decomp modifying input
• #10341: BUG: sparse.linalg/gmres: deprecate effect of callback on semantics…
• #10344: DOC: improve wording of mathematical formulation
• #10345: ENH: Tiled QR wrappers for scipy.linalg.lapack
• #10350: MAINT: linalg: Use the new fft subpackage in linalg.dft tests...
• #10351: BUG: Fix unstable standard deviation calculation in histogram
• #10353: Bug: interpolate.NearestNDInterpolator (issue #10352)
• #10357: DOC: linalg: Refer to scipy.fft.fft (not fftpack) in the dft...
• #10359: DOC: Update roadmap now scipy.fft has been merged
• #10361: ENH: Prefer scipy.fft to scipy.fftpack in scipy.signal
• #10371: DOC: Tweaks to fft documentation
• #10372: DOC: Fix typos
• #10377: TST, MAINT: adjustments for pytest 5.0
• #10378: ENH: _lib: allow new np.random.Generator in check_random_state
• #10379: BUG: sparse: set writeability to be forward-compatible with numpy>=1.17
• #10381: BUG: Fixes gh-7491, pdf at x=0 of fisk/burr/burr12/f distributions.
• #10387: ENH: optimize/bfgs: don’t evaluate twice at initial point for…
• #10392: [DOC] Add an example for _binned_statistic_dd
• #10396: Remove warning about output shape of zoom
• #10397: ENH: Add check_finite to sp.linalg.norm
• #10399: ENH: Add __round__ method to sparse matrix
• #10407: MAINT: drop pybind11 from install_requires, it’s only build-time…
• #10408: TST: use pytest.raises, not numpy assert_raises
• #10409: CI: uninstall nose on Travis
• #10410: [ENH] ncx2 dispatch to chi2 when nc=0
• #10411: TST: optimize: test should use assert_allclose for fp comparisons
• #10414: DOC: add pybind11 to the other part of quickstart guides
• #10417: DOC: special: don’t mark non-ufuncs with a ‘[+]’
• #10423: FIX: Use pybind11::isinstance to check array dtypes
• #10424: DOC: add doctest example for binary data for test_ind_from_stats
• #10425: ENH: Add missing Hermitian transforms to scipy.fft
• #10426: MAINT: Fix doc build bugs
• #10431: Update numpy version for AIX
• #10433: MAINT: Minor fixes for the stats
• #10434: BUG: special: make ‘ndtri’ return NaN outside domain of definition
• #10435: BUG: Allow integer input data in scipy.stats.yeojohnson
• #10438: [DOC] Add example for kurtosis
• #10440: ENH: special: make ‘ellipk’ a ufunc
• #10443: MAINT: ndimage: malloc fail check
• #10447: BLD: Divert output from test compiles into a temporary directory
• #10451: MAINT: signal: malloc fail check
• #10455: BUG: special: fix values of ‘hyperu’ for negative ‘x’
• #10456: DOC: Added comment clarifying the call for dcsrch.f in lbfgsb.f
• #10457: BUG: Allow ckdtrree to accept empty data input
• #10459: BUG:TST: Compute lwork safely
• #10460: [DOC] Add example to entropy
• #10461: DOC: Quickstart Guide updates
• #10462: TST: special: only show max atol/rtol for test points that failed
• #10465: BUG: Correctly align ft inputs
• #10467: ENH: lower-memory duplicate generator checking in spatial.SphericalVoronoi
• #10470: ENH: Normalise the inverse DCT/DST in scipy.fft
• #10472: BENCH: adjust timeout for slow setup_cache
• #10475: CI: include python debug for Travis-ci
• #10476: TST: special: use ‘__tracebackhide__’ to get better error messages
• #10477: ENH: faster region building in spatial.SphericalVoronoi
• #10479: BUG: stats: Fix a few issues with the distributions’ fit method.
• #10480: Add RuntimeError in _distn_infrastructure.py in fit() method
• #10481: BENCH, MAINT: wheel_cache_size has been renamed build_cache_size
• #10494: ENH: faster circumcenter calculation in spatial.SphericalVoronoi
• #10500: Splrep _curfit_cache global variable bugfix
• #10503: BUG: spatial/qhull: get HalfspaceIntersection.dual_points from…
• #10506: DOC: interp2d, note nearest neighbor extrapolation
• #10507: MAINT: Remove fortran fftpack library in favour of pyocketfft
• #10508: TST: fix a bug in the circular import test.
• #10509: MAINT: Set up _build_utils as subpackage
• #10516: BUG: Use nogil contexts in cKDTree
• #10517: ENH: fftconvolve should not FFT broadcastable axes
• #10518: ENH: Speedup fftconvolve
• #10520: DOC: Proper .rst formatting for deprecated features and Backwards…
• #10523: DOC: Improve scipy.signal.resample documentation
• #10524: ENH: Add MGC to scipy.stats
• #10525: [ENH] ncx2.ppf dispatch to chi2 when nc=0
• #10526: DOC: clarify laplacian normalization
• #10528: API: Rename scipy.fft DCT/DST shape argument to s
• #10531: BUG: fixed improper rotations in spatial.transform.rotation.match_vectors
• #10533: [DOC] Add example for winsorize function
• #10539: MAINT: special: don’t register ‘i0’ with ‘numpy.dual’
• #10540: MAINT: Fix Travis and Circle
• #10542: MAINT: interpolate: use cython_lapack
• #10547: Feature request. Add furthest site Voronoi diagrams to scipy.spatial.plotutils.
• #10549: [BUG] Fix bug in trimr when inclusive=False
• #10552: add scipy.signal.upfirdn signal extension modes
• #10555: MAINT: special: move `c_misc` into Cephes
• #10556: [DOC] Add example for trima
• #10562: [DOC] Fix triple string fo trimmed so that __doc__ can show…
• #10563: improve least_squares error msg for mismatched shape
• #10564: ENH: linalg: memoize get_lapack/blas_funcs to speed it up
• #10566: ENH: add implementation of solver for the maximum flow problem
• #10567: BUG: spatial: use c++11 construct for getting start of vector…
• #10568: DOC: special: small tweaks to the ‘zetac’ docstring
• #10571: [ENH] Gaussian_kde can accept matrix dataset
• #10574: ENH: linalg: speed up _compute_lwork by avoiding numpy constructs
• #10582: Fix typos with typos in bundled libraries reverted
• #10583: ENH: special: add the analytic continuation of Riemann zeta
• #10584: MAINT: special: clean up `special.__all__`
• #10586: BUG: multidimensional scipy.fft functions should accept ‘s’ rather…
• #10587: BUG: integrate/lsoda: never abort run, set error istate instead
• #10594: API: Replicate numpy’s fftn behaviour when s is given but not…
• #10599: DOC: dev: update documentation vs. github pull request workflow…
• #10603: MAINT: installer scripts removed
• #10604: MAINT: Change c*np.ones(…) to np.full(…, c, …) in many…
• #10608: Univariate splines should require x to be strictly increasing…
• #10613: ENH: Add seed option for gaussian_kde.resample
• #10614: ENH: Add parallel computation to scipy.fft
• #10615: MAINT: interpolate: remove unused header file
• #10616: MAINT: Clean up 32-bit platform xfail markers
• #10618: BENCH: Added ‘trust-constr’ to minimize benchmarks
• #10621: [MRG] multiple stability updates in lobpcg
• #10622: MAINT: forward port 1.3.1 release notes
• #10624: DOC: stats: Fix spelling of ‘support’.
• #10627: DOC: stats: Add references for the alpha distribution.
• #10629: MAINT: special: avoid overflow longer in `zeta` for negative…
• #10630: TST: GH10271, relax test assertion, fixes #10271
• #10631: DOC: nelder-means uses xtol fixes #10036
• #10633: BUG: interpolate: integral(a, b) should be zero when both limits…
• #10635: DOC: special: complete hypergeometric functions documentation
• #10636: BUG: special: use series for ’hyp1f1’ when it converges rapidly
• #10641: ENH: allow matching of general bipartite graphs
• #10643: ENH: scipy.sparse.linalg.spsolve triangular unit diagonal
• #10650: ENH: Cythonize sosfilt
• #10654: DOC: Vertical alignment of table entries
• #10655: ENH: Dockerfile for scipy development
• #10660: TST: clean up tests for rvs in scipy.stats
• #10664: Throw error on non-finite input for binned_statistic_dd()
• #10665: DOC: special: improve the docstrings for ‘gamma’ and ‘gammasgn’
• #10669: TST: Update scipy.fft real transform tests
• #10670: DOC: Clarify docs and error messages for scipy.signal.butter
• #10672: ENH: return solution attribute when using events in solve_ivp
• #10675: MAINT: special: add an explicit NaN check for ‘iv’ arguments
• #10679: DOC: special: Add documentation for ’beta’ function
• #10681: TST: sparse.linalg: fix arnoldi test seed
• #10682: DOC: special: Add documentation for ‘betainc’ function
• #10684: TST: special: require Mpmath 1.1.0 for ‘test_hyperu_around_0’
• #10686: FIX: sphinx isattributedescriptor is not available in sphinx…
• #10687: DOC: added Docker quickstart guide by @andyfaff
• #10689: DOC: special: clarify format of parameters/returns sections for…
• #10690: DOC: special: improve docstrings of incomplete gamma functions
• #10692: ENH: higher-dimensional input in `spatial.SphericalVoronoi`
• #10694: ENH: ScalarFunction.fun_and_grad
• #10698: DOC: special: Add documentation for `betaincinv`
• #10699: MAINT: remove time print lbfgsb fixes #8417
• #10701: TST, MAINT: bump OpenBLAS to 0.3.7 stable
• #10702: DOC: clarify iterations consume multiple function calls
• #10703: DOC: iprint doc lbfgsb closes #5482
• #10708: TST: test suggested in gh1758
• #10710: ENH: Added nan_policy to circ functions in `stats`
• #10712: ENH: add axis parameter to stats.entropy
• #10714: DOC: Formatting fix rv_continuous.expect docs
• #10715: DOC: BLD: update doc Makefile for python version; add scipy version…
• #10717: MAINT: modernize doc/Makefile
• #10719: Enable setting minres initial vector
• #10720: DOC: silence random warning in doc build for `stats.binned_statistic_dd`
• #10724: DEV: Add doc option to runtests.py
• #10728: MAINT: get rid of gramA, gramB text files that lobpcg tests leave…
• #10732: DOC: add min_only to docstring for Dijkstra’s algorithm
• #10734: DOC: spell out difference between source and target in shortest…
• #10735: Fix for Python 4
• #10739: BUG: optimize/lsqpp: deal with singular BFGS update
• #10742: DOC: special: add to the docstring of ’gammahn’
• #10743: ENH: special: add a real dispatch for ’wrightomega’
• #10746: MAINT: Fix typos in comments, docs and test name
• #10747: Remove spurious quotes
• #10750: MAINT: make cython code more precise
• #10751: MAINT: Check that scipy.linalg.lapack functions are documented
• #10752: MAINT: special: use `sf_error` in Cephes
• #10755: DOC: cluster: Add ‘See Also’ and ‘Examples’ for kmeans2.
• #10763: MAINT: list of minimize methods
• #10768: BUG: Fix corner case for sos2zpk
• #10773: Fix error type for complex input to scipy.fftpack.rfft and irfft
• #10776: ENH: handle geodesic input in `spatial.SphericalVoronoi`.
• #10777: MAINT: minimizer->custom should handle the kinds of bounds/constrain……
• #10781: ENH: solve_triangular C order improvement
• #10787: Fix behavior of `exp1` on branch cut and add docstring
• #10789: DOC: special: add parameters/returns doc sections for erfc/erfcx/erfi
• #10790: Travis CI: sudo is deprecated and Xenial is default distro
• #10792: DOC: special: add full docstring for `exp1`
• #10799: DOC: special: add a complete docstring for `expn`
• #10800: Docs edits (GSoD)
• #10802: BUG: fix UnboundLocalError in Radau (scipy#10775)
• #10804: ENH: Speed up next_fast_len with LRU cache
• #10805: DOC: Fix unbalanced quotes in signal.place_poles

5.12. SciPy 1.4.0 Release Notes
5.13 SciPy 1.3.3 Release Notes

SciPy 1.3.3 is a bug-fix release with no new features compared to 1.3.2. In particular, a test suite issue involving multiprocessing was fixed for Windows and Python 3.8 on macOS. Wheels were also updated to place msvcp140.dll at the appropriate location, which was previously causing issues.

5.16 SciPy 1.3.0 Release Notes
SciPy 1.3.0 is the culmination of 5 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been some API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Before upgrading, we recommend that users check that their own code does not use deprecated SciPy functionality (to do so, run your code with `python -Wd` and check for `DeprecationWarning`s). Our development attention will now shift to bug-fix releases on the 1.3.x branch, and on adding new features on the master branch.

This release requires Python 3.5+ and NumPy 1.13.3 or greater.

For running on PyPy, PyPy3 6.0+ and NumPy 1.15.0 are required.

### 5.16.1 Highlights of this release

- Three new `stats` functions, a rewrite of `pearsonr`, and an exact computation of the Kolmogorov-Smirnov two-sample test.
- A new Cython API for bounded scalar-function root-finders in `scipy.optimize`.
- Substantial CSR and CSC sparse matrix indexing performance improvements.
- Added support for interpolation of rotations with continuous angular rate and acceleration in `RotationSpline`.

### 5.16.2 New features

**scipy.interpolate improvements**

A new class `CubicHermiteSpline` is introduced. It is a piecewise-cubic interpolator which matches observed values and first derivatives. Existing cubic interpolators `CubicSpline`, `PchipInterpolator` and `Akima1DInterpolator` were made subclasses of `CubicHermiteSpline`. 
**scipy.io improvements**

For the Attribute-Relation File Format (ARFF) `scipy.io.arff.loadarff` now supports relational attributes. `scipy.io.mmread` can now parse Matrix Market format files with empty lines.

**scipy.linalg improvements**

Added wrappers for `?syconv` routines, which convert a symmetric matrix given by a triangular matrix factorization into two matrices and vice versa.

`scipy.linalg.clarkson_woodruff_transform` now uses an algorithm that leverages sparsity. This may provide a 60-90 percent speedup for dense input matrices. Truly sparse input matrices should also benefit from the improved sketch algorithm, which now correctly runs in $O(nnz(A))$ time.

Added new functions to calculate symmetric Fiedler matrices and Fiedler companion matrices, named `scipy.linalg.fiedler` and `scipy.linalg.fiedler_companion`, respectively. These may be used for root finding.

**scipy.ndimage improvements**

Gaussian filter performances may improve by an order of magnitude in some cases, thanks to the removal of a dependence on `np.polynomial`. This may impact `scipy.ndimage.gaussian_filter` for example.

**scipy.optimize improvements**

The `scipy.optimize.brute` minimizer obtained a new keyword `workers`, which can be used to parallelize computation.

A Cython API for bounded scalar-function root-finders in `scipy.optimize` is available in a new module `scipy.optimize.cython_optimize` via `cimport`. This API may be used with `nogil` and `prange` to loop over an array of function arguments to solve for an array of roots more quickly than with pure Python.

'interior-point' is now the default method for `linprog`, and 'interior-point' now uses SuiteSparse for sparse problems when the required scikits (scikit-umfpack and scikit-sparse) are available. On benchmark problems (gh-10026), execution time reductions by factors of 2-3 were typical. Also, a new method='revised simplex' has been added. It is not as fast or robust as method='interior-point', but it is a faster, more robust, and equally accurate substitute for the legacy method='simplex'.

differential_evolution can now use a `Bounds` class to specify the bounds for the optimizing argument of a function.

`scipy.optimize.dual_annealing` performance improvements related to vectorization of some internal code.

**scipy.signal improvements**

Two additional methods of discretization are now supported by `scipy.signal.cont2discrete`: impulse and foh.

`scipy.signal.firls` now uses faster solvers.

`scipy.signal.detrend` now has a lower physical memory footprint in some cases, which may be leveraged using the new `overwrite_data` keyword argument.

`scipy.signal.firwin` `pass_zero` argument now accepts new string arguments that allow specification of the desired filter type: 'bandpass', 'lowpass', 'highpass', and 'bandstop'.

Chapter 5. Release Notes
`scipy.signal.sosfilt` may have improved performance due to lower retention of the global interpreter lock (GIL) in the algorithm.

**scipy.sparse improvements**

A new keyword was added to `csgraph.dijkstra` that allows users to query the shortest path to ANY of the passed-in indices, as opposed to the shortest path to EVERY passed index.

`scipy.sparse.linalg.lsmr` performance has been improved by roughly 10 percent on large problems.

Improved performance and reduced physical memory footprint of the algorithm used by `scipy.sparse.linalg.lobpcg`.

CSR and CSC sparse matrix fancy indexing performance has been improved substantially.

**scipy.spatial sparse improvements**

`scipy.spatial.ConvexHull` now has a `good` attribute that can be used alongsize the QGn Qhull options to determine which external facets of a convex hull are visible from an external query point.

`scipy.spatial.cKDTree.query_ball_point` has been modernized to use some newer Cython features, including GIL handling and exception translation. An issue with `return_sorted=True` and scalar queries was fixed, and a new mode named `return_length` was added. `return_length` only computes the length of the returned indices list instead of allocating the array every time.

`scipy.spatial.transform.RotationSpline` has been added to enable interpolation of rotations with continuous angular rates and acceleration.

**scipy.stats improvements**

Added a new function to compute the Epps-Singleton test statistic, `scipy.stats.epps_singleton_2samp`, which can be applied to continuous and discrete distributions.

New functions `scipy.stats.median_absolute_deviation` and `scipy.stats.gstd` (geometric standard deviation) were added. The `scipy.stats.combine_pvalues` method now supports `pearson`, `tippett` and `mudholkar_george` pvalue combination methods.

The `scipy.stats.ortho_group` and `scipy.stats.special_ortho_group` `rvs(dim)` functions’ algorithms were updated from a $O(dim^4)$ implementation to a $O(dim^3)$ which gives large speed improvements for $dim>100$.

A rewrite of `scipy.stats.pearsonr` to use a more robust algorithm, provide meaningful exceptions and warnings on potentially pathological input, and fix at least five separate reported issues in the original implementation.

Improved the precision of `hypergeom.logcdf` and `hypergeom.logsf`.

Added exact computation for Kolmogorov-Smirnov (KS) two-sample test, replacing the previously approximate computation for the two-sided test `stats.ks_2samp`. Also added a one-sided, two-sample KS test, and a keyword `alternative` to `stats.ks_2samp`. 
5.16.3 Backwards-incompatible changes

**scipy.interpolate changes**

Functions from `scipy.interpolate` (spleval, spline, splmake, and spltopp) and functions from `scipy.misc` (bytescale, fromimage, imfilter, imread, imresize, imrotate, imsav, imshow, toimage) have been removed. The former set has been deprecated since v0.19.0 and the latter has been deprecated since v1.0.0. Similarly, aliases from `scipy.misc` (comb, factorial, factorial2, factorialk, logsumexp, pade, info, source, who) which have been deprecated since v1.0.0 are removed. SciPy documentation for v1.1.0 can be used to track the new import locations for the relocated functions.

**scipy.linalg changes**

For `pinv`, `pinv2`, and `pinvh`, the default cutoff values are changed for consistency (see the docs for the actual values).

**scipy.optimize changes**

The default method for `linprog` is now `'interior-point'`. The method’s robustness and speed come at a cost: solutions may not be accurate to machine precision or correspond with a vertex of the polytope defined by the constraints. To revert to the original simplex method, include the argument `method='simplex'`.

**scipy.stats changes**

Previously, `ks_2samp(data1, data2)` would run a two-sided test and return the approximated p-value. The new signature, `ks_2samp(data1, data2, alternative="two-sided", method="auto")`, still runs the two-sided test by default but returns the exact p-value for small samples and the approximated value for large samples. `method="asymp"` would be equivalent to the old version but `auto` is the better choice.

5.16.4 Other changes

Our tutorial has been expanded with a new section on global optimizers.

There has been a rework of the `stats.distributions` tutorials.

*scipy.optimize* now correctly sets the convergence flag of the result to `CONVERR`, a convergence error, for bounded scalar-function root-finders if the maximum iterations has been exceeded, `disp` is false, and `full_output` is true.

*scipy.optimize.curve_fit* no longer fails if `xdata` and `ydata` dtypes differ; they are both now automatically cast to `float64`.

*scipy.ndimage* functions including `binary_erosion`, `binary_closing`, and `binary_dilation` now require an integer value for the number of iterations, which alleviates a number of reported issues.

Fixed normal approximation in case `zero_method == "pratt"` in `scipy.stats.wilcoxon`.

Fixes for incorrect probabilities, broadcasting issues and thread-safety related to stats distributions setting member variables inside `_argcheck()`.

*scipy.optimize.newton* now correctly raises a `RuntimeError` in the following cases: when default arguments are used and if a derivative of value zero is obtained (which is a special case of failing to converge).

A draft toolchain roadmap is now available, laying out a compatibility plan including Python versions, C standards, and NumPy versions.

• #10116: MAINT: update scipy-sphinx-theme
• #10135: BUG: fix linprog revised simplex docstring problem failure

5.17 SciPy 1.2.3 Release Notes

SciPy 1.2.3 is a bug-fix release with no new features compared to 1.2.2. It is part of the long-term support (LTS) release series for Python 2.7.
5.17.1 Authors

- Geordie McBain
- Matt Haberland
- David Hagen
- Tyler Reddy
- Pauli Virtanen
- Eric Larson
- Yu Feng
- ananyashreyjain
- Nikolay Mayorov
- Evgeni Burovski
- Warren Weckesser

Issues closed for 1.2.3

- #4915: Bug in unique_roots in scipy.signal.signaltools.py for roots with same magnitude
- #5546: ValueError raised if scipy.sparse.linalg.expm receives array larger than 200x200
- #7117: Warn users when using float32 input data to curve_fit and friends
- #7906: Wrong result from scipy.interpolate.UnivariateSpline.integral for out-of-bounds
- #9581: Least-squares minimization fails silently when x and y data are different types
- #9901: Isoda fails to detect stiff problem when called from solve_ivp
- #9988: doc build broken with Sphinx 2.0.0
- #10303: BUG: optimize: linprog failing TestLinprogSimplexBland::test_unbounded_below_no_presolve_corrected
- #10376: TST: Travis CI fails (with pytest 5.0 ?)
- #10384: CircleCI doc build failing on new warnings
- #10535: TST: master branch CI failures
- #11121: Calls to scipy.interpolate.splprep increase RAM usage.
- #11198: BUG: sparse eigs (arpack) shift-invert drops the smallest eigenvalue for some k
- #11266: Sparse matrix constructor data type detection changes on Numpy 1.18.0
Pull requests for 1.2.3

- #9992: MAINT: Undo Sphinx pin
- #10071: DOC: reconstruct SuperLU permutation matrices avoiding SparseEfficiencyWarning
- #10076: BUG: optimize: fix curve_fit for mixed float32/float64 input
- #10138: BUG: special: Invalid arguments to ellip_harm can crash Python.
- #10306: BUG: optimize: Fix for 10303
- #10309: BUG: Pass jac=None directly to lsoda
- #10377: TST, MAINT: adjustments for pytest 5.0
- #10379: BUG: sparse: set writeability to be forward-compatible with numpy>=1.17
- #10426: MAINT: Fix doc build bugs
- #10540: MAINT: Fix Travis and Circle
- #10633: BUG: interpolate: integral(a, b) should be zero when both limits are outside of the interpolation range
- #10833: BUG: Fix subspace_angles for complex values
- #10882: BUG: sparse/arpack: fix incorrect code for complex hermitian M
- #10906: BUG: sparse/linalg: fix expm for np.matrix inputs
- #10961: BUG: Fix signal.unique_roots
- #11126: BUG: interpolate/fitpack: fix memory leak in splprep
- #11199: BUG: sparse.linalg: mistake in unsymm. real shift-invert ARPACK eigenvalue selection
- #11269: Fix: Sparse matrix constructor data type detection changes on Numpy 1.18.0

5.18 SciPy 1.2.2 Release Notes

SciPy 1.2.2 is a bug-fix release with no new features compared to 1.2.1. Importantly, the SciPy 1.2.2 wheels are built with OpenBLAS 0.3.7.dev to alleviate issues with SkylakeX AVX512 kernels.
5.18.1 Authors

- CJ Carey
- Tyler Dawson +
- Ralf Gommers
- Kai Striega
- Andrew Nelson
- Tyler Reddy
- Kevin Sheppard +

A total of 7 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

Issues closed for 1.2.2

- #9611: Overflow error with new way of p-value calculation in kendall tau correlation for perfectly monotonic vectors
- #9964: optimize.newton : overwrites x0 argument when it is a numpy array
- #9784: TST: Minimum NumPy version is not being CI tested
- #10132: Docs: Description of nnz attribute of sparse.csc_matrix misleading

Pull requests for 1.2.2

- #10056: BUG: Ensure factorial is not too large in kendaltau
- #9991: BUG: Avoid inplace modification of input array in newton
- #9788: TST, BUG: f2py-related issues with NumPy < 1.14.0
- #9749: BUG: MapWrapper.__exit__ should terminate
- #10141: Update description for nnz on csc.py

5.19 SciPy 1.2.1 Release Notes

SciPy 1.2.1 is a bug-fix release with no new features compared to 1.2.0. Most importantly, it solves the issue that 1.2.0 cannot be installed from source on Python 2.7 because of non-ascii character issues.
It is also notable that SciPy 1.2.1 wheels were built with OpenBLAS 0.3.5.dev, which may alleviate some linear algebra issues observed in SciPy 1.2.0.

5.19.1 Authors

- Eric Larson
- Mark Mikofski
- Evgeni Burovski
- Ralf Gommers
- Eric Moore
- Tyler Reddy

Issues closed for 1.2.1

- #9606: SyntaxError: Non-ASCII character ‘xe2’ in file scipy/stats/_continuous_distns.py on line 3346, but no encoding declared
- #9608: Version 1.2.0 introduces too many indices for array error in…
- #9709: scipy.stats.gaussian_kde normalizes the weights keyword argument…
- #9733: scipy.linalg.qr_update gives NaN result
- #9724: CI: Is scipy/scipy Windows Python36-32bit-full working?

Pull requests for 1.2.1

- #9612: BUG: don’t use array newton unless size is greater than 1
- #9615: ENH: Add test for encoding
- #9720: BUG: stats: weighted KDE does not modify the weights array
- #9739: BUG: qr_updates fails if u is exactly in span Q
- #9725: TST: pin mingw for Azure Win CI
- #9736: TST: adjust to vmImage dispatch in Azure
- #9681: BUG: Fix failing stats tests (partial backport)
- #9662: TST: interpolate: avoid pytest deprecations

5.20 SciPy 1.2.0 Release Notes

Contents

- SciPy 1.2.0 Release Notes
  - Highlights of this release
  - New features
SciPy 1.2.0 is the culmination of 6 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Before upgrading, we recommend that users check that their own code does not use deprecated SciPy functionality (to do so, run your code with `python -Wd` and check for `DeprecationWarning`s). Our development attention will now shift to bug-fix releases on the 1.2.x branch, and on adding new features on the master branch.

This release requires Python 2.7 or 3.4+ and NumPy 1.8.2 or greater.

**Note:** This will be the last SciPy release to support Python 2.7. Consequently, the 1.2.x series will be a long term support (LTS) release; we will backport bug-fixes until 1 Jan 2020.

For running on PyPy, PyPy 3 6.0+ and NumPy 1.15.0 are required.

### 5.20.1 Highlights of this release

- 1-D root finding improvements with a new solver, `toms748`, and a new unified interface, `root_scalar`
- new `dual_annealing` optimization method that combines stochastic and local deterministic searching
- a new optimization algorithm, `shgo` (simplicial homology global optimization), for derivative-free optimization problems
- a new category of quaternion-based transformations are available in `scipy.spatial.transform`
5.20.2 New features

scipy.ndimage improvements

Proper spline coefficient calculations have been added for the mirror, wrap, and reflect modes of `scipy.ndimage.rotate`.

scipy.fftpack improvements

DCT-IV, DST-IV, DCT-I, and DST-I orthonormalization are now supported in `scipy.fftpack`.

scipy.interpolate improvements

`scipy.interpolate.pade` now accepts a new argument for the order of the numerator.

scipy.cluster improvements

`scipy.cluster.vq.kmeans2` gained a new initialization method, kmeans++.

scipy.special improvements

The function `softmax` was added to `scipy.special`.

scipy.optimize improvements

The one-dimensional nonlinear solvers have been given a unified interface `scipy.optimize.root_scalar`, similar to the `scipy.optimize.root` interface for multi-dimensional solvers. `scipy.optimize.root_scalar(f, bracket=[a ,b], method="brenth")` is equivalent to `scipy.optimize.brenth(f, a ,b)`. If no method is specified, an appropriate one will be selected based upon the bracket and the number of derivatives available.

The so-called Algorithm 748 of Alefeld, Potra and Shi for root-finding within an enclosing interval has been added as `scipy.optimize.toms748`. This provides guaranteed convergence to a root with convergence rate per function evaluation of approximately 1.65 (for sufficiently well-behaved functions).

differential_evolution now has the updating and workers keywords. The first chooses between continuous updating of the best solution vector (the default), or once per generation. Continuous updating can lead to faster convergence. The workers keyword accepts an int or map-like callable, and parallelises the solver (having the side effect of updating once per generation). Supplying an int evaluates the trial solutions in N parallel parts. Supplying a map-like callable allows other parallelisation approaches (such as mpi4py, or joblib) to be used.

dual_annealing (and shgo below) is a powerful new general-purpose global optimization (GO) algorithm. dual_annealing uses two annealing processes to accelerate the convergence towards the global minimum of an objective mathematical function. The first annealing process controls the stochastic Markov chain searching and the second annealing process controls the deterministic minimization. So, dual annealing is a hybrid method that takes advantage of stochastic and local deterministic searching in an efficient way.

shgo (simplicial homology global optimization) is a similar algorithm appropriate for solving black box and derivative-free optimization (DFO) problems. The algorithm generally converges to the global solution in finite time. The convergence holds for non-linear inequality and equality constraints. In addition to returning a global minimum, the algorithm also returns any other global and local minima found after every iteration. This makes it useful for exploring the solutions in a domain.
`scipy.optimize.newton` can now accept a scalar or an array.

MINPACK usage is now thread-safe, such that MINPACK + callbacks may be used on multiple threads.

**scipy.signal improvements**

Digital filter design functions now include a parameter to specify the sampling rate. Previously, digital filters could only be specified using normalized frequency, but different functions used different scales (e.g. 0 to 1 for `butter` vs 0 to $\pi$ for `freqz`), leading to errors and confusion. With the `fs` parameter, ordinary frequencies can now be entered directly into functions, with the normalization handled internally.

`find_peaks` and related functions no longer raise an exception if the properties of a peak have unexpected values (e.g. a prominence of 0). A `PeakPropertyWarning` is given instead.

The new keyword argument `plateau_size` was added to `find_peaks`. `plateau_size` may be used to select peaks based on the length of the flat top of a peak.

`welch()` and `csd()` methods in `scipy.signal` now support calculation of a median average PSD, using `average='median'` keyword.

**scipy.sparse improvements**

The `scipy.sparse.bsr_matrix.tocsr` method is now implemented directly instead of converting via COO format, and the `scipy.sparse.bsr_matrix.tocsc` method is now also routed via CSR conversion instead of COO. The efficiency of both conversions is now improved.

The issue where SuperLU or UMFPACK solvers crashed on matrices with non-canonical format in `scipy.sparse.linalg` was fixed. The solver wrapper canonicalizes the matrix if necessary before calling the SuperLU or UMFPACK solver.

The `largest` option of `scipy.sparse.linalg.lobpcg()` was fixed to have a correct (and expected) behavior. The order of the eigenvalues was made consistent with the ARPACK solver (`eigs()`), i.e. ascending for the smallest eigenvalues, and descending for the largest eigenvalues.

The `scipy.sparse.random` function is now faster and also supports integer and complex values by passing the appropriate value to the `dtype` argument.

**scipy.spatial improvements**

The function `scipy.spatial.distance.jaccard` was modified to return 0 instead of `np.nan` when two all-zero vectors are compared.

Support for the Jensen Shannon distance, the square-root of the divergence, has been added under `scipy.spatial.distance.jensenshannon`.

An optional keyword was added to the function `scipy.spatial.cKDTree.query_ball_point()` to sort or not sort the returned indices. Not sorting the indices can speed up calls.

A new category of quaternion-based transformations are available in `scipy.spatial.transform`, including spherical linear interpolation of rotations (`Slerp`), conversions to and from quaternions, Euler angles, and general rotation and inversion capabilities (`spatial.transform.Rotation`), and uniform random sampling of 3D rotations (`spatial.transform.Rotation.random`).
**scipy.stats improvements**

The Yeo-Johnson power transformation is now supported (yeojohnson, yeojohnson_llf, yeojohnson_normmax, yeojohnson_normplot). Unlike the Box-Cox transformation, the Yeo-Johnson transformation can accept negative values.

Added a general method to sample random variates based on the density only, in the new function rvs_ratio_uniforms.

The Yule-Simon distribution (yulesimon) was added – this is a new discrete probability distribution.

stats and mstats now have access to a new regression method, siegelslopes, a robust linear regression algorithm

scipy.stats.gaussian_kde now has the ability to deal with weighted samples, and should have a modest improvement in performance

Levy Stable Parameter Estimation, PDF, and CDF calculations are now supported for scipy.stats.levy_stable.

The Brunner-Munzel test is now available as brunnermunzel in stats and mstats.

**scipy.linalg improvements**

scipy.linalg.lapack now exposes the LAPACK routines using the Rectangular Full Packed storage (RFP) for upper triangular, lower triangular, symmetric, or Hermitian matrices; the upper trapezoidal fat matrix RZ decomposition routines are now available as well.

### 5.20.3 Deprecated features

The functions hyp2f0, hyp1f2 and hyp3f0 in scipy.special have been deprecated.

### 5.20.4 Backwards-incompatible changes

LAPACK version 3.4.0 or later is now required. Building with Apple Accelerate is no longer supported.

The function scipy.linalg.subspace_angles(A, B) now gives correct results for all angles. Before this, the function only returned correct values for those angles which were greater than π/4.

Support for the Bento build system has been removed. Bento had not been maintained for several years, and did not have good Python 3 or wheel support, hence it was time to remove it.

The required signature of scipy.optimize.lingprog method=simplex callback function has changed. Before iteration begins, the simplex solver first converts the problem into a standard form that does not, in general, have the same variables or constraints as the problem defined by the user. Previously, the simplex solver would pass a user-specified callback function several separate arguments, such as the current solution vector xk, corresponding to this standard-form problem. Unfortunately, the relationship between the standard-form problem and the user-defined problem was not documented, limiting the utility of the information passed to the callback function.

In addition to numerous bug-fix changes, the simplex solver now passes a user-specified callback function a single OptimizeResult object containing information that corresponds directly to the user-defined problem. In future releases, this OptimizeResult object may be expanded to include additional information, such as variables corresponding to the standard-form problem and information concerning the relationship between the standard-form and user-defined problems.

The implementation of scipy.sparse.random has changed, and this affects the numerical values returned for both sparse.random and sparse.rand for some matrix shapes and a given seed.

scipy.optimize.newton will no longer use Halley’s method in cases where it negatively impacts convergence.

• #9383: Default value for “mode” in “ndimage.shift”
• #9419: dual_annealing off by one in the number of iterations
• #9442: Error in Defintion of Rosenbrock Function
• #9453: TST: test_eigs_consistency() doesn’t have consistent results

Pull requests for 1.2.0

• #9526: TST: relax precision requirements in signal.correlate tests
• #9507: CI: MAINT: Skip a ckdtree test on pypy
• #9512: TST: test_random_sampling 32-bit handling
• #9494: TST: test_kolmogorov xfail 32-bit
• #9486: BUG: fix sparse random int handling
• #9550: BUG: scipy/_lib/_numpy_compat: get_randint
• #9549: MAINT: make dual_annealing signature match other optimizers
• #9541: BUG: fix SyntaxError due to non-ascii character on Python 2.7
• #7352: ENH: add Brunner Munzel test to scipy.stats.
• #7373: BUG: Jaccard distance for all-zero arrays would return np.nan
- #7374: ENH: Add PDF, CDF and parameter estimation for Stable Distributions
- #8098: ENH: Add shgo for global optimization of NLPs.
- #8203: ENH: adding simulated dual annealing to optimize
- #8259: Option to follow original Storn and Price algorithm and its parallelisation
- #8293: ENH add ratio-of-uniforms method for rv generation to scipy.stats
- #8294: BUG: Fix slowness in stats.mode
- #8295: ENH: add Jensen Shannon distance to scipy.spatial.distance
- #8357: ENH: vectorize scalar zero-search-functions
- #8397: Add fs= parameter to filter design functions
- #8537: ENH: Implement mode parameter for spline filtering.
- #8558: ENH: small speedup for stats gaussian_kde
- #8560: BUG: fix p-value calc of anderson_ksamp in scipy.stats
- #8614: ENH: correct p-values for stats.kendalltau and stats.mstats.kendalltau
- #8670: ENH: Require Lapack 3.4.0
- #8683: Correcting kmeans documentation
- #8725: MAINT: Cleanup scipy.optimize.leastsq
- #8726: BUG: Fix _get_output in scipy.ndimage to support string
- #8733: MAINT: stats: A bit of clean up.
- #8737: BUG: Improve numerical precision/convergence failures of smirnov/kolmogorov
- #8740: BF/ENH: make minpack thread safe
- #8742: BUG: Fix division by zero in trust-region optimization methods
- #8746: MAINT: signal: Fix a docstring of a private function, and fix…
- #8750: DOC clarified description of norminvgauss in scipy.stats
- #8755: DOC: MAINT: Fix link to the wheel documentation in developer…
- #8760: BUG: stats: boltzmann wasn’t setting the upper bound.
- #8763: [DOC] Improved scipy.cluster.hierarchy documentation
- #8765: DOC: added example for scipy.stat.mstats.tmin
- #8788: DOC: fix definition of optional disp parameter
- #8802: MAINT: Suppress dd_real unused function compiler warnings.
- #8803: ENH: Add full_output support to optimize.newton()
- #8804: MAINT: stats cleanup
- #8808: DOC: add note about isinstance for frozen rvs
- #8812: Updated numpydoc submodule
- #8813: MAINT: stats: Fix multinomial docstrings, and do some clean up.
• #8816: BUG: fixed _stats of t-distribution in scipy.stats
• #8817: BUG: ndimage: Fix validation of the origin argument in correlate…
• #8822: BUG: integrate: Fix crash with repeated t values in odeint.
• #8832: Hyperlink DOIs against preferred resolver
• #8837: BUG: sparse: Ensure correct dtype for sparse comparison operations.
• #8839: DOC: stats: A few tweaks to the linregress docstring.
• #8846: BUG: stats: Fix logpdf method of invwishart.
• #8849: DOC: signal: Fixed mistake in the firwin docstring.
• #8854: DOC: fix type descriptors in litisys documentation
• #8865: Fix tiny typo in docs for chi2 pdf
• #8870: Fixes related to invertibility of STFT
• #8872: ENH: special: Add the softmax function
• #8874: DOC correct gamma function in docstrings in scipy.stats
• #8876: ENH: Added TOMS Algorithm 748 as 1-d root finder; 17 test function…
• #8882: ENH: Only use Halley's adjustment to Newton if close enough.
• #8883: FIX: optimize: make jac and hess truly optional for 'trust-constr'
• #8885: TST: Do not error on warnings raised about non-tuple indexing.
• #8887: MAINT: filter out np.matrix PendingDeprecationWarning's in numpy…
• #8889: DOC: optimize: separate legacy interfaces from new ones
• #8890: ENH: Add optimize.root_scalar() as a universal dispatcher for…
• #8899: DCT-IV, DST-IV and DCT-I, DST-I orthonormalization support in…
• #8901: MAINT: Reorganize flapack.pyf.src file
• #8907: BUG: ENH: Check if guess for newton is already zero before checking…
• #8908: ENH: Make sorting optional for cKDTree.query_ball_point()
• #8910: DOC: sparse.csgraph simple examples.
• #8914: DOC: interpolate: fix equivalences of string aliases
• #8918: add float_control(precise, on) to _fpumode.c
• #8919: MAINT: interpolate: improve error messages for common bc_type…
• #8920: DOC: update Contributing to SciPy to say “prefer no PEP8 only…
• #8924: MAINT: special: deprecate hyp2f0, hyp1f2, and hyp3f0
• #8927: MAINT: special: remove errprint
• #8932: Fix broadcasting scale arg of entropy
• #8936: Fix (some) non-tuple index warnings
• #8937: ENH: implement sparse matrix BSR to CSR conversion directly.
• #8938: DOC: add @_ni_docstrings.docfiller in ndimage.rotate
• #8940: Update _discrete_distns.py
- #8943: DOC: Finish dangling sentence in `convolve` docstring
- #8944: MAINT: Address tuple indexing and warnings
- #8945: ENH: spatial.transform.Rotation [GSOC2018]
- #8950: csgraph Dijkstra function description rewording
- #8953: DOC, MAINT: HTTP -> HTTPS, and other linkrot fixes
- #8955: BUG: np.int64 in scipy.fftpack.next_fast_len
- #8958: MAINT: Add more descriptive error message for phase one simplex.
- #8962: BUG: sparse.linalg: add missing conjugate to _ScaledLinearOperator.adjoint
- #8963: BUG: sparse.linalg: downgrade LinearOperator TypeError to warning
- #8965: ENH: Wrapped RFP format and RZ decomposition routines
- #8969: MAINT: doc and code fixes for optimize.newton
- #8970: Added ‘average’ keyword for welch/csd to enable median averaging
- #8971: Better imresize deprecation warning
- #8972: MAINT: Switch np.where(c) for np.nonzero(c)
- #8975: MAINT: Fix warning-based failures
- #8979: DOC: fix description of count_sort keyword of dendrogram
- #8982: MAINT: optimize: Fixed minor mistakes in test_linprog.py (#8978)
- #8984: BUG: sparse.linalg: ensure expm casts integer inputs to float
- #8986: BUG: optimize/slsqp: do not exit with convergence on steps where…
- #8989: MAINT: use collections.abc in basinhopping
- #8990: ENH extend p-values of anderson_ksamp in scipy.stats
- #8991: ENH: Weighted kde
- #8993: ENH: spatial.transform.Rotation.random [GSOC 2018]
- #8994: ENH: spatial.transform.Slerp [GSOC 2018]
- #8995: TST: time.time in test
- #9007: Fix typo in fftpack.rst
- #9013: Added correct plotting code for two sided output from spectrogram
- #9014: BUG: differential_evolution with inf objective functions
- #9017: BUG: fixed #8446 corner case for asformat(array|dense)
- #9018: MAINT: _lib/ccallback: remove unused code
- #9021: BUG: Issue with subspace_angles
- #9022: DOC: Added “See Also” section to lombscargle docstring
- #9034: BUG: Fix tolerance printing behavior, remove meaningless tol…
- #9035: TST: improve signal.bsplines test coverage
- #9037: ENH: add a new init method for k-means
- #9039: DOC: Add examples to fftpack.irfft docstrings
• #9048: ENH: scipy.sparse.random
• #9050: BUG: scipy.io.hb_write: fails for matrices not in csc format
• #9051: MAINT: Fix slow sparse.rand for k < mn/3 (#9036).
• #9054: MAINT: spatial: Explicitly initialize LAPACK output parameters.
• #9055: DOC: Add examples to scipy.special docstrings
• #9056: ENH: Use one thread in OpenBLAS
• #9059: DOC: Update README with link to Code of Conduct
• #9060: BLD: remove support for the Bento build system.
• #9062: DOC add sections to overview in scipy.stats
• #9066: BUG: Correct "remez" error message
• #9069: DOC: update linalg section of roadmap for LAPACK versions.
• #9079: MAINT: add spatial.transform to refguide check; complete some…
• #9081: MAINT: Add warnings if pivot value is close to tolerance in linprog(method='simplex')
• #9084: BUG fix incorrect p-values of kurtosistest in scipy.stats
• #9085: DOC: add sections to mstats overview in scipy.stats
• #9096: BUG: Add test for Stackoverflow example from issue 8174.
• #9101: ENH: add Siegel slopes (robust regression) to scipy.stats
• #9105: allow resample_poly() to output float32 for float32 inputs.
• #9112: MAINT: optimize: make trust-constr accept constraint dict (#9043)
• #9118: Add doc entry to cholesky_banded
• #9120: eigsh documentation parameters
• #9125: interpolative: correctly reconstruct full rank matrices
• #9126: MAINT: Use warnings for unexpected peak properties
• #9129: BUG: Do not catch and silence KeyboardInterrupt
• #9131: DOc: Correct the typo in scipy.optimize tutorial page
• #9133: FIX: Avoid use of bare except
• #9134: DOC: Update of ‘return_eigenvectors’ description
• #9137: DOC: typo fixes for discrete Poisson tutorial
• #9139: FIX: Doctest failure in optimize tutorial
• #9143: DOC: missing sigma in Pearson r formula
• #9145: MAINT: Refactor linear programming solvers
• #9149: FIX: Make scipy.odr.ODR ifixx equal to its data.fix if given
• #9156: DOC: special: Mention the sigmoid function in the expit docstring.
• #9160: Fixed a latex delimiter error in levy()
• #9170: DOC: correction / update of docstrings of distributions in scipy.stats
• #9171: better description of the hierarchical clustering parameter
• #9174: domain check for a < b in stats.truncnorm
• #9175: DOC: Minor grammar fix
• #9176: BUG: CloughTocher2DInterpolator: fix miscalculation at neighborless…
• #9177: BUILD: Document the “clean” target in the doc/Makefile.
• #9178: MAINT: make refguide-check more robust for printed numpy arrays
• #9186: MAINT: Remove np.ediff1d occurrence
• #9188: DOC: correct typo in extending ndimage with C
• #9190: ENH: Support specifying axes for fftconvolve
• #9192: MAINT: optimize: fixed @pv style suggestions from #9112
• #9200: Fix make_interp_spline(…, k=0 or 1, axis<0)
• #9201: BUG: sparse.linalg/gmres: use machine eps in breakdown check
• #9204: MAINT: fix up stats.spearmanr and match mstats.spearmanr with…
• #9206: MAINT: include benchmarks and dev files in sdist.
• #9208: TST: signal: bump bsplines test tolerance for complex data
• #9210: TST: mark tests as slow, fix missing random seed
• #9211: ENH: add capability to specify orders in pade func
• #9217: MAINT: Include success and nit in OptimizeResult returned…
• #9222: ENH: interpolate: Use scipy.spatial.distance to speed-up Rbf
• #9229: MNT: Fix Fourier filter double case
• #9233: BUG: spatial/distance: fix pdist/cdist performance regression…
• #9234: FIX: Proper suppression
• #9235: BENCH: rationalize slow benchmarks + miscellaneous fixes
• #9238: BENCH: limit number of parameter combinations in spatial.*KDTree…
• #9239: DOC: stats: Fix LaTeX markup of a couple distribution PDFs.
• #9241: ENH: Evaluate plateau size during peak finding
• #9242: ENH: stats: Implement _ppf and _logpdf for crystalball, and do…
• #9246: DOC: Properly render versionadded directive in HTML documentation
• #9255: DOC: mention RootResults in optimization reference guide
• #9260: TST: relax some tolerances so tests pass with x87 math
• #9264: TST Use assert_raises “match” parameter instead of the “message”…
• #9267: DOC: clarify expect() return val when moment is inf/nan
• #9272: DOC: Add description of default bounds to linprog
• #9277: MAINT: sparse/linalg: make test deterministic
• #9278: MAINT: interpolate: pep8 cleanup in test_polyint
• #9279: Fixed docstring for resample
• #9280: removed first check for float in get_sum_dtype
• #9281: BUG: only accept 1d input for bartlett / levene in scipy.stats
• #9282: MAINT: dense_output and t_eval are mutually exclusive inputs
• #9283: MAINT: add docs and do some cleanups in interpolate.Rbf
• #9288: Run distance_transform_edt tests on all types
• #9294: DOC: fix the formula typo
• #9298: MAINT: optimize/trust-constr: restore .niter attribute for backward-compat
• #9299: DOC: clarification of default rvs method in scipy.stats
• #9301: MAINT: removed unused import sys
• #9302: MAINT: removed unused imports
• #9303: DOC: signal: Refer to fs instead of nyq in the firwin docstring.
• #9305: ENH: Added Yeo-Johnson power transformation
• #9306: ENH - add dual annealing
• #9309: ENH add the yulestimon distribution to scipy.stats
• #9317: Nested SLSQP bug fix.
• #9320: MAINT: stats: avoid underflow in stats.geom.ppf
• #9326: Add example for Rosenbrock function
• #9332: Sort file lists
• #9340: Fix typo in find_peaks documentation
• #9343: MAINT Use np.full when possible
• #9344: DOC: added examples to docstring of dirichlet class
• #9346: DOC: Fix import of scipy.sparse.linalg in example (#9345)
• #9350: Fix interpolate read only
• #9351: MAINT: special.erf: use the x->-x symmetry
• #9356: Fix documentation typo
• #9358: DOC: improve doc for ksone and kstwobign in scipy.stats
• #9362: DOC: Change datatypes of A matrices in linprog
• #9364: MAINT: Adds implicit none to fftpack fortran sources
• #9369: DOC: minor tweak to CoC (updated NumFOCUS contact address).
• #9373: Fix exception if python is called with -OO option
• #9374: FIX: AIX compilation issue with NAN and INFINITY
• #9376: COBYLA -> COBYLA in docs
• #9377: DOC: Add examples integrate: fixed_quad and quadrature
• #9379: MAINT: TST: Make tests NumPy 1.8 compatible
• #9385: CI: On Travis matrix “OPTIMIZE=-OO” flag ignored
• #9387: Fix default value for ‘mode’ in ‘ndimage.shift’ in the doc
• #9392: BUG: rank has to be integer in rank_filter: fixed issue 9388
• #9399: DOC: Misc. typos
• #9400: TST: stats: Fix the expected r-value of a linregress test.
• #9405: BUG: np.hstack does not accept generator expressions
• #9408: ENH: linalg: Shorter ill-conditioned warning message
• #9418: DOC: Fix ndimage docstrings and reduce doc build warnings
• #9421: DOC: Add missing docstring examples in scipy.spatial
• #9422: DOC: Add an example to integrate.newton_cotes
• #9427: BUG: Fixed defect with maxiter #9419 in dual annealing
• #9431: BENCH: Add dual annealing to scipy benchmark (see #9415)
• #9435: DOC: Add docstring examples for stats.binom_test
• #9443: DOC: Fix the order of indices in optimize tutorial
• #9444: MAINT: interpolate: use operator.index for checking/coercing…
• #9445: DOC: Added missing example to stats.mstats.kruskal
• #9446: DOC: Add note about version changed for jaccard distance
• #9447: BLD: version-script handling in setup.py
• #9448: TST: skip a problematic linalg test
• #9449: TST: fix missing seed in lobpcg test.
• #9456: TST: test_eigs_consistency() now sorts output

5.21 SciPy 1.1.0 Release Notes

Contents

• SciPy 1.1.0 Release Notes
  – New features
    * scipy.integrate improvements
    * scipy.linalg improvements
    * scipy.misc improvements
    * scipy.ndimage improvements
    * scipy.optimize improvements
    * scipy.signal improvements
    * scipy.sparse improvements
    * scipy.special improvements
    * scipy.stats improvements
  – Deprecated features
  – Backwards incompatible changes
SciPy 1.1.0 is the culmination of 7 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Before upgrading, we recommend that users check that their own code does not use deprecated SciPy functionality (to do so, run your code with `python -Wd` and check for `DeprecationWarning`s). Our development attention will now shift to bug-fix releases on the 1.1.x branch, and on adding new features on the master branch.

This release requires Python 2.7 or 3.4+ and NumPy 1.8.2 or greater.

This release has improved but not necessarily 100% compatible with the PyPy Python implementation. For running on PyPy, PyPy 6.0+ and Numpy 1.15.0+ are required.

### 5.21.1 New features

**scipy.integrate improvements**

The argument `tfirst` has been added to the function `scipy.integrate.odeint`. This allows `odeint` to use the same user functions as `scipy.integrate.solve_ivp` and `scipy.integrate.ode` without the need for wrapping them in a function that swaps the first two arguments.

Error messages from `quad()` are now clearer.

**scipy.linalg improvements**

The function `scipy.linalg.ldl` has been added for factorization of indefinite symmetric/hermitian matrices into triangular and block diagonal matrices.

Python wrappers for LAPACK sygst, hegst added in `scipy.linalg.lapack`.

Added `scipy.linalg.null_space`, `scipy.linalg.cdf2rdf`, `scipy.linalg.rsf2csf`.

**scipy.misc improvements**

An electrocardiogram has been added as an example dataset for a one-dimensional signal. It can be accessed through `scipy.misc.electrocardiogram`.

**scipy.ndimage improvements**

The routines `scipy.ndimage.binary_opening`, and `scipy.ndimage.binary_closing` now support masks and different border values.
scipy.optimize improvements

The method trust-constr has been added to scipy.optimize.minimize. The method switches between two implementations depending on the problem definition. For equality-constrained problems it is an implementation of a trust-region sequential quadratic programming solver and, when inequality constraints are imposed, it switches to a trust-region interior point method. Both methods are appropriate for large scale problems. Quasi-Newton options BFGS and SR1 were implemented and can be used to approximate second-order derivatives for this new method. Also, finite-differences can be used to approximate either first-order or second-order derivatives.

Random-to-Best/1/bin and Random-to-Best/1/exp mutation strategies were added to scipy.optimize.differential_evolution as randtobestbin and randtobest1exp, respectively. Note: These names were already in use but implemented a different mutation strategy. See Backwards-incompatible changes below.

The init keyword for the scipy.optimize.differential_evolution function can now accept an array. This array allows the user to specify the entire population.

Added an adaptive option to Nelder-Mead to use step parameters adapted to the dimensionality of the problem.

Minor improvements in scipy.optimize.basinhopping.

scipy.signal improvements

Three new functions for peak finding in one-dimensional arrays were added. scipy.signal.find_peaks searches for peaks (local maxima) based on simple value comparison of neighboring samples and returns those peaks whose properties match optionally specified conditions for their height, prominence, width, threshold and distance to each other. scipy.signal.peak_prominences and scipy.signal.peak_widths can directly calculate the prominences or widths of known peaks.

Added scipy.signal.windows.dpss, scipy.signal.windows.general_cosine and scipy.signal.windows.general_hamming.

scipy.sparse improvements

Previously, the reshape method only worked on scipy.sparse.lil_matrix, and in-place reshaping did not work on any matrices. Both operations are now implemented for all matrices. Handling of shapes has been made consistent with numpy.matrix throughout the scipy.sparse module (shape can be a tuple or splatted, negative number acts as placeholder, padding and unpadding dimensions of size 1 to ensure length-2 shape).

scipy.special improvements

Added Owen’s T function as scipy.special.owens_t.

Accuracy improvements in chndtr, digamma, gammaincinv, lambertw, zetac.
scipy.stats improvements

The Moyal distribution has been added as scipy.stats.moyal.

Added the normal inverse Gaussian distribution as scipy.stats.norminvgauss.

5.21.2 Deprecated features

The iterative linear equation solvers in scipy.sparse.linalg had a sub-optimal way of how absolute tolerance is considered. The default behavior will be changed in a future Scipy release to a more standard and less surprising one. To silence deprecation warnings, set the atol= parameter explicitly.

scipy.signal.windows.slepian is deprecated, replaced by scipy.signal.windows.dpss.

The window functions in scipy.signal are now available in scipy.signal.windows. They will remain also available in the old location in the scipy.signal namespace in future Scipy versions. However, importing them from scipy.signal.windows is preferred, and new window functions will be added only there.

Indexing sparse matrices with floating-point numbers instead of integers is deprecated.

The function scipy.stats.itemfreq is deprecated.

5.21.3 Backwards incompatible changes

Previously, scipy.linalg.orth used a singular value cutoff value appropriate for double precision numbers also for single-precision input. The cutoff value is now tunable, and the default has been changed to depend on the input data precision.

In previous versions of Scipy, the randtobest1bin and randtobest1exp mutation strategies in scipy.optimize.differential_evolution were actually implemented using the Current-to-Best/1/bin and Current-to-Best/1/exp strategies, respectively. These strategies were renamed to currenttobest1bin and currenttobest1exp and the implementations of randtobest1bin and randtobest1exp strategies were corrected.

Functions in the ndimage module now always return their output array. Before, most functions only returned the output array if it had been allocated by the function, and would return None if it had been provided by the user.

Distance metrics in scipy.spatial.distance now require non-negative weights.

scipy.special.loggamma now returns real-valued result when the input is real-valued.

5.21.4 Other changes

When building on Linux with GNU compilers, the .so Python extension files now hide all symbols except those required by Python, which can avoid problems when embedding the Python interpreter.

• #8671: DOC: Replace deprecated matplotlib kwarg
SciPy 1.0.1 is a bug-fix release with no new features compared to 1.0.0. Probably the most important change is a fix for an incompatibility between SciPy 1.0.0 and numpy.f2py in the NumPy master branch.

      - scipy.integrate improvements
      - scipy.linalg improvements
      - scipy.ndimage improvements
5.23.1 Why 1.0 now?

A version number should reflect the maturity of a project - and SciPy was a mature and stable library that is heavily used in production settings for a long time already. From that perspective, the 1.0 version number is long overdue.

Some key project goals, both technical (e.g. Windows wheels and continuous integration) and organisational (a governance structure, code of conduct and a roadmap), have been achieved recently.

Many of us are a bit perfectionist, and therefore are reluctant to call something “1.0” because it may imply that it’s “finished” or “we are 100% happy with it”. This is normal for many open source projects, however that doesn’t make it right. We acknowledge to ourselves that it’s not perfect, and there are some dusty corners left (that will probably always be the case). Despite that, SciPy is extremely useful to its users, on average has high quality code and documentation, and gives the stability and backwards compatibility guarantees that a 1.0 label imply.

5.23.2 Some history and perspectives

- 2001: the first SciPy release
- 2005: transition to NumPy
- 2007: creation of scikits
- 2008: scipy.spatial module and first Cython code added
- 2010: moving to a 6-monthly release cycle
- 2011: SciPy development moves to GitHub
- 2011: Python 3 support
- 2012: adding a sparse graph module and unified optimization interface
- 2012: removal of scipy.maxentropy
- 2013: continuous integration with TravisCI
• 2015: adding Cython interface for BLAS/LAPACK and a benchmark suite
• 2017: adding a unified C API with scipy.LowLevelCallable; removal of scipy.weave
• 2017: SciPy 1.0 release

Pauli Virtanen is SciPy's Benevolent Dictator For Life (BDFL). He says:

Truthfully speaking, we could have released a SciPy 1.0 a long time ago, so I'm happy we do it now at long last. The project has a long history, and during the years it has matured also as a software project. I believe it has well proved its merit to warrant a version number starting with unity.

Since its conception 15+ years ago, SciPy has largely been written by and for scientists, to provide a box of basic tools that they need. Over time, the set of people active in its development has undergone some rotation, and we have evolved towards a somewhat more systematic approach to development. Regardless, this underlying drive has stayed the same, and I think it will also continue propelling the project forward in future. This is all good, since not long after 1.0 comes 1.1.

Travis Oliphant is one of SciPy’s creators. He says:

I'm honored to write a note of congratulations to the SciPy developers and the entire SciPy community for the release of SciPy 1.0. This release represents a dream of many that has been patiently pursued by a stalwart group of pioneers for nearly 2 decades. Efforts have been broad and consistent over that time from many hundreds of people. From initial discussions to efforts coding and packaging to documentation efforts to extensive conference and community building, the SciPy effort has been a global phenomenon that it has been a privilege to participate in.

The idea of SciPy was already in multiple people’s minds in 1997 when I first joined the Python community as a young graduate student who had just fallen in love with the expressibility and extensibility of Python. The internet was just starting to bringing together like-minded mathematicians and scientists in nascent electronically-connected communities. In 1998, there was a concerted discussion on the matrix-SIG, python mailing list with people like Paul Barrett, Joe Harrington, Perry Greenfield, Paul Dubois, Konrad Hinsen, David Ascher, and others. This discussion encouraged me in 1998 and 1999 to procrastinate my PhD and spend a lot of time writing extension modules to Python that mostly wrapped battle-tested Fortran and C-code making it available to the Python user. This work attracted the help of others like Robert Kern, Pearu Peterson and Eric Jones who joined their efforts with mine in 2000 so that by 2001, the first SciPy release was ready. This was long before Github simplified collaboration and input from others and the “patch” command and email was how you helped a project improve.

Since that time, hundreds of people have spent an enormous amount of time improving the SciPy library and the community surrounding this library has dramatically grown. I stopped being able to participate actively in developing the SciPy library around 2010. Fortunately, at that time, Pauli Virtanen and Ralf Gommers picked up the pace of development supported by dozens of other key contributors such as David Cournapeau, Evgeni Burovski, Josef Perktold, and Warren Weckesser. While I have only been able to admire the development of SciPy from a distance for the past 7 years, I have never lost my love of the project and the concept of community-driven development. I remain driven even now by a desire to help sustain the development of not only the SciPy library but many other affiliated and related open-source projects. I am extremely pleased that SciPy is in the hands of a world-wide community of talented developers who will ensure that SciPy remains an example of how grass-roots, community-driven development can succeed.

Fernando Perez offers a wider community perspective:

The existence of a nascent SciPy library, and the incredible –if tiny by today's standards– community surrounding it is what drew me into the scientific Python world while still a physics graduate student in 2001. Today, I am awed when I see these tools power everything from high school education to the research that led to the 2017 Nobel Prize in physics.

Don't be fooled by the 1.0 number: this project is a mature cornerstone of the modern scientific computing ecosystem. I am grateful for the many who have made it possible, and hope to be able to contribute again to it in the future. My sincere congratulations to the whole team!
5.23.3 Highlights of this release

Some of the highlights of this release are:

- Major build improvements. Windows wheels are available on PyPI for the first time, and continuous integration has been set up on Windows and OS X in addition to Linux.
- A set of new ODE solvers and a unified interface to them (*scipy.integrate.solve_ivp*).
- Two new trust region optimizers and a new linear programming method, with improved performance compared to what *scipy.optimize* offered previously.
- Many new BLAS and LAPACK functions were wrapped. The BLAS wrappers are now complete.

5.23.4 Upgrading and compatibility

There have been a number of deprecations and API changes in this release, which are documented below. Before upgrading, we recommend that users check that their own code does not use deprecated SciPy functionality (to do so, run your code with `python -Wd` and check for `DeprecationWarning`s).

This release requires Python 2.7 or >=3.4 and NumPy 1.8.2 or greater.

This is also the last release to support LAPACK 3.1.x - 3.3.x. Moving the lowest supported LAPACK version to >3.2.x was long blocked by Apple Accelerate providing the LAPACK 3.2.1 API. We have decided that it's time to either drop Accelerate or, if there is enough interest, provide shims for functions added in more recent LAPACK versions so it can still be used.

New features

5.23.5 *scipy.cluster* improvements

*scipy.cluster.hierarchy.optimal_leaf_ordering*, a function to reorder a linkage matrix to minimize distances between adjacent leaves, was added.

5.23.6 *scipy.fftpack* improvements

N-dimensional versions of the discrete sine and cosine transforms and their inverses were added as *dctn*, *idctn*, *dstn* and *idstn*.

5.23.7 *scipy.integrate* improvements

A set of new ODE solvers have been added to *scipy.integrate*. The convenience function *scipy.integrate.solve_ivp* allows uniform access to all solvers. The individual solvers (RK23, RK45, Radau, BDF and LSODA) can also be used directly.
5.23.8 **scipy.linalg improvements**

The function `scipy.linalg.subspace_angles` has been added to compute the subspace angles between two matrices.

The function `scipy.linalg.clarkson_woodruff_transform` has been added. It finds low-rank matrix approximation via the Clarkson-Woodruff Transform.

The functions `scipy.linalg.eigh_tridiagonal` and `scipy.linalg.eigvalsh_tridiagonal`, which find the eigenvalues and eigenvectors of tridiagonal Hermitian/symmetric matrices, were added.

5.23.9 **scipy.ndimage improvements**

Support for homogeneous coordinate transforms has been added to `scipy.ndimage.affine_transform`. The `ndimage` C code underwent a significant refactoring, and is now a lot easier to understand and maintain.

5.23.10 **scipy.optimize improvements**

The methods `trust-region-exact` and `trust-krylov` have been added to the function `scipy.optimize.minimize`. These new trust-region methods solve the subproblem with higher accuracy at the cost of more Hessian factorizations (compared to dogleg) or more matrix vector products (compared to ncg) but usually require less nonlinear iterations and are able to deal with indefinite Hessians. They seem very competitive against the other Newton methods implemented in scipy.

`scipy.optimize.linprog` gained an interior point method. Its performance is superior (both in accuracy and speed) to the older simplex method.

5.23.11 **scipy.signal improvements**

An argument `fs` (sampling frequency) was added to the following functions: `firwin`, `firwin2`, `firls`, and `remez`. This makes these functions consistent with many other functions in `scipy.signal` in which the sampling frequency can be specified.

`scipy.signal.freqz` has been sped up significantly for FIR filters.

5.23.12 **scipy.sparse improvements**

Iterating over and slicing of CSC and CSR matrices is now faster by up to ~35%.

The `tocsr` method of COO matrices is now several times faster.

The `diagonal` method of sparse matrices now takes a parameter, indicating which diagonal to return.
5.23.13 **scipy.sparse.linalg improvements**

A new iterative solver for large-scale nonsymmetric sparse linear systems, `scipy.sparse.linalg.gcrotmk`, was added. It implements GCROT(m, k), a flexible variant of GCROT.

`scipy.sparse.linalg.lsmr` now accepts an initial guess, yielding potentially faster convergence.

SuperLU was updated to version 5.2.1.

5.23.14 **scipy.spatial improvements**

Many distance metrics in `scipy.spatial.distance` gained support for weights.

The signatures of `scipy.spatial.distance.pdist` and `scipy.spatial.distance.cdist` were changed to `*args, **kwargs` in order to support a wider range of metrics (e.g. string-based metrics that need extra keywords). Also, an optional `out` parameter was added to `pdist` and `cdist` allowing the user to specify where the resulting distance matrix is to be stored.

5.23.15 **scipy.stats improvements**

The methods `cdf` and `logcdf` were added to `scipy.stats.multivariate_normal`, providing the cumulative distribution function of the multivariate normal distribution.

New statistical distance functions were added, namely `scipy.stats.wasserstein_distance` for the first Wasserstein distance and `scipy.stats.energy_distance` for the energy distance.

**Deprecated features**

The following functions in `scipy.misc` are deprecated: `bytescale`, `fromimage`, `imfilter`, `imread`, `imresize`, `imrotate`, `imsave`, `imshow` and `toimage`. Most of those functions have unexpected behavior (like rescaling and type casting image data without the user asking for that). Other functions simply have better alternatives.

`scipy.interpolate.interpolate_wrapper` and all functions in that submodule are deprecated. This was a never finished set of wrapper functions which is not relevant anymore.

The `fillvalue` of `scipy.signal.convolve2d` will be cast directly to the dtypes of the input arrays in the future and checked that it is a scalar or an array with a single element.

`scipy.spatial.distance.matching` is deprecated. It is an alias of `scipy.spatial.distance.hamming`, which should be used instead.

Implementation of `scipy.spatial.distance.wminkowski` was based on a wrong interpretation of the metric definition. In scipy 1.0 it has been just deprecated in the documentation to keep retro-compatibility but is recommended to use the new version of `scipy.spatial.distance.minkowski` that implements the correct behaviour.

Positional arguments of `scipy.spatial.distance.pdist` and `scipy.spatial.distance.cdist` should be replaced with their keyword version.
Backwards incompatible changes

The following deprecated functions have been removed from scipy.stats: betai, chisqprob, f_value, histogram, histogram2, pdf_fromgamma, signaltonoise, square_of_sums, ss and threshold.

The following deprecated functions have been removed from scipy.stats.mstats: betai, f_value_wilks_lambda, signaltonoise and threshold.

The deprecated a and reta keywords have been removed from scipy.stats.shapiro.

The deprecated functions sparse.csgraph.cs_graph_components and sparse.linalg.symeig have been removed from scipy.sparse.

The following deprecated keywords have been removed in scipy.sparse.linalg: drop_tol from splu, and xtype from bicg, bicgstab, cg, cgs, gmres, qmr and minres.

The deprecated functions expm2 and expm3 have been removed from scipy.linalg. The deprecated keyword q was removed from scipy.linalg.expm. And the deprecated submodule linalg.calc_lwork was removed.

The deprecated functions C2K, K2C, F2C, C2F, F2K and K2F have been removed from scipy.constants.

The deprecated ppform class was removed from scipy.interpolate.

The deprecated keyword iprint was removed from scipy.optimize.fmin_cobyla.

The default value for the zero_phase keyword of scipy.signal.decimate has been changed to True.

The kmeans and kmeans2 functions in scipy.cluster.vq changed the method used for random initialization, so using a fixed random seed will not necessarily produce the same results as in previous versions.

scipy.special.gammaln does not accept complex arguments anymore.

The deprecated functions sph_jn, sph_yn, sph_jyn, sph_in, sph_kn, and sph_inkn have been removed. Users should instead use the functions spherical_jn, spherical_yn, spherical_in, and spherical_kn. Be aware that the new functions have different signatures.

The cross-class properties of scipy.signal.lti systems have been removed. The following properties/setters have been removed:

Name - (accessing/setting has been removed) - (setting has been removed)

- StateSpace - (num, den, gain) - (zeros, poles)
- TransferFunction (A, B, C, D, gain) - (zeros, poles)
- ZerosPolesGain (A, B, C, D, num, den) - ()

signal.freqz(b, a) with b or a >1-D raises a ValueError. This was a corner case for which it was unclear that the behavior was well-defined.

The method var of scipy.stats.dirichlet now returns a scalar rather than an ndarray when the length of alpha is 1.
Other changes

SciPy now has a formal governance structure. It consists of a BDFL (Pauli Virtanen) and a Steering Committee. See the governance document for details.

It is now possible to build SciPy on Windows with MSVC + gfortran! Continuous integration has been set up for this build configuration on Appveyor, building against OpenBLAS.

Continuous integration for OS X has been set up on TravisCI.

The SciPy test suite has been migrated from nose to pytest.

`scipy/_distributor_init.py` was added to allow redistributors of SciPy to add custom code that needs to run when importing SciPy (e.g. checks for hardware, DLL search paths, etc.).

Support for PEP 518 (specifying build system requirements) was added - see `pyproject.toml` in the root of the SciPy repository.

In order to have consistent function names, the function `scipy.linalg.solve_lyapunov` is renamed to `scipy.linalg.solve_continuous_lyapunov`. The old name is kept for backwards-compatibility.

- #7094: MAINT: Fix mistake in PR #7082
- #7098: BF: return NULL from failed Py3 module check
- #7105: MAINT: Customize ?TRSYL call in lyapunov solver
- #7111: Fix error message typo in UnivariateSpline
- #7113: FIX: Add add float to return type in documentation
- #7119: ENH: sparse.linalg: remove _count_nonzero hack
- #7123: ENH: added “interior-point” method for scipy.optimize.linprog
- #7137: DOC: clarify stats.linregress docstring, closes gh-7074
- #7138: DOC: special: Add an example to the airy docstring.
- #7139: DOC: stats: Update stats tutorial
- #7142: BUG: special: prevent segfault in pbwa
- #7143: DOC: special: warn about alternate elliptic integral parameterizations
- #7146: fix docstring of NearestNDInterpolator
- #7148: DOC: special: Add Parameters, Returns and Examples to gamma docstring
- #7152: MAINT: spatial: Remove two unused variables in ckdtree/src/distance.h
- #7153: MAINT: special: remove deprecated variant of gammaln
- #7154: MAINT: Fix some code that generates C compiler warnings
- #7155: DOC: linalg: Add examples for solve_banded and solve_triangular
- #7156: DOC: fix docstring of NearestNDInterpolator
- #7159: BUG: special: fix sign of derivative when x < 0 in pbwa
- #7161: MAINT: interpolate: make Rbf.A array a property
- #7163: MAINT: special: return nan for inaccurate regions of pbwa
- #7165: ENH: optimize: changes to make BFGS implementation more efficient.
- #7166: BUG: Prevent infinite loop in optimize._lsq.trf_linear.py
- #7173: BUG: sparse: return a numpy matrix from _add_dense
- #7179: DOC: Fix an error in sparse argmax docstring
- #7180: MAINT: interpolate: A bit of clean up in interpolate/src/_interpolate.cpp
- #7182: Allow homogeneous coordinate transforms in affine_transform
- #7184: MAINT: Remove hack modifying a readonly attr
- #7185: ENH: Add evaluation of periodic splines #6730
- #7186: MAINT: PPoly: improve error messages for wrong shape/axis
- #7187: DEP: interpolate: deprecate interpolate_wrapper
- #7198: DOC: linalg: Add examples for solve_banded and solve_toeplitz.
- #7200: DOC: stats: Added tutorial documentation for the generalized...
- #7208: DOC: Added docstrings to issparse/isspmatrix(...) methods and...
- #7213: DOC: Added examples to circmean, circvar, circstd
- #7215: DOC: Adding examples to scipy.sparse.linalg.... docstrings
- #7223: DOC: special: Add examples for expit and logit.
- #7224: BUG: interpolate: fix integer overflow in fitpack.bispev
- #7225: DOC: update 1.0 release notes for several recent PRs.
- #7226: MAINT: update docs and code for mailing list move to python.org
- #7233: Fix issue #7232: Do not mask exceptions in objective func evaluation
- #7234: MAINT: cluster: cleaning up VQ/k-means code
- #7236: DOC: Fixed typo
- #7238: BUG: fix syntaxerror due to unicode character in trustregion_exact.
- #7243: DOC: Update docstring in misc/pilutil.py
- #7246: DEP: misc: deprecate imported names
- #7249: DOC: Add plotted example to scipy.cluster.vq.kmeans
- #7252: Fix 5231: docs of factr, ftol in sync w/ code
- #7254: ENH: SphericalVoronoi Input Handling
- #7256: fix for issue #7255 - Circular statistics functions give wrong...
- #7263: CI: use python's faulthandler to ease tracing segfaults
- #7290: BUG: stats: Fix spurious warnings in genextreme.
- #7292: ENH: optimize: added trust region method trust-trlib
- #7296: DOC: stats: Add an example to the ttest_ind_from_stats docstring.
- #7297: DOC: signal: Add examples for chirp() and sweep_poly().
- #7299: DOC: Made difference between brent and fminbound clearer
- #7305: Simplify if-statements and constructor calls in integrate._ode
- #7309: Comply with PEP 518.
- #7313: REL: add python_requires to setup.py, fix Python version check.
- #7315: BUG: Fixed bug with Laguerre and Legendre polynomials
- #7320: DOC: clarify meaning of flags in ode.integrate
- #7333: DOC: Add examples to scipy.ndimage.gaussian_filter1d
- #7337: ENH: add n-dimensional DCT and IDCT to fftpack
- #7353: Add _gels functions
- #7357: DOC: linalg: Add examples to the svdvals docstring.
- #7359: Bump Sphinx version to 1.5.5
- #7361: DOC: linalg: Add some ‘See Also’ links among special matrices...
- #7362: TST: Fix some Fedora 25 test failures.
- #7363: DOC: linalg: tweak the docstring example of svd
- #7365: MAINT: fix refguide_check.py for Sphinx >= 1.5
- #7367: BUG: odrpack: fix invalid stride checks in d_lpkbls.f
- #7368: DOC: constants: Add examples to the ‘find’ docstring.
- #7376: MAINT: bundle Mathjax with built docs
- #7378: Improve wording in tutorial
• #7383: fix KroghInterpolator.derivatives failure with complex input
• #7389: FIX: Copy mutable window in resample_poly
• #7390: DOC: optimize: A few tweaks of the examples in the curve_fit
• #7391: DOC: Add examples to scipy.stats
• #7394: “Weight” is actually mass. Add slugs and slinches/blobs to mass
• #7398: DOC: Correct minor typo in optimize.{brent, brentq}
• #7401: DOC: zeta only accepts real input
• #7413: BUG: fix error messages in _minimize_trustregion_exact
• #7414: DOC: fix ndimage.distance_transform_bf docstring [ci skip]
• #7415: DOC: fix skew docstring [ci skip]
• #7423: Expand binnumbers with correct dimensions
• #7431: BUG: Extend scipy.stats.arcsine.pdf to endpoints 0 and 1 #7427
• #7432: DOC: Add examples to scipy.cluster.hierarchy
• #7448: ENH: stats: Implement the survival function for pareto.
• #7454: FIX Replaced np.assert_allclose with imported assert_allclose
• #7460: TST: fix integrate.ivp test that fails on 32-bit Python.
• #7461: Doc: Added tutorial documentation for stats distributions ksone
• #7463: DOC: Fix typos and remove trailing whitespace
• #7465: Fix some ndimage.interpolation endianness bugs
• #7468: del redundance in interpolate.py
• #7470: Initialize “info” in minpack_lmdif
• #7478: Added more testing of smirnov/smirnovi functions
• #7479: MAINT: update for new FutureWarning’s in numpy 1.13.0
• #7480: DOC: correctly describe output shape of dirichlet.mean() and...
• #7482: signal.lti: Remove deprecated cross-system properties
• #7484: MAINT: Clean-up uses of np.asarray in ndimage
• #7485: ENH: support any order >=0 in ndimage.gaussian_filter
• #7486: ENH: Support k!=0 for sparse.diagonal()
• #7498: BUG: sparse: pass assumeSortedIndices option to scikit.umfpack
• #7501: ENH: add optimal leaf ordering for linkage matrices
• #7506: MAINT: remove overflow in Metropolis fixes #7495
• #7507: TST: speed up full test suite by less eval points in mpmath tests.
• #7509: BUG: fix issue when using python setup.py somecommand --force.
• #7511: fix some alerts found with lgtm
• #7514: Add explanation what the integer returned mean.
• #7516: BUG: Fix roundoff errors in ndimage.uniform_filter1d.
• #7517: TST: fix signal.convolve test that was effectively being skipped.
• #7523: ENH: linalg: allow lstsq to work with 0-shaped arrays
• #7525: TST: Warning cleanup
• #7526: DOC: params in ndimage.interpolation functions not optional
• #7527: MAINT: Encapsulate error message handling in NI_LineBuffer.
• #7528: MAINT: Remove ndimage aliases for NPY_MAXDIMS.
• #7529: MAINT: Remove NI_(UN)LIKELY macros in favor of numpy ones.
• #7537: MAINT: Use accessor function for numpy array internals
• #7541: MAINT: Remove some uses of Numarray types in ndimage.
• #7543: MAINT: Replace all NumarrayTypes uses in ni_fourier.c
• #7544: MAINT: Replace all uses of NumarrayTypes in ni_interpolation.c
• #7545: MAINT: Replace all uses of NumarrayTypes in ni_measure.c
• #7546: MAINT: Replace all uses of NumarrayTypes in ni_morphology.c
• #7548: DOC: make a note in benchmarks README on how to run without rebuilding.
• #7549: MAINT: Get rid of NumarrayTypes.
• #7552: TST: Fix new warnings -> error bugs found on OSX
• #7554: Update superlu to 5.2.1 + fix stdint.h issue on MSVC
• #7556: MAINT: Fix some types from #7549 + miscellaneous warnings.
• #7558: MAINT: Use correct #define NO_IMPORT_ARRAY, not NO_ARRAY_IMPORT...

• #8001: TST: fix test failures from Matplotlib 2.1 update
• #8010: BUG: signal: fix crash in ilfilter
• #8019: MAINT: fix test failures with NumPy master

5.24 SciPy 0.19.1 Release Notes

SciPy 0.19.1 is a bug-fix release with no new features compared to 0.19.0. The most important change is a fix for a severe memory leak in integrate.quad.

5.24.1 Authors

• Evgeni Burovski
• Patrick Callier +
• Yu Feng
• Ralf Gommers
• Ilhan Polat
• Eric Quintero
• Scott Sievert
• Pauli Virtanen
• Warren Weckesser

A total of 9 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

Issues closed for 0.19.1

• #7214: Memory use in integrate.quad in scipy-0.19.0
• #7258: linalg.matrix_balance gives wrong transformation matrix
• #7262: Segfault in daily testing
• #7273: scipy.interpolate._bspl.evaluate_spline gets wrong type
• #7335: scipy.signal.dlti(A,B,C,D).freqresp() fails

Pull requests for 0.19.1

• #7211: BUG: convolve may yield inconsistent dtypes with method changed
• #7216: BUG: integrate: fix refcounting bug in quad()
• #7229: MAINT: special: Rewrite a test of wrightomega
• #7261: FIX: Corrected the transformation matrix permutation
• #7265: BUG: Fix broken axis handling in spectral functions
• #7266: FIX 7262: ckdtrree crashes in query_knn.
• #7279: Upcast half- and single-precision floats to doubles in BSpine...
• #7336: BUG: Fix signal.dfreqresp for StateSpace systems
• #7419: Fix several issues in sparse.load_npz, save_npz
• #7420: BUG: stats: allow integers as kappa4 shape parameters

5.25 SciPy 0.19.0 Release Notes

Contents

• SciPy 0.19.0 Release Notes
  – New features
    • Foreign function interface improvements
    • scipy.linalg improvements
    • scipy.spatial improvements
    • scipy.ndimage improvements
SciPy 0.19.0 is the culmination of 7 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.19.x branch, and on adding new features on the master branch.

This release requires Python 2.7 or 3.4-3.6 and NumPy 1.8.2 or greater.

Highlights of this release include:

• A unified foreign function interface layer, `scipy.LowLevelCallable`.

• Cython API for scalar, typed versions of the universal functions from the `scipy.special` module, via `cimport scipy.special.cython_special`.

### 5.25.1 New features

**Foreign function interface improvements**

`scipy.LowLevelCallable` provides a new unified interface for wrapping low-level compiled callback functions in the Python space. It supports Cython imported “api” functions, ctypes function pointers, CFFI function pointers, PyCapsules, Numba jitted functions and more. See gh-6509 for details.
**scipy.linalg improvements**

The function `scipy.linalg.solve` obtained two more keywords `assume_a` and `transposed`. The underlying LAPACK routines are replaced with “expert” versions and now can also be used to solve symmetric, hermitian and positive definite coefficient matrices. Moreover, ill-conditioned matrices now cause a warning to be emitted with the estimated condition number information. Old `sym_pos` keyword is kept for backwards compatibility reasons however it is identical to using `assume_a='pos'`. Moreover, the `debug` keyword, which had no function but only printing the `overwrite_<a, b>` values, is deprecated.

The function `scipy.linalg.matrix_balance` was added to perform the so-called matrix balancing using the LAPACK xGEBAL routine family. This can be used to approximately equate the row and column norms through diagonal similarity transformations.

The functions `scipy.linalg.solve_continuous_are` and `scipy.linalg.solve_discrete_are` have numerically more stable algorithms. These functions can also solve generalized algebraic matrix Riccati equations. Moreover, both gained a `balanced` keyword to turn balancing on and off.

**scipy.spatial improvements**

`scipy.spatial.SphericalVoronoi.sort_vertices_of_regions` has been re-written in Cython to improve performance.

`scipy.spatial.SphericalVoronoi` can handle > 200 k points (at least 10 million) and has improved performance.

The function `scipy.spatial.distance.directed_hausdorff` was added to calculate the directed Hausdorff distance.

`count_neighbors` method of `scipy.spatial.cKDTree` gained an ability to perform weighted pair counting via the new keywords `weights` and `cumulative`. See gh-5647 for details.

`scipy.spatial.distance.pdist` and `scipy.spatial.distance.cdist` now support non-double custom metrics.

**scipy.ndimage improvements**

The callback function C API supports PyCapsules in Python 2.7

Multidimensional filters now allow having different extrapolation modes for different axes.

**scipy.optimize improvements**

The `scipy.optimize.basinhopping` global minimizer obtained a new keyword, `seed`, which can be used to seed the random number generator and obtain repeatable minimizations.

The keyword `sigma` in `scipy.optimize.curve_fit` was overloaded to also accept the covariance matrix of errors in the data.
**scipy.signal improvements**

The function `scipy.signal.correlate` and `scipy.signal.convolve` have a new optional parameter `method`. The default value of `auto` estimates the fastest of two computation methods, the direct approach and the Fourier transform approach.

A new function has been added to choose the convolution/correlation method, `scipy.signal.choose_conv_method` which may be appropriate if convolutions or correlations are performed on many arrays of the same size.

New functions have been added to calculate complex short time fourier transforms of an input signal, and to invert the transform to recover the original signal: `scipy.signal.stft` and `scipy.signal.istft`. This implementation also fixes the previously incorrect output of `scipy.signal.spectrogram` when complex output data were requested.

The function `scipy.signal.sosfreqz` was added to compute the frequency response from second-order sections.

The function `scipy.signal.unit_impulse` was added to conveniently generate an impulse function.

The function `scipy.signal.lirnotch` was added to design second-order IIR notch filters that can be used to remove a frequency component from a signal. The dual function `scipy.signal.iirpeak` was added to compute the coefficients of a second-order IIR peak (resonant) filter.

The function `scipy.signal.minimum_phase` was added to convert linear-phase FIR filters to minimum phase.

The functions `scipy.signal.upfirdn` and `scipy.signal.resample_poly` are now substantially faster when operating on some n-dimensional arrays when n > 1. The largest reduction in computation time is realized in cases where the size of the array is small (<1k samples or so) along the axis to be filtered.

**scipy.fftpack improvements**

Fast Fourier transform routines now accept `np.float16` inputs and upcast them to `np.float32`. Previously, they would raise an error.

**scipy.cluster improvements**

Methods "centroid" and "median" of `scipy.cluster.hierarchy.linkage` have been significantly sped up. Long-standing issues with using `linkage` on large input data (over 16 GB) have been resolved.

**scipy.sparse improvements**

The functions `scipy.sparse.save_npz` and `scipy.sparse.load_npz` were added, providing simple serialization for some sparse formats.

The `prune` method of classes `bsr_matrix`, `csc_matrix`, and `csr_matrix` was updated to reallocate backing arrays under certain conditions, reducing memory usage.

The methods `argmin` and `argmax` were added to classes `coo_matrix`, `csc_matrix`, `csr_matrix`, and `bsr_matrix`.

New function `scipy.sparse.csgraph.structural_rank` computes the structural rank of a graph with a given sparsity pattern.

New function `scipy.sparse.linalg.spsolve_triangular` solves a sparse linear system with a triangular left hand side matrix.
SciPy Reference Guide, Release 1.7.0

**scipy.special improvements**

Scalar, typed versions of universal functions from `scipy.special` are available in the Cython space via `cimport` from the new module `scipy.special.cython_special`. These scalar functions can be expected to be significantly faster than the universal functions for scalar arguments. See the `scipy.special` tutorial for details.

Better control over special-function errors is offered by the functions `scipy.special.geterr` and `scipy.special.seterr` and the context manager `scipy.special.errstate`.

The names of orthogonal polynomial root functions have been changed to be consistent with other functions relating to orthogonal polynomials. For example, `scipy.special.j_roots` has been renamed `scipy.special.roots_jacobi` for consistency with the related functions `scipy.special.jacobi` and `scipy.special.eval_jacobi`. To preserve back-compatibility the old names have been left as aliases.

Wright Omega function is implemented as `scipy.special.wrightomega`.

**scipy.stats improvements**

The function `scipy.stats.weightedtau` was added. It provides a weighted version of Kendall's tau.

New class `scipy.stats.multinomial` implements the multinomial distribution.

New class `scipy.stats.rv_histogram` constructs a continuous univariate distribution with a piecewise linear CDF from a binned data sample.

New class `scipy.stats.argus` implements the Argus distribution.

**scipy.interpolate improvements**

New class `scipy.interpolate.BSpline` represents splines. BSpline objects contain knots and coefficients and can evaluate the spline. The format is consistent with FITPACK, so that one can do, for example:

```python
>>> t, c, k = splrep(x, y, s=0)
>>> spl = BSpline(t, c, k)
>>> np.allclose(spl(x), y)
```

`spl`* functions, `scipy.interpolate.splev`, `scipy.interpolate.splint`, `scipy.interpolate.splder` and `scipy.interpolate.splantider`, accept both BSpline objects and `(t, c, k)` tuples for backwards compatibility.

For multidimensional splines, `c.ndim > 1`, BSpline objects are consistent with piecewise polynomials, `scipy.interpolate.PPoly`. This means that BSpline objects are not immediately consistent with `scipy.interpolate.splprep`, and one cannot do `>>> BSpline(*splprep([x, y])[0])`. Consult the `scipy.interpolate` test suite for examples of the precise equivalence.

In new code, prefer using `scipy.interpolate.BSpline` objects instead of manipulating `(t, c, k)` tuples directly.

New function `scipy.interpolate.make_interp_spline` constructs an interpolating spline given data points and boundary conditions.

New function `scipy.interpolate.make_lsq_spline` constructs a least-squares spline approximation given data points.
scipy.integrate improvements

Now scipy.integrate.fixed_quad supports vector-valued functions.

5.25.2 Deprecated features

scipy.interpolate.splmake, scipy.interpolate.spleval and scipy.interpolate.spline are deprecated. The format used by splmake/spleval was inconsistent with splrep/splev which was confusing to users.

scipy.special.errprint is deprecated. Improved functionality is available in scipy.special.seterr.

calling scipy.spatial.distance.pdist or scipy.spatial.distance.cdist with arguments not needed by the chosen metric is deprecated. Also, metrics “old_cosine” and “old_cos” are deprecated.

5.25.3 Backwards incompatible changes

The deprecated scipy.weave submodule was removed.

scipy.spatial.distance.squareform now returns arrays of the same dtype as the input, instead of always float64.

scipy.special.errprint now returns a boolean.

The function scipy.signal.find_peaks_cwt now returns an array instead of a list.

scipy.stats.kendalltau now computes the correct p-value in case the input contains ties. The p-value is also identical to that computed by scipy.stats.mstats.kendalltau and by R. If the input does not contain ties there is no change w.r.t. the previous implementation.

The function scipy.linalg.block_diag will not ignore zero-sized matrices anymore. Instead it will insert rows or columns of zeros of the appropriate size. See gh-4908 for more details.

5.25.4 Other changes

SciPy wheels will now report their dependency on numpy on all platforms. This change was made because Numpy wheels are available, and because the pip upgrade behavior is finally changing for the better (use --upgrade-strategy=only-if-needed for pip >= 8.2; that behavior will become the default in the next major version of pip).

Numerical values returned by scipy.interpolate.interp1d with kind="cubic" and "quadratic" may change relative to previous scipy versions. If your code depended on specific numeric values (i.e., on implementation details of the interpolators), you may want to double-check your results.

• #6492: BUG: Fix regression in dblquad: #6458
• #6543: fix the regression in circmean
5.27 SciPy 0.18.0 Release Notes

SciPy 0.18.0 is the culmination of 6 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and
optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.19.x branch, and on adding new features on the master branch.

This release requires Python 2.7 or 3.4-3.5 and NumPy 1.7.1 or greater.

Highlights of this release include:

- A new ODE solver for two-point boundary value problems, `scipy.optimize.solve_bvp`.
- A new class, `CubicSpline`, for cubic spline interpolation of data.
- Spherical Voronoi diagrams, `scipy.spatial.SphericalVoronoi`.
- Support for discrete-time linear systems, `scipy.signal.dlti`.

### 5.27.1 New features

**scipy.integrate** improvements

A solver of two-point boundary value problems for ODE systems has been implemented in `scipy.integrate.solve_bvp`. The solver allows for non-separated boundary conditions, unknown parameters and certain singular terms. It finds a C1 continuous solution using a fourth-order collocation algorithm.

**scipy.interpolate** improvements

Cubic spline interpolation is now available via `scipy.interpolate.CubicSpline`. This class represents a piecewise cubic polynomial passing through given points and C2 continuous. It is represented in the standard polynomial basis on each segment.

A representation of n-dimensional tensor product piecewise polynomials is available as the `scipy.interpolate.NdPPoly` class.

Univariate piecewise polynomial classes, `PPoly` and `Bpoly`, can now be evaluated on periodic domains. Use `extrapolate="periodic"` keyword argument for this.

**scipy.fftpack** improvements

`scipy.fftpack.next_fast_len` function computes the next “regular” number for FFTPACK. Padding the input to this length can give significant performance increase for `scipy.fftpack.fft`.

**scipy.signal** improvements

Resampling using polyphase filtering has been implemented in the function `scipy.signal.resample_poly`. This method upsamples a signal, applies a zero-phase low-pass FIR filter, and downsamples using `scipy.signal.upfirdn` (which is also new in 0.18.0). This method can be faster than FFT-based filtering provided by `scipy.signal.resample` for some signals.

`scipy.signal.firls`, which constructs FIR filters using least-squares error minimization, was added.

`scipy.signal.sosfiltfilt`, which does forward-backward filtering like `scipy.signal.filtfilt` but for second-order sections, was added.
Discrete-time linear systems

`scipy.signal.dlti` provides an implementation of discrete-time linear systems. Accordingly, the `StateSpace`, `TransferFunction` and `ZerosPolesGain` classes have learned the new keyword, `dt`, which can be used to create discrete-time instances of the corresponding system representation.

**scipy.sparse** improvements

The functions `sum`, `max`, `mean`, `min`, `transpose`, and `reshape` in `scipy.sparse` have had their signatures augmented with additional arguments and functionality so as to improve compatibility with analogously defined functions in `numpy`.

Sparse matrices now have a `count_nonzero` method, which counts the number of nonzero elements in the matrix. Unlike `getnnz()` and `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

**scipy.optimize** improvements

The implementation of Nelder-Mead minimization, `scipy.minimize(..., method="Nelder-Mead")`, obtained a new keyword, `initial_simplex`, which can be used to specify the initial simplex for the optimization process.

Initial step size selection in CG and BFGS minimizers has been improved. We expect that this change will improve numeric stability of optimization in some cases. See pull request gh-5536 for details.

Handling of infinite bounds in SLSQP optimization has been improved. We expect that this change will improve numeric stability of optimization in the some cases. See pull request gh-6024 for details.

A large suite of global optimization benchmarks has been added to `scipy/benchmarks/go_benchmark_functions`. See pull request gh-4191 for details.

Nelder-Mead and Powell minimization will now only set defaults for maximum iterations or function evaluations if neither limit is set by the caller. In some cases with a slow converging function and only 1 limit set, the minimization may continue for longer than with previous versions and so is more likely to reach convergence. See issue gh-5966.

**scipy.stats** improvements

Trapezoidal distribution has been implemented as `scipy.stats.trapz`. Skew normal distribution has been implemented as `scipy.stats.skewnorm`. Burr type XII distribution has been implemented as `scipy.stats.burr12`. Three- and four-parameter kappa distributions have been implemented as `scipy.stats.kappa3` and `scipy.stats.kappa4`, respectively.

New `scipy.stats.iqr` function computes the interquartile region of a distribution.

**Random matrices**

`scipy.stats.special_ortho_group` and `scipy.stats.ortho_group` provide generators of random matrices in the SO(N) and O(N) groups, respectively. They generate matrices in the Haar distribution, the only uniform distribution on these group manifolds.

`scipy.stats.random_correlation` provides a generator for random correlation matrices, given specified eigenvalues.
**scipy.linalg improvements**

`scipy.linalg.svd` gained a new keyword argument, `lapack_driver`. Available drivers are `gesdd` (default) and `gesvd`.

`scipy.linalg.lapack.ilaver` returns the version of the LAPACK library SciPy links to.

**scipy.spatial improvements**

Boolean distances, `scipy.spatial.pdist`, have been sped up. Improvements vary by the function and the input size. In many cases, one can expect a speed-up of x2–x10.

New class `scipy.spatial.SphericalVoronoi` constructs Voronoi diagrams on the surface of a sphere. See pull request gh-5232 for details.

**scipy.cluster improvements**

A new clustering algorithm, the nearest neighbor chain algorithm, has been implemented for `scipy.cluster.hierarchy.linkage`. As a result, one can expect a significant algorithmic improvement (\( O(N^2) \) instead of \( O(N^3) \)) for several linkage methods.

**scipy.special improvements**

The new function `scipy.special.loggamma` computes the principal branch of the logarithm of the Gamma function. For real input, `loggamma` is compatible with `scipy.special.gammaln`. For complex input, it has more consistent behavior in the complex plane and should be preferred over `gammaln`.

Vectorized forms of spherical Bessel functions have been implemented as `scipy.special.spherical_jn`, `scipy.special.spherical_kn`, `scipy.special.spherical_in` and `scipy.special.spherical_yn`. They are recommended for use over `sph_*` functions, which are now deprecated.

Several special functions have been extended to the complex domain and/or have seen domain/stability improvements. This includes `spence`, `digamma`, `log1p` and several others.

### 5.27.2 Deprecated features

The cross-class properties of `lti` systems have been deprecated. The following properties/setters will raise a `DeprecationWarning`:

Name - (accessing/setting raises warning) - (setting raises warning) * StateSpace - (num, den, gain) - (zeros, poles) * TransferFunction \((A, B, C, D, \text{gain})\) - (zeros, poles) * ZerosPolesGain \((A, B, C, D, \text{num, den})\) - ()

Spherical Bessel functions, `sph_in`, `sph_jn`, `sph_kn`, `sph_yn`, `sph_jnyn` and `sph_inkn` have been deprecated in favor of `scipy.special.spherical_jn` and `spherical_kn`, `spherical_in`, `spherical_yn`, `spherical_in`.

The following functions in `scipy.constants` are deprecated: `C2K`, `K2C`, `C2F`, `F2C`, `F2K` and `K2F`. They are superseded by a new function `scipy.constants.convert_temperature` that can perform all those conversions plus to/from the Rankine temperature scale.
5.27.3 Backwards incompatible changes

scipy.optimize

The convergence criterion for optimize.bisect, optimize.brentq, optimize.brenth, and optimize. ridder now works the same as numpy.allclose.

scipy.ndimage

The offset in ndimage.iterpolation.affine_transform is now consistently added after the matrix is applied, independent of if the matrix is specified using a one-dimensional or a two-dimensional array.

scipy.stats

stats.ks_2samp used to return nonsensical values if the input was not real or contained nans. It now raises an exception for such inputs.

Several deprecated methods of scipy.stats distributions have been removed: est_loc_scale, vecfunc, veccdf and vec_generic_moment.

Deprecated functions nanmean, nanstd and nanmedian have been removed from scipy.stats. These functions were deprecated in scipy 0.15.0 in favor of their numpy equivalents.

A bug in the rvs() method of the distributions in scipy.stats has been fixed. When arguments to rvs() were given that were shaped for broadcasting, in many cases the returned random samples were not random. A simple example of the problem is stats.norm.rvs(loc=np.zeros(10)). Because of the bug, that call would return 10 identical values. The bug only affected code that relied on the broadcasting of the shape, location and scale parameters.

The rvs() method also accepted some arguments that it should not have. There is a potential for backwards incompatibility in cases where rvs() accepted arguments that are not, in fact, compatible with broadcasting. An example is

stats.gamma.rvs([2, 5, 10, 15], size=(2,2))

The shape of the first argument is not compatible with the requested size, but the function still returned an array with shape (2, 2). In scipy 0.18, that call generates a ValueError.

scipy.io

scipy.io.netcdf masking now gives precedence to the _FillValue attribute over the missing_value attribute, if both are given. Also, data are only treated as missing if they match one of these attributes exactly: values that differ by roundoff from _FillValue or missing_value are no longer treated as missing values.

scipy.interpolate

scipy.interpolate.PiecewisePolynomial class has been removed. It has been deprecated in scipy 0.14.0, and scipy.interpolate.BPoly.from_derivatives serves as a drop-in replacement.
5.27.4 Other changes

Scipy now uses setuptools for its builds instead of plain distutils. This fixes usage of install_requires='scipy' in the setup.py files of projects that depend on Scipy (see Numpy issue gh-6551 for details). It potentially affects the way that build/install methods for Scipy itself behave though. Please report any unexpected behavior on the Scipy issue tracker.

PR #6240 changes the interpretation of the maxfun option in L-BFGS-B based routines in the scipy.optimize module. An L-BFGS-B search consists of multiple iterations, with each iteration consisting of one or more function evaluations. Whereas the old search strategy terminated immediately upon reaching maxfun function evaluations, the new strategy allows the current iteration to finish despite reaching maxfun.

The bundled copy of Qhull in the scipy.spatial subpackage has been upgraded to version 2015.2.

The bundled copy of ARPACK in the scipy.sparse.linalg subpackage has been upgraded to arpack-ng 3.3.0.

The bundled copy of SuperLU in the scipy.sparse subpackage has been upgraded to version 5.1.1.

• #6122: DOC: optimize: linprog docs should say minimize instead of maximize
SciPy Reference Guide, Release 1.7.0

- #6123: DOC: optimize: document the `fun` field in `scipy.optimize.OptimizeResult`
- #6124: Move FFT zero-padding calculation from signaltools to fftpack
- #6125: MAINT: improve special.gammainc in the $a \sim x$ regime.
- #6130: BUG: sparse: Fix COO dot with zero columns
- #6138: ENH: stats: Improve behavior of genextreme.sf and genextreme.isf
- #6146: MAINT: simplify the expit implementation
- #6151: MAINT: special: make generate_ufuncs.py output deterministic
- #6152: TST: special: better test for gammainc at large arguments
- #6153: ENH: Make next_fast_len public and faster
- #6154: fix typo “mush”-->“must”
- #6155: DOC: Fix some incorrect RST definition lists
- #6160: make logsumexp error out on a masked array
- #6161: added missing bracket to rosen documentation
- #6163: ENH: Added “kappa4” and “kappa3” distributions.
- #6164: DOC: Minor clean-up in integrate._bvp
- #6169: Fix mpf_assert_allclose to handle iterable results, such as maps
- #6170: Fix pchip_interpolate convenience function
- #6172: Corrected misplaced bracket in doc string
- #6175: ENH: sparse.csgraph: Pass indices to shortest_path
- #6178: TST: increase test coverage of sf and isf of a generalized extreme…
- #6179: TST: avoid a deprecation warning from numpy
- #6181: ENH: Boundary conditions for CubicSpline
- #6182: DOC: Add examples/graphs to max_len_seq
- #6183: BLD: update Bento build config files for recent changes.
- #6184: BUG: fix issue in io/wavfile for float96 input.
- #6186: ENH: Periodic extrapolation for PPoly and BPoly
- #6192: MRG: Add circle-CI
- #6193: ENH: sparse: avoid setitem densification
- #6196: Fixed missing sqrt in docstring of Mahalanobis distance in cdist,…
- #6206: MAINT: Minor changes in solve_bvp
- #6207: BUG: linalg: for BLAS, downcast complex256 to complex128, not…
- #6209: BUG: io.matlab: avoid buffer overflows in read_element_into
- #6210: BLD: use setuptools when building.
- #6214: BUG: sparse.linalg: fix bug in LGMRES breakdown handling
- #6215: MAINT: special: make loggamma use zdiv
- #6220: DOC: Add parameter
• #6221: ENH: Improve Newton solver for solve_bvp
• #6223: pchip should work for length-2 arrays
• #6224: signal.lti: deprecate cross-class properties/setters
• #6229: BUG: optimize: avoid an infinite loop in Newton-CG
• #6230: Add example for application of gaussian filter
• #6236: MAINT: gumbel_l accuracy
• #6237: MAINT: rayleigh accuracy
• #6238: MAINT: logistic accuracy
• #6239: MAINT: bradford distribution accuracy
• #6240: MAINT: avoid bad fmin in l-bfgs-b due to maxfun interruption
• #6241: MAINT: weibull_min accuracy
• #6246: ENH: Add _support_mask to distributions
• #6247: fixed a print error for an example of ode
• #6249: MAINT: change x-axis label for stats.probplot to “theoretical…
• #6250: DOC: fix typos
• #6251: MAINT: constants: filter out test noise from deprecated conversions
• #6252: MAINT: io/arff: remove unused variable
• #6253: Add examples to scipy.ndimage.filters
• #6254: MAINT: special: fix some build warnings
• #6258: MAINT: inverse gamma distribution accuracy
• #6260: MAINT: signal.decimate - Use discrete-time objects
• #6262: BUG: odr: fix string formatting
• #6267: TST: fix some test issues in interpolate and stats.
• #6269: TST: fix some warnings in the test suite
• #6274: ENH: Add sosfiltfilt
• #6276: DOC: update release notes for 0.18.0
• #6277: MAINT: update the author name mapping
• #6282: DOC: Correcting references for scipy.stats.normaltest
• #6283: DOC: some more additions to 0.18.0 release notes.
• #6284: Add _versionadded:: directive to loggamma.
• #6285: BUG: stats: Inconsistency in the multivariate_normal docstring…
• #6290: Add author list, gh-lists to 0.18.0 release notes
• #6293: TST: special: relax a test’s precision
• #6295: BUG: sparse: stop comparing None and int in bsr_matrix constructor
• #6313: MAINT: Fix for python 3.5 travis-ci build problem.
• #6327: TST: signal: use assert_allclose for testing near-equality in…
• #6330: BUG: spatial/qhull: allocate qhT via malloc to ensure CRT likes…
• #6332: TST: fix stats.iqr test to not emit warnings, and fix line lengths.
• #6334: MAINT: special: fix a test for hypof1
• #6347: TST: spatial.qhull: skip a test on 32-bit platforms
• #6350: BUG: optimize/slsqp: don’t overwrite an array out of bounds
• #6351: BUG: #6318 Interp1d ‘nearest’ integer x-axis overflow issue fixed
• #6355: Backports for 0.18.0

5.28 SciPy 0.17.1 Release Notes

SciPy 0.17.1 is a bug-fix release with no new features compared to 0.17.0.

5.28.1 Issues closed for 0.17.1

• #5817: BUG: skew, kurtosis return np.nan instead of “propagate”
• #5850: Test failed with sgelsy
• #5898: interpolate.interp1d crashes using float128
• #5953: Massive performance regression in cKDTree.query with L_infinity distance…
• #6062: mannwhitneyu breaks backward compatibility in 0.17.0
• #6134: T test does not handle nans

5.28.2 Pull requests for 0.17.1

• #5902: BUG: interpolate: make interp1d handle np.float128 again
• #5957: BUG: slow down with p=nan in 0.17 cKDTree.query
• #5970: Actually propagate nans through stats functions with nan_policy=”propagate”
• #5971: BUG: linalg: fix lwork check in *gelsy
• #6074: BUG: special: fixed violation of strict aliasing rules.
• #6083: BUG: Fix dtype for sum of linear operators
• #6100: BUG: Fix mannwhitneyu to be backward compatible
• #6135: Don’t pass null pointers to LAPACK, even during workspace queries.
• #6148: stats: fix handling of nan values in T tests and kendalltau
SciPy 0.17.0 is the culmination of 6 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.17.x branch, and on adding new features on the master branch.

This release requires Python 2.6, 2.7 or 3.2-3.5 and NumPy 1.6.2 or greater.

Release highlights:

- New functions for linear and nonlinear least squares optimization with constraints: `scipy.optimize.lsq_linear` and `scipy.optimize.least_squares`
- Support for fitting with bounds in `scipy.optimize.curve_fit`.
- Significant improvements to `scipy.stats`, providing many functions with better handing of inputs which have NaNs or are empty, improved documentation, and consistent behavior between `scipy.stats` and `scipy.stats.mstats`.
- Significant performance improvements and new functionality in `scipy.spatial.cKDTree`. 

SciPy Reference Guide, Release 1.7.0

  - Authors
    - Issues closed for 0.17.0
    - Pull requests for 0.17.0
5.29.1 New features

**scipy.cluster improvements**

A new function `scipy.cluster.hierarchy.cut_tree`, which determines a cut tree from a linkage matrix, was added.

**scipy.io improvements**

`scipy.io.mmwrite` gained support for symmetric sparse matrices.

`scipy.io.netcdf` gained support for masking and scaling data based on data attributes.

**scipy.optimize improvements**

**Linear assignment problem solver**

`scipy.optimize.linear_sum_assignment` is a new function for solving the linear sum assignment problem. It uses the Hungarian algorithm (Kuhn-Munkres).

**Least squares optimization**

A new function for *nonlinear* least squares optimization with constraints was added: `scipy.optimize.least_squares`. It provides several methods: Levenberg-Marquardt for unconstrained problems, and two trust-region methods for constrained ones. Furthermore it provides different loss functions. New trust-region methods also handle sparse Jacobians.

A new function for *linear* least squares optimization with constraints was added: `scipy.optimize.lsq_linear`. It provides a trust-region method as well as an implementation of the Bounded-Variable Least-Squares (BVLS) algorithm.

`scipy.optimize.curve_fit` now supports fitting with bounds.

**scipy.signal improvements**

A `mode` keyword was added to `scipy.signal.spectrogram`, to let it return other spectrograms than power spectral density.

**scipy.stats improvements**

Many functions in `scipy.stats` have gained a `nan_policy` keyword, which allows specifying how to treat input with NaNs in them: propagate the NaNs, raise an error, or omit the NaNs.

Many functions in `scipy.stats` have been improved to correctly handle input arrays that are empty or contain infs/nans.

A number of functions with the same name in `scipy.stats` and `scipy.stats.mstats` were changed to have matching signature and behavior. See gh-5474 for details.

`scipy.stats.binom_test` and `scipy.stats.mannwhitneyu` gained a keyword `alternative`, which allows specifying the hypothesis to test for. Eventually all hypothesis testing functions will get this keyword.

For methods of many continuous distributions, complex input is now accepted.

Matrix normal distribution has been implemented as `scipy.stats.matrix_normal`. 
scipy.sparse improvements

The axis keyword was added to sparse norms, scipy.sparse.linalg.norm.

scipy.spatial improvements

scipy.spatial.cKDTree was partly rewritten for improved performance and several new features were added to it:

- the query_ball_point method became significantly faster
- query and query_ball_point gained an n_jobs keyword for parallel execution
- build and query methods now release the GIL
- full pickling support
- support for periodic spaces
- the sparse_distance_matrix method can now return and sparse matrix type

scipy.interpolate improvements

Out-of-bounds behavior of scipy.interpolate.interp1d has been improved. Use a two-element tuple for the fill_value argument to specify separate fill values for input below and above the interpolation range. Linear and nearest interpolation kinds of scipy.interpolate.interp1d support extrapolation via the fill_value="extrapolate" keyword.

fill_value can also be set to an array-like (or a two-element tuple of array-likes for separate below and above values) so long as it broadcasts properly to the non-interpolated dimensions of an array. This was implicitly supported by previous versions of scipy, but support has now been formalized and gets compatibility-checked before use. For example, a set of y values to interpolate with shape (2, 3, 5) interpolated along the last axis (2) could accept a fill_value array with shape () (singleton), (1,), (2, 1), (1, 3), (3,), or (2, 3); or it can be a 2-element tuple to specify separate below and above bounds, where each of the two tuple elements obeys proper broadcasting rules.

scipy.linalg improvements

The default algorithm for scipy.linalg.leastsq has been changed to use LAPACK’s function *gelsd. Users wanting to get the previous behavior can use a new keyword lapack_driver="gelss" (allowed values are “gelss”, “gelsd” and “gelsy”).

scipy.sparse matrices and linear operators now support the matmul (@) operator when available (Python 3.5+). See [PEP 465](https://legacy.python.org/dev/peps/pep-0465/)

A new function scipy.linalg.orqz, for QZ decomposition with reordering, has been added.
5.29.2 Deprecated features

scipy.stats.histogram is deprecated in favor of np.histogram, which is faster and provides the same functionality.

scipy.stats.threshold and scipy.mstats.threshold are deprecated in favor of np.clip. See issue #617 for details.

scipy.stats.ss is deprecated. This is a support function, not meant to be exposed to the user. Also, the name is unclear. See issue #663 for details.

scipy.stats.square_of_sums is deprecated. This too is a support function not meant to be exposed to the user. See issues #665 and #663 for details.

scipy.stats.f_value, scipy.stats.f_value_multivariate, scipy.stats.f_value_wilks_lambda, and scipy.mstats.f_value_wilks_lambda are deprecated. These are related to ANOVA, for which scipy.stats provides quite limited functionality and these functions are not very useful standalone. See issues #660 and #650 for details.

scipy.stats.chisqprob is deprecated. This is an alias. stats.chi2.sf should be used instead.

scipy.stats.betai is deprecated. This is an alias for special.betainc which should be used instead.

5.29.3 Backwards incompatible changes

The functions stats.trim1 and stats.trimboth now make sure the elements trimmed are the lowest and/or highest, depending on the case. Slicing without at least partial sorting was previously done, but didn't make sense for unsorted input.

When variable_names is set to an empty list, scipy.io.loadmat now correctly returns no values instead of all the contents of the MAT file.

Element-wise multiplication of sparse matrices now returns a sparse result in all cases. Previously, multiplying a sparse matrix with a dense matrix or array would return a dense matrix.

The function misc.lena has been removed due to license incompatibility.

The constructor for sparse.coo_matrix no longer accepts (None, (m,n)) to construct an all-zero matrix of shape (m,n). This functionality was deprecated since at least 2007 and was already broken in the previous SciPy release. Use coo_matrix((m,n)) instead.

The Cython wrappers in linalg.cython_lapack for the LAPACK routines *gegs, *gegv, *gelsx, *geqpf, *ggsvd, *ggsvp, *lahrd, *latzm, *tzrqf have been removed since these routines are not present in the new LAPACK 3.6.0 release. With the exception of the routines *ggsvd and *ggsvp, these were all deprecated in favor of routines that are currently present in our Cython LAPACK wrappers.

Because the LAPACK *gegv routines were removed in LAPACK 3.6.0. The corresponding Python wrappers in scipy.linalg.lapack are now deprecated and will be removed in a future release. The source files for these routines have been temporarily included as a part of scipy.linalg so that SciPy can be built against LAPACK versions that do not provide these deprecated routines.
5.29.4 Other changes

Html and pdf documentation of development versions of Scipy is now automatically rebuilt after every merged pull request.

*scipy.constants* is updated to the CODATA 2014 recommended values.

Usage of *scipy.fftpack* functions within Scipy has been changed in such a way that *PyFFTW* can easily replace *scipy.fftpack* functions (with improved performance). See gh-5295 for details.

The *imread* functions in *scipy.misc* and *scipy.ndimage* were unified, for which a *mode* argument was added to *scipy.misc.imread*. Also, bugs for 1-bit and indexed RGB image formats were fixed.

runtests.py, the development script to build and test Scipy, now allows building in parallel with --parallel.

A total of 101 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

**Issues closed for 0.17.0**

- #1923: problem with numpy 0's in stats.poisson.rvs (Trac #1398)
- #2138: scipy.misc.imread segfaults on 1 bit png (Trac #1613)
- #2237: distributions do not accept complex arguments (Trac #1718)
- #2282: scipy.special.hyp1f1(0.5, 1.5, -1000) fails (Trac #1763)
- #2618: poisson.pmf returns NaN if mu is 0
- #2957: hyp1f1 precision issue
- #2997: FAIL: test_qhull.TestUtilities.test_more_barycentric_transforms
- #3129: No way to set ranges for fitting parameters in Optimize functions
- #3191: interp1d should contain a fill_value_below and a fill_value_above…
- #3453: PchipInterpolator sets slopes at edges differently than Matlab’s…
- #4106: ndimage._ni_support._normalize_sequence() fails with numpy.int64
- #4118: scipy.integrate.ode.set_solout called after scipy.integrate.ode.
  set_initial_value fails silently
- #4233: 1D scipy.interpolate.griddata using method=nearest produces nans…
- #4375: All tests fail due to bad file permissions
- #4580: scipy.ndimage.filters.convolve documention is incorrect
- #4627: logsumexp with sign indicator - enable calculation with negative…
- #4702: logsumexp with zero scaling factor
- #4834: gammainc should return 1.0 instead of NaN for infinite x
- #4838: enh: exprel special function
- #4862: the scipy.special.boxcox function is inaccurate for denormal…
- #4887: Spherical harmonic incongruences
- #4895: some scipy ufuncs have inconsistent output dtypes?
- #4923: logm does not aggressively convert complex outputs to float
- #4932: BUG: stats: The fit method of the distributions silently ignores…
- #4956: Documentation error in scipy.special.bi_zeros
- #4957: Docstring for pbvv_seq is wrong
- #4967: block_diag should look at dtypes of all arguments, not only the…
- #5037: scipy.optimize.minimize minimize error messages are printed to stdout…
• #5039: Cubic interpolation: On entry to DGESDD parameter number 12 had…
• #5163: Base case example of Hierarchical Clustering (offer)
• #5181: BUG: stats.genextreme.entropy should use the explicit formula
• #5184: Some? wheels don’t express a numpy dependency
• #5197: mstats: test_kurtosis fails (ULP max is 2)
• #5260: Typo causing an error in splrep
• #5263: Default epsilon in rbf.py fails for colinear points
• #5276: Reading empty (no data) arff file fails
• #5280: 1d scipy.signal.convolve much slower than numpy.convolve
• #5326: Implementation error in scipy.interpolate.PchipInterpolator
• #5370: Test issue with test_quadpack and libm.so as a linker script
• #5426: ERROR: test_stats.test_chisquare_masked_arrays
• #5427: Automate installing correct numpy versions in numpy-vendor image
• #5430: Python3 : Numpy scalar types “not iterable”; specific instance…
• #5450: BUG: spatial.ConvexHull triggers a seg. fault when given nans.
• #5478: clarify the relation between matrix normal distribution and multivariate_normal
• #5539: lstsq related test failures on windows binaries from numpy-vendor
• #5560: doc: scipy.stats.burr pdf issue
• #5571: lstsq test failure after lapack_driver change
• #5577: ordqz segfault on Python 3.4 in Wine
• #5578: scipy.linalg test failures on python 3 in Wine
• #5607: Overloaded ‘isnan(double&)’ is ambiguous when compiling with…
• #5629: Test for lstsq randomly failed
• #5630: memory leak with scipy 0.16 spatial cKDEtree
• #5689: isnan errors compiling scipy/special/Faddeeva.cc with clang++
• #5694: fftpack test failure in test_import
• #5719: curve_fit(method="lm") ignores initial guess

Pull requests for 0.17.0

• #3022: hyp1f1: better handling of large negative arguments
• #3107: ENH: Add ordered QZ decomposition
• #4390: ENH: Allow axis and keepdims arguments to be passed to scipy.linalg.norm.
• #4671: ENH: add axis to sparse norms
• #4796: ENH: Add cut tree function to scipy.cluster.hierarchy
• #4809: MAINT: cauchy moments are undefined
• #4821: ENH: stats: make distribution instances picklable
- #4839: ENH: Add scipy.special.exprel relative error exponential ufunc
- #4859: Logsumexp fixes - allows sign flags and b==0
- #4865: BUG: scipy.io.mmio.write: error with big indices and low precision
- #4869: add as_inexact option to _lib._util._asarray_validated
- #4884: ENH: Finite difference approximation of Jacobian matrix
- #4890: ENH: Port cKDTree query methods to C++, allow pickling on Python…
- #4892: how much doctesting is too much?
- #4896: MAINT: work around a possible numpy ufunc loop selection bug
- #4898: MAINT: A bit of pyflakes-driven cleanup.
- #4899: ENH: add ‘alternative’ keyword to hypothesis tests in stats
- #4903: BENCH: Benchmarks for interpolate module
- #4905: MAINT: prepend underscore to mask_to_limits; delete masked_var.
- #4906: MAINT: Benchmarks for optimize.leastsq
- #4910: WIP: Trimmed statistics functions have inconsistent API.
- #4924: MAINT: if the imaginary part of logm of a real matrix is small,…
- #4930: BENCH: Benchmarks for signal module
- #4941: ENH: update find_repeats.
- #4942: MAINT: use np.float64_t instead of np.float_t in cKDTree
- #4944: BUG: integer overflow in correlate_nd
- #4951: do not ignore invalid kwargs in distributions fit method
- #4958: Add some detail to docstrings for special functions
- #4961: ENH: stats.describe: add bias kw and empty array handling
- #4963: ENH: scipy.sparse.coo.coo_matrix.__init__: less memory needed
- #4968: DEP: deprecate stats.f_value* and mstats.f_value* functions.
- #4969: ENH: review stats.relfreq and stats.cumfreq; fixes to stats.histogram
- #4971: Extend github source links to line ranges
- #4972: MAINT: improve the error message in validate_runtests_log
- #4976: DEP: deprecate scipy.stats.threshold
- #4977: MAINT: more careful dtype treatment in block diagonal matrix…
- #4979: ENH: distributions, complex arguments
- #4984: clarify dirichlet distribution error handling
- #4992: ENH: stats.fligner and stats.bartlett empty input handling.
- #4996: DOC: fix stats.spearmanr docs
- #4997: Fix up boxcox for underflow / loss of precision
- #4998: DOC: improved documentation for `stats.ppcc_max`
- #5000: ENH: added empty input handling `scipy.moment`; doc enhancements
- #5003: ENH: improves rankdata algorithm
- #5005: `scipy.stats`: numerical stability improvement
- #5007: ENH: nan handling in functions that use `stats._chk_asarray`
- #5009: remove coveralls.io
- #5010: Hypergeometric distribution log survival function
- #5014: Patch to compute the volume and area of convex hulls
- #5015: DOC: Fix mistaken variable name in sawtooth
- #5016: DOC: resample example
- #5017: DEP: deprecate `stats.betai` and `stats.chisqprob`
- #5018: ENH: Add test on random input to volume computations
- #5026: BUG: Fix return dtype of `lil_matrix.getnnz(axis=0)`
- #5030: DOC: resample slow for prime output too
- #5033: MAINT: integrate, special: remove unused R1MACH and Makefile
- #5034: MAINT: signal: lift max_len_seq validation out of Cython
- #5035: DOC/MAINT: refguide / doctest drudgery
- #5041: BUG: fixing some small memory leaks detected by cppcheck
- #5044: [GSoc] ENH: New least-squares algorithms
- #5050: MAINT: C fixes, trimmed a lot of dead code from Cephes
- #5057: ENH: sparse: avoid densifying on sparse/dense elementwise mult
- #5058: TST: stats: add a sample distribution to the test loop
- #5061: ENH: spatial: faster 2D Voronoi and Convex Hull plotting
- #5065: TST: improve test coverage for `stats.mvsdist` and `stats.bayes_mvs`
- #5066: MAINT: fitpack: remove a noop
- #5067: ENH: empty and nan input handling for `stats.kstat` and `stats.kstatvar`
- #5071: DOC: optimize: Correct paper reference, add doi
- #5072: MAINT: scipy.sparse cleanup
- #5073: DOC: special: Add an example showing the relation of diric to…
- #5075: DOC: clarified parameterization of `stats.lognorm`
- #5076: use int, float, bool instead of `np.int`, `np.float`, `np.bool`
- #5078: DOC: Rename `fftpack` docs to README
- #5081: BUG: Correct handling of scalar ‘b’ in `lsmr` and `lsqr`
- #5082: loadmat variable_names: don’t confuse [] and None.
- #5083: Fix `integrate.fixed_quad` docstring to indicate None return value
- #5086: Use `solve()` instead of `inv()` for `gaussian_kde`
- #5090: MAINT: stats: add explicit _sf, _isf to gengamma distribution
- #5094: ENH: scipy.interpolate.NearestNDInterpolator: cKDTree configurable
- #5098: DOC: special: fix typesetting in *_roots quadrature* functions
- #5099: DOC: make the docstring of stats.moment raw
- #5104: DOC/ENH fixes and micro-optimizations for scipy.linalg
- #5105: enh: made l-bfgs-b parameter for the maximum number of line search…
- #5106: TST: add NIST test cases to stats.f_oneway
- #5110: [GSoC]: Bounded linear least squares
- #5111: MAINT: special: Cephes cleanup
- #5118: BUG: FIR path failed if len(x) < len(b) in lfilter.
- #5124: ENH: move the filliben approximation to a publicly visible function
- #5126: StatisticsCleanup: stats.kruskal review
- #5131: DOC: differential_evolution, improve docstring for mutation and…
- #5132: MAINT: differential_evolution improve init_population_lhs comments…
- #5133: MRG: rebased mmio refactoring
- #5135: MAINT: stats.mstats consistency with stats.stats
- #5139: TST: linalg: add a smoke test for gh-5039
- #5140: EHN: Update constants.codata to CODATA 2014
- #5145: added ValueError to docstring as possible error raised
- #5146: MAINT: Improve implementation details and doc in stats.shapiro
- #5147: [GSoC] ENH: Upgrades to curve_fit
- #5150: Fix misleading wavelets/cwt example
- #5152: BUG: cluster.hierarchy.dendrogram: missing font size doesn’t…
- #5153: add keywords to control the summation in discrete distributions…
- #5156: DOC: added comments on algorithms used in Legendre function
- #5158: ENH: optimize: add the Hungarian algorithm
- #5162: FIX: Remove lena
- #5164: MAINT: fix cluster.hierarchy.dendrogram issues and docs
- #5166: MAINT: changed stats.pointbiserialr to delegate to stats.pearsonr
- #5167: ENH: add nan_policy to stats.kendalltau.
- #5168: TST: added nist test case (Norris) to stats.linregress.
- #5169: update lpmv docstring
- #5171: Clarify metric parameter in linkage docstring
- #5172: ENH: add mode keyword to signal.spectrogram
- #5177: DOC: graphical example for KDTree.query_ball_point
• #5179: MAINT: stats: tweak the formula for ncx2.pdf
• #5188: MAINT: linalg: A bit of clean up.
• #5189: BUG: stats: Use the explicit formula in stats.genextreme.entropy
• #5193: BUG: fix uninitialized use in lartg
• #5194: BUG: properly return error to fortran from ode_jacobian_function
• #5198: TST: Fix TestCtypesQuad failure on Python 3.5 for Windows
• #5201: allow extrapolation in interp1d
• #5209: MAINT: Change complex parameter to boolean in Y()
• #5213: BUG: sparse: fix logical comparison dtype conflicts
• #5216: BUG: sparse: fixing unbound local error
• #5218: DOC and BUG: Bessel function docstring improvements, fix array_like,…
• #5222: MAINT: sparse: fix COO ctor
• #5224: DOC: optimize: type of OptimizeResult.hess_inv varies
• #5228: ENH: Add maskandscale support to netcdf; based on pupynere and…
• #5229: DOC: sparse.linalg.svds doc typo fixed
• #5234: MAINT: sparse: simplify COO ctor
• #5235: MAINT: sparse: warn on todia() with many diagonals
• #5236: MAINT: ndimage: simplify thread handling/recursion + constness
• #5239: BUG: integrate: Fixed issue 4118
• #5241: qr_insert fixes, closes #5149
• #5246: Doctest tutorial files
• #5247: DOC: optimize: typo/import fix in linear_sum_assignment
• #5248: remove inspect.getargspec and test python 3.5 on Travis CI
• #5250: BUG: Fix sparse multiply by single-element zero
• #5261: Fix bug causing a TypeError in splrep when a runtime warning…
• #5262: Follow up to 4489 (Addition LAPACK routines in linalg.lstsq)
• #5264: ignore zero-length edges for default epsilon
• #5269: DOC: Typos and spell-checking
• #5272: MAINT: signal: Convert array syntax to memoryviews
• #5273: DOC: raw strings for docstrings with math
• #5274: MAINT: sparse: update cython code for MST
• #5278: BUG: io: Stop guessing the data delimiter in ARFF files.
• #5289: BUG: misc: Fix the Pillow work-around for 1-bit images.
• #5291: ENH: call np.correlate for 1d in scipy.signal.correlate
• #5294: DOC: special: Remove a potentially misleading example from the…
• #5295: Simplify replacement of fftpack by pyfftw

5.29. SciPy 0.17.0 Release Notes
• #5296: ENH: Add matrix normal distribution to stats
• #5297: Fixed leaf_rotation and leaf_font_size in Python 3
• #5303: MAINT: stats: rewrite find_repeats
• #5307: MAINT: stats: remove unused Fortran routine
• #5313: BUG: sparse: fix diags for nonsquare matrices
• #5315: MAINT: special: Cephes cleanup
• #5316: fix input check for sparse.linalg.svds
• #5319: MAINT: Cython code maintenance
• #5328: BUG: Fix place_poles return values
• #5329: avoid a spurious divide-by-zero in Student t stats
• #5334: MAINT: integrate: miscellaneous cleanup
• #5340: MAINT: Printing Error Msg to STDERR and Removing iterate.dat
• #5347: ENH: add Py3.5-style matmul operator (e.g. A @ B) to sparse linear…
• #5350: FIX error, when reading 32-bit float wav files
• #5351: refactor the PCHIP interpolant's algorithm
• #5354: MAINT: construct csr and csc matrices from integer lists
• #5359: add a fast path to interp1d
• #5364: Add two fill_values to interp1d.
• #5365: ABCD docstrings
• #5366: Fixed typo in the documentation for scipy.signal.cwt() per #5290.
• #5367: DOC updated scipy.spatial.Delaunay example
• #5368: ENH: Do not create a throwaway class at every function call
• #5372: DOC: spectral: fix reference formatting
• #5375: PEP8 amendments to fpack_basic.py
• #5377: BUG: integrate: builtin name no longer shadowed
• #5381: PEP8ified fftpack_pseudo_diffs.py
• #5385: BLD: fix Bento build for changes to optimize and spatial
• #5386: STY: PEP8 amendments to interpolate.py
• #5387: DEP: deprecate stats.histogram
• #5388: REL: add “make upload” command to doc/Makefile.
• #5389: DOC: updated origin param of scipy.ndimage.filters.convolve
• #5395: BUG: special: fix a number of edge cases related to x = np.inf.
• #5398: MAINT: stats: avoid spurious warnings in lognorm.pdf(0, s)
• #5407: ENH: stats: Handle mu=0 in stats.poisson
• #5409: Fix the behavior of discrete distributions at the right-hand…
• #5412: TST: stats: skip a test to avoid a spurious log(0) warning
• #5413: BUG: linalg: work around LAPACK single-precision lwork computation...
• #5414: MAINT: stats: move creation of namedtuples outside of function...
• #5415: DOC: fix up sections in ToC in the pdf reference guide
• #5416: TST: fix issue with a ctypes test for integrate on Fedora.
• #5419: MAINT: sparse: fix usage of NotImplementedError
• #5420: Raise proper error if maxiter < 1
• #5422: DOC: changed documentation of brent to be consistent with bracket
• #5444: BUG: gaussian_filter, BPoly.from_derivatives fail on numpy int...
• #5445: MAINT: stats: fix incorrect deprecation warnings and test noise
• #5446: DOC: add note about PyFFTW in fftpack tutorial.
• #5459: DOC: integrate: Some improvements to the differential equation...
• #5465: BUG: Relax mstats kurtosis test tolerance by a few ulp
• #5471: ConvexHull should raise ValueError for NaNs.
• #5473: MAINT: update decorators.py module to version 4.0.5
• #5476: BUG: imsave searches for wrong channel axis if image has 3 or...
• #5477: BLD: add numpy to setup/install_requires for OS X wheels
• #5479: ENH: return Jacobian/Hessian from BasinHopping
• #5484: BUG: fix test zero division handling
• #5486: Fix crash on kmeans2
• #5491: MAINT: Expose parallel build option to runtests.py
• #5494: Sort OptimizeResult.__repr__ by key
• #5496: DOC: update the author name mapping
• #5497: Enhancement to binned_statistic: option to unraveled returned...
• #5498: BUG: sparse: fix a bug in sparsetools input dtype resolution
• #5500: DOC: detect unprintable characters in docstrings
• #5505: BUG: misc: Ensure fromimage converts mode `P` to `RGB` or `RGBA`.
• #5514: DOC: further update the release notes
• #5515: ENH: optionally disable fixed-point acceleration
• #5517: DOC: Improvements and additions to the matrix_normal doc
• #5518: Remove wrappers for LAPACK deprecated routines
• #5521: TST: skip a linalg.orth memory test on 32-bit platforms.
• #5523: DOC: change a few floats to integers in docstring examples
• #5524: DOC: more updates to 0.17.0 release notes.
• #5525: Fix to minor typo in documentation for scipy.integrate.ode
• #5527: TST: bump arccosh tolerance to allow for inaccurate numpyp or…
• #5535: DOC: signal: minor clarification to docstring of TransferFunction.
• #5538: DOC: signal: fix find_peaks_cwt documentation
• #5545: MAINT: Fix typo in linalg/basic.py
• #5547: TST: mark TestEig.test_singular as knownfail in master.
• #5550: MAINT: work around lstsq driver selection issue
• #5556: BUG: Fixed broken dogbox trust-region radius update
• #5561: BUG: eliminate warnings, exception (on Win) in test_maskandscale;...
• #5567: TST: a few cleanups in the test suite; run_module_suite and clearer...
• #5568: MAINT: simplify poisson's__argcheck
• #5569: TST: bump GMean test tolerance to make it pass on Wine
• #5572: TST: lstsq: bump test tolerance for TravisCI
• #5573: TST: remove use of np.fromfile from cluster.vq tests
• #5576: Lapack deprecations
• #5579: TST: skip tests of linalg.norm axis keyword on numpy <= 1.7.x
• #5582: Clarify language of survival function documentation
• #5583: MAINT: stats/tests: A bit of clean up.
• #5588: DOC: stats: Add a note that stats.burr is the Type III Burr distribution.
• #5595: TST: fix test_lamch failures on Python 3
• #5600: MAINT: Ignore spatial/ckdtree.cxx and .h
• #5602: Explicitly numbered replacement fields for maintainability
• #5605: MAINT: collection of small fixes to test suite
• #5614: Minor doc change.
• #5624: FIX: Fix interpolate
• #5625: BUG: msvc9 binaries crash when indexing std::vector of size 0
• #5635: BUG: misspelled__dealloc__ in cKDTree.
• #5642: STY: minor fixup of formatting of 0.17.0 release notes.
• #5643: BLD: fix a build issue in special/Faddeeva.cc with isnan.
• #5661: TST: linalg tests used stdlib random instead of numpy.random.
• #5682: backports for 0.17.0
• #5696: Minor improvements to least_squares’ docstring.
• #5697: BLD: fix for isnan/isinf issues in special/Faddeeva.cc
• #5720: TST: fix for file opening error in fftpack test_import.py
• #5722: BUG: Make curve_fit respect an initial guess with bounds
• #5726: Backports for v0.17.0rc2
• #5727: API: Changes to least_squares API
5.30 SciPy 0.16.1 Release Notes

SciPy 0.16.1 is a bug-fix release with no new features compared to 0.16.0.

5.30.1 Issues closed for 0.16.1

- #5077: cKDTree not indexing properly for arrays with too many elements
- #5127: Regression in 0.16.0: solve_banded errors out in patsy test suite
- #5149: linalg tests apparently cause python to crash with numpy 1.10.0b1
- #5154: 0.16.0 fails to build on OS X; can’t find Python.h
- #5173: failing stats.histogram test with numpy 1.10
- #5191: Scipy 0.16.x - TypeError: _asarray_validated() got an unexpected...
- #5195: tarballs missing documentation source
- #5363: FAIL: test_orthogonal.test_j_roots, test_orthogonal.test_js_roots

5.30.2 Pull requests for 0.16.1

- #5088: BUG: fix logic error in cKDTree.sparse_distance_matrix
- #5089: BUG: Don’t overwrite b in lfilter’s FIR path
- #5128: BUG: solve_banded failed when solving 1x1 systems
- #5155: BLD: fix missing Python include for Homebrew builds.
- #5192: BUG: backport as_inexact kwarg to _asarray_validated
- #5203: BUG: fix uninitialized use in lartg 0.16 backport
- #5204: BUG: properly return error to fortran from ode_jacobian_function...
- #5207: TST: Fix TestCtypesQuad failure on Python 3.5 for Windows
- #5352: TST: sparse: silence warnings about boolean indexing
- #5355: MAINT: backports for 0.16.1 release
- #5356: REL: update Paver file to ensure sdist contents are OK for releases.
- #5382: 0.16.x backport: MAINT: work around a possible numpy ufunc loop...
- #5393: TST:special: bump tolerance levels for test_j_roots and test_js_roots
- #5417: MAINT: stats: move namedtuple creating outside function calls.
SciPy 0.16.0 is the culmination of 7 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.16.x branch, and on adding new features on the master branch.

This release requires Python 2.6, 2.7 or 3.2-3.4 and NumPy 1.6.2 or greater.

Highlights of this release include:

- A Cython API for BLAS/LAPACK in scipy.linalg
- A new benchmark suite. It’s now straightforward to add new benchmarks, and they’re routinely included with performance enhancement PRs.
- Support for the second order sections (SOS) format in scipy.signal.
5.31.1 New features

Benchmark suite

The benchmark suite has switched to using Airspeed Velocity for benchmarking. You can run the suite locally via python runtests.py --bench. For more details, see benchmarks/README.rst.

scipy.linalg improvements

A full set of Cython wrappers for BLAS and LAPACK has been added in the modules scipy.linalg.cython_blas and scipy.linalg.cython_lapack. In Cython, these wrappers can now be cimported from their corresponding modules and used without linking directly against BLAS or LAPACK.

The functions scipy.linalg.qr_delete, scipy.linalg.qr_insert and scipy.linalg.qr_update for updating QR decompositions were added.

The function scipy.linalg.solve_circulant solves a linear system with a circulant coefficient matrix.

The function scipy.linalg.invpascal computes the inverse of a Pascal matrix.

The function scipy.linalg.solve_toeplitz, a Levinson-Durbin Toeplitz solver, was added.

Added wrapper for potentially useful LAPACK function *lasd4. It computes the square root of the i-th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix. See its LAPACK documentation and unit tests for it to get more info.

Added two extra wrappers for LAPACK least-square solvers. Namely, they are *gelsd and *gelsy.

Wrappers for the LAPACK *lange functions, which calculate various matrix norms, were added.

Wrappers for *gtsv and *ptsv, which solve A*X = B for tri-diagonalmatrixA, were added.

scipy.signal improvements

Support for second order sections (SOS) as a format for IIR filters was added. The new functions are:

- scipy.signal.sosfilt
- scipy.signal.sosfilt_zi,
- scipy.signal.sos2tf
- scipy.signal.sos2zpk
- scipy.signal.tf2sos
- scipy.signal.zpk2sos.

Additionally, the filter design functions iirdesign, iirfilter, butter, cheby1, cheby2, ellip, and bessel can return the filter in the SOS format.

The function scipy.signal.place_poles, which provides two methods to place poles for linear systems, was added.

The option to use Gustafsson’s method for choosing the initial conditions of the forward and backward passes was added to scipy.signal.filtfilt.

New classes TransferFunction, StateSpace and ZerosPolesGain were added. These classes are now returned when instantiating scipy.signal.lti. Conversion between those classes can be done explicitly now.

An exponential (Poisson) window was added as scipy.signal.exponential, and a Tukey window was added as scipy.signal.tukey.
The function for computing digital filter group delay was added as `scipy.signal.group_delay`.

The functionality for spectral analysis and spectral density estimation has been significantly improved: `scipy.signal.welch` became ~8x faster and the functions `scipy.signal.spectrogram`, `scipy.signal.coherence` and `scipy.signal.csd` (cross-spectral density) were added.

`scipy.signal.lsim` was rewritten - all known issues are fixed, so this function can now be used instead of lsim2; lsim is orders of magnitude faster than lsim2 in most cases.

**scipy.sparse improvements**

The function `scipy.sparse.norm`, which computes sparse matrix norms, was added.

The function `scipy.sparse.random`, which allows to draw random variates from an arbitrary distribution, was added.

**scipy.spatial improvements**

`scipy.spatial.cKDTree` has seen a major rewrite, which improved the performance of the query method significantly, added support for parallel queries, pickling, and options that affect the tree layout. See pull request 4374 for more details.

The function `scipy.spatial.procrustes` for Procrustes analysis (statistical shape analysis) was added.

**scipy.stats improvements**

The Wishart distribution and its inverse have been added, as `scipy.stats.wishart` and `scipy.stats.invwishart`.

The Exponentially Modified Normal distribution has been added as `scipy.stats.exponnorm`.

The Generalized Normal distribution has been added as `scipy.stats.gennorm`.

All distributions now contain a `random_state` property and allow specifying a specific `numpy.random.RandomState` random number generator when generating random variates.

Many statistical tests and other `scipy.stats` functions that have multiple return values now return namedtuples. See pull request 4709 for details.

**scipy.optimize improvements**

A new derivative-free method DF-SANE has been added to the nonlinear equation system solving function `scipy.optimize.root`.

### 5.3.1.2 Deprecated features

`scipy.stats.pdf_fromgamma` is deprecated. This function was undocumented, untested and rarely used. Statsmodels provides equivalent functionality with `statsmodels.distributions.ExpandedNormal`.

`scipy.stats.fastsort` is deprecated. This function is unnecessary, `numpy.argsort` can be used instead.

`scipy.stats.signaltonoise` and `scipy.stats.mstats.signaltonoise` are deprecated. These functions did not belong in `scipy.stats` and are rarely used. See issue #609 for details.

`scipy.stats.histogram2` is deprecated. This function is unnecessary, `numpy.histogram2d` can be used instead.
5.31.3 Backwards incompatible changes

The deprecated global optimizer `scipy.optimize.anneal` was removed.

The following deprecated modules have been removed: `scipy.lib.blas`, `scipy.lib.lapack`, `scipy.linalg.cblas`, `scipy.linalg.fblas`, `scipy.linalg.clapack`, `scipy.linalg.flapack`. They had been deprecated since Scipy 0.12.0, the functionality should be accessed as `scipy.linalg.blas` and `scipy.linalg.lapack`.

The deprecated function `scipy.special.all_mat` has been removed.

The deprecated functions `fprob`, `ksprob`, `zprob`, `randwcdf` and `randwppf` have been removed from `scipy.stats`.

5.31.4 Other changes

The version numbering for development builds has been updated to comply with PEP 440.

Building with `python setup.py develop` is now supported.

5.32 SciPy 0.15.1 Release Notes

SciPy 0.15.1 is a bug-fix release with no new features compared to 0.15.0.

5.32.1 Issues fixed

• #4413: BUG: Tests too strict, f2py doesn’t have to overwrite this array
• #4417: BLD: avoid using NPY_API_VERSION to check not using deprecated…
• #4418: Restore and deprecate scipy.linalg.calc_work

5.33 SciPy 0.15.0 Release Notes

Contents

• SciPy 0.15.0 Release Notes
  – New features
    • Linear Programming Interface
    • Differential evolution, a global optimizer
    • scipy.signal improvements
    • scipy.integrate improvements
    • scipy.linalg improvements
    • scipy.sparse improvements
SciPy 0.15.0 is the culmination of 6 months of hard work. It contains several new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.16.x branch, and on adding new features on the master branch.

This release requires Python 2.6, 2.7 or 3.2-3.4 and NumPy 1.5.1 or greater.

## 5.33.1 New features

### Linear Programming Interface

The new function `scipy.optimize.linprog` provides a generic linear programming similar to the way `scipy.optimize.minimize` provides a generic interface to nonlinear programming optimizers. Currently the only method supported is `simplex` which provides a two-phase, dense-matrix-based simplex algorithm. Callbacks functions are supported, allowing the user to monitor the progress of the algorithm.

### Differential evolution, a global optimizer

A new `scipy.optimize.differential_evolution` function has been added to the `optimize` module. Differential Evolution is an algorithm used for finding the global minimum of multivariate functions. It is stochastic in nature (does not use gradient methods), and can search large areas of candidate space, but often requires larger numbers of function evaluations than conventional gradient based techniques.

### `scipy.signal` improvements

The function `scipy.signal.max_len_seq` was added, which computes a Maximum Length Sequence (MLS) signal.
**scipy.integrate improvements**

It is now possible to use `scipy.integrate` routines to integrate multivariate ctypes functions, thus avoiding callbacks to Python and providing better performance.

**scipy.linalg improvements**

The function `scipy.linalg.orthogonal_procrustes` for solving the procrustes linear algebra problem was added.

BLAS level 2 functions `her`, `syr`, `her2` and `syr2` are now wrapped in `scipy.linalg`.

**scipy.sparse improvements**

`scipy.sparse.linalg.svds` can now take a `LinearOperator` as its main input.

**scipy.special improvements**

Values of ellipsoidal harmonic (i.e. Lame) functions and associated normalization constants can be now computed using `ellip_harm`, `ellip_harm_2`, and `ellip_normal`.

New convenience functions `entr`, `rel_entr`, `kl_div`, `huber`, and `pseudo_huber` were added.

**scipy.sparse.csgraph improvements**

Routines `reverse_cuthill_mckee` and `maximum_bipartite_matching` for computing reorderings of sparse graphs were added.

**scipy.stats improvements**

Added a Dirichlet multivariate distribution, `scipy.stats.dirichlet`.

The new function `scipy.stats.median_test` computes Mood’s median test.

The new function `scipy.stats.combine_pvalues` implements Fisher’s and Stouffer’s methods for combining p-values.

`scipy.stats.describe` returns a namedtuple rather than a tuple, allowing users to access results by index or by name.

### 5.33.2 Deprecated features

The `scipy.weave` module is deprecated. It was the only module never ported to Python 3.x, and is not recommended to be used for new code - use Cython instead. In order to support existing code, `scipy.weave` has been packaged separately: https://github.com/scipy/weave. It is a pure Python package, and can easily be installed with `pip install weave`.

`scipy.special.bessel_diff_formula` is deprecated. It is a private function, and therefore will be removed from the public API in a following release.

`scipy.stats.nanmean`, `nanmedian` and `nanstd` functions are deprecated in favor of their numpy equivalents.
5.33.3 Backwards incompatible changes

**scipy.ndimage**

The functions `scipy.ndimage.minimum_positions`, `scipy.ndimage.maximum_positions` and `scipy.ndimage.extrema` return positions as ints instead of floats.

**scipy.integrate**

The format of banded Jacobians in `scipy.integrate.ode` solvers is changed. Note that the previous documentation of this feature was erroneous.

• #4201: DOC: add blas2 and nan* deprecations to the release notes
• #4243: TST: bump test tolerances
5.34 SciPy 0.14.1 Release Notes

SciPy 0.14.1 is a bug-fix release with no new features compared to 0.14.0.

5.34.1 Issues closed

- #3630: NetCDF reading results in a segfault
- #3631: SuperLU object not working as expected for complex matrices
- #3733: segfault from map_coordinates
- #3780: Segfault when using CSR/CSC matrix and uint32/uint64
- #3781: BUG: sparse: fix omitted types in sparsetools typemaps
- #3802: 0.14.0 API breakage: _gen generators are missing from scipy.stats.distributions API
- #3805: ndimage test failures with numpy 1.10
- #3812: == sometimes wrong on csr_matrix
- #3853: Many scipy.sparse test errors/failures with numpy 1.9.0b2
- #4084: fix exception declarations for Cython 0.21.1 compatibility
- #4093: BUG: fitpack: avoid a memory error in splev(x, tck, der=k)
- #4104: BUG: Workaround SGEMV segfault in Accelerate (maintenance 0.14.x)
- #4143: BUG: fix ndimage functions for large data
- #4149: Bug in expm for integer arrays
- #4154: Backport gh-4041 for 0.14.1 (Ensure that the ‘size’ argument of PIL’s ‘resize’ method is a tuple)
- #4163: Backport #4142 (ZeroDivisionError in scipy.sparse.linalg.lsqr)
- #4164: Backport gh-4153 (remove use of deprecated numpy API in lib/lapack/ f2py wrapper)
- #4180: backport pil resize support tuple fix
- #4168: Lots of arpack test failures on windows 32 bits with numpy 1.9.1
- #4203: Matrix multiplication in 0.14.x is more than 10x slower compared…
- #4218: attempt to make ndimage interpolation compatible with numpy relaxed…
- #4225: BUG: off-by-one error in PPoly shape checks
- #4248: BUG: optimize: fix issue with incorrect use of closure for slsqp.

5.35 SciPy 0.14.0 Release Notes

Contents

- SciPy 0.14.0 Release Notes
  - New features
    - scipy.interpolate improvements
SciPy 0.14.0 is the culmination of 8 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.14.x branch, and on adding new features on the master branch.

This release requires Python 2.6, 2.7 or 3.2-3.4 and NumPy 1.5.1 or greater.

**5.35.1 New features**

**scipy.interpolate improvements**

A new wrapper function `scipy.interpolate.interpn` for interpolation on regular grids has been added. `interpn` supports linear and nearest-neighbor interpolation in arbitrary dimensions and spline interpolation in two dimensions.

Faster implementations of piecewise polynomials in power and Bernstein polynomial bases have been added as `scipy.interpolate.PPoly` and `scipy.interpolate.BPoly`. New users should use these in favor of `scipy.interpolate.PiecewisePolynomial`.

`scipy.interpolate.interp1d` now accepts non-monotonic inputs and sorts them. If performance is critical, sorting can be turned off by using the new assumption keyword.

Functionality for evaluation of bivariate spline derivatives in `scipy.interpolate` has been added.

The new class `scipy.interpolate.Akima1DInterpolator` implements the piecewise cubic polynomial interpolation scheme devised by H. Akima.
Functionality for fast interpolation on regular, unevenly spaced grids in arbitrary dimensions has been added as `scipy.interpolate.RegularGridInterpolator`.

**scipy.linalg improvements**

The new function `scipy.linalg.dft` computes the matrix of the discrete Fourier transform. A condition number estimation function for matrix exponential, `scipy.linalg.expm_cond`, has been added.

**scipy.optimize improvements**

A set of benchmarks for optimize, which can be run with `optimize.bench()`, has been added. `scipy.optimize.curve_fit` now has more controllable error estimation via the `absolute_sigma` keyword. Support for passing custom minimization methods to `optimize.minimize()` and `optimize.minimize_scalar()` has been added, currently useful especially for combining `optimize.basinhopping()` with custom local optimizer routines.

**scipy.stats improvements**

A new class `scipy.stats.multivariate_normal` with functionality for multivariate normal random variables has been added. A lot of work on the `scipy.stats` distribution framework has been done. Moment calculations (skew and kurtosis mainly) are fixed and verified, all examples are now runnable, and many small accuracy and performance improvements for individual distributions were merged. The new function `scipy.stats.anderson_ksamp` computes the k-sample Anderson-Darling test for the null hypothesis that k samples come from the same parent population.

**scipy.signal improvements**

`scipy.signal.iirfilter` and related functions to design Butterworth, Chebyshev, elliptical and Bessel IIR filters now all use pole-zero (“zpk”) format internally instead of using transformations to numerator/denominator format. The accuracy of the produced filters, especially high-order ones, is improved significantly as a result. The Savitzky-Golay filter was added with the new functions `scipy.signal.savgol_filter` and `scipy.signal.savgol_coeffs`. The new function `scipy.signal.vectorstrength` computes the vector strength, a measure of phase synchrony, of a set of events.

**scipy.special improvements**

The functions `scipy.special.boxcox` and `scipy.special.boxcox1p`, which compute the Box-Cox transformation, have been added.
scipy.sparse improvements

- Significant performance improvement in CSR, CSC, and DOK indexing speed.
- When using Numpy >= 1.9 (to be released in MM 2014), sparse matrices function correctly when given to arguments of np.dot, np.multiply and other ufuncs. With earlier Numpy and Scipy versions, the results of such operations are undefined and usually unexpected.
- Sparse matrices are no longer limited to $2^{31}$ nonzero elements. They automatically switch to using 64-bit index data type for matrices containing more elements. User code written assuming the sparse matrices use int32 as the index data type will continue to work, except for such large matrices. Code dealing with larger matrices needs to accept either int32 or int64 indices.

5.35.2 Deprecated features

anneal

The global minimization function scipy.optimize.anneal is deprecated. All users should use the scipy.optimize.basinhopping function instead.

scipy.stats

randwcdf and randwppf functions are deprecated. All users should use distribution-specific rvs methods instead.

Probability calculation aliases zprob, fprob and ksprob are deprecated. Use instead the sf methods of the corresponding distributions or the special functions directly.

scipy.interpolate

PiecewisePolynomial class is deprecated.

5.35.3 Backwards incompatible changes

scipy.special.lpmn

lpmn no longer accepts complex-valued arguments. A new function clpmn with uniform complex analytic behavior has been added, and it should be used instead.

scipy.sparse.linalg

Eigenvectors in the case of generalized eigenvalue problem are normalized to unit vectors in 2-norm, rather than following the LAPACK normalization convention.

The deprecated UMFPACK wrapper in scipy.sparse.linalg has been removed due to license and install issues. If available, scikits.umfpack is still used transparently in the spsolve and factorized functions. Otherwise, SuperLU is used instead in these functions.
**scipy.stats**

The deprecated functions `glm`, `oneway` and `cmedian` have been removed from `scipy.stats`. `stats.scoreatpercentile` now returns an array instead of a list of percentiles.

**scipy.interpolate**

The API for computing derivatives of a monotone piecewise interpolation has changed: if `p` is a `PchipInterpolator` object, `p.derivative(der)` returns a callable object representing the derivative of `p`. For in-place derivatives use the second argument of the `__call__` method: `p(0.1, der=2)` evaluates the second derivative of `p` at `x=0.1`.

The method `p.derivatives` has been removed.

5.36 SciPy 0.13.2 Release Notes

SciPy 0.13.2 is a bug-fix release with no new features compared to 0.13.1.

5.36.1 Issues fixed

• 3096: require Cython 0.19, earlier versions have memory leaks in fused types
• 3079: ndimage.label fix swapped 64-bitness test
• 3108: optimize.fmin_slsqp constraint violation

5.37 SciPy 0.13.1 Release Notes

SciPy 0.13.1 is a bug-fix release with no new features compared to 0.13.0. The only changes are several fixes in ndimage, one of which was a serious regression in ndimage.label (Github issue 3025), which gave incorrect results in 0.13.0.

5.37.1 Issues fixed

• 3025: ndimage.label returns incorrect results in scipy 0.13.0
• 1992: ndimage.label return type changed from int32 to uint32
• 1992: ndimage.find_objects doesn’t work with int32 input in some cases
5.38 SciPy 0.13.0 Release Notes

SciPy 0.13.0 is the culmination of 7 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.13.x branch, and on adding new features on the master branch.

This release requires Python 2.6, 2.7 or 3.1-3.3 and NumPy 1.5.1 or greater. Highlights of this release are:

- support for fancy indexing and boolean comparisons with sparse matrices
- interpolative decompositions and matrix functions in the linalg module
- two new trust-region solvers for unconstrained minimization

### 5.38.1 New features

**scipy.integrate** improvements

**N-dimensional numerical integration**

A new function `scipy.integrate.nquad`, which provides N-dimensional integration functionality with a more flexible interface than `dblquad` and `tplquad`, has been added.

**dopri* improvements**

The intermediate results from the `dopri` family of ODE solvers can now be accessed by a `solout` callback function.

**scipy.linalg** improvements

**Interpolative decompositions**

Scipy now includes a new module `scipy.linalg.interpolative` containing routines for computing interpolative matrix decompositions (ID). This feature is based on the ID software package by P.G. Martinsson, V. Rokhlin, Y. Shkolnisky, and M. Tygert, previously adapted for Python in the PymatrixId package by K.L. Ho.

**Polar decomposition**

A new function `scipy.linalg.polar`, to compute the polar decomposition of a matrix, was added.

**BLAS level 3 functions**

The BLAS functions `symm, syrk, syr2k, hemm, herk` and `her2k` are now wrapped in `scipy.linalg`. 
Matrix functions

Several matrix function algorithms have been implemented or updated following detailed descriptions in recent papers of Nick Higham and his co-authors. These include the matrix square root ($\text{sqrtm}$), the matrix logarithm ($\text{logm}$), the matrix exponential ($\text{expm}$) and its Frechet derivative ($\text{expm_frechet}$), and fractional matrix powers ($\text{fractional_matrix_power}$).

**scipy.optimize improvements**

Trust-region unconstrained minimization algorithms

The `minimize` function gained two trust-region solvers for unconstrained minimization: `dogleg` and `trust-ncg`.

**scipy.sparse improvements**

Boolean comparisons and sparse matrices

All sparse matrix types now support boolean data, and boolean operations. Two sparse matrices $A$ and $B$ can be compared in all the expected ways $A < B$, $A \geq B$, $A != B$, producing similar results as dense Numpy arrays. Comparisons with dense matrices and scalars are also supported.

CSR and CSC fancy indexing

Compressed sparse row and column sparse matrix types now support fancy indexing with boolean matrices, slices, and lists. So where $A$ is a (CSC or CSR) sparse matrix, you can do things like:

```python
>>> A[A > 0.5] = 1  # since Boolean sparse matrices work
>>> A[:, 2] = 2
>>> A[[1, 2], 2] = 3
```

**scipy.sparse.linalg improvements**

The new function `onenormest` provides a lower bound of the 1-norm of a linear operator and has been implemented according to Higham and Tisseur (2000). This function is not only useful for sparse matrices, but can also be used to estimate the norm of products or powers of dense matrices without explicitly building the intermediate matrix.

The multiplicative action of the matrix exponential of a linear operator ($\text{expm_multiply}$) has been implemented following the description in Al-Mohy and Higham (2011).

Abstract linear operators (`scipy.sparse.linalg.LinearOperator`) can now be multiplied, added to each other, and exponentiated, producing new linear operators. This enables easier construction of composite linear operations.

**scipy.spatial improvements**

The vertices of a ConvexHull can now be accessed via the `vertices` attribute, which gives proper orientation in 2-D.
scipy.signal improvements

The cosine window function `scipy.signal.cosine` was added.

scipy.special improvements

New functions `scipy.special.xlogy` and `scipy.special.xlog1py` were added. These functions can simplify and speed up code that has to calculate $x \times \log(y)$ and give 0 when $x == 0$.

scipy.io improvements

Unformatted Fortran file reader

The new class `scipy.io.FortranFile` facilitates reading unformatted sequential files written by Fortran code.

scipy.io.wavfile enhancements

`scipy.io.wavfile.write` now accepts a file buffer. Previously it only accepted a filename.

`scipy.io.wavfile.read` and `scipy.io.wavfile.write` can now handle floating point WAV files.

scipy.interpolate improvements

B-spline derivatives and antiderivatives

`scipy.interpolate.splder` and `scipy.interpolate.splantider` functions for computing B-splines that represent derivatives and antiderivatives of B-splines were added. These functions are also available in the class-based FITPACK interface as `UnivariateSpline.derivative` and `UnivariateSpline.antiderivative`.

scipy.stats improvements

Distributions now allow using keyword parameters in addition to positional parameters in all methods.

The function `scipy.stats.power_divergence` has been added for the Cressie-Read power divergence statistic and goodness of fit test. Included in this family of statistics is the “G-test” (https://en.wikipedia.org/wiki/G-test).

`scipy.stats.mood` now accepts multidimensional input.

An option was added to `scipy.stats.wilcoxon` for continuity correction.

`scipy.stats.chisquare` now has an `axis` argument.

`scipy.stats.mstats.chisquare` now has `axis` and `ddof` arguments.

5.38.2 Deprecated features

`expm2` and `expm3`

The matrix exponential functions `scipy.linalg.expm2` and `scipy.linalg.expm3` are deprecated. All users should use the numerically more robust `scipy.linalg.expm` function instead.
scipy.stats functions

`scipy.stats.oneway` is deprecated; `scipy.stats.f_oneway` should be used instead.

`scipy.stats glm` is deprecated. `scipy.stats.ttest_ind` is an equivalent function; more full-featured general (and generalized) linear model implementations can be found in statsmodels.

`scipy.stats.cmedian` is deprecated; `numpy.median` should be used instead.

5.38.3 Backwards incompatible changes

LIL matrix assignment

Assigning values to LIL matrices with two index arrays now works similarly as assigning into ndarrays:

```python
>>> x = lil_matrix((3, 3))
>>> x[[0,1,2],[0,1,2]]=[0,1,2]
>>> x.todense()
matrix([[ 0., 0., 0.],
        [ 0., 1., 0.],
        [ 0., 0., 2.]])
```

rather than giving the result:

```python
>>> x.todense()
matrix([[ 0., 1., 2.],
        [ 0., 1., 2.],
        [ 0., 1., 2.]])
```

Users relying on the previous behavior will need to revisit their code. The previous behavior is obtained by `x[numpy.ix_([0,1,2],[0,1,2])] = ....`

Deprecated radon function removed

The `misc.radon` function, which was deprecated in scipy 0.11.0, has been removed. Users can find a more full-featured `radon` function in scikit-image.

Removed deprecated keywords `xa` and `xb` from `stats.distributions`

The keywords `xa` and `xb`, which were deprecated since 0.11.0, have been removed from the distributions in `scipy.stats`.

Changes to MATLAB file readers / writers

The major change is that 1D arrays in numpy now become row vectors (shape 1, N) when saved to a MATLAB 5 format file. Previously 1D arrays saved as column vectors (N, 1). This is to harmonize the behavior of writing MATLAB 4 and 5 formats, and adapt to the defaults of numpy and MATLAB - for example `np.atleast_2d` returns 1D arrays as row vectors.

Trying to save arrays of greater than 2 dimensions in MATLAB 4 format now raises an error instead of silently reshaping the array as 2D.
scipy.io.loadmat('afile') used to look for *afile* on the Python system path *(sys.path)*; now loadmat only looks in the current directory for a relative path filename.

### 5.38.4 Other changes

Security fix: *scipy.weave* previously used temporary directories in an insecure manner under certain circumstances. Cython is now required to build *unreleased* versions of scipy. The C files generated from Cython sources are not included in the git repo anymore. They are however still shipped in source releases.

The code base received a fairly large PEP8 cleanup. A *tox pep8* command has been added; new code should pass this test command.

Scipy cannot be compiled with gfortran 4.1 anymore (at least on RH5), likely due to that compiler version not supporting entry constructs well.

### 5.38.5 Authors

This release contains work by the following people (contributed at least one patch to this release, names in alphabetical order):

5.39 SciPy 0.12.1 Release Notes

SciPy 0.12.1 is a bug-fix release with no new features compared to 0.12.0. The single issue fixed by this release is a security issue in scipy.weave, which was previously using temporary directories in an insecure manner under certain circumstances.

5.40 SciPy 0.12.0 Release Notes

Contents

• SciPy 0.12.0 Release Notes
  – New features
    • scipy.spatial improvements

      • Basin hopping global optimization (scipy.optimize.basinhopping)
    • scipy.special improvements
      • Revised complex error functions
      • Faster orthogonal polynomials
    • scipy.sparse.linalg features
    • Listing Matlab(R) file contents in scipy.io
    • Documented BLAS and LAPACK low-level interfaces (scipy.linalg)
    • Polynomial interpolation improvements (scipy.interpolate)
  – Deprecated features
SciPy 0.12.0 is the culmination of 7 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.12.x branch, and on adding new features on the master branch.

Some of the highlights of this release are:

- Completed QHull wrappers in scipy.spatial.
- cKDTree now a drop-in replacement for KDTree.
- A new global optimizer, basinhopping.
- Support for Python 2 and Python 3 from the same code base (no more 2to3).

This release requires Python 2.6, 2.7 or 3.1-3.3 and NumPy 1.5.1 or greater. Support for Python 2.4 and 2.5 has been dropped as of this release.

### 5.40.1 New features

**scipy.spatial improvements**

**cKDTree feature-complete**

Cython version of KDTree, cKDTree, is now feature-complete. Most operations (construction, query, query_ball_point, query_pairs, count_neighbors and sparse_distance_matrix) are between 200 and 1000 times faster in cKDTree than in KDTree. With very minor caveats, cKDTree has exactly the same interface as KDTree, and can be used as a drop-in replacement.

**Voronoi diagrams and convex hulls**

*scipy.spatial* now contains functionality for computing Voronoi diagrams and convex hulls using the Qhull library. (Delaunay triangulation was available since Scipy 0.9.0.)

**Delaunay improvements**

It's now possible to pass in custom Qhull options in Delaunay triangulation. Coplanar points are now also recorded, if present. Incremental construction of Delaunay triangulations is now also possible.
Spectral estimators (*scipy.signal*)

The functions *scipy.signal.periodogram* and *scipy.signal.welch* were added, providing DFT-based spectral estimators.

*scipy.optimize* improvements

Callback functions in L-BFGS-B and TNC

A callback mechanism was added to L-BFGS-B and TNC minimization solvers.

Basin hopping global optimization (*scipy.optimize.basinhopping*)

A new global optimization algorithm. Basinhopping is designed to efficiently find the global minimum of a smooth function.

*scipy.special* improvements

Revised complex error functions

The computation of special functions related to the error function now uses a new Faddeeva library from MIT which increases their numerical precision. The scaled and imaginary error functions *erfcx* and *erfi* were also added, and the Dawson integral *dawson* can now be evaluated for a complex argument.

Faster orthogonal polynomials

Evaluation of orthogonal polynomials (the *eval_* routines) in now faster in *scipy.special*, and their *out_* argument functions properly.

*scipy.sparse.linalg* features

- In *scipy.sparse.linalg.spsolve*, the *b* argument can now be either a vector or a matrix.
- *scipy.sparse.linalg.inv* was added. This uses *spsolve* to compute a sparse matrix inverse.
- *scipy.sparse.linalg.expm* was added. This computes the exponential of a sparse matrix using a similar algorithm to the existing dense array implementation in *scipy.linalg.expm*.

Listing Matlab(R) file contents in *scipy.io*

A new function *whosmat* is available in *scipy.io* for inspecting contents of MAT files without reading them to memory.

Documented BLAS and LAPACK low-level interfaces (*scipy.linalg*)

The modules *scipy.linalg.blas* and *scipy.linalg.lapack* can be used to access low-level BLAS and LAPACK functions.
Polynomial interpolation improvements (scipy.interpolate)

The barycentric, Krogh, piecewise and pchip polynomial interpolators in `scipy.interpolate` accept now an `axis` argument.

5.40.2 Deprecated features

`scipy.lib.lapack`

The module `scipy.lib.lapack` is deprecated. You can use `scipy.linalg.lapack` instead. The module `scipy.lib.blas` was deprecated earlier in Scipy 0.10.0.

`fblas` and `cblas`

Accessing the modules `scipy.linalg.fblas`, `cblas`, `flapack`, `clapack` is deprecated. Instead, use the modules `scipy.linalg.lapack` and `scipy.linalg.blas`.

5.40.3 Backwards incompatible changes

Removal of `scipy.io.save_as_module`

The function `scipy.io.save_as_module` was deprecated in Scipy 0.11.0, and is now removed.

Its private support modules `scipy.io.dumbdbm_patched` and `scipy.io.dumb_shelve` are also removed.

`axis` argument added to `scipy.stats.scoreatpercentile`

The function `scipy.stats.scoreatpercentile` has been given an `axis` argument. The default argument is `axis=None`, which means the calculation is done on the flattened array. Before this change, `scoreatpercentile` would act as if `axis=0` had been given. Code using `scoreatpercentile` with a multidimensional array will need to add `axis=0` to the function call to preserve the old behavior. (This API change was not noticed until long after the release of 0.12.0.)

5.40.4 Authors

5.41 SciPy 0.11.0 Release Notes

SciPy 0.11.0 is the culmination of 8 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. Highlights of this release are:

- A new module has been added which provides a number of common sparse graph algorithms.
- New unified interfaces to the existing optimization and root finding functions have been added.

All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Our development attention will now shift to bug-fix releases on the 0.11.x branch, and on adding new features on the master branch.

This release requires Python 2.4-2.7 or 3.1-3.2 and NumPy 1.5.1 or greater.
5.41.1 New features

Sparse Graph Submodule

The new submodule `scipy.sparse.csgraph` implements a number of efficient graph algorithms for graphs stored as sparse adjacency matrices. Available routines are:

- `connected_components` - determine connected components of a graph
- `laplacian` - compute the laplacian of a graph
- `shortest_path` - compute the shortest path between points on a positive graph
- `dijkstra` - use Dijkstra’s algorithm for shortest path
- `floyd_warshall` - use the Floyd-Warshall algorithm for shortest path
- `breadth_first_order` - compute a breadth-first order of nodes
- `depth_first_order` - compute a depth-first order of nodes
- `breadth_first_tree` - construct the breadth-first tree from a given node
- `depth_first_tree` - construct a depth-first tree from a given node
- `minimum_spanning_tree` - construct the minimum spanning tree of a graph

**scipy.optimize improvements**

The optimize module has received a lot of attention this release. In addition to added tests, documentation improvements, bug fixes and code clean-up, the following improvements were made:

- A unified interface to minimizers of univariate and multivariate functions has been added.
- A unified interface to root finding algorithms for multivariate functions has been added.
- The L-BFGS-B algorithm has been updated to version 3.0.

**Unified interfaces to minimizers**

Two new functions `scipy.optimize.minimize` and `scipy.optimize.minimize_scalar` were added to provide a common interface to minimizers of multivariate and univariate functions respectively. For multivariate functions, `scipy.optimize.minimize` provides an interface to methods for unconstrained optimization (`fmin`, `fmin_powell`, `fmin_cg`, `fmin_ncg`, `fmin_bfgs` and `anneal`) or constrained optimization (`fmin_l_bfgs_b`, `fmin_tnc`, `fmin_cobyla` and `fmin_slsqp`). For univariate functions, `scipy.optimize.minimize_scalar` provides an interface to methods for unconstrained and bounded optimization (`brent`, `golden`, `fminbound`). This allows for easier comparing and switching between solvers.

**Unified interface to root finding algorithms**

The new function `scipy.optimize.root` provides a common interface to root finding algorithms for multivariate functions, embedding `fsolve`, `leastsq` and `nonlin` solvers.
**scipy.linalg improvements**

**New matrix equation solvers**

Solvers for the Sylvester equation (scipy.linalg.solve_sylvester, discrete and continuous Lyapunov equations (scipy.linalg.solve_lyapunov, scipy.linalg.solve_discrete_lyapunov) and discrete and continuous algebraic Riccati equations (scipy.linalg.solve_continuous_are, scipy.linalg.solve_discrete_are) have been added to scipy.linalg. These solvers are often used in the field of linear control theory.

**QZ and QR Decomposition**

It is now possible to calculate the QZ, or Generalized Schur, decomposition using scipy.linalg.qz. This function wraps the LAPACK routines sgges, dgges, cgges, and zgges.

The function scipy.linalg.qr_multiply, which allows efficient computation of the matrix product of \( Q \) (from a QR decomposition) and a vector, has been added.

**Pascal matrices**

A function for creating Pascal matrices, scipy.linalg.pascal, was added.

**Sparse matrix construction and operations**

Two new functions, scipy.sparse.diags and scipy.sparse.block_diag, were added to easily construct diagonal and block-diagonal sparse matrices respectively.

scipy.sparse.csc_matrix and csr_matrix now support the operations sin, tan, arcsin, arctan, sinh, tanh, arcsinh, arctanh, rint, sign, expm1, log1p, deg2rad, rad2deg, floor, ceil and trunc. Previously, these operations had to be performed by operating on the matrices’ data attribute.

**LSMR iterative solver**

LSMR, an iterative method for solving (sparse) linear and linear least-squares systems, was added as scipy.sparse.linalg.lsmr.

**Discrete Sine Transform**

Bindings for the discrete sine transform functions have been added to scipy.fftpack.

**scipy.interpolate improvements**

For interpolation in spherical coordinates, the three classes scipy.interpolate.SmoothSphereBivariateSpline, scipy.interpolate.LSQSphereBivariateSpline, and scipy.interpolate.RectSphereBivariateSpline have been added.
**Binned statistics (scipy.stats)**

The stats module has gained functions to do binned statistics, which are a generalization of histograms, in 1-D, 2-D and multiple dimensions: scipy.stats.binned_statistic, scipy.stats.binned_statistic_2d and scipy.stats.binned_statistic_dd.

## 5.41.2 Deprecated features

scipy.sparse.cs_graph_components has been made a part of the sparse graph submodule, and renamed to scipy.sparse.csgraph.connected_components. Calling the former routine will result in a deprecation warning.

scipy.misc.radon has been deprecated. A more full-featured radon transform can be found in scikits-image.

scipy.io.save_as_module has been deprecated. A better way to save multiple Numpy arrays is the numpy.savez function.

The xa and xb parameters for all distributions in scipy.stats.distributions already weren’t used; they have now been deprecated.

## 5.41.3 Backwards incompatible changes

### Removal of scipy.maxentropy

The scipy.maxentropy module, which was deprecated in the 0.10.0 release, has been removed. Logistic regression in scikits.learn is a good and modern alternative for this functionality.

### Minor change in behavior of splev

The spline evaluation function now behaves similarly to interp1d for size-1 arrays. Previous behavior:

```python
>>> from scipy.interpolate import splev, splrep, interp1d
>>> x = [1,2,3,4,5]
>>> y = [4,5,6,7,8]
>>> tck = splrep(x, y)
>>> splev([1], tck) 4.
>>> splev(1, tck) 4.
```

Corrected behavior:

```python
>>> splev([1], tck)
array([4.])
>>> splev(1, tck)
array(4.)
```

This affects also the UnivariateSpline classes.
**Behavior of `scipy.integrate.complex_ode`**

The behavior of the $y$ attribute of `complex_ode` is changed. Previously, it expressed the complex-valued solution in the form:

$$z = \text{ode}.y[::2] + ij \ast \text{ode}.y[1::2]$$

Now, it is directly the complex-valued solution:

$$z = \text{ode}.y$$

**Minor change in behavior of T-tests**

The T-tests `scipy.stats.ttest_ind, scipy.stats.ttest_rel` and `scipy.stats.ttest_1samp` have been changed so that $0/0$ now returns NaN instead of 1.

**5.41.4 Other changes**

The SuperLU sources in `scipy.sparse.linalg` have been updated to version 4.3 from upstream.

The function `scipy.signal.bode`, which calculates magnitude and phase data for a continuous-time system, has been added.

The two-sample T-test `scipy.stats.ttest_ind` gained an option to compare samples with unequal variances, i.e. Welch's T-test.

`scipy.misc.logsumexp` now takes an optional `axis` keyword argument.

**5.41.5 Authors**

This release contains work by the following people (contributed at least one patch to this release, names in alphabetical order):

5.42 SciPy 0.10.1 Release Notes

Contents

• SciPy 0.10.1 Release Notes
  – Main changes
  – Other issues fixed

SciPy 0.10.1 is a bug-fix release with no new features compared to 0.10.0.

5.42.1 Main changes

The most important changes are:

1. The single precision routines of \texttt{eigs} and \texttt{eigsh} in \texttt{scipy.sparse.linalg} have been disabled (they internally use double precision now).

2. A compatibility issue related to changes in NumPy macros has been fixed, in order to make scipy 0.10.1 compile with the upcoming numpy 1.7.0 release.

5.42.2 Other issues fixed

• #835: stats: nan propagation in stats.distributions
• #1202: io: netcdf segfault
• #1531: optimize: make curve_fit work with method as callable.
• #1560: linalg: fixed mistake in eig_banded documentation.
• #1565: ndimage: bug in ndimage.variance
• #1457: ndimage: standard_deviation does not work with sequence of indexes
• #1562: cluster: segfault in linkage function
• #1568: stats: One-sided fisher_exact() returns \( p < 1 \) for 0 successful attempts
• #1575: stats: zscore and zmap handle the axis keyword incorrectly
5.43 SciPy 0.10.0 Release Notes

SciPy 0.10.0 is the culmination of 8 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a limited number of deprecations and backwards-incompatible changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.10.x branch, and on adding new features on the development master branch.

Release highlights:

• Support for Bento as optional build system.
• Support for generalized eigenvalue problems, and all shift-invert modes available in ARPACK.

This release requires Python 2.4-2.7 or 3.1- and NumPy 1.5 or greater.
5.43.1 New features

Bento: new optional build system

Scipy can now be built with Bento. Bento has some nice features like parallel builds and partial rebuilds, that are not possible with the default build system (distutils). For usage instructions see BENTO_BUILD.txt in the scipy top-level directory.

Currently Scipy has three build systems, distutils, numscons and bento. Numcons is deprecated and is planned and will likely be removed in the next release.

Generalized and shift-invert eigenvalue problems in scipy.sparse.linalg

The sparse eigenvalue problem solver functions scipy.sparse.eigs/eigh now support generalized eigenvalue problems, and all shift-invert modes available in ARPACK.

Discrete-Time Linear Systems (scipy.signal)

Support for simulating discrete-time linear systems, including scipy.signal.dlsim, scipy.signal.dimpulse, and scipy.signal.dstep, has been added to SciPy. Conversion of linear systems from continuous-time to discrete-time representations is also present via the scipy.signal.cont2discrete function.

Enhancements to scipy.signal

A Lomb-Scargle periodogram can now be computed with the new function scipy.signal.lombscargle.

The forward-backward filter function scipy.signal.filtfilt can now filter the data in a given axis of an n-dimensional numpy array. (Previously it only handled a 1-dimensional array.) Options have been added to allow more control over how the data is extended before filtering.

FIR filter design with scipy.signal.firwin2 now has options to create filters of type III (zero at zero and Nyquist frequencies) and IV (zero at zero frequency).

Additional decomposition options (scipy.linalg)

A sort keyword has been added to the Schur decomposition routine (scipy.linalg.schur) to allow the sorting of eigenvalues in the resultant Schur form.

Additional special matrices (scipy.linalg)

The functions hilbert and invhilbert were added to scipy.linalg.
Enhancements to scipy.stats

- The one-sided form of Fisher's exact test is now also implemented in stats.fisher_exact.
- The function stats.chi2_contingency for computing the chi-square test of independence of factors in a contingency table has been added, along with the related utility functions stats.contingency.margins and stats.contingency.expected_freq.

Enhancements to scipy.special

The functions logit(p) = log(p/(1-p)) and expit(x) = 1/(1+exp(-x)) have been implemented as scipy.special.logit and scipy.special.expit respectively.

Basic support for Harwell-Boeing file format for sparse matrices

Both read and write are support through a simple function-based API, as well as a more complete API to control number format. The functions may be found in scipy.sparse.io.

The following features are supported:

- Read and write sparse matrices in the CSC format
- Only real, symmetric, assembled matrix are supported (RUA format)

5.43.2 Deprecated features

scipy.maxentropy

The maxentropy module is unmaintained, rarely used and has not been functioning well for several releases. Therefore it has been deprecated for this release, and will be removed for scipy 0.11. Logistic regression in scikits.learn is a good alternative for this functionality. The scipy.maxentropy.logsumexp function has been moved to scipy.misc.

scipy.lib.blas

There are similar BLAS wrappers in scipy.linalg and scipy.lib. These have now been consolidated as scipy.linalg.blas, and scipy.lib.blas is deprecated.

Numscons build system

The numscons build system is being replaced by Bento, and will be removed in one of the next scipy releases.

5.43.3 Backwards-incompatible changes

The deprecated name invnorm was removed from scipy.stats.distributions, this distribution is available as invgauss.

The following deprecated nonlinear solvers from scipy.optimize have been removed:
5.43.4 Other changes

`scipy.constants` has been updated with the CODATA 2010 constants.

`__all__` dicts have been added to all modules, which has cleaned up the namespaces (particularly useful for interactive work).

An API section has been added to the documentation, giving recommended import guidelines and specifying which submodules are public and which aren’t.

5.43.5 Authors

This release contains work by the following people (contributed at least one patch to this release, names in alphabetical order):

- Jeff Armstrong +
- Matthew Brett
- Lars Buitinck +
- David Cournapeau
- FISH 2000 +
- Michael McNeil Forbes +

- Fabian Pedregosa
- Josef Perktold
- Thomas Robitaille +
A total of 35 people contributed to this release. People with a “+” by their names contributed a patch for the first time.

## 5.44 SciPy 0.9.0 Release Notes

### Contents

- SciPy 0.9.0 Release Notes
  - Python 3
  - Scipy source code location to be changed
  - New features
    - Delaunay tessellations (scipy.spatial)
    - N-dimensional interpolation (scipy.interpolate)
    - Nonlinear equation solvers (scipy.optimize)
    - New linear algebra routines (scipy.linalg)
    - Improved FIR filter design functions (scipy.signal)
    - Improved statistical tests (scipy.stats)
  - Deprecated features
    - Obsolete nonlinear solvers (in scipy.optimize)
  - Removed features
    - Old correlate/convolve behavior (in scipy.signal)
    - scipy.stats
SciPy 0.9.0 is the culmination of 6 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.9.x branch, and on adding new features on the development trunk.

This release requires Python 2.4 - 2.7 or 3.1 - and NumPy 1.5 or greater.

Please note that SciPy is still considered to have “Beta” status, as we work toward a SciPy 1.0.0 release. The 1.0.0 release will mark a major milestone in the development of SciPy, after which changing the package structure or API will be much more difficult. Whilst these pre-1.0 releases are considered to have “Beta” status, we are committed to making them as bug-free as possible.

However, until the 1.0 release, we are aggressively reviewing and refining the functionality, organization, and interface. This is being done in an effort to make the package as coherent, intuitive, and useful as possible. To achieve this, we need help from the community of users. Specifically, we need feedback regarding all aspects of the project - everything - from which algorithms we implement, to details about our function’s call signatures.

### 5.44.1 Python 3

SciPy 0.9.0 is the first SciPy release to support Python 3. The only module that is not yet ported is `scipy.weave`.

### 5.44.2 Scipy source code location to be changed

Soon after this release, Scipy will stop using SVN as the version control system, and move to Git. The development source code for Scipy can from then on be found at

https://github.com/scipy/scipy

### 5.44.3 New features

**Delaunay tessellations (scipy.spatial)**

Scipy now includes routines for computing Delaunay tessellations in N dimensions, powered by the Qhull computational geometry library. Such calculations can now make use of the new `scipy.spatial.Delaunay` interface.
N-dimensional interpolation (**scipy.interpolate**)

Support for scattered data interpolation is now significantly improved. This version includes a *scipy.interpolate.griddata* function that can perform linear and nearest-neighbour interpolation for N-dimensional scattered data, in addition to cubic spline (C1-smooth) interpolation in 2D and 1D. An object-oriented interface to each interpolator type is also available.

Nonlinear equation solvers (**scipy.optimize**)

Scipy includes new routines for large-scale nonlinear equation solving in *scipy.optimize*. The following methods are implemented:

- **Newton-Krylov** (*scipy.optimize.newton_krylov*)
- (Generalized) secant methods:
  - Limited-memory Broyden methods (*scipy.optimize.broyden1, scipy.optimize.broyden2*)
  - Anderson method (*scipy.optimize.anderson*)
- Simple iterations (*scipy.optimize.diagbroyden, scipy.optimize.excitingmixing, scipy.optimize.linearmixing*)

The *scipy.optimize.nonlin* module was completely rewritten, and some of the functions were deprecated (see above).

New linear algebra routines (**scipy.linalg**)

Scipy now contains routines for effectively solving triangular equation systems (*scipy.linalg.solve_triangular*).

Improved FIR filter design functions (**scipy.signal**)

The function *scipy.signal.firwin* was enhanced to allow the design of highpass, bandpass, bandstop and multi-band FIR filters.

The function *scipy.signal.firwin2* was added. This function uses the window method to create a linear phase FIR filter with an arbitrary frequency response.

The functions *scipy.signal.kaiser_atten* and *scipy.signal.kaiser_beta* were added.

Improved statistical tests (**scipy.stats**)

A new function *scipy.stats.fisher_exact* was added, that provides Fisher’s exact test for 2x2 contingency tables.

The function *scipy.stats.kendalltau* was rewritten to make it much faster (O(n log(n)) vs O(n^2)).
5.44.4 Deprecated features

Obsolete nonlinear solvers (in scipy.optimize)

The following nonlinear solvers from scipy.optimize are deprecated:

- `broyden_modified` (bad performance)
- `broyden1_modified` (bad performance)
- `broyden_generalized` (equivalent to `anderson`)
- `anderson2` (equivalent to `anderson`)
- `broyden3` (obsoleted by new limited-memory broyden methods)
- `vackar` (renamed to `diagbroyden`)

5.44.5 Removed features

The deprecated modules `helpmod`, `pexec` and `ppimport` were removed from scipy.misc.

The `output_type` keyword in many scipy.ndimage interpolation functions has been removed.

The `econ` keyword in scipy.linalg.qr has been removed. The same functionality is still available by specifying `mode='economic'`.

Old correlate/convolve behavior (in scipy.signal)

The old behavior for scipy.signal.convolve, scipy.signal.convolve2d, scipy.signal.correlate and scipy.signal.correlate2d was deprecated in 0.8.0 and has now been removed. Convolve and correlate used to swap their arguments if the second argument has dimensions larger than the first one, and the mode was relative to the input with the largest dimension. The current behavior is to never swap the inputs, which is what most people expect, and is how correlation is usually defined.

scipy.stats

Many functions in scipy.stats that are either available from numpy or have been superseded, and have been deprecated since version 0.7, have been removed: `std`, `var`, `mean`, `median`, `cov`, `corrcov`, `z`, `zs`, `stderr`, `samplestd`, `samplevar`, `pdfapprox`, `pdf_moments` and `erfc`. These changes are mirrored in scipy.stats.mstats.

scipy.sparse

Several methods of the sparse matrix classes in scipy.sparse which had been deprecated since version 0.7 were removed: `save`, `rowcol`, `getdata`, `lisprint`, `ensure_sorted_indices`, `matvec`, `matmat` and `rmatvec`.

The functions `spkron`, `speye`, `spidentity`, `lil_eye` and `lil_diags` were removed from scipy.sparse.

The first three functions are still available as scipy.sparse.kron, scipy.sparse.eye and scipy.sparse.identity.

The `dims` and `nmax` keywords were removed from the sparse matrix constructor. The `colind` and `rowind` attributes were removed from CSR and CSC matrices respectively.
5.44.6 Other changes

ARPACK interface changes

The interface to the ARPACK eigenvalue routines in scipy.sparse.linalg was changed for more robustness. The eigenvalue and SVD routines now raise ArpackNoConvergence if the eigenvalue iteration fails to converge. If partially converged results are desired, they can be accessed as follows:

```python
import numpy as np
from scipy.sparse.linalg import eigs, ArpackNoConvergence

m = np.random.randn(30, 30)
try:
    w, v = eigs(m, 6)
except ArpackNoConvergence, err:
    partially_converged_w = err.eigenvalues
    partially_converged_v = err.eigenvectors
```

Several bugs were also fixed.

The routines were moreover renamed as follows:

- `eigen` → `eigs`
- `eigen_symmetric` → `eigsh`
- `svd` → `svds`

5.45 SciPy 0.8.0 Release Notes

## Contents

- SciPy 0.8.0 Release Notes
  - Python 3
  - Major documentation improvements
  - Deprecated features
    * Swapping inputs for correlation functions (scipy.signal)

  - New features
    * DCT support (scipy.fftpack)
    * Single precision support for fft functions (scipy.fftpack)

5.45. SciPy 0.8.0 Release Notes
SciPy 0.8.0 is the culmination of 17 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.8.x branch, and on adding new features on the development trunk. This release requires Python 2.4 - 2.6 and NumPy 1.4.1 or greater.

Please note that SciPy is still considered to have “Beta” status, as we work toward a SciPy 1.0.0 release. The 1.0.0 release will mark a major milestone in the development of SciPy, after which changing the package structure or API will be much more difficult. Whilst these pre-1.0 releases are considered to have “Beta” status, we are committed to making them as bug-free as possible.

However, until the 1.0 release, we are aggressively reviewing and refining the functionality, organization, and interface. This is being done in an effort to make the package as coherent, intuitive, and useful as possible. To achieve this, we need help from the community of users. Specifically, we need feedback regarding all aspects of the project - everything - from which algorithms we implement, to details about our function’s call signatures.

- Correlation functions now implement the usual definition (scipy.signal)
- Additions and modification to LTI functions (scipy.signal)
- Improved waveform generators (scipy.signal)
- New functions and other changes in scipy.linalg
- New function and changes in scipy.optimize
- New sparse least squares solver

- Removed features
  - scipy.io

SciPy Reference Guide, Release 1.7.0
5.45.1 Python 3

Python 3 compatibility is planned and is currently technically feasible, since Numpy has been ported. However, since the Python 3 compatible Numpy 1.5 has not been released yet, support for Python 3 in Scipy is not yet included in Scipy 0.8. SciPy 0.9, planned for fall 2010, will very likely include experimental support for Python 3.

5.45.2 Major documentation improvements

SciPy documentation is greatly improved.

5.45.3 Deprecated features

Swapping inputs for correlation functions (scipy.signal)

Concern correlate, correlate2d, convolve and convolve2d. If the second input is larger than the first input, the inputs are swapped before calling the underlying computation routine. This behavior is deprecated, and will be removed in scipy 0.9.0.

Obsolete code deprecated (scipy.misc)

The modules helpmod, ppimport and pexec from scipy.misc are deprecated. They will be removed from SciPy in version 0.9.

Additional deprecations

- linalg: The function solveh_banded currently returns a tuple containing the Cholesky factorization and the solution to the linear system. In SciPy 0.9, the return value will be just the solution.
- The function constants.codata.find will generate a DeprecationWarning. In Scipy version 0.8.0, the keyword argument ‘disp’ was added to the function, with the default value ‘True’. In 0.9.0, the default will be ‘False’.
- The qshape keyword argument of signal.chirp is deprecated. Use the argument vertex_zero instead.
- Passing the coefficients of a polynomial as the argument f0 to signal.chirp is deprecated. Use the function signal.sweep_poly instead.
- The io.recaster module has been deprecated and will be removed in 0.9.0.

5.45.4 New features

DCT support (scipy.fftpack)

New realtransforms have been added, namely dct and idct for Discrete Cosine Transform; type I, II and III are available.
Single precision support for fft functions (scipy.fftpack)

fft functions can now handle single precision inputs as well: fft(x) will return a single precision array if x is single precision. At the moment, for FFT sizes that are not composites of 2, 3, and 5, the transform is computed internally in double precision to avoid rounding error in FFTPACK.

Correlation functions now implement the usual definition (scipy.signal)

The outputs should now correspond to their matlab and R counterparts, and do what most people expect if the old_behavior=False argument is passed:

- correlate, convolve and their 2d counterparts do not swap their inputs depending on their relative shape anymore;
- correlation functions now conjugate their second argument while computing the slid sum-products, which correspond to the usual definition of correlation.

Additions and modification to LTI functions (scipy.signal)

- The functions impulse2 and step2 were added to scipy.signal. They use the function scipy.signal.lsim2 to compute the impulse and step response of a system, respectively.
- The function scipy.signal.lsim2 was changed to pass any additional keyword arguments to the ODE solver.

Improved waveform generators (scipy.signal)

Several improvements to the chirp function in scipy.signal were made:

- The waveform generated when method="logarithmic" was corrected; it now generates a waveform that is also known as an “exponential” or “geometric” chirp. (See https://en.wikipedia.org/wiki/Chirp.)
- A new chirp method, “hyperbolic”, was added.
- Instead of the keyword qshape, chirp now uses the keyword vertex_zero, a boolean.
- chirp no longer handles an arbitrary polynomial. This functionality has been moved to a new function, sweep_poly.

A new function, sweep_poly, was added.

New functions and other changes in scipy.linalg

The functions cho_solve_banded, circulant, companion, hadamard and leslie were added to scipy.linalg.

The function block_diag was enhanced to accept scalar and 1D arguments, along with the usual 2D arguments.

New function and changes in scipy.optimize

The curve_fit function has been added; it takes a function and uses non-linear least squares to fit that to the provided data.

The leastsq and fsolve functions now return an array of size one instead of a scalar when solving for a single parameter.
New sparse least squares solver

The `lsqr` function was added to `scipy.sparse`. This routine finds a least-squares solution to a large, sparse, linear system of equations.

ARPACK-based sparse SVD

A naive implementation of SVD for sparse matrices is available in `scipy.sparse.linalg.eigen.arpack`. It is based on using an symmetric solver on \( <A, A> \), and as such may not be very precise.

Alternative behavior available for `scipy.constants.find`

The keyword argument `disp` was added to the function `scipy.constants.find`, with the default value `True`. When `disp` is `True`, the behavior is the same as in Scipy version 0.7. When `False`, the function returns the list of keys instead of printing them. (In SciPy version 0.9, the default will be reversed.)

Incomplete sparse LU decompositions

SciPy now wraps SuperLU version 4.0, which supports incomplete sparse LU decompositions. These can be accessed via `scipy.sparse.linalg.spilu`. Upgrade to SuperLU 4.0 also fixes some known bugs.

Faster matlab file reader and default behavior change

We’ve rewritten the matlab file reader in Cython and it should now read matlab files at around the same speed that Matlab does.

The reader reads matlab named and anonymous functions, but it can’t write them.

Until scipy 0.8.0 we have returned arrays of matlab structs as numpy object arrays, where the objects have attributes named for the struct fields. As of 0.8.0, we return matlab structs as numpy structured arrays. You can get the older behavior by using the optional `struct_as_record=False` keyword argument to `scipy.io.loadmat` and friends.

There is an inconsistency in the matlab file writer, in that it writes numpy 1D arrays as column vectors in matlab 5 files, and row vectors in matlab 4 files. We will change this in the next version, so both write row vectors. There is a `FutureWarning` when calling the writer to warn of this change; for now we suggest using the `oned_as='row'` keyword argument to `scipy.io.savemat` and friends.

Faster evaluation of orthogonal polynomials

Values of orthogonal polynomials can be evaluated with new vectorized functions in `scipy.special: eval_legendre, eval_chebyt, eval_chebyu, eval_chebyc, eval_chebys, eval_jacobi, eval_laguerre, eval_genlaguerre, eval_hermite, eval_hermitenorm, eval_gegenbauer, eval_sh_legendre, eval_sh_chebyt, eval_sh_chebyu, eval_sh_jacobi`. This is faster than constructing the full coefficient representation of the polynomials, which was previously the only available way.

Note that the previous orthogonal polynomial routines will now also invoke this feature, when possible.
Lambert W function

`scipy.special.lambertw` can now be used for evaluating the Lambert W function.

Improved hypergeometric 2F1 function

Implementation of `scipy.special.hyp2f1` for real parameters was revised. The new version should produce accurate values for all real parameters.

More flexible interface for Radial basis function interpolation

The `scipy.interpolate.Rbf` class now accepts a callable as input for the “function” argument, in addition to the built-in radial basis functions which can be selected with a string argument.

5.45.5 Removed features

`scipy.stsci`: the package was removed

The module `scipy.misc.limits` was removed.

`scipy.io`

The IO code in both NumPy and SciPy is being extensively reworked. NumPy will be where basic code for reading and writing NumPy arrays is located, while SciPy will house file readers and writers for various data formats (data, audio, video, images, matlab, etc.).

Several functions in `scipy.io` are removed in the 0.8.0 release including: `npyfile, save, load, create_module, create_shelf, objload, objsave, fopen, read_array, write_array, fread, fwrite, bswap, packbits, unpackbits, and convert_objectarray`. Some of these functions have been replaced by NumPy's raw reading and writing capabilities, memory-mapping capabilities, or array methods. Others have been moved from SciPy to NumPy, since basic array reading and writing capability is now handled by NumPy.

5.46 SciPy 0.7.2 Release Notes

SciPy 0.7.2 is a bug-fix release with no new features compared to 0.7.1. The only change is that all C sources from Cython code have been regenerated with Cython 0.12.1. This fixes the incompatibility between binaries of SciPy 0.7.1 and NumPy 1.4.
5.47 SciPy 0.7.1 Release Notes

SciPy 0.7.1 is a bug-fix release with no new features compared to 0.7.0.

5.47.1 scipy.io

Bugs fixed:

- Several fixes in Matlab file IO

5.47.2 scipy.odr

Bugs fixed:

- Work around a failure with Python 2.6

5.47.3 scipy.signal

Memory leak in lfilter have been fixed, as well as support for array object

Bugs fixed:

- #880, #925: lfilter fixes
- #871: bicgstab fails on Win32
5.47.4 scipy.sparse

Bugs fixed:

- #883: scipy.io.mmread with scipy.sparse.lil_matrix broken

5.47.5 scipy.special

Several bugs of varying severity were fixed in the special functions:

- #503, #640: iv: problems at large arguments fixed by new implementation
- #623: jv: fix errors at large arguments
- #679: struve: fix wrong output for v < 0
- #803: pbdv produces invalid output
- #804: lqmn: fix crashes on some input
- #823: betainc: fix documentation
- #834: exp1 strange behavior near negative integer values
- #852: jn_zeros: more accurate results for large s, also in jnp/yn/ynp_zeros
- #853: jv, yv, iv: invalid results for non-integer v < 0, complex x
- #854: jv, yv, iv, kv: return nan more consistently when out-of-domain
- #927: ellipj: fix segfault on Windows
- #946: ellpj: fix segfault on Mac OS X/python 2.6 combination.
- ive, jve, yve, kv: with real-valued input, return nan for out-of-domain instead of returning only the real part of the result.

Also, when scipy.special.errprint(1) has been enabled, warning messages are now issued as Python warnings instead of printing them to stderr.

5.47.6 scipy.stats

- linregress, mannwhitneyu, describe: errors fixed
- kstwobign, norm, expon, exponweib, exponpow, frechet, genexpon, rdist, truncexpon, planck: improvements to numerical accuracy in distributions
5.47.7 Windows binaries for python 2.6

python 2.6 binaries for windows are now included. The binary for python 2.5 requires numpy 1.2.0 or above, and the one for python 2.6 requires numpy 1.3.0 or above.

5.47.8 Universal build for scipy

Mac OS X binary installer is now a proper universal build, and does not depend on gfortran anymore (libgfortran is statically linked). The python 2.5 version of scipy requires numpy 1.2.0 or above, the python 2.6 version requires numpy 1.3.0 or above.

5.48 SciPy 0.7.0 Release Notes

SciPy 0.7.0 is the culmination of 16 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.7.x branch, and on adding new features on the development trunk. This release requires Python 2.4 or 2.5 and NumPy 1.2 or greater.
Please note that SciPy is still considered to have “Beta” status, as we work toward a SciPy 1.0.0 release. The 1.0.0 release will mark a major milestone in the development of SciPy, after which changing the package structure or API will be much more difficult. Whilst these pre-1.0 releases are considered to have “Beta” status, we are committed to making them as bug-free as possible. For example, in addition to fixing numerous bugs in this release, we have also doubled the number of unit tests since the last release.

However, until the 1.0 release, we are aggressively reviewing and refining the functionality, organization, and interface. This is being done in an effort to make the package as coherent, intuitive, and useful as possible. To achieve this, we need help from the community of users. Specifically, we need feedback regarding all aspects of the project - everything - from which algorithms we implement, to details about our function’s call signatures.

Over the last year, we have seen a rapid increase in community involvement, and numerous infrastructure improvements to lower the barrier to contributions (e.g., more explicit coding standards, improved testing infrastructure, better documentation tools). Over the next year, we hope to see this trend continue and invite everyone to become more involved.

### 5.48.1 Python 2.6 and 3.0

A significant amount of work has gone into making SciPy compatible with Python 2.6; however, there are still some issues in this regard. The main issue with 2.6 support is NumPy. On UNIX (including Mac OS X), NumPy 1.2.1 mostly works, with a few caveats. On Windows, there are problems related to the compilation process. The upcoming NumPy 1.3 release will fix these problems. Any remaining issues with 2.6 support for SciPy 0.7 will be addressed in a bug-fix release.

Python 3.0 is not supported at all; it requires NumPy to be ported to Python 3.0. This requires immense effort, since a lot of C code has to be ported. The transition to 3.0 is still under consideration; currently, we don’t have any timeline or roadmap for this transition.

### 5.48.2 Major documentation improvements

SciPy documentation is greatly improved; you can view a HTML reference manual online or download it as a PDF file. The new reference guide was built using the popular Sphinx tool.

This release also includes an updated tutorial, which hadn’t been available since SciPy was ported to NumPy in 2005. Though not comprehensive, the tutorial shows how to use several essential parts of Scipy. It also includes the ndimage documentation from the numarray manual.

Nevertheless, more effort is needed on the documentation front. Luckily, contributing to Scipy documentation is now easier than before: if you find that a part of it requires improvements, and want to help us out, please register a user name in our web-based documentation editor at [https://docs.scipy.org/](https://docs.scipy.org/) and correct the issues.

### 5.48.3 Running Tests

NumPy 1.2 introduced a new testing framework based on nose. Starting with this release, SciPy now uses the new NumPy test framework as well. Taking advantage of the new testing framework requires nose version 0.10, or later. One major advantage of the new framework is that it greatly simplifies writing unit tests - which has all ready paid off, given the rapid increase in tests. To run the full test suite:

```python
>>> import scipy
>>> scipy.test('full')
```

For more information, please see The NumPy/SciPy Testing Guide.

We have also greatly improved our test coverage. There were just over 2,000 unit tests in the 0.6.0 release; this release nearly doubles that number, with just over 4,000 unit tests.
5.48.4 Building SciPy

Support for NumScons has been added. NumScons is a tentative new build system for NumPy/SciPy, using SCons at its core.

SCons is a next-generation build system, intended to replace the venerable Make with the integrated functionality of autoconf/automake and ccache. Scons is written in Python and its configuration files are Python scripts. NumSCons is meant to replace NumPy's custom version of distutils providing more advanced functionality, such as autoconf, improved fortran support, more tools, and support for numpy.distutils/scons cooperation.

5.48.5 Sandbox Removed

While porting SciPy to NumPy in 2005, several packages and modules were moved into scipy.sandbox. The sandbox was a staging ground for packages that were undergoing rapid development and whose APIs were in flux. It was also a place where broken code could live. The sandbox has served its purpose well, but was starting to create confusion. Thus scipy.sandbox was removed. Most of the code was moved into scipy, some code was made into a scikit, and the remaining code was just deleted, as the functionality had been replaced by other code.

5.48.6 Sparse Matrices

Sparse matrices have seen extensive improvements. There is now support for integer dtypes such int8, uint32, etc. Two new sparse formats were added:

- new class dia_matrix: the sparse DIAGONal format
- new class bsr_matrix: the Block CSR format

Several new sparse matrix construction functions were added:

- sparse.kron: sparse Kronecker product
- sparse.bmat: sparse version of numpy.bmat
- sparse.vstack: sparse version of numpy.vstack
- sparse.hstack: sparse version of numpy.hstack

Extraction of submatrices and nonzero values have been added:

- sparse.tril: extract lower triangle
- sparse.triu: extract upper triangle
- sparse.find: nonzero values and their indices

csr_matrix and csc_matrix now support slicing and fancy indexing (e.g., A[1:3, 4:7] and A[[3,2,6,8], :]). Conversions among all sparse formats are now possible:

- using member functions such as .tocsr() and .tolil()
- using the .asformat() member function, e.g. A.asformat('csr')
- using constructors A = lil_matrix([[1,2]]); B = csr_matrix(A)

All sparse constructors now accept dense matrices and lists of lists. For example:

- A = csr_matrix( rand(3,3) ) and B = lil_matrix( [[1,2],[3,4]] )

The handling of diagonals in the spdiags function has been changed. It now agrees with the MATLAB(TM) function of the same name.
Numerous efficiency improvements to format conversions and sparse matrix arithmetic have been made. Finally, this release contains numerous bugfixes.

### 5.48.7 Statistics package

Statistical functions for masked arrays have been added, and are accessible through `scipy.stats.mstats`. The functions are similar to their counterparts in `scipy.stats` but they have not yet been verified for identical interfaces and algorithms.

Several bugs were fixed for statistical functions, of those, `kstest` and `percentileofscore` gained new keyword arguments. Added deprecation warning for `mean`, `median`, `var`, `std`, `cov`, and `corrcoef`. These functions should be replaced by their numpy counterparts. Note, however, that some of the default options differ between the `scipy.stats` and numpy versions of these functions.

Numerous bug fixes to `stats.distributions`: all generic methods now work correctly, several methods in individual distributions were corrected. However, a few issues remain with higher moments (`skew`, `kurtosis`) and entropy. The maximum likelihood estimator, `fit`, does not work out-of-the-box for some distributions - in some cases, starting values have to be carefully chosen, in other cases, the generic implementation of the maximum likelihood method might not be the numerically appropriate estimation method.

We expect more bugfixes, increases in numerical precision and enhancements in the next release of scipy.

### 5.48.8 Reworking of IO package

The IO code in both NumPy and SciPy is being extensively reworked. NumPy will be where basic code for reading and writing NumPy arrays is located, while SciPy will house file readers and writers for various data formats (data, audio, video, images, matlab, etc.).

Several functions in `scipy.io` have been deprecated and will be removed in the 0.8.0 release including `npfile`, `save`, `load`, `create_module`, `create_shelf`, `objload`, `objsave`, ` fopen`, `read_array`, `write_array`, `fread`, `fwrite`, `bswap`, `packbits`, `unpackbits`, and `convert_objectarray`. Some of these functions have been replaced by NumPy's raw reading and writing capabilities, memory-mapping capabilities, or array methods. Others have been moved from SciPy to NumPy, since basic array reading and writing capability is now handled by NumPy.

The Matlab (TM) file readers/writers have a number of improvements:

- default version 5
- v5 writers for structures, cell arrays, and objects
- v5 readers/writers for function handles and 64-bit integers
- new struct_as_record keyword argument to `loadmat`, which loads struct arrays in matlab as record arrays in numpy
- string arrays have `dtype='U...'` instead of `dtype=object`
- `loadmat` no longer squeezes singleton dimensions, i.e. `squeeze_me=False` by default
5.48.9 New Hierarchical Clustering module

This module adds new hierarchical clustering functionality to the scipy.cluster package. The function interfaces are similar to the functions provided MATLAB(TM)'s Statistics Toolbox to help facilitate easier migration to the NumPy/SciPy framework. Linkage methods implemented include single, complete, average, weighted, centroid, median, and ward.

In addition, several functions are provided for computing inconsistency statistics, cophenetic distance, and maximum distance between descendants. The fcluster and fclusterdata functions transform a hierarchical clustering into a set of flat clusters. Since these flat clusters are generated by cutting the tree into a forest of trees, the leaders function takes a linkage and a flat clustering, and finds the root of each tree in the forest. The ClusterNode class represents a hierarchical clusterings as a field-navigable tree object. to_tree converts a matrix-encoded hierarchical clustering to a ClusterNode object. Routines for converting between MATLAB and SciPy linkage encodings are provided. Finally, a dendrogram function plots hierarchical clusterings as a dendrogram, using matplotlib.

5.48.10 New Spatial package

The new spatial package contains a collection of spatial algorithms and data structures, useful for spatial statistics and clustering applications. It includes rapidly compiled code for computing exact and approximate nearest neighbors, as well as a pure-python kd-tree with the same interface, but that supports annotation and a variety of other algorithms. The API for both modules may change somewhat, as user requirements become clearer.

It also includes a distance module, containing a collection of distance and dissimilarity functions for computing distances between vectors, which is useful for spatial statistics, clustering, and kd-trees. Distance and dissimilarity functions provided include Bray-Curtis, Canberra, Chebyshev, City Block, Cosine, Dice, Euclidean, Hamming, Jaccard, Kulinski, Mahalanobis, Matching, Minkowski, Rogers-Tanimoto, Russell-Rao, Squared Euclidean, Standardized Euclidean, Sokal-Michener, Sokal-Sneath, and Yule.

The pdist function computes pairwise distance between all unordered pairs of vectors in a set of vectors. The cdist computes the distance on all pairs of vectors in the Cartesian product of two sets of vectors. Pairwise distance matrices are stored in condensed form; only the upper triangular is stored. squareform converts distance matrices between square and condensed forms.

5.48.11 Reworked fftpack package

FFTW2, FFTW3, MKL and DJBFFT wrappers have been removed. Only (NETLIB) fftpack remains. By focusing on one backend, we hope to add new features - like float32 support - more easily.

5.48.12 New Constants package

scipy.constants provides a collection of physical constants and conversion factors. These constants are taken from CODATA Recommended Values of the Fundamental Physical Constants: 2002. They may be found at physics.nist.gov/constants. The values are stored in the dictionary physical_constants as a tuple containing the value, the units, and the relative precision - in that order. All constants are in SI units, unless otherwise stated. Several helper functions are provided.
5.48.13 New Radial Basis Function module

`scipy.interpolate` now contains a Radial Basis Function module. Radial basis functions can be used for smoothing/interpolating scattered data in n-dimensions, but should be used with caution for extrapolation outside of the observed data range.

5.48.14 New complex ODE integrator

`scipy.integrate.ode` now contains a wrapper for the ZVODE complex-valued ordinary differential equation solver (by Peter N. Brown, Alan C. Hindmarsh, and George D. Byrne).

5.48.15 New generalized symmetric and hermitian eigenvalue problem solver

`scipy.linalg.eigh` now contains wrappers for more LAPACK symmetric and hermitian eigenvalue problem solvers. Users can now solve generalized problems, select a range of eigenvalues only, and choose to use a faster algorithm at the expense of increased memory usage. The signature of the `scipy.linalg.eigh` changed accordingly.

5.48.16 Bug fixes in the interpolation package

The shape of return values from `scipy.interpolate.interp1d` used to be incorrect, if interpolated data had more than 2 dimensions and the axis keyword was set to a non-default value. This has been fixed. Moreover, `interp1d` returns now a scalar (0D-array) if the input is a scalar. Users of `scipy.interpolate.interp1d` may need to revise their code if it relies on the previous behavior.

5.48.17 Weave clean up

There were numerous improvements to `scipy.weave.blitz++` was relicensed by the author to be compatible with the SciPy license. `wx_spec.py` was removed.

5.48.18 Known problems

Here are known problems with scipy 0.7.0:

- weave test failures on windows: those are known, and are being revised.
- weave test failure with gcc 4.3 (std::labs): this is a gcc 4.3 bug. A workaround is to add #include <cstdlib> in `scipy/weave/blitz/blitzfuncs.h` (line 27). You can make the change in the installed scipy (in site-packages).
